## Abstract

Unification has been investigated both in modal logics and in description logics, albeit with different motivations. In description logics, unification can be used to detect redundancies in ontologies. In this context, it is not sufficient to decide unifiability, one must also compute appropriate unifiers and present them to the user. For the description logic  $\mathcal{EL}$ , which is used to define several large biomedical ontologies, deciding unifiability is an NP-complete problem. It is known that every solvable  $\mathcal{EL}$ -unification problem has a *minimal unifier*, and that every minimal unifier is a *local unifier*. Existing unification algorithms for  $\mathcal{EL}$  compute all minimal unifiers, but additionally (all or some) non-minimal local unifiers. Computing only the minimal unifiers would be better since there are considerably less minimal unifiers than local ones, and their size is usually also quite small.

In this paper we investigate the question whether the known algorithms for  $\mathcal{EL}$ -unification can be modified such that they compute exactly the minimal unifiers without changing the complexity and the basic nature of the algorithms. Basically, the answer we give to this question is negative.

## 1 Introduction

It is well-known that there is a close connection between modal logics (MLs) and description logics (DLs). In fact, many DLs are syntactic variants of classical MLs. Unification has been introduced in both areas [4], with the same formal meaning, but with different applications in mind. In ML, unification [14, 15, 19] was mainly investigated in the context of the admissibility problem for inference rules [18, 16, 11]. Unification is simpler than the admissibility problem in the sense that it can easily be reduced to it, but in some cases (e.g., if the unification problem is effectively finitary, i.e., finite complete sets of unifiers can be computed) there is also a reduction in the other direction (see, e.g., [17]). An important open problem in the area is the question whether unification in the basic modal logic  $\mathbf{K}$ , which corresponds to the DL  $\mathcal{ALC}$ , is decidable. It is only known that relatively minor extensions of  $\mathbf{K}$  have an undecidable unification problem [20].

Unification in DLs has been introduced as a novel inference service that can be used to detect redundancies in ontologies [9]. For example, assume that one developer of a medical ontology defines the concept of a *patient with severe head injury* as

$$\text{Patient} \sqcap \exists \text{finding} . (\text{Head\_injury} \sqcap \exists \text{severity} . \text{Severe}), \quad (1)$$

whereas another one represents it as

$$\text{Patient} \sqcap \exists \text{finding} . (\text{Severe\_finding} \sqcap \text{Injury} \sqcap \exists \text{finding\_site} . \text{Head}). \quad (2)$$

Formally, these two concept descriptions are not equivalent, but they are nevertheless meant to represent the same concept. They can obviously be made equivalent by treating the concept names `Head_injury` and `Severe_finding` as variables, and substituting the first one by `Injury  $\sqcap$   $\exists$ finding_site.Head` and the second one by  `$\exists$ severity.Severe`. In this case, we say that the descriptions are unifiable, and call the substitution that makes them equivalent a *unifier*. Intuitively, such a unifier proposes definitions for the concept names that are used as variables: in our example, we know that, if we define `Head_injury` as `Injury  $\sqcap$   $\exists$ finding_site.Head` and `Severe_finding` as  `$\exists$ severity.Severe`, then the two concept descriptions (1) and (2) are equivalent w.r.t. these definitions.

Of course, this example was constructed such that the unifier actually provides sensible definitions for the concept names used as variables. In general, the existence of a unifier only says that there is a structural similarity between the two concepts. The developer that uses unification as a tool for finding redundancies in an ontology or between two different ontologies needs to inspect the unifier(s) to see whether the definitions it suggests really make sense. Thus, a decision procedure for unifiability is not sufficient in this context. One needs a procedure that also produces appropriate unifiers.

Due to the fact that the decidability status of unification in the DL  $\mathcal{ALC}$  is a long-standing open problem (at least in its ML variant of unification in  $\mathbf{K}$ ), the work on unification in DLs has mostly concentrated on sub-Boolean fragments of  $\mathbf{K}$ . Originally, unification in DLs has been investigated in [9] for the DL  $\mathcal{FL}_0$ , which offers the constructors conjunction ( $\sqcap$ ), value restrictions ( $\forall r.C$ ), and the top-concept ( $\top$ ). However, the usability of unification in this DL is impaired by the facts that, on the one hand, there are almost no ontologies that use only  $\mathcal{FL}_0$ , and on the other hand, the complexity of the unification problem is quite high (ExpTime-complete).

In this paper, we consider unification in the DL  $\mathcal{EL}$ , which differs from  $\mathcal{FL}_0$  by offering existential restrictions ( $\exists r.C$ ) in place of value restrictions, and thus corresponds to the fragment of  $\mathbf{K}$  that uses only diamond, conjunction, and the truth constant “true.”  $\mathcal{EL}$  has recently drawn considerable attention since, on the one hand, important inference problems such as the subsumption problem are polynomial in  $\mathcal{EL}$  [1, 12]. On the other hand, though quite inexpressive,  $\mathcal{EL}$  can be used to define biomedical ontologies. For example, both the large medical ontology SNOMED CT and the Gene Ontology<sup>1</sup> can be expressed in  $\mathcal{EL}$ . In [6], we were able to show that unification in  $\mathcal{EL}$  is of considerably lower complexity than unification in  $\mathcal{FL}_0$ : the decision problem for  $\mathcal{EL}$  is NP-complete. The main steps in the proof of this statement given in [6] were the following. First, the inverse subsumption order on concept descriptions was used to define an order on substitutions:

$$\sigma \succeq \theta \text{ iff } \sigma(X) \sqsubseteq \theta(X) \text{ holds for all variables } X,$$

---

<sup>1</sup>see <http://www.ihtsdo.org/snomed-ct/> and <http://www.geneontology.org/>

and it was shown that this order is well-founded. As an immediate consequence of the well-foundedness of  $\succeq$ , every solvable unification problem has a minimal unifier. Second, it was shown that every minimal unifier is a local substitution, where local substitutions are built from a polynomial number of so-called atoms determined by the unification problem. Finally, a brute-force “guess and then test” NP-algorithm was described, which guesses a local substitution and then checks (in polynomial time) whether it is a unifier.

An obvious disadvantage of this brute-force algorithm is that it blindly guesses a local substitution and only afterwards checks whether the guessed substitution is a unifier. Thus, in general many substitutions will be generated that only in the subsequent check turn out not to be unifiers. In contrast, the SAT reduction presented in [7] is such that only unifiers are generated. To be more precise, it was shown in [7] how a given unification problem  $\Gamma$  can be translated in polynomial time into a propositional formula  $\phi_\Gamma$  such that the satisfying valuations of  $\phi_\Gamma$  correspond to the local unifiers of  $\Gamma$ . The translation into SAT allows us to employ existing highly optimized state-of-the-art SAT solvers for implementing the unification algorithm. While this yields a quite efficient decision procedure for unifiability, the fact that all local unifiers, rather than only minimal ones, are generated turned out to be problematic if one wants to show the unifiers to the user. In fact, even very small unification problems can have hundreds of local unifiers, many of which do not make sense in the application. The set of all minimal unifiers is a subset of the set of all local unifiers, whose cardinality is usually much smaller.<sup>2</sup> Another advantage of minimal unifiers is that they are usually of smaller size (where the size of a substitution is the sum of the sizes of the concept terms substituted for the variables), and are thus easier to read and comprehend.

In [8] we describe a goal-oriented unification algorithm for  $\mathcal{EL}$ , in which non-deterministic decisions are only made if they are triggered by “unsolved parts” of the unification problem. By construction, this algorithm can only compute local unifiers, and it is shown in [8] that all minimal ones are among the ones computed by it. Though in our initial tests the number of unifiers computed by the goal-oriented algorithm turned out to be usually much smaller than of the ones computed by the SAT reduction, the goal-oriented algorithm is not guaranteed to compute only minimal unifiers.

Following the assumption that it is desirable to compute only minimal unifiers rather than all (or some additional non-minimal) local ones, this paper asks the question whether the NP decision procedures for unification in  $\mathcal{EL}$  presented in [7] and [8] can be appropriately modified such that the successful runs of the procedure produce exactly the minimal unifiers of the given  $\mathcal{EL}$ -unification problem. We show in Section 4 that the answer to this question is negative if

---

<sup>2</sup> In the above example, the unifier we have described is the only minimal unifier, but the SAT-translation computes 64 local unifiers, albeit first the minimal one.

Name	Syntax	Semantics
concept name	$A$	$A^{\mathcal{I}} \subseteq \Delta^{\mathcal{I}}$
role name	$r$	$r^{\mathcal{I}} \subseteq \Delta^{\mathcal{I}} \times \Delta^{\mathcal{I}}$
top-concept	$\top$	$\top^{\mathcal{I}} = \Delta^{\mathcal{I}}$
conjunction	$C \sqcap D$	$(C \sqcap D)^{\mathcal{I}} = C^{\mathcal{I}} \cap D^{\mathcal{I}}$
existential restriction	$\exists r.C$	$(\exists r.C)^{\mathcal{I}} = \{x \mid \exists y : (x, y) \in r^{\mathcal{I}} \wedge y \in C^{\mathcal{I}}\}$

Table 1: Syntax and semantics of  $\mathcal{EL}$ .

we use a slightly more general definition of the order  $\succeq$ , where the subsumption test  $\sigma(X) \sqsubseteq \theta(X)$  can be restricted to a subset of all variables. This restriction is justified by the fact that the user may be interested only in the substitution-images of some of the variables. In fact, the algorithms in [7] and [8] first flatten the input problem, which introduces auxiliary variables. These auxiliary variables are internal to the unification procedure and are not shown to the user.

All three  $\mathcal{EL}$ -unification algorithms mentioned above (the brute-force algorithm, the goal-oriented algorithm, and the one based on a reduction to SAT) actually do not directly compute local unifiers, but so-called acyclic assignments, which can be seen as compact representations of local unifiers. In Section 3 we ask what properties of the acyclic assignment make the induced unifiers small. To this purpose, we introduce a natural order on acyclic assignments and compare it with the order  $\succeq$  on the induced unifiers.

## 2 Unification in $\mathcal{EL}$

Starting with a finite set  $N_C$  of *concept names* and a finite set  $N_R$  of *role names*,  $\mathcal{EL}$ -*concept descriptions* are built using the concept constructors *top-concept* ( $\top$ ), *conjunction* ( $C \sqcap D$ ), and *existential restriction* ( $\exists r.C$  for every  $r \in N_R$ ).

An *interpretation*  $\mathcal{I} = (\Delta^{\mathcal{I}}, \cdot^{\mathcal{I}})$  consists of a nonempty domain  $\Delta^{\mathcal{I}}$  and an interpretation function  $\cdot^{\mathcal{I}}$  that assigns binary relations on  $\Delta^{\mathcal{I}}$  to role names and subsets of  $\Delta^{\mathcal{I}}$  to concept descriptions, as shown in the semantics column of Table 1.

The concept description  $C$  is *subsumed by* the concept description  $D$  (written  $C \sqsubseteq D$ ) iff  $C^{\mathcal{I}} \subseteq D^{\mathcal{I}}$  holds for all interpretations  $\mathcal{I}$ . We say that  $C$  is *equivalent to*  $D$  (written  $C \equiv D$ ) iff  $C \sqsubseteq D$  and  $D \sqsubseteq C$ , i.e., iff  $C^{\mathcal{I}} = D^{\mathcal{I}}$  holds for all interpretations  $\mathcal{I}$ .

We will also need the notion of an acyclic TBox  $\mathcal{T}$ , which is a finite set of concept definitions of the form  $A \equiv C$ , where  $A$  is a concept name and  $C$  a concept description, that is unambiguous and acyclic (see [3] for details). The interpretation  $\mathcal{I}$  is a model of  $\mathcal{T}$  iff it satisfies all concept definitions in  $\mathcal{T}$ , i.e.,  $A^{\mathcal{I}} = C^{\mathcal{I}}$

holds for all  $A \equiv C$  in  $\mathcal{T}$ . The concept description  $C$  is *subsumed by* the concept description  $D$  w.r.t. the acyclic TBox  $\mathcal{T}$  (written  $C \sqsubseteq_{\mathcal{T}} D$ ) iff  $C^{\mathcal{I}} \subseteq D^{\mathcal{I}}$  holds for all models  $\mathcal{I}$  of  $\mathcal{T}$ .

An  $\mathcal{EL}$ -concept description is an *atom* if it is an existential restriction or a concept name. The atoms of an  $\mathcal{EL}$ -concept description  $C$  are the subdescriptions of  $C$  that are atoms, and the top-level atoms of  $C$  are the atoms occurring in the top-level conjunction of  $C$ . Obviously, any  $\mathcal{EL}$ -concept description is the conjunction of its top-level atoms, where the empty conjunction corresponds to the top-concept  $\top$ .

When defining unification in  $\mathcal{EL}$ , we assume that the set of concept names is partitioned into a set  $N_v$  of concept variables (which may be replaced by substitutions) and a set  $N_c$  of concept constants (which must not be replaced by substitutions). A *substitution*  $\sigma$  is a mapping from  $N_v$  into the set of all  $\mathcal{EL}$ -concept descriptions. This mapping is extended to concept descriptions in the usual way, i.e., by replacing all occurrences of variables in the description by their  $\sigma$ -images. Unification tries to make concept descriptions equivalent by applying a substitution.

**Definition 1.** An  $\mathcal{EL}$ -unification problem is of the form  $\Gamma = \{C_1 \equiv^? D_1, \dots, C_n \equiv^? D_n\}$ , where  $C_1, D_1, \dots, C_n, D_n$  are  $\mathcal{EL}$ -concept descriptions. The substitution  $\sigma$  is a *unifier* (or *solution*) of  $\Gamma$  iff  $\sigma(C_i) \equiv \sigma(D_i)$  for  $i = 1, \dots, n$ . In this case,  $\Gamma$  is called *solvable* or *unifiable*.

We will sometimes use the subsumption  $C \sqsubseteq^? D$  as abbreviation for the equivalence  $C \sqcap D \equiv^? C$ . Obviously, the substitution  $\sigma$  solves this subsumption iff  $\sigma(C) \sqsubseteq \sigma(D)$ .

## Flattening

As mentioned before, the algorithms in [7] and [8] first flatten the unification problem. An atom is called *flat* if it is a concept name or an existential restriction of the form  $\exists r.A$  for a concept name  $A$ . The unification problem  $\Gamma$  is called *flat* if it contains only flat subsumptions of the form  $C_1 \sqcap \dots \sqcap C_n \sqsubseteq^? D$ , where  $n \geq 0$  and  $C_1, \dots, C_n, D$  are flat atoms.<sup>3</sup>

Let  $\Gamma$  be a unification problem. By introducing auxiliary variables,  $\Gamma$  can be transformed in polynomial time into a flat unification problem  $\Gamma'$  such that the unifiability status remains unchanged, i.e.,  $\Gamma$  has a unifier iff  $\Gamma'$  has a unifier. More precisely, it can be shown that, restricted to the variables of  $\Gamma$ , every unifier of  $\Gamma'$  is also a unifier of  $\Gamma$ . Conversely, every unifier of  $\Gamma$  can be extended to a unifier

<sup>3</sup>If  $n = 0$ , then we have an empty conjunction on the left-hand side, which as usual stands for  $\top$ .

of  $\Gamma'$  by defining appropriate images for the auxiliary variables. Thus, we may assume without loss of generality that our input  $\mathcal{EL}$ -unification problems are flat.

## Local unifiers

Let  $\Gamma$  be a flat unification problem. The atoms of  $\Gamma$  are the atoms of all the concept descriptions occurring in  $\Gamma$ . We define

$$\begin{aligned} \text{At} &:= \{C \mid C \text{ is an atom of } \Gamma\} \text{ and} \\ \text{At}_{\text{nv}} &:= \text{At} \setminus N_v \quad (\text{non-variable atoms}). \end{aligned}$$

Every assignment  $S$  of subsets  $S_X$  of  $\text{At}_{\text{nv}}$  to the variables  $X$  in  $N_v$  induces the following relation  $>_S$  on  $N_v$ :  $>_S$  is the transitive closure of

$$O_S := \{(X, Y) \in N_v \times N_v \mid Y \text{ occurs in an element of } S_X\}.$$

We call the assignment  $S$  *acyclic* if  $>_S$  is irreflexive (and thus a strict partial order). Any acyclic assignment  $S$  induces a unique substitution  $\sigma_S$ , which can be defined by induction along  $>_S$ :

- If  $X$  is a minimal element of  $N_v$  w.r.t.  $>_S$ , then we define  $\sigma_S(X) := \prod_{D \in S_X} D$ .
- Assume that  $\sigma_S(Y)$  is already defined for all  $Y$  such that  $X >_S Y$ . Then we define  $\sigma_S(X) := \prod_{D \in S_X} \sigma_S(D)$ .

We call a substitution  $\sigma$  *local* if it is of this form, i.e., if there is an acyclic assignment  $S$  such that  $\sigma = \sigma_S$ . If the unifier  $\sigma$  of  $\Gamma$  is a local substitution, then we call it a *local unifier* of  $\Gamma$ .

**Theorem 2** ([6]). *Let  $\Gamma$  be a flat unification problem. If  $\Gamma$  has a unifier, then it also has a local unifier.*

The theorem shows that, in order to decide unifiability of  $\Gamma$ , it is sufficient to guess an acyclic assignment and then check whether the induced substitution is a unifier. The remaining problem is that the induced unifier may be of exponential size. However, in order to check whether a given acyclic assignment  $S$  induces a unifier of  $\Gamma$ , one does not need to construct the unifier  $\sigma_S$  explicitly. In fact,  $S$  can be turned into an acyclic TBox

$$\mathcal{T}_S := \{X \equiv \prod_{D \in S_X} D \mid X \in N_v\},$$

and it is easy to see that the following holds for arbitrary concept descriptions  $E, F$ :  $\sigma_S(E) \sqsubseteq \sigma_S(F)$  iff  $E \sqsubseteq_{\mathcal{T}_S} F$ . Since unification in  $\mathcal{EL}$  w.r.t. acyclic TBoxes

can be decided in polynomial time [1], this obviously yields a way for checking, in polynomial time, whether  $\sigma_S$  solves all equations of  $\Gamma$ .

The original proof of Theorem 2 in [6] was based on the notion of a minimal unifier, though subsequent simpler proofs [7, 2] no longer need this notion.

For readers familiar with unification theory [10], it should be pointed out that the order we use to define minimality of local unifiers (see below) is *not* the instantiation pre-order on substitutions. In fact, it is an easy consequence of the definition of local substitutions that they are ground (i.e., the images of variables under these substitutions do not contain variables), and thus there is no further instantiation possible.

## Minimal unifiers

Given a set of variables  $\mathcal{X} \subseteq N_v$ , we define

$$\begin{aligned} \sigma \succeq_{\mathcal{X}} \theta & \text{ iff } \sigma(X) \sqsubseteq \theta(X) \text{ holds for all variables } X \in \mathcal{X}, \\ \sigma \succ_{\mathcal{X}} \theta & \text{ iff } \sigma \succeq_{\mathcal{X}} \theta \text{ and } \theta \not\succeq_{\mathcal{X}} \sigma. \end{aligned}$$

We say that the unifier  $\sigma$  of  $\Gamma$  is  $\mathcal{X}$ -*minimal* iff there is no unifier  $\theta$  of  $\Gamma$  such that  $\sigma \succ_{\mathcal{X}} \theta$ . We say that two substitutions  $\sigma, \theta$  are *equivalent* ( $\sigma \equiv \theta$ ) iff  $\sigma(X) \equiv \theta(X)$  holds for all  $X \in N_v$ . Note that we have  $\sigma \equiv \theta$  iff  $\sigma \succeq_{N_v} \theta$  and  $\theta \succeq_{N_v} \sigma$ .

**Lemma 3** ([8]). *Let  $\Gamma$  be a flat unification problem.*

1. *If  $\Gamma$  is solvable, then it also has an  $N_v$ -minimal unifier.*
2. *Every  $N_v$ -minimal unifier is equivalent to a local unifier.*

The first part of the lemma is an immediate consequence of the fact [8] that  $\succ_{N_v}$  is well-founded, whereas the proof of the second part in [8] is rather long and intricate. Theorem 2 is an immediate consequence of Lemma 3.

## 3 Minimal unifiers versus minimal assignments

As mentioned before, we are interested in computing only the  $N_v$ -minimal unifiers rather than all local unifiers of a given unification problem. All three  $\mathcal{EL}$ -unification algorithms mentioned in the introduction (the brute-force algorithm, the goal-oriented algorithm, and the one based on a reduction to SAT) actually compute acyclic assignments rather than directly local unifiers. Thus, one can ask what properties of the assignment make unifiers small w.r.t.  $\succeq_{N_v}$ . To answer this question, we define an order similar to  $\succeq_{N_v}$  on acyclic assignments. Let  $S, T$

be acyclic assignments of subsets  $S_X, T_X$  of  $\text{At}_{N_v}$  to the variables  $X$  in  $N_v$ . We define

$$S \geq T \text{ iff } S_X \supseteq T_X \text{ holds for all } X \in N_v.$$

Smaller assignments indeed yield smaller unifiers.

**Lemma 4.** *If  $S \geq T$ , then  $\sigma_S \succeq_{N_v} \sigma_T$ .*

*Proof.* Obviously,  $S \geq T$  implies  $O_S \supseteq O_T$ , and thus  $>_S \supseteq >_T$ . We show  $\sigma_S(X) \sqsubseteq \sigma_T(X)$  for all  $X \in N_v$  by induction along  $>_S$ .

If  $X$  is a minimal element of  $N_v$  w.r.t.  $>_S$ , then it is also a minimal element of  $N_v$  w.r.t.  $>_T$  since  $>_S \supseteq >_T$ . Thus,  $\sigma_S(X) = \prod_{D \in S_X} D$  and  $\sigma_T(X) = \prod_{E \in T_X} E$ . Consequently,  $S_X \supseteq T_X$  implies that  $\sigma_S(X) \sqsubseteq \sigma_T(X)$ .

Assume that  $\sigma_S(Y) \sqsubseteq \sigma_T(Y)$  holds for all  $Y$  such that  $X >_S Y$ . Since  $>_S \supseteq >_T$ , this implies that  $\sigma_S(Z) \sqsubseteq \sigma_T(Z)$  holds for all  $Z$  such that  $X >_T Z$ . Since the concept constructors of  $\mathcal{EL}$  are monotonic w.r.t. subsumption and  $S_X \supseteq T_X$ , this implies

$$\sigma_S(X) = \prod_{D \in S_X} \sigma_S(D) \sqsubseteq \prod_{D \in T_X} \sigma_S(D) \sqsubseteq \prod_{D \in T_X} \sigma_T(D) = \sigma_T(X).$$

This completes the proof of the lemma. □

As an easy consequence of this lemma we obtain that minimal unifiers are induced by minimal acyclic assignments.

**Theorem 5.** *Let  $\Gamma$  be a flat unification problem. Then the set*

$$\{\sigma_S \mid \sigma_S \text{ is a unifier of } \Gamma \text{ and there is no acyclic assignment } T \text{ for } \Gamma \\ \text{ such that } \sigma_T \text{ is a unifier of } \Gamma \text{ and } S > T\}$$

*contains all  $N_v$ -minimal unifiers of  $\Gamma$  up to equivalence.*

*Proof.* Let  $\theta$  be an  $N_v$ -minimal unifier of  $\Gamma$ . By Lemma 3,  $\theta$  is (equivalent to) a local unifier, and thus there exists an acyclic assignment  $T$  such that  $\theta \equiv \sigma_T$ . Let  $S$  be minimal among all assignments that induce a substitution equivalent to  $\theta$ , i.e.,  $\theta \equiv \sigma_S$  and there is no acyclic assignment  $T$  for  $\Gamma$  such that  $\sigma_T \equiv \theta$  and  $S > T$ .

We claim that this implies that there is no acyclic assignment  $T$  for  $\Gamma$  such that  $\sigma_T$  is a unifier of  $\Gamma$  and  $S > T$ . Assume that such an assignment  $T$  exists. Then Lemma 4 implies that  $\sigma_S \succeq_{N_v} \sigma_T$ . Minimality of  $S$  among all assignments that induce a unifier equivalent to  $\theta$  implies that  $\sigma_S \not\equiv \sigma_T$ , and thus  $\sigma_S \succ_{N_v} \sigma_T$ . This contradicts the assumption that  $\theta \equiv \sigma_S$  is  $N_v$ -minimal. □

Thus, if one wants to generate *all* minimal unifiers, it is enough to generate only the minimal acyclic assignments yielding unifiers. If the converse of Lemma 4 were true, we could also show that these assignments yield *only* minimal unifiers. Unfortunately, the converse of Lemma 4 is not true, as demonstrated by the following example.

**Example 6.** Let

$$\Gamma := \{X \equiv^? \exists r.Y, X \equiv^? \exists r.Z, Y \equiv^? A, Z \equiv^? A\}.$$

Consider the acyclic assignments  $S, T$  with

$$\begin{aligned} S_X &:= \{\exists r.Y\}, & S_Y &:= \{A\}, & S_Z &:= \{A\}; \\ T_X &:= \{\exists r.Z\}, & T_Y &:= \{A\}, & T_Z &:= \{A\}. \end{aligned}$$

Then  $\sigma_S(Y) = A = \sigma_T(Y)$ ,  $\sigma_S(Z) = A = \sigma_T(Z)$ , and  $\sigma_S(X) = \exists r.A = \sigma_T(X)$ , i.e.,  $\sigma_S = \sigma_T$  and this substitution is a unifier of  $\Gamma$ . In particular, this implies  $\sigma_S \succeq_{N_v} \sigma_T$ . However,  $S \geq T$  obviously does *not* hold since  $S_X \not\supseteq T_X$ .

It is easy to see that  $S$  and  $T$  are minimal among the acyclic assignments generating unifiers of  $\Gamma$ . This shows that the same  $N_v$ -minimal unifier can be generated by different minimal assignments.

We can also use a unifier  $\sigma$  of  $\Gamma$  to define an acyclic assignment  $S^\sigma$ :

$$S_X^\sigma := \{D \in \text{At}_{\text{nv}} \mid \sigma(X) \sqsubseteq \sigma(D)\}.$$

As shown in [2], this assignment is indeed acyclic.

Surprisingly, the analog of Lemma 4 does not hold: going from unifiers to the induced acyclic assignments is neither monotone nor antitone.

**Lemma 7.** *In general,  $\theta \succeq_{N_v} \sigma$  implies neither  $S^\theta \geq S^\sigma$  nor  $S^\sigma \geq S^\theta$ , even if  $\sigma$  and  $\theta$  are equivalent to local unifiers of the given unification problem  $\Gamma$ .*

*Proof.* Consider the unification problem

$$\Gamma := \{A \sqsubseteq^? X, \exists r.X \sqsubseteq^? Y, Y \sqsubseteq^? \exists r.X'\}.$$

The following substitutions are obviously unifiers of  $\Gamma$ :

$$\begin{aligned} \sigma &:= \{X \mapsto \top, X' \mapsto \top, Y \mapsto \exists r.\top\}, \\ \theta &:= \{X \mapsto A, X' \mapsto \top, Y \mapsto \exists r.\top\}. \end{aligned}$$

and they satisfy  $\theta \succeq_{N_v} \sigma$ .

The non-variable atoms of  $\Gamma$  are  $A$ ,  $\exists r.X$ , and  $\exists r.X'$ , and thus

$$\begin{aligned} S_X^\sigma &= \emptyset, & S_{X'}^\sigma &= \emptyset, & S_Y^\sigma &= \{\exists r.X, \exists r.X'\}, \\ S_X^\theta &= \{A\}, & S_{X'}^\theta &= \emptyset, & S_Y^\theta &= \{\exists r.X'\}. \end{aligned}$$

Since  $S_Y^\sigma \not\subseteq S_Y^\theta$ , we do *not* have  $S^\theta \geq S^\sigma$ ; and since  $S_X^\theta \not\subseteq S_X^\sigma$  we do *not* have  $S^\sigma \geq S^\theta$ .

Finally, note that (up to equivalence)  $\sigma$  and  $\theta$  are local since they are the substitutions respectively induced by  $S^\sigma$  and  $S^\theta$ , i.e.,  $\sigma \equiv \sigma_{S^\sigma}$  and  $\theta \equiv \sigma_{S^\theta}$ .  $\square$

The example constructed in the above proof actually strengthens Example 6 in the sense that it shows that the converse of Lemma 4 is not even true if we assume  $\sigma_S \succ_{N_v} \sigma_T$  rather than  $\sigma_S \succeq_{N_v} \sigma_T$ . Just take  $S = S^\theta$  and  $T = S^\sigma$ . Indeed, we have  $\sigma_{S^\theta} \succ_{N_v} \sigma_{S^\sigma}$ , but  $S^\theta \not\geq S^\sigma$ .

A similar example can be used to show that the set

$$\{\sigma_S \mid \sigma_S \text{ is a unifier of } \Gamma \text{ and there is no acyclic assignment } T \text{ for } \Gamma \\ \text{such that } \sigma_T \text{ is a unifier of } \Gamma \text{ and } S > T\}$$

may in general contain unifiers that are not  $N_v$ -minimal.

**Example 8.** Let

$$\Gamma := \{A \sqsubseteq^? X, Y \equiv^? \exists r.X, \exists r.A \sqsubseteq^? Y\}.$$

The non-variable atoms of  $\Gamma$  are  $A$ ,  $\exists r.X$ , and  $\exists r.A$ . The acyclic assignments

$$S_X = \emptyset, \quad S_Y = \{\exists r.X\}, \\ T_X = \{A\}, \quad T_Y = \{\exists r.A\}$$

generate the unifiers  $\sigma_S = \{X \mapsto \top, Y \mapsto \exists r.\top\}$  and  $\sigma_T = \{X \mapsto A, Y \mapsto \exists r.A\}$  of  $\Gamma$ . We have  $\sigma_T \succ_{N_v} \sigma_S$ , and thus  $\sigma_T$  is not  $N_v$ -minimal. However, it is easy to see that there is no acyclic assignment  $U < T$  such that  $\sigma_U$  is a unifier of  $\Gamma$ .

In fact, assume that  $U < T$ . If  $U_Y = \emptyset$ , then  $\sigma_U(Y) = \top$ , and thus  $\sigma_U$  does not solve the equivalence  $Y \equiv^? \exists r.X$  independent of whether  $U_X = \{A\}$  or  $U_X = \emptyset$ . Consequently, we must have  $U_Y = \{\exists r.A\} = T_Y$ , and thus  $\sigma_U(Y) = \exists r.A$ . However, then  $U < T$  implies  $U_X = \emptyset$ , i.e.,  $\sigma_U(X) = \top$ . But then  $\sigma_U$  again does not solve the equivalence  $Y \equiv^? \exists r.X$ .

This example shows that, even if we only generate minimal acyclic assignments that induce unifiers, this may yield additional local unifiers that are not  $N_v$ -minimal.

We finish this section by investigating what happens if we compose the two transformations  $S \mapsto \sigma_S$  and  $\sigma \mapsto S^\sigma$ .

**Lemma 9.** *Let  $S$  be an assignment and  $\sigma$  a substitution. Then  $S^{\sigma_S} \geq S$  and  $\sigma \succeq_{N_v} \sigma_{S^\sigma}$ . If  $\sigma$  is a local substitution, then we even have  $\sigma \equiv \sigma_{S^\sigma}$ .*

*Proof.* If  $D \in S_X$ , then  $\sigma_S(D)$  is a top-level conjunct of  $\sigma_S(X)$ , and thus  $\sigma_S(X) \sqsubseteq \sigma_S(D)$ , which shows  $D \in S_X^{\sigma_S}$ .

We show the other inequality by induction along  $>_{S^\sigma}$ . If  $X$  is minimal, then no variables occur in  $S_X^\sigma$ , and thus  $\sigma(D) = D$  for all  $D \in S_X^\sigma$ . This yields  $\sigma_{S^\sigma}(X) = \prod_{D \in S_X^\sigma} D \sqsupseteq \sigma(X)$  since all  $D \in S_X^\sigma$  satisfy  $\sigma(X) \sqsubseteq \sigma(D) = D$ .

Assume that for all  $Y \in N_v$  with  $X >_{S^\sigma} Y$  we have  $\sigma_{S^\sigma}(Y) \sqsupseteq \sigma(Y)$ . Consider  $\sigma_{S^\sigma}(X) = \prod_{D \in S_X^\sigma} \sigma_S^\sigma(D)$ . Since  $D \in S_X^\sigma$  contains only variables that are smaller than  $X$  w.r.t.  $>_{S^\sigma}$  and the concept constructors of  $\mathcal{EL}$  are monotone w.r.t. subsumption, the induction assumption yields

$$\prod_{D \in S_X^\sigma} \sigma_S^\sigma(D) \sqsupseteq \prod_{D \in S_X^\sigma} \sigma(D).$$

Finally, since all  $D \in S_X^\sigma$  satisfy  $\sigma(X) \sqsubseteq \sigma(D)$ , we have

$$\prod_{D \in S_X^\sigma} \sigma(D) \sqsupseteq \sigma(X).$$

Since the subsumption relation is transitive, this completes the proof that  $\sigma \succeq_{N_v} \sigma_{S^\sigma}$ .

Finally, assume that  $\sigma$  is local, i.e., there is an acyclic assignment  $T$  such that  $\sigma = \sigma_T$ . We must show  $\sigma_{S^\sigma} \succeq_{N_v} \sigma$ . Because of the first statement of the lemma, we have  $S^{\sigma_T} \geq T$ , and thus  $\sigma_{S^\sigma} = \sigma_{S^{\sigma_T}} \succeq_{N_v} \sigma_T = \sigma$  by Lemma 4.  $\square$

## 4 The complexity of computing exactly the minimal unifiers

The three  $\mathcal{EL}$ -unification algorithms mentioned in the introduction (the brute-force algorithm, the goal-oriented algorithm, and the one based on a reduction to SAT) are NP-decision procedures for unifiability that additionally compute local unifiers in the following sense: each successful run of the nondeterministic algorithm generates an acyclic assignment that induces a unifier. The brute-force algorithm and the SAT-based algorithm generate all local unifiers, whereas the goal-oriented algorithm generates all  $N_v$ -minimal unifiers, but may also generate some additional, non-minimal local unifiers. In this section we investigate the question whether there can exist an NP-algorithm that produces exactly the minimal unifiers in this sense, i.e., where the successful runs yield a set of acyclic assignments that induces exactly the set of minimal unifiers. For the general case of  $\mathcal{X}$ -minimality for an arbitrary subset  $\mathcal{X}$  of  $N_v$ , we give a negative answer to this question.

To this purpose, we consider the following decision problem, which we call the *minimal unifier containment problem*:

**Given:** A flat  $\mathcal{EL}$ -unification problem  $\Gamma$ , a set  $\mathcal{X} \subseteq N_v$ , a concept constant  $A \in N_c$ , and a concept variable  $X \in \mathcal{X}$ .

**Question:** Is there an  $\mathcal{X}$ -minimal unifier  $\sigma$  of  $\Gamma$  such that  $\sigma(X) \sqsubseteq A$ ?

**Theorem 10.** *The minimal unifier containment problem is  $\Sigma_2^p$ -complete.*

*Proof.* Containment in  $\Sigma_2^p$  is easy to see. Guess an acyclic assignment  $S$  of  $\Gamma$  and check (in polynomial time, using  $\mathcal{T}_S$ ) whether it induces a unifier  $\sigma_S$  of  $\Gamma$  that satisfies  $\sigma_S(X) \sqsubseteq A$ . If this check succeeds, then use an NP-oracle to check whether  $\sigma_S$  is  $\mathcal{X}$ -minimal. In fact, an NP procedure for testing whether  $\sigma_S$  is *not*  $\mathcal{X}$ -minimal guesses an acyclic assignment  $T$ , and then uses subsumption tests w.r.t.  $\mathcal{T}_S$  to check whether  $\sigma_S \succ_{\mathcal{X}} \sigma_T$ .

To show  $\Sigma_2^p$ -hardness, we use a reduction from the *minimal model deduction problem*:

**Given:** A propositional formula  $\phi$  in conjunctive normal form and a propositional variable  $x$ .

**Question:** Is there a minimal model  $M$  of  $\phi$  such that  $M \models x$ ?

Here, minimality of propositional models is defined w.r.t. the following order on propositional valuations:  $V' \geq V$  iff for all propositional variables  $x$ ,  $V \models x$  implies  $V' \models x$ .  $\Sigma_2^p$ -completeness of the minimal model deduction problem is an immediate consequence of Lemma 3.1 in [13].

In order to reduce the minimal model deduction problem (as specified above) to the minimal unifier containment problem, we adapt the proof of NP-hardness of  $\mathcal{EL}$ -matching given in [5]. Let  $\phi = \phi_1 \wedge \dots \wedge \phi_m$  be a propositional formula in conjunctive normal form and let  $\{x_1, \dots, x_n\}$  be the propositional variables of this problem. Assume without loss of generality that  $x = x_1$ .

For the propositional variables, we introduce the concept variables

$$\{X_1, \dots, X_n, \bar{X}_1, \dots, \bar{X}_n\},$$

which encode  $x_i$  and  $\neg x_i$ , respectively. In addition, we introduce concept variables  $\{Y_1, \dots, Y_n\}$ , which are used for minimization, i.e.,

$$\mathcal{X} = \{Y_1, \dots, Y_n\}.$$

Furthermore, we need concept constants  $A$  and  $B$  (encoding the truth values) and a role name  $r$ . The unification problem  $\Gamma_{\phi, x}$  constructed from the given minimal model deduction problem consists of the equations introduced below.

First, we specify equations that ensure that  $A, B$  encode the truth values. For all  $i, 1 \leq i \leq n$ , we add the equation

$$\exists r.X_i \sqcap \exists r.\bar{X}_i \equiv? \exists r.A \sqcap \exists r.B.$$

Obviously, any solution of this equation replaces

- either  $X_i$  by a concept description equivalent to  $A$  and  $\overline{X}_i$  by a concept description equivalent to  $B$  (corresponding to  $x_i = true$ ),
- or  $X_i$  by a concept description equivalent to  $B$  and  $\overline{X}_i$  by a concept description equivalent to  $A$  (corresponding to  $x_i = false$ ).

In order to encode  $\phi$ , we introduce an equation for every conjunct  $\phi_j$  of  $\phi$ , where we view  $\phi_j$  as the set of its disjuncts:

$$B \sqcap \prod_{x_i \in \phi_j} X_i \sqcap \prod_{\neg x_i \in \phi_j} \overline{X}_i \equiv? A \sqcap B$$

For example, if  $\phi_j = x_1 \vee \overline{x}_2 \vee x_3 \vee \overline{x}_4$ , then the corresponding equation is  $B \sqcap X_1 \sqcap \overline{X}_2 \sqcap X_3 \sqcap \overline{X}_4 \equiv? A \sqcap B$ . The above equation ensures that, among all the concept variables occurring on the left-hand side, at least one must be replaced by a concept description equivalent to  $A$ . This corresponds to the fact that, in the conjunct  $\phi_j$ , there must be at least one literal that evaluates to *true*. Note that we need the concept name  $B$  on the left-hand side to cover the case where all the variables occurring in it are substituted with  $A$ .

It is easy to see that (up to equivalence) the unifiers of the equations introduced until now (which do not contain the variables in  $\mathcal{X}$ ) correspond exactly to the propositional models of  $\phi$ . Given a propositional valuation  $V$  of  $\phi$ , we define the corresponding substitution  $\sigma_V$  as follows:

- if  $V \models x_i$ , then  $\sigma_V(X_i) := A$  and  $\sigma_V(\overline{X}_i) := B$ ;
- if  $V \models \neg x_i$ , then  $\sigma_V(X_i) := B$  and  $\sigma_V(\overline{X}_i) := A$ .

According to our observations above,  $V$  is a model of  $\phi$  iff  $\sigma_V$  is a unifier of the equations introduced above. In addition, any unifier of these equations is equivalent to a unifier of the form  $\sigma_M$  for a model  $M$  of  $\phi$ .

It remains to express minimal models as  $\mathcal{X}$ -minimal unifiers. For this purpose, we add the equations

$$A \sqcap B \equiv? B \sqcap \overline{X}_i \sqcap Y_i \tag{3}$$

for all  $i, 1 \leq i \leq n$ . This completes the description of the unification problem  $\Gamma_{\phi, x}$ .

The effect of equation (3) is the following:

- If  $X_i$  is substituted with a concept description equivalent to  $A$  (corresponding to  $x_i$  being evaluated to *true*), then  $\overline{X}_i$  is substituted with a concept description equivalent to  $B$ , and thus  $Y_i$  must be substituted by a concept description equivalent to  $A$  or  $A \sqcap B$ . In an  $\mathcal{X}$ -minimal unifier, it is thus substituted with a concept description equivalent to  $A$ .

- If  $X_i$  is substituted with a concept description equivalent to  $B$  (corresponding to  $x_i$  being evaluated to *false*), then  $\bar{X}_i$  is substituted with a concept description equivalent to  $A$ , and thus  $Y_i$  can be substituted by a concept description equivalent to  $\top$ ,  $A$ ,  $B$ , or  $A \sqcap B$ . In an  $\mathcal{X}$ -minimal unifier, it is thus substituted with a concept description equivalent to  $\top$ .

We extend the definition of the substitution  $\sigma_V$  induced by a propositional valuation  $V$  by setting:

- if  $\sigma_V(X_i) = A$ , then  $\sigma_V(Y_i) := A$ ;
- if  $\sigma_V(X_i) = B$ , then  $\sigma_V(Y_i) := \top$ .

We claim that the minimal models of  $\phi$  correspond to the  $\mathcal{X}$ -minimal unifiers of  $\Gamma_{\phi,x}$ .

Let  $M$  be a minimal model of  $\phi$ , and  $\sigma_M$  the corresponding unifier of  $\Gamma_{\phi,x}$ , as defined above. Assume that  $\sigma_M$  is not  $\mathcal{X}$ -minimal. Then there is an  $\mathcal{X}$ -minimal unifier  $\theta$  of  $\Gamma_{\phi,x}$  such that  $\sigma_M \succ_{\mathcal{X}} \theta$ . Define the propositional valuation  $U$  by setting  $U(x_i) := \text{true}$  iff  $\theta(X_i) \equiv A$ . We claim that  $\theta \equiv \sigma_U$ . For  $X \in \{X_1, \dots, X_n, \bar{X}_1, \dots, \bar{X}_n\}$ , we clearly have  $\theta(X) \equiv \sigma_U(X)$ . For  $X \in \{Y_1, \dots, Y_n\}$ ,  $\theta(X) \equiv \sigma_U(X)$  is a consequence of the fact that, for a  $\mathcal{X}$ -minimal unifier  $\theta$ ,  $\theta(Y_i) \equiv A$  iff  $\theta(X_i) \equiv A$  and  $\theta(Y_i) \equiv \top$  iff  $\theta(X_i) \equiv B$ . Since  $\theta$  is a unifier of  $\Gamma_{\phi,x}$ , the same is true for  $\sigma_U$ , and thus  $U$  is a model of  $\phi$ . However, it is easy to see that  $\sigma_M \succ_{\mathcal{X}} \theta \equiv \sigma_U$  implies that  $M > U$ , which contradicts minimality of  $M$ . In fact, assume that  $U \models x_i$ , i.e.,  $\sigma_U(X_i) = A$ . Then  $\sigma_U(Y_i) = A$ , which implies  $\sigma_M(Y_i) = A$  (due to  $\sigma_M \succeq_{\mathcal{X}} \sigma_U$ ), and thus  $M \models x_i$ . This shows  $M \geq U$ . Since  $\sigma_M \succ_{\mathcal{X}} \sigma_U$ , there is an index  $i$  such that  $\sigma_M(Y_i) \sqsubset \sigma_U(Y_i)$ . This is only possible if  $\sigma_M(Y_i) = A$  and  $\sigma_U(Y_i) = \top$ . But then  $\sigma_M(X_i) = A$  and  $\sigma_U(X_i) = B$ , and thus  $M \models x_i$  and  $U \not\models x_i$ . This yields  $M > U$ . To sum up, we have shown:

*If  $M$  is a minimal model of  $\phi$ , then  $\sigma_M$  is an  $\mathcal{X}$ -minimal unifier of  $\Gamma_{\phi,x}$ .*

Conversely, assume that  $\theta$  is a minimal unifier of  $\Gamma_{\phi,x}$ . As shown above, the propositional valuation  $U$  defined as  $U(x_i) := \text{true}$  iff  $\theta(X_i) \equiv A$  is such that  $U$  is a model of  $\phi$  and  $\theta \equiv \sigma_U$ . We claim that  $U$  is a *minimal* model of  $\phi$ . Assume that  $M$  is a model of  $\phi$  such that  $U > M$ . First, note that  $U \geq M$  implies  $\sigma_U \succeq_{\mathcal{X}} \sigma_M$ , i.e.,  $\sigma_U(Y_i) \sqsubseteq \sigma_M(Y_i)$  for all  $i, 1 \leq i \leq n$ . To see this, it is enough to show that  $\sigma_M(Y_i) = A$  implies  $\sigma_U(Y_i) = A$ . However,  $\sigma_M(Y_i) = A$  implies  $\sigma_M(X_i) = A$ , which in turn implies  $M \models x_i$ . But then  $U \geq M$  yields  $U \models x_i$ , and thus  $\sigma_U(X_i) = A$ , which finally implies  $\sigma_U(Y_i) = A$ . Since  $U > M$ , there is an index  $i$  such that  $U \models x_i$ , but  $M \not\models x_i$ . But then  $\sigma_U(Y_i) = A$  and  $\sigma_M(Y_i) = \top$ , and thus  $\sigma_U(Y_i) \sqsubset \sigma_M(Y_i)$ . This shows  $\sigma_U \succ_{\mathcal{X}} \sigma_M$ , which contradicts the  $\mathcal{X}$ -minimality of  $\theta \equiv \sigma_U$ . To sum up, we have shown:

If  $\theta$  is an  $\mathcal{X}$ -minimal unifier of  $\Gamma_{\phi,x}$ , then there is a minimal model  $M$  of  $\phi$  such that  $\theta \equiv \sigma_M$ .

To finish the proof of the theorem, first assume that there is a minimal model  $M$  of  $\phi$  such that  $M \models x_1$ . Then the  $\mathcal{X}$ -minimal unifier  $\sigma_M$  of  $\Gamma_{\phi,x}$  satisfies  $\sigma_M(Y_1) = A$ , and thus  $\sigma_M(Y_1) \sqsubseteq A$ . Conversely, assume that there is an  $\mathcal{X}$ -minimal unifier  $\theta$  of  $\Gamma_{\phi,x}$  such that  $\theta(Y_1) \sqsubseteq A$ . Then there is a minimal model  $M$  of  $\phi$  such that  $\theta \equiv \sigma_U$ . But then  $\sigma_U(Y_1) \equiv \theta(Y_1) \sqsubseteq A$  yields  $\sigma_U(Y_1) = A$ , which implies  $M \models x_1$ .

To sum up, we have described a polynomial-time reduction of the minimal model deduction problem to the minimal unifier containment problem. Since the former problem is known to be  $\Sigma_2^p$ -hard, this shows  $\Sigma_2^p$ -hardness of the latter problem.  $\square$

As an immediate consequence of this theorem, we can show that there cannot be an NP-algorithm that generates exactly the minimal unifiers of the given  $\mathcal{EL}$ -unification problem.

**Corollary 11.** *Unless the polynomial hierarchy collapses, there cannot exist an NP-decision procedure for unifiability in  $\mathcal{EL}$  that, given a flat  $\mathcal{EL}$ -unification problem  $\Gamma$  and a subset  $\mathcal{X}$  of the concept variables occurring in  $\Gamma$ , not only decides unifiability of  $\Gamma$ , but additionally computes exactly the  $\mathcal{X}$ -minimal unifiers of  $\Gamma$  in the following sense:*

- *each successful run of the nondeterministic procedure generates an acyclic assignment  $S$  such that the induced local unifier  $\sigma_S$  is an  $\mathcal{X}$ -minimal unifier of  $\Gamma$ , and*
- *for every  $\mathcal{X}$ -minimal unifier  $\theta$  of  $\Gamma$  there is a successful run of the nondeterministic procedure that generates an acyclic assignment  $S$  such that  $\sigma_S \equiv \theta$ .*

*Proof.* Assume that there exists an NP-decision procedure for unifiability in  $\mathcal{EL}$  that computes exactly the  $\mathcal{X}$ -minimal unifiers of  $\Gamma$  in the sense introduced above. Then we could decide the minimal unifier containment problem within NP. In fact, the NP-procedure for deciding this problem is obtained by using the one that computes exactly the  $\mathcal{X}$ -minimal unifiers, but for every successful path of that procedure checks whether the generated acyclic assignment  $S$  satisfies  $X \sqsubseteq_{\tau_S} A$ . This test can be performed in polynomial time, and it yields the same result as testing whether  $\sigma_S(X) \sqsubseteq A$ . Since the acyclic assignments generated by the original NP-procedure correspond exactly to the  $\mathcal{X}$ -minimal unifiers, there is a successful path of the extended NP-procedure iff there is an  $\mathcal{X}$ -minimal unifier  $\theta$  satisfying  $\theta(X) \sqsubseteq A$ . Thus, this extended procedure decides the minimal unifier containment problem within NP. Obviously, membership of a  $\Sigma_2^p$ -complete problem in NP would imply  $\Sigma_2^p = NP$ . It is well-known that this would imply that the whole polynomial hierarchy collapses.  $\square$

## 5 Conclusion

The results of this paper indicate that it is not easy to compute all and only the minimal unifiers of a given  $\mathcal{EL}$ -unification problem. On the one hand, while it is sufficient to compute only minimal acyclic assignment to obtain all minimal unifiers, this restriction does not guarantee that only minimal unifiers are generated. On the other hand, NP-procedures cannot generate exactly the  $\mathcal{X}$ -minimal unifiers for subsets  $\mathcal{X}$  of the set of all variables. It is an open problem whether this last fact is also true if  $\mathcal{X}$  is required to be the set of all variables.
