where C_j is the centroid of class *j*. It is to be noted that the input patterns are normalized in the interval [0,1].

The type-1 fuzzy membership values of input patterns for each class are used as inputs to the BP neural network. Therefore, the dimension of the input to the BP neural network is the same as the number of classes. Fig. 3 illustrates the structure of our proposed general T2 FMF generation method applied to a BP neural network.

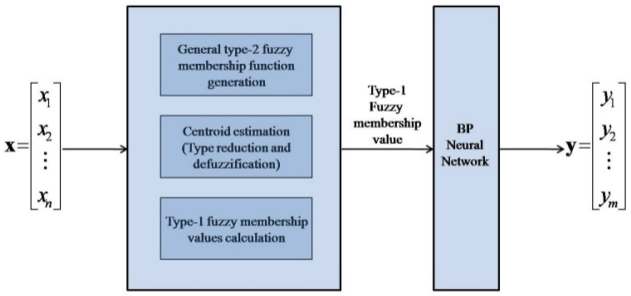

Fig. 3. Structure of the proposed general T2 FMF generation method applied in a BP neural network.

V. EXPERIMENTAL RESULTS

To show the performance of our proposed general T2 FMF design, BP neural network classification results are given for "T-shape" data sets and segmentation results for real images.

A. "T-shape" data

For our first example, we use the "T-shape" data set that consists of 447 patterns (228 and 219 patterns for each class) with 2 features and 2 classes. All pattern features are normalized between 0 and 1. We select 10% patterns for testing and the remaining patterns for training. This procedure is repeated for all the patterns, hence, every pattern will be tested only one time. Fig. 4 shows the scatter plot of the data.

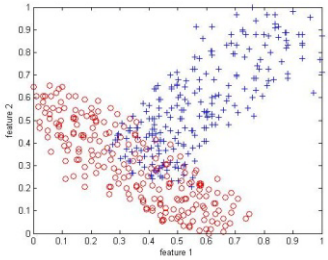

Fig. 4. Scatter plot for "T-shape" data.

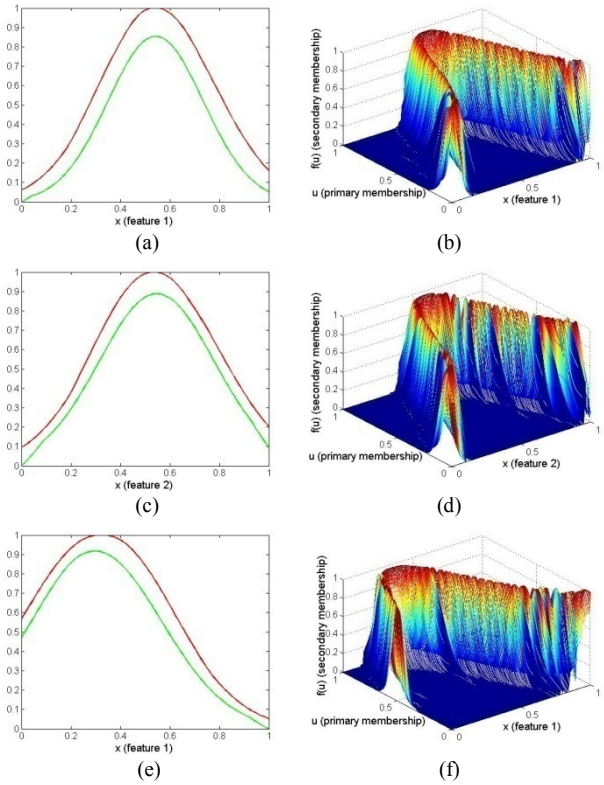
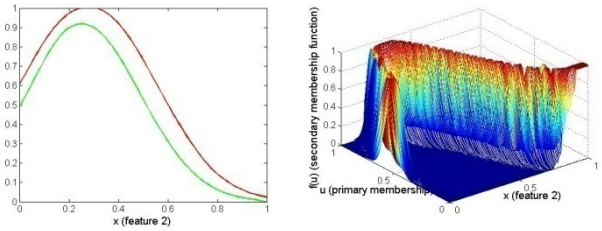
As described above, we obtain general T2 FMFs by fitting Gaussian functions to the histograms of the lower and upper membership values at each vertical slice *x* domain values for each class and feature, which are obtained from the histograms of the training data. Fig. 5(a) and (b) ((c) and (d)) shows the FOU and 3D plot of the general T2 FMF for class 1 of feature 1(2), respectively. Fig. 5(e) and (f) ((g) and (h)) shows the FOU and 3D plot of the general T2 FMF for class 2 of feature 1(2), respectively.

We next estimate the centroid of the general T2 FSs by performing type reduction and defuzzification procedure using the α-plane representation and Karnik-Mendel algorithms. We extract type-1 fuzzy membership values for training data using the distance between the centroid and training data.





(g) (h)

Fig. 5. FOUs and 3D graph of general T2 FMF for: (a) and (b) class1 of feature1, (c) and (d) class 1 of feature2, (e) and (f) class2 of feature1, and (g) and (h) class2 of feature2.

Next, we train a BP neural network using the type-1 fuzzy membership values for training data as inputs. The test patterns are then classified using the trained BP neural network. Fig. 6 shows the classification results for the type-1 fuzzy membership values using IT2 FMF and general T2 FMF method, and for crisp input patterns as inputs to the BP neural network according to the number of hidden neurons. As shown in figure, BP neural networks trained with fuzzy inputs outperform the case with crisp inputs.

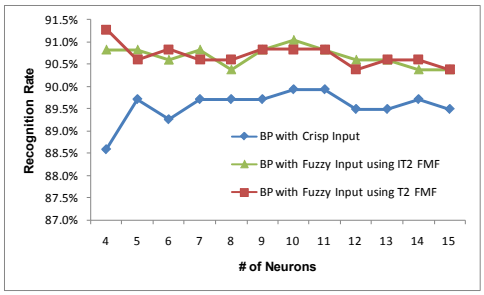


Fig. 6. Classification results for "T-shape" data.

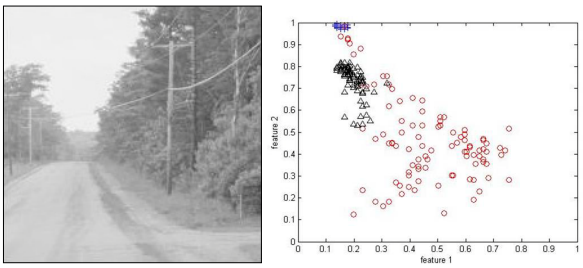
B. *Real image data segmentation*

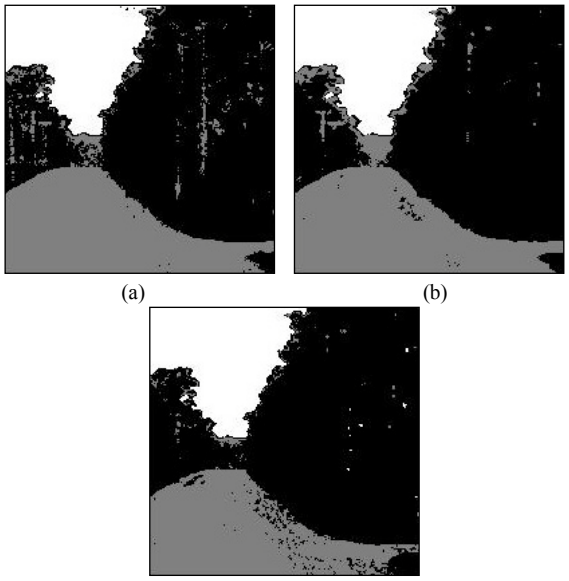
In this example, we show segmentation results for a 200×200 real scene image that consists of three regions, namely road, forest, and sky. The gray levels of median and excess green filtered images were used as feature values. We then randomly select 100 samples in each region and the feature values are used for training data. Fig. 7(a) and (b) shows the original image and the scatter plot of randomly selected sample data, respectively.



(a) (b)

Fig. 7. Real image example: (a) original image and (b) scatter plot of sample data.

As in the previous example, we generate general T2 FMFs and extract type-1 fuzzy membership values for training data. Next, we train BP neural networks using the type-1 fuzzy membership values for training data. Finally, fuzzy membership values for all feature data of the original image were classified into three classes using the trained BP neural network. Fig. 8(a), (b) and (c) shows the segmentation results for crisp inputs, fuzzy inputs using the IT2 FMF, and fuzzy inputs using the general T2 FMF, respectively, when 10 hidden neurons were used. Fig. 9 shows the recognition rate according to the number of hidden neurons. The recognition rate was improved by 3.2% compared to IT2 FMF method. Table I shows the confusion matrix for the results in Fig. 8. Although the recognition showed little improvement, the segmentation result showed a more significant visual improvement.



(a) (b)

(c)

Fig. 8. Segmentation results for BP neural network with 10 hidden neurons: (a) crisp input, (b) fuzzy input using IT2 FMF, and (c) fuzzy input using T2 FMF.

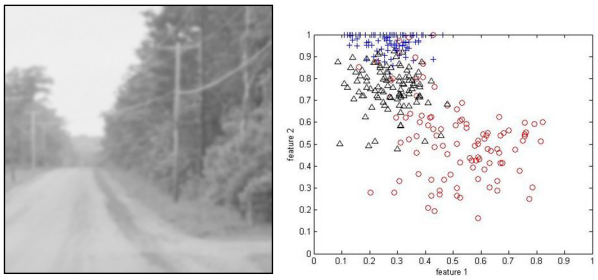
TABLE I
CONFUSION MATRIX FOR SEGMENTATION RESULTS IN FIG. 8(B) AND (C)

Real Image	BP neural network using fuzzy inputs using IT2 FMF Recognition rate = 90.7%			BP neural network using fuzzy inputs using T2 FMF Recognition rate = 93.9%		
	Road	Forest	Sky	Road	Forest	Sky
Road	8150	70	0	7876	344	0
Forest	3162	21785	499	1536	23381	529
Sky	3	16	6315	3	16	6315

C. Noisy image data segmentation

For our final experiment, we apply 5% Gaussian noise to Fig. 7(a). The training and testing procedure are the same as previous example. Fig. 10(a) and (b) shows the noisy image and the scatter plot of sample data, respectively. Fig. 11(a), (b), and (c) illustrates the segmentation results for crisp inputs, fuzzy inputs using IT2 FMF, and fuzzy inputs using general T2 FMF, respectively, when 8 hidden neurons were used in BP neural network training. As shown in Fig. 12, the recognition rate was improved about 4% at most compared to crisp input and the variation of results for various neurons is more stable than the IT2 FMF method.



(a) (b)

(a) (b)

(c)

Fig. 11. Segmentation results for BP neural network with 8 hidden neurons: (a) crisp input, (b) fuzzy input using IT2 FMF, and (c) fuzzy input using T2 FMF.

VI. CONCLUSION

In this paper, we proposed a general T2 FMF design method and applied the type-1 fuzzy membership values, which are estimated from the centroid of the T2 FMF, as inputs to train BP neural networks. The experimental results showed an improvement in classification performance over the case when crisp inputs were trained and IT2 FMF was used.

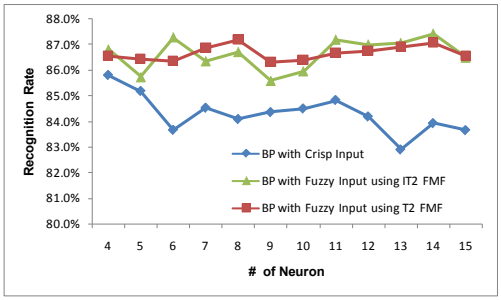

Fig. 12. Recognition rate of noisy image for various number of neurons.

This indicates that our proposed general T2 FMF design method can effectively manage the uncertainty of pattern data. Other general T2 FMF generation methods are currently under investigation.

***Abstract*—Shape and motion are two most distinct cues observed from human actions. Traditionally, K-Nearest Neighbor (K-NN) classifier is used to compute crisp votes from multiple cues separately. The votes are then combined using linear weighting scheme. Usually, the weights are determined in a brute-force or trial-and-error manner. In this study, we propose a new classification framework based on sum-rule fusion of fuzzy K-NN classifiers. Fuzzy K-NN classifier is capable of producing soft votes, also known as fuzzy membership values. Based on Bayes theorem, we show that the fuzzy membership values produced by the classifiers can be combined using sum-rule. In our experiment, the proposed framework consistently outperforms the conventional counterpart (K-NN with majority voting) for both Weizmann and KTH datasets. The improvement may attribute to the ability of the proposed framework to handle data ambiguity due to similar poses present in different action classes. We also show that the performance of our method compares favorably with the state-of-the-arts.**

***Index Terms*—Action recognition, Sum-Rule Fusion, Fuzzy K-NN**

I. Introduction

Human can recognize an action in a seemingly effortless fashion. In contrast, the solutions using computer vision have, in many cases, proved to be immensely difficult. The challenges include: huge collection of possible actions, poor recording settings, temporal variations, inter/intra-personal differences etc. In addition, the choice of optimal representation for an action is still an open problem. Recent approaches can be categorized into global and local representations. For global representation, the region-of-interest (obtained by tracking or background subtraction) is encoded as a whole. In other words, the entire human figure is considered. Silhouette, optical flow, edge and space-time volume fall into this category. Efros *et al.* [1] used blurred optical flows to recognize the actions of small human figures. Blank *et al.* [2] stacked silhouettes over a sequence to form space-time volumes. Poisson equation was used to compute local space-time saliency and orientation features. Ikizler *et al.* [3] extended the motion descriptor of Efros by using spatial and directional binning and then combined it with line shape descriptor. Following that, they proposed to use histogram of oriented rectangles as the shape descriptor [4]. Likewise, Lin *et al.* [5] used silhouettes as the shape descriptor by counting the number of foreground pixels and motion-compensated optical flow as motion descriptor. On the contrary, local representation encodes the image or video frames as a collection of local patches. Common local representation includes spatio-temporal interest points such as 3D Harris, cuboid, Hessian, Dense etc. Usually the interest points are extracted at different spatial and temporal scales. Laptev and Lindeberg [6] proposed to extend Harris corner detector to the third dimension. Dollár *et al.* [7] cuboid detector is based on temporal Gabor filter. Willems *et al.* [8] measured the saliency with the determinant of the 3D Hessian matrix.

According to Ikizler *et al.* [4], an action is defined by three key elements: (a) pose of the body, (b) speed of body motion, and (c) relative ordering of the poses. Actions such as jogging, walking and running can be easily confused if only pose information is used due to similar postures in the action sequences. It has been suggested that combinations of multiple cues may overcome the limitations of a single representation [9]. This is because different inputs may offer complimentary information about the patterns to be classified. In view of this, previous studies which used multiple cues were mainly based on linear weighting of classifiers' votes [3], feature vectors concatenation [5], [10], and hierarchical system [4], [3], [11]. While linear weighting scheme may seem straightforward, the weights are usually obtained in a brute-force or trial-and-error manner.

Apart from the uncertainty in determining the correct weight, most of the previous studies relied on conventional K-nearest neighbor classifier [12]. However, the algorithm has a major drawback: each prototype is considered equally important in the assignment of input patterns. Atypical data are weighted as much as the data from the true class. This can cause ambiguity in those places where the data overlap.

In this work, we address the aforementioned problems in two ways. First, we propose to use fuzzy K-NN classifiers to classify shape and motion feature respectively. The outputs of the classifiers can be regarded as the confidence levels of the input belonging to different classes. Next, we show that based on Bayes theorem the outputs of the classifiers can be fused using sum-rule.

The paper is organized as follows. In Section II we give an overview of the proposed action recognition framework. Next, we describe the details of shape and motion feature extraction in Section III. Subsequently, we outline the fuzzy K-NN algorithm and propose the sum-rule as the fusion strategy of the fuzzy outputs in Section IV. Section V sets the backdrop

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

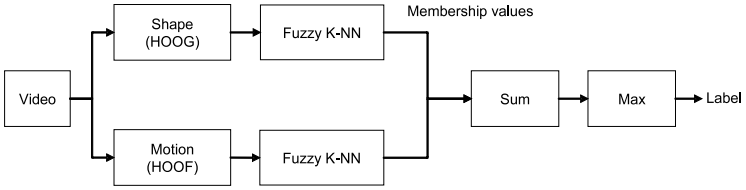

Fig. 1. The proposed shape-motion path combination strategy using Fuzzy K-NN with sum-rule.

for the experimental evaluation while Section VI shows the results with some comparisons to the state-of-the-art methods. Finally, Section VII gives the conclusion remarks of the paper.

II. System Overview

The proposed system is illustrated in Fig. 1. From the shape path, fuzzy K-NN classifier produces membership value $\boldsymbol{\mu}_i = \{\mu_{i1}, \mu_{i2}, \ldots, \mu_{iC}\}$ for each snippet where C denotes the number of classes. Given a video sequence with M snippets, we then compute the average of the membership values from all snippets, i.e., $\boldsymbol{U_s} = (\sum_i \boldsymbol{\mu}_i)/M = \{U_1, U_2, \ldots, U_C\}$ and normalize it to $\widetilde{\boldsymbol{U_s}} \in [0, 1]$. Likewise, we compute the normalized membership values $\widetilde{\boldsymbol{U_m}}$ from the motion path. Next, we combined the membership values from both shape and motion inputs using sum-rule

$$\boldsymbol{U} = \widetilde{\boldsymbol{U}}_{\boldsymbol{s}} + \widetilde{\boldsymbol{U}}_{\boldsymbol{m}} \tag{1}$$

Finally, we apply winner-takes-all principle to determine the class label.

Since the proposed system will be compared with the conventional system (K-NN with majority voting), we briefly discuss the architecture of the latter (see Fig. 2). Consider the shape path first, for each test snippet we find the K-nearest snippets from the training set and assign its label to the class most common among its neighbors. We can obtain crisp votes $\boldsymbol{v}_i = \{v_{i1}, v_{i2}, \ldots, v_{iC}\}$ from the i-th snippet. The votes from the individual snippets (from the same video) are then summed up, i.e., $\boldsymbol{V_s} = \sum_i \boldsymbol{v}_i = \{V_1, V_2, \ldots, V_C\}$. The step is repeated for the motion path to obtain the votes $\boldsymbol{V_m}$. The crisp votes from the shape and motion paths are combined using linear weighting scheme

$$\boldsymbol{V} = \alpha \boldsymbol{V_s} + (1 - \alpha)\boldsymbol{V_m} \tag{2}$$

where $\alpha \in [0, 1]$ is a design parameter that adjust the relative importance of shape and motion votes. Finally, the video is assigned to the class that has the highest votes, $\boldsymbol{V}$.

III. Motion and Shape Feature Extraction

As delineated in the introduction part, observing shape and motion is a very natural way to recognize an action. Motivated by the robustness of the histogram of feature, we use histogram-of-oriented gradient (HOOG) and histogram-of-oriented optical flow (HOOF) as the shape and motion descriptors respectively. We adopt the histogram formation method which was originally introduced by Chaudhry *et al.* [13]. The method is more robust against scale variation and the change of motion direction. The method is illustrated in Fig. 3(a) with example of creating a 4-bin histogram. The main idea is to bin the vectors according to their primary angles from the horizontal axis. Therefore, the vectors are symmetry about the vertical axis. As a result, the histogram of a person moving from left to right will be same as the one with a person moving in the opposite direction. The contribution of each vector is proportional to its magnitude. The histogram is normalized to sum up to unity to make it scale-invariant. Therefore, we do not normalize the size of the bounding box. We further enhance Chaudhry *et al.* algorithm by including spatial information. This is done by dividing the bounding box of the subject into 4×4 regions as shown in Fig. 3(b).

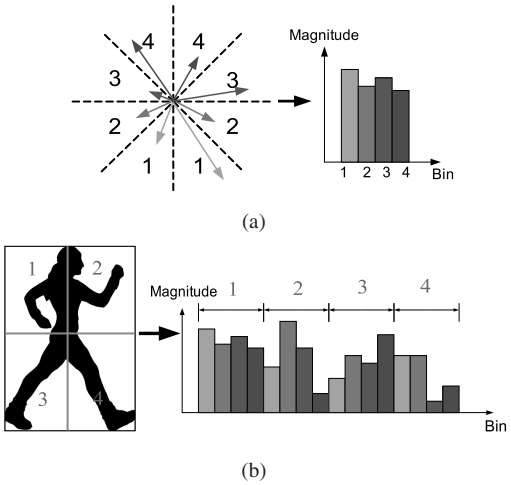

Fig. 3. (a) Histogram binning, (b) the bounding box is divided into 4×4 grid and the resultant histograms from each region are concatenated.

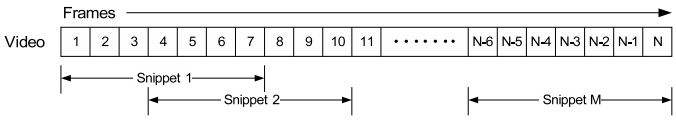

Fig. 4. An example of video sequence that is divided into overlapping snippets.

The pose ordering and time-warping effect can be handled by using overlapping snippets instead of a single frame. Fig. 4 shows an example of 7-frame snippet with four overlapped frames, which is the setting that we used for all experiments in this study.

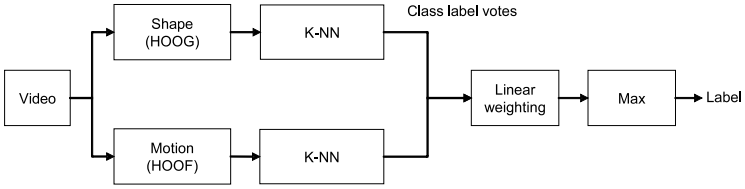

Fig. 2. The conventional shape-motion path combination strategy using K-NN with linear weighting.

IV. Sum-Rule Fusion of Fuzzy K-Nearest Neighbor Classifiers

Unlike the conventional crisp K-NN, fuzzy K-NN algorithm [14] assigns class membership value to an input data rather than class label. The membership assignment is based on the distance between the input data and its K-nearest neighbors and those neighbors' memberships (pre-computed during initialization process) in the possible classes. Let $S = \{\mathbf{x}_1, \mathbf{x}_2, \cdots, \mathbf{x}_n\}$ be a set of n labeled samples. Also, let $\mu_j(\mathbf{x})$ be the membership assigned to the input data $\mathbf{x}$, and $\mu_{ij}(\mathbf{x})$ be the membership in the jth class of the ith labeled prototype.

$$\mu_j(\mathbf{x}) = \frac{\sum_{i=1}^{K} \mu_{ij}\left(1/\hbar(\mathbf{x}, \mathbf{x}_i)^{2/(m-1)}\right)}{\sum_{i=1}^{K}\left(1/\hbar(\mathbf{x}, \mathbf{x}_i)^{2/(m-1)}\right)} \tag{3}$$

Note that in this work $\hbar(\mathbf{x}, \mathbf{x}_i)$ denotes Hellinger distance instead of Euclidean distance [14] because the former provides a more accurate histogram-type feature similarity measure. The parameter m ($m > 1$) is used to scale the effect of the distance measure. The algorithm requires the prototype membership value to be initialized:

$$\mu_{ij}(x) = \begin{cases} 0.51 + (n_j/K) * 0.49 & \text{if } j = i \\ (n_j/K) * 0.49 & \text{if } j \neq i \end{cases} \tag{4}$$

where n_j is the number of the neighbors which belong to the jth class. This initialization procedure ensures the prototype is more informative. The more accurate the initial membership value is, the more accurate the classification result will be.

Suppose there are R classifiers and each rth classifier will classify a distinct input vector $\mathbf{x}_r$, $(r = 1, \ldots, R)$. Bayes rule can be applied to find the class label, c_{j^*}:

$$j^* = \arg\max_j \left(P(c_j|\mathbf{x}_1, \ldots, \mathbf{x}_R)\right) \tag{5}$$

where

$$P(c_j|\mathbf{x}_1, \ldots, \mathbf{x}_R) = \frac{p(\mathbf{x}_1, \ldots, \mathbf{x}_R|c_j)P(c_j)}{p(\mathbf{x}_1, \ldots, \mathbf{x}_R)} \tag{6}$$

In order to evaluate (5), the joint probability density function $p(\mathbf{x}_1, \ldots, \mathbf{x}_R|c_j)$, which is difficult to infer, must be computed. Based on two assumptions, sum-rule can be used to combine the outputs of multiple classifiers [9]. The assumptions are: (a) the inputs $\mathbf{x}_r$ are conditionally statistically independent, and (b) a posteriori probabilities of individual classifier $P(c_j|\mathbf{x}_r)$ will not deviate from the prior probabilities $P(c_j)$ by a large margin. The first assumption is readily satisfied because we are using two types of representations: shape and motion. Moreover, the second assumption can be satisfied when the discriminatory information is highly ambiguous due to the high level of noise. For example, KTH dataset has very strong intra-subject variations due to different recording scenarios. The sum-rule is given as:

$$j^* = \arg\max_j \left[(1-R)P(c_j) + \sum_{r=1}^{R} P(c_j|\mathbf{x}_r)\right] \tag{7}$$

When priors are equal, (7) can be reduced to:

$$j^* = \arg\max_j \left(\sum_{r=1}^{R} P(c_j|\mathbf{x}_r)\right) \tag{8}$$

For fuzzy K-NN, we can approximate $P(c_j|\mathbf{x})$ as:

$$P(c_j|\mathbf{x}) \approx \mu_j(\mathbf{x}) \tag{9}$$

Notice that unlike the estimation of posterior probability from Neural Network where normalization of output is required [9], there is no need to normalize the output of fuzzy K-NN classifier because $\mu_j(\mathbf{x}) \in [0, 1]$.

There are some other forms of classifiers combination strategies such as product-rule, min-rule, max-rule, and majority voting proposed by Kittler *et al.* [9]. We will compare the performance of sum-rule to these variants in Section VI.

V. Experiments

We performed various experiments to evaluate the proposed action recognition framework on two publicly available datasets (see Fig. 5):

- **Weizmann** The dataset was originally introduced in [2]. The dataset contains 90 low-resolution (180×144 pixels) video sequences with 9 subjects performing 10 actions: bend (*bend*), jumping-jack (*jack*), jump-forward (*jump*), jump-in-place (*pjump*), run (*run*), gallop-sideways (*side*), jump-forward-one-leg (*skip*), walk (*walk*), wave-one-hand (*wave1*), and wave-two-hands (*wave2*)[1]. We used the silhouettes provided to compute the bounding boxes for the subjects. HOOG and HOOF features are extracted from the silhouettes.

- **KTH** The dataset was introduced in [15]. There are 25 subjects performing 6 actions: boxing, handclapping, handwaving, jogging, running, and walking. The low resolution (160×120) videos were recorded under four

[1]Note that there are two versions of Weizmann dataset, the original one has 9 actions while the augmented version has 10 which includes *skip* action.

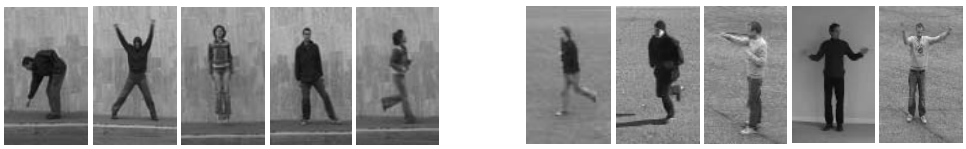

Fig. 5. Examples of different actions from databases Weizmann (left) and KTH (right).

scenarios (s1- outdoors, s2- outdoors with scale variation, s3- outdoor with different clothes, s4- indoors with lighting variation) and each video was split into 4 sub-clips. Originally, the dataset has (4 settings) $\times$ (25 subjects) $\times$ (6 actions) $\times$ (4 sub-clips) = 2400 clips. However, only 2391 clips are available because 8 clips were missing. We used the bounding box provided by Lin *et al.* [5] to locate the subject. Nevertheless, we did not compute the silhouette because object segmentation is not our focus in this work. Therefore, HOOG and HOOF features are extracted directly from the raw grayscale video frames.

In the literature, KTH dataset has been regarded either as one large set with strong intra-subject variations (*all-in-one*) or as four independent scenarios. In the latter case, each scenario is trained and tested separately. In this work, we only focus on the *all-in-one* case. Since KTH dataset size is much larger than Weizmann dataset, we use K-means algorithm to cluster the training data. Each class is quantized into 500 clusters. This can reduce the intra-class variation and computational time. Leave-one-out cross validation (LOOCV) protocol is used in all evaluations.

For Fuzzy K-NN, we set parameter $m = 2$ such that the influence of of each neighbor is weighted by the square of reciprocal of its distance from the query point. The parameter K is varied from 3, then 5 to 7 to evaluate the effect of the neighborhood size.

VI. Results and Discussions

From the experiment on Weizmann dataset using the proposed framework and the conventional framework, it is evident that neighborhood size of 3 consistently gives better performance than other sizes. Table I shows the LOOCV recognition rate for Weizmann dataset when using neighborhood of K = 3. By comparing the results using single representation (either shape or motion feature only), it is noticed that fuzzy K-NN always performed better than K-NN counterparts with improvement of 3.33% and 2.22% when using the shape and motion features respectively. When the outputs from fuzzy K-NN classifiers were combined using sum-rule, the proposed system yielded 100% accuracy. In contrast, the conventional K-NN with linear weighting scheme only achieved 97.78%. Note that for this conventional scheme, the weight, α was set to 0.5 so that the shape and motion features were equally important to facilitate a common comparison setting for both systems.

The result for KTH dataset is tabulated in Table II. It is worth noting that fuzzy K-NN consistently outperforms K-NN counterpart when using single representation only. The advantage of the proposed framework is even more prominent when both shape and motion inputs are combined. The classification accuracy is improved by as much as 5% when $K = 3$. We also investigate the effect of neighborhood size K. The results show that $K = 3$ gives the best results for both frameworks. Considering all three neighborhood sizes, the proposed framework outperforms the conventional counterpart by 3.59% in classification accuracy on average.

TABLE I
Weizmann Average Accuracy (K=3, LOOCV).

Framework	Shape	Motion	Combined
KNN + Linear weighting	92.22%	92.22%	97.78%
Fuzzy K-NN + Sum Rule	95.55%	94.44%	**100**%

TABLE II
KTH Average Accuracy (*all-in-one*, LOOCV).

Framework	K	Shape	Motion	Combined
KNN + Linear weighting	3	74.22%	82.44%	85.80%
	5	72.73%	82.14%	85.46%
	7	72.57%	82.14%	85.12%
Fuzzy K-NN + Sum Rule	3	77.97%	83.13%	**90.80**%
	5	76.91%	82.25%	88.43%
	7	74.76%	83.59%	87.93%

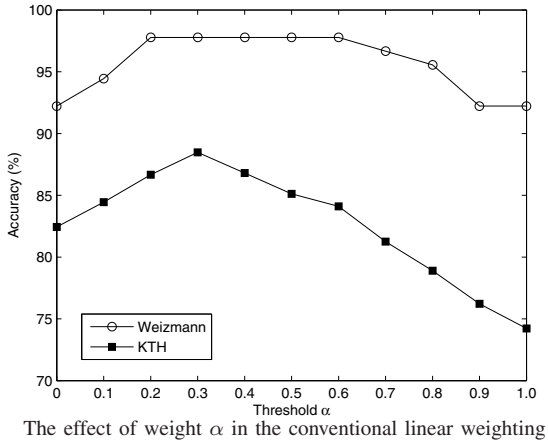

Fig. 6. The effect of weight α in the conventional linear weighting scheme on the average classification rate for Weizmann and KTH datasets. The weight is used to control the relative importance of the votes from shape and motion cues. $\alpha = 0$ corresponds to motion only while $\alpha = 1$ corresponds to shape only. The neighbor size, K is set to 3.

The results from Table I and II suggest that the contribution of each feature is dataset dependant. For instance, the shape feature is slightly better than the motion feature for

Fig. 7. Similar poses observed from *jogging* (left) and *running* (right) action sequences.

Weizmann dataset. On the other hand, we observe that for KTH dataset motion feature is much more discriminative than the shape feature. This implies that in the conventional linear weighting approach the contribution of each feature must be pre-determined by finding a suitable weight, α. Therefore, we evaluated the effect of α as shown in Fig. 6. The best results are only 97.78% for Weizmann and 88.48% for KTH. This provides clear evidence that regardless of the weight values, the conventional framework is still inferior to our implicitly weight-free framework. Another interesting observation from Table II is that the performance improvement brought by fuzzy K-NN classifier is more significant on the classification based on shape rather than motion features. The reason could be that fuzzy K-NN is able to handle the uncertainty in the poses better compared to conventional K-NN classifier. The uncertainty can arise from similar postures in action sequences such as jogging and running as shown in Fig. 7. Recall that fuzzy K-NN has an initialization procedure to weight the training sample which potentially resolves the data overlap problem. On the contrary, conventional K-NN suffers from the drawback that each training sample is considered equally important which causes atypical sample is weighted as much as the sample from the true class.

Finally, we investigate the performance of sum-rule compared to other combining schemes. The result from Table III clearly show that sum-rule delivers the best classification rate, closely followed by product-rule, max-rule, min-rule, and majority voting schemes. The result is consistent with Kittler *et al.* [9] findings that sum-rule produces the most reliable decisions due to its robustness against estimation error.

TABLE III
CLASSIFICATION RATE FOR KTH DATASET USING DIFFERENT COMBINING SCHEMES

Combining Schemes	Accuracy (%)
Sum-rule	**90.80**
Product-rule	89.61
Max-rule	87.94
Min-rule	86.09
Majority vote	81.94

The confusion matrix for KTH is given in Fig. 8. Most of the errors occur when *running* action is misclassified as *jogging* action. This is followed by *boxing* and *clapping* actions. This observation is consistent with the results reported in [10], [8], [16]. Although the main goal of this work is to compare our framework to the conventional K-NN with linear weighting method, we also compare the results against state-of-the-art action recognition approaches. Table IV shows that our method achieved the same perfect accuracy as [17] for Weizmann dataset. As for KTH dataset, it may be argued that the results are not directly comparable as different authors employed different evaluation protocol (splits vs. LOOCV). While not definitive, Table V still provides some indicative comparison. The result shows that our system remains competitive compared to the other methods. In fact, our method achieved the second best result (only slightly inferior to Lin *et al.* [5]). One possible reason is that Lin *et al.* used silhouette for feature extraction. It is well known that silhouette requires good background modelling which is more restrictive than the bounding box-based approach. In contrast, our KTH experiment only used the original grayscale image containing inside the bounding box. From the result, it can be deduced that our method can perform very well even without using silhouette. In addition, it should be noted that in Lin *et al.* work the prototype tree is only used for quantization when matching the frame to prototype. The algorithm still relies on dynamic time warping which are computationally expensive when the video is long. Our framework has the advantage of efficient computation.

VII. CONCLUSION

This paper presents a new fuzzy-KNN with sum-rule fusion framework to perform action recognition from shape-motion features. The novelty is in the new approach to fuse the decisions from shape-motion cues which is very efficient in implementation. We demonstrated that fuzzy K-NN classifier can deliver better performance than the conventional K-NN classifier especially when dealing with data uncertainty. This is evident when classifying actions with similar poses. The introduction of sum-rule to combine fuzzy K-NN classifiers outputs has shown promising results compared to other combining schemes such as product-rule, max-rule etc. One major advantage of using sum-rule is that the process of choosing the suitable weight through trial-and-error is no longer required. The method described in this paper facilitates a generic framework that can also be used to combine the classification results from heterogenous inputs other than shape and motion.

***Abstract*—In this paper, the kernel fuzzy c-means clustering algorithm is extended to an adaptive cluster model which maps data points to a high dimensional feature space through an optimal convex combination of homogenous kernels with respect to each cluster. This generalized model, called Fuzzy C-Means with Multiple Kernels (FCM-MK), strives to find a good partitioning of the data into meaningful clusters and the optimal kernel-induced feature map in a completely unsupervised way. It constructs the kernel from a number of Gaussian kernels and learns a resolution specific weight for each kernel function in each cluster. This allows better characterization and adaptability to each individual cluster. The effectiveness of the proposed algorithm is demonstrated for several toy and real data sets.**

***Index Terms*—Fuzzy Clustering, Multiple Kernels, Resolution Weights.**

I. Introduction

Clustering methods have been used extensively in computer vision and pattern recognition. Fuzzy clustering, where an object can belong to multiple clusters with a certain degree of membership, has been shown to be more effective than crisp clustering where a point can be assigned to only one cluster. This is particularly useful when the boundaries among the clusters are not well separated and ambiguous. Moreover, the memberships may help in discovering more hidden relations between a given object and the disclosed clusters. The Fuzzy C-Means (FCM) is one of the most popular fuzzy clustering algorithms [1]. The basic FCM uses the squared-norm to measure similarity between prototypes and data points, and is suitable for identifying spherical clusters. Many extensions of the FCM have been proposed to cluster more general data set. Most of those algorithms are realized by replacing the squared-norm in the object function of FCM with other similarity measures [1][2]. Others, such as the Kernel-based fuzzy c-means (KFCM) [3] adopts a kernel-induced metric in the data space to replace the original Euclidean norm. By replacing the inner product with an appropriate kernel function, one can implicitly perform a nonlinear mapping to a high dimensional feature space without increasing the number of parameters. This kernel approach has been successfully applied to many learning systems [4], such as Support Vector Machines (SVMs), kernel principal component analysis and kernel fisher discriminant analysis [5].

Kernel-based clustering relies on a kernel function to project data samples into a high-dimensional kernel-induced feature space. A good choice of the kernel function is therefore imperative to the success of the clustering. However, one of the central problems with kernel methods in general is that it is often unclear which kernel is the most suitable for a particular task [6][7][8]. Thus, instead of using a single fixed kernel, recent developments in SVM and other supervised kernel methods have shown encouraging results in constructing the kernel from a number of homogeneous or even heterogeneous kernels [7][9] [10][11]. This provides extra flexibility and also allows domain knowledge from possibly different information sources to be incorporated to the base kernels. However, previous work in this so-called multiple kernel learning approach have all been focused on the supervised and semi-supervised learning settings. Therefore, how to efficiently learn and adopt multiple kernels in unsupervised learning, or fuzzy clustering in particular, is still an interesting yet unexplored research topic.

In this paper, we propose a new fuzzy clustering with multiple kernels algorithm (FCM-MK). FCM-MK strives to find a good partitioning of the data into meaningful clusters and the optimal kernel-induced feature map in a completely unsupervised way. FCM-MK is a generalization of the KFCM algorithm and uses a new optimization criterion to learn the optimal convex combination of homogenous kernels with respect to each cluster. It constructs the kernel from a number of Gaussian kernels and learns a resolution-specific weight for each kernel function in each cluster. This allows better characterization and adaptability to each individual cluster.

The organization of this paper is as follows. In section II, we give a brief overview of the Kernel-based learning algorithms. In section III, we describe the proposed fuzzy c-means with multiple kernels algorithm. Experiments are discussed in section IV and conclusions are provided in section V.

II. Related work

Kernel-based learning algorithms [12][13], are based on Cover's theorem. By nonlinearly transforming a set of complex and nonlinearly separable patterns into a higher-dimensional feature space, it is possible to separate these patterns linearly [14]. The difficulty of the curse of dimensionality can be overcome by the kernel trick, arising from Mercer's theorem [14]. By designing and calculating an inner-product kernel, we can avoid the time-consuming, sometimes even infeasible process to explicitly describe the nonlinear mapping $\Phi : X \mapsto \mathcal{F}$ from the input space X to a high dimensional feature space $\mathcal{F}$ and

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

compute the corresponding points in the transformed space. Computing the Euclidean distances in $\mathcal{F}$ without explicit knowledge of Φ is possible using the so called distance kernel trick:

$$\begin{aligned}\|\Phi(x_i) - \Phi(x_j)\|^2 &= (\Phi(x_i) - \Phi(x_j)).(\Phi(x_i) - \Phi(x_j)) \\ &= \Phi(x_i).\Phi(x_i) + \Phi(x_j).\Phi(x_j) - 2\Phi(x_i).\Phi(x_j) \\ &= K(x_i, x_i) + K(x_j, x_j) - 2K(x_i, x_j) \end{aligned} \quad (1)$$

Thus, the computation of the distances in the feature space is just a function of the input vectors. In fact, every algorithm in which input vectors appear only in dot products with other input vectors can be kernelized [15].
In (1), $K(x_i, x_j) = \Phi(x_i).\Phi(x_j)$ is the Mercer Kernel. It is a symmetric function $K : X \times X \to \mathbb{R}$ and satisfies

$$\sum_{i=1}^{N}\sum_{j=1}^{N} c_i c_j K(x_i, x_j) \geq 0 \qquad \forall n \geq 2, \quad (2)$$

where $c_r \in \mathbb{R}$, and $r = 1, \ldots, N$. Examples of Mercer kernels include [16]

- Linear

$$K^{(l)}(x_i, x_j) = x_i.x_j \quad (3)$$

- Polynomial of degree p

$$K^{(p)}(x_i, x_j) = (1 + x_i.x_j)^p, \qquad p \in \mathbb{N} \quad (4)$$

- Gaussian

$$K^{(g)}(x_i, x_j) = \exp\left(-\frac{\|x_i - x_j\|}{2\sigma^2}\right), \qquad \sigma \in \mathbb{R} \quad (5)$$

Kernel-based clustering algorithms have the following main advantages.

1) They are more likely to obtain a linearly separable hyperplane in the high-dimensional, or even in an infinite feature space;
2) They can identify clusters with arbitrary shapes;
3) Kernel-based clustering algorithms, like support vector clustering (SVC), have the capability of dealing with noise and outliers;
4) For SVC, there is no requirement for prior knowledge to determine the system topological structure. In [17], the kernel matrix can provide the means to estimate the number of clusters.

The kernelized metric Fuzzy C-Means [18] is one of the most common kernel-based clustering algorithm. It minimizes the following objective function.

$$J^{\phi} = \sum_{i=1}^{K}\sum_{j=1}^{N} u_{ij}^m \|\phi(x_j - \phi(v_i)\|^2, \quad (6)$$

subject to

$$u_{ij} \in [0, 1] \quad and \quad \sum_{i=1}^{K} u_{ij} = 1 \; \forall j \quad (7)$$

In (6), u_{ij} denotes the membership of x_j in cluster i, v_i is the center of cluster i in the input space, and ϕ is the mapping from the input space $\mathcal{X}$ to the feature space $\mathcal{F}$. Minimization of the function in (6) has been proposed only in the case of a Gaussian kernel. The reason is that the derivative with respect to the v_i in this case allows to use the kernel trick:

$$\frac{\partial K(x_j, v_i)}{\partial v_i} = \frac{(x_j, v_i)}{\sigma^2} K(x_j, v_i) \quad (8)$$

It can be shown [18] that the update equation for the membership is

$$u_{ij}^{-1} = \sum_{h=1}^{K} \left(\frac{1 - K(x_j, v_i)}{1 - K(x_j, v_h)}\right)^{1/(m-1)}, \quad (9)$$

and for the codevectors

$$v_i = \frac{\sum_{j=1}^{N} u_{ij}^m K(x_j, v_i) x_j}{\sum_{j=1}^{N} u_{ij}^m K(x_j, v_i)}. \quad (10)$$

A critical issue related to kernel-based clustering is the selection of an "optimal" kernel for the problem at hand. In fact, the performance of a kernel-based clustering depends critically on the selection of the kernel function, and on the setting of the involved parameters. The kernel function in use must conform with the learning objectives in order to obtain meaningful results. While solutions to estimate the optimal kernel function and its parameters have been proposed in a supervised setting [19][20][21][22], the problem presents open challenges when no labeled data are provided.

III. Fuzzy C-Means with Multiple Kernels

Given N data points, $x_j \in \mathbb{R}^d$, for $j = 1, \ldots, N$. Then, x_j is transformed via S mappings $\Phi_l(x_j) \mapsto \mathbb{R}^{d_l'}$ for $l = 1, \ldots, S$ from the input space into S feature spaces $(\Phi_1(x_j), \ldots, \Phi_S(x_j))$ where d_l' denotes the dimensionality of the l^{th} feature space. By using the closure properties of kernel functions [23], we construct a new cluster dependent similarity based on kernel K^i, between object j and cluster i. In particular, we define K^i as a linear combination of S Gaussian kernels $K_1, \ldots, K_S$, with spread parameters $\sigma_1, \ldots, \sigma_S$, respectively. That is,

$$\begin{aligned} K^{(i)}(x_j, v_i) &= \sum_{l=1}^{S} w_{il} K_l(x_j, v_i) \\ &= \sum_{l=1}^{S} \frac{w_{il}}{\sigma_l} \exp\left(-\frac{\|x_j - v_i\|^2}{2\sigma_l^2}\right) \end{aligned} \quad (11)$$

In (11), $W = [w_{il}]$, where $w_{il} \in [0, 1]$ is a resolution-specific weight for the kernel matrix K_l with respect to cluster i. A low value of w_{il} indicates that the bandwidth of kernel K_l is not relevant for the density estimation of cluster i, and that this matrix should not have a significant impact on the creation of this cluster. Similarly, a high value of w_{il} indicates that the bandwidth of kernel K_l is highly relevant for the density estimation of cluster i, and that this matrix should be the main factor in the creation of this cluster.
We normalize the kernel $K^{(i)}$ to construct a new kernel $\widetilde{K}^i$,

where $\widetilde{K}^i(x_j, x_j) = 1$, for $j = 1, \ldots, N$. This normalized kernel is defined as

$$\widetilde{K}^{(i)}(x_j, v_i) = \frac{K^{(i)}(x_j, v_i)}{\sqrt{K^{(i)}(x_j, x_j).K^{(i)}(v_i, v_i)}} = \sum_{l=1}^{S} \frac{w_{il}}{\sigma_l} \exp(-\frac{\|x_j - v_i\|^2}{2\sigma_l^2}) \times \frac{1}{\sum_{l=1}^{S} \frac{w_{il}}{\sigma_l}} \quad (12)$$

After kernel normalization, the distance in (1) becomes

$$\|\widetilde{\Phi}^{(i)}(x_j) - \widetilde{\Phi}^{(i)}(v_i)\|^2 = 2 - 2\widetilde{K}^{(i)}(x_j, v_i) \quad (13)$$

Substituting the distance in (13) into the kernelized metric Fuzzy C-Means objective function (6), we define the objective function of the proposed FCM-MK algorithm as

$$J(U, V, W) = 2 \sum_{i=1}^{C} \sum_{j=1}^{N} u_{ij}^m \left(1 - \sum_{l=1}^{S} \frac{w_{il}}{\sigma_l} \exp(-\frac{\|x_j - v_i\|^2}{2\sigma_l^2}) \times \frac{1}{\sum_{l=1}^{S} \frac{w_{il}}{\sigma_l}}\right) \quad (14)$$

subject to

$$u_{ij} \in [0, 1], \; and \sum_{i=1}^{C} u_{ij} = 1, \; for \, j = 1, \ldots, N; \quad (15)$$

and

$$w_{il} \in [0, 1], \; and \sum_{l=1}^{S} w_{il} = 1, \; for \, i = 1, \ldots, C. \quad (16)$$

In (14), C and N represent the number of clusters and the number of data points respectively, u_{ij} is the fuzzy membership of point x_j in cluster i, v_i are the centers or prototypes of the clusters, and $m \in (1, \infty)$ denotes the fuzzifier.

The goal of the FCM-MK is to identify the resolution-specific weight w_{il}, the membership values u_{ij} and the cluster prototypes v_i by optimizing (14). In order to compute the optimal values of w_{il}, u_{ij} and v_i, we use an alternating optimization method, where we will alternate the optimization of w_{il}, u_{ij} and of v_i.

To optimize (14) with respect to the memberships, we first rewrite (14) as

$$J(U, V, W) = \sum_{i=1}^{C} \sum_{j=1}^{N} u_{ij}^m dist_{ij}^2 \quad (17)$$

where

$$dist_{ij}^2 = \left(2 - 2 \sum_{l=1}^{S} \frac{w_{il}}{\sigma_l} \frac{\exp(-\frac{\|x_j - v_i\|^2}{2\sigma_l^2})}{\sum_{l=1}^{S} \frac{w_{il}}{\sigma_l}}\right) \quad (18)$$

Note that in (18), $dist_{ij}^2$ is not a function of the fuzzy memberships u_{ij}.

Then, to optimize (17) with respect to u_{ij} subject to (15), we use the Lagrange multiplier technique and obtain

$$J = \sum_{i=1}^{C} \sum_{j=1}^{N} u_{ij}^m dist_{ij}^2 - \sum_{j=1}^{N} \lambda_j \left(\sum_{i=1}^{C} u_{ij} - 1\right). \quad (19)$$

By setting the gradient of J to zero, we obtain the following update equation for the membership

$$u_{ij} = \frac{1}{\sum_{t=1}^{C} (dist_{ij}^2 / dist_{tj}^2)^{\frac{1}{m-1}}} \quad (20)$$

where $dist_{ij}^2$ is as defined in (18).

To optimize (14) with respect to te cluster prototypes v_i, we take the first derivative of J with respect to v_i and set it to zero. This yields the following update equation for the prototypes

$$v_i = \frac{\sum_{j=1}^{N} u_{ij}^m \overline{K}^{(i)}(x_j, v_i) x_j}{\sum_{j=1}^{N} u_{ij}^m \overline{K}^{(i)}(x_j, v_i)} \quad (21)$$

where

$$\overline{K}^{(i)}(x_j, v_i) = \left(\sum_{l=1}^{S} \frac{w_{il}}{\sigma_l^3} \exp(-\frac{\|x_j - v_i\|^2}{2\sigma_l^2}) \times \frac{1}{\sum_{l=1}^{S} \frac{w_{il}}{\sigma_l}}\right) \quad (22)$$

The optimization of (14) with respect to the resolution-specific weights has no closed form solution. Thus, we use the gradient descent method and update w_{il} iteratively using

$$w_{il}^{(new)} = w_{il}^{(old)} - \rho \frac{\partial J}{\partial w_{il}} \quad (23)$$

where ρ is a scalar parameter that determines the learning rate. In our approach, ρ is optimized via a line-search method.
It can be shown that the gradient of J with respect to w_{il} is given by

$$\frac{\partial J}{\partial w_{il}} = -2 \sum_{j=1}^{N} \frac{u_{ij}^m}{\sigma_l} \left(\frac{\exp(-\frac{\|x_j - v_i\|^2}{2\sigma_l^2})}{\sum_{t=1}^{S} \frac{w_{it}}{\sigma_t}} - \frac{\sum_{t=1}^{S} \frac{w_{it}}{\sigma_t} \exp(-\frac{\|x_j - v_i\|^2}{2\sigma_t^2})}{\left(\sum_{t=1}^{S} \frac{w_{it}}{\sigma_t}\right)^2}\right) = -2 \sum_{j=1}^{N} \frac{u_{ij}^m}{\sigma_l \sum_{t=1}^{S} \frac{w_{it}}{\sigma_t}} \left(K_l(x_j, v_i) - \widetilde{K}^{(i)}(x_j, v_i)\right) \quad (24)$$

The resulting FCM-MK algorithm is summarized in Algorithm 1.

The time complexity of the first step of the algorithm is $\mathcal{O}(NCdS)$ where N is the number of samples or data points, C is the number of clusters, d is the number of features or dimensions and S is the number of Gaussian kernels. In the second step of FCM-MK to update the prototypes, the time complexity is also $\mathcal{O}(NCdS)$. The time spend in the membership update is $\mathcal{O}(NC^2)$. We use the gradient descent technique to update the resolution-specific weight. If we note by τ_{gd} the number of iterations for the gradient descent

Algorithm 1 Fuzzy C-Means with Multiple Kernels

Fix the number of clusters C, fuzzification parameter $m > 1$, stopping criterion ϵ, maximum number of iterations $qmax$ and iteration counter $q = 1$;
Initialize the fuzzy partition matrix **U**;
Initialize cluster prototypes **V**;
Pick the Gaussian parameters $\sigma_1, \ldots, \sigma_S$ and initialize $w_{il}^{(0)} = 1/S$
repeat
1. Compute total similarities $\widetilde{K}^{(i)}$ using (12);
2. Update cluster prototypes using (21);
3. Update fuzzy membership using (20);
repeat
4.1 Update $w_{il}^{(q-1)} = w_{il}^{(q)}$
4.2 Compute the gradients $\frac{\partial J}{\partial w_{il}}$ using (24)
4.3 Update resolution-specific weights using (23);
until $\|w_{il}^{(q)} - w_{il}^{(q-1)}\| < \epsilon$ or $q = qmax$
until (fuzzy memberships do not change);

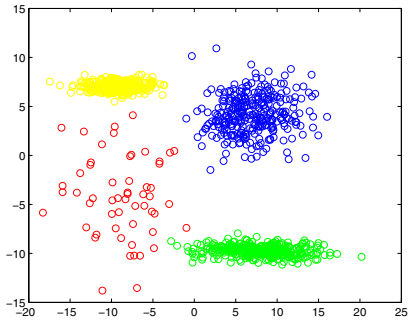

Fig. 1. Data set with 4 clusters of different shapes and densities

to converge, the time complexity of step 6 is $\mathcal{O}(\tau_{gd} NdS)$. Therefore, the total computational complexity of FCM-MK is

$$\mathcal{O}\left(\tau(NCdS + NC^2) + \tau\tau_{gd} NdS\right) \tag{25}$$

where τ is the number of iterations.

IV. Experimental results

To illustrate the ability of FCM-MK to learn appropriate local density fitting functions and cluster the data simultaneously, we use it to categorize a synthetic data set (refer to figure 1), that includes categories with unbalanced sizes and densities, and two real-world data sets selected from the UCI repository (digits and ionosphere). For the digits data, we focus on the pair 3 vs 8 that is difficult to differentiate [24]. We summarize all of these in Table I.

For each data set, we show the effectiveness of the proposed algorithm by evaluating the resolution specific weights assigned to each kernel induced-similarity. A low value of w_{il} indicates that the bandwidth σ_l of kernel K_l is not relevant for the density fitting of cluster i, and that the distance matrix computed with this kernel should not have significant impact on the creation of this cluster. Similarly, a high value of w_{il} indicates that the bandwidth σ_l of kernel K_l is highly relevant for fitting the points in cluster i, and that this matrix should be the main factor in the creation of this cluster. We demonstrate the effectiveness of FCM-MK by comparing the clustering results to the following algorithms:

1) FCM with the Euclidean norm;
2) Kernel metric FCM (KFCM) where K is a gaussian kernel with S different values of σ, $\sigma_1, \ldots, \sigma_S$;
3) KFCM with a kernel K constructed as the sum of the S Gaussian kernels, $K(x_j, v_i) = \sum_{l=1}^{S} \exp(-\frac{\|x_j - v_i\|^2}{2\sigma_l^2})$

For all algorithms, we use the same initialization, the same number of clusters, and the same fuzzifier. In all experiments, we choose the number of kernels $S = 4$ and $\sigma = 0.1 * D, 0.2 * D, 0.3 * D, 0.4 * D$ where $D = \left[\sum_{k=1}^{d} \left(\max(X^k) - \min(X^k)\right)^2\right]^{\frac{1}{2}}$ and X^k is the k^{th} attribute of the data set.

To assess the performance of the different clustering algorithms and compare them, we assume that the ground truth is known and we use some relative cluster evaluation measures [25]: the accuracy rate (Q_{RR}), the *Jaccard coefficient* (Q_{JC}), the *Folkes-Mallows index* (Q_{FMI}) and the *Hubert index* (Q_{HI}).

Cluster3	0.212	0.284	0.358	0.145	(3.77, 0.54)
Cluster4	0.296	0.390	0.202	0.114	(2.10, 0.42)

The FCM algorithm cannot categorize the data in figure 1 as it can be seen in figure 2a. This is due to the fact that FCM is designed to seek compact spherical clusters. However, the geometry of this data is more complex. The clusters are close to each others and have different densities. Similarly, the KFCM algorithm, using a single bandwidth, was not able to categorize this data correctly as it can be seen from figures 2b-2e. The KFCM algorithm, using a kernel constructed as the average of the 4 Gaussian kernels K_l with bandwidth σ_l, also cannot categorize the data. This is because one global bandwidth cannot take into account the variations of the different clusters.

On the other hand, the resolution weights learned by our approach (see table II) make it possible to identify the four clusters correctly. In table II, cluster4 has an ellipsoidal shape with a true standard deviation of 2.10 in the horizontal

TABLE III
RESOLUTION WEIGHTS LEARNED BY FCM-MK FOR DIGITS3V8

	$\sigma_1 = 5$	$\sigma_2 = 10$	$\sigma_3 = 15$	$\sigma_4 = 20$	True σ
digit3	0.198	0.356	0.256	0.190	7.89
digit8	0.202	0.395	0.236	0.167	7.25

TABLE IV
RESOLUTION WEIGHTS LEARNED BY FCM-MK FOR IONOSPHERE

	$\sigma_1 = 0.5$	$\sigma_2 = 1$	$\sigma_3 = 1.5$	$\sigma_4 = 2$	True σ
Cluster1	0.174	0.266	0.361	0.199	1.41
Cluster2	0.172	0.202	0.258	0.368	1.59

direction and 0.42 in the vertical direction. The geometry of cluster4 is captured by our algorithm. In fact, higher weights were assigned to $\sigma_l = 0.5$ and $\sigma_l = 1$ which reflects the existence of some points with small variance along the horizontal direction and some points with larger variance along the vertical direction. Similarly, the other three clusters were assigned different weights. The clustering performances of the different algorithms on this data are reflected on the cluster evaluation measures in table VI. As it can be seen, the statistics provided by FCM-MK are higher than the statistics provided by the other algorithms.

For the digits0689 data set, the FCM-MK assigned high weight to $\sigma_l = 10$ for all clusters (refer to table V). This is an indication that the clusters within this data have similar distributions and one global σ is sufficient for this data. This explains the comparable behavior of FCM-MK with KFCM with kernel K_2 as reported in table IX.

On the other hand, for the ionosphere data set, FCM-MK assigned different weights to the different clusters as reported in table IV. This indicates that the clusters within this data have different distributions. Thus, the statistics provided by FCM-MK are higher than the statistics of the other competing algorithms.

V. CONCLUSIONS

In this paper, we proposed a new fuzzy clustering algorithm with multiple kernels. The proposed FCM-MK algorithm uses a fixed set of kernels with different resolutions that cover the spectrum of the entire data. Data points are mapped to a high dimensional feature space through a convex combination of these kernels. The kernel weights are adapted to the different clusters to reflect their distributions. The FCM-MK algorithm optimizes one objective function to identify the optimal clusters' prototypes, their fuzzy membership degrees, and the optimal convex combination of the homogeneous kernels in an unsupervised way.

The effectiveness of the proposed algorithm is demonstrated and compared to similar algorithms using synthetic and real data sets. We showed that when the data has clusters with similar densities, the FCM-MK performance is comparable to the kernel FCM with one kernel. However, for data sets that have clusters with different densities, the proposed FCM-MK learns different kernel weights and outperforms the kernel FCM.

In the current implementation, the FCM-MK algorithm uses fuzzy memberships that are constrained to sum to one. This makes the algorithm sensitive to noise and outliers. In fact, noise points can lead the algorithm to learn kernel weights that do not reflect the overall distribution of the clusters. One way to address this limitation is to adapt the FCM-MK to use possibilistic membership functions. We are currently investigating this alternative.

***Abstract*—Kernel clustering methods have been very important in application of non-supervised machine learning to real problems. Kernel methods possess many advantages other than non-linearity such as modularity, ability to work with heterogeneous descriptions of data, incorporation of prior knowledge etc. In this paper, we present a clustering method based on kernel functions for partitioning a set of interval-valued data. In addition, this method is compared to a fuzzy partitioning approach for interval data introduced previously. Experiments with real and syntectic symbolic interval-valued data sets are presented. The evaluation of the clustering results furnished by the methods is performed regarding the computation of an external cluster validity index and the global error rate of classification.**

***Index Terms*—Kernel, clustering, interval-valued data, fuzzy.**

I. Introduction

With the growing interest in automatically to understand, process and summarize data, several application domains like pattern recognition, machine learning, data mining, computer vision, computational biology and classification of statistical findings in social studies have used clustering algorithms [1] [2]. The objective of the cluster analysis is to group a set of elements into clusters such that elements within a cluster have a high degree of similarity, while elements belonging to different clusters have a high degree of dissimilarity. Clustering techniques may be divided into hierarchical clustering and partitioning clustering: hierarchical clustering groups data objects with a sequence of partitions dividing one group with all individuals in singleton clusters or vice versa, while partitioning clustering directly divides data objects into some fixed number of clusters with no hierarchical structure [3] and makes this division based on the optimization of a suitable objective function.

The partitioning methods may be classified in hard partitioning and fuzzy partitioning. The hard partitioning associates each element of the data to a single class, while in the fuzzy partitioning each element of the data is associated with all classes of the partition, the elements not belong a single cluster only and so that the memberships are calculated. When the memberships have values between 0 and 1, the sum of the all possibilities of an element belong to some classes is equal to 1 and the method is the type probabilistic [4]. But when the memberships have values 0 or 1, the method is the type crisp and the fuzzy method becomes equivalent to a hard method [5].

Kernel clustering methods have been very important in the application of non-supervised machine learning to real problems. These methods are able to produce nonlinear separating hyper surfaces among clusters [6]. The use of kernels allows to map implicitly data into a high dimensional space, called feature space; computing a linear partitioning in this feature space results in a nonlinear separation between clusters in the input space. Several clustering methods has been modified including the use of the kernel functions such as SOM [7], k-means [8], fuzzy c-means (FCM)[9] and so on. The kernel k-means was proposed [10] as an extension of the standard hard partitioning method k-means and the kernel fuzzy c-means was proposed [11] aiming to replace a kernel-induced distance metric for the original Euclidean distance of the fuzzy partitioning method.

In classical cluster analysis, data are often represented as arrays of quantitative or qualitative values, where each column represents a variable. In particular, each individual takes a single value for each variable. However, research study has shown that this presentation is not as rich in information to represent the complexity of data such as intervals or distributions found in real problems [12]. The main goal of *Symbolic Data Analysis* (SDA) concerns to model more complex information through a set-valued (interval or multi-valued) or modal (weight or probability distribution) variables also termed symbolic and extend classical data analysis techniques, such as, clustering, factorial techniques, decision trees and other to symbolic data. These data allow to take account variability and/or uncertainty, making the symbolic data analysis more comprehensive than the classical data analysis.

In this paper, we present a new clustering method based in kernel functions for partitioning a set of interval-valued data. This method is an extension of the fuzzy c-means cluster algorithm based on kernelization of metric [11] to interval-valued data. In addition, this method is compared with a fuzzy c-means method for interval data introduced in [13]. The paper is organized as follows. In Section 2, we describe the fuzzy c-means clustering method for symbolic interval data. In Section 3, we introduce the new kernel-based fuzzy clustering method for symbolic interval data. In order to validate this new method, Section 4 presents experiments with real and syntectic symbolic interval data sets. The evaluation of the clustering results furnished by the methods is based on the computation of an external cluster validity index and the global error rate of classification. In Section 5, the concluding remarks are given.

II. Introduction to a fuzzy c-means method for interval data

This section initially shows an brief description of the fuzzy c-means method for symbolic interval data [13] (here called FCM-IV). This method is a suitable extension of the standard fuzzy c-means clustering algorithm that furnishes a fuzzy partition and a prototype for each cluster by optimizing an adequacy criterion based on a suitable squared Euclidean distance between vectors of intervals.

Consider Ω a set of n objects indexed by i and formed by p symbolic interval-valued variables indexed by j. Each object i is represented by a vector of intervals $\mathbf{x}_i = ([a_i^1, b_i^1], \ldots, [a_i^p, b_i^p])^T$. Similar to the object, the prototype of a cluster C_k $(k = 1, \ldots, K)$ is also represented as a vector of intervals $\mathbf{y}_k = ([\alpha_i^1, \beta_i^1], \ldots, [\alpha_i^p, \beta_i^p])^T$. Thus the partition $P = (C_1, \ldots, C_K)$ from Ω in K clusters where each cluster has a prototype L_k described by the vector $\mathbf{y}_k$.

The problem of clustering concerns to find a partition of Ω into K disjoint clusters $C_1, \ldots, C_K$ such that minimizes locally a clustering criterion defined as

$$J(P, L) = \sum_{k=1}^{K} \sum_{i \in C_k} (u_{ik})^m d^2(x_i, y_k). \quad (1)$$

where the squared Euclidian distance d^2 measuring the dissimilarity between a pair of vectors of intervals is given as

$$d^2(x_i, y_k) = \sum_{j=1}^{p} \left[\left(a_i^j - \alpha_k^j \right)^2 + \left(b_i^j - \beta_k^j \right)^2 \right]. \quad (2)$$

The term u_{ik} is the membership degree of pattern i in cluster C_k and $m \in]1, +\infty[$ is a parameter that controls the fuzziness of membership for each pattern i. The membership degree $u_{ik} (i = 1, \ldots, n)$ of each pattern i in each cluster C_k, minimizing the clustering criterion J under $u_{ik} \geq 0$ and $\sum_{k=1}^{K} u_{ik} = 1$, is updated according to the following expression:

$$u_{ik} = \left[\sum_{h=1}^{K} \left(\frac{\sum_{j=1}^{p} \left[\left(a_i^j - \alpha_k^j \right)^2 + \left(b_i^j - \beta_k^j \right)^2 \right]}{\sum_{j=1}^{p} \left[\left(a_i^j - \alpha_h^j \right)^2 + \left(b_i^j - \beta_h^j \right)^2 \right]} \right)^{\frac{1}{m-1}} \right]^{-1}. \quad (3)$$

The prototype $\mathbf{y}_k = ([\alpha_i^1, \beta_i^1], \ldots, [\alpha_i^p, \beta_i^p])^T$ of C_k which minimizes the clustering criterion J has the bounds of each interval $[\alpha_i^j, \beta_i^j]$ $(j = 1, \ldots, p)$ updated according to the following expressions:

$$\alpha_k^j = \frac{\sum_{i=1}^{n} (u_{ik})^m a_k^j}{\sum_{i=1}^{n} (u_{ik})^m} \quad (4)$$

$$\beta_k^j = \frac{\sum_{i=1}^{n} (u_{ik})^m b_k^j}{\sum_{i=1}^{n} (u_{ik})^m} \quad (5)$$

The algorithm schema of the FCM-IV algorithm for interval data is as follows:

Schema of the FCM-IV algorithm

1) **Initialization step**
   The parameters c $(2 \leq c \leq n)$, m $(1 < m < \infty)$ and $\varepsilon > 0$ are fixed.
   1.1 Initialize u_{ik} $(i = 1, \ldots, n)$ and $(k = 1, \ldots, K)$ such that $u_{ik} \geq 0$ and $\sum_{k=1}^{K} u_{ik} = 1$.
   1.2 Compute J^0 using Eq. 1 and do $t = 1$.
2) **Representation step**
   Compute the prototype $\mathbf{y}_k$ of the cluster $C_k (k = 1, \ldots, K)$ using the Eqs. 4 and 5.
3) **Fuzzy membership step**
   Update the fuzzy membership degree u_{ik} of the pattern i belonging to cluster $C_k (k = 1, \ldots, K)$ using the Eq. 3.
4) **Stopping criterion**
   If $|J_t - J_{t-1}| \leq \varepsilon$, STOP; else update $t = t + 1$ and go step 2.

III. A Kernel Fuzzy c-Means Method for Interval Data

The kernel fuzzy c-means (KFCM) method is an extension of the fuzzy c-means (FCM) cluster algorithm proposed in [11]. KFCM adopts a new kernel-induced metric in the data space to replace the original Euclidean norm metric in FCM, thus KFCM can implicitly perform a nonlinear mapping to a high dimensional feature space.

This section presents an extension of the kernel fuzzy c-means method to interval-valued data. The main idea of this method (here called KFCM-IV) consist in manipulating a kernel function for interval data and to use the approach fuzzy for generate a fuzzy partitions based on the idea of partial membership expressed by the degree of membership of each pattern in a given cluster.

Regarding interval data, each object i $(i = 1, \ldots, n)$ of Ω is represented as a vector of intervals $\mathbf{x}_i = ([a_i^1, b_i^1], \ldots, [a_i^p, b_i^p])^T$ and a nonlinear function $\xi : \mathbf{x}_i \to \xi(\mathbf{x}_i)$ performs the mapping from the input space to a high dimensional feature space H. Consider k centers $\mathbf{g}_1^\xi, \ldots, \mathbf{g}_k^\xi$ as prototypes of the clusters where $\mathbf{g}_k^\xi \subset H$ $(k = 1, \ldots, K)$.

Using the classic kernel fuzzy c-means methodology, the problem of clustering concerns to find a partition of Ω into K disjoint clusters $C_1, \ldots, C_K$ such that minimizes a clustering error defined as:

$$E = \sum_{k=1}^{K} \sum_{i \in C_k} u_{ik}^m \|\xi(\mathbf{x}_i) - \xi(\mathbf{v}_k)\|^2 \quad (6)$$

The squared Euclidian distance between $\xi(\mathbf{x}_i)$ and $\xi(\mathbf{v}_k)$ is given by:

$$\|\xi(\mathbf{x}_i) - \xi(\mathbf{g}_k)\|^2 = K(\mathbf{x}_i, \mathbf{x}_i) - 2K(\mathbf{x}_i, \mathbf{v}_k) + K(\mathbf{v}_k, \mathbf{v}_k) \quad (7)$$

The Gaussian kernel function $K_{il} = K(\mathbf{x}_i, \mathbf{x}_l)$ for interval data is defined as:

$$K(\mathbf{x}_i, \mathbf{x}_l) = exp(-\|\mathbf{x}_i - \mathbf{x}_l\|^2 / 2\delta^2) \quad (8)$$

with

$$\|\mathbf{x}_i - \mathbf{x}_l\|^2 = \sum_{j=1}^{p} \left[(a_i^j - a_l^j)^2 + (b_i^j - b_l^j)^2 \right]$$

The membership u_{ik} of the object x_i in class C_k assuming values in the interval $[0, 1]$ and satisfying $\sum_{k=1}^{K} u_{ik} = 1$ is defined as:

$$u_{ik} = \frac{(1/(1 - K(x_i, v_k)))^{1/(m-1)}}{\sum_{l=1}^{K} (1/(1 - K(x_i, v_l)))^{1/(m-1)}} \quad (9)$$

The prototypes are given by:

$$v_k = \frac{\sum_{i=1}^{n} u_{ik}^m K(x_i, v_k) x_i}{\sum_{i=1}^{n} u_{ik}^m K(x_i, v_k)} \quad (10)$$

The weighting exponent m is called the fuzzifier and it can have an influence on the clustering performance of the method. The algorithm schema of the KFCM-IV algorithm for interval data is as follows:

SCHEMA OF THE KFCM-IV ALGORITHM

1) **Pre-processing step: compute a kernel matrix**
   Compute the matrix $\boldsymbol{K}$ using the Eq. 8 for $i = 1, \ldots, n$ and $l = 1, \ldots, n$.
2) **Initialization step**
   The parameters c $(2 \leq c \leq n)$, m $(1 < m < \infty)$ and $\varepsilon > 0$ are fixed.
   1.1 Initialize u_{ik} $(i = 1, \ldots, n)$ and $(k = 1, \ldots, K)$ such that $u_{ik} \geq 0$ and $\sum_{k=1}^{K} u_{ik} = 1$.
   1.2 Compute the criterion error E^0 using Eq. 6 and do $t = 1$.
3) **Representation step**
   Update the prototypes v_k $(k = 1, \ldots, K)$ with Eq. 7.
4) **Membership step**
   Update the memberships u_{ik} $(k = 1, \ldots, K)$ and $(i = 1, \ldots, n)$ with Eq. 6.
5) **Stopping criterion**
   If $|E_{t+1} - E_t| \leq \varepsilon$ then STOP calculate error criterion E using the Eq. 5, otherwise do $t = t + 1$ and go to step 3.

IV. EXPERIMENTAL RESULTS

In order to validate the proposed method for interval data, this section presents the experimental results regarding synthetic and real symbolic data sets. Our aim is to achieve a comparison between this method and the fuzzy c-means method introduced in the Section II. The evaluation was performed in the framework of a Monte Carlo experience with 100 replications for each synthetic interval data set. Concerning real symbolic data, an application with two data sets is also considered.

To assess the clustering results provided by FCM-IV and KFCM-IV methods, we used the corrected Rand index (CR) and the overall error rate of classification (OERC). The index CR [14] takes its values in the interval $[-1, 1]$ where the value 1 indicates a perfect agreement between the partitions, values close to 0 correspond to more or less random cluster agreement, and negative values to insufficient recovery properties. The OERC takes its values in the interval $[0, 1]$ where the value 0 indicates a perfect agreement between the partitions, unlike the value 1.

In all experiments for KFCM-IV method, it was used the Gaussian kernel defined in Eq. 8 with parameter $\sigma = 1$. For FCM-IV and KFCM-IV methods, it used the parameter m equal to 2.

A. The Monte Carlo experiment results and comparison

First, we simulated two classical quantitative data sets in $\Re^2$ with nonlinear clusters. Thus, interval data sets is built from these quantitative data sets, each point (y_1, y_2) of these data sets is considered as the 'seed' of a rectangle. Each rectangle is therefore a vector of two intervals defined by:

$$([y_1 - \gamma_1/2, y_1 + \gamma_1/2], [y_2 - \gamma_2/2, y_2 + \gamma_2/2])$$

The parameters γ_1 and γ_2 are the width and the height of the rectangle. They are drawn randomly within a given range of values.

Data set 1 is formed by two rings, each representing a class. The first ring has radius equals to 12 and 100 individuals. The second ring has radius equals to 5 and 50 individuals. From this data, we can observe that the classes are nonlinearly separable and similar points sets can be found in [10]. Figure 1 represents an interval data set with two rings using width and the height of all the rectangles drawn randomly within the interval $[1, 2]$.

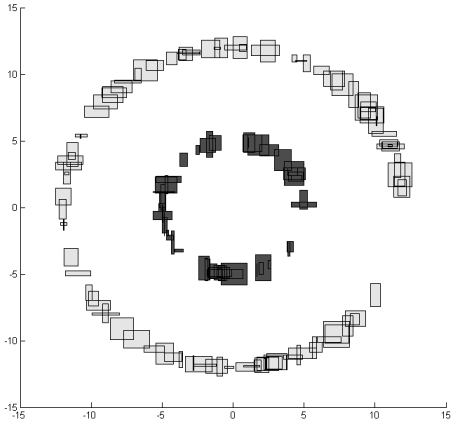

Fig. 1. Symbolic interval data set 1: two rings

Data set 2 is formed by data follow a similar training to Archimedean spiral, where each arm of the spiral is defined in polar coordinates (r, θ) by the equation:

$$r = a + b\theta \quad (11)$$

where a and b are real numbers and θ in angular measurements. The parameter a controls the initial radius of the each arm of the spiral, while b is related with distance between successive turns. This data set has 90 individuals distributed among the classes contained 15, 20, 25 and 30. The total angle $\theta = 120$ degrees with $a = 10$ and $b = 5$. Figure 2 represents the interval data set 2 width and the height of all the rectangles drawn randomly within the interval $[1, 5]$.

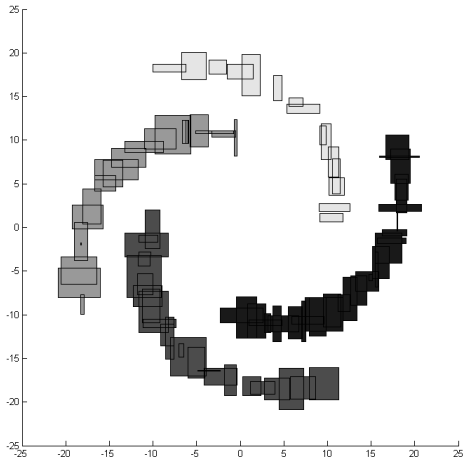

Fig. 2. Symbolic interval data set 2: spiral of four classes

In the framework of a Monte Carlo experiment, 100 replications of the previous process were carried out for parameters γ_1 γ_2 drawn randomly 100 times from each of the following intervals: $[1, 2], [1, 5], [1, 10]$, $[1, 15]$ and $[1, 20]$. This process has also been repeated for interval data sets 1 and 2. The KFCM-IV and FCM-IV methods have been performed on these data sets. The cluster partition obtained with these clustering methods were compared with the class partition known a priori based on CR index and the OERC metric. For each 100 replications, the average CR index and the average OERC are calculated.

Tables I and II give the values of the average and standard-deviation (in parenthesis) of the CR index and OERC for the FCM-IV and KFCM-IV methods and the data sets 1 and 2, respectively. As expected, the KFCM-IV method outperforms the FCM-IV one considering CR index and OERC metric.

TABLE I
COMPARISON OF THE CLUSTERING METHODS FOR DATA SET 1

Predefined Interval	FCM-IV		KFCM-IV	
	CR index	OERC	CR index	OERC
[1,2]	0.0000 (0.0114)	0.4771 (0.0345)	0.4391 (0.0665)	0.1352 (0.0155)
[1,5]	-0.0001 (0.0099)	0.4767 (0.0354)	0.4401 (0.0756)	0.1359 (0.0177)

[1,15]	0.0012 (0.0134)	0.4769 (0.0389)	0.2695 (0.0615)	0.1742 (0.0140)
[1,20]	-0.0005 (0.0091)	0.4782 (0.0328)	0.1609 (0.0787)	0.1996 (0.0176)

B. Results and comparison with a city-temperature interval data set

This interval data set [15] concerns 37 cities, each city is described by 12 interval variables which are minimum and the maximum temperatures of 12 months in degree centigrade. Table III shows part of this data set.

The 4-cluster partitions obtained with these clustering methods were compared with the 4-cluster partition known a priori.

TABLE II
COMPARISON OF THE CLUSTERING METHODS FOR DATA SET 2

Predefined Interval	FCM-IV		KFCM-IV	
	CR index	OERC	CR index	OERC
[1,2]	0.3207 (0.0030)	0.5482 (0.0285)	0.3814 (0.0412)	0.2809 (0.0274)
[1,5]	0.3204 (0.0028)	0.5481 (0.0318)	0.3826 (0.0425)	0.2837 (0.0295)
[1,10]	0.3204 (0.0026)	0.5471 (0.0306)	0.3843 (0.0423)	0.2799 (0.0264)
[1,15]	0.3204 (0.0023)	0.5523 (0.0267)	0.3815 (0.0382)	0.2827 (0.0292)
[1,20]	0.3213 (0.0028)	0.5492 (0.0291)	0.3752 (0.0381)	0.2871 (0.0303)

TABLE III
MINIMUM AND THE MAXIMUM TEMPERATURES OF CITIES IN DEGREE CENTIGRADE

Cities	**January**	**February**	...	**November**	**December**
Amsterdan	$[-4, 4]$	$[-5, 3]$	...	$[1, 10]$	$[-1, 4]$
Athens	$[6, 12]$	$[6, 12]$	...	$[11, 18]$	$[8, 14]$
Bahrain	$13, 19]$	$[14, 19]$	...	$[20, 26]$	$[15, 21]$
Bombay	$[19, 28]$	$[19, 28]$	...	$[14, 26]$	$[10, 20]$
Calcutta	$[13, 27]$	$[16, 29]$	...	$[18, 29]$	$[13, 26]$
Colombo	$[22, 30]$	$[22, 30]$	...	$[23, 29]$	$[22, 30]$
⋮	⋮	⋮	⋮	⋮	⋮
Toronto	$[-8, -1]$	$[-8, -1]$	...	$[-1, 17]$	$[-5, 1]$
Vienna	$[-2, 1]$	$[-1, 3]$	...	$[2, 7]$	$[1, 3]$
Zurich	$[-11, 9]$	$[-8, 15]$	...	$[0, 19]$	$[-11, 8]$

The a priori classification, indicated by the suffix attached to the city temperature, is as follows:

a) Class 1: Bahraim: 3, Bombay: 4, Cairo: 5, Calcutta: 6, Colombo: 7, Dubal: 9, Hong Kong: 12, Kula Lampur: 13, Madras: 16, Manila: 18, Mexico: 20, Nairobi: 23, New Delhi: 24, Sydney: 30 and Singapore: 32
b) Class 2: Amsterdam: 1, Athens: 2, Copenhagen: 8, Frankfurt: 10, Geneva: 11, Lisbon: 14, London: 15, Madrid: 17, Moscow: 21, Munich: 22, New York: 25, Paris: 26, Rome: 27, San Francisco: 28, Seoul: 29, Stockholm: 31, Tokyo: 34, Toronto: 35, Vienna: 36 and Zurich: 37
c) Class 3: Mauritius: 19
d) Class 4: Tehran: 33

Table IV shows the clusters (individual labels) given by the a priori partition according to the categorical variable, as well as the clusters obtained by the kernel fuzzy c-means and fuzzy c-means methods concerning the temperature interval data set.

The CR index obtained from the comparison between the a priori partition and the partitions given by the FCM-IV and KFCM-IV methods are, respectively, 0.466 and 0.714. The OERC for FCM-IV and KFCM-IV methods are, respectively, 0.405 and 0.216. Therefore, the KFCM-IV method is very superior to FCM-IV for this data set.

C. Results and comparison with the agaricus interval data set

This data set was extracted from [16] and contains information on species of fungi. Agaricus is a genus of mostly medium to large gilled mushrooms. Well known members of the genus

TABLE IV
CLUSTERING RESULTS FOR TEMPERATURE OF CITIES DATA SET

	Cluster 1	Cluster 2	Cluster 3	Cluster 4
A priori Partition	3 4 5 6 7 9 12 13 16 18 20 23 24 30 32	1 2 8 10 11 14 15 17 21 22 25 26 27 28 29 31 34 35 36 37	19	33
FCM-IV	3 5 9 12 20 23 24 32	1 8 10 11 15 21 22 26 31 35 36 37	2 14 17 25 27 28 29 33 34	4 6 7 13 14 18 19 30
KFCM-IV	3 4 6 7 9 13 16 18 24 30	1 8 10 11 14 15 17 21 22 25 26 27 28 29 31 34 35 36 37	2 5 12 20 33	19 23 32

Agaricus are the bisporus, the "button mushroom" common in supermarkets and the campestris, the "meadow mushroom", a popular edible mushroom which is common in pastures and grasslands in many temperate areas of the world. This data set consists of 24 mushrooms, each mushroom described by 5 interval variables: width of the pileus, width of the stipe, thickness of the stipe, height and width of spores. Table V shows part of this data set. It is composed of two classes: edible (E) and inedible (I).

TABLE V
INFORMATION ABOUT AGARICUS SPECIES KNOWN TO OCCUR IN CALIFORNIA

Species	pileus's width	stipe's width	stipe's thickness	spores's height	spores's width
Albolutescens	$[6, 12]$	$[2, 7]$	$[1.5, 3]$	$[6, 7.5]$	$[4, 5]$
Arvensis	$[6, 21]$	$[4, 14]$	$[1, 3.5]$	$[6.5, 9]$	$[4.5, 6]$
Benesii	$[4, 8]$	$[5, 11]$	$[1, 2]$	$[5, 6]$	$[3, 4]$
Bernardii	$[7, 16]$	$[4, 7]$	$[3, 4.5]$	$[5.5, 7]$	$[5.5, 6.5]$
Bisporus	$[5, 12]$	$[2, 5]$	$[1.5, 2.5]$	$[6, 8.5]$	$[4.5, 6]$
⋮	⋮	⋮	⋮	⋮	⋮
Subrutilescens	$[6, 14]$	$[6, 12]$	$[1, 2]$	$[4, 6]$	$[3.5, 4.5]$
Subrufescens	$[6, 13]$	$[6, 12]$	$[1.5, 2.5]$	$[5.5, 6.5]$	$[4, 4.5]$
Xanthodermus	$[5, 17]$	$[4, 14]$	$[1, 3.5]$	$[5, 6]$	$[4, 5.5]$

Table VI shows the elements grouped by clusters given by the a priori partition according to the categorical variable edible or inedible, as well as the clusters obtained by the kernel fuzzy c-means and fuzzy c-means methods concerning the agaricus interval data set.

TABLE VI
CLUSTERING RESULTS FOR AGARICUS DATA SET

	Cluster 1	Cluster 2
A priori Partition	1 2 3 4 5 6 8 9 10 11 12 14 15 16 17 19 20 21 22 23	7 13 18 24
FCM-IV	2 4 6 11 13 14 16 17 18 20 21 22 23 24	1 3 5 7 8 9 10 12 15 19
KFCM-IV	1 2 3 4 5 6 7 8 9 10 11 12 15 16 17 19 20 21 22 23	13 14 18 24

The CR index calculated from the comparison between the a priori partition and the partitions given by the FCM-IV and KFCM-IV methods are, respectively, -0.037 and 0.613. The OERC for the FCM-IV and KFCM-IV methods are, respectively, 0.500 and 0.082. Again, the KFCM-IV is very superior to the FCM-IV for the agaricus data set.

V. CONCLUSIONS

In this paper, we have presented a new clustering method for symbolic interval data based on kernel. This method is an extension of the kernel fuzzy c-means to symbolic interval data. The evaluation of this method in comparison with a fuzzy c-means clustering method for interval data was carried out. The accuracy of the results provided by these clustering methods regarding synthetic interval data sets were assessed by the corrected Rand index and overall error rate in the framework of a Monte Carlo experience. An application with two real interval data sets was also performed. Concerning the CR index and overall error rate, the proposed method in this paper surpassed the fuzzy c-means method in all interval data sets.

***Abstract*—Accurate Short Term Load Forecasting (STLF) is essential for a variety of decision making processes. However, forecasting accuracy may drop due to presence of uncertainty in the operation of energy systems or unexpected behavior of exogenous variables. This paper proposes the application of Interval Type-2 Fuzzy Logic Systems (IT2 FLSs) for the problem of STLF. IT2 FLSs, with extra degrees of freedom, are an excellent tool for handling prevailing uncertainties and improving the prediction accuracy. Experiments conducted with real datasets show that IT2 FLS models appropriately approximate future load demands with an acceptable accuracy. Furthermore, they demonstrate an encouraging degree of accuracy superior to feedforward neural networks used in this study.**

***Index Terms*—Load forecasting, type-2 fuzzy logic.**

I. Introduction

By definition, forecasting is a phenomenon of calculating or estimating a measure in the next coming time periods. Tools and models for accurate forecasting of electric power load are essential to the operation and planning of utility companies. Load forecasts are used by participants in electric energy generation, transmission, distribution, and markets for a variety of decision-making processes, such as economy dispatch, unit commitment, hydro-thermal coordination, transaction evaluation, and expansion planning.

There has always been a need for accurate forecasting of future load demands. However, the need has intensified in the last decade due to deregulation of the energy industries in developed countries. As the energy prices may be boosted by a factor of ten or more during periods of peak demands, precise short and medium term load forecasting becomes vitally important to the utilities. Taking into account this as well as rapid fluctuations of demands and abrupt changes in weather condition, access to reliable models for accurate prediction of load demand is essential.

Studies conducted by scholars and industry practioners for load forecasting can be divided into two broad categories: (i) traditional methods, such as Box-Jenkins models, regression models, Autoregressive Integrated Moving Average (ARIMA) (in general time series), Kalman filtering models, and splines [1] [2], [3] [4]; and (ii) Artificial Intelligence (AI) methods, such as Neural Networks (NNs), Fuzzy Logic Systems (FLSs), and expert systems. Models in the former category are typically linear and cannot cope with the level of nonlinearity and seasonality present in the behavior of electric loads. There exists no best method that always outperforms others in the field of load forecasting. However, recent reviewing studies in the field of prediction and forecasting show that AI-based models, and in particular NNs, often outperform the traditional modeling techniques in terms of prediction accuracy and generalization power [5].

Both NN and FLSs are universal approximators with the capability of identification and approximation of nonlinear relationships between independent (inputs) and dependent (targets) variables to any arbitrary degree of accuracy [6] [7]. While black-box NN models have their excellent learning capabilities, transparent FLS models can simultaneously handle quantitative and qualitative information, and as so uncertainties. Both model types are of the best alternatives for modeling, prediction, and forecasting purposes. A good review of NN-based Short Term Load Forecasting (STLF) can be found in [6] and [7] (and references within) [1]. Recently Khosravi et al. [9] [10] investigated the application of NN–based prediction intervals for quantifying uncertainties associated with forecasted loads. They showed that prediction intervals provide more information about uncertainties present in the process of load forecasting. However, construction of prediction intervals using the proposed methods is computationally expensive.

Studies on application of FLSs and neuro-fuzzy systems for STLF can be found in [11] [12] [13]. The Achilles heel of traditional FLSs is their precise Type-1 Fuzzy Sets (T1 FSs). Once the type-1 Membership Functions (MFs) are selected and adjusted, all uncertainties disappear. Type-2 FLS (T2 FLS) is a new emerging paradigm that uses Type-2 Fuzzy Sets (T2 FS). T2 FSs are characterized by a three dimensional fuzzy MF including a footprint of uncertainty. The footprint of uncertainty and the third dimension of MFs provide additional degrees of freedom that make it possible to directly model and handle uncertainties. Therefore, a T2 FLS has the potential to outperform a Type-1 FLS (T1 FLS) [14].

Zadeh [15] originally introduced the concept of type-2 fuzzy sets as an extension of the concept of an ordinary type-1 fuzzy set in 1975. Mendel [16] and Karnik et al. [17] [18] further developed the theory of T2 FLSs. The structure of rules in the T2 FLS and its inference engine are similar to those in T1 FLS. A T2 FLS includes a fuzzifier, a rule base, fuzzy inference engine, and an output processing unit composed of a type reducer and a defuzzifier (Fig. 1).

[1] Similar studies for the case of electricity price forecasting can be found in [8].

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

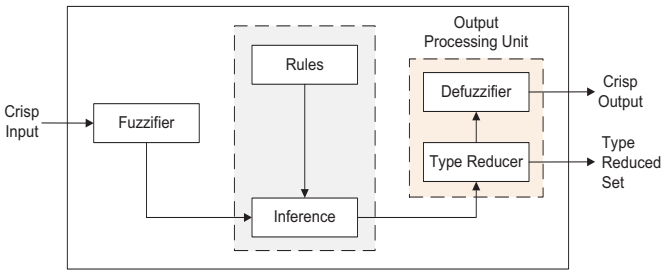

Fig. 1. Structure of a T2 FLS.

The computational complexity of general T2 FLSs has until recently hindered their widespread use in practical applications. As a restricted class of T2 FLSs, Interval T2 FLSs (IT2 FLSs) [19] were introduced to avoid massive computational requirement (mainly due to type reduction stage). IT2 FLSs are characterized by secondary MFs that only take the value of 1 over their domain. Such a restriction greatly reduces the computational burden of performing inference compared with general T2 FLSs. In the last few years, T2 FLSs, and in particular, to IT2 FLSs have drawn a great deal of attention from both academia and industry. IEEE Computational Intelligence Magazine, February 2007 contains several papers reviewing theory and application of T2 FLSs and IT2 FLSs [20] [21] [22]. Also more recent work on application of IT2 FLSs and their combination with neural networks can be found in [23] [24].

Motivated by these recent trends in academia, this paper investigates the use of IT2 FLSs for STLF problem. Takagi-Sugeno-Kang (TSK) fuzzy inference systems are used for developing IT2 TSK FLSs for load forecasting. It is expected that load forecasting accuracy will be improved due to excellent capabilities of IT2 FLSs in handling uncertainties in data. Feedforward NN models are also used for STLF problem and their forecasting performance and accuracy is compared with performance of IT2 TSK FLS models.

The rest of this article is organized as follows: Section II introduces IT2 TSK FLSs. Section III describes how IT2 TSK FLSs are developed and trained in this study. Experimental procedure and used datasets are discussed in Section IV. Simulation results are demonstrated in Section V. Finally, we draw conclusions and discuss future work in section VI.

II. Interval Type-2 TSK Fuzzy Logic Systems

IT2 TSK FLSs are TSK fuzzy models, where (at least) antecedent MFs are IT2 FSs. As per this definition, three classes of models can be formed:

- A2-C1: Antecedents are IT2 FSs, and consequents are interval T1 FSs.
- A2-C0: Antecedents are similar to the case of A2-C1 model, however, consequent parameters are crisp (similar to the case of traditional type-1 TSK fuzzy models).
- A1-C1: Antecedents and consequents are both type-1 fuzzy sets.

We use class A2-C1 in this study, as it is the most general form of IT2 TSK FLS models with the largest degrees of freedom. The extra flexibility of these models allows for efficient handling of uncertainties and minimizing their effects on the quality of forecasts.

In an IT2 TSK FLS (A2-C1) with a rule base of M rules in which each rule has p antecedents, let the lth rule be denoted by R^l,

$$R^l: \; If \; x_1 \; is \; \tilde{F}_1^l, \; x_2 \; is \; \tilde{F}_2^l, \cdots, \; and \; x_p \; is \; \tilde{F}_p^l, \; then$$
$$y^l \; = \; C_0^l + \sum_{i=1}^{p} C_i^l \; x_i \tag{1}$$

where $l = 1, ..., M$. $\tilde{F}_i^l$ is the ith IT2 FS ($i = 1, ..., p$) composed of a lower and upper bound MFs,

$$\mu_{\tilde{F}_i^l}(x_i) = [\underline{\mu}_{\tilde{F}_i^l}(x_i), \; \bar{\mu}_{\tilde{F}_i^l}(x_i)] \tag{2}$$

C_i^l is also an interval T1 FS, where its center and spread are c_i^l and s_i^l respectively,

$$C_i^l = [c_i^l - s_i^l, \; c_i^l + s_i^l] \tag{3}$$

Given an input $x = (x_1, x_2, ..., x_p)$, the result of the input and antecedent operations (firing strength) is an interval type-1 set, $F^l = [\underline{f}^l, \bar{f}^l]$, where,

$$\underline{f}^l(x) = \underline{\mu}_{\tilde{F}_1^l}(x_1) * \underline{\mu}_{\tilde{F}_2^l}(x_2) * \cdots * \underline{\mu}_{\tilde{F}_p^l}(x_p) \tag{4}$$

$$\bar{f}^l(x) = \bar{\mu}_{\tilde{F}_1^l}(x_1) * \bar{\mu}_{\tilde{F}_2^l}(x_2) * \cdots * \bar{\mu}_{\tilde{F}_p^l}(x_p) \tag{5}$$

where * represents a t-norm. It is assumed that singleton fuzzyfier is used in obtaining (4) and (5).

y^l in (1) is the output from the lth If-Then rule, which is a T1 FS, $Y^l = [y_L^l, y_R^l]$. y_L^l and y_R^l are evaluated as,

$$y_L^l = \sum_{i=1}^{p} c_i^l \; x_i + c_0^l \; - \; \sum_{i=1}^{p} s_i^l \; |x_i| - s_0^l \tag{6}$$

$$y_R^l = \sum_{i=1}^{p} c_i^l \; x_i + c_0^l \; + \; \sum_{i=1}^{p} s_i^l \; |x_i| - s_0^l \tag{7}$$

The final output of the IT2 TSK FLS model is obtained through combining the outcomes of M rules, as shown in (8).

$$Y = [y_L, y_R] = \int_{y^1 \in [y_L^1, y_R^1]} \cdots \int_{y^M \in [y_L^M, y_R^M]} \int_{f^l \in [f_L^l, f_R^l]} \cdots \int_{f^M \in [f_L^M, f_R^M]} \frac{1}{\frac{\sum_{l=1}^{M} f^l y^l}{\sum_{l=1}^{M} f^l}} \tag{8}$$

Before generating a crisp output, the outputs of the inference engine should be type-reduced and then defuzzified.

Unfortunately, there is no direct theoretical solution (closed-form formula) for calculation of y_L and y_R in (8). However, they can be calculated using the iterative Karnik-Mendel (KM) procedure [18] for type reduction (transferring a T2 FS into a T1 FS using the concept of center of sets). In the KM algorithm, y_L^l are reordered in ascending order. A switch point, L, is iteratively found that minimizes the value of y_L. The same procedure can be applied for calculation of y_R, where a switch point, R, is determined for maximizing y_R. y_L and y_R are given below,

$$y_L = \frac{\sum_{l=1}^{L} \bar{f}_i^l y_L^l + \sum_{l=L+1}^{M} \underline{f}_i^l y_L^l}{\sum_{l=1}^{L} \bar{f}_i^l + \sum_{l=L+1}^{M} \underline{f}_i^l} \tag{9}$$

$$y_R = \frac{\sum_{l=1}^{R} \underline{f}_i^l y_R^l + \sum_{l=K_R+1}^{M} \bar{f}_i^l y_R^l}{\sum_{l=1}^{R} \underline{f}_i^l + \sum_{l=K_R+1}^{M} \bar{f}_i^l} \tag{10}$$

Details of the KM type reduction algorithm can be found in [18] [25]. Finally, the defuzzified crisp output from the IT2 TSK FLS is the mean of y_L and y_R,

$$y = \frac{y_L + y_R}{2} \tag{11}$$

III. Structure and Training of IT2 TSK FLS Models

A. Membership Functions of IT2 TSK FLS

The performance of an IT2 TSK FLS depends on several factors, such as type and quantity of MFs, training algorithm, number of inputs, and the amount of available data for training. The antecedent MFs used in this study are assumed to be Gaussian with a fixed mean and uncertain standard deviations,

$$\mu_{\tilde{F}_i^l}(x_{i,k}) = exp\left[-\frac{1}{2}\left(\frac{x_{i,k} - m_i^l}{\sigma_i^l}\right)^2\right] = \mathcal{N}(m_i^l, [\sigma_{i,1}^l, \sigma_{i,2}^l]) \tag{12}$$

where $i = 1, ..., p$, $l = 1, ..., M$, and k indicates the sample index. The upper and lower MFs are,

$$\underline{\mu}_{\tilde{F}_i^l}(x_{i,k}) = \mathcal{N}(m_i^l, \sigma_{i,1}^l) \tag{13}$$

$$\bar{\mu}_{\tilde{F}_i^l}(x_{i,k}) = \mathcal{N}(m_i^l, \sigma_{i,2}^l) \tag{14}$$

Fig. 2 shows the graphical representation of these two MFs for arbitrary chosen values for m_i^l, $\sigma_{i,1}^l$, and $\sigma_{i,2}^l$. The uniformly shaded region is the footprint of uncertainty for the IT2 Gaussian MF.

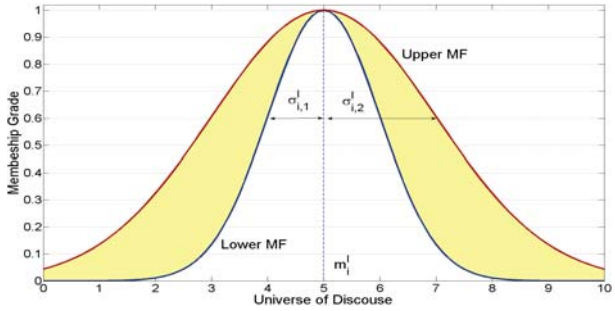

Fig. 2. The IT2 Gaussian MFs with fixed mean and uncertain standard deviation.

B. Genetic Algorithm for Training

The Genetic Algorithm (GA) is used for adjusting parameters of the IT2 TSK FLS models. By simultaneously exploring different parts of the parameter space, GAs increase the probability of finding the global solution to the minimization problem. The GA includes three main operators, namely reproduction (elitism), crossover, and mutation. Offsprings (new populations) are generated through crossover and mutation. Reproduction is a process in which individual chromosomes are copied according to their scaled fitness function values. Mutation introduces random changes to the chromosomes by altering the value to a gene with a probability called the mutation rate. Crossover operator determines how the GA combines two parents to form an offspring (crossover child) for the next generation.

Once a decision on the number of inputs and MFs per input is made, we can code the IT2 TSK FLS parameters into a chromosome. In each rule, premise parameters (mean and two standard deviations of each input membership function) and consequent parameters, as shown in (3), are coded as real variables and allowed to take real values. The Root Mean Squared Error (RMSE) is considered as the fitness function,

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(Act_i - Pre_i)^2} \tag{15}$$

where Act_i and Pre_i are the ith actual load and the ith forecasted load. n is also the number of load samples.

Parameters of premise and consequent parts of IT2 TSK FLS (A2-C1) are randomly initialized. Exploration of solution space continues until termination conditions are met. The maximum number of iterations, a minimum convergence speed, and a satisfactory small value of RMSE are the stopping criteria used in our experiments. After termination of the GA optimization, test samples are used for examining performance of the trained model.

Table I lists parameters used in the optimization algorithm. The cross over method is single point. This randomly selects a crossover point within a chromosome, and then interchanges the two parent chromosomes at this point to produce two new offspring. Parameters summarized in Table I are obtained through trial and error. The preliminary experiments were

TABLE I
PARAMETERS USED IN EXPERIMENTS AND GA-BASED TRAINING METHOD

Parameter	Numerical value
Population size	100
Parent selection	Stochastic uniform
Reproduction (elite count)	2
Cross over fraction (single point)	0.8
Number of MFs	3
Type of MFs	Gaussian (Fig. 2)
D_{train}	80% of all samples
D_{test}	20% of all samples

carried out with the aim to ensure optimization convergence within a short time (minimum number of generations), but to avoid premature convergence.

IV. DATA AND EXPERIMENT PROCEDURE

A. Data

The dataset in this study is the same that used previously in [9] and [10]. The purpose is to forecast the two-day-ahead loads based on past observations. The inputs to the IT2 TSK FLS models have been listed in Table II. These inputs are the mean of loads in the last three hours, the current temperature, and the day of week (coded as a number between 1 and 7). Other combinations of inputs and inclusion of lagged loads (up to even one year ago) can improve the quality of load forecasting results, however, determination of such a subset is beyond the scope of this paper. Furthermore, inclusion of more inputs will substantially increase the complexity of developed models.

The profile of loads for three years is shown in Fig 3. There is seasonal behavior with rapid fluctuations in the amount of consumed loads. Load peaks occur in summer, where load demand is minimum in winter. Additionally, there is an upward trend in the curve, which indicates an annual growth load demand.

IT2 TSK FLSs are data-driven techniques, and their forecasting performance intimately hinges on data used for their training. With the purpose of an objective assessment, the available dataset is split into training samples (80%, D_{train}) and test samples (20%, D_{test}). The IT2 TSK FLS is first trained using training samples, where the fitness function (RMSE) is minimized using the GA.

All available data are pre-processed to have zero mean and unit variance. This is done in particular for inputs (those listed in Table II) to give them an equal chance for contribution to models and load forecasting.

For the purpose of comparison, we benchmark performance of IT2 TSK FLS models by feedforward Neural Network (NNs). A two layer NN with 10 neurons in each hidden layer is trained using the Levenberg-Marquardt training algorithm. Simulations and forecasting procedure are repeated twenty times and averaged results are reported. This is done to avoid misleading results and subjective judgment due to random initialization of NN parameters.

TABLE II
INPUTS OF IT2 TSK FLS FOR STLF

Input	Quantity
Load demand in the last three hours	3
Current temperature	1
Day of the week	1

B. Performance Evaluation

Prediction performance of the developed models for STLF can be measured using three statistical measures. Coefficient of determination, designated by R^2, is one of the best choices, as it provides a measure of target variation captured by the model. R^2 is calculated as follows,

$$R^2 = 1 - \frac{\sum_{i=1}^{n} \left(Act_i - Pre_i\right)^2}{\sum_{i=1}^{n} \left(Act_i - \overline{Act}\right)^2} \tag{16}$$

where Act_i, Pre_i, and $\overline{Act}$ are the ith actual load, the ith forecasted load, and the mean of loads, respectively. A coefficient of determination close to unity (or 100%)) is an indication that forecasted values are close to actual data, and performance of the developed model is acceptable.

The two other performance measures used are RMSE (which also used as the fitness function) and correlation coefficient.

V. RESULTS AND ANALYSIS

The convergence behavior of the optimization algorithm and minimization of the fitness function (RMSE) is illustrated in Fig. 4. The fitness function is reduced several orders of magnitude from its initial value. The fitness function continuously decreases at a high rate up to generation 60. The optimization process then slows and converges to the optimal solution at iteration 109. During optimization, the fitness function drops from 0.5019 to 0.1283. This indicates that randomly selected initial values for IT2 TSK FLS (A2-C1) models are not optimal, leading to a large forecasting error.

Fig. 5 shows the plot of forecasted load demands versus their actual values. It is evident that there is a good agreement between the observed and forecasted load demands. The correlation coefficient between these values is 89.92%, which is sufficiently large. Also, forecasting errors are shown in Fig. 6. In some cases, the gap between actual and forecasted values is large. The maximum forecasting error (underestimation) is 3185 MWs. Such a large error can be due to unknown patterns in data or lack of informative variables.

Table III summarizes quantitative values of three performance measures for results obtained from IT2 TSK FLS (A2-C1) and NN models. These results are for test samples, which were not used for model training. The performance measures for NNs are averaged values obtained from 20 replicates of experiments. The main conclusions from the results listed in Table III are as follows:

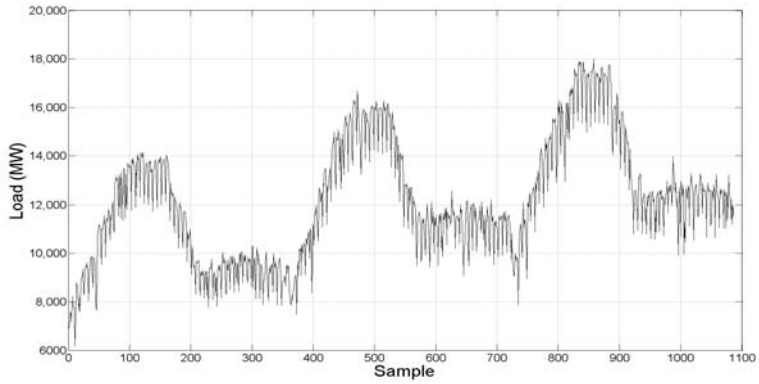

Fig. 3. The profile of loads used in this study.

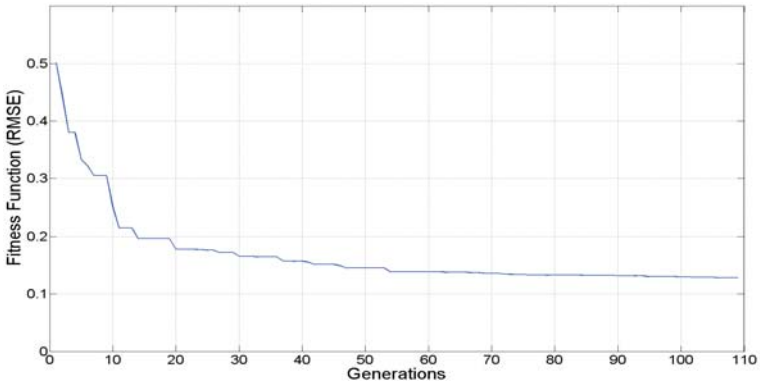

Fig. 4. Illustration of the convergence history of optimization algorithm for minimization of fitness function (RMSE) and adjusting parameters of IT2 TSK FLS (A2-C1).

- IT2 TSK FLS (A2-C1) models accurately forecast two day ahead load demands for test samples. A large R^2 and a small RMSE are indications of satisfactory results.
- The performance of IT2 TSK FLS (A2-C1) model is superior to multilayer NN models for STLF. This superiority is due to use of IT2 MFs in our forecasting models. This supports the claim that T2 FLSs have an excellent capability in handling uncertainties and minimizing their effects.
- NN models cannot appropriately cope with uncertainties in data. These uncertainties significantly degrade performance of NN models and cause a large forecasting error. This is due to fact that NNs are deterministic models and show a poor performance in case of multivalued targets [9] [26] [10] [27].

TABLE III
PERFORMANCE MEASURES FOR IT2 TSK FLS AND NN MODELS

Performance Measure	Neural Network	IT2 TSK FLS (A2-C1)
Correlation coefficient	86.48%	89.92%
RMSE	0.1685	0.1394
R^2	62.52%	77.02%

STLF performance of IT2 TSK FLS (A2-C1) models can be further improved through the use of other types of IT2 MFs with more degrees of freedom. An example is the Gaussian MF with uncertain mean and standard deviation. The number of MFs per inputs is 3 in experiments conducted (totally 81 rules). Increasing resolution of models by considering more MFs will improve the forecasting performance of models. The forecasting error for more complicate models (with more MFs) will also be further decreased in case of applying more generations in GAs for training of models. Inclusion of more inputs and using a validation set will also improve the accuracy of forecasting results obtained from both IT2 TSK FLS (A2-C1) and NN models.

VI. CONCLUSION

In this paper, interval type-2 TSK fuzzy logic systems are used for the problem of short term load forecasting. Lagged load demands and weather and calendar information are used as inputs to the forecasting model. Created models are trained using the genetic algorithm, where mean squared error is the cost function. The conclusion of this research is that short term power demand can be accurately forecasted using interval type-2 TSK fuzzy logic systems. The extra degrees of freedom of these models provide the analyzers with sufficient capacity for modeling nonlinear relationships and handling of uncertainties. The coefficient of determination between actual and forecasted loads is 77%, which is approximately 15%

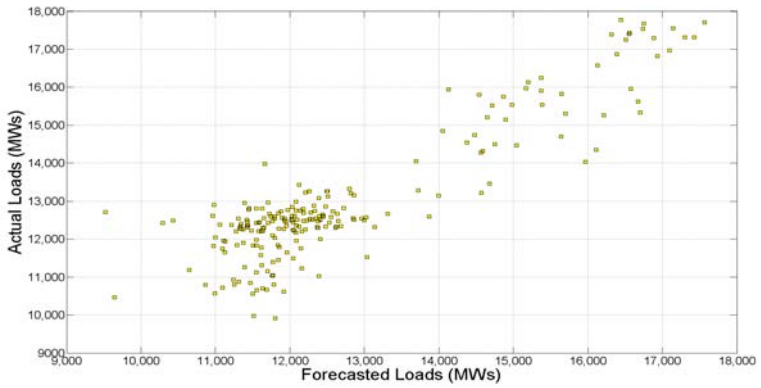

Fig. 5. Forecast vs. actual power demand with a correlation coefficient equal to 89.92%.

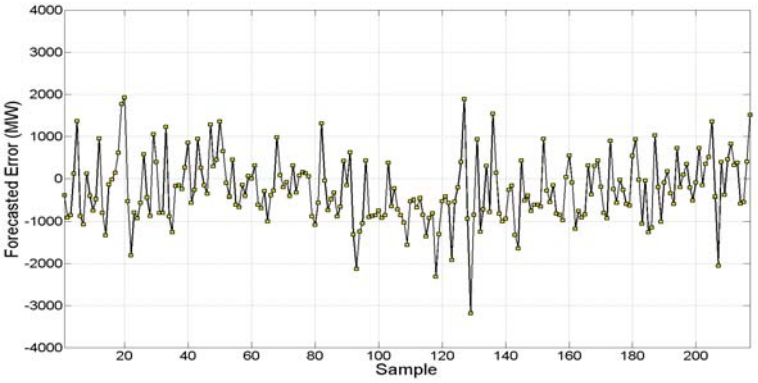

Fig. 6. Forecasting error for test samples (D_{test}).

greater than coefficient of determination for results obtained using neural networks.

IT2 TSK FLS (A2-C1) models used in this study can also be applied to the problem of medium and long term load forecasting. It is expected that these models will efficiently handle uncertainties and minimize their effects on forecasted long and short term load demands. Electricity price estimation is another research field, where these models could be used to handle prevailing uncertainties. Further research in these fields is continuing.

The work presented in this paper is a pioneer study on application of IT2 TSK FLS (A2-C1) for STLF problem. It will have a significant impact on the way artificial intelligence methods are used to forecast power load demands. It is expected that results of this paper will encourage other research groups to devote further effort into the application of IT2 FLS models for addressing problems in the power engineering field.

***Abstract*—A Fuzzy Logic System (FLS) is generally credited with being an adequate methodology for real world applications which are subject to high uncertainty levels. Recent works have shown that interval type-2 FLSs can outperform type-1 FLSs in the applications which encompass high uncertainty levels. However, the majority of interval type-2 FLSs handle the linguistic and input numerical uncertainties using singleton interval type-2 FLSs that mix the numerical and linguistic uncertainties to be handled only by the linguistic labels type-2 fuzzy sets. This ignores the fact that if input numerical uncertainties were present, they should affect the incoming inputs to the FLS. Even in the papers that employed nonsingleton type-2 FLSs, the input signals were assumed to have a predefined shape (mostly Gaussian or triangular) which might not reflect the real uncertainty distribution which can vary with the associated measurement. In our previous work, we have presented some of the theoretical basis for generating an adaptive type-2 fuzzy input which is better able to represent the encountered uncertainty at a given measurement. The nonsingleton type-2 fuzzy inputs are dynamic and they are automatically generated from data and they do not assume a specific shape about the uncertainty distribution associated with the given sensor. In this paper, we will present an overview on how the adaptive type-2 input based nonsingleton interval type-2 FLS can operate in real time. We will present real world experiments using a mobile robot which will show how under high input uncertainty levels, the nonsingleton type-2 FLS can give a good performance and outperform its singleton type-2 and type-1 FLSs counterparts.**

Keywords- type-2 nonsingleton, interval type-2 fuzzy logic systems, uncertainty, measurement data, mobile robots

I. INTRODUCTION

The Fuzzy Logic System (FLS) is credited with being an adequate methodology for dealing with the uncertainties and imprecision present in real world applications. While traditionally type-1 FLSs have been widely employed in real world applications, recent years have shown a rapidly growing interest in the research and application of type-2 FLSs. This is because, it has become apparent that type-1 FLSs cannot fully handle the large amounts of uncertainties encountered in real world environments and applications. Interval type-2 FLSs have shown to provide better performance when compared to type-1 FLSs in applications with high levels of uncertainty. The difference in performance has been attributed to the nature of interval type-2 fuzzy sets which can better account for the uncertainties as they incorporate a Footprint of Uncertainty (FOU) and they can be assumed to embed a large number of type-1 fuzzy sets. However, the majority of the type-2 FLSs handle the linguistic and input numerical uncertainties using singleton interval type-2 FLSs that mix the numerical and linguistic uncertainties to be handled only by the linguistic labels type-2 fuzzy sets. Input numerical uncertainties are associated with the noise, imprecision and uncertainty associated with sensors and input devices. However, the linguistic uncertainties are associated with human words and perceptions. Hence, it seems paradoxical to use singleton type-2 FLSs to handle the input numerical uncertainties, as this ignores the fact that if input numerical uncertainties were present, they should affect the incoming inputs to the FLS. Thus we cannot treat the incoming FLS inputs as perfect signals as in the case of singleton FLSs. Hence, there is a need to employ nonsingleton FLSs to handle the input numerical uncertainties by modelling the inputs as fuzzy inputs rather than crisp values.

Although, there are many papers on type-1 FLSs, limited number of papers considered the usage of type-1 nonsingleton FLSs such as [1-6] and even fewer number considered type-2 nonsingleton FLS [7-11]. The work done so far in (type-1 and type-2) nonsingleton FLSs use predefined shapes for the uncertainty distribution affecting the FLSs inputs (mainly Gaussian and triangular) which might not reflect the real uncertainty distribution associated with the given sensor [12-14]. For example in the case of a sonar sensor, the numerical input uncertainties depend on many factors such as the shape and type of objects reflecting the sonar signal as well as wind speed, humidity and temperature. Moreover, the uncertainty distribution also varies with the measured values where for the case of a sonar sensor, the amount of uncertainty affecting measurement readings at 20cm distance could be much less than the uncertainties affecting the measurement at large distances such as 3m. Hence, it is not fair to consider that there

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

is specific shape for the uncertainty distribution (triangular, Gaussian, etc.) with fixed parameters (average, standard deviation, etc.) for all the measured values.

In our previous work [15], we have presented some of the theoretical basis for generating an adaptive type-2 fuzzy input which is better able to represent the encountered uncertainty at a given measurement. The nonsingleton type-2 fuzzy inputs are dynamic and they are automatically generated from data and they are piece-wise linear type-2 fuzzy sets which are changing for different measurements to model the encountered uncertainty. Piece-wise linear fuzzy sets were used in [16] for the representation of membership functions. However, we use piece-wise linear fuzzy sets to represent the type-2 fuzzy input variables. In this paper, we will present an overview on how the adaptive type-2 input based nonsingleton interval type-2 FLS can operate in real time. We will present real world experiments using a mobile robot which will show how under high input uncertainty levels, the nonsingleton type-2 FLS can give a good performance and outperform its singleton type-2 and type-1 FLSs counterparts.

Section II will give a summary of the structure of the real – time type-2 nonsingleton type-2 FLS. Section III will present the experiments and results. Finally Section IV provides conclusions and future work.

II. THE TYPE-2 NONSINGLETON TYPE-2 FLS

A. The Structure of Type-2 Nonsingleton Type-2 FLS

The structure of the type-2 nonsingleton type-2 FLS [15] is illustrated in Fig.1. The type-2 nonsingleton type-2 FLS employs interval type-2 fuzzy sets to handle the encountered linguistic uncertainty associated with the linguistic labels while the nonsingleton type-2 fuzzy input variables handle the encountered numerical input uncertainties.

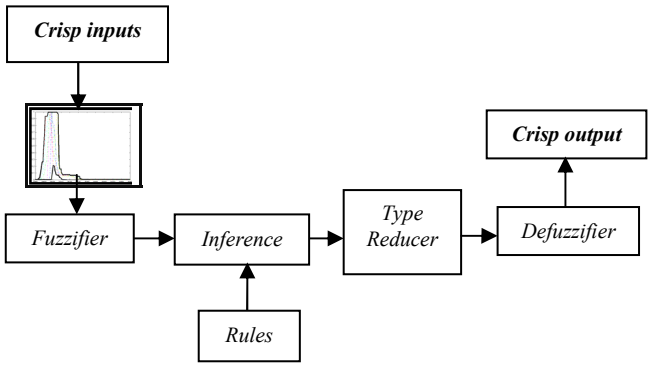

Figure 1. The structure of type-2 nonsingleton type-2 FLS.

B. Modeling Type-2 Fuzzy Input Variables

Fig.2 shows a high level overview on the steps taken to model the type-2 fuzzy input variables at given measurement values. The first step involves sampling the given input at different measurements by logging many readings at the same measurement value (for example for a sonar sensor, collecting 10,000 readings at 20cm, 40cm, etc.) which will create a data distribution (or a histogram). The data distributions are then converted into piece-wise linear type-1 fuzzy sets that are convex and normal as explained in [15] and [17]. We then repeat the same process under various uncertainty conditions (for the sonar sensors, subjecting it to humidity, heat, wind, different surfaces, etc.) which will create different type-1 fuzzy sets for the different uncertainty conditions [15], [17]. We then combine the various type-1 fuzzy sets at the given measurement value to form a type-2 fuzzy set that models the uncertainty at the given measurement value.

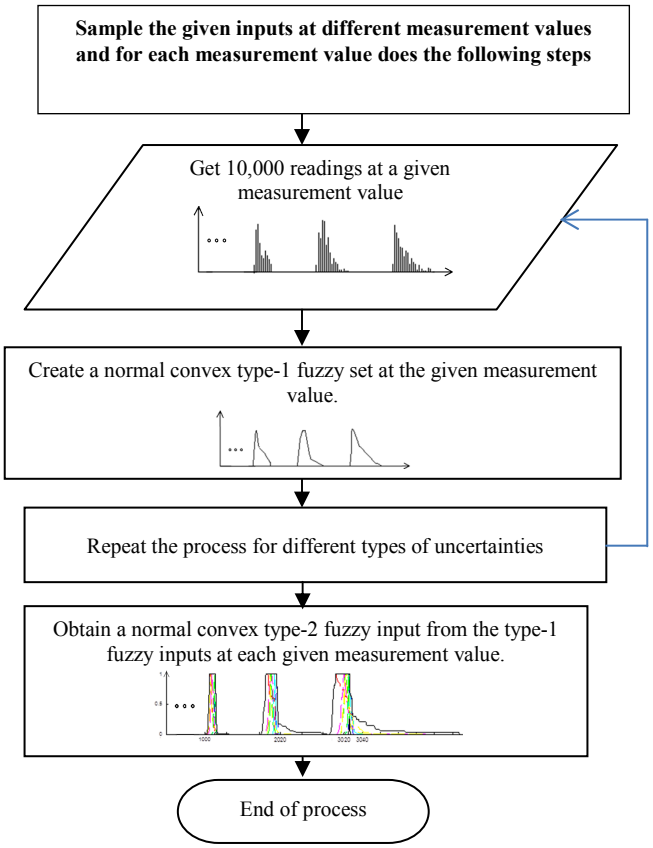

Figure 2. The off-line process of obtainig the type-2 fuzzy input at certain measusrement values.

As we cannot generate the type-2 fuzzy sets for all the measurements values, hence, we need to interpolate the type-2 fuzzy set for an incoming measurement value by interpolating the type-2 fuzzy sets representing the measurements to the left and right of the incoming measurement value. For each control cycle (as shown in Fig.3), we have a measurement window which takes 5 consecutive crisp measurements from the sensor at the given instance and takes the average to form an incoming measurement value which interpolates type-2 fuzzy sets at the right and left of the incoming measurement to generate an interpolated type-2 fuzzy input as explained in [17]. The type-2 fuzzy input is then fuzzified and then it triggers the inference engine and the rule base to generate a type-2 fuzzy output which is then type-reduced and defuzzified to generate the final crisp output of the FLS.

Fig.4-6 present the real-world shapes of the nonsingleton type-2 fuzzy inputs generated at given measurements of a given sonar sensor at 1m, 2m, and 3m respectively. The top figures of each pair set of figures (Fig.4-Fig.6) are the type-2 fuzzy input variable for the front sonar sensor and the figures below are

related to back sonar sensor of the mobile robot shown in Fig.11. For each given measurement, we log 10,000 readings from the sensor. In the case of a sonar sensor for the robot shown in Fig.11, we keep the distance fixed and read 10,000 readings at the same fixed distance which will result in a data distribution or a histogram. Following the steps in Fig. 2, we then create a normal convex type-1 fuzzy set from the given data distribution, which will model the uncertainties at the given measurement conditions. We then apply various environmental conditions, which could affect the input measurements. As for the case of a sonar sensor, we can consider changing shapes and materials of the objects as well as changing temperature, sound noise and wind. Each condition will then have an associated type-1 fuzzy set which models the uncertainty at the given measurement (fixed distance). We then combine the various type-1 fuzzy sets to create a convex type-2 fuzzy set (as explained in [15] and [17]) which models the various uncertainties encountered at each measurement value.

The upper and lower membership functions of type-2 fuzzy input for the considered sonar sensors are shown by black lines in Fig.4-Fig.6, while the related type-1 fuzzy input for each case of uncertainty is shown by dashed lines. Fig.4-Fig.6 illustrate that not only the shape of type-2 fuzzy sets change for different range of distances, but also the sonar sensors may not be effected in a same way.

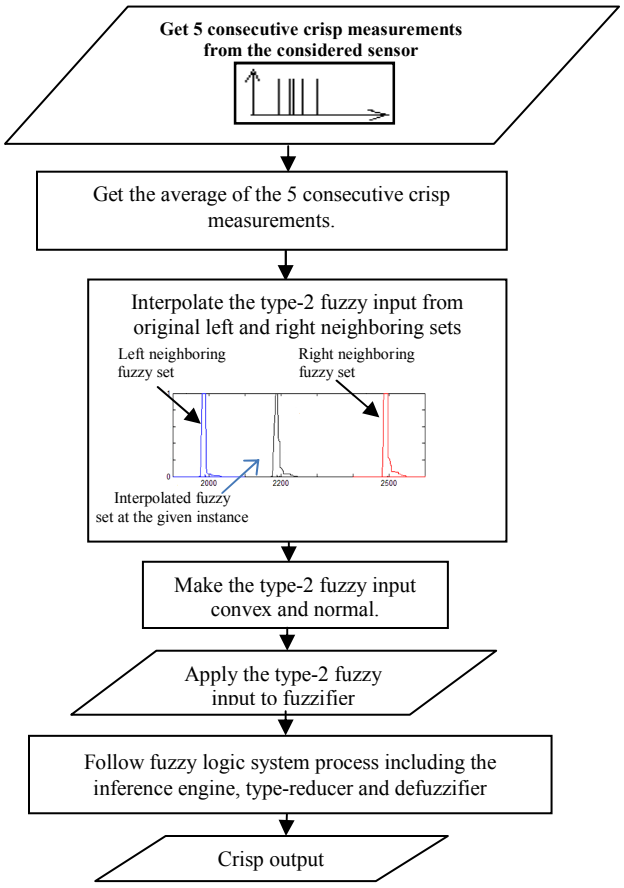

Figure 3. The process of the on-line nonsingleton type-2 FLS

C. The Type-2 Nonsingleton Type-2 Fuzzification

The fuzzifier converts the fuzzy inputs into linguistic labels with given membership values to activate the rule base and inference engine. The fuzzification operation between the type-2 fuzzy input variables and the type-2 fuzzy sets assigned for linguistic labels (the antecedent type-2 fuzzy set specified by F_k^l) to obtain lower and upper membership values of input k within rule l are shown in Equations (1) and (2) respectively:

$$\overline{\mu}_k^l(x_k) = \sup_{x_k \in X_k} (\overline{\mu}_{x_k}(x_k) * \overline{\mu}_{F_k^l}(x_k)) \quad (1)$$

$$\underline{\mu}_k^l(x_k) = \sup_{x_k \in X_k} (\underline{\mu}_{x_k}(x_k) * \underline{\mu}_{F_k^l}(x_k)) \quad (2)$$

The $\overline{\mu}_{x_k}(x_k)$ and $\underline{\mu}_{x_k}(x_k)$ are the upper and lower membership functions of the type-2 fuzzy input variable and $\overline{\mu}_{F_k^l}(x_k)$ and $\underline{\mu}_{F_k^l}(x_k)$ are the upper and lower membership functions of the antecedent type-2 fuzzy sets (representing the linguistic labels) respectively. The sup operation has been considered as maximum t-conorm, and the * operation is minimum t-norm. In [17], we described the theory of type-2 nonsingleton type-2 FLS, and how the fuzzification output is calculated for the upper membership functions. The process of finding the output of the fuzzifier follows Equations (1) and (2) to find the upper and lower membership values to the given respective linguistic label. Due to the limited space, in this subsection, we will concentrate on presenting the process followed to find the lower membership value to the given respective linguistic label. The process is quite complicated as the input type-2 fuzzy variable is a piece-wise linear function (as shown in Fig.7).

According to Equation (2), to get lower bound of the membership to the given respective linguistic label, we need to apply the t-norm (minimum operation) between the type-1 membership functions $\underline{\mu}_{x_k}(x_k)$ and $\underline{\mu}_{F_k^l}(x_k)$. This will result in a type-1 fuzzy set (shown by thick line in Fig.8 - Fig.10), where we need to find its sup (maximum) to find $\underline{\mu}_k^l(x_k)$.

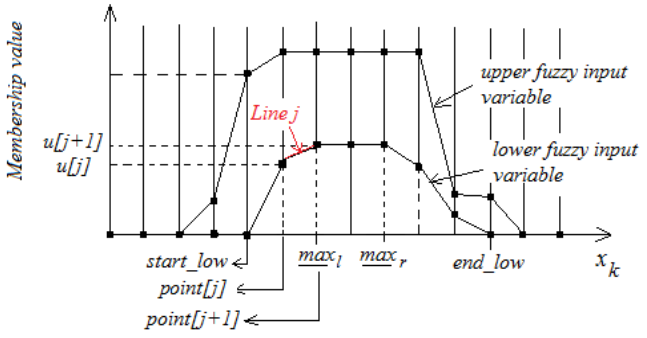

Figure 7. The piece-wise linear type-2 fuzzy input variable.

Due to the limited space in this paper, we will present a sample for the operation between the antecedent type-2 fuzzy set and the type-2 fuzzy input variable for the lower bound when the starting point *start_low* (shown in Fig.8 - Fig.10) (of the lower membership function for type-2 fuzzy input variable) is smaller than d_{m2} (of the lower membership function antecedent type-2 fuzzy set) and the ending point *end_low* (of the lower membership function for type-2 fuzzy input variable) is greater than a_{m2} (of the lower membership function of antecedent type-2 fuzzy set).

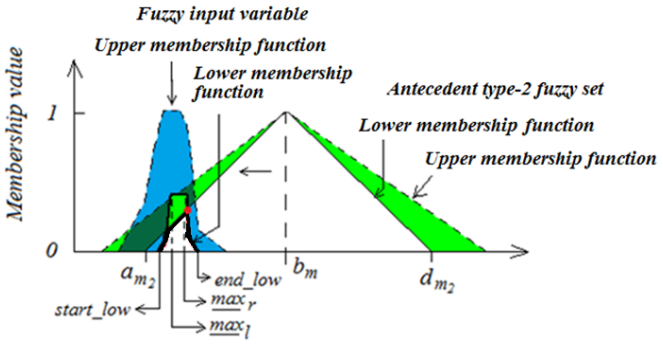

Figure 8. Finding $\underline{\mu}_k^l(x_k)$ for Case 1 .

The case 1 in Fig.8 happens when the intersection between the lower membership function of the type-2 fuzzy input and the lower membership function of the antecedent is located on the antecedent line from b_m to a_{m2} , but the intersection does not happen on the maximum of the lower membership function of the type-2 fuzzy input. In that case, we need to obtain the first intersection point from right to left starting from the pieces of line j ending at *end_low*. As the slope of the antecedent line from b_m to a_{m2} is positive, the first intersection from right side has the highest membership value, which will be the result of max-min operation between the two fuzzy sets to lead to $\underline{\mu}_k^l(x_k)$.

The given line *j* (of fuzzy input) ranges from *point[j]* to *point [j+1]* in the x-axis line where *j+1* is the line connecting to the line *j* and located at its right in the piece-wise linear function. The *u[j]* and *u[j+1]* are also membership value at *point[j]* and *point[j+1]* respectively. The membership value for any point x_k located on line *j* is obtained from Equation (3) as follows:

$$\frac{\mu_{x_k}(x_k) - u[j]}{x_k - point[j]} = \frac{u[j+1] - u[j]}{point[j+1] - point[j]}$$

$$\mu_{x_k}(x_k) = \frac{u[j+1] - u[j]}{point[j+1] - point[j]} x_k + \frac{point[j+1]u[j] - point[j]u[j+1]}{point[j+1] - point[j]} \quad (3)$$

The membership value $\mu_{F_k^l}(x_k)$ of any point x_k on a line of the antecedent fuzzy set (starting from an extreme left point "*left*" (a_{m2} in our case) and ending at an extreme right point "*right*" (b_m in our case)) is obtained as follows:

$$\frac{\mu_{F_k^l}(x_k) - \mu_{F_k^l}(left)}{x_k - left} = \frac{\mu_{F_k^l}(right) - \mu_{F_k^l}(left)}{right - left}$$

$$\mu_{F_k^l}(x_k) = \frac{\mu_{F_k^l}(right) - \mu_{F_k^l}(left)}{right - left} x_k + \frac{right\mu_{F_k^l}(left) - left\mu_{F_k^l}(right)}{right - left} \quad (4)$$

At the intersection point $x_{k,c}$ between an antecedent line and a line j of the fuzzy input variable, $\mu_{x_k}(x_k)$ in Equation (3) is equal to $\mu_{F_k^l}(x_k)$ in Equation (4). Hence $x_{k,c}$ could be found as follows:

$$x_{k,c} = \frac{\left[\begin{array}{l}(right\mu_{F_k^l}(left) - left\mu_{F_k^l}(right))(po\,\mathrm{int}[j+1] - po\,\mathrm{int}[j]) + \\ (right - left)(po\,\mathrm{int}[j]u[j+1] - po\,\mathrm{int}[j+1]u[j])\end{array}\right]}{\left[\begin{array}{l}(right - left)(u[j+1] - u[j]) + \\ (\mu_{F_k^l}(left) - \mu_{F_k^l}(right))(po\,\mathrm{int}[j+1] - po\,\mathrm{int}[j])\end{array}\right]} \quad (5)$$

Subsistuting with the value of $x_k = x_{k,c}$ in Equation (3) or (4), we can find $\underline{\mu}_k^l(x_k) = \mu_k^l(x_k)$.

The case 2 in Fig.9 happens when at least one intersection between lower membership function of the type-2 fuzzy input and the lower membership function of the antecedent happens on the maximum of the lower membership function of the type-2 fuzzy input (or it can happens when the fuzzy input variable is within a_{m2} to d_{m2} domain but no intersection occurres). In that case, $\underline{\mu}_k^l(x_k)$ is equal to the maximum membership value of the lower membership function of type-2 fuzzy input.

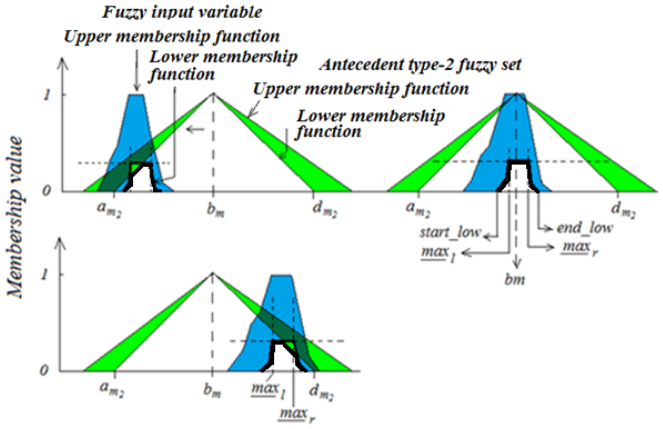

Figure 9. Finding $\underline{\mu}_k^l(x_k)$ for Case 2 .

The case 3 in Fig.10 happens when the intersection between lower membership function of the type-2 fuzzy input and the lower membership function of the antecedent is located on the antecedent line from b_m to d_{m2}, but the intersection does not happen on the maximum of the lower membership function of the type-2 fuzzy input. In that case, we need to obtain the first intersection point from left to right side strating from the pieces of line j starting at *start_low*. As the slope of the antecedent line from b_m to d_{m2} is negative, the first intersection from left has the highest membership value. Hence $\underline{\mu}_k^l(x_k)$, could be found using the same approach followed in Equations (3 –5).

Following the same procedure the upper and lower membership values ($\underline{\mu}_k^l(x_k)$ and $\overline{\mu}_k^l(x_k)$) could be found for the various cases as explained in [17].

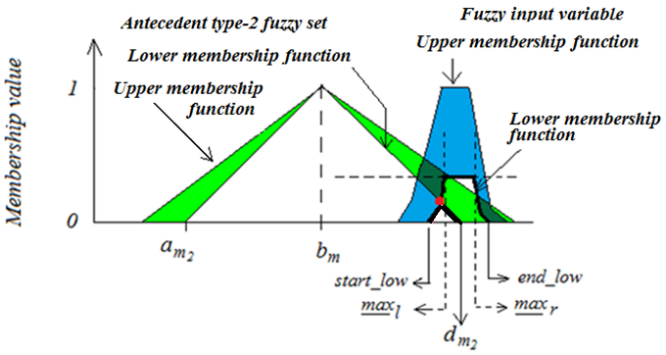

Figure 10. Finding $\underline{\mu}_k^l(x_k)$ for Case 3 .

D. Rule Base

The rule base of singleton and nonsingleton FLS are similar. Considering a FLS having inputs $x_1 \in X_1, \ldots, x_p \in X_p$ and one output y∈ Y, the rule *l* is defined as [12]:

$$\text{If } x_1 \text{ is } \tilde{F}_1^l \ldots \text{and } x_p \text{ is } \tilde{F}_p^l, \text{ then y is } \tilde{G}^l \quad (6)$$

Where *l=1, ..., M* and *M* is the total number of rules in the rule base. The $\tilde{F}_k^l$ is the antecedent membership function for input *k* and rule *l*, and $\tilde{G}^l$ is consequent membership function for rule *l*.

E. Inference Engine

We have shown in the fuzzifier subsection, how to find the upper and lower membership values of a given type-2 fuzzy input variable to a given linguistic label. The process needs to be done for all inputs *(k=1,..., p)*. At the end, the firing strength of each rule $F^l = [\underline{f}^l, \overline{f}^l]$ could be found where $\underline{f}^l$ and $\overline{f}^l$ will be obtained as follows:

$$\underline{f}^l = T_{k=1}^p \{\underline{\mu}_k^l(x_k)\} \quad (7)$$

$$\overline{f}^l = T_{k=1}^p \{\overline{\mu}_k^l(x_k)\} \quad (8)$$

F. Type-Reduction and Defuzzification

After obtaining the lower and upper firing strengths for each rule from the inference engine and obtaining the centroid of consequent membership function, the center of sets type-reducer [12] is used to produce the type-reduced sets. We then take the average of the type-reduced set to provide the final defuzzified crisp output.

III. Experiments and Results

A. The Robots and the Experimental Setup

In our experiments, we have employed a four-wheel mobile robot (shown in Fig. 11) with two sonar sensors to follow an edge made of cylindrical objects. In order to test the robot under unseen input uncertainties, we have applied various sources of uncertainties to the input sonar sensors as shown in Fig.11a where we have used a hair dryer stuck on robot to blow hot air through the path of front sonar sensor. We have also employed a fan fixed at a certain position on ground to create cold wind at the starting robot position. These employed

uncertainties are introduced during the online operation of the robot and they have not been seen by the robot during the FLS design. We chose changing the wind speed (through the fan and dryer) and temperature (through the hair dryer) to introduce input uncertainties to the sonar sensors. This is because the wind, temperature variations and atmospheric turbulences are all meteorological conditions [18] that have an effect on sound propagation (as we used sonar sensors). The speed of sound in air is proportional to the square root of absolute temperature as follows:

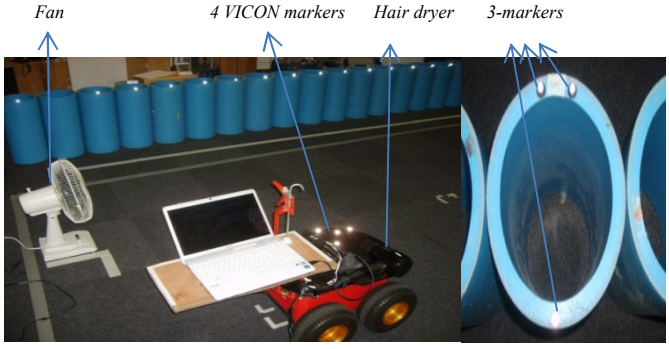
$$c = 20.05\sqrt{T + e/p} \tag{9}$$

Where T is absolute temperature in Kelvin, and e is partial pressure of water vapor, and p is barometric pressure. Wind is also another factor affecting the sound travel. The wind in the same direction of sound will cause the wave propagation to be bent downward, and in the upwind direction, sound waves move upward which cause no direct sound penetration [18].

To obtain the position of the robot in a precise way, the VICON system is used in which six cameras are employed. To be able to recognize the robot, four markers are used (as shown in Fig.11). The top of the cylinders are also marked to be able to check if the edges of the cylinders are in a same line where the starting and ending cylinders are modeled in VICON to be able to distinguish the certain position of wall (one of them is shown in Fig.11b).

B. The FLSs Design

We have designed a type-1 FLS which is able to give a good performance under the normal lab conditions. The performance of the type-1 FLS is considered to be acceptable when it produces small overshoots/undershoots and small steady state error in a usual room temperature without applying external uncertainty. The antecedent membership functions for the type-1 FLS are shown in Fig.12 (drawn with thin line). We have then blurred the type-1 fuzzy sets by a given uncertainty value to generate the FOU of the type-2 fuzzy sets (shown in Fig.12 by thick line) for the interval (singleton and nonsingleton) type-2 FLS. The consequent membership functions (for all FLSs) are type-1 fuzzy sets as there are no major uncertainties associated with robot outputs. The rule-base (employed for all FLSs) is shown in Table I.



(a) (b)

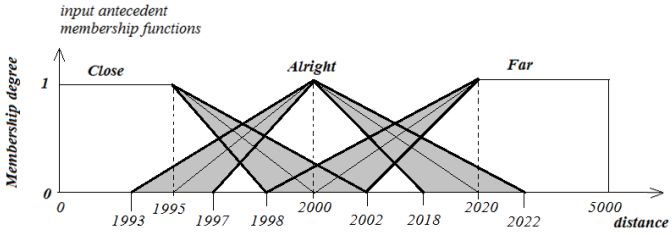

Figure 12. Antecedent membership functions for both the front and back senors. The type-1 fuzzy sets are shown in thin line while the interval type-2 fuzzy sets are shown in thick lines.

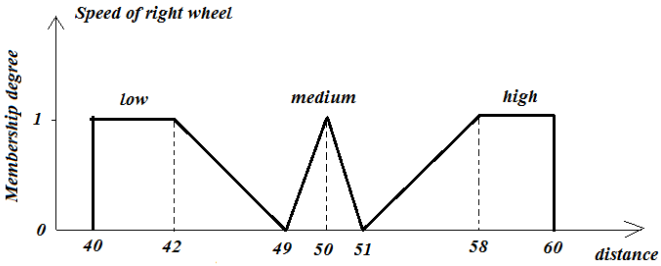

Figure 13. The consequent type-1 fuzzy sets for the used FLSs

TABLE I. THE RULE BASE FOR ALL THE FLSS. THE RULE BASE OUTPUT IS THE SPEED OF RIGHT WHEEL.

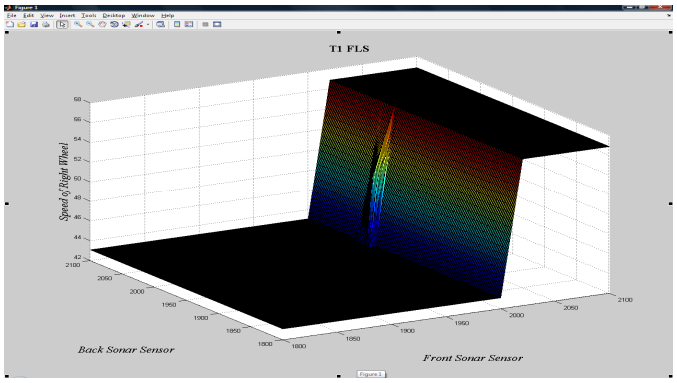
Front sonar	Back sonar		
	Close	Alright	Far
Close	*low*	*low*	*low*
Alright	*low*	*medium*	*low*
Far	*high*	*high*	*high*

C. Control Surface Analysis

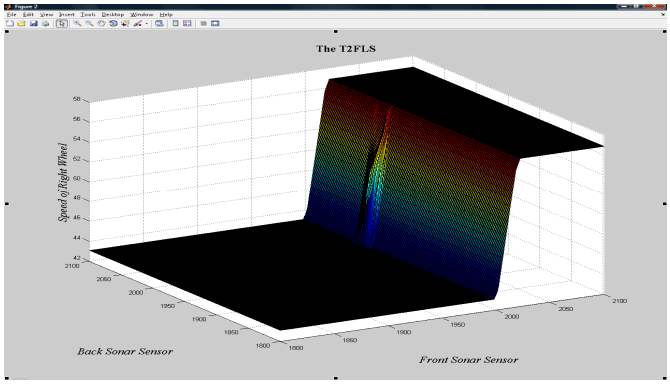
The control surface graphically represents the unknown function articulated by the FLS. Fig. 14 shows the control surfaces for the singleton type-1 and type-2 FLSs and the type-2 nonsingleton type-2 FLS. The control surfaces show the front and back sensors plotted against the speed of right wheel. Note that a smooth shape of a control surface translates to a smooth control response that can deal with uncertainty and imprecision.

As seen from Fig.14a, the control surface of the type-1 FLS is rather steep which means it can be affected by high levels of uncertainties in the inputs where small change in the inputs can result in large output changes which might cause high overshoots/undershoots and steady state errors in addition to moving towards an unstable situation. On the other hand the control surface of the singleton type-2 FLS (shown in Fig.14b) is smoother than the type-1 FLS, which means it can handle higher level of uncertainties. However, the control surface of the type-2 nonsingleton type-2 FLS (shown in Fig.14c) is much smoother where there are smooth transition at all parts of the control surface where any small change in inputs will

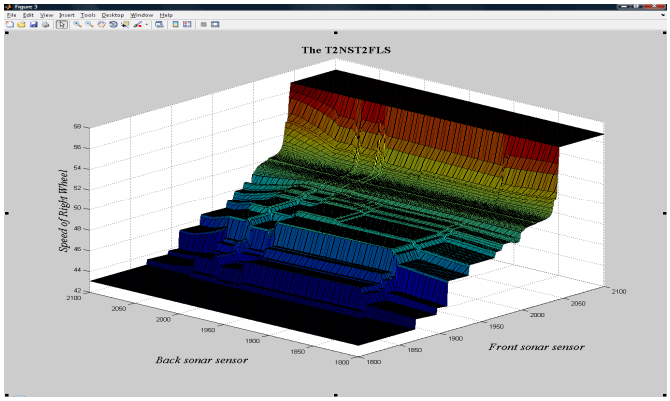
result in a small change in the outputs. Thus using the type-2 input based nonsingleton type-2 FLS result in a control surface which is smoother than the singleton type-1 and type-2 FLSs. This smooth response will consequently give a very good control performance that can handle the high levels of uncertainties and disturbances where small variations in inputs will not cause significant changes to outputs. Thus, it is expected that the type-2 nonsingleton type-2 FLS will be able to handle higher levels of uncertainties than its singleton type-1 and type-2 FLSs counterparts. This will be evidenced in the real world experiments reported in the following subsection.



(a)



(b)



(c)

Figure 14. The control surface of (a) The singleton type-1 FLS. (b) The singleton interval type-2 FLS. (c) The type-2 nonsingleton intreval type-2 FLS.

D. Real World Experiments

Fig.15 and Fig.16 show the results of some robotic experiments, which compare the performance of singleton type-1, singleton type-2 and type-2 input based nonsingleton type-2 FLS to realize an edge following behavior at a desired distance of 2m. The robot starts from the distance of 1.8m from the nearest edge. Fig. 15 shows the robots paths of singleton type-1, type-2 and nonsingleton type-2 FLS under no induced uncertainty. As shown in Fig.15 and Table II (as expected under no uncertainty), the performance of all the FLSs will be quite similar where the type-1 FLS will be slightly better. However, as high levels of uncertainties are introduced (by blowing hot wind through the way of one sonar) as shown in Fig.16 and Table II, the type-2 nonsingleton type-2 FLS gives the best performance in terms of the Root Mean Squared Error (RMSE) (which could represent the average error) and the Standard Deviation (STD) (which could represent the size of the overshoots/undershoots from the average). In terms of control performance, the type-2 nonsingleton type-2 FLS provides the best performance followed (by a large margin) by the singleton type-2 FLS and then the singleton type-1 FLS which performs poorly.

Fig.16 evidences the control surface analysis in Fig.14 where the type-2 nonsingleton type-2 FLS recovers quickly from the uncertainties with relatively smaller overshoot/undershoot.

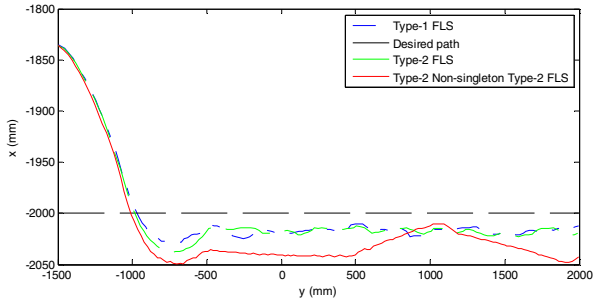


Figure 15. The robot's paths when employing singleton type-1, type-2 and nonsingleton type-2 FLS under no uncerantity.

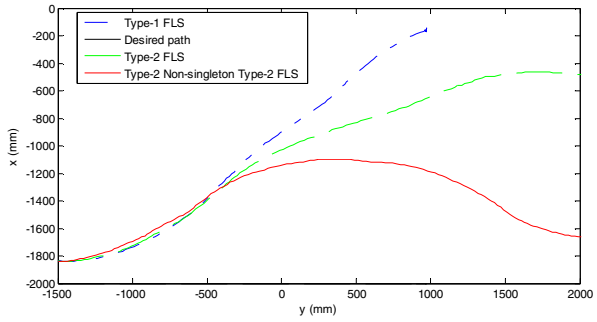

Figure 16. The robot's paths when employing singleton type-1, type-2 and nonsingleton type-2 FLS under high uncerantity levels.

TABLE II. SUMMARY RESULTS OF WALL FOLLOWING FOR THE THREE TYPES OF FLSS.

Different Conditions	Different Types of FLS		
	Type-1 FLS	***Type-2 FLS***	***Type-2 nonsingleton Type-2***
No uncertainty	STD =45.7 RMSE =45.6	STD =46.7 RMSE=46.6	STD =48.1 RMSE=51.2
Large uncertainty	STD =626.7 RMSE=1268.2	STD=478.7 RMSE=1037.8	STD =245.0 RMSE=634.4

IV. CONCLUSION

In this paper, we have presented an adaptive type-2 fuzzy input based nonsingleton type-2 FLS which is better able to handle the encountered input uncertainties. The nonsingleton type-2 fuzzy inputs are dynamic and they are automatically generated from data and they do not assume a specific shape about the uncertainty distribution associated with the given sensor. We have presented an overview on how the adaptive type-2 input based nonsingleton interval type-2 FLS can operate in real time. We have shown through control surface analysis, how the nonsingleton type-2 FLS can produce much smoother control surface than the singleton type-1 and type-2 FLSs. This should result in a better control response that handles high uncertainty levels. This was evidenced through the real world experiments using mobile robots where under high uncertainty levels, the nonsingleton type-2 FLS can outperform its singleton type-2 and type-1 FLSs counterparts. This work has shown the benefits achieved when using type-2 nonsingleton type-2 FLSs in applications characterized by high input uncertainty levels. In our future work, we aim to allow the various parameters of the type-2 nonsingleton type-2 FLSs to be learnt directly from data online.

ACKNOWLEDGMENT

The authors would like to thank Mr. Robin Dowling who supported the project by providing facilities and Mr. John Oyekan who helped to obtain data from VICON system.

***Abstract*—This paper proposes a fuzzy preference relation approach to evaluate the hospital service quality in Taiwan. Pairwise comparisons based on consistent reciprocal additive transitivity are utilized to derive the importance weights of evaluation criteria and to obtain the performance rating of feasible hospitals with respect to each criterion. By multiplying the importance weights of evaluation criteria, and the performance ratings of feasible hospitals, the service qualities of hospital are determined. An illustrative example elicited from 5 public hospitals in southern Taiwan is used to demonstrate the evaluation procedures of this proposed approach.**

Keywords-hospital service quality; fuzzy preferece relations; performance evaluation; consistent reciprocal additive transitivity

I. INTRODUCTION

In 1995, Taiwanese National Health Insurance program was put into practice, the residents enjoyed high quality but relatively cheaper medical care compared with the developed countries. Hospital care is an industry with the characteristics of highly specialized medical capability and close contact with many persons. The importance of medical service and quality leaves no room for doubt, since good or bad quality of medical treatments directly affect the survival possibility. Recently the request for hospital service quality is gaining momentum in the world [1]. To manage a hospital successfully, the primary goals are providing good medical service quality and meeting various kinds of demands for the patients then retaining as many customers as possible [2]. Hospital, like other commercial or non-profit organizations, uses resources to provide many types of services, which is a measure of output for health-care organizations [3]. At the end of 2010, there are 19,329 public and private medical care institutions in Taiwan, so it is very difficult and complicated for the government to manage them. In order to manage so many medical care institutions efficiently, comparative performance evaluation, usually evaluated with itself over time or by comparison with others in the same industry, is used as an essential resolution of the managerial control function [3]. There are papers discussing the hospital or medical care service quality evaluation problems. Andaleeb [4] compared the quality of services provided by private and public hospitals in urban Bangladesh. Li [5] explored the relationship between hospital quality management and service quality performance for a sample of US community hospitals using a path analytic model. Raju [6] examined the impact of service quality and marketing on financial performance in the hospital industry. Andaleeb [7] surveyed the service quality perceptions and patient satisfaction of hospitals in a developing country. Li [8] identified strategic operations management decisions in the US community hospitals, showed their causal relationships, and identified their effects on hospital performance. Goldman [9] compared the quality of rural hospitals participating in a public reporting initiative to that of their urban counterparts using Hospital Compare, a new national database containing process measures. Tsai [10] used fuzzy hierarchy sensitive with Delphi method to evaluate hospital organization performance. Many critical factors are considered in the hospital service quality evaluation; so this issue is regarded as a multicriteria decision making problem. This study therefore proposes an analytic hierarchy framework based on the consistent fuzzy preference relations to evaluate the service quality of these medical care institutions. The next section will briefly discuss the consistent fuzzy preference relations. An analytic hierarchy framework based on the consistent reciprocal additive transitivity for evaluate hospital service quality is derived in Section III. In Section IV, an illustrative example is presented. Finally, discussion and conclusion are given in Section V.

II. CONSISTENT FUZZY PREFERENCE RELATIONS

The decision information is frequently represented with the system of preference relations in many decision-making approaches. Herrera-Viedma et al. [11] proposed the consistent fuzzy preference relations, with the ability which not only enables decision makers to express preferences over a set of alternatives with the least judgments, but also avoids checking the inconsistency in decision-making process. Wang and Parkan [12] investigated the aggregation of fuzzy preference relations with an application to broadband internet service selection. Wang and Chen [13] applied fuzzy linguistic preference relations to improve the inconsistency of fuzzy AHP. Chao and Chen [14] evaluated the criteria and effectiveness of distance e-learning with consistent fuzzy preference relations. Chang and Wang [15] measured the success possibility of implementing advanced manufacturing technology by utilizing the consistent fuzzy preference relations. Wang and Chang [16] applied the consistent fuzzy preference relations in predicting the success of knowledge management implementation. Wang and Chang [17] forecasted the probability of successful knowledge management by consistent fuzzy preference

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

relations. Wang and Chen [18] applied the consistent fuzzy preference relations to partnership selection. Wang and Lin [19] applied consistent fuzzy preference relations to select merger strategy for commercial banks in new financial environments. The following briefly describes some definitions and propositions discussed in [20-28].

Given $X=\{x_1,x_2,...,x_n,\ n\geq 2\}$ be a finite set of alternatives to be pairwise assessed by a finite set of experts ($E=\{e_1,e_2,...,e_m,\ m\geq 2\}$). We can assume that the experts' preferences toward the set of alternatives X may be expressed in the following ways [29]:

(1) ***Multiplicative preference relation***. A multiplicative preference relation A on a set of alternatives X is indicated by a matrix $A\subset X\times X$, $\mathrm{A}=(a_{ij})$, a_{ij} is the ratio of the preference degree of alternative x_i over alternative x_j, A is assumed multiplicative reciprocal, that is

$$a_{ij}\otimes a_{ji}=1\ \ \forall i,j\in\{1,...,n\} \tag{1}$$

(2) ***Additive fuzzy preference relation***. An expert's preferences on a set of alternatives X is denoted by a positive preference relation matrix $P\subset \mathrm{X}\times\mathrm{X}$, with membership function: $\mu_p:\mathrm{X}\times\mathrm{X}\to[0,\ 1]$, where $\mu_p(x_i,x_j)=p_{ij}$ indicates the ratio of the preference intensity of alternative x_i over alternative x_j. If $p_{ij}=\frac{1}{2}$ implies indifference between x_i and x_j ($x_i\sim x_j$), $p_{ij}=1$ indicates x_i is absolutely preferred to x_j, $p_{ij}=0$ indicates x_j is absolutely preferred to x_i. P is assumed additive reciprocal, given by

$$p_{ij}+p_{ji}=1\ \ \forall i,j\in\{1,...,n\} \tag{2}$$

Suppose there is a set of alternatives being associated with a multiplicative preference relation $\mathrm{A}=(a_{ij})$ with $a_{ij}\in[\frac{1}{9},\ 9]$. Then the corresponding fuzzy preference relation $P=(p_{ij})$ with $p_{ij}\in[0,\ 1]$ to $\mathrm{A}=(a_{ij})$ is defined as:

$$p_{ij}=g(a_{ij})=\tfrac{1}{2}(1+\log_9 a_{ij}) \tag{3}$$

A consistent fuzzy preference relation P' on $X=\{x_1,x_2,...,x_n,\ n\geq 2\}$ from $n-1$ preference values $\{p_{12},p_{23},...,p_{n-1n}\}$ can be constructed as follow.

$$B=\{p_{ij},i<j\wedge p_{ij}\notin\{p_{12},p_{23},...,p_{n-1n}\}\} \tag{4}$$

$$p_{ji}=\frac{j-i+1}{2}-p_{ii+1}-p_{i+1i+2}\cdots-p_{j-1j} \tag{5}$$

$$a=\left|\min\{B\cup\{p_{12},p_{23},...,p_{n-1n}\}\}\right| \tag{6}$$

$$P=\{p_{12},...,p_{n-1n}\}\cup B\cup\{1-p_{12},...,1-p_{n-1n}\}\cup\neg B \tag{7}$$

$$f:[-a,\ 1+a]\to[0,\ 1],\quad f(x)=\frac{x+a}{1+2a} \tag{8}$$

III. Framework to Evaluate Hospital Service Quality by Using Fuzzy Preference Relations

This section proposes an analytic hierarchy model based on fuzzy preference relations to evaluate the hospital service quality. The procedures consist of: determining the importance weights of evaluation criteria, evaluating the performance rating of feasible hospitals with respect to each criterion, and ranking the alternative hospitals.

A. Identify the evaluation criteria for hospital service quality

The evaluation criteria are derived through literature review [2], widespread investigation and consultation with several experts. They are: ***hospital environment*** (C_1:well-equipped medical equipment, warm and comfortable environment in the hospital, clear marked signs in the hospital); ***service attitude*** (C_2: tidy appearance of service personnel, service personnel with good communication skills, caring attitude of medical staff, cordial attitude of service personnel); ***pharmacy treatment*** (C_3: pharmacist's advices on taking medicine, medicine preservation advices by pharmacists, feeling a sense of security when medical services are provided); ***professional capability*** (C_4: medical staff with professional abilities, trusted medical staff with professional competence of health care, detailed description of the patient's condition by the medical doctor, service personnel with immediate problem-solving abilities) and ***administrative policy*** (C_5: ease of use of hospital reservation system, operating procedures of the emergency room, exact outpatient locations guided by service personnel, patient meals services, outpatient drug-picking services, outpatient waiting time for medical treatment, processes of hospitalized services).

B. Determining the importance weight of evaluation criterion

This study provides the evaluators linguistic variables quantified in a scale of $[\frac{1}{9},\ 9]$ to express their preferences toward the importance weights of evaluation criteria (see Table I) and the performance rating of feasible alternatives (see Table II) with respect to each criterion [30]. Fuzzy preference relations proposed by Herrera -Viedma et al. [11] are employed in this study since it constructs a complete preference relation matrix that has n elements with the least ($n-1$) pairwise comparisons.

TABLE I
LINGUISTIC VARIABLES FOR THE IMPORTANCE WEIGHT OF CRITERIA

Definition	Intensity of importance
Equally important (EQ)	1
Weakly more important (WK)	3
Strongly more important (ST)	5
Very strongly more important (VS)	7
Absolutely more important (AB)	9
Intermediate values presenting compromise	2,4,6,8

TABLE II
LINGUISTIC VARIABLES FOR THE PERFORMANCE RATING OF ALTERNATIVES

Definition	Intensity of importance
Medium good (M)	1
Fairly good (FG)	3
Good (G)	5
Very good (VG)	7
Absolutely good (AG)	9
Intermediate values presenting compromise	2,4,6,8

(1) The evaluators (E_k, $k=1,2,...,m$) are asked which is the more important of each two adjoining evaluation criteria (C_i, $i=1,2,...,n$) for a set of $n-1$ preference values $\{a_{12}, a_{23}, ..., a_{n-1n}\}$, for example

$$A^k = \begin{array}{c} \\ C_1 \\ C_2 \\ C_3 \\ \vdots \\ C_n \end{array} \begin{array}{c} \begin{array}{ccccc} C_1 & C_2 & C_3 & \cdots & C_n \end{array} \\ \begin{bmatrix} 1 & a_{12}^k & \times & \times & \times \\ \times & 1 & a_{23}^k & \times & \times \\ \times & \times & 1 & a_{34}^k & \times \\ \vdots & \vdots & \vdots & \ddots & a_{n-1n}^k \\ \times & \times & \times & \times & 1 \end{bmatrix} \end{array} \tag{9}$$

where a_{ij}^k denotes the preference intensity toward criterion i and criterion j assessed by k^{th} evaluator. The sign "×" indicates the remaining a_{ij}^k which can be obtained by inverse comparison methods.

(2) Use Eq. (3) to transform the preference value $a_{ij}^k \in [\frac{1}{9}, 9]$ into $p_{ij}^k \in [0, 1]$. The remaining p_{ij}^k can be calculated using Eqs. (2) and (5). If this preference matrix contains any values that are not included in the interval $[0, 1]$, then a transformation function is required to preserve the reciprocity and additive transitivity, given by

$$f(p_{ij}^k) = \frac{p_{ij}^k + a}{1+2a}, \tag{10}$$

where $a = \left|\min\{p_{12}, p_{23}, ..., p_{n-1n}\}\right|$

(3) Utilize the method of average value to integrate the judgments of m evaluators, namely

$$p_{ij} = \frac{1}{m}(p_{ij}^1 + p_{ij}^2 + ... + p_{ij}^m) \tag{11}$$

(4) Use r_{ij} to indicate the normalized fuzzy preference value of each criterion, such as

$$r_{ij} = \frac{p_{ij}}{\sum_{i=1}^{n} p_{ij}}, \quad i,j = 1,2,\ldots,n \tag{12}$$

(5) Given the ϖ_i denoting the importance weight of evaluation criterion i, the importance weight of which is obtained by

$$\varpi_i = \frac{\sum_{j=1}^{n} r_{ij}}{\sum_{i=1}^{n}\sum_{j=1}^{n} r_{ij}} \tag{13}$$

C. Evaluating the performance rating of feasible alternatives with respect to each criterion

The evaluators are invited to express their subjective judgments regarding the performance ratings of feasible alternatives (A_u, $u=1,2,...,t$) with respect to each criterion by using linguistic variables, as listed in Table II.

(1) Under each criterion, the evaluators are asked to compare the performance rating of adjoining alternatives for a set of $t-1$ preference data $\{b_{12}, b_{23}, ..., b_{t-1t}\}$, for example

$${}_iB = \begin{array}{c} \\ A_1 \\ A_2 \\ A_3 \\ \vdots \\ A_t \end{array} \begin{array}{c} \begin{array}{ccccc} A_1 & A_2 & A_3 & \cdots & A_t \end{array} \\ \begin{bmatrix} 1 & {}_ib_{12}^k & \times & \times & \times \\ \times & 1 & {}_ib_{23}^k & \times & \times \\ \times & \times & 1 & {}_ib_{34}^k & \times \\ \vdots & \vdots & \vdots & \ddots & {}_ib_{t-1t}^k \\ \times & \times & \times & \times & 1 \end{bmatrix} \end{array} \tag{14}$$

where ${}_ib_{uv}^k$ represents the performance rating assessed by k^{th} evaluator for alternative A_u and alternative A_v with respect to evaluation criterion i.

(2) Using Eq. (3), the performance rating ${}_ib_{uv}^k$ is transformed into ${}_iq_{uv}^k$ in a scale $[0, 1]$. If this preference matrix contains any values that are not included in the interval $[0, 1]$, then a transformation function is required, given by

$$f({}_iq_{uv}^k) = \frac{{}_iq_{uv}^k + a}{1+2a}, \tag{15}$$

where $a = \left|\min\{q_{12}, q_{23}, ..., q_{t-1t}\}\right|$

(3) Synthesize the different judgments of m evaluators, namely

$${}_iq_{uv} = \frac{1}{m}({}_iq_{uv}^1 + {}_iq_{uv}^2 + ... + {}_iq_{uv}^m) \tag{16}$$

(4) Take ${}_i\lambda_u$ to indicate the normalized performance rating of alternative A_u with respect to evaluation criterion i.

$${}_i\lambda_u = \frac{{}_iq_{uv}}{\sum_{u=1}^{t}\sum_{v=1}^{t} {}_iq_{uv}}, \quad u,v = 1,2,\ldots,t \tag{17}$$

D. Ranking the alternatives

Ranking the alternatives by the performance value Q which is defined as

$$Q_u = \sum_{i=1}^{n} {}_i\lambda_u \varpi_i \tag{18}$$

where ϖ_i is the importance weight of evaluation criterion i, and the best alternative is the one which has the largest performance value Q.

IV. EMPERICAL ANALYSIS

This study chooses 4 public hospitals located in southern Taiwan to be evaluated by 5 evaluators according to 5 major evaluation criteria (including 21 sub-criteria). Analytic hierarchy selections based on the fuzzy preference relations are adopted to solve this multiple criteria performance evaluation problem. The computations of this proposed framework are described as follows.

A. Weighting calculation for evaluation criteria

Pairwise comparisons for these 5 major evaluation criteria are obtained via a series of interviews with 5 evaluators. The following examples clarify the computational process involved in obtaining the importance weights of evaluation criteria using the consistent fuzzy preference relations.

(1) The pairwise comparison matrices derived from 5 evaluators for a set of 4 adjoining evaluation criteria $\{a_{12}, a_{23}, a_{34}, a_{45}\}$ are listed in Table III.

TABLE III
LINGUISTIC TERMS ASSIGNED FOR 5 CRITERIA BY 5 EVALUATORS

	E_1	E_2	E_3	E_4	E_5	
C_1	VT	LVS	LVS	LST	LAB	C_2
C_2	ST	AB	LST	VS	SW	C_3
C_3	LAB	LVLA	LAB	LVS	LVS	C_4
C_4	AB	VS	AB	AV	VS	C_5

(2) Using Eq. (3) to transform the linguistic variables quantified in $[\frac{1}{9}, 9]$ listed in Table III into an interval $[0, 1]$, taking E_1 as an example and yielding the following values:

$a_{12} = VT = 6$, $p_{12} = (1+\log_9 6)/2 = 0.908$
$a_{23} = LST = \frac{1}{5}$, $p_{23} = (1+\log_9 \frac{1}{5})/2 = 0.134$
$a_{34} = \mathrm{LVS} = \frac{1}{7}$, $p_{34} = (1+\log_9 \frac{1}{7})/2 = 0.057$
$a_{45} = VS = 7$, $p_{45} = (1+\log_9 7)/2 = 0.943$

(3) Using Eq. (11), the aggregated pairwise comparison matrix is obtained. The result is shown in Table IV.

TABLE IV
AGGREGATIVE MATRIX OF IMPORTANCE WEIGHT OF CRITERIA

	C_1	C_2	C_3	C_4	C_5
C_1	2.500	1.405	2.674	0.913	2.672
C_2	3.595	2.500	3.768	2.008	3.767
C_3	2.326	1.232	2.500	0.740	2.498
C_4	4.087	2.992	4.260	2.500	4.259
C_5	2.328	1.233	2.502	0.741	2.500
Total	14.836	9.362	15.704	6.902	15.696

(4) The importance weight and rank of each evaluation criterion is then obtained by Eqs. (12) & (13), and the results are listed in Table V. Taking ϖ_1 as an example,

$$r_{11} = \frac{2.5}{2.5 + 3.595 + 2.326 + 4.087 + 2.328} = 0.169$$

$$\varpi_1 = \frac{0.169 + 0.150 + 0.286 + 0.132 + 0.170}{0.907 + 1.443 + 0.822 + 1.684 + 0.822} = 0.160$$

TABLE V
NORMALIZED MATRIX OF IMPORTANCE WEIGHT AND RANK OF EVALUATION CRITERIA

	C_1	C_2	C_3	C_4	C_5	Weight (ϖ_i)	Rank
C_1	0.169	0.150	0.286	0.132	0.170	0.160	**3**
C_2	0.242	0.267	0.403	0.291	0.240	0.254	**2**
C_3	0.157	0.132	0.267	0.107	0.159	0.145	**5**
C_4	0.275	0.320	0.455	0.362	0.271	0.297	**1**
C_5	0.157	0.132	0.267	0.107	0.159	0.145	**4**

The results show that the importance order of 5 evaluation criteria is: professional capability (0.297) > service attitude (0.254) > hospital environment (0.160) > administrative policy (0.145) > pharmacy treatment (0.145).

B. Calculation the performance rating of feasible hospitals with respect to criteria

The performance rating of 4 feasible hospitals is calculated as follows.

(1) These 5 evaluators are interviewed to assess which hospital is better than another according to each evaluation criterion. The linguistic variables derived from Evaluator 1 are used as examples and listed in Table VI. The linguistic terms are translated into corresponding numbers, then into the interval $[\frac{1}{9}, 9]$ and finally in $[0, 1]$.

(2) Since there are values in Table VII are not in the range of $[0, 1]$, this study uses Eq. (15) to transform the values. The transformed results are shown in Table VIII. We find that the absolute vale of minimum in Table VII is 0.158, so the $f({}_1q_{12}^1) = \frac{0.057 + 0.158}{1 + 2 * 0.158} = 0.163$.

(3) Use Eq. (16) to aggregate the different evaluators' preference, the aggregated decision matrix is shown in Table IX.

(4) Using Eq. (17) to normalize the performance rating of 4 feasible hospitals with respect to evaluation criteria. The results are listed in Table IX.

	A2	0.837	0.500	0.620	**1.000**
	A3	0.717	0.380	0.500	0.880
	A4	0.337	**0.000**	0.120	0.500

C. *Ranking the performance degree of hospitals*

Using Eq. (18) to multiply the importance weights of evaluation criteria by the performance ratings of feasible hospitals, an aggregative performance value Q_u for hospital A_u is obtained. Generally speaking, the performance value is the-larger-the-better. Taking Q_3 as an example,

$$Q_3 = (0.160\times0.330\ ) + (0.254\times0.320\ ) + (0.145\times0.317\ ) + (0.297\times0.269\ ) + (0.145\times0.324\ ) = 0.307$$

The performance values of 4 feasible hospitals are listed in Table X. The ranking of 4 hospitals is Q3>Q1>Q4>Q2. The best hospital is A3.

TABLE X
PERFORMANCE VALUE AND RANK OF 4 HOSPITALS

	A1	A2	A3	A4
Q	0.251	0.214	0.307	0.228
Rank	**2**	**4**	**1**	**3**

V. CONCLUSION

Good service quality is a significant factor leads to the success of a hospital operation and management. The proposed approach is based on the reciprocal additive consistent fuzzy preference relations, rather than using conventional multiplicative preference relation. Namely, this method considers only $n-1$ pairwise comparisons, whereas the traditional AHP takes $\frac{n(n-1)}{2}$ judgments in a preference matrix with n elements, it is clear that the proposed approach is faster to execute and more efficient than the conventional pairwise comparison methods. According to the importance weights of evaluation criteria, the professional capability and service attitude are more important than other criteria. Furthermore, this proposed method is proved to be applicable in solving the multiple criteria decision making problems.

jeng@mail.ncku.edu.tw

***Abstract*—Project has witnessed a high rate of failure. The project management is concerned with disciplines that better manage the project inherent strengths and weaknesses. In contrast to the hard factors, soft factors are very often ignored during project management. Such factors, involved with the internal services within the team, are concerned with working with people, ensuring customer satisfaction and creating a conducive environment for the project team to deliver high quality products which meeting stakeholder expectations. This research aims to investigate the intertwined effects of project team internal soft factors. Combining the exploratory factor analysis and fuzzy decision making trial and evaluation laboratory (DEMATEL) technique, an empirical case is demonstrated to show the effectiveness of the proposed method. The exploratory factor analysis is applied for extracting the dimension and criteria structure. The fuzzy DEMATEL technique is then used to analyze the intertwined effect. The proposed method has proven to be an effective one for analyzing the complex interrelation of human psychological concerns.**

Keywords-exploratory factor analysis, decision making trial and evaluation laboratory (DEMATEL), fuzzy logic, project management, internal service.

I. INTRODUCTION

Project management is important in order to control projects throughout the entire project life cycle and to eventually lead to project success and better project performance. It can also have "strategic value when a clear connection is made between how efficiently and effectively a project is done and how the project's products and services provide business value" [23] (p.19). In order to properly manage a project, it is necessary to understand the controllable factors and its intertwined effects that impact the project team's performance.

There has been a significant amount of research done on project success factors within the Western cultural settings (e.g. [1],[6],[37],[38]). However, most of these researches focused on the team hard factors and rarely discuss how soft factors internally in the project team may influence the overall project success. Hard factors relate to technical abilities in implementing the project, while soft factors relate to teamwork and interpersonal skills. Soft factors are often neglected in previous studies; however, it plays significant in project success.

As culture impacts the values and norms [15][20], the culture setting must be taken into consideration when investigating impact factors in non-Western settings. No research has been found that investigate the impact of soft factors have within a Chinese cultural setting on project performance. In addition, the research of soft skills on project management has rarely seen in the literatures. Understand the intertwined effects of soft factors on project success is critical to managers who conduct projects. These criteria that affecting that project success are numerous and influence one another.

The purpose of this paper is to first indentify the hierarchy structure of soft skills that influence on project success and then analyze the intertwined effects between the criteria. Exploratory factor analysis is applied to generate the independent factors/criteria. Then, the DEMATEL (Decision Making Trial and Evaluation Laboratory) technique [10][11] is adopted. In recent years, a number of scholars have proposed Multiple Criteria Decision-Making (MCDM) theories to strengthen the comprehensiveness and reasonableness of the decision-making process [28][46][50], and DEMATEL technique is commonly used to illustrate the interrelations among criteria.

The remainder of this paper is organized as follows. The research background and literature reviews on factors that impact project performance are presented in Section 2. In Section 3, a brief introduction of exploratory factor analysis and the fuzzy DEMATEL technique is given. An empirical study in the case of soft factors on project success is presented in Section 4, while a hierarchy structure with dimension and criteria is proposed and its intertwined effects is analyzed by fuzzy DEMATEL. In Section 5, the analysis result is discussed and the implication is drawn. Finally, the concluding remarks are presented in Section 6.

II. FACTORS IMPACT PROJECT PERFORMANCE

Project performance metrics can be viewed as the key attributes and objectives which must be met or reached to consider a project successful [27]. Most researchers agree that time, cost, and quality should be used as performance metrics and the key determinants of project success [1][6] [7][27][37][47]. However, many agree that success criteria should not be limited to the iron triangle of time, cost, and quality [1][27][29][47].

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

A team's project performance is influenced by factors both external and internal to the team, while culture and soft factors are highly impacted.

A. Cultural Context

Culture, both national and corporate [16], can be defined as "the collective programming of the mind which distinguishes the members of one group or society from those of another" (p. 82). Within each nation, there can be dominant groups and non-dominant groups. All the groups will have their own and sometimes similar group-ideologies, beliefs, and values, but the national culture will resemble the largest or more influential dominant group's. Therefore, it is vital to understand the dominant group's underlying views if one is to gain a general understanding of the views of the people within that culture [44]. As previous studies have taken place in Western cultural settings, their findings are not adequate when applying in the Chinese cultural context, which is highly influenced by the teachings of Confucius. "Confucian social theory is concerned with the question of how to establish a harmonious secular order in the man-centered world" [25](p.65). The term guanxi (role-relationship) is deeply embedded in Confucian social theory and uses the term architect to refer to Confucian individuals who build their guanxi throughout their life, creating their own social networks outside their family structure [19][25].

In Taiwan, Hofstede's [15] study has found that in supporting the Confucianism regarding unequal relationships, it was found to rank on the higher end of power distance, meaning hierarchal structures are common. For the Confucianism regarding the importance of upholding 'he', or harmony, Hofstede [15] showed that the Taiwanese culture leans toward collectivism rather than individualism, meaning that individuals are focused on the group's interest rather than their individual self. This is further supported by the findings of Gao [12], who conducted a study on understanding Chinese speaking practices, and found that in the Chinese culture the self involves and is made up of multiple relationships. For Hofstede's [15] last two dimensions (*i.e.* uncertainty avoidance and masculinity), Taiwanese would prefer to avoid uncertainty and show characteristics of both masculinity and femininity as the masculinity score is modest. Further studies have confirmed that both the Confucian values and cultural dimensions are reflected in the work values that Taiwanese employees hold [16][17].

B. Soft Factors

A team's project performance will depend heavily on how well the team works together. The factors that impact these dynamics are the relationships between the team members, and the perceived quality of the 'internal services' between the team members as work flows between them. The scope of the internal-team factors for this study is limited to interactions and relationships between project group members.

In terms of work-flow, McGrath's [32] paper on the theory of group's assumes groups to be "complex, intact social systems…that engage in purposeful activity at three partially nested levels: projects, tasks, and steps" (p. 151). It is thus clear that work may flow from one team member to the next at the level of steps and tasks. This work-flow is an internal service between the team members, and the interaction related to the work being passed on to the next step is the service encounter. The service encounter can be viewed as the "dyadic interaction between an internal customer and an internal service provider" [13](p.35).

The perceived quality of the service encounter is evaluated by an internal customer after the service encounter takes place, whereby an internal customer evaluates the individual internal service quality attributes to gain an overall perception of the quality of the service encounter [13]. Improving and managing this perceived quality is important for organizations since researchers have found linkages between high levels of internal service quality (ISQ) and higher productivity, improved relationships between departments and groups, lower employee turnover, increased external customer satisfaction, and increased profits [13][35] [36][39][41].

While previous studies have mostly applied western internal service quality attributes to the Taiwanese setting (e.g. [8][9][28][30]), as an organization's culture – which is based largely on national culture – has a direct impact on the internal service providers and internal customers' values, norms, behavior, or even way of thinking [4][20][42], using Western attributes in an Eastern cultural setting could produce inadequate results as cultural differences create unique work places with different views, values, practices, etc. [16]. To overcome this limitation, Stanworth et al. [43] developed the internal service quality attribute that is Taiwanese context based, which 29 service quality attributes were derived.

As stated, Confucianism is shown to have an undisputable impact on the national and organizational culture of Taiwan, where it is important to maintain harmony within relationships [16]. Furthermore, studies related to group project performance within the Chinese context have shown that focusing on creating friendly relationships within organizations and groups can positively impact project performance by increasing their odds of success [22][24], while Bromiley and Cummings [2] found that a harmonious relationship based on trust can lead to lower costs and shorter durations when conducting business. Thus, as relationships play a major role within Taiwan due to the Confucian influence. Furthermore, Katz [24] found that high levels of internal communication between all project members will lead to higher project performance.

Based on the above literature reviews, this research adopts Stanworth et al.'s [43] internal service quality structure and slightly modified as follows: two items are removed when changing the negative attributes to a positive (Incomplete Professional Knowledge and Quarrel), as they are in fact a polar opposites of positives already present (Detailed Professional Knowledge and Consensus), and one item is expanded into two separate items (Work Loading to Work Loading and Accessible) to better capture the complexity of the attribute. This leaves a total of 26 attributes. In addition, Pinto and Prescott's [37] two trouble-shooting attributes (trouble-shooting and handle deviations), and Jin and Ling's [22] seven relationship attributes were added to our list. Thus, the final scale to be investigated in this study is made up of 35 team internal soft factors includes friendly (chin-chieh), polite (ke-

chi), patience, positive/proactive (jiji), responsible, trouble-shooting, handle deviations, please supervisor, competent, effective, detailed and professional knowledge, consensus, shows empathy, shared objective, considerate, reliable, internal efficiency, external efficiency, harmony, personnel connection, emotionally stable, internal communication, litigation, risk exposure, change orders and claims, mutual understanding, client satisfaction, learning culture, help each other, cooperation, coordination, work loading, accessible, bureaucracy, exchange thoughts.

III. Building a Structural Model

In reality, it is difficult to quantify a precise value in human psychological feeling. However, the complex phenomenon can be divided into many criteria to more easily judge differences or measure scores of the divided criteria. The exploratory factor analysis method is commonly used to gather criteria into groups. These criteria may have interdependent relationships; therefore, the DEMATEL technique is used to construct the interrelations between criteria.

A. Finding Independent Factors for Building a Hierarchical System

Based on the suitable measuring method, the criteria can be categorized into distinct aspects. When the evaluated criteria are too large to determine the dependent or independent relation with others, using factor analysis can verify independent factors.

Exploratory factor analysis is a dimension reduction method of multivariate statistics, which explores the latent variables from manifest variables. It is used to uncover the underlying structure of a relatively large set of variables. The main procedure of exploratory factor analysis can be described in the following steps:

Step 1: Find the correlation matrix (***R***) or variance-covariance matrix for the objects to be assessed.

Step 2: Find the eigenvalues $(\lambda_k, k = 1, 2, \ldots, m)$ and eigenvectors $(\beta_k = [\beta_{1k}, \ldots, \beta_{ik}, \ldots, \beta_{pk}])$ for assessing the factor loading $(a_{ik} = \sqrt{\lambda_k}\beta_{ik})$ and the number of factors (m).

Step 3: Consider the eigenvalue ordering $(\lambda_1 > \cdots > \lambda_k > \cdots > \lambda_m; \lambda_m > 1)$ to decide the number of common factors, and pick the number of common factors to be extracted by a predetermined criterion.

Step 4: To facilitate the interpretation of factors, choose a rotation methods. In this study, the promax rotation method is applied which allows the factors to be correlated.

Step 5: Name the factor referring to the combination of manifest variables.

When a large set of variables are factored, the method first extracts the combinations of variables, explaining the greatest amount of variance, and then proceeds to combinations that account for progressively smaller amounts of variance. Two kinds of criteria are used for selecting the number of factors: latent root criterion and percentage of variance criterion. The former criterion is that any individual factor should account for the variance $(\mathrm{Var}(Y_k) = \lambda_k)$ of at least a single variable if it is to be retained for interpretation. In this criterion only the factors having eigenvalues greater than 1 (*i.e.* $\lambda_k \geq 1, k = 1, 2, \ldots, m$) are considered significant. The latter criterion is based on achieving a specified cumulative percentage of total variance extracted by successive factors. Its purpose is to ensure the extracted factors can explain at least a specified amount of variance. Practically, to be satisfactory the total amount of variance explained by factors should be at least 95% in the natural sciences, and 60% in the social sciences. However, no absolute threshold has been adopted for all applications [14].

B. Fuzzy DEMATEL Technique for Building Structural Model

DEMATEL [10][11] is a comprehensive method for building and analyzing a structural model involved of causal relationships between complex factors. It was developed in the belief that the proper use of scientific research methods could facilitate comprehension of the specific problematique, the cluster of intertwined problems, and contribute to recognition of practical solutions by a hierarchical structure. The methodology, according to the characteristics of objective affairs, can verify the interdependence among the variables/attributes/criteria and confine the relation that reflects the characteristics with an essential system and evolution trend [5][18]. The method is a practical and useful tool, especially for visualizing the structure of complex causal relationships with matrices or digraphs. The matrices or digraphs show a contextual relation between the elements of the system, in which a numeral represents the strength of influence of each element. Thus, the DEMATEL technique is able to convert the relationship between the causes and effects of criteria into an intelligible structural model of systems [48].

Fuzzy set theory can be efficiently dealt with the vagueness of human thought and expression in making decisions. To tackle the ambiguities involved in the process of decision-making, the linguistic terms can be more effective in estimation.

A fuzzy set $\widetilde{A}$ is a subset of a universe of discourse X, which is a set of ordered pairs and is characterized by a membership function $\mu_{\widetilde{A}}(x)$ representing a mapping $\mu_{\widetilde{A}}(x): X \to [0,1]$. The function value of $\mu_{\widetilde{A}}(x)$ for the fuzzy set $\widetilde{A}$ is called the membership value of x in $\widetilde{A}$, which represents the degree of truth that x is an element of the fuzzy set $\widetilde{A}$. It is assumed that $\mu_{\widetilde{A}}(x): X \in [0,1]$, where $\mu_{\widetilde{A}}(x) = 1$ reveals that x completely belongs to $\widetilde{A}$, while $\mu_{\widetilde{A}}(x) = 0$ indicates that x does not belong to the fuzzy set $\widetilde{A}$.

$$\widetilde{A} = \left\{\left(x, \mu_{\widetilde{A}}(x)\right)\right\}, \quad x \in X \tag{1}$$

where $\mu_{\widetilde{A}}(x)$ is the membership function and $X = \{x\}$ represents a collection of elements x.

A triangular fuzzy number $\widetilde{N}$ can be defined as a triplet (l, m, u), and the membership function $\mu_{\widetilde{N}}(x)$ is defined as:

$$\mu_{\widetilde{N}}(x)=\begin{cases}0, & x<l\\ (x-l)/(m-l), & l\le x\le m\\ (r-x)/(u-m), & m\le x\le u\\ 0, & x>u\end{cases} \tag{2}$$

where l, m, and r are real numbers and $l < m < u$.

To deal with the problems of group decision-making in a fuzzy environment, an effective fuzzy aggregation method is required. The human judgments with fuzzy linguistic variables are fuzzy numbers, which a defuzzification method is required to transform the crisp elements into scores. Proposed by Opricovic & Tzeng [33], the CFCS (Converting Fuzzy data into Crisp Scores) defuzzification method is based on the procedure of determining the low and up scores by fuzzy min and fuzzy max, and the total score is determined as a weighted average according to the membership functions. This would provide a more appropriate crisp value comparing with other methods.

Let $\widetilde{z}_{ij}^{k}=\left(l_{ij}^{k},m_{ij}^{k},u_{ij}^{k}\right)$ indicates the fuzzy assessment of evaluator k (k=1,2,…,p) about the degree to which the criterion i affects the criterion j, the CFCS algorithm can be described in following five steps:

(1) Normalization:

$$xl_{ij}^{k}=\left(l_{ij}^{k}-\min l_{ij}^{k}\right)\Big/\Delta_{\min}^{\max} \tag{3}$$

$$xm_{ij}^{k}=\left(m_{ij}^{k}-\min l_{ij}^{k}\right)\Big/\Delta_{\min}^{\max} \tag{4}$$

$$xr_{ij}^{k}=\left(r_{ij}^{k}-\min l_{ij}^{k}\right)\Big/\Delta_{\min}^{\max} \tag{5}$$

where $\Delta_{\min}^{\max}=\max r_{ij}^{k}-\min l_{ij}^{k}$.

(2) Compute left (ls) and right (rs) normalized value:

$$x\,\mathrm{ls}_{ij}^{k}=xm_{ij}^{k}\Big/\left(1+xm_{ij}^{k}-xl_{ij}^{k}\right) \tag{6}$$

$$x\,\mathrm{rs}_{ij}^{k}=xr_{ij}^{k}\Big/\left(1+xr_{ij}^{k}-xm_{ij}^{k}\right) \tag{7}$$

(3) Compute total normalized crisp value:

$$x_{ij}^{k}=\left[x\,\mathrm{ls}_{ij}^{k}\left(1-x\,\mathrm{ls}_{ij}^{k}\right)+x\,\mathrm{rs}_{ij}^{k}\,x\,\mathrm{rs}_{ij}^{k}\right]\Big/\left[1-x\,\mathrm{ls}_{ij}^{k}+x\,\mathrm{rs}_{ij}^{k}\right] \tag{8}$$

(4) Compute crisp values:

$$z_{ij}^{k}=\min l_{ij}^{k}+x_{ij}^{k}\Delta_{\min}^{\max} \tag{9}$$

To further the practicality of the conventional DEMATEL technique for group decision-making in a fuzzy environment, the process is illustrated as follows:

Step 1: Design the fuzzy linguistic scale. To deal with the ambiguities of human assessments, the linguistic variable ''influence'' is used with five linguistic terms as {No, Very low, Low, High, Very high} that are expressed in positive triangular fuzzy numbers $\left(l_{ij},m_{ij},u_{ij}\right)$.

Step 2: Calculate the fuzzy direct-influence matrix by scores (depending on the views of the experts by linguistic scales of natural language) and evaluate the relationship among elements based on Table 2, we can obtain the fuzzy direct-influence matrix $\widetilde{\boldsymbol{D}}$ by Eq. (15).

$$\widetilde{\boldsymbol{D}}=[\widetilde{d}_{ij}]_{n\times n},\ \text{where}\ \widetilde{d}_{ij}=(d_{ij}^{l},d_{ij}^{m},d_{ij}^{u}) \tag{10}$$

Step 3: Normalize the fuzzy direct-influence matrix: Based on the fuzzy direct-influence matrix $\widetilde{\boldsymbol{D}}$, the normalized fuzzy direct-relation matrix $\widetilde{\boldsymbol{N}}$ is acquired by using Eq. (16).

$$\widetilde{\boldsymbol{N}}=\widetilde{\boldsymbol{D}}/u \tag{11}$$

where

$u=\max\limits_{i,j}\left\{\max_i\sum_{j=1}^{n}d_{ij},\max_j\sum_{i=1}^{n}d_{ij}\right\},\ i,j\in\{1,2,\ldots,n\}$,

$\widetilde{\boldsymbol{N}}=[\widetilde{e}_{ij}]_{n\times n}$, $\widetilde{e}_{ij}=(e_{ij}^{l},e_{ij}^{m},e_{ij}^{u})$.

Step 4: Attain the fuzzy total-influence matrix: once the normalized fuzzy direct-influence matrix $\widetilde{\boldsymbol{N}}=(\boldsymbol{N}^{l},\boldsymbol{N}^{m},\boldsymbol{N}^{u})$ obtained, where $\boldsymbol{N}^{l}=[e_{ij}^{l}]_{n\times n}$, $\boldsymbol{N}^{m}=[e_{ij}^{m}]_{n\times n}$, and $\boldsymbol{N}^{u}=[e_{ij}^{u}]_{n\times n}$; the fuzzy total-influence matrix $\widetilde{\boldsymbol{T}}$ is arrived at through Eq. (12), in which the $\boldsymbol{I}$ is denoted as the identity matrix.

$$\widetilde{\boldsymbol{T}}=[\widetilde{t}_{ij}]_{n\times n},\ \text{where}\ \widetilde{t}_{ij}=(t_{ij}^{l},t_{ij}^{m},t_{ij}^{u}) \tag{12}$$

where, $\boldsymbol{T}^{l}=[t_{ij}^{l}]_{n\times n}=\boldsymbol{N}^{l}(\boldsymbol{I}-\boldsymbol{N}^{l})^{-1}$,

$\boldsymbol{T}^{m}=[t_{ij}^{m}]_{n\times n}=\boldsymbol{N}^{m}(\boldsymbol{I}-\boldsymbol{N}^{m})^{-1}$ and

$\boldsymbol{T}^{u}=[t_{ij}^{u}]_{n\times n}=\boldsymbol{N}^{u}(\boldsymbol{I}-\boldsymbol{N}^{u})^{-1}$ respectively; the elements of triangular fuzzy numbers in fuzzy total-influence matrix $\widetilde{\boldsymbol{T}}$ are divided into $\boldsymbol{T}^{l}$, $\boldsymbol{T}^{m}$ and $\boldsymbol{T}^{u}$, and $\boldsymbol{T}^{l}=[t_{ij}^{l}]_{n\times n}\prec\boldsymbol{T}^{m}=[t_{ij}^{m}]_{n\times n}\prec\boldsymbol{T}^{u}=[t_{ij}^{u}]_{n\times n}$, when $e_{ij}^{l}<e_{ij}^{m}<e_{ij}^{u}$ for any $i,j\in\{1,2,\ldots,n\}$.

Step 5: Defuzzy into the crisp values. Using the CFCS method showing in Eqs. (3)-(9), the total fuzzy influence matrix $\widetilde{\boldsymbol{T}}=[\widetilde{t}_{ij}]_{n\times n}$ are defuzzified as crisp values into the total-influence matrix $\boldsymbol{T}=[t_{ij}]_{n\times n}$.

Step 6: Analyze the results: in the stage, the sum of rows (given influence) and the sum of columns (received influence) are separately expressed as influential vector $\boldsymbol{d}=\left(d_1,\ldots,d_i,\ldots,d_n\right)'$ by factor j (j = 1,2,...,n) and influential vector $\boldsymbol{r}=\left(r_1,\ldots,r_j,\ldots,r_n\right)'$ by factor i (i = 1,2,...,n) using Eqs. (13)-(15). Then, when $i,j\in\{1,2,\ldots,n\}$ and $i=j$ the horizontal axis vector ($\boldsymbol{d}$+$\boldsymbol{r}$) is made by adding vector $\boldsymbol{d}$ to vector $\boldsymbol{r}$, which exhibits total important influence of each criterion. Similarly,

the vertical axis vector ($\boldsymbol{d}-\boldsymbol{r}$) is made by deducting vector $\boldsymbol{d}$ from vector $\boldsymbol{r}$, which may separate criteria into a cause group and an affected group. In general, when the value of d_i-r_i is higher, the criterion is belonging to the cause group. On the contrary, if the value of d_i-r_i is lower, the criterion is belonging to the affected group. Therefore, the causal-and-effect graph can be achieved by plotting the data set of $\{(d_i+r_i,\ d_i-r_i) \mid i = 1,2,\ldots,n\}$, providing valuable approaching for making decisions.

$$\boldsymbol{T} = \left[t_{ij}\right]_{n\times n}, \quad i, j \in \{1,2,\ldots,n\}, \tag{13}$$

$$d = \left[\sum_{j=1}^{n} t_{ij}\right]_{n\times 1} = \left[t_i\right]_{n\times 1} = \left[d_i\right]_{n\times 1}, \tag{14}$$

$$r = \left[\sum_{i=1}^{n} t_{ij}\right]_{n\times 1}' = \left[t_j\right]_{n\times 1} = \left[r_j\right]_{n\times 1}, \tag{15}$$

where vector $d = (d_1,\ldots, d_i, \ldots, d_n)$ and vector $r = (r_1,\ldots, r_j,\ldots, r_n)$ express the sum of rows and the sum of columns based on total-influence matrix $\boldsymbol{T} = [t_{ij}]_{n\times n}$, separately.

IV. Empirical Study: Case of Project Success

The empirical experiment was focused on Taiwanese firms that consist of project group. The study includes two parts, the exploratory factor analysis and fuzzy DEMATEL analysis, as detail described below.

A. The Exploratory Factor Analysis to Obtain Independent Criteria Groups

The questionnaire was sent to several Taiwanese companies that have project groups consisting of Taiwanese working professionals, and was explained that through the study, they can receive a clearer understanding of which factors are perceived to lead to greater project performance, which ultimately leads to increasing the probability of project success. A total of 224 questionnaires were collected for this study, while 16 questionnaires were not fully completed, this makes 208 useable feedbacks.

For the soft factor items, a clear structure emerged on the third iteration using a kappa rotation of 7. The Kaiser-Meyer-Olkin (KMO) test and the Bartlett's test are both acceptable on each iteration, with the lowest KMO being 0.949 and highest Bartlett's being 0.000. The Cronbach's Alpha and Pearson's Correlation were also both acceptable on each iteration with the lowest alpha being 0.851 and the lowest correlation being 0.618. After iterations one and two, the original 35 item list was reduced to a final 26 items that categorized into eight dimensions. Eigenvalues are all greater than 1 and all items' item-to-total correlations are above the cutoff value 0.5. The exploratory factor analysis final iteration result is shown in Table I.

B. The Fuzzy DEMATEL Method to Find the Interrelation between Criteria

According to the factor analysis results, 50 project managers and senior team members were invited to score the influence level of criteria based on the fuzzy DEMATEL method.

TABLE I. Dimension and Criteria Extracted

Extracted Dimensions	Items / Criteria	Factor Loading	Eigenvalues (Rotated)	Item-to-Total Correlation
Synergy (D_1)	Work Loading (C_{11})	1.22	14.27	0.79
	Accessible (C_{12})	0.95		0.84
	Reliable (C_{13})	0.90		0.79
	Considerate (C_{14})	0.87		0.83
	Coordination (C_{15})	0.83		0.87
	Help each other (C_{16})	0.81		0.84
	Cooperation (C_{17})	0.74		0.86
	Consensus (C_{18})	0.68		0.83
	Shared objective (C_{19})	0.63		0.75
Competence (D_2)	Trouble-shooting (C_{21})	0.95	12.08	0.80
	Handle deviations (C_{22})	0.93		0.86
	Positive/proactive (jiji) (C_{23})	0.86		0.85
	Responsible (C_{24})	0.80		0.81
Attitude (D_3)	Polite (ke-chi) (C_{31})	1.08	9.93	0.77
	Friendly (chin-chieh) (C_{32})	0.86		0.79
	Patience (C_{33})	0.69		0.70
Relationship (D_4)	Learning culture (C_{41})	1.04	11.62	0.69
	Client satisfaction (C_{42})	0.81		0.79
	Bureaucracy (C_{43})	0.59		0.68
Consideration (D_5)	Shows empathy (C_{51})	0.85	10.43	0.75
	Competent (C_{52})	0.84		0.73
	Effective (C_{53})	0.53		0.69
Risk Exposure (D_6)	Risk exposure (C_{61})	0.86	4.92	N/A
	Change orders and claims (C_{62})	0.80		N/A
Litigation (D_7)	Litigation (C_{71})	0.91	3.71	N/A
Personnel Connection (D_8)	Personnel connection (C_{81})	0.84	2.49	N/A

Followed by the above mentioned steps, the initial fuzzy direct-influence matrix $\widetilde{\boldsymbol{D}}$ was produced. The normalized fuzzy direct-influence matrix $\widetilde{\boldsymbol{N}}$ is then retrieved based on Eq. (11). Subsequently, the fuzzy total-influence matrix $\widetilde{\boldsymbol{T}}$ was calculated. Next, the CFCS method listed on Eq. (3)-(9) was used to aggregate the fuzzy data. Table II shows the defuzzied total-influence matrix $\boldsymbol{T}$. The degree of influence in dimension level and criteria level are presented in Table III and IV, respectively. Based on the above analysis, the dimension and criteria impact relation maps can be generated in Fig. 1 and Fig. 2, respectively.

V. DISCUSSION AND IMPLICATION

The proposed hybrid method has proven to be an effective model for evaluating the complex psychological intertwined effects. Based on our empirical experiments, factor analysis was used to classify each element/criteria into eight different independent factors/dimensions. Those criteria under the same dimension had some interrelations with each other. The direct/indirect influential relationship of criteria was figured using the fuzzy DEMATEL method.

A clear structure of the Team-Internal impact factors for project performance within the Taiwanese cultural context was created through exploratory factor analysis (see Table I). By combining Stanworth et al.'s [43] 26 attributes from ISQ, Pinto and Prescott's [37] two trouble-shooting attributes, Jin and Ling's [22] seven relationship attributes, thus the final scaleinvestigated in this study was made up of 35 attributes. The exploratory factor analysis was then conducted and extracted a final structure of eight dimensions and 26 criteria: Synergy (9 criteria), Competence (4 criteria), Attitude (3 criteria), Relationship (3 criteria), Consideration (3 criteria), Risk Exposure (2 criteria), Litigation (1 criterion), and Personnel Connection (1 criterion).

According to the fuzzy DEMATEL analysis, the factors which show greater values of (d_i-r_i) are intensely affecting others, the factors show lesser values of (d_i-r_i) are intensely

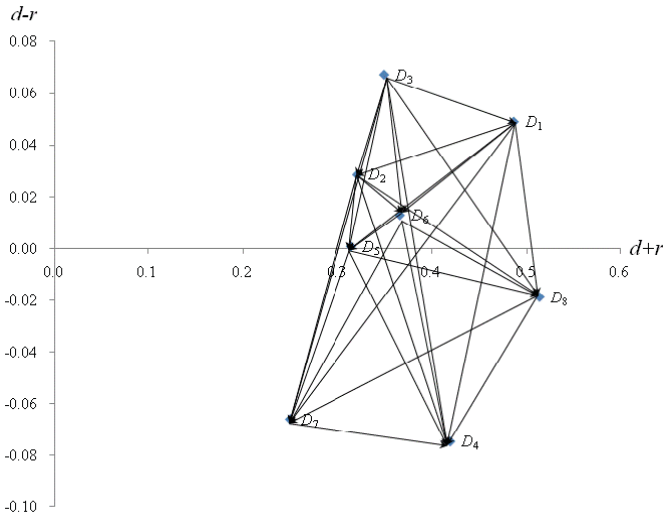

Figure 1. Dimensional impact relation map

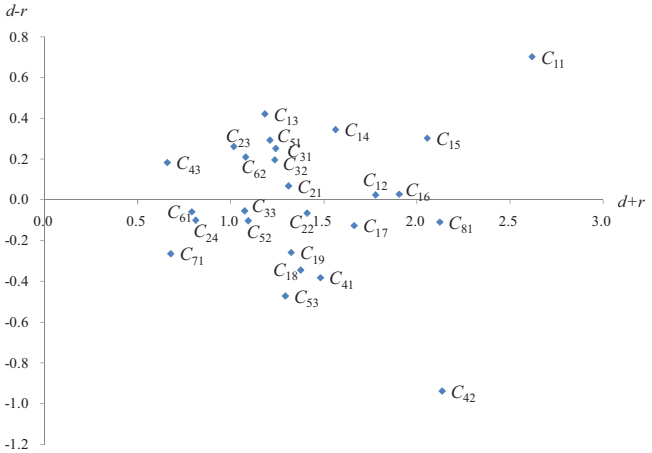

Figure 2. Criteria impact relation map

affected by the others. Figure 1 and 2 show a clear picture of intertwined effect in between dimensions and criteria.

Based on Figure 1, the attitude (D_3) plays a significant role that highly influences other soft factors towards the project success. On the other hand, the relationship (D_4) is impacted by all dimensions. The personal connection (D_8) presents a high relationship with other dimensions. From Figure 2 cross-dimensionally, the work loading (C_{11}) is a key factor that greatly impacts all other criteria, while ultimately meets the customer satisfaction (C_{42}). Bureaucracy (C_{43}) and litigation (C_{71}) show less relationship with other factors.

Project leadership requires more than just technical competence and encompasses the ability to manage a team. Stated by Kloppenborg and Petrick [26], skills in managing relationships are critical to achieve stakeholder satisfaction through all stages of the project. Creating the right relationships between team members is one of the biggest challenges that face project managers [3][45][34]. Whitty [49] mentioned that "projects are simply a synthesis of human sensations and expectations about how multiple resources are to be used" (p.577). Ropponen and Lyytinen [40] stated that personnel management is one of the major risk components in software development project. Above evidences highlight the importance of understanding the interrelation of project team soft factors.

The result of this study gives a clear picture to the project manager on the intertwined effects of team internal soft factors. As work loading plays as a key influencer, when more resources such as people are needed than are available, the tasks need to be rescheduled concurrently or even sequentially to manage the constraint. The project manager should apply resource leveling to resolve the conflicts of schedule instead of overloading the work to a single resource. Attitude is the one that project team should emphasize in order to create a harmony working environment, which can further build the team synergy. From internal service point of view, Jeng [21] stated that rewards and recognition can be the best strategy to enhance the team internal service operation.

VI. Concluding Remarks

This research proposed a hybrid method combines the factor analysis and fuzzy DEMATAL technique to understand the factors intertwined effect in complex system. Supported by previous qualitative studies, exploratory factor analysis is applied to extract a clear factor structure consist of dimension and criteria. Then, the fuzzy DEMATEL technique is utilized to analyze the intertwined effect between the extracted dimension and criteria. Based on the impact relation map, project manager can gain a clear picture on the impact of soft factors on project performance. A project manager may set the strategies to better manage the working environment and team atmosphere. The result provides directions to enhance the team synergy, increase relationship, and ultimately achieving the project success. This study may also provides the information for a company to further adopt effective training agenda and employee assistance programs (EAPs) that improve the working atmosphere of the project team.

***Abstract*—This paper considers a robust portfolio selection problem considering a confidence interval with subjectivity to the weight for the standard deviation. Since the proposed model is formulated as an ill-defined problem due to fuzziness and bi-object derived from maximizing both robustness and investor's satisfaction level to the total profit, it is hard to solve it directly. Therefore, introducing fuzzy goals for the bi-objective functions, the proposed model is transformed into the deterministic equivalent problem. Furthermore, in order to obtain the exact optimal portfolio analytically, the solution method is developed introducing a parameter and doing the equivalent transformations.**

Keywords-component; portfolio selection problem; robust programming; confidential interval; fuzzy goal;

I. INTRODUCTION

In recent years, not only big companies and institutional investors but also many individual investors take part in investment. Therefore, the role of investment theory, which is generally called portfolio theory, becomes increasingly important. Of course, investors confront several uncertainties derived from changes in social conditions such as price escalation and burst of the economic bubble which have a great influence on the future return, and from insufficiency of available information. Under such conditions, investors must find ways to reduce risks as well as maximizing the total profit.

Until now, various studies concerning portfolio selection problems have been performed. Regarding the research history on the mathematical approach, Markowitz [21] proposed the mean-variance model. Since then, it has been the centre of research activities in the real financial field, and numerous researchers have contributed to the development of modern portfolio theory. Then, many researchers have proposed models of portfolio selection problems that have extended the Markowitz model; mean-absolute-deviation model (Konno et al. [18, 19]), semi-variance model (Bawa and Lindenberg [1]), safety-first model (Elton and Gruber [7]), Value-at-Risk (VaR) and conditional Value-at-Risk model (CVaR) (Rockafellar and Uryasev [22]) etc..

On the other hand, investors may receive a lot of data or information in the current market, but it is almost impossible to determine strict random distributions of future returns. These distributions may be statistically determined as a confidence interval to the total profit involving the mean value and variance. Therefore, using these statistical distributions, it is more important to considering that decision makers optimize the problem in the worst case; i.e. robust optimization problem.

Recently, the robust optimization problem becomes a more active area of research, and there exists various studies (For example, Ben-Tal and Nemirovski [2, 3], Ghaoui and Lebret [8]). Particularly, there are some studies of robust portfolio selection problems determining optimal investment strategy using the robust approach (For example, Goldfarb and Iyengar [9], Lobo [20]). The expected return and variance of each asset are mainly estimated from historical data based on the statistical analysis. However, in the case that we consider the value of received information, the investor's subjectivity to the trend of current market, and the satisfaction function to the achievement of objects such as maximizing the total profit, we need to consider that statistical distribution or confidential interval considering these conditions includes some ambiguity and is involved some flexibility. In this paper, we propose an extended model of robust portfolio selection problems including fuzziness.

Until now, there are some basic researches under various uncertainty conditions with respect to portfolio selection problems (Bilbao-Terol et al. [4], Carlsson et al. [5], Guo and Tanaka [10], Hasuike et al. [11], Huang [12, 13], Inuiguchi et al. [14, 15], Katagiri et al. [17, 18], Tanaka et al. [23, 24], Watada [25]). However, there are few models considering the confidential interval with investor's subjectivity. Furthermore, there are no researches which are analytically extended and explicitly solved these types of portfolio selection problems. Therefore, we develop the exact solution algorithm for the proposed robust portfolio selection problem. Since our model is a multi-objective programming problem with investor's subjectivity, in this paper, we transform main problems into the deterministic equivalent problems, and obtain the exact optimal portfolio.

This paper is organized as follows. In Section II, we introduce a robust portfolio selection problem maximizing the region of confidential interval to the total profit. Furthermore, we propose the bi-objective programming problem maximizing

the total profit as well as the region of confidential interval. In Section III, introducing fuzzy goals to both objective functions, we propose the maximin robust portfolio selection problem and develop the strict solution algorithm. In the solution algorithm, we need to solve a convex programming problem, repeatedly. Therefore, in order to solve the problem analytically and explicitly, in Section IV, we perform the deterministic equivalent transformations, and obtain the exact optimal portfolio. Finally, in Section V, we conclude this paper and discuss future researches.

II. Formulation of a Robust Portfolio Selection Problem with Confidential Interval

In this section, we consider a robust portfolio selection problem with a confidential interval. First of all, we set parameters in portfolio optimization. The expected return of total future profit $E(\boldsymbol{r})$ and the total variance $\mathbf{Var}(\boldsymbol{r})$ is defined as follows:

$$E(\boldsymbol{r}) = \bar{\boldsymbol{r}}^t \phi, \quad \mathbf{Var}(\boldsymbol{r}) = \phi^t \mathbf{V} \phi \tag{1}$$

where the notation means as follows:
$\boldsymbol{r}$: Future return vector assumed to be a random variable
$\bar{\boldsymbol{r}}$: Mean value vector of random variable $\boldsymbol{r}$
$\mathbf{V}$: Variance-covariance matrix of random variable $\boldsymbol{r}$
ϕ : Portfolio with respect to each asset j, $(j = 1, 2, ..., n)$

In general, a confidential interval is represented by mean value and standard deviation of each random variable such as normal distribution, student's t-distribution, etc.. Therefore, in this paper, we define d -confidential interval using $E(\boldsymbol{r})$ and $\mathbf{Var}(\boldsymbol{r})$ based on the study (Watada et al. [26]):

$$\left[E(\boldsymbol{r}) - d\sqrt{\mathbf{Var}(\boldsymbol{r})}, E(\boldsymbol{r}) + d\sqrt{\mathbf{Var}(\boldsymbol{r})}\right] \tag{2}$$

With respect to this confidential interval, in this case that constant value of parameter d is larger, the considerable region is also wide, and it urges the investor to deal with more robust case than the small value of d . In this paper, in terms of considering such robust case by maximizing parameter d , the following robust portfolio selection problem is formulated:

$$\begin{aligned} &\text{Maximize } d \\ &\text{subject to } E(\boldsymbol{r}) - d\sqrt{\mathbf{Var}(\boldsymbol{r})} \geq f, \\ &\qquad E(\boldsymbol{r}) \geq f', \\ &\qquad \mathbf{1}^t \phi = 1 \end{aligned} \tag{3}$$

where f and f' are the worst and standard target values of total future return, respectively. In this paper, we assume $f \leq f'$ and these parameters are initially determined by the investor. Since the first constraint of problem (3) is equivalently transformed into the following form;

$$E(\boldsymbol{r}) - d\sqrt{\mathbf{Var}(\boldsymbol{r})} \geq f \;\Leftrightarrow\; \frac{E(\boldsymbol{r}) - f}{\sqrt{\mathbf{Var}(\boldsymbol{r})}} \geq d,$$

problem (3) is equivalently transformed into the following problem:

$$\begin{aligned} &\text{Maximize } \frac{E(\boldsymbol{r}) - f}{\sqrt{\mathbf{Var}(\boldsymbol{r})}} \\ &\text{subject to } E(\boldsymbol{r}) \geq f', \\ &\qquad \mathbf{1}^t \phi = 1 \end{aligned} \tag{4}$$

This problem is a convex programming problem similar to the probability maximization model, and so we obtain the optimal solution using the convex programming approach.

However, in practical investment situations, it is natural for the investor to consider maximizing the target total profit as well as minimizing the total risk, i.e., maximizing the region of confidential interval in terms of robustness. Therefore, the proposed model is reformulated as the following problem:

$$\begin{aligned} &\text{Maximize } d \\ &\text{Maximize } f \\ &\text{subject to } E(\boldsymbol{r}) - d\sqrt{\mathbf{Var}(\boldsymbol{r})} \geq f, \\ &\qquad E(\boldsymbol{r}) \geq f', \\ &\qquad \mathbf{1}^t \phi = 1 \end{aligned} \tag{5}$$

III. Fuzzy Programming Approach to the Proposed Robust Portfolio Selection Problem

In addition to bi-criteria in Section 2, taking account of subjectivity of investment decision and flexibility for the execution of portfolio management, the investor often has satisfaction functions for target parameters d and f called fuzzy goals. In this paper, we defined each fuzzy goal as the fuzzy set characterized by a linear membership function:

$$\begin{aligned} \mu_{\tilde{d}}(\omega) &= \begin{cases} 1 & (d_U \leq \omega) \\ \dfrac{\omega - d_L}{d_U - d_L} & (d_L < \omega < d_U) \\ 0 & (\omega \leq d_L) \end{cases} \\ \mu_{\tilde{G}}(f) &= \begin{cases} 1 & (f_U \leq f) \\ \dfrac{f - f_L}{f_U - f_L} & (f_L < f < f_U) \\ 0 & (f \leq f_L) \end{cases} \end{aligned} \tag{6}$$

where d_L, d_U and f_L, f_U are constant values determined by the investor. Then, substituting $z_d(\boldsymbol{x}) = \dfrac{E(\boldsymbol{r}) - f}{\sqrt{\mathbf{Var}(\boldsymbol{r})}}$ into fuzzy goal $\mu_{\tilde{d}}(\omega)$, the following formula is obtained:

$$\mu_{\tilde{g}(d)}(z_d(\boldsymbol{x})) = \begin{cases} 1 & (\omega \leq g_U(d)) \\ \dfrac{g_L(d) - \omega}{\left((d_U - d_L)\sqrt{\mathbf{Var}(\boldsymbol{r})}\right)} & (g_U(d) < \omega < g_L(d)) \\ 0 & (g_L(d) \leq \omega) \end{cases} \tag{7}$$

$$g_L(d) = E(\boldsymbol{r}) - d_L\sqrt{\mathbf{Var}(\boldsymbol{r})},\ g_U(d) = E(\boldsymbol{r}) - d_U\sqrt{\mathbf{Var}(\boldsymbol{r})}$$

With respect to problem (5), this problem is a bi-objective programming problem, and so without introducing some criterion of optimality for the bi-objective functions, it is hard to solve this problem directly. Therefore, considering fuzzy goals (6) and (7) for the bi-object and $f' = f_U$ for the standard target profit, we transform problem (5) into the following maximin programming problem:

$$\begin{aligned} &\text{Maximize} \ \min\left\{\mu_{\tilde{g}(d)}\left(z_d(\boldsymbol{x})\right), \mu_{\tilde{G}}(f)\right\} \\ &\text{subject to} \ E(\boldsymbol{r}) \geq f_U, \\ &\qquad \mathbf{1}^t\boldsymbol{\phi} = 1 \end{aligned} \tag{8}$$

This problem is also equivalently transformed into the following single-objective programming problem introducing parameter h which means the common target satisfaction level:

$$\begin{aligned} &\text{Maximize} \ h \\ &\text{subject to} \ \min\left\{\mu_{\tilde{g}(d)}\left(z_d(\boldsymbol{x})\right), \mu_{\tilde{G}}(f)\right\} \geq h, \\ &\qquad E(\boldsymbol{r}) \geq f_U, \\ &\qquad \mathbf{1}^t\boldsymbol{\phi} = 1 \end{aligned} \tag{9}$$

With respect to the first constraint of problem (9), we obtain the following deterministic equivalent transformations:

$$\begin{aligned} &\min\left\{\mu_{\tilde{g}(d)}\left(z_d(\boldsymbol{x})\right), \mu_{\tilde{G}}(f)\right\} \geq h, \\ &\Leftrightarrow \ \mu_{\tilde{g}(d)}\left(z_d(\boldsymbol{x})\right) \geq h, \ \mu_{\tilde{G}}(f) \geq h \\ &\Leftrightarrow \ \exists f : \frac{g_L(d) - f}{\left((d_U - d_L)\sqrt{\mathbf{Var}(\boldsymbol{r})}\right)} \geq h, \ \frac{f - f_L}{f_U - f_L} \geq h \\ &\Leftrightarrow \ \exists f : g_L(d) + h(d_L - d_U)\sqrt{\mathbf{Var}(\boldsymbol{r})} \geq f, f \geq (1-h)f_L + hf_U \\ &\Leftrightarrow \ E(\boldsymbol{r}) - d_L\sqrt{\mathbf{Var}(\boldsymbol{r})} + h(d_L - d_U)\sqrt{\mathbf{Var}(\boldsymbol{r})} \geq (1-h)f_L + hf_U \\ &\Leftrightarrow \ E(\boldsymbol{r}) - d_L\sqrt{\mathbf{Var}(\boldsymbol{r})} - f_L \geq h\left((d_U - d_L)\sqrt{\mathbf{Var}(\boldsymbol{r})} + (f_U - f_L)\right) \\ &\Leftrightarrow \ \frac{E(\boldsymbol{r}) - d_L\sqrt{\mathbf{Var}(\boldsymbol{r})} - f_L}{(d_U - d_L)\sqrt{\mathbf{Var}(\boldsymbol{r})} + (f_U - f_L)} \geq h \end{aligned} \tag{10}$$

Consequently, the proposed model is transformed into the following problem:

$$\begin{aligned} &\text{Maximize} \ h \\ &\text{subject to} \ \frac{E(\boldsymbol{r}) - d_L\sqrt{\mathbf{Var}(\boldsymbol{r})} - f_L}{(d_U - d_L)\sqrt{\mathbf{Var}(\boldsymbol{r})} + (f_U - f_L)} \geq h, \\ &\qquad E(\boldsymbol{r}) \geq f_U, \\ &\qquad \mathbf{1}^t\boldsymbol{\phi} = 1 \end{aligned} \tag{11}$$

i.e.,

$$\begin{aligned} &\text{Maximize} \ \frac{E(\boldsymbol{r}) - d_L\sqrt{\mathbf{Var}(\boldsymbol{r})} - f_L}{(d_U - d_L)\sqrt{\mathbf{Var}(\boldsymbol{r})} + (f_U - f_L)} \\ &\text{subject to} \ E(\boldsymbol{r}) \geq f_U, \\ &\qquad \mathbf{1}^t\boldsymbol{\phi} = 1 \end{aligned} \tag{12}$$

This objective function is fractional, but the numerator $E(\boldsymbol{r}) - d_L\sqrt{\mathbf{Var}(\boldsymbol{r})} - f_L$ is a concave function and the denominator $(d_U - d_L)\sqrt{\mathbf{Var}(\boldsymbol{r})} + (f_U - f_L)$ is a convex function, and so the objective function is convex. Then, all constraints are linear functions, and so problem (12) is a convex programming problem. Furthermore, this problem is similar to the model proposed by Dinkelbach [6].

In Dinkelbach [6], the following parametric programming problem $\mathbf{P}(q)$ introducing parameter q has been considered:

$$\begin{aligned} &\text{Maximize} \ E(\boldsymbol{r}) - d_L\sqrt{\mathbf{Var}(\boldsymbol{r})} - f_L \\ &\qquad - q\left((d_U - d_L)\sqrt{\mathbf{Var}(\boldsymbol{r})} + (f_U - f_L)\right) \\ &\text{subject to} \ E(\boldsymbol{r}) \geq f_U, \\ &\qquad \mathbf{1}^t\boldsymbol{\phi} = 1 \\ &\Leftrightarrow \ \text{Maximize} \ E(\boldsymbol{r}) - (1-q)f_L - qf_U \\ &\qquad - \left((1-q)d_L + qd_U\right)\sqrt{\mathbf{Var}(\boldsymbol{r})} \\ &\quad \text{subject to} \ E(\boldsymbol{r}) \geq f_U, \\ &\qquad \mathbf{1}^t\boldsymbol{\phi} = 1 \end{aligned} \tag{13}$$

With respect to this problem $\mathbf{P}(q)$, the following theorem holds.

Theorem 1 (Dinkelbach [6]): Let the objective function of $\mathbf{P}(q)$ be $F(q, \boldsymbol{\phi})$, and optimal solution of problem (12) be $\boldsymbol{\phi}^*$. Then,

$$q^* = \frac{\overline{\boldsymbol{r}}^t\boldsymbol{\phi}^* - d_L\sqrt{\boldsymbol{\phi}^{*t}\mathbf{V}\boldsymbol{\phi}^*} - f_L}{(d_U - d_L)\sqrt{\boldsymbol{\phi}^{*t}\mathbf{V}\boldsymbol{\phi}^*} + (f_U - f_L)}$$

if, and only if, $F(q^*, \boldsymbol{\phi}^*) = 0$.

Consequently, we develop the following exact solution algorithm for the proposed robust portfolio selection problem based on Dinkelbach [6].

Solution algorithm.

STEP1: Set $q_0 = 0$, and solve $\mathbf{P}(q_0)$. If there is no feasible solution, then terminate this algorithm. In this case, there is no feasible solution of main problem and it is necessary to reset fuzzy goals. Else if there is an optimal portfolio, let the optimal portfolio of $\mathbf{P}(q_0)$ be $\boldsymbol{\phi}_1$, and set $k = 1$. Go to STEP2.

STEP2: Evaluate

$$q_k = \frac{\overline{\boldsymbol{r}}^t\boldsymbol{\phi}_k - d_L\sqrt{\boldsymbol{\phi}_k^t\mathbf{V}\boldsymbol{\phi}_k} - f_L}{(d_U - d_L)\sqrt{\boldsymbol{\phi}_k^t\mathbf{V}\boldsymbol{\phi}_k} + (f_U - f_L)},$$

and go to STEP3.

STEP3: Solve $\mathbf{P}(q_k)$, and denote the optimal solution by $\boldsymbol{\phi}_{k+1}$. Go to STEP4.

STEP4: With respect to sufficiently small number ε, if $F(q_k, \boldsymbol{\phi}_{k+1}) < \varepsilon$, then terminate this algorithm. In

this case, ϕ_{k+1} is the optimal portfolio. Else if $F(q_k, \phi_{k+1}) \geq \varepsilon$, $k \leftarrow k+1$ and return to STEP2.

IV. Exact Optimal Portfolio of $\mathbf{P}(q)$

In the solution algorithm in Section 3, we need to solve problem $\mathbf{P}(q_k)$ on each q_k, repeatedly. Therefore, it is also important to consider the solution algorithm for $\mathbf{P}(q)$. In this section, we develop the strict solution algorithm to obtain the exact optimal portfolio of $\mathbf{P}(q)$.

We consider the following problem which is equivalent to be $\mathbf{P}(q)$:

$$\begin{aligned} &\text{Minimize} \quad -\bar{\boldsymbol{r}}^t\phi + f_q + d_q\sqrt{\phi^t\mathbf{V}\phi} \\ &\text{subject to} \quad \bar{\boldsymbol{r}}^t\phi \geq f_U, \\ &\qquad\qquad \mathbf{1}^t\phi = 1 \end{aligned} \tag{14}$$

where $f_q = (1-q)f_L + qf_U$ and $d_q = (1-q)d_L + qd_U$. Then, f_q and d_q are positive values. With respect to this problem, since $\mathbf{V}$ is a variance-covariance matrix which is positive definite, we perform the following equivalent transformations of variables:

$$\begin{aligned} &\phi^t\mathbf{V}\phi = \boldsymbol{x}^t\boldsymbol{x} \\ &\mathbf{V} = \mathbf{Q}^t\mathbf{\Lambda}\mathbf{Q}, \ \begin{pmatrix}\mathbf{Q}: \textit{unitary matrix} \\ \textit{consisting of eigen vectors of } \mathbf{V}\end{pmatrix} \\ &\mathbf{\Lambda} = \begin{pmatrix}\lambda_1 & & \mathbf{0} \\ & \ddots & \\ \mathbf{0} & & \lambda_n\end{pmatrix}, \ (\lambda_i : \textit{eigen value of } \mathbf{V}) \\ &\mathbf{\Lambda} = \left(\mathbf{\Lambda}^{1/2}\right)^t\mathbf{\Lambda}^{1/2}, \ \mathbf{\Lambda}^{1/2} = \left(\mathbf{\Lambda}^{1/2}\right)^t = \begin{pmatrix}\sqrt{\lambda_1} & & \mathbf{0} \\ & \ddots & \\ \mathbf{0} & & \sqrt{\lambda_n}\end{pmatrix} \\ &\boldsymbol{x} = \mathbf{\Lambda}^{1/2}\mathbf{Q}\phi, \ \bar{\boldsymbol{r}}' = \left(\mathbf{\Lambda}^{1/2}\right)^{-1}\mathbf{Q}\bar{\boldsymbol{r}}, \ \boldsymbol{a} = \left(\mathbf{\Lambda}^{1/2}\right)^{-1}\mathbf{Q}\mathbf{1} \end{aligned} \tag{15}$$

Using these transformations of variables, problem (15) is equivalently transformed into the following problem:

$$\begin{aligned} &\text{Minimize} \quad -\bar{\boldsymbol{r}}'^t\boldsymbol{x} + f_q + d_q\sqrt{\boldsymbol{x}^t\boldsymbol{x}} \\ &\text{subject to} \quad \bar{\boldsymbol{r}}'^t\boldsymbol{x} \geq f_U, \\ &\qquad\qquad \boldsymbol{a}^t\boldsymbol{x} = 1 \end{aligned} \tag{16}$$

This problem still includes a square root term as well as problem (14). Therefore, in order to obtain the exact optimal portfolio to problem (16), we introduce the following auxiliary problem using a parameter R not including the square root term:

$$\begin{aligned} &\text{Minimize} \quad R\left(-\bar{\boldsymbol{r}}'^t\boldsymbol{x} + f_q\right) + \frac{d_q}{2}\left(\boldsymbol{x}^t\boldsymbol{x}\right) \\ &\text{subject to} \quad \bar{\boldsymbol{r}}'^t\boldsymbol{x} \geq f_U, \\ &\qquad\qquad \boldsymbol{a}^t\boldsymbol{x} = 1 \end{aligned} \tag{17}$$

Since this problem is a quadratic convex programming problem, we solve problem (17) more easily than problem (16). Furthermore, with respect to the relation between problem (16) and its auxiliary problem (17), the following theorem holds.

Theorem 2: Let the optimal solution of auxiliary problem (17) be $\boldsymbol{x}(R)$. If $R = \sqrt{\sum_{j=1}^{n} x_j(R)^2}$ is satisfied, $\boldsymbol{x}(R)$ is also the optimal solution of problem (16).

Proof: We compare Karush-Kuhn-Tucker (KKT) conditions of problem (16) with that of problem (17). the KKT condition of problem (16) is as follows:

$$\begin{aligned} L &= -\sum_{j=1}^{n}\bar{r}'_j x_j + f_q + d_q\sqrt{\sum_{j=1}^{n}x_j^2} \\ &\quad + u\left(f_U - \sum_{j=1}^{n}\bar{r}'_j x_j\right) + v\left(1 - \sum_{j=1}^{n}a_j x_j\right) \\ \frac{\partial L}{\partial x_j} &= -\bar{r}'_j + d_q\frac{x_j}{\sqrt{\sum_{j=1}^{n}x_j^2}} - u\bar{r}'_j - va_j = 0 \end{aligned} \tag{18}$$

the KKT condition of auxiliary problem (17) is also obtained as follows:

$$\begin{aligned} L' &= -R\sum_{j=1}^{n}\bar{r}'_j x_j + Rf_q + \frac{d_q}{2}\left(\sum_{j=1}^{n}x_j^2\right) \\ &\quad + u'\left(f_U - \sum_{j=1}^{n}\bar{r}'_j x_j\right) + v'\left(1 - \sum_{j=1}^{n}a_j x_j\right) \\ \frac{\partial L'}{\partial x_j} &= -R\bar{r}'_j + d_q x_j - u'\bar{r}'_j - v'a_j = 0 \end{aligned} \tag{19}$$

With respect to these KKT conditions, we set $u = u'/R$, $v = v'/R$. Then, satisfying $R = \sqrt{\sum_{j=1}^{n} x_j(R)^2}$, the KKT condition of problem (17) is equal to that of problem (16). Therefore, this theorem holds. □

This theorem means that we can obtain the optimal solution of problem (14) by solving the auxiliary quadratic programming problem (17) setting the appropriate parameter R.

With respect to problem (17) and the KKT condition (19), we consider the following two cases. We reconsider the following KKT condition of problem (17) including complementary conditions:

$$\begin{cases} \dfrac{\partial L}{\partial \boldsymbol{x}} = -R\overline{\boldsymbol{r}}' + d_q \boldsymbol{x} - u\overline{\boldsymbol{r}}' - v\boldsymbol{a} = 0 \\ u\left(f_U - \overline{\boldsymbol{r}}'^t \boldsymbol{x}\right) = 0 \\ \boldsymbol{a}^t \boldsymbol{x} = 1 \end{cases} \tag{20}$$

First, in the case of $f_U - \overline{\boldsymbol{r}}'^t \boldsymbol{x} = 0$, KKT condition (20) is degenerated as follows:

$$\begin{cases} -R\overline{\boldsymbol{r}}' + d_q \boldsymbol{x} - u\overline{\boldsymbol{r}}' - v\boldsymbol{a} = 0 \\ f_U - \overline{\boldsymbol{r}}'^t \boldsymbol{x} = 0 \\ \boldsymbol{a}^t \boldsymbol{x} = 1 \end{cases} \tag{21}$$

Since we obtain $\boldsymbol{x} = \dfrac{(R+u)\overline{\boldsymbol{r}}' + v\boldsymbol{a}}{d_q}$ from the first equation of (21), we calculate the following solution for each parameter:

$$\begin{cases} v = \dfrac{d_q\left(\left\|\overline{\boldsymbol{r}}'\right\|^2 - f_U\left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)\right)}{\left\|\overline{\boldsymbol{r}}'\right\|^2 \left\|\boldsymbol{a}\right\|^2 - \left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)^2} \\ (R+u) = \dfrac{d_q\left(f_U \left\|\boldsymbol{a}\right\|^2 - \left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)\right)}{\left\|\overline{\boldsymbol{r}}'\right\|^2 \left\|\boldsymbol{a}\right\|^2 - \left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)^2} \end{cases} \tag{22}$$

Consequently, we obtain the optimal portfolio of problem (14) as follows:

$$\begin{aligned} \boldsymbol{x}^* &= \frac{\overline{\boldsymbol{r}}'}{d_q}\left(\frac{d_q\left(f_U \left\|\boldsymbol{a}\right\|^2 - \left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)\right)}{\left\|\overline{\boldsymbol{r}}'\right\|^2 \left\|\boldsymbol{a}\right\|^2 - \left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)^2}\right) + \frac{\boldsymbol{a}}{d_q}\left(\frac{d_q\left(\left\|\overline{\boldsymbol{r}}'\right\|^2 - f_U\left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)\right)}{\left\|\overline{\boldsymbol{r}}'\right\|^2 \left\|\boldsymbol{a}\right\|^2 - \left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)^2}\right) \\ \Leftrightarrow \quad \boldsymbol{x}^* &= \frac{\left(f_U \left\|\boldsymbol{a}\right\|^2 - \left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)\right)}{\left\|\overline{\boldsymbol{r}}'\right\|^2 \left\|\boldsymbol{a}\right\|^2 - \left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)^2}\overline{\boldsymbol{r}}' + \frac{\left(\left\|\overline{\boldsymbol{r}}'\right\|^2 - f_U\left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)\right)}{\left\|\overline{\boldsymbol{r}}'\right\|^2 \left\|\boldsymbol{a}\right\|^2 - \left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)^2}\boldsymbol{a} \\ \Leftrightarrow \quad \boldsymbol{\Lambda}^{1/2}\mathbf{Q}\boldsymbol{\phi}^* &= \frac{\left(f_U \left\|\left(\boldsymbol{\Lambda}^{1/2}\right)^{-1}\mathbf{Q}\mathbf{1}\right\|^2 - \left(\overline{\boldsymbol{r}}'^t \mathbf{Q}^t \boldsymbol{\Lambda}^{-1}\mathbf{Q}\mathbf{1}\right)\right)}{\left\|\left(\boldsymbol{\Lambda}^{1/2}\right)^{-1}\mathbf{Q}\overline{\boldsymbol{r}}\right\|^2 \left\|\left(\boldsymbol{\Lambda}^{1/2}\right)^{-1}\mathbf{Q}\mathbf{1}\right\|^2 - \left(\overline{\boldsymbol{r}}'^t \mathbf{Q}^t \boldsymbol{\Lambda}^{-1}\mathbf{Q}\mathbf{1}\right)^2}\overline{\boldsymbol{r}}' \\ &\quad + \frac{\left(\left\|\left(\boldsymbol{\Lambda}^{1/2}\right)^{-1}\mathbf{Q}\overline{\boldsymbol{r}}\right\|^2 - f_U\left(\overline{\boldsymbol{r}}'^t \mathbf{Q}^t \boldsymbol{\Lambda}^{-1}\mathbf{Q}\mathbf{1}\right)\right)}{\left\|\left(\boldsymbol{\Lambda}^{1/2}\right)^{-1}\mathbf{Q}\overline{\boldsymbol{r}}\right\|^2 \left\|\left(\boldsymbol{\Lambda}^{1/2}\right)^{-1}\mathbf{Q}\mathbf{1}\right\|^2 - \left(\overline{\boldsymbol{r}}'^t \mathbf{Q}^t \boldsymbol{\Lambda}^{-1}\mathbf{Q}\mathbf{1}\right)^2}\boldsymbol{a} \\ \Leftrightarrow \quad \boldsymbol{\phi}^* &= \frac{\left(f_U\left(\mathbf{1}^t\mathbf{V}^{-1}\mathbf{1}\right) - \left(\overline{\boldsymbol{r}}'^t\mathbf{V}^{-1}\mathbf{1}\right)\right)\overline{\boldsymbol{r}}' + \left(\left(\overline{\boldsymbol{r}}'^t\mathbf{V}^{-1}\overline{\boldsymbol{r}}\right) - f_U\left(\overline{\boldsymbol{r}}'^t\mathbf{V}^{-1}\mathbf{1}\right)\right)\boldsymbol{a}}{\left(\overline{\boldsymbol{r}}'^t\mathbf{V}^{-1}\mathbf{1}\right)\left(\mathbf{1}^t\mathbf{V}^{-1}\mathbf{1}\right) - \left(\overline{\boldsymbol{r}}'^t\mathbf{V}^{-1}\mathbf{1}\right)^2} \end{aligned} \tag{23}$$

From solution (23), by calculating only inverse matrix $\mathbf{V}^{-1}$ of variance-covariance matrix $\mathbf{V}$, we obtain optimal portfolio $\boldsymbol{\phi}^*$. Furthermore, we find that the optimal portfolio of problem $\mathbf{P}(q)$ in the case $f_U - \overline{\boldsymbol{r}}'^t \boldsymbol{x} = 0$ does not depend on parameter d_q to represent robustness.

Second, in the case of $f_U - \overline{\boldsymbol{r}}'^t \boldsymbol{x} > 0$, i.e., $u = 0$, KKT condition (20) is degenerated as follows:

$$\begin{cases} \dfrac{\partial L}{\partial \boldsymbol{x}} = -R\overline{\boldsymbol{r}}' + d_q \boldsymbol{x} - v\boldsymbol{a} = 0 \\ \boldsymbol{a}^t \boldsymbol{x} = 1 \end{cases} \tag{24}$$

Since we obtain $\boldsymbol{x} = \dfrac{R\overline{\boldsymbol{r}}' + v\boldsymbol{a}}{d_q}$ from the first equation of (24), we calculate the following solution for v:

$$\begin{aligned} & \boldsymbol{a}^t \boldsymbol{x} = 1 \\ \Leftrightarrow \ & \boldsymbol{a}^t\left(\frac{R\overline{\boldsymbol{r}}' + v\boldsymbol{a}}{d_q}\right) = 1 \\ \Leftrightarrow \ & v = \frac{d_q - R\left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)}{\left\|\boldsymbol{a}\right\|^2} \end{aligned} \tag{25}$$

Therefore, we also calculate solution $\boldsymbol{x}$ including parameter R as follows:

$$\begin{aligned} & \boldsymbol{x} = \frac{R}{d_q}\overline{\boldsymbol{r}}' + \frac{v}{d_q}\boldsymbol{a} = \frac{R}{d_q}\overline{\boldsymbol{r}}' + \frac{d_q - R\left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)}{d_q\left\|\boldsymbol{a}\right\|^2}\boldsymbol{a} \\ \Leftrightarrow \ & \boldsymbol{x}(R) = \frac{R}{d_q}\left(\overline{\boldsymbol{r}}' - \frac{\left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)}{\left\|\boldsymbol{a}\right\|^2}\boldsymbol{a}\right) + \frac{\boldsymbol{a}}{\left\|\boldsymbol{a}\right\|^2} \end{aligned} \tag{26}$$

By substituting $\boldsymbol{x}(R)$ of (26) into optimal condition for parameter R : $R = \sqrt{\sum_{j=1}^{n} x_j(R)^2}$, we solve the following equation:

$$\begin{aligned} R^2 &= \left(\frac{R}{d_q}\left(\overline{\boldsymbol{r}}' - \frac{\left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)}{\left\|\boldsymbol{a}\right\|^2}\boldsymbol{a}\right) + \frac{\boldsymbol{a}}{\left\|\boldsymbol{a}\right\|^2}\right)^t \left(\frac{R}{d_q}\left(\overline{\boldsymbol{r}}' - \frac{\left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)}{\left\|\boldsymbol{a}\right\|^2}\boldsymbol{a}\right) + \frac{\boldsymbol{a}}{\left\|\boldsymbol{a}\right\|^2}\right) \\ R^2 &= \frac{R^2}{d_q^2}\left(\overline{\boldsymbol{r}}' - \frac{\left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)}{\left\|\boldsymbol{a}\right\|^2}\boldsymbol{a}\right)^t \left(\overline{\boldsymbol{r}}' - \frac{\left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)}{\left\|\boldsymbol{a}\right\|^2}\boldsymbol{a}\right) \\ &\quad + \frac{2R}{d_q}\left(\overline{\boldsymbol{r}}' - \frac{\left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)}{\left\|\boldsymbol{a}\right\|^2}\boldsymbol{a}\right)\frac{\boldsymbol{a}}{\left\|\boldsymbol{a}\right\|^2} + \frac{1}{\left\|\boldsymbol{a}\right\|^2} \\ R^2 &= \frac{R^2}{d_q^2}\left(\left\|\overline{\boldsymbol{r}}'\right\|^2 - \frac{\left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)^2}{\left\|\boldsymbol{a}\right\|^2}\right) + \frac{1}{\left\|\boldsymbol{a}\right\|^2} \\ d_q^2\left\|\boldsymbol{a}\right\|^2 R^2 &= R^2\left(\left\|\overline{\boldsymbol{r}}'\right\|^2 \left\|\boldsymbol{a}\right\|^2 - \left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)^2\right) + 1 \\ \left(d_q^2\left\|\boldsymbol{a}\right\|^2 + \left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)^2 - \left\|\overline{\boldsymbol{r}}'\right\|^2 \left\|\boldsymbol{a}\right\|^2\right) R^2 &= 1 \\ R^* &= \sqrt{\frac{1}{d_q^2\left\|\boldsymbol{a}\right\|^2 + \left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)^2 - \left\|\overline{\boldsymbol{r}}'\right\|^2 \left\|\boldsymbol{a}\right\|^2}} \ \left(\because R \geq 0\right) \end{aligned} \tag{27}$$

Consequently, we obtain the exact optimal solution of $\boldsymbol{x}$ as

$$\boldsymbol{x}^* = \frac{R^*}{d_q}\left(\overline{\boldsymbol{r}}' - \frac{\left(\overline{\boldsymbol{r}}'^t \boldsymbol{a}\right)}{\left\|\boldsymbol{a}\right\|^2}\boldsymbol{a}\right) + \frac{\boldsymbol{a}}{\left\|\boldsymbol{a}\right\|^2},$$

and so the exact optimal solution of problem (14) is represented as the following form:

$$\phi^* = \mathbf{V}^{-1}\left(\frac{R^*}{d_q}\left(\bar{\boldsymbol{r}} - \frac{\left(\bar{\boldsymbol{r}}^t\mathbf{V}^{-1}\mathbf{1}\right)}{\mathbf{1}^t\mathbf{V}^{-1}\mathbf{1}}\mathbf{1}\right) + \frac{1}{\mathbf{1}^t\mathbf{V}^{-1}\mathbf{1}}\mathbf{1}\right)$$
$$R^* = \sqrt{\frac{1}{\left(d_q^2 - \left(\bar{\boldsymbol{r}}^t\mathbf{V}^{-1}\bar{\boldsymbol{r}}\right)\right)\left(\mathbf{1}^t\mathbf{V}^{-1}\mathbf{1}\right) + \left(\bar{\boldsymbol{r}}^t\mathbf{V}^{-1}\mathbf{1}\right)}} \qquad (28)$$

From solution (28), by calculating only inverse matrix $\mathbf{V}^{-1}$ of variance-covariance matrix $\mathbf{V}$, we obtain optimal parameter R^* and portfolio ϕ^*. Furthermore, we find that the optimal portfolio of problem $\mathbf{P}(q)$ in the case $f_U - \bar{\boldsymbol{r}}'^t\boldsymbol{x} > 0$ does not depend on parameter f_U to represent the standard target profit.

V. CONCLUSION

In this paper, we have proposed a robust portfolio selection problem considering the confidential interval to the total profit with investor's subjectivity. Since the proposed model is a bi-objective programming problem with fuzziness, we have introduced fuzzy goals for both objective functions, and transformed it into the deterministic equivalent problems. Furthermore, in order to obtain the explicit optimal portfolio, we have developed the exact solution algorithm based on the Dinkelbach's algorithm and auxiliary quadratic programming problem without loss of optimality. Our proposed model includes some existing robust portfolio selection problems, and specific random distributions are not assumed in the model. Therefore, we may apply our models to the more flexible and complex portfolio selection problems in real investment markets than the previous models.

As future studies, we need to consider the application of our proposed model and solution algorithm to large-scale or multi-period portfolio selection problems. Then, we are now attacking the sensitivity analysis for parameters of the proposed robust portfolio model.

***Abstract*—In this paper we introduce several fuzzy resemblance relations between different combinations of crisp and fuzzy colors. As a starting point, we discuss about fuzzy colors and fuzzy color spaces as a way to represent color information, providing examples of conjunctive and disjunctive use of fuzzy colors for this purpose. Then we determine different types of relations measuring the degree of matching between color information of different kinds, using well known results from fuzzy sets and possibility theories. We study the particular case in which the user considers there is no resemblance between the fuzzy colors comprising the fuzzy color space under consideration. The proposal is based on definitions of fuzzy color and fuzzy color space provided by the authors in previous works.**

***Index Terms*—Fuzzy Color Information, Fuzzy Relations.**

I. Introduction

Humans and computers describe colors in a completely different way, a problem that is known as the *semantic gap*. Whilst computers represent colors as points in some three-dimensional (color) space, humans employ a comparatively much smaller collection of linguistic terms like *red*, *light blue*, and *strong green*.

This fact poses very interesting problems when developing applications for managing color information in which the source or destination of part of the information is a human user, whilst the rest has been obtained by means of sensors or has been generated synthetically [1]. This is the case in applications like generating descriptions of pictures for visually impaired people, determining the suitability of a certain soil for a specific cultivation, or detecting potentially cancerogenous areas in the skin, just to mention a few among a huge number.

In this paper, we are interested in problems about uncertainty in both the representation and the relationships between pieces of color information. Several authors have pointed out the suitability of the theory of fuzzy sets for this purpose, leading to the introduction of notions like *fuzzy color* for representing the compatibility between triplets of real values (crisp colors) and linguistic terms [2]–[12].

However, to the best of our knowledge, no deep study of how to use these concepts for representing uncertain color information, or relating pieces of color information for flexible query answering, have been made available in the literature. Our objective in this work is to go a step forward in this direction.

This work has been partially supported by the Spanish Government under project TIN2009-08296.

The rest of the paper is organized as follows. In section II we describe the approach to fuzzy colors and fuzzy color spaces introduced in [12]. Possible uses of fuzzy colors for representing color information are described in section III. In section IV we introduce different fuzzy relations for evaluating different types of matching queries involving color information. These relations are particularized to the case of a specific resemblance relation between fuzzy colors in section V. Finally, section VI contains our conclusions and future research plans in this area.

II. Fuzzy Modelling of Colors

All along the paper, we will consider the notions of fuzzy color (section II-A) and fuzzy color space (section II-B) introduced in [12]. We introduce these notions in the following sections.

A. Fuzzy color

In order to represent the semantic compatibility between crisp colors and linguistic color terms, in [12] we introduce the following definition of fuzzy color:

Definition 2.1: [12] A fuzzy color $\widetilde{C}$ is a normalized fuzzy subset of crisp colors.

As previously explained, crisp colors can be represented as a triplet of real numbers corresponding to coordinates in a color space. Hence, a fuzzy color can be defined as a normalized fuzzy subset of points of a color space. From now on, we shall assume that a generic color space with components X, Y and Z whose domains are D_X, D_Y and D_Z respectively, is employed. We shall call this color space XYZ (not to be confused with the CIE XYZ color space, which is just one particular case). This leads to the following more specific definition [12]:

Definition 2.2: [12] A fuzzy color $\widetilde{C}$ is a linguistic label whose semantics is represented in a color space XYZ by a normalized fuzzy subset of $D_X \times D_Y \times D_Z$.

Def. 2.2 implies that for each fuzzy color $\widetilde{C}$ there is at least one crisp color $\mathbf{r}_{\widetilde{C}}$ such that $\widetilde{C}(\mathbf{r}_{\widetilde{C}}) = 1$. Also, the membership function is not required to be convex. This leaves open the possibility to define color terms like for example *chocolat*, that may be represented by the union of the fuzzy sets for color

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

terms like *white*, *dark brown*, and *black*. Following this idea, we shall consider two kind of fuzzy colors:

- *Atomic colors*, those colors that are not defined on the basis of other colors, like *white*, *dark brown*, and *black* in the previous example. We shall consider that atomic colors are represented by means of convex fuzzy sets; in particular this implies ${}^{\alpha}\widetilde{C}$ is a convex volume $\forall \alpha \in (0,1]$, where ${}^{\alpha}\widetilde{C}$ is the α-cut of degree α of the fuzzy color $\widetilde{C}$.
- *Derived colors*, those defined on the basis of other colors by means of logical operations, like the color *chocolat* of the previous example.

Since the representation of fuzzy colors is a matter of semantics, we have that not every convex fuzzy subset of colors corresponds necessarily to an atomic fuzzy set. Another important problem related to the semantics arises because it is possible to represent the same fuzzy color by means of different fuzzy subsets on different color spaces, provided they have the same expressive power. For example, a fuzzy color *red* may be represented as a fuzzy subset with semantics "approximately [255,0,0]" if we employ the RGB color space or as a fuzzy subset with semantics "approximately [0,1,128]" if we use the HSV space. However, if we apply a transformation of the crisp colors in "approximately [255,0,0]" to HSV and we maintain the membership degrees, the result may not be "approximately [0,1,128]"; even worst, when performing such transformations from one color space to another, we can obtain a non-convex fuzzy set! Hence, a fuzzy subset of colors that semantically is an atomic fuzzy color has a non-convex representation in other spaces.

A particular case of this problem comes from the fact that the expressive power (the *gamut*) is not the same for every color space, so it could be the case that some crisp colors with degree 0 appear inside the convex volume when changing the representation, corresponding to colors that the original color space is not able to represent. However, non-convexity on the support of the fuzzy set could in principle arise as well because of the transformation from one color space to another because of a spatial redistribution of crisp colors in the color space, even if both color spaces have the same gamut. As a consequence, the notion of atomic fuzzy color may be dependent on the color space employed in the definition of the membership function. Hence, we introduce the following definitions: let XYZ be a (crisp) color space.

Definition 2.3: [12] A XYZ fuzzy color is a fuzzy color whose membership function is defined on XYZ.

Definition 2.4: [12] An atomic XYZ fuzzy color is a fuzzy color whose membership function is convex on XYZ.

From now on we will say that a fuzzy color is simply *atomic* when it is atomic in some color space XYZ.

B. Fuzzy color space

For extending the concept of color space to the case of fuzzy colors, and assuming a fixed color space XYZ, with D_X, D_Y and D_Z being the domains of the corresponding color components, the following definition is introduced in [12]:

Definition 2.5: [12] A fuzzy color space $\widetilde{XYZ}$ is a set of atomic XYZ fuzzy colors that define a partition of $D_X \times D_Y \times D_Z$.

We consider that a fuzzy partition of the color space XYZ is a crisp set of m fuzzy colors $\widetilde{C}_1, \ldots, \widetilde{C}_m$ verifying the following properties [12]:

1) $\bigcup_{\{1,\ldots,m\}} sup(\widetilde{C}_i) = XYZ$, i.e., the union of the support of the $\widetilde{C}_i$ covers the whole space.
2) $ker(\widetilde{C}_i) \cap ker(\widetilde{C}_j) = \emptyset \ \forall i \neq j$, i.e., the kernels of the $\widetilde{C}_i$ and $\widetilde{C}_j$ are pairwise disjoint.
3) $\forall i \in \{1,\ldots,m\} \ \exists \mathbf{c} \in XYZ$ such that $\widetilde{C}_i(\mathbf{c}) = 1$, i.e., there is at least one object fully representative of the fuzzy color $\widetilde{C}_i$.

Condition 3 is always verified by definition of fuzzy color. Condition 1 implies $\forall \mathbf{c} \in XYZ \ \exists i \in \{1,\ldots,m\}$ such that $\widetilde{C}_i(\mathbf{c}) > 0$. Conditions 2 and 3 imply $\widetilde{C}_i \not\subseteq \widetilde{C}_j \ \forall i \neq j$.

III. Color Information

Fuzzy colors allow us to represent color information in a computer, filling the semantic gap with human's perception of color. However, it is important to remark that the same fuzzy color may represent information with different semantics depending on its use.

Fuzzy colors can be used both in a conjunctive and disjunctive way as pieces of information [13]–[16]. An example of a conjunctive use is to answer with a fuzzy color $\widetilde{C}$ to the question "which are the red colors?". In this case, each crisp color c is part of the answer with a degree given by $\widetilde{C}(c)$. An example of disjunctive use is to provide a fuzzy color for answering the question "what's the color of that car?". In this second case, the true answer is a single crisp color, but we do not know exactly what one, so we answer by giving a restriction on the set of crisp colors given by the fuzzy color $\widetilde{C}$, i.e., the possibility that a certain crisp color c is the color of the car is $\widetilde{C}(c)$. Hence, a disjunctively-used fuzzy color is a possibility distribution on the set of crisp colors. From now on we shall denote the conjunctive (resp. disjunctive) use of fuzzy colors as Cu (resp. Du), i.e., we shall say that a fuzzy color is conjunctively used (Cu) or disjunctively used (Du).

Hence, in this paper we shall consider that color information may be expressed by means of:

1) A crisp color $c \in XYZ$, e.g., *this pixel has color* **[0,0,0]** *in RGB*.
2) A conjunctively-used fuzzy color, e.g., *I like* **red** *cars*; *the grass is* **green**. It defines the compatibility degree between a linguistic term and the crisp colors in a crisp color space.
3) A disjunctively-used fuzzy color (possibility distribution on the set of crisp colors), corresponding to a description by means of a flexible restriction of our knowledge about the actual value of a variable whose possible values are crisp colors. For example, *my car is* **red**;

Table I indicates the actual information represented by each of the previous cases, as well as the presence of imprecision and/or uncertainty.

TABLE I
COLOR INFORMATION, TYPE OF VALUE REPRESENTED, AND PRESENCE OF IMPRECISION AND/OR UNCERTAINTY IN THE REPRESENTATION.

Representation	Value	Imprec.	Uncert.
Crisp	Crisp color	No	No
Cu	Cu Fuzzy Color	Yes	No
Du	Crisp color	No	Yes

IV. MATCHING COLOR INFORMATION

Matching color information is crucial for practical applications involving fuzzy color spaces. In particular, when we are given statements involving color information coming from different sources, the assessment of these statements depends usually in the degree of matching between them. In this section we propose how to calculate the degree of matching associated to certain expressions involving two pieces of color information, depending on the semantics of the color information employed (any of those explained in the previous section).

The basic information to be employed in color information matching is intimately linked to the own definition of a fuzzy color space, since the representation of each fuzzy color is the fuzzy set of crisp colors that are compatible with the fuzzy color. This representation induces a resemblance relation for crisp colors based on the idea that crisp colors appearing to a certain degree in the representation of a fuzzy color are supposed to be resemblant at least to the minimum of those degrees. This notion of *resemblance induced by a fuzzy color* can be extended to *resemblance induced by a fuzzy color space* just taking the maximum degree among all the fuzzy colors of the fuzzy color space, as we shall see. We shall denote by $r_{\widetilde{C}}$ and $R_{\widetilde{XYZ}}$ the resemblance relations induced by $\widetilde{C}$ and $\widetilde{XYZ}$, respectively. For the sake of simplicity, when there is a single clear fuzzy color space $\widetilde{XYZ}$, we shall denote the relations as r and R, respectively.

In addition to defining each fuzzy color, we shall consider that users can provide their perception of *resemblance between fuzzy colors* by means of a fuzzy resemblance relation (reflexive and symmetric), that we will denote by $S_{\widetilde{XYZ}}$ (or, again, simply S when the fuzzy color space is known). Notice that S is not expected to be transitive in general, and this is consistent with our view of fuzzy color resemblance. For example, one might say that *red* and *orange* are resemblant to some degree, and *orange* and *yellow* are resemblant to the same degree, but *red* and *yellow* are resemblant to a lesser degree than the former. Let us point out that this resemblance is to be taken into account only when the fuzzy color is used in a conjunctive way (as a whole).

Let us remark that compatibility and resemblance of fuzzy colors are different relations, in particular we assume S to be independent of the representation of fuzzy colors. Hence, there is no problem in considering that two fuzzy colors are compatible to a certain degree $\alpha > 0$ (i.e., there is at least one crisp color whose membership degree to both fuzzy colors is at least α) and, at the same time, their resemblance is 0, meaning that both colors are semantically distinguishable and different. This is also consistent with the fact that the user considered both colors in his/her definition of the fuzzy color space since, conceptually, the fuzzy color space is a (fuzzy) partition of the crisp color space.

TABLE II
MOST USUAL CASES WHEN MATCHING PIECES OF COLOR INFORMATION, AND THE CORRESPONDING EQUATION NUMBER.

	c'	Cu $\widetilde{C}'$	Du $\widetilde{C}'$
c	R (2)	K (3)	Pos (4) Nec (5)
Cu $\widetilde{C}$		K (6) R (7)	Pos (8) Nec (9)
Du $\widetilde{C}$			Pos (10) Nec (11) Inc (15) R (17)

Hence, we separate the relationship between a crisp and a fuzzy color from the relationship between fuzzy colors. In other words, S is not necessarily obtained by performing operations on the representations of the fuzzy colors. As a particular case, in this work we devote some effort to the study of the relation S^0 given by $S^0(\widetilde{C}, \widetilde{C'}) = 1$ iff $\widetilde{C} = \widetilde{C'}$, and 0 otherwise. This is the simplest relation one may consider, and it is fully consistent with the view of $\widetilde{XYZ}$ as a partition of the set of crisp colors (though a fuzzy one in which colors may be compatible to some degree). The fact that under S^0 colors are all different but compatible illustrates very clearly the independence between fuzzy color definition and similarity. Other relations and how to obtain them for representing specific semantics will be studied in forthcoming papers.

The possible situations we may encounter when matching pieces of color information correspond to the cells in Table II, where **c**, **c'** $\in XYZ$ are crisp colors, and $\widetilde{C}$, $\widetilde{C}' \in \widetilde{XYZ}$ are fuzzy colors. We shall denote R=resemblance relation, K=compatibility relation, Inc=inclusion. Pos and Nec mean possibility and necessity, respectively.

A first notion of resemblance between crisp colors is that of resemblance induced by a single fuzzy color, defined as follows:

Definition 4.1: The resemblance between crisp colors induced by a single fuzzy color $\widetilde{C}$ is

$$r_{\widetilde{C}}(c, c') = \min(\widetilde{C}(c), \widetilde{C}(c')) \quad (1)$$

It is easy to show that $r_{\widetilde{C}}$ is symmetric and max-min transitive, but not reflexive unless $\widetilde{C}$ is crisp. Reflexivity may be imposed by forcing $r_{\widetilde{C}}(c, c) = 1$ in the previous definition, allowing us to interpret directly a fuzzy color as a group of similar crisp colors, defined by a fuzzy equivalence relation. However, this introduces a discontinuity in the fuzzy set "being similar to c following $\widetilde{C}$", whose membership function is given for every c' by $r_{\widetilde{C}}(c, c')$, even when $\widetilde{C}$ is continuous. This condition may be eliminated if continuity is desired and

reflexivity is not mandatory. Anyway, this discussion is not very important from a practical point of view, since what is important in practical applications is the generalization of this notion to that of resemblance induced by a whole fuzzy color space, considering a user-defined resemblance relation S between fuzzy colors, as follows:

Definition 4.2: The resemblance between crisp colors c and c' induced by a fuzzy color space $\widetilde{XYZ}$ is

$$R_{\widetilde{XYZ}}(c,c') = \max_{(\widetilde{C},\widetilde{C}')\in\widetilde{XYZ}\times\widetilde{XYZ}} \min\{\widetilde{C}(c),\widetilde{C}'(c'),S(\widetilde{C},\widetilde{C}')\} \tag{2}$$

Definition 4.2 is useful in practice when answering questions like *What RGB colors are resemblant to color c?*, or *Give me images containing colors that resemble that of pixel p*, etc. Notice that in this case, the relation is reflexive iff the kernels of the fuzzy colors form a crisp partition of the crisp color space; otherwise, we have to impose $R_{\widetilde{XYZ}}(c,c)=1$ and we have again a discontinuity in the similarity to a fixed crisp color c. Notice however that, taking into account the notion of fuzzy partition that we consider in Section II-B, we are allowed to consider a fuzzy color space consisting of non-crisp fuzzy subsets of colors whose kernels form a crisp partition of the color space, since we allow $\sum_{\widetilde{C}\in\widetilde{XYZ}}\widetilde{C}(c)>1$. Hence, we may obtain a reflexive fuzzy relation $R_{\widetilde{XYZ}}$ in which $R_{\widetilde{XYZ}}(c,c')$ is continuous for every fixed c (provided every $\widetilde{C}\in\widetilde{XYZ}$ is continuous) from a suitable fuzzy color space $R_{\widetilde{XYZ}}$ having non-crisp fuzzy colors.

The following definitions correspond to the rest of cases as shown in Table II. We shall assume from now on that we work with a fuzzy color space $\widetilde{XYZ}$, avoiding it explicitly in the notations. Notice that we shall always employ the same notation (letters R and K to denote resemblance and compatibility, respectively, etc.), although the definitions correspond to different resemblance and compatibility relations. Finally, we shall assume that only a subset of crisp colors in the color space XYZ are considered (this is always the case when working with computers).

Definition 4.3: The compatibility between a crisp color c and a Cu fuzzy color $\widetilde{C}\in\widetilde{XYZ}$ is

$$K(c,\widetilde{C}) = \max_{\widetilde{C}'\in\widetilde{XYZ}} \min\{\widetilde{C}(c),\widetilde{C}'(c),S(\widetilde{C},\widetilde{C}')\} \tag{3}$$

Definition 4.3 is useful when answering questions like *To what degree pixel p is* **red***?*, or *Give me images containing* **red** *pixels*, etc.

Definition 4.4: The possibility and the necessity that a certain color variable V takes value c knowing that its value is in a Du fuzzy color $\widetilde{C}\in\widetilde{XYZ}$ are, respectively

$$pos(V=c|V \text{ is } \widetilde{C}) = \widetilde{C}(c) \tag{4}$$

and

$$nec(V=c|V \text{ is } \widetilde{C}) = 1 - \max_{c'\in\widetilde{XYZ} \mid c'\neq c} \{\widetilde{C}(c')\} \tag{5}$$

Definition 4.4 is useful when answering questions like *Knowing that my car is* **red***, what is the possibility/necessity that my car is painted in the RGB color c?*. Notice that for any fuzzy color $\widetilde{C}\in\widetilde{XYZ}$ such that its kernel is not a singleton, $Nec(V=c|V \text{ is } \widetilde{C})=0$. On the other hand, if $\widetilde{C}$ is a singleton, it is easy to show that

$$pos(V=c|V \text{ is } \{c'\}) = Nec(V=c|V \text{ is } \{c'\}) = \\ = \begin{cases} 1 & c=c' \\ 0 & \text{otherwise} \end{cases}$$

Definition 4.5: The compatibility between two Cu fuzzy colors is

$$K(\widetilde{C},\widetilde{C'}) = \max_{(\widetilde{C''},\widetilde{C'''})\in\widetilde{XYZ}\times\widetilde{XYZ}} \max_{c\in XYZ}\{ \\ \min\{S(\widetilde{C},\widetilde{C''}),\widetilde{C''}(c),S(\widetilde{C'},\widetilde{C'''}),\widetilde{C'''}(c)\}\} \tag{6}$$

Definition 4.5 is useful when answering questions like *To what extent it is possible to find a crisp color that is* **red** *and* **orange***?*.

Definition 4.6: The resemblance between two Cu fuzzy colors is

$$R(\widetilde{C},\widetilde{C'}) = S(\widetilde{C},\widetilde{C'}) \tag{7}$$

where S is a resemblance relation defined by the user.

Definition 4.6 is useful when answering questions like *To what extent* **red** *is similar to* **orange***?*.

Definition 4.7: The possibility and the necessity that a certain color variable V takes a value compatible with a Cu fuzzy color $\widetilde{C}$ knowing that the value of V is in a Du fuzzy color $\widetilde{C'}$ are, respectively

$$pos(K(V,\widetilde{C})|V \text{ is } \widetilde{C'}) = \\ = \max_{\widetilde{C''}\in\widetilde{XYZ}} \max_{c\in XYZ} \min\{\widetilde{C'}(c),\widetilde{C''}(c),S(\widetilde{C},\widetilde{C''})\} \tag{8}$$

and

$$nec(K(V,\widetilde{C})|V \text{ is } \widetilde{C'}) = 1 - pos(\neg K(V,\widetilde{C})|V \text{ is } \widetilde{C'}) = \\ = 1 - \max_{\widetilde{C''}\in\widetilde{XYZ}} \max_{c\in XYZ} \min\{\widetilde{C'}(c),1-\widetilde{C''}(c),S(\widetilde{C},\widetilde{C''})\} \tag{9}$$

where $pos(\neg K(V,\widetilde{C})|V \text{ is } \widetilde{C'})$ is the possibility that V *does not* take a value compatible with $\widetilde{C}$ given that the value of V is in $\widetilde{C'}$.

Definition 4.7 is useful when answering questions like *She told me the car was* **red***, what is the possibility/necessity that the car was* **orange***?*

Definition 4.8: The possibility and the necessity that a certain color variable V takes a value compatible with a Du fuzzy color $\widetilde{C}$ knowing that the value of V is in a Du fuzzy color $\widetilde{C'}$ are, respectively

$$pos(K(V,\widetilde{C})|V \text{ is } \widetilde{C'}) = \max_{c\in XYZ} \min\{\widetilde{C'}(c),\widetilde{C}(c)\} \tag{10}$$

$$nec(K(V,\widetilde{C})|V \text{ is } \widetilde{C'}) = 1 - \max_{c\in XYZ} \min\{\widetilde{C'}(c),1-\widetilde{C}(c)\} \tag{11}$$

Definition 4.8 is useful when answering questions like *Jim saw a* ***red*** *car, and Tim saw an* ***orange*** *car, what's the*

possibility/necessity that both cars were painted in the same color?.

In order to define degrees of inclusion, we will employ the following definition from [17]:

Definition 4.9 ([17]): Let I a contrapositive fuzzy implication[1] satisfying:

1) $(\forall x, y \in [0,1])(x \leq y \Leftrightarrow I(x,y) = 1)$
2) $(\forall x, y \in [0,1])(x = 1 \wedge y = 0 \Leftrightarrow I(x,y) = 0)$

and let A, B be two fuzzy sets defined on a crisp set X. Then, the family of functions given by

$$Sub(A,B) = \min_{x \in X} I(A(x), B(x)) \tag{12}$$

is a family of *inclusion indicators* that satisfy all the Sinha-Dougherty axioms [17].

An example of contrapositive fuzzy implication I satisfying the conditions above is the Lukasiewicz's implicator [17], given by

$$I_a(x,y) = \min(1, 1 - x + y) \tag{13}$$

On this basis, a family of similarity indicators between fuzzy sets can be defined as follows [18]: let A, B be two fuzzy sets defined on a crisp set X. Then, the family of functions given by

$$Sim(A,B) = \min\{Sub(A,B), Sub(B,A)\} \tag{14}$$

is a family of similarity indicators.

The inclusion indicator (resp. similarity indicator) between pieces of color information is useful when answering questions like *To what extent Jim's knowledge about my car's color is more specific than (resp. similar to) Tim's?*.

Definition 4.10: The degree of inclusion of a Du fuzzy color $\widetilde{C}$ in another Du fuzzy color $\widetilde{C'}$ is calculated by means of a suitable, application-depending inclusion indicator in the family given by Eq. 12, i.e.,

$$Inc(\widetilde{C}, \widetilde{C'}) = Sub(\widetilde{C}, \widetilde{C'}) = \min_{c \in \widetilde{XYZ}} I(\widetilde{C}(c), \widetilde{C'}(c)) \tag{15}$$

In particular, the degree of inclusion of a Du fuzzy color $\widetilde{C}$ in another Du fuzzy color $\widetilde{C'}$ based on Lukasiewicz's implicator is

$$Inc(\widetilde{C}, \widetilde{C'}) = \min_{c \in \widetilde{XYZ}} \min(1, 1 - \widetilde{C}(c) + \widetilde{C'}(c)) \tag{16}$$

Definition 4.11: The degree of resemblance between two Du fuzzy colors $\widetilde{C}$ and $\widetilde{C'}$ is calculated by means of one function of the family Sim given by Eq. 14, i.e.,

$$R(\widetilde{C}, \widetilde{C'}) = Sim(\widetilde{C}, \widetilde{C'}) \tag{17}$$

[1]A fuzzy implication I is contrapositive if $I(x,y) = I(N_I(y), N_I(x))$ $\forall x, y \in [0,1]$, with N_I being the induced negator of I defined as $N_I(x) = I(x,0)$ $\forall x \in [0,1]$.

c	R (18)	K (19)	Pos (4) Nec (5)
Cu $\widetilde{C}$		K (20) R (21)	Pos (22) Nec (23)
Du $\widetilde{C}$			Pos (10) Nec (11) Inc (15) R (17)

V. THE CASE OF THE RESEMBLANCE RELATION S^0

In this section we consider the particular case of the relation S^0 given by $S^0(\widetilde{C}, \widetilde{C'}) = 1$ iff $\widetilde{C} = \widetilde{C'}$, and 0 otherwise. As explained in the previous section, the resemblance relation S between fuzzy colors is not necessarily obtained from the membership functions of the fuzzy colors. In principle, we assume there is independence between both these aspects, i.e., they are two different types of information to be provided by humans. Whilst membership functions define the compatibility between crisp and fuzzy colors, the resemblance relation S define the semantic resemblance between fuzzy colors, that depend on how a particular use perceive and use them.

Since a fuzzy color space is defined as a partition of a crisp color space using fuzzy colors, it is reasonable to consider that these fuzzy colors are the different groups that may be distinguished and separated. The fact that the partition is fuzzy allows fuzzy colors to be compatible, i.e., to share crisp colors in their support, but this is not incompatible with the view that colors in $\widetilde{XYZ}$ are totally different.

This consideration is useful for building a fuzzy color space by asking users to enumerate the collection of different colors they can clearly distinguish as different. Hence, S^0 is the simplest relation between fuzzy colors and, at the same time, the less computationally complex. In [12] we proposed an approach for defining a fuzzy color space from a collection of color names and a corresponding set of representative crisp colors, one for each name, both sets provided by the user. If the user is asked to provide these sets by assuming S^0 as the resemblance between fuzzy colors, we have in a very simple way all the necessary information for defining a fuzzy color space and for using this space for representing and matching color information for different purposes.

Using S^0, the relations studied in section IV reduce to those referred in Table III. Some expressions (those not involving the similarity between fuzzy colors S) are the same. New formulae are given in equations (18) - (23).

$$R_{\widetilde{XYZ}}(c,c') = \max_{\widetilde{C} \in \widetilde{XYZ}} \min\{\widetilde{C}(c), \widetilde{C}(c')\} \tag{18}$$

$$K(c, \widetilde{C}) = \widetilde{C}(c) \tag{19}$$

$$K(\widetilde{C}, \widetilde{C'}) = \max_{c \in \widetilde{XYZ}} \min\{\widetilde{C}(c), \widetilde{C'}(c)\} \tag{20}$$

$$R(\widetilde{C}, \widetilde{C'}) = 1 \text{ if } C = C',\ 0 \text{ otherwise.} \tag{21}$$

$$pos(K(V,\widetilde{C})|V \text{ is } \widetilde{C'}) = \max_{c\in XYZ} \min\{\widetilde{C}(c), \widetilde{C'}(c)\} \quad (22)$$

$$nec(K(V,\widetilde{C})|V \text{ is } \widetilde{C'}) = 1 - pos(\neg K(V,\widetilde{C})|V \text{ is } \widetilde{C'}) =$$

$$= 1 - \max_{c\in XYZ} \min\{\widetilde{C'}(c), 1-\widetilde{C}(c)\} \quad (23)$$

VI. Conclusions and future work

Our work lies in the framework of Zadeh's Computational Theory of Perceptions [19]. Fuzzy color spaces are intended to represent the collection of terms employed by a particular user, either in general or in a certain application, for describing his/her perception about colors. By representation we understand the (fuzzy) compatibility between crisp colors and these terms, expressed as membership functions defined on a crisp color space. In addition, we consider separately the user's perception of resemblance between colors, the latter seen as abstract notions, by means of a fuzzy relation S. These models allow us to fill the semantic gap between the representation of colors in computers and the perception of colors by humans, and to represent different types of color information. As a consequence, we are able to provide computational procedures for matching color information of different types, something very useful in determining the compatibility between linguistic terms and images for color image description, for image and visual information retrieval, flexible query answering in image databases, etc.

As future work, we shall use the relations introduced here in many applications, in particular for developing image retrieval systems working with linguistic queries and flexible queries to image databases, as well as for identifying visual concepts and the automatic generation of linguistic descriptions of images on the basis of color information [20]. We will also employ these techniques for color image segmentation [21], [22]. Another important future work concerns the study of the computational complexity of calculating the measures proposed in this work, when it is possible to precalculate this information, and how to develop efficient algorithms for using them in practice. Finally, we shall study the semantics of different similarity relations between fuzzy colors, in particular on the basis of hierarchical fuzzy color spaces, a notion that we are currently developing.

***Abstract*—The electro-hydraulic variable rotational speed pump-controlled system (EHVRSPCS) performs specific characteristics on non-linearity and time-varying. An exact model-based controller is difficult to be realized. In this study, the design method and experimental implementation of an adaptive fuzzy controller with on-line self-tuning fuzzy sliding-mode compensation (AFC-STFSMC) are proposed to deal with the system time-varying and non-linear uncertain behaviours by adjusting the control rule parameters. This control strategy employs the adaptive fuzzy approximation technique to design the equivalent controller of the conventional sliding-mode control (SMC). Furthermore, the fuzzy sliding-mode control scheme with self-tuning ability is introduced to compensate the approximation error of the equivalent controller for improving the control performance. The tuning algorithms are derived in the sense of the Lyapunov stability theorem; thus, the stability of the system can be guaranteed. The experimental results show that the AFC-STFSMC can perform excellent positioning control for the EHVRSPCS.**

Keywords: electro-hydraulic pump-controlled system, AC servo motor, fuzzy sliding mode control, adaptive fuzzy, sliding-mode control

I. INTRODUCTION

Hydraulic servo systems are widely used in the industry due to the advantages of high power-weight ratio, large driving forces, high response and good conduction of heat out of components by pressure fluid. However, oil viscosity, friction force, and leakage cause highly nonlinear time-variant dynamics, load sensitivity and parameter uncertainty in the hydraulic servo control systems result in the control complexity and difficulty [1-2]. In view of the hydraulic circuits, two different hydraulic systems are classified as the high-response but low-energy efficiency hydraulic valve-controlled system and the high-energy efficiency but lower response hydraulic pump-controlled system. The hydraulic valve-controlled systems have been applied widely in the industrial servo control. And, recently, the investigations on high response pump-controlled systems driven by AC servo motors or switch reluctance motor are introduced [3]. Helduser [3] first presented the concept of hydraulic pump-controlled system, driven by gear pumps and AC servo motors with variable rotational speed for injection moulding machines in 1995. Ruhlicke [4] studied the position control of asymmetrical cylinder with double pump-controlled system driven by AC servo motor with variable rotational speed, which the position accuracy, about 50μm, is still unsatisfactory. Kazmeier and Feldmann [5] used Fuzzy control to study the pump-controlled system with variable rotational speed for positioning control with small power, max. 330W, and small stroke 0,5mm. Helduser [6] developed an electric-hydrostatic drive using AC servo motor and constant displacement internal gear pump for energy-saving power and motion control system. In recent years, AC servo motors combined with internal gear pumps were used mostly, and they can reach 50μm accuracy in position control. New applications of the high response in different hydraulic servo machines are still being developed. Therefore, this paper aims to investigate the position control performance of the high response pump-controlled system driven by an AC servo motor with variable rotational speed. Instead of internal gear pumps, a constant displacement axial piston pump is used in this paper for positioning control of hydraulic servo machines.

The classical SMC [7-9] have been proposed for solving the hydraulic servo control problems during the past decades. However, the drawbacks of classical SMC, such as chattering, large control effort and difficulty for deciding the equivalent control, limit its practical applicability. Moreover, the boundary of the uncertainty has to be estimated in order to guarantee the stability of the SMC systems. Thus, the SMC systems are still difficulty in real-world applications.

The fuzzy control, which doesn't require mathematical models of the system, has been used in several industrial applications. Zhao and Vivalo [10-11] developed a fuzzy state controller for a hydraulic position servo system with unknown load. Deticek [12] proposed an intelligent position control of electro-hydraulic drive using hybrid FC structure. The design of a traditional fuzzy controller mostly depends on expert experience for establishing the fuzzy rule base However, for complex systems there are no guide rules for designing the fuzzy rule base and parameters. Thus, self-tuning algorithms were introduced in FC for adjusting fuzzy parameters and improving the control performance based upon a specified performance index [13-14]. However, a complicated learning mechanism or a specific performance decision table designed by trial-and-error is required. Thus, its application still presents certain difficulty, and the large amount of the fuzzy rules also makes the analysis complex.

For reducing the fuzzy rules in FC, FC design methods based on SMC scheme, namely fuzzy sliding-mode control (FSMC), have proposed [15-16]. Since only one variable is defined as the fuzzy input variable, the main advantage of FSMC lies in less fuzzy rules than FC. Although FC and FSMC are both effective design methods, their major drawback is that the fuzzy rules should be previously tuned by time-consuming trial-and-error procedures. In order to tackle this problem, adaptive fuzzy control (AFC) based on the Lyapunov synthesis approach has been extensively studied [17-18]. With this approach, the fuzzy rules can be automatically adjusted to achieve system response by an adaptive law.

The objective of this paper is forcing on experimental implementation of the adaptive fuzzy controller with self-tuning fuzzy sliding-mode compensation (AFC-STFSMC) for the positioning control with high response in the EHVRSPCS. The AFC-STFSMC combines the adaptive fuzzy control and the self-tuning fuzzy sliding-mode control scheme. The adaptive fuzzy approximation method is to establish the unknown equivalent controller for releasing the model-based requirement. Furthermore, the fuzzy sliding-mode control scheme with self-tuning ability is introduced to compensate the function approximation error of the equivalent controller for improving the control performance and reducing the implementation difficulty. The AFC-STFSMC approach comprises the advantages of which the fuzzy rules can be automatically adjusted, similar to AFC, and can reduce the fuzzy rules, like FSMC. All controller parameters of this scheme are tuned in the Lyapunov sense, thus the stability of the system can be guaranteed.

II. FORMULATION OF ELECTRO-HYDRAULIC VARIABLE ROTATIONAL SPEED PUMP-CONTROLLED SYSTEM

The EHVRSPCS is designed and set up for investigating the dynamic performance and control effect. The test rig layout of the EHVRSPCS is shown in Fig.1. The hydraulic servo cylinder system of EHVRSPCS contains a double-rod symmetrical hydraulic cylinder fitted with a linear encoder with the resolution of 0.1 μm. The hydraulic power supply system, which consists of a swash plate axial piston pump with constant displacement of 12 ml/rev and is driven by an AC servo motor of 7.0 kW, adjusts the supply volume flow by the rotational speed controlled by the AC servo motor. The mathematics models of the main elements in this system are discussed as below:

(a) Servo motor control unit

The servo motor control unit proportionally transfers the input voltage into the rotational speed of the servo motor, and can be described as

$$\omega = K_a \cdot u \tag{1}$$

where w indicates the rotational speed of the servo motor, K_a is the gain of servo control unit and u is the input voltage.

(b) Swash plate axial piston pump with constant displacement

The pump volumetric displacement of the swash plate axial piston pump D_l is supposed to be constant. The load volume flow Q_l from the pump to the controlled hydraulic cylinder can be described as

$$Q_l = D_l \cdot w - C_l \cdot P_l \tag{2}$$

where w indicates the pump rotational speed, C_l is the leakage coefficient of the pump, P_l is the load pressure.

(c) The controlled cylinder

The continuity equation of the controlled cylinder chamber is given by

$$Q_l = A_p \dot{x}_p + C_t P_l + \left(\frac{V_t}{4\beta_e} \right) \dot{P}_l \tag{3}$$

where A_p is the effective area of piston, x_p is the position of piston rod, C_t is the leakage coefficient of cylinder, V_t is the total compressed volume and β_e is the effective bulk modulus of hydraulic oil. Substituting Eq. (1) and Eq. (2) into Eq. (3), we have

$$D_l \cdot k_a \cdot u = A_p \dot{x}_p + \left(C_l + C_t \right) P_l + \left(\frac{V_t}{4\beta_e} \right) \dot{P}_l \tag{4}$$

According to the Newton's 2nd law, the motion equation of controlled cylinder on position control can be derived as

$$A_P P_l - f_l = M \ \ddot{x}_P + B\dot{x}_P + Kx_P \tag{5}$$

where M indicates the total mass of piston, rod and load, B is the viscous damping coefficient, K is the spring constant and f_l is the arbitrary load force on piston. By combining Eqs. (1)-(5), the state equations of the EHVRSPCS model can be achieved as follows

$$\begin{aligned} \dot{x}_1 &= x_2(t) \\ \dot{x}_2 &= x_3(t) \\ \dot{x}_3 &= -\sum_1^3 a_i x_i(t) + g(\underline{x})u + d(\underline{x}) = f(\underline{x}) + g(\underline{x})u + d(\underline{x}) \end{aligned} \tag{6}$$

where

$$\underline{x}(t) = \left[x_1(t) \quad x_2(t) \quad x_3(t) \right]^T = \left[x_p(t) \quad \dot{x}_p(t) \quad \ddot{x}_p(t) \right]^T$$

$$a_1(t)=\frac{4\beta_e(C_l+C_t)K}{MV_t} \quad a_2(t)=\frac{K}{M}+\frac{4\beta_e A_p^2}{MV_t}+\frac{4\beta_e(C_l+C_t)B}{MV_t}$$

$$a_3(t)=\frac{B}{M}+\frac{4\beta_e(C_l+C_t)}{V_t},\ g(\underline{x})=\frac{4A_p\beta_e D_l K_a}{MV_t}$$

$$d(\underline{x})=-(\frac{4\beta_e(C_l+C_t)}{V_t M}f_l+\frac{1}{M}\dot{f}_l)$$

in which $g(\underline{x})$ is a constant with positive value.

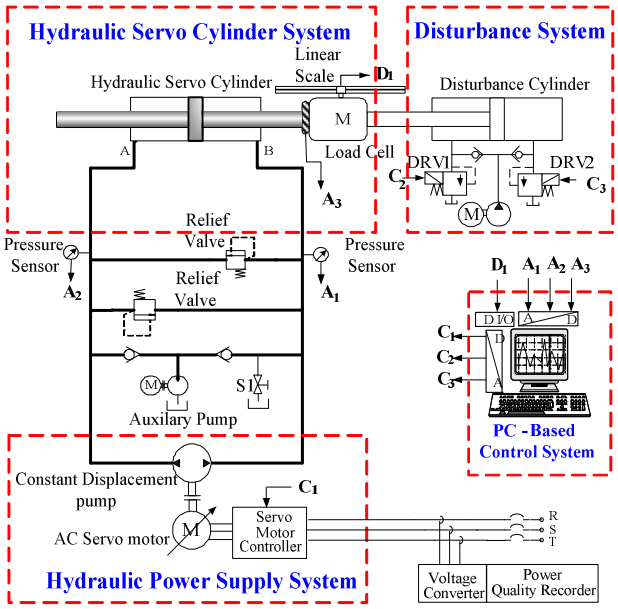

Fig. 1: Layout of the electro-hydraulic variable rotational speed pump-controlled system

III. CONTROLLER DESIGN AND STABILITY ANALYSIS

The design of a sliding mode controller requires the system models and has to find the inverse form of the inertia term in system dynamics. However, the accurate mathematical models are sometimes difficult to be formulated or even not available. To solve these problems, an AFC-STFSMC is proposed in this paper for realizing the positioning control in EHVRSPCS. The block diagram of the AFC-STFSMC control system for EHVRSPCS is shown in Fig.2 in the last page.

A. Fuzzy control

According to the definitions [12], the basic configuration of fuzzy logic systems consists of four components: a fuzzifier, a fuzzy rule base, a fuzzy inference engine and a defuzzifier. In this paper single-input single-output rules will be used in formulation of the control law. Assume that there are *n* rules in a fuzzy base and each of them has the following form:

$$R^i: \text{IF } S \text{ is } F^i \text{ THEN } u \text{ is } \alpha_i \qquad (7)$$

where S is the input variable of the fuzzy system; u is the output variable of the fuzzy system; F^i are the triangular-type membership functions; and α_i are the singleton control actions for $i=1,2,...,n$. The defuzzification of the FC output is accomplished by the method of center-of-gravity [12]

$$u=\frac{\sum_{i=1}^{n}\alpha_i\times w_i}{\sum_{i=1}^{n}w_i}=\underline{\alpha}^T\underline{\xi} \qquad (8)$$

where w_i is the firing weight of the *i*th rule, $\underline{\alpha}=[\alpha_1,\alpha_2,...,\alpha_n]^T$ is the parameter vector and $\underline{\xi}=[\xi_1,\xi_2,...,\xi_n]^T$ is the vector of fuzzy basis functions

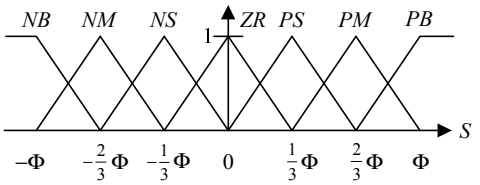
$$\xi_i=\frac{w_i}{\sum_{i=1}^{n}w_i} \qquad (9)$$

In conventional FC, the control actions α_i should be previously assigned through a lot of trails for achieving satisfactory control performance. In this paper, an adaptive algorithm will be proposed to tune these control actions on-line.

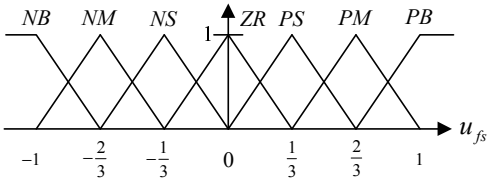
B. Fuzzy Sliding-Mode Control

Hwang *et al.* [13] proposed the methods to design the fuzzy sliding-mode controller for a non-linear system with 2nd order where the error and the error change rate were used to synthesize fuzzy reasoning rules. However, the rule number was larger and did not give the mathematical expression. Thus, it is difficult to analyze the properties of the control system. To overcome this problem, this paper adopts the sliding surface $S=0$ of SMC and extends it to the fuzzy sliding surface $\tilde{S}=\tilde{0}$, and make S be a linguistic description of $\tilde{S}$. In this study the two triangular-typed functions are used to define the membership functions of IF-part and THEN-part, which are depicted in Figs.3 (a) and 3(b) respectively. The fuzzy rules are given in the following form

$$R^l: \text{IF } S \text{ is } \tilde{F}_s^l \text{ THEN } u_{fs} \text{ is } \tilde{F}_u^{8-l},\ l=1,...,7. \qquad (10)$$



(a)



(b)

Figs.3 Fuzzy partitions and membership functions of S and u_{fs} in the respective universe of discourse

According to the sup-min compositional rule of inference and the defuzzification of the control output accomplished by the method of center-of-area, the mathematical expression can be derived as

$$u_{fs}=\begin{cases} 1 & ,if \quad z<-1 \\ \dfrac{7.5z^2+13.5z+5}{9z^2+15z+5} & ,if \quad -1\le z<-\dfrac{2}{3} \\ \dfrac{9z^2+11z+2}{18z^2+18z+2} & ,if \quad -\dfrac{2}{3}\le z<-\dfrac{1}{3} \\ \dfrac{1.5z^2+1.5z}{9z^2+3z-1} & ,if \quad -\dfrac{1}{3}\le z<0 \\ \dfrac{-1.5z^2+1.5z}{9z^2-3z-1} & ,if \quad 0\le z<\dfrac{1}{3} \\ \dfrac{-9z^2+11z-2}{18z^2-18z+2} & ,if \quad \dfrac{1}{3}\le z<\dfrac{2}{3} \\ \dfrac{-7.5z^2+13.5z-5}{9z^2-15z+5} & ,if \quad \dfrac{2}{3}\le z<1 \\ -1 & ,if \quad z\ge 1 \end{cases} \tag{11}$$

where $z=\dfrac{S}{\Phi}$, and as $|S|\ge\Phi$, it is easy to check $u_{fs}=-\mathrm{sgn}(S)$.

C. Adaptive Fuzzy Controller with Self-Tuning Fuzzy Sliding-Mode Compensation

The control objective is to find a control law that can make the hydraulic actuator of EHVRSPCS tracking the desired target $x_d(t)$. Define the tracking error $e(t)$ as

$$e(t)=x_d(t)-x(t) \tag{12}$$

where $x(t)$ indicates the control output and $x_d(t)$ is the desired target. Define a sliding surface as

$$S(t)=\ddot{e}(t)+k_1\dot{e}(t)+k_2e(t) \tag{13}$$

where k_1 and k_2 are non-zero positive constants. Assume that parameters of the system in Eq. (6) are well known and the external load disturbance is measurable, then the control law can be defined as

$$u^*=g^{-1}(\underline{x})[\eta S_\Delta(t)-f(\underline{x})-d(\underline{x})+\ddot{x}_d+k_1\ddot{e}(t)+k_2\dot{e}(t)] \tag{14}$$

where $S_\Delta(t)=S(t)-\Phi sat(S(t)/\Phi)$ and Φ is the boundary layer width of the sliding surface S. The properties of the function S_Δ that are useful in the design of adaptive law [14] are described as below.

Property1: As $|S|>\Phi,\ \Rightarrow |S_\Delta|=|S|-\Phi$ and $\dot{S}_\Delta=\dot{S}$.

Property2: When $|S|\le\Phi,\ \Rightarrow S_\Delta=\dot{S}_\Delta=0$.

The above properties of the boundary layer concept are exploited in the design of controller to cease adaptation as soon as the boundary layer is reached and to avoid the possibility of unbounded growth. Differentiating Eq. (13), we have

$$\dot{S}(t)=-f(\underline{x})-g(\underline{x})u-d(\underline{x})+\dddot{x}_d+k_1\ddot{e}(t)+k_2\dot{e}(t) \tag{15}$$

Substituting Eq. (16) into Eq.(17) gives

$$\dot{S}(t)+\eta S_\Delta(t)=0,\qquad \eta>0. \tag{16}$$

Equation (16) shows that $\underline{e}(t)=[e(t),\dot{e}(t),\ddot{e}(t)]$ will converge to the neighborhood of zero as $t\to\infty$, and the value of the neighborhood depends on the value of Φ [19]. However, the system parameters may be unknown or perturbed; the controller u^* cannot be precisely implemented. Therefore, in accordance with the universal approximation theorem [11], for any $\rho^*>0$, an optimal fuzzy control $\hat{u}_{fz}(S,\underline{\alpha}^*)$ exists in the form of Eq. (10) that satisfies

$$\left|u^*-\hat{u}_{fz}(S,\underline{\hat{\alpha}}^*)\right|=\rho^* \tag{17}$$

where ρ^* is assumed to be bounded by $|\rho^*|\le M$. Utilize a fuzzy controller $\hat{u}_{fz}(S,\underline{\hat{\alpha}})$ to approximate u^* as

$$\hat{u}_{fz}(S,\underline{\hat{\alpha}})=\underline{\hat{\alpha}}^T\underline{\xi} \tag{18}$$

where $\underline{\hat{\alpha}}$ is the estimated values of $\underline{\alpha}^*$. The control law for the developed AFC-STFSMC is defined as the following form:

$$u=\hat{u}_{fz}(S,\underline{\hat{\alpha}})+u_{comp}(S) \tag{19}$$

where the fuzzy controller $\hat{u}_{fz}$ is designed to approximate the control u^* and the fuzzy sliding-mode compensation u_{comp} is proposed to compensate the difference between the controller u^* and fuzzy controller $\hat{u}_{fz}(S,\underline{\hat{\alpha}})$. Through Eqs. (14), (15) and (19), the dynamical equation can be derived as:

$$\dot{S}(t)+\eta S_\Delta(t)=g[u^*-\hat{u}_{fz}(\mathrm{S},\underline{\hat{\alpha}})-u_{rb}(S)] \tag{20}$$

In order to derive the adaptive laws for ensuring convergence to the boundary layer, a candidate Lyapunov function is defined as:

$$V(S_\Delta,\underline{\tilde{\alpha}},\tilde{\rho})=\frac{1}{2}\frac{S_\Delta^2}{g}+\frac{1}{2\eta_1}\underline{\tilde{\alpha}}^T\underline{\tilde{\alpha}}+\frac{1}{2\eta_2}\tilde{\rho}^2 \tag{21}$$

where $\underline{\tilde{\alpha}}^{\mathrm{T}}=\underline{\hat{\alpha}}^{*\mathrm{T}}-\underline{\hat{\alpha}}^{\mathrm{T}}$ and $\tilde{\rho}=\rho^*-\hat{\rho}$ are the approximation error of the parameter vectors $\underline{\hat{\alpha}}^{*\mathrm{T}}$ and ρ^* respectively. In addition, η_1 and η_2 are positive constants. Differentiate Eq. (21) with respect to time as

$$\dot{V}(S_\Delta,\underline{\tilde{\alpha}},\tilde{\rho})=\frac{S_\Delta\dot{S}_\Delta}{g}+\frac{1}{\eta_1}\underline{\tilde{\alpha}}^T\underline{\dot{\tilde{\alpha}}}+\frac{1}{\eta_2}\tilde{\rho}\dot{\tilde{\rho}}. \tag{22}$$

Thus, if $|S|\le\Phi$, then $S_\Delta=0$, it follows $\dot{V}(S_\Delta,\underline{\tilde{\alpha}},\tilde{\rho})=0$. If $|S|>\Phi$, then $\dot{S}_\Delta=\dot{S}$. By substituting Eq. (20) into Eq. (22), Eq. (23) can be obtained

$$\dot{V}(S_\Delta,\underline{\tilde{\alpha}},\tilde{\rho})=-\eta\frac{S_\Delta^2}{g}+S_\Delta[u^*-\hat{u}_{fz}(S,\underline{\hat{\alpha}})]-S_\Delta u_{rb}(S)+\frac{1}{\eta_1}\underline{\tilde{\alpha}}^T\dot{\underline{\tilde{\alpha}}}+\frac{1}{\eta_2}\tilde{\rho}\dot{\tilde{\rho}}$$
$$=-\eta\frac{S_\Delta^2}{g}+S_\Delta[u^*-\hat{u}_{fz}(S,\underline{\hat{\alpha}}^*)+\hat{u}_{fz}(S,\underline{\hat{\alpha}}^*)-u_{fz}(S,\underline{\hat{\alpha}})]-S_\Delta u_{rb}(S)+\frac{1}{\eta_1}\underline{\tilde{\alpha}}^T\dot{\underline{\tilde{\alpha}}}+\frac{1}{\eta_2}\tilde{\rho}\dot{\tilde{\rho}}$$
$$\le-\eta\frac{S_\Delta^2}{g}+|S_\Delta|\left|u^*-\hat{u}_{fz}(S,\underline{\hat{\alpha}}^*)\right|+S_\Delta[\hat{u}_{fz}(S,\underline{\hat{\alpha}}^*)-\hat{u}_{fz}(S,\underline{\hat{\alpha}})]-S_\Delta u_{rb}(S)+\frac{1}{\eta_1}\underline{\tilde{\alpha}}^T\dot{\underline{\tilde{\alpha}}}+\frac{1}{\eta_2}\tilde{\rho}\dot{\tilde{\rho}}$$
$$=-\eta\frac{S_\Delta^2}{g}+[|S_\Delta|\rho^*-S_\Delta u_{rb}(S)-\frac{1}{\eta_2}\tilde{\rho}\dot{\hat{\rho}}]+\underline{\tilde{\alpha}}^T(S_\Delta\xi(S)-\frac{1}{\eta_1}\dot{\underline{\hat{\alpha}}}) \tag{23}$$

For achieving $\dot{V}(S_\Delta,\underline{\tilde{\alpha}},\tilde{\rho})\le 0$, the adaptive laws of AFC-STFSMC are chosen as

$$\dot{\underline{\hat{\alpha}}}=\eta_1\cdot S_\Delta\cdot\xi(S) \tag{24}$$

$$u_{comp}(S)=-\hat{\rho}\cdot u_{fs} \tag{25}$$

$$\dot{\hat{\rho}}=\eta_2\cdot|S_\Delta| \tag{26}$$

Thus Eq. (23) can be rewritten as

$$\dot{V}(S_\Delta,\underline{\tilde{\alpha}},\tilde{\rho})\le-\eta\cdot\frac{S_\Delta^2}{g}\le 0 \tag{27}$$

Equations (24)-(27) guarantee only $S_\Delta\in L_\infty$ but don't guarantee convergence. Integrating both sides of (27) and using some derivation, we have

$$\int_0^\infty S_\Delta^2 dt\le\frac{V(S_\Delta(\infty),\underline{\tilde{\alpha}},\tilde{\rho})-\dot{V}(S_\Delta(0),\underline{\tilde{\alpha}},\tilde{\rho})}{\frac{\eta}{g}}. \tag{28}$$

Since the right side of Eq. (28) is bounded, $S_\Delta\in L_2$. Using Barbalat's lemma [19], $\lim_{t\to\infty}S_\Delta=0$ can be shown. That means that the inequality $|S|\le\Phi$ is obtained asymptotically, so the tracking error $e(t)$ converges to neighborhood of zero. In summary, AFC-STFSMC is derived in Eq. (19), where $\hat{u}_{fz}$ is given in Eq. (18) with the parameters $\underline{\hat{\alpha}}$ adjusted by Eq. (24) and u_{comp} is given in Eq. (25) with the parameter $\hat{\rho}$ adjusted by Eq. (26). By applying these adaptive laws, the controller of Eq. (19) can be guaranteed the EHVRSPCS to be stable.

IV. EXPERIMENTS

For verifying the control performance of the proposed AFC-STFSMC controller, the positioning control experiments in EHVRSPCS are implemented under different strokes and different external loadings.

(a) Positioning control at different strokes with external loading force

The experiment is respectively achieved for different stroke set points such as 100, 200 and 300 mm with external loading force 30kN. Fig.4 shows the response for different strokes. The experimental results show that the piston of cylinder can, at different strokes with loading force 30kN, reach the set point within a little overshoot 18μm and remain the steady state error within 10μm.

(b) Positioning control under different loading conditions

For confirming the control performance under different external loading conditions, the experiments of position control under three constant external loading conditions, such as 10kN, 30kN and 50kN, are investigated. Fig.5 indicates the step responses of the position control of 300 mm stroke with different loadings. The experimental results show that the piston of cylinder can, under 10kN and 30kN loading conditions, reach the set point within a little overshoot 14μm and remain the steady state error within 3.6μm. Even under 50kN loading condition, the piston can reach the set point within 38μm overshoot and remain the steady state error within 17μm.

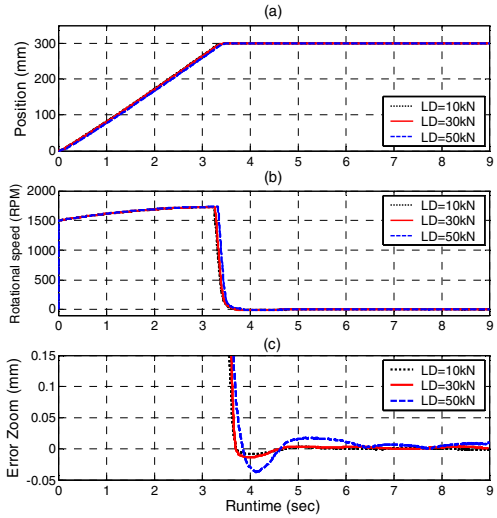

Fig.5: Experimental results of positioning control of 300mm stroke with different loadings in variable rotational speed pump-controlled system: (a) position control response (b) controller input (c) control error

V. CONCLUSIONS

This paper develops a new EHVRSPCS driven by an AC servo motor for realizing motion control of hydraulic servo machines with high response. The swash plate axial piston pump with constant displacement combines with the AC servo motor due to the better response, instead of the internal gear pump used in [3-6]. The positioning control in different loading conditions are implemented and verified experimentally for EHVRSPCS in this paper. For achieving better control performance, an AFC-STFSMC is proposed for positioning control of the EHVRSPCS. The AFC-STFSMC strategy combining with the adaptive fuzzy control and the self-tuning fuzzy sliding-mode control scheme is comprised of the adaptive fuzzy approximation technique to establish the equivalent controller of the traditional SMC and the FSMC scheme with self-tuning ability for compensating the approximation error of equivalent controller and external disturbance. Excellent self-adaptability with regard to various strokes and uncertain external disturbance force are verified experimentally.

***Abstract*—Explanation ability of a fuzzy rule-based classifier is its ability to explain why an input pattern is classified as a particular class in a convincing way. This ability is important especially when fuzzy rule-based classifiers are used as support systems for human users. This is because human users often want to know why the current input pattern is classified as a particular class. The explanation ability looks similar to the interpretability. They are, however, clearly different concepts. Whereas the explanation ability is directly related to the classification of each pattern, the interpretability is usually independent of classification results. The interpretability has been taken into account in multiobjective design of fuzzy rule-based classifiers. However, the explanation ability has not been used for fuzzy rule-based classifier design. This is because its quantitative definition is very difficult. In this paper, we discuss various factors that are related to quantitative definition of the explanation ability of fuzzy rule-based classifiers. Using simple numerical examples, we explain that the complexity minimization of fuzzy rule-based classifiers does not always lead to the explanation ability maximization. We also explain that the accuracy of fuzzy rules is related to the explanation ability.**

Keywords—pattern classification; fuzzy systems; fuzzy rule-based classifiers; explanation ability; interpretability; complexity.

I. INTRODUCTION

Fuzzy rule-based classifier design has been often handled as the search for accurate and interpretable fuzzy rule-based classifiers. That is, accuracy and interpretability have been used as design criteria in fuzzy rule-based classifier design. These two criteria are combined into a single overall criterion in single-objective approaches [1]-[4] whereas they are handled as different objectives in multiobjective approaches [5]-[9]. Since there exists a tradeoff relation between these two criteria [10], multiobjective approaches usually find a large number of non-dominated fuzzy rule-based classifiers with different tradeoffs (i.e., from simple classifiers with high interpretability and low accuracy to complicated classifiers with high accuracy and low interpretability). It is implicitly assumed that a single fuzzy rule-based classifier is chosen from a large number of obtained non-dominated ones by human users based on their preference in multiobjective approaches. In single-objective approaches, parameter values in a single overall design criterion are often assumed to be specified by human users' preference.

In some early studies on multiobjective fuzzy rule-based classifier design [5], [6], interpretability maximization was formulated as complexity minimization using complexity measures such as the number of fuzzy rules and the total number of antecedent conditions (i.e., total rule length). Recently more sophisticated interpretability measures have been used in multiobjective approaches to fuzzy rule-based classifier design [7]-[9]. Definition of interpretability itself is currently a hot research issue in fuzzy systems [11]-[19].

Whereas the interpretability of fuzzy rule-based classifiers has been frequently discussed in the literature [11]-[19], the explanation ability has not been discussed in many studies [20]-[24]. In this paper, we use the term "*explanation ability*" to mean the ability of a fuzzy rule-based classifier to explain why an input pattern is classified as a particular class in a convincing way. It should be noted that the interpretability and the explanation ability are different concepts. On the one hand, the interpretability of a fuzzy rule-based classifier is often defined by its structural features (e.g., the shape of membership functions, the overlap of adjacent membership functions, the number of fuzzy rules, and the number of antecedent conditions) independent of the classification of each pattern. On the other hand, the explanation ability is directly related to classification results from its definition: the ability of a fuzzy rule-based classifier to explain why an input pattern is classified as a particular class in a convincing way.

In this paper, we discuss various factors that are related to quantitative definition of the explanation ability of a fuzzy rule-based classifier. We assume the use of a single winner-based fuzzy reasoning method for pattern classification. This means that each input pattern is classified by a single winner rule. Thus the explanation of the classification result of an input pattern is performed by showing the corresponding single winner rule. In this situation, the following factors seem to be related to the explanation ability:

(1) Compatibility of the input pattern with its winner rule: If the winner rule has high compatibility with the input pattern, it may have high explanation ability since its antecedent conditions can be viewed as describing the input pattern very well (i.e., without large inconsistency).
(2) Interpretability of the winner rule: If the winner rule has high interpretability, it may have high explanation ability since the explanation is easy for human users to understand.
(3) Accuracy of the winner rule: If the winner rule has high accuracy, it may have high explanation ability since the

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

classification result is highly reliable.

(4) Coverage of the winner rule: If the winner rule classifies many patterns, it may have high explanation ability since the same explanation is applicable to many patterns.

For discussing these factors, this paper is organized as follows. First we explain our fuzzy rule-based classifier with the single winner-based fuzzy reasoning method in Section II. Then we discuss mathematical formulations of the above-mentioned four factors in details in Section III using simple numerical examples. Finally we conclude this paper in Section IV where we also suggest some future research directions.

II. Fuzzy Rule-Based Classifiers

We assume that we have an M-class pattern classification problem in an n-dimensional normalized hyper-cube $[0, 1]^n$. For this problem, we use fuzzy rules of the following type:

$$\text{Rule } R_q: \text{If } x_1 \text{ is } A_{q1} \text{ and } \ldots \text{ and } x_n \text{ is } A_{qn} \text{ then Class } C_q \text{ with } CF_q, \quad (1)$$

where R_q is the label of the qth fuzzy rule, $\mathbf{x}=(x_1, \ldots, x_n)$ is an n-dimensional pattern vector, A_{qi} is an antecedent fuzzy set $(i=1,2,\ldots,n)$, C_q is a class label, and CF_q is a real number in the unit interval [0, 1] which represents a rule weight. The rule weight can be specified by a heuristic manner [25]. It can be also adjusted by a learning algorithm [26]. We use the n-dimensional fuzzy vector $\mathbf{A}_q=(A_{q1}, \ldots, A_{qn})$ for representing the antecedent part of the fuzzy rule R_q in (1) in a concise manner.

Let S be a set of fuzzy rules of the type in (1). That is, S is a fuzzy rule-based classifier. When an n-dimensional input pattern $\mathbf{x}_p=(x_{p1}, \ldots, x_{pn})$ is presented to S, first the compatibility grade of $\mathbf{x}_p$ with the antecedent part $\mathbf{A}_q$ of each fuzzy rule R_q in S is calculated by the product operator as

$$\mu_{\mathbf{A}_q}(\mathbf{x}_p) = \mu_{A_{q1}}(x_{p1}) \times \cdots \times \mu_{A_{qn}}(x_{pn}) \quad \text{for } R_q \in S, \quad (2)$$

where $\mu_{Aqi}(.)$ shows the membership function of A_{qi}. Then a single winner rule $R_{w(\mathbf{x}_p)}$ is identified for $\mathbf{x}_p$ as follows:

$$CF_{w(\mathbf{x}_p)} \times \mu_{\mathbf{A}_{w(\mathbf{x}_p)}}(\mathbf{x}_p) = \max\{CF_q \times \mu_{\mathbf{A}_q}(\mathbf{x}_p) \mid R_q \in S\}, \quad (3)$$

where $w(\mathbf{x}_p)$ denotes the rule index of the winner rule for $\mathbf{x}_p$.

The pattern $\mathbf{x}_p$ is classified by the single winner rule $R_{w(\mathbf{x}_p)}$ as its consequent class. If there is no fuzzy rule with a positive compatibility grade with $\mathbf{x}_p$ (i.e., if $\mathbf{x}_p$ is not covered by any fuzzy rules in S), the classification of $\mathbf{x}_p$ is rejected. The classification of $\mathbf{x}_p$ is also rejected if multiple fuzzy rules with different consequent classes have the same maximum value in the right-hand side of (3). In this case, $\mathbf{x}_p$ is exactly on the classification boundary between the different classes.

We use the single winner-based fuzzy reasoning method in (3) for pattern classification. This is because a responsible fuzzy rule can be always identified for the classification result of each input pattern when we use the single winner-based fuzzy reasoning method. For other fuzzy reasoning methods (e.g., a voting-based method), see [27]-[29] where other types of fuzzy rules (e.g., fuzzy rules with no rule weights, fuzzy rules with multiple consequent classes) were also explained.

III. Explanation Ability

In this section, we discuss each of the four factors related to the explanation ability of a fuzzy rule-based classifier in detail: compatibility, interpretability, accuracy and coverage.

A. A Simple Test Problem and Fuzzy Rule-Based Classifiers

For visual explanation, let us consider a simple three-class two-dimensional pattern classification problem with 20 patterns from each class in Fig. 1. Using three linguistic values (*small*, *medium* and *large*) in Fig. 1 as antecedent fuzzy sets for each of the two attributes, we can generate 3×3 fuzzy rules. Let S_1 be the fuzzy rule-based classifier with those nine fuzzy rules (for simplicity, the rule weight is specified as 1.0 in S_1):

S_1: Fuzzy rule-based classifier with nine fuzzy rules

R_1: If x_1 is *small* and x_2 is *small* then Class 2 with 1.0,
R_2: If x_1 is *small* and x_2 is *medium* then Class 2 with 1.0,
R_3: If x_1 is *small* and x_2 is *large* then Class 1 with 1.0,
R_4: If x_1 is *medium* and x_2 is *small* then Class 2 with 1.0,
R_5: If x_1 is *medium* and x_2 is *medium* then Class 2 with 1.0,
R_6: If x_1 is *medium* and x_2 is *large* then Class 1 with 1.0,
R_7: If x_1 is *large* and x_2 is *small* then Class 3 with 1.0,
R_8: If x_1 is *large* and x_2 is *medium* then Class 3 with 1.0,
R_9: If x_1 is *large* and x_2 is *large* then Class 3 with 1.0.

The location of each rule is shown in Fig. 2 (a). All the 60 patterns in Fig. 1 are correctly classified by S_1 with these nine rules in S_1 as shown in Fig. 3 (a).

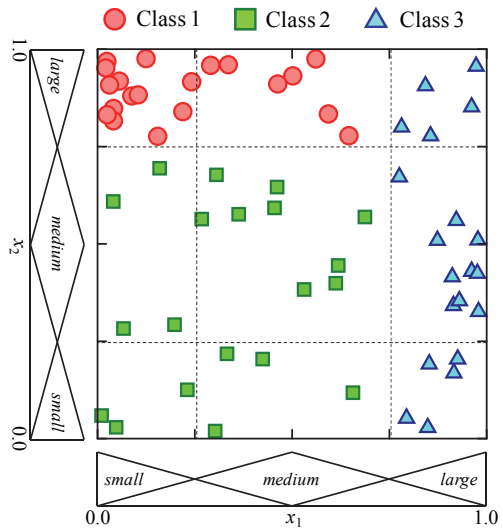

Fig. 1. A simple three-class two-dimensional test problem.

Let us try to simplify the fuzzy rule-based classifier S_1. We can see from Fig. 1 that all training patters with large values of x_1 are from Class 3. Accordingly, the last three fuzzy rules R_7, R_8 and R_9 in S_1 with the same antecedent condition "x_1 is *large*" have the same consequent class (i.e., Class 3). This

observation suggests us to combine the last three rules R_7, R_8, and R_9 of S_1 into a single fuzzy rule:

R_{789}: If x_1 is *large* then Class 3 with 1.0.

Using this fuzzy rule, S_1 can be simplified as follows:

S_2: Fuzzy rule-based classifier with seven fuzzy rules

R_1: If x_1 is *small* and x_2 is *small* then Class 2 with 1.0,
R_2: If x_1 is *small* and x_2 is *medium* then Class 2 with 1.0,
R_3: If x_1 is *small* and x_2 is *large* then Class 1 with 1.0,
R_4: If x_1 is *medium* and x_2 is *small* then Class 2 with 1.0,
R_5: If x_1 is *medium* and x_2 is *medium* then Class 2 with 1.0,
R_6: If x_1 is *medium* and x_2 is *large* then Class 1 with 1.0,
R_{789}: If x_1 is *large* then Class 3 with 1.0.

This fuzzy rule-based classifier S_2 is illustrated in Fig. 2 (b). All the 60 patterns in Fig. 1 are correctly classified by S_2 as shown in Fig. 3 (b). From Fig. 3 (a) and Fig. 3 (b), we can see that S_1 and S_2 have slightly different classification boundaries.

If we use the negation of *large* (i.e., "*not large*") in the antecedent part, the number of fuzzy rules in S_2 can be further decreased as follows:

S_3: Fuzzy rule-based classifier with three fuzzy rules

R_{1245}: If x_1 is *not large* and x_2 is *not large*
then Class 2 with 1.0,
R_{36}: If x_1 is *not large* and x_2 is *large* then Class 1 with 1.0,
R_{789}: If x_1 is *large* then Class 3 with 1.0.

The membership function of "*not large*" is defined as

$$\mu_{not\ large}(x) = 1 - \mu_{large}(x) \quad for\ 0 \le x \le 1, \tag{4}$$

where $\mu_{large}(x)$ is the membership function of the antecedent fuzzy set *large*.

The fuzzy rule-based classifier S_3 with the three fuzzy rules is illustrated in Fig. 2 (c). All the 60 patterns are correctly classified by S_3 as shown in Fig. 3 (c). From Fig. 3 (a)-(c), we can see that the three fuzzy rule-based classifiers S_1, S_2 and S_3 have slightly different classification boundaries.

The fuzzy rule-based classifier S_3 can be viewed as having the following tree-structure:

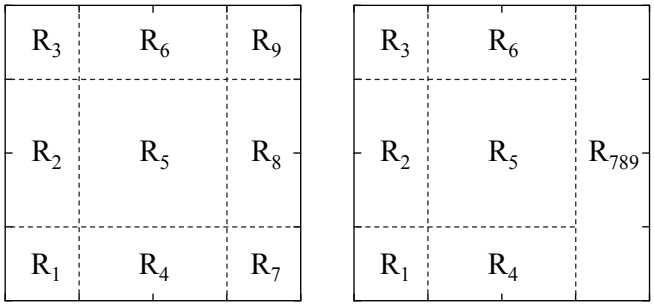
If x_1 is *large* then Class 3 with 1.0,
else if x_2 is *large* then Class 1 with 1.0,
else Class 2 with 1.0. (5)

A simple fuzzy rule-based classifier can be also obtained by selecting fuzzy rules from S_1 rather than combining fuzzy rules. For example, the following fuzzy rule-based classifier with four fuzzy rules has the same classification boundaries as S_1 with the nine fuzzy rules (see Fig. 2 (d) and Fig. 3 (d)):

S_4: Fuzzy rule-based classifier with four fuzzy rules

R_5: If x_1 is *medium* and x_2 is *medium* then Class 2 with 1.0,
R_6: If x_1 is *medium* and x_2 is *large* then Class 1 with 1.0,
R_8: If x_1 is *large* and x_2 is *medium* then Class 3 with 1.0,
R_9: If x_1 is *large* and x_2 is *large* then Class 3 with 1.0.

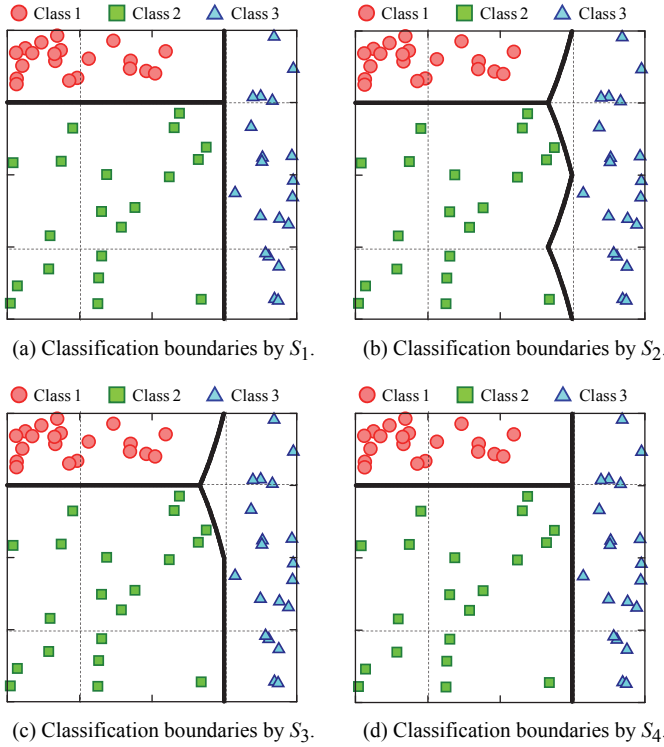
Strictly speaking, patterns with $x_1 = 0.0$ or $x_2 = 0.0$ cannot be classified by S_4 whereas those patterns can be classified by S_1. Thus the classification results by S_1 and S_4 are not exactly the same. However, except for those special cases, S_1 and S_4 have the same classification results as shown in Fig. 3.



(a) Fuzzy rule-based classifier S_1. (b) Fuzzy rule-based classifier S_2.

(c) Fuzzy rule-based classifier S_3. (d) Fuzzy rule-based classifier S_4.

Fig. 2. Fuzzy rules in S_1, S_2, S_3 and S_4.



(a) Classification boundaries by S_1. (b) Classification boundaries by S_2.

(c) Classification boundaries by S_3. (d) Classification boundaries by S_4.

Fig. 3. Classification boundaries by S_1, S_2, S_3 and S_4.

Since S_4 is a subset of S_1, it is clear that S_4 is simpler (i.e., less complicated) than S_1 (see Fig. 2 (a) and Fig. 2 (d)). It is also clear that S_2 is simpler than S_1 since the three fuzzy rules R_7, R_8 and R_9 in S_1 are merged into the single fuzzy rule R_{789} in S_2. However, the comparison of S_3 with the other fuzzy rule-based classifiers is not easy since S_3 has the special antecedent fuzzy set "*not large*". If we use the number of fuzzy rules as a complexity measure, we have the following order of the four fuzzy rule-based classifiers with respect to their complexity:

$$Complex(S_1) > Complex(S_2) > Complex(S_4) > Complex(S_3), \quad (6)$$

where $Complex(S)$ is a complexity measure.

If we think that fuzzy rules with "*not large*" are more complicated than other fuzzy rules with no negations, we may have the following order

$$Complex(S_1) > Complex(S_2) > Complex(S_3) > Complex(S_4). \quad (7)$$

B. Compatibility of Each Input Pattern with Its Winner Rule

Let us consider the classification of a new pattern $\mathbf{x}_1 = (0.05, 0.05)$ by the four fuzzy rule-based classifiers S_1, S_2, S_3 and S_4. This pattern is classified as Class 2 by the following winner rule in each classifier:

R_1 in S_1: If x_1 is *small* and x_2 is *small* then Class 2 with 1.0,

R_1 in S_2: If x_1 is *small* and x_2 is *small* then Class 2 with 1.0,

R_{1245} in S_3: If x_1 is *not large* and x_2 is *not large* then Class 2 with 1.0,

R_5 in S_4: If x_1 is *medium* and x_2 is *medium* then Class 2 with 1.0.

It seems that the fuzzy rule R_1 is a convincing explanation about the classification of $\mathbf{x}_1$ as Class 2. This is because $\mathbf{x}_1$ is linguistically described as "x_1 is *small* and x_2 is *small*", which means that $\mathbf{x}_1$ has high compatibility with the antecedent part of the fuzzy rule R_1. The compatibility is calculated as

$$\mu_{\mathbf{A}_1}(\mathbf{x}_1) = \mu_{small}(0.05) \times \mu_{small}(0.05) = 0.9 \times 0.9 = 0.81. \quad (8)$$

On the contrary, it seems that the fuzzy rule R_5 in S_4 is not a convincing explanation about the classification of $\mathbf{x}_1$ as Class 2. This is because $\mathbf{x}_1$ does not have high compatibility with the antecedent part of R_5. Human users do not think that the input pattern $\mathbf{x}_1 = (0.05, 0.05)$ is well-described by the antecedent conditions "x_1 is *medium* and x_2 is *medium*". The compatibility of $\mathbf{x}_1$ with the antecedent part of R_5 is calculated as

$$\mu_{\mathbf{A}_5}(\mathbf{x}_1) = \mu_{medium}(0.05) \times \mu_{medium}(0.05) = 0.1 \times 0.1 = 0.01. \quad (9)$$

From these discussions, we can see that the compatibility of the input pattern $\mathbf{x}_p$ with the antecedent part $\mathbf{A}_{w(\mathbf{x}_p)}$ of its winner rule $R_{w(\mathbf{x}_p)}$ is related to the explanation ability of the fuzzy rule-based classifier. Let D_{Test} be the set of input patterns to be classified. This pattern set can be viewed as testing data that are not used for the design of the fuzzy rule-based classifier. The average compatibility of each input pattern with the antecedent part of its winner rule is calculated over the pattern set D_{Test} as follows:

$$Compatibility(S, D_{\text{Test}}) = \frac{\sum_{\mathbf{x}_p \in D_{\text{Test}}} \mu_{\mathbf{A}_{w(\mathbf{x}_p)}}(\mathbf{x}_p)}{|D_{\text{Test}}|}, \quad (10)$$

where S is a fuzzy rule-based classifier, $|D_{\text{Test}}|$ is the cardinality of D_{Test} (i.e., the number of patterns in D_{Test}), and $\mathbf{A}_{w(\mathbf{x}_p)}$ is the antecedent part of the winner rule $R_{w(\mathbf{x}_p)}$ for the input pattern $\mathbf{x}_p$ in D_{Test}. Since the winner rule $R_{w(\mathbf{x}_p)}$ is selected from the fuzzy rule-based classifier S, S is included in the left hand side whereas S is not explicitly shown in the right hand side.

The input pattern $\mathbf{x}_1 = (0.05, 0.05)$ is fully compatible with the antecedent part of th fuzzy rule R_{1245} in S_3:

$$\mu_{\mathbf{A}1245}(\mathbf{x}_1) = \mu_{not\ large}(0.05) \times \mu_{not\ large}(0.05) = 1.0 \times 1.0 = 1.0. \quad (11)$$

Thus the fuzzy rule R_{1245} in S_3 has high explanation ability in terms of the compatibility with the input pattern. One may think that R_1 in S_1 seems to have higher explanation ability than R_{1245} in S_3 whereas R_{1245} has higher compatibility than R_1. This intuition is related to the interpretability of each rule, which will be discussed later in the next section.

Let us consider another input pattern $\mathbf{x}_2 = (0.95, 0.05)$. This pattern is classified as Class 3 by the following winner rules:

R_7 in S_1: If x_1 is *large* and x_2 is *small* then Class 3 with 1.0,

R_{789} in S_2: If x_1 is *large* then Class 3 with 1.0,

R_{789} in S_3: If x_1 is *large* then Class 3 with 1.0,

R_8 in S_4: If x_1 is *large* and x_2 is *medium* then Class 3 with 1.0.

The fuzzy rule R_7 seems to be a convincing explanation about the classification of $\mathbf{x}_2$ because $\mathbf{x}_2$ is linguistically described as "x_1 is *large* and x_2 is *small*". The compatibility of $\mathbf{x}_2$ with the antecedent part of R_7 is calculated as

$$\mu_{\mathbf{A}_7}(\mathbf{x}_2) = \mu_{large}(0.95) \times \mu_{small}(0.05) = 0.9 \times 0.9 = 0.81. \quad (12)$$

Whereas S_4 is simpler than S_1, S_4 does not have higher explanation ability than S_1. For example, the fuzzy rule R_8 in S_4 seems to be less convincing than R_7 in S_1 because "x_1 is *large* and x_2 is *medium*" is not highly compatible with $\mathbf{x}_2 = (0.95, 0.05)$. The compatibility of $\mathbf{x}_2$ with the antecedent part of R_8 is calculated as

$$\mu_{\mathbf{A}_8}(\mathbf{x}_2) = \mu_{large}(0.95) \times \mu_{medium}(0.05) = 0.9 \times 0.1 = 0.09. \quad (13)$$

On the contrary, the fuzzy rule R_{789} in S_2 and S_3 seems to be a good linguistic explanation. This is because its antecedent condition "x_1 is *large*" describes $\mathbf{x}_2 = (0.95, 0.05)$ very well. The compatibility of $\mathbf{x}_2$ with the antecedent part of R_{789} is

$$\mu_{\mathbf{A}_{789}}(\mathbf{x}_2) = \mu_{large}(0.95) = 0.90. \quad (14)$$

These discussions on the classification of $\mathbf{x}_2 = (0.95, 0.05)$ also suggest that the compatibility of the input pattern $\mathbf{x}_p$ with

the antecedent part $\mathbf{A}_{w(\mathbf{x}_p)}$ of its winner rule $R_{w(\mathbf{x}_p)}$ is related to the explanation ability of the fuzzy rule-based classifier.

C. Interpretability of the Winner Rule for Each Input Pattern

In a fuzzy rule-based classifier with the single winner-based fuzzy reasoning method, the winner rule for an input pattern is used as the explanation for its classification result. Thus the interpretability of the winner rule is directly related to the explanation ability of the fuzzy rule-based classifier.

Let us consider the classification of the input pattern $\mathbf{x}_1 = (0.05, 0.05)$ again. This pattern is classified by R_1 in S_1:

R_1 in S_1: If x_1 is *small* and x_2 is *small* then Class 2 with 1.0.

The fuzzy rule R_1 seems to have higher interpretability than the winner rule R_{1245} in S_3:

R_{1245} in S_3: If x_1 is *not large* and x_2 is *not large* then Class 2 with 1.0.

This is because R_{1245} looks more complicated than R_1.

When the same pattern $\mathbf{x}_1$ is presented to the fuzzy rule-based classifier S_4, it is classified as Class 2 by R_5:

R_5 in S_4: If x_1 is *medium* and x_2 is *medium* then Class 2 with 1.0.

This winner rule R_5 in S_4 can be viewed as having the same interpretability as R_1 in S_1. This is because these two fuzzy rules have the same structure. As explained in the previous subsection, R_1 seems to have higher explanation ability for $\mathbf{x}_1$ than R_5 because R_1 has higher compatibility. However, with respect to their interpretability, we cannot differentiate these two fuzzy rules.

Let us consider the other input pattern $\mathbf{x}_2 = (0.95, 0.05)$. This pattern is classified as Class 3 by R_7 in S_1 and R_{789} in S_2:

R_7 in S_1: If x_1 is *large* and x_2 is *small* then Class 3 with 1.0,

R_{789} in S_2: If x_1 is *large* then Class 3 with 1.0.

The interpretability of R_{789} seems to be higher than that of R_7. This is because R_{789} has a simpler antecedent condition than R_7. As in the case of the comparison between the two fuzzy rules R_1 and R_5, the winner rule R_7 in S_1 can be viewed as having the same interpretability as the winner rule R_8 in S_4:

R_8 in S_4: If x_1 is *large* and x_2 is *medium* then Class 3 with 1.0.

Let $R_{w(\mathbf{x}_p)}$ be the winner rule of the input pattern $\mathbf{x}_p$. As in the previous subsection, let D_{Test} be the set of input patterns to be classified. In this case, the average interpretability of the winner rules over the pattern set D_{Test} is calculated as follows:

$$Interpretability(S, D_{\text{Test}}) = \frac{\sum_{\mathbf{x}_p \in D_{\text{Test}}} Interpretability(R_{w(\mathbf{x}_p)})}{|D_{\text{Test}}|}. \quad (15)$$

In (15), the problem is how to define the interpretability of each fuzzy rule. In the above discussions, we intuitively use the complexity of the antecedent part of each fuzzy rule. A simple measure to evaluate the complexity of the antecedent part is the number of antecedent conditions. This measure seems to be too simple because it cannot differentiate between R_{1245} with the antecedent condition "If x_1 is *not large* and x_2 is *not large*" and R_1 with the antecedent condition "If x_1 is *small* and x_2 is *small*".

We may be able to refer to a lot of existing studies on the interpretability of fuzzy rule-based systems [11]-[19]. It should be noted, however, that the interpretability in those studies was usually discussed for fuzzy rule-based classifiers rather than each individual fuzzy rule. In (15), the interpretability of each winner rule is used. The interpretability in (15) can be viewed as the understandability of the winner rule for human users.

D. Accuracy of the Winner Rule for Each Input Pattern

In multiobjective fuzzy rule-based classifier design, the accuracy of classifiers is not viewed as a factor related to the interpretability. This is because the accuracy is handled as a separate objective from the interpretability in multiobjective fuzzy rule-based classifier design. However, the accuracy of the winner rule seems to be an important factor related to the explanation ability of fuzzy rule-based classifiers.

Let us consider the following fuzzy rule-based classifier with three rules for our three-class test problem:

S_5: Fuzzy rule-based classifier with three fuzzy rules

R_{123}: If x_1 is *small* then Class 1 with 1.0,
R_{456}: If x_1 is *medium* then Class 2 with 1.0,
R_{789}: If x_1 is *large* then Class 3 with 1.0.

The classification boundaries by S_5 are shown in Fig. 4. Several training patterns from Class 1 and Class 2 are misclassified while all the 20 patterns from Class 3 are correctly classified in Fig. 4.

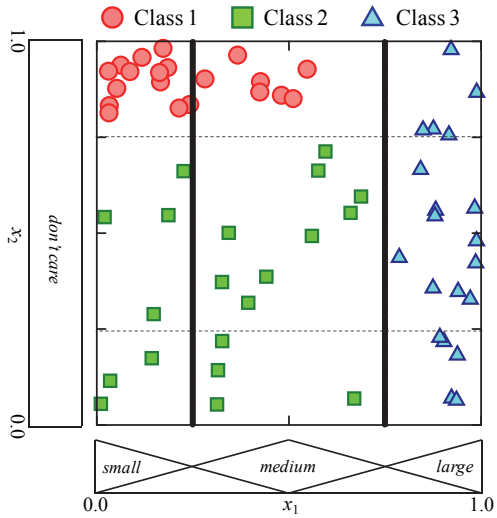


Fig. 4. Classification boundaries by S_5.

As in the previous two subsections, let us consider the classification of the input pattern $\mathbf{x}_1 = (0.05, 0.05)$. This pattern is classified as Class 1 by the winner rule R_{123} in S_5:

R_{123} in S_5: If x_1 is *small* then Class 1 with 1.0.

This winner rule R_{123} has high compatibility with $\mathbf{x}_1 = (0.05, 0.05)$. This winner rule has also has high interpretability thanks to its simple antecedent condition. As a result, this winner rule is viewed as having high explanation ability with respect to the compatibility and the interpretability. However, we do not think that the winner rule R_{123} explains the classification result of $\mathbf{x}_1$ in a convincing manner. The winner rule R_{123} classifies $\mathbf{x}_1 = (0.05, 0.05)$ as Class 1. However, this classification result is not likely to be correct in Fig. 4 because many training patterns close to $\mathbf{x}_1$ in Fig. 4 are from Class 2. That is, we may think that the explanation ability of R_{123} is low since the accuracy of R_{123} is low.

From these discussions, we can see that the accuracy of the winner rule is related to the explanation ability of a fuzzy rule-based classifier. The average accuracy of the winner rule $R_{w(\mathbf{x}p)}$ can be defined over the pattern set D_{Test} as follows:

$$Accuracy(S, D_{\text{Test}}) = \frac{\sum_{\mathbf{x}_p \in D_{\text{Test}}} Accuracy(R_{w(\mathbf{x}_p)})}{|D_{\text{Test}}|} . \quad (16)$$

In (16), the problem is the definition of the accuracy of each fuzzy rule. One candidate definition is as follows:

$$Accuracy(R_q) = \frac{\text{Number of patterns correctly classified by } R_q}{\text{Number of patterns classified by } R_q} . \quad (17)$$

Let us assume that a single fuzzy rule correctly classifies 18 out of 20 patterns for which it is selected as the winner rule. The accuracy of this rule is calculated as 18/20 (i.e., 0.9) in (17). This accuracy is summed up 20 times in the numerator of (16), which is calculated as 18 (i.e., the same as the number of correctly classified patterns by this fuzzy rule). From this discussion, we can see that (16) is the same as the classification rate when we use (17) as the accuracy of each fuzzy rule:

$$Accuracy(S, D_{\text{Test}}) = \frac{\text{Number of patterns correctly classified by } S}{|D_{\text{Test}}|} . \quad (18)$$

In this definition based on (16) and (17), the accuracy of the fuzzy rule-based classifier S is directly used as a factor related to its explanation ability.

The accuracy of the fuzzy rule R_q can be also defined as

$$Accuracy(R_q) = \frac{\sum_{\mathbf{x}_p \in D_{\text{Test}}(C_q)} \mu_{\mathbf{A}_q}(\mathbf{x}_p)}{\sum_{\mathbf{x}_p \in D_{\text{Test}}} \mu_{\mathbf{A}_q}(\mathbf{x}_p)} , \quad (19)$$

where $D_{\text{Test}}(C_q)$ is the set of patterns in D_{Test} from Class C_q (i.e., the same class as the consequent class of the fuzzy rule R_q). In the field of fuzzy data mining [29]-[32], the accuracy in (19) is referred to as the confidence of the fuzzy rule R_q.

In (19), it is possible to use the training data rather than the test data. In data mining, the confidence is usually defined using the training data. If we use the 60 patterns in Fig. 4 as the data set D_{Test} in (19), the accuracy (i.e., confidence) of each rule in S_5 is calculated from (19) as follows:

$Accuracy(R_{123}) = Confidence(R_{123}) = 0.591,$
$Accuracy(R_{456}) = Confidence(R_{456}) = 0.469,$
$Accuracy(R_{789}) = Confidence(R_{789}) = 0.911.$

If we also use the 60 patterns in Fig. 4 as the data set D_{Test} in (16), the accuracy measure of the fuzzy rule-based classifier S_5 is calculated as follows:

$Accuracy(S_5, D_{\text{Test}}) = 0.657.$

For comparison, we calculate the accuracy measure for each of the other fuzzy rule-based classifiers S_1, S_2, S_3 and S_4 in the same manner as follows:

$Accuracy(S_1, D_{\text{Test}}) = 0.846,$
$Accuracy(S_2, D_{\text{Test}}) = 0.848,$
$Accuracy(S_3, D_{\text{Test}}) = 0.837,$
$Accuracy(S_4, D_{\text{Test}}) = 0.784.$

We can see that S_1, S_2, S_3 and S_4 with no misclassified pattern have larger values of the accuracy measure than S_5 with many misclassified patterns.

E. Coverage of the Winner Rule for Each Input Pattern

Roughly speaking, fuzzy rules with small covering regions in the pattern space tend to have high accuracy. Let us consider an extreme case where each fuzzy rule covers only a single pattern. In this extreme case, the accuracy of each fuzzy rule is always 1.0. However, such a fuzzy rule with a very small covering region may have small explanation ability.

Let us consider the following two cases:

Case 1: Most patterns are classified by a few winner rules. That is, many patterns share the same winner rule.

Case 2: Each pattern is classified by a different winner rule. That is, each winner rule classifies only a single pattern.

We think that Case 1 has higher explanation ability than Case 2. This is because human users do not have to examine many winner rules in Case 1.

In fuzzy data mining, coverage is defined as follows:

$$Coverage(R_q) = \frac{\sum_{\mathbf{x}_p \in D_{\text{Test}}(C_q)} \mu_{\mathbf{A}_q}(\mathbf{x}_p)}{|D_{\text{Test}}(C_q)|} , \quad (20)$$

where $|D_{\text{Test}}(C_q)|$ is the number of D_{Test} from Class C_q.

We can also define the coverage of R_q using the number of correctly classified patterns as

$$Coverage(R_q) = \frac{\text{Number of correctly classified patterns by } R_q}{|D_{\text{Test}}(C_q)|} . \quad (21)$$

We can see that the coverage of a fuzzy rule in (21) is large when it correctly classifies many patterns (i.e., when it is selected as the winner rule for many patterns from its consequent class). The coverage in (20) has a similar meaning: The coverage of a fuzzy rule in (20) has a large value when it covers many patterns from its consequent class.

The average value of coverage of the winner rule is calculated over the pattern set D_{Test} as follows:

$$Coverage(S, D_{\text{Test}}) = \frac{\sum_{\mathbf{x}_p \in D_{\text{Test}}} Coverage(R_{w(\mathbf{x}_p)})}{|D_{\text{Test}}|} . \quad (22)$$

If we use the 60 patterns in Fig. 4 as the pattern set D_{Test}, the average value of coverage in (22) is calculated for each fuzzy rule-based classifier for the definition in (21) as follows:

$Coverage(S_1, D_{\text{Test}}) = 0.408$,
$Coverage(S_2, D_{\text{Test}}) = 0.617$,
$Coverage(S_3, D_{\text{Test}}) = 1.000$,
$Coverage(S_4, D_{\text{Test}}) = 0.875$,
$Coverage(S_5, D_{\text{Test}}) = 0.767$.

We can see that high coverage is obtained from fuzzy rule-based classifiers with a small number of fuzzy rules (e.g., S_3 and S_5 with three fuzzy rules, and S_4 with four fuzzy rules). Since many patterns are misclassified by S_5, its coverage by (21) is much smaller than S_3 whereas they have the same number of fuzzy rules.

If we use the definition of (20), the average value of coverage in (22) is calculated for each fuzzy rule-based classifier as follows:

$Coverage(S_1, D_{\text{Test}}) = 0.326$,
$Coverage(S_2, D_{\text{Test}}) = 0.494$,
$Coverage(S_3, D_{\text{Test}}) = 0.875$,
$Coverage(S_4, D_{\text{Test}}) = 0.364$,
$Coverage(S_5, D_{\text{Test}}) = 0.641$.

We can also see that high coverage is obtained from fuzzy rule-based classifiers with a small number of fuzzy rules (e.g., S_3 and S_5 with three fuzzy rules). Since many patterns are misclassified by S_5, its coverage by (20) is much smaller than S_3 whereas they have the same number of fuzzy rules.

IV. CONCLUSIONS

In this paper, first we defined the explanation ability as "the ability of a fuzzy rule-based classifier to explain why an input pattern is classified as a particular class in a convincing way." Then we pointed out the following four factors related to the quantitative definition (i.e., mathematical formulation) of the explanation ability:

(1) Compatibility of an input pattern with its winner rule
(2) Interpretability of the winner rule
(3) Accuracy of the winner rule
(4) Coverage of the winner rule

We discussed the formulation of each factor. It was clearly shown through the discussions on these four factors that the explanation ability of a fuzzy rule-based classifier is related to both its accuracy and its interpretability. Since we formulated each factor, we may be able to formulate the explanation ability by combining those formulations into a single overall measure. A discussion on how to combine them into a single overall measure is a future research issue. This issue does not exclude the possibility of combining the four factors into two measures with different characteristic features.

We may need further discussions on each factor as well as the above-mentioned discussions on their integration. It may be interesting to examine relations among the four factors. We also need further discussions on the possibility of other factors that are related to the explanation ability. Moreover, it may be a promising research issue to use the explanation ability instead of or together with the interpretability in multiobjective fuzzy rule-based classifier design. In this case, both of the classifier-level accuracy and the rule-level accuracy will be used to measure different aspects of fuzzy rule-based classifiers.

***Abstract*—A multi-level decision making problem confronts several issues especially in coordinating decision in hierarchic processes and in compromising conflicting objectives for each decision level. Therefore, its mathematical model plays a pivotal role in solving such problem, and is influencing to the final result. However, it is sometimes difficult to estimate the coefficients of objective functions of the model in real situations specifically when the statistical data contain random and fuzzy information. Thus, decision making scheme should provide an appropriate method to handle the presence of such uncertainties. Hence, this paper proposes a fuzzy random regression method to estimate the coefficients value for the objective functions of multi-level multi-objective model. The algorithm is constructed to obtain a satisfaction solution, which fulfills at least weak Pareto optimality. A numerical example illustrates the proposed solution procedure.**

Keywords- fuzzy random regression model, multi-level problem; multi-objective; additive fuzzy goal programming.

I. INTRODUCTION

Organizational decision making is usually based on the multi-level structure that consists of the top-level decision maker and subsequent levels of decision making power. At least, one decision maker (DM) is located at each level and controls a decision for optimizing their level or unit's objectives. Decision making process in multi-level organization should pay an attention to the central administrations issues and the coordination among lower-level activities. Although the execution of decision moves from an upper level to a lower level, the reaction of a lower-level decision maker affects the optimization of the decision at an upper level decision maker ([1]; [2]; [3]). In such cases, a proper distribution of decision powers with respect to problem belongs to the DM in the respective level must be addressed in most multi-level decision situations.

The structure of multi-objective problem in each level of organization increases the complexities of decision making and planning. DM has to resolve several conflicting objectives at different levels and preference which cause dissatisfaction among decision makers. Although the standard mathematical programming problems are able to solve the multi-objective problem, it is usually considering only one DM in a single-level structure. Thus, multi-objective optimizations in the multi-level structure are required to address this problem. Mathematical programming that takes a multi-level structure, with each level controlling several conflicting objectives is known as multi-level multi-objective programming ([4]; [5]).

In a multi-level decision-making context, each DM which represents decision-making unit should have a motivation to cooperate with others. The satisfactions of a DM at other levels are important and must be considered to accomplish overall organization's goal. Therefore, a satisfaction approach is needed to support the decision-making in multi-level structure that confronts a multiple objective problem at each level. Even though the standard mathematical programming was used to solve the multi-objective problem, these kinds of model are basically unable to accommodate multi-objective problem in multi-level structure due to the presence of decision makers in each level of decision structure.

Moreover, one often needs to make a decision under uncertainty in the real-situation decision making problems. In this study, uncertainties are characterized by fuzzy and random information. The uncertainties were observed during the model settings where the statistical data used to estimate the coefficients may include either random or fuzzy information. We explain the situation as follows. Assume that a profit of crop is reliant on weathers, which this scenarios occur in random. The profit itself may be estimated as a fuzzy number as well. That is, the profit is expressed by a fuzzy random variable. Furthermore, if multiple decision makers are involved in evaluating the same subject, for instance in the multi-attribute evaluation problem, the difference of decision maker's evaluation also should be considered ([6]; [7]). Hence, such situation may take place in real situation and should be handled sufficiently.

Additionally, estimating the model coefficients is essential under the coexistence of fuzzy and random information in the decision evaluation. Though, the coefficients usually are not exactly known, as relevant data are sometimes not given or are

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

sometimes difficult to obtain. However, it makes these decisions crucial and influential to the model's result and the occurrence of errors in the determination of the coefficients might ruin the model formulation [8]. Consequently, the model coefficients are then important in the model settings and should be determined.

Motivated by the above situations, in this paper the satisfaction-based optimization method of additive FGP is introduced to solve multi-level multi-objective (MLMO) problem where the objective functions are developed from Fuzzy Random Regression (FRR) model in the initial phase of model setting. The methodology presented in this paper embraces two objectives. First, the FRR model is used to estimate the coefficients and develop the fuzzy random based objective functions for multi-objective model settings. Second, the additive FGP method is then used to solve the multi-objective linear problem in the multi-level decision making structures.

The remainder of this paper is divided into six sections. Section II describes the construction of fuzzy random objective function. Section III explains important components of FGP based on additive model. Section IV describes the algorithm for solving MLMO decision making with fuzzy random objective function built in prior. An illustrative example of production planning is presented in Section V. Discussions and conclusions are given in Sections VI and VII.

II. BUILDING FUZZY RANDOM OBJECTIVE FUNCTION

Building appropriate objective function in the multi-objective model problem is important and influence the overall model result. Thus this section is spent to explain the solution to estimate the model coefficient and further develop a fuzzy random objective function by using FRR model [6].

The FRR model is constructed based on fuzzy random variables and its confidence intervals. To describe the fuzzy random variables, let Pos be a possibility measure defined on the power set $P(\Gamma)$ in a universe Γ. Let $\Re$ be the set of real numbers. A function $Y : \Gamma \to \Re$ is a fuzzy variable defined on Γ [9]. The possibility distribution μ_Y of Y is defined by $\mu_Y(t) = Pos\{Y = t\}, t \in \Re$ which is the possibility of the event $\{Y = t\}$. The possibility and necessity of the event $\{Y \le r\}$ for fuzzy variable Y with possibility distribution μ_Y, are given respectively in the following forms:

$$\begin{aligned} Pos\{Y \le r\} &= \sup_{t \le r} \mu_Y(t), \\ Nec\{Y \le r\} &= 1 - \sup_{t > r} \mu_Y(t). \end{aligned} \tag{1}$$

The expected value of a fuzzy variable is defined as follows:

Definition 1: Let Y be a fuzzy variable. The expected value of Y where the two integrals are finite is defined as

$$\begin{aligned} E[Y] = &\int_0^\infty \left(\frac{1}{2}\left[1 + \sup_{t \ge r} \mu_Y(t) - \sup_{t < r} \mu_Y(t) \right] \right) dr \\ &- \int_{-\infty}^0 \left(\frac{1}{2}\left[1 + \sup_{t \le r} \mu_Y(t) - \sup_{t > r} \mu_Y(t) \right] \right) dr, \end{aligned} \tag{2}$$

From (1), the expected value of Y is $E[Y] = \frac{1}{4}\left(a^l + 2c + a^r\right)$ when Y is a triangular fuzzy number (c, a^l, a^r). Fuzzy random variables and their expected value operators are defined as follows.

Definition 2: Let (Ω, Σ, Pr) be a probability space and F_v, a collection of fuzzy variables defined on possibility space $(\Gamma, P(\Gamma), \mathrm{Pos})$. A fuzzy random variable is a map $X : \Omega \to F_v$ such that for any Borel subset B of $\Re$, $Pos\{X(\omega) \in B\}$ is a measureable function of ω.

Let X be a fuzzy random variable on Ω. For any fuzzy random variable X on Ω, the expected value of the fuzzy variable $X(\omega)$ is denoted by $E[X(\omega)]$ [10].

The expected value of the fuzzy random variable X is then defined as the mathematical expectation of the random variable $E[X(\omega)]$.

Definition 3: Let X be a fuzzy random variable defined on a probability space $(\Omega, \Sigma, \mathrm{Pr})$. The expected value of X is defined as

$$E[X] = \int_\Omega \left[\int_0^\infty \left(\frac{1}{2}[a] \right) dr - \int_{-\infty}^0 \left(\frac{1}{2}[b] \right) dr \right] Pr(d\omega) \tag{3}$$

where $a = 1 + \sup_{t \ge r} \mu_{X(\omega)^{(t)}} - \sup_{t < r} \mu_{X(\omega)^{(t)}}$ and $b = 1 + \sup_{t \le r} \mu_{X(\omega)^{(t)}} - \sup_{t > r} \mu_{X(\omega)^{(t)}}$.

Definition 4: Let X be a fuzzy random variable defined on a probability space $(\Omega, \Sigma, \mathrm{Pr})$ with expected value e. The variance of X is defined based on $e = E[X]$ from Definition 3, as follows:

$$var[X] = E[(X-e)^2]. \tag{4}$$

The fuzzy random data Y_i and X_{ik} for all $i = 1, \cdots, N$ and $k = 1, \cdots, K$ are defined as $Y_i = \bigcup_{t=1}^{M_{Y_i}} \{(Y_i^t, Y_i^{t,l}, Y_i^{t,r})_\Delta, p_i^t\}$, and $X_{ik} = \bigcup_{t=1}^{M_{X_{ik}}} \{(X_{ik}^t, X_{ik}^{t,l}, X_{ik}^{t,r})_\Delta, q_{ik}^t\}$, with probability p_i^t and q_{ik}^t for $i = 1, \cdots, N$, $k = 1, \cdots, K$ and $t = 1, \cdots, M$ or $t = 1, \cdots, M_{X_{ik}}$, respectively.

Let us denote a fuzzy linear model with fuzzy coefficients $\tilde{C}_i, \cdots, \tilde{C}_K$ as $\overline{Y}_i = \tilde{C}_i X_{i1} + \cdots + \tilde{C}_K X_{iK}$. Each $\overline{Y}_i$ denotes an estimate of the output and

$\widetilde{C}_k = \left(\frac{1}{2}\left[\widetilde{c}_k^{\,l} + \widetilde{c}_k^{\,r}\right], \widetilde{c}_k^{\,l}, \widetilde{c}_k^{\,r} \right)_{\Delta}$ are symmetric triangular fuzzy coefficients for given triangular fuzzy random data X_{ik} for $i = 1, \cdots, N$ and $k = 1, \cdots, K$.

The input data $X_{ik} = (x_{ik}, x_{ik}^{l}, x_{ik}^{r})_{\Delta}$ and output data $\overline{Y}_i = (y_k, y_i^{l}, y_i^{r})_{\Delta}$ for all $i = 1, \cdots, N$ and $k = 1, \cdots, K$, are fuzzy random variables. Therefore, the following relation should hold:

$$\overline{Y}_i = \widetilde{C}_i X_{i1} + \ldots + \widetilde{C}_K X_{iK} \underset{FR}{\supseteq} Y_i, \quad i = 1, \cdots, N , \tag{5}$$

where $\underset{FR}{\supseteq}$ is a fuzzy random inclusion relation. The inclusion relation is based on the expectation-based inclusion and the fuzzy random regression was converted to the expected value regression model with fuzzy inclusion relation at level h [11].

By using the one-sigma $(1 \times \sigma)$ confidence interval, the interval is obtained by the expectation and variance of a fuzzy random variable as follows:

$$I[e_X, \sigma_X] \underline{\Delta} \left[E(X) - \sqrt{var\,(X)}, \quad E(X) + \sqrt{var\,(X)}\right] \tag{6}$$

Hence, the FRR model with $1 \times \sigma$ – confidence intervals is expressed as follows:

$$\begin{aligned} &\underset{A}{min} \;\; J(C) = \sum_{k=1}^{K} \left(\widetilde{C}_k^{r} - \widetilde{C}_k^{l}\right) \\ &\widetilde{C}_k^{r} \geq \widetilde{C}_k^{l}, \\ &Y_i = \widetilde{C}_i\, I\left[e_{X_{i1}}, \sigma_{X_{i1}}\right] + \cdots + \widetilde{C}_K I\left[e_{X_{i1}}, \sigma_{X_{i1}}\right] \underset{\widetilde{h}}{\supseteq} I\left[e_{Y_i}, \sigma_{Y_i}\right] \\ &\text{for } \; i=1,\cdots,N \quad k=1,\cdots,K. \end{aligned} \tag{7}$$

The FRR model with the confidence interval is given in the following form:

$$\overline{Y}_i^{*} = \widetilde{C}_K\, I[e_{X_{iK}} + \sigma_{X_{iK}}], \quad i = 1,...,N \tag{8}$$

Using the fuzzy random variables-based regression model, we estimate the coefficient ξ_{ij} for decision parameters. The coefficients of FRR model results in a close interval $\left[c_j^{l}, c_j^{r}\right]$. Considering the center value of $\hat{\xi}_{ij} = \frac{\left(c^{l} + c^{r}\right)}{2}$, the fuzzy random based objective function is built as

$$F_j(x) = \left\{\overline{Y}_i = \xi_{ij}(X_i)\right\}. \tag{9}$$

Hence, the coefficients c_{ij} of objective function are identified through regression model that is based on a hybrid uncertainty including the fuzziness and the randomness that co-exist in formal decision problem, and these objective functions are further used in the setting of multi-objective model.

III. MLMO Decision Making based on Fuzzy Goal Programming: An Additive Model.

Let us consider an organization that has a multi-level programming problem with multi-objective function $f_i(x)$ for $i = 1, \cdots, p,$. Assume that the decisions are made sequentially beginning with top level DM_1, which controls a vector $x_1 \in X_1$, down through DM_p , which controls a vector $x_p \in X_p$, where x_i is nonempty subset of $\Re^{n_i}$, $i = 1, \cdots, p$, $n_i = n_1 + \cdots + n_p$ and $x_i = x_1, \cdots, x_p$.

The decision maker DM_i at the i^{th} level has authority over the decision variable x_i . Mathematically, the multi-level multi-objective linear programming problem is a nested optimization problem ([1]; [12]) and has the following structures:

$$\begin{aligned} &\text{Find } x \text{ so as to satisfy} \\ &\min_{x_1 \in X_1} F_1(x) = \min_{x_1}\left\{f_{11}(x), \cdots, f_{1m_1}(x)\right\}, \\ &\text{where } x_1 \text{ solves} \\ &\min_{x_2 \in X_2} F_2(x) = \min_{x_2}\left\{f_{21}(x), \cdots, f_{2m_1}(x)\right\}, \\ &\vdots \\ &\text{where } x_2, \ldots, x_p \text{ solves} \\ &\min_{x_p \in X_p} F_p(x) = \min_{x_p}\left\{f_{p1}(x), \cdots, f_{pm_p}(x)\right\} \\ &\text{subject to :} \\ &x \in X \\ &X = \left\{x \in \Re^{n} : Ax(\leq, \geq, =) b, x \geq 0\right\} \end{aligned} \quad \begin{matrix} \left.\vphantom{\begin{matrix}a\\b\\c\\d\end{matrix}}\right\}\text{level p} \\ \left.\vphantom{\begin{matrix}a\\b\\c\\d\end{matrix}}\right\}\text{level 2} \\ \left.\vphantom{\begin{matrix}a\\b\\c\\d\end{matrix}}\right\}\text{level 1} \end{matrix} \tag{10}$$

where $f_{ij}(x) = c_1^{ij} x_1 + \cdots + c_p^{ij} x_p$, $i = 1, \cdots, p,$ $j = 1, \cdots, m_i,$ is the objective function. c_k^{ij} are the constants, and A_i are coefficients matrices of size $m \times n_i$. n_i is the number of decision makers involved.

The FGP [13] based optimization solution is utilized to solve problem model (10). The goal value g_{ij} and tolerance value μ_{ij} are determined by computing the individual best and least solution to obtain the satisfaction degree [14].

The linear membership functions for the fuzzy objective $\mu_{f_{ij}}(x)$ for maximization case of $F_i(x) \gtrsim g_i$ can be formulated as follows:

$$\mu_{F_i}(x) = \begin{cases} 1 & \text{if } f_{ij}(x) \geq \mu_{ij} \\ \dfrac{f_{ij}(x) - \mu_{ij}}{g_{ij} - \mu_{ij}} & \text{if } \mu_{ij} \leq f_{ij}(x) \leq g_{ij} \\ 0 & \text{if } f_{ij}(x) \leq \mu_{ij} \end{cases} \tag{11}$$

In a multi-level decision-making situation in which the decisions made at each level are influenced by the upper level's decision, there exist decision variables that are controlled by upper-level decision makers. Let $t_k^{i_L}$ and $t_k^{i_R}$ be the lower bound and upper bound of tolerance values for the decision vectors considered by the i^{th} level decision maker, respectively.

The triangular fuzzy numbers of decision vectors x_{ik} are $\left(x_{ik}^{*}-t_k^{i_L}, x_{ik}^{*}, x_{ik}^{*}+t_k^{i_R}\right)$. Thus, the linear membership functions for each of the K_i components of the decision vector $x^{i*}=\left(x_1^{i*},\ldots,x_p^{i*}\right)$ controlled by the decision makers of the upper $p-1$ levels can be formulated as follows:

$$\mu_{x_{ik}}(\mathbf{x})=\begin{cases}\dfrac{x_{ik}-\left(x_{ik}^{*}-t_k^{i_L}\right)}{t_k^{i_L}} & \text{if } x_{ik}^{*}-t_k^{i_L}\le x_{ik}\le x_{ik}^{*}\\ \dfrac{\left(x_{ik}^{*}+t_k^{i_R}\right)-x_{ik}}{t_k^{i_R}} & \text{if } x_{ik}^{*}\le x_{ik}\le x_{ik}^{*}+t_k^{i_R}\\ 0 & \text{otherwise}\end{cases} \quad (12)$$

Let V represent the fuzzy achievement function consisting of membership functions for fuzzy objectives μ_i. Recall the fuzzy random objective function of Equation (9), the additive FGP model for multi-level decision-making with fuzzy random objective function is written as follows:

$$\begin{aligned}&\max\ V(\mu_p)=\sum_{j=1}^{m_1}\mu_{1j}+\cdots+\sum_{j=1}^{m_p}\mu_{pj}+\sum_{k=1}^{n_{p-1}}\left[\mu(x)_{p-1k}^{L}+\mu(x)_{p-1k}^{R}\right],\\ &\text{subject to}\\ &\mu_{\mathrm{F}_i(\mathbf{x})}=\frac{\mu_{ij}-\left(\xi_1^{ij}x_1+\cdots+\xi_p^{ij}x_p\right)}{g_{ij}-\mu_{ij}},\ i=1,\ldots,p,\ j=1,\ldots,m_i,\\ &\mu_{x_{ik}(\mathbf{x})}^{L}=\frac{x_{ik}-\left(x_{ik}^{*}-t_k^{i_L}\right)}{t_k^{i_L}},\ i=1,\ldots,p-1,k=1,\ldots,m_{K_i},\\ &\mu_{x_{ik}(\mathbf{x})}^{R}=\frac{\left(x_{ik}^{*}-t_k^{i_R}\right)-x_{ik}}{t_k^{i_R}},\ i=1,\ldots,p-1,k=1,\ldots,m_{K_i},\\ &A_1x_1+\cdots+A_px_p(\le,\ge,=)b,\ \mathbf{x}\ge 0,\\ &\mu_i\in[0,1],\ i=1,\ldots,m.\end{aligned} \quad (13)$$

Because the objectives are fuzzy unlike the conventional goal programming that minimizes deviation, the fuzzy decision function consisting of μ_i must be maximized.

IV. The Additive Fuzzy Goal Programming for MLMO Problem Based on Fuzzy Random Objective Function

The process flow of decision-making under multi-level additive FGP model is illustrated in the following algorithm. The additive FGP is separately solved for the i^{th} level multi-objective program where $i=1,\ldots,p-1$.

Phase I: Building fuzzy random objective functions

1) Determine all the objectives for MLMO problem.
2) Solve each objective described in the model to find the estimate's coefficients. For each of the goal constraints $f_{ij}(x)$,
   - prepare the fuzzy random input-output data.
   - calculate the one sigma confidence interval in terms of Equation (6).
   - perform FRR model by means of Equation (7).
3) Build fuzzy random based objective function as Equation (9) including the confidence interval value.
4) Formulate the MLMO linear program model (10) to illustrate the model for the respective problem. Substitute the fuzzy random-based objective function as Equation (9) that is derived from Step 3) in the MLMO model.

Phase II: Solving MLMO problems

For each objective established at each level in the MLMO Model (10), compute the individual solutions to determine the target goal g_{ij} and tolerance μ_{ij}, respectively.

A: First-Level Additive-FGP

1) Assume $p=l$. Set $l=1$.
2) Create the fuzzy achievement function V_{μ_1} consisting of μ_{ij} for $i=1,\ldots,p \quad j=1,\ldots,m_i$ in level 1.
3) Create the fuzzy objective membership function $\mu_{F_i(x)}$ with the aspiration value g_{ij} and μ_{ij} for the fuzzy goals of the first level controlled by DM_1.
4) Formulates the additive FGP model based on Model (10) for the first-level problem to obtain a satisfactory solution.
5) Send the obtained solutions of the objective function $\mathrm{x}^{1*}=\left(\mathrm{x}_1^{1*},\ldots,\mathrm{x}_p^{1*}\right)$ decisions to the next lower level.

B: Second-Level towards p^{th} -Level Additive-FGP.

1) Set $l=l+1$. Determine the obtained solutions $\mathrm{x}^{l-1*}=\left(\mathrm{x}_1^{l-1*},\ldots,\mathrm{x}_p^{l-1*}\right)$ decisions from the higher level l–1.
2) Let the decision maker decide the lower bound and upper bound of the tolerance values $t_k^{i_L}$ and $t_k^{i_R}$ on the decision vector $\mathrm{x}^{l-1*}=\left(\mathrm{x}_1^{1*},\ldots,\mathrm{x}_p^{1*}\right)$.
3) Develop the fuzzy achievement function V_{μ_p} consisting of $\mu_{f_{ij}}$ for $i=1,\ldots,l,\ j=1,\ldots,m_l$ and $\mu_{x_{ik}}$ for $i=1,\ldots,l-1;$ $k=1,\ldots,n_{l-1}$.
4) Create the fuzzy objectives membership function $\mu_{f_i(x)}$ with the aspiration values g_{ij} and μ_{ij} for the fuzzy goals of the first level controlled by the DM_1.
5) Develop the decision vector membership function $\mu_{x_{ik}(x)}, i=1,\ldots,p-1, k=1,\ldots,K_i$ based on Equation (12).
6) Formulate the additive-FGP Model (10) of the p -level problem to obtain a satisfactory solution to the first-level FGP problem.
7) Solve the model to obtain $\mathrm{x}^{l*}=\left(\mathrm{x}_1^{l*},\ldots,\mathrm{x}_p^{l*}\right)$.
8) Repeat step 1 until $l<p$, to generate a satisfactory solution $\mathrm{x}^{l*}=\left(\mathrm{x}_1^{l*},\ldots,\mathrm{x}_p^{l*}\right)$ for the MLMO linear programming problem.

TABLE I. THE OBJECTIVES

Decision Maker	*The Objectives*	
Government level, DM_1 (upper-level)	f_{11}	Maximize the export revenue
	f_{12}	Maximize the national level profit
	f_{13}	Minimize the capital,
State level, DM_2 (middle-level)	f_{21}	Maximize the production volume
	f_{22}	Maximize the profit for state level
	f_{23}	Minimize the cost of production
City level, DM_3 (lower-level)	f_{31}	Maximize the production volume
	f_{32}	Minimize the cost of production

V. NUMERICAL EVALUATIONS AND DISCUSSIONS

The following multi-objective linear programming problem is illustrated to demonstrate the proposed procedure. The problem situation is described as follows. One export-oriented country is concentrating on producing three important products x_1 , x_2 and x_3 which are manufactured by company C_m, $m = 1, \cdots, M$. This company has distributed branch B_m, $m = 1, \cdots, M$, in city level for producing the products.

There are 3 levels of decision making related to this case and each level are responsible to accomplish the objectives that are decided in prior. Table 1 summarizes the objectives decided in each level.

Let us assume f_{ij} represent the DM_i objective in each level. The multi-level multi-objective problem can be summarized as follows:

Find x so as to satisfy:

$$\begin{aligned}
&[\text{Level1}]\\
&\min_{x_1} F_1(x) = \{f_{11}(x), f_{12}(x), f_{13}(x)\},\\
&\text{where } x_2 \text{ and } x_3 \text{ solve}\\
&[\text{Level2}]\\
&\min_{x_2} F_2(x) = \{f_{21}(x), f_{22}(x), f_{23}(x)\},\\
&\text{where } x_3 \text{ solves}\\
&[\text{Level3}]\\
&\min_{x_3} F_3(x) = \{f_{31}(x), f_{32}(x)\},
\end{aligned} \tag{14}$$

Subject to constraints:

$$\begin{aligned}
&\text{raw} && 3.815x_1 + 0.910x_2 + 0.220x_3 <= 87.75;\\
&\text{labor} && 0.650x_1 + 0.900x_2 + 0.125x_3 <= 4.425;\\
&\text{mills} && 17.50x_1 + 2.160x_2 + 4.775x_3 <= 95.20;\\
&\text{capital} && 1.350x_1 + 0.980x_2 + 0.890x_3 <= 20.15;
\end{aligned} \tag{15}$$

Phase I: Building fuzzy random objective functions

The initial step in this phase is the data preparation to estimate the decision coefficients through a fuzzy random-based regression and further develop the objective function. The previously collected data set is then pre-processed ([7]; [15]). In this example, three types of product are produced from three different production plants. The probabilities are assigned as the proportion of product being produced in i^{th} plant to the total production numbers.

An FRR model (7) is used to estimate the weights of the decision parameters x_1, x_2 and x_3 and to develop the objective function for each objective that was defined in Table 1. Using the fuzzy random data format of input-output data, we solve the linear program (7) and obtain the estimated coefficients c_i^l and c_i^r for all objectives. For the other objective functions we run the same procedure. The interval $\left[c_i^l, c_i^r\right]$ shows the estimated coefficients for the decision parameters.

The objective functions are developed based on the central value of the interval coefficients as follows:

$$F_1 = \begin{cases} f_{11} = (2.078)_T I[e_{X_1}, \sigma_{X_1}] + (0.260)_T I[e_{X_2}, \sigma_{X_2}] + (0.170)_T I[e_{X_3}, \sigma_{X_3}] \\ f_{12} = (1.010)_T I[e_{X_1}, \sigma_{X_1}] + (1.700)_T I[e_{X_2}, \sigma_{X_2}] + (0.476)_T I[e_{X_3}, \sigma_{X_3}] \\ f_{13} = (0.438)_T I[e_{X_1}, \sigma_{X_1}] + (0.796)_T I[e_{X_2}, \sigma_{X_2}] + (0.512)_T I[e_{X_3}, \sigma_{X_3}] \end{cases} \tag{16}$$

$$F_2 = \begin{cases} f_{21} = (1.126)_T I[e_{X_1}, \sigma_{X_1}] + (0.100)_T I[e_{X_2}, \sigma_{X_2}] + (0.097)_T I[e_{X_3}, \sigma_{X_3}] \\ f_{22} = (0.856)_T I[e_{X_1}, \sigma_{X_1}] + (1.473)_T I[e_{X_2}, \sigma_{X_2}] + (0.443)_T I[e_{X_3}, \sigma_{X_3}] \\ f_{23} = (0.380)_T I[e_{X_1}, \sigma_{X_1}] + (0.737)_T I[e_{X_2}, \sigma_{X_2}] + (0.277)_T I[e_{X_3}, \sigma_{X_3}] \end{cases} \tag{17}$$

$$F_3 = \begin{cases} f_{31} = (0.921)_T I[e_{X_{31}}, \sigma_{X_{31}}] + (0.050)_T I[e_{X_{32}}, \sigma_{X_{32}}] + (0.526)_T I[e_{X_{33}}, \sigma_{X_{33}}] \\ f_{32} = (0.380)_T I[e_{X_{31}}, \sigma_{X_{31}}] + (0.737)_T I[e_{X_{32}}, \sigma_{X_{32}}] + (0.216)_T I[e_{X_{33}}, \sigma_{X_{33}}] \end{cases} \tag{18}$$

The three sets of objective functions (16), (17) and (18) represent the objective functions on each decision making level. At this step, we end the Phase I on the development of objective functions. Next, we move to the second phase to solve the MLMO problem through an additive-FGP approach.

Phase II: Solving MLMO problem

The MLMO problem (10) can be rewritten by considering the result from Phase I as follows:

$$\min_{x_1} = \begin{pmatrix} f_{11} = 2.078\,x_1 + 0.260\,x_2 + 0.170\,x_3, \\ f_{12} = 1.010\,x_1 + 1.700\,x_2 + 0.476\,x_3, \\ f_{13} = 0.438\,x_1 + 0.796\,x_2 + 0.512\,x_3. \end{pmatrix}$$

where x_2 and x_3 solves,

$$\min_{x_2} = \begin{pmatrix} f_{21} = 1.126\,x_1 + 0.100\,x_2 + 0.097\,x_3, \\ f_{22} = 0.856\,x_1 + 1.473\,x_2 + 0.443\,x_3, \\ f_{23} = 0.380\,x_1 + 0.737\,x_2 + 0.277\,x_3. \end{pmatrix} \tag{19}$$

whe re x_3 solves,

$$\min_{x_3} = \begin{pmatrix} f_{31} = 0.921\,x_1 + 0.050\,x_2 + 0.526\,x_3, \\ f_{32} = 0.380\,x_1 + 0.737\,x_2 + 0.216\,x_3. \end{pmatrix}$$

subject to : system constraint s (15);

$x_i \geq 0$;

The first step for solving MLMO problem starts with computation of the individual solutions to determine the goal g_{ij} and its tolerance u_{ij} of each objective function. Table 2

tabulates the individual solutions of all objectives functions for the three levels of the MLMO problem.

Based on the procedure stated in Phase II, the equivalent linear program (19) for the first-level decision making as follows:

$$\begin{aligned}
&\max = u_1 + u_2 + u_3; \\
&u_1 = 0.183x_1 + 0.023x_2 + 0.015x_3; \\
&u_2 = 0.078x_1 + 0.131x_2 + 0.036x_3; \\
&u_3 = 1\text{-}(0.038x_1 + 0.069x_2 + 0.044x_3); \\
&\text{system constraint s (15);} \\
&x_i \geq 0.
\end{aligned} \tag{20}$$

LINGO© computer software is used to run the equivalent ordinary linear programming model. The solution of the first level is $x^{1*} = (x_1^{1*}, x_2^{1*}, x_3^{1*}) = (5.30, 1.08, 0.00)$. Let DM_1 decide $x_1^1 = 5.30$ from the first level solution and the negative and positive tolerance are decided to be $t_1^{1L} = 0.5$ and $t_1^{1R} = 0.5$ respectively. The second level solution proceeds as follows:

$$\begin{aligned}
&\max = u_1 + u_2 + u_3 + u_4 + u_5 + u_6 + ux_1^L + ux_1^R; \\
&u_1 = 0.183x_1 + 0.023x_2 + 0.015x_3; \\
&u_2 = 0.078x_1 + 0.131x_2 + 0.036x_3; \\
&u_3 = 1\text{-}(0.038x_1 + 0.069x_2 + 0.044x_3); \\
&u_4 = 0.183x_1 + 0.016x_2 + 0.015x_3; \\
&u_5 = 0.072x_1 + 0.125x_2 + 0.037x_3; \\
&u_6 = 1\text{-}(0.054x_1 + 0.106x_2 + 0.040x_3); \\
&ux_1^L = 2x_1\text{-}9.6; \\
&ux_1^R = 9.6\text{-}2x_1; \\
&\text{system constraint s (15);} \\
&x_i \geq 0.
\end{aligned} \tag{21}$$

The solution of the second level is observed as $x^{2*} = (x_1^{2*}, x_2^{2*}, x_3^{2*}) = (4.80, 1.19, 1.80)$. Let DM_2 decide $x_2^2 = 1.19$, $t_1^{2L} = 0.75$ and $t_1^{2R} = 0.25$. The solution for the third level is shown in the following equivalent linear programming problem.

$$\begin{aligned}
&\max = u_1 + u_2 + u_3 + u_4 + u_5 + u_6 + u_7 \\
&+ u_8 + ux_1^L + ux_1^R + ux_2^L + ux_2^R; \\
&u_1 = 0.183x_1 + 0.023x_2 + 0.015x_3; \\
&u_2 = 0.078x_1 + 0.131x_2 + 0.036x_3; \\
&u_3 = 1\text{-}(0.038x_1 + 0.069x_2 + 0.044x_3); \\
&u_4 = 0.183x_1 + 0.016x_2 + 0.015x_3; \\
&u_5 = (0.072x_1 + 0.125x_2 + 0.037x_3); \\
&u_6 = 1\text{-}(0.054x_1 + 0.106x_2 + 0.040x_3); \\
&u_7 = 0.087x_1 + 0.004x_2 + 0.009x_3; \\
&u_8 = 1\text{-}(0.065x_1 + 0.127x_2 + 0.037x_3); \\
&ux_2^R = 2x_1\text{-}9.6; \\
&ux_2^R = 9.6\text{-}2x_1; \\
&ux_2^R = 1.333x_2\text{-}0.586; \\
&ux_2^R = 3.76\text{-}4x_2; \\
&\text{system constraint s (15);} \\
&x_i \geq 0.
\end{aligned} \tag{22}$$

The satisfactory solution of the MLMO problem is $x^{3*} = (x_1^{3*}, x_2^{3*}, x_3^{3*}) = (4.80, 0.69, 0.00)$. The procedure brings to an end as $l = p = 3$, and the satisfactory solution is obtained.

$f_{32} = 2.84$	$\mu_{32} = 0.60$	5.77

VI. Results and Discussions

In this section, the results of the industrial problem case are explained. The FRR Model (7) was applied to the datasets of the manufacturing production. The coefficients are obtained as shown in Table III, where each coefficient is represented in interval-valued form. This result illustrates the coefficients for each attribute and shows the range of their evaluations. The coefficients ξ_i are the fuzzy random coefficients for the decision variables x_i.

The coefficients values derived by the FRR approach are represented by the interval valued form which shows the fuzzy judgments and supports the range of values around expected value that is likely to contain the estimation target. Table IV summarizes the objective function value and the achievement of each objective function. Objective f_{11} and f_{21} in the first and second level achieve about 90% which maximized the export revenues. However, the objective of maximizing the profit only achieved about 46% and 43% in the government and state level. 77% goal achievement is gained for the objective to maximize the capital in the government level. From the results, decision makers can perform decision analysis to consider the solution derived by the mathematical approach. The decision maker can reevaluate the solution and change the decision and repeat the process. Since the proposed method is based on satisfaction approach, the decision makers may involve in evaluating the results to achieve better satisfying solution.

VII. Conclusions

In this study, an additive FGP approach is used to solve multi-level multi-objective decision problem. The initial model setting specifically the objective functions were developed by FRR model to treat the fuzziness and randomness in the evaluation. In the solution, each multi-objective problem at each level was solved separately, starting with the highest level. The main advantage of this algorithm is to allow a decision maker to select the desired satisfactory value from the higher level that is then used in the following level. The procedure also enables the decision maker of the respective decision making unit to decide the decision value by means of the mathematical solution based on their satisfaction. Additionally, the proposed method uses one-sigma confidence intervals when developing the objective functions which include the mean interval values of all samples in the model. Using the confidence intervals, we could provide a more complete description of the information in the data about the estimation target. Our model also supports the range of values around expected value that is likely to contain the estimation target.

Abstract- **The article proposes a model for customer satisfaction measuring, which is adapted to use in automobile industries. The proposed methodology evaluates the satisfaction level of a set of customers in different aspect of customer focus based on hypothesis values. It permits to evaluate the validity of a service/manufacturing operation from the point of view of consumers. The main advantages of this method are fully considered the qualitative form of customers' judgments through fuzzy theory and evaluate customers' satisfaction in different aspect of customer focus. This model also allows fully evaluates by analysis of all possible hypothesis cases. In the end, we implement our model in KHODRO CO. in IRAN and show the results. This research does asking the opinions of the experts through a number of questionnaires related to the L90 auto customers of PARS KHODRO CO. in 5 fields. Customer's satisfaction of L90 auto in above fields attains among 81 hypotheses and concludes the following result:**

"Product quality is good, financial problems is good, Total quality of services is good and Guarantee is medium then customer satisfaction is good''. Finally, future research directions are provided.

Keywords- fuzzy hypothesis test; customer satisfaction analysis; subjective judgments

I. Introduction

Paper's introduction is in two parts as customer satisfaction models and fuzzy hypothesis testing. According to our knowledge and researches, there is not a method for customer satisfaction measuring based on fuzzy hypothesis testing approach.

A. Customer satisfaction models

Globalization and free trade carry on remodeling the business environment and expanding global competition. Customer satisfaction is a resume notion and show the actual state of satisfaction which can vary from person to person and product/service to product/service. Therefore, customer satisfaction should be determined and rendered into a number of quantifiable parameters [1]. Also Since, customer satisfaction index (CSI) have been widely developed in both theory and applications [2, 3, 4, 5], especially in the fields of marketing, education, medical treatment, guesthouse management ,therefore customer satisfaction has been one of the most frequently surveyed topics in literature. The work done by Berry et al. [6] between 1985 and 1988 delivered SERVQUAL (it is a service-quality scheme that has been incorporated into customer-satisfaction surveys [7]), supports the basis for the measurement of customer satisfaction with a service by using the gap between the customer's expectation of achievement and their perceived experience of achievement. In 1989, the first model of CSI was built by Swedish researchers [8]. The American customer satisfaction index (ASCI) was set up in 1994 [9]. Another well-known CSI was built by 11 countries of European Union in 1999 [10, 11]. Some researchers introduce modified CSI for using in the different fields. Hsu (2008) proposes an index for online customer satisfaction, which was adapted from an American Customer Satisfaction Index (ACSI). It predicts customer loyalty and overall customer satisfaction via a way that was similar to the average for the online retail industry in ACSI and the partial least squares (PLS) method [12]. Web-based customer satisfaction don´t terminate in the above paper. Customer satisfaction measurement index system via mail service is designed by LIU et al. (2006) [13]. Some of researches also focused on the relationship between customer satisfaction and financial performance [14, 15,16]. According to Grigoroudis et al. (2000), customer satisfaction information is analyzed based

on a preference disaggregation model. Their tool (Software) is termed as TELOS that follows the principles of Multicriteria analysis and uses subjective customers' judgments [17]. Therefore, they propose a model that called MUSA (Multicriteria Satisfaction Analysis). It is a preference disaggregation model following the principles of ordinal regression analysis. Same as their mentioned paper, MUSA model uses subjective customers' judgments, too [18]. The Research of Mihelis et al are concerned with a model that is based on the principles of Multicriteria analysis and preference disaggregation modeling and it is implemented in private bank sector. It determines critical service dimensions and the investigation to customer classes with distinctive preferences and expectations [19]. Jaime and Fonseca (2009) consider the latent segment models (LSM) approach for evaluation of customer's service satisfaction that quantified through multiple indicators. They selected a three latent segment model that represents "The Very Satisfied", "The Well Satisfied" and "Satisfaction Demanders" [20]. Since Zadeh introduces fuzzy set theory in 1965 [21], researchers intend to use it in their quests. For example, Xiaohong (2008) introduce new method for calculating the e-commerce customer satisfaction index (ECSI), using fuzzy techniques [22], so that ECSI obtains by fusion of comparison customers' cognition in e-commerce and their acclaims and complaints.

The purpose of our study is to utilize the fuzzy hypothesis testing for customer satisfaction measuring, such that, satisfaction level is caused by six fields as product quality , financial problems , total quality of services , guarantee , complaints and loyalty. The fuzzy hypothesis test is developed crisp hypothesis testing but it challenge the all possible hypotheses. In other hand, it utilizes ambiguity and vagueness of subjective judgments by fuzzy logic.

B. Fuzzy hypothesis testing

As discussed in previous section, main structure of our method is based on fuzzy hypothesis testing. In the real world, sometimes data cannot be recorded or collected precisely. Therefore, the fuzzy sets theory is naturally used as an appropriate tool in modeling the statistical models when the fuzzy data have been observed [23]. The concept of fuzzy sets used here was originally introduced in [21] and described in more detail e.g. in [24, 25]. It should be noted that in this paper only the hypotheses are allowed to be fuzzy and the data are assumed to remain crisp. Furthermore, the 'classical' way of statistical inference is generalized to fuzzy hypothesis. Note that there is a fundamental difference between a membership function of a linguistic term and a prior probability distribution. The membership function just gives a description of the linguistic term, whereas a prior probability distribution gives prior information about the truth of the hypotheses under consideration. Arnold [26, 27] proposed the fuzzification of usual statistical hypotheses and considered the hypotheses testing under fuzzy constraints on the type I and II errors. Casals and Gil [28] and Son et al. [29] considered the Neyman–Pearson type testing hypotheses. Saade [30, 31] considered the binary hypotheses testing and discussed the fuzzy likelihood functions in the decision making process by applying a fuzzified version of the Bayes criterion. Gil et al. [32] also discussed the likelihood ratio test for goodness of fit with fuzzy observations by means of the minimum inaccuracy principle of point estimation. Casals and Gil [33], Casals and Gil [34], and Gil et al. [35] considered the Bayesian sequential tests and χ^2 tests for goodness of fit with fuzzy observations by means of the notion of fuzzy information. Grzegorzewski [36], Watanabe and Imaizumi [37] proposed the fuzzy test for hypotheses testing with vague data, and the fuzzy test gave the acceptability of the null and alternative hypotheses. Niskanen [38] discussed the applications of soft statistical hypotheses in the human sciences. The fuzzy hypothesis testing is developed of classic statistical hypothesis testing which zero and one are using for acceptance or rejection of any hypothesis. However, fuzzy hypothesis testing has two strength points versus classic statistical hypothesis testing. They are: (1) it considers all the possible hypotheses and (2) accepts them relatively by numbers in [0,1]. The fuzzy hypothesis testing – like the classic statistical hypothesis testing - has four steps: hypothesis formulation, sampling, hypothesis testing and decision-making. In hypothesis formulation step, all the possible hypotheses are formulated. Classical hypotheses define two type hypotheses as null hypothesis and alternative. However, fuzzy hypotheses formulated by a block consist of hard-core and associated auxiliary hypotheses. In the sampling step, subsets of all data are selected. The sample should has enough data to be a good indication of the all data. In hypothesis testing step, fuzzy conclusion for any hypothesis is done and then, results are aggregated by aggregation function. In final step, total result has to be analyzed and associated decisions made.

The paper organization is according to the follows:

Section II, describes information collection tools, its validity and reliability, and some information about case location. Section III, is describes our methodology which is consist of fuzzy hypothesis concept, structure of our approach, model implementing and its finding. Finally the last section, conclude the models efficiency and results.

II. Information Collection

A. Case Location and Sampling

Pars Khodro Company (P.K.C.) is an automobile manufacturer company that is established in 1956 and since then is operational. In P.K.C. the environment of the competitive markets changes intensely and it is necessary to improve the manufacturing quality continuously. Hence, we introduce a way to evaluate the P.K.C's manufacturing quality, which is based on the degree of user satisfaction. The statistical universe of this

paper is considered from total customers of L90 (one of the Pars Khodro products started in 2009) .In this paper, random systematic method for sampling is used [39] and due to list of total customers of L90 in 2009, Morgan table is utilized for numbers of samples [40] in which the best sample numbers corresponded to any universe cardinality. Accordingly, a sample of 380 from 20000 customers is considered as good representative of total data.

B. Tools

In this paper, main information collecting tool is questionnaires and interviews. Interview is used to analyze customers' viewpoints before questionnaire designing. Questionnaire also is used to measure the satisfaction samples in framework of hypothesis. Initial questionnaire has six essential fields and each field has several sub-fields as follows:

1. Product quality
1.1. Apparent form
1.2. Safety
1.3. Car body specifications
1.4. Motor power and fuelling
1.5. Good ventilation and power means
1.6. Technical documents quality

2. Financial problems
2.1. Cost of product
2.2. Fair relation between cost and quality
2.3. Purchase styles
2.4. Financial operation rapidity
2.5. Attention and clarity in financial affairs

3. Total quality of services
3.1. Managers and experts communication manner
3.2. Inform manner quality
3.3. Delivery quality
3.4. Guarantee conditions

4. Guarantee
4.1. Provide the spare parts
4.2. Parts ampleness and quality
4.3. Guarantee access
4.4. Repairs quality
4.5. Guarantee cost and wage

5. Complaints
5.1. Complaints receiving ways
5.2. Complaints investigation quickness
5.3. Complaints consideration

6. Loyalty
6.1. Continuing cooperation
6.2. Looking forward to the fresh products
6.3. Suggest to other peoples

After the initial collection of 30 questionnaires and evaluation of feedbacks, we integrate them with experts' opinions. Accordingly, due to overlapping and concluded by another, loyalty eliminated from questionnaires and then, final questionnaire is formed. The Response of any question was set according to Likert scale [41], which scaled as: poor satisfaction ، Medium poor satisfaction ، Fair ، medium good satisfaction and good satisfaction.

C. Validity and Reliability

The method of explority factor analysis has been used to analyze the questionnaire validity [39]. The KMO* value of questionnaire is 0.895 in 0.01 significant level which imply to sampling sufficiency for method of explority factor analysis. Varimax rotation was used for explority factor analysis, and result implies that: first factor (product quality) explains the 75% changes, second factor (financial problems) explains the 81% changes, third factor (Total quality of services) explains the 73% changes, Guarantee factor explains 74% changes and finally, complaints factor explains the 79% changes. Generally, the questionnaire forecast the 73% changes that indicate the validity. Of course, load factor of fields was greater than 0.5. The Cronbach's alpha method has been used to analyze the questionnaire reliability [42] which was calculated Cronbach's alpha for product quality , 75% ; financial problem , 79% ; Total quality of services , 72% ; Guarantee , 80% and complaints, 79%. This result indicates the reliability of customer satisfaction measurement scale. It is necessary to mention that the investigations have been done by MINITAB 15.0 software.

III. Mathematical Framework of Fuzzy Hypothesis Testing

Fuzzy hypothesis test is extension of classical statistics hypothesis test. It leads to importance degree of each hypothesis compare with auxiliary rules. Let, X be universes of discourse, $D = \{x_1 , x_2 , \dots , x_n\}$ be sample set and $H = \{H_1 , H_2 , \dots , H_n\}$ be if-then rule statements. In this view, we can demonstrate a fuzzy if-then rule as follows:

H_i: IF $\{\text{Condition } 1, \text{Condition } 2, \dots , \text{Condition } k\}$ to be considered true, THEN x is a member of F by membership degree $\mu(x)$ .Nevertheless, general structure of fuzzy hypothesis test is as Table 1:

*Kaiser - Meyer- Olkin

TABLE1. Fuzzy hypothesis test matrix

If-then statements	Samples				$M_j(D)$
	x_1	x_2	…	x_n	
H_1					
H_2					
⋮					
H_r					
					Summation=1

It should be noted that, auxiliary rules are in $\{\text{Condition } 1, \text{Condition } 2, \ldots, \text{Condition k}\}$ and main hypothesis is included in F notation. The if-part of the rule is called the antecedent, while the then-part is called the consequent or conclusion. Each sample x_i satisfies condition 1 ، condition 2 through condition k within $\mu_1(x_i)$ ، $\mu_2(x_i)$ through $\mu_k(x_i)$, respectively. In other hand, x_i satisfies the consequent within $\mu(x)$ that is defined as:

$$\mu : (H, x) \rightarrow [0,1] \quad (1)$$

Due to multiple parts related to the antecedent and consequent, apply fuzzy logic operators and resolve them to a single number between 0 and 1,therefore we apply multiplication operator (P.M. Larson relation) for combining the antecedent and consequent such as fuzzy logic operators. So, satisfaction degree of each hypothesis by x_i sample calculates by equation (2). Hence, attain associated array of j^{th} row and i^{th} column for Table (1).

$$\text{Sat}_{x_i}(H_j) = \mu_1(x_i) \times \mu_2(x_i) \times \ldots \times \mu_k(x_i) \times \mu(x_i) \quad (2)$$

To determine the verification degree of each hypothesis (claim), so it is necessary to calculate all possible $\text{Sat}_{x_i}(H_j)$ $\forall i, j$ and then, find arithmetic mean as follows:

$$M_j(D) = \frac{\sum_{i=1}^{n} \text{Sat}_{x_i}(H_j)}{n} \quad j = 1,2, \ldots, r \quad (3)$$

A. Fuzzy hypothesis testing in customer satisfaction measuring

In this section, we intend to introduce the set of hypothesis in our model. Claims $H = \{H_1, H_2, \ldots, H_n\}$ have been introduced and are calculated verification degree of each ($\mu_k(x_i)$). As discussed in section II., five fields are used in this model ; product quality, financial problems, Total quality of services, Guarantee are antecedents and then complaints is rule's consequent that implies to customer satisfaction level. We classify each of them in to the three scales as, good ، medium and bad. As an example, Total qualities of services investigate in the three classes; good Total quality، medium Total quality and bad Total quality. So, to analyze the total classifications of fields, we will have $3 \times 3 \times 3 \times 3 = 81$ hypothezies. All hypothezies have been analyzed in our paper. As an example, one of the hypothesis could be "product quality is good, financial problem is good, Total quality of services is bad, Guarantee is medium and then customer satisfaction level (complaints) is medium". The fuzzy classifications are as shown in Fig. 1.

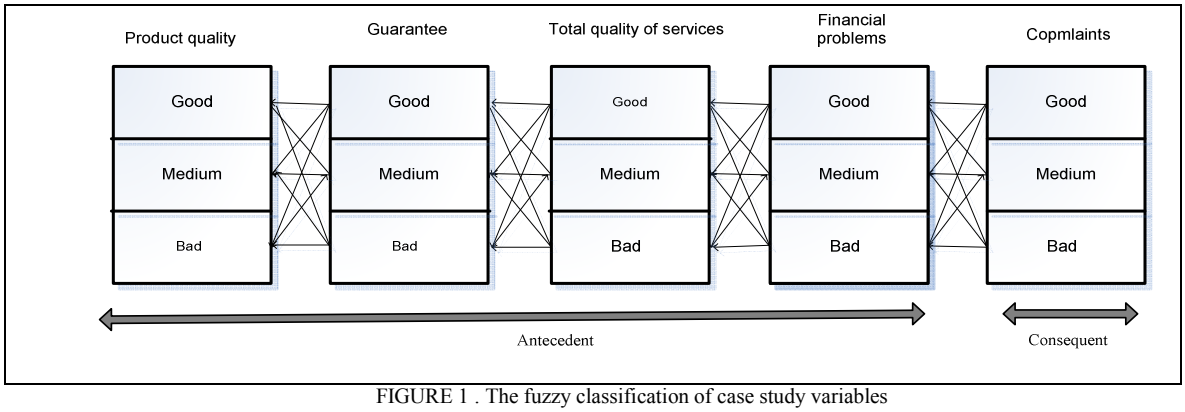

FIGURE 1 . The fuzzy classification of case study variables

As discussed in above, linguistic terms have been used in any classifications. Good ، medium and bad are our linguistic terms. So, accordingly we need to design theirs fuzzy distributions. Fig. 2 demonstrates the linguistic values of any linguistic variable in which ranges have been got from interview with company experts. Note that, concept of

The parameters have been allotted as Fig. 2.So, the membership functions of good, medium and bad linguistic terms are indicated as follows:

"complaint" is negative, so, the more values imply to worse condition. Fig. 3 demonstrates the linguistic terms that are based on the parameters which are different in each field.

$$\mu_{good}(x) = \begin{cases} \frac{1}{e-d}(x-d) & x \in [d,e] \\ 1 & x \in [e,f] \end{cases} \quad (4)$$

$$\mu_{medium}(x) = \begin{cases} \frac{1}{c-b}(x-b) & x \in [b,c] \\ 1 & x \in (c,d] \\ \frac{-1}{e-d}(x-d)+1 & x \in (d,e] \end{cases} \quad (5)$$

$$\mu_{bad}(x) = \begin{cases} \frac{1}{a}x & x \in [0,a] \\ 1 & x \in (a,b] \\ \frac{-1}{c-b}(x-c) & x \in (b,c] \end{cases} \quad (6)$$

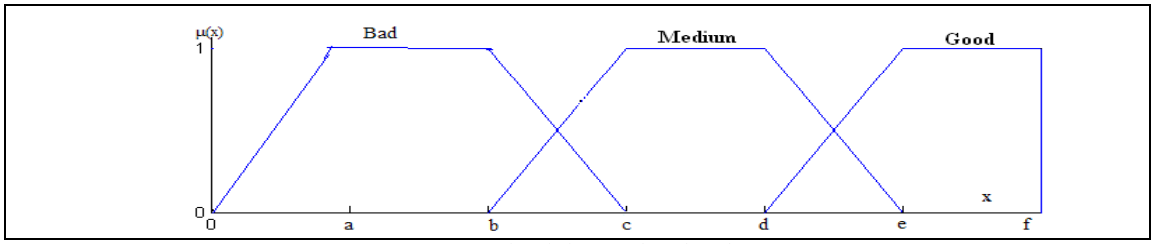

FIGURE 3 . Linguistic terms based on the parameters

	Bad = (0,12,20,25) Medium=(20,25,40,45) Good=(40,45,60,60)	Product Quality
	Bad = (0,7,11,14) Medium=(11,14,23,26) Good=(23,26,35,35)	Financial problems
	Bad = (0,14,23,29) Medium=(23,29,46,52) Good=(46,52,70,70)	Total quality of service
	Bad = (0,9,15,18) Medium=(15,18,30,33) Good=(30,33,45,45)	Guarantee
	Good = (0,1,2,3) Medium=(2,3,5,7) Bad =(5,7,inf,inf)	Complaints

FIGURE 2 . Distribution of good, medium and bad linguistic values

In this stage, the verification degree of each claim has been calculated according to the customers´ data. As an example, let "product quality is medium, financial problems is good, total quality of services is medium, Guarantee is medium and customer satisfaction level is medium" for one of the customer (Due to Table 2). So, the verification degree for this customer is $0.8 \times 0.25 \times 0.14 \times 0.87 \times 1 = 0.02$. In a similar way, via each customer, the verification degree for other hypotheses has been calculated. This procedure repeats for other customers and the verification degree of each 81 hypothesis are calculated as described in section III. Note that, customer i play role of x_i that is explained in sectionIII. Table 2 depicts satisfaction degree of each linguistic variable by one of the customer .

TABLE 2 . Satisfaction degree of each linguistic variable by one of the customer

Ling. variables	**Product quality**				**Financial problem**				**Total quality of services**				**Guarantee**				**Customer satisfaction level (Complaint)**			
Ling. values	G[1]	M[2]	B[3]	Score	G	M	B	Score	G	M	B	Score	G	M	B	Score	G	M	B	Score
Sat. degree	0.2	0.8	-	42	0.25	0.75	-	36	0.86	0.14	-	32	0.13	0.87	-	35	-	1	-	4

1. G : Good 2. M : Medium 3. B : Bad

B. Findings

The results of hypotheses testing have been introduced as $M_{H_1}, M_{H_2}, \ldots, M_{H_{81}}$ which are verification degrees of $H_1, H_2, \ldots, H_{81}$ hypotheses. If verification degrees of H_i be greater than other hypotheses, then, we can conclude that H_i accurance possibility is greater than others. As shown in Table 3, the top five highest verification degrees are shown and the hypothesis "product quality is good, financial problem is good, Total quality of services is good and Guarantee is medium and as a result, customer satisfaction is good'' has the highest verification degree among the others. So, we can say, this claim has the more conformances in company case. This findings lead to get safeguarding strategy in product quality, financial problem, Total quality of services fields and improvement strategy in Guarantee approach.

TABLE 3.The top five highest verification degrees of hypotheses for L90

Priority	**Hypothesis**
1	product quality is good , financial problems is good, Total quality of services is good , Guarantee is medium and as a result, customer satisfaction is good
2	product quality is good , financial problems is good, Total quality of services is good , Guarantee is good and as a result, customer satisfaction is good
3	product quality is medium, financial problems is good, Total quality of services is medium , Guarantee is medium and as a result, customer satisfaction is medium
4	product quality is good , financial problems is medium, Total quality of services is medium , Guarantee is medium and as a result, customer satisfaction is medium
5	product quality is medium, financial problems is medium, Total quality of services is medium , Guarantee is bad and as a result, customer satisfaction is medium

IV. Conclusion

Due to increase global competition, customer satisfaction should be determined and rendered into a number of quantifiable parameters. Accordingly, different methods have been introduced to customer satisfaction measurement. Nevertheless, none of them did not use vagueness of customers' judgments and did not probe comprehensively the varied satisfaction fields. The proposed Method used the fuzzy hypothesis testing for utilizing the intuitive judgments and decision-making vagueness and Diagnoses the satisfaction customers associated fields. It Leads to the real satisfaction level and specifies the foible, strength and improvement opportunity, which they are essential information in the strategic management and latest planning in a company. This paper was implemented in Pars Khodro Co. and study L90 satisfaction customers in 2009. Finally, the result of this research emphasize on "product quality is good, financial problem is good, Total quality of services is good and Guarantee is medium then customer satisfaction is good'' hypothesis. Compare to the other researches, this approach presents more realistic results.

***Abstract*—A fuzzy particle swarm optimization (PSO) for the minimization of makespan in permutation flow shop scheduling problem is presented in this paper. In the proposed fuzzy PSO, the inertia weight of PSO and the control parameter of the cross-mutated operation are determined by a set of fuzzy rules. To escape the local optimum, cross-mutated operation is introduced. In order to make PSO suitable for solving permutation flow shop scheduling problem, a roulette wheel mechanism is proposed to convert the continuous position values of particles to job permutations. Meanwhile, a swap-based local search for scheduling problem is designed for the local exploration on a discrete job permutation space. Flow shop benchmark functions are employed to evaluate the performance of the fuzzy PSO for flow shop scheduling problems and the results indicate that the algorithm performs better compared with existing hybrid PSO algorithms.**

***Index Terms*—Flow shop Scheduling, Fuzzy logic, Particle swarm optimization.**

I. Introduction

Permutation flow shop scheduling problem is a NP hard problem, existing mathematical methods, i.e., integer programming, branch-and-prune method, dynamic programming, etc, are only applicable to small-scale problem and they are difficult to find the global solution of the problem. Thus, various global algorithms such as genetic algorithm (GA) [1] ,differential evolution (DE) [2] and ant colony optimization (ACO) [3] [4] are proposed. Recently, a new global searching algorithm namely particle swarm optimization (PSO) is widely used to different industrial areas [5]–[8]. Especially, it is effectively to tackle the flow shop scheduling problems [9]–[14]. Comparing with other population based stochastic optimization methods, such as evolutionary algorithms, PSO has comparable or even superior search performance for many hard optimization problems with faster and more stable convergence rates [15], [16]. However, observations reveal that PSO converges sharply in the early stage of the searching process, but saturates or even terminates in the later stage. It behaves like the traditional local searching methods that trap in local optima.

Recently, different hybrid PSO methods have been proposed to overcome the drawback of trapping in local optima. The hybrid PSO has been first proposed in 1998 [17], in which a standard selection mechanism is integrated with PSO. A new hybrid gradient descent PSO (HGPSO), which is integrated with gradient information to achieve faster convergence without getting trapped in local minima is proposed [18]. However, the computational demand of HGPSO is increased by the process of the gradient descent. In addition, it is poor to handle the multimodel problem that contain many local minima. In [19], a hybrid PSO algorithm named HGAPSO is proposed, which incorporates GA's evolutionary operations of crossover, mutation and reproduction. In the paper [5], a hybrid PSO named HPSOM is proposed, in which a constant mutating space is used in mutation. In both HGAPSO and HPSOM, the solution space can be explored by performing mutation operations on particles along the search, and premature convergence is more likely to be avoided. However, the mutating space is kept unchanged all the time throughout the search, and the space for the permutation of particles in PSO is also fixed. It can be improved by varying the mutating space along the search. A hybrid PSO with wavelet mutation operation (HPSOWM) is proposed [8], which the mutating space is varying by applying wavelet theory. The solution quality and solution reliability (standard deviation upon many trials) are improved.

In order to make PSO be suitable to solve the combinational (scheduling) problem, a converting process from the continuous position values of particles to job permutations is used. Conventionally, the Smallest Position Value (SPV) rule [11]–[13] is actually a mapping from an N-dimensional continuous space to a sequence with N numbers. The corresponding sequence is represented by the order of the vector. As we know, the positions of the particles in PSO are updated that causes velocity and evolution. In some case, the positions of the particles are updated, the corresponding sequence is still unchange by using SPV rule [14]. This kind of inefficiency of the continuous space will result in the decrease in convergence rate. To overcome this drawback, a sequence-order system based on the roulette wheel mechanism is proposed in this paper. In this mechanism, the probability representation is instead of the position value which is represented by SPV rule.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

In [20], an improved version of PSO with an inertia weight factor is introduced. The aim of the inertia weight provides a balance between the global exploration and local exploitation and it is governed by a linear characteristic function. However, not all the optimization problems are linear. Thus, in this paper, a hybrid fuzzy logic-based PSO with cross-mutated operation is proposed. This proposed approach can be divided into two main parts. First, an adaptive inertia weight is proposed, which incorporates with the fuzzy inference system. Fuzzy logic is good in representing some expert knowledge and experience in some linguistic rule which can be easily understood by the human being. Using fuzzy inference to determine the inertia weight of PSO, such that, the characteristic of function of inertia weight becomes nonlinear. It will be shown that the nonlinear characteristic of the inertia weight performs more better solution quality in this paper. Second, a new operation namely cross-mutated (CM) operation is introduced. The CM operation effectively solves the drawback of PSO, which makes PSO easier to trap in the local optima. In CM operation, the control parameter is determined by fuzzy rules and the operation becomes adaptive. Additionally, a swap-based local search method is designed for the local exploration on a discrete job permutation space. This method is used to fine tune the sequence of the flow shop scheduling problem. In this paper, a suite of benchmark problems for permutation flow shop scheduling problem are used to illustrate the performance of the proposed approach. The resulting adaptive inertia weight and CM operation aid the proposed fuzzy logic-based PSO with cross-mutated operation to perform better solution quality compared with improved PSO (IPSO) [20] and other hybrid PSO methods [5], [8], [18], [19].

This paper is organized as follows. Section 2 presents the formulation of flow shop scheduling problem. The implementation of the flow shop scheduling problem with hybrid PSO will be discussed in Section 3. In this section, the solution representation, hybrid fuzzy-based PSO with cross-mutated operation, and the swap local search method are discussed. In Section 4, benchmark problems will be given to evaluate the performance of the proposed method. Finally, a conclusion will be drawn in Section 5.

II. Permutation Flow shop scheduling problem formulation

The formulation of the permutation flow shop scheduling problem is described in this section. Suppose there is a set of n jobs to be processed in a set of m machines in the same order. The processing time $p_{j,k}$ for job j $(j = 1, 2, ..., n)$ on machine k $(k = 1, 2, ..., m)$ is given. The objective is to find a sequence for the processing of jobs in the machines to minimize the total completion time or makespan (C_{max}). There are several assumptions on this scheduling problem [21]: 1) Each job j can be processed at most on one machine k at the same time; 2) Each machine m can process only one job j at a time; 3)The processing of a job j on a machine k cannot be interrupted; 4) All jobs are independent and are available for processing at time 0; 5) The setup times of the jobs on machines are negligible; 6) The machines are continuously available; and 7) If the next machine on the sequence needed by a job is not available, the job can wait and join the queue at that machine.

Let $\pi = J_1, J_2, ..., J_n$ denote a permutation of all jobs, and $C(J_j, k)$ denotes the completion time of job J_j on the machine, then the completion time $C(J_j, k)$ can be calculated as follows:

$$C\left(J_1, 1\right) = p_{J_1,1} \tag{1}$$

$$C\left(J_j, 1\right) = C\left(J_{j-1}, 1\right) + p_{J_j,1}, j = 2, ..., n \tag{2}$$

$$C\left(J_1, k\right) = C\left(J_1, k-1\right) + p_{J_1,k}, k = 2, ..., m \tag{3}$$

$$C\left(J_j, k\right) = \max\left\{C\left(J_{j-1}, k\right), C\left(J_j, k-1\right)\right\} + p_{J_j,k}, \quad j = 2, ..., n, k = 2, ..., m \tag{4}$$

$$C_{\max}\left(\pi\right) = C\left(J_n, m\right). \tag{5}$$

So, the flow shop problem with the makespan criterion is to find a permutation π^* in the set of all permutations Π such that,

$$C_{\max}\left(\pi^*\right) \leq C\left(J_n, m\right), \forall \pi \in \Pi \tag{6}$$

III. The hybrid fuzzy-based PSO for flow shop scheduling

A. Solution representation: roulette wheel mechanism

As mentioned in the introduction section, the existing solution representation method, smallest position value (SPV) rule has a drawback which is to decrease the convergence rate and performance. In this section, a sequence-order system based on the *roulette wheel mechanism* is proposed. In this method, the value of the continuous position of particles represents the probability of the higher ranking. In other words, the position of the higher value of the element of particles will have a higher chance to be select to job sequence list firstly. In this section, the process of the methodology is discussed.

The process of the solution representation with roulette wheel mechanism is described as follows. The roulette wheel mechanism is shown in Fig. 1.

(1) Given a continuous position (element) of the particle x_j, j = 1, 2,... , n.
(2) Assign a probability q_j to the x_j such that: $q_j = \frac{x_j}{\sum_{j=1}^{n} x_j}$. Note that $\sum q_j$ should equal to 1.
(3) Evaluate a cumulative probability $\hat{q}_j$ for each x_j such as: $\hat{q}_j = \sum_{l=1}^{j} q_l$.
(4) Generate a set of floating-point numbers $d_h \in \left[\begin{array}{cc} 0 & 1 \end{array}\right]$ randomly, $h = 1, 2, ..., \eta$; η is the number of generated floating-point number. These floating point numbers should be sorted with ascending order. Normally, the

number of generated floating-point number η equals to $20 \times n$.

(5) Count the total number of the floating-point numbers for each j are in the range of $\left[\ \hat{q}_{j-1} \quad \hat{q}_j\ \right]$ such as: $S_j = count\left(\hat{q}_{j-1} \le d_h \le \hat{q}_j\right)$, where $count()$ is a function to count how many statement is met the condition. Note that $\hat{q}_0 = 0$.

(6) Convert the continuous position of S_j to the sequence of job by using largest position value rule. For a given continuous position like [23, 12, 41, 6], the corresponding sequence is represented by the order of the value. For example, in decent order, 41 is the largest value, so the first of the sequence should be 3; the second largest value is 2, so the second job of sequence should be 1. Thus, we can obtain the corresponding job sequence π is [3, 1, 2, 4].

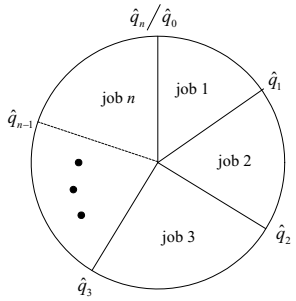

Fig. 1. The roulette wheel mechanism

B. Fuzzy logic-based PSO with cross-mutated operation

Particle swarm optimization (PSO) is a stochastic optimization method which developed in 1995 [15]. It models the processes of the sociological behavior associated with bird flocking and fish schooling. It uses a number of particle that constitute a swarm. Each particle traverses the search space looking for the global optimum. In recently, an improved PSO (IPSO) is proposed [20] where constriction and inertia weight factors are introduced and the searching ability is improved compared with standard PSO [15]. Based on the IPSO, an improved fuzzy logic-based particle swarm optimization with cross-mutated operation namely FPSOCM is proposed to tackle the permutation flow shop scheduling problem and shown in Fig. 2.

From Fig.2, $X\left(t\right)$ is denoted as a swarm at the t-th iteration. Each particle $\mathbf{x}^i\left(t\right) \in X\left(t\right)$ contains n elements $x_j^i\left(t\right) \in \mathbf{x}^i\left(t\right)$ at the t-th iteration, where i = 1, 2,... , γ and j = 1, 2,... , n; γ denotes the number of particles in the swarm and n is the dimension of a particle. First, the particles of the swarm are initialized and then evaluated by a defined cost (objective) function. The evaluation cost value is represented by $f\left(\mathbf{x}^i\left(t\right)\right)$. In the same time, current generation number t is initially set at 0. The objective of PSO is to minimize the cost values of particles iteratively. The swarm evolves from iteration $t+1$ by repeating the processes as shown in Fig.2.

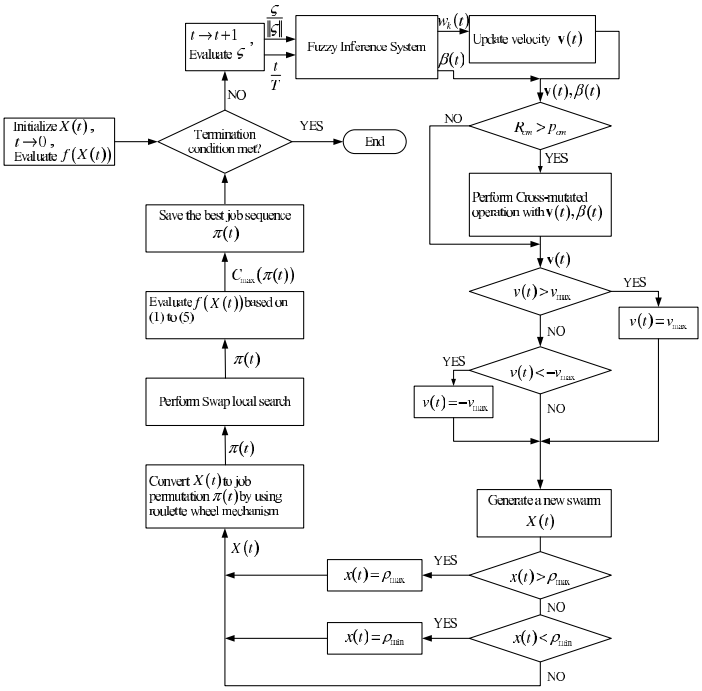

Fig. 2. The process diagram of FPSOCM for flow shop scheduling

In PSO, there has one important term and called velocity. The velocity is corresponding to the flight speed in the search space. The velocity $v_j^i\left(t\right)$ and the position $x_j^i\left(t\right)$ of the j-th element of the p-th particle at the t-th generation can be calculated using the following formulae:

$$v_j^i\left(t\right) = k \cdot \left\{\omega_k\left(t\right) \cdot v_j^i\left(t-1\right) + \varphi_1 \cdot r_1 \cdot \left(p_j^i - x_j^i\left(t-1\right)\right) + \varphi_2 \cdot r_2 \cdot \left(g_j - x_j^i\left(t-1\right)\right)\right\} \tag{7}$$

$$x_j^i\left(t\right) = x_j^i\left(t-1\right) + v_j^i\left(t\right) \tag{8}$$

where $p^i = \left[\ p_1^i \quad p_2^i \quad ,\ldots \quad p_n^i\ \right]$ and $g = \left[\ g_1 \quad g_2 \quad ,\ldots \quad g_n\ \right]$; the best position of a particle i is represented as p^i; the position of the best particle among all the particles is represented as g; r_1 and r_2 return a uniform random number in the range of [0,1], where ω_k is an inertia weight factor to provide a balance between the global and local explorations; φ_1 and φ_2 are acceleration constants; k is a constriction factor derived from the stability analysis of equation (7) to ensure the system to be converged but not prematurely [20]. Mathematically, k is a function of φ_1 and φ_2 as reflected in the following equation:

$$k = \frac{2}{\left|2 - \varphi - \sqrt{\varphi^2 - 4\varphi}\right|} \tag{9}$$

where $\varphi = \varphi_1 + \varphi_2$ and $\varphi > 4$.

In this proposed fuzzy PSO, there are two main contributions that will enhance the performance of searching compared to other PSO methods. Firstly, an adaptive inertia weight $\omega_k(t)$ is proposed to improve the solution quality of searching. Secondly, cross-mutated (CM) operation is given to solve the drawback of IPSO that it is easier to trap into local minima. From Fig.2, we can see that the adaptive inertia weight $\omega_k(t)$ and the control parameter $\beta(t)$ of CM operation are determined by a fuzzy inference system.

1) Adaptive inertia weight: In IPSO [20], the inertia weight is used to provide a balance between the global exploration and local exploitation. A linear inertia weight is adopted in IPSO. In IPSO, when the value of t/T is smaller which implies that it is doing global exploration. Similarly, higher value of t/T implies that it is doing fine-tuning (local exploitation). We can see that the characteristic of this function is linear. However, some of the optimization problems are nonlinear. Thus, an adaptive (nonlinear) inertia weight is proposed to enhance the performance of the searching. In this paper, an adaptive inertia weight $\omega_k(t)$ is proposed, which is incorporated with a fuzzy inference system. In a fuzzy inference system, there are two inputs and two outputs. One of the output is adaptive inertia weight $\omega_k(t)$, the other one is control parameter $\beta(t)$ of CM (It will discussed in later). The inputs of the fuzzy system are $\varsigma(t)/\|\varsigma(t)\|$ and t/T. $\varsigma(t)/\|\varsigma(t)\|$ is a normalized standard deviation of cost value among all the particles. A larger value of $\varsigma(t)/\|\varsigma(t)\|$ implies that the variance between each cost value of particle $f(X^p(t))$ is larger. Conversely, when the value of $\varsigma(t)/\|\varsigma(t)\|$ is smaller, that means the variance between each cost value of particle $f(X^i(t))$ is smaller. In other words, the location of each particles are closer. The formulation of $\varsigma(t)/\|\varsigma(t)\|$ is defined as follows:

$$\varsigma(t) = \sqrt{\frac{1}{\gamma}\sum_{i}^{\gamma}\left(f\left(\mathrm{x}^i(t)\right) - \bar{f}\left(\mathrm{x}^i(t)\right)\right)^2} \tag{10}$$

where

$$\bar{f}\left(\mathrm{x}^i(t)\right) = \frac{1}{\gamma}\sum_{i=1}^{\gamma} f\left(\mathrm{x}^i(t)\right) \tag{11}$$

$\|\cdot\|$ denotes the l_2 vector norm.

The adaptive inertia weight $\omega_k(t)$ is governed by the following fuzzy rules:

$$\text{Rule } j: \text{IF } \varsigma(t)/\|\varsigma(t)\| \text{ is } \mathrm{N}_1^j, \text{ AND } t/T \text{ is } \mathrm{N}_2^j, \text{ THEN } \omega_k(t) = \sigma_j,$$

$$j = \quad 1, \quad 2, \quad \ldots, \quad \varepsilon \tag{12}$$

where N_1^j and N_2^j are fuzzy terms of rule j, ε denotes the number of rules, $\sigma_j \in \left[\begin{array}{cc} \omega_{min} & \omega_{min} \end{array}\right]$ is the singleton to be determined. In this paper, ω_{min} and ω_{min} are set at 0.1 and 1.1 respectively [8]. The final value of $\omega_k(t)$ is given by:

$$\omega_k(t) = \sum_{j=1}^{\varepsilon} m_j(t)\sigma_j \tag{13}$$

where

$$m_j(t) = \frac{\mu_{\mathrm{N}_1^j}\left(\varsigma(t)/\|\varsigma(t)\|\right) \times \mu_{\mathrm{N}_2^j}(t/T)}{\sum_{j=1}^{r_m}\left(\mu_{\mathrm{N}_1^j}\left(\varsigma(t)/\|\varsigma(t)\|\right) \times \mu_{\mathrm{N}_2^j}(t/T)\right)} \tag{14}$$

$\mu_{\mathrm{N}_1^j}\left(\varsigma(t)/\|\varsigma(t)\|\right)$ and $\mu_{\mathrm{N}_2^j}(t/T)$ are the membership function corresponding to N_1^j and N_2^j respectively.

In the proposed algorithm, there are 3 membership functions for each input and shown in Fig. 3. The 3 fuzzy terms are namely L (Low), M (Middle), and H (High). Based on the characteristic of $\varsigma(t)/\|\varsigma(t)\|$ and t/T, there are 9 linguistic IF-THEN fuzzy rules and the fuzzy rule table for determine $\omega_k(t)$ is shown in Fig. 4 (a). The rationale of the selected fuzzy rules for determine $\omega_k(t)$ is described as follows: the value of $\omega_k(t)$ is determined by fuzzy inputs $\varsigma(t)/\|\varsigma(t)\|$ and t/T. The value of t/T represents the iteration stage (smaller value of t/T represents the searching process in the early stage, a larger value of t/T represents the searching process in the later stage). The value of $\omega_k(t)$ should be higher as the value of t/T is smaller (in early stage) implies that a larger value of velocity of particle element is given for global searching. Similarly, a larger value of t/T implies that a higher value of velocity of particle element for local searching. Because of it, the values of $\omega_k(t)$ at t/T is "L", are larger than t/T is set at"M". For the same reason, the values of $\omega_k(t)$ at t/T is "M" are larger than that as t/T is "H". The value of $\omega_k(t)$ should be smaller as t/T increase in order to reduce the value of velocity of particle element for fine-tuning.

As mentioned before, $\varsigma(t)/\|\varsigma(t)\|$ is a normalized standard deviation of cost value among all the particles. A larger value of $\varsigma(t)/\|\varsigma(t)\|$ implies that the variance between each cost value of particle $f(X^i(t))$ is larger. In other words, the location of each particle is far away. At t/T is "L", which the searching process is in early stage and when $\varsigma(t)/\|\varsigma(t)\|$ is "H", that implied the location of each particle is far away in early stage. Thus, a larger value of $\omega_k(t)$ should be given for global exploration. In a special case, when $\varsigma(t)/\|\varsigma(t)\|$ is "L", that implies the location of each particle is closed in early stage.

We also set $\omega_k(t)$ to a larger value, because there has a high chance that the solutions are trap into local optima (it is affected from the smaller value of $\varsigma(t)/\|\varsigma(t)\|$). Therefore, a larger value of $\omega_k(t)$ is given to force the particle escape the local optima. As the value of $\varsigma(t)/\|\varsigma(t)\|$ is "M", we set the value of $\omega_k(t)$ is slight smaller than that $\varsigma(t)/\|\varsigma(t)\|$ is "L" and $\varsigma(t)/\|\varsigma(t)\|$ is "H" in early stage (t/T is "L"). When t/T is "M", which the searching process is in middle stage. The rationale of the suggested value of $\omega_k(t)$ is similar to rules that when When t/T is "L". However, there is one difference that when $\varsigma(t)/\|\varsigma(t)\|$ is "L", the value of $\omega_k(t)$ is smaller than $\varsigma(t)/\|\varsigma(t)\|$ is "H". It is because the optimal solution may be found in middle stage where a smaller value of $\omega_k(t)$ is given. At t/T is "H", which the searching process is in later stage . In this stage, the searching process is undergo fine-tuning process (local exploitation) to find the optimal solution. Because of it, when the value of $\varsigma(t)/\|\varsigma(t)\|$ is "L" that implied the position

(b)

Fig. 4. The fuzzy rule table for determining (a) $w_k(t)$, and (b) $\beta(t)$

2) Cross-mutated operation: In this section, a cross-mutated (CM) operation is introduced. This new CM operation is merged the idea of crossover and mutation operation of genetic algorithm. The aim of the CM operation is force the particle escape the local optima. Furthermore, a control parameter $\beta(t)$ is introduced into the CM operation, and the operation becomes more adaptive. This control parameter is governed by some fuzzy rules with human knowledge. By introducing the CM operation, the performance of the proposed PSO method is improved.

The details of the CM operation is as follows. Every velocity of particle element of the swarm will have a chance to undergo CM operation governed by a probability of cross-mutated operation, $p_{cm} \in \left[\begin{array}{cc} 0 & 1 \end{array}\right]$, which is defined by user. For each velocity of particle element, a random number R_{cm} between 0 and 1 will be generated such that if it is less than or equal to p_{cm}, the CM operation will take place on that element. The sensitivity of the p_{cm} with experimental results and the analysis will be discussed in later. The choice of the p_{cm} will affect the quality of solution.

The resulting velocity of particle element under the CM operation is given by:

$$\bar{v}_j^i(t) = (1-\beta(t))\, v_j^i(t) + \beta(t)\tilde{v}_j^i(t) \qquad (15)$$

where

$$\tilde{v}_j^i(t) = \frac{1}{4}\left\{r_3 \cdot \left(\rho_{\max_j} - \rho_{\min_j}\right) - \rho_{\max_j}\right\} \qquad (16)$$

$v_j^i(t)$ is determined by (7), $\tilde{v}_j^i(t)$ is a random velocity of particle element and the value of this velocity is randomly generated and bounded with 0.25 of the dynamic range of the particle element. $r_3 \in \left[\begin{array}{cc} -1 & 1 \end{array}\right]$ is an uniform random number. In (15), the resulting velocity of particle element $\bar{v}_j^i(t)$ is combined with the information of $v_j^i(t)$ and $\tilde{v}_j^i(t)$. This information exchanging process is like as crossover operation. However, in CM operation, $\bar{v}_j^i(t)$ is changed (mutated) one-by-one which is like as mutation operation. Therefore, we called it is cross-mutated (CM) operation.

In (15), the control parameter $\beta(t)$ provides a balance to control the resulting velocity $\bar{v}_j^i(t)$ converge toward $v_j^i(t)$ or $\tilde{v}_j^i(t)$. If $\beta(t)$ is approaching 0, the $\bar{v}_j^i(t)$ will tends to the $v_j^i(t)$. Conversely, when $\beta(t)$ is approaching 1,the $\bar{v}_j^i(t)$ will tends to the $\tilde{v}_j^i(t)$. The proposed random velocity $\tilde{v}_j^i(t)$ in (16) has ability to force the particle element to escape the local optima with a random movement. In this operation, the value of the $\beta(t)$ is governed by nine fuzzy-rules. The fuzzy inference system is same as before we mentioned. The inputs of the fuzzy system are same. They are $\varsigma(t)/\|\varsigma(t)\|$ and t/T. Now, there are 9 linguistic fuzzy rules and the fuzzy rule table for determine $\beta(t)$ is shown in Fig. 4 (b).

The rationale of the selected fuzzy rules is similar to the rules of adaptive inertia weight in last sub-section. The brief description of the choosing fuzzy rules for CM operation is given as follows: the value of $\beta(t)$ is determined by $\varsigma(t)/\|\varsigma(t)\|$ and t/T, and some fuzzy rules. As mention before, the value of the t/T represents the iteration stage. We can see as t/T is "L", where the searching process is in early stage and as t/T is "H", where the searching process is in later stage, the values of $\beta(t)$ in early stage are larger than the values of $\beta(t)$ in later stage. It is because a significant random velocity (higher value of $\beta(t)$ in (15)) provides a global exploration in early stage. Conversely, the effect of the random velocity should be reduced in later stage for fine-tuning (local exploitation) with smaller value of $\beta(t)$.

Till now, we have discussed about the effect of the $\varsigma(t)/\|\varsigma(t)\|$, the concept is same as the rules of adaptive inertia weight. In the early stage, when $\varsigma(t)/\|\varsigma(t)\|$ is "L", that implies the location of each particle is closed. Thus, we need to set the value of $\beta(t)$ to be larger than that when $\varsigma(t)/\|\varsigma(t)\|$ is "M". The reason lies in the fact that a higher chance that the solution being trapped into a local optimum. Conversely, in the later stage, the searching process undergoes fine-tuning process (local exploitation) to find the optimal solution. Because of this, when the value of $\varsigma(t)/\|\varsigma(t)\|$ is "L" that implies the position of most particles are closed (similar) and near the best solution. Thus, a smallest value of $\beta(t)$ is given.

In (7), the particle velocity is limited by a maximum value $v_{\max}$. The parameter $v_{\max}$ determines the resolution with which regions are to be searched between the present

position and the target position. This limit enhances the local exploitation of the problem space and it realistically simulates the incremental changes of human learning. If $v_{\max}$ is too high, particles might fly past good solutions. If $v_{\max}$ is too small, particles may not explore sufficiently beyond local solutions. Empirically, $v_{\max}$ is often set at 10% to 20% of the dynamic range of the element on each dimension.

A new swarm $X(t)$ is updated after the velocity of all particles are updated. To ensure all particle elements x_j^i in $X(t)$ fall within the range $\left[\ \rho_{\mathbf{min}},\ \ \rho_{\mathbf{max}}\ \right]$, the following conditions are considered as follows: If $x_j^i(t)\ > \rho_{\max_j}$, then the updated $x_j^i(t)$ should equal to $\rho_{\max_j}$. Similarly, If $x_j^i(t)\ < \rho_{\min_j}$, then the updated $x_j^i(t)$ should equal to $\rho_{\min_j}$. Here, $\rho_{\mathbf{min}} = \left[\ \rho_{\min_1}\ \ \rho_{\min_2}\ \ \cdots\ \ \rho_{\min_n}\ \right]$ and $\rho_{\mathbf{max}} = \left[\ \rho_{\max_1}\ \ \rho_{\max_2}\ \ \cdots\ \ \rho_{\max_n}\ \right]$; $\rho_{\min_j}$ and $\rho_{\max_j}$ are minimum and maximum values of $x_j^i(t)$ respectively and $j = 1, 2, ..., n$.

After an updated swarm is generated. Next, convert all the particles in the swarm to job permutation $\pi(t)$ by using the sequence-order system based on the roulette wheel mechanism. After going through the process of the sequence-order system, a set of job sequence will be formed and then undergo swap based local search operation for local exploration on a job permutation space.

3) Swap based-Local search: Local searches are very important for the exploitation. In this paper, a swap-based local search method is designed for fine-tuning on the flow shop scheduling problem. The operation of this local search is simply to swap the selected two job order number. The operation of swap based local searching method is described as follows.

(1) Given a sequence of jobs π, where $\pi = J_1, J_2, ..., J_{i-1}, J_i, J_{i+1}, ...J_n$.
(2) Randomly picks 2 jobs, i.e., J_i and J_{i+1} .
(3) Swap the selected 2 jobs.

After the process, the new sequence of jobs should be J_1, J_2, ..., J_{i-1}, J_{i+1}, J_i, ...J_n. An example of swap based-local search method is given in Fig.5. In this figure, the job 7 and the job 1 are selected to undergo the swap process. After going through the swap operation, a new job sequence is generated. By using (1)-(5), a updated makespan C_{max} will be evaluated. The optimization process will repeat until a termination condition is met. The iterative process will be terminated when a defined number of iteration is met.

IV. Computational results

To test the performance of the proposed FPSOCM to flow shop scheduling problem, computational simulation is carried out with a suite of flow shop benchmark problems [22].

A. Experimental setup

The performance of HPSOWM [8], HPSOM [5], HGAPSO [19], HGPSO [18], IPSO [20], and the proposed FPSOCM on solving the flow-shop benchmarking problems are evaluated.

The following simulation conditions are in use:

For All PSOs:

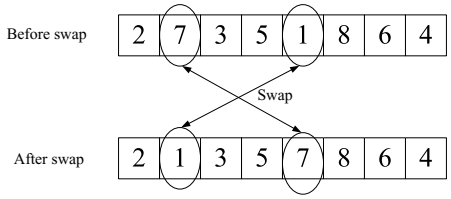

Fig. 5. The example of the swap-based local search method.

- Swarm size (γ): 100
- Number of runs: 20
- Acceleration constant φ_1: 2.05
- Acceleration constant φ_2: 2.05
- Maximum velocity v_{max}: 0.2
- Initial population: it is generated uniformly at random

For FPSOCM:

- Probability of cross-mutated operation (p_{cm}):
  p_{cm} = 0.05 for Car3, Car8;
  p_{cm} = 0.01 for Car1, Car2, Car4, Car5, Car6, Car7;

For HPSOWM, HPSOM, and HGAPSO:

- Probability of mutation operation (p_m): it is chosen by trial and error through experiments for good performance for all functions. (p_m= 0.2 for Car1 - Car8)

For HPSOWM:

- Shape parameter of the wavelet mutation: it is chosen by trial and error through experiments for good performance for all functions
- Parameter g of the wavelet mutation: 10000

For HGPSO:

- Learning rate: it is chosen by trial and error through experiments for good performance for all functions

For HGAPSO:

- Probability of crossover operation: 0.8

B. Results

In this section, the results for the 8 flow shop problem are given to validate the FPSOCM, which is proven to perform well on flow shop scheduling problem. The experimental results in terms of the average relative error (ARE), best relative error (BRE), and worst relative error (WRE) are summarized in Table I. The number of iterations 100 is adopted in all approaches. From the table, we can see that FPSOCM algorithm obtains a smaller ARE, BRE and WRE in all problems. In problem Car6 which is a 8 jobs 9 machines flow shop scheduling problem, the ARE of the FPSOCM is 0. Comparing with other algorithms, only FPSOCM can reach the optimal value. In Problem Car3, the ARE of FPSOCM is 0.06 which imply around 2.5 - 6 times improvement compared

COMPARISON RESULTS OF FPSOCM, HPSOWM, HPSOM, HGAPSO, HGPOS, AND IPSO. ALL RESULTS ARE AVERAGED ONES OVER 20 RUNS (A: CAR1-4, B: CAR5-8).

with other algorithm. Similarly, in Problem Car5, the ARE of FPSOCM is 0.019 which imply around 8 - 18 times improvement. So FPSOCM algorithm for flow shop scheduling problem to minimize makespan is more effective.

V. CONCLUSION

In this paper, we have proposed a hybrid particle swarm optimization which incorporates a fuzzy system and a new cross-mutated operation to tackle job shop scheduling problem. An adaptive inertia weight of PSO is presented. It is determined by a fuzzy system. Moreover, in order to solve the local optimum problem of PSO, a new operation namely cross-mutated operation is proposed. With these proposed operations, the solution quality is improved. The performance of the proposed hybrid PSO is compared with other hybrid PSOs with respect to the same set of flow scheduling problems. The results demontrate the effectiveness of the proposed algorithm for the flow shop scheduling problem.

Patent Valuation with a Fuzzy Binomial Model

Xiaolu Wang
Institute for Advanced Management Systems Research

Email: xiaolu.wang@abo.fi

***Abstract*—Patent valuation has always been a difficult task due to the considerable uncertainty involved in both the patent application procedure and the patent exploitation. This paper proposes, under the fuzzy framework, a multiperiod binomial approach for patent valuation of the latter case. We depart from the model introduced in S. Muzzioli et al. [1] by utilizing binomial tree to simulate the movement of patent monopoly benefits through time and representing the volatility of the patent monopoly benefits with fuzzy numbers, which is triggered by the fact that, in most cases, the Intellectual Property Rights (IPR) managers may not have good information on the parameters, and that the conventional probability theory is incapable of capturing this type of imprecision. Our model also reveals the values of the managerial flexibilities embedded in the patent exploitation.**

***Keywords*—Patent valuation; fuzzy sets; American call option**

I. Introduction

Patented inventions have played a very important role in human life and, in fact, pervaded every aspect of it, from telephone (patent held by Alexander Graham Bell) and first computer (patent held by Herman Hollerith), to insulin (patent held by the University of Toronto) and holography (patent held by Gábor Dénes). Having been granted the right to negate the use of the underlying inventions by others, which is also known as the underlying intellectual asset, the patent holders are obliged to disclose information on their inventions publicly for exploitation and further improvement by other researchers and inventors, which "enriches the total body of technical knowledge in the world, and therefore promotes further creativity and innovation in others" [2]. In addition to the monopolistic status, another principal incentive to file for patents is the interdependency between patent protection and research and development (R&D). On the one hand, powerful patent protection stimulates and facilitates economically efficient R&D, and the investments in R&D, on the other hand, require legal protection for its outputs. E. Eicher et al. [3] describes this interdependency between expenditures in IPR protection and research investments as follows "a lower degree of protection reduces the returns from research and hence the incentives to do R&D; similarly, a low level of R&D will reduce the return to investment in IPR protection". Therefore, it is of great interest to not only the patent applicants, but also those who manage granted patents and are to make crucial decisions about their management to know the values of both the underlying inventions and their patents (if granted) accurately and adequately. It is worth emphasizing that projects of commercializing the underlying inventions and patents protecting those inventions are two distinct entities [4], and in our study, we focus on the latter alone. Additionally, the patent valuation model to be presented is considered from the microeconomic perspective, that is to say, it is designed to evaluate individual patents, patent families and patent portfolios instead of the benefits they bring to the economy as a whole.

Patent valuation, however, is often a difficult task, primarily because both patent application process and patent exploitation are subject to various choices and decisions at a number of successive stages and thus involve a particularly high degree of flexibility. For example, patents can be licensed, sold, abandoned at any time in the post-grant phase or simply kept in force for own use by paying the annual renewal fee. Even the patent applicants may confront the decisions as to whether to file a foreign application and whether to continue with the on-going patent application at several decision points. It therefore makes perfect sense to employ real option valuation methods in hope of capturing the embedded flexibilities and thus acquiring a more accurate estimate of the value of the underlying patents. There has been much research on patent valuation that is based on real options-thinking and can be categorized into different subsets according to the methodologies that have been used. A. Pakes [5] considers the post-grant phase of a patent as *a series of call options* on the monopoly benefits of the coming year with the strike price of each option being the next renewal fee. He also claims that the IPR manager will renew the patent only if the monopoly benefits over the coming year plus the value of the option to renew the patent at the end of the year exceeds the renewal fee. H. Weeds [6] takes into consideration the possibilities of sleeping patents and studies a two-stage investment project, with research carried out and then a patent filed for the new invention in the first stage and irreversible market entry in the second, and models the two-stage problem as *real sequential compound options*. In more specific terms, exercising the option to conduct research and file a patent for any resultant invention buys the inventor a second option to commercialize the innovation. In addition, extensive literature on the management of patenting decisions has combined game theory and real option theory to study the effect of *strategic interactions* between different firms, as in R. Meng [7]. This is promoted by the fact that, in many real-world asset markets, the firms under consideration are not necessarily "monopolists or entities in a perfectly competitive market" [7], and therefore "exercise strategies cannot be determined separately, but must be formed as part of a strategic equilibrium" [8].

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Another problem which could arise when we deal with patent valuation is that the volatility of the underlying asset, which is assumed to be constant in the Discounted Cash Flow (DCF) analysis and Black-Scholes formula, is likely to vary drastically throughout both the patent application process and the life of the patent since "the fact that the patent has survived thus far makes it increasingly likely that it will be successful and profitable" [4]. This therefore provides the incentives for using fuzzy set theory to better formalize these uncertainties as "fuzzy sets are sets that allow gradation of belonging and serve as a representation of uncertain or imprecise knowledge" [9]. M. Collan et al. [10] introduced patent valuation with the fuzzy pay-off method [9], which is based on real option-thinking and specifically suitable for asset valuation involving uncertainty on the future cash-flow and estimation inaccuracy. E. Agliardi [11] also combined a real option to litigate with fuzzy valuation due to the unpredictable outcomes of trials.

Our study is an extension of the ideas of applying the conventional multiperiod binomial model to patent valuation, which is also juiced up with the work of S. Muzzioli et al. [1]. The original idea was triggered by the observation that the managerial flexibilities embedded in patents resemble the possibilities financial options grant their holders, and more specifically, that a patent asset is like an American call option with the underlying asset being the cash flow generated from the patent, which can be priced under the risk-neutral valuation paradigm by adopting numerical methods of finance such as the binomial model. In Section (II), we briefly introduce the multiperiod binomial pricing model for American (call) options and continue shortly on fuzzy sets and fuzzy numbers. Section (III) is devoted to the proposed patent valuation method. The last section concludes and suggests the possible future work.

II. Preliminaries

A. The Binomial Model for the Pricing of an American Option

An American option is a financial instrument which gives its holder the right, but not the obligation, to trade in a certain amount of underlying assets at a predetermined price at or before a specified date. A call (resp. put) option gives the right to buy (resp. sell) the underlying assets. The Cox-Ross-Rubinstein (or CRR) model presented in Cox et al. [12] is a simple discrete-time binomial model for option pricing, which allows preference-free or arbitrage pricing of every contingent claim[1], and only requires the following inputs: the strike price K, the present value of the underlying asset S_0, the number of time steps to maturity n, the risk-free interest rate r and the upward and downward jumping factors of the underlying asset price u and d, respectively. Cox et al. [12] also makes the following fundamental assumptions:

1) The asset price satisfies a multiplicative binomial process over discrete periods.
2) There are no transaction costs, margin requirements or taxes.
3) The risk-free interest rate r is constant.
4) In order to rule out arbitrage opportunities, it is assumed that $d < 1 + r < u$.
5) The model is complete.

In addition, we assume for simplicity that no dividends will be paid during the entire life cycle of the option.

First we look at the single-period binomial model, which is $n = 1$. In a complete market, the fair price of every contingent claim H is equal to the initial value of the unique replicating portfolio V_0, which can be calculated explicitly as the expected value of the discounted claim $\overline{H}$ under the risk-neutral probability measure Q defined by $(q, 1-q)$ such that $Q(S_1 = uS_0) = q$ and $Q(S_1 = dS) = 1 - q$. Therefore, for a single-period binomial model, we have

$$V_0 = \mathbb{E}_Q[\overline{H}].$$

The discounted asset price also has constant expectation under the risk-neutral probability measure Q so as to fulfill the no-arbitrage assumption, which implies[2]

$$S_0 = \mathbb{E}_Q[\overline{S}_1]$$

that is

$$1 = q\frac{u}{1+r} + (1-q)\frac{d}{1+r}$$

leading to

$$q = \frac{(1+r)-d}{u-d}, \tag{1}$$

$$1-q = \frac{u-(1+r)}{u-d}. \tag{2}$$

The upward and downward jumping factors of the underlying asset price are approximated by (see Cox et al. [12])

$$u = e^{\sigma\sqrt{\Delta t}}, \tag{3}$$

$$d = e^{-\sigma\sqrt{\Delta t}}, \tag{4}$$

where σ is the volatility of the underlying asset.

For the multiperiod binomial model, the replicating portfolio at each stage is formed exactly in the same way as in the single-period model. Therefore, without loss of generality, the values of the American (call) option at the terminal and intermediate stages can be determined as follows:

$$\begin{aligned}
V_n^i &= \left(S_n^i - K\right)^+, \\
S_n^i &= S_0 u^i d^{n-i},\ i = 0, \ldots, n, \\
V_m^j &= \max\left(S_m^j - K, \frac{1}{1+r}\left(qV_{m+1}^{j+1} + (1-q)V_{m+1}^j\right)\right), \\
S_m^j &= S_0 u^j d^{m-j},\ m = 0, \ldots, n-1,\ j = 0, \ldots, m.
\end{aligned}$$

[1] "A contingent claim represents the potential liability inherent in a derivative security". (Elliott and Kopp [13])

[2] We compute the risk-neutral probabilities based on the risk neutrality assumption which gives the same result as the replicating portfolio approach (or the arbitrage pricing theory approach), which is presented in Elliott and Kopp [13] and Shreve [14].

B. Fuzzy Sets and Fuzzy Numbers

Fuzzy sets serve as a approach of representing vague concepts expressed in natural language [15]. It provides us with a tool of describing the ambiguous notions, such as "the weather today is sunny" and "someone is tall". Mathematically, a fuzzy set A in a given universal set X can be defined as a set of ordered pairs, with the first element of each pair from X and the second element being its grade of membership standing for the degree to which the individual in the universe corresponds to the concept represented by the fuzzy set A, and with exactly one ordered pair assigned to each element of X. This implies the following membership function of A

$$\mu_A = X \to [0,1]\,,$$

where 0 and 1 represent non-membership and complete membership respectively, while the values in between represent the intermediate degrees of membership.

The γ-cut is an important concept associated with fuzzy sets, which is defined as follows:

Definition 1. *A γ-cut (or γ-level set) of a fuzzy set A of X is a non-fuzzy set denoted by $[A]^\gamma$ and defined by*

$$[A]^\gamma = \begin{cases} \{x \in X \mid A(x) \geq \gamma\}\,, & \text{if } \gamma > 0 \\ cl(suppA), & \text{if } \gamma = 0 \end{cases}$$

where $cl(suppA)$ denotes the closure of the support of A, which has the following form

$$supp(A) = \{x \in X \mid A(x) > 0\}\,.$$

Before we can bring up the definition of fuzzy numbers, the following concepts are needed first,

Definition 2. *[16] A fuzzy set A of X is called convex if $[A]^\gamma$ is a convex subset of X for all $\gamma \in [0,1]$.*

Definition 3. *[16] A fuzzy set A of a classical set X is called normal if there exists an $x \in X$ such that $A(x) = 1$. Otherwise A is subnormal.*

Essentially fuzzy numbers are nothing more than a special type of fuzzy sets which are defined on the real line $\mathbb{R}$, and their membership functions have the form

$$\mu_A = \mathbb{R} \to [0,1]\,.$$

Therefore they are generally used to "capture our intuitive conceptions of approximate numbers or intervals" [15]. For example a triangular fuzzy number (with center a) and a trapezoidal fuzzy number (with core $[a,b]$) can be seen as fuzzy quantities "x is approximately equal to a given real number a" and "x is approximately in a given interval $[a,b]$ of real numbers", respectively.

Definition 4. *[16] A fuzzy number A is a fuzzy set of the real line with a normal, (fuzzy) convex and continuous membership function of bounded support.*

Remark 1. *The terms membership function and fuzzy set and their notations can be interchangeably used since each fuzzy set is uniquely defined by its membership function [15].*

Definition 5. *A fuzzy set A is called a triangular fuzzy number with center (or peak) a, left width $\alpha > 0$ and right width $\beta > 0$ if its membership function has the following form*

$$A(x) = \begin{cases} 0, & \text{for } x < a-\alpha \text{ and } x > a+\beta \\ 1 - \frac{a-x}{\alpha}, & \text{for } a-\alpha \leq x \leq a \\ 1 - \frac{x-a}{\beta}, & \text{for } a < x \leq a+\beta \end{cases}$$

and can be denoted by $A = (\alpha, a, \beta)$. It is easy to show that

$$\begin{aligned} [A]^\gamma &= [a-(1-\gamma)\alpha, a+(1-\gamma)\beta] \\ &= [a-\alpha+\gamma\alpha, a+\beta-\gamma\beta] \end{aligned}$$

for all $\gamma \in [0,1]$, and therefore the support of A is $(a-\alpha, a+\beta)$.

Definition 6. *A fuzzy set A is called a trapezoidal fuzzy number with core (or tolerance interval) $[a,b]$, left width $\alpha > 0$ and right width $\beta > 0$ if its membership function has the following form*

$$A(x) = \begin{cases} 0, & \text{for } x < a-\alpha \text{ and } x > a+\beta \\ 1 - \frac{a-x}{\alpha}, & \text{for } a-\alpha \leq x < a \\ 1, & \text{for } a \leq x \leq b \\ 1 - \frac{x-b}{\beta}, & \text{for } b < x \leq b+\beta \end{cases}$$

and can be denoted by $A = (a, b, \alpha, \beta)$. It is easy to verify that

$$\begin{aligned} [A]^\gamma &= [a-(1-\gamma)\alpha, b+(1-\gamma)\beta] \\ &= [a-\alpha+\gamma\alpha, b+\beta-\gamma\beta] \end{aligned}$$

for all $\gamma \in [0,1]$, and therefore the support of A is $(a-\alpha, b+\beta)$.

III. The Fuzzy Binomial Model for Patent Valuation

Before proceeding to the discussion of the proposed model, it is worth emphasizing the concept of patents first. A patent can be defined as a set of exclusive rights, usually granted by national governments, to make exclusive use of a new, non-obvious invention for a predetermined (limited) period of time in return for publication of the underlying invention. Generally speaking, most patent applicants and patentees face the following four basic decision types at different stages [4]

1) Whether to file a patent application.
2) Whether to continue with the ongoing patent application at a few decision points.
3) Whether to maintain any patent granted in effect or abandon it.
4) Whether and how to exploit the patent after it is granted.

Here we only consider decision type 4, that is to say, we want to maintain the patent granted by paying renewal fees annually and look to make extra profits by licensing, besides monopoly benefits due to holding the patent.

In this study, a fuzzy binomial model is adopted to simulate the movement of patent monopoly benefits through time. As mentioned above, the opportunity of licensing for extra revenues is also taken into consideration on a regular basis,

which is usually once a year. That is, the patent would be evaluated annually and licensed to other investors if the monopoly benefits are high enough. This, however, would have an effect upon the existing competitive edge to some extent and would bring down the monopoly profits accordingly. Therefore, this flexibility takes the form of enabling the patent to be licensed in exchange for licensing fees and royalties on incurring a reduction in the monopoly profits, which is very similar to an embedded American option.

To capture the side effect on the monopoly benefits due to patent licensing, we introduce a triangular fuzzy discount factor[3] $\delta = (\alpha_\delta, a_\delta, \beta_\delta)$, which, by the conception of fuzzy numbers presented in Section (II-B), represents "the set of real numbers close to a_δ" [15]. This is to be determined according to experts' estimation and has the following form

$$\begin{aligned} \delta &= [\delta_{\min}, \delta_{\max}] \\ &= [a_\delta - \alpha_\delta, a_\delta - \beta_\delta], \end{aligned}$$

where $0 < a_\delta - \alpha_\delta < a_\delta - \beta_\delta < 1$.

A triangular fuzzy number $\sigma = (\alpha_\sigma, a_\sigma, \beta_\sigma)$ is also utilized to represent the volatility of the monopoly benefits, which, for simplicity of the notations, is defined in terms of its γ-cut by

$$\begin{aligned} \sigma &= [a_\sigma - (1-\gamma)\alpha_\sigma, a_\sigma + (1-\gamma)\beta_\sigma] \\ &= [a_\sigma - \alpha_\sigma + \gamma\alpha_\sigma, a_\sigma + \beta_\sigma - \gamma\beta_\sigma], \end{aligned} \tag{5}$$

where $\gamma \in [0,1]$. According to (3) and (4), the fuzzy[4] upward and downward jumping factors can be determined as follows:

$$\begin{aligned} u &= [u_{\min}, u_{\max}] \\ &= \left[e^{a_\sigma - \alpha_\sigma + \gamma\alpha_\sigma}, e^{a_\sigma + \beta_\sigma - \gamma\beta_\sigma}\right] \\ d &= [d_{\min}, d_{\max}] \\ &= \left[e^{-(a_\sigma + \beta_\sigma - \gamma\beta_\sigma)}, e^{-(a_\sigma - \alpha_\sigma + \gamma\alpha_\sigma)}\right] \end{aligned}$$

where $\triangle t = 1$ in our case since the evaluation is performed annually. Assumption 4. in Section (II-A) implies that

$$d_{\max} < 1 + r < u_{\min}$$

which is

$$-(a_\sigma - \alpha_\sigma) < \ln(1+r) < a_\sigma - \alpha_\sigma$$

when γ is set to be 0.

Next we adopt the approach presented in S. Muzzioli et al. [1] to determine the fuzzy risk-neutral probabilities. By using (1) and (2), we have

$$\frac{\partial q}{\partial u} = \frac{\partial\left(\frac{(1+r)-d}{u-d}\right)}{\partial u} = \frac{d-(1+r)}{(u-d)^2} < 0$$

and

$$\frac{\partial q}{\partial d} = \frac{\partial\left(\frac{(1+r)-d}{u-d}\right)}{\partial d} = \frac{(1+r)-u}{(u-d)^2} < 0,$$

which implies that the maximum (resp. minimum) of q is obtained at $u_{\min}$ and $d_{\min}$ (resp. $u_{\max}$ and $d_{\max}$). Analogously, it is easy to verify

$$\frac{\partial(1-q)}{\partial u} = \frac{\partial\left(\frac{u-(1+r)}{u-d}\right)}{\partial u} = \frac{(1+r)-d}{(u-d)^2} > 0$$

and

$$\frac{\partial(1-q)}{\partial d} = \frac{\partial\left(\frac{u-(1+r)}{u-d}\right)}{\partial d} = \frac{u-(1+r)}{(u-d)^2} > 0,$$

that is, the maximum (resp. minimum) of $1-q$ is obtained at $u_{\max}$ and $d_{\max}$ (resp. $u_{\min}$ and $d_{\min}$). Therefore, the fuzzy risk-neutral probabilities are as follows:

$$\begin{aligned} q &= [q_{\min}, q_{\max}] \\ &= \left[\frac{(1+r)-d_{\max}}{u_{\max}-d_{\max}}, \frac{(1+r)-d_{\min}}{u_{\min}-d_{\min}}\right], \\ 1-q &= [(1-q)_{\min}, (1-q)_{\max}] \\ &= \left[\frac{u_{\min}-(1+r)}{u_{\min}-d_{\min}}, \frac{u_{\max}-(1+r)}{u_{\max}-d_{\max}}\right], \end{aligned}$$

and they satisfy the following equalities

$$q_{\min} + (1-q)_{\max} = 1 \text{ and } q_{\max} + (1-q)_{\min} = 1.$$

By applying the fuzzy risk-neutral probabilities and the fuzzy upward and downward jumping factors, our model becomes[5]

$$\begin{aligned} V_n^i &= \max\left(S_n^i - R, \delta S_n^i - R + L\right), \\ S_n^i &= S_0\left[u_{\min}^i, u_{\max}^i\right] \otimes \left[d_{\min}^{n-i}, d_{\max}^{n-i}\right],\ i = 0, \ldots, n, \\ V_m^j &= \max\Bigg(\delta S_m^j - R + L, \frac{1}{1+r}\Big([q_{\min}, q_{\max}] V_{m+1}^{j+1} \oplus \\ &\qquad [(1-q)_{\min}, (1-q)_{\max}] V_{m+1}^j\Big)\Bigg), \\ S_m^j &= S_0\left[u_{\min}^j, u_{\max}^j\right] \otimes \left[d_{\min}^{m-j}, d_{\max}^{m-j}\right], \\ &\qquad m = 0, \ldots, n-1, j = 0, \ldots, m, \end{aligned}$$

[3]Triangular fuzzy numbers are adopted for simplicity.

[4]See G. J. Klir et al. [15] for the characteristics of arithmetic operations on fuzzy numbers. From this point forward, all fuzzy numbers are represented by the bounded intervals, which should not be confused with the γ-cut.

[5]We define the arithmetic operations on fuzzy number and the ordering of fuzzy numbers as follows: let $A = [a_1, a_2]$ and $B = [b_1, b_2]$ be two fuzzy numbers, we define

$$\begin{aligned} A \oplus B &= [a_1 + b_1, a_2 + b_2], \\ A \ominus B &= [a_1 - b_2, a_2 - b_1], \\ A \otimes B &= [a_1 b_1, a_2 b_2], \end{aligned}$$

and, provided that $0 \notin [b_1, b_2]$,

$$A \oslash B = [a_1/b_1, a_2/b_2];$$

let $c \in \mathbb{R}$, then we define

$$\begin{aligned} \max(A, B) &= [\max(a_1, b_1), \max(a_2, b_2)], \\ \max(A, c) &= [\max(a_1, c), \max(a_2, c)]. \end{aligned}$$

where

V = the fuzzy patent values
S_0 = the present value of the monopoly benefits from the underlying patent
R = annual patent renewal fees
L = patent licensing fees and royalties[6]
δ = the fuzzy discount rate of the monopoly profits due to patent licensing
n = time periods to patent maturity.

Note that, by adjusting γ in (5), this valuation model is capable of providing the patentees varying weighted intervals of the fair price of the patent. If $\gamma = 1$, the bounded interval collapses to one crisp number which is the "most likely" [17] patent value.

IV. Discussion and conclusions

In this paper, we extend the ideas of applying the conventional multiperiod binomial model to patent valuation by taking into consideration the uncertainty on the volatility of the patent monopoly benefits, which is formalized in our study through fuzzy set-based methodology. We started from determining the fuzzy upward and downward jumping factors according to Cox et al. [12], which leads to the fuzzy risk-neutral probabilities calculated by following the method presented in S. Muzzioli et al. [1]. Additionally, we take into consideration the side effect of patent licensing through introducing a fuzzy discount factor on the monopoly benefits. Together with the derived fuzzy risk-neutral probabilities, the patent value is determined in the similar way as in the American option pricing method.

Our model allows direct input of estimates of the volatility parameter, instead of assuming an interval of possible values for the upward and downward jumping factors respectively as in S. Muzzioli et al. [1] and [17]. However, the single option to license the underlying patent is a limitation of this model, since the option of direct commercialization, a combination of commercialization and licensing, outright sale or abandonment [4] may also exist in practical cases. For example, S.-H. Liao et al. [18] have proposed an approach to evaluate investment project under uncertainty, which has taken into account the managerial flexibility to expand or contract its scale of operation at a specific time.

In our model, we only consider the case when the underlying patent has been granted and we want to exploit it while keeping the patent in force. However, the decision type 1 and 2 mentioned in Section (III) are also of great interest to IPR managers as the patent application procedure is not just "a simple investment project with initial costs and near certain future returns" [4] but a very complex process, each stage of which involves cost, actual profits or potential future profits with great uncertainties and decision-making points of whether to continue the application or not. Therefore, patent application valuation is intuitively the natural candidate for our future work.

[6]Both patent licensing fees and royalties are assumed to be constant for simplicity.

***Abstract*—In this paper, we propose a natural way to define topologies by using fuzzy metrics; here the value of the distance between two points is a non-negative fuzzy number. With such topology, we also define notions like continuity, convergent sequence, Cauchy sequences and complete spaces. As an application, we provide a fixed point theorem quite similar to the classical Banach's theorem.**

Keywords: *Fuzzy metric, fixed point, fuzzy numbers, α-cuts, intervals, topology, continuity.*

I. Introduction

The first concept of *fuzzy metrics* was introduced by Kramosil and Michalek [1], which adaptated the notion of statistical metric spaces — or Menger spaces (see [2]) — to the fuzzy viewpoint. There, the distance between two points, a and b, is seen as a probabilistic distribution, and the expression $d(a,b)(t)$ denotes the assertion: "the probability of the distance from a to b is less than t". In [3], Kaleva and Seikkala introduced another concept of fuzzy metric; in this case, the distance between two points is a non-negative fuzzy number and the same expression $d(a,b)(t)$ now means: "the possibility (see [4]) of the distance between a and b is t".

There are several investigations concerning such approaches of fuzzy metric spaces, with results such as: fixed-point theorems, completions, separability, etc. (see [5], [6], [7]). In both cases, such generalizations are based on changing the usual valuation space $\langle \mathbb{R}^+, \leq \rangle$ to a suitable one. With the usual valuation, a metric on a set M is a function, satisfying some properties, which returns a quantitative information about the distance between two points. With such formalization it is possible to define a topology on M by using the concept of open ball; which is an entity with a strong geometric appeal. With this kind of topology, it is possible to abstract important concepts which reside in the world of real numbers; namely: continuity, completeness, compactness, etc.

The basic metric properties are stated in terms of the natural order, "$\leq$", and the sum on $\mathbb{R}$. This establishes a connection between the axiomatics and the structure of the valuation. Thus, in principle, to modify the valuation space in order to preserve basic properties, the new valuation space should retain both: a notion of sum and a notion of order. However, in [8], we introduced a new kind of generalization by modifying the usual valuation; $\mathbb{R}$ was replaced by an ordered (preordered) set $(G, \leq)$ with smallest element, also endowed with a new kind of relation; called: *semi-auxiliary relation* for $\leq$. The resulting valuation space was named *Informative Metric Valuation* or just **IMV** and a function $d : M \times M \rightarrow G$ satisfying suitable axioms was designated by *Informative Metrics*. Such generalization produced topologies very similar to the usual case; since the basic building blocks (open balls) where easily recovered.

Kaleva and Seikkala showed in [3] that, in a particular case, their proposed fuzzy metrics is very similar to the usual metric when an addition and an order relation are defined on the set of non-negative fuzzy numbers. In that case, the resulting fuzzy metric space becomes a *generalized metric* in the sense of [9], which is a bridge to the IMV approach. Following such bridge, we apply the ideas of [8] to define a natural topology on a fuzzy metric space. With such topology, concepts like: continuity, completeness, convergent and Cauchy sequences arise naturally. They are investigated here and an application of them: a fixed-point theorem is provided. A very important aspect of such applicaton is that its proof follows steps similar to those in the proof of classical Banach theorem (see [10]) which depend only on the topological concepts listed above. This does not happen with the most of the proofs of fixed-points theorems for fuzzy metric spaces, revealing that our approach does not only have an advantage, but that it also gives a way to obtain similar classical results and notions that are built on usual topological concepts.

II. Preliminaries

In this section, we introduce the basic concepts that will be used in the whole paper, such as: fuzzy numbers, fuzzy arithmetic, partial order on the fuzzy numbers and some required properties.

A. Fuzzy Numbers: arithmetic and order

A fuzzy number is a fuzzy set $A : \mathbb{R} \longrightarrow [0,1]$ satisfying:

1) A is normal (exists $t \in \mathbb{R}$ such that $A(t) = 1$);
2) The support of A — i.e. the set $suppA = \{t \in \mathbb{R};\ A(t) > 0\}$ — is a bounded set;
3) For every $\alpha \in (0,1]$, the α-cut $A_\alpha = \{t \in \mathbb{R};\ A(t) \geq \alpha\}$ is a closed interval.

Every real number r can be seen as a fuzzy number, by the following membership function:

$$\mu_r(t) = \begin{cases} 1, \text{ if } t = r \\ 0, \text{ if } t \neq r \end{cases}.$$

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

This fuzzy numbers will be denoted by $\tilde{r}$. For other examples of fuzzy numbers, like triangular and trapezoidal fuzzy numbers, see [11].

The following theorem gives the characterization of fuzzy numbers.

Theorem II.1. *Let $A : \mathbb{R} \longrightarrow [0,1]$ be a fuzzy set. Then, A is a fuzzy number iff there exists a closed interval $[a,b]$ and functions $l : (-\infty, a) \longrightarrow [0,1]$ and $r : (b, \infty) \longrightarrow [0,1]$, where l is non-decreasing, continuous from the right and there exists ω_1 such that $l(t) = 0$, for all $t < \omega_1$ and r is non-increasing, continuous from the left and there exists $\omega_2 \in \mathbb{R}$ such that $r(t) = 0$ for all $t > \omega_2$ such that:*

$$A(t) = \begin{cases} 1, \text{ if } t \in [a,b] \\ l(t), \text{ if } t < a \\ r(t), \text{ if } t > b \end{cases}.$$

Proof: See [11]. ■

A non-negative fuzzy number A is a fuzzy number such that $A(t) = 0$ for all $t < 0$. If $r > 0$, then $\tilde{r}$ is a non-negative fuzzy number. The set of all non-negative fuzzy numbers will be denoted by G.

If $A \in G$ and $\alpha \in (0,1]$, then we use the notation $A_\alpha = [\underline{a_\alpha}, \overline{a_\alpha}]$.

Since the fuzzy sets are uniquely defined by your α-cuts, we can define an arithmetic and a partial order in G from an arithmetic and a partial order on the set of closed real intervals $\mathbb{IR}$.

Let $\mathbb{IR}^+$ be the set of all intervals $[a,b]$ such that $0 \leq a \leq b$. We consider the following operations on $\mathbb{IR}^+$:

i) $[a,b] + [c,d] = [a+b, c+d]$;
ii) $[a,b] \cdot [c,d] = [ac, bd]$.

This operations are the same operations defined by Moore (see [12]) for the set $\mathbb{IR}$ of all closed intervals. We define the partial order $\leq_{km}$ (Kulisch-Miranker order, see [13]) by: $[a,b] \leq_{km} [c,d] \Leftrightarrow a \leq c$ *and* $b \leq d$. The next proposition gives some properties of $\mathbb{IR}^+$.

Proposition II.1. *Let $A, B, C, D \in \mathbb{IR}^+$, where $A = [\underline{a}, \overline{a}]$, $B = [\underline{b}, \overline{b}]$, $C = [\underline{c}, \overline{c}]$ and $D = [\underline{d}, \overline{d}]$. The following properties are hold:*

1) $[0,0] \leq_{km} A$, *for all* $A \in \mathbb{IR}^+$;
2) $A + (B + C) = (A + B) + C$ *and* $A \cdot (B \cdot C) = (A \cdot B) \cdot C$;
3) $A^n = [\underline{a}^n, \overline{a}^n]$;
4) *If* $A \leq_{km} B$ *and* $C \leq_{km} D$, *then* $A + C \leq_{km} B + D$ *and* $A \cdot C \leq_{km} B \cdot D$;
5) *If* $\overline{b} < 1$, *then* $A \cdot B <_{km} A$, *ie,* $A \cdot B \leq_{km} A$ *and* $A \cdot B \neq A$.

Proof: For items 2) and 3) see [12]. The proof of items 1), 4) and 5) are immediate. ■

From the above interval operations, we can define similar operations on G.

Definition II.1. *Let $A, B \in G$. We define:*

1) *The sum between A and B is the fuzzy number $A \oplus B \in G$ such that $(A \oplus B)_\alpha = A_\alpha + B_\alpha$, for all $\alpha \in (0,1]$;*
2) *The product between A and B is the fuzzy number $A \odot B \in G$ such that $(A \odot B)_\alpha = A_\alpha \cdot B_\alpha$, for all $\alpha \in (0,1]$;*
3) *The partial order $\preceq$ is defined by $A \preceq B \Leftrightarrow A_\alpha \leq_{km} B_\alpha$, for all $\alpha \in (0,1]$.*

Proposition II.2. *Let $A, B, C, D \in G$. The following properties are hold:*

1) $\tilde{0} \preceq A$, *for all* $A \in G$;
2) $A \oplus (B \oplus C) = (A \oplus B) \oplus C$ *and* $A \odot (B \odot C) = (A \odot B) \odot C$;
3) $(A^n)_\alpha = (A \odot ... \odot A)_\alpha = [\underline{a_\alpha}^n, \overline{a_\alpha}^n]$, *for all* $\alpha \in (0,1]$;
4) *If* $A \preceq B$ *and* $C \preceq D$, *then* $A \oplus C \preceq B \oplus D$ *and* $A \odot C \preceq B \odot D$;
5) *If* $\overline{b_\alpha} < 1$, *for all* $\alpha \in (0,1]$, *then* $A \odot B \prec A$, *ie,* $A \odot B \leq_{km} A$ *and* $A \odot B \neq A$.

Proof: It's straightforward from the proposition II.1. ■

In an usual metric space, we define the open balls $B(a,r)$ using the strict relation $<$. The strict relation $\prec$ on G — namely $A \preceq B$ iff $A \preceq B$ and $A \neq B$ — has proved inadequate for this purpose, so we need to define a relation that will make the role of the strict relation.

Definition II.2. *Let $A, B \in G$. The relation $\prec\prec$ is defined by: $A \prec\prec B$ iff there exists $r_1, r_2 > 0$ such that $\underline{b_\alpha} - \underline{a_\alpha} > r_1$ and $\overline{b_\alpha} - \overline{a_\alpha} > r_2$, for all $\alpha \in (0,1]$.*

Example II.1. *If $a, b \in \mathbb{R}^+$, with $a < b$, then $\tilde{a} \prec\prec \tilde{b}$.*

Example II.2. *A triangular fuzzy numbers is a fuzzy set with a "triangle shape". Its membership function A is defined by: $A(x) = 0$, if $x \leq a_1$, $A(x) = l(x)$, if $a_1 \leq x \leq a_2$, where $l(x)$ is the straight line connecting the points $(a_1, 0)$ and $(a_2, 1)$, $A(x) = r(x)$, if $a_2 \leq x \leq a_3$, where $r(x)$ is the straight line connecting the points $(a_2, 1)$ and $(a_3, 0)$ and $A(x) = 0$, if $x \geq a_3$. The numbers a_1, a_2 and a_3 completely determine A, so we use the notation $A = (a_1, a_2, a_3)$. If $A = (a_1, a_2, a_3)$ and $B = (b_1, b_2, b_3)$ are two triangular fuzzy numbers, then $A \prec\prec B$ if, and only if, $a_1 < b_1$, $a_2 < b_2$ and $a_3 < b_3$.*

Proposition II.3. *Let $A, B, C, D \in G$. The following properties are valid:*

1) *If* $A \prec\prec B$, *then* $A \prec B$;
2) *If* $A \preceq B \prec\prec C \preceq D$, *then* $A \prec\prec D$;
3) *If* $A \preceq C$ *and* $B \prec\prec D$, *then* $A \oplus B \prec\prec C \oplus D$.

Proof:

1) It's straighforward.
2) There exists $r_1, r_2 > 0$, such that $\underline{c_\alpha} - \underline{b_\alpha} > r_1$ and $\overline{c_\alpha} - \overline{b_\alpha} > r_2$, for all $\alpha \in (0,1]$. Since $\underline{b_\alpha} \geq \underline{a_\alpha}$, $\overline{b_\alpha} \geq \overline{a_\alpha}$, $\underline{d_\alpha} \geq \underline{c_\alpha}$ and $\overline{d_\alpha} \geq \overline{c_\alpha}$, for all $\alpha \in (0,1]$, we can conclude that $\underline{d_\alpha} - \underline{a_\alpha} > r_1$ and $\overline{d_\alpha} - \overline{a_\alpha} > r_2$, for all $\alpha \in (0,1]$, so $A \oplus B \prec\prec C \oplus D$
3) There exists $r_1, r_2 > 0$ such that $\underline{d_\alpha} - \underline{b_\alpha} > r_1$ and $\overline{d_\alpha} - \overline{b_\alpha} > r_2$. We have $\underline{c_\alpha} - \underline{a_\alpha} \geq 0$ and $\underline{c_\alpha} - \underline{a_\alpha} \geq 0$, so $\underline{d_\alpha} - \underline{b_\alpha} + \underline{c_\alpha} - \underline{a_\alpha} > r_1$ and $\overline{d_\alpha} - \overline{b_\alpha} + \overline{c_\alpha} - \overline{a_\alpha} > r_2 \Rightarrow A \oplus B \prec\prec C \oplus D$.

■

Corollary II.2. *Let $A, B, C \in G$. Then:*

1) *If $A \preceq B \prec\prec C$, then $A \prec\prec C$;*
2) *If $A \prec\prec B \preceq C$, then $A \prec\prec C$.*

Proof: It's straightforward. ∎

It also follows from the above results that the relation $\prec\prec$ is transitive.

The next results are very important to ensure that the class of open sets in the following is Hausdorff.

Theorem II.3. *If $A, B \in G$, with $\tilde{0} \prec\prec A$ and $\tilde{0} \prec\prec B$ then exists $C \in G$, with $\tilde{0} \prec\prec C$, such that $C \preceq A$ and $C \preceq B$.*

Proof: Since $\tilde{0} \prec\prec A$ and $\tilde{0} \prec\prec B$, then exists $r_1, r_2 > 0$ such that $\overline{a_\alpha} \geq \underline{a_\alpha} > r_1$ and $\overline{b_\alpha} \geq \underline{b_\alpha} > r_2$. So take $C \in G$ defined by $C = \tilde{r}$, where $r = \min\{r_1, r_2\} > 0$. So, trivially we have $\tilde{0} \prec\prec C$, $C \preceq A$ and $C \preceq B$. ∎

Theorem II.4. *If $A, B \in G$ with $A \prec\prec B$, then there exists $C \in G$, with $\tilde{0} \prec\prec C$ such that $A \oplus C \prec\prec B$.*

Proof: There exists $r_1, r_2 > 0$ such that $\underline{b_\alpha} - \underline{a_\alpha} > r_1$ and $\overline{b_\alpha} - \overline{a_\alpha} > r_2$. It sufficient to take $C \in G$ defined by $C(t) = \begin{cases} 1, \text{ if } t = r/2 \\ 0, \text{ if } t \neq r/2 \end{cases}$, where $r = \min\{r_1, r_2\}$. ∎

Theorem II.5. *If $A \in G$, with $\tilde{0} \prec\prec A$, then exists $B, C \in G$, with $\tilde{0} \prec\prec B$ and $\tilde{0} \prec\prec C$ such that $B \oplus C \prec\prec A$.*

Proof: Since $\tilde{0} \prec\prec$, there exists $r > 0$ such that $\overline{a_\alpha} \geq \underline{a_\alpha} > r$. It sufficient to take $B, C \in G$ defined by $B(t) = C(t) = \begin{cases} 1, \text{ if } t \in [r/8, r/4] \\ 0, \text{ if } t \notin [r/8, r/4] \end{cases}$. ∎

III. Fuzzy Metric

In their paper, Kaleva and Seikkala gave the following definition of fuzzy metric:

Definition III.1. *Let be M a non-empty set, a mapping $d : M \times M \longrightarrow G$ and $L, R : [0,1] \times [0,1] \longrightarrow [0,1]$ two mappings symmetric, non-decreasing on both arguments and satisfying $L(0,0) = 0$ and $R(1,1) = 1$. The quadruple (X, d, L, R) is called a fuzzy metric space and d a fuzzy metric, when:*

i) $d(x,y) = \tilde{0}$ if and only if $x = y$;
ii) $d(x,y) = d(y,x)$, for all $x, y \in M$;
iii) Given $x, y \in M$, use notation $[d(x,y)]_\alpha = [\lambda_\alpha(x,y), \rho_\alpha(x,y)]$. Thus, for all $x, y, z \in M$,

1) *$d(x,y)(s+t) \geq L(d(x,z)(s), d(y,z)(t))$, whenever $s \leq \lambda_1(x,z)$, $t \leq \lambda_1(z,y)$ and $s + t \leq \lambda_1(x,y)$;*
2) *$d(x,y)(s+t) \leq R(d(x,z)(s), d(y,z)(t))$, whenever $s \geq \lambda_1(x,z)$, $t \geq \lambda_1(z,y)$ and $s + t \geq \lambda_1(x,y)$;*

Example III.1 (Kaleva and Seikkala)**.** *Let E be the set of all fuzzy numbers. The function $d : E \times E \longrightarrow G$ defined by*

$$d(x,y) = \begin{cases} |x - y| & , \text{ if } x \neq y \\ \tilde{0} & , \text{ if } x = y \end{cases} \quad (1)$$

is a fuzzy metric where $L \equiv 0$ and $R = \max$

There are several functions L and R satisfying the conditions in Definition III.1. For example, for $L = \min$ and $R = \max$ the following result is hold:

Theorem III.1. *In a fuzzy metric space $(X, d, \min, \max)$, the condition $iii)$ of the definition III.1 is equivalent to:*

$$d(x,z) \preceq d(x,y) \oplus d(y,z).$$

Proof: See [3]. ∎

In this case, a function $d : M \times M \longrightarrow G$ is a fuzzy metric if and only if it satisfies:

i) $d(x,y) = \tilde{0}$ if and only if $x = y$;
ii) $d(x,y) = d(y,x)$, for all $x, y \in M$;
iii') $d(x,z) \preceq d(x,y) \oplus d(y,z)$.

Thus, a fuzzy metric is a generalized metric in the sense given in [9]. The condition iii'), or triangle inequality, takes a closer way than usual. In this paper, we consider only fuzzy metric in this sense and we will call them gf-metrics.

Example III.2. *If $d : M \times M \longrightarrow \mathbb{R}$ is an usual metric, then $d_f : M \times M \longrightarrow G$ defined by $d_f(x,y) = \tilde{d(x,y)}$ is a **gf-metric**.*

Example III.3. *Let $d_1, d_2, d_3, d_4 : M \times M \longrightarrow \mathbb{R}$ be usual metrics such that $d_1 \leq d_2 \leq d_3 \leq d_4$. The function $d_f : M \times M \longrightarrow G$ defined by:*

$$d_f(x,y)(t) = \begin{cases} 1/2, \text{ if } d_1(x,y) \leq t < d_2(x,y) \\ 1, \text{ if } d_2(x,y) \leq t \leq d_3(x,y) \\ 1/2, \text{ if } d_3(x,y) < t \leq d_4(x,y) \\ 0, \text{ in other cases} \end{cases}$$

is a gf-metric.

Theorem III.2. *Let $d : M \times M \longrightarrow G$ be a gf-metric. If $d(a,b) \prec\prec R$, where $\tilde{0} \prec\prec R$, then exists $\tilde{0} \prec\prec D$ such that $d(b,c) \prec\prec D \Rightarrow d(a,c) \prec\prec R$.*

Proof: Since $d(a,b) \prec\prec R$, it follows from theorem II.4 that there exists $\tilde{0} \prec\prec D$ such that $d(a,b) \oplus D \prec\prec R$. Suppose that $d(b,c) \prec\prec D$. So, follows from the proposition II.3 that $d(a,b) \oplus d(b,c) \prec\prec d(a,b) \oplus D \prec\prec R \Rightarrow d(a,b) \oplus d(b,c) \prec\prec R$. From the triangle inequality, it follows that $d(a,c) \preceq d(a,b) \oplus d(b,c) \prec\prec R \Rightarrow d(a,c) \prec\prec R$. ∎

The above theorem guarantees that all fuzzy metric is an informative metric, where the IMV is $(G, \preceq, \prec\prec, \tilde{0})$ (see [8]).

A. Topology via Fuzzy Metric

We begin this section with a definition of open ball that has the same geometric sense of open balls in usual metric spaces.

Definition III.2. *Let (M, d) be an gf-metric space. Given $a \in M$ and $R \in G$, with $\tilde{0} \prec\prec R$, the open ball of center a and radius R is the set $B(a,R) = \{b \in M; d(a,b) \prec\prec R\}$. A subset $O \subseteq M$ is an **open set**, if for every $a \in O$ exists an open ball $B(a,R)$, such that $B(a,R) \subseteq O$.*

Observation III.1. *The empty set is an open set by convention.*

Theorem III.3. *Let (M, d) be an gf-metric space. The class $\Im(M)$ of the open sets of M is a topology on M.*

Proof: It must be proved that: $\emptyset, M \in \Im(M)$, if $\{A_\lambda\}_{\lambda\in L} \subseteq \Im(M)$, then $\bigcup_{\lambda\in L} A_\lambda \in \Im(M)$, and if $A, B \in \Im(M)$, then $A \cap B \in \Im(M)$. The first two conditions are immediate. Let $A, B \in \Im(M)$. Take $a \in A \cap B$. Since A and B are open sets, there are two open balls $B(a, R_1)$ and $B(a, R_2)$ such that $B(a, R_1) \subseteq A$ and $B(a, R_2) \subseteq B$. By the definition of open ball, we have $\tilde{0} \prec\prec R_1$ and $\tilde{0} \prec\prec R_2$, so, from the theorem II.3, there is $D \in G$, with $\tilde{0} \prec\prec D$ such that $D \preceq R_1$ and $D \preceq R_2$. Thus, consider the open ball $B(a, D)$. Take $b \in B(a, D)$, which implies that $d(a, b) \prec\prec D$. Thus, follows from the proposition II.3 that $d(a, b) \prec\prec R_1 \Rightarrow b \in B(a, R_1)$ which implies that $B(a, D) \subseteq B(a, R_1)$. Similarly it is proved that $B(a, D) \subseteq B(a, R_2)$. Thus, $B(a, D) \subseteq A \cap B$, and so $A \cap B \in \Im(M)$. ∎

Proposition III.1. *Let (M, d) be an gf-metric space. Every open ball are open sets.*

Proof: Follows directly from theorem III.2. ∎

The class of all open balls in a gf-metric space (M, d) is a basis for the topology $\Im(M)$.

In [3], the authors defined a topology generated by a fuzzy metric space (M, d, L, R), it is based on the following definition of open ball:

$$B(a, \varepsilon, \alpha) = \{y \in M; \rho_\alpha(x, y) < \varepsilon\} \tag{2}$$

Note that, the definition in 2 depends only on the upperbound of α-cuts $d(x, y)_\alpha$. Thus, the topology generated does not fully incorporate the vagueness expressed by the fuzzy number $d(x, y)$. However, the definition proposed here incorporates all the information contained in $d(x, y)$, since the relation used to define the open balls depends both: on upper and lowerbounds of each α-cut.

Remark III.1. *In usual metric spaces the strong order "$<$" is used to define open balls. Those spaces has the property: "$0 < d(x, y)$, whenever $x \neq y$". In the last section we defined the notion of open balls in terms of "$\prec\prec$" relation and in what follows we define gf-spaces which share the corresponding property.*

Definition III.3 (Hausdorff gf-metric spaces)**.** *A gf-metric space which satisfies: "$\tilde{0} \prec\prec d(x, y)$, whenever $x \neq y$" is called a **Hausdorff gf-metric space**.*

Theorem III.4. *Let (M, d) be a Hausdorff gf-metric space. The resulting topology, $\Im(M)$, is a Hausdorff topology.*

Proof: Let (M, d) be a gf-metric space. Take $a, b \in M$, where $a \neq b$. Thus, we have $\tilde{0} \prec\prec d(a, b)$. From the theorem II.5 follows that there exists $B, C \in G$, with $\tilde{0} \prec\prec B$ and $\tilde{0} \prec\prec C$ such that $B \oplus C \prec\prec d(a, b)$. Define the open balls $B(a, B)$ and $B(b, C)$. Suppose there exists $c \in B(a, B) \cap B(b, C)$, which implies $d(a, c) \prec\prec B$ and $d(c, b) \prec\prec C$, so $d(a, b) \preceq d(a, c) \oplus d(b, c) \prec\prec B \oplus C \prec\prec d(a, b) \Rightarrow d(a, b) \prec\prec d(a, b)$, so $d(a, b) \prec d(a, b)$, which is a contradiction. ∎

From now on we consider just Hausdorff gf-metric spaces.

Definition III.4. *Let x_n be a sequence in a gf-metric space (M, d). We shall say that x_n **converges to** $L \in M$ if for every $\tilde{0} \prec\prec R$, there exists $n_0 \in \mathbb{N}$, such that if $n \geq n_0$, then $d(x_n, L) \prec\prec R$. In this case, we say x_n is **gf-convergent** and L is the **gf-limit of** x_n; we use the notation: "$x_n \longrightarrow L$". A sequence x_n is said to be a **gf-cauchy sequence**, if for every $\tilde{0} \prec\prec R$, there exists $n_0 \in \mathbb{N}$, such that if $m, n \geq n_0$, then $d(x_m, x_n) \prec\prec R$.*

Observation III.2. *The theorem III.4 guarantees the unicity of the limit of a convergent sequence.*

Definition III.5. *A gf-metric space is said to be complete if every gf-cauchy sequence is convergent.*

Example III.4. *In a gf-metric space, every convergent sequence is a gf-cauchy sequence.*

In fact, if $x_n \longrightarrow L$, then for every $\tilde{0} \prec\prec R$, there exists $n_1 \in \mathbb{N}$ such that $n > n_1 \Rightarrow d(x_n, L) \prec\prec R_1$, and there exists $n_2 \in \mathbb{N}$, such that $m > n_2 \Rightarrow d(x_m, L) \prec\prec R_2$, where $\tilde{0} \prec\prec R_1$, $\tilde{0} \prec\prec R_2$ and $R_1 \oplus R_2 \prec\prec R$. Define $n_0 = \max\{n_1, n_2\}$. Thus, if $n > n_0$, then $d(x_n, x_m) \preceq d(x_n, L) \oplus d(L, x_m) \prec\prec R_1 \oplus R_2 \preceq R \Rightarrow d(x_n, x_m) \prec\prec R$.

B. gf-Continuity

In this section, we present the concept of gf-continuity, which represents the idea of contunuity in the fuzzy context.

Definition III.6. *A function $f : M \longrightarrow N$ between the two gf-metric spaces (M, d_1) and (N, d_2) is called **gf-continuous at** $a \in M$, if for every $\tilde{0} \prec\prec R$ there exist $\tilde{0} \prec\prec D$ such that, if $d_1(a, b) \prec\prec D$, then $d_2(f(a), f(b)) \prec\prec R$. If f is gf-continuous for all $a \in M$, then we will simply say that f is gf-continuous.*

The next theorem shows how the gf-continuity is linked with the usual topological concept of continuity.

Theorem III.5. *A function $f : M \longrightarrow N$ is continuous with respect to the topologies $\Im(M)$ and $\Im(N)$ iff f is gf-continuous.*

Proof: The proof follows the same steps of the usual case (see [10]). ∎

If $(\mathbb{R}^n, d)$ is a gf-metric space then constant functions, the identity function, sums and products(for $n = 1$) of gf-continuous functions are all gf-continuous functions.

Theorem III.6. *Let (M, d_1) and (N, d_2) be two gf-metric spaces and consider the mapping $f : M \longrightarrow N$. If f is gf-continuous at $a \in M$ and x_n is a sequence in M such that $x_n \longrightarrow a$, then $f(x_n) \longrightarrow f(a)$.*

Proof: Given $\tilde{0} \prec\prec R$, there exists $\tilde{0} \prec\prec D$ such that $d(a, x) \prec\prec D \Rightarrow d(f(a), f(x)) \prec\prec R$. Since $x_n \longrightarrow a$, there exists $n_0 \in \mathbb{N}$ such that $n > n_0 \Rightarrow d(x_n, a) \prec\prec D$, so $d(f(x_n)f(a)) \prec\prec R$, ie, $f(x_n) \longrightarrow f(a)$. ∎

IV. Application: Fixed Point Theorem

The fixed point theorems play an important role in applications. All these theorems involves convenient definitions of

contractions. Below, we present the definition of contractions in gf-metric spaces.

Definition IV.1. *Let (M,d) be a gf-metric space and $T : M \longrightarrow M$ a mapping. We say that T is a **gf-contraction** if exists $K \in G$, with $K \prec\prec \tilde{1}$, such that $d(T(x),T(y)) \preceq K \odot d(x,y)$.*

Observation IV.1. *Note that if $K \prec\prec \tilde{1}$, then there exists $0 < r < 1$ such that $\overline{k_\alpha} < r$, for all $\alpha \in (0,1]$.*

Proposition IV.1. *Let (M,d) be a gf-metric space and $T : M \longrightarrow M$ a mapping. If T is a gf-contraction, then T is gf-continuous*

Proof: Let $a \in M$. Since T is a gf-contraction, we have $d(T(x),T(y)) \preceq d(x,y)$, for all $x,y \in M$. Thus, given $\tilde{0} \prec\prec R$, take $D = R$ and suppose that $d(a,x) \prec\prec D = R$. So, $d(T(a),T(x)) \preceq d(a,x) \prec\prec D = R \Rightarrow d(T(a),Y(x)) \prec\prec R$. Thus, T is gf-continuous at any $a \in M$ and so, T is gf-continuous. ∎

Below, we proof a fixed point theorem in gf-metric spaces which is very similar to the classical Banach's theorem.

Theorem IV.1 (Fixed Point Theorem)**.** *Let (M,d) be a complete gf-metric space and $T : M \longrightarrow M$ a contraction. Thus, T has a unique fixed point.*

Proof: Take $x_0 \in M$ and define the sequence x_n by $x_1 = T(x_0)$ and $x_{n+1} = T(x_n)$. Thus, $d(x_2,x_1) = d(T(x_1),T(x_0)) \preceq K \odot d(x_1,x_0)$, $d(x_3,x_2) = d(T(x_2),T(x_1)) \preceq K \odot d(x_2,x_1) \preceq K \odot (K \odot d(x_1,x_0)) = K^2 \odot d(x_1,x_0)$, etc.. In general, we have

$$d(x_{n+1},x_n) \preceq K^n \odot d(x_0,x_1). \tag{3}$$

Given $m,n \in \mathbb{N}$, with $m > n$, using the triangle inequality and (3) we have:

$$\begin{aligned} d(x_m,x_n) &\preceq d(x_n,x_{n+1}) \oplus d(x_{n+1},x_{n+2}) \\ &\oplus \ldots \oplus d(x_{m-1},x_m) \\ &\preceq (K^n \odot d(x_1,x_0)) \oplus (K^{n+1} \odot d(x_1,x_0)) \\ &\oplus \ldots \oplus (K^{m-1} \odot d(x_1,x_0)) \\ &= \left(K^n \oplus \ldots \oplus K^{m-1}\right) \odot d(x_1,x_0), \text{ so} \\ d(x_m,x_n) &\preceq \left(K^n \oplus \ldots \oplus K^{m-1}\right) \odot d(x_1,x_0) \end{aligned} \tag{4}$$

Consider $r > 0$ as in the observation IV.1.

If $K_\alpha = [\underline{k_\alpha}, \overline{k_\alpha}]$, for all $\alpha \in (0,1]$, then $K_\alpha^n = [\underline{k_\alpha}^n, \overline{k_\alpha}^n]$, so

$$\begin{aligned} \left(K^n \oplus \ldots \oplus K^{m-1}\right)_\alpha &= \left[\sum_{i=n}^{m-1} \underline{k_\alpha}^i, \sum_{i=n}^{m-1} \overline{k_\alpha}^i\right] \\ &\leq_{km} \left[\sum_{i=n}^{m-1} r^i, \sum_{n=1}^{m-1} r^i\right]. \end{aligned} \tag{5}$$

Since the serie $\sum r^n$ is convergent, given $\varepsilon > 0$, there exists $n_0 \in \mathbb{N}$ such that $m > n > n_0 \Rightarrow \sum_{i=n}^{m-1} \underline{k_\alpha}^i \leq \sum_{i=n}^{m-1} \overline{k_\alpha}^i \leq \sum_{i=n}^{m-1} r^i < \varepsilon$, for all $\alpha \in (0,1]$, so

$$\left[\sum_{i=n}^{m-1} \underline{k_\alpha}^i, \sum_{i=n}^{m-1} \overline{k_\alpha}^i\right] \leq_{km} [\varepsilon,\varepsilon], \text{ for all } \alpha \in (0,1]. \tag{6}$$

Since *supp* $d(x_1,x_0)$ is bounded, there exists $l > 0$ such that $0 < \lambda_\alpha(x_1,x_0) \leq \rho_\alpha(x_1,x_0) < l$, for all $\alpha \in (0,1]$, where $(d(x_1,x_0))_\alpha = [\lambda_\alpha(x_1,x_0), \rho_\alpha(x_1,x_0)]$.

Given $\tilde{0} \prec\prec R$, we know there is $d > 0$ such that $d < \underline{r_\alpha} \leq \overline{r_\alpha}$, for all $\alpha \in (0,1]$. Take $0 < \varepsilon < \frac{d}{2l}$. Thus, there exists $n_0 \in \mathbb{N}$ such that:

$$\begin{aligned} m > n > n_0 \quad &\Rightarrow \quad \left(K^n \oplus K^{n+1} \oplus \ldots \oplus K^{m-1}\right)_\alpha \\ &\leq_{km} \quad [\varepsilon,\varepsilon] \\ &\Rightarrow \quad \left(K^n \oplus K^{n+1} \oplus \ldots \oplus K^{m-1}\right)_\alpha \\ &\cdot \quad [\lambda_\alpha(x_1,x_0), \rho_\alpha(x_1,x_0)] \\ &\leq_{km} \quad [\varepsilon,\varepsilon] \cdot [\lambda_\alpha(x_1,x_0), \rho_\alpha(x_1,x_0)] \end{aligned} \tag{7}$$

Thus, we have $\left[\left(K^n \oplus \ldots \oplus K^{m-1}\right) \odot d(x_1,x_0)\right]_\alpha \leq_{km} [\varepsilon\lambda_\alpha(x_1,x_0), \varepsilon\rho_\alpha(x_1,x_0)]$, for all $\alpha \in (0,1]$, ie,

$$\left(K^n \oplus \ldots \oplus K^{m-1}\right) \odot d(x_1,x_0) \preceq [\varepsilon,\varepsilon] \odot d(x_1,x_0). \tag{8}$$

Note that $\lambda_\alpha(x_1,x_0) < l \Rightarrow \varepsilon\lambda_\alpha(x_1,x_0) < \varepsilon l < \frac{d}{2l} l = \frac{d}{2}$, so, from $\underline{r_\alpha} > d$, follows that $\underline{r_\alpha} - \frac{d}{2} > \frac{d}{2} \Rightarrow \underline{r_\alpha} - \varepsilon\lambda_\alpha(x_1,x_0) > \frac{d}{2}$. Analogously, we proof that $\overline{r_\alpha} - \varepsilon\rho_\alpha(x_1,x_0) > \frac{d}{2}$. Thus, we can conclude that $[\varepsilon\lambda_\alpha(x_1,x_0), \varepsilon\rho_\alpha(x_1,x_0)] \prec\prec R$, so, for all $m > n > n_0$, we have

$$\begin{aligned} d(x_m,x_n) &\preceq \left(K^n \oplus K^{n+1} \oplus \ldots \oplus K^{m-1}\right) \odot d(x_1,x_0) \\ &\preceq [\varepsilon,\varepsilon] \odot d(x_1,x_0) \\ &\prec\prec R. \end{aligned}$$

Thus, we conclude that x_n is a gf-Cauchy sequence. Since the gf-metric space (M,d) is complete, we have that x_n is convergent. Let $a \in M$ such that $x_n \longrightarrow a$. Since T is continuous, we have $T(x_n) \longrightarrow T(a)$, but, $T(x_n) = x_{n+1}$, so $T(x_n) \longrightarrow a$. Thus, as the limit of x_n is unique, we have $T(a) = a$, ie, a is a fixed point of T.

Now, suppose that $x,y \in M$ and $T(x) = x$, $T(y) = y$, with $x \neq y$. Follows that:

$$\begin{aligned} d(x,y) &= d(T(x),T(y)) \preceq K \odot d(x,y) \prec d(x,y) \\ &\Rightarrow d(x,y) \prec d(x,y), \text{ which is a contradiction.} \end{aligned}$$

So, the fixed point must to be unique. ∎

V. Conclusion

The fuzzy metric proposed by Kaleva and Seikkala with $L = \min$ and $R = \max$ satisfies a very natural triangle inequality. In this case we showed how to define a Hausdorff topology, which carries more information than the original one defined in [3], since it depends on $d(x,y)$, and not just on a piece of $d(x,y)$, as in the original definition. With this definition it was possible to create natural notions of fuzzy continuity and fuzzy convergent sequence, from which we proved a fixed point theorem very similar to the classical Banach's theorem. In future works, we attempted to verify other classical results

on metric spaces in the fuzzy context and, mainly, to investigate ways to reduce the triangle inequality iii) for a more natural form, where L and R are arbitrary functions satisfying the conditions of the Kaleva and Seikkala's definition. We also intend to propose a concept of fuzzy quasi-metric, following the same ideas developed in this paper. Achieving that, we have in hands a topology that can not be Hausdorff, but will have other properties of separability, like the T_1 spaces (see [10]).

***Abstract*—The fuzzy cross entropy of intuitionistic fuzzy sets, so-called intuitionistic cross entropy, is introduced by analogy with the cross entropy of probability distributions. This paper introduces the concepts of discrimination information and cross-entropy in the intuitionistic fuzzy sets. Based on this improved entropy measure, we add information of an intuitionistic fuzzy index and reveal an intuitive and mathematical connection between the notions of entropy for intuitionistic fuzzy sets in terms of fuzziness and intuitionism. Finally, a fault diagnosis example of the turbine has been illustrated. The example demonstrates that the proposed method cannot only diagnose the main fault types of the turbine, it can also detect useful information for future trends and multi-fault analysis.**

Keywords-Intuitionistic fuzzy sets; cross-entropy; similarity measure; fault diagnosis

I. INTRODUCTION

The technique of fault diagnosis has produced the huge economic benefits by scheduling preventive maintenance and preventing extensive downtime periods caused by extensive failure. Therefore, it has become a research hotspot. However, fault occurred in a very complex mechanism, the same set of signs of failure which were observed, may be caused by the other failure reasons, in addition, the Characteristics of state failure which were extracted from the failure detection often have a characteristics of fuzziness, coupled with the uncertainty of the signs and the very failures, such as the fuzziness of the sign, the uncertainty of the knowledge of empirical diagnosis and so on, making the problems of diagnosis even more difficult. Fuzzy relative theory can be a good description and characterization of this complex concept, and use the method of computing and transform the vague sets for fault diagnosis and reasoning.

The steam turbine generator unit is a kind of important equipments in power plant with complexity in equipment structure and particularity in operating environment. Failures of steam turbine generator units can usually be specified according to the different amplitude ratio of vibration signal in several different frequency ranges [16]. Since the failure and its vibration symptom are not one-to-one corresponding, many studies have been performed on the intelligent diagnosis methods for turbine generator based on expert system (such as [22], [23], [13], [7], [24]), artificial neural network (such as [17], [6], [9], [28], [11]) fuzzy theory or their combination in recent years (such as [10], [8], [25], [26]).

In the problem at hand, little research has been devoted to the situation where the value of the amplitude ratio of vibration signal is vague and linguistic ambiguity. Actually the value of the amplitude ratio of vibration signal in real circumstance is usually inaccuracy and vague valued. The estimation of precise value of possibility becomes very difficult in many cases. So the methods mentioned above would thus obtain wrong results under the intuitionistic fuzzy circumstance for they could not get the precise value of amplitude ratio of vibration signal.

The aim of this paper is to develop a fault diagnosis method of turbine based on an improved cross entropy measures under the intuitionistic fuzzy circumstance. In order to handle the uncertain situation and insufficient vague information, a concept of intuitionistic fuzzy sets (IFSs) developed by Atanassov [1] is introduced in this paper. The fundamental characteristics of IFSs are that the values of its membership function and non-membership vague values rather than exact numbers. Therefore, it could be used to simulate any activities and process requiring human expertise and knowledge, which are inevitably imprecise values. The distance between two IFSs is also defined taking into account the intuitionistic fuzzy values. And the similarity measure is conducted based on the Euclidean distance. Then, a new method of the fault diagnosis of turbine is presented in the basis of the cross entropy measures among IFSs. The similarity degree between the detecting sample and the knowledge of system fault is evaluated in the fault diagnosis of turbine vibration by the proposed measured method among IFSs. The smaller the value of distance measure, the more the similarity between the detecting sample and a type of fault knowledge. Then, the type of vibration fault is determined according to the value of similarity measure. Examples explain the validity and reasonability in the fault diagnosis problems based on the distance measures among IFSs.

The remainder of this study is organized as follows: In Section II, the relative basic concepts including IFSs, fuzzy cross-entropy (FCE) and intuitionistic fuzzy cross-entropy (IFCE) method are described. Section III presents an improved

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

IFCE approach, and illustrates an example for fault diagnosis in Section IV. Finally, a conclusion is drawn in section V.

II. Related works

A. IFSs Theroy

Fuzzy sets theory has proposed by Zadeh in 1965 [27], has shown successful applications in various fields. A fuzzy set is defined as: $\tilde{A} = \{(x, \mu_{\tilde{A}}(x)) | x \in U, \mu_{\tilde{A}}(x) \in [0, 1]\}$, where U э x is the universe of discourse and $\mu_{\tilde{A}}(x) \in [0, 1]$ is the membership function of A. For further details, the reader may refer to [27].

In this theory, the membership of an element to a fuzzy set is a single value between zero and one. But in reality, it may not always be certain that the degree of non-membership of an element to a fuzzy set is just equal to 1 minus the degree of membership, i.e. there may be some intuitionistic fuzzy index. Thus, as a generalization of fuzzy sets, the concept of IFSs was introduced by Atanassov in 1986. Bustince and Burillo [5] showed that this notion coincides with the notion of vague sets (VSs).

The IFSs is as an extension of fuzzy sets. An IFSs A in a fixed set E is an objective with the expression

$$A = \{\langle x, \mu_A(x), \nu_A(x)\rangle | x \in E\}, \tag{1}$$

where the functions $\mu_A : E \to [0,1]$ and $\nu_A : E \to [0,1]$ denote the degree of membership and the degree of non-membership of the element $x \in E$, respectively. For every $x \in E$,

$$0 \le \mu_A(x) + \nu_A(x) \le 1. \tag{2}$$

When $\mu_A(x) + \nu_A(x) = 1$, for every $x \in E$, then the IFSs will degenerate to a fuzzy set. Hence, we can consider a fuzzy set with its membership function $u_A(x)$, having the IFSs expression as

$$A = \{\langle x, \mu_A(x), 1 - \mu_A(x)\rangle | x \in E\}. \tag{3}$$

Under the condition of $v_A(x) = 1 - u_A(x)$, for every $x \in E$.

For each IFSs A in E, "intuitionistic fuzzy index" has consideration. We call the intuitionistic fuzzy index of an element $x \in E$ in A by the following expression:

$$\pi_A(x) = 1 - \mu_A(x) - \nu_A(x), \tag{4}$$

we can consider $\pi_A(x)$ as an intuitionistic fuzzy index of x to A. From Eq.(4) it is evident that

$$0 \le \pi_A(x) \le 1 \text{ for all } x \in E. \tag{5}$$

Therefore, to describe an intuitionistic fuzzy set completely; we need at least two functions from the triplet ([2][3]): (1) membership function; (2) non-membership function; (3) intuitionistic fuzzy index.

B. FCE Method

Let us recall the definition of the cross entropy by Shannon in 1948 [19]. Let $P = \{p(x_i), i = 1,2,...,n\}$ is a probability distribution on X. where $p(x_i) \in [0,1]$ and $\sum_{i=1}^{n} p(x_i) = 1$. Then the entropy of probability distribution P has been defined as follows,

$$H(P) = -\sum_{x_i \in X} p(x_i) \ln p(x_i). \tag{6}$$

Kullback [12] advance lets $Q = \{q(x_i), i = 1,2,...,n\}$ as the other probability distributions of the discrete random variable X, where $q(x_i) \in [0,1]$ and $\sum_{i=1}^{n} q(x_i) = 1$. Then the cross-entropy measure of P from Q can be obtained as

$$H(P,Q) = \sum_{x_i \in X} p(x_i) \ln \frac{p(x_i)}{q(x_i)}, \tag{7}$$

which measures the amount of discrimination of P from Q. However, Lin [15] pointed out that Eq. (7) is undefined if $q(x_i) = 0$ and $p(x_i) = 0$ for any $x_i \in X$. In order to overcome this drawback, a modified cross-entropy measure has be provided as

$$H(P,Q) = \sum_{x_i \in X} p(x_i) \ln \frac{p(x_i)}{\frac{1}{2}p(x_i) + \frac{1}{2}q(x_i)}. \tag{8}$$

Based on Eq. (8), Shang and Jiang [18] defined the FCE approach between two fuzzy numbers as the following,

$$M_{FS}(\tilde{A},\tilde{B}) = \sum (\mu_{\tilde{A}}(x_i) \ln \frac{\mu_{\tilde{A}}(x_i)}{\frac{1}{2}(\mu_{\tilde{A}}(x_i) + \mu_{\tilde{B}}(x_i))} + (1 - \mu_{\tilde{A}}(x_i)) \ln \frac{1 - \mu_{\tilde{A}}(x_i)}{1 - \frac{1}{2}(\mu_{\tilde{A}}(x_i) + \mu_{\tilde{B}}(x_i))}). \tag{9}$$

Due $M_{FS}(\tilde{A},\tilde{B})$ is not symmetric with respect to its arguments. Thus, Shang and Jiang [18] have also defined a symmetric discrimination information measure as the following,

$$D_{FS}(\tilde{A},\tilde{B}) = M_{FS}(\tilde{A},\tilde{B}) + M_{FS}(\tilde{B},\tilde{A}). \tag{10}$$

In addition, Shang and Jiang [18] have proofed that $D_{FS}(\tilde{A},\tilde{B}) \ge 0$ and $D_{FS}(\tilde{A},\tilde{B}) = 0$ if and only if $\tilde{A} = \tilde{B}$.

Based on above mentions theoretical background, an intuitionistic fuzzy cross entropy method has been described as the next subsection.

C. IFCE Method

Let us consider two sets $A, B \in U(X)$. In order to derive a cross-entropy measure for IFSs, we have to exploit the information carried by both the membership and the non-membership function. In an analogous manner to Bhandari and Pal [4], we consider the following quantity:

$$H^{\mu}(A,B;x_i) = \ln \frac{\mu_A(x_i)}{\mu_B(x_i)}, \tag{11}$$

as the amount of information for discrimination of $u_A(x_i)$ from $u_B(x_i)$. Therefore, the expected information for discrimination of A against B, based solely on the membership function, is given by

$$H^{\mu}(A,B) = \sum_{i=1}^{n} \mu_A(x_i) \ln \frac{\mu_A(x_i)}{\mu_B(x_i)}. \tag{12}$$

Similarly, considering the non-membership function we have

$$H^{v}(A,B)=\sum_{i=1}^{n}\nu_A(x_i)\ln\frac{\nu_A(x_i)}{\nu_B(x_i)}. \quad (13)$$

Hence, the information for discrimination in favor of A against B is obtained as the sum of the quantities $H^{u}(A,B)$ and $H^{v}(A,B)$, i.e.,

$$H''_{IFS}(A,B)=\sum_{i=1}^{n}\left[\mu_A(x_i)\ln\frac{\mu_A(x_i)}{\mu_B(x_i)}+\nu_A(x_i)\ln\frac{\nu_A(x_i)}{\nu_B(x_i)}\right]. \quad (14)$$

In order to overcome the drawback of Eq. (14) being undefined if $u_B(x_i)=0$ or $v_B(x_i)=0$ for any $x_i\in X$, a modified version of Eq. (14) is introduced based on Eq. (8) and is given by

$$H_{IFS}(A,B)=\sum_{i=1}^{n}\left[\mu_A(x_i)\ln\frac{\mu_A(x_i)}{\frac{1}{2}(\mu_A(x_i)+\mu_B(x_i))}+\nu_A(x_i)\ln\frac{\nu_A(x_i)}{\frac{1}{2}(\nu_A(x_i)+\nu_B(x_i))}\right] \quad (15)$$

According to Shannon's inequality, Lin [15] pointed out that one can easily prove that $H_{IFS}(A,B)\geq 0$ and $H_{IFS}(A,B)=0$ if and only if $A = B$. A similar measure for FSs, denoted by $H_{FS}(\tilde{A},\tilde{B})$, was defined by Bhandari and Pal [4]. For FSs in general $H_{FS}(\tilde{A},\tilde{B})\neq H_{FS}(\tilde{A}^c,\tilde{B}^c)$. However, for IFSs the following equality holds:

$$H_{IFS}(A,B)=H_{IFS}(A^c,B^c), \quad (16)$$

where A^c and B^c are the complementary sets of A and B, respectively. Therefore, in analogy with Eq. (9), we proceed to the following definition of the intuitionistic fuzzy cross-entropy.

Definition 1. For two sets $A,B\in U(X)$, $H_{IFS}(A,B)$ is the intuitionistic fuzzy cross-entropy between A and B. $H_{IFS}(A,B)$ can also be called discrimination information for IFSs. However, one can observe that $H_{IFS}(A,B)$ is not symmetric with respect to its arguments. Therefore, a symmetric measure is defined as follows:

Definition 2. For two sets $A,B\in U(X)$,

$$D_{IFS}(A,B)=H_{IFS}(A,B)+H_{IFS}(B,A) \quad (17)$$

is called a symmetric discrimination information measure for IFSs. It can easily be verified that $H_{IFS}(A,B)$ and $D_{IFS}(A,B)$ degenerate to their fuzzy counterparts when A and B are FSs.

III. An Improved IFCE Approach

It is easy to see that cross-entropy proposed by Vlachos and Sergiadis [21] only involve the first two parameters. That is, the membership degree and non-membership degree of IFSs. Furthermore, it dose not take the third parameter (intuitionistic fuzzy index) into account in the above derivation and discrimination measure of IFSs.

Furthermore, Szmidt and Kacprzyk [20] have showed that omitting one of the three parameters may lead to incorrect results, and thus all the three parameters should be taken into account when calculating association or distance between two IFSs.

Motivated by the idea of Szmidt and Kacprzyk [20], we improve the feasibility of original IFCE by add the third parameter (intuitionistic fuzzy index) consideration. Therefore, a modified formulation is improved to reach better discrimination measure of IFCE approach.

Following the Eqs. (12) and (13), we may keep considering the function of an intuitionistic fuzzy index for discrimination measure similarly. Thus, we can obtained

$$H^{\pi}(A,B)=\sum_{i=1}^{n}\pi_A(x_i)\ln\frac{\pi_A(x_i)}{\pi_B(x_i)}. \quad (18)$$

Next, the information for discrimination in favor of A against B can be calculated as the sum of the quantities $H^{u}(A,B)$, $H^{v}(A,B)$, and $H^{\pi}(A,B)$. The Eq. (14) can be revised as

$$H'_{IFS}(A,B)=\sum_{i=1}^{n}\left[\mu_A(x_i)\ln\frac{\mu_A(x_i)}{\mu_B(x_i)}+\nu_A(x_i)\ln\frac{\nu_A(x_i)}{\nu_B(x_i)}+\pi_A(x_i)\ln\frac{\pi_A(x_i)}{\pi_B(x_i)}\right]. \quad (19)$$

To avoid the drawback of Eq. (19) being undefined if $u_B(x_i)=0$, $v_B(x_i)=0$ or $\pi_B(x_i)=0$ for any $x_i\in X$, an improved version of Eq. (19) is introduced based on Eq. (15) and is given as

$$H_{IFS}(A,B)=\sum_{i=1}^{n}\left[\mu_A(x_i)\ln\frac{\mu_A(x_i)}{\frac{1}{2}(\mu_A(x_i)+\mu_B(x_i))}+\nu_A(x_i)\ln\frac{\nu_A(x_i)}{\frac{1}{2}(\nu_A(x_i)+\nu_B(x_i))}+\pi_A(x_i)\ln\frac{\pi_A(x_i)}{\frac{1}{2}(\pi_A(x_i)+\pi_B(x_i))}\right] \quad (20)$$

One can also prove that $H_{IFS}(A,B)\geq 0$ and $H_{IFS}(A,B)=0$ if and only if $A = B$, according to Shannon's inequality. A similar measure for IFSs, the following equality also holds:

$$H_{IFS}(A,B)=H_{IFS}(A^c,B^c), \quad (21)$$

where A^c and B^c are the complementary sets of A and B, respectively. Therefore, in analogy with Eq. (20), we can also proceed to the symmetric discrimination definition of the proposed intuitionistic fuzzy cross-entropy.

$$D_{IFS}(A,B)=H_{IFS}(A,B)+H_{IFS}(B,A) \quad (22)$$

IV. Illustrative Example for Fault Diagnosis of Turbine

In this section, the proposed measured method is applied to fault diagnosis of steam turbine generator unit under intuitionistic fuzzy circumstance. The knowledge of system fault and detecting sample adopted from Li and Wan [14] are listed. We select the amplitude ratio of vibration signal in six different frequency ranges, such as less than 0.4*f*, 0.5*f*, *f*, 2*f*, 3*f* and more than 3*f*, as the characteristic value. Therein, *f* is the fundamental frequency of the rotor. Three typical failures are selected as failures pattern. Here, P_1 is oil whip, P_2 is unbalance, P_3 is misalignment. And B_1, B_2 are the two samples to be evaluated.

Table I presents the six different frequency ranges for the failures pattern. Another, the six different frequency ranges for two samples are be evaluated in Table II. Each element of the tables, is given in the form of a pair of numbers corresponding to the membership, non-membership values, respectively, e.g., the pattern (P_1) vs. frequency (< 0.4f) is described by (μ, ν) = (0.06, 0.84).

TABLE I. THE KNOWLEDGE OF SYSTEM FAULT PATTERN

B_1	(0.01, 0.96)	(0.00, 0.97)	(0.37, 0.60)	(0.46, 0.51)	(0.31, 0.66)	(0.21, 0.75)
B_2	(0.00, 0.98)	(0.05, 0.92)	(0.69, 0.27)	(0.04, 0.93)	(0.03, 0.94)	(0.00, 0.97)

In order to find a proper diagnosis, we calculate for each sample, B_i, where $i \in \{1,2\}$, the symmetric discrimination information measure for IFSs $D_{IFS}(P_j, B_i)$ between sample characteristics and the set of knowledge for system fault pattern that are characteristics for each fault diagnosis P_j, with $j \in \{1,2,3\}$. Based on Eq. (22), we assign the lowest symmetric discrimination information measure to the ith sample the diagnosis. Therefore, we assign to the ith sample the diagnosis whose characteristics have the lowest symmetric discrimination information measure from sample's characteristics. The fault diagnosed results for the considered samples are given in Table III.

According to Table III, we know that the degree of distance between failure pattern P_j , j = 1, 2, 3, and sample B_1 has been ranked and we have $D_{IFS}(P_3, B_1) \succ D_{IFS}(P_2, B_1) \succ D_{IFS}(P_1, B_1)$. It is clear that the degree of distance between P_3 and B_1 is the smallest one, the sample B_1 belongs to fault P_3 and the most possible type of vibration fault is misalignment. Also we have $D_{IFS}(P_2, B_2) \succ D_{IFS}(P_3, B_2) \succ D_{IFS}(P_1, B_2)$. from Table III and the degree of distance between P_2 and B_2 is the smallest one, the sample B_2 belongs to fault P_2 and the most possible type of vibration fault is unbalance.

TABLE III. THE DIAGNOSED RESULTS BY THE IMPROVED IFCE APPROACH

	Information measure		
	$D_{IFS}(P_1, B_1)$	$D_{IFS}(P_2, B_1)$	$D_{IFS}(P_3, B_1)$
Sample 1	2.5233	1.5131	0.4754
Rank	**3**	**2**	**1**
	$D_{IFS}(P_1, B_2)$	$D_{IFS}(P_2, B_2)$	$D_{IFS}(P_3, B_2)$
Sample 2	2.1259	0.3906	1.2854
Rank	**3**	**1**	**2**

V. CONCLUSIONS

In this paper, taking into account the intuitionistic fuzzy sets, an improved cross entropy measure of IFSs on the basis of the Euclidean distance was defined. And the proposed method has been applied to the fault diagnosis of turbine among IFSs in this paper. This method can overcome the situation that the value of the amplitude ratio of vibration signal is uncertain and thus has promising future in the engineering application. Furthermore, ranking of the similarity degree can not only reveal the most possible type of fault occurred but also point out the sequence of fault diagnosis. Finally, an illustrative example has been provided to illustrate the validity and reasonability of the developed approach.

***Index Terms*—fuzzy logic, fuzzy topology, separation axiom**

I. Introduction and Preliminaries

The usual notion of a set was generalized with the introduction of fuzzy sets by Zadeh in the classical paper [1]. The concept of fuzzy topology was first defined by Chang[2] and later redefined in a somewhat different way by Lowen[3] and Hutton and Reilly[4] and others. Several authors have expansively developed the theory of fuzzy sets and its applications. Closure and interior are alternative approaches to open sets in topology. So, many researchers have studied for these notions. The notions of fuzzy δ-closure and fuzzy θ-closure of a fuzzy set in a fuzzy topological space were introduced by Ganguly and Saha[5] and Mukherjee and Sinha[6], respectively. Furthermore, the notion of strong δ-continuity was investigated in [7] and the concept of δ-continuity on function spaces was studied in [8]. The notion of θ-closure and θ-interior also expanded in more generalized spaces, intuitionistic fuzzy topological spaces [9]. In [10] we also have introduced fuzzy δ-topology and fuzzy δ-compactness, and studied their properties.

In order to prove many important theorems of topology we need the Hausdorff condition, because Hausdorff condition implies the uniqueness of limit. Moreover most of the important spaces in mathematics are Hausdorff spaces. For this reason, many different definitions are introduced and studied as in [11], [12], [13], [14], [15], [16], [17], [18]. The aim of this paper is to introduce separation axioms in a fuzzy δ-topological space, which is both harmonious in itself and compatible with fuzzy δ-compactness. In this manner, we will define a new type of separation axioms, which is called fuzzy δ-separation axioms by using the concept of fuzzy δ-open sets introduced in [10]. We will investigate the relation between the separation property and the subspaces. We will show that fuzzy δ-separation axioms are hereditary in fuzzy regular open subspaces. It is interesting that there are some deviations in the behavior of these axioms as compared to those in the general topology.

Throughout this paper by $(X, \mathcal{T})$ or simply by X, we mean a fuzzy topological space (briefly fts) due to Chang [2]. A fuzzy point in X with support $x \in X$ and value $\alpha (0 < \alpha \leq 1)$ is denoted by x_α. When no confusion will arise, we omit the value α and write the fuzzy point x_α simply as x. For a fuzzy set A in X, a fuzzy point $x_\alpha \in A$ iff $\alpha \leq A(x)$. A fuzzy point x_α is said to be quasi-coincident (q-coincident, for short) with A, denoted by $x_\alpha \; q \; A$, iff $\alpha > A^c(x)$, or $\alpha + A(x) > 1$, where A^c denotes the complement of A, defined by $A^c = 1 - A$. A fuzzy set A in a fts X is said to be a q-neighbourhood (q-nbd, for short) of a fuzzy point x_α iff there exists a fuzzy open set B such that $x_\alpha \; q \; B$ and $B \leq A$. For two fuzzy sets A and B, $A \leq B$ iff $A \tilde{q} B^c$. A fuzzy point $x_\alpha \in \mathrm{cl}(A)$ iff each q-nbd of x_α is q-coincident with A (See [19]). A fuzzy set A in a fts X is called a fuzzy regular open set iff A = int(cl(A)), and the complement of a fuzzy regular open set is called a fuzzy regular closed set (See [20]).

Definition 1.1: ([5]) A fuzzy point x_α is said to be a fuzzy δ-cluster point of a fuzzy set A iff every fuzzy regular open q-nbd U of x_α is q-coincident with A. The set of all fuzzy δ-cluster points of A is called the fuzzy δ-closure of A, and denoted by $\mathrm{cl}_\delta(A)$.

Remark 1.2: ([10]) For any fuzzy set A in a fts $(X, \mathcal{T})$, the δ-closure of A is represented as follows;

$$\mathrm{cl}_\delta(A) = \bigwedge \{\mathrm{cl}(U) \mid A \leq \mathrm{cl}(U), U \in \mathcal{T}\}.$$

Definition 1.3: ([6]) A fuzzy set A is said to be a fuzzy δ-nbd of a fuzzy point x_α iff there exists a fuzzy regular open q-nbd V of x_α such that $V \leq A$.

Definition 1.4: ([5]) A fuzzy set A is said to be fuzzy δ-closed iff $A = \mathrm{cl}_\delta(A)$, and the complement of a fuzzy δ-closed set is called a fuzzy δ-open set.

Since δ-open set is the complement of an δ-closed set, G is δ-open iff $G = \mathrm{int}_\delta(G)$. And we know that $1 - \mathrm{int}_\delta(1 - A) = \mathrm{cl}_\delta(A)$. A fuzzy set A is fuzzy δ-open in a fts X if and only if for each fuzzy point x_α with $x_\alpha q A$, A is a fuzzy δ-nbd of x_α ([21]).

It is easy to show that $\mathrm{cl}(A) \leq \mathrm{cl}_\delta(A) \leq \mathrm{cl}_\theta(A)$ for any fuzzy set A in a fts X. However, for a fuzzy open set A in a fts $(X, \mathcal{T})$, we have $\mathrm{cl}(A) = \mathrm{cl}_\delta(A)$ (See [6]). Moreover, it is clear that any regular open set is δ-open, and any δ-open set is open.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

For any fuzzy set A in a fts $(X, \mathcal{T})$, $\mathrm{cl}_\delta(A)$ is a fuzzy δ-closed set. That is, $\mathrm{cl}_\delta(\mathrm{cl}_\delta(A)) = \mathrm{cl}_\delta(A)$ (See [10]).

Definition 1.5: ([5]) A function $f : X \to Y$ is said to be *fuzzy δ-continuous (f.δ.c., for short)* if and only if for each fuzzy point x_α in X and for any regular open q-nbd V of $f(x_\alpha)$ in Y, there exists a regular open q-nbd U of x_α such that $f(U) \leq V$.

Remark 1.6: ([10]) $f : X \to Y$ is fuzzy δ-continuous if and only if for each fuzzy δ-open set U of Y, $f^{-1}(U)$ is fuzzy δ-open in X. Therefore the composition of two fuzzy δ-continuous mappings is also fuzzy δ-continuous.

Definition 1.7: Let $f : (X, \mathcal{T}) \to (Y, \mathcal{H})$ be a fuzzy mapping.
(1) f is *fuzzy δ-open* if for each fuzzy δ-open set A in X, $f(A)$ is a fuzzy δ-open in Y.
(2) f is *fuzzy δ-closed* if for each fuzzy δ-closed set B in X, $f(B)$ is fuzzy δ-closed in Y.

Theorem 1.8: ([10]) If $f : X \to Y$ is fuzzy δ-continuous, then the following are equivalent.
(a) $f(\mathrm{cl}_\delta(A)) \leq \mathrm{cl}_\delta(f(A))$.
(b) $\mathrm{cl}_\delta(f^{-1}(A)) \leq f^{-1}(\mathrm{cl}_\delta(A))$.
(c) For each fuzzy δ-closed set A in Y, $f^{-1}(A)$ is fuzzy δ-closed in X.
(d) For each fuzzy δ-open set A in Y, $f^{-1}(A)$ is fuzzy δ-open in X.

In 1993, M. Macho Stadler and M.Á. De Prada Vicente[22] have introduced a new concept of subspaces in fuzzy topological spaces. In Section 4 we will define the concept of fuzzy δ-separation axioms in this subspace.

Definition 1.9: ([22]) Let $(X, \mathcal{T})$ be a fts and $\mu \in I^X$. Let $X^\mu = \{V \wedge \mu \mid V \in I^X\}$. The family $\mathcal{T}^\mu = \{V \wedge \mu \mid V \in \mathcal{T}\}$ is called the fuzzy μ-topology induced by $\mathcal{T}$ over μ. The ordered pair $(\mu, \mathcal{T}^\mu)$ is called the subspace. The elements of $\mathcal{T}^\mu$ are called fuzzy open sets in the subspace μ. $V \in X^\mu$ is called fuzzy closed in μ if $\mu - V \in \mathcal{T}^\mu$.

Definition 1.10: Let x_r be a fuzzy point in μ, i.e. $x_r \in \mu$. We say that $N \in X^\mu$ is a fuzzy neighborhood of x_r in the subspace μ if there is a $U \in \mathcal{T}^\mu$ such that $x_r \in U \leq N$.

Remark 1.11: In [22] "$x_r \in U$" means that $r < U(x)$. But in this paper it means that $r \leq U(x)$. And if $\mu = \chi_A$ for any crisp fuzzy subset $A \subseteq X$, then $\mathcal{T}^\mu$ is a subspace in the sense of general topology.

Theorem 1.12: ([22]) Let $U \in X^\mu$. Then $U \in \mathcal{T}^\mu$ iff for each $x_r \in U$, U is a fuzzy neighborhood of x_r in μ.

Definition 1.13: ([22]) Let $V \in X^\mu$. We define the interior of V in the subspace μ as the largest fuzzy open set in μ contained in V, that is

$$\mathrm{int}^\mu(V) = \sup_{U \in \mathcal{T}^\mu} \{U \mid U \leq V\}.$$

Similarly we define the closure of V in μ as the smallest closed set in μ contains V, that is

$$\mathrm{cl}^\mu(V) = \inf_{U \in \mathcal{T}^\mu} \{\mu - U \mid V \leq \mu - U\}.$$

Definition 1.14: ([23]) Let $A \in X^\mu$ and $x_r \in X$. x_r is said to be q-coincident with A in the subspace μ if $r + A(x) > \mu(x)$. And $x_r q A[\mu]$ represents it.

Definition 1.15: ([23]) Let $x_r \in \mu$. We say that $N \in X^\mu$ is a fuzzy q-nbd of x_r in μ if there is a $U \in \mathcal{T}^\mu$ such that $x_r q U[\mu]$ and $U \leq N$.

Theorem 1.16: ([23]) Let $U \in X^\mu$. Then $U \in \mathcal{T}^\mu$ iff for each $x_r q U[\mu]$, U is a q-neighborhood of x_r in μ.

Lemma 1.17: ([22]) Let $(X, \mathcal{T})$ be a fuzzy topological space and $(\mu, \mathcal{T}^\mu)$ a fuzzy subspace.
(1) If $A \in X^\mu$, then $\mathrm{int}(A) \leq \mathrm{int}^\mu(A)$.
(2) $\mathrm{int}(A) = \mathrm{int}^\mu(A) \wedge \mathrm{int}(\mu)$ for any fuzzy subset $A \in X^\mu$.
(3) If $\mu \in \mathcal{T}$ and $A \in X^\mu$, $\mathrm{int}(A) = \mathrm{int}^\mu(A)$.

II. FUZZY δ-SEPARATION AXIOMS

In this section, we construct new separation axioms, by using the concept of fuzzy δ-open sets. As for the fuzzy disjointness, we know that only the implication $\mu_1 \wedge \mu_2 = 0 \Rightarrow \mu_1 \leq \mu_2^c$ holds, but the reverse implication does not hold. With this principle, we now define a new fuzzy δ-separation axioms.

Definition 2.1: A fts X is called fuzzy δ-T_0 if for any pair of fuzzy points p and q with different supports in X, there is a fuzzy δ-open set U with $p \leq U \leq q^c$ or $q \leq U \leq p^c$.

This separation axiom is different from the fuzzy T_0 axiom as in the following example.

Example 2.2: Let $X = [0, 1]$ and for any $\alpha \in (0, 1)$

$$U_\alpha(x) = \begin{cases} 1 & \text{if } 0 \leq x \leq \alpha \\ 0 & \text{if } \alpha < x \leq 1. \end{cases}$$

Let $\mathcal{T} = \{\bar{0}, \bar{1}\} \cup \{U_\alpha \mid \alpha \in (0, 1)\}$. Then clearly $\mathcal{T}$ is a fuzzy topology on X and the set of all fuzzy δ-open sets in $(X, \mathcal{T})$ is $\{\bar{0}, \bar{1}\}$. Therefore for any two distinct fuzzy points of $(X, \mathcal{T})$ there is a fuzzy open subset of X which contains one but not the other. Hence $(X, \mathcal{T})$ is fuzzy T_0 but not fuzzy δ-T_0.

Theorem 2.3: Let $f : X \to Y$ be injective and fuzzy δ-continuous. If Y is fuzzy δ-T_0, then so is X.

Proof: Take any two points p and q with different supports in X. Since f is injective, $f(p)$ and $f(q)$ are two fuzzy points with different supports in Y. Since Y is fuzzy δ-T_0, there is a fuzzy δ-open set U with $f(p) \leq U \leq f(q)^c$ or $f(q) \leq U \leq f(p)^c$. Therefore $p \leq f^{-1}(U) \leq q^c$ or $q \leq f^{-1}(U) \leq p^c$. And since f is fuzzy δ-continuous, $f^{-1}(U)$ is fuzzy δ-open. Hence X is fuzzy δ-T_0. □

Definition 2.4: A fts X is called fuzzy δ-T_1 if for any pair of fuzzy points p and q with different supports in X, there are two fuzzy δ-open sets U_1, U_2 with $p \leq U_1 \leq q^c$ and $q \leq U_2 \leq p^c$.

Clearly every fuzzy δ-T_1 space is fuzzy δ-T_0.

Example 2.5: Let $X = \{a, b\}$ and $\mathcal{T} = \{b_s \mid s \in [0, 1]\} \cup \{\bar{1}, \bar{0}\}$, where b_s is the fuzzy point with value s at the support b. Then clearly $\mathcal{T}$ is a fuzzy topology and all elements in $\mathcal{T}$ are fuzzy regular open, so they are fuzzy δ-open. Take any two fuzzy points a_r and b_s where r and s are nonzero. Then there is a fuzzy δ-open set b_s such that $b_s \leq b_s \leq a_r^c$, and $\bar{1}$ is an only fuzzy δ-open set with $a_r \leq \bar{1}$. Clearly, for any s, $\bar{1} \not\leq b_s^c$. Hence $(X, \mathcal{T})$ is fuzzy δ-T_0, but it is not fuzzy δ-T_1.

Theorem 2.6: A fts X be fuzzy δ-T_1 iff any crisp fuzzy point in X is fuzzy δ-closed.

Proof: Let X be fuzzy δ-T_1. Take any crisp fuzzy point p in X. We will show that p^c is fuzzy δ-open. We can take a fuzzy point $q \in p^c$ with different support from p. Since X is fuzzy δ-T_1, there is a fuzzy δ-open set U with $q \leq U \leq p^c$. Thus $p^c = \bigcup_{q \in p^c} \{U \mid q \leq U \leq p^c, U \text{ is fuzzy } \delta\text{-open in } X\}$. Since $\bigcup_{q \in p^c} \{U \mid q \leq U \leq p^c, U \text{ is fuzzy } \delta\text{-open in } X\}$ is fuzzy δ-open, p^c is fuzzy δ-open. Hence p is fuzzy δ-closed. □

Corollary 2.7: Let X be a fuzzy topological space. X is fuzzy δ-T_1 if and only if $x_\alpha = \bigcap\{\text{cl}_\delta(U) \mid x_\alpha \leq \text{cl}_\delta(U)\}$.

Theorem 2.8: Let $f : X \to Y$ be injective and fuzzy δ-continuous. If Y is fuzzy δ-T_1, then so is X.

Proof: Take any two fuzzy points p and q with different supports in X. Since f is injective, $f(p)$ and $f(q)$ are two fuzzy points with different supports in Y. Since Y is fuzzy δ-T_1, there are two fuzzy δ-open sets U_1, U_2 with $f(p) \leq U_1 \leq f(q)^c$ and $f(q) \leq U_2 \leq f(p)^c$. Therefore $f^{-1}(U_1)$ and $f^{-1}(U_2)$ are fuzzy δ-open sets in X with $p \leq f^{-1}(U_1) \leq q^c$ and $q \leq f^{-1}(U_2) \leq p^c$. Hence X is fuzzy δ-T_1. □

Definition 2.9: A fts X is called fuzzy δ-Hausdorff, or fuzzy δ-T_2, if for any pair of fuzzy points p and q with different supports in X, there are fuzzy δ-open sets U_1 and U_2 with $p \leq U_1 \leq q^c$, $q \leq U_2 \leq p^c$ and $U_1 \leq U_2^c$.

Obviously every fuzzy δ-T_2 space is fuzzy δ-T_1.

Theorem 2.10: Let $(X, \mathcal{T})$ be a fuzzy δ-T_1 space. If the complement of each fuzzy δ-open set is also fuzzy δ-open, then $(X, \mathcal{T})$ is fuzzy δ-T_2.

Proof: Take any two fuzzy points p and q in X with different supports. Since X is fuzzy δ-T_1, there is a fuzzy δ-open set U such that $p \leq U \leq q^c$ or $q \leq U \leq p^c$. We may assume that $p \leq U \leq q^c$. Then we have that $q \leq U^c \leq p^c$. By the assumption, U^c is fuzzy δ-open. Hence $(X, \mathcal{T})$ is fuzzy δ-T_2. □

Theorem 2.11: If for any $x \in X$ the crisp fuzzy point x_1 is fuzzy δ-open in $(X, \mathcal{T})$, then $(X, \mathcal{T})$ is fuzzy δ-T_2.

Proof: Take any two fuzzy points p and q with different supports. Then $p \leq p_1 \leq q^c$ and $q \leq q_1 \leq p^c$. Clearly $p_1 \leq q_1^c$, and by the assumption p_1 and q_1 are fuzzy δ-open. Hence $(X, \mathcal{T})$ is fuzzy δ-T_2. □

Theorem 2.12: Let $f : X \to Y$ be injective and fuzzy δ-continuous. If Y is fuzzy δ-T_2, then so is X.

Proof: Take any two points p and q with different supports in X. Since f is injective, $f(p)$ and $f(q)$ are two fuzzy points with different supports in Y. Since Y is fuzzy δ-T_2, there are two fuzzy δ-open sets U_1, U_2 with $f(p) \leq U_1 \leq f(q)^c$, $f(q) \leq U_2 \leq f(p)^c$ and $U_1 \leq U_2^c$. Therefore $f^{-1}(U_1)$ and $f^{-1}(U_2)$ are fuzzy δ-open sets in X with $p \leq f^{-1}(U_1) \leq q^c$ and $q \leq f^{-1}(U_2) \leq p^c$. Furthermore $f^{-1}(U_1) \leq (f^{-1}(U_2))^c$. Hence X is fuzzy δ-T_2. □

Definition 2.13: A fts X is called fuzzy δ-regular if for any fuzzy point p in X and any fuzzy δ-closed set K with $p \leq K^c$, there are fuzzy δ-open sets U_1 and U_2 with $p \leq U_1$, $K \leq U_2$ and $U_1 \leq U_2^c$. A fts X is called fuzzy δ-T_3 if it is fuzzy δ-regular and fuzzy δ-T_1.

We can easily prove that every fuzzy δ-T_3 space is fuzzy δ-T_2.

We have known that for any fuzzy closed set K, $\text{int}(K)$ is fuzzy regular open. Thus it is also fuzzy δ-open. Therefore the following theorem is hold.

Theorem 2.14: For a fts $(X, \mathcal{T})$, the following are equivalent:
(1) X is fuzzy δ-regular.
(2) For any fuzzy point p and any fuzzy δ-open set V containing p, there is a fuzzy δ-open set U such that $p \leq U \leq \text{cl}_\delta(U) \leq V$.
(3) For any fuzzy δ-closed set K and any fuzzy point p such that $p \leq K^c$, there are fuzzy δ-open sets U_1 and U_2 such that $p \leq U_1, K \leq U_2$ and $\text{cl}(U_1) \leq (\text{cl}(U_2))^c$.
(4) For any fuzzy δ-closed set K and any fuzzy point p such that $p \leq K^c$, there are fuzzy open sets U_1 and U_2 such that $p \leq U_1, K \leq U_2$ and $\text{cl}(U_1) \leq (\text{cl}(U_2))^c$.

Proof: (1) $\Rightarrow$ (2) Let p be a fuzzy point set and V a fuzzy δ-open set containing p. Then there exist fuzzy δ-open sets U_1 and U_2 such that $p \leq U_1, 1 - V \leq U_2$ and $U_1 \leq 1 - U_2$. So $p \leq U_1 \leq 1 - U_2 \leq V$. Thus $p \leq U_1 \leq \text{cl}_\delta(U_1) \leq \text{cl}_\delta(1 - U_2) = 1 - U_2 \leq V$.
(2) $\Rightarrow$ (3) Let K be a fuzzy δ-closed subset of X and p a fuzzy point set such that $p \leq K^c$. Then $1 - K$ is a fuzzy δ-open set with $p \leq K^c$. By (2) there is a fuzzy δ-open set U such that $p \leq U \leq \text{cl}_\delta(U) \leq 1 - K$. Since U is a fuzzy δ-open set containing p, there is a fuzzy δ-open set V such that $p \leq V \leq \text{cl}_\delta(V) \leq U \leq \text{cl}_\delta(U) \leq 1 - K$. Put $U_1 = V$ and $U_2 = (\text{cl}_\delta(U))^c$. Then U_1 and U_2 are fuzzy δ-open sets with $p \leq U_1, K \leq U_2$. Furthermore $\text{cl}(U_2) \leq \text{cl}((\text{cl}_\delta(U))^c) \leq \text{cl}(U^c) = U^c$. Hence $\text{cl}(U_1) = \text{cl}(V) \leq U \leq (\text{cl}(U_2))^c$.
(3) $\Rightarrow$ (4) it is obvious.
(4) $\Rightarrow$ (1) Let K be a fuzzy δ-closed subset of X and p a fuzzy point set such that $p \leq K^c$. By (4), there are fuzzy open sets U and V such that $p \leq U, K \leq V$ and $\text{cl}(U) \leq (\text{cl}(V))^c$. Since $p \leq U \leq \text{cl}(U)$, $p \leq \text{int}(U) = U \leq \text{int}(\text{cl}(U))$. Put $U_1 = \text{int}(\text{cl}(U))$, then U_1 is fuzzy δ-open and $p \leq U_1$. Since $K \leq V \leq \text{cl}(V)$, $K \leq \text{int}(V) = V \leq \text{int}(\text{cl}(V))$. Put $U_2 = \text{int}(\text{cl}(V))$, then U_2 is fuzzy δ-open and $K \leq U_2$. Furthermore, since $\text{int}(\text{cl}(U)) \leq \text{cl}(U) \leq (\text{cl}(V))^c \leq (\text{int}(\text{cl}(V)))^c$, we have $U_1 \leq U_2^c$. □

Definition 2.15: A fts X is called fuzzy δ-normal if for any pair of fuzzy δ-closed subsets K, L with $K \leq L^c$ in X,

there are fuzzy δ-open sets U_1 and U_2 in X with $K \leq U_1$, $L \leq U_2$ and $U_1 \leq U_2^c$. A fts X is called fuzzy δ-T_4 if it is fuzzy δ-T_1 and fuzzy δ-normal.

Clearly every fuzzy δ-T_4 space is a fuzzy δ-T_3 space.

Theorem 2.16: For a fts $(X, \mathcal{T})$, the following are equivalent:

(1) X is fuzzy δ-normal.

(2) For any fuzzy δ-closed set K and any fuzzy δ-open set U containing K, there exists a fuzzy δ-open set V such that $K \leq V \leq \text{cl}(V) \leq U$.

(3) For any fuzzy δ-closed set K and any fuzzy δ-open set U containing K, there exists a fuzzy open set V such that $K \leq V \leq \text{cl}(V) \leq U$.

(4) For any pair of fuzzy δ-closed subsets K, L with $K \leq L^c$ in X, there are fuzzy open sets U_1 and U_2 with $K \leq U_1$, $L \leq U_2$ and $\text{cl}(U_1) \leq (\text{cl}(U_2))^c$.

Proof: (1)⇒(2) Let K be a fuzzy δ-closed set and U a fuzzy δ-open set containing K. Then U^c is a fuzzy δ-closed set with $U^c \leq K^c$. Thus there are fuzzy δ-open sets V_1 and V_2 such that $K \leq V_1, U^c \leq V_2$ and $V_1 \leq V_2^c$. So $K \leq V_1 \leq V_2^c \leq U$ and $V_1 \leq \text{cl}_\delta(V_1) \leq \text{cl}_\delta(V_2^c) = V_2^c$. Hence $K \leq V_1 \leq \text{cl}(V_1) \leq \text{cl}_\delta(V_1) \leq U$.

(2)⇒(3) It is obvious.

(3)⇒(4) Let K and L be fuzzy δ-closed subsets of X with $K \leq L^c$. Then L^c is a fuzzy δ-open set containing K. By (3) there is a fuzzy open set V such that $K \leq V \leq \text{cl}(V) \leq L^c$. Since $\text{cl}(V)$ is fuzzy δ-closed and L^c is a fuzzy δ-open set containing $\text{cl}(V)$, there is a fuzzy open set U such that $K \leq V \leq \text{cl}(V) \leq U \leq \text{cl}(U) \leq L^c$. Let $U_1 = V$ and $U_2 = (\text{cl}(U)^c$, then U_1 and U_2 are fuzzy open sets with $K \leq U_1, L \leq U_2$. And $\text{cl}(U_2) = \text{cl}((\text{cl}(U))^c) \leq \text{cl}(U^c) = U^c$. So $\text{cl}(U_1) = \text{cl}(V) \leq U \leq (\text{cl}(U_2))^c$.

(4)⇒(1) Let K and L be fuzzy δ-closed subsets of X with $K \leq L^c$. Then, by (4), there are fuzzy open sets U and V such that $K \leq U, L \leq V$ and $\text{cl}(U) \leq (\text{cl}(V))^c$. Furthermore since $K \leq U \leq \text{cl}(U)$, $K \leq U = \text{int}(U) \leq \text{int}(\text{cl}(U)$. Put $U_1 = \text{int}(\text{cl}(U)$, then U_1 is fuzzy δ-open and $K \leq U_1$. Similarly put $U_2 = \text{int}(\text{cl}(V))$, then U_2 is fuzzy δ-open and $L \leq U_2$. And since $\text{int}(\text{cl}(U)) \leq \text{cl}(U) \leq (\text{cl}(V))^c \leq (\text{int}(\text{cl}(V)))^c$, $U_1 \leq U_2^c$. □

Example 2.17: Let $X = [0, 1]$ and for each $\alpha \in X$, $U_\alpha(x) = \alpha$ for all $x \in X$. And let $\mathcal{T} = \{U_\alpha \mid \alpha \in X\}$. Then $\mathcal{T}$ is a fuzzy topology and each U_α is fuzzy δ-open. Therefore $\mathcal{T}$ is fuzzy δ-normal and fuzzy δ-regular. But it is not fuzzy δ-T_1. So it is neither fuzzy δ-T_3 nor fuzzy δ-T_4.

Example 2.18: Let $X = [0, 1]$ and for each $\alpha \in X$

$$U_\alpha(x) = \begin{cases} 1 & \text{if } 0 \leq x \leq \alpha \\ 0 & \text{if } \alpha < x \leq 1, \end{cases}$$

$$V_\alpha(x) = \begin{cases} 0 & \text{if } 0 \leq x \leq \alpha \\ 1 & \text{if } \alpha < x \leq 1. \end{cases}$$

Let $\mathcal{T}$ be a fuzzy topology on X generated by the subbase $\{U_\alpha \mid \alpha \in X\} \cup \{V_\alpha \mid \alpha \in X\}$. Then $\mathcal{T}$ is a fuzzy topology and $\text{int}(\text{cl}(U_\alpha)) = U_\alpha$ for all $\alpha \in X$. So every U_α is fuzzy δ-open. Similarly every V_α is also fuzzy δ-open. Therefore $(X, \mathcal{T})$ is fuzzy δ-T_4 and also fuzzy δ-T_3.

III. Fuzzy δ-closure and δ-interior in the fuzzy subspace μ

Let $(X, \mathcal{T})$ be a fuzzy topological space and μ a fuzzy subset of X. We denote by $(\mu, \mathcal{T}^\mu)$ the fuzzy subspace on μ. If μ is fuzzy regular open(regular closed) in X, then $(\mu, \mathcal{T}^\mu)$ is said to be a fuzzy regular open(resp. regular closed) subspace.

Definition 3.1: Let $A \in X^\mu$. We say that A is fuzzy regular open(regular closed) in the subspace μ if $A = \text{int}^\mu(\text{cl}^\mu(A))$ (resp. $\text{cl}^\mu(\text{int}^\mu(A))$).

Definition 3.2: Let $A \in X^\mu$. A fuzzy point $x_r \in \mu$ is said to be a fuzzy δ-cluster point of A in μ iff every fuzzy regular open q-nbd U of x_r in μ is q-coincident with A in μ. The set of all fuzzy δ-cluster point of A in μ is called the fuzzy δ-closure of A in μ and is denoted by $\text{cl}_\delta^\mu(A)$.

Theorem 3.3: Let $A \in X^\mu$ and $x_r \in \mu$. $x_r \in \bigwedge\{F \in X^\mu \mid A \leq F, F = \text{cl}^\mu(\text{int}^\mu(F))\}$ if and only if every fuzzy regular open q-nbd U of x_r in μ is q-coincident with A in μ.

Proof: Suppose that N is a fuzzy regular open q-nbd of x_r with $N\tilde{q}A$. Then N is also a fuzzy open set in μ such that $x_r q N \leq N$ and $A\tilde{q}N$. Since N^c is fuzzy regular closed and $A \leq N^c$, $\bigwedge\{F \in X^\mu \mid A \leq F, F = \text{cl}^\mu(\text{int}^\mu(F))\} \leq N^c$. And since $x_r \notin N^c$, we have $x_r \notin \bigwedge\{F \in X^\mu \mid A \leq F, F = \text{cl}^\mu(\text{int}^\mu(F))\}$. Conversely suppose that $x_r \notin \bigwedge\{F \in X^\mu \mid A \leq F, F = \text{cl}^\mu(\text{int}^\mu(F))\}$. Then there is a fuzzy regular closed set F such that $x_r \notin F$ and $A \leq F$. Thus F^c is a fuzzy regular open set with $x_r q F^c$ and $A\tilde{q}F^c$. Hence x_r is not a fuzzy δ-cluster point of A in μ. □

By the above theorem, in a fuzzy subspace $(\mu, \mathcal{T}^\mu)$, we have

$$\text{cl}_\delta^\mu(A) = \bigwedge\{F \in X^\mu \mid A \leq F, F = \text{cl}^\mu(\text{int}^\mu(F))\}$$

for any set $A \in X^\mu$. Now we define the δ-interior in a subspace.

Definition 3.4: Let $A \in X^\mu$. The δ-interior of A in μ is defined as follows;

$$\text{int}_\delta^\mu(A) = \mu - \text{cl}_\delta^\mu(\mu - A).$$

We have known that $\text{cl}^\mu(A) = \mu - \text{int}^\mu(\mu - A)$ for any fuzzy subset A of X^μ. So we have the following remark.

Remark 3.5:

$$\begin{aligned} \text{int}_\delta^\mu(A) &= \mu - \text{cl}_\delta^\mu(\mu - A) \\ &= \mu - \bigwedge\{F \in X^\mu \mid \mu - A \leq F, \\ &\quad F = \text{cl}^\mu(\text{int}^\mu(F))\} \\ &= \bigvee\{\mu - F \in X^\mu \mid \mu - F \leq A, \\ &\quad \mu - F = \mu - \text{cl}^\mu(\text{int}^\mu(F))\} \\ &= \bigvee\{U \in X^\mu \mid U \leq A, U = \text{int}^\mu(\text{cl}^\mu(U))\}. \end{aligned}$$

We will show that for any fuzzy set A in a fuzzy subspace $(\mu, \mathcal{T}^\mu)$,

$$\mathrm{cl}^\mu_\delta(A) = \bigwedge\{\mathrm{cl}^\mu(U) \mid A \le \mathrm{cl}^\mu(U), U \in \mathcal{T}^\mu\}.$$

For the sake, we will prove two lemmas.

Lemma 3.6: Let $(\mu, \mathcal{T}^\mu)$ be a fuzzy subspace. If $V \in \mathcal{T}^\mu$, then $\mathrm{cl}^\mu(V)$ is fuzzy regular closed in μ.

Proof: Since $V \le \mathrm{cl}^\mu(V)$, $V = \mathrm{int}^\mu(V) \le \mathrm{int}^\mu(\mathrm{cl}^\mu(V))$ and hence $\mathrm{cl}^\mu(V) \le \mathrm{cl}^\mu(\mathrm{int}^\mu(\mathrm{cl}^\mu(V)))$. Conversely since $\mathrm{int}^\mu(\mathrm{cl}^\mu(V)) \le \mathrm{cl}^\mu(V)$, $\mathrm{cl}^\mu(\mathrm{int}^\mu(\mathrm{cl}^\mu(V))) \le \mathrm{cl}^\mu(\mathrm{cl}^\mu(V)) = \mathrm{cl}^\mu(V)$. Hence $\mathrm{cl}^\mu(V) = \mathrm{cl}^\mu(\mathrm{int}^\mu(\mathrm{cl}^\mu(V)))$. □

Lemma 3.7: Let $(\mu, \mathcal{T}^\mu)$ is a fuzzy subspace. Then $\{\mathrm{cl}^\mu(U) \mid U \in \mathcal{T}^\mu\} = \{F \in X^\mu \mid F$ is fuzzy regular closed in $\mu\}$.

Proof: We know that for any fuzzy open set U in μ, $\mathrm{cl}^\mu(U)$ is fuzzy regular closed in μ. Conversely, take any fuzzy regular closed set F in μ. Then $F = \mathrm{cl}^\mu(\mathrm{int}^\mu(F)) = \mathrm{cl}^\mu(\bigvee\{U \mid U \le F, U \in \mathcal{T}^\mu\}) \in \{\mathrm{cl}^\mu(U) \mid U \in \mathcal{T}^\mu\}$. □

We may have a problem in finding the fuzzy δ-closure of any fuzzy set. But from the above lemmas we have the clue to find it.

Theorem 3.8: For any fuzzy set A in a fuzzy subspace $(\mu, \mathcal{T}^\mu)$,

$$\mathrm{cl}^\mu_\delta(A) = \bigwedge\{\mathrm{cl}^\mu(U) \mid A \le \mathrm{cl}^\mu(U), U \in \mathcal{T}^\mu\}.$$

Proof: The proof is straightforward. □

In general, $\mathrm{cl}^\mu(A) \ne \mathrm{cl}(A) \wedge \mu$ and $\mathrm{int}(A) = \mathrm{int}^\mu(A) \wedge \mathrm{int}(\mu)$ for any fuzzy subset $A \in X^\mu$. But for any crisp fuzzy subset Y of X, if $\mu = \chi_Y$, then $\mathrm{cl}^\mu(A) = \mathrm{cl}(A) \wedge \mu$ for any fuzzy subset $A \in X^\mu$ (See [19]).

Furthermore, if μ is fuzzy open in X and $\mu = \chi_Y$, $\mathrm{cl}^\mu_\delta(A) = \mathrm{cl}_\delta(A) \wedge \mu$ for any fuzzy subset A of μ. Now we will prove it.

Lemma 3.9: Let X be a fuzzy topological space and $\mu = \chi_Y$ a fuzzy open subset of X. Suppose that $A \in X^\mu$. If A is fuzzy regular open in X, then A is fuzzy regular open in μ.

Proof: For any fuzzy subset $A \in X^\mu$, the following holds.

$$\begin{aligned}
\mathrm{int}^\mu(\mathrm{cl}^\mu(A)) &= \mathrm{int}^\mu(\mathrm{cl}(A) \wedge \mu) \\
&= \mathrm{int}(\mathrm{cl}(A) \wedge \mu) \\
&= \mathrm{int}(\mathrm{cl}(A)) \wedge \mathrm{int}(\mu) \\
&= \mathrm{int}(\mathrm{cl}(A)) \wedge \mu.
\end{aligned}$$

Hence if $A = \mathrm{int}(\mathrm{cl}(A))$, then $\mathrm{int}^\mu(\mathrm{cl}^\mu(A)) = \mathrm{int}(\mathrm{cl}(A)) \wedge \mu = A \wedge \mu = A$. □

Theorem 3.10: Let $(X, \mathcal{T})$ is a fuzzy topological space and Y a crisp fuzzy subset of X. If $\mu = \chi_Y$ and μ is fuzzy regular open in X, then

$$\mathrm{cl}^\mu_\delta(A) = \mathrm{cl}_\delta(A) \wedge \mu$$

for any fuzzy subset $A \in X^\mu$.

Proof: Suppose that $x_r \notin \mathrm{cl}^\mu_\delta(A)$. Then there is a fuzzy regular open q-nbd N of x_r in μ with $N\tilde{q}A[\mu]$. i.e. $\mathrm{int}^\mu(\mathrm{cl}^\mu(N)) \le A^c$. Since $x_r q N[\mu]$, $x_r q N$ and N is fuzzy open in X, $N = \mathrm{int}(N) \le \mathrm{int}(\mathrm{cl}(N))$. Note that $\mathrm{int}(\mathrm{cl}(N))$ is a fuzzy regular open q-nbd of x_r in X. Since $\mathrm{int}(\mathrm{cl}(N)) = \mathrm{int}(\mathrm{cl}(N \wedge \mu)) = \mathrm{int}(\mathrm{cl}^\mu(N)) \le \mathrm{int}^\mu(\mathrm{cl}^\mu(N))\tilde{q}A[\mu]$, we have $\mathrm{int}(\mathrm{cl}(N))\tilde{q}A$. Thus $x_r \notin \mathrm{cl}_\delta(A) \wedge \mu$. Conversely take $x_r \in \mathrm{cl}^\mu_\delta(A)$ and a fuzzy regular open q-nbd N of x_r in X. Then $N(x) + r > 1$ and so $(N \wedge \mu)(x) + r > 1$. Thus $N \wedge \mu$ is a fuzzy regular open q-nbd of x_r in X. By the above lemma, $N \wedge \mu$ is also a fuzzy regular open q-nbd of x_r in μ. Since $x_r \in \mathrm{cl}^\mu_\delta(A)$, $(N \wedge \mu) q A$. Hence NqA. Therefore x_r is a fuzzy δ-cluster point of A in X. □

In general every fuzzy regular open subset in μ is not fuzzy regular open in X. On the other hand, if $\mu = \chi_Y$ is a fuzzy regular open set in X, then a fuzzy δ-open set in X which is contained in X^μ is also fuzzy δ-open in μ. The following theorem shows it.

Theorem 3.11: Let $(X, \mathcal{T})$ be a fuzzy topological space and Y a crisp fuzzy subset of X. Let $\mu = \chi_Y$ be fuzzy regular open in X and $A \in X^\mu$. Then

$$\mathrm{int}^\mu_\delta(A) = \mathrm{int}_\delta(A).$$

Proof:

$$\begin{aligned}
\mathrm{int}^\mu_\delta(A) &= \mu - \mathrm{cl}^\mu_\delta(\mu - A) \\
&= \mu - (\mathrm{cl}_\delta(\mu - A) \wedge \mu) \\
&= \mu \wedge (\mathrm{cl}_\delta(\mu - A) \wedge \mu)^c \\
&= \mu \wedge ((\mathrm{cl}_\delta(\mu - A))^c \vee \mu^c) \\
&= \mu \wedge (\mathrm{cl}_\delta(\mu - A))^c \\
&= \mu \wedge (1 - \mathrm{cl}_\delta(\mu - A)) \\
&= \mu \wedge \mathrm{int}_\delta(1 - (\mu - A)) \\
&= \mathrm{int}_\delta(\mu \wedge (1 - (\mu - A))) \\
&= \mathrm{int}_\delta(A).
\end{aligned}$$

□

IV. Fuzzy δ-separation axioms in the fuzzy subspace μ

Now we define the fuzzy δ-separation axioms on the fuzzy subspaces. Note that $A^c = \mu - A$ in the fuzzy subspace μ, for any set $A \in X^\mu$.

Definition 4.1: A fuzzy subspace $(\mu, \mathcal{T}^\mu)$ is called fuzzy δ-T_0 if for any pair of fuzzy points p and q with different supports in μ, there is a fuzzy δ-open set U in μ with $p \le U \le q^c$ or $q \le U \le p^c$.

Theorem 4.2: Let $(X, \mathcal{T})$ be a fuzzy δ-T_0 space. Suppose that Y is a crisp fuzzy subset of X and a fuzzy regular open set of X. Then $(\mu = \chi_Y, \mathcal{T}^\mu)$ is fuzzy δ-T_0.

Proof: Let X be a fuzzy δ-T_0 space and $\mu = \chi_Y$ a fuzzy regular open subset of X. Take any fuzzy points p and q with different supports in a subspace $(\mu, \mathcal{T}^\mu)$. Then p and q

are also fuzzy points with different supports in the space X. Since X is fuzzy δ-T_0, there is a fuzzy δ-open set U in X with $p \leq U \leq q^c$ or $q \leq U \leq p^c$. And since $U \wedge \mu$ is fuzzy δ-open in X with $U \wedge \mu \leq \mu$, $U \wedge \mu$ is also fuzzy δ-open in μ. Furthermore $p \leq U \wedge \mu \leq (\mu - q)$ or $q \leq U \wedge \mu \leq (\mu - p)$. Hence $(\mu, \mathcal{T}^\mu)$ is fuzzy δ-T_0. □

Definition 4.3: A fuzzy subspace $(\mu, \mathcal{T}^\mu)$ is called fuzzy δ-T_1 if for any pair of fuzzy points p and q with different supports in μ, there are two fuzzy δ-open sets U_1, U_2 in μ with $p \leq U_1 \leq q^c$ and $q \leq U_2 \leq p^c$.

Theorem 4.4: A fuzzy subspace $(\mu, \mathcal{T}^\mu)$ is fuzzy δ-T_1 iff every crisp fuzzy point in μ is fuzzy δ-closed in μ.

Proof: Take any crisp fuzzy point p in μ. We will show that $\mu - p$ is fuzzy δ-open in μ. We can take a fuzzy point $q \in \mu - p$ with different support from p. Since $(\mu, \mathcal{T}^\mu)$ is fuzzy δ-T_1, there is a fuzzy δ-open set U in μ with $q \leq U \leq \mu - p$. Thus $\mu - p = \bigcup_{q \in \mu - p} \{U \mid q \leq U \leq \mu - p, U \text{ is fuzzy } \delta\text{-open in } \mu\}$. Since $\bigcup_{q \in \mu - p} \{U \mid q \leq U \leq \mu - p, U \text{ is fuzzy } \delta\text{-open in } \mu\}$ is fuzzy δ-open in μ, $\mu - p$ is fuzzy δ-open in μ. Hence p is fuzzy δ-closed in μ. □

Corollary 4.5: Let $(\mu, \mathcal{T}^\mu)$ be a fuzzy subspace. μ is fuzzy δ-T_1 if and only if $x_\alpha = \bigcap \{\mathrm{cl}_\delta(U) \mid x_\alpha \leq \mathrm{cl}_\delta(U)\}$ for any $x_\alpha \in \mu$.

Theorem 4.6: Let $(X, \mathcal{T})$ be a fuzzy δ-T_1 space. Suppose that Y is a crisp fuzzy subset of X and fuzzy regular open in X. Then $(\mu = \chi_Y, \mathcal{T}^\mu)$ is fuzzy δ-T_1.

Proof: It is obvious. □

Definition 4.7: A fuzzy subspace $(\mu, \mathcal{T}^\mu)$ is called fuzzy δ-Hausdorff, or fuzzy δ-T_2, if for any pair of fuzzy point p and q with different supports in μ, there are fuzzy δ-open sets U_1 and U_2 in μ with $p \leq U_1 \leq q^c$, $q \leq U_2 \leq p^c$ and $U_1 \leq U_2^c$.

Obviously every fuzzy δ-T_2 subspace is fuzzy δ-T_1.

Theorem 4.8: Let $(X, \mathcal{T})$ be a fuzzy δ-T_2 space. Suppose that Y is a crisp fuzzy subset of X and fuzzy regular open in X. Then $(\mu = \chi_Y, \mathcal{T}^\mu)$ is fuzzy δ-T_2.

Proof: Take any fuzzy points p and q with different supports in a subspace $(\mu, \mathcal{T}^\mu)$. Then p and q are also fuzzy points with different supports in the space X. Since X is fuzzy δ-T_2, there are fuzzy δ-open sets U_1 and U_2 in X such that $p \leq U_1 \leq 1 - q$, $q \leq U_2 \leq 1 - p$ and $U_1 \leq 1 - U_2$. Thus there are fuzzy δ-open sets $U_1 \wedge \mu$ and $U_2 \wedge \mu$ in μ such that $p \leq (U_1 \wedge \mu) \leq (1 - q) \wedge \mu = \mu - q$, $q \leq (U_2 \wedge \mu) \leq (1 - p) \wedge \mu = \mu - p$ and $(U_1 \wedge \mu) \leq (1 - U_2) \wedge \mu = \mu - (U_2 \wedge \mu)$. So μ is fuzzy δ-T_2. □

Definition 4.9: A fuzzy subspace $(\mu, \mathcal{T}^\mu)$ is called fuzzy δ-regular if for every pair consisting of a fuzzy point p in μ and a fuzzy δ-closed set K in μ with $p \leq K^c$, there are fuzzy δ-open sets U_1, U_2 in μ with $p \leq U_1$, $K \leq U_2$ and $U_1 \leq U_2^c$. A fuzzy subspace $(\mu, \mathcal{T}^\mu)$ is called fuzzy δ-T_3 if it is fuzzy δ-regular and fuzzy δ-T_1.

We can easily prove that every fuzzy δ-T_3 subspace is fuzzy δ-T_2.

We have known that for any fuzzy closed set K in μ, $\mathrm{int}^\mu(K)$ is fuzzy regular open in μ. Thus it is also fuzzy δ-open. Therefore the following theorem holds.

Theorem 4.10: For a fuzzy subspace $(\mu, \mathcal{T}^\mu)$, the following are equivalent:
(1) $(\mu, \mathcal{T}^\mu)$ is fuzzy δ-regular.
(2) For any fuzzy point p and any fuzzy δ-open set V containing p in $(\mu, \mathcal{T}^\mu)$, there is a fuzzy δ-open set U in μ such that $p \leq U \leq \mathrm{cl}^\mu_\delta(U) \leq V$.
(3) For any fuzzy δ-closed set K and any fuzzy point p in $(\mu, \mathcal{T}^\mu)$ such that $p \leq (\mu - K)$, there are fuzzy δ-open sets U_1 and U_2 in μ such that $p \leq U_1, K \leq U_2$ and $\mathrm{cl}^\mu(U_1) \leq (\mu - \mathrm{cl}^\mu(U_2))$.
(4) For any fuzzy δ-closed set K and each fuzzy point p in $(\mu, \mathcal{T}^\mu)$ such that $p \leq (\mu - K)$, there are fuzzy open sets U_1 and U_2 in $(\mu, \mathcal{T}^\mu)$ such that $p \leq U_1, K \leq U_2$ and $\mathrm{cl}^\mu(U_1) \leq (\mu - \mathrm{cl}^\mu(U_2))$.

Proof: (1) ⇒ (2) Let p be a fuzzy point set in μ and V a fuzzy δ-open set in μ containing p. Then there exist fuzzy δ-open sets U_1 and U_2 in μ such that $p \leq U_1, \mu - V \leq U_2$ and $U_1 \leq \mu - U_2$. So $p \leq U_1 \leq \mu - U_2 \leq V$. Thus $p \leq U_1 \leq \mathrm{cl}^\mu_\delta(U_1) \leq \mathrm{cl}^\mu_\delta(\mu - U_2) = \mu - U_2 \leq V$.
(2) ⇒ (3) Let K be a fuzzy δ-closed subset in μ and p a fuzzy point in μ such that $p \leq \mu - K$. Then $\mu - K$ is a fuzzy δ-open set in μ with $p \leq \mu - K$. By (2) there is a fuzzy δ-open set U in μ such that $p \leq U \leq \mathrm{cl}^\mu_\delta(U) \leq \mu - K$. Since U is a fuzzy δ-open set in μ containing p, there is a fuzzy δ-open set V in μ such that $p \leq V \leq \mathrm{cl}^\mu_\delta(V) \leq U \leq \mathrm{cl}^\mu_\delta(U) \leq \mu - K$. Put $U_1 = V$ and $U_2 = \mu - \mathrm{cl}^\mu_\delta(U)$. Then U_1 and U_2 are fuzzy δ-open sets in μ with $p \leq U_1, K \leq U_2$. Furthermore $\mathrm{cl}^\mu(U_2) \leq \mathrm{cl}^\mu(\mu - \mathrm{cl}^\mu_\delta(U)) \leq \mathrm{cl}^\mu(\mu - U) = \mu - U$. Since $\mathrm{cl}^\mu(V) \leq \mathrm{cl}^\mu_\delta(V)$, $\mathrm{cl}^\mu(U_1) = \mathrm{cl}^\mu(V) \leq U \leq \mu - \mathrm{cl}^\mu(U_2)$.
(3) ⇒ (4) it is obvious.
(4) ⇒ (1) Let K be a fuzzy δ-closed subset in μ and p a fuzzy point in μ such that $p \leq \mu - K$. By (4), there are fuzzy open sets U and V in μ such that $p \leq U, K \leq V$ and $\mathrm{cl}^\mu(U) \leq \mu - \mathrm{cl}^\mu(V)$. Since $p \leq U \leq \mathrm{cl}^\mu(U)$, $p \leq \mathrm{int}^\mu(U) = U \leq \mathrm{int}^\mu(\mathrm{cl}^\mu(U))$. Put $U_1 = \mathrm{int}^\mu(\mathrm{cl}^\mu(U))$, then U_1 is fuzzy δ-open in μ and $p \leq U_1$. Since $K \leq V \leq \mathrm{cl}^\mu(V)$, $K \leq \mathrm{int}^\mu(V) = V \leq \mathrm{int}^\mu(\mathrm{cl}^\mu(V))$. Put $U_2 = \mathrm{int}^\mu(\mathrm{cl}^\mu(V))$, then U_2 is fuzzy δ-open in μ and $K \leq U_2$. Furthermore, since $\mathrm{int}^\mu(\mathrm{cl}^\mu(U)) \leq \mathrm{cl}^\mu(U) \leq \mu - \mathrm{cl}^\mu(V) \leq \mu - \mathrm{int}^\mu(\mathrm{cl}^\mu(V))$, $U_1 \leq \mu - U_2$. □

Definition 4.11: A fuzzy subspace $(\mu, \mathcal{T}^\mu)$ is called fuzzy δ-normal if for any pair of fuzzy δ-closed subsets K, L in μ with $K \leq L^c$, there are fuzzy δ-open sets U_1, U_2 in μ with $K \leq U_1$, $L \leq U_2$ and $U_1 \leq U_2^c$. A fuzzy subspace $(\mu, \mathcal{T}^\mu)$ is called fuzzy δ-T_4 if it is fuzzy δ-T_1 and fuzzy δ-normal.

Clearly every fuzzy δ-T_4 subspace is fuzzy δ-T_3.

Theorem 4.12: For a fuzzy subspace $(\mu, \mathcal{T}^\mu)$, the following are equivalent:
(1) $(\mu, \mathcal{T}^\mu)$ is fuzzy δ-normal.
(2) For any fuzzy δ-closed set K and any fuzzy δ-open set U containing K in $(\mu, \mathcal{T}^\mu)$, there exists a fuzzy δ-open set V in

μ such that $K \leq V \leq \mathrm{cl}^{\mu}_{\delta}(V) \leq U$.
(3) For any fuzzy δ-closed set K and any fuzzy δ-open set U containing K in $(\mu, \mathcal{T}^{\mu})$, there exists a fuzzy δ-open set V in μ such that $K \leq V \leq \mathrm{cl}^{\mu}(V) \leq U$.
(4) For any fuzzy δ-closed set K and any fuzzy δ-open set U containing K in $(\mu, \mathcal{T}^{\mu})$, there exists a fuzzy open set V in μ such that $K \leq V \leq \mathrm{cl}^{\mu}(V) \leq U$.
(5) For any pair of fuzzy δ-closed subsets K and L with $K \leq \mu - L$ in $(\mu, \mathcal{T}^{\mu})$, there are fuzzy open sets U_1 and U_2 in μ with $K \leq U_1$, $L \leq U_2$ and $\mathrm{cl}^{\mu}(U_1) \leq (\mu - \mathrm{cl}^{\mu}(U_2))$.

Proof: (1)⇒(2) Let K be a fuzzy δ-closed set in μ and U a fuzzy δ-open set in μ containing K. Then $\mu - U$ is a fuzzy δ-closed set in μ with $\mu - U \leq \mu - K$. Thus there are fuzzy δ-open sets V_1 and V_2 in μ such that $K \leq V_1, \mu - U \leq V_2$ and $V_1 \leq \mu - V_2$. So $K \leq V_1 \leq \mu - V_2 \leq U$ and $V_1 \leq \mathrm{cl}^{\mu}_{\delta}(V_1) \leq \mathrm{cl}^{\mu}_{\delta}(\mu - V_2) = \mu - V_2$. Hence $K \leq V_1 \leq \mathrm{cl}^{\mu}_{\delta}(V_1) \leq U$.
(2)⇒(3), (3)⇒(4) It is obvious.
(4)⇒(5) Let K and L be fuzzy δ-closed subsets in μ with $K \leq \mu - L$. Then $\mu - L$ is a fuzzy δ-open set in μ containing K. By (3) there is a fuzzy open set V in μ such that $K \leq V \leq \mathrm{cl}^{\mu}(V) \leq \mu - L$. Since $\mathrm{cl}^{\mu}(V)$ is fuzzy δ-closed in μ and $\mu - L$ is a fuzzy δ-open set in μ containing $\mathrm{cl}^{\mu}(V)$, there is a fuzzy open set U in μ such that $K \leq V \leq \mathrm{cl}^{\mu}(V) \leq U \leq \mathrm{cl}^{\mu}(U) \leq \mu - L$. Let $U_1 = V$ and $U_2 = \mu - \mathrm{cl}^{\mu}(U)$, then U_1 and U_2 are fuzzy open sets in μ with $K \leq U_1$ and $L \leq U_2$. Also $\mathrm{cl}^{\mu}(U_2) = \mathrm{cl}^{\mu}(\mu - \mathrm{cl}^{\mu}(U)) \leq \mathrm{cl}^{\mu}(\mu - U) = \mu - U$. So $\mathrm{cl}^{\mu}(U_1) = \mathrm{cl}^{\mu}(V) \leq U \leq \mu - \mathrm{cl}^{\mu}(U_2)$.
(5)⇒(1) Let K and L be fuzzy δ-closed subsets in μ with $K \leq \mu - L$. Then, by (4), there are fuzzy open sets U and V in μ such that $K \leq U, L \leq V$ and $\mathrm{cl}^{\mu}(U) \leq \mu - \mathrm{cl}^{\mu}(V))$. Since $K \leq U \leq \mathrm{cl}^{\mu}(U)$, we have $K \leq U = \mathrm{int}^{\mu}(U) \leq \mathrm{int}^{\mu}(\mathrm{cl}^{\mu}(U)$. Put $U_1 = \mathrm{int}^{\mu}(\mathrm{cl}^{\mu}(U)$, then U_1 is fuzzy δ-open in μ and $K \leq U_1$. Similarly put $U_2 = \mathrm{int}^{\mu}(\mathrm{cl}^{\mu}(V))$, then U_2 is fuzzy δ-open in μ and $L \leq U_2$. And since $\mathrm{int}^{\mu}(\mathrm{cl}^{\mu}(U)) \leq \mathrm{cl}^{\mu}(U) \leq \mu - \mathrm{cl}^{\mu}(V) \leq \mu - \mathrm{int}^{\mu}(\mathrm{cl}^{\mu}(V))$, we have $U_1 \leq \mu - U_2$. □

Theorem 4.13: Let $(X, \mathcal{T})$ be a fuzzy δ-regular space. Suppose that Y is a crisp fuzzy subset of X and fuzzy regular open in X. Then $(\mu = \chi_Y, \mathcal{T}^{\mu})$ is fuzzy δ-regular.

Proof: Let U be a fuzzy δ-open set in μ and p a fuzzy point in μ with $p \leq U$. Since μ is fuzzy regular open in X, U is also fuzzy δ-open in X. Since X is fuzzy δ-regular, there is a fuzzy δ-open set W of X such that $p \leq W \leq \mathrm{cl}_{\delta}(W) \leq U$. Thus there is a fuzzy δ-open set $W_{\mu} = W \wedge \mu$ in μ such that $p \leq W_{\mu} \leq \mathrm{cl}_{\delta}(W) \wedge \mu = \mathrm{cl}^{\mu}_{\delta}(W_{\mu}) \leq U \wedge \mu = U$. Hence μ is fuzzy δ-regular. □

Lemma 4.14: Let $(X, \mathcal{T})$ be a fuzzy δ-normal space. Suppose that μ is a crisp fuzzy subset of X and fuzzy regular closed in X. If $K \in X^{\mu}$ is fuzzy regular closed in μ, then K is also fuzzy regular closed in X.

Proof: $K = \mathrm{cl}^{\mu}_{\delta}(K) = \mathrm{cl}_{\delta}(K) \wedge \mu = \mathrm{cl}_{\delta}(K) \wedge \mathrm{cl}_{\delta}(\mu) \geq \mathrm{cl}_{\delta}(K \wedge \mu) = \mathrm{cl}_{\delta}(K) \geq K$. □

Theorem 4.15: Let $(X, \mathcal{T})$ be a fuzzy δ-normal space. Suppose that Y is a crisp fuzzy subset of X and fuzzy regular clopen in X. Then $(\mu = \chi_Y, \mathcal{T}^{\mu})$ is fuzzy δ-normal.

Proof: Let X be a fuzzy δ-normal space and μ a fuzzy δ-clopen subspace of X. Let K, L be fuzzy δ-closed subsets in μ with $K \leq (\mu - L)$. Since μ is fuzzy δ-closed in X, K and L are also fuzzy δ-closed in X with $K \leq (1 - L)$. Since X is fuzzy δ-normal, there exist fuzzy δ-open sets U_1 and U_2 in X with $K \leq U_1$, $L \leq U_2$ and $U_1 \leq U_2^c$. So there exist fuzzy δ-open sets $(\mu \wedge U_1)$ and $(\mu \wedge U_2)$ in μ with $K \leq (\mu \wedge U_1)$, $L \leq (\mu \wedge U_2)$ and $(\mu \wedge U_1) \leq \mu - (\mu \wedge U_2)$ in the subspace μ. □

V. Conclusion

In this paper, we introduced fuzzy δ-separation axioms in fuzzy topological spaces, and proved that

$$\delta\text{-}T_4 \Rightarrow \delta\text{-}T_3 \Rightarrow \delta\text{-}T_2 \Rightarrow \delta\text{-}T_1 \Rightarrow \delta\text{-}T_0.$$

Also we defined fuzzy δ-separation axioms in the fuzzy subspace in the sense of [22]. We have shown the hereditariness of fuzzy δ-separation in the fuzzy regular subspaces. However we cannot find counterexamples for the reverse directions of the above implications except $\delta\text{-}T_0 \not\Rightarrow \delta\text{-}T_1$. In the subsequential research, we will find these examples and investigate other properties of fuzzy separation axioms.

***Abstract*—Cluster analysis is the assignment of grouping a set of observations into clusters so that observations in the same cluster are similar in some sense. One of the key features for clustering is how to define a sensible similarity measure. However, classical clustering algorithms have no ability to cluster data instances and imprecise concepts using traditional distance measures. In this paper, we proposed a (dis)similarity measure based on a new knowledge representation framework called label semantics. Based on this new measure, we can automatically cluster data instance and descriptive concepts represented by logical expressions of linguistic labels. Experimental results on a toy problem in image classification demonstrate the effectiveness of the new proposed clustering algorithm. Since the new proposed measure can be extended to measuring distance between any two granularities, the new clustering algorithms can also be extended to clustering data instance and imprecise concepts represented by other granularities.**

***Index Terms*—Clustering; Label Semantics; Linguistic Expressions; K-means; Imprecise Concept Modeling**

I. Introduction

Cluster analysis is considered as the most important forms of unsupervised learning [17]. It deals with finding similar patterns in a collection of unlabeled data. A cluster is therefore a collection of objects which are "similar" and are "dissimilar" to the objects belonging to other clusters. Another kind of clustering is conceptual clustering. Two or more objects belong to the same cluster if this one defines a concept common to all objects. In other words, objects are grouped according to their fit to descriptive concepts, not according to simple similarity measures.

Clustering algorithms can be applied in many fields, such as marketing, bio-informatics, video analysis [13] and so on. Hence, in past decades, many classical clustering algorithms, for example K-means, Fuzzy K-means, Hierarchical clustering algorithms, have been proposed and some of them have been successfully applied in resolving practical problems. They group the "similar" objects into one cluster. In this sense, the clustering results depend heavily on the distance measure between objects. Euclidean distance and Mahalanobis distance are two of the most used distance measure. Other (dis)similarity measures may be used for some particular data type. For example, Kullback-Leibler (KL) distance is good for measuring the divergence between two probability distributions. But its unsymmetrical properties make it unsuitable as to be a good universal measure of data distance. In literatures, the objects handled by these classical clustering algorithms are restricted to numerical data, though they could be high-dimensional complex data. However, what we hope to cluster are not limited to numerical data, it could be some high-level knowledge of imprecise concepts or linguistic descriptions [11]. For example, if we are given a set of human age $Age = \{16, 17, 19, 22, 40, 67, 68, 70, 82\}$ and three descriptive concepts $\{young, middle\text{-}aged, old\}$ which are defined by fuzzy membership functions. How can we cluster these two type of data if given the cluster number $K = 3$? Ideally, if the imprecise concept of human age are sensibly defined, we should obtain the following 3 clusters: $\{young, 16, 17, 19, 22\}$, $\{middle\text{-}aged, 40\}$ and $\{old, 67, 68, 70, 82\}$.

Unfortunately, these objects can not be well handled by the existed clustering algorithms. The main reason is there is no good metric for measuring dissimilarity between numerical data and linguistic descriptions [3][6]. In this paper we proposed a novel distance measure which can measure the distance between numeral data and logical expressions of linguistic labels based on *label semantics* [5]. Label semantics uses a set of linguistic labels to represents imprecise concepts in terms of a probability distribution on appropriate label sets. This new proposed measure make it possible to cluster a set of objects including numerical data, concepts, and linguistic descriptions, by modifying the distance measure based on the classical K-means clustering algorithm.

II. Label Semantics

In order to understand the use of natural language for information and knowledge processing in computer systems, Zadeh proposed the concept of Computing with Words paradigm [14]. He suggested a form of precisiated natural language (PNL) based on the theory of generalized constraints and linguistic variables: $\mathbf{x}$ *isr* θ, where $\mathbf{x}$ is the constrained variable, r is the constraining relation, and r is a discrete valued modal variable. The "is" in *isr* is simply its natural meaning- the conjugated verb "to be" and other defined modalities include: possibilistic ($r = blank$); probabilistic ($r = p$); veristic ($r = v$); random set ($r = rs$); fuzzy graph($r = fg$); bimodal ($r = bm$); and Pawlakset ($r = ps$) [15]. However, since the invention of PNL, there is no applicable calculus developed to solve problems in natural language understanding, though some thoughts had been used in designing a search engines by combining it with other computational linguistics technologies [1][10]. Label semantics, proposed by Lawry [4] [5], provides an alternative

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

representation for modeling with words. In contrast to Zadeh's methodology this approach is based on measures of an agent's subjective belief that a logical expression is appropriate to describe a particular object or value. It provides a set of applicable calculus that has been successfully used in many supervised learning applications [4] [9] [11].

Label semantics is a random set framework for modeling with words. The fundamental notion underlying label semantics is that when individuals make assertion of the form ' $\mathbf{x}$ is θ ', different from Zadeh's approach discussed above [15], they are essentially providing information about what labels are appropriate for the value of the underlying variable $\mathbf{x}$ [5]. For $x \in \Omega$ the label description of x is a random set from V into the power set of $\mathbb{L}$, denoted by D_x, with associated distribution m_x, which is referred to as mass assignment:

$$\forall S \subseteq \mathbb{L}, m_x(S) = P(I \in V : D_x^I = S). \tag{1}$$

To evaluate how appropriate a label is for describing a particular value of variable x, *appropriateness degrees* are defined.

$$\forall x \in \Omega, \forall L \in \mathbb{L}, \mu_L(x) = \sum_{S \subseteq \mathbb{L}: L \in S} m_x(S) \tag{2}$$

Example 1: Given a set of labels defined on the height of an adult: $\mathbb{L}_{Height} = \{short, medium, tall\}$ and a voting space with size of 10. Suppose 4 of 10 people agree that *medium* is the only appropriate label for the height of $173cm$ and 6 support that both *short* and *medium* are appropriate labels, according to Eq. 1, the mass assignment for $173cm$ is: $m_{173} = \{medium\} : 0.4, \{short, medium\} : 0.6$. Based on the appropriateness measure given in Eq. 2, the appropriateness degree of *medium* as a description of $173cm$ is

$$\mu_{medium}(173) = 0.4 + 0.6 = 1 \tag{3}$$

and that of *short* is $\mu_{short}(173) = 0.6$.

The mass assignment is extendable to multi-dimensional case. For example, multi-dimensional color labels $\{red, orange, yellow, \ldots\}$ can be used to describe a pixel of color image $\mathbf{p}$ in the HSV space. The mass assignment can be represented in the form of

$$m_{\mathbf{p}} = \{red, orage\} : 0.3, \{red\} : 0.7$$

Such representations will be used in our experiments.

Given a universe of discourse Ω containing a set of objects or instances to be described, it is assumed that all relevant expression can be generated recursively from a finite set of basic labels $\mathbb{L} = \{L_1, L_2, ..., L_n\}$ Operators for combing expressions are restricted to the standard logical connectives of negation '$\neg$', conjunction '$\wedge$', disjunction '$\vee$' and implication '$\rightarrow$'. Hence, the set of logical expressions of labels can be formally defined as follows:

Definition 1 (Logical expressions of labels): The set of logical expressions, *LE*, is defined recursively as follows:

(i) $L_i \in LE \quad for \quad i = 1, 2, ..., n$. (ii) If θ, $\varphi \in LE$ then $\neg\theta, \theta \wedge \varphi, \theta \vee \varphi, \theta \rightarrow \varphi \in LE$.

Basically, we interpret the main logical connectives as follows:

- $\neg L$ means that L is not an appropriate label.
- $L_1 \wedge L_2$ means both L_1 and L_2 are appropriate labels.
- $L_1 \vee L_2$ means that either L_1 or L_2 are appropriate labels.
- $L_1 \rightarrow L_2$ means that L_2 is an appropriate label whenever L_1 is.

As well as labels for a single variable, we may want to evaluate the appropriateness degree of a complex logical expression $\theta \in LE$. Consider the set of logical expressions LE obtained by recursive application of the standard logical connectives. In order to evaluate the appropriateness degrees of such expressions we must identify what information they provide regarding the appropriateness of labels. In general, for any logical expression θ we should be able to identify a maximal set of label sets, $\lambda(\theta)$, that are consistent with θ so that the meaning of θ can be interpreted as the constraint $D_x \in \lambda(\theta)$.

Definition 2 (λ-Function): Let θ and φ be expressions generated by recursive application of the connectives $\neg, \wedge, \vee$ and $\rightarrow$ to the elements of $\mathbb{L}$ (i.e. $\theta \in LE$). Then the set of possible label sets defined by a linguistic expression can be determined recursively as follows:

(i) $\lambda(L_i(x)) = \{S \subseteq \mathbb{F} | \{L_i\} \subseteq S\}$.
(ii) $\lambda(\neg\theta) = \overline{\lambda(\theta)}$.
(iii) $\lambda(\theta \vee \varphi) = \lambda(\theta) \bigcap \lambda(\varphi)$.
(iv) $\lambda(\theta \wedge \varphi) = \lambda(\theta) \bigcup \lambda(\varphi)$.
(v) $\lambda(\theta \rightarrow \varphi) = \overline{\lambda(\theta)} \bigcap \lambda(\varphi)$.

where $\mathbb{F}$, which is refereed to as *focal set*, represents the subsets of labels with possible non-zero masses into the power set of $\mathbb{L}$. The formal definition of focal set is as follows:

Definition 3 (Focal set): Given a universe Ω for variable x, the focal set of $\mathbb{L}$ is a set of focal elements defined as:

$$\mathbb{F} = \{S \subseteq \mathbb{L} | \exists x \in \Omega, m_x(S) > 0\} \tag{4}$$

In label semantics theory, λ-function is a useful tool to represent logical expressions into a set of linguistic labels [11], i.e.: $\lambda(\mathbb{L}) \rightarrow \mathbb{F}$. More details on the label semantics theory are available in [4]. Label semantics has been well applied in data mining and machine learning, a brief review on label semantics based data mining algorithms are given in [12].

III. Distance of Logical Expressions

Based on theory of fuzzy sets many similarity/dissimilarity measures [3] [6] have been proposed for measuring the degree of similarity between fuzzy sets. But those measures are not proper to deal with the similarity/dissimilarity measures between logical expressions which are concepts based on given linguistic variables. Label semantics focus on the decision making process, an intelligent agent must go through in order to identify which labels or logical expressions can actually be used to describe an object or value. For this reason, the appropriateness degree is proposed for measuring the appropriateness of using a particular subset of labels to describe

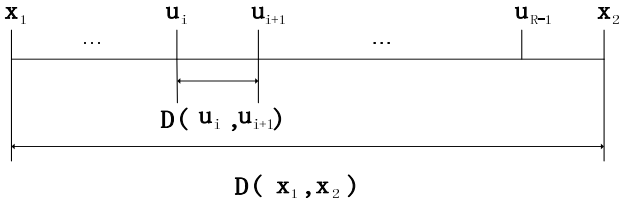

Fig. 1. Illustration of calculating the distance between two data points. The overall dissimilarity between $\mathbf{x}_1$ and $\mathbf{x}_2$ is the aggregated dissimilarity of all the neighboring points $\mathbf{u}_i$ and $\mathbf{u}_{i+1}$ for $i \in R$.

an object or value. One step further, we present a measure to evaluate the dissimilarity of logical expressions based on the mass assignments which can quantize the divergences between logical expressions. This measure is also extendable to measure distance between any two granular sets.

Definition 4 (Distance between data points): Given two data points $\mathbf{x}_1$ and $\mathbf{x}_2$ from an multi-dimensional universe Ω who is fully covered by n labels $\mathbb{L} = \{L_1, ..., L_n\}$, then the distance between $\mathbf{x}_1$ and $\mathbf{x}_2$ in this linguistic label space is defined by:

$$D(\mathbf{x}_1, \mathbf{x}_2) = \sum_{i=0}^{R-1} D(\mathbf{u}_i, \mathbf{u}_{i+1}) \tag{5}$$

where

$$D(\mathbf{u}_i, \mathbf{u}_{i+1}) = \sum_{S \in \lambda(\mathbb{L})} (m_{\mathbf{u_i}}(S) - m_{\mathbf{u_{i+1}}}(S))^2 \tag{6}$$

$$\mathbf{u}_i = \mathbf{x}_1 + \frac{i}{R}(\mathbf{x}_2 - \mathbf{x}_1) \tag{7}$$

Fig. 1 intuitively explains the above definition. To calculate the distance between two data points, we divide the distance between them into R ($R > 0$) pieces and calculate the the dissimilarity $D(\mathbf{u}_i, \mathbf{u}_{i+1})$ between two neighboring points $(\mathbf{u}_i, \mathbf{u}_{i+1})$ in the space of linguistic labels. The overall dissimilarity $D(\mathbf{x}_1, \mathbf{x}_2)$ is the sum of the above R pieces of dissimilarity. Thus the accuracy of the distance measure will be improved with increasing the value of R. As we can easily seen that this measure can be generalized to calculate the dissimilarity between any granular sets or a data point to a granular set. In addition, this distance measure has two important properties:

Theorem 1: The distance defined by Equation 5 is symmetric.

$$D(\mathbf{x}_i, \mathbf{x}_j) = D(\mathbf{x}_j, \mathbf{x}_i) \tag{8}$$

Theorem 2: If given $\mathbf{x}_1 < \mathbf{x}_2 < \mathbf{x}_3$[1], then

$$D(\mathbf{x}_1, \mathbf{x}_3) \geq D(\mathbf{x}_1, \mathbf{x}_2) \tag{9}$$

Theorem 2 demonstrates that this measure has non-negative correlation with the distance of $\mathbf{x}$. Both theorems have been proved in [16].

Above definition tells us the way of calculating distance between two data elements. Now we consider the question of how can we design a measure to calculate the distance between a data element point and an imprecise concept represented by logical expressions of linguistic labels. Given a data point $\mathbf{x}_0$ and a linguistic label set $S \in \mathbb{F}$ that covers a continuous area $\delta(S)$ on the universe Ω, the distance between $\mathbf{x_0}$ and S is defined as follows:

$$D(\mathbf{x}_0, S) = \frac{\int_{\delta(S)} D(\mathbf{x}_0, \mathbf{x}) d\mathbf{x}}{\delta(S)} \tag{10}$$

Furthermore, distance of sets of labels which is used to measure the divergence between them can be defined as follows:

Definition 5 (Distance between sets of labels): Given two sets of labels S_i, $S_j \in \mathbb{F}$ and S_i covering a continuous area $\delta(S_i)$ and S_j covering a continuous area $\delta(S_j)$. Then distance between these two sets is defined as:

$$D(S_i, S_j) = \frac{\int_{\delta(S_i)} \int_{\delta(S_j)} D(\mathbf{x}_i, \mathbf{x}_j) d\mathbf{x}_i d\mathbf{x}_j}{\delta(S_i)\delta(S_j)} \tag{11}$$

where $\mathbf{x}_i \in \delta(S_i), \mathbf{x}_j \in \delta(S_j)$, and when $i = j$:

$$D(S_i, S_j) = D(S_i, S_i) = 0 \tag{12}$$

For the symmetry of the distance between two variables, it is obviously that the distance of sets of labels is also symmetric. As we have discussed in Section II, λ-function provides a way of mapping from logical expressions of labels to random set descriptions of labels. So we also can define the distance between two logical expressions as the following.

Definition 6 (Distance between logical expressions): Given two logical expressions $\theta, \varphi \in LE$, then the distance between θ and φ is

$$D(\theta, \varphi) = \frac{1}{pr} \sum_{i=1}^{r} \sum_{j=1}^{p} D(S_i^{\theta \wedge \neg\varphi}, S_j^{\varphi}) - \frac{1}{qt} \sum_{k=1}^{t} \sum_{l=1}^{q} D(S_k^{\varphi \wedge \neg\theta}, S_l^{\theta}) \tag{13}$$

where p, q, r, t, respectively, represent the cardinality of label set $\mathbb{S}^{\varphi}$, $\mathbb{S}^{\theta}$, $\mathbb{S}^{\theta \wedge \neg\varphi}$, $\mathbb{S}^{\varphi \wedge \neg\theta}$, respectively, where:

$$S_i^{\theta} \in \mathbb{S}^{\theta} = \{S | S \in \lambda(\theta)\}, i = 1, 2, ..., q.$$

$$S_j^{\varphi} \in \mathbb{S}^{\varphi} = \{S | S \in \lambda(\varphi)\}, j = 1, 2, ..., p.$$

$$S_k^{\theta \wedge \neg\varphi} \in \mathbb{S}^{\theta \wedge \neg\varphi} = \{S | S \in \lambda(\theta) \bigcap \overline{\lambda(\varphi)}\}, k = 1, 2, ..., r.$$

$$S_l^{\varphi \wedge \neg\theta} \in \mathbb{S}^{\varphi \wedge \neg\theta} = \{S | S \in \lambda(\varphi) \bigcup \overline{\lambda(\theta)}\}, l = 1, 2, ..., t.$$

When $\mathbb{S}^{\varphi \wedge \neg\theta} = \emptyset$,

$$D(\theta, \varphi) = \frac{1}{pr} \sum_{i=1}^{r} \sum_{j=1}^{p} D(S_i^{\theta \wedge \neg\varphi}, S_j^{\varphi}) \tag{14}$$

[1]if $dim(\mathbf{x}) > 2$, we define: $\mathbf{x}_1 \geq \mathbf{x}_2$ if $d(\mathbf{x}_1, 0) \geq d(\mathbf{x}_2, 0)$, where $d(\cdot)$ is the Euclidean distance.

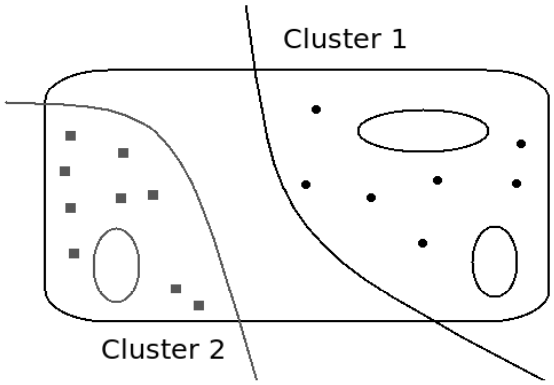

Fig. 2. A schematic illustration of mixed objects clustering. The imprecise concepts are represented by ellipses and data instances are by dots.

When $\mathbb{S}^{\theta\wedge\neg\varphi} = \emptyset$,

$$D(\theta,\varphi) = \frac{1}{qt}\sum_{k=1}^{t}\sum_{l=1}^{q} D(S_k^{\varphi\wedge\neg\theta}, S_l^{\theta}) \tag{15}$$

The above logical expression is one dimensional, which can be used by agents to describe one of the features of the object. If we have a multi-dimensional objects, linguistic rule can be used to described the object such as "x is *big* AND y is *medium* $\wedge$ *large*".

Based on Definition 1, a linguistic rule is a rule that can be represented as a multi-dimensional logical expressions of linguistic labels.

Definition 7: (Multi-dimensional logical expressions of labels) $MLE^{(n)}$ is the set of all multi-dimensional label expressions that can be generated from the logical label expression $LE_j : j = 1, ..., n$ and is defined recursively by

(i) If $\theta \in LE_j$ for $j = 1, ..., n$ then $\theta \in MLE^{(n)}$.

(ii) If $\theta, \varphi \in MLE^{(n)}$ then $\neg\theta, \theta \wedge \varphi, \theta \vee \varphi, \theta \rightarrow \varphi \in MLE^{(n)}$

Similarly we could give the definition of distance between two $MLE^{(n)}$.

Definition 8: (Distance between multi-dimensional logical expressions) Given two n-dimensional logical expressions: Φ, Ψ with

$$\Phi = \theta_{D_1} \wedge \theta_{D_2} \wedge ... \wedge \theta_{D_n}$$

$$\Psi = \varphi_{D_1} \wedge \varphi_{D_2} \wedge ... \wedge \varphi_{D_n}$$

where θ_{D_i}, φ_{D_i} respectively means the logical expressions in dimension D_i. hence, the distance between Φ and Ψ is defined as follows:

$$D(\Phi,\Psi) = \sqrt{\sum_{i=1}^{n} |D(\theta_{D_i}, \varphi_{D_i})|^2} \tag{16}$$

TABLE I
THE DESCRIPTION OF LOGICAL DISTANCE BASED K-MEANS ALGORITHM

Given unlabeled data set DB=$\{\mathbf{obj}_i : i = 1, ..., N\}$ in $\mathbb{R}^d$ and cluster number $K > 0$, counter $p = 0$, $\varepsilon > 0$
Randomly initialize the K centers $\mathbf{c}_1$,..., $\mathbf{c}_K$

While(TRUE): $p++$

Step 1: For each $i \in \{1, ..., N\}$, determine the cluster for all objects in DB: $\mathbf{obj}_i \leftarrow c_j$, if:
$D(\mathbf{obj}_i, \mathbf{c}_j^{(p-1)})$=min$\{D(\mathbf{obj}_i, \mathbf{c}_k^{(p-1)}) : k = 1, ..., K\}$

Step 2: Compute the cluster centers $\mathbf{c}_i^{(p)}$ which satisfy:
$\sum_{\mathbf{obj}_j \in \mathbb{C}_i} D(\mathbf{c}_i^{(p)}, \mathbf{obj}_j)$=min$\{\sum_{\mathbf{obj}_j \in \mathbb{C}_i} D(\mathbf{x}, \mathbf{obj}_j)\}$

Until $|\mathbf{c}^{(p)}$-$\mathbf{c}^{(p-1)}| < \varepsilon$.

IV. CLUSTERING OF MIXED OBJECTS

Based on the above dissimilarity measure, the distance between objects including numerical data, concepts, and linguistic description can be easily measured. Further more, a set of these objects can be grouped into clusters using clustering algorithms.

K-means [8] is one of the simplest unsupervised learning algorithms that solve clustering problem. The procedure follows a simple way to group a given data set to a certain number of clusters. Suppose that we have N sample feature vectors $\langle \mathbf{x}_1, \mathbf{x}_2, ..., \mathbf{x}_N \rangle$ that are all from the same class, and we know that they fall into K ($K < N$) compact clusters, . Let $\mathbf{m}_j$ be the mean of the vectors in cluster j. We can use a minimum-distance to separate them. That is, we can say $\mathbf{x}$ belongs to cluster j if $||\mathbf{x} - \mathbf{m}_j||$ is the minimum of all the K distances. Hence, this algorithm aims at minimizing an objective function J:

$$J = \sum_{j=1}^{K}\sum_{i=1}^{N} ||\mathbf{x}_i^{(j)} - \mathbf{m}_j||^2 \tag{17}$$

Fig. 2 gives a schematic illustration of mixed objects clustering where the ellipses represent some imprecise concepts can could be interpreted into linguistic labels or other granularity. Such mixed objects can be clustered by combining the classical clustering algorithms with our proposed distance measure. Formally, suppose we are given an unlabeled data set $\mathbf{obj}_1, ..., \mathbf{obj}_n$ in which there are numerical data, labels (concepts), and logical expressions (linguistic description). Now we focus on clustering them using K-means algorithm. The algorithm is as same as the classical K-means clustering and the pseudo-code are shown in Table I.

There are two points which are worthy of highlighting. First and the most important, we adopted the new proposed distance metric in last section as the distance measure of these mixed objects. The novel distance definition makes it possible to cluster data and imprecise concepts represented by linguistic labels. Second, in the algorithm implementation, the center of each cluster should be numerical data but not logical expressions.

TABLE II
DISTANCES BETWEEN SETS OF LABELS DEFINED ON H VALUES.

	$\{r\}$	$\{r,o\}$	$\{o\}$	$\{o,y\}$	$\{y\}$
$\{r\}$	0	0.0288	0.0626	0.0950	0.1246

$\{o\}$	0.0626	0.0354	0	0.0336	0.0626
$\{o,y\}$	0.0950	0.0673	0.0336	0	0.0304
$\{y\}$	0.1246	0.0968	0.0626	0.0304	0

TABLE III
DISTANCES BETWEEN EACH TWO LOGICAL EXPRESSIONS θ, φ AND γ DEFINED ON H VALUES.

	$\theta = \neg orange$	$\varphi = red \vee orange$	$\gamma = red$
$\theta = \neg orange$	0	0.1413	0.1735
$\varphi = red \vee orange$	0.1413	0	0.0650
$\gamma = red$	0.1735	0.0650	0

V. EXPERIMENTAL STUDIES

In this section we did two experiments to verify the new proposed measure and the clustering problem. The first experiment is to illustrate the properties of the proposed logical distance measure. The second experiments shows image scene clustering based on a benchmark problem.

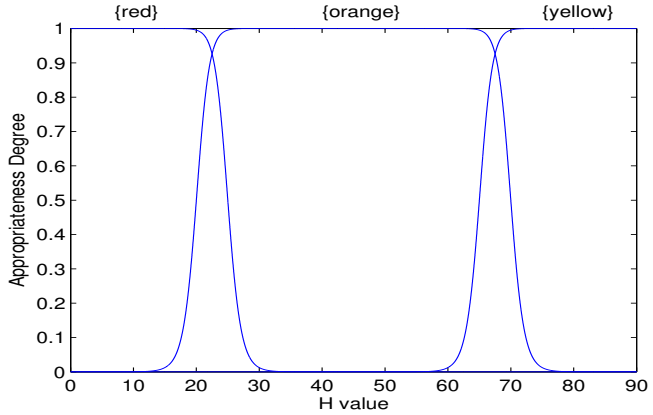

Fig. 3. Three linguistic labels: red (r), orange (o) and yellow (y). They are defined by bell-shape fuzzy sets on the Hue (H) values.

A. Logical Distance

Color of an object is a vague concept and largely depends on the observer's subjective belief. Human eye can distinguish about 10 million different colors but we only use very limited number of words to describe them. There is no general principle for human beings to decide using the most appropriate word such as yellow or red to describe the color of an object. However, people know the difference among these colors, which is difficult to be defined with some specific numerical value. We often make classifications based on these vague and subjective differences among objects. We can use the method proposed in this research to quantize these differences in order to let the agents have the ability to distinguish different objects.

HSV color space can be well visualized by the conical representation model accords with human beings' visual features. Fig. 3 shows three linguistic labels defined on the Hue (H)

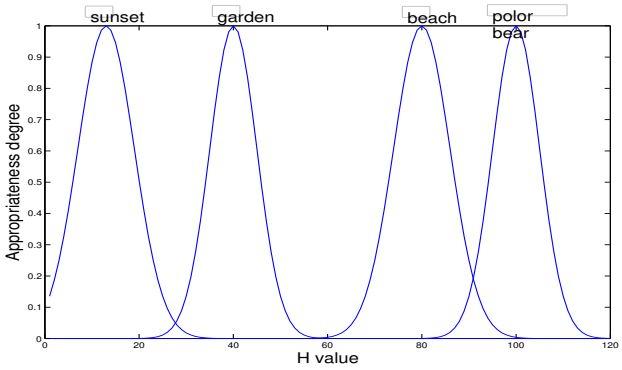

Fig. 4. Four image labels are predefined on the HSV space. This is the mapping of the labels on Hue (H) axis.

value. Based on Definition 3, we can infer that the focal set is:

$$\mathbb{F} = \{\{r\}, \{r,o\}, \{o\}, \{o,y\}, \{y\}\}$$

The distances between these label sets based on Definition 5 is calculated and shown into Table II, from which we can clearly see the symmetric property of this distance measure.

Given the same example above, if there is imprecise concept of the color is not orange, or formally denoted by θ: $\theta = \neg orange$. There are also two other descriptions about the colors φ and γ:

$$\varphi = red \vee orange, \ \gamma = red$$

According to Definition 2, the possible label sets of the given logical expressions θ, γ and φ are calculated as follows:

$$\lambda(\neg o) = \{\{r\}, \{y\}\}, \ \lambda(r) = \{\{r\}, \{r,o\}\}$$
$$\lambda(o) = \{\{r,o\}, \{o\}\, \{o,y\}\}$$

so that

$$\lambda(\theta) = \{\{r\}, \{y\}\}, \ \lambda(\gamma) = \{\{r\}, \{r,o\}\}$$
$$\lambda(\varphi) = \{\{r\}, \{r,o\}, \{o\}\, \{o,y\}\}$$

Then according to Definition 6 and Table II, we could calculate all the distances and fill in Table III. It is illustrated that distances between LEs are symmetric and could reasonably reflect the logical divergences between LEs.

B. Images and Labels Clustering

To show how to use our proposed approach to cluster data and imprecise concept, we built a toy application which can cluster images and image labels which are defined based on image global color feature. One hundred images are evenly picked up from four categories of the Corel image data set [2][7]. And each category has 25 images. We first resize these images into 192×128. We then artificially designed four linguistic labels on color: "$sunset$", "$beach$", "$garden$", and "$polar\ bear$" based on the image content. These labels can be considered as the linguistic descriptors of images which convey the semantic of images. Since the main goal of this

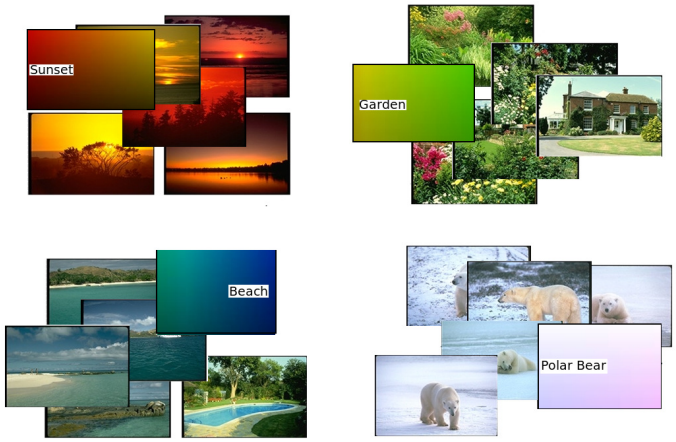

Fig. 5. Sample results of images and linguistic labels clustering. Linguistic labels on color: *sunset, garden, beach* and *polar bear* are areas of color in HSV space. For each cluster, four images and one label (the colored shape on the top of stack of images) are shown.

TABLE IV
PERFORMANCE OF THE IMAGE CLUSTERING.

	sunset	*beach*	*garden*	*polar bear*
Performance	72%	60%	64%	96%

work is to present a new approach to cluster data and vague concepts, we did not use complicated image features like SIFT and LBP.

The only feature we used in this experiment is the global average of HSV color. Fig. 4 shows the mappings of these predefined labels on the Hue (H) axis. The original labels are 3-dimensional granularity in the HSV space. Thus after artificially designing the image labels and extracting image color feature, the data set need to be clustered is with one hundred images and the above four image labels which are represented by granularity on HSV space. The experimental results are shown in Table IV and the code and image set are also open to public at the web address of [18] and [19], respectively. In the future work, such linguistic labels can be used as constraints guide clustering process by using high-level knowledge. It allows us to develop a new human-machine interface by using linguistic labels.

In addition although low-level image features, such as color and texture, are useful information to describe images in this experiment. In practice the features extraction are very important and the clustering algorithms are always only one step of the procedure. High-level image features can convey much more accurate information of the content of the images. In real-world application of image clustering, SIFT, LBP or other complex image features are better choice.

VI. CONCLUSION

In this paper we proposed a novel clustering algorithm by employing a new distance measure based on label semantics. The new algorithm can be used to cluster data and imprecise concepts. The distance defined in linguistic label space differs from the other measures by focusing on the difference of logical meanings the objects convey. It has the ability to measure the linguistic divergence between numerical data and concepts which are presented in the form of linguistic labels. Experimental studies on a toy image clustering problem showed that our approach is an effective to group data and linguistic labels reasonably.

Because the new proposed measure is calculated by considering the accumulated dissimilarities alone the trials connecting to imprecise concepts. It is extendable to measuring distance between any granularities. In the future work, we hope to apply this clustering algorithms to other application areas beside image classification. We will also investigate the advantages and disadvantages of this measure studying other concepts represented by other granularity.

***Abstract*—This paper proposes the practical realization of a fuzzy variable structure control applied to a PWM inverter. Variable structure Control (VSC) is a robust control method for handling nonlinear systems where occur parameter variations and external disturbances. However, control input chattering round sliding surface exists, and may deteriorate the system performance. To reduce the chattering, a fuzzy logic for VSC is applied to overcome the problem. By composing the advantages of both VSC and fuzzy logic (FL), the PWM Inverter system can be designed and produces low total harmonic distortion (THD) output voltage and fast dynamic response under different types of load. Experimental results on a single-phase PWM inverter laboratory prototype controlled by a dSPACE-based DSP controller are presented to illustrate the improved performance, particularly under severe rectifier load. Moreover, for comparison purposes, a conventional variable structure controlled single-phase PWM inverter is also tested on the same experimental system.**

Keywords-Variable structure Control (VSC), chattering, fuzzy logic (FL),total harmonic distortion (THD), PWM Inverter

I. INTRODUCTION

With the increasing demands for high-quality power sources, a pulse-width modulated PWM inverter has been used as a key element for a high-performance power conversion system for critical loads, like data processing systems, telephone switching systems, and life support equipment in hospitals. In that kind of applications it is necessary that the inverter generates by itself the voltage waveform. That kind of inverters, named voltage source inverters, are becoming more and more popular in standalone applications like Microgrids, being able to operate in parallel by using droop method or virtual inertias.

The critical point of these inverters is its performance that generally lies on the following criteria: (1) output voltage waveform with low harmonic distortion (THD) for linear and nonlinear loads; (2) fast transient response for load step changes; and (3) the steady-state error as small as possible. In order to achieve above criteria, proportional-integral (PI) controllers perform reasonably well under constant load conditions. However, the consistent regulation performance is not achieved when the process is subject to fluctuating load disturbances [1], [2], [3]. Also, various control schemes can be found in literature, such as the multi-loop control [4], the deadbeat control [5], the fourier transform (DFT)-based harmonic elimination technique [6], and so on. However, these methods require complex mathematical models or large computation time.

Variable structure control has been recognized as a powerful device capable of exhibiting good robustness, even invariant under certain condition, with respect to system parameter variations and external disturbances [7], [8]. Many VSC applications to PWM inverter systems have been reported. In [9], a control strategy for DC/AC inverter is proposed in which an inverter is controlled by a double-loop regulation scheme. However, the control design uses a typical VSC and cumbersome analog implementation, and thus incurs distorted output voltage during steady-state operation when supplying a nonlinear load. Reference [10] utilizes two sliding control laws to achieve DC/AC converter tracking control. This method has a complicated hardware design and an undesirable chattering phenomenon. In the earlier works of [11] and [12], they adopt conventional VSC for PWM inverters, resulting in problems of chattering and steady-state errors. However, as mentioned above [9-12], owing to the sampling action of digital implementation and delay of switch device, the chattering exists in a VSC system is fearful to control system; In case of these inverter applications, chattering has caused serious voltage harmonics.

FL was developed in 1970s [13], and further developed in inverter applications, since its operation principle does not require precise knowledge of the load parameters, FL controllers have the potential of operating successfully under a wide range of load variation [14], [15]. Thus, in this paper, we will use a simple FL to reduce the chattering effect. By incorporating a VSC with FL, not only the sliding surface is fuzzified by FL, thus reducing the chattering, but also VSC accomplishes the rejection of system uncertainties. This proposed algorithm is then applied to the control of a PWM inverter system in which the control law is realized on a dSPACE DSP and will show the effectiveness of low output voltage distortion, fast dynamic response, and insensitive to load variation even under rectifier loads. Experimental results are finally shown to validate the performance of this proposed controller.

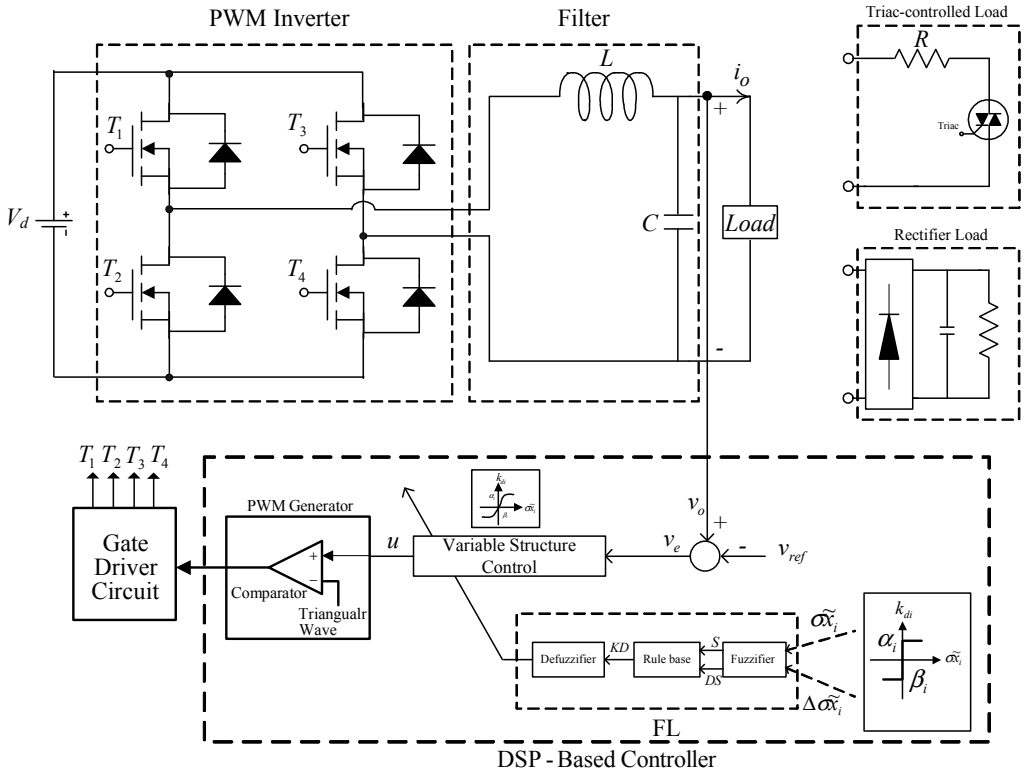

Fig. 1 Block diagram of PWM inverter system.

II. MATHEMATICAL MODELING

The system block diagram of PWM Inverter is shown in Fig. 1 [16]. Let v_o be the load voltage, v_{ref} be the desired sinusoidal waveform, and $v_e = v_o - v_{ref}$ be the voltage error. Assuming that the switching frequency is high enough, PWM inverter can be regarded as a constant gain, K_{pwm}. Choosing $\tilde{x}_1 = v_e$ and $\dot{\tilde{x}}_1 = \tilde{x}_2$, the resulting error dynamic state equation can be derived as

$$\begin{bmatrix} \dot{\tilde{x}}_1 \\ \dot{\tilde{x}}_2 \end{bmatrix} = \underbrace{\begin{bmatrix} 0 & 1 \\ -\frac{1}{LC} & -\frac{1}{RC} \end{bmatrix}}_{A} \begin{bmatrix} \tilde{x}_1 \\ \tilde{x}_2 \end{bmatrix} + \underbrace{\begin{bmatrix} 0 \\ \frac{K_{pwm}}{LC} \end{bmatrix}}_{B} u + \underbrace{\begin{bmatrix} 0 \\ -\frac{1}{LC} v_{ref} - \frac{1}{RC} \dot{v}_{ref} - \ddot{v}_{ref} \end{bmatrix}}_{f} \quad (1)$$

The control objective is to make the output voltage be equal to a reference input. The above system takes the following form

$$\dot{\tilde{x}} = A\tilde{x} + Bu + f \quad (2)$$

where $\tilde{x}$ is the error state vector, u is the control input, A is the system matrix, B is the control matrix, and f is the disturbance.

Then the sliding function is given by

$$\sigma = c_1\tilde{x}_1 + \tilde{x}_2 = c^T\tilde{x} \quad (3)$$

where c is the sliding surface coefficient vector.

The control input u is chosen as

$$u = -K^T\tilde{x} \quad (4)$$

where K is the feedback gain vector.

The dynamics in sliding motion can be written as

$$\dot{\sigma} = 0 \quad (5)$$

Then, for $det(cB) \neq 0$, the equivalent control u_{eq} is derived as follows

$$\dot{\sigma}\big|_{u=u_{eq},\, f=0} = c^T\dot{\tilde{x}} = c^T(A\tilde{x} + Bu_{eq}) = 0 \quad (6)$$

Therefore, the equivalent control can be expressed as

$$u_{eq} = -K_{eq}^T\tilde{x} \quad (7)$$

where K_{eq}^T is the equivalent feedback gain vector.

From (6) and (7), it yields obtains

$$K_{eq}^T = (c^TB)^{-1}c^TA \quad (8)$$

The hitting control law guarantees a system trajectory that moves toward the sliding surface from any initial condition if the following condition occurs:

$$\lim_{\sigma \to 0} \sigma\dot{\sigma} < 0 \quad (9)$$

Let system control u be composed by K_{eq}^T and $K_s^T sign(\sigma\tilde{x})$, that is,

$$u = -K_{eq}^T - K_s^T sign(\sigma\tilde{x}) \quad (10)$$

For two-order system case, K_s^T can be written as

$$K_s^T = \begin{bmatrix} k_{s1} \\ k_{s2} \end{bmatrix} \tag{11}$$

and k_{si}, $i = 1$ to 2 is given by

$$k_{si} = \begin{cases} \alpha_i & if \quad \sigma\tilde{x}_i > 0 \\ 0 & if \quad \sigma\tilde{x}_i = 0 \\ \beta_i & if \quad \sigma\tilde{x}_i < 0 \end{cases} \tag{12}$$

Thus, the condition in (12) is represented to satisfy the inequality (9) and the system state (2) will be transferred on the sliding surface (5). Obviously, (12) uses a sign function and often causes chattering problem in practice. To solve such a problem, fuzzy logic is introduced, and the design is described in detail in Section III.

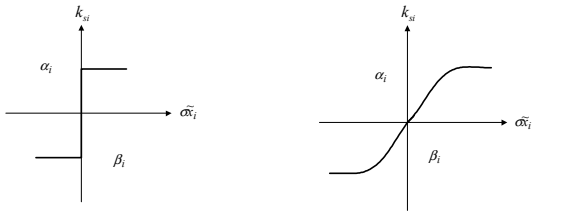
III. Design of Fuzzy Variable Structure Control

FL is a direct method for controlling a system without the need of a mathematical model. FL gets crisp data from various sensors. These data are changed to linguistic or fuzzy membership functions via the fuzzification process. After that, they go through a set of fuzzy "IF-THEN" rules in an inference engine and result in fuzzy outputs. These fuzzy outputs are then changed back to crisp values by the defuzzification.

If the VSC is implemented by means of a digital signal processor (DSP), the switching actions with chattering will occur in (12), which is a crisp version. In other words, the sliding surface is a particular fuzzy case, and its membership function is defined as

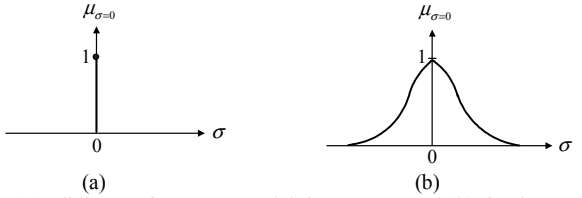
$$\mu_{\sigma=0} = \begin{cases} 1 & , \quad \sigma = 0 \\ 0 & , \quad \text{otherwise} \end{cases} \tag{13}$$

To alleviate the chattering, fuzziness of the sign function and sliding surface are shown as Fig. 2 and Fig. 3, respectively.



(a) (b)

Fig. 2 (a) Switching criteria with the sign function, and (b) fuzziness of the *sign* function.



(a) (b)

Fig. 3 (a) Sliding surface as a special fuzzy case, and (b) fuzziness of the sliding surface.

Then the human experience is fixed as linguistic rules with the help of in the following statements:

IF farther from the sliding surface
THEN larger feedback gain (14)

The design steps are described as follows:

Step 1: To govern system dynamic, define two inputs, $\sigma\tilde{x}_i$ and $\Delta\sigma\tilde{x}_i$ (the change of $\sigma\tilde{x}_i$).

Step2: To determine the system dynamic behavior, we define a crisp sliding surface, $\sigma = c^T\tilde{x}$.

Step3: The fuzzy linguistics and the membership functions of the fuzzy input and output variables S, DS, KD are nominated as shown in Fig. 4.

Step 4: The output of each rule is determined by inference method as follows:

IF S.P and DS.P THEN KD.PB
IF S.P and DS.ZO THEN KD.PM
IF S.P and DS.N THEN KD.PS
IF S.ZO and DS.P THEN KD.PS
IF S.ZO and DS.ZO THEN KD.ZO
IF S.ZO and DS.N THEN KD.NS
IF S.N and DS.P THEN KD.NS
IF S.N and DS.ZO THEN KD.NM
IF S.N and DS.N THEN KD.NB

where

S.P: S is positive
S.ZO: S is zero
S.N: S is negative
DS.P: DS is positive
DS.ZO: DS is zero
DS.N: DS is negative
KD.PB: KD is positive big
KD.PM: KD is positive medium
KD.PS: KD is positive small
KD.NS: KD is negative small
KD.NM: KD is negative medium
KD.NB: KD is negative big

Step 5: Quantification of the crisp input variables $\sigma\tilde{x}_i$ and $\Delta\sigma\tilde{x}_i$ is carried out by multiplying the scaling factors GS and GDS, respectively, i.e., $\sigma\tilde{x}_i \times GS$, and $\Delta\sigma\tilde{x}_i \times GDS$.

$$k_{si} = T(\bullet) \times GKS \tag{15}$$

where $T(\bullet)$ indicates the fuzzy rules, and GKS is the scaling factor of k_{si}.

Step 6: The control input u is written as

$$u = -\sum_{i=1}^{2} (k_{eqi} + k_{di})\tilde{x}_i \tag{16}$$

where k_{eqi} are the elements of equivalent feedback gain, K_{eq}^T.

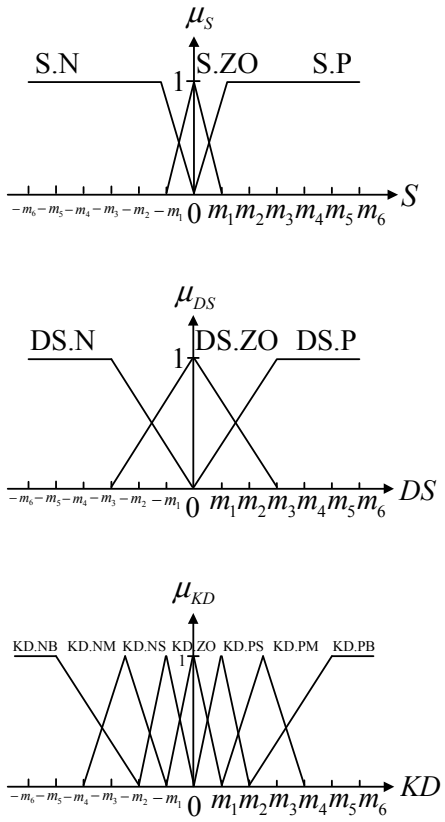


Fig. 4 Fuzzy membership functions of *S*, *DS* and *KD*.

IV. EXPERIMENTAL RESULTS

In order to confirm the effective performance of the PWM inverter, key experiment under rectifier load were done. The controller is validated with a hardware setup. The control algorithms are designed and implemented using MATLAB/Simulink and the codes are then compiled and loaded to a dSPACE DS1102 controller board implement the controller. The system parameters are summarized in Table I.

Table I System parameters

DC-bus Voltage V_d	250V
Output Voltage V_o	$110V_{rms}$
Output Frequency f	60 Hz
Filter Inductor L	2 mH
Filter Capacitor C	30 μF
Switching Frequency f_s	18 kHz
Rated Load R	20 Ω

In order to test the transient performance, the load-step change response is shown in Fig. 5 when the rated load is suddenly connected. We found that the proposed controller exhibits small voltage sag and fast recover time under load-step changes. On the contrary, the waveform shown in Fig. 6 with conventional VSC exhibits worst voltage compensation at the firing angle. The rectifier load consists of a full wave rectified with a parallel resistor, a 55Ω resistance and 100μF filter capacitor. A comparison of the performance by using the proposed controller and the conventional VSC are shown in Fig. 7 and Fig. 8, respectively. Fig. 7 depicts the output voltage waveform which is nearly sinusoidal and has low distortion (%THD of 2.89%), which is under the industrial standard of 5%. Fig. 8 exhibits a noticeable distortion (%THD of 8.15%). Indeed, the chattering is alleviated by the proposed controller, and thus the inverter output voltage can obtain a significant improvement reducing the voltage THD under rectifier-type load condition.

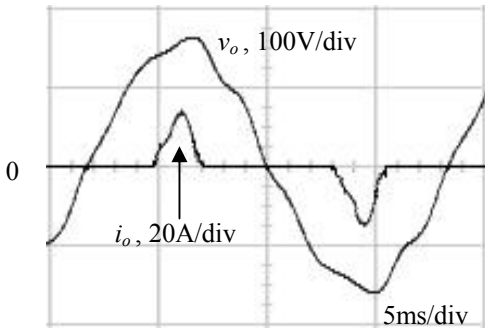

Fig. 8 Voltage and current waveforms when supplying a rectifier load, using conventional VSC

V. CONCLUSIONS

This paper proposes a fuzzy VSC applied to PWM inverter in order to achieve the following features: fast dynamic response, chattering reduction, and low THD output voltage. The proposed controller not only has the merits of the conventional VSC but also reduces the chattering problem by using fuzzy logic. The system's performance has been verified by means of experimental tests on a laboratory inverter prototype, confirming the proposed methodology. Compared to the conventional VSC under the same operating conditions, the proposed controller exhibits better inverter performance.

Abstract—**In this paper, fuzzy logic control systems and real coded quantum inspired evolutionary algorithm (RCQIEA) are integrated for intelligent control. Here, RCQIEAs is utilized as an adaptive method for selection and definition of fuzzy control rules and for tuning the parameters of membership function for each fuzzy control rule in two different ways. The majority of fuzzy logic controllers (FLCs) to date are working based on the expert knowledge base derived from heuristic knowledge of experienced operators. These approaches are difficult and time consuming for experts. Moreover, because manual coded FLCs use expert knowledge, there is no guarantee that the FLCs obtained will have sufficiently good performance, especially for a complex system problem with a large number of input variables. On the contrary, our proposed approach is an automatic knowledge acquisition learning method for generating or adapting FLCs using RCQIEA. In order to check the effectiveness of our proposed approach, it has been applied to solve the truck-and-trailer controller, which is well known test-bed for fuzzy control systems. The fuzzy controller obtained by the proposed approach performs better and effectively realizes the trajectory control of the truck with trailer.**

Keywords-Fuzzy Logic Controller; Fuzzy Rule Base; Real Coded Quantum-Inspired Evolutionary Algorithm; Optimization; Truck-and-Trailer controller

I. INTRODUCTION

Fuzzy rule-based model is used to solve a wide range of problems providing flexible solutions. A fuzzy rule-based model is a set of fuzzy rules and the associated membership functions (MFs) that maps inputs to outputs. Fuzzy rules are either provided by human experts or learned from sample data. Many decision-making and problem-solving tasks are too complex to be understood quantitatively. People however succeed by using knowledge that is imprecise rather than precise. The construction of fuzzy logic controllers (FLCs) based on the appropriate expert knowledge base (KB) can be quick and effective. On the other hand, without such an expert KB the design of FLCs can be slow as it relies on trial and error rather than a guided approach.

To surmount this shortcoming, real coded quantum inspired evolutionary algorithm (RCQIEA) can be considered as a powerful tool to find out efficient fuzzy rule sets [1], and tuning of MFs parameters. These algorithms mimics the natural evolution and provide an effective way for searching a large and complex solution space to give close to optimal solutions in much faster times than random trial-and-error.

For most fuzzy logic control problems, the most important issue is to determine the parameters that define the MFs. Because of this, the MFs optimization problems can be regarded as parameter optimization problems. These parameters are generally based on the expert KB that is derived from heuristic knowledge of experienced control engineers and/or generated automatically. A variety of methods such as genetic algorithms (GAs), neural networks (NNs), self-organizing feature map (SOFM), tabu search (TS), particle swarm optimization (PSO) have been used to improve the behavior of parameter optimization problem as well as selection and definition of fuzzy rules.

GA was used by Belarbi [2] in fuzzy rule base (RB) minimization. Belarbi applied GA to design FLC for the control of the pole and cart system and the control of the concentration in continuously stirred tank reactor. Kim [1] presented a method to find out efficient fuzzy rule sets using quantum inspired evolutionary. They design a fuzzy logic control system for path planning of mobile robot. Meredith [3] also applies GA to the fine tuning of MFs in a FLC for a helicopter. Bagis [4] have presented an approach for the determination of the structure and parameters of fuzzy RB. He applied this approach in the modeling of the nonlinear or complex systems. Bai and Chen [5] proposed an automatic method for a students' evaluation task. The purpose was to automatically construct the grade MFs of lenient-type grades, strick-type grades, and normal-type grades of fuzzy rules. Yang and Bose [6] has presented a method for generating fuzzy MFs with an unsupervised learning using SOFM. The SOFM approach is a two-step procedure; firstly, generate the proper clusters and secondly generate the fuzzy MF according to the clusters in the first step. They applied this method to pattern recognition. Huang [7] has presented a fuzzy knowledge integration technique based on the PSO. Their proposed approach consists of two phases: Firstly, it encodes the fuzzy rule sets and fuzzy sets with its corresponding MFs. Secondly, the particle swarm algorithm is used to explore the fuzzy rule sets, fuzzy sets and MFs to its optimal or the approximately optimal extent. Koga, et. al. [8] has presented a method, the self-organizing relationship (SOR) network with fuzzy inference based evaluation for backing up a truck-and-trailer controller. They use SOR network to establish desired I/O (Rule base) relationship of a target system.

In a classical evolutionary algorithm like GA, information is stored as classical binary (0 or 1) format. So information stored in a classical register represents a single state. But in quantum inspired evolutionary algorithm, smallest unit of information is called Q-bit which may be in '0'state or '1'

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

state or any superposition state of them. Superposition of logical state can be expressed as "$\alpha|0\rangle+\beta|1\rangle$". Another way of writing "superposition" is as a vector:

$$\alpha|0\rangle+\beta|1\rangle \leftrightarrow \begin{pmatrix}\alpha\\ \beta\end{pmatrix}$$

The complex number α and β are called the "amplitudes" of the superposition. $|\alpha_i|^2$ gives the probability that the Q-bit will be found in "0" state and $|\beta_i|^2$ gives the probability that the Q-bit will be found in "1" and they satisfy the normalization condition $|\alpha_i|^2+|\beta_i|^2=1$. A Q-bit individual as a string of m Q-bits is defined as:

$$q=\begin{bmatrix}\alpha_1 & \alpha_2 & \dots & \alpha_m\\ \beta_1 & \beta_2 & \dots & \beta_m\end{bmatrix}$$

where $|\alpha_i|^2+|\beta_i|^2=1$, $i=1, 2, 3\ldots..m$. So a Q-bit individual of m bits can represent 2^m states at a time.

Quantum inspired evolutionary algorithms has a better characteristic of population diversity than others, since it can represent linear superposition of states probabilistically. But higher value of m needs higher computing time of the algorithm. For an optimization problem with fitness function $f(x_1, x_2, \cdots, x_n)$, if we represent each real variable x_i by k bits then the total number of Q-bits in an Q-bit individual $m=k\times n$. So if we apply the evolutionary operators on huge number of bits then they will definitely take a significant amount of time to execute.

In this paper, FLCs and RCQIEA are integrated for the intelligent control of a truck-and-trailer controller problem. RCQIEA is employed as an adaptive method for selection and definition of fuzzy control rules of the FLC as well as shape of MFs. It is found that our proposed integrated architecture is able to generate comprehensible and reliable fuzzy rules with appropriate shape of MFs by a self-learning adaptive method.

The organization of this paper is as follows: In Section II, we review the literature relevant to the FLC. In the third section we explain the problem truck-and-trailler controller in a greater detail. In section IV, we provide the integrated FLCs and RCQIEA architecture and also show how it can be used to solve highly nonlinear complex problems. We also introduce the basic principle of RCQIEAs and discuss how they can be used to generate a satisfactory fuzzy rule base and select appropriate shape of MFs simultaneously for FLCs. Section V presents our simulation results. Finally, section VI provides some concluding remarks and future directions.

II. FUZZY LOGIC CONTROLLER

The idea of fuzzy logic was first introduced in 1960s by Professor Lofti Zadeh [9]. The general configuration of FLC, can be divided into four main parts; fuzzification interface, a rule base, an inference mechanism and defuzzification interface (Fig.1).

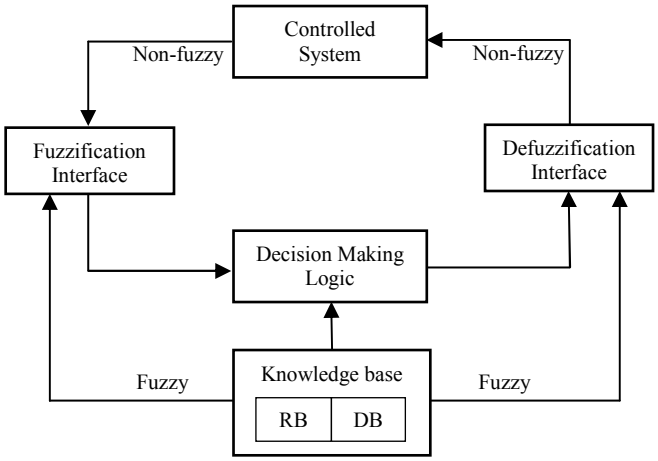

Figure 1. Fuzzy Logic Controller (FLC)

A. Fuzzifier

Fuzzy sets can be defined as μ_A, membership function that associates with each element $x\in X$ where X is the universe of discourse, a number called membership grade $\mu_A(x)\in[0,1]$. The *function* of the *fuzzifier* is to map a crisp input value $x\in X$ into a fuzzified value in $A\in U(universe)$.

B. Fuzzy rule base

The general form of a fuzzy rule used in most FLCs is as follows:

R^k : IF x_1 is F_1^k,....., and x_n is F_n^k, THEN y is G^k.

$l=1, 2, 3,....., M$, M = number of rules in the RB

where $x_1, x_2,....., x_n$, and y are the input and output linguistic variables respectively. F_i^k and G^k are type-1 fuzzy sets in input sets $X\in X_1\times X_2\times X_n$ and output sets *Y*.

B. Fuzzy Inference Engine

A fuzzy relation R^l can be defined as:

$$R^l : X\times Y=\{(\vec{x}, y) : x\in X, y\in Y\}$$

where $\vec{x}$ is a vector of the form $(x_1, x_2, ...x_n)^T$. This relation R^l is the actual process of mapping from fuzzy sets in X to fuzzy sets in Y, $F_1^l\times F_2^l\times....F_n^l\rightarrow G^l$, can be called fuzzy inference process.

C. Modified Height Defuzzifier

The modified height defuzzifer was used to handle the consequent uncertainty [10, 11], The expression generally used for a fuzzy set is as follows:

$$y_{mh}=\frac{\sum_{i=1}^{M} y^k \mu_{B^k}(\bar{y^k})/\delta^{k^2}}{\sum_{i=1}^{M} y^k \mu_{B^k}(\bar{y^k})/\delta^{k^2}}$$

where δ^k is the spread measure of the *kth* consequent set. For gaussian membership function δ^k is the standard deviation whereas triangular membership function δ^k is the length of its base.

III. PROBLEM STATEMENT

A. Model of Backing up a Truck-and-Trailer

The task is to back up a simulated truck-and-trailer to a loading dock in planner parking lot, depicted in Fig. 2. The four state variables ϕ_t, ϕ_c, x and y exactly determine the truck-and-trailer position. The angle ϕ_t specifies the angle of the trailer with the horizontal and ϕ_c is the relative angle of the cab with the trailer. The coordinate pair (x, y) specifies the position of the rear center of the trailer in the plane. The goal is to make the trailer arrive at the loading dock at a right angle $(\phi_t = 90^0)$ and to align the position (x, y) of the trailer with the desired loading dock (x_f, y_f) and the truck is allowed to move backward by some fixed distance *b* at every stage. The loading zone corresponded to the plane $[0,0]\times[100,100]$ and (x_f, y_f) equaled (50, 100). At every stage our proposed approach should produce the output angle β to update the θ and angle ϕ_t of the trailer with horizontal that backs up the trailer to the loading dock from any initial position. The truck-and- trailer only moves backward with fixed distance. The variable ranges were as follows:

$$-100 \le x \le 100$$
$$-90^0 \le \phi_t \le 270^0$$
$$-90^0 \le \phi_c \le 90^0$$
$$-30^0 \le \beta \le 30^0$$

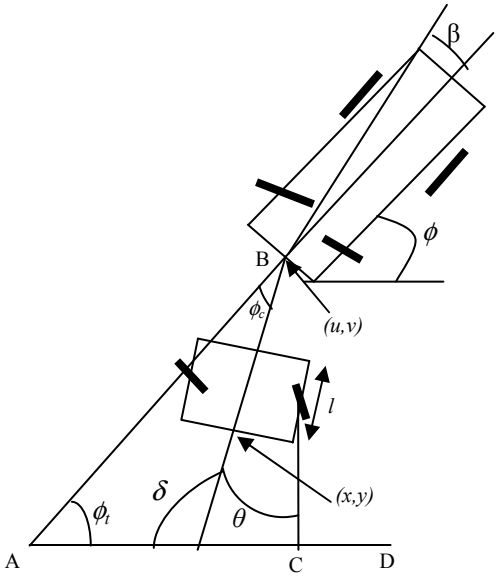

Figure 2. Diagram of truck-and-trailer

The state space of the system is four dimensional. The variable *x* gives the horizontal position of the midpoint of the rear of the trailer and the variable *y* gives the vertical position of the midpoint. Fuzzy variable ϕ_t specified the angle of the trailer with the horizontal. The fuzzy variable ϕ_c specified the relative cab angle with respect to the center line along the trailer. The extreme cab angle 90^0 and -90^0 corresponds to two "jack knife" positions of the cab with respect to the trailer. Positive ϕ_c value indicated that the cab resided on the left-hand side of the trailer. Negative value indicated that is resides on the right hand side and Fig.2 shows a positive angle value of ϕ_c.

The following inputs and outputs are chosen to represent the system and illustrated in Fig.2.

Three Inputs:

- *x,* Cartesian *x*-coordinate of truck rear end.
- ϕ_t, Angle of the trailer with horizontal.
- ϕ_c, Relative angle of the cab with the trailer.

One Output

- β, Angle of the trailer updated at each step.

Fuzzy variable ϕ_t, ϕ_c and x defined the input variables. Fuzzy variable β defined the output variable. The angle that is needed to update the trailer is β. With the output β value computed, the updated angle of the trailer with the horizontal is $\phi_t^/$:

$$\phi_t^/ = \phi_t + \beta \tag{1}$$

The trailer position is (x, y) moved to the new position $(x^/, y^/)$:

$$x^/ = x + r\cos(\phi_t^/)$$
$$y^/ = y + r\sin(\phi_t^/) \tag{2}$$

where *r* denotes a fixed backing distance. Then the joint of the truck and trailer (u, v) moved to the new position $(u^/, v^/)$:

$$u^/ = x^/ - l\cos(\phi_t^/)$$
$$y^/ = y^/ - l\sin(\phi_t^/) \tag{3}$$

Where *l* denotes the trailer length.

Again, the steering angle

$$\theta = \phi_{c,h}^/ - \phi_{c,h}$$
$$\phi_{c,h}^/ = \phi_{c,h} + \theta \tag{4}$$

Where $\phi_{c,h}^/$ denotes the updated cab angle with horizontal and $\phi_{c,h}$ denotes the cab angle with horizontal.

From ΔABC,

$$180^0 = \phi_c + \phi_t + \delta$$
$$\delta = 180^0 - (\phi_c + \phi_t) \quad (5)$$

And from $\angle BCA$ and $\angle$BCD,

$$\angle BCA + \angle \text{BCD} = 180^0$$
$$\delta + \phi_{c,h} = 180^0$$
$$180^0 - (\phi_c + \phi_t) + \phi_{c,h} = 180^0$$
$$\phi_{c,h} = \phi_c + \phi_t \quad (6)$$

Let, $\theta = \frac{\beta}{2}$

From equation (4) and equation (6) the updated relative angle of the cab with the trailer:

$$\phi'_{c,h} = \phi'_c + \phi'_t$$
$$\theta + \phi_{c,h} = \phi'_c + \phi'_t$$
$$\phi'_c = \theta + \phi_{c,h} - \phi'_t$$
$$\phi'_c = -\frac{\beta}{2} + \phi_c + \phi_t - \beta - \phi_t$$
$$\therefore \phi'_c = \phi_c - \frac{3}{2}\beta \quad (7)$$

Then the steering angle value $\theta = \phi'_{c,h} - \phi_{c,h}$ where $\phi_{c,h}$ denotes the cab angle with the horizontal.

IV. Integration Of FLCs And RCQIEA

The first step in designing an integrated FLC and RCQIEA, as shown in Fig.3, is to decide which parts of the KB are subject to be optimized by the RCQIEA. The KB of fuzzy system is made of two components: the parameters of the fuzzy RB, constituted of the collection of fuzzy rules as well as the shape of MFs and MFs type associated with the linguistic labels of each fuzzy control rule. In this case, selection and definition of fuzzy control rules as well as the shape of MFs are adapted using RCQIEA.

In RCQIEA, each Q-bit contains directly a real variable x_i along with two probability amplitudes (α_i, β_i) consisting an allele of real coded triploid chromosome. So each real coded triploid chromosome requires only n Q-bits (alleles) and thus reduces the execution time of the evolutionary operators, hence whole algorithm.

In this paper, *Ri*, a fuzzy rule is similar to the x_i described above. Each *Ri* consists of several real variables and those will need so many Q-bits if we use quantum inspired evolutionary algorithm. To reduce the execution time we use RCQIEA instead of quantum inspired evolutionary algorithm. Moreover, RCQIEA uses discrete crossover operator which expand the search space providing better exploration and exploitation characteristic of the algorithm.

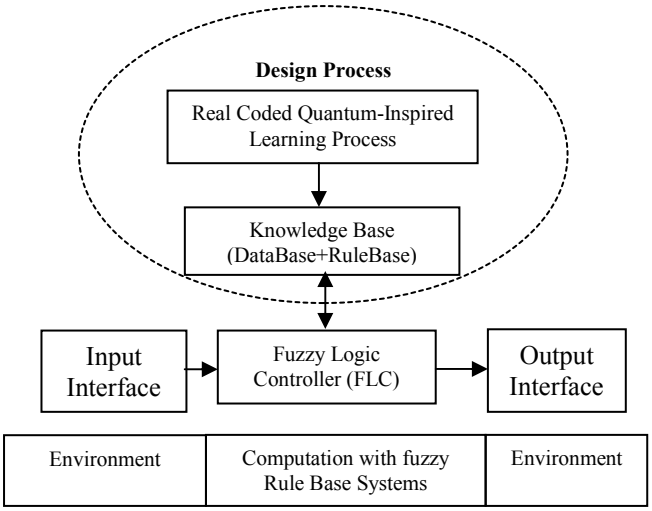

Figure 3. Learning schema of Real Coded Quantum Inspired Evolutionary Algorithm based FLCs

A. Divide the input output variables range

At first identify the variables (inputs, states and outputs) of the problem. Then partition the input and output universe of discourse or the interval spanned by each variable into a number of fuzzy regions (fuzzy sets) and assign a fuzzy MF, i.e., linguistic term of each region. For truck-and-trailer controller divide the state space input x, ϕ_t, and ϕ_c variable space and output β variable space into fuzzy regions and assign a fuzzy MFs of each region. In our running example, we divide the domain for x, ϕ_t, ϕ_c and θ into 5, 7, 3and 7 regions respectively. The linguistic levels for these regions are defined as of Table 1.

TABLE I. DEFINITION OF LINQUISTIC VARIABLE

x	ϕ_t	ϕ_c	β
LE – Left End LC – Left Center CE – Center RC – Right Center RE – Right End	LB – Left Below LU – Left Upper LV – Left Vertical VE – Vertical RV – Right Vertical RB – Right Below RU – Right Upper	NE-Negative ZR -Zero PO -Positive	NL – Negative Large NM – Negative Medium NS – Negative Small ZE – Zero PS – Positive Small PM – Positive Medium PL – Positive Large

B. Encoding Technique

After defining the regions, encode the input and output spaces fuzzy regions into strings (real value) and the fuzzy rule is written a string (real valued) as depicted in Fig.4.

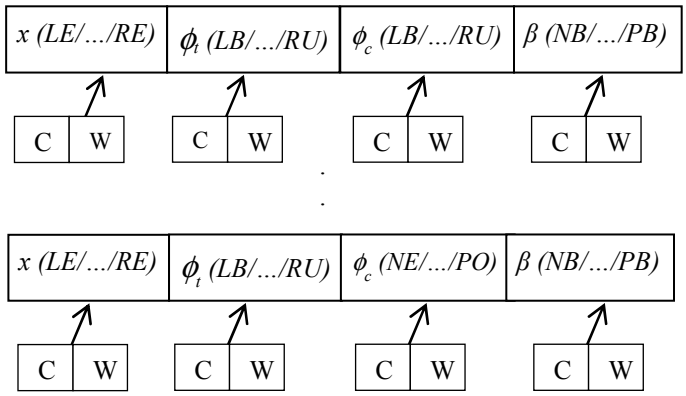

Figure 4. Chromosome structure

C. Real Coded Quantum-Inspired Evolutionary Procedure

The choice of input-output (IO) control signal to be set for each fuzzy rule is made by the RCQIEA. It initializes randomly a population of complete real valued strings. Each of these real values strings is then decoded into fuzzy rules and evaluated by a FLC. Each real valued string's fitness is defined as the error between the state of the system and the target set. RCQIEA procedures, such as selection, crossover and mutation then proceed according to the fitness values produced by the FLC for each real valued-string. The RCQIEA then performs a self-directed search, learning to look for better and better fuzzy rules and optimal MFs parameters. A mechanism for acceptance of a set of fuzzy control rules generated by the RCQIEA is needed. We only accept a set of fuzzy rules with generation ρ , where ρ is a specified number. The overall real coded quantum inspired evolutionary procedure to adapt the FLCs is shown in Fig.5.

D. Representation of RB and MFs in RCQIEA

In this paper, we consider RCQIEA where population consists of real coded triploid chromosomes [12]. Each chromosome of RCQIEA population is defined based on the fuzzy rules. So, the chromosome for this control system can be defined as follows:

$$\begin{pmatrix} R_1 \cdots R_i \cdots R_n \\ \alpha_1 \cdots \alpha_i \cdots \alpha_n \\ \omega_1 \cdots \omega_i \cdots \omega_n \end{pmatrix} \quad (8)$$

where $(R_i\ \alpha_i\ \omega_i)^T$, i =1, 2…. n is the *i-th* allele of real-coded triploid chromosome, R_i is the *i-th* rule in the fuzzy rule base and it is represented using center (c) and width (w) of input and output variables as follows:

C_1W_1	C_2W_2	C_3W_3	C_4W_4
Input x	Input φ_t	Input φ_c	Output β

A pair of probability amplitudes of one Q-bit is $(\alpha_i,\ \omega_i)^T$ which must satisfy the normalization condition $|\alpha_i|^2+|\omega_i|^2=1$. Here, n is the length of real-coded triploid chromosome which is 105 for this fuzzy controller. At each generation t RCQEA maintains a population of real- coded triploid chromosome $P^t=\{p_1^t,\cdots,p_j^t,\cdots,p_N^t\}$, where$p_j^t$ is an individual defined in (8). A rule $R_{j,i}^t$ in p_j^tcontains eight values, center (c) and width (w) for each of four variables ($x, \varphi_c, \varphi_t$and β).

E. Fitness function

An evaluation function is used for evaluating the status of each chromosome or string and consider as an important link between the RCQIEA and the system. The FLCs generates a fitness value for each RB and MFs parameters according to the following evaluation function defined based on the trajectory error:

Trajectory error/fitness =

$$\frac{Length\ of\ truck\ trajectory}{Distance(\ initial\ position,\ \ desired\ final\ position)} \quad (9)$$

F. Mutation

In RCQIEA, evolutionary operators (mutation and crossover) are applied to make change in the population having fuzzy rules which helps to adjust the FLCs to back up the truck-and-trailer more perfectly. Mutation operator is applied to i^{th} allele selected randomly from p_j^t. The fuzzy rule of that allele is updated by using gaussian mutation where centers for the input and output variables are changed as follows:

$$C^{t+1} = C^t + (\ Max - Min)\ N\ (0,\ (\sigma_{j,i}^t)^2) \quad (10)$$

Where Max and Min are respectively upper and lower bound of the regions in which the center C^t lies. The value of

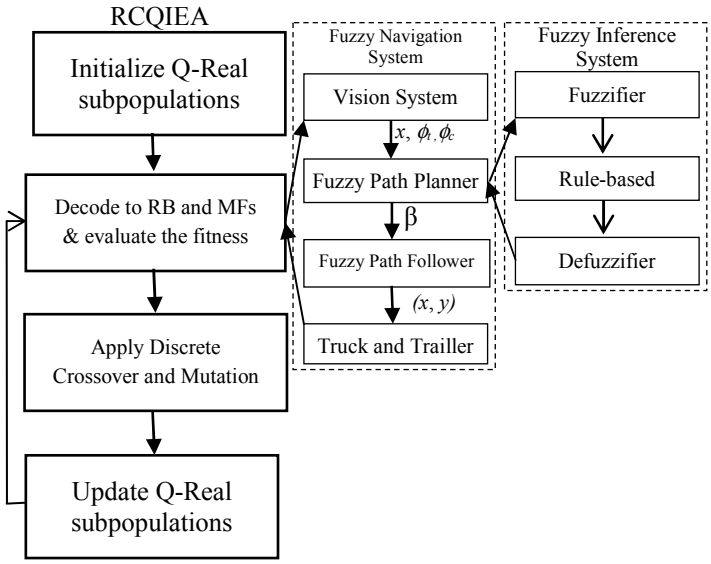

Figure 5. Data flow of proposed RCQIEA with fuzzy navigation system and fuzzy inference system

C^{t+1} may not remain in the region of C^t so it is clipped into that region. The center of β is not kept in a particular region rather its range is considered always the whole range of β. The value of variance $(\sigma_{j,i}^t)^2$ is either $|\alpha_{j,i}^t|^2$ or $|\omega_{j,i}^t|^2/5$ subject to "Fine Search" or "Coarse Search" to be implemented [12]. Now the width (W^{t+1}) of each center is calculated from the new centers of the variables as follows:

$$W^{t+1} = \begin{cases} r * (Max - C^{t+1}) & if C^{t+1} > (Max + Min)/2 \\ r * (C^{t+1} - Min) & Otherwise \end{cases} \quad (11)$$

Where r is the uniformly distributed random number in the range [0, 1]. The pair probability amplitudes of the i^{th} allele is updated by the rotation gate as follows:

$$\begin{pmatrix} \alpha_{j,i}^{t+1} \\ \omega_{j,i}^{t+1} \end{pmatrix} = \begin{pmatrix} \cos(\Delta\Theta_{j,i}^t) & -\sin(\Delta\Theta_{j,i}^t) \\ \sin(\Delta\Theta_{j,i}^t) & \cos(\Delta\Theta_{j,i}^t) \end{pmatrix} \begin{pmatrix} \alpha_{j,i}^t \\ \omega_{j,i}^t \end{pmatrix} \quad (12)$$

where rotation angle $\Delta\Theta_{j,i}^t$ of qubit is calculated as follows,

$$\Delta\Theta_{j,i}^t = sgn(\alpha_{j,i}^t \omega_{j,i}^t)\Theta_0 \exp\left(\frac{|\omega_{j,i}^t|}{|\alpha_{j,i}^t| + \gamma}\right) \quad (13)$$

where Θ_0 is the initial rotation angle, γ is the scale parameter, Θ_0 and γcontrol the value of the rotation angle together and

have an effect on the speed of convergence, the sign *sgn*(.) determines the direction of the rotation angle.

G. Discrete Crossover and Elitism

To backing up the truck-and-trailer with minimized trajectory error (fitness value) the FLCs have to search for the suitable angle of the trailer β with respect to input variables. Discrete Crossover (DC) is used here to expand the search space for the FLC. DC is performed after a fixed number of generations that is after a defined interval τ. Here DC is performed m times for each individual of the population. The process of DC can be explained as follows: First, for individual p_u^t, $u = 1,\cdots,n$, select randomly another individual p_v^t, $v = 1,\cdots,n$, where $u \neq v$. Let p_u^t and p_v^t be considered as parents. Then, every corresponding allele of them is exchanged with a 0.5 probability, and two new individuals (off springs) p_k^t, $k = 1, 2$, are formed. Figure 6 describes DC.

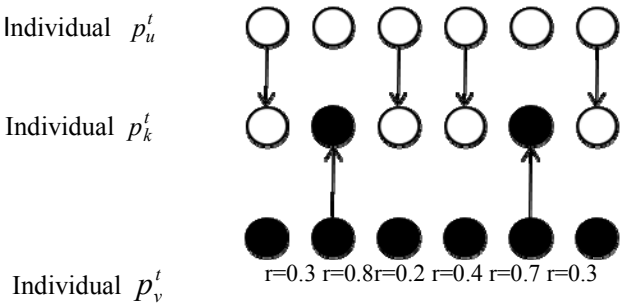

Figure 6. Discrete Crossover

The elitism technique is used to select the individuals with minimized fitness value which also ensure that the rule bases with best fitness value will not be lost.

V. EXPERIMENTAL RESULTS

This section presents the simulation results obtained from the proposed FLC simulating the truck and trailer controller problem. The RCQEA runs for 5 times with generation = 200, population size =10, scale parameter $\gamma = 5$ and initial rotation angle $\Theta_0 = 0.1\pi$. Table 2 shows the simulation parameters of RCQIEA for FLC. Figure 7(a) shows the shape of the membership functions by RCQIEA and 7 (b) shows an example of MF form of fuzzy rule.

An important characteristic of fuzzy models, FM, is the partitioning of the input and output space of system variables (input, output) into fuzzy regions using fuzzy sets [8]. The range of x is divided into five non-uniform intervals [0, 32.5], [32.5, 47.5], [47.5, 52.5], [52.5, 67.5], and [67.5, 100]. The range of ϕ_t is divided into seven non-uniform regions [-90, 0], [0, 66.5], [66.5. 86], [86.5, 94.5], [94.5, 113.5], [113.5, 182.5], [182.5, 270]. For another input ϕ_c, the linguistic variables are NE (Negative), ZR (Zero) and PO (Positive) and the space $-90 \le \phi_c \le 90$ has been divided into three intervals [-90,-12.5], [-12.5, 12.5], [12.5, 90]. Similarly seven divided regions of the range of β [-30, -20], [-20, -7.5], [-7.5, -2.5], [-2.5, 2.5], [2.5, 7.5], [7.5, 20], [20, 30] are represented by variables NL, NM, NS, ZE, PS, PM and PL.

Figure 8. FAM bank of the truck–and-trailler control System

At the beginning of the simulation, the antecedent and consequent part of each rule, i.e., fuzzy associative memories (FAM) cells are empty. To get the antecedent and consequent part of each rule in terms of linguistic language form and shape of MFs from the developed RCQIEA generator block, we start the simulation from twenty initial positions (x_o, y_o, ϕ_{t0} , ϕ_{c0}): (25, 30, 60^0, 30^0), (80, 30, 150^0, and 60^0)..etc. The initial positions are randomly selected and cover the simulated truck-and-trailer loading zone.

For all the given initial positions the RCQIEA converges to some sets of fuzzy IF-THEN rules. During the simulation, we generate twenty sets of values associated to fuzzy rules from twenty different initial positions. After translating the parameter values into sets of rules, these RB are combined together to form the final FAM as shown in Fig.8 using Fuzzy Amalgamation (FA) methodology [13]. The FA method starts with an empty new FAM. Then it compares and combines two FAMs as follows. If the corresponding cells of two FAMs are same then add the cell entries into the corresponding cell of the new FAM. On the other hand, if corresponding cells of two FAMs are different, then an average of the two different entries is computed using the following formula:

$$Numeric - Value(NV) = \frac{1}{n}\sum_{i=1}^{n} N_i$$

where n is the number of combining tables (Here n = 2), N_i is the numeric values (center) of fuzzy rule. Find the linguistic term (fuzzy set) for NV where it has the highest membership value, and return that linguistic term as a result of two different entries into the corresponding cell of the new FAM. There are 105 fuzzy rules (fuzzy RB or FAM can be formed as a 5×(3×7) tables with rows to hold the corresponding actions (outputs) as shown in fig.8.

With the above FAM rules (shown in Fig.8), the fuzzy truck- and-trailler controller produced successful truck–and-trailler trajectories starting form any given initial condition. Figure 9 shows the typical example of fuzzy truck-and-trailler trajectories.

In each generation, all chromosomes are evaluated by the FLC to generate the fitness error. Chromosomes are sorted according to the fitness error and the best one among all chromosomes is selected in each generation. Figure 10 shows a graph of fitness generation by generation.

VI. CONCLUSIONS

In this paper, a new RCQIEA is applied to search for optimal settings of the MFs shapes and gains of the inputs and outputs of FLC for a truck-and-trailer controller problem. The proposed RCQIEA represents a new way of self-learning adaptive FLCs. The simulation results show that it can generate the fuzzy control rules and the MFs in a consequent way automatically without any priori expert knowledge. Moreover the designed adapted fuzzy logic controller effectively realizes the trajectory control of the truck with trailer. The proposed approach may be seen as a step in the development of a better accepting of how to incorporate a fuzzy logic controller with a quantum inspired evolutionary algorithm to achieve asignificant adaptive learning capability.

Suggestions for follow-up works that may come after this paper are as follows: This research work is to be extended for intelligent control of a mobile robot, control of a robotic arm in the presence of moving or fixed obstacle, the path planning problem for multiple mobile robots with more than one obstacle either moving or fixed in the workspace. Moreover, this work also to be extended in the analysis of the behavior of the cooperative real coded quantum inspired evolutionary learning proposal with high dimensional problems, where it might be necessary to include a variable feature selection component into the learning approach.

***Abstract*—This paper proposes a hybrid particle swarm optimization algorithm for solving Job Shop Scheduling Problems (JSSP) to minimize the maximum makespan. A new hybrid heuristic, based on Particle Swarm Optimization (PSO), Tabu Search (TS) and Simulated Annealing (SA), is presented. PSO combines local search (by self-experience) with global search (by neighboring experience), achieving a high search efficiency. TS uses a memory function to avoid being trapped at a local minimum, and has emerged as an effective algorithmic approach for the JSSP. This method can also be referred to as calculation of the horizontal direction. SA employs certain probability to avoid becoming trapped in a local optimum and the search process can be controlled by the cooling schedule (also known as calculation of vertical direction). By reasonably combining these three different search algorithms, we develop a robust, fast and simply implemented hybrid optimization algorithm HPTS (Hybrid of Particle swarm optimization, Tabu search and Simulated annealing). This hybrid algorithm is applied to the standard benchmark sets and compared with other approaches. The experimental results show that the proposed algorithm could obtain the high-quality solutions within relatively short computation time. For 6 of 43 instances, new upper bounds among the unsolved problems are found in a short time in HPTS.**

***Index Terms*—Job Shop Scheduling Problem, Particle Swarm Optimization, Tabu Search.**

I. Introduction

The Job Shop Scheduling Problem (JSSP) is one of the existing combinatorial optimization problems and it has been demonstrated to be an NP-hard problem [1]. In JSSP, each one of n jobs ($n \geq 1$) must be processed passing through m machines ($m \geq 1$) in a given sequence. The sequence of m machines is different for each different job and cannot be changed during the processing. When one job was processed on a machine, it can be considered as one operations, each job j needs a combination of m operations to complete the work. One operation is processed on one of m machines, and just only one operation can be processed at a time. Any job cannot interrupt the machine that is processing one operation of another job. Each machine can process at most one operation at the same time. The main objective of the JSSP is to find a schedule of operations that can minimize the maximum completion (called makespan) that is the completed time of carrying out total operations in the schedule for n jobs and m machines [2].

JSSP can be applied to the manufacture processing and actually effects the production time and the cost of production for a plant. During the past few decades, JSSP has attracted many researchers to develop algorithms. Because JSSP is an NP-hard problem, it is difficult to develop a perfect algorithm to find a solution with a reasonable time especially for higher dimensions. Recently, many researchers made use of evolution algorithm to solve the problem. such as shifting bottleneck approach (SB) [3], tabu search algorithm(TS) [4], genetic algorithm(GA) [5], simulated annealing(SA) [6], particle swarm optimization(PSO) [7], and ant colony(ACO) [8]. Most studies indicate that a single technique can not solve this stubborn problem. Much work has been done on hybrid methods involving GA,SA,TS,and SB techniques as hybrid methods can provide high-quality solution within reasonable computing time, such as Goncalves' HGA [5], Tsung-Lieh Lin's MPSO [2], Wei-Jun Xia's HPSO [9], Fevrier Valdez's PSO+GA [10] [11]. A comprehensive survey of scheduling techniques can be seen from Blazevicz et al. and Jain and Meeran. In addition, many research results of the JSSP show that it is very difficult to obtain a good-enough solution only by single search scheme. Motivated by these perspectives, we propose an efficient hybrid intelligent algorithm for the JSSP based on PSO, TS and SA. PSO, TS and SA are evolution computation techniques. They exhibit implicit parallelism and contain certain redundancy and

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

historical information of past solutions. Moreover, TS and SA also have better local search features. Therefore, the proposed hybrid particle swarm optimization algorithm also effectively exploits the capabilities of distributed and parallel computing of swarm intelligence approaches to achieve the better solution for JSSP.

In this paper, we present an efficient hybrid particle swarm optimization for the Job Shop Scheduling Problem. The remainder of the paper is organized as follows. In Section II, we present the different classes of schedules. In section III, we discusses and analyzes our approach to solve the JSSP. Section IV gives experimental results of the HPTS algorithm and other competitive approaches. Finally, the main conclusions are drawn.

II. Problem Formulation

A. Job Shop Scheduling Problem

The JSSP consists of n jobs and m machines. Each job must go through m machines to complete its work. We consider one job consists of m operations. Each operation uses one of m machines to complete one job's work for a fixed time interval. Once one operation is processed on a given machine, it cannot be interrupted before it finishes the job's work. The sequence of operations of one job should be predefined and maybe different for any job. In general, one job being processed on one machine is considered as one operation as noted above, then every job has a sequence of m operations. Each machine can process only one operation during the time interval. The objective of JSSP is to find an appropriate operation permutation for all jobs that can minimize the makespan C_{max}, i.e., the maximum completion time of the final operation in the schedule of $n \times m$ operations.

Let $J = 0, 1, ..., n, n+1$ denote the set of operations to be scheduled and $M = 0, 1, ..., m, m+1$ the set of machines. The operations 0 and $n+1$ are dummy, have no duration and represent the initial and final operations. The operations are interrelated by two kinds of constraints. Firstly, the precedence constraints, which force each operation j to b scheduled after all predecessor operations, P_i, are completed. Secondly, operation j can only be scheduled if the machine it requires is idle. Further, let dj denote the fixed duration (processing time) of operation j.

Let F_j represent the finish time of operation j. A schedule can be represented by a vector of finish times $(F_1, ...F_m, F_{m+1})$. Let $A(t)$ be the set of operations being processed at time t, and let r_{jm} = 1 if operation j requires machine m to be processed and r_{jm} = 0 otherwise.

The conceptual model of the JSSP can be described in the following way [5]:

$$Minimize F_{n+1}(C_{max}) \tag{1}$$

$$F_k \leq F_j - d_j, j = 1, ...n+1, k \in P_j \tag{2}$$

$$\sum_{j \in A(t)} r_{jm} \leq 1, m \in M, t \geq 0 \tag{3}$$

$$F_j \geq 0, j = 1, ...n+1 \tag{4}$$

The objective of Eq.1 minimizes the finish time of operation $n+1$ (the last operation), and therefore minimizes the makespan. Constraints in Eq.2 impose the precedence relations between operations and constraints in Eq.3 state that one machine can only process one operation at a time. Finally Eq.4 forces the finish times to be nonnegative.

B. Particle Swarm Optimization

Particle Swarm Optimization (PSO) algorithm is introduced by Kennedy and Eberhart [12] [13] based on the social behavior metaphor. In PSO, a group of particles, without quality and volume, fly through a D-dimensional space, adjusting their positions in search space according to their own experience and their neighbors. Although approximation methods do not guarantee achieving optimal solutions, they are able to attain near-optimal solutions. Therefore, approximation methods are more suitable for larger problems. The particle swarm concept was based on the premise of social behavior. The original intent was to graphically simulate the graceful but unpredictable choreography of a bird flock. A PSO algorithm mimics the behavior of flying birds and their means of information exchange to solve optimization problems. PSO has been introduced as an optimization technique in real-number spaces. But many optimization problems are set in a space featuring discrete components. Typical examples include problems that require ordering and route planning, such as in scheduling and routing problems [14]. They are described as follows [15]:

$$\begin{aligned} V_{id} &= \omega \times V_{id} + C_1 \times \mathrm{Rand}() \times \left(\mathrm{P}_{\mathrm{id}}^{\mathrm{best}} - \mathrm{P}_{\mathrm{id}}\right) \\ &+ C_2 \times \mathrm{Rand}() \times \left(\mathrm{P}_{\mathrm{gid}}^{\mathrm{best}} - \mathrm{P}_{\mathrm{id}}\right) \end{aligned} \tag{5}$$

$$P_{id} = P_{id} + V_{id} \tag{6}$$

where V_{id} represents the velocity of particle i. It also can be regarded as the distance to be traveled by particle i from its current position. P_{id} represents the particle position, P_{id}^{best} called "pbest", the local best solution, represents particle i's best previous position, and P_{gid}^{best} called "gbest", the global best solution, represents the best position among all particles in the swarm. ω is an inertia weight. It regulates the trade-off between the global exploration and local exploitation abilities of the swarm. The acceleration constants C_1 and C_2 represent the weights of the stochastic acceleration terms that pull each particle toward "pbest" and "gbest" positions. $\mathrm{Rand}()$ is a random function with range $[0, 1]$.

For Eq.5, the first part represents the inertia of previous velocity; the second part is the "cognition" part, which represents individuals thinking independently; and the third part is the "social" part, which represents cooperation among the particles [16].

III. The Proposed algorithm for JSSP

A. Implementation of Hybrid Particle Swarm Optimization

Some issues are in applying PSO algorithm to solve scheduling problems. The original PSO design is developed

to solve continuous function. The PSO algorithm is problem-independent, which means little specific knowledge relevent to a given problem is required. All we have to know is the fitness evaluation of each solution. This advantage makes PSO more robust than many other search algorithms. However, since PSO is a stochastic search algorithm, it is prone to inadequate global search at the end of a run. PSO may fail to find the required optimum in cases when the problem to be solved is too complicated and complex. SA employs certain probability to avoid becoming trapped in a local optimum, and the search process can be controlled by the cooling schedule. by designing the neighborhood structure and cooling schedule of TS and SA, we can control the search process and avoid individuals being trapped in local optimum more efficiently. Therefore, a hybrid algorithm of PSO, TS and SA, named HPTS, is presented in Figure 1.

1) Encoding scheme and initial solution: Suppose that the searching space is D-dimensional and m particles form the swarm. The ith particle represents a D-dimensional vector X_i (i = 1, 2,..., m). It means that the ith particle locates at X_i = (x_{i1}, x_{i2},..., x_{iD}) (i = 1, 2,..., m). The position of each particle is a potential result. We could calculate the particle's fitness by putting its position into a designated objective function. The ith particle "flying" velocity is also a D-dimensional vector, denoted as V_i = (v_{i1}, v_{i2},..., v_{iD}) (i = 1, 2,..., m). Denote the best position of the ith particle as P_i = (p_{i1}, p_{i2},..., p_{iD}), and the best position of the swarm as G_i = (g_{i1}, g_{i2},..., g_{iD}), respectively.

2) The neighborhood search: The neighborhood search strategy is directly effective on the efficiency of the local search for the JSSP, and unnecessary and infeasible moves must be eliminated if it is possible. Currently, the most well-known neighborhood structures are all based on the concept of blocks. In the HTPS algorithm, taking into account a balance of the effectiveness and efficiency, we ultimately adopt $N6$[1] neighborhood structure, which is introduced by Balas and Vazacopoulos [17].

3) Tabu list: The main task is to avoid the search process turning back to the solutions visited in the previous steps. The elements stored in the tabu list are the attributes of moves, rather than the attributes of solutions for the considered problem. The main purpose of using this attributive representation is to reduce the computational cost. In HPTS, the size of the list is set the same as the swarm size. During the algorithm running, the tabu list will be updated dynamically.

4) Fitness function: Fitness function is usually used as the performance evaluation of particles in the swarm, which is represented to map an original objective function value to a fitness function that represents relative superiority of particles. In HPTS, each particle's fitness function is expressed by the makespan of the corresponding schedule.

5) Cooling schedule: The SA process can be controlled by the cooling schedule. In general, the cooling schedule is specified by several parameters and/or methods, namely the initial temperature T_0, the rule designated how to lower the temperature, and the termination condition. In proposed algorithm, the initial temperature T_0 is set by $T_0 = \Delta\ f_{max}$, where $\Delta\ f_{max}$ is the maximal difference in fitness values between any two neighboring solutions. We specify the temperature with T_k = $B \times T_{k-1}$ during the kth epoch (k = 1,2,3,...), where B is a parameter called decreasing rate and has a value less than 1.

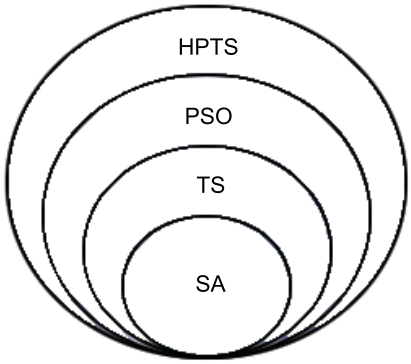

Fig. 1. The structure of HPTS.

6) Termination criterion: If one of the following conditions is satisfied: whether the algorithm stops when the algorithm has performed a given total number of iterations, or the elite solution stack has been exhausted, or the solution is proved to be optimal.

B. The Process of Proposed Algorithm

In the HPTS, three different operations are defined: PSO operation, TS operation and SA operation. PSO combines local search (by self-experience) with global search (by neighboring experience), achieving a high search efficiency. TS uses a memory function to avoid being trapped at a local minimum. It has emerged as an effective algorithmic approach for the JSSP. This method can also be referred to as calculation of the horizontal direction. SA employs certain probability to avoid being trapped in a local optimum and the search process can be controlled by the cooling schedule (also known as calculation of vertical direction). The groups use a random initialization, which generates initial particle's initial position and velocity in the search space. Each particle's best position is set to the current location. The current position of the corresponding fitness value is calculated for each particle, according to the evolutionary structure. The hybrid HPTS framework can be converted to the traditional PSO that provides initial solution for TS and SA during the hybrid search process. Such hybrid HPTS strategy retains the advantages of TS and SA, which provides a promising methodology to solve JSSP. In addition, HPTS can be applied to many combinatorial optimization problems by simple modification. The description of HPTS is shown in algorithm 1 and algorithm 2. The process of implementing the framework is as follows:

$Step$ 1: Initialize a swarm of particles with random position and velocities in the D-dimensional problem space.

$Step$ 2: For each particle, evaluate the desired optimization fitness function.

Step 3: Individual particle's fitness value are with D-dimensional problem space. If the current value is better than , then set the position equal to the current value, and the position equal to the current position in the D-dimensional problem space.

Step 4: Compare the fitness evaluation value with the swarm's best fitness value obtained so far. If current value is better than , then reset to the current particle's fitness value.

Step 5: Change the velocity and position of the particle according to Eq.5 and Eq.6, respectively.

Step 6: Loop to step (2) until a termination criterion is met, usually a sufficiently good fitness or a specified number of generations.

Algorithm 1 PSO

1: **while** the maximum of generation is not met **do**
2: Generation++;
3: Generate next swarm;
4: Find a new local optimum ($gbest$) and a global optimum ($pbest$);
5: Update $gbest$ and $pbest$;
6: **end while**

Algorithm 2 TS (SA)

1: Set iteration $iter$ = $iter$ + 1, generate neighbors of the current solution $s*$ by a neighborhood structure. If the $s*$ is optimal, then stop;
2: Select the best neighbor which is not tabu or satisfies the aspiration criterion, and store it as the new current solution $s*$, update the tabu list;
3: **for** $gbest$ particle s of swarm **do**
4: Tempreture T_k = T_0;
5: **while** $T_k \geq T_{end}$ **do**
6: Generate a neiborhood solution $s*$ from s by pair-exchange method;
7: Compute the fitness of $s*$;
8: Evaluate $s*$, Δ = f(s*)-f(s);
9: **if** min[1,exp(-Δ/T_k)] $<$ random[0,1] **then**
10: Accept $s*$;
11: Update the best solution found so far if possible;
12: **end if**
13: **end while**
14: T_k= B * T_{k-1} (weight value parameters are included in B);
15: **end for**
16: If $iter \leq improveiter$ then go to loop;
17: If a termination criterion is satisfied then stop. Otherwise 'pop' a solution on top of the solution stack L, shift the solution to active schedule and install the active solution as the current solution s*, set $iter$ = 0, and empty tabu list. Go to step 2;

IV. EXPERIMENTAL RESULTS

To illustrate the effectiveness of the HPTS algorithm for JSSP to minimize the makespan, 43 instances taken from OR-Library [18] as test benchmarks to test our new proposed algorithm. In the 43 instances, FT06, FT10, and FT20 were designed by Fisher and Thompson [19]. Instances LA01-LA40 that were designed by Lawerence [20].

The proposed approach was coded in MATLAB programming language and run on a 2.27 GHz Intel(R) Core(TM)2 Duo CPU, RAM 4GB personal computer. Each instance is executed for 10 runs. The algorithm ran with the settings of the control parameters which can be shown in Tabel I. The proper

values of these parameters were experimentally determined in a pre-processing phase. Specifically, the performance of the proposed HPTS was compared against that of Goncalves' HGA [5], Tsung-Lieh Lin's MPSO [2], Wei-Jun Xia's HPSO [9].

Due to the stochastic behavior of these algorithms, and the fact that none of them has a natural termination point, it was decided to run the algorithms for the same fix time duration and report the best solution obtained after this time has elapsed. The benchmarks range from small size instances with 6 jobs and 6 machines to large size instances with 30 jobs and 10 machines.

In Tabel II, $Problem$ denotes the JSSP problems, $Size$ represents the Problem size n jobs on m machines. BKS represents the well-known optimal solutions in the benchmark. Among 43 instaces, HPTS can find the well-known optimal solutions with 40 instances that is much better than HGA (33), MPSO (36), and HPSO (35). Moreover, in about 93 % of the instances, and the deviation of the minimum found makespan from the well-known optimal solutions is only on average 0.4 %. The proposed algorithm yields a significant improvement in solution quality with respect to almost all the other algorithms, except for the HGA, MPSO and HPSO approaches that has a better performance in the LA29, LA36, LA37, LA38, LA40 instances mainly. For instances LA24, LA25, LA27, LA28, LA29, LA36, LA37, LA38, LA39, LA40, the deviation between the best minimum founded solution and the best known solution are all less than the deviation results of HGA. HPTS can obtain better solution for instances LA24, LA27, LA29, LA36, LA37, LA38, LA40 than MPSO. Except for LA29, HPTS also can obtain better solution (LA24, LA36, LA37, LA38, LA39, LA46) than HPSO.

Obviously, the experimental results show that HPTS is more efficient than other existing discrete particle swarm optimization and genetic algorithms, respectively. The superior results also indicate the successful incorporation of the improved PSO, TS and SA, which facilitates the escape from local minimum points and increases the possibility of finding a better solution. Therefore, the computational results show that the proposed algorithm could obtain the high-quality solutions within relatively short computation time. So, it is a robust, fast and simply hybrid optimization algorithm.

V. Conclusion

Although there are many literatures on classical PSO, the PSO for JSSP does not have rich literatures. In this paper, a new hybrid heuristic HPTS, based on Particle Swarm Optimization (PSO), Tabu Search (TS) and Simulated Annealing (SA), is presented. We have applied the HPTS algorithm to JSSP in minimizing makespan. The experimental results show the effectiveness of the proposed approach. Moreover, our HPTS algorithm outperforms HGA, MPSO, and HPSO algorithms in some solution quality thoroughly. For 6 of 43 instances, new upper bounds among the unsolved problems are found in a short time in HPTS. It can achieve the optimal value in the search space quickly with smaller population size, making use of its better local searching ability to get the final optimal solution at the end of evolution.

In addition, we have proposed a new algorithm structure: three-tier structure of hybrid algorithm, which brings the new research direction and inspiration for the hybrid algorithm. To improve the algorithm performance, we plan to apply parallel and distributed computing to the HPTS algorithm.

***Abstract*—This paper addresses the inherent unreliability and instability of the multiple uncertain characteristics of complex embedded multiprocessor systems, such as MPSoC (multi-processor system on chip) systems. In this work, we propose a fuzzy sets description for the multiple uncertain characteristics of system, and using fuzzy set membership calculation to determine the scheduling priorities of tasks and resources, in order to improve the capability of concurrent executions of tasks. And also we present a method estimation of comprehensive analysis on the multiple performances in order to increase utilization factor and balancing loads on processors. Through simulation, we demonstrate that the fuzzy dynamic scheduling algorithm can handle wide variety requirements of multiple performances, and we also show an improved approach to solve its demerit of partial adjustment. We implemented a prototype MPSoC system, which utilizes the proposed fuzzy dynamic scheduling algorithm to allocating tasks onto the multiprocessors. And in our case studies, we design a parallel architecture h.264 encoder, running on a multicore MPSoC system on FPGA. The speedup ratio of this prototype application system is up to 12.69.**

Keywords-MPSoC System; Dynamic Scheduling; Multi-characteristics; Priority Level; Fuzzy Set; Video Processing; Parallel Processing

I. INTRODUCTION

With the rapid improvement of microprocessor technology, MPSoC system, featured as high in performance, extensible, small in size and low in power consumption, is able to meet requirements of complex embedded systems for computing performance, power consumption and cost, thus having become one of the mainstream development trends of embedded systems [1], [2]. Currently, MPSoC is widely used in computer communication, digital media, auto electronics, medical electronics, aviation and aerospace, industrial control and many other fields, and the relevance of research topics on MPSoC has engaged many enterprises and institutes in research on MPSoC, such as programming model, task scheduling, system development, debugging environment and system safety; among these, real-time dynamic scheduling has become an important topic [3], [4].

While scheduling of multicore processor is NP-Hard [5], there is no optimal polynomial-time algorithm. Meanwhile, realization of a scheduler applicable to systems of different structures and application fields becomes a new challenge. Researchers apply heuristic search to find a partial optimal scheduling solution for this system [16], [17], [18], [19]. Priority scheduling algorithms are most commonly used. Scheduling algorithms based on task priority mainly include RM, EDF, LSF [6], [7], [8], [9], and some complex fix-priority policies such as the policy of integrated priority [10], [11]. And the myopic [12], [13], thrift [14], group-proper [15] algorithms analyzed in this paper are integrated priority.

However, the above algorithms are dependent on prior characteristic values of the system and loads, and can only provide performance guarantee in a predictable environment when all constraints of system and tasks are known accurately. In actual applications however, characteristics of many tasks are always uncertain and fuzzy. Furthermore, execution performance of computing and control algorithms, real-time operating system, scheduling and network delay may cause delays and errors, and system overload or failures may also lead to uncertain changes in the system. And also some characteristics of tasks are time-varying, such as the laxity time of tasks, the executed ratio of tasks and the remaining ratio of tasks. These characteristics can't be calculated completely accurately, so they can be considered as fuzzy and uncertain random variables. Further, the key features of tasks are relative, and it is not suitable to use a certain value describing the criticality of tasks distinguishingly.

Hence some researchers have proposed to utilize the fuzzy theory for dynamic scheduling, fuzzy sets for description of uncertainties and priority levels of different tasks, and the rules of fuzzy sets for determination of priority levels. Some fuzzy dynamic scheduling algorithms [16], [17] and some fuzzy model [18], [19] for representation of fuzzy constraint rules, but most description functions in these papers are certain, it is inflexible to use certain functions for description of time-varying uncertain characteristics; in addition, all the above methods give no consideration to other characteristics such as key features of tasks, resource factor or limited priority levels, and more system performances. They just only focus on a certain feature or a certain performance of system scheduling, that is unable to meet diversified requirements of a system, such as success ratio of scheduling, schedule time length etc.

This work was supported by the China National Natural Science Foundation under Grant 60773186, and the High-level Personnel Training Project of Beijing University of Technology.

The main goal of this paper is to establish fuzzy model of complex MPSoC system, and apply proper scheduling policy to meet composite requirements for multiple performances. In order to do that, we propose a new real-time fuzzy scheduling algorithm for MPSoC, multi-characteristics fuzzy dynamic scheduling (Multi-Fuzzy algorithm), It uses language fuzzy sets for modeling various characteristics of tasks and system, and calculates the target priority functions of tasks and resources based on the membership rules of these fuzzy sets, and this paper further proposes the solution for partial adjustment.

The rest of this paper is organized as follows: section II Introduces our models, definitions and computation methods of algorithm, section III discusses the multi-characteristics fuzzy dynamic scheduling algorithm. In section IV a case study and simulation results are presented and discussed. Finally, section V summarizes the work.

II. CONCEPTS, DEFINITIONS, METHODS

A. System and Task Model

Provided a real-time MPSoC system S has m processors (m>1), r resources (r>1) and n tasks in a task set (n>>1), this system can be described as below:

$$S = \{P_m, R_r\} \mid T_n \mid H$$

Definitions of the key parameters are summarized in Table I.

TABLE I. SYMBOLS AND DEFINITIONS IN ALGORITHM

symbol	definition
$t_{a\tau}$	Task arriving time
$t_{d\tau}$	Task deadline
$t_{e\tau}$	Task executing time
$ret(\tau)$	The remaining executing time of task τ
$ts(\tau)$	The laxity time of task τ , $ts(\tau) = td\tau - t - ret(\tau)$;
wt_1, wt_2	The weights in time factor for tasks
EAT	The earliest available time
ft	Factor time, $ft = [t_{d\tau} + wt_1 \times EAT(\tau) + wt_2 * ts(\tau)] / t_{e\tau}$
fp	Factor parallel level $fp = \min(tk_{R1}(\tau), ..., tk_{Rn}(\tau))$
fc	Factor parallel level $fc = fc_0 + t_{e\tau} - ret(\tau)$
wp	The weights in processors priority
$U_P(p)$	The utilization ratio of processors
$EAT_P(p)$	The earliest available time of processors

In system resource R_k has r_k access tokens tk (maximum number of shared access), tokens are independent and each enables a shared access. The available resource state can be signed as

$$\{tk_1^{Rk}(EAT_1^{Rk}), \ldots, tk_{r_k}^{Rk}(EAT_{r_k}^{Rk})\}$$

Each of the r_k access tokens has a time label EAT^{Rk}..it means this token's earliest available time. And setting EAT_{Rk_s} , EAT_{Rk_e} denote the EAT of resource R_k in shared mode and exclusive mode, then

$$\begin{aligned} EAT_{Rk_s} &= \min(EAT_j^{Rk}), \\ EAT_{Rk_e} &= \max(EAT_j^{Rk}), \\ 0 &< j \le r_k \end{aligned} \quad (1)$$

So, the EAT f source for task τ s denoted as:

$$EAT_R = \max(\max(EAT_{Rj_e}), \max(EAT_{Rj_s})) \quad (2)$$

The EAT of system processors is

$$EAT_P = \min(EAT_{Pj}), 0 < j \le m \quad (3)$$

EAT_{Pj} is the EAT of processor *Pj*.

Then, the earliest available time of task τ should be

$$EAT(\tau) = \max(t_{a\tau}, EAT_p, EAT_R(\tau)) \quad (4)$$

B. Fuzzy Set Model

Fuzzy sets are described based on uncertain multi-characteristics of tasks, and target priority function $H_T(\tau)$ is worked out after computation and quantitative evaluation based on the rules of fuzzy sets.

- Relative time ft

ft is an evaluation value of the time factor of all tasks. It changes with increase of scheduling time. As described in Table 1, ft is a weighted comprehensive estimation of $t_{d\tau}$, $EAT(\tau)$ and $ts(\tau)$. Therefore, the relative time of tasks is uncertain and can be described with fuzzy sets, such as "most urgent (shortest)", "urgent (short)", "moderate (medium)", "slack (long)", "slackest (longest)" and etc., and expressed as $A(sa_1), \ldots, A(sa_n)$ fuzzy sets. It is denoted as

$$Sa(ft) = \frac{u_{A(sa1)}(ft)}{A(sa1)} + \ldots + \frac{u_{A(san)}(ft)}{A(san)}, \quad (5)$$

Here $u_{A(sai)}(ft)$ is the membership of relative time to fuzzy set $A(sa_i)$, and $\sum_{i=1}^{n} u_{A(sai)}(ft) = 1$.

- Parallel level fp

Similarly, the capability of parallel execution of tasks is decided by the resources available tokens at that time. fp is equal to the minimum of number of available resources tokens($fp \geq 0$), and task of lower fp value will be given higher priority. The system resources access tokens are time-varying by the system scheduling process. So fp is also uncertain and can be described with fuzzy sets, classified as "higher", "medium", "lower", and denoted as

$$Sb(fp) = \frac{u_{b1}(fp)}{B(s_{b1})} + \ldots + \frac{u_{bn}(fp)}{B(s_{bn})}, \tag{6}$$

- Key feature fc

Key feature is the importance mark of a task in the task set, which is describing the criticality of tasks. And as shown in Table 1, it is related to the executed time of task, which is time-varying. So we use fuzzy sets express it as "important", "ordinary" and "unimportant", and denoted as

$$Sc(fc) = \frac{u_{C1}(fc)}{C(sc_1)} + \ldots + \frac{u_{Cn}(fc)}{C(sc_n)}, \tag{7}$$

C. Calculation Methods

- Composite target function of task priority

Let g indicating uncertain characteristics be represented by $\{A, \ldots, G\}$, and the jth fuzzy set of uncertain characteristic xi as $A(aj)(xi)$; fuzzy membership $u_{A(aj)(xi)}$ is the possibility of task τ belonging to $A(aj)(xi)$; then matrix $Q_f(\tau)$ represents the possible membership of a task in various fuzzy sets:

$$Q_f(\tau) = \begin{bmatrix} u_{A(sa1)(x1)} & \ldots & u_{A(san)(x1)} \\ \ldots & \ldots & \ldots \\ u_{G(sg1)(xg)} & \ldots & u_{G(sgn)(xg)} \end{bmatrix} \tag{8}$$

To decide the importance of fuzzy sets and multi-characteristics in priority levels, we set up resultant weight vector W_f and evaluation level vector Δ_f of different fuzzy characteristics, shown as:

$$H_T(\tau) = W_f \circ Q_f(\tau) \cdot \Delta_f \tag{9}$$

Here,

$$\Delta_f = [\Delta_{f1}, \ldots, \Delta_{f\eta}]^T, W_f = [w_1, \ldots, w_g]$$

We get the membership of task priority level, through the computation on max-min rules of fuzzy set, as $Pb = W_f \circ Q_f(\tau) = [p_{b1}, \ldots, p_{b\eta}]$ and then Pb is multiplied by Δ_f to get the corresponding value of $H_T(\tau)$. Scheduling of tasks should be decided according to the $H_T(\tau)$ value of current tasks. And generally, the smaller the $H_T(\tau)$ value is, the higher the priority level is.

- Target function of processor priority

In the policy of processor selection, we should consider the relationships between the feasible time of tasks, available time of resources and available time of processors, and select the appropriate processor in available processor subsets to reduce the schedule time length of task sets and improve processor utilization.

$$\begin{aligned} &H_P(p) = EAT_P(p) + W_P * U_P(p), \\ &Pchoose() \\ &= \{p_{\min} \mid H_P(p_{\min}) = \min(H_P(p_j)), p_j \in P\} \end{aligned} \tag{10}$$

- Auto-adjustment

```

18    then w ← w + Δw ;
19    fi;
20  od
21  return ;
```

Figure 1. Multi-Fuzzy Algorithm

The method of auto-adjustment is for purposes of better comprehensive performances in scheduling success, schedule time length and resource utilization, and modification of the weights of various fuzzy characteristics of priority levels , if the schedule performance of a partial task subset is lower than the initial threshold value during scheduling of task sets, namely $W_f' = W_f + \Delta W_f$; and then adjusting step by step until the

schedule performance reaches the initial threshold, so as to improve scheduling performance of task sets.

III. MULTI-FUZZY SCHEDULING ALGORITHM

A. Description of Multi-Fuzzy Algorithm

As described in Fig.1, multi-fuzzy algorithm is divided into several parts: Lines1 to 2 are designed for initial setting of the system, and line 3 for updating tasks ready for the task ready queue T_ready, in the order of increasing deadlines; Lines 4 to 19for heuristic scheduling; specifically, lines 6 for feasibility analysis of tasks in the search window ws; lines 8 to 10 for further extension of partial schedule only when feasible, selecting proper tasks and processors for execution, updating the status table after execution, while system scheduling goes to line 5 for the next scheduling; lines 12 to 14 forces search tree to backtrack to the upper level schedule and for resetting the processor choose l when unfeasible, while lines 17 to 19 for auto-adjustment of the algorithm's weight parameter W, so as to properly adjust weight ratios between various characteristics.

B. Metrics for Performance Evaluation

For task scheduling of MPSoC, success ratio is an important metric for evaluation; meanwhile, other metrics such as schedule time length, average scheduling cost and processor utilization, affect scheduling performance directly and reflect the scheduling efficiency per unit of time, the power consumption of the system and effective utilization of resources. Hence this paper studies the metrics of these performances.

- Success Ratio $SR(T)$:

$$SR(T) = N_{success} / N_{sum} \times 100\% \quad (11)$$

$N_{success}$, number of task sets that can be successfully scheduled; N_{sum} , total number of task sets.

- Scheduling Time Length $\overline{TL}$:

$$\overline{TL} = \sum_{i=1}^{N_{success}} t_{finish}(i) / N_{success} \quad (12)$$

$t_{finish}(i)$, scheduling time for each task set; $\overline{TL}$, the average value of schedule time of all the task set available for scheduling;

- Average scheduling cost $\overline{N}_H$

$\overline{N}_H$ refers to the number of times that local scheduling function is called during scheduling of task sets, namely the average length of total schedule number of calculation of task priority and evaluation value of processors.

- Processor Utilization UR_P :

$$UR_{Pj} = \sum_{Pj} t_{e\tau} / t_{finish} \times 100\% \quad (13)$$

$\sum_{Pj} t_{e\tau}$ refers to the total execution time of tasks allocated to processor P_j .

IV. CASE STUDIES

A. Simulation Experiments

The primary MPSoC system is built on the XUPV5-LX110T Development Board from Xilinx, this board has a Virtex-5 XC5VLX110T FPGA, and a video VGA input and DVI output hardware. Our experiments are simulated on the FPGA, setting the MPSoC system on FPGA processing the video data, and output the video multi-display onto a PC screen.

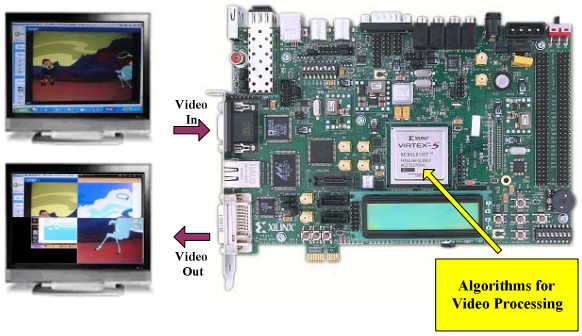

Figure 2. Experiment Platform Overview.

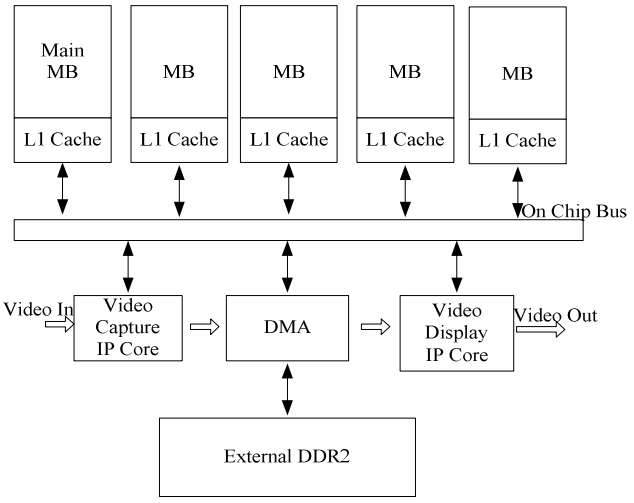

Figure 3. Architecture of MPSoC System for Video Processing.

The video processing is divided into some tasks to be executed on multiprocessors, and each processor has a local BRAM resource and share an external DDR2 SDRAM. The overview of the experiment platform is given in Fig. 2. And the

architecture of MPSoC System for Video Processing is shown in Fig. 3.

B. Results Analysis

Fig. 4 shows effects of laxity r on success ratio SR of algorithms. SR of the four algorithms becomes higher when r increases; specifically, when r falls in the interval (0, 0.1), SR of multi-fuzzy algorithms are relatively low; but it increases rapidly when r is over 0.3, exceeds other algorithms when r is around 0.5 and remains the highest when r is above 0.5. For multi-fuzzy algorithm with different weights, the success ratio varies significantly when r value is small, and the rate of change is different as r increases, but after r exceeds 0.5, the

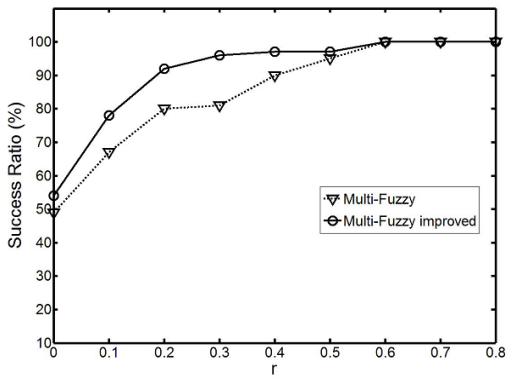

Figure 9. Improvement of Multi-Fuzzy Algorithm

difference becomes insignificant, falling within 10%. The performance test of Average number of backtracking sets maximum backtracking number N as 10. As show in Fig. 5, all algorithms decreases slowly with r; thrift algorithm is the highest, 3-4 times per task set; that of group-proper algorithm is the second highest with a level of 2.5-3.5 times per task set; and larger number of backtracking means a lower probability of successful search for a feasible solution, and the corresponding scheduling cost and time of the scheduler are added. In Fig. 6, scheduling costs of thrift and group-proper algorithms are obviously higher when r value is small; as r the scheduling costs of algorithms increases, and when laxity r is over 0.6, SR of all algorithms is close to each other, multi-fuzzy algorithm is just only higher than myopic algorithm. $\overline{N}_H$ (shown in Fig. 7) of thrift and group-proper is longer and increases linearly with laxity r, while that of myopic and multi-fuzzy algorithms tend to be stable around 340-350 time units, close to the basic time length of task set generator SC(330 on average); this resulted from effects of the policy of processor allocation of algorithms. And for UR_P in Fig. 8, single processor utilization of the thrift algorithm is the highest, up to 94%; that of myopic and group-proper algorithms are 74% and 85% respectively, and that of the multi-fuzzy algorithm is 92%. In terms of equalizing in processor utilization, performance of the multi-fuzzy algorithm is the best, for loads on various processors are the most even.

C. *Improvement Policy of Multi-Fuzzy Algorithm*

In the test in section IV-A, SR of multi-fuzzy algorithm is not so high when laxity *r* is low, thus we adjust part of the scheduling policy. Standards for processor selection can be properly loosened so as to select feasible processors with a suboptimal evaluation function value or a value closer to the average, providing more opportunities for those infeasible tasks. For example, the processor with a $H_P(P)$ value close to $\overline{H}_P$ can be selected, as

$$f_P(r)=\begin{cases}1, & r>0.3\\ Lt(\overline{H}_P), & r\le 0.3\end{cases} \tag{14}$$

with set $f_P(r)$ as a selection parameter of the algorithm. When r is no higher than 0.3, $Lt(\overline{H}_P)$ is the sequence number of processor whose $H_P(P)$ is closest to and less than $\overline{H}_P$; A simulation test is performed in reference to the adjustment policy. It can be seen from simulation results in Fig. 9 that the algorithm is significantly improved when time constraints are tight (r≤0.3), in that SR is increased from 20%-30% to 50%.

D. *Implement h.264 Encoder on FPGA*

A high performance FPGA was used to implement an MPSoC of h.264 encoder, as shown in Fig. 10, and the heterogeneous multi-core processor architecture has been designed for the special use of mass data computation. The MPSoC has five MBs (MicroBlaze), which is a software IP core of 32bit general CPU. These MBs are connected by the on chip high speed interconnection network directly. The Main Processor is in charge of the system initialization and system controlling, and other Synergistic Processors execute parallel video data computation separately. Each processor has a local L1 cache to load and store data used by executing unit. So there is potential competition to the occupation of data transmission. The Multi-Fuzzy Scheduling is running on the Main MB to be evaluated for scheduling and communication of system.

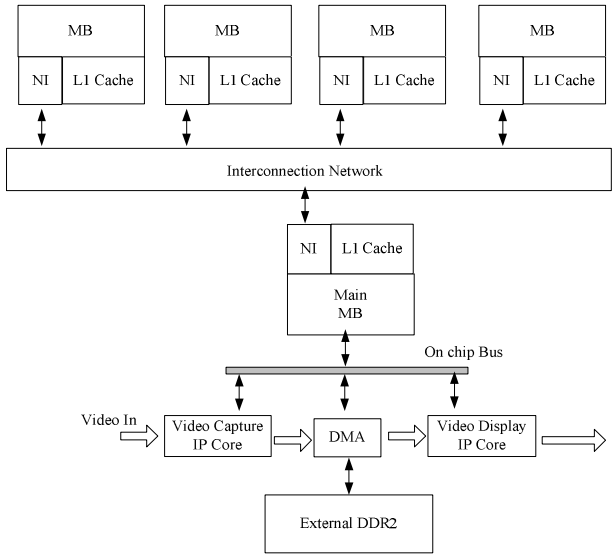

Figure 10. Architecture of Heterogeneous Multiprocessor System for Video Processing

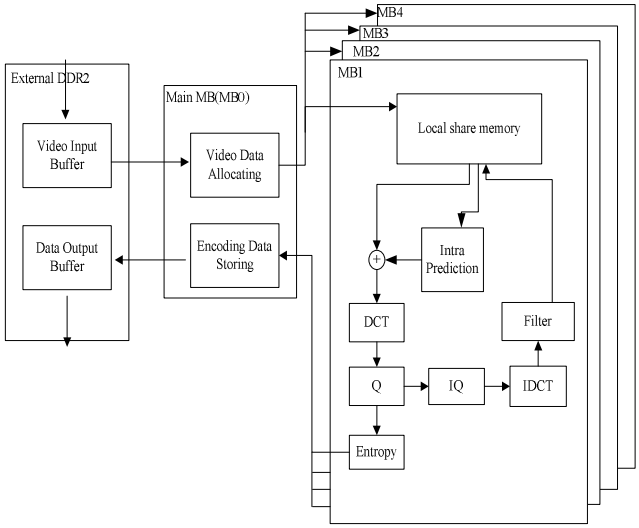

Figure 11. The Data Flow and Task Allocation of h.264 Encoder

In the h.264 video encoding application, the prototype system will capture the video stream as input, encode these video data and stored the encoded data to the output buffer. Fig. 11 outlines the data flow and task mapping of this application. In this application, the main MB is charge for allocating video stream data to the other Synergistic Processors, and gathering the encoded data from the video processing

processors to output into the external memory. Each MB will execute a complete h.264 encoding process. This process is divided up into several tasks: Intra Prediction, Forward and Inverse Transforms, Forward and Inverse Quantization, Reconstruction and Entropy Coder. We map these tasks onto different cores in each MB subsystem.

In the h.264 encoding processing, a frame is divided into many macroblocks. Hence it becomes the basic processing object for each core. The shared local memory (L1 cache) and some buffers between cores (such as FIFOs) are using for cache data, by which the one-way data stream can be divided into Multi-stage pipeline to greatly improve the system parallel performances.

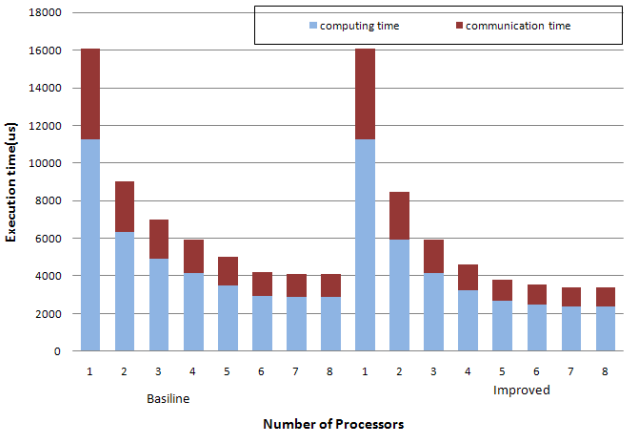

Figure 12. Execution Time of h.264 Encoder

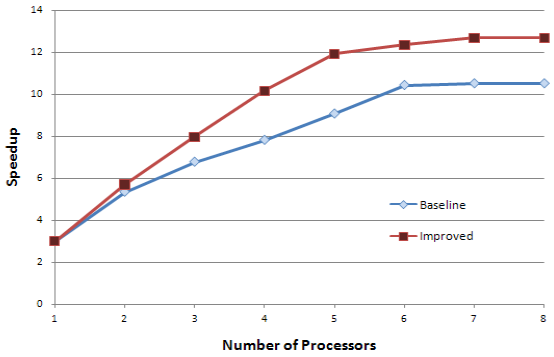

Figure 13. Speedup Ratio of h.264 Encoder

The Fig. 12 shows the execution time of the h.264 encoding for different number of processors. We have run the encoder under 100MHz system clock. In this example the baseline case allocates the tasks with the invariable macroblocks onto these processors, and the improved case use the fuzzy dynamic scheduling to allocate the macroblocks onto the appropriate processor. And the Fig. 13 shows the parallel speedup ratio performance, with the increase of number of processors, the speedup ratio of this application is improved. The highest speedup ratio is up to 10.53 and 12.69 in baseline case and improved case. The improved case can achieve better speedup ratio performance, because it minimize the difference of each processor's executing time so that there are less communications and high utilization.

V. CONCLUSION

The multiple performances are keys for scheduling algorithms and scheduler. By referring to these scheduling performance parameters, we can study the corresponding performances in detail, such as cost efficiency, scheduling efficiency. The multi-fuzzy algorithm is better suited to task scheduling in a complex system with multiple characteristics, and it works well in various scheduling performances, thus able to meet the requirements for dynamic task scheduling more effectively.

In different target systems actually designed, performance parameter standards and weights may vary significantly due to difference in design key points. Therefore, algorithms should be applied according to actual conditions during design of scheduler.

And we implement a prototype design with the fuzzy dynamic scheduling method for the hierarchical MPSoC architecture, which adopts a MPSoC h.264 encoder. The speedup ratio of this prototype application system is up to 12.69.

***Abstract*— Analytical structure of a fuzzy logic system (FLS) is to establish its mathematical input-output relationship. In this paper, the analytical structure of a class of Interval type-2 (IT2) fuzzy PD and PI controllers are derived by dividing the input space and identifying the input-output relationship for each region. Unlike the symmetric fuzzy PD and PI controller [12] which have three different consequent sets $H_4 < H_3 = H_2 < H_1$, the IT2 fuzzy PD and PI controllers considered in this paper have four different consequent sets $H_4 < H_3 < H_2 < H_1$. Compared with the symmetric IT2 fuzzy controllers investigated in [12], the relatively large number of divisions of the input space indicates the potential of this class of IT2 fuzzy controllers in achieving better performance. The equations describing the input-output relationship for each region provide mathematical tools for further investigations of these IT2 fuzzy PD controllers.**

***Index Terms*— Interval type-2 fuzzy logic system, analytical structure, fuzzy PD and PI controller, Karnik-Mendel type-reduction method.**

I. Introduction

Numerical studies have shown that the IT2 fuzzy logic controller (FLC) may outperform the type-1 (T1) FLC in complex control systems, particularly in faces of complicated imprecision and uncertainty. One possible reason is that the 3-dimensional structure of an IT2 FS allows additional design parameters to be introduced. These additional design freedom may enable the IT2 FLC to produce satisfactory performance. But most of the efforts to demonstrate the advantages of the IT2 FLC over the T1 FLC have been made through case studies, and their conclusions may not be general enough to provide guidelines for the design of IT2 FLCs for other complex plants. As a result, the IT2 FLCs are generally treated as black-box systems whose parameters are optimized through genetic algorithms or other optimization algorithms only. Such FLCs may not be amenable for analysis and interpretation by engineers.

As an efficient theoretical tool, the analytical structure of a T1 fuzzy controller may be described by mathematical equations relating the output of the fuzzy controller and its inputs [3]-[10]. This analytical tool can overcome the limitation of fuzzy logic system—lack of explicit model, and reveal how the design parameters affect the input-output relationship. More importantly, this analytical tool can provide guidelines for the design of T1 FLCs in choosing a t-norm operation, the shapes of antecedent sets and tuning the design parameters. An early effort to derive the analytical structure of IT2 fuzzy controllers has been made in [11]. In this work, the authors approximated the output of the controller by averaging 16 embedded T1 FLSs, instead of the widely used Karnik-Mendel (KM) type-reduction method.

The KM type-reduction method is established on wavy-slice representation theorem: an IT2 fuzzy set (FS) contains an infinite number of embedded T1 FSs whose centroids will form an interval, the type-reduced set. In an IT2 FLS, the type-reduced set is formed by the centroid of all possible embedded T1 FLSs. The smallest and largest centroid which are the left and right endpoints of the interval respectively, can be searched using the Karnik-Mendel iterative algorithm [2]. There lacks closed-form expressions relating the output and inputs of an IT2 FLS. The left and right endpoints have been proven to be generated by the centroids of the output sets weighted by the upper or lower bound of the corresponding firing sets. Therefore, the challenge that impedes the derivation of analytical structure for IT2 fuzzy controllers is to figure out the situations when the upper or lower bound of firing sets should be applied. An effort has been made to derive the analytical structure for a class of symmetrical IT2 fuzzy PD or PI controllers [12]. Although this work has shed some lights on how to derive the analytical structure for IT2 fuzzy controllers, it is limited to symmetrical IT2 FLSs whose consequent sets H_1, H_2, H_3, H_4 satisfy $H_1 > H_2 = H_3 > H_4$. In this paper, another class of IT2 fuzzy controllers whose consequent sets satisfy $H_1 > H_2 > H_3 > H_4$ is considered. The main contribution of this paper is to propose an algorithm for deriving the analytical structure of the considered IT2 FLCs and to derive the analytical structure by following the proposed algorithm. The following parts of this paper are organized as: Section II describes the configurations of IT2 fuzzy PD and PI controllers; Section III presents the algorithm to derive their analytical structure, followed by the detailed derivation of the analytical structure of IT2 fuzzy controllers In Section IV. A conclusion is given in Section V.

II. Configuration Of Interval T2 Fuzzy PD and PI Controller

Fig. 1 contains the schematic diagram of an IT2 FLS. A two-inputs single-output fuzzy system commonly used for feedback control may be defined as

$$\triangle U(n) = f(E(n), R(n)) \tag{1}$$

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

where $E(n) = K_e e(n) = K_e(SP(n) - y(n))$, $R(n) = K_r r(n) = K_r(e(n) - e(n-1))$, $y(n)$ is the output of the closed-loop system, $SP(n)$ is the reference signal, K_e and K_r are the scaling constants. The output $\triangle U(n)$ may be interpreted directly as the control signal or as the rate of change in the actuation signal. Depending how the output of the fuzzy controller is defined, it may be interpreted as a fuzzy PD or a fuzzy PI controller.

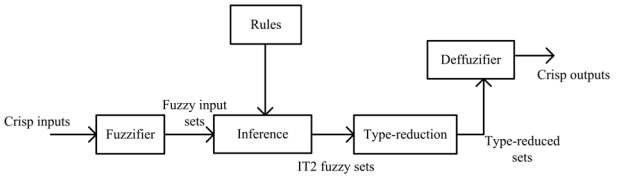

Fig. 1. The structure of IT2 FLS

For this study, two IT2 FSs are used to partition the space of each input: EN and EP for $E(n)$, **RN** and **RP** for $R(n)$. By shifting the membership of two symmetrical T1 FSs vertically by the amount of θ_1, the upper and lower membership of EN and EP, $\overline{\mathbf{EN}}$, $\underline{\mathbf{EN}}$, $\overline{\mathbf{EP}}$ and $\underline{\mathbf{EP}}$ in Fig. 2, can be obtained. In the same way, θ_2 represents the amount by which the upper and lower membership of RN and RP are shifted to obtain $\overline{\mathbf{RN}}$, $\underline{\mathbf{RN}}$, $\overline{\mathbf{RP}}$ and $\underline{\mathbf{RP}}$ in Fig. 3. Based on whether its value depends on the inputs, the lower bound or upper bound of any antecedent set can be decomposed into dependent part or independent segment (0 or 1). For example,

$$\overline{\mathbf{EN}} = \begin{cases} \overline{EN} = \frac{1}{2L_1}E(n) + 0.5 + \theta_1 \\ \qquad \text{for } -L_1 + P_1 \le E(n) \le L_1 + P_1 \\ 0 \qquad \text{for } E(n) \ge L_1 + P_1 \\ 1 \qquad \text{for } E(n) \le -L_1 + P_1 \end{cases} \tag{2}$$

where $\overline{EN}$ is the segment of the membership function of $\overline{\mathbf{EN}}$ that is dependent on the input, while the other part are independent of the input. (2) reveals the relationship between the membership grade and the input.

For fuzzy systems that partition the input space using IT2 fuzzy sets shown in Fig. 2 and 3, a commonly used rule base comprises of the following IF-THEN statements:

- Rule 1: IF $E(n)$ is Positive AND $R(n)$ is Positive THEN $\triangle U(n)$ is H_1
- Rule 2: IF $E(n)$ is Positive AND $R(n)$ is Negative THEN $\triangle U(n)$ is H_2
- Rule 3: IF $E(n)$ is Negative AND $R(n)$ is Positive THEN $\triangle U(n)$ is H_3
- Rule 4: IF $E(n)$ is Negative AND $R(n)$ is Negative THEN $\triangle U(n)$ is H_4

where H_1, H_2, H_3 and H_4 are the four singleton consequent fuzzy sets.

The result of the input and antecedent operations is an IT1 set called the firing set. Using Zadeh fuzzy AND operator as the t-norm operator, the firing set for each rule are as follows:

$$R_1 = [\underline{R}_1, \overline{R}_1] = [\min(\underline{\mathbf{EP}}, \underline{\mathbf{RP}}), \min(\overline{\mathbf{EP}}, \overline{\mathbf{RP}})] \quad \text{for } \triangle U(n) = H_1 \tag{3}$$

$$R_2 = [\underline{R}_2, \overline{R}_2] = [\min(\underline{\mathbf{EP}}, \underline{\mathbf{RN}}), \min(\overline{\mathbf{EP}}, \overline{\mathbf{RN}})] \quad \text{for } \triangle U(n) = H_2 \tag{4}$$

$$R_3 = [\underline{R}_3, \overline{R}_3] = [\min(\underline{\mathbf{EN}}, \underline{\mathbf{RP}}), \min(\overline{\mathbf{EN}}, \overline{\mathbf{RP}})] \quad \text{for } \triangle U(n) = H_3 \tag{5}$$

$$R_4 = [\underline{R}_4, \overline{R}_4] = [\min(\underline{\mathbf{EN}}, \underline{\mathbf{RN}}), \min(\overline{\mathbf{EN}}, \overline{\mathbf{RN}})] \quad \text{for } \triangle U(n) = H_4 \tag{6}$$

The output of the fuzzy inference engine, an interval type-2 fuzzy set, is obtained by combining the fired output consequent sets, where each fired output consequent set is the union of the firing set and the output consequent sets. Using the Mendel-John Representation theorem [1] (Theorem 1), the IT2 FS formed by the fuzzy inference engine may be viewed as the collection of all of its embedded IT1 FSs. Hence, the output of the inference engine may be type-reduced into an IT1 set comprising of the centroids of all embedded T1 FSs.

$$\triangle U_j = \frac{R_1^* * H_1 + R_2^* * H_2 + R_3^* * H_3 + R_4^* * H_4}{R_1^* + R_2^* + R_3^* + R_4^*} \tag{7}$$

where R_i^* is a value within the lower and upper bound of the firing set for the ith rule, R_i. In summary, the type-reduced set $\triangle U_{TR}(n)$ may be expressed mathematically as $[\triangle U_j^{min}, \triangle U_j^{max}]$, $\triangle U_j^{min}$ and $\triangle U_j^{max}$ are respectively the smallest and largest centroid of all the possible embedded T1 FS. Lastly, using the height defuzzification, the crisp output of the IT2 FLC is

$$\triangle U(n) = \frac{\triangle U_j^{min} + \triangle U_j^{max}}{2} \tag{8}$$

The four singleton consequent sets H_4, H_3, H_2, H_1 are equally spaced. Further, it is assumed that $H_4 < H_3 < H_2 < H_1$, which is shown in Fig. 4.

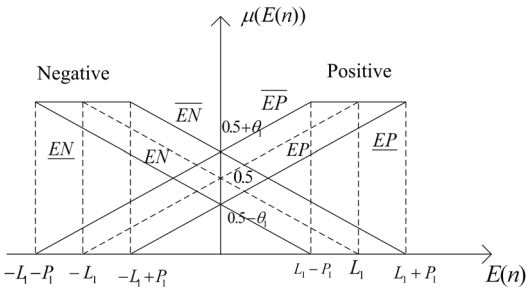

Fig. 2. IT2 FSs EN and EP as antecedent sets for the input $E(n)$ ($P_1 = 2L_1\theta_1$)

III. Algorithms to Derive the Analytical Structure of IT2 Fuzzy PD Controllers

This section will first establish the mathematical model of the left and right endpoints $\triangle U_j^{min}$ and $\triangle U_j^{max}$, and then present the algorithm to identify the mathematical expression for each firing strength in the IT2 fuzzy PD controller.

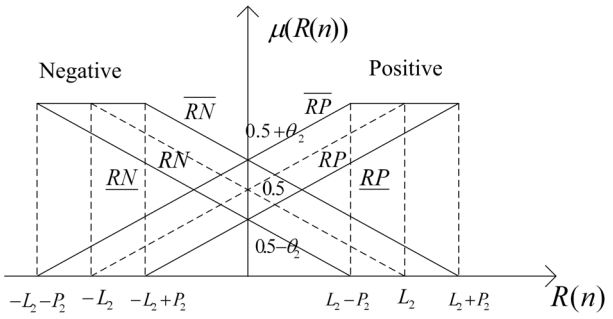

Fig. 3. IT2 FSs RN and RP as antecedent sets for the input $R(n)$ ($P_2 = 2L_2\theta_2$)

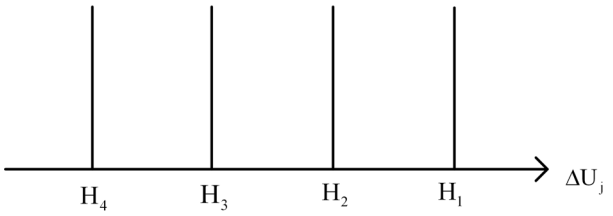

Fig. 4. Singleton consequent fuzzy sets of IT2 fuzzy PD controller

A. Mathematical model for the left endpoint $\triangle U_j^{min}$

From the Karnik-Mendel type-reduction method [2], the left and right endpoint $\triangle U_j^{min}$ and $\triangle U_j^{min}$ can be re-expressed as

$$\triangle U_j^{min} = \frac{\sum_{i=1}^{L-1} \underline{R}_i H_i + \sum_{i=L}^{4} \overline{R}_i H_i}{\sum_{i=1}^{L-1} \underline{R}_i + \sum_{i=L}^{4} \overline{R}_i} \tag{9}$$

$$\triangle U_j^{max} = \frac{\sum_{i=1}^{R-1} \overline{R}_i H_i + \sum_{i=R}^{4} \underline{R}_i H_i}{\sum_{i=1}^{R-1} \overline{R}_i + \sum_{i=R}^{4} \underline{R}_i} \tag{10}$$

where the switch point L and R coincide with the location of one of the 3 singleton consequent sets (H_1, H_2, H_3, H_4). From the derivation of the Karnik-Mendel type-reduction method [2], the following can be observed:

$$H_L \leq \triangle U_j^{min} < H_{L-1} \tag{11}$$

$$H_R \leq \triangle U_j^{max} < H_{R-1} \tag{12}$$

Due to the constraint that the switch point L and R must be positioned at one of the three singleton consequent sets and the inequalities in (11) and (12), it may be concluded that L and R can assume one of the three values i.e. $L = \{4, 3, 2\}$ and $R = \{4, 3, 2\}$. Hence, the only three possible expressions for $\triangle U_j^{min}$ may be written as

$$\begin{aligned}
&\text{Mode 1}: \quad \text{When } H_4 \leq \triangle U_j^{min} \leq H_3 \Leftrightarrow L = 4, \\
&\triangle U_j^{min} = \triangle U_{j1}^{min} \\
&= \frac{\overline{R}_4 * H_4 + \underline{R}_3 * H_3 + \underline{R}_2 * H_2 + \underline{R}_1 * H_1}{\overline{R}_4 + \underline{R}_3 + \underline{R}_2 + \underline{R}_1}
\end{aligned} \tag{13}$$

$$\begin{aligned}
&\text{Mode 2}: \quad \text{When } H_3 \leq \triangle U_j^{min} \leq H_2 \Leftrightarrow L = 3 \\
&\triangle U_j^{min} = \triangle U_{j2}^{min} \\
&= \frac{\overline{R}_4 * H_4 + \overline{R}_3 * H_3 + \underline{R}_2 * H_2 + \underline{R}_1 * H_1}{\overline{R}_4 + \overline{R}_3 + \underline{R}_2 + \underline{R}_1}
\end{aligned} \tag{14}$$

$$\begin{aligned}
&\text{Mode 3}: \quad \text{When } H_2 \leq \triangle U_j^{min} \leq H_1 \Leftrightarrow L = 2 \\
&\triangle U_j^{min} = \triangle U_{j3}^{min} \\
&= \frac{\overline{R}_4 * H_4 + \overline{R}_3 * H_3 + \overline{R}_2 * H_2 + \underline{R}_1 * H_1}{\overline{R}_4 + \overline{R}_3 + \overline{R}_2 + \underline{R}_1}
\end{aligned} \tag{15}$$

Based on the output conditions for Mode 1 ($H_4 \leq \triangle U_j^{min} \leq H_3$), Mode 2 ($H_3 \leq \triangle U_j^{min} \leq H_2$) and Mode 3 ($H_2 \leq \triangle U_j^{min} \leq H_1$), the input conditions when the three embedded T1 FLSs in (13)-(15) are respectively used as the left endpoint $\triangle U_j^{min}$ may be established as follows:

1) The condition when the switch point changes from the position of $L = 4$ to $L = 3$ and vice versa can be established as

$$\triangle U_j^{min} = \triangle U_{j1}^{min} = \triangle U_{j2}^{min} = H_3 \tag{16}$$

By replacing $\triangle U_{j1}^{min}$ and $\triangle U_{j2}^{min}$ with the expressions (13) and (14), the above equation may be written as

$$\overline{R}_4(H_4 - H_3) = \underline{R}_2(H_3 - H_2) + 2\underline{R}_1(H_3 - H_1)$$

Because of the assumption that the four consequent sets are equally spaced and $H_4 < H_2 < H_3 < H_1$, the condition established above may be reduced to

$$\overline{R}_4 = \underline{R}_2 + 2\underline{R}_1 \tag{17}$$

Further, the input subregions where (13) is used to calculate the left endpoint of the type-reduced set (Mode 1) can be found using its corresponding output condition:

$$\triangle U_j^{min} = \triangle U_{j1}^{min} \leq H_3 \Leftrightarrow \overline{R}_4 \geq \underline{R}_2 + 2\underline{R}_1 \tag{18}$$

and the areas where the IT2 fuzzy PD controller operate in Mode 2, i.e. the output is defined by (14), should satisfy the condition:

$$\triangle U_j^{min} = \triangle U_{j2}^{min} \geq H_3 \Leftrightarrow \overline{R}_4 \leq \underline{R}_2 + 2\underline{R}_1 \tag{19}$$

2) The condition when the switch point changes from the position of $L = 3$ to $L = 2$ and vice versa can be established as

$$\triangle U_j^{min} = \triangle U_{j2}^{min} = \triangle U_{j3}^{min} = H_2 \tag{20}$$

By replacing $\triangle U_{j2}^{min}$ and $\triangle U_{j3}^{min}$ with the corresponding expression in (14)-(15), the above equation may be written as

$$2\overline{R}_4 + \overline{R}_3 = \underline{R}_1 \tag{21}$$

Further, the subregions where (14) is used to calculate the left endpoint of the type-reduced set (Mode 2) can be found using the following equality

$$\triangle U_j^{min} = \triangle U_{j1}^{min} \leq H_2 \Leftrightarrow 2\overline{R}_4 + \overline{R}_3 \geq \underline{R}_1 \quad (22)$$

and the areas where the IT2 fuzzy PD controller operates in Mode 3, i.e. the output is defined by (15), should satisfy the condition:

$$\triangle U_j^{min} = \triangle U_{j3}^{min} \geq H_2 \Leftrightarrow 2\overline{R}_4 + \overline{R}_3 \leq \underline{R}_1 \quad (23)$$

B. Methodology for deriving analytical structure of IT2 fuzzy PD controller

An investigation of the conditions (18)-(19) and (22)-(23) reveals that

1) As stated above, the regions in the input space where the left endpoint $\triangle U_j^{min}$ is operating at Mode 1 and Mode 2 satisfy the condition (18) and (19) respectively. For the embedded T1 FLS of Mode 3, its corresponding region in the input space also satisfies (19) because its output condition $\triangle U_j^{min} \geq H_2$ and the assumption $H_2 > H_3$ may lead to $\triangle U_j^{min} > H_3$. Due to the complementarities between (18) and (19), the inequality (18) can be used to identify the corresponding region for the embedded T1 FLS of Mode 1.
2) Similarly, the regions in the input space which correspond to Mode 2 and Mode 3 satisfy (22) and (23) respectively. The corresponding region of Mode 1 in the input space also satisfies the inequality (22) because its output condition $\triangle U_j^{min} \leq H_3$ and the assumption $H_3 < H_2$ may result in $\triangle U_j^{min} < H_2$. Consequently, the region for the embedded T1 FLS of Mode 3 can be identified using the inequality (23).

On the other hand, by comparing the expressions of the three embedded T1 FLSs in (13)-(15), their properties can be generalized as

1) The weight associated with H_1 is always the lower bound of the firing set for Rule 1. Similarly, H_4 is weighted by the upper bound of the firing set for Rule 4. Consequently, the weight on H_1 and H_4 is independent of the switch points L and R.
2) In Mode 1, H_3 is weighted by the lower bound $\underline{R}_3$, while the corresponding upper bounds $\overline{R}_3$ is used to weight H_3 in Mode 2 and 3. On the other hand, the lower bound $\underline{R}_2$ weights H_2 in Mode 1 and 2, while in Mode 3 H_2 is weighted by the corresponding upper bound $\overline{R}_2$.

The first property shows that the firing strength of Rule 1 and Rule 4 used to calculate $\triangle U_j^{min}$ is independent of the switch point L, and the firing strength of Rule 1 and Rule 4 is always governed by the lower and upper bound of the firing set i.e. $\underline{R}_1$ and $\overline{R}_4$. Based on this observation, the first step in partitioning the input space in order to derive closed form firing level is performed by considering the outcomes of Zadeh AND operations (minimum operator) for Rule 1 and Rule 4. As stated in the second property, the firing strength for Rule 2 and Rule 3 can be the lower or upper bound of their corresponding firing set, depending on which embedded T1 FLS in (13)-(15) dominates the sub-region. Hence, the specification of the firing strength for Rule 2 and Rule 3 can be done only after the regions for the three embedded T1 FLSs in (13)-(15) are identified.

Because the conditions (18) and (23) contains three of R_1, R_2, R_3 and R_4, the challenge is how to identify the sub-regions in the input space for the three embedded T1 FLSs when only the expressions of R_1 and R_4 are known. To achieve the goal of identifying the regions for Mode 1 and Mode 3, the following technique will be used in the second step:

- Assuming that $\underline{R}_2$ weights H_2 in the whole input space, the firing strength of Rule 2 can be specified by considering the following Zadeh AND operation:

$$\underline{R}_2 = \min(\underline{\mathbf{EP}}, \underline{\mathbf{RN}}) \quad (24)$$

  Then the relative value of $\underline{R}_1$, $\underline{R}_2$ and $\overline{R}_4$ can be examined via (18) to identify the region for Mode 1.
  This assumption does not enlarge the area of the region for Mode 1 because in the region where H_2 is weighted by its upper bound $\overline{R}_2$, the property $2\overline{R}_4 + \underline{R}_3 \leq \underline{R}_1$ holds which leads to $\overline{R}_4 < \underline{R}_2 + 2\underline{R}_1$ and thus contradicts the inequality (18).
- Under the assumption that H_3 is weighted by its corresponding upper bound $\overline{R}_3$, the firing strength of Rule 3 can be mathematically expressed by considering the following Zadeh operation:

$$\overline{R}_3 = \min(\overline{\mathbf{EN}}, \overline{\mathbf{RP}}) \quad (25)$$

  According to (23), the relative value of $\underline{R}_1$, $\overline{R}_3$ and $\overline{R}_4$ may be examined to determine the sub-regions for Mode 3.
  The assumption made above does not affect the size of the region for Mode 3. This is because the regions where the lower bound $\underline{R}_3$ weights H_3 satisfies $\overline{R}_4 \geq \underline{R}_2 + 2\underline{R}_1$ which contradicts the inequality (23).

Once the regions for Mode 1 and Mode 3 are respectively identified, the firing strength for Rule 2 and Rule 3 may also be mathematically expressed by considering the corresponding Zadeh AND operations in the subregions. In summary, the proposed algorithm to derive the mathematical expression of the firing strength in $\triangle U_j^{min}$ may be presented as:

Step 1 : The firing strength of Rule 1 ($\underline{R}_1$) and Rule 4 ($\overline{R}_4$) can be specified by dividing the input space via the outcomes of Zadeh AND operations (minimum operator) for Rule 1 and Rule 4 i.e.

$$\underline{R}_1 = \min\{\underline{\mathbf{EP}}, \underline{\mathbf{RP}}\} \quad (26)$$

$$\overline{R}_4 = \min\{\overline{\mathbf{EN}}, \overline{\mathbf{RN}}\} \quad (27)$$

Step 2 : This step is to identify the regions in the input space that correspond to Mode 1 and Mode 3 respectively. Then the other region must correspond to Mode 2.

1) *Step 2.1* : Assuming that H_2 is weighted by its corresponding lower bound $\underline{R}_2$ in the whole input space, $\underline{R}_2$

can be specified as

$$\underline{R}_2 = \min(\underline{\mathbf{EP}}, \underline{\mathbf{RN}}) \tag{28}$$

The partitions obtained using $\underline{R}_1$, $\overline{R}_4$ in Step 1 and $\underline{R}_2$ are further examined to find out the group for Mode 1 (M_{L1}) satisfying the following inequality (18):

$$\text{Mode 1}: \quad \overline{R}_4 \geq \underline{R}_2 + 2\underline{R}_1$$

2) *Step 2.2* : Assume that in the input space H_3 is always weighted by its upper bound $\overline{R}_3$ and thus specify $\overline{R}_3$ as

$$\overline{R}_3 = \min(\overline{\mathbf{EN}}, \overline{\mathbf{RP}}) \tag{29}$$

The relative values of $\overline{R}_4$, $\underline{R}_1$ obtained in Step 1 and $\overline{R}_3$ are examined to find out the group for Mode 3 (M_{L3}) which satisfies the inequality (23):

$$\text{Mode 3}: \quad 2\overline{R}_4 + \overline{R}_3 \leq \underline{R}_1$$

Step 3 : In Step 3, the firing strength associated with Rule 2 and 3 can be specified via the Zadeh AND operation.

1) *Step 3.1* : Since Step 2.1 divides the whole input space into two parts: the group M_{L1} for Mode 1 and the other region for Mode 2 and 3, the firing strength associated with Rule 3 can be respectively specified as follows:
In the group M_{L1}, H_3 is weighted by its lower bound $\underline{R}_3$. By considering the Zadeh AND operation the firing strength for Rule 3 may be specified as

$$\underline{R}_3 = \min\{\underline{\mathbf{EN}}, \underline{\mathbf{RP}}\} \tag{30}$$

In the other regions for Mode 2 and Mode 3, the corresponding upper bound $\overline{R}_3$ weights H_3 and thus the firing strength for Rule 3 can be specified as

$$\overline{R}_3 = \min\{\overline{\mathbf{EN}}, \overline{\mathbf{RP}}\} \tag{31}$$

2) *Step 3.2* : The whole input space is divided into two parts in Step 2.2: the group M_{L3} for Mode 3 and the other region for Mode 1 and Mode 2. Therefore, the firing strength for Rule 2 can be specified by using Zadeh AND operation to divide the input space as follows:
The upper bound $\overline{R}_2$ weights H_2 in the region M_{L3}. The regions M_{L3} is divided by the Zadeh AND operation as

$$\overline{R}_2 = \min\{\overline{\mathbf{EP}}, \overline{\mathbf{RN}}\} \tag{32}$$

In the other regions, H_2 is weighted by the corresponding lower bound $\underline{R}_2$. The Zadeh AND operation divides the regions as

$$\underline{R}_2 = \min\{\underline{\mathbf{EP}}, \underline{\mathbf{RN}}\} \tag{33}$$

Step 4 : Superimpose all the partitions obtained by considering the mode switch and Zadeh AND operations.

Similarly, the firing strength for the right endpoint $\triangle U_j^{max}$ can be specified.

IV. Derivation of the analytical structure of IT2 Fuzzy PD controller

By following the proposed algorithm presented in the last section, the analytical structure of the fuzzy PD controller will be derived in this section.

A. The specification of the firing strength

By following the proposed algorithm, the specification of the firing strength for the left endpoint $\triangle U_j^{min}$ will be derived as an example to show the procedures:

Step 1 is to mathematically express the firing strength for Rule 1 ($\underline{R}_1$) and Rule 4 ($\overline{R}_4$) by dividing the input space into regions.

Step 2 is to sperate the input space into the three groups where the three embedded T1 FLSs in (13)-(15) are respectively used as the left endpoint $\triangle U_j^{min}$.

1) By superimposing the partitions of $\overline{R}_1$, $\underline{R}_3$ and $\underline{R}_4$, nine regions in Fig. 5(a) are generated: S_{L1}^1-S_{L9}^1. Whether the IT2 fuzzy PD controller operates in Mode 1 (M_{L1}) depends on the relative values of $\overline{R}_4$, $\underline{R}_1$ and $\underline{R}_2$.
   - Region S_{L1}^1: $\underline{R}_2 = \underline{R}_1 = 0$ and $\overline{R}_4 > 0$. Hence, $\overline{R}_4 > \underline{R}_2 + 2\underline{R}_1$ and thus for any input pair in Region S_{L1}^1, the IT2 fuzzy PD controller is operating in Mode 1. ($S_{L1} \in M_{L1}$)
   - Region S_{L2}^1: $\overline{R}_4 = \overline{RN}, \underline{R}_2 = 0, \underline{R}_1 = \underline{EP}$. The inequality (18) can be simplified into $\overline{RN} \geq 2\underline{EP}$. As shown in Fig. 5(b), the condition $\overline{RN} = 2\underline{EP}$ is denoted by the red line EG.
   - Region S_{L3}^1: $\overline{R}_4 = \overline{EN}, \underline{R}_2 = 0, \underline{R}_1 = \underline{RP}$. The fact $\overline{EN} < \overline{RN}$ and $\overline{RN} < \underline{RP}$ in Region S_{L3}^1 lead to $\overline{EN} < \underline{RP}$. Hence, in Region S_{L3}^1, the property $\overline{R}_4 < \underline{R}_2 + 2\underline{R}_1$ holds and the IT2 fuzzy PD controller operates in Mode 2 or 3.
   - Region S_{L4}^1: $\overline{R}_4 = \overline{RN}, \underline{R}_2 = \underline{RN}, \underline{R}_1 = \underline{EP}$. The inequality (18) leads to $\overline{RN} \geq \underline{RN} + 2\underline{EP}$ which is the left side of the red line IJ in Fig.5(b).
   - Region S_{L5}^1: $\overline{R}_4 = \overline{RN}, \underline{R}_2 = \underline{EP}, \underline{R}_1 = \underline{EP}$ and then the condition (18) can be simplified into $\overline{RN} > 3\underline{EP}$. The line EF includes all input pairs where $\overline{RN} = 3\underline{EP}$ holds in Region S_{L5}.
   - Region S_{L6}^1: $\overline{R}_4 = \overline{EN}, \underline{R}_2 = \underline{EP}, \underline{R}_1 = \underline{RP}$. The condition in (18) leads to $\overline{EN} \geq \underline{EP} + 2\underline{RP}$. The boundary $\overline{EN} = \underline{EP} + 2\underline{RP}$ is denoted by the red line MG in Fig.5(b).
   - Region S_{L7}^1: $\overline{R}_4 = \overline{EN}, \underline{R}_2 = \underline{RN}, \underline{R}_1 = \underline{RP}$. Due to the fact $\overline{R}_4 < \underline{R}_2 + 2\underline{R}_1$ in Region S_{L7}, the IT2 fuzzy PD controller is operating at Mode 2 or 3.
   - Region S_{L8}^1: $\overline{R}_4 = \overline{EN}, \underline{R}_2 = \underline{EP}, \underline{R}_1 = 0$. The condition (18) can be reduced to $EN_U \geq EP_L$, which is the left side of the red line GN in Fig.5(b).
   - Region S_{L9}^1: $\overline{R}_4 = \overline{EN}, \underline{R}_2 = \underline{RN}, \underline{R}_1 = 0$. In Region S_{L9}, there exists $\overline{R}_4 < \underline{R}_2 + 2\underline{R}_1$ and thus Region S_{L9}^1 does not belong to M_{L1}.
2) Step 2.2 seeks to identify the region M_{L3} where the IT2 fuzzy PD controller is operating at Mode 3. As stated in the proposed algorithm, the superimposition of the partitions of $\underline{R}_1$, $\overline{R}_3$ and $\overline{R}_4$ creates 5 regions in Fig. 6(a): S_{L1}^2-S_{L5}^2. As shown in Fig. 6(b), in the regions above the line QSV, the IT2 fuzzy controller is operating at Mode 3 while in the other regions, the fuzzy controller works at Mode 1 or Mode 2.

In this manner, the whole input space is divided into the three parts: M_{L1}, M_{L2} and M_{L3}, where the fuzzy controller is operating at Mode 1, Mode 2 or Mode 3, respectively.

Step 3 This step is to specify the firing strength for Rule 2 and Rule 3 by considering the corresponding Zadeh AND operation in the subregions for Mode 1-3.

1) In the region M_{L1} for Mode 1, the firing strength for Rule 3 can be specified by considering the following Zadeh AND operation: $\underline{R}_3 = \min\{\underline{\mathbf{EN}}, \underline{\mathbf{RP}}\}$ while in the other regions M_{L2} and M_{L3}, the following Zadeh AND operation is considered to specify the firing strength for Rule 3:$\overline{R}_3 = \min\{\overline{\mathbf{EN}}, \overline{\mathbf{RP}}\}$ The red and blue lines in Fig. 7 show the divisions of the input space for Rule 3.
2) As shown in Fig. 7, the red lines and yellow lines show the partition for Rule 2. In the subregion M_{L1} and M_{L2}, H_2 is weighted by the lower bound $\underline{R}_2$. Hence, the firing strength for Rule 2 in these regions can be specified by considering $\underline{R}_2 = \min\{\underline{\mathbf{EP}}, \underline{\mathbf{RN}}\}$ In the subregion M_{L3}, the firing strength for Rule 2 can be specified using $\overline{R}_2 = \min\{\overline{\mathbf{EP}}, \overline{\mathbf{RN}}\}$.

Step 4 Similarly, the partitions by the right endpoint $\triangle U_j^{max}$ can be derived in Fig. 8. At last, the partition of the input space for the IT2 fuzzy controllers in Fig. 9 can be obtained by superimposing all the results derived in Step 1-3.

B. The expressions of IT2 fuzzy PD controller

Fig. 10 shows the partitions of the input space when $\theta_1 = \theta_2$. The mathematical expressions of the firing strengths for 34 regions in Fig. 10 has been listed in Table I. By replacing the firing strength in (9) and (10) with their mathematical expressions, the mathematical equations relating the output of the fuzzy controller and its inputs can be derived. The region IC 1 is taken as an example to show the procedure. Table I shows that in IC1, $R_4 = R_2 = \overline{RN} = -\frac{1}{2L_2}R(n) + 0.5 + \theta_2$, $R_3 = \overline{EN} = -\frac{1}{2L_1}E(n) + 0.5 + \theta_1$, $R_1 = \underline{EP} = \frac{1}{2L_1}E(n) + 0.5 - \theta_1$. After simple manipulation, $\triangle U_j^{min}$ for IC 1 can be expressed into functions of $E(n)$ and $R(n)$ in (34).

C. Discussion

Comparing with the IT2 FLSs in [12], the introduction of the additional consequent set results in three possible embedded T1 FLSs for each endpoint $\triangle U_j^{min}$ or $\triangle U_j^{max}$, instead of the two in [12]. An observation of Fig. 7 and 8 indicates that the input space is divided into three parts that corresponds to the embedded T1 FLSs which produce the left or right endpoint $\triangle U_j^{min}$ or $\triangle U_j^{max}$. A comparative study of the partitions in Fig. 9 and that in [12] shows the introduced parameters produces 14 more regions, which indicates the potential of the considered IT2 fuzzy controllers to produce better performance.

V. Conclusion

In this paper, the analytical structure of the IT2 fuzzy controller has been derived by following the proposed algorithm. The relative large number of divisions provides the potential to produce better performance. The unique divisions may assistant the research community to understand the configurations of the considered IT2 fuzzy controllers. The equations relating the output and the input of the IT2 fuzzy controller provide tools for further investigations of their characteristics.

***Abstract*—In this paper, the problem of estimating the asymptotic stability region (ASR) of uncertain nonlinear systems is considered. Our approach is based on Takagi-Sugeno (T-S) fuzzy model and variable structure control (VSC) technique. To simplify the problem, we use a state transformation to reduce the system order of the T-S fuzzy systems. Then we design the sliding surface for the transformed system. By the Lyaponov stability theorem, the ASR can be estimated. A simulation example is presented to verify the effectiveness of the proposed scheme.**

Keywords-component; asymptotic stability region; Takagi-Sugeno fuzzy model; variable structure control; sliding mode controller

I. INTRODUCTION

As we know that, design a sliding mode control system[1-5], only need to use a rough mathematical model to describe the physical system. Design of the controller and analysis of the complex nonlinear systems is very difficult task. Thus, the fuzzy technique has been widely adopted to model complex nonlinear plants [6]. Among the many types of fuzzy modules, the Takagi-Sugeno (T-S) fuzzy model [7] is a popular and convenient tool for nonlinear system. T-S type fuzzy models which are the local dynamics in different state-space regions are represented by linear models and the nonlinear system is approximated by the overall fuzzy linear models. In recent years, the problem of fuzzy control systems based on T-S model for complex nonlinear system has become more and more popular [8-17].

Although the complex nonlinear system can be represented by T-S model, there are many uncertainties in actual situations for the nonlinear system. The uncertainty may include parameter variations, modeling errors, extraneous disturbances, and fuzzy approximation errors, etc. To solve this problem, some authors [5, 18-21], use the variable structure control (VSC) theory to deal with the problem of an uncertainty, it can more effectively achieve the control objective.

The VSC technique has been used to control complex nonlinear systems with their T-S fuzzy models [19-23]. The robust variable structure controller is designed to ensure the existence of a sliding mode and to overcome the effect of the uncertainty. If the VSC theory and T-S fuzzy model are combined to apply to the nonlinear systems, the dynamic performance of nonlinear systems can be improved by taking advantage of their respective merit [24-27].

In VSS, due to physical constraints, the control input magnitude must be bounded. The problem of estimating the asymptotic stability region (ASR) for uncertain systems with bounded sliding mode controllers is proposed in [28]. In [28], the conception of combining different Lyapunov function along with a state transformation is used to estimate ASR. By using an example and under the same conditions, the method of estimating the ASR in [29] is better than in [28]. These methods [28 , 29] of using state transformation matrices are indirect and complex. So, they do not seem to be useful in designing a sliding surface. Thus, the method of using linear matrix inequalities (LMIs) to deal with the problem is presented [30], and its method of estimating the ASR is better than the methods presented in [28 , 29]. But, these cases are limited to the explicit linear system [28 – 30], their examples are only the numerical example, it does not seem to be useful in estimating the ASR of the real model. In this paper, the method of estimating the ASR via T–S fuzzy modeling method and VSC technique is presented. Our approach is to use the T-S fuzzy model to approximately a class of the complex nonlinear systems, and design the sliding mode controllers for the T-S fuzzy model.

II. SYSTEM DESCRIPTION

The fuzzy model is described by fuzzy If-Then rules and will be employed here to deal with the control design problem for nonlinear systems. In this section, we consider the following uncertain T-S fuzzy control systems with r plant rules that can be represented as:

Plant Rule *i*:

If ϕ_1 is F_1^i and $\cdots$ and ϕ_n is F_n^i

Then (1)

$$\dot{\mathbf{x}}(t) = (\mathbf{A}_i + \Delta\mathbf{A}_i(t))\,\mathbf{x}(t) + (\mathbf{B}_i + \Delta\mathbf{B}_i(t))\,\mathbf{u}(t) + \mathbf{g}_i(t,\mathbf{x})$$

where $\mathbf{x}(t) = [x_1(t),\ldots, x_n(t)]^T \in \Re^n$ is the state vector, $\mathbf{u}(t) \in \Re^m$ is the input vector, $\phi_j\,(j = 1,2,\ldots,n)$ are the state variables, $F_1^i,\ldots, F_n^i$ are the fuzzy sets $(i = 1,2,\ldots,r)$,

This work was supported in part by the National Science Council of Taiwan under Grant NSC 99-2221-E-036-021 and NSC 99-2221-E-262 -021.

$\mathbf{A}_i \in \Re^{n\times n}$ and $\mathbf{B}_i \in \Re^{n\times m}$ are system matrices, $\Delta\mathbf{A}_i(t)$ and $\Delta\mathbf{B}_i(t)$ stand for the uncertainties in $\mathbf{A}_i$ and $\mathbf{B}_i$, respectively, $\mathbf{g}_i(t,\mathbf{x})$ is the external disturbances.

Given the a pair $(\mathbf{x},\mathbf{u})$, using the singleton fuzzifier, product inference, and center average defuzzifier [7], the final state of the uncertain T-S fuzzy control systems is obtained as follows:

$$\dot{\mathbf{x}}(t)=\sum_{i=1}^{r} h_i(\phi_j)[(\mathbf{A}_i+\Delta\mathbf{A}_i(t))\mathbf{x}(t)+(\mathbf{B}_i+\Delta\mathbf{B}_i(t))\mathbf{u}(t) + \mathbf{g}_i(t,\mathbf{x})] \tag{2}$$

where $h_i(\phi_j)$ is the fuzzy basis functions given as

$$h_i(\phi_j)=\frac{\prod_{j=1}^{n}\mu_{ij}(\phi_j)}{\sum_{i=1}^{r}\prod_{j=1}^{n}\mu_{ij}(\phi_j)},\ i=1,2,\ldots,r \tag{3}$$

in which $\mu_{ij}(x_j(t))$ is the grade of membership function of $x_j(t)$ in F_j^i, $h_i(\phi_j)$ can be regarded as the normalized weight of each If-Then rule and satisfies

$$h_i(\phi_j)\ge 0,\ \ i=1,\ldots,r \tag{4}$$

and

$$\sum_{i=1}^{r} h_i(\phi_j)=1 \tag{5}$$

To simplify the formula (2), we make the following assumptions:

Assumption 1 [21]: There exist $\boldsymbol{\beta}_A(t)\in\Re^{m\times n}$, $\boldsymbol{\beta}_B(t)\in\Re^{m\times n}$ and $\mathbf{f}(t,\mathbf{x})\in\Re^{m\times 1}$ such that $\Delta\mathbf{A}_i(t)=\mathbf{B}_i\boldsymbol{\beta}_A(t)$, $\Delta\mathbf{B}_i(t)=\mathbf{B}_i\boldsymbol{\beta}_B(t)$ and $\mathbf{g}_i(t)=\mathbf{B}_i\mathbf{f}(t,\mathbf{x})$.

Assumption 2 [21]: There exist known continuous positive scalar-valued functions $\rho_A(t,\mathbf{x})$, $\rho_f(t,\mathbf{x})$ and known constant $0\le\varphi<1$ such that $\|\boldsymbol{\beta}_A(t)\mathbf{x}(t)\|\le\rho_A(t,\mathbf{x})$, $\|\mathbf{f}(t,\mathbf{x})\|\le\rho_f(t)$, and $\|\boldsymbol{\beta}_B(t)\|\le\varphi$.

Assumption 3 [21]: The $n\times m$ matrix $\mathbf{B}$ has full rank m defined by

$$\mathbf{B}=\frac{1}{r}\sum_{i=1}^{r}\mathbf{B}_i \tag{6}$$

According to assumption 1, assumption 2 and assumption 3, the uncertain T-S fuzzy control systems (2) can be rewritten as follows:

$$\dot{\mathbf{x}}(t)=\sum_{i=1}^{r} h_i(\phi_j)\mathbf{A}_i\mathbf{x}(t)+\overline{\mathbf{B}}[\mathbf{u}(t)+\mathbf{h}(t,\mathbf{u},\mathbf{x})] \tag{7}$$

where $\overline{\mathbf{B}}=\mathbf{B}+\mathbf{KFR}$, $\mathbf{K}=\frac{1}{2}[(\mathbf{B}-\mathbf{B}_1),\cdots,(\mathbf{B}-\mathbf{B}_r)]\in\Re^{n\times rm}$, $\mathbf{F}=Diag[(1-2h_1)\mathbf{I},\cdots,(1-2h_r)\mathbf{I}]\in\Re^{n\times rm}$, $\mathbf{R}=[\mathbf{I},\cdots,\mathbf{I}]^T\in\Re^{rm\times m}$, and $\mathbf{h}(t,\mathbf{u},\mathbf{x})$ is the lumped uncertainty given as $\mathbf{h}(t,\mathbf{u},\mathbf{x})=\boldsymbol{\beta}_A(t)\mathbf{x}(t)+\boldsymbol{\beta}_B(t)\mathbf{u}(t)+\mathbf{f}(t,\mathbf{x})$.

III. Estimation of Asymptotic Stability Region of System State

A variable structure system (VSS) is a control system implementing different control laws in different regions of the state space. The regions of the VSS are divided by a set of boundary manifolds which represent the checking conditions of the VSS. Thus, we consider the uncertain T-S fuzzy control systems (7) and define the following linear switching surface [2].

$$\Omega=\{\mathbf{x}:\boldsymbol{\sigma}(\mathbf{x})=\mathbf{S}\mathbf{x}(t)=0\} \tag{8}$$

where $\mathbf{S}\in\Re^{m\times n}$ with full rank *m*. We assume that the switching surface parameter matrix $\mathbf{S}$ satisfies the following properties [21, 30].

Property 1: $\mathbf{S}\overline{\mathbf{B}}>0$ for any $h_i(\phi_j)$ satisfying $h_i(\phi_j)\ge 0$ and $\sum_{i=1}^{r}h_i(\phi_j)=1$.

Property 2: By using an appropriately chosen stabilizing feedback control law, the system trajectory is already stably restricted to the linear switching surface $\mathbf{S}\mathbf{x}(t)=0$, the reduced (*n-m*)th order sliding mode dynamics is asymptotically stable.

Our problem can be formulated as follows: 1) Design a sliding mode control for the complex nonlinear systems with matched uncertainties so that the systems are asymptotically stable. 2) Estimate the ASR of (7) for a given $\mathbf{S}$ satisfying *Property 1* and *Property 2*.

Referring to [30], we define nonsingular transformation matrix $\mathbf{M}$ as follows:

$$\mathbf{M}=\begin{bmatrix}\boldsymbol{\Phi}^T\\ (\overline{\mathbf{B}}^T\overline{\mathbf{B}})^{-1}\overline{\mathbf{B}}^T\end{bmatrix}\ \text{and}\ \mathbf{M}^{-1}=[\boldsymbol{\Phi}\quad\overline{\mathbf{B}}]. \tag{9}$$

And we have the associated state $\mathbf{v}(t)$ by (9) as follows:

$$\mathbf{v}(t)=\begin{bmatrix}\mathbf{v}_1(t)\\ \mathbf{v}_2(t)\end{bmatrix}=\mathbf{M}\mathbf{x}(t)=\begin{bmatrix}\boldsymbol{\Phi}^T\mathbf{x}(t)\\ (\overline{\mathbf{B}}^T\overline{\mathbf{B}})^{-1}\overline{\mathbf{B}}^T\mathbf{x}(t)\end{bmatrix} \tag{10}$$

where $\mathbf{v}_1(t)\in\Re^{(n-m)\times 1}$ and $\mathbf{v}_2(t)\in\Re^{m\times 1}$. From (8), (9) and (10), we obtain

$$\mathbf{S}\mathbf{x}(t)=\mathbf{S}\mathbf{M}^{-1}\mathbf{v}(t)=\mathbf{S}\boldsymbol{\Phi}\,\mathbf{v}_1(t)+\mathbf{S}\overline{\mathbf{B}}\,\mathbf{v}_2(t)=\mathbf{0}. \tag{11}$$

Under a sliding condition, the trajectory asymptotically goes to the zero of the phase plant. The dynamics can be formulated as (11). Thus, from the equivalent control method [1], we can design the equivalent controllers as follows:

$$\mathbf{u}_{eq}(t)=-\sum_{i=1}^{r}h_i(\phi_j)(\mathbf{S}\overline{\mathbf{B}})^{-1}\mathbf{S}\mathbf{A}_i\mathbf{x}(t)-\mathbf{h}(t,\mathbf{u},\mathbf{x}). \tag{12}$$

Proposition 1: If there exists positive scalar $\varepsilon\in\Re$ and positive-define matrix $\mathbf{P}$ satisfy the following conditions

$$\mathbf{P}>0,\boldsymbol{\Phi}^T(\mathbf{A}_i\mathbf{P}+\mathbf{P}\mathbf{A}_i^T)\boldsymbol{\Phi}<0,\ i=1,2,\ldots,r \tag{13}$$

$$\varepsilon>0,\quad \mathbf{S}\mathbf{P}=\varepsilon\overline{\mathbf{B}}^T \tag{14}$$

then the switching surface parameter matrix $\mathbf{S}$ satisfying *Property 1* and *Property 2* for the uncertain T-S fuzzy control systems (2.5) where $\boldsymbol{\Phi}\in\Re^{n\times(n-m)}$ is any full rank matrix such that $\overline{\mathbf{B}}^T\boldsymbol{\Phi}=\mathbf{0}$ and $\boldsymbol{\Phi}^T\boldsymbol{\Phi}=\mathbf{I}$.

Proof:

Our aim is to choose an appropriate $\mathbf{P}$ such that the systems motion on the sliding surface is asymptotically stable. In order to obtain the dynamics on the sliding surface, we must do a transformation for the state $\mathbf{x}(t)$.

From the above transformation and the time derivative of (10), the dynamics as follows:

$$\begin{aligned}\dot{\mathbf{v}}(t) &= \mathbf{M}\left(\sum_{i=1}^{r} h_i(\phi_j)\,\mathbf{A}_i\mathbf{x}(t) + \overline{\mathbf{B}}[\mathbf{u}(t)+\mathbf{h}(t,\mathbf{u},\mathbf{x})]\right)\\ &= \sum_{i=1}^{r} h_i(\phi_j)\,\mathbf{M}\mathbf{A}_i\mathbf{M}^{-1}\mathbf{v}(t) + \mathbf{M}\overline{\mathbf{B}}[\mathbf{u}(t)+\mathbf{h}(t,\mathbf{u},\mathbf{x})]\\ &= \sum_{i=1}^{r} h_i(\phi_j)[\boldsymbol{\Phi} \quad \overline{\mathbf{B}}(\overline{\mathbf{B}}^T\overline{\mathbf{B}})^{-1}]^T\mathbf{A}_i[\boldsymbol{\Phi} \quad \overline{\mathbf{B}}(\overline{\mathbf{B}}^T\overline{\mathbf{B}})^{-1}]^{-T}\mathbf{v}(t)\\ &\quad + [\boldsymbol{\Phi} \quad \overline{\mathbf{B}}(\overline{\mathbf{B}}^T\overline{\mathbf{B}})^{-1}]^T\overline{\mathbf{B}}[\mathbf{u}(t)+\mathbf{h}(t,\mathbf{u},\mathbf{x})]\\ &= \sum_{i=1}^{r} h_i(\phi_j)\begin{bmatrix}\boldsymbol{\Phi}^T\mathbf{A}_i\boldsymbol{\Phi} & \boldsymbol{\Phi}^T\mathbf{A}_i\overline{\mathbf{B}}\\ (\overline{\mathbf{B}}^T\overline{\mathbf{B}})^{-1}\overline{\mathbf{B}}^T\mathbf{A}_i\boldsymbol{\Phi} & (\overline{\mathbf{B}}^T\overline{\mathbf{B}})^{-1}\overline{\mathbf{B}}^T\mathbf{A}_i\overline{\mathbf{B}}\end{bmatrix}\mathbf{v}(t)\\ &\quad + \begin{bmatrix}\mathbf{0}\\ \mathbf{I}\end{bmatrix}(\mathbf{u}(t)+\mathbf{h}(t,\mathbf{u},\mathbf{x})).. \end{aligned} \tag{15}$$

Substituting (12) into (15) and consider (11), we obtain the dynamics $\mathbf{v}_1(t)$ and $\mathbf{v}_2(t)$ as follows:

$$\begin{bmatrix}\dot{\mathbf{v}}_1(t)\\ \dot{\mathbf{v}}_2(t)\end{bmatrix} = \sum_{i=1}^{r} h_i(\phi_j)\begin{bmatrix}\boldsymbol{\Phi}^T\mathbf{A}_i\boldsymbol{\Phi}\mathbf{v}_1(t) - \boldsymbol{\Phi}^T\mathbf{A}_i\overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\mathbf{S}\boldsymbol{\Phi}\boldsymbol{\Phi}_1(t)\\ ((\overline{\mathbf{B}}^T\overline{\mathbf{B}})^{-1}\overline{\mathbf{B}}^T\mathbf{A}_i - \mathbf{B}(\mathbf{S}\overline{\mathbf{B}})^{-1}\mathbf{S}\mathbf{A}_i)\mathbf{M}^{-1}\mathbf{v}(t)\end{bmatrix} \tag{16}$$

From (16), we have the reduced $(n-m)$ order sliding mode dynamics restricted to the switching surface $\boldsymbol{\sigma}(\mathbf{x}) = \mathbf{S}\mathbf{x}(t) = 0$, i.e., the reduced $(n-m)$ order equivalent system dynamics is given by

$$\dot{\mathbf{v}}_1(t) = \sum_{i=1}^{r} h_i(\phi_j)[\boldsymbol{\Phi}^T\mathbf{A}_i\boldsymbol{\Theta}\boldsymbol{\Phi}\mathbf{v}_1(t)]\,. \tag{17}$$

where $\boldsymbol{\Theta} = \mathbf{I} - \overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\mathbf{S}$.

Now, we consider the Lyapunov function candidate $\overline{V} = \mathbf{v}_1^T(t)\mathbf{P}_0^{-1}\mathbf{v}_1(t)$, then, the equivalent system dynamics (17) is asymptotically stable if there exists a positive definite matrix $\mathbf{P}_0^{-1} \in \Re^{(n-m)\times(n-m)}$ such that

$$\dot{\overline{V}}(t) = \mathbf{v}_1^T(t)\mathbf{P}_0^{-1}\dot{\mathbf{v}}_1^T + \dot{\mathbf{v}}_1^T(t)\mathbf{P}_0^{-1}\mathbf{v}_1^T < 0\,. \tag{18}$$

Substituting (17) into (18), we have

$$\begin{aligned}\dot{\overline{V}}(t) &= \sum_{i=1}^{r} h_i(\phi_j)\{\mathbf{v}_1(t)\mathbf{P}_0^{-1}\boldsymbol{\Phi}^T\mathbf{A}_i\boldsymbol{\Theta}\mathbf{P}_0\mathbf{P}_0^{-1}\mathbf{v}_1(t)\\ &\qquad + \mathbf{v}_1(t)\mathbf{P}_0^{-1}\mathbf{P}_0\boldsymbol{\Phi}^T\boldsymbol{\Theta}^T\mathbf{A}_i^T\boldsymbol{\Phi}\mathbf{P}_0^{-1}\mathbf{v}_1(t)\}\\ &= \sum_{i=1}^{r} h_i(\phi_j)\{\mathbf{v}_1(t)\mathbf{P}_0^{-1}[\boldsymbol{\Phi}^T\mathbf{A}_i\boldsymbol{\Theta}\mathbf{P}_0\\ &\qquad + \mathbf{P}_0\boldsymbol{\Phi}^T\boldsymbol{\Theta}^T\mathbf{A}_i^T\boldsymbol{\Phi}]\,\mathbf{P}_0^{-1}\mathbf{v}_1(t)\}\\ &= \sum_{i=1}^{r} h_i(\phi_j)\{\mathbf{v}_1(t)\mathbf{P}_0^{-1}\boldsymbol{\Phi}^T[\boldsymbol{\Phi}^T\mathbf{A}_i\boldsymbol{\Theta}\mathbf{P}_0\boldsymbol{\Phi}^T\\ &\qquad + \boldsymbol{\Phi}\mathbf{P}_0\boldsymbol{\Phi}^T\boldsymbol{\Theta}^T\mathbf{A}_i^T\boldsymbol{\Phi}]\,\boldsymbol{\Phi}\mathbf{P}_0^{-1}\mathbf{v}_1(t)\}\\ &= \sum_{i=1}^{r} h_i(\phi_j)\{\mathbf{v}_1(t)\mathbf{P}_0^{-1}\boldsymbol{\Phi}^T[\mathbf{A}_i\mathbf{P}^T + \mathbf{P}\mathbf{A}_i^T]\,\boldsymbol{\Phi}\mathbf{P}_0^{-1}\mathbf{v}_1(t)\} \end{aligned} \tag{19}$$

where

$$\mathbf{P} = \boldsymbol{\Phi}\mathbf{P}_0\boldsymbol{\Phi}^T\boldsymbol{\Theta}^T = \boldsymbol{\Phi}\mathbf{P}_0\boldsymbol{\Phi}^T(\mathbf{I} - \overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\mathbf{S})^T\,. \tag{20}$$

From (19) and (20), we get the dynamics (17) is asymptotically stable if $\boldsymbol{\Phi}^T(\mathbf{A}_i\mathbf{P}^T + \mathbf{P}\mathbf{A}_i^T)\boldsymbol{\Phi} < 0$ and $\mathbf{P} > 0$ where the matrix $\mathbf{P}$ satisfy the condition (14). The dynamics (17) is asymptotically stable imply that the $\mathbf{v}_2(t) = 0$ by (11).

Lemma: $\mathbf{P} = \boldsymbol{\Phi}\mathbf{P}_0\boldsymbol{\Phi}^T(\mathbf{I} - \overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\mathbf{S})^T$ is a positive definite matrix in (20).

Proof:

Form $\mathbf{P} = \boldsymbol{\Phi}\mathbf{P}_0\boldsymbol{\Phi}^T(\mathbf{I} - \overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\mathbf{S})^T$ we obtain

$$(\mathbf{I} - \overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\mathbf{S})\mathbf{P} = (\mathbf{I} - \overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\mathbf{S})\boldsymbol{\Phi}\mathbf{P}_0\boldsymbol{\Phi}^T(\mathbf{I} - \overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\mathbf{S})^T \tag{21}$$

By (21) and must be satisfy (14), we have

$$\mathbf{P} = (\mathbf{I} - \overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\mathbf{S})\boldsymbol{\Phi}\mathbf{P}_0\boldsymbol{\Phi}^T(\mathbf{I} - \overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\mathbf{S})^T + \varepsilon\overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\overline{\mathbf{B}}^T \tag{22}$$

where if there exists $\mathbf{P}_0$, ε in proposition 1 and $\mathbf{S}$ satisfying property 1, we have $\mathbf{P} > 0$.

Suppose that the proposition 1 has a solution for $\mathbf{P}$ and ε, then there exists a linear switching surface parameter matrix $\mathbf{S}$ satisfying property 1 and property 2, it can be parameterized as follows [2]:

$$\boldsymbol{\sigma}(\mathbf{x}) = \mathbf{S}\mathbf{x}(t) = \overline{\mathbf{B}}^T\mathbf{P}^{-1}\mathbf{x}(t) \tag{23}$$

By the *Projection lemma* and *Finsler's lemma* [32], (13) is equivalent to the following linear matrix inequalities (LMIs) [31]:

$$\mathbf{P} > 0,\ \mathbf{A}_i\mathbf{P} + \mathbf{P}\mathbf{A}_i^T - \mathbf{E}\overline{\mathbf{B}}^T - \overline{\mathbf{B}}\mathbf{E}^T < 0, i = 1,2,\cdots,r. \tag{24}$$

$$\begin{bmatrix}\mathbf{P} & \mathbf{E}\\ \mathbf{E}^T & \mathbf{I}\end{bmatrix} > 0 \tag{25}$$

$$\begin{bmatrix}\mathbf{P} & \mathbf{I}\\ \mathbf{I} & \alpha\mathbf{I}\end{bmatrix} > 0 \tag{26}$$

where $\alpha > 0$. Therefore we have the following theorem.

Theorem 1: If there exists symmetric matrix $\mathbf{P}_0 \in \Re^{(n-m)\times(n-m)}$, matrix $\mathbf{E} \in \Re^{n\times m}$ and positive scalars $\varepsilon \in \Re$, $\alpha \in \Re$ satisfy the following LMIs

$$\boldsymbol{\Theta}\boldsymbol{\Phi}\mathbf{P}_0\boldsymbol{\Phi}^T\boldsymbol{\Theta}^T + \varepsilon\overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\overline{\mathbf{B}}^T > 0 \tag{27}$$

$$\begin{aligned}&\mathbf{A}_i\boldsymbol{\Theta}\boldsymbol{\Phi}\mathbf{P}_0\boldsymbol{\Phi}^T\boldsymbol{\Theta}^T + \varepsilon\mathbf{A}_i\overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\overline{\mathbf{B}}^T - \mathbf{E}\overline{\mathbf{B}}^T\\ &+ (\mathbf{A}_i\boldsymbol{\Theta}\boldsymbol{\Phi}\mathbf{P}_0\boldsymbol{\Phi}^T\boldsymbol{\Theta}^T + \varepsilon\mathbf{A}_i\overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\overline{\mathbf{B}}^T - \overline{\mathbf{B}}\mathbf{E}^T)^T < 0\end{aligned} \tag{28}$$

$$\begin{bmatrix}\boldsymbol{\Theta}\boldsymbol{\Phi}\mathbf{P}_0\boldsymbol{\Phi}^T\boldsymbol{\Theta}^T + \varepsilon\overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\overline{\mathbf{B}}^T & \mathbf{E}\\ \mathbf{E}^T & \mathbf{I}\end{bmatrix} > 0 \tag{29}$$

$$\begin{bmatrix}\boldsymbol{\Theta}\boldsymbol{\Phi}\mathbf{P}_0\boldsymbol{\Phi}^T\boldsymbol{\Theta}^T + \varepsilon\overline{\mathbf{B}}(\mathbf{S}\overline{\mathbf{B}})^{-1}\overline{\mathbf{B}}^T & \mathbf{I}\\ \mathbf{I} & \alpha\mathbf{I}\end{bmatrix} > 0 \tag{30}$$

then the switching surface parameter matrix **S** satisfies *Property 1* and *Property 2*.

Proof:

By *Projection lemma* and *Finsler's lemma* we can show that any **S** satisfying *Property 1* and *Property 2* if exists a solution $\mathbf{P}_0$, **E** and ε , α satisfy (27)-(30) in which **P** can be obtained by (22). From *Lemma*, we know that **P** is a positive definite matrix and satisfy the condition (14) if there exists symmetric matrix $\mathbf{P}_0$ and positive scalar $\varepsilon \in \Re$, and from (13) we see that the sliding mode dynamics (17) is asymptotically stable.

Referring to [2] and [30], we consider the following switching feedback control law.

Control Rule i :

If ϕ_1 is F_1^i and $\cdots$ and ϕ_n is F_n^i

$$\text{Then } \mathbf{u}(t) = -\eta_i \frac{\boldsymbol{\sigma}(\mathbf{x})}{\|\boldsymbol{\sigma}(\mathbf{x})\|} \tag{31}$$

where $\phi_j (j = 1,2,\ldots,n)$ are the state variables and $\eta_i (i = 1,2,\ldots,r) \in \Re$ are the controller parameters for each subsystems and $\eta_{\max} = \max\{\eta_1, \eta_2, \ldots, \eta_r\}$ is assumed.

The overall controller inferred as the weighted average of the each local controller as follows:

$$\mathbf{u}(t) = -\sum_{i=1}^{r} h_i(\phi_j)\eta_i \frac{\boldsymbol{\sigma}(\mathbf{x})}{\|\boldsymbol{\sigma}(\mathbf{x})\|} \tag{32}$$

To support the following theorem, we make the assumptions as follows:

Assumption 4: There exist a known nonnegative constant $\rho = \dfrac{\rho_A + \rho_B}{1-\varphi}$ such that $\mathbf{h}(t,\mathbf{u},\mathbf{x}) \le \rho$ for all *t*.

Assumption 5: The difference $\eta_{\max} - \rho = \zeta$ is positive.

Theorem 2: Suppose that assumption 4 and assumption 5 hold and a switching surface $\boldsymbol{\sigma}(\mathbf{x}) = 0$ guaranteeing *Property 1* and *Property 2* are satisfied. Consider the uncertain T-S fuzzy system of (7) with the controller (32). The following region is an estimate of the ASR:

$$B_S = \left\{ \mathbf{x}(t) : \| \mathbf{x}(t) \| \le \frac{\zeta}{\sqrt{\alpha}} \right\} \tag{33}$$

proof:

We define the Lyapunov function as

$$V = \mathbf{x}(t)\mathbf{P}^{-1}\mathbf{x}(t) \tag{34}$$

The time of derivative of the Lyapunov function V is as follows:

$$\begin{aligned}
\dot{V} &= 2\sum_{i=1}^{r} h_i(\phi_j)\mathbf{x}^T(t)\mathbf{P}^{-1}\mathbf{A}_i\mathbf{x}(t) + 2\mathbf{x}^T(t)\mathbf{P}^{-1}\overline{\mathbf{B}}(\mathbf{u}(t) + \mathbf{h}(t,\mathbf{u},\mathbf{x})) \\
&= \sum_{i=1}^{r} h_i(\phi_j)\mathbf{x}^T(t)\mathbf{P}^{-1}[\mathbf{A}_i\mathbf{P} + \mathbf{P}\mathbf{A}_i^T - \mathbf{E}\overline{\mathbf{B}}^T - \overline{\mathbf{B}}\mathbf{E}^T]\mathbf{P}^{-1}\mathbf{x}(t) \\
&\quad + 2\mathbf{x}^T(t)\mathbf{P}^{-1}\overline{\mathbf{B}}(\mathbf{u}(t) + \mathbf{E}^T\mathbf{P}^{-1}\mathbf{x}(t) + \mathbf{h}(t,\mathbf{u},\mathbf{x}))
\end{aligned} \tag{35}$$

Substituting (32) into (35), we have

$$\begin{aligned}
\dot{V} &= \sum_{i=1}^{r} h_i(\phi_j)\mathbf{x}^T(t)(-\mathbf{Q}_i)\mathbf{x}(t) \\
&\quad + 2\mathbf{x}^T(t)\mathbf{P}^{-1}\overline{\mathbf{B}}(-\sum_{i=1}^{r} h_i(\phi_j)\eta_i \frac{\boldsymbol{\sigma}(\mathbf{x})}{\|\boldsymbol{\sigma}(\mathbf{x})\|} + \mathbf{E}^T\mathbf{P}^{-1}\mathbf{x}(t) \\
&\quad + \mathbf{h}(t,\mathbf{u},\mathbf{x})) \\
&\le \sum_{i=1}^{r} h_i(\phi_j)\mathbf{x}^T(t)(-\mathbf{Q}_i)\mathbf{x}(t) \\
&\quad + \left\| 2\mathbf{x}^T(t)\mathbf{P}^{-1}\overline{\mathbf{B}}(-\sum_{i=1}^{r} h_i(\phi_j)\eta_i \frac{\boldsymbol{\sigma}(\mathbf{x})}{\|\boldsymbol{\sigma}(\mathbf{x})\|} + \mathbf{E}^T\mathbf{P}^{-1}\mathbf{x}(t) \right. \\
&\quad \left. + \mathbf{h}(t,\mathbf{u},\mathbf{x})) \right\|
\end{aligned} \tag{36}$$

where $\mathbf{P}^{-1}[\mathbf{A}_i\mathbf{P} + \mathbf{P}\mathbf{A}_i^T - \mathbf{E}\overline{\mathbf{B}}^T - \overline{\mathbf{B}}\mathbf{E}^T]\mathbf{P}^{-1} = -\mathbf{Q}_i$ and $\mathbf{Q}_i > 0, \forall i = 1,2,\ldots,r.$

From assumption 4 and assumption 5, (36) implies that

$$\begin{aligned}
\dot{V} &\le -\sum_{i=1}^{r} h_i(\phi_j)\lambda_{\min}(\mathbf{Q}_i)\| \mathbf{x}(t) \|^2 + 2\| \mathbf{x}^T(t)\mathbf{P}^{-1}\overline{\mathbf{B}} \| \\
&\quad \cdot (\| \mathbf{E}^T\mathbf{P}^{-1}\mathbf{x}(t) \| - \zeta)
\end{aligned} \tag{37}$$

Therefore, in the region

$$\Omega_0 = \{\mathbf{x}(t) : \mathbf{x}^T(t)\mathbf{P}^{-1}\mathbf{E}\mathbf{E}^T\mathbf{P}^{-1}\mathbf{x}(t) \le \zeta^2\} \tag{38}$$

the following inequality holds:

$$\dot{V} \le -\sum_{i=1}^{r} h_i(\phi_j)\lambda_{\min}(\mathbf{Q}_i)\| \mathbf{x}(t) \|^2 \le 0 \tag{39}$$

and implies that the $\Omega_1 = \{\mathbf{x}(t) : \mathbf{x}^T(t)\mathbf{P}^{-1}\mathbf{x}(t) \le \zeta^2\}$.

The constraint $\Omega_1 \subset \Omega_0$ is satisfied if $\mathbf{P}^{-1} > \mathbf{P}^{-1}\mathbf{E}\mathbf{E}^T\mathbf{P}^{-1}$ which can be rewritten as the LMI (25) by using the Schur complement formula [31]. From (26), we can find the inequality $\alpha\mathbf{I} > \mathbf{P}^{-1}$ satisfying the constraint $\Omega_{ASR} \subset \Omega_1$ where the region Ω_{ASR} is an estimate of the ASR as follows:

$$\Omega_{ASR} = \{\mathbf{x}(t) : \mathbf{x}^T(t)\alpha\mathbf{I}\,\mathbf{x}(t) \le \zeta^2\} \tag{40}$$

From (40), we can obtain (33).

Remark: If the uncertain systems (1) satisfy assumption 1-assumption 5, then there exist a positive definite matrix **P** satisfy (24)-(26). The switching surface can be designed and some LMI problems of the (27)-(30) can be solved. The ASR can be estimated.

IV. Simulation Example

We consider the inverted pendulum via gear train [27], described by the following sates equation:

$$\begin{bmatrix} \dot{x}_1(t) \\ \dot{x}_2(t) \\ \dot{x}_3(t) \end{bmatrix} = \begin{bmatrix} x_2(t) \\ (g/l)\sin(x_1) + (NK_m/ml^2)x_3 \\ -(V_b/L_a)x_2 - (R_a/L_a)x_3 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 1/L_a \end{bmatrix} u(t) \tag{41}$$

where $x_1(t)$ is the angle of the pendulum, $x_2(t)$ is the angle velocity, $x_3(t)$ is the current of the motor. K_m is the motor torque constant, V_b is the back emf constant, R_a is the resistance, L_a is the inductance of armature circuit, N is the gear ratio.

In this simulation, $g = 9.8m/s^2$, $l = 1m$, $m = 1kg$, $N = 10$, $K_m = 0.1Nm/A$, $K_b = 0.1Vs/rad$, $R_a = 1\Omega$, and $L_a = 100mH$. Using the values of the system parameter in (41), we have

$$\begin{bmatrix} \dot{x}_1(t) \\ \dot{x}_2(t) \\ \dot{x}_3(t) \end{bmatrix} = \begin{bmatrix} x_2(t) \\ 9.8\sin(x_1) + x_3 \\ -10x_2 - 10x_3 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 10 \end{bmatrix} u(t) \tag{42}$$

The following dynamic fuzzy model is used to represent the nonlinear system (42):

Plant Rule 1 :

If x_1 is G_1

$$\text{Then } \dot{\mathbf{x}}(t) = \begin{bmatrix} 0 & 1 & 0 \\ 9.8 & 0 & 1 \\ 0 & -10 & -10 \end{bmatrix} \mathbf{x}(t) + \begin{bmatrix} 0 \\ 0 \\ 10 \end{bmatrix} u(t) \tag{43}$$

Plant Rule 2:

If x_1 is G_2

$$\text{Then } \dot{\mathbf{x}}(t) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -10 & -10 \end{bmatrix} \mathbf{x}(t) + \begin{bmatrix} 0 \\ 0 \\ 10 \end{bmatrix} u(t) \tag{44}$$

and we consider $\rho_A = 0.25$, $\varphi = 0.1$, $\rho_f = 0$, and $\eta_{\max} = 7$. The membership functions as follows [27]:

$$G_1 = \frac{1 - 1/[1 + \exp(-5(x_1 - 1))]}{1 + \exp(-5(x_1 - 1))} \text{ and } G_2 = 1 - G_1 \tag{45}$$

Now, we checking the $\overline{\mathbf{B}}^T\mathbf{\Phi} = \mathbf{0}$ and $\mathbf{\Phi}^T\mathbf{\Phi} = \mathbf{I}$, the $\mathbf{\Phi}^T = \begin{bmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \end{bmatrix}$ can be obtained from MATLAB code [33]. By solving the LMI problem we can obtain the following arguments:

$$\mathbf{P} = \begin{bmatrix} 2.6795 & -8.8122 & 16.3451 \\ -8.8122 & 32.6026 & -97.2679 \\ 16.3451 & -97.2679 & 632.8051 \end{bmatrix}, \ \mathbf{E} = \begin{bmatrix} -0.6149 \\ 2.1290 \\ -2.6274 \end{bmatrix}$$

$$\mathbf{P}_0 = \begin{bmatrix} 32.6026 & 8.8122 \\ 8.8122 & 2.6795 \end{bmatrix}, \ \alpha = 120.1430, \text{ and } \varepsilon = 1.8074.$$

And we can be obtained the estimate of ASR as follows:

$$ASR = \{\mathbf{x}(t) : \| \mathbf{x}(t) \| \le 0.61\} \tag{46}$$

Fig. 1 gives the simulation results of $x_1(t)$. Fig. 2 gives the simulation results of $x_2(t)$. Fig. 3 gives the simulation results of $x_3(t)$. From Fig. 4, it can be clearly seen here that the system enters into a sliding mode and is confined to the vicinity of the switching surface.

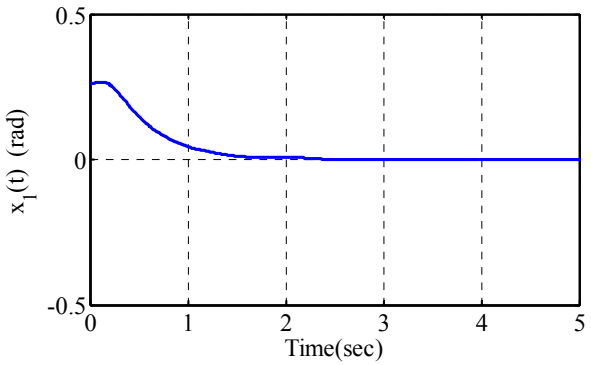

Fig. 1. The locus of $x_1(t)$ for initial conditions $\mathbf{x}(0) = [\pi/12 \quad 0 \quad 0]^T$.

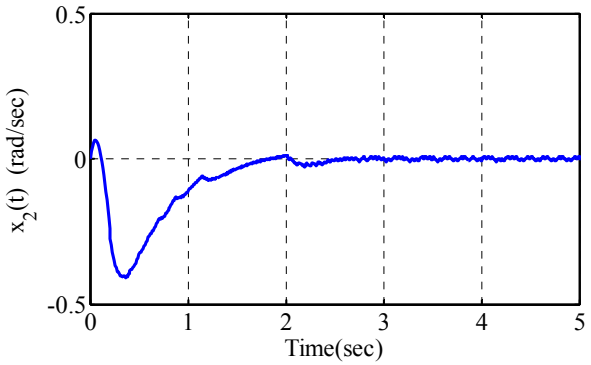

Fig. 2. The locus of $x_2(t)$ for initial conditions $\mathbf{x}(0) = [\pi/12 \quad 0 \quad 0]^T$.

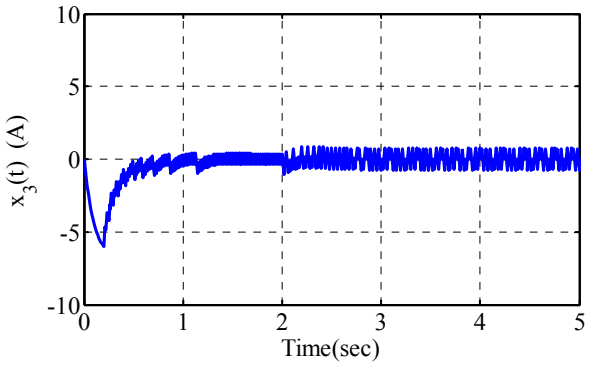

Fig. 3. The locus of $x_3(t)$ for initial conditions $\mathbf{x}(0) = [\pi/12 \quad 0 \quad 0]^T$.

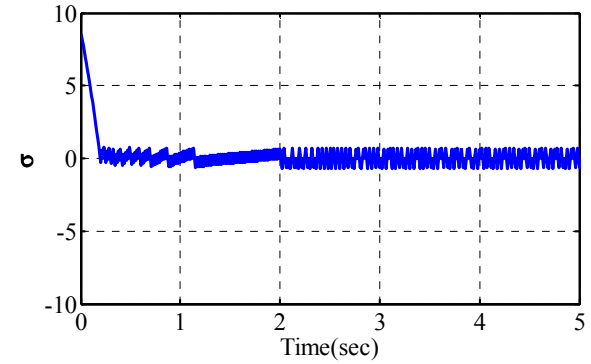

Fig. 4. The switching surface for initial conditions $\mathbf{x}(0) = [\pi/12 \quad 0 \quad 0]^T$.

V. CONCLUSIONS

The T-S fuzzy model is presented to approximate the uncertain nonlinear systems. By the Lyapunov stability theorem, the variable structure controllers can be designed with the linear matrix inequalities (LMIs). And the asymptotic stability region (ASR) can be obtained. The simulation example showed the effectiveness of the proposed scheme.

***Abstract*—Atanassov [1][9][10] defined Intuitionistic Fuzzy Graphs(IFGs) using five types of Cartesian products. In this paper IFGs so defined are named. Homomorphism, weak isomorphism and co-weak isomorphism of minmax IFGs are defined with suitable illustrations. Some of the properties of isomorphism on IFG and isomorphism on strong IFG are also analyzed.**

***Index Terms*—$\mu-$product IFG, $\nu-$product IFG, minmax IFG, maxmin IFG, homomorphism, weak isomorphism and co-weak isomorphism.**

I. Introduction

The motivation for introducing IFGs is due to [1][9][10]. The first definition and concept of Intuitionistic Fuzzy Graph(IFG) was introduced by Krassimir T. Atanassov 1994[1]. R.Parvathi and M.G.Karunambigai analyzed the properties of minmax IFGs in [3][8]. Shannon and Atanassov[1][9][10] defined intuitionistic fuzzy graphs using five types of Cartesian products. In this paper IFGs so defined are named. Some isomorphic properties on IFGs are discussed. Nagoor Gani, et al., discussed the properties of isomorphism on fuzzy graphs and properties of isomorphism on strong fuzzy graphs in [4][5][6] which motivated us to develop the same on IFGs and on strong IFGs.

The main aim of this study is to build basic definitions of an IFG which will be useful for the researchers for their future study in IFGs. Since Atanassov[1][9][10] is the pioneer of our study, the title of the paper is given so. For graph theoretical definitions see[2] and throughout this paper all the properties are analyzed for simple minmax IFG.

II. Atanassov's IFG

Definition 2.1: [1] Let E_1 and E_2 be two universes and let
A = $\{\langle x, \mu_A(x), \nu_A(x)\rangle / x \in E_1\}$
B = $\{\langle x, \mu_B(x), \nu_B(x)\rangle / x \in E_2\}$
be two IFSs; A $-$over E_1 and B $-$over E_2. Then define
$A \otimes_1 B = \{\langle\langle x, y\rangle, \mu_A(x) \bullet \mu_B(y), \nu_A(x) \bullet \nu_B(y)\rangle | \langle x, y\rangle \in E_1 \times E_2\}$,
$A \otimes_2 B = \{\langle\langle x, y\rangle, \mu_A(x) + \mu_B(y) - \mu_A(x) \bullet \mu_B(y), \nu_A(x) \bullet \nu_B(y)\rangle | \langle x, y\rangle \in E_1 \times E_2\}$,
$A \otimes_3 B = \{\langle\langle x, y\rangle, \mu_A(x) \bullet \mu_B(y), \nu_A(x) + \nu_B(y) - \nu_A(x) \bullet \nu_B(y)\rangle | \langle x, y\rangle \in E_1 \times E_2\}$,
$A \otimes_4 B = \{\langle\langle x, y\rangle, min(\mu_A(x), \mu_B(y)), max(\nu_A(x), \nu_B(y))\rangle | \langle x, y\rangle \in E_1 \times E_2\}$,
$A \otimes_5 B = \{\langle\langle x, y\rangle, max(\mu_A(x), \mu_B(y)), min(\nu_A(x), \nu_B(y))\rangle | \langle x, y\rangle \in E_1 \times E_2\}$.

We must note that $A \times_i B$ is an IFS, but it is an IFS over the universe $E_1 \times E_2$, where $\otimes_i$ is one of the five Cartesian products above, $\times$ is the classical Cartesian product on ordinary sets and $\bullet$ is a crisp product. An Intuitionistic Fuzzy Graph (IFG) is of the form $G = (V, E)$ where

(i) $V = \{v_1, v_2, ..., v_n\}$ such that $\mu_1 : V \to [0, 1]$ and $\nu_1 : V \to [0, 1]$, denotes the degree of membership and non-membership of the element $v_i \in V$ respectively and $0 \leq \mu_1(v_i) + \nu_1(v_i) \leq 1$, for every $v_i \in V, (i = 1, 2, ..., n)$,

(ii) $E \subseteq V \times V$ where $\mu_2 : V \times V \to [0, 1]$ and $\nu_2 : V \times V \to [0, 1]$, are such that
$\mu_2(v_i, v_j) \leq (\mu_1(v_i) \circ \mu_1(v_j))$
$\nu_2(v_i, v_j) \leq (\nu_1(v_i) \circ \nu_1(v_j))$,
denotes the degree of membership and non-membership of an edge $(v_i, v_j) \in E$ respectively, where, $\circ \in \{\otimes_1, \otimes_2, \otimes_3, \otimes_4, \otimes_5\}$ and $0 \leq \mu_2(v_i, v_j) + \nu_2(v_i, v_j) \leq 1$, for every $(v_i, v_j) \in E$.

Notations 2.1: The triple $(v_i, \mu_{1i}, \nu_{1i})$ denotes the degree of membership and non-membership of the vertex v_i. The triple $(e_{ij}, \mu_{2ij}, \nu_{2ij})$ denotes the degree of membership and non- membership of the edge relation $e_{ij} = (v_i, v_j)$ on V.

Note 2.1: (1) When $\mu_{2ij} = 0, \nu_{2ij} = 0$ for some i and j, then there is no edge between v_i and v_j.

(2) When either one of the following is true, then there is an edge between v_i and v_j
- $\mu_{2ij} = 0$ or $\nu_{2ij} > 0$
- $\mu_{2ij} > 0$ or $\nu_{2ij} = 0$

The IFGs defined by Atanassov[1] by using five Cartesian products and those IFGs are defined and named here as follows:

A. Product IFG

An Intuitionistic Fuzzy Graph (IFG) $G = (V, E)$ is said to be a product IFG if

(i) $V = \{v_1, v_2, ..., v_n\}$ such that $\mu_1 : V \to [0, 1]$ and $\nu_1 : V \to [0, 1]$, denotes the degree of membership and non-membership of the element $v_i \in V$ respectively and $0 \leq \mu_1(v_i) + \nu_1(v_i) \leq 1$, for every $v_i \in V, (i = 1, 2, ..., n)$,

(ii) $E \subseteq V \times V$ where $\mu_2 : V \times V \to [0, 1]$ and $\nu_2 : V \times V \to [0, 1]$, are such that
$\mu_2(v_i, v_j) \leq (\mu_1(v_i) \bullet \mu_1(v_j))$
$\nu_2(v_i, v_j) \leq (\nu_1(v_i) \bullet \nu_1(v_j))$,
denotes the degree of membership and non-membership

of an edge $(v_i, v_j) \in E$ respectively, where, $0 \leq \mu_2(v_i, v_j) + \nu_2(v_i, v_j) \leq 1$, for every $(v_i, v_j) \in E$.

B. $\mu-$Product IFG

An Intuitionistic Fuzzy Graph (IFG) $G = (V, E)$ is said to be a $\mu-$ product IFG if

(i) $V = \{v_1, v_2, ..., v_n\}$ such that $\mu_1 : V \to [0, 1]$ and $\nu_1 : V \to [0, 1]$, denotes the degree of membership and non-membership of the element $v_i \in V$ respectively and $0 \leq \mu_1(v_i) + \nu_1(v_i) \leq 1$, for every $v_i \in V$, $(i = 1, 2, ..., n)$,

(ii) $E \subseteq V \times V$ where $\mu_2 : V \times V \to [0, 1]$ and $\nu_2 : V \times V \to [0, 1]$, are such that
$\mu_2(v_i, v_j) \leq (\mu_1(v_i) \bullet \mu_1(v_j))$
$\nu_2(v_i, v_j) \leq (\nu_1(v_i) + \nu_1(v_j) - \nu_1(v_i) \bullet \nu_1(v_j))$,
denotes the degree of membership and non-membership of an edge $(v_i, v_j) \in E$ respectively, where, $0 \leq \mu_2(v_i, v_j) + \nu_2(v_i, v_j) \leq 1$, for every $(v_i, v_j) \in E$.

C. $\nu-$Product IFG

An Intuitionistic Fuzzy Graph (IFG) $G = (V, E)$ is said to be a $\nu-$ product IFG if

(i) $V = \{v_1, v_2, ..., v_n\}$ such that $\mu_1 : V \to [0, 1]$ and $\nu_1 : V \to [0, 1]$, denotes the degree of membership and non-membership of the element $v_i \in V$ respectively and $0 \leq \mu_1(v_i) + \nu_1(v_i) \leq 1$, for every $v_i \in V, (i = 1, 2, ..., n)$,

(ii) $E \subseteq V \times V$ where $\mu_2 : V \times V \to [0, 1]$ and $\nu_2 : V \times V \to [0, 1]$, are such that
$\mu_2(v_i, v_j) \leq (\mu_1(v_i) + \mu_1(v_j) - \mu_1(v_i) \bullet \mu_1(v_j))$
$\nu_2(v_i, v_j) \leq (\nu_1(v_i) \bullet \nu_1(v_j))$,
denotes the degree of membership and non-membership of an edge $(v_i, v_j) \in E$ respectively, where, $0 \leq \mu_2(v_i, v_j) + \nu_2(v_i, v_j) \leq 1$, for every $(v_i, v_j) \in E$.

D. Minmax IFG

An Intuitionistic Fuzzy Graph (IFG) $G = (V, E)$ is said to be a minmax IFG if

(i) $V = \{v_1, v_2, ..., v_n\}$ such that $\mu_1 : V \to [0, 1]$ and $\nu_1 : V \to [0, 1]$, denotes the degree of membership and non-membership of the element $v_i \in V$ respectively and $0 \leq \mu_1(v_i) + \nu_1(v_i) \leq 1$, for every $v_i \in V$, $(i = 1, 2, ..., n)$,

(ii) $E \subseteq V \times V$ where $\mu_2 : V \times V \to [0, 1]$ and $\nu_2 : V \times V \to [0, 1]$, are such that
$\mu_2(v_i, v_j) \leq min(\mu_1(v_i), \mu_1(v_j))$
$\nu_2(v_i, v_j) \leq max(\nu_1(v_i), \nu_1(v_j))$,
denotes the degree of membership and non-membership of an edge $(v_i, v_j) \in E$ respectively, where, $0 \leq \mu_2(v_i, v_j) + \nu_2(v_i, v_j) \leq 1$, for every $(v_i, v_j) \in E$.

E. Maxmin IFG

An Intuitionistic Fuzzy Graph (IFG) $G = (V, E)$ is said to be a maxmin IFG if

(i) $V = \{v_1, v_2, ..., v_n\}$ such that $\mu_1 : V \to [0, 1]$ and $\nu_1 : V \to [0, 1]$, denotes the degree of membership and non-membership of the element $v_i \in V$ respectively and $0 \leq \mu_1(v_i) + \nu_1(v_i) \leq 1$, for every $v_i \in V, (i = 1, 2, ..., n)$,

(ii) $E \subseteq V \times V$ where $\mu_2 : V \times V \to [0, 1]$ and $\nu_2 : V \times V \to [0, 1]$, are such that
$\mu_2(v_i, v_j) \leq max(\mu_1(v_i), \mu_1(v_j))$
$\nu_2(v_i, v_j) \leq min(\nu_1(v_i), \nu_1(v_j))$,
denotes the degree of membership and non-membership of an edge $(v_i, v_j) \in E$ respectively, where, $0 \leq \mu_2(v_i, v_j) + \nu_2(v_i, v_j) \leq 1$, for every $(v_i, v_j) \in E$.

F. Type n IFG

An Intuitionistic Fuzzy Graph (IFG) $G = (V, E)$ is said to be a type n IFG if

(i) $V = \{v_1, v_2, ..., v_n\}$ such that $\mu_1 : V \to [0, 1]$ and $\nu_1 : V \to [0, 1]$, denotes the degree of membership and non-membership of the element $v_i \in V$ respectively and $0 \leq \mu_1(v_i) + \nu_1(v_i) \leq 1$, for every $v_i \in V, (i = 1, 2, ..., n)$,

(ii) $E \subseteq V \times V$ where $\mu_2 : V \times V \to [0, 1]$ and $\nu_2 : V \times V \to [0, 1]$, are such that
$\mu_2(v_i, v_j) \leq (\mu_1^n(v_i) \bullet \mu_1^n(v_j))$
$\nu_2(v_i, v_j) \leq (\nu_1^n(v_i) \bullet \nu_1^n(v_j))$,
denotes the degree of membership and non-membership of an edge $(v_i, v_j) \in E$ respectively, where, $0 \leq \mu_2(v_i, v_j) + \nu_2(v_i, v_j) \leq 1$, for every $(v_i, v_j) \in E$.

Note 2.2: If $n = 1$, then the IFG is a type 1 IFG which is the product IFG, if $n = 2$, then the IFG is called a type 2 IFG, if $n = 3$, then the IFG is called a type 3 IFG and so on .

III. PRELIMINARIES

Definition 3.1: [3] An IFG $G : (V, E)$ is said to be a *strong* IFG if $\mu_2(v_i, v_j) = min(\mu_1(v_i), \mu_1(v_j))$ and $\nu_2(v_i, v_j) = max(\nu_1(v_i), \nu_1(v_j))$, $\forall (v_i, v_j) \in E$.

Definition 3.2: [3] An IFG $G : (V, E)$ is said to be a *complete* IFG if $\mu_2(v_i, v_j) = min(\mu_1(v_i), \mu_1(v_j))$ *and* $\nu_2(v_i, v_j)$=$max(\nu_1(v_i), \nu_1(v_j))$, $\forall v_i, v_j \in V$.

Definition 3.3: [3] A *path* P in an IFG is a sequence of distinct vertices $v_1, v_2, ..., v_n$ such that either one of the following condition is satisfied.

(i) $\mu_{2ij} > 0$ *and* $\nu_{2ij} = 0$ for some i *and* j.

(ii) $\mu_{2ij} = 0$ *and* $\nu_{2ij} > 0$ for some i *and* j.

Definition 3.4: [3] The *$\mu-$strength* of a path $P = v_1, v_2, ..., v_n$ is defined as min$(\mu_2(v_i, v_j))$ for all i and j and is denoted by S_μ.
The *$\nu-$strength* of a path $P = v_1, v_2, ..., v_n$ is defined as max$(\nu_2(v_i, v_j))$ for all i *and* j and is denoted by S_ν.

Note 3.1: If same edge possesses the value of both $\mu-$strength and $\nu-$strength, then it is the strength of the path P. In other words, the strength of a path is defined to be the weight of the weakest edge of the path. That is the strength of a path is denoted by (S_μ, S_ν).

Definition 3.5: Let $G : (V, E)$ be an IFG. The *$\mu-$strength of the paths* connecting any two vertices v_i, v_j is defined as max(S_μ) and is denoted by μ_{2ij}^∞. The *$\nu-$strength of the paths*

connecting any two vertices v_i, v_j is defined as $\min(S_\nu)$ and is denoted by ν^{∞}_{2ij}.

Note 3.2: If same edge possesses both the $\mu-$strength and $\nu-$strength values, then it is the strength of the strongest path P and it is denoted by $S_P = (\mu^{\infty}_{2ij}, \nu^{\infty}_{2ij})$ for all $i, j = 1, 2, ..., n$.

Definition 3.6: An edge (v_i, v_j) is said to be a *strong edge* in an IFG, $G = (V, E)$, if $\mu_{2ij} \geq \mu^{\infty}_{2ij}$, $\nu_{2ij} \leq \nu^{\infty}_{2ij}$.

Definition 3.7: A path is said to be a *strong path* in $G : (V, E)$ if it consists of only strong edges.

Definition 3.8: [7] The *order* of an IFG $G = (V, E)$ is defined to be $O(G) = (O_\mu(G), O_\nu(G))$ where

$$O_\mu(G) = \sum_{v_i \in V} \mu_1(v_i)$$

$$O_\nu(G) = \sum_{v_i \in V} \nu_1(v_i)$$

Definition 3.9: [7] The *size* of an IFG is defined to be $S(G) = (S_\mu(G), S_\nu(G))$

$$S_\mu(G) = \sum_{v_i, v_j \in V} \mu_2(v_i, v_j)$$

$$S_\nu(G) = \sum_{v_i, v_j \in V} \nu_2(v_i, v_j)$$

Definition 3.10: [7] The *degree* of a vertex v_i is defined by $d(v_i) = (d_\mu(v_i), d_\nu(v_i))$ where

$$d_\mu(v_i) = \sum_{v_i \neq v_j} \mu_2(v_i, v_j)$$

$$d_\nu(v_i) = \sum_{v_i \neq v_j} \nu_2(v_i, v_j)$$

Definition 3.11: [3] The *complement* of an IFG $G = (V, E)$ is an IFG $\bar{G} = (\bar{V}, \bar{E})$, where

(i) $\bar{V} = V$
(ii) $\bar{\mu}_{1i} = \mu_{1i}$ and $\bar{\nu}_{1i} = \nu_{1i}$, for all $i = 1, 2, ..., n$.
(iii) $\bar{\mu}_{2ij} = min(\mu_{1i}, \mu_{1j}) - \mu_{2ij}$ and $\bar{\nu}_{2ij} = max(\nu_{1i}, \nu_{1j}) - \nu_{2ij}$, for all $i, j = 1, 2, ..., n$.

Definition 3.12: [3] Consider the two IFGs $G_1 = (V_1, E_1)$ and $G_2 = (V_2, E_2)$. An *isomorphism* between two IFGs G_1 and G_2, denoted by $G_1 \cong G_2$,is a bijective map $I : V_1 \to V_2$ which satisfies

$$I(v_i) = v'_i, v_i \in V$$

$$\mu_1(v_i) = \mu'_1(I(v_i)), \nu_1(v_i) = \nu'_1(I(v_i)), \forall v_i \in V$$

$$\mu_2(v_i, v_j) = \mu'_2(I(v_i), I(v_j)) \text{ and}$$

$$\nu_2(v_i, v_j) = \nu'_2(I(v_i), I(v_j)), \forall v_i, v_j \in V.$$

Definition 3.13: A *homomorphism* between two IFGs $G_1 = (V_1, E_1)$ and $G_2 = (V_2, E_2)$ is defined as $H : V_1 \to V_2$ is a map which satisfies

$$H(v_i) = v'_i, v_i \in V$$

$$\mu_1(v_i) \leq \mu'_1(H(v_i)), \nu_1(v_i) \geq \nu'_1(H(v_i)), \forall v_i \in V_1$$

$$\mu_2(v_i, v_j) \leq \mu'_2(H(v_i), H(v_j)) \text{ and}$$

$$\nu_2(v_i, v_j) \geq \nu'_2(H(v_i), H(v_j)), \forall v_i, v_j \in V.$$

Definition 3.14: A *weak isomorphism* between two IFGs $G_1 = (V_1, E_1)$ and $G_2 = (V_2, E_2)$ is defined as $I : V_1 \to V_2$ is a bijective homomorphism that satisfies

$$\mu_1(v_i) = \mu'_1(I(v_i)), \ \nu_1(v_i) = \nu'_1(I(v_i)), \forall v_i \in V.$$

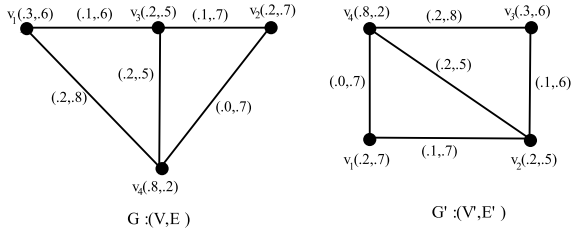

Fig. 1. G_1 is isomorphic to G_2

Definition 3.15: A *co-weak isomorphism* between two IFGs $G_1 = (V_1, E_1)$ and $G_2 = (V_2, E_2)$ is defined as $I : V_1 \to V_2$ is a bijective homomorphism that satisfies

$$\mu_2(v_i, v_j) = \mu'_2(I(v_i), I(v_j)) \text{ and}$$

$$\nu_2(v_i, v_j) = \nu'_2(I(v_i), I(v_j)), \forall v_i, v_j \in V_1$$

Definition 3.16: An *automorphism* of an intuitionistic fuzzy graph $G : (V, E)$ is an isomorphism of $G : (V, E)$ to itself.

IV. Properties of Isomorphism on Intuitionistic Fuzzy Graphs

Theorem 4.1: For any two isomorphic IFG their order and size are same.

Proof: If $h : G \to G'$ is an isomorphism between the IFG G and G' with the underlying sets V and V' respectively then
$\mu_1(v_i) = \mu'_1(h(v_i))$ and $\nu_1(v_i) = \nu'_1(h(v_i))$, $\forall v_i \in V$.
$\mu_2(v_i, v_j) = \mu'_2(h(v_i), h(v_j))$ and
$\nu_2(v_i, v_j) = \nu'_2(h(v_i), h(v_j))$, $\forall v_i, v_j \in V$.
we know that

$$order(G_\mu) = \sum_{v_i \in V} \mu_1(v_i) = \sum_{v_i \in V} \mu'_1(h(v_i)) = order(G'_\mu)$$

$$order(G_\nu) = \sum_{v_i \in V} \nu_1(v_i) = \sum_{v_i \in V} \nu'_1(h(v_i)) = order(G'_\nu)$$

$$size(G_\mu) = \sum_{v_i,v_j \in V} \mu_2(v_i, v_j)$$
$$= \sum_{v_i,v_j \in V} \mu_2'(h(v_i), h(v_j))$$
$$= size(G_\mu')$$

$$size(G_\nu) = \sum_{v_i,v_j \in V} \nu_2(v_i, v_j)$$
$$= \sum_{v_i,v_j \in V} \nu_2'(h(v_i), h(v_j))$$
$$= size(G_\nu')$$

■

Corollary 4.1: Converse of the above theorem need not be true.

Example 4.1: Here, $O_\mu(G)$ = 1.2, $O_\nu(G)$ = 1.8, $S_\mu(G)$ = .4, $S_\nu(G)$ = 1.5, $O_\mu(G')$ = 1.2, $O_\nu(G')$ = 1.8, $S_\mu(G')$ = .4, $S_\nu(G')$ = 1.5.

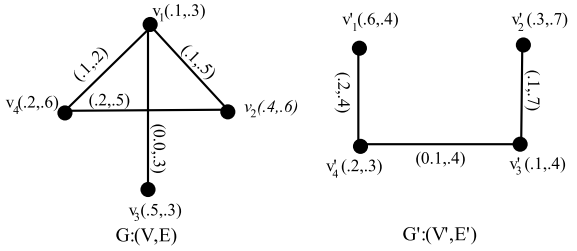

Fig. 2. Graphs of same order and size but not isomorphic

Remark 4.1: If the IFGs are weak isomorphic then their order are same. But the IFGs are of same order need not be weak isomorphic.

Example 4.2:

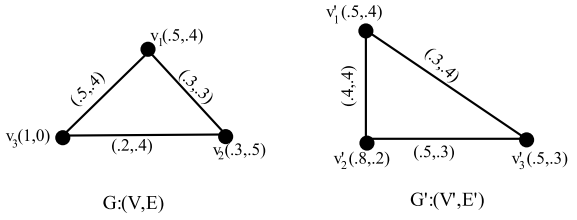

Fig. 3. Graphs of same order but not weak isomorphic

Remark 4.2: If the IFGs are co-weak isomorphic then their size are same. But the IFGs are of same size need not be co-weak isomorphic.

Example 4.3:

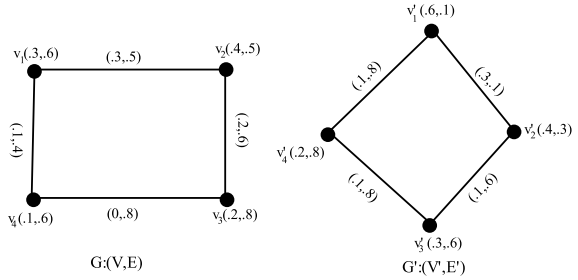

Fig. 4. Graphs of same size but not co-weak isomorphic

Theorem 4.2: If G and G' are isomorphic IFGs then the degrees of their vertices are preserved.

Proof: Let $h : V \to V'$ be an isomorphism of G and G'. By the definition of an isomorphism,
$\mu_2(v_i, v_j) = \mu_2'(h(v_i), h(v_j)), \forall v_i, v_j \in V$.
$\nu_2(v_i, v_j) = \nu_2'(h(v_i), h(v_j)), \forall v_i, v_j \in V$.

$$d_\mu(v_i) = \sum_{v_i \neq v_j} \mu_2(v_i, v_j)$$
$$= \sum_{v_i \neq v_j} \mu_2'(h(v_i), h(v_j))$$
$$= d_\mu[h(v_i)]$$

$$d_\nu(v_i) = \sum_{v_i \neq v_j} \nu_2(v_i, v_j)$$
$$= \sum_{v_i \neq v_j} \nu_2'(h(v_i), h(v_j))$$
$$= d_\nu(h(v_i))$$

■

Corollary 4.2: Converse of the above theorem need not be true.

Example 4.4: Consider the two graphs $G : (V, E)$ and $G' : (V', E')$ which preserving the degree of vertices but G and G' are not isomorphic.

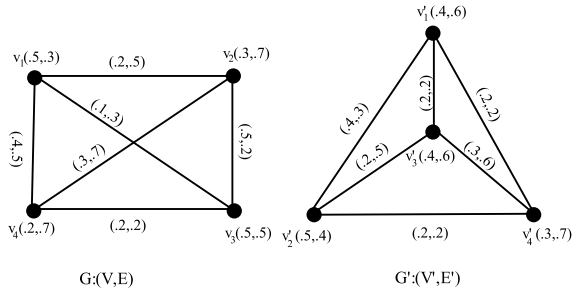

Fig. 5. Graphs preserving the degree of the vertices but not isomorphic

Theorem 4.3: Isomorphism between IFG is an equivalence relation.

Proof: Let $G : (V, E)$, $G' : (V', E')$, $G'' : (V'', E'')$ be IFGs.
(i) Reflexive:

Consider the identity map $h : V \to V$, such that

$$h(v_i) = v_i, \forall v_i \in V \tag{1}$$

This h is bijective map satisfying

$$\mu_1(v_i) = \mu_1(h(v_i)) \tag{2}$$

$$\nu_1(v_i) = \nu_1(h(v_i)), \forall v_i \in V \tag{3}$$

$$\mu_2(v_i, v_j) = \mu_2(h(v_i), h(v_j)) \tag{4}$$

$$\nu_2(v_i, v_j) = \nu_2(h(v_i), h(v_j)), \forall v_i, v_j \in V \tag{5}$$

Hence h is an isomorphism of an IFG onto itself.
(ii) Symmetric:
Let $h : V \to V'$,

$$h(v_i) = v_i', v_i \in V \tag{6}$$

be an isomorphism of G onto G' satisfying,

$$\mu_1(v_i) = \mu_1'(h(v_i)), \nu_1(v_i) = \nu_1'(h(v_i)), \forall v_i \in V \tag{7}$$

$$\mu_2(v_i, v_j) = \mu_2'(h(v_i), h(v_j)) \ and \tag{8}$$

$$\nu_2(v_i, v_j) = \nu_2'(h(v_i), h(v_j)), \forall v_i, v_j \in V \tag{9}$$

from equation (6) we have $h^{-1}(v_i') = v_i, \forall v_i' \in V$,
Therefore,

$$\mu_1(h^{-1}(v_i')) = \mu_1'(v_i'), \nu_1(h^{-1}(v_i')) = \nu_1'(v_i'), \forall v_i' \in V' \tag{10}$$

$$\mu_2(h^{-1}(v_i'), h^{-1}(v_j')) = \mu_2'(v_i', v_j') \ and \tag{11}$$

$$\nu_2(h^{-1}(v_i'), h^{-1}(v_j')) = \nu_2'(v_i', v_j'), \forall v_i', v_j' \in V' \tag{12}$$

which implies $h^{-1} : V' \to V$ is a bijective map and $G' \cong G$.
(iii) Transitive:
Let $h : V \to V'$ and $g : V' \to V''$ be two isomorphisms of the IFGs G onto G' and G' onto G'' respectively.
Then we have to prove that $g \circ h$ is a one $-$ one onto map from V to V'',
where $(g \circ h)(v_i) = g(h(v_i)), \forall v_i \in V$.
As h is an isomorphism, we have, $h(v_i) = v_i', \forall v_i \in V$.

$$\mu_1(v_i) = \mu_1'(h(v_i)), \nu_1(v_i) = \nu_1'(h(v_i)), \forall v_i \in V \tag{13}$$

$$\mu_2(v_i, v_j) = \mu_2'(h(v_i), h(v_j)) \ and \tag{14}$$

$$\nu_2(v_i, v_j) = \nu_2'(h(v_i), h(v_j)), \forall v_i, v_j \in V \tag{15}$$

using equation (6)

$$\mu_1(v_i) = \mu_1'(v_i'), \nu_1(v_i) = \nu_1'(v_i') \tag{16}$$

$$\mu_2(v_i, v_j) = \mu_2'(v_i', v_j') \ and \tag{17}$$

$$\nu_2(v_i, v_j) = \nu_2'(v_i', v_j') \tag{18}$$

As g is an isomorphism from V' to V'', we have,
$g(v_i') = v_i'', v_i' \in V'$ and

$$\mu_1'(v_i') = \mu_1''(g(v_i')), \nu_1'(v_i') = \nu_1''(g(v_i')), \forall v_i' \in V' \tag{19}$$

$$\mu_2'(v_i', v_j') = \mu_2''(g(v_i'), g(v_j')) \ and \tag{20}$$

$$\nu_2'(v_i', v_j') = \nu_2''(g(v_i'), g(v_j')), \forall v_i', v_j' \in V' \tag{21}$$

from equations (16) and (19) and using $h(v_i) = v_i', v_i \in V$, we get

$$\mu_1(v_i) = \mu_1'(v_i') = \mu_1''(g(v_i')),$$
$$\mu_1(v_i) = \mu_1''(g(h(v_i))), \forall v_i \in V$$
$$\nu_1(v_i) = \nu_1'(v_i') = \nu_1''(g(v_i')),$$
$$\nu_1(v_i) = \nu_1''(g(h(v_i))), \forall v_i \in V$$

from equations (17), (18), (20) and (21), we get

$$\begin{aligned}\mu_2(v_i, v_j) &= \mu_2'((v_i'), (v_j')) \\ &= \mu_2''(g(v_i'), g(v_j')) \ , \forall v_i', v_j' \in V' \\ &= \mu_2''(g(h(v_i)), g(h(v_j))), \forall v_i, v_j \in V \\ \nu_2(v_i, v_j) &= \nu_2'((v_i'), (v_j')) \\ &= \nu_2''(g(v_i'), g(v_j')) \ , \forall v_i', v_j' \in V' \\ &= \nu_2''(g(h(v_i)), g(h(v_j))), \forall v_i, v_j \in V\end{aligned}$$

Therefore $g \circ h$ is an isomorphism between G and G''. Hence isomorphism between IFGs is an equivalence relation. ■

V. Properties of Isomorphism on Strong Intuitionistic Fuzzy Graphs

Theorem 5.1: If $G \cong G'$ then G is a strong IFG if and only if G' is also a strong IFG .

Proof: Let $G = (V, E)$ and $G' = (V', E')$ be an IFG. If $G \cong G'$ then there exists an isomorphism $I : V \to V'$, which is bijective that satisfies

$$\mu_1(v_i) = \mu_1'(I(v_i)), \nu_1(v_i) = \nu_1'(I(v_i)), \forall v_i \in V \tag{22}$$

$$\mu_2(v_i, v_j) = \mu_2'(I(v_i), I(v_j)) \ and \tag{23}$$

$$\nu_2(v_i, v_j) = \nu_2'(I(v_i), I(v_j)), \forall v_i, v_j \in V \tag{24}$$

G is a strong IFG if and only if

$$\mu_2(v_i, v_j) = min(\mu_1(v_i), \mu_1(v_j)),$$
$$\nu_2(v_i, v_j) = max(\nu_1(v_i), \nu_1(v_j)), \forall (v_i, v_j) \in E$$

if and only if

$$\mu'_2(I(v_i), I(v_j)) = min(\mu'_1(I(v_i)), \mu'_1(I(v_j)))$$
$$\nu'_2(I(v_i), I(v_j)) = max(\nu'_1(I(v_i)), \nu'_1(I(v_j))), \forall (v_i, v_j) \in E$$

if and only if

$$\mu'_2(v_i', v_j') = min(\mu'_1(v_i'), \mu'_1(v_j'))$$
$$\nu'_2(v_i', v_j') = max(\nu'_1(v_i'), \nu'_1(v_j')), \forall (v_i', v_j') \in E'$$

if and only if G' is also a strong IFG. ■

Theorem 5.2: If G is co-weak isomorphic with a strong IFG G', then G is also a strong IFG.

Proof: If G is co-weak isomorphic with G', then there exists a co-weak isomorphism $I : V \to V'$ which is bijective that satisfies

$$\mu_1(v_i) \leq \mu_1'(I(v_i)), \ \nu_1(v_i) \geq \nu_1'(I(v_i)), \forall v_i \in V \tag{25}$$

$$\mu_2(v_i, v_j) = \mu_2'(I(v_i), I(v_j)) \ and \tag{26}$$

$$\nu_2(v_i, v_j) = \nu_2'(I(v_i), I(v_j)), \forall v_i, v_j \in V \tag{27}$$

Since G_2 is a strong IFG, we've

$$\mu'_2(I(v_i), I(v_j)) = min(\mu'_1(I(v_i)), \mu'_1(I(v_j)))$$
$$\nu'_2(I(v_i), I(v_j)) = max(\nu'_1(I(v_i)), \nu'_1(I(v_j))), \forall v_i, v_j \in V$$

Now we consider,

$$\begin{aligned} min(\mu'_1(I(v_i)), \mu'_1(I(v_j))) &= \mu'_2(I(v_i), I(v_j)) \\ &= \mu_2(v_i, v_j) \\ &\leq min(\mu_{1i}, \mu_{1j}) \\ &\leq min(\mu'_1(I(v_i)), \mu'_1(I(v_j))), \forall (v_i, v_j) \in E \\ \Rightarrow \mu_2(v_i, v_j) &= min(\mu_{1i}, \mu_{1j}), \forall (v_i, v_j) \in E \end{aligned}$$

Now,we consider,

$$\begin{aligned} max(\nu'_1(I(v_i)), \nu'_1(I(v_j))) &= \nu'_2(I(v_i), I(v_j)) \\ &= \nu_2(v_i, v_j) \\ &\leq max(\nu_{1i}, \nu_{1j}) \\ &\leq max(\nu'_1(I(v_i)), \nu'_1(I(v_j))), \forall (v_i, v_j) \in E \\ \Rightarrow \nu_2(v_i, v_j) &= max(\nu_{1i}, \nu_{1j}), \forall (v_i, v_j) \in E \end{aligned}$$

Hence G is a strong IFG. ■

Theorem 5.3: $G = (V, E)$ is a strong IFG if and only if $\bar{G}$ =$(\bar{V}, \bar{E})$ is also a strong IFG

Proof: G is a strong IFG if and only if

$$\mu_2(v_i, v_j) = min(\mu_1(v_i), \mu_1(v_j)),$$
$$\nu_2(v_i, v_j) = max(\nu_1(v_i), \nu_1(v_j)), \forall (v_i, v_j) \in E$$

if and only if

$$\bar{\mu}_2(v_i, v_j) = \begin{cases} 0, & \forall (v_i, v_j) \in E \\ min(\mu_{1i}, \mu_{1j}), & \forall (v_i, v_j) \notin E \end{cases}$$

$$\bar{\nu}_2(v_i, v_j) = \begin{cases} 0, & \forall (v_i, v_j) \in E \\ max(\nu_{1i}, \nu_{1j}), & \forall (v_i, v_j) \notin E \end{cases}$$

Hence,

$$\bar{\mu}_2(v_i, v_j) = min(\mu_1(v_i), \mu_1(v_j)),$$
$$\bar{\nu}_2(v_i, v_j) = max(\nu_1(v_i), \nu_1(v_j)), \forall (v_i, v_j) \in \bar{E}$$

if and only if $\bar{G} = (\bar{V}, \bar{E})$ is a strong IFG. ■

Theorem 5.4: If $G = (V, E)$ is an IFG then

$$S_\mu(G) + S_\mu(\bar{G}) \leq 2 \sum_{v_i \neq v_j} \mu_2(v_i, v_j)$$
$$S_\nu(G) + S_\nu(\bar{G}) \leq 2 \sum_{v_i \neq v_j} \nu_2(v_i, v_j).$$

Proof: By definition, order of G = order of $\bar{G}$. That is

$$O_\mu(G) = O_\mu(\bar{G}),\ O_\nu(G) = O_\nu(\bar{G})$$

$$\mu_2(v_i, v_j) \leq min(\mu_1(v_i), \mu_1(v_j)), \tag{28}$$

$$\nu_2(v_i, v_j) \leq max(\nu_1(v_i), \nu_1(v_j)), \forall (v_i, v_j) \in E \tag{29}$$

$$\bar{\mu}_2(v_i, v_j) = min(\mu_{1i}, \mu_{1j}) - \mu_{2ij}, \forall v_i, v_j \in V \tag{30}$$

$$\mu_2(v_i, v_j) + \bar{\mu}_2(v_i, v_j) = min(\mu_{1i}, \mu_{1j}) \tag{31}$$

Also,

$$\bar{\mu}_2(v_i, v_j) \leq min(\mu_{1i}, \mu_{1j}) \tag{32}$$

From equation(28),(31) and (32), we get

$$\begin{aligned} min(\mu_{1i}, \mu_{1j}) &= \mu_2(v_i, v_j) + \bar{\mu}_2(v_i, v_j) \\ &\leq 2\ min(\mu_{1i}, \mu_{1j}), \forall v_i, v_j \in V \\ \mu_2(v_i, v_j) + \bar{\mu}_2(v_i, v_j) &\leq 2\ min(\mu_{1i}, \mu_{1j}), \forall v_i, v_j \in V \end{aligned}$$

Taking summation on both sides, weget

$$\begin{aligned} \sum_{v_i, v_j \in V} \mu_2(v_i, v_j) + \sum_{v_i, v_j \in V} \bar{\mu}_2(v_i, v_j) \\ \leq\ 2 \sum_{v_i, v_j \in V} min(\mu_{1i}, \mu_{1j}) \end{aligned}$$

By the definition of size, we get

$$\begin{aligned} S_\mu(G) + S_\mu(\bar{G}) &\leq 2 \sum_{v_i, v_j \in V} min(\mu_{1i}, \mu_{1j}) \\ &= 2 \sum_{v_i, v_j \in V} \mu_2(v_i, v_j) \end{aligned}$$

Now,

$$\bar{\nu}_2(v_i, v_j) = max(\nu_{1i}, \nu_{1j}) - \nu_{2ij}, \forall v_i, v_j \in V \tag{33}$$

$$\nu_2(v_i, v_j) + \bar{\nu}_2(v_i, v_j) = max(\mu_{1i}, \mu_{1j}) \tag{34}$$

Also,

$$\bar{\nu}_2(v_i, v_j) \leq max(\nu_{1i}, \nu_{1j}) \tag{35}$$

From equation(29),(34) and (35), we get

$$\begin{aligned} max(\nu_{1i}, \nu_{1j}) &= \nu_2(v_i, v_j) + \bar{\nu}_2(v_i, v_j) \\ &\leq 2\ max(\nu_{1i}, \nu_{1j}), \forall v_i, v_j \in V \\ \nu_2(v_i, v_j) + \bar{\nu}_2(v_i, v_j) &\leq 2\ max(\nu_{1i}, \nu_{1j}), \forall v_i, v_j \in V \end{aligned}$$

Taking summation on both sides, we get

$$\begin{aligned} \sum_{v_i, v_j \in V} \nu_2(v_i, v_j) + \sum_{v_i, v_j \in V} \bar{\nu}_2(v_i, v_j) \\ \leq\ 2 \sum_{v_i, v_j \in V} max(\mu_{1i}, \mu_{1j}) \end{aligned}$$

By the definition of size, we get

$$\begin{aligned} S_\nu(G) + S_\nu(\bar{G}) &\leq 2 \sum_{v_i, v_j \in V} max(\mu_{1i}, \mu_{1j}) \\ &= 2 \sum_{v_i, v_j \in V} \nu_2(v_i, v_j). \end{aligned}$$

■

VI. Conclusion

This paper presents the basic definitions and some properties of isomorphism on strong IFG. We have shown that if $G : (V, E)$ is a strong IFG then its complement is also strong IFG and vice-versa. We've also given the boundary conditions for $\mu-$ size and $\nu-$ size of an IFG. The main motivation of this paper is to encourage IFG researchers to pursue similar ideas in the field in order to advance the use of IFGs in all other fields.

***Abstract*—Due to irregular wind velocity, the output power of a wind turbine generator system (WTGS) is fluctuated. There are many methods to propose to generate smooth output power of a wind turbine. For example, energy storage devices, electric double layer capacitors, flywheels are well-known. But these methods are required a significant extra cost for installation and maintenance. In recent years, some researches have been conducted to generate smooth output power by using inertia or by controlling kinetic energy of a wind turbine. The major benefit of this method, it does not require extra energy storage to generate smooth output power. So, it can reduce of a system cost significantly. But this method is reduced output power radically at the steady wind velocity as compare with maximum power point tracking (MPPT) control method. To overcome this problem, this paper is proposed a fuzzy controller based output power smoothing method by controlling kinetic energy of a wind turbine. The generator electrical speed is controlled by the proposed method that helps to generate efficient smooth output power at different wind speeds. The proposed method is compared with conventional method and MPPT control method. The effectiveness of the proposed method is verified by MATLAB SIMULINK with *SimPowerSystems* and *Fuzzy Logic Toolbox*.**

Keywords-wind turbine generator system; power leveling; kinetic energy; inertia; fuzzy controller.

I. INTRODUCTION

Due to crisis of fossil fuels (e.g. coal, oil, gas) and to reduce the emission of CO_2, the world is going to achieve safe, clean and economical energy. In recent years, wind turbine conversion systems (WTCS) have received increasing attention in order to lack of fossil fuels [1]. Especially, variable speed wind turbine (VSWT) system with a power electronics interface has attracted interest. The use of permanent magnet synchronous generator (PMSG) also have increased [2]. Because PMSG has simple structure and high efficiency, it is expected that more large size wind turbine generator (WTG) systems will adapt it. Currently, WTCS using PMSG generally uses AC-DC-AC methods. WTG system using the method does not need to synchronize the rotational speed of the WTG with power system frequency. Moreover, the gearbox can be omitted resulting in lower costs. However, wind energy has a drawback of having only 1/800 gm/cm^3 density as compared with water energy and it is not constant, and wind turbine output power is proportional to the cube of wind speed. As a result, the generated power of WTG is fluctuated. A wind farm with many WTG has a tendency of smoothing output power. Various methods have been utilized to generate smooth wind power, including the use of ultra capacitors [3], superconducting magnetic energy storage (SMES) [4], flywheel energy storage system (FESS) [5], storage batteries, aqua electrolyze fuel cell, and backup generator. Each method has its advantages and disadvantages. The high frequency charge and discharges affect the efficiency of the lead-acid battery thereby shortening its life. SMES and capacitor are very expensive. Aqua electrolyze with fuel cell system is very large. Back-up generator requires operational cost.

Among various control methods for a stand-alone WTGS output power control such as output power smoothing by using pitch angle control or the inertia of wind turbine [2,6,7]. The inertia stores kinetic energy during acceleration of a wind turbine at high wind velocity. It releases kinetic energy during deceleration of a wind turbine at low wind velocity. This phenomenon helps to generate smooth output power of a wind turbine. When wind velocity is fluctuated, the inertia power smoothing technique is effective. This method can generate efficient output power as compared with MPPT control method. On the other hand, when wind velocity moves to steady state, this method reduced output power rapidly as compared with MPPT control method. So, the total system efficiency is decreased at different wind velocities. It is important to overcome this problem.

This paper represents a fuzzy-controller-based output power smoothing method of a WTGS with a PMSG using the inertia. The fuzzy controller system adjust the integral/averaging time (T) at different wind speeds. In a conventional control system, the integral/averaging time (T=6s) remains constant. So, the final outcomes of the controller such as reference electrical speed for WTGS becomes more adjustable by using proposed method. It helps to generate smooth and efficient output power at different wind velocities. The proposed method is compared with conventional and MPPT control methods. The effectiveness of the proposed method is verified by MATLAB SIMULINK environment.

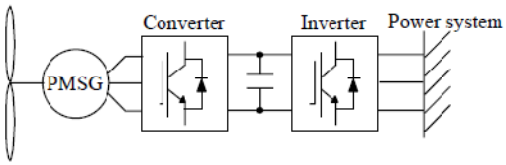

Fig. 1 Gearless wind generation system using PMSG

II. WIND TURBINE CONVERSION SYSTEM

A. System configuration

The system configuration of a WTG system is shown in Fig. 1. Wind power energy is obtained from the wind turbine. It is sent to PMSG. Due to generate maximum power and smoothing power, the rotational speed of PMSG are controlled by the generator-side converter. Here, PMSG output power is supplied to the power system through a generator-side converter and grid-side inverter.

B. Wind turbine model

The input power of wind turbine P_{wind} is expressed as

$$P_{wind} = \frac{1}{2}\rho\pi R_o^2 V_w^3 \quad (1)$$

where R_o is the wind turbine blade radius, V_w is the wind speed and ρ is air density. The wind turbine input torque T_{wind} can be described as

$$T_{wind} = \frac{\lambda}{\omega_w} P_{wind} = \frac{1}{2}\rho\pi R_o^3 V_w^2 \quad (2)$$

where ω_w is the angular velocity of wind turbine and λ is the tip speed ratio, which can be defined as $\lambda = \frac{R_0 \omega_w}{V_w}$. The wind turbine output power P_w and windmill output torque T_w are given by the following equations:

$$P_w = \frac{1}{2} C_p(\lambda,\beta)\rho\pi R_o^2 V_w^3 \quad (3)$$

$$T_w = \frac{1}{2} C_p(\lambda,\beta)\rho\pi R_o^3 V_w^2 / \lambda \quad (4)$$

where β is pitch angle. The wind turbine power coefficient C_p is defined by the following equation :

$$C_p = 0.22\left(\frac{116}{\Gamma} - 0.4\beta - 5\right)\exp^{-\frac{12.5}{\Gamma}} \quad (5)$$

$$\Gamma = \frac{1}{\frac{1}{\lambda + 0.08\beta} - \frac{0.035}{\beta^3 + 1}} \quad (6)$$

The motion equation of wind turbine is expressed as:

$$T_w = J_w \frac{d\omega_w}{dt} + T_{lw} \quad (7)$$

where J_w is the wind turbine inertia and T_{lw} is the load torque which corresponds to the input torque of generator. Input

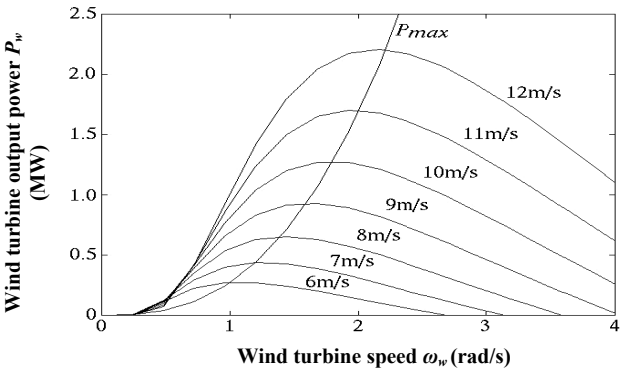

Fig. 2. Wind turbine output power characteristics.

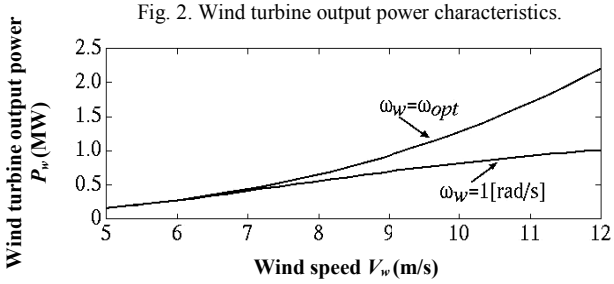

Fig. 3. Wind speed Vs. wind turbine output power characteristics.

power to the generator P_{in} is expressed as

$$P_{in} = -T_{lw}\omega_g \quad (8)$$

where ω_g is the angular velocity of the generator. The output power of generator P_g is expressed as:

$$P_g = -T_e\omega_g \quad (9)$$

where T_e is the generator electric torque.

C. Maximum power point tracking control system

From equations (3) and (5), the wind turbine output power characteristics are described in Fig. 2, from which it can be realized that, for any particular wind speed, there is a rotational speed ω_{opt}, called the optimum rotational speed, which generates the maximum power P_{max}. In this way, the MPPT control for each wind speed increases the energy generation in variable speed wind generation (VSWG) system. The optimum rotational speed ω_{opt} is calculated by differentiating C_p with respect to ω_w. Therefore, ω_{opt} is approximated by

$$\omega_{opt} = 0.2V_w - 0.2 \quad (10)$$

If $\omega_w = \omega_{opt}$, the wind turbine maximum output power P_{max} can be obtained. Fig. 3 shows the simulation results of wind speed versus wind turbine output power characteristics for fixed speed operation and variable speed operation with the MPPT control, where ω_w = 1rad/s is optimum rotational speed for V_w =6 m/s. In case of fixed speed operation, it is clear that energy loss for wind turbine is increased as the distance from 6 m/s. The MPPT control is applied when wind speed V_w is smaller than the rated wind speed $V_{w\text{-}ref}$. If wind speed V_w is greater than the rated wind speed $V_{w\text{-}ref}$, then the output power of

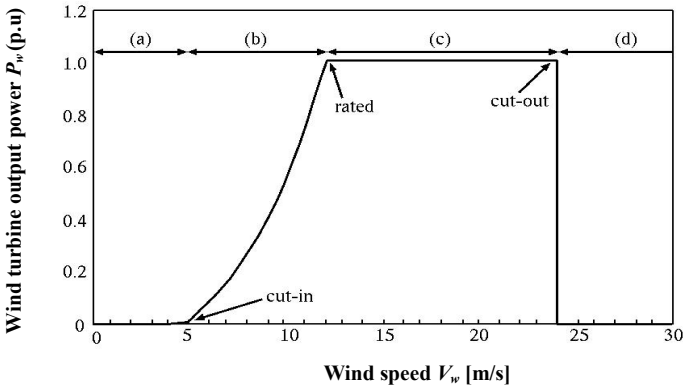

Fig. 4. Pitch angle control law.

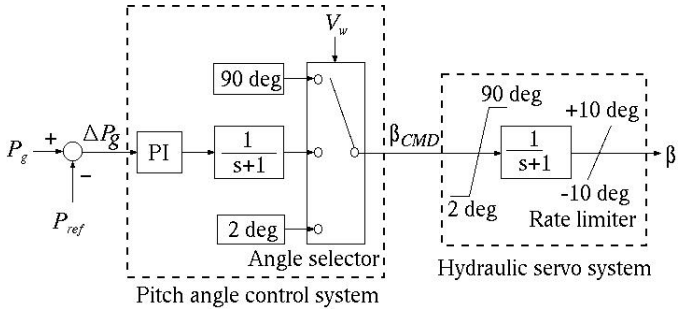

Fig. 5. Pitch angle control system.

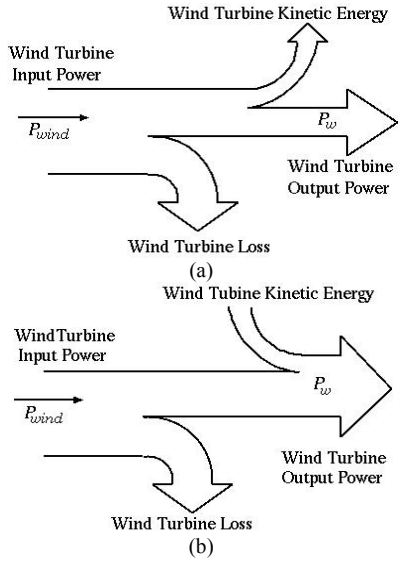

Fig. 6. Power flow (a) acceleration, (b) deceleration.

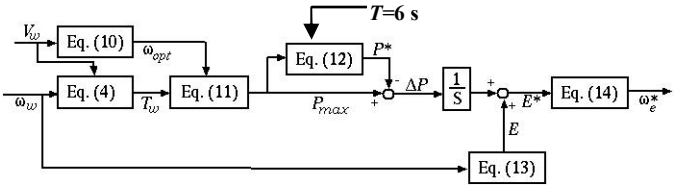

Fig. 7. Conventional power leveling control system.

PMSG is controlled by the pitch angle control system. Pitch angle β is controlled according to the pitch angle control law shown in Fig. 4. For example, in Fig. 4 (a) wind speed range is P_w = 0 pu so that pitch angle is fixed at β= 90° because the energy of the wind turbine is smallest at 90°, (b) is P_w = 0 pu to P_w = 1 pu so that pitch angle is fixed as β = 2°, (c) is P_w = 1 pu so that pitch angle β is selected to keep wind turbine output P_w = 1 pu, and finally, (d) is P_w = 0 pu so that pitch angle is fixed at β = 90° for safety reasons.

Fig. 5 shows the pitch angle control system that resolves pitch angle β, where output power error ΔP_g is used as input into PI controller. Actually, the pitch angle control system includes a hydraulic servo system. The system has nonlinear characteristics, but it is able to make first-order lag system. Therefore, in this paper it is simulated by a first-order lag system where the time constant is 1 s. Moreover, the pitch angle β is limited by a limiter in the range of 2°-90°, and the maximum rate of change is ±10°/s.

III. Output Power Smoothing Control

WTG system output power smoothing is controlled by the both charge and discharge of the kinetic energy in response to the wind speed. The charging stage is occurred when the wind turbine rotational speed accelerates at high wind speed, while discharge follows the deceleration of the wind turbine at low wind speed. Fig. 6 shows the power flow diagram for a WTG system.

A. Conventional power smoothing control system

The conventional output power smoothing control system is shown in Fig. 7. First, wind turbine maximum output power, P_{max} is calculated by

$$P_{\max} = T_w \omega_{opt} \tag{11}$$

Next, the average value of the wind turbine maximum output power is calculated as

$$P^* = \frac{1}{T}\int_{t-T}^{t} P_{\max} dt \tag{12}$$

where t denotes the present time and T is the averaging time. The difference ΔP, between the maximum output power and the average value of maximum output power is calculated. The $\int \Delta P dt$ gives the wind turbine storing and restoring energy. Wind turbine kinetic energy, E, is determined as

$$E = \frac{1}{2} J_{eq} \omega_w^2. \tag{13}$$

where J_{eq}= generator inertia (J_g) + wind turbine inertia (J_w) is equivalent inertia. The wind turbine speed command, ω_w^*, is determined from kinetic energy command, E^* (sum of $\int \Delta P dt$ and E), as

$$\omega_w^* = \sqrt{\frac{2E^*}{J_{eq}}} \tag{14}$$

The generator electrical speed reference ω_e^* for the proposed method, is determined from gear ratio, R_n, and the number of pole pairs p, as

$$\omega_e^* = R_n \omega_w^* p \quad (15)$$

and for the MPPT

$$\omega_e^* = R_n \omega_{opt} p \quad (16)$$

In this paper, the gear ratio R_n is set as 1 because a gearless PMSG is considered.

B. Fuzzy Controller based power leveling control system

The averaging time T in Eq. (12) is one of the key component for the conventional output power smoothing control. When the averaging time becomes large, the output power of the WTG system is reduced and generates smooth output power. In case of the small averaging time, the output power of the WTG system tends to generate same power as the MPPT control system with fluctuation. If the wind velocity is fluctuated in any region, the averaging time will be large to generate smooth output power. On the other hand, when the wind velocity remains steady, the averaging time can be small to generate same power as MPPT control system. But wind velocity for a particular region can be both fluctuated and steady state. So, adjustment is required for the averaging time to achieve maximum efficiency from this power leveling method. Fig. 8 shows the characteristic between the averaging time and the output power of a WTG system. The dotted line is shown the maximum output power of a WTG system during a simulation time. The conventional method output power is moved to the maximum power when the averaging time becomes smaller. From this figure (Fig. 8), it can be realized that a constant averaging time can be decreased the system efficiency at different wind speeds. The conventional power smoothing control method using inertia or controlling kinetic energy is always measured by a constant averaging time.

So, an adaptive averaging time is necessary to improve overall performance of conventional power smoothing method (instead of constant averaging time) for a WTG system. It can be implemented by a fuzzy controller. The wind velocity and fluctuation of wind velocity are online determined an averaging time. The fluctuation of wind velocity is calculated by the first derivative of wind speed. It is an input of fuzzy controller. Another input of fuzzy controller is wind velocity.

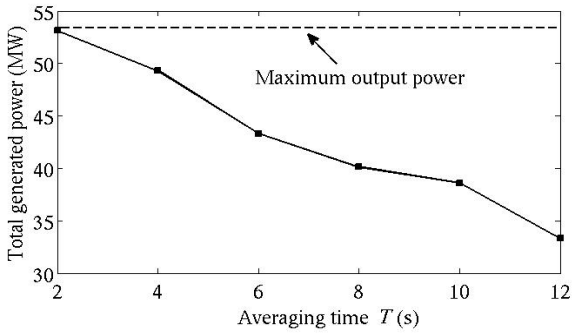

Fig. 8. Averaging time Vs. total generated power characteristics.

Depending on inputs, the fuzzy controller generates a averaging time (T) as an output. The fuzzy membership functions and fuzzy rules are shown in Fig. 9.

The fuzzy rules depict that when the change of wind velocity is large, the averaging time is set to large value. In contrast, the averaging time is small value, when the change of wind velocity is small. In case of wind velocity, when the wind velocity is very large, the averaging time is set to large value. The averaging time is set to small value, when the wind velocity becomes small.

IV. SIMULATION RESULTS

The entire control system of power smoothing method is shown in Fig. 10. The dotted block represents the proposed power smoothing control system. The effectiveness of the proposed fuzzy controller based method is evaluated by the simulation results. The MPPT control method, conventional power smoothing method, and proposed fuzzy based output power smoothing method are compared in this simulation. Simulation parameters of a wind turbine, PMSG, and power converter are shown in Table 1.

The wind velocity is shown in Fig. 11(a). This wind velocity data has significant fluctuation and speed. The Fig. 11(b) and 11(c) are input and output of fuzzy control. From Fig. 11(d), it is observed that the WTGS speed fluctuates significantly. As seen in Fig. 11(e), as the wind velocity increases, the turbine rotational speed accelerates thereby transforming the wind energy into wind turbine kinetic energy.

TABLE 1. Simulation parameters.

Parameters of windmill	
Blade radius	R_o = 41 m
Air density	ρ = 1.205 kg/m^3
Gear ratio	R_n = 1
Equivalent inertia	J_{eq} = 8000 kg.m^2
Rated wind speed	$V_{w\ rated}$ = 12 m/s
Averaging time (conventional method)	T = 6 s
Parameters of PMSG	
Rated power	$P_{g\ rated}$ = 2 MW
Number of poles pair	p = 80
Stator resistance	R_a = 0.1 Ω
Inductance	L = 0.005 H
Field flux	K = 10.68 V.s/rad
Rotational damping	D = 0
Parameters of power converter	
PWM carrier frequency	f_p = 10 kHz
Rated DC-link voltage	$V_{dc\ rated}$ = 7.1 kV

Similarly, as the wind velocity decreases, a discharge of the wind turbine kinetic energy occur, through decrease in turbine rotational speed. Fig. 11(f) shows a comparison of the generator electric torque. The power smoothing method decreases the fluctuation of electric torque significantly as compare with MPPT.

This contributes the reduction of mechanical stress of generator. Fig. 11(g) shows the pitch angle of the wind turbine. Fig. 11(h) shows a comparison of generated output power from the PMSG. From this figure, the proposed method generates smooth output power with high efficiency as compared with conventional method. Both methods are compared with MPPT control method. The conventional method reduced output power significanty when wind velocity becomes steady as compare with MPPT control method.

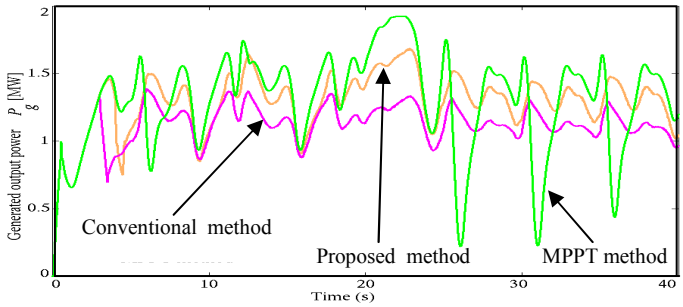
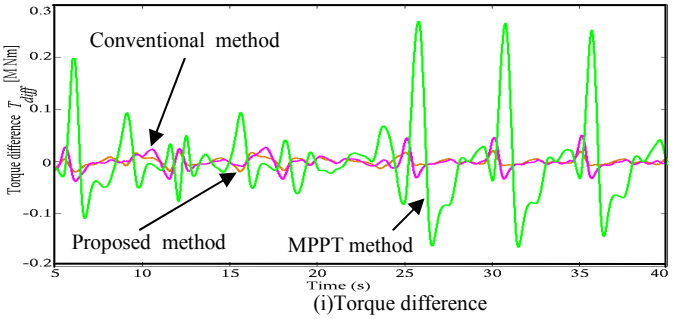
(g) Pitch angle



(h) Output power



(i)Torque difference

Fig. 11 Simulation results

Fig. 11(i) shows the torque difference which is smoothed extensively as compare with MPPT control method. So, it is possible to mitigate the mechanical stress of the shaft in WTCS.

V. CONCLUSION

A fuzzy controller based output power smoothing method of a wind turbine has been proposed in this paper. It is simulated by using an adaptive averaging or integral time which depends on wind velocity and fluctuation of wind velocity. The conventional system is simulated by a constant averaging time (T=6s). If it is lower than 6s, the generated power will be fluctuated like MPPT method. Alternatively, if it is above than 6s, the performance will be more degraded. The propose method is compared with both conventional method and MPPT control method. The fuzzy based propose method can adjust the averaging time and generates efficient output power smoothing. From the simulation results, the overall performance are improved by using our proposed method.

***Abstract*—The formalism of fuzzy cognitive maps as used for the modeling of various dynamical systems is presented with a critical point of view. Various issues related to terminology, concepts, sensitivities, time dependence, iteration procedures, and stability, are systematically considered with critical mind, aiming at making the overall system models be more realistic and useful, and to initiate discussions that can lead to clarifications and to uniformities. Emphasis is given to applications in social, political, economic and engineering systems.**

Keywords-fuzzy cognitive maps.

I. INTRODUCTION

Fuzzy cognitive maps (FCM) have been used to model dynamical systems in diverse fields, such as in computer science (knowledge representation, reasoning, inference, robotics, adaptation, learning, classification,) engineering (controls, robotics, adaptation), production systems (planning), management (decision making, game theory, logistics), medical/health systems (diagnostics, classification), economic/financial systems, education, environment/ecology, social/political/military systems (policy making, social dynamics, conflict resolution) [1-11].

An FCM is a system of interrelated (interconnected) concepts, also found in literature with many other names such as characteristics, factors, parameters, attributes, states, events, actions, values, goals, trends, components, resources. These concepts embed the dynamical cause-effect relationships that model a specific domain of interest.

The strength (or degree of effectiveness) of the interconnecting relations among the various concepts is governed by the degree that a concept *i* affects a concept *j*. These are called by different names in the literature such as sensitivity, weights, causality, etc. Many a times, for better appraisal of the relevant dynamics, they are graphically represented. In this formalism, the concepts are connected through directed graphs. The intensity of the interrelationships is not clearly known, and not agreed by all concerned. Thus, suitable membership functions may be used. By using appropriate systematic process it is possible to estimate the effect of a change in a specific state (concept) on any other concept (or set of concepts) of the system.

Once the parameters have been identified and initialized, the system is allowed to evolve through appropriate simulation procedures. When and if ultimately the system settles, a researcher/user can observe the effects of a change of one factor on the intensity of another. It is pointed that a modeled system may not quasi-settle to finite states, but rather may go through a limit cycle, or even exhibit chaotic behaviour [12, 13].

The work reported here is mainly involved with a critical examination of some various issues related to terminology, concepts, sensitivities, time dependence, iteration procedures, and stability, in relation to proper functioning of the FCMs, aiming at making the overall system models be more realistic and useful. Ultimately, it is hoped to initiate discussions that can lead to clarifications and to uniformities.

Emphasis is given to applications in social, political, economic and engineering systems.

II. THE FCM SYSTEM

An FCM system of n interrelated concepts, which are connected by causal relations, here called sensitivities, may be represented with the following system of equations.

Let the sensitivity relating the changes in the activation of a concept C_j to changes in the activation of a concept C_i be defined by:

$$s_{ij} \equiv \frac{\partial C_j}{\partial C_i} \tag{1}$$

The total accumulated change in the activation of concept C_j due to changes in concepts C_i is then given by:

$$\delta C_j = \sum_{i,i\neq j}^{n} \frac{\partial C_j}{\partial C_i}\delta C_i = \sum_{i,i\neq j}^{n} s_{ij}\delta C_i \quad (2)$$

where,

C is the activation strength of the concept of interest.

s_{ij} is the sensitivity (weight) as defined in equation 1. The way sensitivity is defined here, it implies that it is a measure on how much a change in the current standing of concept C_i affects the changes in the standing of concept C_j.

In discrete time form the above equation becomes:

$$C_j(t+\delta t) = C_j(t) + \delta C_j = C_j(t) + \sum_{i=1}^{n} s_{ij}\left(\delta C_i\right) \quad (3)$$

and in iterative form can be implemented by:

$$C_j(k+1) = C_j(k) + \sum_{i,i\neq j}^{n} s_{ij}\left(C_i(k) - C_i(k-1)\right) \quad (4)$$

where k is the iteration counter.

In most of the published literature, it is more common to represent the FCM systems in a different form, as shown in equation 5.

$$A_j(k+1) = f\left(A_j(k) + \sum_{i,i\neq j}^{n} w_{ij}A_i(k)\right) \quad (5)$$

or,

$$A_j(k+1) = f\left(\sum_{i,i\neq j}^{n} w_{ij}A_i(k)\right) + A_j(k) \quad (6)$$

where,

A is the activation strength of the concept C.

w_{ij} is the weight (sensitivity)

f is a transformation (smoothening) function, usually of sigmoid form.

The above equation is also found in different variants, such as [5]:

$$A_j(k+1) = f\left(A_j(k)\sum_{i,i\neq j}^{n} w_{ij}A_i(k)\right) - d_j A_j(k) \quad (7)$$

where d_j is a decay factor.

It is pointed here that the suggested approach of equation 4 is different than the approach that is followed by most FCM implementations of equation 5 in two important respects:

i) The weights (sensitivities) are defined differently, as previously explained, and

ii) No smoothening activation function f has been used.

The updating is done quasi-statically and interactively until the system evolves to settlement specified by desired boundaries. Any changes in the various concepts affect either directly or indirectly all the other concepts of the system.

III. Important Considerations When Building FCM

The important aspects to be considered when building and implementing FCMs for systems simulations may be organized as follows:

A. Terminology/Nomenclature

B. Model dynamics

C. Concept identification and initial values

D. Sensitivity identification

E. Smoothening functions

F. Time dependence

In the following exposition, these areas are critically examined. Suggestions for improved FCMs are made wherever possible. The various points that are raise are clarified with appropriate examples. It is hoped that discussions will be initiated that can lead to clarifications and to uniformities.

A. Considerations on terminology and nomenclature.

In the relevant literature there have been different names for different features of FCM. The most diversified nomenclature proposed is for the concepts. The numerous terms that have been used for the concepts are mainly reflecting the application at hand. The most common names given are the following: *Concepts, Characteristics, Factors, Parameters, Attributes, States, Events, Actions, Values, Goals, Trends, Components, Resources.* This is not surprising, and it is not a serious problem when it comes to specific applications. For the fundamental theory though, it creates unnecessary confusions, and it is better to adopt a single term. To this end, we propose the adoption of the term ACTION CONCEPTS, as this term encompasses to a large extend those listed before, and is appropriate for many applications in social sciences, engineering and medicine.

Concerning the notation used, there doesn't seem to be a serious problem by using either A for the activations or action concepts (AC), or C for the concept values. As for the interconnecting strengths, we believe that using the symbol s for sensitivity is better than using w for weights, which are more commonly used for the synaptic weights of the neural network paradigms. The term sensitivity will more easily guide the user to establish more realistic values for the interconnecting strengths.

B. Dynamical modeling.

The most commonly used formalism for describing the system dynamics for an FCM are those shown in equation 5, and the occasional variant expressed in equation 6.

We believe that the form of system dynamics as proposed in equation 4 is more appropriate for two main reasons.

i) It is more compatible with the mathematical expression for finite differentials, and

ii) It does not need to use the smoothening function f, that is quite arbitrary, and poorly or even totally unjustified. Of course if one still wants to use a squashing function with equation 4, then it should be modified as shown in equation 8.

$$C_j(k+1) = f\left(C_j(k) + \sum_{i,i\neq j}^{n} s_{ij}\left(C_i(k) - C_i(k-1)\right)\right) \quad (8)$$

C. Establishing the types of action concepts and their initial values.

With respect to this aspect, there is hardly any disagreement that the important AC that need to be incorporated in an FCM system will have to be identified by highly knowledgeable persons (experts in the field(s)). However, there are certain important issues/questions to be raised. Namely,

i) How certain are we that those AC are indeed the most influential and the most appropriate ones to capture the system dynamics? Maybe it is desirable to assign a degree of certainty (or ignorance) to each AC, that will somehow be embedded in the system. Certainly, the more the experts, the better is the realistic model.
ii) Are these AC constant during the whole period of simulation, or some vanish and others may emanate? This is a problem specific issue that needs to be tackled when a specific system is being modeled. However, the relevant equations and algorithms have to be reformulated.
iii) How independent to each other are? The FCM model to a certain extend, captures this interdependence.

Another important issue in relation to the ACs is how and in what scale to establish the initial values of the ACs in the system under study. For socio-economic-political systems, in the systems that we have simulated, we have adopted a scaling from 0 to 100%.

Thus, it seems that there is some room for improvements in this aspect. It is definitely advantageous to receive information from very many different experts, and if needed to get the weight average from their propositions.

Also, it would be most beneficial if a methodology is being developed that will enable a user to check and verify the relevance of the various ACs and their initial values.

D. Establishing the values of the sensitivities connecting the ACs.

This is one of the most crucial aspects of building FCMs. The comments made in *section C* are also valid for this issue.

In addition, there are also some important aspects such as:

i) Do all the experts have same understanding of the terms that are being used? To this end we propose that the sensitivity is defined by equation 1, that specifies the differential contribution of a change in AC i to a change in AC j. For example, for a social system, a 100% increase (doubling) say in nationalism, to how much (%) is it estimated that the risk of conflict will be?
ii) How certain/fuzzy are they, and how to fuzzify/defuzzify them?
iii) Can these relationships be learned? This can be done, provided there is available a large database of passed cases/examples, as is usually the case with some medical system applications.
iv) How to handle conflicting or even mutually exclusive values proposed by the different experts?
v) Who can be considered as an expert? On what basis? Should they be weighted? Should they be eliminated depending on how well they predict?
vi) Can the sensitivities be extracted through automated procedures, e.g. NEFCLASS?

E. Smoothening (or squashing) functions

To us, the use of squashing functions, especially in sociopolitical systems, is quite artificial and not properly justified. In the system we propose there is no such need. In certain systems though, such as in controls, they may serve the purpose that they were meant, i.e to confine the various values to manageable levels.

F. Time dependence

We think that this is one of the most important aspects that has not been given proper attention. Certain observations are being made that will enable us to find ways to tackle this issue:

i) The various AC have different time responses when they are given a certain sudden change (input). Some respond slowly, others faster. For instance, a new law that makes the learning of a foreign language imperative will affect the students' attitudes many years later. Also, there may be a dead time before a system responds to a certain input. Thus, not only is the time constant (exponential time) important, but also the dead time. Some argue that the logistic sigmoid serves this purpose, but this is not the case, because the response in the functionals f that are used for the sigmoids, is instant.
ii) How can time dependencies be incorporated in an FCM?
iii) In what kind of problems and FCM models are the time dependent issues most important?
iv) How about the problems of synchronization that may be important in real systems? How are they captured in a simplistic iterative method?

Considering the above, then for better representation of real system dynamics, each expert could give also information on the dead time and the time constant associating an AC i to an AC j. Such information will also make the understanding of the problem better, thus enabling a better model of the system of interest.

Abstract -- **Falls are dangerous among the elderly population and are a major health concern. Many investigators have reported the use of accelerometers for fall detection. In addition, the use of miniature gyroscopes has also been reported to be able to detect falls, but the effects of sensor placement on the back of a person have not been studied thoroughly. In this paper we present a simple solution for effective fall detection using both an accelerometer and two gyroscopes placed, as a single unit, on three different positions along the thoracic vertebrae (i.e., T-4, T-7, and T-10). Results indicated that T-10 was not a good location for the gyroscope placement for fall detection. However, both T-4 and T-7 were suitable, with the results for T-4 being slightly better. Using a simple rule-based multi-thresholds algorithm that utilizes the recorded resultant gravitational acceleration, angular change, angular velocity, and angular acceleration, we were able to successfully detect all 60 falls and differentiate between falls and activities of daily living (ADL) with no false positives on young volunteers. More testing data is needed, especially for backward falls, to test the robustness of our simple algorithm and to improve the sensor portability for future trial studies on geriatric populations.**

Keywords: accelerometer, activities of daily living (ADL), fall detection, gyroscope, T-4, sensor.

I. INTRODUCTION

Unfortunately, falls are very common among the elderly population, which can lead to high health care costs and mortality [1-3]. After a serious fall has occurred, the fear of future falling can also tax a heavy psychological toll on the patient, leading to functional declines and even eventually limit the person to be placed in an institution for the elderly [4]. Numerous researchers have performed fall detection using body-worn accelerometers [5-7]. Several accelerometer-based fall detection reports use simple threshold values to differentiate between falls and activities of daily living (ADL) for patients. These systems mostly rely on a single threshold value to detect whether an activity is considered as a fall or simply an ADL, therefore are prone to false positives. In addition, an accelerometer-only system cannot measure movements with constant velocities and is limited in its use for serious gait analysis for potential fall *prevention* for any individual patient. Similarly, research has been conducted where gyroscopes were used to detect falls [8-9]. This kind of system has been able to clearly distinguish between falls and ADL using simple threshold-based algorithms, as well as providing more info on gaits. Therefore, we have used both an accelerometer and a gyroscope and placed them together at the same location of a person's back for robust fall detection. Most of the reported accelerometers have been placed near the trunk or the thigh region [5-7] and gyroscopes have usually been placed on the anterior aspect of the trunk [8-9]. Since our interest lies on fall detection of the elderly, it is expected that they would rather have a device on their backs than on the front on their chests [10]. Commercially available systems are available (e.g., SwayStar™ [11]) and are rather effective for gait analysis and with very high resolution (<0.01 degree/sec). However, this system is expensive and not FDA-approved. We hope the devices and algorithms we developed can be used eventually as a low-cost alternative to gait and risk of fall analysis.

II. SENSORS BASICS

Finding a suitable location for the placement of both an accelerometer and gyroscopes as an integrated unit is important, as a single fall-detection sensor can be more wearable and the readings can cross-check each other to better distinguish falls vs. ADL. During our testing three places were considered as regions of interests: T-4, T-7 and T-10 in the thoracic vertebrae as shown in Fig. 1. The sensors were built with commercially available components. The accelerometer used is Freescale semiconductor's MMA7341LC, which has a selectable range of +/-3g or +/-11g. In this work the accelerometer is set to +/-11g. The gyroscopes used are the LPR530AL dual axis gyroscope (pitch and roll) and the LY530ALH single axis gyroscope (yaw); both have a sensitivity of +/- 300 °/sec and are from the ST Microelectronics.

III. METHODOLGY

Team members volunteered to perform the fall trials. They were asked to fall certain ways (e.g., face first, left side, right side) multiple times per condition to improve the statistical power. The same team members also performed ADL wearing the same sensors shown in Fig. 2.The falls were conducted using three team members falling onto two large stacked 4" thick therapy mats. The team members ranged from 22 to 28 years of age. Each test was repeated five times. Both the gyroscope data and the accelerometer data were collected from the sensors using the National Instruments NI-DAQ™ USB 6009. Matlab™ was used as the main program for both gathering the data as well as data processing. To conduct the fall tests, data was continuously read with the NI-DAQ™ at a sampling rate of 1 kHz. Similarly, ADL were also recorded using the sensors shown in Fig. 2. Since the main idea was to select an optimal location for the placement of the sensors for fall detection, all tests were conducted for all three regions where the sensors are placed (i.e., T-4, T-7 and T-10) and then analyzed. The tests conducted were similar to those reported by Bourke (6,9). In this prototype study, sensors are not tested on any geriatric cohort.

IV. RESULTS

Using the data recorded from the accelerometer and the gyroscopes, a simple rule-based multi-thresholds algorithm was developed to calculate the gravitational acceleration, the angular velocity and the angular acceleration (i.e., the derivative of angular velocity) recorded by the sensors. All these three parameters were calculated for all fall and ADL as shown in Fig. 3. Note that during falls and ADL only the peak values are plotted here. The use of the peak values is important because sometimes the peak value may not always happen during the exact time of the fall but may be occurring slightly afterwards. For example, the accelerometer might record a high value when the subject is about to sit down but the gyroscope will record a high value when the subject is fully upright on the chair. We have, therefore, allowed a freedom of 300ms across the peaks of the accelerometer and gyroscope data. For example if we detect a peak in the accelerometer data at 3.4 s, we will check the gyroscope data between 3.1 to 3.7 seconds to detect a peak in the gyroscope data and vice-versa.

The results from the falls and ADL are shown in Figure 3. We have recorded data from several different falls: falling forward (FF), falling sideways (FS), falling forward knee flexion (FF KF), falling sideways to the right (FSR), and falling sideways to the left (FSL). For ADL we have recorded when the subject is sitting down in a chair, when standing up, and when walking with a norm speed. Looking at the data we can clearly see that T-10 is the worst location for the sensors placement, since there is a large overlap between the highest recorded values for ADL and the lowest recorded values for falls. T-7 and T-4 regions can be used since from the recorded data we can distinguish falls from ADL; however, when we examine the highest recorded values of ADL vs. the lowest recorded values of falls, T-4 sensors data generally exhibits a slightly larger separation with better distinction. For example, the lowest recorded value of falls by the gyroscope was 2.74 rad/sec and of the highest recorded ADL was 2.5 rad/sec when sensors are placed at the T-4 region, while for the T-7 region the highest recorded value of the ADL was 2.34 rad/sec and the lowest value of falls was 2.38 rad/sec. Therefore, T-4 should be close to the optimal location when we place both the integrated 3D gyroscope with the 3D accelerometer at the back for fall detection.

From the data collected, the minimum threshold values for falls were determined for the case of T-4 placement. The equations used to calculate the resultant gravitational acceleration, angular velocity, angular acceleration and total angular change are given below.

$$Resultant\ Gravitational\ Acc. = \sqrt{A_x{}^2 + A_y{}^2 + A_z{}^2}$$

$$Resultant\ Angular\ Velocity = \sqrt{x^2 + y^2 + z^2}$$

$$Resultant\ Angular\ Acc. = \sqrt{(\frac{d}{dt}x)^2 + (\frac{d}{dt}y)^2 + (\frac{d}{d}(z)^2}$$

$$Total\ Angular\ Change = \sum\sqrt{x^2 + y^2 + z^2}$$

The threshold values are set as 2.73g for the accelerometer, 2.74 rad/sec for the resultant angular velocity and 0.04 rad/sec^2 for the resultant angular acceleration. Using these threshold values we were able to distinguish between falls and ADL successfully. From Fig.4, one can see that the data of ADL(i) did not exceed any threshold values (red dashed lines), so it cannot be classified as a fall. For ADL(ii) and Fall(i) shown in Fig. 4, one can see that their angular acceleration are close to each other. Since we also calculate the thresholds of the resultant gravitational acceleration and the resultant angular velocity, and that ADL(ii) only has its angular acceleration close to its threshold, it can not be classified as a fall.

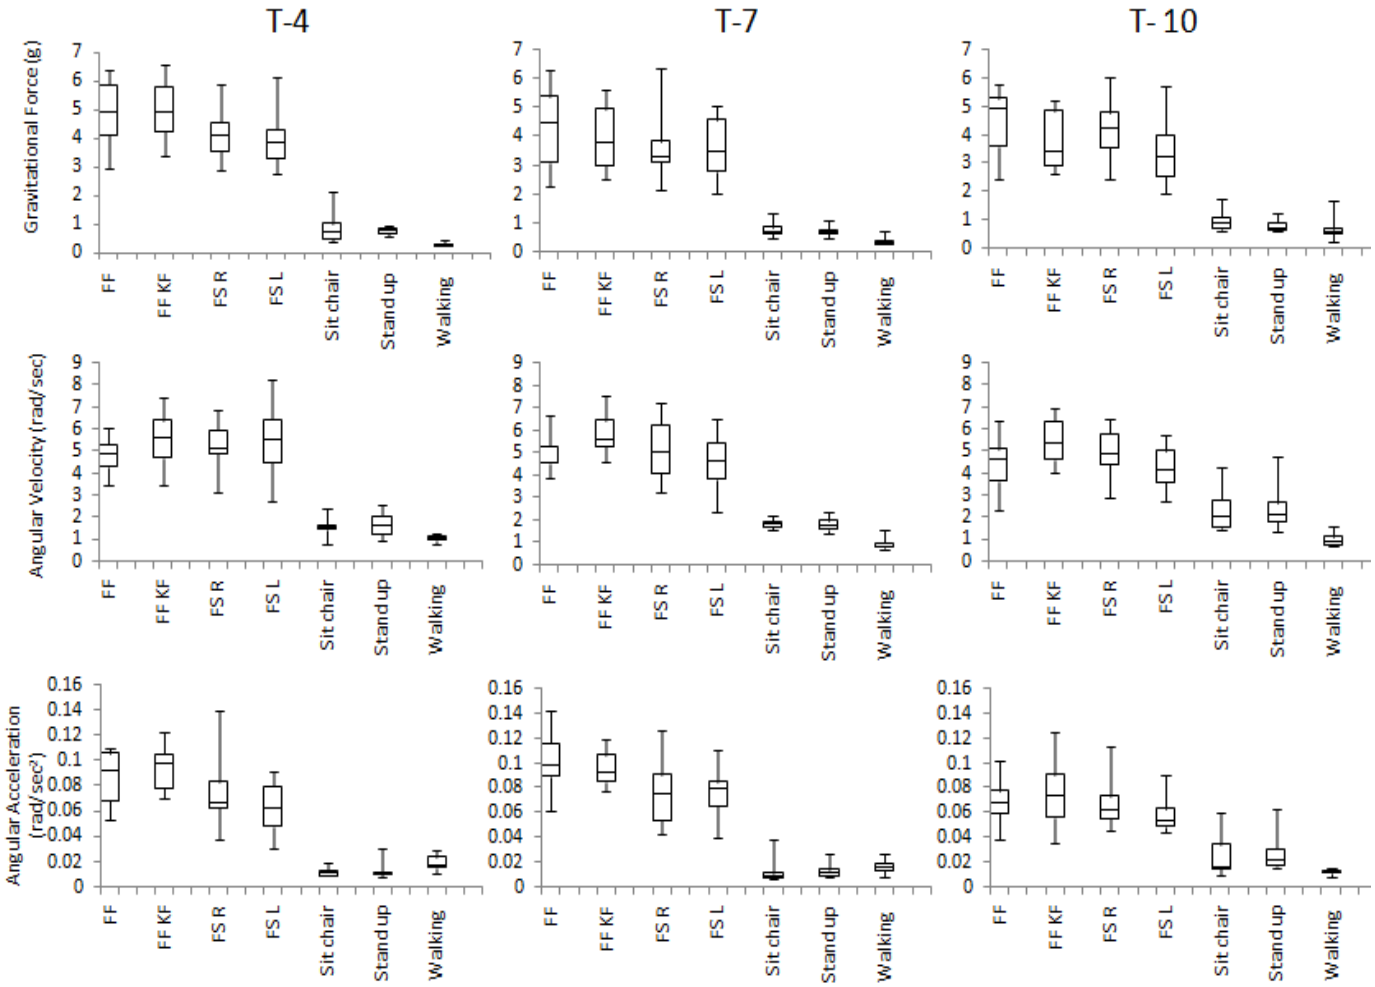

Figure 3: Box plots showing the peak values of measured acceleration, angular velocity and angular acceleration at T-4, T-7 and T-10 for different falls and ADL. FF: Falling Forward, FS: Falling Sideways, KF: Knee Flexion, R: Right, L: Left. The upper edge of each box indicates the 75th percentile of the data value and the lower edge of the box plot indicates the 25th percentile of the data value. The line inside each box indicates the median. The ends of the vertical lines indicate the maximum and the minimum values of each dataset (i.e., the data range).

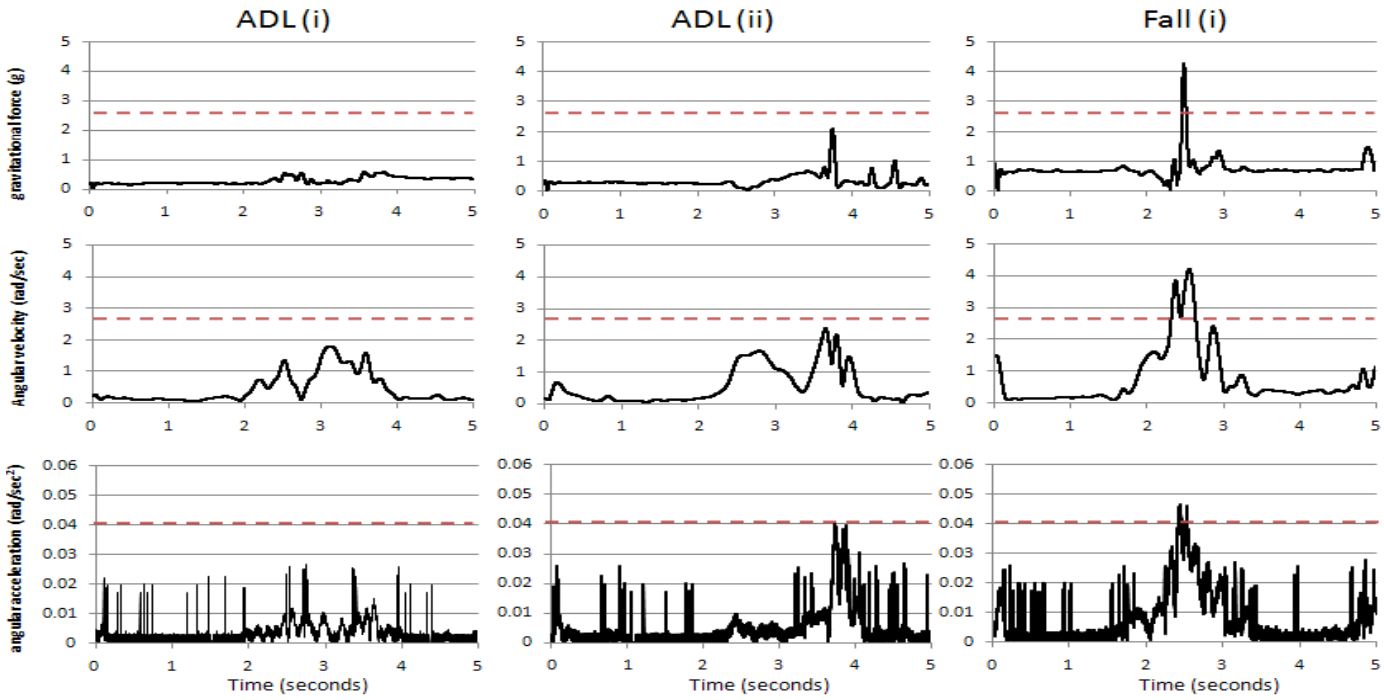

Figure 4: The resultant gravitational acceleration, angular velocity and angular acceleration from several ADL cases. (Left): ADL(i), an ADL that did not exceed any thresholds; (MIDDLE): ADL(ii): an ADL that has only the angular acceleration close to the threshold; and (RIGHT): Fall (i). Note if the sensor data exceeds all three threshold values, it will automatically be classified as a fall.

Note in our initial algorithm, if *all three thresholds* are exceeded, it will automatically be classified as a fall. However, after considering an actual fall case where the sensed data only exceed two threshold value but not three thresholds, we have improved our algorithm by using additional thresholds from the angular changes from the gyroscope data. Fig. 5 shows a flowchart of our simple but effective thresholds-based fall detection algorithm. Note here we also used the total angular change threshold and the thresholds of each axial angular orientation (i.e., the 3 angular changes in the individual axes) in our fall detection algorithm. Here the threshold value for the resultant total angular change was set to be 31° (i.e., "Th4" in Fig, 5). To detect a person falling, a threshold value of -21° in the y-axis is used (i.e., "Th6" in Fig, 5). Similarly, after taking the absolute value of the data from the X-axis, a threshold value of 25° was set (i.e., "Th5" in Fig, 5) and the threshold for angular change in the Z-axis was 21° (i.e., "Th7" in Fig, 5). In this manner, we were able to successfully detect all falls. It needs to be noted that angular change should be used along with other thresholds from the angular acceleration and gravitational force experienced by the sensors. For example, there was one fall case where angular change did not go above any of the threshold values; however, using the entire set of the 4 threshold values, all 60 falls were successfully detected within 2 seconds with no false positives, as will be explained next.

Let us look at these realistic scenarios we encountered: there is one measured fall data that has a peak value of 2.7g, below the gravitational acceleration threshold value of (2.73g); and there is a 2nd fall data that has a peak value of 2.7rad/sec, below the angular velocity threshold of 2.74rad/sec. If we consider a total of 60 falls, and calculate the fall detection sensitivity for this 1st case (Table I, 1st row), we can see that if we use the accelerometer threshold only we will miss detecting this 1st fall and achieve 98.33% sensitivity. Similarly if we use the angular velocity as the only threshold we will miss detecting the 2nd fall and achieve 98.33% sensitivity. Now if we use both the gravitational acceleration and the angular velocity thresholds, the fall detection sensitivity will drop even further because now two falls are not detected since they do not pass both of the two threshold values (i.e., sensitivity of 96.33% in Table I). However, if we take into accounts of the gravitational acceleration, angular velocity, angular acceleration and total angular change as the threshold values (i.e., Th1, Th2, Th3, Th4), and if we consider an event as a fall where as long as three out of the four thresholds have been exceeded, we are able to achieve 100 percent sensitivity as shown in Table 1. Similarly, if we use four out of seven threshold values, we can achieve 100 percent sensitivity as well. Using this simple algorithm that considers all 7 thresholds as shown in Fig. 5, 100 percent specificity is obtained for these 60 falls. More fall data is needed to improve the robustness of the threshold values selection and specificity.

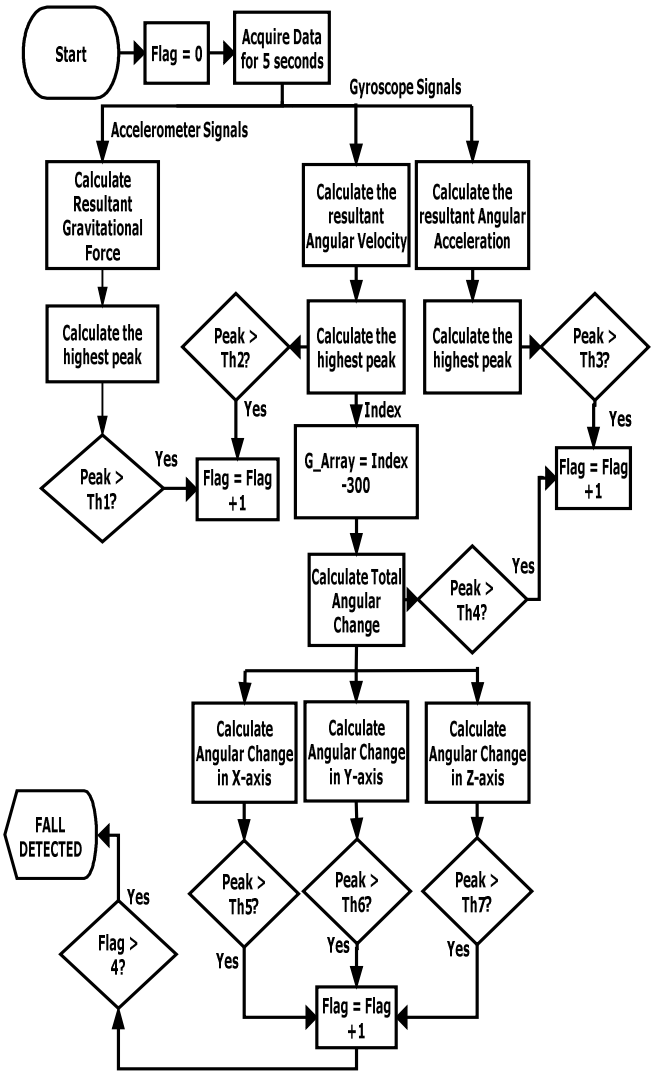

Figure 5: A flowchart of our rule-based multi-thresholds algorithm for fall detection. Th1: accelerometer threshold; Th2: angular velocity threshold; Th3: angular acceleration threshold; Th4: total angular change threshold; Th5: angular change in the X-axis threshold; Th6: angular change in the Y-axis threshold; Th7: Angular change in the Z-axis threshold.

Table I: Fall detection sensitivity percentage obtained using our simple rule-based multi-thresholds algorithm from sensors mounted at T-4.

Different Thresholds to Classify Falls	**Sensitivity (%)**
Accelerometer (Th1) only	98.33
Angular velocity threshold (Th2) only	98.33
Angular acceleration threshold (Th3) only	100
Two thresholds together (Th1, Th2)	96.66
Two thresholds together (Th2,Th3)	98.33
Three thresholds out of four (Th1, Th2, Th3, Th4)	100
Four thresholds out of seven (Th1, Th2, Th3, Th4, Th5, Th6, Th7)	100

V. CONCLUSION AND FUTURE WORK

Placing both the 3-D accelerometer and 3-D gyroscope sensors in different locations on a person's back, we were able to find a suitable location for the concurrent placement of our sensors close to the T-4 region. We also developed a simple thresholds-based algorithm by calculating the gravitational force, the resultant angular velocity, the resultant angular acceleration, etc. In this manner, all 60 falls were successfully detected and with no false positives. In our fall detection algorithm we use the threshold values from the gravitational force, angular velocity and angular acceleration along with the resultant angular change and the angular change of each individual axis. If an event exceeds 4 or more threshold values, then the event will be classified as a fall. Using this simple algorithm we have accomplished a sensitivity of 100 percent with no false positives on young volunteers. Table II shows the summary of our prototype system's preliminary test results on young volunteers compared with other fall detection systems reported.

Presently, the system collects 5 seconds of data and the analysis is later done in MatLab™. This data analysis can be further improved by using real-time software like LABVIEW™ and with wireless transmission and smaller fixture size. It can also be improved by creating an adaptive algorithm along with a height and weight profile to automatically calculate the necessary threshold values for each individual. Therefore, more data needs to be collected, including additional falls (especially backwards falling data that is lacking here in this work) and other activities of daily living. Please note that younger subjects were used in this present work as proxies for older persons as a study limitation. After the data collected on young volunteers demonstrates our sensors and algorithms are effective and robust, we will start conducting testing on a more appropriate cohort using our system.

Table II: Summary and comparison of our system with other fall detection systems.

Paper	Accelero-meter	Gyro-scope	Specificity (%)	Fall Dataset	Placement of sensors
[6]	2	0	100	240	Trunk and Thigh
[8]	2	2	92	70	Chest and Thigh
[9]	0	1	100	240	Sternum

***Abstract* - AHP (Analytic Hierarchy Process) has been widely used in a domain of decision making, and there are a lot of extensions using fuzzy measure and integrals. In the previous research, we propose a kind of sensitivity analyses for AHP or fuzzy measure AHP, because it often occurs that data of AHP loses its reliability. In other words a comparison matrix there in does not always have enough consistency. Also in these cases, the authors propose one representation for weights using results from the sensitivity analysis. In this paper we refine fuzzy weights representation for fuzzy measure AHP. It can show how results of (fuzzy) AHP have fuzziness when the comparison matrix does not have relatively good consistency.**

Keywords-decision making; AHP; fuzzy measure; fuzzy sets; sensitivity analysis

I. INTRODUCTION

The AHP was proposed by Saaty, T.L. in 1977 [2], [3], and it has been widely used in a field of decision making since it includes the natural feelings of human. Normalized eigenvector that corresponds to a Frobenius root of comparison matrix is usually used as weight.

On the other hand, fuzzy measure AHP [4], an extension of the normal AHP, allows us to obtain two types of decisions by use of fuzzy measure. Substitutive and complementary properties are considered in the method.

However, it often occurs that data of fuzzy measure AHP loses its reliability, because a comparison matrix does not always have consistency. The consistency of a comparison matrix A is usually measured by the following consistency index

$$\text{C.I.} = \frac{\lambda_A - n}{n-1} \tag{1}$$

where n is the order of matrix A, and λ_A is its Frobenius root. In these cases, it is very important to investigate how components of a pairwise comparison matrix influence on its consistency or on weights. The sensitivity analysis[5] is useful to investigate them. In this study, the authors apply a sensitivity analysis for fuzzy measure AHP that some of the present authors have proposed before [6]. It evaluates a fluctuation of the consistency index and weights, when a comparison matrix is perturbed. Moreover, we suppose that answers from a decision-maker have ambiguous or fuzziness in these cases. Therefore, it is natural for the weights to be represented by fuzzy sets. Then, we refine the representation by use of results from the sensitivity analysis and fuzzy sets operations.

II. NON-ADDITIVE WEIGHTS OF AHP

Since the weights of criteria in AHP are normalized as their sum becomes 1, it can be regarded as additive measure similar to the probability measure. Because of the additive property of the weights, substitutive and complementary evaluations are not considered in the normal AHP. The substitutive evaluation prefers an alternative that is particularly excellent, and the complementary evaluation prefers one with as few defects as possible. Further, reversals of priority orders can occur due to the addition of a similar criterion.

Meanwhile, with fuzzy measure AHP[4], we can obtain two types of decisions using the possibility measure and the necessity measure that are non-additive fuzzy measure. Substitutive and complementary decisions are considered in it. Results from the normal AHP can be regarded as the midway evaluation between substitutive and complementary. Moreover, the reversals of the priority orders due to the addition of a similar criterion are mitigated.

Let x_i and $\boldsymbol{w}=(w_i)$ $(i=1,\ldots, n)$ denote criteria and their weights, y_p $(p=1,\ldots,m)$ be the alternatives, and $f_p(x_i)$ be a weight of x_i with respect to y_p. In the normal AHP the weight $\boldsymbol{w}$ is normalized as their sum of components becomes 1. But in fuzzy measure AHP, $\boldsymbol{w}$ is considered to be possibility measure (or necessity measure). Therefore, w_i is regarded as the degree of importance expressed by possibility (or necessity) measure of the i-th criterion. Weight $\boldsymbol{w}$ is eigenvector as in normal AHP, however the conditions are $0 \leqq w_i \leqq 1$, and $\exists i$, $w_i=1$. Weights $f_p(x_i)$ only satisfy $0 \leqq f_p(x_i) \leqq 1$. When w_i takes q values $r_1 < r_2 < \ldots < r_q = 1$, we can make a set A_l such as

$$A_l = \{x_i \mid w_i \geq r_l\}, \quad (l = 1,\ldots,q) \tag{2}$$

Thus, the basic probability assignment of A_l becomes

$$m(A_l) = r_l - r_{l-1} \tag{3}$$

where $r_0=0$. The upper limit expectation E^* based on possibility measure and the lower limit expectation E_* based on necessity measure are found as follows

$$E_p^* = \sum_l^q m(A_l) \max_{x \in A_l} f_p(x), \quad (4)$$

$$E_{*p} = \sum_l^q m(A_l) \min_{x \in A_l} f_p(x). \quad (5)$$

Accordingly, the most preferable alternatives are

$$y^* = \{y_p \mid \max_p E_p^*\},$$

$$y_* = \{y_p \mid \max_p E_{*p}\}.$$

If a decision-maker desires a substitutive decision, then y^* is acceptable. And if he or she prefers a complementary decision, y_* is acceptable.

It should be noted that weights of alternatives y^* and y_* in fuzzy measure AHP are not fuzzy value but crisp, although fuzzy measure is used.

III. Sensitivity Analyses

When we actually use AHP, it often occurs that a comparison matrix is not consistent or that there is not great difference among the overall weights of the alternatives. In these cases, it is very important to investigate how components of the pairwise comparison matrix influence on its consistency or on the weights. To analyse how results are influenced when a certain variable has changed, we can use sensitivity analysis.

In this study, we use a method that some of the present authors have proposed before. It evaluates a fluctuation of the consistency index and the weights when the comparison matrix is perturbed. It is useful because it does not change a structure of the data.

Since the pairwise comparison matrix is a positive square matrix, Perron-Frobenius theorem holds [1]. From Perron-Frobenius theorem, following theorem about a perturbed comparison matrix holds.

Theorem 1 *Let $A = (a_{ij})$, $(i, j = 1, \ldots, n)$ denote a comparison matrix and let $A(\varepsilon) = A + \varepsilon D_A$, $D_A = (a_{ij} d_{ij})$ denote a matrix that has been perturbed. Let λ_A be the Frobenius root of A, $\boldsymbol{w}$ be the eigenvector corresponding to λ_A, and $\boldsymbol{v}$ be the eigenvector corresponding to the Frobenius root of A'. Then, a Frobenius root $\lambda(\varepsilon)$ of $A(\varepsilon)$ and a corresponding eigenvector $\boldsymbol{w}(\varepsilon)$ can be expressed as follows*

$$\lambda(\varepsilon) = \lambda_A + \varepsilon \lambda^{(1)} + o(\varepsilon), \quad (6)$$

$$\boldsymbol{w}(\varepsilon) = \boldsymbol{w} + \varepsilon \boldsymbol{w}^{(1)} + \boldsymbol{o}(\varepsilon), \quad (7)$$

where

$$\lambda^{(1)} = \frac{\boldsymbol{v}' D_A \boldsymbol{w}}{\boldsymbol{v}' \boldsymbol{w}}, \quad (8)$$

$\boldsymbol{w}^{(1)}$ is an n-dimension vector that satisfies

$$(A - \lambda_A I)\boldsymbol{w}^{(1)} = -(D_A - \lambda^{(1)} I)\boldsymbol{w}\ , \quad (9)$$

where $\boldsymbol{o}(\varepsilon)$ denotes an n-dimension vector in which all components are $o(\varepsilon)$.

About a fluctuation of the consistency index, following corollary can be obtained from Theorem 1.

Corollary 1 *Using appropriate g_{ij}, we can represent the consistency index* C.I.(ε) *of the perturbed comparison matrix $A(\varepsilon)$ as follows*

$$\text{C.I.}(\varepsilon) = \text{C.I.} + \varepsilon \sum_i^n \sum_j^n g_{ij} d_{ij} + o(\varepsilon). \quad (10)$$

To see g_{ij} in the equation (10) in Corollary 1, how the components of a comparison matrix impart influence on its consistency can be found.

A. Analysis for weights of normal AHP

About the fluctuation of the weights, following corollary also can be obtained from Theorem 1.

Corollary 2 *Using appropriate $h_{ij}^{(k)}$, we can represent the fluctuation $\boldsymbol{w}^{(1)} = (w_k^{(1)})$ of the weight* (*i.e. the eigenvector corresponding to the Frobenius root*) *as follows*

$$w_k^{(1)} = \sum_i^n \sum_j^n h_{ij}^{(k)} d_{ij}. \quad (11)$$

From the equation (7) in Theorem 1, the component that has a great influence on weight $\boldsymbol{w}(\varepsilon)$ is the component which has the greatest influence on $\boldsymbol{w}^{(1)}$. Accordingly, from Corollary 2, how components of a comparison matrix impart influence on the weights, can be found, to see $h_{ij}^{(k)}$ in the equation (11).

Calculations or proofs of these theorem and corollaries are shown in [8].

B. Analysis for fuzzy measure AHP

About the fluctuation of the basic probability assignment, following corollary also can be obtained from corollary 2..

Corollary 3 *Using appropriate $e_{ij}^{(k)}$, we can represent the fluctuation $m(A_l)^{(1)}$ of the basic probability assignment as follows*

$$m(A_l)^{(1)} = \sum_i^n \sum_j^n e_{ij} d_{ij} + o(\varepsilon) \quad (12)$$

(Proof)

Let $\boldsymbol{w}(\varepsilon) = (w(\varepsilon)_i)$, $(\max w(\varepsilon)_i = 1)$ be the eigenvector that corresponds to the Frobenius root of the perturbed comparison matrix $A(\varepsilon)$. It is possible to replace the elements as arranged the order from the smallest. When $w(\varepsilon)_i$ takes q values $r(\varepsilon)_1 < r(\varepsilon)_2 < \ldots < r(\varepsilon)_q = 1$, from formula (2) the basic probability assignment is

$$m(A_l)(\varepsilon) = r(\varepsilon)_l - r(\varepsilon)_{l-1} \quad (13)$$

$$r(\varepsilon)_0 = 0, \quad (l = 1,...,q)$$

and from Corollary 2, it can be expressed as

$$m(A_l)(\varepsilon) = m(A_l) + \varepsilon \sum_i^n \sum_j^n (h_{ij}^{(l)} - h_{ij}^{(l-1)}) d_{ij} + o(\varepsilon) \qquad (14)$$

However, different from the proof of corollary 2 of normal AHP, we should be careful that the standard of the calculation of $h^{(l)}_{ij}$ is w_t=0, where t is satisfied max $w_i = w_t$.

(Q.E.D)

Following theorem can be obtained from the process of fuzzy measure AHP and Corollary 3.

Theorem 2 *Let $A = (a_{ij})$, $(i, j = 1,..., n)$ be a comparison matrix and E^*_p $(p= 1,...,m)$ be the overall weight of the p-th alternative be. Let E^*_p (ε) denote weight of the p-th alternative based on a perturbed comparison matrix $A(\varepsilon) = A+ \varepsilon D_A$, $D_A=(a_{ij}d_{ij})$. Then using appropriate $z_{ij}^{(p)}$, weights $E^*_p(\varepsilon)$ is represented as*

$$E^*_p(\varepsilon) = E^*_p + \varepsilon \sum_i^n \sum_j^n z_{ij}^{(p)} d_{ij} + o(\varepsilon). \qquad (15)$$

(Proof)
Let $f_p(x_i)$ denote weight of the criterion x_i of alternative p. From equation (4) and Corollary 3, the upper limit expectation (substitutive evaluation value) becomes as follows.

$$E^*_p(\varepsilon) = E^*_p + \varepsilon \sum_i^n \sum_j^n \{\sum_l^q (h_{ij}^{(l)} - h_{ij}^{(l-1)}) \max_{x \in A_l} f_p(x)\} d_{ij} + o(\varepsilon) \qquad (16)$$

Accordingly, the fluctuation part of the weight of the alternatives is also expressed by the linear combination of d_{ij}.
(Q.E.D)

From Theorem 2, the component of the comparison matrix that has the greatest influence on weight $E^*_p(\varepsilon)$ can be found. In a complementary case, evaluation also becomes possible with a similar way.

IV. Fuzzy Weights Representations

It often occurs that data of fuzzy measure AHP loses its reliability, when a comparison matrix has not so good consistency (i.e. 0.1<C.I.<0.2). In these cases, we consider that components of a comparison matrix of criteria have fuzziness, because they are results from fuzzy judgement of a decision-maker. Therefore weights could be treated as fuzzy sets. Here, to represent fuzziness of weights of alternatives, we use L-R fuzzy number.

The multiple of coefficients $g_{ij}z_{ij}^{(p)}$ found in Corollary 1 and Theorem 2 is considered as the influence concerned with a_{ij} from the fluctuation of the consistency index.

Since g_{ij} is always positive, if the coefficient $z_{ij}^{(p)}$ is positive, the real weight of alternative p is considered as bigger than E^*_p, and if $h_{ij}^{(k)}$ is negative, the real weight of criterion k is considered as smaller. Therefore, a sign of $z_{ij}^{(p)}$ represents a direction of a spread of the fuzzy number. Of course the absolute value $g_{ij}|z_{ij}^{(p)}|$ represents the amount of the influence.

On the other hand, C.I. becomes bigger then the judgement becomes fuzzier.

Consequently, multiple C.I. $g_{ij}|z_{ij}^{(p)}|$ can be regarded as a spread of a fuzzy weight $\widetilde{E}^*_p$ concerned with a_{ij}.

Definition (fuzzy weights for fuzzy measure AHP) *Let E^*_p be the crisp weight of alternative p in fuzzy measure AHP using possibility measure. g_{ij}, $z_{ij}^{(p)}$ denote the coefficients found in Corollary* 1 *and Theorem* 2 and C.I. *denotes consistency index of the comparison matrix of the criteria. When* C.I.<0.2 *holds, a fuzzy weight $\widetilde{E}^*_p$ is defined by*

$$\widetilde{E}^*_p = (E^*_p, l_p, r_p)_{LR} \qquad (17)$$

where

$$l_p = \text{C.I.} \sum_i^n \sum_j^n s(-, z_{ij}^{(p)}) g_{ij} |z_{ij}^{(p)}|, \qquad (18)$$

$$r_p = \text{C.I.} \sum_i^n \sum_j^n s(+, z_{ij}^{(p)}) g_{ij} |z_{ij}^{(p)}|, \qquad (19)$$

$$s(+, z) = \begin{cases} 1 & (z > 0), \\ 0 & (z \le 0), \end{cases}$$

$$s(-, z) = \begin{cases} 0 & (z > 0), \\ 1 & (z \le 0). \end{cases}$$

We can calculate the fuzzy weights of alternatives in fuzzy measure AHP using Definition 1. They show how the result from fuzzy measure AHP has fuzziness. In a complementary case, it is also possible to represent with a similar way.

And this definition can be used when weights of the alternatives with respect to criterion is also fuzzy number weights, even if comparison matrices of alternatives do not have enough consistency.

V. Conclusions

We propose one representation of the weights of fuzzy measure (non–additive weight) AHP by use of fuzzy sets and the result of the sensitivity analysis. It will be useful for case for the cases that consistency of a comparison matrix is not so good. It was refined from our old representation. It can show not only how to represent weights, but also how the result from the fuzzy measure AHP has fuzziness, especially when some bad consistency exists.

***Abstract*—In recent years, knowledge management has become an important issue for many organizations to boost their intellectual capital and business performance. Rather than the emphasis of system functions, a social cognitive model is proposed to examine the associations among members' cognition, interpersonal relationships, and their knowledge contribution behavior. The research results demonstrate that the online members' outcome expectancy, personal efficacious beliefs, as well as the strength of online ties among online peers, have positive and direct influence on their knowledge contribution behavior. Moreover, the mediating effects of outcome expectancy and self-efficacy are both significantly proved on members' engagement in knowledge contribution.**

Keywords-knowledge contribution, outcome expectancy, self-efficacy, knowledgecontribution satisfaction, strength of ties

I. INTRODUCTION

An online community, established and developed through information and computer technology, is composed of individuals with the same goals or similar needs. This new type of interpersonal networks have impact on activities like retrieving and using of community resources, taking collective actions, seeking emotional comfort, and developing working strategies [1, 2]. Even though the benefit of knowledge management has been widely recognized, information technology is not a solution to all problems. Behavior of learning and knowledge sharing has to be interactively adjusted among personal beliefs and the environment [3, 4]. knowledge management is not an objective and individual phenomenon in an organization [5], but is embedded in the close connection among individuals, environment and behaviors that are constantly under the influence of social background, system regulations and interpersonal interactions [3, 6, 7].

The purpose of this research expects to demonstrate the reciprocal relationships among individuals' cognition and affection toward knowledge contribution engagement. In this paper, we focus on the social cognitive and interpersonal relationship perspectives to explore individuals' outcome expectation toward online knowledge community participation, personal efficacious beliefs and satisfaction in knowledge contribution, as well as members' relational ties emerged in the online environment, where the knowledge contribution behavior further arises.

II. THEORETICAL BACKGROUND AND RESEARCH HYPOTHESES

A. Outcome Expectancy

According to Vroom's expectancy theory, the reason why an individual takes certain action is not just because of his special likes, but also depends on his judgment on the possibility of expected results [8]. An outcome expectation indicates the judgment of the likely consequences that one specific action will produce [9]. The attractiveness and expectancy of goal attainment would affect an individual's determination and promise to achieve certain goals, by making effort to fulfill the goal and would not give up easily [10]. Behavior of knowledge contribution comes from the expectation and satisfaction with extrinsic rewards and reciprocal relationships [11]. Only when they are certain that sharing can create other benefits, like monetary rewards, respect from others, or contribute to maintaining reciprocal relationships with others will knowledge sharing be smoothly processed. People think that they can actually fulfill some kind of expectation and benefits through the sharing and reuse of knowledge, they will be encouraged to participate in related activities [12], such as acquiring new knowledge, getting recreation and entertainment, enhancing interpersonal communication, promoting professional skills, and enhancing closeness of family.

According to perspective of public good, an individual's willingness to share knowledge with others is considered to be the collective benefits of the social community but not their own profits [3, 13]. Through sharing and solving other people's problems, one feels pleasant and recognizes the value of oneself. Besides, the "perceived enjoyment" (PE) has a significant influence on the willingness to use work-related information systems [14]. In terms of knowledge contribution of online communities, the sharing and communication of both information resources and knowledge skills not only help with

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

the execution of tasks, but the contents and process of the sharing may also include interactive pleasure and emotional support [1, 15]. Finally, self-actualization – the highest level in Maslow's hierarchy of need theory, refers to how an individual does what he wants to do, demonstrates the inner potentials, equips oneself with creativity and adjustability, faces challenge and grows aggressively according to self-awareness [16]. Bandura argues that how an individual considers an activity with rewarding values derives from self- satisfaction after actualizing his personal achievement, which is even more meaningful than substantial monetary rewards [17]. Hendriks [18] and Andriesses [19] argue that the actualization of personal achievement and values is the primary factor of the willingness to knowledge sharing.

From all of the above discussion about one's outcome expectancy of altruistic good, hedonic expectancy, and value of self-actualization, the first hypothesis can be raised from this research:

H1: The outcome expectancy of knowledge contribution has a direct and positive influence on knowledge contribution behavior.

B. Self-Efficacy

The concept of self-efficacy refers to the judgment on one's capabilities for completing specific task, further affecting what kind of strategic move to plan, how much efforts to put in, the persistence when they encounter obstacles and adversities, the capability of recovery and the feasibility of achieving anticipated objectives. Many studies have proved the significant effect of self-efficacy on the performance in various settings, such as workplace, health management, and educational development. Caprara and others [20] have demonstrated the influence of teachers' self-efficacy beliefs on their satisfaction with teaching and students' learning achievement. In terms of related researches on self-efficacy and knowledge management, Bock & Kim [21] point out that an individual's judgment on whether he can make the expected contribution is a key issue that affects how he processes knowledge management activities in an organization. When organizational employees think they have the ability to contribute to better performance and target achievement, they hold a more positive and affirmative attitude toward knowledge contribution.

In the discourse of social cognitive theories, Bandura further points out that outcome expectancy is an important factor that affects on whether certain behavior can produce certain results, and the levels of efficacy belief are different for the anticipation of behavioral outcome [17]. People with higher self-efficacy believe that their action can lead to good results; therefore, it is positive and stimulating in actual action to achieve the desired outcome. In the field of information management, the relationship between self-efficacy and outcome expectancy is verified that people with higher self-efficacy expect to use ICT to increase other people's recognition in one's ability, enhance one's sense of achievement with work, and have chances of getting a job promotion [22, 23]. Then, the outcome expectancy has a significant influence and explanation to the intention of utilizing information systems.

Based on the above-mentioned argument concerning how self-efficacy affects the behavior and the relationship between individual's self-efficacy and outcome expectancy, we raise the following two hypotheses:

H2: The self-efficacy of knowledge contribution has a direct and positive influence on knowledge contribution behavior.

H3: The self-efficacy of knowledge contribution has a direct and positive influence on the outcome expectancy of knowledge contribution.

C. Knowledge Contribution Satisfaction

User satisfaction indicates that how individuals compare the actual performance of a service or product with prior expectation. When they feel satisfied with the service or product, he can be prompted to continue to use it. Alavi et al. [24] indicate that satisfaction is a useful indicator to evaluate learning effectiveness derived from instructions and assistance from other users. Within the realm of knowledge management practice, the facilitation of individuals' satisfaction with knowledge management also becomes a critical cognitive dimension to evaluate the state of organizational knowledge management [25, 26]. An individual's perceived knowledge satisfaction, instead of the objective assessment of knowledge effectiveness, constitutes an essential element of one's access to the resources and the personal commitment to greater knowledge contribution for the reciprocal or future exchange within their social group [27, 28]. Accordingly, we propose the following hypothesis,

H4: The user satisfaction with online knowledge community has a direct and positive influence on knowledge contribution behavior.

Individuals' satisfaction derived from the successful experience can increase their self-efficacy perception from a sense of personal fulfillment, reflecting the degree to how well they feel capable of completing the specific task [17]. Based on the positive perceptions and self-efficacy beliefs toward the learning program and expected outcome of ICT utilization [29-31], our study also attempts to examine the relationship between satisfaction and self-efficacy regarding knowledge contribution in the online community. Thus, the hypothesis is proposed as follows,

H5: The user satisfaction with online knowledge community has a direct and positive influence on knowledge contribution self-efficacy.

D. Online Ties

According to social capital theory, the establishment and maintenance of social relations help individuals obtain the power to get resources available with his identity as a member of the social network [32-34]. Granovetter [35] identifies the social relations as strength of ties, which reflect intensified, emotionally oriented and reciprocal relationship, continue to

Identify applicable sponsor/s here. *(sponsors)*

offer reliable support and speed up the flow of information to resolve the conflicts, crisis, or uncertainties that the members face in the social environment [36, 37]. The mutual experience, goal-setting, resources exchange and emotional support among members can invoke creativity and learning efficiency, as well as boost the production and application of intellectual capital [38]. Through the special properties of online environment which is unconfined by space or time and facilitated by ICT, members of the online community not only know other peers, they also realize under what circumstance can they win resources like the support of their peers, coordination, cooperation, and mutual learning [39, 40]. Moreover, Coleman [41] emphasizes the forming of social capital comes from the structural obligations, expectations, and trustworthiness among members in a closed social network. Due to the mutual benefits or sense of responsibility within the group, online community members with closer community recognition, mutual trust and obligation awareness are more willing to express their feelings and opinions toward something with no conservation.

To conclude the aforementioned points, we assume in this research that members of online communities form their social recognition as well as relationships, and have an influence on their knowledge contribution behavior as well as high expectancy on the reward generated from participating in the activities of knowledge contribution.

H6: The online ties of knowledge community members have a direct and positive influence on their knowledge contribution behavior.

H7: The online ties of knowledge community members have a direct and positive influence on their outcome expectancy of knowledge contribution.

Through the collective faith that social interaction contributes to sharing, community members put together their knowledge, skills and resources to provide mutual support among members, form alliance, collaborate mutually to solve problems and promote living qualities [42]. With collective social persuasion, the level of an individual's self-efficacy can be affected. Through the establishment and maintaining of relationships between social members, the vicarious experience produced by the social models further make them realize the possibility of fulfillment toward the behaviors [43-45]. Accordingly, we assume that the strength of ties among members of an online knowledge community would affect how an individual judges whether he has the ability to contribute knowledge, resources or experience. So we come up with the following hypothesis:

H8: The online ties of online knowledge community members have a direct and positive influence on their knowledge contribution self-efficacy.

In the context of interpersonal relationships, individuals develop beliefs and values as a major source of happiness as well as a buffer against conflicts [46]. The expressive interaction increases group partners' feelings of relationship satisfaction and commitment to remain in the relationship [47]. Since the sense of belonging in the online community encourages participants' collective actions to create and share instrumental resources or emotional support [48], their satisfaction with accessibility and adequacy of needed knowledge can be reinforced [25, 49]. Thus, this study proposes the following hypothesis:

H9: The online ties of knowledge community members have a direct and positive influence on their satisfaction with online knowledge community.

According to the previous literature review, our research model is depicted as Figure 1.

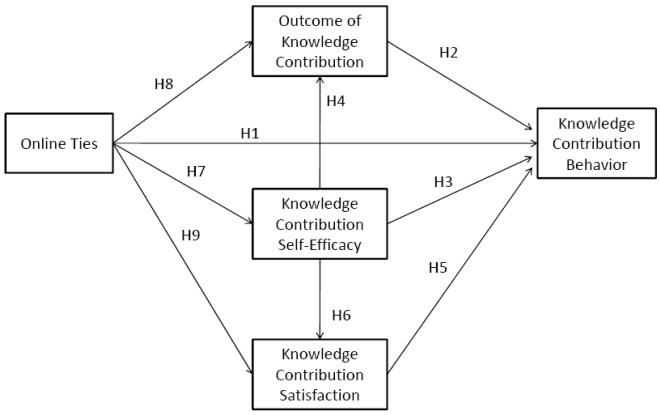

Figure 1: Research Model

III. RESEARCH DESIGN AND DATA ANALYSIS

A. Participants and Data Collection

This study focuses on a teachers' professional online learning community, the biggest web-based KMS for the teacher professional community in Taiwan. Practically, teachers need to upgrade their domain knowledge and teaching skills in order to work effectively with their students [50, 51]. The teacher communities of practice may facilitate professional collaborations and enhance better understanding about teachers' teaching practices, frustration, needs, and desires [52].

For this study, we adopt a survey methodology to collect and analyze empirical data. The operational definition and its references for the research model is demonstrated in Table 1. The instrument was examined by three senior members to examine the construct validity in ease of understanding, logical consistencies, and context fitness. The questionnaire was placed on the web site for members' voluntary participation. 433 survey responses were received, with 22 being discarded owing to their incomplete answers. The remaining 411 questionnaires were brought into further examination and analysis.

Table 1: Operational Definitions of Constructs

Construct	Operational definition	Sources
Outcome expectancy of knowledge contribution	An individual's outcome expectation of contributing knowledge in the online knowledge community, such as helping others, increasing one's own happiness and enjoyment, demonstrating the competence, gaining other's recognition, and achieving the desired goal.	Wasko & Faraj, 2005; (Kankanhalli, Tan, & Wei, 2005; Davis et al., 1992; Sun & Zhang, 2006 ; Maslow, 1954; Tickle, 2001, 2005; Woods, 2002
Knowledge contribution self-efficacy	An individual's judgment on his ability in executing knowledge contribution in the online knowledge community.	Bandura ,1989, 1997, 2002; Chan and Cheng, 2004; Smith, Kass, Rotunda, & Schneider 2006
Knowledge contribution satisfaction	An individual's perceptual evaluation of knowledge contribution, reflecting members' motives when engaging in the .online knowledge community.	Becerra-Fernandez and Sabherwal, 2001; Kulkarni, Ravindran, and Freeze, 2006-7
Online ties	The strength of relationships linking individuals with other members in the online knowledge community.	Hansen, 1999 ; BarNir & Smith, 2002; Jenssen & Koenig, 2002
Knowledge contribution behavior	The behavior that an individual contributes his/her resources, knowledge, experience, or emotional support to other members in the online knowledge community.	Morahan-Martin and Schumacher, 2003; Wasko and Faraj, 2000, 2005; Wellman & Gulia, 1999

B. *Measurement Instrument*

The measurement items (see the appendix) are developed on the basis of literature discussed above.

1) Outcome expectancy of knowledge contribution: Three aspects of outcomes are considered in terms of altruism, enjoyment, and self-actualization, indicating that online members expect to provide teaching resources and opinions to help solve other members' problem. By contributing their valuable knowledge or experience, people believe they will feel pleasant, interesting, and accomplished with the professional development.

2) Knowledge contribution of self-efficacy: To measure the online community members' confidence in contributing knowledge, we develop eight items to assess the level of subjects' beliefs in sharing their teaching practices, resources, and personal experiences with other members in the online knowledge community.

3) Knowledge contribution satisfaction: According to Bhattacherjee (2001), the concept of satisfaction is measured via three items to assess if the online members feel satisfied and content while contributing their knowledge with others. Furthermore, they would like to recommend this online community to their friends.

4) Online ties: Three items are adopted to examine their reciprocal identification from complete unknown stranger to good partners with common goals or interests. We suppose that more strength of ties can lead to more knowledge contribution.

5) Knowledge contribution behavior: As for the knowledge contribution behavior in the online knowledge community, we develop five items to measure the discussion, upload teaching resources, experience, or skills, as well as share their own emotional stories and express the concern or encourage to other members.

C. *Data Analysis and Resultss*

In this study, the structural equation analysis — partial least square (PLS), is used to test the research hypotheses. The first step in PLS is to assess the measurement reliability and validity by Confirmatory Factor Analysis (CFA). The internal consistency, convergent validity, and discriminant validity are examined. As a result, the factor loadings of each item is greater than 0.5 [53]. The CR value exceeds the generally recommended threshold values of 0.7 [54]. Finally, the square root of average variance extracted [55] is compared with the correlations among constructs [56]. All square roots of Ave values are greater than the correlations between pairs of constructs. Thus, all the constructs and items meet the requirement of internal reliability, convergent validity, and discriminant validity.

Table 2: CFA Results for Reliability and Validity of Measurement Items

Construct	Original items	Mean	SD	Factor loading	Cronbach's alpha	Composite reliability	Average variance extracted
Online ties	Ra1	3.88	2.33	0.91	0.80	0.88	0.73

	Ksa2	5.42	1.27	0.89			
	Ksa3	5.14	1.21	0.93			
Knowledge contribution behavior	Kcb6	3.76	1.80	0.88	0.93	0.95	0.78
	Kcb7	3.45	1.96	0.84			
	Kcb8	3.53	1.85	0.93			
	Kcb9	2.94	1.71	0.86			
	Kcb10	3.45	1.84	0.91			

Table 3: Discriminant validity for the research constructs

Construct	OT	OE	KCSE	KSA	KCB
OT	0.85				
OE	0.35	0.89			
KCSE	0.40	0.61	0.83		
KSA	0.27	0.70	0.52	0.91	
KCB	0.43	0.43	0.47	0.36	0.88

OT = Online tie; OE = Outcome expectancy of knowledge contribution; KCSE = Knowledge contribution self-efficacy; KSA = Knowledge contribution satisfaction KCB = Knowledge contribution behavior

Diagonal elements represent the square root of AVE for each construct; off diagonal elements are correlations among constructs.

After assessing the validity and reliability of the research construct, we continue to use PLS to test hypotheses by measuring the relationship between constructs. As demonstrated in Figure 2, except for the relationship between individuals' satisfaction and their knowledge contribution behavior (H4), the other three paths (H1, H2, and H6) are significant. The R^2 value shows that outcome expectancy, self-efficacy, satisfaction, and online members' strength of ties account for 31.7% of the variance in knowledge contribution behavior. Furthermore, the path between self-efficacy and outcome expectancy is also supported (H3); while individuals' satisfaction and their online ties with other members are both significant to influence their self-efficacious belief in knowledge contribution (H5 and H8). Finally, online ties in this study are proved to have significant influence on online members' outcome expectancy and self-efficacy in the realm of knowledge contribution.

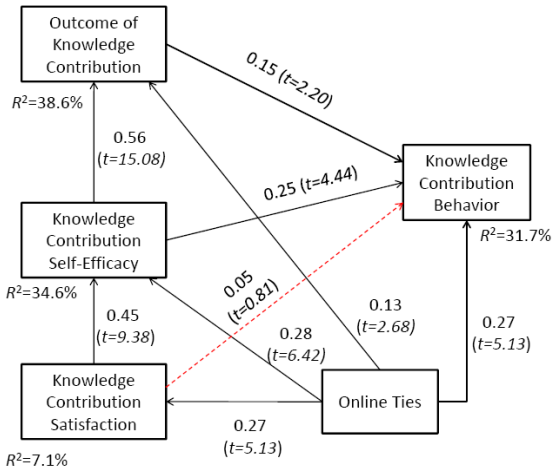

Figure 2: Results of model test

IV. Discussion and Clusion

In recent years, knowledge economy has emerged as an important issue for many organizations to establish the online community as internal or inter-organizational platforms of knowledge management. By using the existing human resources and intellectual capital to strength organizational members' interpersonal connection, knowledge management help increase resource-sharing, promote task-execution, boost learning, evoke knowledge innovations, and promote organizational performance [57-59]. Although the benefit of knowledge management has been emphasized via the utilization of information and computer technologies (ICTs), it is not a total solution to all knowledge management practices. Actually, the formation and application of knowledge is embedded in people's everyday activities, involving a knowing and understanding state of mind, as well as a process that focuses on the relationships among members.

In this paper, we propose a social cognitive framework of knowledge management to understand the associations among online members' outcome expectancy, self-efficacy, satisfaction regarding knowledge contribution, the strength of online ties, and individuals' knowledge contribution behavior. The hypotheses tested in this study are all supported, with the exception of people's satisfaction with their knowledge contribution in the online community. Consistent with the studies of Watson and Hewett [12], Andriesses [19], as wll as Bock et al., [11], as people think they can achieve some expectation and benefits in terms of the collective good, perceived enjoyment, and self-actualization, they are more willing to participant in knowledge management activities. Online members' perception of self-efficacy also plays an important role in determining one's behavior and outcome expectancy of knowledge contribution. The more beliefs that one can provide the instrumental resources or emotional support to help others, the more knowledge they would like to contribute, with the positive evaluation of good results that their knowledge contribution can lead to.

Although online members' satisfaction with knowledge contribution does not significantly influence their knowledge contribution behavior, it is consistent with Bandura's social cognition perspective that satisfaction derived from the successful experience can increase people's self-efficacy perception, indicating they can feel capable of completing one specific task. In this study, self-efficacy reflects a stronger mediating effect to influence online members' outcome expectancy and participation of knowledge contribution. Finally, the development of social relationships among online knowledge community members is proven to help them get potential resources and reliable support with one's identity as a member of the social network. It is useful to speed up the flow of information to resolve the conflicts, crisis, or uncertainties that online members face in their social settings [36]. Furthermore, the mutual experience, goal-setting, resources exchange and emotional support among members can increase creativity and learning performance, as well as enhance the production and application of intellectual capital [38].

Our research results support the view that knowledge management is not confined to only system functions. Instead of an illusionary space where people may meet without face-to-face interaction, learning and sharing derived from knowledge contribution has to be reciprocally adjusted among personal cognition and the environment. Therefore, the online members' outcome expectation, efficacious beliefs, satisfactory perception, and the strength of online ties are critical to the success in knowledge management practices.

APPENDIX

Outcome expectancy of knowledge contribution

1. As the online community members need teaching resources, I provide what I have to them.
2. As the online community members need suggestion for teaching,, I will provide what I have to them.
3. As the online community members express their emotion, I will response and encourage them.
4. It is joyful for me to contribute knowledge in SCTNet.
5. It is pleasant for me to contribute knowledge in SCTNet.
6. It is interesting for me to contribute knowledge in SCTNet.
7. Contributing knowledge in SCTNet can enhance my professional capabilities and development.
8. Contributing knowledge in SCTNet can enhance my professional capabilities and development.
9. Contributing knowledge in SCTNet can help increase my concentration and enthusiasm for teaching.
10. Contributing knowledge in SCTNet can help release my frustrations and stresses of teaching.

Kowledge contribution slf-efficacy

1. I have confidence in contributing my teaching experience with other SCTNet members.
2. I have confidence in contributing my teaching resources with other SCTNet members.
3. I have confidence in sharing my emotion with other SCTNet members.
4. Even I have different opinions from other SCTNet members, I have confidence in keeping discussion on related issues.
5. Even my opinion may be an offense to other SCTNet members, I have confidence in keeping discussion on related issues.
6. I have confidence in sharing my success or joyfulness with other SCTNet members, rather than worrying that it is regarded as show off.
7. I have confidence in sharing my failure or frustration with other SCTNet members, rather than worrying that I may be ridiculed.
8. I have confidence in engaging the knowledge contribution activities in SCTNet.

Knowledge contribution satisfaction

1. I feel satisfied with contributing knowledge in SCTNet.
2. I will recommend SCTNet to my friends.
3. I am content to contribute knowledge in SCTNet.

Oline ties

1. Is there any SCTNet member with whom I contribute knowledge?

   Yes. Our relationship varies from totally unknown stranger to the partner in the same camp.
2. Is there any discussion group member with whom I contribute knowledge?

   Yes. Our relationship varies from totally unknown stranger to the partner in the same camp.
3. On the whole, is there any SCTNet member with whom we share our knowledge to each other?

   Yes. Our relationship varies from totally unknown stranger to the partner in the same camp.

Knowledge contribution behavior

1. I often respond to the topics discussed in SCTNet.
2. I often upload my teaching resources to SCTNet.
3. I often contribute my teaching experience, knowledge or skill in SCTNet.
4. I often share my emotion in SCTNet.
5. I often express my concern or encourage to other SCTNet members.

***Abstract*—To effectively exploit large-scale data sets using a limited storage space, it is necessary to find a special treatment which reduces them. There are certain methods with this intention. We can quote clustering method. However, this method proves its limits in the case of large-scale data sets. In this paper, we propose to reduce the workspace using the Principal Component Analysis (PCA). We work with fuzzy clustering of a data set in which users don't know the optimal number of clusters to be generated. We proved the effectiveness of the pre-processing use of this technique before any clustering operation.**

Keywords-Clustering; Fuzzy Logic; Principal Component Analysis; Sampling; Data Compression.

I. INTRODUCTION

The evolution of the data processing and storage technologies and tools involved an explosion of available data. This phenomenon was reinforced by the awakening of the decision makers of the potential knowledge value which contain their databases (DB). Nevertheless, the available large data don't bring any appreciation in absence of exploration and analysis methods. In this case, the installation of treatments tools to clarify the available knowledge in these data is fundamental and represents one of the major stakes of the Knowledge Discovery from Database (KDD).

The reduction of the space of description and the number of data are two dual approaches which bring brief replies to this problem. We often gather them under name "reduction of dimensions". Their objective is to select or extract an optimal subset from characteristics and/or objects for a fixed criterion. By eliminating non relevant or redundant information according to the criterion used, these approaches make it possible to reduce the size of the data set according to its two dimensions to make it more representative to a given problem.

They have the following objectives: (1) simplify the data visualization and comprehension; (2) reduce the storage space; (3) reduce the time of training and use, and (4) identify the relevant factors.

Several works were proposed in the literature to seek and improve the Data Mining methods among which we quote the Information Retrieval (IR), the data querying, the clustering, the Formal Concept Analysis (FCA) etc.

In this work, we focus ourselves on fuzzy clustering of large-scale data sets.

Several works improve this method while proving its performances in the management of the large-scale data sets that on the determination of the optimal number of clusters.

However, these solutions are insufficient to ensure a good clustering of the large-scale datasets, in which the data can have hundred attributes or variables and make the clustering in this space extremely difficult.

The Principal Component Analysis (PCA) permits to solve these problems while putting in considerations the following objectives: (1) represent observations moreover than 2 variables into 2 or 3 dimensions; (2) reduce dimension in a relevant way while guaranteeing a minimal loss of information.

The new variables obtained have the following characteristics: (1) they are ordered according to the information which it restores of the initial variables; (2) they are not linearly correlated between them.

The rest of the paper is organized as follows: section 2 presents some works on the clustering large data sets. Section 3 presents our approach for fuzzy clustering of large-scale data sets while using the PCA. Section 4 presents experimentation and evaluates the approach. Section 5 concludes the paper and presents the future work.

II. CLUSTERING OF LARGE DATA SETS

When we treat large datasets, the problem of the resources always emerges. In our case, the traditional clustering techniques have important complexities, so, it is not obvious to apply them to large datasets, because they are so enormous that we cannot store it in memory. A solution consists of applying compression technique to prevent that these kind of datasets exceeds the memory space.

For this, several techniques and approaches were applied to the methods and existing algorithms to deal with the problem of the clustering in the large datasets, we divided them into data reduction and dimension reduction techniques.

For data reduction, several researchers studied the concept of sampling and data compression [9], [10], [11], [12], [13], [14], [15], [16]. Table 1 presents a comparative study of these approaches.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

TABLE I. COMPARATIVE STUDY OF LARGE DATA SETS CLUSTERING ALGORITHMS

Name	Type	Inputs	Used techniques (sampling or compression)	Optimized for
CURE	Hierarchical	*X+C+* Number of representatives	Sampling	Large Data sets
CLARANS	Partition-based clustering	*X+C+* Maximum number of the nearest	Sampling	Spatial data sets
GEFFCM	Partition-based clustering	*X+C*	Sampling	Large Data sets
Single pass k Means	Partition-based clustering	$X+C+V_i$	Compression	Large Data sets
Single pass fuzzy C-Means	Partition-based clustering	*X+C+P*	Compression	Large Data sets
WEFCM	Partition-based clustering	*X*	Compression	Large Data sets

Were X is the data set, C is the number of clusters, V the initial centers and P the sampling data.

The majority of the algorithms presented above are interesting, but they present some limits. Although they solve the problem of the clustering of large datasets, they require also the number of clusters like input parameter. However WEFCM (Weighted Enhance Fuzzy C-Means) [19] presents a good automatic system of clustering while provides the optimal number of clusters. Based on this point, and since this algorithm allows only the data reduction, we will associate to him a dimension reduction procedure. This is to facilitate the clustering of large-scale datasets.

The principle of this algorithm is as follow: suppose we intend to cluster a large data sets present on a disk. We can only load a certain percentage of the data based on the available memory allocation. If we load 1% of the data into memory at a time then we have to do it 100 times to scan through the entire data set. We call each such data access a Partial Data Access (PDA). The number of partial data accesses will depend on how much data we load each time.

In this algorithm, after the first PDA, data is clustered into c partitions using EFCM [8]. Then the data in memory is condensed into c weighted points and clustered with new points loaded in the next PDA. These points are calculated by summing the membership of examples in a cluster. In each PDA new singleton points are loaded into memory and clustered along with the past c weighted points obtained from the previous clustering. It is called Partial Data Clustering (PDC). After clustering these new singleton points along with the past c weighted points, they are condensed again into c new higher weighted points and clustered with examples loaded in the next PDA. This continues until all the data has been scanned once.

The evaluation of the clustering with WEFCM is done globally and locally. So, it uses the following measures:

Global Weighted Separation-Compactness: given a cluster scheme $C=\{C_1,C_2,...,C_c\}$ for a data set $X=\{x_1,x_2,...,x_N\}$, let $C'=\{C_{pj}\,|\,C$ and C_{pj} is not singleton, $j=1,2,...,k$ where $k=|C'|\}$, the global weighted separation-compactness, WSC, of a cluster scheme C is given equation (1).

$$WSC=\frac{k^2}{c}\frac{\left(\sum_{j=1}^{c}\min_{1\le k\le c}\left\{\left\|v_j-v_k\right\|^2\right\}/c\right)}{\sum_{j=1}^{k}\left(\sum_{x_i\in C_{pj},x_i\neq v_j}w_i\mu_j(x_i)^2\left\|x_i-v_j\right\|^2/\sum_{x_i\in C_{pj},x_i\neq v_j}w_i\mu_j(x_i)^2\right)} \quad (1)$$

where $\mu_j(x_i)$ is the membership degree of data x_i to j^{th} cluster and w_i the weight of a data [19].

Then, the objective of WEFCM algorithm is to find the cluster scheme which solves:

$$\max_{2\le c\le\sqrt{N}}\left\{\max_{\Omega_C}\{WSC\}\right\} \quad (2)$$

Where Ω_C denotes all of the candidate cluster schemes for a certain number of clusters c.

We still use the measures of separation and compactness to evaluate individual clusters (except singleton).

Local Weighted Separation-Compactness: given a cluster scheme $C=\{C_1,C_2,...,C_c\}$ for a dataset $X=\{x_1,x_2,...,x_N\}$, for each $C_j\in C$, if C_j is not singleton, the local weighted separation-compactness of C_j, denoted as wsc_j, is given by equation (3) [19].

$$wsc_j=(\min_{1\le j\le c,k\neq j}\left\|v_j-v_k\right\|^2)\times\left(\frac{\sum_{x_i\in C_j,x_i\neq v_j}w_iu_j(x_i)^2}{\sum_{x_i\in C_j,x_i\neq v_j}w_iu_j(x_i)^2\left\|x_i-v_j\right\|^2}\right) \quad (3)$$

Thus, the "worst" cluster is the one with the least wsc_j value.

Procedure 1 *Weighted Merge-based Process* [19]

Step 1:	Build the array $C^*=\{C^*_1,C^*_2,...,C^*_c,C^*_{c+1}\}$, such that each v^*_j is the center of cluster $C^*_j\in C^*$.
Step 2:	Calculate *wsc* value for each C^*_j in C^*,
Step 3:	Delete the center of cluster with the least *wsc* value from C^*, recalculate the cluster centers. Store the new cluster scheme $C=\{C_1,C_2,...,C_c\}$.

Procedure 2 *Recalculate the cluster centers* [19]

Step 1:	Choose the nearest center v^*_j for each element $x_i\in X$, and group x_i into cluster C^*_j whose center is v^*_j.
Step 2:	Calculate the data median for each C^*_j as the new center for it; denote it as v_j, output the cluster scheme $C=\{C_1,C_2,...,C_c\}$.
Step 3:	If $(C^*\neq C)$ and maximum step is not reached, go to step1.
Step 4:	Output C.

Let p the fraction of data loaded in each PDA, d the number of PDA's required by WEFCM and $1\le r\le d$.

WEFCM follows the following steps [19]:

Step 1:	The first PDA. Applying the EFCM clustering algorithm.
Step 2:	**Repeat** Clustering will be applied on singleton points freshly loaded in the d^{th} PDA along with c_{opt} weighted points obtained after condensation from the $(d-1)^{th}$ PDA. So, there will be $n_d + c$ points in the memory for clustering using EFCM by taking in account of weighted local and global measures. **Until** r=d.

However, data used in clustering can have hundreds attributes or variables. Clustering in such space of high dimensionality is extremely difficult. The calculation of similarity becomes very expensive.

Another problem can occur in a space of high dimension, it is the presence of non relevant attributes which affect proximity measurements. In fact, this phenomenon can appear with data of low dimension, but the possibility of presence and the number of the non relevant attributes increase with the dimensionality.

There are certain techniques for dimension reduction to solve the problems above, such as the technique of selection of attributes, the reduction of dimensionality, classification under-spaces and Co-classification [17], [15].

We present, in the next section, a new algorithm for clustering large-scale data sets while using the PCA.

III. CLUSTERING OF LARGE-SCALE DATASETS USING PCA

The clustering is often used to facilitate the training and decrease the processing time. Particularly in the case when the clustering is made on the two levels.

It should be noted that the data clustering, in order to gather them in a number of representative clusters is the most used, but we can also make a scale clustering in order to reduce their number.

A. PCA Terminology

The purpose of PCA is to create one or more variables which are a linear combination of n variables. A data described by n variables belonging to R can be represented by a point in a space R with n dimensions.

The PCA allows, starting from n variables belonging to R^n, to build p $(\leq n)$ other variables, called principal components (or factorial axes), which are linear combinations of the n initial variables. Each principal component will be defined by a linear equation bringing into account the initial variables which take part in its construction.

If there are only two variables a_j and a_k, we give the graph giving a_j according to a_k and we see immediately if there is linear correlation or not. If there are more than two variables, this geometrical approach does not function any more, because we are unable to understand a space with more than 3 dimensions.

The fundamental idea of the PCA is the following one: considering the group of points in P dimensions (in this space, 1 point = 1 data), we seek to find the plan (the two-dimensional representation that we will be able to see and understand) in which the projection of the points of the cloud is least possible distorted therefore most reliable possible.

For that, we start by seeking the line Δ_1 which minimizes the squared sum of the distances between each point and the line.

This line has the property to be the direction according to which the variance of the points is biggest. Then, we look for a second line Δ_2 perpendicular to Δ_2 and have the same property; and we continue until obtaining P lines which form an orthogonal reference mark.

We note that, like any statistical method, the number of data and the number of attributes must be relatively important so that the conclusions of the PCA have a meaning;

Let take the example of data in table II which describes 10 persons by their physical characteristics and their annual average notes.

TABLE II. DATA EXAMPLE

Data	Weight	Tall	Age	Mark
1	45	1.5	13	14
2	50	1.6	13	16
3	50	1.65	13	15
4	60	1.75	15	9
5	60	1.7	14	10
6	60	1.7	14	7
7	70	1.6	14	8
8	65	1.6	13	13
9	60	1.55	15	17
10	65	1.7	14	11

B. Distances Calculation, Data Centering and Reduction

It is necessary to start by defining a distance concept between two data. So, if we take the Euclidean geometry, we could write:

$$d^2(x_i, x_j) = \sum_{k=1}^{k=P} (x_{i,k} - x_{j,k}) \quad (4)$$

Let us consider data x_4, x_5 and x_6. We have $d^2(x_4, x_5) = 2.0$, $d^2(x_4, x_6) = 5.0$ and $d^2(x_5, x_6) = 9.0$. Now if we express the talls in centimeters, the distances become: $d^2(x_4, x_5) = 27$, $d^2(x_4, x_6) = 30$ and $d^2(x_5, x_6) = 9$. It is noted that according to the unit used, data x_6 is closer to the 4th or of 5th, we use reduced centered variables to avoid this problem.

In this case, we obtain $d^2(x_4, x_5) = 2.3$, $d^2(x_4, x_6) = 2.6$ and $d^2(x_5, x_6) = 0.8$, whatever the units used.

Afterwards, we consider that the data are centered and reduced. The definition of distances given above means that all attributes have the same importance in the distance measure.

We use equation (5) to balance the attributes to have more or less importance:

$$d^2(x_1,x_2)=\sum_{k=1}^{k=P} w_k\left(x_{i,k}-x_{j,k}\right) \quad (5)$$

where a weight w_k belongs to R and balances each component of the distance for each attribute.

If all the attributes have the same importance, we take w_k all equals. We suppose here that all the attributes have the same importance and that $w_k=1$. For this the calculation of the averages and standard deviations is essential for data centering and reduction. $\bar{x}$ is the arithmetic mean of each column, it is presented by equation (6).

$$\bar{x}=\frac{1}{N}\sum_{i=1}^{N} x_i \quad (6)$$

The standard deviation is the square root of the variance; it is presented by equation (7):

$$\delta^2=\frac{1}{N}\sum_{i=1}^{N}\left(x_i-\bar{x}\right)^2 \quad (7)$$

Table III gives the average and the standard deviation of each variable (column).

TABLE III. CHARACTERISTICS OF THE GRAVITY CENTER

	Weight	Size	Age	Note
Average	58.5	1.64	13.8	12.0
Standard deviation	7.84	0.08	0.79	3.50

Once we calculate the average and the standard deviation of each column, we determine the centered and reduced coordinates of each data in a new reference mark whose origin is the gravity center and whose axes are parallel to the original ones (of the non reduced and non centered data).

Table IV presents the new centered and reduced data.

TABLE IV. DATA CENTRING AND REDUCTION

	Weight	Size	Age	Note
1	-1.72	-1.72	-1.01	0.57
2	-1.09	-0.45	-1.01	1.14
3	-1.09	0.19	-1.01	0.86
4	0.19	1.47	1.52	-0.86
5	0.19	0.83	0.25	-0.57
6	0.19	0.83	0.25	-1.43
7	1.47	-0.45	0.25	-1.14
8	0.83	-0.45	-1.01	0.29
9	0.19	-1.09	1.52	1.43
10	0.83	0.83	0.25	-0.29

Next, we suppose that we centered and reduced the data, $\overline{x_j}=0$ is the average of j^{th} column and $\sigma(x_j)=1\ \forall j\in\{1,...,P\}$.

This assumption simplifies the calculations and the notations. The N data described by their P characters can be put in the form of a matrix having N lines and P columns: one line describes a data and each column corresponds to an attribute. Let us note this matrix X.

C. Matrix Counting

To determine the principal components, we start from a square matrix. The choice of the matrix type is a parameter of the PCA. It is directly function of metric adapted to the problem.

- Covariance matrix

The covariance of two variables V_1 and V_2 is an indicator of the simultaneous variation. Covariance is positive when V_2 grows each time V_1 increases. It is negative when V_2 decrease each time V_1 increases. It is null if V_1 and V_2 are independent. Covariance and correlation are of the same sign. Covariance is function of the coefficient of correlation. It is given in equation (8).

$$Cov(V_1,V_2)=Stand\text{-}Dev\ (V_1)*Stand\text{-}Dev\,(V_2)*Cor(V_1,V_2) \quad (8)$$

Where *Cov* is the covariance, *Stand-Dev* is the standard deviation and *Cor* the correlation.

If there are homogeneous data with identical magnitude orders, then there is an Euclidean metric and we work with a covariance matrix.

With each couple (V_1,V_2), the value of each element of the matrix is that of the covariance of the couple (V_1,V_2).

- Correlation Matrix

For each couple (V_1,V_2), the value of each element of the correlation matrix is the correlation coefficient between V_1 and V_2. It is given in equation (9).

$$Cor(V_1,V_2)=Cov(V_1,V_2)/(Stand\text{-}Dev\,(V_1)*Stand\text{-}Dev\,(V2)) \quad (9)$$

If there are heterogeneous data with different magnitude orders, we work with a correlation matrix. It is given in equation (10)

$$R=\begin{pmatrix} 1 & r(a_1,a_2) & r(a_1,a_2)\ldots r(a_1,a_2) \\ & 1 & r(a_2,a_3)\ldots r(a_1,a_P) \\ & & \ddots \quad \vdots \\ & & 1 \end{pmatrix} \quad (10)$$

R is symmetric since $r(a_j,a_k)=r(a_k,a_j)$ (the left lower triangle was not indicated). For centered and reduced variables, these two matrices are equal: $R=V$.

We have the relation: $R=\frac{1}{P}X^TX$ where X^T indicates the transposed of the matrix X. The examination of the correlation matrix is interesting: it makes it possible to immediately locate the strongly correlated variables and the variables which are not correlated.

The calculation of the eigenvalues and the eigenvectors of R provide all required information.

Let we note $\lambda_i\in\{1,...,P\}$ the P eigenvalues of R ordered in a decreasing way: $\lambda_1\geq\lambda_2\geq...\geq\lambda_P$ and their P associated

eigenvectors $\vec{v}_i \quad i \in \{1,...,P\}$. R is symmetric and defined positive, its values are real and positive and its own vectors have real coordinates.

If there exists one, or many, null eigenvalues, we understand that the attributes are not linearly independent some of the others: one, or several, attributes are obtained by linear combination of the others.

Eigenvectors are unit and orthogonal two by two and form an orthonormal basis. They are the required main axes. The main axis is that associated to the biggest eigenvalue. Therefore, the q main axes are the lines whose unit vectors are the eigenvectors associated to the q biggest eigenvalues and going by G.

We obtain the principal coordinates of the data by projecting them in this space, i.e. by making the scalar product of the coordinates (centered reduced) of a data by each one of the P eigenvectors. By taking $q = 2$, we can represent the N data in the principal plan.

The data distribution in the principal plan must be realized and studied. The problem is to know if the representation in the principal plan is faithful to the initial group of data. We approach this point below.

In the rest, we give an explanation on the calculation of eigenvectors and eigenvalues of the correlation matrix.

The first question is "What are we looking for"? The answer is that we seek the directions of greater lengthening of the data group, these directions having to be orthogonal to obtain an orthogonal base.

The second question is "How to determine lengthening according to a certain direction $\vec{v}$ of the data group? We determine it by the variance according to this direction which is obtained by $V^T R V$.

The third question is "How we obtain the direction of greater lengthening? We look for the vector $\vec{V}$ which maximizes this lengthening, so which cancels the derivative of this lengthening. We seek $\vec{v}$ a vector with norm 1 which cancels $\frac{d \vec{v}^T R \vec{v}}{d \vec{v}}$. The direct calculation of this derivative don't give anything interesting, the trick consists in calculating the derivative of this same quantity divided by 1; the norm of $\vec{v}$ is 1 (by assumption); this norm is worth $\vec{v}^T R \vec{v}$; we are interested in $\vec{v}$ which cancels $\frac{(d \vec{v}^T R \vec{v})/(\vec{v}^T \vec{v})}{d \vec{v}}$. So that this derivative is null, the relation obtained is: $R \vec{v} = \left(\vec{v}^T R \vec{v} \right) \vec{v} = \lambda \vec{v}$.

Therefore, $\vec{v}$ must be an eigenvector of R associated to the eigenvalue. We must be interested in the eigenvector associated to the greatest eigenvalue. More generally, the set ordered eigenvectors according to their decreasing eigenvalues will provide the set of directions corresponding to lengthening in the decreasing order of the data group.

The matrix R is symmetric and definite positive. It has only real and positive or null eigenvalues. Moreover, eigenvectors form an orthonormal base. The rank of the eigenvalues indicates their importance. If some eigenvalues have much more important values than the others that mean that the essence of information is given by these main axes and that the others axes give little information.

On the contrary, if all the eigenvalues have approximately the same value, then no main axis can be left. The ideal situation is, when one or two eigenvalues are very important compared to the others. Notice that $\sum_{i \in \{1,...,P\}} \lambda_i = P$, the importance of an eigenvalue compared to the others is well measured by its inertia. It is given in equation (11).

$$\lambda_i = \frac{\lambda_i}{P} \tag{11}$$

λ_i is the variance along the main axis carried by the eigenvector; therefore $\vec{V}_i$ is the variance of the principal component z_i.

Also we note that the covariance matrix in principal space is diagonal: by a PCA, we obtain a representation in a data space in which the components are not linearly correlated. It is a very interesting property, knowing that projection in the principal plan deforms reality by shortening the distances (the distribution of the data in the first space).

It is necessary to be able to estimate this deformation. For that, we calculate the cosine of the angle formed by the half-line going of the origin to the initial point and the half-line going of the origin to the projection of the point in principal space, either an axis, or a plan.

We note $\theta_{i \in \{1,...,N\}, j \in \{1,...,p\}}$ the angle between the half-line passing by the origin and the initial point x_i and the main axis j. $\theta_{i \in \{1,...,N\}, j \in \{1,...,p\} \times k \in \{1,...,p\}}$ is the angle between the half-line passing by the origin and the plan formed by the main axes j and k. The square cosine of these angles is given in equation (12) and (13).

$$\cos^2 \theta_{i \in \{1,...,N\}, j \in \{1,...,p\}} = \frac{{z_{ij}}^2}{\sum_{j \in \{1,...,P\}} {x_{ij}}^2} \tag{12}$$

$$\cos^2 \theta_{i \in \{1,...,N\}, j \in \{1,...,p\} \times k \in \{1,...,p\}} = \frac{{z_{ij}}^2 + {z_{ik}}^2}{\sum_{j \in \{1,...,P\}} {x_{ij}}^2} \tag{13}$$

Where z_{ij} and z_{ik} are the coordinates on the main axes j and k of the data x_i. A square cosine lower than 0.3 indicates an important deformation (>57°).

The linear coefficient of correlation between the j^{th} initial variable x_j and the k^{th} principal component z_k is given in equation (14).

$$r_{j,k} = \vec{v}_k[j] \times \sqrt{\lambda_k} \tag{14}$$

All the axes can have their utility. To judge some, it is necessary to compare the various eigenvalues (seen above). For each one, we can measure their inertia I_j and their cumulated inertia. It is given in equation (15).

$$C_i = \sum_{j \le i} I_j \tag{15}$$

D. Dimension Reduction

The dimension reduction procedure makes it possible to reduce the number of variables of the data set while maximizing the information (variance) contained in the simplified model.

Procedure 3*Dimension Reduction by PCA*

Step 1: Data centering and reduction by using equations 6 and 7.

Step 2: Calculation of the correlation or covariance matrix using the equations 8 and 9.

Step 3: Calculation of eigenvalues and eigenvectors of the matrix.

Step 4: Sort out the eigenvalues thanks to their inertia given by the equation 11.

Step 5: Select the $K \le P$ eigenvectors and generate the whole data in a new presentations structure using the equation 15.

Step 6: Look into the correlation between the initial and the principal data using the equation 14.

This procedure will be applied to the data set in order to ensure a dimension reduction. Once reduced, WEFCM can be applied to classify the data. The new algorithm was named SR-WEFCM (Scale Reduction-Weighted Enhance Fuzzy C-Means).

E. Illustrative Example

For a better assimilation of PCA, we take again the example given above with persons and their characteristics. It is given by equation (16).

$$R = \begin{pmatrix} & Weight & Tall & Age & Mark \\ Weight & 1 & 0.37 & 0.48 & -0.56 \\ Tall & 0.36 & 1 & 0.39 & -0.32 \\ Age & 0.48 & 0.39 & 1 & -0.32 \\ Mark & -0.56 & -0.62 & -0.32 & 1 \end{pmatrix} \tag{16}$$

The eigenvalues and eigenvectors are given in equation (17).

$$\lambda_1 = 2.391, \ \vec{v}_1 = (0.5080, 0.5038, 0.4455, -0{,}5383) \tag{17}$$

$$\lambda_2 = 0.750, \ \vec{v}_2 = (0.3065, 0.4641, 0.7085, -0{,}4381)$$

$$\lambda_3 = 0.584, \ \vec{v}_3 = (-0.6593, 0.5253, 0.4712, -0{,}2593)$$

$$\lambda_4 = 0.274, \ \vec{v}_4 = (-0.4619, 0.5042, 0.2855, -0{,}6715)$$

We notice that no eigenvalue is null and we can verify that the 4 eigenvectors are unit and orthogonal two to two. We can calculate the inertia and the cumulated inertia of each eigenvalue in table V.

TABLE V. INERTIA AND CUMULATED INERTIA FOR EACH EIGENVALUE

λ	I	C
2.391	0.59775	0.59775
0.750	0.1875	0.78525
0.584	0.146	0.93125
0.274	0.0685	1.0

The data coordinates in the new reference mark are calculated as given in equation (18).

$$\begin{pmatrix} (x_{1,1} & x_{1,2} & x_{1,3} & x_{1,4})\vec{V}_1 \\ (x_{1,1} & x_{1,2} & x_{1,3} & x_{1,4})\vec{V}_2 \\ (x_{1,1} & x_{1,2} & x_{1,3} & x_{1,4})\vec{V}_3 \\ (x_{1,1} & x_{1,2} & x_{1,3} & x_{1,4})\vec{V}_4 \end{pmatrix} \tag{18}$$

For example, the coordinates of first data are: (-2,64;-0,20;-0,10; 1,04).

The data coordinates on the principal's axis are given in table VI.

TABLE VI. DATA COORDINATES IN THE NEW PRINCIPAL PLAN

Data	Coordinates
1	(-2.64, -0.20,-0.10 ,1.04)
2	(-1.94, -0.36, 0.32,-0.35)
3	(-1.44,-0.80, 0.59,-0.35)
4	(2.08,-0.08, 1.20, 0.19)
5	(0.99,-0.42, 0.30,-0.05)
6	(1.47,-0.82, 0.06, 0.56)
7	(1.32,-0.35,- 1.45, 0.41)
8	(-0.43,-0.14, -1.25,-0.67)
9	(-0.57, 2.39, 0.41,-0.07)
10	(1.17,-0.08, -0.07,-0.57)

In table VII, we calculate the correlation between initial variables and principal components.

TABLE VII. STUDY OF THE CORRELATION BETWEEN INITIAL VARIABLES AND PRINCIPAL COMPONENTS

	z_1	z_2	z_3	z_4
Weight	0.785	0.266	-0.504	-0.242
Tall	0.779	-0.403	0.402	-0.264
Age	0.689	0.611	0.360	0.150
Mark	-0.832	0.380	0.198	-0.352

We notice that: the 4 variables are strongly correlated (in absolute value) with the first main axis. The variable Mark is correlated negatively with the three other variables. And finally to estimate the deformation due to projection in the principal plan, we calculate $\cos^2$. It is given in table VIII.

TABLE VIII. ILLUSTRATION OF THE DEFORMATION DUE TO THE PROJECTION

Data	$\cos^2 \theta_{1,1}$	$\cos^2 \theta_{1,2}$	$\cos^2 \theta_{1,3}$	$\cos^2 \theta_{1,4}$
1	**0.859**	**0.005**	**0.82**	**0.82**
2	**0.916**	**0.031**	**0.94**	**0.94**
3	**0.628**	**0.195**	**0.83**	**0.74**
4	**0.745**	**0.001**	**0.75**	**0.99**
5	**0.785**	**0.142**	**0.88**	**0.79**
6	**0.690**	**0.212**	**0.87**	**0.67**
7	**0.419**	**0.030**	**0.45**	**0.93**
8	**0.084**	**0.008**	**0.09**	**0.79**
9	**0.053**	**0.919**	**0.97**	**0.08**
10	**0.804**	**0.004**	**0.80**	**0.80**

IV. EXPERIMENTATION AND EVALUATION

We evaluated in experiments the algorithm SR-WEFCM on large-scale data such as isolet5. We then carried out a comparison of the results given when we applied only WEFCM to the data and in the case when we applied SR-WEFCM.

ISOLET5 is a subset of the ISOLET (Isolated Letter Speech Recognition) set, the letter of the experiment of voice recognition. This subset was prepared in the same way that in [18]. Ten classes out of 26 (represents the letters of the alphabet) were selected by chance (this set is composed of 1559 data and 617 attributes) [18]. The optimal number of clusters for this whole data is 10.

The comparative study will be made according to tow axes: the first consists of the dimension reduction, the second will be the clustering quality.

A. Dimension Reduction

Our dimension reduction procedure using PCA produces two files: the first contains a general data analysis like columns average, their standard deviation, the values, the vectors and some other information about correlation between the initial variable and principles components. The second file contains new coordinates of each data in the new plan.

The performance and importance of the dimension reduction approach using PCA becomes clear when we examine the isolet5 data set. Thanks to this method we could reduce the variables number. After this analysis, we obtain 3 principles components instead of 617 attributes. Each principle component presents and synthesizes a set of initial variables.

During this first step, we could reduce the attributes number to a restricted number of principles components. In other word, we were aware of information quantity observed in the initial data set while tacking only few reduced principles components. We obtained the new coordinates in the new mark. The next step will be the data reduction, which means that we will apply the WEFCM clustering algorithm on the new data set.

B. Clustering Quality

We applied WEFCM and SR-WEFCM to ISOLET5, 10 is the optimal the number of clusters. The matrix of the output centers was the following one:

TABLE IX. MATRIX OF CENTERS BY WEFCM

	Variable 1	**…**	**Variable 100**	**…**
Cluster 1	-0.032180	…	0.103958	…
…	…	…	…	…
…	…	…	…	…
Cluster 10	0.074184	…	0.055395	…

We point out that each element contains 617 Attributes, and therefore we chose to represent only some attributes, and only for some clusters.

TABLE X. MATRIX OF GENERATED C ENTERS BY SR-WEFCM

	Variable 1	**Variable 2**	**Variable 3**
Cluster 1	0.216584	-0.036261	-0.000480
…	…	…	…
…	…	…	…
Cluster 10	-0.002041	0.000196	0.152780

In the same way, we drew the tables of the associated indices relating to ISOLET5.

Table VII presents the validity indices obtained when we use WEFCM clustering algorithm.

TABLE XI. VALIDITY INDICES WITH WEFCM

Number of clusters	**Validity indices**
11	0.026344
10	0.050870
9	0.046293
8	0.028907
7	0.029964
6	0.020478
5	0.017594
4	0.013673
3	0.006801
2	0.001851

As we can see, the optimal number of clusters is obtained with the biggest value of validity index.

Table VIII presents the validity indices obtained when we use SR-WEFCM clustering algorithm.

TABLE XII. VALIDITY INDICES WITH SR-WEFCM

Number of clusters	Validity indices
11	0.049331
10	0.283013
9	0.030206
8	0.044234
7	0.036985
6	0.245792
5	0.120833
4	0.022860
3	0.046677
2	0.001674

According to table VIII, the biggest value of the index corresponded to the optimal number of clusters is equal to 10.

We note that in spite of the dimension reduction, the suggested system proved its performances in the determination and the evaluation of the number of clustering.

Table IX presents the run time of both WEFCM and SR-WEFCM clustering algorithms.

TABLE XIII. RUN TIME

WEFCM	71.076442
SR-WEFCM	0.288956

The importance of our system was quite remarkable also when we examine the run time of the clustering algorithm for large-scale data set, (the isolet5 in our case). It is noticed that the difference in run time is very important, so, we can say that the reduction of large-scale data set by dimension reduction procedure involves necessarily a run time reduction.

V. CONCLUSION

Recent progress in data filing field offers new challenges to the theorists of Data Mining. One of these challenges is to manage large data sets, in which traditional algorithms and researcher's intuition have multiple difficulties.

In this direction, clustering proposes important and effective techniques of data sampling and compression in order to reduce the memory size dedicated to the data which will be classified.

So, it is possible to know, that only a small number of variables have interest. In this case, these variables can be selected and the other thrown, in order to reduce the data set dimensionality. More generally, dimension and data reduction prove to be necessary for the management of large-scale data sets.

The scale-reduction is a complex problem which has been largely studied. In this paper, we have proposed a new clustering algorithm, called SR-WEFCM, used in the case of large-scale data sets and based on, both a compression technique to reduce the data, and PCA to reduce the variables (or attributes).

With SR-WEFCM, our objective is reached. We work out an automatic clustering algorithm for large-scale data set. This is ensured through both an enhanced compression technique and validity measures which allow the evaluation of obtained clustering while giving the optimal number of clusters. It ensures a double reduction, the dimension and the data.

As future work, we propose to i) test our approaches with other large-scale data sets and ii) take into account uncertain data and keep only the data representative by using a selection variables technique.

***Abstract*—In this paper, two novel soft subspace clustering algorithms, namely fuzzy weighting subspace clustering with competitive agglomeration (FWSCA) and entropy weighting subspace clustering with competitive agglomeration (EWSCA), are proposed to overcome the problems of the unknown number of clusters and the initialization of prototypes for soft subspace clustering. The main advantage of FWSCA and EWSCA lies in the fact that they effectively integrate the merits of soft subspace clustering and the good properties of fuzzy clustering with competitive agglomeration. This makes it possible to obtain the appropriate number of clusters during the clustering progress. Moreover, FWSCA and EWSCA algorithms can converge regardless of the initial number of clusters and initialization. Substantial experimental results on both synthetic and real data sets demonstrate the effectiveness of FWSCA and EWSCA in addressing the two problems.**

Keywords-subspace clustering; competitive agglomeration; fuzzy weighting subspace clustering; entropy weighting subspace clustering; optimal number of clusters

I. INTRODUCTION

Clustering has long been a hot research topic in various disciplines. It has been widely utilized as an efficient tool for data analysis and visualization in areas such as machine learning and data mining [1]. Clustering partitions the unlabeled input vectors into different groups, called clusters, such that data points within a cluster are more similar to each other than they are to those belonging to different clusters, i.e., by maximizing the intra-cluster similarity while minimizing the inter-class similarity [2]. However, clustering high dimensional data has become an emerging research field, since dimensions might have locally varying relevance for different groups of objects in high dimensional spaces [3]. For example, given a subset of data points identified in a cluster, it is possible that these points exhibit different characteristics from others when varied subsets of dimensions are observed.

The difficulty that traditional clustering algorithms encounter in dealing with high dimensional data sets inspired the invention of subspace clustering or projected clustering [4], which has been studied extensively in recent years [3-13]. The goal of subspace clustering is to locate clusters embedded in different subspaces of the original data space with their own associated dimensions. Based on the ways that the subspaces of clusters are determined, subspace clustering algorithms can be generally classified into two main categories : hard subspace clustering and soft subspace clustering [5]. Hard subspace clustering methods identify the exact subspaces for different clusters, which can be divided into bottom-up [4, 6] and top-down [7] subspace methods according to their subspace searching methods. Soft subspace clustering methods can measure the importance of each dimensionality to a particular cluster in the clustering process by automatically assigning different weightings to different dimensions of clusters embedded in subspaces. In this paper, we focus on soft subspace clustering. Many different soft subspace clustering algorithms have been proposed recently [8-13] and the resulting algorithms can be grouped into two main categories [9, 11]: fuzzy weighting subspace clustering (FWSC) and entropy weighting subspace clustering (EWSC). The final partition of both the FWSC and EWSC approaches assumes that the number of clusters is known prior to clustering. However, this is rarely the case and the optimal number of clusters is hard to determine.

In order to deal with the above problem for traditional clustering algorithms, Frigui and Krishnapuram introduced a regularization term to the original objective function of FCM and derived the fuzzy clustering with competitive agglomeration algorithm (FCA) [14]. In FCA, the initial partition has an over-specified number of clusters, which is progressively reduced until an optimum is reached. Zhang et al. revisited and reformulated the FCA algorithm from the point of view of entropy minimization, and proposed four generalized competitive clustering algorithms: RECA, SECA, CA-p and RECA-p [15]. Grira et al. presented a new algorithm, active fuzzy constrained clustering, in the categorization of image database by minimizing a competitive agglomeration cost function with fuzzy terms corresponding to pairwise constraints provided by the user [16]. Recently, Jeng et al. proposed an interval competitive agglomeration clustering algorithm, which uses the theory of competitive agglomeration for clustering the symbolic interval-values data [17]. However, all these competitive agglomeration-based clustering algorithms are applied in full dimensional space. It is anticipated that the performance of clustering can be further enhanced by including subspace selection in the clustering process.

By considering the advantages of competitive agglomeration, clustering algorithms can be rapidly converged in a few iterations regardless of the initial number of clusters, and can also converge to the same optimal partition regardless of its initialization. Inspired by this fact of competitive agglomeration, we propose two novel soft subspaces clustering

* Corresponding author: email (longbing.cao-1@uts.edu.au)

algorithms: fuzzy weighting subspace clustering with competitive agglomeration (FWSCA) and entropy weighting subspace clustering with competitive agglomeration (EWSCA). FWSCA and EWSCA not only inherit the merits of soft subspace clustering, but also receive the beneficial properties of fuzzy clustering with competitive agglomeration. Our experiment results demonstrate that FWSCA and EWSCA are generally effective in subspace clustering and can achieve superior performance over traditional soft subspace clustering and competitive agglomeration-based clustering algorithms in most cases. Furthermore, a link between FWSCA, EWSCA algorithms and FWSC, EWSC algorithms is established in Section III.A. Thus, the FWSC and EWSC algorithms are regarded as a special case of the proposed FWSCA and EWSCA algorithms. The rest of this paper is organized as follows. In Section Ⅱ, a brief overview of existing algorithms for soft subspace clustering is provided. The proposed FWSCA and EWSCA algorithms are presented and their properties are explained in Section Ⅲ. In Section Ⅳ, the clustering performances of FWSCA and EWSCA, as compared with other algorithms, on artificial and UCI data sets are reported. Finally, conclusions and future work are presented in Section Ⅴ.

II. SOFT SUBSPACE CLUSTERING

Soft clustering aims at grouping a set of given data points $X = \{x_1, x_2, \cdots x_n\} \subset R^d$ into a set of clustering prototypes $V = \{v_i,\ 1 \le i \le c\}$. Let u_{ij} denote the membership degree of x_j belonging to v_i, then we can define the fuzzy *c*-partition *U* of the given data set, i.e., $U = \{u_{ij} \mid 1 \le i \le c,\ 1 \le j \le n\}$. To discover clusters from different subspaces, it is important that a soft clustering algorithm has the capability of clustering data points in a subspace by automatically weighting features in the clustering process. Based on the importance of the *k*-th dimension on the formation of *i*-th cluster, a weighting w_{ik} is assigned to each dimension in soft subspace clustering. The subspaces of different clusters can be identified by the weight matrix $W = \{w_{ik} \mid 1 \le i \le c,\ 1 \le k \le d\}$ after clustering [11, 12].

A. Fuzzy weighting subspace clustering

Fuzzy weighting subspace clustering (FWSC) aims to find clusters from fuzzy weighting subspaces [8, 10, 12]. In all the fuzzy weighting subspace clustering algorithms, a fuzzy weight w_{ik}^m is assigned to the features of different clusters with a fuzzy weighting index m. The objective function of FWSC is generally formulated as:

$$J_{FWSC} = \sum_{i=1}^{c}\sum_{j=1}^{n} u_{ij}^2 \sum_{k=1}^{d} w_{ik}^m (x_{jk} - v_{ik})^2 \tag{1}$$

$$\text{s. t. } 0 \le u_{ij} \le 1, \sum_{i=1}^{c} u_{ij} = 1, 0 \le w_{ik} \le 1, \sum_{k=1}^{d} w_{ik} = 1.$$

By minimizing (1) using Lagrangian optimization, the updating equation for estimating center v_i, fuzzy weighting w_{ik} and membership u_{ij} can be derived.

B. Entropy weighting subspace clustering

The entropy concept, which is used to represent the certainty of dimensions in the identification of a cluster, is introduced into soft subspace clustering [9, 11, 13]. Because the weights in extended subspace clustering algorithms are controllable by entropy, these types of algorithms are referred to as entropy weighting subspace clustering (EWSC). In general, the objective function of EWSC can be defined as:

$$J_{EWSC} = \sum_{i=1}^{c}\sum_{j=1}^{n} u_{ij}^2 \sum_{k=1}^{d} w_{ik} (x_{jk} - v_{ik})^2 + \gamma \sum_{i=1}^{c}\sum_{k=1}^{d} w_{ik} \log w_{ik} \tag{2}$$

$$\text{s. t. } 0 \le u_{ij} \le 1, \sum_{i=1}^{c} u_{ij} = 1, 0 \le w_{ik} \le 1, \sum_{k=1}^{d} w_{ik} = 1.$$

The Lagrange multipliers method is also applied to minimize the objective function in (2). It can result in the equations for updating the estimations of center v_i, entropy weighting w_{ik} and membership u_{ij}. In (1) and (2), to cater for the fuzzy partition, we specify $0 \le u_{ij} \le 1$, while $u_{ij} \in \{0,1\}$ is used in the K-means framework-based FWSC [8, 10, 12] and EWSC algorithms [11, 13] for hard partition.

By observing the existing soft subspace clustering algorithms, we find that the final partition of both FWSC and EWSC is based on the assumption that the number of clusters is known prior to clustering. However, this is rarely the case, and the optimal number of clusters is difficult to determine. As a result, the clustering algorithms are sensitive to the initialization. An effective way to overcome the above problems is to extend the concept of the competitive agglomeration (CA) in FWSC and EWSC, since CA can help to determine the initialization and the number of clusters during the clustering progress.

III. SOFT SUBSPACE CLUSTERING WITH COMPETITIVE AGGLOMERATION

A. Objective function based on the theory of competitive agglomeration

How to find an "appropriate" number of clusters is an important issue for partition-based clustering. Fuzzy clustering with competitive agglomeration (FCA) was introduced to solve the problem by adding a regularization term to the cost function [14]. The regularization term can avoid overfitting of a data set with too many prototypes, make clusters compete for membership of data points, and result in the number of clusters gradually being reduced until an optimum is reached.

To incorporate the idea of competitive agglomeration into FWSC and EWSC, we add a term to agglomerate all data points into one cluster in the objective functions to generate fuzzy weighting and entropy weighting-based subspace clustering with competitive agglomeration, namely FWSCA, EWSCA, which minimize:

$$J_{FWSCA} = \sum_{i=1}^{c}\sum_{j=1}^{n} u_{ij}^2 \sum_{k=1}^{d} w_{ik}^m (x_{jk} - v_{ik})^2 - \alpha \sum_{i=1}^{c}\left[\sum_{j=1}^{n} u_{ij}\right]^2 \quad (3)$$

and

$$J_{EWSCA} = \sum_{i=1}^{c}\sum_{j=1}^{n} u_{ij}^2 \sum_{k=1}^{d} w_{ik} (x_{jk} - v_{ik})^2 + \gamma \sum_{i=1}^{c}\sum_{k=1}^{d} w_{ik} \log w_{ik} - \alpha \sum_{i=1}^{c}\left[\sum_{j=1}^{n} u_{ij}\right]^2 \quad (4)$$

under the same constraint of (1) or (2).

By comparing the objective functions (3) and (4) for FWSCA and EWSCA and those in (1) and (2) for FWSC and EWSC, the first terms of objective functions for FWSCA and EWSCA are similar to those of FWSC and EWSC. The first term of FWSCA is the sum of the squared distances to the prototypes weighted by the constrained feature weightings and fuzzy memberships; and the first term of EWSCA is the sum of the intra-cluster dispersions and the negative weight entropy. Both components allow us to control the shapes and sizes of the clusters and lead to the compact clusters. The global minimum of these components is achieved when the number of clusters c is equal to the number of data points n. The last terms of (3) and (4) are the sum of squares of the cardinalities of the clusters, which allows us to control the number of clusters. By minimizing this term, all data points are agglomerated into one cluster, as shown by Theorem 1.

Theorem 1: Given $0 \le u_{ij} \le 1$ and $\sum_{i=1}^{c} u_{ij} = 1$, the membership constraint function $f(u_{11}, u_{12}, \cdots u_{cn}) = -\sum_{i=1}^{c}\left[\sum_{j=1}^{n} u_{ij}\right]^2$ reaches its minimum, i.e. $-n^2$, when u_{ij} is equal to 1 and u_{kj} are equal to 0 for all other $k \ne i$ $(1 \le j \le n)$.

Therefore, the parameter α in (3) and (4) controls the balance between the two components in order to find an optimal number of clusters c. It should be noted that c is dynamically updated during the process of FWSCA and EWSCA. Fig. 1 shows the relationship between the objective function and the number of clusters for FWSCA and EWSCA on a synthetic data set used in Section Ⅳ. To show the dynamics of three curves simultaneously, all values are normalized into the interval [3, 15], since the optimal number of clusters and the initial number of clusters are 3 and 15, respectively. It shows that the first term of the FWSCA and EWSCA objective function increases as the number of clusters c decreases. On the other hand, the last term of the objective functions becomes smaller when the number of clusters c decreases. The dynamics of the objective function shows that, if α is properly chosen, adjacent clusters will compete for the data points; those clusters lost in competition will gradually be discarded and disappear. Consequently, an appropriate number of clusters is obtained.

B. *Fuzzy weighting subspace clustering with Competitive Agglomeration (FWSCA)*

To minimize the objective function of FWSCA in (3), we apply Lagrange multipliers and obtain the V and W updating equation based on the theorems below.

Theorem 2: Given that U and W are fixed, and $m > 1$, $\alpha > 0$, J_{FWSCA} reaches the local minimum if and only if V meets the following condition:

$$v_{ik} = \frac{\sum_{j=1}^{n} u_{ij}^2 x_{jk}}{\sum_{j=1}^{n} u_{ij}^2} \quad (5)$$

Theorem 3: Given that U and V are fixed, and $m > 1$, $\alpha > 0$, J_{FWSCA} reaches the local minimum if and only if W meets the following condition:

$$w_{ik} = \frac{1}{\sum_{s=1}^{d}\left[\frac{\sum_{j=1}^{n} u_{ij}^2 (x_{jk} - v_{ik})^2}{\sum_{j=1}^{n} u_{ij}^2 (x_{js} - v_{is})^2}\right]^{\frac{1}{m-1}}} \quad (6)$$

To obtain the updating equation u_{ij}, J_{FWSCA} is minimized with respect to U for fixed V and W, and both are set to zero. We apply Lagrange multipliers to (3) and obtain:

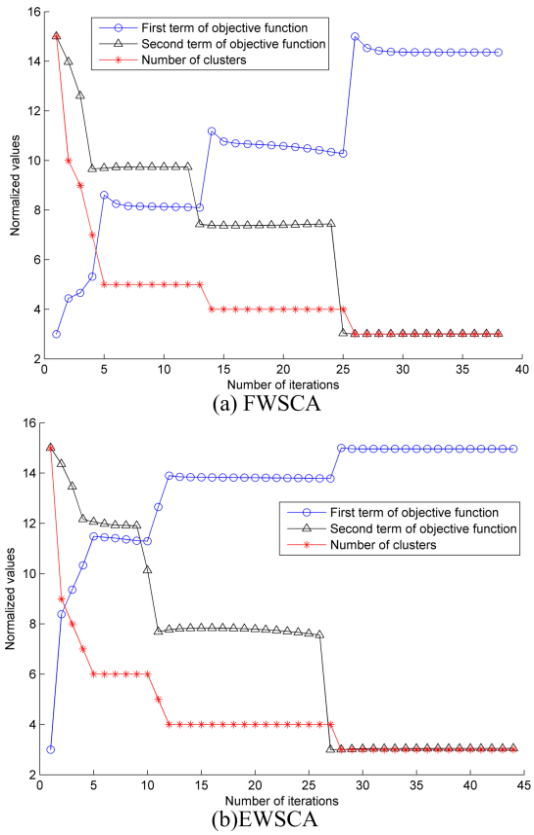

Fig. 1 The change curve of the objective function and the number of clusters. (a) FWSCA, (b) EWSCA

$$\phi(u_{ij}) = \sum_{i=1}^{c}\sum_{j=1}^{n} u_{ij}^2 \sum_{k=1}^{d} w_{ik}^m (x_{jk} - v_{ik})^2 - \alpha \sum_{i=1}^{c}\left[\sum_{j=1}^{n} u_{ij}\right]^2 - \sum_{j=1}^{n} \lambda_j^u \left(\sum_{i=1}^{c} u_{ij} - 1\right) \quad (7)$$

With (7), we can compute the optimal value of u_{ij} by setting $\partial\phi/\partial u_{ij} = 0$. These derivatives yield the following relationship:

$$\frac{\partial \phi}{\partial u_{ij}} = 2u_{ij}\left(\sum_{k=1}^{d} w_{ik}^m (x_{jk} - v_{ik})^2\right) - 2\alpha\left(\sum_{j=1}^{n} u_{ij}\right) - \lambda_j^u = 0 \quad (8)$$

The solution of (8) can be simplified by assuming that the membership values do not change significantly from one iteration to another. With this assumption, and by computing the cardinality of cluster i, $N_i = \sum_{j=1}^{n} u_{ij}$ using the membership values from previous iteration, (8) is converted to

$$u_{ij} = \frac{2\alpha N_i + \lambda_j^u}{2\left(\sum_{k=1}^{d} w_{ik}^m (x_{jk} - v_{ik})^2\right)} \quad (9)$$

Using the membership constraint $\sum_{s=1}^{c} u_{sj} = 1$, we obtain

$$\lambda_j^u = \frac{1 - \alpha \sum_{s=1}^{c}\left[N_s \Big/ \left(\sum_{k=1}^{d} w_{sk}^m (x_{jk} - v_{sk})^2\right)\right]}{\sum_{s=1}^{c}\left[1 \Big/ \left(2\sum_{k=1}^{d} w_{sk}^m (x_{jk} - v_{sk})^2\right)\right]} \quad (10)$$

Substituting (10) in (9), we obtain the following updated equation for the membership of data point x_j to center v_i after rearranging the terms.

$$u_{ij} = u_{ij}^{FCM} + u_{ij}^{Bias} \quad (11)$$

where

$$u_{ij}^{FCM} = \frac{1}{\sum_{s=1}^{c}\left[\left(\sum_{k=1}^{d} w_{ik}^m (x_{jk} - v_{ik})^2\right) \Big/ \left(\sum_{k=1}^{d} w_{sk}^m (x_{jk} - v_{sk})^2\right)\right]} \quad (12)$$

and

$$u_{ij}^{Bias} = \alpha \frac{N_i - \bar{N}_j}{\sum_{k=1}^{d} w_{ik}^m (x_{jk} - v_{ik})^2} \quad (13)$$

In (13), $\bar{N}_j$ is defined as

$$\bar{N}_j = \frac{\sum_{s=1}^{c}\left[1 \Big/ \left(\sum_{k=1}^{d} w_{sk}^m (x_{jk} - v_{sk})^2\right) N_s\right]}{\sum_{s=1}^{c}\left[1 \Big/ \left(\sum_{k=1}^{d} w_{sk}^m (x_{jk} - v_{sk})^2\right)\right]} \quad (14)$$

which is simply a weighted average of the cluster cardinalities.

The updated function (11) for FWSCA brings about several benefits. The first component in (11) is the same as that in FCM, and considers only the relative distances of a data point to all clusters. The second component contributes to the reduction of the cardinality of spurious clusters, which are discarded when their cardinality drops below a threshold. Indeed, u_{ij}^{Bias} is also a signed bias term that depends on the difference between the cardinality N_i of the cluster i and the weighted average of the cardinalities $\bar{N}_j$ from x_j. For the clusters with cardinality lower than the average value, the bias term is negative. The membership value is then decreased.

Further, α plays an important role in FWSCA in (13) for balancing the two components of (11). To make FWSCA independent of the distance measure, α should be chosen such that both terms in (11) are of the same order of magnitude [14, 16]. Thus, α should be proportional to the ratio of the two terms. In this paper, α is chosen as

$$\alpha(itr) = \tau(itr) \frac{\sum_{i=1}^{c}\sum_{j=1}^{n} u_{ij}^2 \sum_{k=1}^{d} w_{ik}^m (x_{jk} - v_{ik})^2}{\sum_{i=1}^{c}\left[\sum_{j=1}^{n} u_{ij}\right]^2} \quad (15)$$

where *itr* is an iteration index. The best choice for τ is the exponential factor defined in [16]

$$\tau(itr) = \tau_0 \exp(-|itr - itr_0| / \xi) \quad (16)$$

In our experiments, the initial value τ_0, the time constant itr_0, and ξ in (16) are set as 0.8, 10 and 20, respectively.

Finally, let us discuss the agglomeration process of FWSCA. As discussed in [16], FCA [14] discards spurious clusters whose cardinalities drop below a threshold; however the clustering is sensitive to the threshold parameter. In this paper, we investigate an alternative process to improve the agglomeration. The details of the process are given as follows.

We first compute the average cardinality of clusters at the *itr-th* iteration below.

$$Card_{avg}(itr) = \frac{\sum_{i=1}^{c}\sum_{j=1}^{n} u_{ij}}{num_of_cluster(itr)} = \frac{n}{c(itr)} \quad (17)$$

where *itr* is an iteration index, *n* is the number of data points and *c*(*itr*) is the number of clusters at the *itr-th* iteration. So the minimum cardinality threshold (*MCT*) can be defined by

$$MCT(itr) = \eta \times Card_{avg}(itr) \quad (18)$$

where η is the agglomeration threshold parameter. When the cardinality of a cluster reduces below the *MCT* at the *itr-th* iteration, we discard the cluster, and update the number of clusters. The selection of η will be discussed in the experiments in Section Ⅳ.

Next, we compute the distances between pairs of prototypes *d*(*r*), for $r = 1, \cdots, R$, $R = c(itr) \times (c(itr) - 1)/2$. If *min* is the index corresponding to the pair having the minimal distance

Procedures of FWSCA clustering algorithm

Step1. Set the maximum number of clusters c=c_{max} ($2 \le c_{max} \le n$), the fuzzy weighting index m and the agglomerate threshold parameter η, initialize the fuzzy partition $u_{ij}^{(1)}$ and fix the iterative index itr=1;
Step2. Compute the clustering centers matrix $\boldsymbol{V}(itr+1)$ using Eq.(5);
Step3. Compute the weight matrix $\boldsymbol{W}(itr+1)$ using Eq. (6);
Step4. Compute the cardinality N_i for $1 \le i \le c$;
Step5. Update $\alpha(itr)$ using Eq. (15) and Eq. (16);
Step6. Compute the partition matrix $\boldsymbol{U}(itr+1)$ using Eq. (11);
Step7. If N_i is smaller than minimum cardinality threshold (Eq. (18)) or the minimal distance between pairs of prototypes is satisfied Eq. (19) then discard the cluster;
Step8. Update the number of clusters $c(itr+1)$;
Step9. If prototype parameters are stabilized, then output the clustering result and terminate, otherwise itr=itr+1, go to Step 2.

Figure 2. Description of the proposed FWSCA algorithm

d_{min}, then we discard the cluster, and update the number of clusters when the following criterion is satisfied:

$$d_{min} < 0.2 \times \sum_{r=1}^{R} d(r) \Big/ R \tag{19}$$

where $d_{min} = \min\{d(r) \mid r = 1, \cdots, R\}$ and $\sum_{r=1}^{R} d(r) \Big/ R$ is the average distances between pairs of prototypes at the *itr-th* iteration.

Fig. 2 shows the procedure of FWSCA algorithm.

C. *Entropy weighting subspace clustering with Competitive Agglomeration (EWSCA)*

To minimize the objective function of EWSCA defined in (4), the Lagrange multipliers method is applied, and we obtain the following Theorems 4 and 5, which can help the optimization of the EWSCA procedure.

Theorem 4: Given that U and W are fixed, and $\gamma > 0, \alpha > 0$, J_{EWSCA} reaches the local minimum if and only if V meets the following condition:

$$v_{ik} = \frac{\sum_{j=1}^{n} u_{ij}^2 x_{jk}}{\sum_{j=1}^{n} u_{ij}^2} \tag{20}$$

Theorem 5: Given that U and V are fixed, and $\gamma > 0, \alpha > 0$, J_{EWSCA} reaches the local minimum if and only if W meets the following condition:

$$w_{ik} = \frac{\exp(-\sum_{j=1}^{n} u_{ij}^2 (x_{jk} - v_{ik})^2 \Big/ \gamma)}{\sum_{s=1}^{d} \exp(-\sum_{j=1}^{n} u_{ij}^2 (x_{js} - v_{is})^2 \Big/ \gamma)} \tag{21}$$

Similar to the deriving procedures of FWSCA, we obtain the updating equation u_{ij} of EWSCA:

$$u_{ij} = u_{ij}^{FCM'} + u_{ij}^{Bias'} \tag{22}$$

where

$$u_{ij}^{FCM'} = \frac{1}{\sum_{s=1}^{c} \left[\left(\sum_{k=1}^{d} w_{ik} (x_{jk} - v_{ik})^2 \right) \Big/ \left(\sum_{k=1}^{d} w_{sk} (x_{jk} - v_{sk})^2 \right) \right]} \tag{23}$$

$$u_{ij}^{Bias'} = \alpha \frac{N_i - \bar{N}_j}{\sum_{k=1}^{d} w_{ik} (x_{jk} - v_{ik})^2} \tag{24}$$

Procedures of EWSCA clustering algorithm

Step1. Set the maximum number of clusters c=c_{max} ($2 \le c_{max} \le n$), the entropy weighting index γ and the agglomerate threshold parameter η, initialize the fuzzy partition $u_{ij}^{(1)}$ and fix the iterative index itr=1;
Step2. Compute the clustering centers matrix $\boldsymbol{V}(itr+1)$ using Eq.(20);
Step3. Compute the weight matrix $\boldsymbol{W}(itr+1)$ using Eq. (21);
Step4. Compute the cardinality N_i for $1 \le i \le c$;
Step5. Update $\alpha(itr)$ using Eq. (15) and Eq. (16);
Step6. Compute the partition matrix $\boldsymbol{U}(itr+1)$ using Eq. (22);
Step7. If N_i is smaller than minimum cardinality threshold (Eq. (18)) or the minimal distance between pairs of prototypes is satisfied Eq. (19) then discard the cluster;
Step8. Update the number of clusters $c(itr+1)$.
Step9. If prototype parameters are stabilized, then output the clustering result and terminate, otherwise itr=itr+1, go to Step 2.

Figure 3. Description of the proposed EWSCA algorithm.

In (24), $\bar{N}_j$ is defined as

$$\bar{N}_j = \frac{\sum_{s=1}^{c} \left[1 \Big/ \left(\sum_{k=1}^{d} w_{sk} (x_{jk} - v_{sk})^2 \right) N_s \right]}{\sum_{s=1}^{c} \left[1 \Big/ \left(\sum_{k=1}^{d} w_{sk} (x_{jk} - v_{sk})^2 \right) \right]} \tag{25}$$

which is simply a weighted average of the cluster cardinalities.

The selection of α and the agglomeration process of EWSCA are similar to that of FWSCA. Accordingly, we describe the procedures of EWSCA as shown in Fig. 3.

D. *Convergence and computational complexity of FWSCA and EWSCA*

When (5), (6) and (11) are adopted, J_{FWSCA} will certainly converge, because FWSCA degenerates into FWSC when α takes zero, and J_{FWSCA} with $\alpha > 0$ can easily be proved to be convergent using the similar proof in [10]. Similarly, the proposed EWSCA algorithm is indeed an extension of EWSC. By employing a strategy similar to that used in EWSC [11], it can be inferred that the proposed EWSCA algorithm, at least along a subsequence, converges to either a local optimal solution or a saddle point of its objective function.

Thus, FWSC and EWSC can be regarded as special cases of FWSCA and EWSCA respectively. Consequently, FWSCA and EWSCA have the same upper bound of the computational complexity as FWSC and EWSC, i.e., $O(ncdT)$ where n denotes the number of all data points, c denotes the number of the cluster centers which varies from $\boldsymbol{c_{max}}$ to $\boldsymbol{c_{final}}$, d denotes the dimensionality of the data points, and T denotes the maximal number of iterations. As the numbers of clusters for FWSCA and EWSCA are decreased during the clustering progress, they actually require more computational time, and converge a little more slowly than FWSC and EWSC.

IV. Experiments and Evaluation

Two sets of experiments are conducted to compare the clustering results of FWSCA and EWSCA with FCA, FWSC and EWSC. All data sets are preprocessed by normalizing the feature in each dimension into the interval [0, 1]. The initial fuzzy partitions for FCA, FWSCA and EWSCA are obtained by performing the FCM algorithm in the first ten iterations respectively. Normalized mutual information (NMI) [18] and

Rand Index [19] are used to evaluate the performance of five clustering algorithms.

A. *Performance evaluation on synthetic data sets*

In this experiment, we adopt a simulated data set to examine whether FWSCA and EWSCA converge to the appropriate partition and evaluate the clustering performance of five algorithms. The data set consists of three clusters in 2-D space which satisfies the normal distribution: the centers of three clusters are (28, 22), (60, 30) and (45, 38) respectively. For the first two clusters, the number of data points per cluster is 120 and their respective covariance matrices are $\begin{bmatrix} 100 & 0 \\ 0 & 9 \end{bmatrix}$ and $\begin{bmatrix} 9 & 0 \\ 0 & 144 \end{bmatrix}$, respectively. For the last cluster centered at (45, 38), there are 140 data points and its covariance matrix is $\begin{bmatrix} 9 & 0 \\ 0 & 9 \end{bmatrix}$. Fig.4 plots this data set, which is used to test the clustering results, since the data points belonging to three clusters locate at different subspaces. In this experiment, we tried many different values of c_{max} ranging from 9 to 21, and set m=3 in FWSC and FWSCA, $\gamma = 1$ in EWSC and EWSCA, and the agglomeration threshold parameter η of 0.75 in FCA, FWSAC and EWSCA.

First, we analyze the independence of the proposed algorithms from the selection of the initial number of the clusters c_{max}. By setting different c_{max} value (9, 12, 15, 18 and 21), we reduce the number of clusters to observe whether FWSCA and EWSCA converge to the same final partition. As shown in Fig. 5 (a) and (b), we find that FWSCA and EWSCA are insensitive to the initial number of clusters; both algorithms can converge in a few iterations as long as c_{max} is higher than the optimal number of clusters.

Second, we analyze the insensitivity of FWSCA and EWSCA to the initial clustering centers. Fig. 6 (a) and (b) show the relationship between the selection of the initial clustering centers and the number of iterations. The initial clustering centers are randomly selected with c_{max} =15. The results show that both algorithms converge to the same appropriate partition regardless of the initialization of centers.

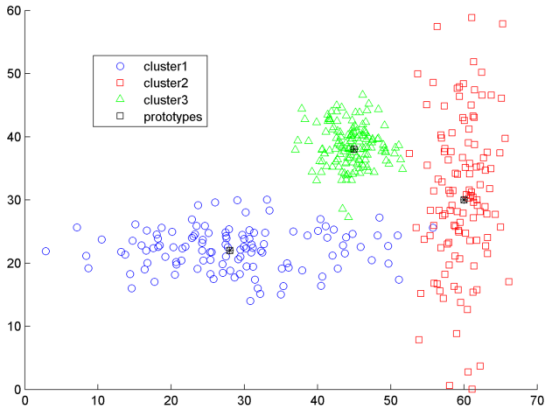

Figure 4. Synthetic data set.

Finally, we compare the clustering performance of FWSCA, EWSCA, FCA, FWSC and EWSC on the synthetic data set. Experiments are conducted by running each algorithm 20 times. The clustering results are evaluated in terms of the means and standard deviations of the NMI and Rand Index values, are shown in Table Ⅰ. From the comparison, we observe that: (1) soft subspace clustering algorithms outperform FCA, since they integrate subspace feature weighting into the clustering process. (2) FWSCA and EWSCA outperform FWSC and EWSC by achieving better and more stable results. This is due to the fact that FWSC and EWSC are sensitive to the initialization, and they can easily get into a local minimum. (3) As we discussed in Section III.D, FWSCA and EWSCA have a slightly higher average number of iterations and average CPU running time (in seconds) than FWSC and EWSC as shown in Table Ⅱ.

B. *Performance evaluation on UCI data sets*

We further evaluate the performance of FWSCA and EWSCA against FCA, FWSC and EWSC on six UCI data sets [20] as shown in Table Ⅲ. In our experience, FWSCA and EWSCA algorithms are independent of the initial number of

clusters c_{max}, when c_{max} is chosen to be much larger than the expected number of clusters and the agglomerate threshold parameter η is appropriately chosen. Our proposed algorithms can produce a sequence of partitions with a decreasing number of clusters and can finally find the appropriate number of clusters. In this paper, we display the clustering results when c_{max} is chosen to be 15.

First, we test the sensitivity of FWSCA and EWSCA on the agglomeration threshold η. For all six UCI data sets, experiments are performed for different values of η ranging from 0.6 to 0.9. For each η, the percentage of 'match' is calculated on the data sets by running each algorithm 20 times. Here 'match' means that the number of clusters identified by FCA, FWSCA and EWSCA is equal to the true number of clusters in a data set. Fig. 7 presents the match percentage on datasets iris and wine for FCA, FWSCA and EWSCA, under a series of agglomeration thresholds η.

As shown in Fig. 7, the match percentage of FWSCA and EWSCA is bigger than FCA, and the effective region of FWSCA and EWSCA is wider than that of FCA. Therefore, FWSCA and EWSCA are less sensitive to η.

Second, we compare the performance of FWSCA and EWSCA against FCA, FWSC and EWSC on the six UCI data sets. We evaluate the cluster validity index NMI and Rand Index under different η values when the algorithms find the true number of clusters. Experiments are conducted by running each algorithm 20 times. The clustering results are shown in terms of mean and standard deviation of NMI and Rand Index, as in Tables Ⅳ and Ⅴ respectively. They show that EWSCA performs better than all other algorithms in most cases.

TABLE Ⅲ UCI DATA SETS USED IN THE EXPERIMENT

Data sets information	Iris	Wine	Heart	Australian	Blood	Pid
Size of data set	150	178	270	690	748	768
Number of dimensions	4	13	13	14	4	8
Number of clusters	3	3	2	2	2	2

Finally, Tables Ⅵ and Ⅶ show the average number of iterations and the average CPU running time (in seconds) of the five algorithms on the UCI data sets. We can see that the iteration numbers and CPU running time of FWSCA and EWSCA are higher than those of FWSC and EWSC. This is due to the fact that the number of clusters for FWSCA and EWSCA decreases during the clustering progress. We also find that the computational complexity of FWSCA and EWSCA is sometimes lower than FCA, since the selection of different subspaces can accelerate the clustering convergence.

In summary, experimental results on both synthetic and real data sets demonstrate that FWSCA and EWSCA have the following advantages. First, both FWSCA and EWSCA outperform the classic soft subspace clustering and competitive agglomeration-based clustering algorithms in most cases. Second, FWSCA and EWSCA can obtain the appropriate number of clusters during the clustering progress regardless of the initial number of clusters. Third, FWSCA and

EWSCA are insensitive to the initialization of the clusters, and can avoid trapping into the local minimum. Furthermore, although both FWSCA and EWSCA assign a weight to each dimension in the clustering process to measure the contribution of the dimension in forming a particular cluster, the experiment results show that EWSCA is better than FWSCA in most case. We attempt to merge the results of both algorithms and see if new insights do emerge in the near future.

V. CONCLUSION

Clustering algorithms face two typical challenges: the unknown number of clusters and the initialization of prototypes in the clustering. This paper has proposed two algorithms to address these problems. First, two novel objective functions have been proposed by extending the fuzzy and entropy subspace clustering objective functions, and integrating the theory of competitive agglomeration. Second, the two soft subspace clustering algorithms with competitive agglomeration, namely FWSCA and EWSCA, have been developed. Extensive experiments on artificial and UCI data sets have shown that FWSCA and EWSCA outperform the classic algorithms FCA, FWSC and EWSC in terms of identifying the number of clusters and the initialization of prototypes in the clustering.

While FWSCA and EWSCA hold great potential for soft subspace clustering, we are further enhancing them, for instance, to improve detection of the true number of clusters and the convergence speed, and to conduct a theoretical study on the sensitive parameters setting of FWSCA and EWSCA algorithms.

***Abstract*—Unconstrained human hand motions consisting grasp motion and in-hand manipulation lead to a fundamental challenge that many algorithms have to face in both theoretical and practical development, mainly due to the complexity and dexterity of the human hand. In this paper, fuzzy active curve axis Gaussian Mixture Model (FAcaGMM) is proposed by introducing a weighting exponent on the fuzzy membership into active curve axis Gaussian Mixture Models (AcaGMM) to improve its convergence efficiency, and then FAcaGMM is used to recognize human hand motions. In addition, a comparative study of recognition methods including FAcaGMM, Time Clustering (TC), Empirical Copula (EC), GMM and HMM is presented to recognize human hand motions including both grasps and in-hand manipulations from different subjects with varying training samples.**

***Keywords*—Motion Recognition; Gaussian Mixture Models; Active Curve Axis Gaussian Mixture Models; Fuzzy Active Curve Axis Gaussian Mixture Models**

I. INTRODUCTION

Human-robot skill transfer is of great importance in order to develop advanced multifingered manipulation planning and control systems. Learning from human hand motions is preferred for human-robot skill transfer in that, unlike teleoperation-related methods, it provides non-contact skill transfer from human motions to robot motions by a paradigm that can endow artifacts with the ability for skill growth and life-long adaptation without detailed programming [1].

During the learning process, hand motion recognition is still an open problem due to the complexity and dexterity of the human hand, though it had been investigated in the past two decades. The attractiveness of applying neural network could be due to the nonlinearity of the network. Neural network approaches demonstrated its powerful grasp recognition in Glove-Talk project [2], [3]. Sato et al. [4] identified predetermined gestures in a fast and robust manner by using a neural network which has been properly trained beforehand. Support vector machine (SVM) was employed by Zoellner *et al* [5] to classify dynamic grasps in the framework of Programming by Demonstration. In addition, David *et al.* [6] used a combination of discriminative (SVM, conditional random fields) and generative approaches, Hidden Markov Model (HMMs), for the modeling and recognition of actions through motor primitives. However, the choice of the SVM kernel function has a significant effect on its performance and the best choice is application dependent. Natal *et al* [7] and Bedregal *et al* [8] developed fuzzy rule-based methods for the recognition of hand gestures, however the methods are highly dependent on a detailed previous analysis of the recognized gesture features with manual transfer involved. Note that Heumer *et al* [9] attempted to provide a performance criteria for hand grasp classification including 28 algorithms provided by Weka data mining software package. However these algorithms usually require more parameters such as finger angular speed instead of position trajectories only, they have also paid less attention to the context of intelligent robotics, for instance, real-time recognition requirement.

In addition, state of the art in human hand motion recognition can be represented by Gaussian Mixture Model (GMMs), HMM and their variants, since they are very rich in mathematical structure and hence their theoretical basis can be adopted for a wide range of applications. Calinon and Billard [10] proposed an approach to teach incrementally human gestures to a humanoid robot, which consists of projecting the movement data in a latent space and encoding the resulting signals in a GMM. Kaustubh *et al.* [11] used GMMs to classify one-handed gestures based on ultrasonic sensors, and the experiment showed simplified one-handed gestures can be recognized with a high accuracy. On the other hand, in [12], the moving hand is tracked and analyzed by Fourier descriptor (FD) from image sequences, and then the feature vector consisting the spatial and temporal features is processed by HMMs for recognition of the hand gesture. Bernardin et al. [13] presented a method using HMMs to recognize continuously executed sequences of grasping gestures. Both finger-joint angles and information about contact surfaces, captured by a data glove and tactile sensors, are used. By using the Kamakura taxonomy, most of all grasps used by humans in everyday life can be classified, increasing the system's application domain to general manipulation tasks. For 12 grasp classes, and with very little training data, a recognition accuracy of up to 89% for a single-user

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

system and 95% for a multiple-user system could be reached. Ju *et al* [14] compared Time Clustering (TC) with HMMs and GMMs on the recognition rate of 13 types of different grasps. Just et al. [15] provided an empirical comparison of two state-of-the-art techniques, HMMs and Input/Output HMMs, for temporal event modeling combined with specific features on two different datasets.

Gaussian Model is confined to normal distributed clusters, so that more Gaussian components are needed for approximating the data with curve manifolds[16], [17]. In order to solve this problem, Active curve axis Gaussian Model (AcaGM), proposed by Baibo[18], is a new non-linear probability model imagined as Gaussian Model being bent at the first principal axis. Inspired from the mechanism of Fuzzy C-means (FCM) [19], in this paper, we firstly introduce a weighting exponent on the fuzzy membership into active curve axis Gaussian Mixiture Model (AcaGMM) in order to improve the efficiency of convergence and then use the proposed fuzzy active curve axis Gaussian Mixture Model (FAcaGMM) to recognize the human hand motions. In addition, a comparative study of recognition methods including FAcaGMM, Time Clustering (TC), Empirical Copula (EC), GMM and HMM is presented. This paper is organized as follows: Section II revisits the mechanism of AcaGMM. Section III proposes the FAcaGMM with an improved convergence speed. Section IV proposes the algorithm to recognize hand motions using FAcaGMM. The comparative experiments are presented in section V. Finally the paper is concluded with remarks and future work.

II. Active Curve Axis Gaussian Model

Let $\mathcal{X} = \{x_1, \cdots, x_n\}$ be a d-dimensional observed dataset of n vectors. The distribution of $\mathcal{X}$ is based on one Gaussian or bent Gaussian. First, the samples are mapped to the coordinate system determined by PCA:

$$y_i = Q \times (x_i - T) \tag{1}$$

where T and Q denote the translation vector and rotation matrix of PCA individually. Let $\mathcal{Y} = \{y_1, \cdots, y_n\}$ be the transferred coordinates of $\mathcal{X}$ by PCA. The d dimensions of $\mathcal{Y}$ are then denoted as $v = [v_1, \cdots, v_d]^T$.

Then least-squares fitting method [20] is used to fit the coordinates $[v_1, v_2]^T$, which are in $\mathcal{Y}$'s principal plane, with the standard curve which is defined as

$$y = ax^2 + b \tag{2}$$

The quadratic term coefficient a indicates the bend degree of the curve. The bigger a is, the more the principal axis bends. b is the offset of the curve. The principal axis is bent to be $y = ax^2 + b$ and the Gaussian model with the bent axis is AcaGM. An example of AcaGM is given on the left of Fig. 1.

The projective points of one sample can be thought as the points on the principal axis who have the local minimal distances with the sample. The distances between sample and points along the principal axis have zero derivatives at the sample's projective points. Given any sample $[v_{1t}, v_{2t}]^T$ which

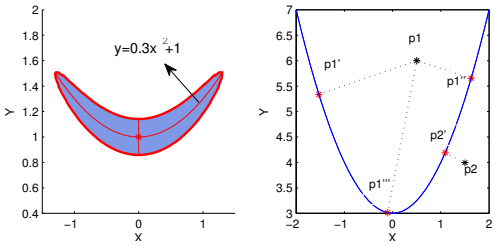

Fig. 1. AcaGM(left) and projection points on the principal curve axis(right).

is the transferred coordinates from x_t, its distance to a point $z = [z_1, z_2]^T$ on the standard curve satisfies

$$d^2 = (v_{1t} - z_1)^2 + (v_{2t} - z_2)^2$$

Using the Lagrange method, the partial derivatives to z_1 and z_2 of $d^2 - \lambda(z_2 - az_1^2 - b)$ are equal to zero,

$$(z_1 - v_{1t}) - \lambda a z_1 = 0$$

$$2(z_2 - v_{2t}) - \lambda = 0$$

Eliminate λ,

$$z_1 - v_{1t} = 2az_1(z_2 - v_{2t}) \tag{3}$$

with the standard curve equation $z_2 = az_1^2 + b$, we can solve all the real roots of this equation, which are the projective points of sample $[v_{1t}, v_{2t}]$. In the principal plane, one point may have several projection points on the principal curve axis, because bending the principal axis may cause one point locates in several different normal directions of the curve axis as shown on the right of Fig. 1. Supposing $z = [z_{1j}, z_{2j}]^T$ is the jth projective point of the sample $[v_{1t}, v_{2t}]$, the arc length of z is formulated as

$$l_j(v_{1t}) = \int_{(0,b)}^{(z_{1j}, z_{2j})} \sqrt{(dz_{1j})^2 + (dz_{2j})^2}$$

z is on the standard curve, so it satisfies $z_2 = az_1^2 + b$. So we have

$$\begin{aligned} l_j(v_{1t}) &= \tfrac{1}{2} z_{1j} \sqrt{1 + 4a^2 z_{1j}^2} \\ &+ \tfrac{1}{4|a|} \ln\left(2|a| z_{1j} + \sqrt{1 + 4a^2 z_{1j}^2}\right) \end{aligned} \tag{4}$$

The distance between the sample $[v_{1t}, v_{2t}]^T$ and its projective point z is

$$l_j(v_{2t}) = \sqrt{(v_{1t} - z_{1j})^2 + (v_{2t} - z_{2j})^2} \tag{5}$$

Then the probability density function of point x_t is the sum probability of its projective points:

$$p(x_t|\theta) = \sum_{j=1}^{J_t} \prod_{s=1}^{2} \frac{\exp(-l_j^2(v_{st})/2\Sigma_s)}{\sqrt{2\pi|\Sigma_s|}} \prod_{s=3}^{d} \frac{\exp(-v_{st}^2/2\Sigma_s)}{\sqrt{2\pi|\Sigma_s|}} \tag{6}$$

Where the parameter set $\theta = (\mu, \Sigma, C, Q, T)$; C denotes the control parameters of a standard curve $f : y = ax^2 + b$; J_t is the number of the projective points of sample x_t.

III. Fuzzy Active Curve Axis Gaussian Mixture Models

For a faster convergence speed of AcaGMMs, based on the dissimilarity function in Fuzzy C-means [21], a dissimilarity function for FAcaGMMs is defined as:

$$d_{it}^2 = \frac{1}{\alpha_i p_i(x_t|\theta_i)} \tag{7}$$

where α_i is the weight of ith component; $p_i(x_t|\theta_i)$ is from equation 6,

Compared to the standard dissimilarity function in Fuzzy C-means, the dissimilarity function defined by equation 7 consists of not only the distance but also the covariance and mixture weights, and it is in direct ratio with the exponent of the distance. The objective function is extended from Fuzzy C-means objective function as:

$$J_m(U, \mathcal{X}, \mu, \Sigma) = \sum_{t=1}^{n}\sum_{i=1}^{k}(u_{it}^m d_{it}^2) \tag{8}$$

Minimizing J_m is performed by the same u_{it} operations of FCM using

$$u_{it} = \left[\sum_{j=1}^{k}(\frac{d_{it}}{d_{jt}})^{\frac{2}{m-1}}\right]^{-1} \tag{9}$$

The new mixture weights are estimated by:

$$\alpha_i^{new} = \frac{\sum_{t=1}^{n} u_{it}^m}{\sum_{i=1}^{k}\sum_{t=1}^{n} u_{it}^m} \tag{10}$$

The parameters of curve axis (a_i, b_i) in C_i can be achieved by

$$(C_i^{new}, T_i^{new}, Q_i^{new}) = LSFM(PCA(\mathcal{X}_i')) \tag{11}$$

where

$$\mathcal{X}_i' = [w_{i1}, \cdots, w_{in}] \cdot [x_1, \cdots, x_n] \tag{12}$$

$PCA()$ is principal component analysis function for estimating the translation matrix T_i^{new} and rotation matrix U_i^{new}. $LSFM()$ is least-squares fitting method for estimating control parameters $C_i^{new} = (a, c)$ which shapes the curve axis with standard curve $y = ax^2 + b$; The centers and covariances can be computed through equations 13-15.

$$\begin{aligned}\mu_i^{new} &= (Q_i^{new})^{-1}\underbrace{[0, b, 0, \cdots, 0]^T}_{d} + T_i^{new} \\ &= (Q_i^{new})^{-1}\underbrace{[0, b, 0, \cdots, 0]^T}_{d} + \frac{\sum_{t=1}^{n} u_{it}^m x_t}{\sum_{t=1}^{n} u_{it}^m}\end{aligned} \tag{13}$$

$$\Sigma_{ie}^{new} = \frac{\sum_{t=1}^{n} u_{it}^m \bar{L}_{te}^{(i)}}{\sum_{t=1}^{n} u_{it}^m} \qquad (e = 1, 2) \tag{14}$$

$$\Sigma_{i(3-d)}^{new} = \frac{\sum_{t=1}^{n} u_{it}^m (x_t - \mu_i^{new})_{(3-d)} (x_t - \mu_i^{new})_{(3-d)}^T}{\sum_{t=1}^{n} u_{it}^m} \tag{15}$$

Where $\Sigma_{i(3-d)}$ is the covariance in the $d-3$ dimension space orthogonal to the principal plane.

With new centers and covariances, the log-likelihood expression is given by:

$$\begin{aligned}\log(\mathcal{L}(\Theta|\mathcal{X})) &= \log\left(\prod_{t=1}^{n} p(x_t|\Theta)\right) \\ &= \sum_{t=1}^{n}\log\left(\sum_{i=1}^{k}\alpha_i p_i(x_t|\theta_i)\right)\end{aligned} \tag{16}$$

where $p_i(x_t|\theta_i)$ is from equation 6.

The EM algorithm of FAcaGMMs is provided in algorithm 1 where d_{it} is obtained from equation 7.

Algorithm 1 EM algorithm of FAcaGMMs.

Require: Fix k, m and ε {k is the number of components $2 < k < n$; m is the degree of fuzziness $m > 1$; ε is a small preset real positive number}.

1: $U \leftarrow fcm(data, k)$ {Use FCM to generate matrix U satisfying equation 9}
2: **repeat**
3: **for all** i such that $1 \le i \le k$ **do**
4: $\alpha_i^{new} \leftarrow equation10$ {Compute the k fuzzy mixture weights α_i^{new} using equation 10}
5: $a_i \leftarrow equation11$
6: $\{C_i^{new}, T_i^{new}, Q_i^{new}\} \leftarrow equation11$ {Compute the k fuzzy control parameters of standard curve, translation and rotation matrices using equation 11 }
7: $\mu_i^{new} \leftarrow equation13$ {Compute the k fuzzy centers using equation 13}
8: $\Sigma_i^{new} \leftarrow equations14 - 15$ {Compute the k fuzzy covariance matrices using equations 14-15 }
9: **end for**
10: $U^{new} \leftarrow equation9$ {Upgrade the fuzzy membership using equation 9 }
11: $\log(\mathcal{L}(\Theta|\mathcal{X}))^{new} \leftarrow equation16$ {Compute the log-likelihood using equation 16}
12: **until** $\frac{\log(\mathcal{L}(\Theta|\mathcal{X}))^{new}}{\log(\mathcal{L}(\Theta|\mathcal{X}))^{old}} - 1 \le threshold$ {Stop if the relative difference of the log-likelihood between two adjacent iterations is blow the preset threshold}

An example of the comparison of AcaGMMs with fuzzy AcaGMMs in terms of the convergence speed could be seen in Fig. 2, where the overall fitnesses of these two methods are almost similar while fuzzy AcaGMMs need much less iterations. For more details about the convergence comparisons, please refer to our previous papers [22], [19].

IV. Recognition via FAcaGMM

The algorithm of equation 17 and equation 18 is constructed to recognize the testing motions. Supposing there are a attributes in the human hand motion dataset. The dissimilarity

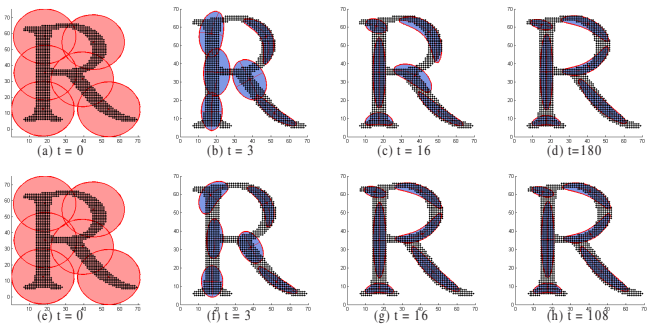

Fig. 2. A comparison of Convergence processes of AcaGMM (first row) and FAcaGMM (second row). t is the number of iterations

of the testing motion and the trained model of FAcaGMM is defined as

$$Dis = \frac{1}{a}\sum_{k=1}^{a} AvgDis^{(k)} \tag{17}$$

where k is the number of the attributes; $AvgDis^{(k)}$ is the average distance of the k^{th} attribute and is calculated by

$$AvgDis^{(k)} = \frac{1}{Cnum^{(k)}}\sum_{i=1}^{Cnum^{(k)}} |(Tmotion^{(k)}(t_i) - Center^{(k)}(i))| \tag{18}$$

where $Cnum$ is the number of the Gaussian components which is set before applying EM algorithm; $i = 1, ..., Cnum$ is the index of the Gaussian components; t_i is the time pint of i^{th} Gaussian component; $Tmotion(t_i)$ is the angle value or finger tip position of the testing hand motion at t_i; $Center(i)$ is the i^{th} model center. The corresponding motion points at the time t_i are identified according to the time points of the model centers, and then the average distances between the centers and these points which are in the same time as these FAcaGMM's centers along the dash line are calculated, as shown in the Fig 3. It calculates the average distance between testing motions and FAcaGMM centers. The testing sample is recognized as the corresponding grasp class with the minimum dissimilarity.

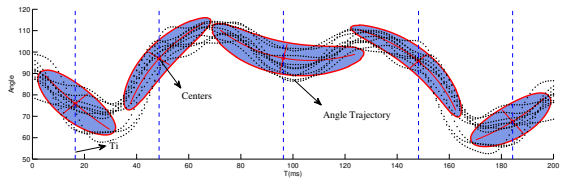

Fig. 3. An example of FAcaGMMs based in-hand manipulation motion recognition

V. Experiment

In order to evaluate the proposed algorithms, a comparative study is constructed by comparing FAcaGMM with TC, EC, GMM and HMM [14], [23]. TC is a fuzzy time-modeling approach based on fuzzy clustering and Takagi-Sugeno modeling with numerical value as output, and its details can be seen in our previous paper [14]. EC was introduced to recognize human hand motions for the first time using the proposed motion template and matching algorithm in [23]. The experiments are implemented under two scenarios a) training with various samples from single subject; b) training with various samples from multiple subjects. In this study, two datasets, 13 grasps and 10 in-hand manipulations, are employed.

A. Experiment Set-up

A fully instrumented data glove, CyberGlove from Immersion Corporation, has been employed to measure the finger joint angles during the hand movement. It can accurately transform hand and finger motions into real-time digital joint angle data by proprietary resistive bend-sensing technology. The sampling frequency of CyberGlove system in our experiments was set to 100Hz without any filter. The joint angles are measured by 22 bend sensors, which include three flexion sensors per finger, four abduction sensors, a palm-arch sensor, and sensors to measure flexion and abduction. Each sensor is extremely thin and flexible and is virtually undetectable in the lightweight elastic glove. CyberGlove is calibrated through the software from the company, and displayed by VirtualHand Studio software which converts the data into a graphical hand mirroring the subtle movements of the physical hand.

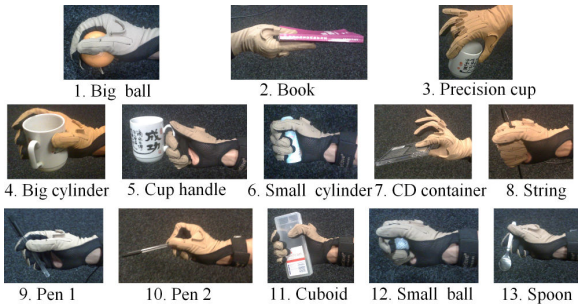

Fig. 4. Selected grasping tasks

Six (2 female, 4 male) healthy right-handed subjects volunteered for the study, their ages range from 23 to 35 with the average is 29.5 years. All subjects were trained to manipulate different objects, each grasp or in-hand manipulation is repeated 20 times for every subject. Both grasps and in-hand manipulation are considered in the study of object manipulation.

1) Grasp: According to the human hand grasp taxonomy [24], hand grasps are classified into 6 atomic different types, for instance, power grasps, precision grasps, and circular/prismatic grasps, etc. We selected 13 different grasp gestures as shown in Fig. 4 to test the algorithm recognition ability. Cup has been selected three times respectively in motions 3, 4 and 5 with different strategies. In motion 3, only three fingers are used to precisely contact the cup top; in motion 4, five fingers are laterally attached to the cup and cup handle is grasped with three fingers in motion 5.

2) In-hand Manipulation: The other dataset is for in-hand manipulation, which is much more complex than simple grasp

TABLE I
10 TYPES OF IN-HAND MANIPULATIONS

1	Open a mobile phone and then close it.
2	Screw to open a small bottle using only thumb, index finger and middle finger.
3	Pick up a coin and move it from the fingertip to the palm
4	Remove the pencil from back to front for writing, as shown in figure 5: (a) pencil walking
5	Pick up a pencil and simply rotate to write, as show in figure 5:(c) simple rotation
6	Pick up a pencil and complexly rotate to write, as show in figure 5:(d) complex rotation
7	Screw to open a big bottle using all five fingers
8	Roll a small cylinder
9	Pick up a scissor and cut paper
10	Pencil flips, as shown in figure 5:(b) pencil flips

motion and associated with the most complex human motor skills. It's the ability to change the position/orientation or adjust an object within one hand. Ten types of manipulations are recorded also by Cyberglove as listed in table I, and a few examples are shown in Fig. 5.

B. Experiment 1- Training with Various Samples from Single Subject

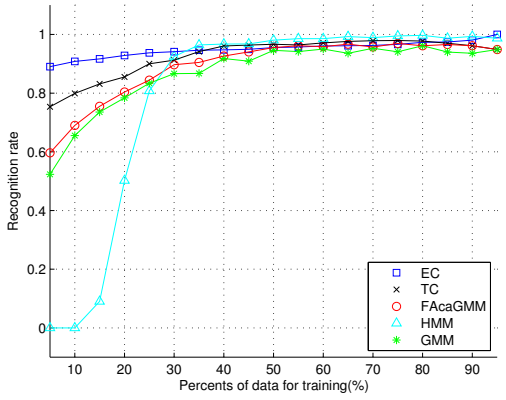

Fig. 6. Recognition results with various training percentages from single subject on grasp dataset

An empirical study was designed to evaluate sensitivity of these five methods in terms of change of the rate of training samples for the single subject. There are 13 grasp models

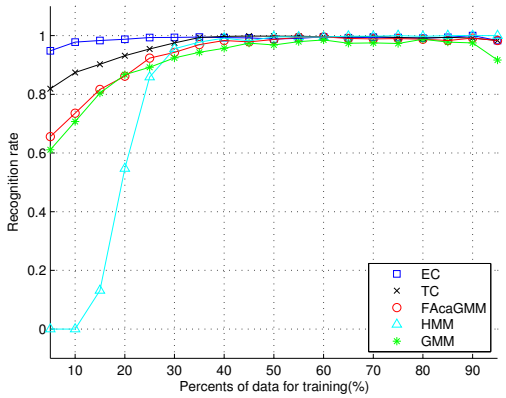

Fig. 7. Recognition results with various training percentages from single subject on in-hand manipulation dataset

and 10 in-hand manipulation models for each single subject, where each subject repeated 20 times for each motion. Each model of any subject is trained with various percentage of the data ranging from 5% to 95% from the same subject. The trained model is used to test other unused data from the same subject. The experimental results with various percentage of training data are illustrated in Fig. 6 and Fig. 7 for the two datasets. It finds that the performance of these five methods are all improved with the increase of the training datasets and their accuracies stabilize with more than 30% training data. The recognition rate of HMM improves from 0% to more than 90% when training data increase from 5 to 30 percentages and it reaches as high as that of EC with more than one third training data. Compared with GMM, FAcaGMM achieves a better result with all the various sample rates. TC stays in the middle of EC and FAcaGMM, EC presents the best overall performance among the five methods. The results demonstrate that the variation of the training samples does substantially affect performance of these methods. The increase of the training data can result in about 90, 30, 30, 20 and 10 percent increases of the recognition rates for HMM, GMM, FAcaGMM, TC, EC. It presents that HMM is sensitive to the varying training data more than any of the other four methods.

C. Experiment 2- Training with Various Samples from Multiple Subjects

Similarly an experiment was conducted to evaluate the effects of different training rates on the classifiers' performance for multiple subjects. Regarding to experiment 2, there are 13 grasp models and 10 in-hand manipulation models for all the six subjects. Each model was trained by the mixed samples from all six subjects. Each subject contributes the same amount of samples to the training data. All the other samples which are not included in the training data are used to evaluate the models trained by multiple subjects' samples. The percentage of the training data ranges from 5% to 95%

The experimental results are provided in Figs. 8 and 9 for grasp and in-hand manipulation datasets respectively. HMM

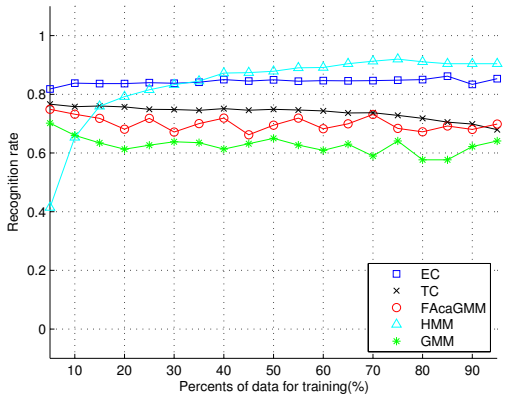

Fig. 8. Recognition results with various training percentages from multiple subjects on grasp dataset

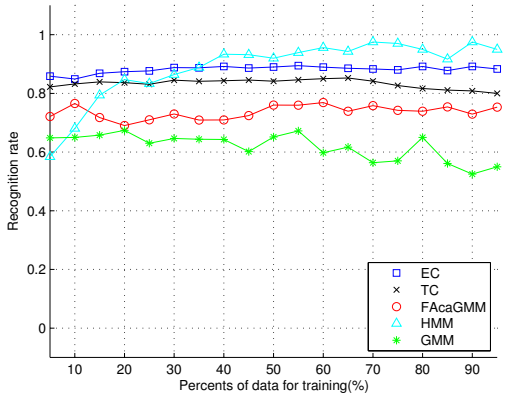

Fig. 9. Recognition results with various training percentages from multiple subjects on in-hand manipulation dataset

achieves an improvement of the recognition rate from less than 50% to 90% in terms of usage of the training samples. Different from the previous experiment results, there are no significant changes of recognition rates for the other methods with varying training samples. It is confirmed that HMM is the most sensitive method responding to varying training samples. HMM can achieve the highest accuracy with more than 40 percent training samples, but the proposed FAcaGMM, like EC and TC, outperforms HMM and GMM when the training samples are less than one fifth due to the insensitiveness to the varying percentage of the training data. FAcaGMM's performance is consistently better than GMM's thanks to the non-linear characteristic, and the Gaussian Mixture Regression (GMR) could be potentially used to generate the desired trajectory.Though TC and EC have higher recognition rate than FAcaGMM, TC is limited to the motion planning directly transfered from recognition results which are numerical values [14], and it is hard to generate desired trajectory from the dependence structure for EC [23]. FAcaGMM provides an effective solution to the applications which require abstracted patterns to store the motion features, and require an approach to generate the desired trajectory from these features.

VI. CONCLUSIONS

In this paper, we have proposed a novel FAcaGMM with a fast convergence speed, which is used to recognize human hand motions. A comparative study covering different subjects and different training samples has been conducted to compare the methods including FAcaGMM, TC, EC, GMM and HMM. Two datasets consisting of 13 different types of grasps and 10 in-hand manipulations have been employed for the algorithm evaluation. Experiment results have demonstrated that FAcaGMM consistently outperforms GMM in terms of the recognition rate because it is a component-based modeling method having the capability of modeling datasets with curve manifolds. FAcaGMM, like TC and EC, is insensitive to the varying training samples to certain extent, which means that it has advantages over practical applications, especially when requiring a fast training model process or lacking sufficient training datasets. Its performance substantially depends on the number of Gaussian components. It utilizes abstracted patterns to store the motion features, and the desired trajectory can be generated from these features. In the future work, the proposed algorithms will be applied to applications such as EMG based human motion recognition for prosthetic hands and human-robot skill transfer.

***Abstract*—In this study, a fuzzy control policy is presented for dynamic walking of a biped robot that is modeled as a simulated five-link biped robot. Due to complex ground contact models, it is difficult to precisely model its dynamics. Besides, a spring/damper ground model and a simplified inverted pendulum model are presented to represent the ground contact relation and the approximated model of biped robots as well. Moreover, Finite State Machine (FSM) is utilized to decompose a cycle of walking gait. Under zero moment point (ZMP) constraint, each joint follows desired trajectories in each state that are generated by quintic spline curve through the model free controller (i.e., fuzzy control). In addition, its robustness is investigated by imposing pulse perturbation on torso for some directions. The results are demonstrated in simulations as well as animation and then the proposed controller is compared with a PID controller as well.**

Keywords-Biped robot; ZMP constraint; Fuzzy control; Finite state machine; PID;

I. INTRODUCTION

The biped robot possesses nonlinear dynamics and numerous degrees of freedom that are difficult to manipulate. For biped robots, it is also unavoidable to be subjected to all kinds of external disturbance (e.g. contact with ground, different ground situations). As a result, accurately modeling the dynamics of biped robot systems is quite difficult. Additionally, walking stably is also another challenge for biped robots.

A fuzzy control policy with robustness is adopted for biped walking and simultaneously a FSM approach is utilized to decompose the cycle of the walking gait. Then the biped robot system is approximated by a simplified inverted pendulum model and keeps dynamic walking based on the ZMP constraint. In summary, the contribution of this study is the development of the fuzzy control policy with robustness for the walking of the simulated 3D biped robot. The simulation and animation are done to demonstrate the validity of the proposed methodology.

A. Related Works

In recent years, the research about walking of biped robots is a popular topic. Walking stably and keeping balance are essential functions. For the dynamic walking of biped robots, ZMP analysis is an important stability criterion for dynamic walking stably [1, 2]. Recently, [3]-[5] discuss stable biped walking through direct regulation of ZMP and generate stable walking trajectories. Besides, in order to enhance walking robustness, Morimoto and Atkeson [6] use differential dynamic programming (DDP) with a minimax criterion to make the humanoid robot generate low torque for walking and insure the policy is robust. Additionally, for keeping balance, Atkeson and Stephens [7,8] investigate ankle, hip and stepping strategies to help the humanoid robot recovery under the external push. From above studies, we can get the information that ZMP control and the walking with robustness are important for biped robots. Furthermore, due to the complex nonlinear dynamics and high dimensional state space, it's quite difficult to model the biped robot precisely. In general, it has two solvable ways. One is for the use of a simplified inverted pendulum model and some studies discuss it and have verified its effectiveness. Stramigioli et al. [9] adopt a simplification of multi-body dynamics that is achieved by instantaneously reducing it to be an equivalent single inertial entity in legged robot. In [10], Goswami introduced the Reaction Mass Pendulum (RMP) and presented an extension of the inverted pendulum that modeled the rotational inertia and angular momentum of a robot through its centroidal composite rigid body. The other one is for the use of the fuzzy controller. So far, fuzzy control has already been applied into many controlled systems including bipeds [11]-[15] as well as different kinds of commercial products successfully. The reasons are that it can handle nonlinear system well and is ease of implementation.

B. Control Policies For Walking

In general, the walking process is composed of a single support phase (SS) and a double support phase (DS) for the walking phase of a biped robot. In this work, a FSM approach is presented for the walking gaits of biped robots that decompose walking gaits into different states based on SS and DS phase. In these states, a quintic spline curve is utilized to generate smooth desired trajectories of each joint. Furthermore, a simplified inverted pendulum model is used to approximate the biped robot system and the biped robot keeps balance during walking based on the ZMP constraint. Concerning a trajectory tracking of each joint, it is achieved

by fuzzy feedback control policy. An important contribution of fuzzy systems theory is to provide a systematic procedure for transforming a set of linguistic rules into a nonlinear mapping. A fuzzy control algorithm [16]-[18] consists of a set of heuristics decision rules and is regarded as an intelligent control algorithm, which is attractive in many cases where the controlled system can't be well defined or modeled. The fuzzy theory uses "IF-THEN" rules to state the relationship between the input and output of the control plan. Also, it uses the linguistic variables instead to describe the characteristics of the system.

This paper is organized as follows: in section II, the system dynamics is constructed and trajectory planning, control policies for the biped walking robot are described in section III, and the simulation and animation results demonstrate its effectiveness under the ideal situation (i.e., without any perturbations) and external disturbance in section IV. Finally, the conclusions and further works of this paper are given in section V.

II. SYSTEM DYNAMICS AND TRAJECTORY PLANNING

The system (as in Fig. 1) is a simulated 3D biped composed of five-links: one torso, two thighs, and two calves. It is a symmetric 12 DOF system including roll and pitch for each hip, pitch for a knee and roll, pitch, and yaw for each ankle on each side. Therefore it is actuated by 12 torque-controlled joints. These joints are respectively simplified as hip abduction/adduction (HAA) that is roll angle between the pelvis and the thigh, hip flex/extend (HFE) that is the pitch angle between the pelvis and the thigh, knee flex/extend (KFE) that is pitch angle between the thigh and the calf, ankle abduction/adduction (AAA) that is the roll angle between the calf and vertical, ankle flex/extend (AFE) that is pitch angle between the calf and vertical and ankle rotation (AR) that is the rotation about the calf. Furthermore, the system states position and velocity of each DOF, so it is a 24 dimensional state space. Also, the system parameters for the simulation are similar to our real humanoid robot made by Sarcos. Its weight is 78 kg, with a 50 kg torso and 14 kg legs. The legs are 0.81 m long and the center of mass is 1 m above the ground when it stands straight. The distance between the hips is 0.213 m. In addition, the biped robot will interact with the ground during walking. Therefore, considering impact with interaction is necessary. In this paper, its ground contact relation is modeled as a spring/damper ground model as following Equations (1)-(4):

$$F_z = k_z z + b_z \dot{z} \quad (1)$$

$$F_x = k_x (x - x_0) + b_x \dot{x} \quad (2)$$

$$F_y = k_y (y - y_0) + b_y \dot{y} \quad (3)$$

$$M_z = k_a (a - a_0) + b_a \dot{a} \quad (4)$$

where x_0 and y_0 are initial contact positions and a_0 is initial contact yaw angle of the foot of $Z-$ axis, k_z, k_x, k_y and k_a are spring constants, b_z, b_x, b_y and b_a are damping constants, F_z, F_x, F_y and M_z are friction force and moment respectively. According to above parameters, SDFAST software is used to generate the rigid body dynamics for the biped robot. For this study, the desired trajectories of the hip, knee and ankle joints are all generated by quintic spline curves during walking. At knot points the quintic spline curves can enforce second derivative continuity of combined curve so that smooth transition, acceleration and jerk could be ensured. Each joint is driven to its desired position through fuzzy feedback controller that is described by the following section.

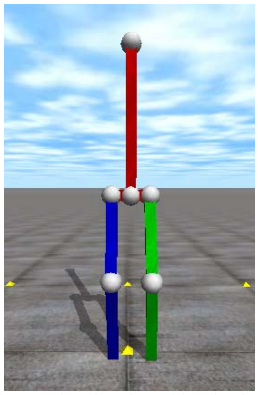

Fig. 1. Simulated 3D biped robot.

III. CONTROL POLICIES FOR BIPED ROBOT

A. Approximation Using An Inverted Pendulum Model and The ZMP Constraint

In order to simplify dynamic analysis, the biped model can be regarded as an inverted pendulum model that has been proved to be able to represent whole biped dynamics effectively. Consequently, in this study a simplified inverted pendulum model in the sagittal plane represented as Fig. 2 is described to approximate the biped robot model where forward direction is the positive X axis and above direction is positive Z axis. The height for the Center of Mass (CoM) in the walking process is assumed to be constant. From geometric relations, Equation (5) is derived where F is a net force applied on the CoM, g is the gravity acceleration and θ is the angle with vertical. Equation (6) expresses energy conservation and v is the velocity of the CoM. From Equations (5) and (6), the minimum roll distance of x direction (i.e., $x_{\min}$) is represented as Equation (7). During walking, CoM is kept within ZMP constraints via regulating the walking step and gait.

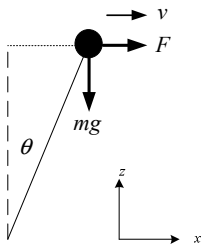

Fig.2. A simplified inverted pendulum model in the sagittal plane.

$$F/mg = \tan\theta = -x/z \tag{5}$$

$$-\int F dx = m v^2/2 \tag{6}$$

$$x_{\min} = \sqrt{x^2 - z v^2/g} \tag{7}$$

Calculating $x_{\min}$ value is to predict how far the biped system will move to. Liftoff action occurs when $x_{\min} < x_{d\min}$ where $x_{d\min}$ is a desired minimum move distance. In this paper, the value of $x_{d\min}$ is assigned as 0.07. In addition, the touchdown action occur a fixed time interval after turnaround.

B. Finite State Machine

Our proposed controllers are based on a FSM, with each state having its own trajectory for internal joint angles. A walking cycle of the human walking gait is imitated and decomposed by a FSM that is employed to plan walking gaits including eleven states. (1) WAITING (2) DS1 (double support, left leg in front) (3) LIFTOFF1 (double support, lifting right leg) (4) SSL1 (first phase of single support, left leg in stance) (5) SSL2 (second phase of single support, left leg in stance) (6) DS2 (double support, right leg in front) (7) LIFTOFF2 (double support, lifting left leg) (8) SSR1 (first phase of single support, right leg in stance) (9) SSR2 (second phase of single support, right leg in stance) (10) LAUNCH1 (squat) (11) LAUNCH2 (launch state, like DS1). These states form one cycle's walking gaits of the biped robot and transfer into other state at prescribed time or conditions described in Fig. 3 where waiting time and launch1 time are prescribed time in advance. Also, foot states and CoM velocity of Y direction are transition conditions. Besides the desired smooth trajectories generated by the quintic spline curve in each state and in any given state, the joints apply torques computed by fuzzy control in order to drive each joint to its desired local angle.

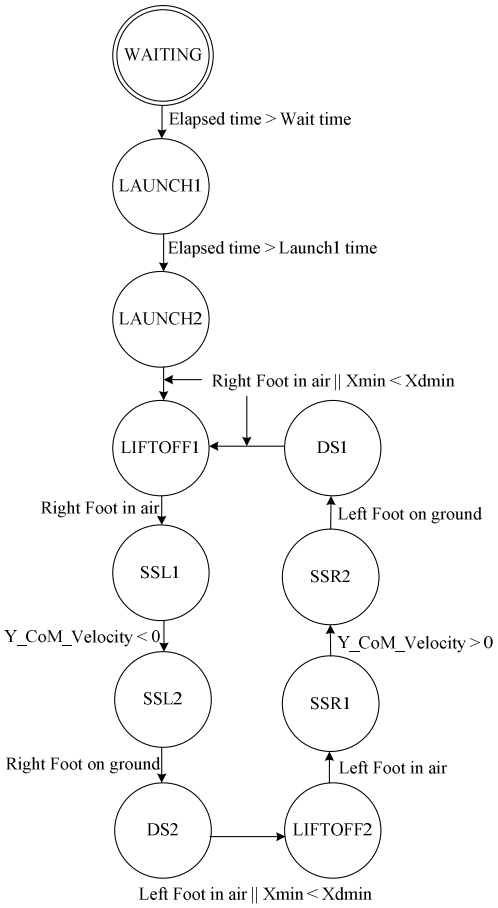

Fig. 3. FSM diagram for the biped walking.

C. Fuzzy Control Policy

The basic configuration of the fuzzy system consists of a fuzzifier, an inference engine and a defuzzifier. The fuzzifier part is to map a crisp set into a fuzzifier set. Moreover, two normalizing input scaling factors are determined. They make error and its derivative located in between -1 and 1 where error $e_i(t)$ is individual difference between desired position and actual position of each joint. Therefore, two inputs of fuzzy rule table of the *ith* subsystem are $\overline{e}_i(t) = g_{e_i} e_i(t)$ and $\dot{\overline{e}}_i(t) = g_{\dot{e}_i} \dot{e}_i(t)$, $i = 1 \sim 12$, where g_{e_i} and $g_{\dot{e}_i}$ are two normalizing input scaling factors respectively. $\overline{e}_i(t)$ and $\dot{\overline{e}}_i(t)$ are called fuzzy variables. They are quantized into the following eleven qualitative fuzzy variables: (i) Positive Huge (PH) (ii) Positive Big (PB) (iii) Positive Medium (PM) (iv) Positive Small (PS) (v) Positive Infinite (PI) (vi) Zero (ZE) (vii) Negative Infinite (NI) (viii) Negative Small (NS) (ix) Negative Medium (NM) (x) Negative Big (NB) (xi) Negative Huge (NH). The membership functions of the fuzzy variables are with triangular type as in Fig. 4 in this paper.

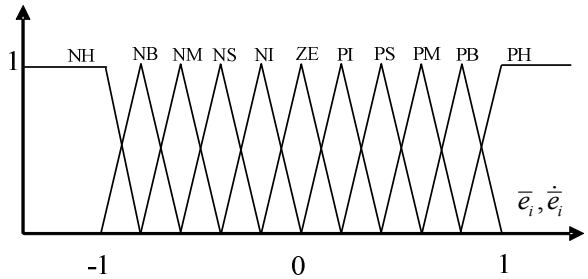

Fig. 4. Membership functions with triangular type.

In addition, the inference engine is usually composed of a series of fuzzy rules i.e., "IF-THEN" rules. The fuzzy logic subsystem *i* as in Fig. 5 performs a mapping from $X_i \in \Re^2$ to $\Re$.

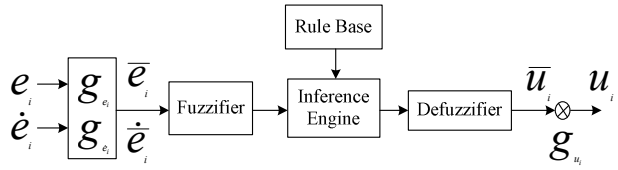

Fig. 5. Configuration of the *ith* fuzzy logic system.

There are *l* fuzzy control rules and the upper script *k* denotes the *kth* fuzzy rule:

IF $\bar{e}_i$ is $F_{1_i}^k$ and $\dot{\bar{e}}_i$ is $F_{2_j}^k$, THEN $\bar{u}_i$ is G_i^k (8)

where $\left[\bar{e}_i(t) \quad \dot{\bar{e}}_i(t)\right]^T \in X_i \subset \Re^2$, with $\bar{e}_i(t) = g_{e_i} e_i(t)$, $\dot{\bar{e}}_i(t) = g_{\dot{e}_i} \dot{e}_i(t)$, and $\bar{u}_i(t) \in V_i \subset \Re$ are the inputs and output of the fuzzy logic subsystem *i*, respectively; $F_{j_i}^k (1 \le i, j \le 2, 1 \le k \le l)$ and G_i^k are labels of sets in X_i and V_i, respectively. The parameters g_{e_i} and $g_{\dot{e}_i}$ are chosen such that $\bar{e}_i(t)$ and $\dot{\bar{e}}_i(t) \in [-1, 1]$. The fuzzy inference engine performs a mapping from fuzzy sets in $X_i \subset \Re^2$ to fuzzy sets in $V_i \subset \Re$, based upon the fuzzy IF-THEN rules in the fuzzy rule base and the compositional rule of inference. The defuzzifier part is to utilize the center-average method to get the crisp control input signal $\bar{u}_i(t)$. In summary, overall fuzzy logic system can be employed to form a look-up Table 2 that directly relates the inputs $\bar{e}_i$(t) and $\dot{\bar{e}}_i(t)$ with the output $\bar{u}_i(t)$. Also, the output $\bar{u}_i(t)$ of the look-up table ranges between from -1 and 1 that is multiplied by output scaling factor g_{u_i} to be real control output torque $u_i(t)$ as Eq. (9). Output scaling factor can be regarded as saturation limit of the actuators. Generally speaking, a larger output scaling factor is assigned, a smaller tracking error and a faster response are achieved; however, the risk of transient or oscillatory response increases after transience happen.

$$u_i(t) = g_{u_i} \bar{u}_i(t) = g_{u_i} \left[\bar{e}_i(t) + \Delta_i(t) \operatorname{sgn}(\bar{e}_i)\right], \; i = 1 \sim 12. \quad (9)$$

where $\bar{u}_i(t)$ is fuzzy variable of $u(t)$, and $\Delta_i(t) > 0 \; \forall t$ denotes the switching gain, which is related to Table 2. Furthermore, the roll torque of ankle in SS is constant. Moreover, hip roll torque needs to hold the torso up, so the desired position tracks ankle roll angles. In DS, it is occupied a very short time during the all of the walking period and then hip and ankle roll are pure torque sources (i.e., constant torques).

IV. SIMULATIONS AND DISCUSSIONS

Through the investigations of $e_i(t)$ and $\dot{e}_i(t)$ range from each joint, the control parameters g_{e_i} values are all selected as 0.01 and the $g_{\dot{e}_i}$ values respectively are selected as $\{0.009, 0.01, 0.01, 0.01, 0.005, 0.01\}$ at one side respectively such that their values are located between -1 and 1. They have the same values at another side. In addition, g_{u_i} values are assigned as $\{3500, 1300, 1700, 300, 45000, 200\}$ at one side. Also, these values are identical to another side. In general, a larger output scaling factor is assigned, a smaller tracking error and a faster response are achieved; however, the risk of transient response happens.

For ideal conditions (i.e., no any perturbations and uncertainties), the responses of each joint are illustrated in Fig. 6 that shows the responses of left hip, knee and ankle pitch angles. From these results shown, based on fuzzy controller and FSM method the responses of each joint have good trajectory tracking performance. In addition, PID controller is also applied to biped walking and it still obtains stable walking. For simplicity, these responses are omitted. However, to investigate further whether the fuzzy controller I propose has robustness, the external pulse force of 25 Newton is imposed on torso during 2.0~2.1 seconds from lateral push (i.e., positive *Y* direction) and those control parameters are the same with ones of ideal conditions. These simulation results are illustrated in Fig. 7. Moreover, Fig. 8 represents the responses under the same conditions by PID controller. It will crash at about 3 seconds. From these illustrations of the simulation results, it reveals the proposed controller is with better robustness to resist some extent disturbance and possess good performance. Except the computer simulation, it is also displayed walking of the 3D simulated biped robot using animation that reveals the proposed strategy is effective for the biped walking. In summary, they both exhibit acceptable performance under with or without uncertainty and disturbance. Further, it is also verified that the approximation of a simplified inverted pendulum model with ground contact relation for the biped robot is feasible and effective.

V. CONCLUSIONS

In this paper, the simulated 3D biped robot is considered as a simplified inverted pendulum model with ground contact relation. The fuzzy control policy and FSM approach are proposed for the periodic walking of the simulated 3D biped robot based on ZMP constraint. Under without perturbations, it has good response for the trajectory tracking on each joint. In addition, the lateral pulse perturbation force on torso is imposed to verify the robustness of the proposed controller. Finally, through the demonstration of the simulation, the responses are shown to possess good trajectory tracking as well as better robustness as compared with PID controller. Moreover, the animation also displayed that the biped robot can walk stably and periodically.

In future works, a real biped robot by the proposed control will be implemented. Additionally, it will be compared with other control strategies with respect to the robustness and performance.

Abstract: Recently, multi-robot systems have been discussed to realize a large size of distributed autonomous system. Furthermore, multi-robot systems have been applied to various problems such as autonomous guided vehicles, soccer robots, and search and rescue system by multi-robot. This paper proposes intelligent formation behavior for the multi-robot based on sensor fusion. First, we discuss multi-agent systems and wireless network technologies. Next, we explain the hardware specification of robot and tele-operated system and wireless communication. Finally, we show experimental results, and discuss the availability of intelligent formation behavior for multi-robot.

Keywords; Multiple Robots, Formation Behaviors, Fuzzy Control, Tele-operation

I. INTRODUCTION

Recently, various types of intelligent multi-agent systems have been proposed to realize a large size of autonomous systems [1-8]. Multi-agent systems have been applied to various problems such as autonomous guided vehicles, soccer robots, and search and rescue system by multi-robot. Network robots are also assumed as one of multi-agent systems. We should discuss two different types of problems in multi-agent systems simultaneously. The first one is the relationship of each agent with its environment from individual point of view. The other is the internal relationship among agents with their outer environmental conditions from the collective point of view. Furthermore, intelligent technologies including fuzzy, neural network, and evolutionary computing, have been applied to such the intelligent systems interacting with environments [9-13]. However, the high level of integration of the collective intelligence and individual intelligence has not discussed much yet. Therefore, we proposed the formation control methods for multi-robot system, and discussed the applicability of the proposed methods in various environmental conditions [14-17]. However, we did not use multiple mobile robots in real world conditions on network technologies.

As the progress of wireless network technologies and ubiquitous computing, various types of network robots have been developed [18-21]. The research on wireless sensor networks combines three components of sensing, processing, and communicating into a single tiny device. The ubiquitous computing integrates computation into the environment. The ubiquitous computing is conceptually different from sensor network, but both aim at the same research direction. Sensor networks and ubiquitous computing have been incorporated into robotics. These researches are called network robotics and ubiquitous robotics, respectively. If the robot can receive the environmental data through the network without the measurement by sensors, the size of the robot can be easily reduced and the received environmental data are more precise because the sensors equipped in the environment are designed suitable to the environmental conditions. The available communication channels are limited under the real world conditions. Therefore, we apply different standards of network channels, e.g., ZigBee for the network communication among mobile robots, and between a host computer and mobile robots.

Furthermore, we discuss the formation behavior based on available sensing data. Next, we explain the multi-objective behavior coordination, and we propose the sensor fusion method based on various types of sensor inputs. Next, we propose monitoring system to enable environmental measurement under unknown environment by using multi-robot. Finally, we show several experimental results of the proposed method.

II. TELE-OPERATION OF MULTIROBOT

A. A Mobile Robot for Information Seeking

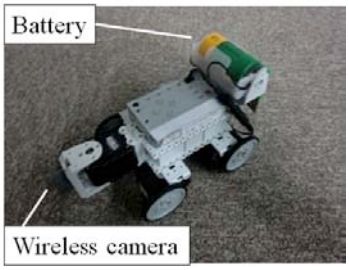
We developed various types of mobile robots using Bioloid [22]. The robot can perform the wireless communication by ZigBee with host computers or other robots. Figure 1 shows developed the mobile robots developed in this paper. This leader robot is controlled by the manual operation with a joystick. The first mobile robot shown in Fig.1 (a) equips a wireless camera. The size of the robot in Fig.1 (a) is 140 x 120 x 90 [mm].

The follower robot shown in Fig.1 (b) equips two cameras and a laser range finder (LRF). Furthermore, the small size of PC is attached on the robot to perform autonomous behavior by using web camera and LRF. This robot constructs a formation according to the position of the leader robot. One wireless camera is used for the expanding view area for the human operator in order to present the area surrounding the

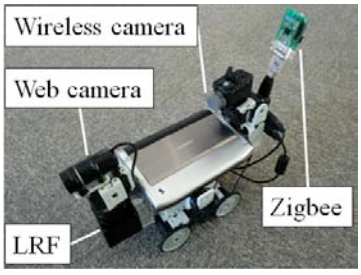
978-1-4244-7316-8/11/$26.00 ©2011 IEEE

leader robot. Another camera is used for the target tracing behavior, and LRF is used for collision avoidance behavior. The size of the robot in Fig.1 (b) is 300 x 150 x 250 [mm]. The communication range of the wireless camera and ZigBee with the host computer is 30 [m]. ZigBee is one of the Near Field Communications (NFC) suitable to short range and high frequency communication for home appliances. Moreover, the ZigBee can form various types of network topologies such as star type, tree type and mesh type according to the aim and environmental conditions.

Table 1 shows the specification of two robots. A human operator sends a control command to the leader robot from the host computer based on images received directly from the wireless camera.



(a) A leader robot



(b) A follower robot

Figure 1. Tele-operated mobile robots

TABLE I. SPECIFICATION OF TWO ROBOTS

Type	*Leader*	*Follower*
Weight	0.8kg	2.0kg
Speed	Max 1.7 m/s	Max 1.8 m/s
Sensor	Wireless camera	Wireless camera Web camera LRF
Operation method	Manual (Joystick)	Autonomous

B. Tele-operation system

We developed a human interface for the tele-operation based on graphical user interface (GUI) from the host computer. The image data of wireless camera equipped with the leader robot are transmitted to the host computer, and the operator can monitor those data (Fig.2 (a)).

The behaviors of the leader robot are based on the semi-autonomous control. Figure 2 (b) shows a snapshot of the control of the robot by the operator. The operator can navigate the leader robot by using a joystick. The collision avoidance and target trace of the follower robot with obstacles are done automatically. Therefore, the operator can focus on the monitoring of the environment with the low human load of navigation based on the semi-autonomous control mode.

Figure 2 (c) shows the user interface for the remote monitoring and remote control of three mobile robots. A view image from the leader robot is displayed in the upper on the screen, and that from the follower robot is displayed in the lower left and right. The operator can see the facing situation from the camera of the leader robot from the local point of view, while he or she can see the surrounding situation from the camera of the follower robot from the global point of view. In this way, the operator can control these mobile robots by changing the viewpoint of an operator.

(c) Camera images of tele-operated mobile robots in the monitoring display

Figure 2. Tele-operattion system

C. Formation Behaviors

The multi-robot system should update the shape of formation according to the aim of information seeking under the features of environmental conditions, e.g., unknown, dynamic, and/or unreliable. For example, we show five types of shapes of formation in Figure 3 where the number of robots is 3, the equipped sensors are camera and LRF, and blue fan-shaped area and green fan-shaped area mean the measurable ranges by LRF and wireless camera, respectively.

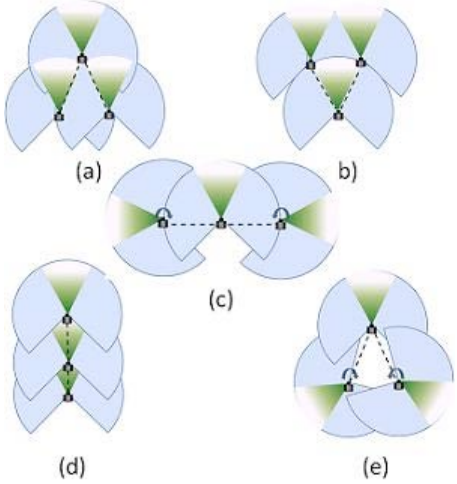

Figure 3. various type of formation

Figure 3 (a) is a basic triangular formation by three robots where one leader robot and two follower robots. The operator controls the leader, while two follower robots gather their surrounding environmental information. Figure 3 (b) shows a formation in unknown or dangerous environment where the two top followers gather the environmental information in order to detect dangerous state and others, and the operator controls the leader robot from the backward. Figure 3 (c) shows a formation of three robots arranged in a single horizontal row. This formation can gather wide range of images to display the global environmental state at a glance. Figure 3 (d) shows a formation of three robots arranged in a single tandem line in a narrow path, small space, and many obstacles. Figure 3 (e) shows a formation of three robots to observe all-around view in dynamic or changing environment when three mobile robots stop at a point. In this way, we can change the formation of robots according to the aim of information seeking under different environmental conditions. In this paper, we focus on the basic triangular formation behavior as the first step of this study.

III. FORMATION BEHAVIORS

A. Functions for Formation Behaviors

Each robot needs to understand its relative position with other robots to build the global formation shape by multiple robots. Consequently, the robot should localize the self-position relative to its neighboring robots, and share the information on position and posture with other robots. A dead-reckoning algorithm is often used to estimate the global self-position, but this method has a problem of accumulating errors in the estimation. Therefore, we use web cameras and LRF for the relative localization. The web camera image is used for relative localization, and the wireless camera image is used for remote monitoring and control by a human operator.

B. Object Detection

Various types of pattern recognition methods and image processing methods have been proposed [23-30]. We applied the continuously adaptive mean shift (CAMSHIFT) algorithm using Open CV library to extract the landmark of the leader mobile robot from the camera image of the follower mobile robot. Because the basic CAMSHIFT algorithm updates the target template sequentially, it is difficult to trace a target landmark if the mobile robot fails to recognize the current target template.

(a) Leader robot (b) follower robot

Figure 4. Landmarks used for visual tracking

In order to detect and identify other robots, we use landmark identifiers based on combination of two different colors (Fig.4). We use a steady-state genetic algorithm (SSGA) for object detection as one of search methods, because SSGA can easily obtain feasible solutions through environmental changes with low computational cost. SSGA simulates a continuous model of the generation, which eliminates and generates a few

of individuals in a generation (iteration). A template is composed of numerical parameters of $g_{i,1}$, $g_{i,2}$, $g_{i,3}$, and $g_{i,4}$. The number of individuals is G. One iteration is composed of selection, crossover, and mutation. The worst candidate solution is eliminated ("Delete least fitness" selection strategy), and is replaced with the candidate solution generated by the crossover and the mutation. We use the elitist crossover and adaptive mutation. The elitist crossover randomly selects one individual and generates an individual by combining genetic information from the randomly selected individual and the best individual. Next, the following adaptive mutation is performed to the generated individual,

$$g_{i,j} \leftarrow g_{i,j} + \left(\alpha_j + \frac{f_{\max} - f_i}{f_{\max} - f_{\min}} + \beta_j \right) \cdot N(0,1) \qquad (1)$$

where f_i is the fitness value of the ith individual, $f_{\max}$ and $f_{\min}$ are the maximum and minimum of fitness values in the population; $N(0,1)$ indicates a normal random variable with a mean of zero and a variance of one; α_j and β_j are the coefficients ($0 < \alpha_j < 1.0$) and offset ($\beta_j > 0$), respectively. In the adaptive mutation, the variance of the normal random number is relatively changed according to the fitness values of the population.

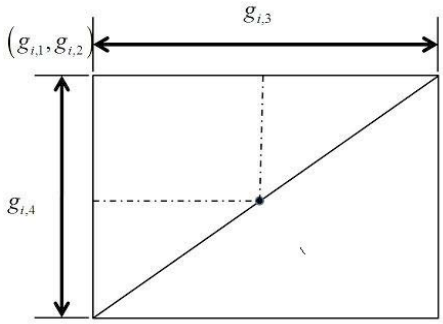

Figure 5. A candidate solution for object detection

The template of each candidate solution is evaluated as the sum of local evaluations in small subareas shown in Fig.6. Each subarea is evaluated by different weights in the following;

$$f_i = \sum_{a=1}^{n_1} \sum_{b=1}^{n_2} \sum_{c=1}^{n_3} M_{a,b,c} C_{a,b,c} \qquad (2)$$

where $C_{a,b,c}$ and $M_{a,b,c}$ are the number of pixels of the cth color in the subarea (a,b), and its evaluation weight. We can perform the search of landmarks with different color distribution. If the fitness value of the best candidate solution is higher than the predefined threshold, its corresponding template is recognized as the target landmark. The position (u,v) of the landmark in the local coordinate on the camera image is calculated as

$$(u,v) = \left(g_{b,1} + \frac{g_{b,3}}{2}, g_{b,2} + \frac{g_{b,4}}{2} \right) \qquad (3)$$

where b is the best candidate solution. The relative angle (ξ) between the moving direction of the follower robot and the position of the leader robot is calculated by

$$\xi = \tan^{-1} \left(\frac{2 \cdot u \cdot \tan \frac{\omega}{2}}{Q} \right) \qquad (4)$$

where the size of pixels on the camera image is $P \times Q$, ω is the view angle of the web camera in Fig.7. Next, we obtain the distance information (L_{leader}) by referring to the distance measured by LRF.

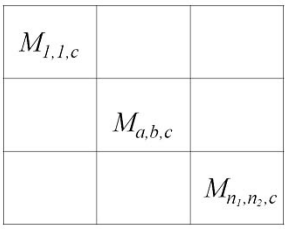

Figure 6. A template matching evaluation using subarea

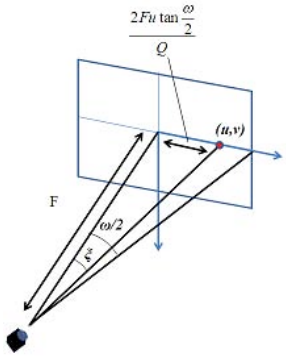

Figure 7. Estimation of the relative angle

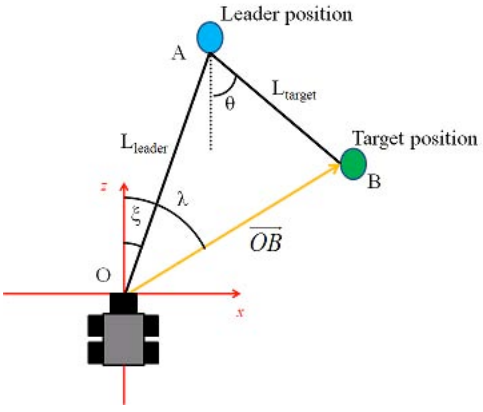

Figure 8. Estimation of the relative position

C. Multi-Objective Behavior Coordination

Various types of intelligent control methods for mobile robots have been proposed such as production rules, Bayesian networks, neural networks, fuzzy inference systems, and classifier systems [31-34]. We have applied fuzzy inference systems to represent behavior rules of mobile robots, because the behavioral rules can be designed easily and intuitively by human linguistic representations. A behavior of the robot can be represented using fuzzy rules based on simplified fuzzy inference [31]. In general, a fuzzy if-then rule is described as follows,

If x_1 is $A_{i,1}$ and ... and x_M is $A_{i,M}$
Then y_1 is $w_{i,1}$ and ... and y_N is $w_{i,N}$

where $A_{i,j}$ and $w_{i,k}$ are the Gaussian membership function for the jth input and the singleton for the kth output of the ith rule; M and N are the numbers of inputs and outputs, respectively. Fuzzy inference is performed by,

$$\mu_{A_{i,j}}(x_j) = \exp\left(-\frac{(x_j - s_{i,j})^2}{t_{i,j}^2}\right) \tag{5}$$

$$\mu_i = \prod_{j=1}^{M} \mu_{A_{i,j}}(x_j) \tag{6}$$

$$y_k = \frac{\sum_{i=1}^{R} \mu_i w_{i,k}}{\sum_{i=1}^{R} \mu_j} \tag{7}$$

where $s_{i,j}$ and $t_{i,j}$ are the central value and the width of the membership function $A_{i,j}$; R is the number of rules. Outputs of the robot are output levels of the left and right motors (N=2). Fuzzy controller is used for collision avoidance and target tracing behaviors. The inputs to the fuzzy controller for collision avoidance are the measured distance to the obstacle by LRF. The inputs to the fuzzy controller for target tracing are the estimated distance to the target point and the relative angle to the target point from the moving direction (M_i=2).

In general, a mobile robot has a set of behaviors for achieving various objectives, and must integrate these behaviors according to the environmental conditions. Therefore, we proposed the method for multi-objective behavior coordination [14,15]. The multi-objective behavior coordination can integrate outputs of several behaviors according to the time-series of perceptual information, while the original subsumption architecture selects one behavior [13]. This multi-objective behavior coordination is composed of a sensory network, behavior coordinator, and behavior weight updater. The sensory network outputs perceptual information based on sensing data and updates the parameters of sensors recursively according to the perceptual information [33]. A behavior weight is assigned to each behavior. The output is calculated by

$$y_k = \frac{\sum_{j=1}^{K} wgt_j(t) \cdot y_{j,k}}{\sum_{j=1}^{K} wgt_j(t)} \tag{8}$$

where K is the number of behaviors; $wgt_j(t)$ is a behavior weight of the jth behavior over the discrete time step t. By updating the behavior weights, the robot can take a multi-objective behavior according to the time series of perceptual information. The update amount of each behavior is calculated as follows,

$$\begin{bmatrix} \Delta wgt_1 \\ \Delta wgt_2 \\ \vdots \\ \Delta wgt_K \end{bmatrix} = \begin{bmatrix} dw_{1,1} & dw_{1,2} & \cdots & dw_{1,L} \\ dw_{2,1} & & & \\ \vdots & & \ddots & \vdots \\ dw_{K,1} & & \cdots & dw_{K,L} \end{bmatrix} \begin{bmatrix} si_1 \\ si_2 \\ \vdots \\ si_L \end{bmatrix} \tag{9}$$

where si_i is the parameter on the perceptual information; L is the number of perceptual inputs. This method can be considered as a mixture of experts if the behavior coordinator is considered as a gating network.

IV. EXPERIMENTAL RESULTS

This section shows several experimental results of the proposed method. We use one leader robot for tele-operation and two follower robots to extend the view area for the monitoring and control by human operators. The size of the experiment environment is 3,000 [mm] ×7,000 [mm] including three obstacles. The suitable distance between two robots is set at 500 [mm]. The number of candidate solutions in SSGA is 50; the number of evaluations is 1,500 (corresponding to 30 iterations of discrete generations). If the fitness value of the best candidate solution is larger than 200, its corresponding template is considered as a detected landmark, and the mobile robot traces the rear of the leader robot with the predefined relative angle.

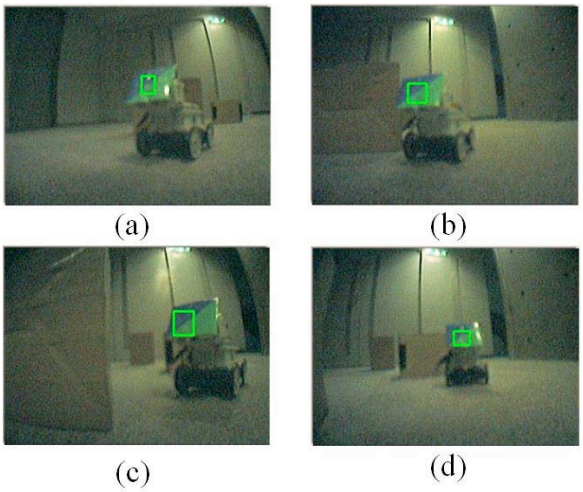

Figure 9. Follower's camera view

(e)

Figure 10. Leader's camera view

First, we show experimental results of image processing for target tracing. Figure 9 shows an experimental result of image processing by SSGA for landmark detection using camera images of the follower robot where a green frame indicates the detected landmark attached with the leader robot. Furthermore, the human operator can understand the environmental state in front of the leader robot, but this image is not enough to control the leader robot (Fig.10). On the other hand, the image from the follower robots includes the environmental state surrounding the leader robot (Fig.11 (a)-(d)). Therefore, the human operator can easily understand the situation of the leader robot, and can control the leader robot by using two types of images from the leader robot and follower robots.

Next, we show experimental results of tandem formation behavior of three robots. Figures 11 and 12 show overview of an experimental result of tele-operation and images sent from robots, respectively. In Figure 11 (d), the solid and dotted lines indicate the trajectories of the leader robot and follower robots, respectively. The follower robot traces the rear of the leader robot by extracting the landmark with keeping the suitable distance with the leader robot, while avoiding the collision with other obstacles. Figure 13 shows the change of fitness value and the degree of danger in the tandem formation behavior of second robot (Follower 1). In the experimental result, since the fitness value is larger than threshold (200) for the target tracing, the robot successfully traces the rear of the leader robot. The behavior weight is updated according to the degree of danger calculated by the minimal distance to obstacles. If the value is high, the behavior weight for collision avoidance is high. The motor output signals are calculated every 300 msec. In the experimental result, because the degree of danger is high, the follower robot tried to avoid the collision. As a result, the fitness value is not so high because the ratio of target tracing behavior is not high (Figure 11 (d).

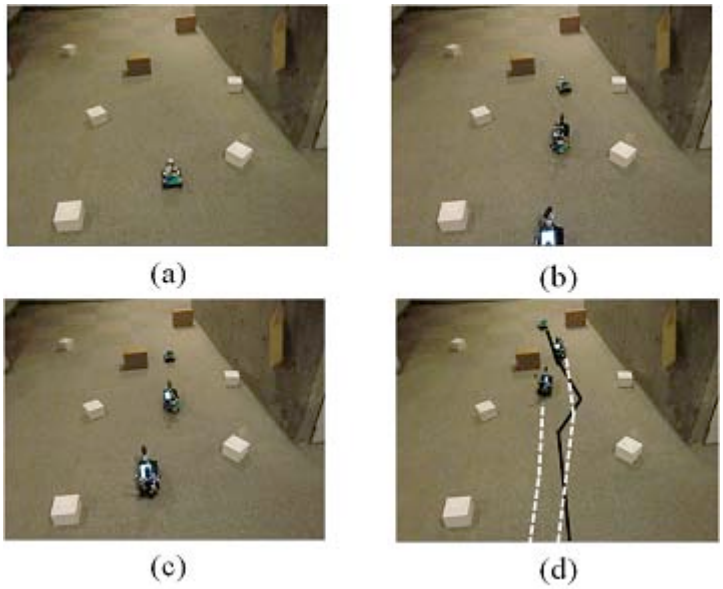

Figure 11. Appearance of line experiment

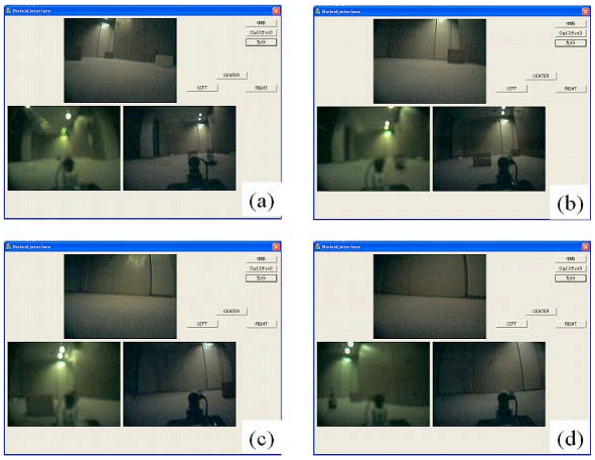

Figure 12. Images sent from robots in tandem formation behavior

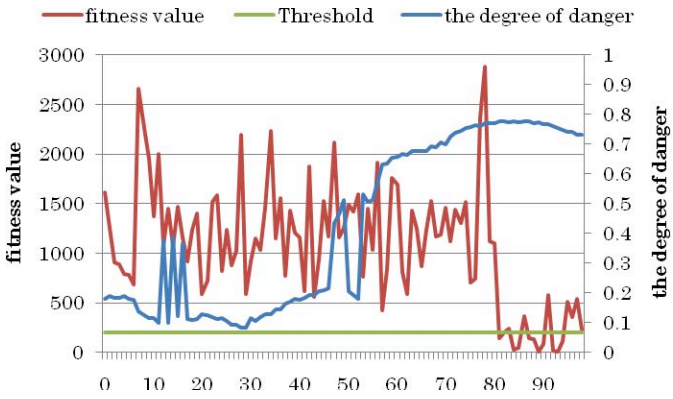

Figure 13. The change of fitness value and the degree of danger in the tandem formation behavior

Next, we show experimental results of a basic triangular formation behavior of three robots. Here we use 30 degree of relative angle to construct the shape of equilateral triangle. Figures 14 and 15 show overview of an experimental result of tele-operation and images sent from robots, respectively. In Figure 14 (d), the solid and dotted lines indicate the trajectories of the leader robot and follower robots, respectively. The follower robot traces the rear of the leader robot with suitable angle and distance. Figure 16 shows the change of fitness value and the degree of danger in the tandem formation behavior.

Figure 16 shows the change of fitness value and the degree of danger in the triangle formation behavior of second robot (Follower 1). In the experimental result, since the fitness value is larger than the threshold (200) for the target tracing, the robot successfully traces the rear of the leader robot. In this case the maximum fitness is not stable as in the tandem formation. Tandem formation always captured landmark at a front. However, triangle formation captured landmark at an angle. So the triangle formation's maximum fitness is unstable.

Finally, we compare the view areas expanded by the tandem formation behavior and basic triangular formation behavior. In case of tandem formation behavior, the image sent from the last follower robot includes the far but wide range surrounding the leader robot. On the other hand, in case of basic triangular formation behavior, the image sent from two follower robots can expand the view area of left and right sides, respectively, but these two images are not symmetrical from the position of the leader position. In this way, these two formation behaviors have one advantage and one disadvantage, respectively. In order to solve this problem, we are developing a 3D visualization method based on distance and color information.

V. SUMMARY

In this paper, we discussed the formation behavior of multi-robot based on sensor fusion under different environmental conditions. Furthermore, we proposed the method of image processing by a steady-state genetic algorithm for relative localization, and applied a multi-objective behavior coordination method based on fuzzy control. The experimental results showed the effectiveness of the proposed method for target tracing and collision avoidance of the Follower under the tele-operation of the Leader. However, the hybrid communication by wireless LAN, ZigBee, XBee, and Bluetooth is under development. We will propose a control method of several communication technologies. Furthermore, we discuss how to change or update the shape of a formation of three robots according to environmental conditions.

***Abstract*—In human robot interaction, intuitive interface is necessary. A specific interaction device, for instance, a joystick or a teaching pendant, is not usually intuitive and needs trainings for a general user. Instruction by gesture is one of the intuitive interfaces and a potential user does not need any training for showing a gesture. Pointing is one of the simplest gestures. Hibino et. al.[1] proposed a simple human pointing recognition system for a mobile robot that has an upward directed camera and recognizes human pointing and navigate itself to the place a user is pointing by simple visual feedback control. This paper shows improvement of the method and investigates the validity and usefulness of the proposed method with questionnaire investigations with the proposed and conventional user interfaces.**

Keywords-pointing navigation interface; spherical vision system; omni-directional mobile robot

I. Introduction

Recently, robots are getting popular not only in factory environments but also in human daily life environments. Especially, entertainment robots, for instance, AIBO from Sony[2] and Nao from Aldebaran[3], attract the general people. On the other hand, more practical mobile robots becomes gradually popular, for example, rumba from iRobot[4] and SO-ZI from CCP[5], as a vacuum cleaner robot. More practical robots interacting with a general user are going to be popular in near future although the current vacuum cleaner robots work automatically without human interaction.

In human robot interaction, intuitive interface is necessary. A specific interaction device, for instance, a joystick or a teaching pendant, is not usually intuitive and needs trainings for a general user. Instruction by gesture is one of the intuitive interfaces and a potential user does not need any training for showing a gesture.

Most conventional studies related to gesture recognition assume that height of camera position is about the one of human torso[6], [7], [8]. This assumption is reasonable for a robot that is as tall as a human, however, it is not for a smaller robot like a vacuum cleaner robot for a general user, for example, rumba.

On the other hand, localization and navigation with an upward directed camera on a mobile robot has been studied[9], [10], so far. The mobile robot watches ceiling above and localizes by itself. The method has some advantages over the other vision-based localization methods. One of them is that ceiling image can be captured with less occlusion than side view. Another one is less computational cost for localization based on image processing. A ceiling image has almost only parallel and rotation transform with less magnification transform while the mobile robot moves on the flat. Therefore, visual processing can eliminate an image magnification factor. For instance, template matching needs less computational cost if it does not have to deal with the image magnification factor.

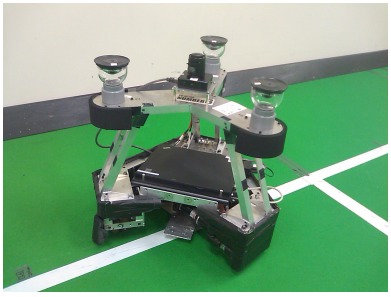

Fig. 1. Mobile Robot with a Spherical Vision System consists of an Upward Directed Fish-Eye Camera and Cameras with Omni-Mirrors

A fish-eye upward directed camera has not only same advantages with the conventional upward-directed-camera based localization methods but also wide view angle. The camera captures not only ceiling but also a human as a potential general user, simultaneously. Therefore, a robot with a fish-eye upward directed camera can localize itself with ceiling image while it recognizes a human gesture.

Hibino et. al.[1] proposed a simple human pointing recognition system for a mobile robot. The mobile robot with a fish-eye upward directed camera recognizes human pointing and navigates itself to the place the human points with a simple visual feedback controller. A human user can navigate the mobile robot intuitively by pointing at desired position on a field with his hand. However, the human pointing system proposed by Hibino et. al.[1] has low operability where the robot goes far from the user. This paper shows improvement of the proposed method with a simple visual feedback control system. Real robot experiments and questionnaire investigation with 11 persons in their twenties are conducted to show the validity and usefulness of the proposed method.

II. Mobile Robot with Spherical Vision System

Figure 1 shows an omni-directional vehicle with a spherical vision system consists of an upward-directed fish-eye camera and cameras with omni-mirrors, which we designed and built. The upward-directed fish-eye camera captures a sight upper

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

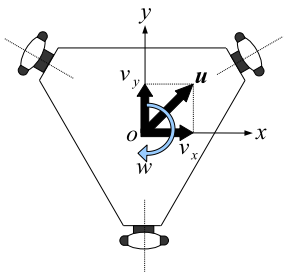

Fig. 2. Robot Coordinate

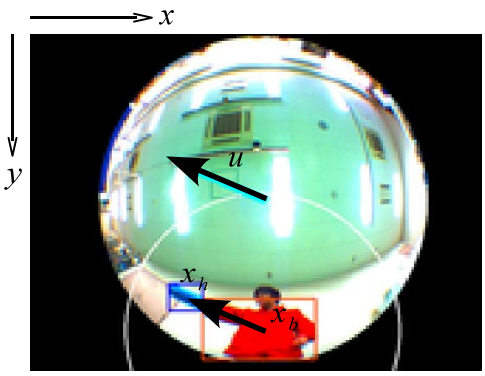

Fig. 3. Simple Visual Feedback for Navigation

than horizon while cameras with omni-mirrors capture sight lower than horizon. Height of the robot is about 50cm and the cameras capture a human surrounding the robot. The method proposed in this paper focuses on the captured images by the upward-directed fish-eye camera. Figure 7 shows captured images. For simplicity of a vision system, a human wears a red jacket and a blue glove.

Figure 2 shows a model of our omni-directional vehicle with three omni-wheels. Coordinates x and y indicate left and front directions of the robot. The robot has two omni-wheels at left and right front and the other at back. It can move toward any direction v_x, v_y including rotation w on a plane surface.

III. Recognition of Human Pointing and Navigation

Recognition of human pointing is realized with a simple algorithm. A vision system extracts red and blue regions on the captured image to recognize positions of the human torso and hand. In order to reduce hand recognition error, blue regions within a certain distance from a red/torso region (shown by white circles in Figure 7) are regarded as candidates of hand region. The largest region of them is recognized as a hand.

Navigation algorithm is designed as a simple visual feedback. The robot moves to the position so that the hand comes to the human torso region on the fish-eye camera image. The human hand comes to the torso area where the robot locates at the place human is pointing as shown in Figure 7(e). The hand position is far from the torso region when the human points with his hand at a position where the robot does not locate as shown in Figure 7(b). The intuitive idea leads to a simple visual feedback based navigation controller. The movement vector $\boldsymbol{u} = (v_x, v_y)$ for the navigation is designed by Hibino at al.[1] as followings:

$$\boldsymbol{u} = k(\boldsymbol{x}_h - \boldsymbol{x}_b) \tag{1}$$

while k, $\boldsymbol{x}_h$, and $\boldsymbol{x}_b$ are a control gain and center position vectors of the extracted human hand and torso on the captured image, respectively (see Figure 3).[1] Actually an object located at right side is projected to left side on a ceiling image and vice versa, therefore, x direction on a ceiling image is reversed when it calculate the movement vector $\boldsymbol{u}$. Furthermore, in general image processing, y coordinate is set from top to down as shown in Figure 3. We just flips y coordinate upside down in order to follow the robot coordinate shown in Figure 2. This means that upper and right directions on the camera image correspond to forward and left in the robot coordinate.

However, the controller designed by Eq.1 has low operability where the robot goes far from the user. The region of the user in the image captured by the upward-directed fish-eye camera becomes smaller if the user is farther from the robot. This means Eq.1 gives smaller movement vector when the user is farther from the robot while it is larger vector when the user is nearer to the robot. In order to compensate the length of the movement vector depending on the distance from the robot and the user, the movement vector is magnified based on the scale of the user region in the image. If the user is projected small in the image, the image is virtually magnified so that the user region in the image becomes same size of the user region projected in the image when the user is near to the robot. This means that the user size in the image is virtually kept as constant so that the length from the torso and the and of the user keeps constant if the user shows exact same pointing gesture to the robot. The concrete adaptive gain control is designed as followings:

$$\boldsymbol{u} = k\frac{f(S_{\max})}{f(S)}(\boldsymbol{x}_h - \boldsymbol{x}_b) \tag{2}$$

where S, $S_{\max}$, $f(S)$ are red region size in the current image, the red region size when the user stands nearest to the robot, and length of the vector between the red(torso) and blue(hand) regions, respectively. $\frac{f(S_{\max})}{f(S)}$ magnifies the moving vector as long as the user stands nearest to the robot. Data of relationship between the red region size and the length of vector between red and blue regions while the user is pointing horizontally as shown at bottom right in Figure 4 are collected beforehand. The data is approximated with the function Eq.3.

$$f(S) = aS^2 + bS + c \tag{3}$$

Parameters, a, b, and c, of the function $f(S)$ are tuned based on the data. Figure 4 shows the data and the function with tuned parameters. [2]

[1]Rotation speed w is fixed to zero because it is not directory related to the navigation in experiments.

[2]$a = -0.000000234337$, $b = 0.0111673$, $c = 39.9448$

IV. Performance Evaluation of Human Pointing Navigation

First of all, control performance of the proposed human pointing navigation is evaluated. Experiments are carried out on a small soccer field in order to evaluate the performance of the proposed method. Figure 5 shows a experimental setup for evaluation of human pointing and navigation. The yellow and blue regions indicate goals. A human stands on (0, 0) depicted in Figure 5 and faces the opposite side line. The human points with his right hand at one point on one of the dots depicted in Figure 5. An omni-directional mobile robot with an upward-directed fish-eye camera recognizes the human pointing and navigates itself to the pointed place. Errors between the pointed place and the robot destination are recorded.

Figure 6 shows how the robot works with human pointing. While the human does not show his hand to the robot, the robot stays around the human (Figure 6(a)). When the human points with his right hand at a certain point on the field, the robot recognizes hand and torso region on the fish-eye camera image and moves to the point successfully (Figures 6(b)(c)(d)(e)).

In order to evaluate navigation performance, error between a query point and converged location of the navigated robot is investigated. A human points at one of the dots depicted in Figure 5. The size between the dots is 0.5 [m] by 0.5 [m]. Figure 8 show the query points on the field and the final locations of the navigated robot based on the controller with adaptive gain control. Red crosses and heads of green arrows indicate the query points and the final locations of the navigated robot, respectively.

The error becomes small when the query point is close to the pointing user because pointing vector is detected large while the robot is close to the human. The controller with the adaptive gain control (Figure8) shows less errors when the robot starts from the region [-2m to 2m] horizontally. Unfortunately, the error becomes over 0.5[m] if the pointed place is over 2m from the user. The reason is that the red (torso

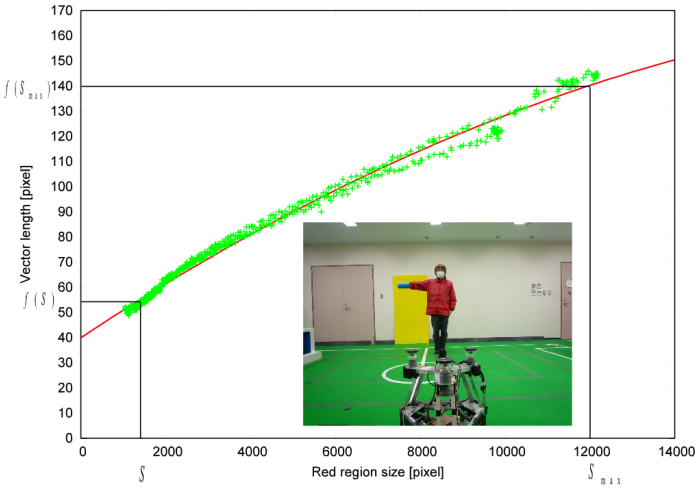

Fig. 4. Relationship between Red Region Size and Length of Vector between Red and Blue Regions

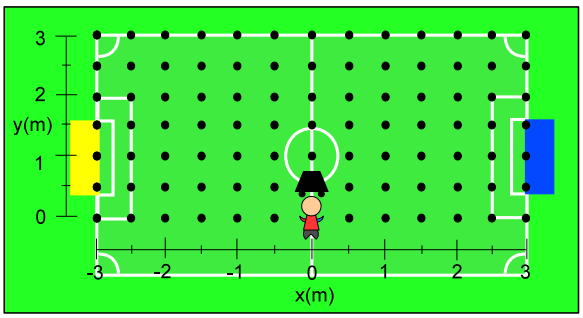

Fig. 5. Experimental Setup for Evaluation of Human Pointing Navigation

of the user) region in the image becomes too small when the robot goes far from the user to compensate the moving vector accordingly.

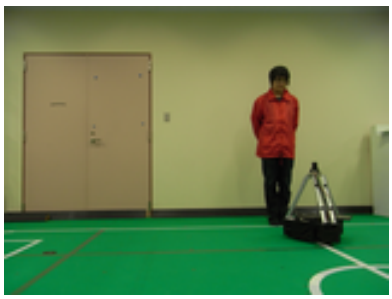
The errors on the right side on the field are smaller than the ones on the left side. One of the reasons is that the projection of the human right hand to the fish-eye camera image tends to be smaller while the human points left side of the field. Another reason is that the center of the torso is not proper position of origin of the moving vector as described in Eqs.1 and 2. Actually, the position of the right shoulder should be the position of the origin when the user points with his right hand. When the user points in right side, the center of the torso is close to the position of the right shoulder but it becomes far if the user points in the left side.

Figure 9 shows a comparison on the error rate between the adaptive gain control and the fixed one[1]. A user stands at [0m, 0m] on the field and point [0m, 1m] with his right hand. The robot starts to navigate to the point from one of points depicted with red crosses. It is apparent that the adaptive gain control leads the robot to more accurate point than the fixed one. The fixed gain control shows larger errors vertically because the size of vector on the projected image by the fish-eye camera, that is, $\boldsymbol{x}_h - \boldsymbol{x}_b$ in Eqs. (1) and (2), tends to be too small to lead the robot to the query point. On the other hand, the adaptive gain control compensates the effect by tuning the gain accordingly.

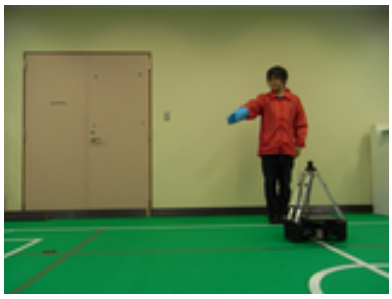
V. Usability Evaluation of Human Pointing Navigation

In order to evaluate usability of the proposed human pointing navigation, questionnaire investigation with 11 persons in their twenties are conducted. We prepare 4 methods for robot navigation: Pointing with fixed control gain, pointing with adaptive gain control (Figure 10(a)), a joystick control (Figure 10(b)), and a game-pad one (Figure 10(c)). A subject is asked to navigate the robot as he/she like with one of the method for about half a minute to become used to the method. After he/she becomes used to the method, he/she navigates the robot along a 2.1m by 1.5m rectangle on the soccer field for about one minute. He/she repeats the procedure for all methods. Then, he/she answers questionnaires as shown below:

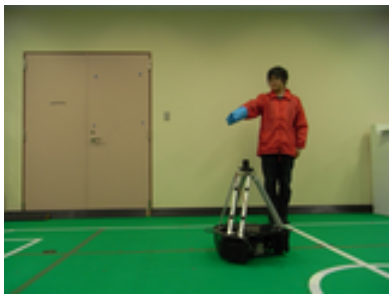
- Amusement: no fun(1) - fun(5)
- Operability: hard(1) - easy(5)



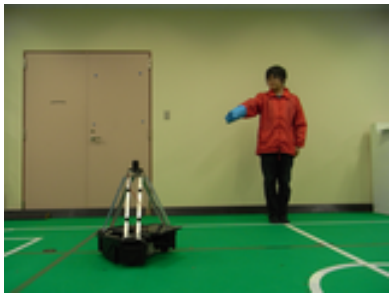
(a)



(b)



(c)



(d)

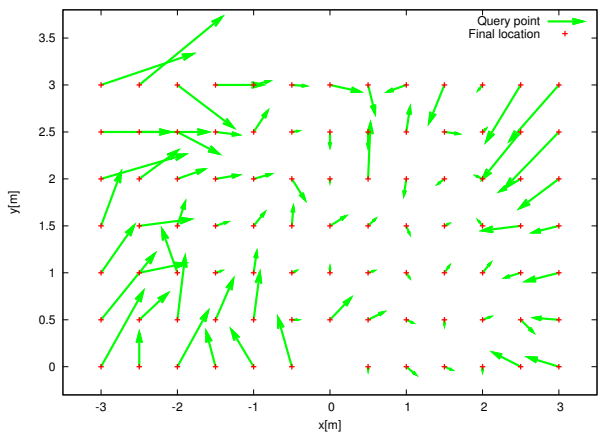

Fig. 8. Navigation Errors with Adaptive Gain Control

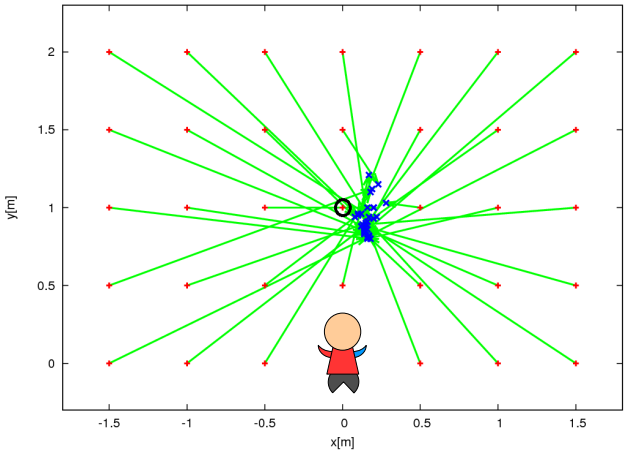
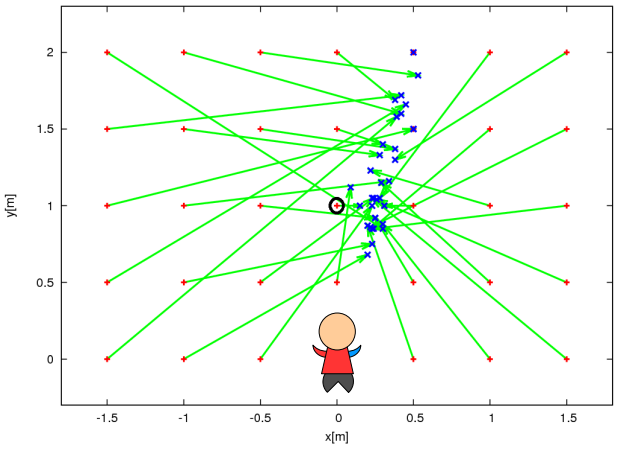


(a) adaptive gain



(b) fixed gain

Fig. 9. Errors with Adaptive/Fixed Gain Control during Navigation to a Fixed Point

- Favorite: dislike(1) - like(5)

Figures 11, 12, and 13 show the questionnaire results. Vertical axes indicate number of votes for each degree (from 1 to 5) of the items (amusement, operability, and favorite). The most subjects are used to the gamepad because they sometimes play computer games but not used to the joystick. They feel fun with the joystick and the pointing with fixed/adaptive control gain because of new experiences for them. They feel hard to navigate the robot with the joystick and the pointing with fixed control gain because they are not used to the joystick and the the pointing with fixed control gain makes the robot behave in different way depending on the distance from the robot to the user. On the other hand, the gamepad shows the best operability because they are used to it and the pointing with adaptive control gain shows the 2nd best. Eventually, the pointing with adaptive control gain shows the best favorite evaluation over all. The reason is that the subjects enjoy the new experience and the operability is well nevertheless they are not used to the pointing navigation interface.

VI. Conclusions and Future Work

We proposed a simple human pointing recognition system for a mobile robot and investigate the validity and usefulness with a real robot. Our mobile robot with a fish-eye upward directed camera recognizes human pointing and navigates itself to the place the human points. A human user can navigate the mobile robot intuitively by simply pointing at desired position on a field with his hand. Experimental results show that the proposed method reasonably works and the user can control and navigate the robot intuitively. Adaptive control gain works well so that it reduces the different behavior of the robot according to distance from the robot and the pointing user and increases the operability and favorite of the user.

The current method forces a potential user to wear bright and uniform color jacket and glove to detect them by simple color extraction processing on vision system. It is not convenient for him/her to wear them every time to navigate the robot. A method extracting user region on the upward directed fish-eye camera image should be developed.

At this moment, a potential user has to keep pointing at desired position until a robot reach it. As future work, the proposed method is extended so that a robot estimates direction and distance of the pointed place from a captured image of the pointing user. Nagai et al.[11] proposed a model of "joint attention" that enables a robot to look at an object which its caregiver watches. Their model trains a map from a caregiver's face camera image to an input to head direction control. A similar idea might be applicable for our purpose, that is, a mobile robot learns a map from a captured image of a pointing user to a direction and distance of the pointing place as well.

***Abstract*— Shape Memory Alloy (SMA) wires are currently employed in robotics, as well as prosthetic limbs and medical equipment. Due to advantages such as reducing the size in the application, high power-to-weight ratio, elimination of complex transmission systems and noiseless actuation, and human–machine interface, these materials are used as actuators in the prosthesis limb. Because of hysteresis property and nonlinear behavior of SMA, control of these actuators is very complicated. In this paper, the design of control algorithms has been discussed for SMA actuators in the artificial fingers with 3 DOF, which includes PID-fuzzy controller. Gains of controllers are set so that the current applied to SMA wires has minimum overshoot and output of system has minimal time to achieve stability. The simulation results compared with actual measured data show how well the controllers decrease the overshoot and time of stability of input signal to SMA wires.**

Keywords- shape memory alloy; artificial hand; Fuzzy and Fuzzy-PID controller.

I. INTRODUCTION

Actuators are components of robot drive and caused the movement of them. Based of motion, actuators are divided in two types: linear and rotation, and based on performance they are divided in various types: electrical, hydraulic and pneumatic. Using actuators with physical characteristics of them such as weight and size has some limitation. So much activity on these systems has been carried out. In humanoid robots and artificial limbs, due to multiple active joints in limited space, need lightweight, small and powerful actuators for making large placement. SMA is used in robotics because of high ability such as reducing the size of robot and Compatibility with the human body. SMA constitutes a group of metallic materials with the ability of recovering a previous defined length or shape when stands under a thermodynamic process. The transition from one form of crystalline structure to another creates a mechanism by which the shape change occurs in SMAs. This change involves transition from a monoclinic crystal form (martensite) to an ordered cubic crystal form (austenite). The austenite phase is stable at high temperature, and the martensite is stable at lower temperatures. So, the phase transformation between the two phases, martensite and austenite, is accompanied by variations in its resistivity [1]. The typical attribute of these materials is that their parameters can't be determined by simple interpolation of properties of alloys included in the compound. superplasticity, superelasticty, acid resistance and the shape memory effect (SME) make these compounds technically important. Due to advantages such as reducing the size in the application, high power-to-weight ratio, elimination of complex transmission systems and noiseless actuation, and human–machine interface, these materials are used as actuators in the prosthesis limb [2]. Disadvantages of these materials can be cited to hysteresis property. Despite these limitations, they are used in robotic hands and biomaterials.

In recent years, much researches aimed at controlling SMA actuators have been carried out in an artificial limb. Hull and et al. presented a PI controller for obtaining the desired position in SMA actuator [3]. Neguyen presented a new development of a SMA position control system by using a self-tuning fuzzy PID controller [4]. This control algorithm is used by tuning the parameters of the PID controller thereby integrating fuzzy inference and producing a fuzzy adaptive PID controller, which can then be used to improve the control performance of nonlinear systems. Bizdoaca presented a fuzzy logic controller for a SMA tentacle robotic structure [5]. Nicu-George was investigated PI, PD, PID and fuzzy logic controllers are connected to the single link SMA actuation [6]. Ahn used a PID controller for position control of SMA actuator that the parameters of this controller obtained by genetic algorithm [7]. J.Park presented combination of compliant tendon cables and one-way shape memory alloy (SMA) wires that form a set of agonist–antagonist artificial muscle pairs for the required flexion/extension or abduction/adduction of the finger joints [8]. The performance of the proposed actuation system is demonstrated using a 4

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

DOF artificial finger and for evaluation of finger's efficiency, he used PWM-PD controller.

In this paper, according to a dynamic model for an artificial finger with three degrees of freedom using the actuator of SMA [9], fuzzy-PID controller has been designed for position control of SMA actuators. Gains of controllers are carried out so that the current applied to SMA wires has minimum overshoot and output of system has minimal time to achieve stability.

II. DYNAMIC MODEL OF ROBOT

A dynamic model for an artificial finger by using properties of the SMA actuator is designed and presented [9]. This robotic finger has been designed and modeled with 3 DOF, revolute joints, SMA wires as the tendon in order to adduct each phalange of finger and springs to restore each phalanges of finger to original position. In this model, the direct and inverse kinematics of robot and robot motion equations are presented. Mechanism schematic of robot with 3 DOF, parameters and coordinate system is shown in Fig. 1. As shown in this figure, the SMA wire as an actuator after passing the pulley is connected to links of robot. When electrical current is applied in these wires, the wires are hot and after the phase changing, their lengths become shorter so the link of robot starts to turn. After removal of current, the wires are cooled gradually and return to their initial length. Torsion springs in the joints will cause the links to go to the original position.

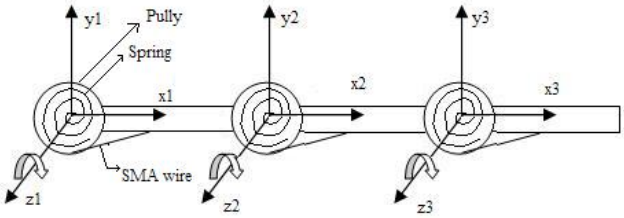

Figure 1. Mechanism schematic of robot with 3 DOF, parameters and coordinate

Kinetic of this robot with SMA actuators and thermodynamic properties of these actuators that include heat transfer, constitutive and phase transformation models are reviewed in reference [9]. Equation of motion of each robot's link by using Lagrange relations is expressed according to (1):

$$\tau_{ji} - \tau_{si} = \sum_{j=1}^{n} D_{ij}(q)\ddot{q}_i + \sum_{k=1}^{n}\sum_{j=1}^{n} c_{kj}^{i}(q)\dot{q}_k\dot{q}_j + h_i(q) + b_i(\dot{q}) \qquad \iota=1,2,3 \quad (1)$$

For each link i, D_{ij} is mass matrix, c^{i}_{kj} is waste viscose term, h_i is terms related to the gravitational potential energy and b_i is frictional force. This model is ignored from friction of joints. Also τ_{si} the torque due to tensional spring and τ_{ji} the torque applied by the SMA actuator [9].

All elements expressed in equation (1), derived according equation and tables in [9].

Dynamic model of this artificial finger simulated in MATLAB/SIMULINK, as shown in Fig. 2. The entering input to and exiting output from this model are current and angles of joints respectively.

This simulation of dynamic model consists of SMA wire heat transfer model, SMA constitutive model and SMA phase transformation model.

The results of simulation model didn't have any offset and steady error; this means that after cutting off current, joints return to their initial position. Also joints reached the desired angle without fluctuation. In addition, after applying the current, joints begin to move immediately and it means that simulation didn't have delay and system motion is perfect (close to actual conditions).

III. DESIGN OF CONTROL SYSTEM

One of the most important parts of control system design is determining the appropriate controller parameters [10]. Planning system and achieving the best behavior is the definition that all the positive factors such as increased stability and reduced steady state error have been in the system.

In this paper a closed loop control method is expressed that is simulated in MATLAB /Simulation.

The design of a fuzzy-PID controller can be achieved in different ways. One way is to build a fuzzy controller with three inputs: the error (proportional action-GE), the delta error (derivative action-GCE) and the sum of the error (integral action-GIE) (see Fig. 3). The inconvenience for such a controller is that the number of rules will grow and instead of 25 rules (for system with 5 membership functions on each input), this controller will have 125 rules, making the tuning task very difficult .The solution is to divide the controller in two controllers, one that is the PD equivalent and another one

that provides the integral action. It will reduce the number of rules to 30 (see Fig. 4).

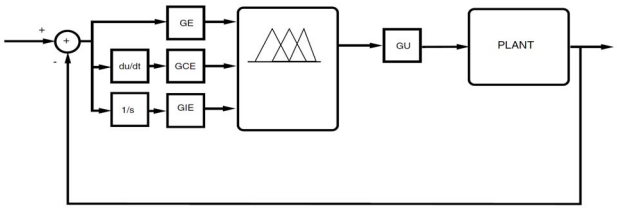

Figure 3. Fuzzy PID controller [10]

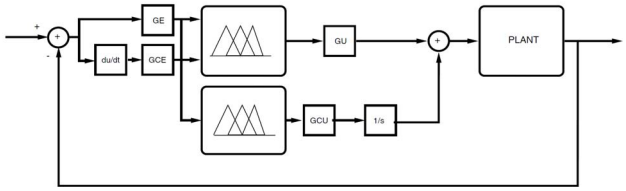

Figure 4. Fuzzy PD+I controller [10]

The use of the "gain constants" can be avoided using a more complex initialization on the fuzzy system where the inputs are not scaled and the singletons of the output are calculated using its direct relation with model values of the membership function in the antecedents, in the similar way as the rules are initialized in the training algorithm.

Further improvement will be done by trial and error, if there is no model of the plant, or via optimization, if a model is available. Using this initialization, the controller will guarantee a performance at least as good as the one provided by the linear PID controller.

Some of the typical actions in the trial-and-error procedure are to increase the impact of the proportional action when the error is very large and slightly reduces the integral action. These two actions tend to reduce the settling time and the overshoot.

In PID-fuzzy, value of desired angle is compared with the amount of feedback. Difference between these two signals is called the position error that it is input of fuzzy controller. The inputs of first fuzzy controller in each link are error (proportional action) and the delta error (derivative action) and because of fuzzy controller introduction in normal form, output is multiplied in a gain. The input of second fuzzy controller in each link is error (proportional action) and output of this controller is multiplied in a gain firstly then enters into the integral. Finally, the total outputs of both controllers are added together, current rate of SMA wire for achieving the desired angle is obtained.

In this section the structure of the fuzzy controller designed for artificial fingers, is investigated. Assuming five membership functions as Negative Big (NB), Negative Small (NS), Zero (Z), Positive Small (PS) and Positive Big (PB) on each input of the fuzzy controller and seven membership functions as Very Low (VL), Low (L), Middle Low (ML), Middle (M), Middle High (MH), High (H) and Very High (VH) in the output of the fuzzy controller. The membership functions of inputs and output, which are defined normally, are shown in Fig. 5 and Fig. 6 respectively.

To express the rules, we need to note, the negative error means that the value of position is upper than desired position and applied current must be reduced for reducing the temperature of the wire and the positive error means that the value of position is lower than desired position, so the applied current should be increased for increasing the temperature of wire. With this definition, rules of first and second fuzzy controller are shown in Table 1 and Table 2 respectively.

Gain scheduling has been used extensively on industrial applications. The advantage of this technique is the use of liner techniques to design controllers for nonlinear systems by applying linearization around the different operating points. In this way several linear controllers are designed and "connected" to the plant according to the current operating point. Fuzzy systems offer to these techniques the advantage of integrating in one mechanism the detection of the operating point and the interpolation among the different operating points, providing a smooth nonlinear control law. It has been proved that the fuzzy controllers can be seen as smooth gain scheduling controllers [10].

We used an approach intelligent to determine gain, so that for optimization of fuzzy controller, the code is written for checking the behavior of the system to different inputs and obtaining optimal output (angle of link) in the system. Then this code has been approximated as a linear relationship for each link and is used for obtaining value of error's gain and delta error's gain.

Before entering error to fuzzy controller at the first link, a gain $GE_1(t)$ is used which is obtained by (2):

$$GE_1(t) = 1/ (Setpoint1 -3) \quad (2)$$

And before entering delta error to fuzzy controller at the first link, a gain $GCE_1(t)$ is used which is obtained by (3):

$$GCE_1(t)=1/(GE_1(t)*10) \quad (3)$$

Before entering error to fuzzy controller at the second link, a gain $GE_2(t)$ is obtained by (4):

$$GE_2(t) = 1/ (Setpoint2 -2) \quad (4)$$

And before entering delta error to fuzzy controller at the second link, a gain $GCE_2(t)$ is used which is obtained by (5):

$$GCE_2(t)=1/(GE_2(t)*10) \quad (5)$$

Before entering error to fuzzy controller at the third link, a gain $GE_3(t)$ is obtained by (6):

$$GE_3(t) = 1/ (Setpoint3 -3) \quad (6)$$

And before entering delta error to fuzzy controller at the third link, a gain $GCE_3(t)$ is used which is obtained by (7):

$$GCE_3(t)=1/(GE_3(t)*10) \quad (7)$$

The output gain of the first controller is chosen to be constant at 0.9 (GU). Maximum rate of reducing temperature in the wire is achieved with minimum current and maximum rate of increasing temperature in the wire is achieved with maximum current. Due to the overheating phenomenon in the wire, maximum applied current is 0.9A.

Also is used a gain in constant 0.001 (GCU), after exiting of output from the second fuzzy controller which decreases fluctuations in the output of system.

IV. DISCUSSION

In this section, results have been investigated by using membership functions in first and second fuzzy controller and system simulation in MATLAB.

A. Performance of PID-Fuzzy controller in position control on the first link of artificial finger

Fig. 7 shows control signal is generated by the PID-Fuzzy controller with the setpoint 12 (degrees) at the first link. Output of system to this setpoint is shown in Fig. 8.

As shown in Fig. 7 and Fig. 8, Less time to reach the desired angle and uniformity of control signal show successful performance of controller at the first link of artificial finger. Also system is not disturbed and fluctuated and its steady state error is low.

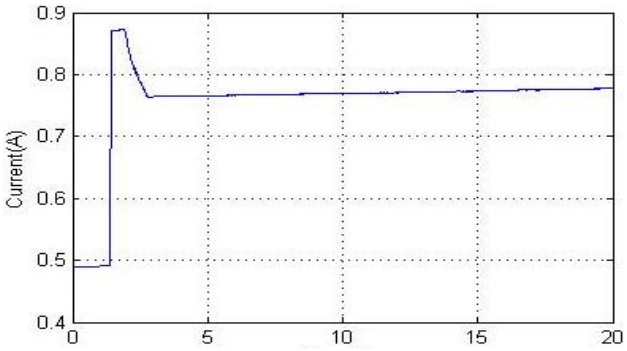

Figure 7. Output of PID-fuzzy (current) in the first link

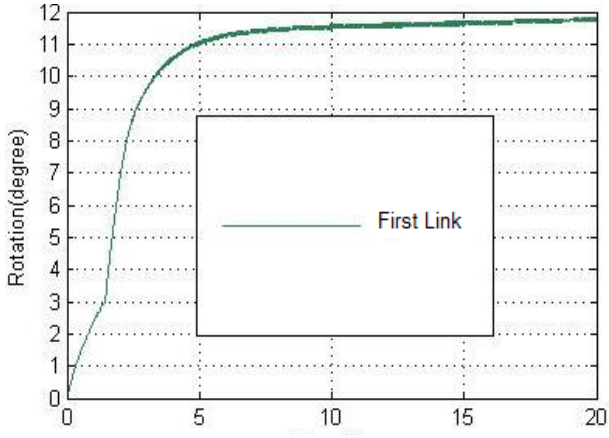

Figure 8. Output of system (rotation of link) in the first link

B. Performance of PID-Fuzzy controller in position control on the second link of artificial finger

Fig. 9 shows control signal is generated by the PID-Fuzzy controller with the setpoint 10 (degrees) at the second link. Output of system to this setpoint is shown in Fig. 10.

As shown in fig. 9 and Fig. 10, time to reach stability is acceptable and appropriate. Less time to reach the desired angle and uniformity of control signal shows successful performance of controller at the first link of artificial finger. Also system is not disturbed and fluctuated and its steady state error is low.

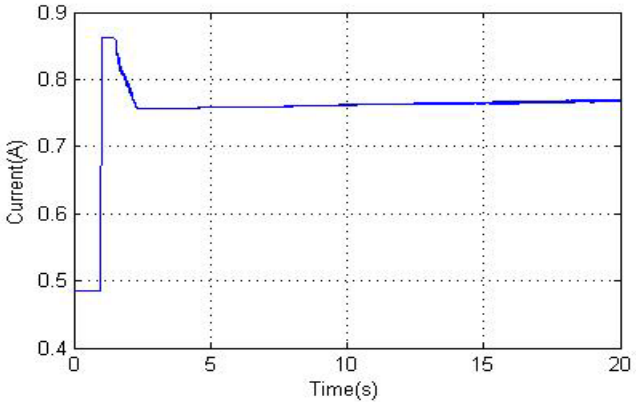

Figure 9. Output of PID-fuzzy (current) in the second link

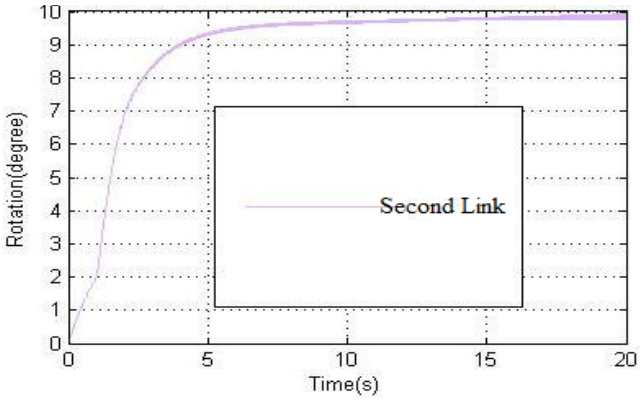

Figure 10. Output of system (rotation of link) in the second link

C. Performance of PID-Fuzzy controller in position control on the thired link of artificial finger

Fig. 11 shows control signal is generated by the PID-Fuzzy controller with the setpoint 8 (degrees) at the third link. Output of system to this setpoint is shown in Fig. 12.

As shown in Fig. 11 and Fig 12 Less time to reach the desired angle and uniformity of control signal show successful performance of controller at the first link of artificial finger. Also system is not disturbed and fluctuated and its steady state error is low.

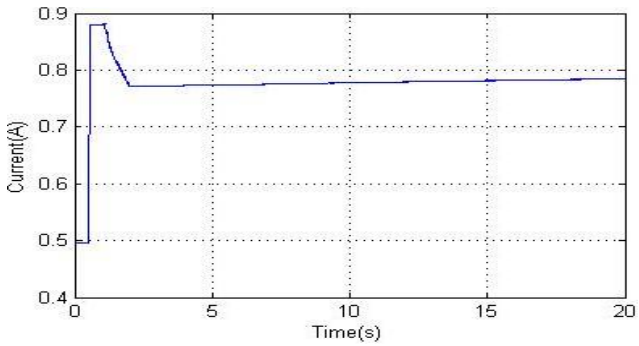

Figure 11. Output of PID-fuzzy (current) in the third link

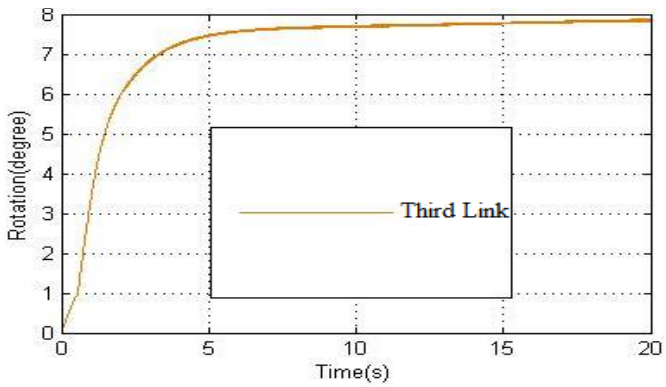

Figure 12. Output of system (rotation of link) in the third link

Results of control system which is designed to bind the model to this controller has been compared with the results of PWM-PD control system which were provided by Bundhoo [11]. Bundhoo designed a PD controller, which is designed to control the current applied to SMA actuator for arriving links of artificial fingers to desired position. Figure 13 shows output of PD controller provided by Bundhoo (apply current to the actuator in the first link).

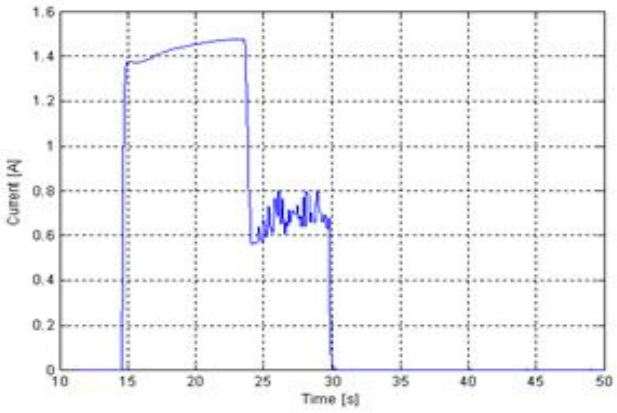

Figure 13. The current profile of the corresponding SMA actuator [11]

The obtained results in this paper with PID-fuzzy controller (first link Fig. 7) is better than Bundhoo's controller because

the overshoot and time stability of output signal in PID-fuzzy controller are smaller and less than Bundhoo's controller.

V. CONCLUSIONS

In this paper, algorithm and performance results of PID-fuzzy controller for the artificial finger with three degrees of freedom are presented. Gains of controllers are carried out so that the current applied to SMA wires has minimum overshoot and output of system has minimal time to achieve stability. Results obtained from simulation and comparison with experimental results show that the PID-fuzzy controllers have good performance in reducing the maximum overshoot and stability of time in input signal to the SMA actuators. Also this controller was able to produce reliable outputs with relatively small errors.

***Abstract*—In the era of data intensive management and discovery, the volume of images repositories requires effective means for mining and classifying digital image collections. Recent studies have evidenced great interest in image processing by "mining" visual information for objects recognition and retrieval. Particularly, image disambiguation based on the shape produces better results than traditional features such as color or texture. On the other hand, the classification of objects extracted from images appears more intuitively formulated as a shape classification task.**

This work introduces an approach for 2D shapes classification, based on the combined use of geometrical and moments features extracted by a given collection of images. It achieves a shape-based classification exploiting fuzzy clustering techniques, which enable also a query-by-image.

***Index Terms*—fuzzy clustering, image data mining, image retrieval.**

I. Introduction

The evolution of multimedia computing and applications has seen an explosive growth of digital images in many application domains. This development has remarkably increased the need for image recognition management and image retrieval systems that are able to effectively classify a large amount of images and to efficiently retrieve them based on their visual contents. In developing a visual content-based image retrieval system, two different approaches have been applied: one based on textual information, the other based on image content information. The choice of image features, or combinations of image features to be used for image indexing and retrieval purposes is a critical decision for the efficacy of the adopted approach.

The retrieval based on textual information considers attached textual metadata to each image in the database, then a keyword-based query may be submitted to the system to get relevant images [1]. This approach requires a preliminary annotation activity which often is laborious and time-consuming; moreover, it is a human driven process: that means similar images characteristics can be expressed by different terminologies, according to the subjective evaluation and feeling of the user, affecting the performance of the keyword-based image search. For these shortcomings, (semi-)automatic approaches have been achieved to process the image in order to get more "objective" *content-based* image properties such as color, texture, and shape.

Content-Based Image Retrieval (CBIR) systems instead characterize an image through a set of features; retrieval or classification is then performed by measuring similarity to a required query image [2] contrasting to the effort needed to annotate images. Because images can be particularly complex to manage; CBIR techniques often require a translation of high-level user perceptions into low-level image features. To cope with the so called "semantic gap" problem, these features should be consistent and invariant to remain representative for the images collection in a database.

On the other hand, the CBIR technology tries to address two intrinsic problems: (a) how to mathematically describe an image, and (b) how to assess the similarity between a pair of images based on their abstracted descriptions. Recent methodology development employs statistical and machine learning techniques in various aspects of the CBIR technology. In image classification methods, the approaches are based on learning-based and non-parametric classifiers. As been pointed out in [3], despite the large performance gap between non-parametric classifiers and state-of-the-art learning-based, the non-parametric image classification have been considerably under-valued and offer several advantages: (i) can naturally handle a huge number of classes; (ii) avoid overfitting of parameters, which is a central issue in learning based approaches; (iii) require no learning/training phase.

This work presents an approach for image classification and retrieval based on 2D shape features and extends a previous work [4] for further investigations on shape classification, through fuzzy clustering techniques.

The remainder of the paper is organized as follows. Section II gives a sketched overview of the related works in this area. Section III provides a background on the image processing for the image analysis and features extraction whereas Section IV-A introduces the fuzzy clustering algorithms exploited in this approach. Finally, Section V describes the experiments and provides the results and comparisons. Conclusions and future works close the paper.

II. Related Works

The large repository of digital information needs enhanced image acquisition technologies and computer-assisted image

understanding tools in order to get an efficient assistance in image processing, query and retrieval. CBIR aims at efficient retrieval of relevant images form large databases exploiting automatically derived image features [5]. Popular CBIR systems are QBIC, Virage, RetrievalWare, Photobook, Chabot, VisualSeek, WebSeek, MARS system, SurfImage, Netra, and CANDID (for a complete survey, refer to[6]); almost all of these approaches are based on indexing imagery in a feature space. A feature is a certain visual property of an image, either globally for the entire image or locally for a small group of pixels. The feature extraction is often considered as a preprocessing step, which represents the inputs to subsequent image analysis tasks. These features are typically extracted from color, texture, shape and region. Particularly, shapes can be represented by their contours, i.e. a potentially large number of points from their boundaries. Shape descriptors have been used widely as features to characterize an image for classification and image retrieval tasks, such as character recognition [7], word recognition [8] and copyrighted trademark retrieval [7][9]. Like for the texture features, shape features can be used to distinguish between objects where the color feature reveals an unreliable classification due to different objects in image representation can have the same color.

Also the increasing diffusion of images compression requires challenging techniques to extract visual features [10]: sophisticated global features such as the wavelets [11] and large collection of local image descriptors as SIFT [12].

Some other techniques improve the effectiveness of image retrieval through multi-features combination [13],[14] and then, by measuring similarity to a required query image [2]. Combination of words and features characterize annotated training sets of images [8], which will be used for classification or retrieval.

The image description and the user's perception of these features evidence the imprecise nature of the retrieval which can benefit by fuzzy techniques. Fuzzy logic is suitable for expressing linguistic expression by means of fuzzy rather than crisp features values [15].

Applying fuzzy processing techniques to CBIR approaches has been extensively investigated in literature. In general, fuzzy retrieval models offer more flexibility in the representation of the terms' index, preferences among terms in a query and ranked results. In particular CBIR models take advantage by using technique based on fuzzy theory for knowledge representation, for uncertainty management, against traditional information retrieval models based on boolean, vector-based or probabilistic representation. An example is given in [16] where a fuzzy information retrieval model for textual data has been extended to implement a model in image context. In [17], fuzzy logic has been employed to interpret the overall color information of images: according to the human perception, nine classes of colors are defined as features.

A fuzzy color histogram approach in [18] allows the evaluation of similarity through fuzzy logic-based operations. In [19], instead the similarity of two images has been defined by considering the overall similarity between families of fuzzy features. More specifically, each image has been associated to a family of fuzzy features (fuzzy set) representing color, texture, and shape properties. This approach reduces the influence of inaccurate segmentation, compared with other similarity measures based on regions and with crisp-valued feature representations.

Many CBIR approaches exploit clustering for preprocessing activities [20], specifically, fuzzy techniques are widely employed in image classification methods. In [21], a method to calculate image similarity measure using fuzzy partition of the HSI color space has been presented. In particular, the fuzzy c-means (FCM) clustering algorithm [22] has been shown to provide effective partitions for image segmentation on medical images [23][24], satellite images [25][26], and so on. Some extension and modification of FCM are applied to image segmentation in infrared images domain [27]. In [28] a modified version of FCM has been proposed, to solve the problem of large-scale image retrieval and classification, even though the clustering step is performed in lower-dimension space, and image retrieval is only performed in clustered prototypes. Yet, in the most of approaches, the execution time of the clustering algorithm is a critical point, which finds a solution in [27].

III. Design of the feature space

The first step toward the shape analysis of a given image involves separating the object (or region) of interest from other non-important image structures by using an image segmentation approach. There are several approaches for the extraction of the shape from a given image based on clustering methods, histogram methods, edge detection, level set methods, graph partitioning methods and so on. In general there is no a general solution and there is always an image where an approach does not yield good result, i.e., if the foreground and background share many similar colors, an approach could give a result with parts of background labeled as foreground object. This is challenging in shapes classification because any approach must take into account this drawback. In our implementation, we adopt the k-means clustering algorithm for image segmentation which is suitable when the foreground and background colors contrast sufficiently with each other.

A shape descriptor is a set of numbers that are extracted from the region of interest in order to describe a given shape feature. Efficient shape features must present some essential properties such as identifiability, invariance, noise resistance, statistically independence and so on.

In this work, we adopt three types of such shape descriptions: geometric description, invariant moments and affine moments. The geometric features discriminate shapes with large difference. They are useful to eliminate false hits and usually are not suitable as single description, in fact they are combined with other shape descriptors to better discriminate shapes. The moment instead, represents a mathematical concept coming from the concept of moment in physics. It is used in computer vision for both contour and region of a shape. In particular, the invariant moments [29] are one of the most popular and

widely used contour-based shape descriptors. Affine moments invariants are instead features computed from moments that do not change their value in affine transformation.

In the case of geometric features, let P and A denote the shape perimeter and area, respectively. Note that perimeter and area are invariants respect to translation and rotation but when combined, they are not invariant with respect to scale. The features we adopt are:

- Eccentricity E is the measure of aspect ratio. It is defined as the ratio $E = W_{bb}/H_{bb}$ where W_{bb} and H_{bb} are, respectively, the width and height of minimal bounding rectangle of the shape.
- Rectangularity R represents how rectangular a shape is, i.e. how much it fills its minimum bounding box. It is defines as $R = A/A_{bb}$ where A_{bb} is the area of the minimum bounding rectangle.
- Compactness C is a measure that combines area with perimeter. It is defined as $C = L^2/4\pi A$.
- The value π_{gen} is a measure of the compactness of a shape respect to a circle. It is defined as $\pi_{gen} = P/W_{bb}$.

Among the region-based descriptors, invariant moments m_{pq} are the simplest and is given as:

$$m_{pq} = \sum_x \sum_y x^p y^q f(x,y) \qquad p,q = 0,1,2,\ldots$$

where $f(x,y)$ is the intensity function at position (x,y) in a 2D gray level image. In order to obtain translation invariance, the central moments μ_{pq} should be applied:

$$\mu_{pq} = \sum_x \sum_y (x-\overline{x})^p (y-\overline{y})^q f(x,y) \qquad p,q = 0,1,2,\ldots$$

where $\overline{x} = m_{10}/m_{00}$ and $\overline{y} = m_{01}/m_{00}$. Given central moments we are able to compute a set of 7 invariant moments [29], given by:

$$\begin{aligned}
I_1 &= \eta_{20} + \eta_{02} \\
I_2 &= (\eta_{20} - \eta_{02})^2 + 4\eta_{11}^2 \\
I_3 &= (\eta_{30} - 3\eta_{12})^2 + (3\eta_{21} - \eta_{03})^2 \\
I_4 &= (\eta_{30} + \eta_{12})^2 + (\eta_{21} + \eta_{03})^2 \\
I_5 &= (\eta_{30} - 3\eta_{12})(\eta_{30} + \eta_{12})[(\eta_{30} - \eta_{12})^2 - 3(\eta_{21} - \eta_{03})^2] + \\
&\quad (3\eta_{21} - \eta_{03})(\eta_{21} + \eta_{03})[(3\eta_{30} + \eta_{12})^2 - (\eta_{21} - \eta_{03})^2] \\
I_6 &= (\eta_{20} - \eta_{02})[(\eta_{30} + \eta_{12})^2 - (\eta_{21} - \eta_{03})^2] + \\
&\quad 4\eta_{11}^2(\eta_{30} + \eta_{12})(\eta_{21} + \eta_{03}) \\
I_7 &= (3\eta_{21} - \eta_{03})(\eta_{30} + \eta_{12})[(\eta_{30} - \eta_{12})^2 - 3(\eta_{21} - \eta_{03})^2] + \\
&\quad (3\eta_{12} - \eta_{03})(\eta_{21} + \eta_{03})[(3\eta_{30} + \eta_{12})^2 - (\eta_{21} + \eta_{03})^2]
\end{aligned}$$

where $\eta_{pq} = \mu_{pq}^{\gamma}$ and $\gamma = 1 + (p+q)/2$ for $p+q = 2,3,\ldots$. These moments are simple to calculate and they are invariant to translation, rotation and scaling but have an information redundancy drawback since the basis in not orthogonal[30]. From central moments with a little computational effort we are able to obtain also an affine transform invariance which includes the similarity transform and in addition to that stretching and second rotation. We adopt affine moments as defined in [31] and given as:

$$\begin{aligned}
AMI_1 &= (\mu_{20}\mu_{02} - \mu_{11}^2)/\mu_{00}^4 \\
AMI_2 &= (\mu_{30}^2\mu_{03}^2 - 6\mu_{30}\mu_{21}\mu_{12}\mu_{03} + 4\mu_{30} + \mu_{12}^3 + \\
&\quad 4\mu_{03}\mu_{21}^3 - 3\mu_{21}^3\mu_{12}^3)/\mu_{00}^{10} \\
AMI_3 &= (\mu_{20}(\mu_{21}\mu_{03} - \mu_{12}^2) - \mu_{11}(\mu_{30}\mu_{03} - \mu_{21}\mu_{12}) + \\
&\quad \mu_{02}(\mu_{30}\mu_{12} - \mu_{21}^2))/\mu_{00}^7
\end{aligned}$$

All these features are sufficient to characterize the shape of an image. The rationale behind the choice of these moments is that we are interesting in translation, rotation, scale, and projective transform invariance in order that the location, orientation, and scaling of the shape do not affect the extracted features. Further information on these approaches is discussed in [32].

IV. Unsupervised clustering techniques for the image arrangement

The clustering algorithms achieves a partitioning of given data into clusters. In general a partition holds two properties: homogeneity within the clusters (data in a cluster must be similar) and separation between clusters (data of different clusters have to be as different as possible).
The data are opportunely translated into a matrix, where each row is a characteristic vector which represents an image. In fact, the images set has been processed (as described previously) to pull out a such data matrix, whose rows and columns are respectively the collected images and the relative extracted features. Two clustering algorithms have been take into account: the well-known fuzzy C-Means (briefly FCM) algorithm [22] which takes as input the whole data set of images and the approach presented in [33] that works with more than one (sub-)set of data, trying to reconcile them in one complete final partitioning.

A. Fuzzy clustering

FCM represents the most common fuzzy clustering, particularly useful for flexible data organization. It takes as input a collection of patterns of a universe U in form of matrix and produces fuzzy partitions of the given patterns into (prefixed) c clusters.
The FCM algorithm recognizes spherical clouds of points (clusters) in a multi-dimensional data space and each cluster is represented by its center point (prototype). This process is completely unsupervised, aimed at identifying some inherent structures in a set of data.
The fuzzy version of clustering produces a more flexible partitioning of data. Precisely, each pattern (in our case, an image) is not associated exclusively to a cluster, but it can belong to more than one. After the fuzzy clustering execution, each pattern has associated a c-dimensional vector, where each cell represents the membership (in the range $[0,1]$) of that pattern to each cluster.

Compared to the crisp version, the fuzzy clustering generates a flexible partitioning, more intuitive to interpret: a pattern can have some characteristics that are natively representative of more than one cluster, and the exclusive belonging to one

cluster is a too restricted condition. In the fuzzy approach, the membership values better reveal the nature of data set and allow a clearer data analysis. Anyway, it is conceivable to assign a pattern to the cluster, whose membership is the highest.

More formally, each row of the matrix is a vector that represents an image $I \longleftrightarrow \underline{x} = (x_1, x_2, \ldots, x_h)$, where each component of vector is a value computed for a feature. The FCM algorithm aims at minimizing the objective function constituted by the weighted sum of the distances $dist_{i,k}$ between data points $\underline{x}_k = (x_{k,1}, x_{k,2}, \ldots, x_{k,h})$ and the centers (or prototypes) $\underline{v}_i = (v_{i,1}, v_{i,2}, \ldots, v_{i,h})$, according to this formula:

$$Q(U, c) = \sum_{i=1}^{c} \sum_{k=1}^{n} u_{i,k}^{m} (dist(\underline{x}_k, \underline{v}_i))^2 \quad (1)$$

where $c \geq 2$ is the number of clusters, $u_{i,k} \in$ [0,1] is the membership degree of $\underline{x}_k$ (k=1, …, n) in the i-th cluster A_i (i=1, …, c), and $m > 1$ is the fuzzifier, which controls the quantity of fuzziness in the classification process (common choice of fuzzifier is $m = 2$) and finally $dist(\underline{x}_k, \underline{v}_i)$ is:

$$dist(\underline{x}_k, \underline{v}_i) = \sqrt{(||\underline{x}_k - \underline{v}_i||^2)} \quad (2)$$

represents the euclidean distance between the data $\underline{x}_k$ and the center $\underline{v}_i$ of the i-th cluster.

In details, $U = (u_{i,k})$ is a $c \times n$ matrix of cluster memberships satisfying some constraints. In particular, M_{fc} is a family of fuzzy partition matrices:

$$M_{fc} = \left\{ U | u_{i,k} \in [0,1]; \sum_{i=1}^{c} u_{i,j} = 1; 0 < \sum_{k=1}^{n} u_{i,j} < n, \forall\, i, j \right\}, \quad (3)$$

and $V = (\underline{v}_1, \ldots, \underline{v}_c)$ is the ordered collections of cluster centers.

In our study, the data matrix is composed of n images, each one with h values, associated to the corresponding features. The FCM algorithm produces a partitioning of this collection into a prefixed number c of clusters.

The algorithm finds an optimal fuzzy partition of the data, which is carried out through an iterative optimization of (1).

Let us note the only actual parameter of this algorithm is the number c of clusters. In general, this number is not known a priori. Selecting a different number of initial clusters can effectively affect the final partitioning of the data. The problem for finding an optimal c is usually called cluster validity [34]. The objective is to find optimal c clusters that can validate the best description of the data structure. Each of these optimal c clusters should be compact and separated from other clusters. In the literature, many heuristic criteria have been proposed for evaluating fuzzy partitions; some of traditional cluster validity indexes, which have been frequently used, are Bezdek's partition coefficient (PC) [35], partition entropy (PE) [34], Xie-Beni's index [36].

B. Collaborative clustering

The clustering presented in [33] proposes an approach which takes as input two or more subsets of the reference data domain. It achieves a collaborative and proximity-based mechanism of clustering through a collaborative and highly synergistic discovery of structure in data. The collaborative clustering exploits FCM clustering to get a thorough arrangement of data, according to their different typologies of features. In other words, the subsets of features identify collections of descriptors which represent different views of the interest domain, i.e., the structure at different levels of granularity (clusters), providing a scheme of incorporating collaboration. At the end, a collection of homogeneous clusters are given that often better group the data.

More formally, let us consider a collection of patterns (objects) X whose features are described by distinct feature spaces, say $X[1], X[2], \ldots, X[p]$. Let us note X is composed by concatenating all the sub-datasets $X = X[1]X[2] \ldots X[p]$. The approach uses FCM as basic clustering technique and minimizes a objective function given in (1). As said the final outcome of this clustering is a partition matrix that reveals all details about the structure of the data set.

The collaborative clustering achieves two levels of processing:

- numeric: it involves original data sets. FCM clustering is applied to each feature spaces. The approach assumes the number of the clusters by $c_1, c_2, \ldots, c_p$ are different values. The final results are a set of partition matrices $U[1], U[2], \ldots, U[p]$.
- granular: it is based upon membership grades computed through the partition matrices. As the comparison among partition matrices is not possible (they are built with different number of the clusters), the proximity matrices are computed. Let us recall, that for two patterns x_i and x_j the proximity measure returns a number in [0,1] such that it is equal to 1 if $i = j$. Moreover, this measure is symmetric.

  Given a partition matrix $U[k], (k = 1, \ldots, p)$ the proximity between pattern "i" and "j" based on the values of their corresponding entries is [37]:

$$Prox[k](i, j) = \sum_{l=1}^{c} min(u(l, i), u(l, j)) \quad (4)$$

  The results of final consensus are reached through reconciling proximities based upon the clusters.

Thus, the performance index to optimize is described by the following formula:

$$V = \sum_{k=1}^{p} \sum_{i=1}^{N} \sum_{j=1}^{N} [Prox(U)(i, j) - Prox[k](i, j)]^2 \quad (5)$$

where $Prox(U)$ is the proximity matrices computed by Eq. (4) on the whole data set $X(= X[1]X[2] \ldots X[p])$.

The optimization of V is carried out using a standard gradient-based mechanism, thus the minimization of V proceeds over successive iterations until when the difference between two successive partition matrices is insignificant.

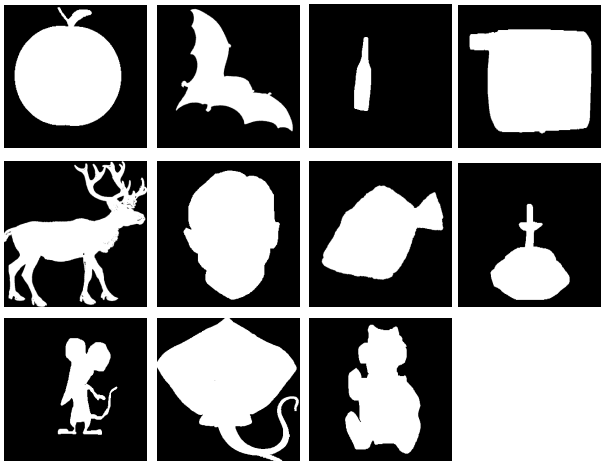

Fig. 1. Sample images representing classes of MPEG-7 CE data set used in the experiment

C. Query by Image

Query by image is a technique that involves providing the CBIR system with an example image that it will then base its search upon. The underlying search approach may vary depending on the application, but result images should all share common descriptors with the provided example. There are essentially two options in providing image: a) the user chooses an image from a given data set. b) the user draws a sketch of the image they are looking for. Both options simplifies the process of describe images with words which can arise in several mismatches during the search.

We explored query by image using as example image a shape draws by the user. For each shape, we compute the shape descriptor associated with it using the approach described in this section. Formally, given a shape descriptor s, a number c of centers v_i, and a fuzziness threshold ϵ, we use the following criteria to obstain the cluster membership. The potential cluster i is found by taking into account the minimal distance center with the shape descriptor, that is

$$i = min_{1 \leq j \leq c} \{j | dist(s, v_j)\}$$

A reference data x point belonging to the cluster i and immediately below the fuzziness threshold is obtained as

$$x_i = min_{1 \leq k \leq n} \{x_k | u_{k,i} \geq \epsilon\}$$

where, n is the size of cluster i. Then, if $dist(v_i, s) \leq dist(v_i, x_i)$, the query is in the space computed as a sphere, with radius equals to $dist(v_i, x_i)$. Then, we return all the images contained in the cluster i sorted based on euclidean distance and whose membership is above the fuzziness threshold. This ranked list represents the answer to the given query.

V. Experimental results

The testing phase consider three datasets. The first experiment considers a subset of the MPEG-7 Core Experiment Shape-1 dataset, which is frequently used to evaluate shape matching and recognition algorithms. In particular, we have used the MPEG-7 CE Shape-1 Part-B dataset [38], composed of 70 shape categories, each of which has 20 samples with in-plane rotations, articulations and occlusions. We have used eleven shape classes, considering all the twenty shape samples. The shape classes are: apple, bat, bottle, cellular phone, deer, face, flatfish, fountain, rat, ray, teddy, shown in Figure 1. The shape classes are very distinct, but the data set shows some within-class variations. All the fourteen features presented above has been exploited in the experiment: geometrical features (E,R, C, π_{gen}), invariants moments features (I_1, I_2, I_3, I_4, I_5, I_6, I_7), and affine moments features (AMI_1,AMI_2, AMI_3).

The 220×14 data matrix has been given as input to FCM. Further, we would like to get a direct association between cluster and class (i.e., each cluster is representative of a class), thus, the number of clusters is equal to the number of images categories ($c = 11$).

Then, according to the natural grouping of features, three data matrices have been built: one has the size 220×4,including only the geometrical features; a 220×7 matrix describing the invariant moments and then a 800×3 matrix representing the affine moments. These matrices have been given as an input to the collaborative clustering, setting the number of clusters c_1, c_2, c_3 to 4, 5, 3, respectively. Also in this setting configuration, $c = 11$, i.e., the number of images categories.

In the fuzzy clustering techniques, the membership of an image may be distributed on more than one clusters. Usually, an image (in general, a pattern) is associated to the cluster in which its membership is the highest. In order to emphasize the natural flexibility of the fuzzy clustering methods in the distribution of data, we have processed the dataset on crisp k-means too.

Table I synthesizes the results, showing the confusion matrix associated to this experiment for the three clustering algorithms. Each cell indeed, contains the results computed for k-means, FCM and collaborative clustering algorithms, respectively. A single value zero means all the results are zero. Let us note that many correspondences are revealed between the generated clusters (*predicted*) and the given (*actual*) images classes. The worst case is computed exploiting k-means: some classes are not well-identified; for instance the class *deer* is composed of only eight images, while the most of its images is placed in the class *ray*. Even, class *cellular phone* is completely empty and most of its images is within the class *teddy*. This emphasizes that the k-means is not suitable to cluster these data. Differently, it is evident how the FCM and collaborative provides meaningful results. In fact, some clusters look very homogeneous; most of them includes averagely about 80% of proper images. Just to give some example, on the FCM clustering, the elements of the classes represented by *bat, bottle, deer, face* are well-placed in each individual cluster (100% of individuals appear in the right cluster). This is not true any longer for the cluster concerning the class *ray*, due to some overlaps among categories. Finally, some clusters are representative of specific classes, even though a certain percentage of elements of other classes appears in them (for

instance, see the clusters representing the classes *apple, flatfish*, etc.). The classification produces improvements, exploiting the collaborative clustering, where the "uncertain" classes such as *apple* and *cellular phone* are almost completely identified.

Other two experiments have been executed on a collection of images downloaded through Google images[1]. Fig. 2 shows a sample of ten images for each considered category. The first testbed consists of a sample of 800 images, composed of five classes of about 160 images, ranked as follows: images in the range 1-160 represent bottles; in the range 161-320 there are images of guitars, then the images of apples cover the range 321-480, the motorcycles images are in 481-640 and finally the last images set consists of guns in the range 641-800. The dataset has been given as an input to the three clustering algorithms. All the clustering algorithm set the number of cluster equals to the number of images categories ($c = 5$). The k-means and the FCM work on all the features set considering a 800×14 matrix , while the collaborative clustering takes as an input three submatrices: one has the size 800×4, including only the geometrical features; a 800×7 matrix describing the invariant moments and then a 800×3 matrix representing the affine moments. The setting the number of clusters is $c_1 = 4, c_2 = 5, c_3 = 4$.

TABLE II
800DATASET: CLUSTER-BASED EVALUATION OF CLUSTERING RESULTS, FOR K-MEANS, FCM AND COLLABORATIVE CLUSTERING, RESPECTIVELY

Classes	*# Misclassified.*	*# Undecided.*	*Recall. %*	*Precision. %*
bottle	0-8-7	0-2-2	86-95-95	95-100-100
guitar	0-3-3	0-0-0	95-98-98	95-93-96
apple	0-12-12	0-0-0	89-92-94	97-100-100
motorcycle	0-5-4	0-1-0	91-96-97	77-88-90
gun	0-13-10	0-3-2	91-91-93	93-93-95

TABLE III
965DATASET: CLUSTER-BASED EVALUATION OF CLUSTERING RESULTS, FOR K-MEANS, FCM AND COLLABORATIVE CLUSTERING, RESPECTIVELY

Classes	*# Misclassified.*	*# Undecided.*	*Recall. %*	*Precision. %*
bottle	21-6-3	0-0-1	86-96-97	93-100-100
guitar	7-3-3	0-0-1	95-98-98	95-96-97
leaf	92-58-45	0-7-5	44-64-72	41-78-81
apple	94-16-14	0-2-0	41-90-91	79-92-94
motorcycle	17-22-17	0-5-4	89-86-90	57-70-78
gun	13-14-10	0-3-3	91-91-93	92-93-96

Table II shows a synthetic view of the results computed for the three algorithms. Each row provides the name of the class, the *misclassified* images, i.e. those images that appear to belong to a cluster, different by the expected one (i.e., they have the highest membership in another class), the *undecided* images, viz. all the images which membership is almost equally distributed among two or more clusters. Recall that, due to the crisp nature of the k-means algorithm, there are no resulting *undecided* images. Then a *recall* and *precision* that is evaluated for each cluster.
In fact, in order to evaluate the recall and precision inside each cluster, we define the *local recall* and the *local precision* as follows:

$$Recall = \frac{relevant\ retrieved\ images}{relevant\ images} \tag{6}$$

$$Precision = \frac{relevant\ retrieved\ images}{retrieved\ images} \tag{7}$$

where the *relevant images* are the images which are expected in a certain class, the *retrieval images* are all the (correct and incorrect) images which are returned in that cluster, while the *relevant retrieved images* are just the images that really belong to the right cluster, associated to the correct class.

From the analysis of resulting partitioning, let us note that the collaborative clustering tends to get better results in terms of recall and precision. Nevertheless, the cluster associated to the class *motorcycle* presents the lowest membership distribution, even though the most of images are well placed in the right cluster.

Last test considers the same dataset of 800 images, but adds 165 images representing *leaf*. We have choice deliberately a set composed of very heterogeneous image samples of leaf, in order to evaluate the performance of FCM and collaborative clustering algorithms in this case study. Table III shows the results for the three clustering algorithms. The introduction of the set of leaf makes the resulting partition more confused: most of misclassified data appear in cluster of apples; this is due to the different shapes of leaves: after the image processing, some leaves present rounded shapes that can be easily confused with apples. In fact, values computed for geometrical features such as Pi and compactness are close to those ones of apples. The best performance are obtained exploiting the collaborative clustering even though the recall and precision values, computed for the class *leaf* are quite low, anyway.

VI. CONCLUSION

The work presents an image classification and content-based retrieval. After an initial phase of image analysis for extracting visual shape-based features, fuzzy clustering techniques have been applied. These techniques provide a relaxed distribution of images (compared to the crisp clustering); moreover they are robust respect to an image segmentation approaches based on k-means segmentation which meet some difficulties foreground and background colors do not contrast sufficiently. The effectiveness of this approach is evaluated through recall and precision, revealing discrete performance.

Let us observe that the use of fuzzy clustering techniques which, even though requires an a-priori fixed number of clusters, avoid overfitting of parameters and does not require a learning/training phase. Moreover an image retrieval technique has been proposed through a query-by-image. As future extensions of this work we would investigates in this direction as well as introduce additional features particularly, some moments that are invariant to elastic transformations and convolution.

***Abstract*—Imaging spectroscopy refers to methods for identifying materials in a scene using cameras that digitize light into hundreds of spectral bands. Each pixel in these images consists of vectors representing the amount of light reflected in the different spectral bands from the physical location corresponding to the pixel. Images of this type are called hyperspectral images. Hyperspectral image analysis differs from traditional image analysis in that, in addition to the spatial information inherent in an image, there is abundant spectral information at the pixel or sub-pixel level that can be used to identify materials in the scene. Spectral unmixing techniques attempt to identify the material spectra in a scene down to the sub-pixel level. In this paper, a piece-wise convex hyperspectral unmixing algorithm using both spatial and spectral image information is presented. The proposed method incorporates possibilistic and fuzzy clustering methods. The typicality and membership estimates from those methods can be combined with traditional material proportion estimates to produce more meaningful proportion estimates than obtained with previous spectral unmixing algorithms. An analysis of the utility of using all three estimates produce a better estimate is given using real hyperspectral imagery.**

***Index Terms*—hyperspectral, endmember, spectral unmixing, possibilistic, fuzzy, piece-wise convex, linear mixing, convex geometry model.**

I. Introduction

Hyperspectral images are three-dimensional data cubes that have two spatial and one spectral dimension. Hyperspectral imagers collect data about an image scene across many narrow, contiguous spectral wavelengths. As opposed to image processing, spectral information (rather than spatial information) is generally the focus in hyperspectral image analysis. *Endmember detection* and *spectral unmixing* are two major goals in hyperspectral image analysis. Endmembers are spectra that are defined by analogy to standard spectroscopy.

In standard spectroscopy, the basic elements (oxygen, nitrogen, etc.) making up a substance are identified. Each element has a unique spectral signature and the spectral properties of the substance are defined by combinations of the pure elements in the substance. Endmembers are thought of as representing the "pure" spectral signatures of the materials found in the scene. However, the analogy is not strict for several reasons. It is generally not possible to get enough resolution to identify pure elements. In addition, it may not even be useful to identify them. For example, when an intelligent system is analyzing a scene, it may only need to know where the grass, trees, concrete, water, etc. are located in a scene. Therefore, in hyperspectral image analysis applications, the endmembers represent spectra of the basic scene elements such as these. We refer to these endmembers as "pure materials" in the scene with the understanding that they may really represent the types of materials discussed above.

Spectral unmixing determines the *proportion* (or *abundance*) of each endmember found in every hyperspectral pixel. The standard model applied during hyperspectral unmixing is the linear mixing model [**?**]. In the linear mixing model, the spectral signatures in a hyperspectral scene are modeled as convex combinations of the endmember signatures. This model can be written as follows.

$$\mathbf{x}_i = \sum_{k=1}^{M} p_{ik}\mathbf{e}_k + \epsilon_i, \quad 1 \leq i \leq N \tag{1}$$

where N is the number of pixels, M is the number of endmembers, ϵ_i is an error term, p_{ik} is the abundance of endmember k in pixel i, and $\mathbf{e}_k$ is the k^{th} endmember. The abundances of this model satisfy the following constraints.

$$p_{ik} \geq 0 \quad \forall k = 1, \ldots, M \tag{2}$$

$$\textstyle\sum_{k=1}^{M} p_{ik} = 1 \tag{3}$$

Given the input hyperspectral data, $\mathbf{X}$, endmember detection estimates the spectral signatures of the endmembers, $\mathbf{E}$, and spectral unmixing determines the values of the proportions (or abundances) $\mathbf{P}$ of each endmember in every hyperspectral data point. By following this model, finding endmembers amounts to estimating the spectral signatures whose convex hull enclose the hyperspectral data.

Numerous hyperspectral unmixing methods based on the linear mixing model have been developed in the literature. Generally, these methods search for a single set of endmembers and, therefore, assume that pixels are a combination of all endmembers in the scene. However, in real hyperspectral

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

data, pixels are often combinations of only a subset of the endmembers.

In this paper, an endmember extraction and spectral unmixing algorithm using fuzzy and possibilistic clustering methods is presented. The proposed method represents an input hyperspectral scene using multiple sets of endmembers with a piecewise convex representation. By estimating fuzzy membership and typicality values for each set of endmembers (i.e. a convex region) meaningful proportion values are estimated where the majority of pixels are combinations of a subset of the endmembers in the scene, some pixels may be identified as highly-mixed and combinations of most or all of the endmembers in the scene, and some pixels are identified as outliers. We refer to pixels in categories as single-region pixels,

The piece-wise convex representation for hyperspectral imagery was first developed in [**?**] and [**?**]. Endmember detection methods that incorporate spatial information include [**?**], [**?**], [**?**]. However, these methods do not employ a piece-wise convex model.

An exciting contribution of this approach is that the initial estimates of the proportions, memberships, and typicality all play important roles in defining more meaningful and realistic final proportion estimates. There are three categories of pixels: single-region pixels, overlap-region pixels, and outlier pixels.

A single-region pixel is composed of only those endmembers that are associated with one convex region. In this case, the typicality value for the convex region containing the pixel should be 1, the membership value for the corresponding region should also be 1, and the proportion values should the proportions of the endmembers associated with that convex region for the data point. Therefore, in the single convex region case, the final proportion vector will be the proportion values found for the endmembers in the convex region containing the data point.

Overlap-region pixels are convex combination of endmembers associated with two or more convex regions in the data. The typicality values for the pixel in all of the associated convex regions should be 1, the product of the membership values and the proportion vectors for each convex region will sum-to-one. This product will result in a final proportion vector for the data point with appropriate weights for all of the endmembers that compose the pixel.

In the outlier pixel case, the pixels are not convex combinations of the endmembers found in the scene. In this case, the typicality values for all convex regions should be small and tend towards zero. By using the product of the typicality, membership and proportion values, the final proportions for the outlier pixels should sum to less than one. This indicates that the pixel is not fully described by the endmembers found in the scene. This lack of information is represented directly in the final proportions rather than indirectly by large error. If only membership is used, then the proportions will still sum to one but they will certainly not be correct. Thus, the final proportion values calculated using the initial proportions, the memberships, and the typicality will represent the true level of information available in the scene.

In the following, Section 2 outlines the algorithm, Section 3 presents experimental results and Section 4 provides a discussion and conclusions.

II. Method

A. P-COMMEND

The P-COMMEND (Piece-wise Convex Multiple Model Endmember Detection) algorithm [**?**] performs alternating optimization to autonomously estimate the endmembers, $\mathbf{E}$, abundances, $\mathbf{P}$, and membership values, $\mathbf{U}$, for a given hyperspectral image. P-COMMEND iteratively minimizes the objective function in Equation **??** subject to the constraints in Equation **??**, $\sum_{i=1}^{C} u_{ij} = 1$ and $u_{ij} \geq 0$.

$$\begin{aligned} J &= \sum_{i=1}^{C}\sum_{j=1}^{N} u_{ij}^{m} \left(\mathbf{x}_j - \mathbf{p}_{ij}\mathbf{E}_i\right)\left(\mathbf{x}_j - \mathbf{p}_{ij}\mathbf{E}_i\right)^T \\ &+ \alpha \sum_{i=1}^{C} \left(M \cdot trace(\mathbf{E}_i\mathbf{E}_i^T) - 1_{1\times M}\mathbf{E}_i\mathbf{E}_i^T 1_{M\times 1}\right) \end{aligned} \tag{4}$$

where $\mathbf{x}_j$ is a $1 \times d$ vector representing the j^{th} pixel of the image, N is the number of pixels in the image, M is the number of endmembers in each convex region (or model), P_i is a $N \times M$ matrix such that $\mathbf{p}_{ij}$, is the vector of abundances associated with pixel j with respect to model i, p_{ijk} is the proportion of endmember k in pixel j with respect to model i, and $\mathbf{E}_i$ is a $M \times d$ matrix such that each row of $\mathbf{E}_i$, $\mathbf{e}_{ik}$, is a $1 \times d$ vector representing the k^{th} endmember with respect to model i. The notation $1_{S\times T}$ denotes an $S \times T$ matrix with all entries equal to 1. The multiple models compete for data $\mathbf{X}$ through a set of weights u_{ij} which represent the memberships of the data points $\mathbf{X}$ in the i^{th} model where m is the "fuzzifier" parameter controlling the degree to which the data points are shared among the models.

The first term of this objective function represents the residual error incurred by representing each spectra using the estimated endmembers, abundances and fuzzy membership values. The use of the fuzzy membership values is related to the fuzzy c-means and the Multiple Model General Linear Regression algorithms [**?**], [**?**]. The second term is related to the volume enclosed by the endmembers by representing the sum of squared distances (SSD) between the endmembers and encourages the endmembers to have a tight fit around the data. The SSD term is the same volume-related term used by ICE (Iterated Constrained Endmembrs) and SPICE (Sparsity Promoting Iterated Constrained Endmembers) for endmember detection [**?**], [**?**].

When updating membership values, the objective function is minimized subject to the constraint that all the membership values for a data point must sum to one. This results in the following update equation given abundances and endmembers,

$$u_{ij} = \frac{1}{\sum_{q=1}^{C}\left(\frac{(\mathbf{x}_j - \mathbf{p}_{ij}\mathbf{E}_i)(\mathbf{x}_j - \mathbf{p}_{ij}\mathbf{E}_i)^T}{(\mathbf{x}_j - \mathbf{p}_{qj}\mathbf{E}_q)(\mathbf{x}_j - \mathbf{p}_{qj}\mathbf{E}_q)^T}\right)^{\frac{1}{m-1}}}. \tag{5}$$

The endmembers are updated given the following equation,

$$\mathbf{E}_i = \left(\sum_j u_{ij}^m \mathbf{p}_{ij}^T \mathbf{p}_{ij} + 2\alpha D \right)^{-1} \left(\sum_j u_{ij}^m \mathbf{p}_{ij}^T \mathbf{x}_j \right) \quad (6)$$

where $D = MI_{M\times M} - 1_{M\times M}$. Finally, abundance values are updated by minimizing Equation **??** subject to the constraints in Equation **??** by using a Lagrange multiplier term and evaluating and applying the required KKT conditions to enforce Equation **??**. The resulting update equations are

$$\mathbf{p}_{ij}^T = \left(\mathbf{E}_i \mathbf{E}_i^T\right)^{-1} \left(\mathbf{E}_i \mathbf{x}_j^T - \frac{\lambda_{ij}}{2} 1_{M\times 1} \right) \quad (7)$$

and

$$\mathbf{p}_{ij}^{KKT} = max\left(\mathbf{p}_{ij}^T, 0\right) \quad (8)$$

where $\lambda_{ij} = 2\frac{1_{1\times M}\left(\mathbf{E}_i\mathbf{E}_i^T\right)^{-1}\mathbf{E}_i\mathbf{x}_j^T - 1}{1_{1\times M}\left(\mathbf{E}_i\mathbf{E}_i^T\right)^{-1}1_{M\times 1}}$.

B. FLICM

Spatial information is incorporated by encouraging neighboring pixels in the image to have similar membership values to the different convex regions. This is accomplished by adopting the spatially-smooth fuzzy c-means method, FLICM (Fuzzy Local Information C-Means), developed in [**?**]. The FLICM algorithm adds a term, G, to the objective function that influences the updates of the membership values by incorporating spatial information. The G term, adapted for use in the proposed algorithm, is shown in Equation **??**.

$$G_{ij} = \sum_{\substack{k\in N_j \\ j\neq k}} \frac{1}{d_{jk}+1} (1-u_{ik})^m \left|\left|\mathbf{x}_k - \mathbf{p}_{ik}\mathbf{E}_i\right|\right|_2^2 \quad (9)$$

where the $\mathbf{x}_j$ is the center pixel in the local window under consideration, N_j is the neighborhood around the center pixel (such as a 3x3 window), d_{ij} is the Euclidean distance in pixel space of the image indices between pixels $\mathbf{x}_j$ and $\mathbf{x}_k$. Therefore, the G term scales the influence of neighboring pixels based on their distance in the index space. Also, when a neighboring pixel has high membership in a convex region, the point under consideration is encouraged to also have a high membership in that region. G_{ij} term is updated each iteration and treated as a constant during updates to the endmembers, abundances and membership values. With the addition of G, the objective function for is shown in Equation **??**.

$$\begin{aligned} J &= \sum_{i=1}^{C}\sum_{j=1}^{N} u_{ij}^m \left(\left(\mathbf{x}_j - \mathbf{p}_{ij}\mathbf{E}_i\right)\left(\mathbf{x}_j - \mathbf{p}_{ij}\mathbf{E}_i\right)^T + G_{ij} \right) \\ &+ \alpha \sum_{i=1}^{C} \left(M \cdot trace(\mathbf{E}_i\mathbf{E}_i^T) - 1_{1\times M}\mathbf{E}_i\mathbf{E}_i^T 1_{M\times 1} \right) \end{aligned} \quad (10)$$

When incorporating FLICM into the P-COMMEND algorithm, the update equations for the endmembers and abundances remain the same as in Equations **??** and **??**. Membership updates change as shown below.

$$u_{ij} = \frac{1}{\sum_{q=1}^{C} \left(\frac{(\mathbf{x}_j - \mathbf{p}_{ij}\mathbf{E}_i)(\mathbf{x}_j - \mathbf{p}_{ij}\mathbf{E}_i)^T + G_{ij}}{(\mathbf{x}_j - \mathbf{p}_{qj}\mathbf{E}_q)(\mathbf{x}_j - \mathbf{p}_{qj}\mathbf{E}_q)^T + G_{qj}} \right)^{\frac{1}{m-1}}}. \quad (11)$$

C. PFCM Clustering

The proposed method adopts the approach presented in the PFCM (Possibilistic Fuzzy Clustering Method) [**?**]. PFCM determines both typicality and membership values for each data and every cluster.

D. Proposed Method

Incorporating FLICM and PFCM into the P-COMMEND objective function results in the objective function shown in Equation **??**.

$$\begin{aligned} J &= (1-\alpha)\sum_{i=1}^{C}\sum_{j=1}^{N} a u_{ij}^m \left(\left(\mathbf{x}_j - \mathbf{p}_{ij}\mathbf{E}_i\right)\left(\mathbf{x}_j - \mathbf{p}_{ij}\mathbf{E}_i\right)^T + G_{ij} \right) \\ &+ bt_{ij}^n \left(\mathbf{x}_j - \mathbf{p}_{ij}\mathbf{E}_i\right)\left(\mathbf{x}_j - \mathbf{p}_{ij}\mathbf{E}_i\right)^T \\ &+ \alpha \sum_{i=1}^{C} \left(M \cdot trace(\mathbf{E}_i\mathbf{E}_i^T) - 1_{1\times M}\mathbf{E}_i\mathbf{E}_i^T 1_{M\times 1} \right) \\ &+ \sum_{i=1}^{C} \gamma_i \sum_{j=1}^{N} (1-t_{ij})^n \end{aligned} \quad (12)$$

As shown in the equation above, spatial information is used in the membership terms only. In future work, incorporating this information when updating typicality will be investigated and implemented as well. The update equations for the proportions remain the same as for the P-COMMEND algorithm described in Section II A. The membership update equations remain the same shown in Equation **??**. The endmember update equation becomes as shown below.

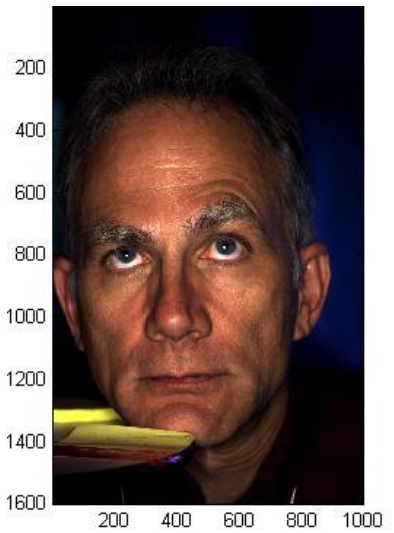
$$\begin{aligned} \mathbf{E}_i = &\left(\sum_j (a u_{ij}^m + bt_{ij}^n) \mathbf{p}_{ij}^T \mathbf{p}_{ij} + 2\alpha D \right)^{-1} \\ &\left(\sum_j (a u_{ij}^m + bt_{ij}^n) \mathbf{p}_{ij}^T \mathbf{x}_j \right) \end{aligned} \quad (13)$$

The update equation for the typicality results the following.

$$t_{ij} = \frac{1}{1 + \left(\frac{b}{\gamma_i} \left|\left|\mathbf{x}_j - \mathbf{p}_{ij}\mathbf{E}_i\right|\right|_2^2 \right)^{\left(\frac{1}{n-1}\right)}} \quad (14)$$

The γ_i value in the above equation is set to be the mean of the $\left|\left|\mathbf{x}_j - \mathbf{p}_{ij}\mathbf{E}_i\right|\right|_2^2$ value for all of the pixels in the associated convex region. Therefore, each iteration, the γ_i value gets updated.

The final proportion values are computed by taking the production of the initial proportion values, membership and typicality for data point and convex region.



(a)

Fig. 1. Color image of hyperspectral face data used for testing.

III. Experimental Results

The proposed algorithm was tested on VIS/NIR hyperspectral face imagery. This data was collected by Norsk Elektro Optikk using their HySpex hyperspectral sensor on participants at the 2010 IEEE Workshop on Hyperspectral Image and Signal Processing: Evolution in Remote Sensing (WHISPERS10). The data contain 160 spectral bands ranging in wavelength from 410 to 990nm. An image was selected from this data set and spatially sub-sampled by selecting every 4th row and column in the image. A color image created using the hyperspectral data is shown in Figure **??**. The size of this image is 400×250 pixels.

Using the PCA algorithm, the dimensionality of the hyperspectral data was reduced from 160 dimensions to 5 dimensions. The algorithm was run on the dimensionality-reduced imagery using the following parameters: $\alpha = 0.001$, $a = 20$, $b = 0.1$, $m = 2$ and $n = 1.1$. Results are shown in the following figures.

By examining the final proportion maps shown in Figure **??**, it can be seen that an effective segmentation of the imagery is found by the method. The first convex region corresponds to skin, both shadowed and bright skin. The second convex region corresponds to the table and eyes. The third convex region corresponds to background. The fourth convex region corresponds to the shirt. The fifth convex region corresponds to hair and eyebrows.

The membership and typicality maps associated with each convex region is shown in Figure **??**.

There were several pixels of glare with a high specular reflection in the imagery. These pixels were a result of reflection from the lighting in the room on pixels in the eyes of the photographed individual. As desired, the typicality for these outliers were found by the method to be zero for all convex regions.

IV. Conclusion

By using a combination of initial proportions, typicality, fuzzy membership and fuzzy spatial information, excellent segementation and identification of endmembers in the scene is achieved. Future work will involve applying this algorithm to a large set of data. Also, parameter sensitivity and a reduction in the number of parameters will be investigated.

Abstract— **This paper describes the early vision of bio-inspired neuromorphic system enhanced by fuzzy processing, mimicking the primitive behaviour of visual cortex. The proposed bio-inspired system exhibits the biologically plausible function of mimicking the cat's visual cortex experimentation of Hubel and Wiesel. The neuromorphic implementation of vision is inspired by the directional visual signal selectivity of cortex and the CMOS spiking neuron based on Hodgkin-Huxley formalism. The membership function is introduced to improve the early vision and the improvement is demonstrated for robust applications, based on the recognition of human head figures.**

Keywords-neuromorhic; neural networks; CMOS; vision, visual cortex, simple cell, Hodgkin-Huxley formalism, membershio function

I. INTRODUCTION

There have been many works proposed recently for bio-inspired vision and neuromorphic vision devices. Although, computer vision algorithms are effective in their condition of usage, at most times, they lack the robustness of the human vision. We describe here the early vision of bio-inspired implementation of primary visual cortex, based on the neuron of Hodgkin-Huxley formalism and the visual cortex experimentation of Hubel and Wiesel. In this paper, the elements of neuromorphic implementation of visual cortex are presented with the enhanced performance by introduction of membership function.

The feasibility of bio-inspired visual signal processing is evaluated showing robustness for gray scale image and single color component image. Potential application for such system is explored in human detection in wide range of environment; passenger occupancy detection, pedestrian detection and human detection in the conference presentation. The latter environment was explored with a view to further extend it into gesture detection.

II. PRIMARY VISUAL CORTEX FUNCTION AND BIO-INSPIRED SPIKING NEURON BASED ON CMOS CIRCUIT

The physiological studies about visual cortex from the investigation of cat's striate cortex by Hubel and Wiesel have confirmed the consensus of knowledge [1], though there are many models about visual cortex. The idea on the primary visual cortex of simple cell motivated various theories of object recognition from characters to complex natural images [2]. For an idea of neural system implementation, the research on neurophysiology introduced the principles and demands of biologically plausible electronic implementation. In this paper, we employ the new way of implementing the neuromorphic VLSI for the primary visual cortex, inspired by the ideas on the primary visual cortex by Hubel and Wiesel's experimentation and the neurophysiological model of neuron by Hodgkin and Huxley [3]. The design motivation is from the well-known experimentation of simple cell in Fig. 1 by Hubel and Wiesel. The experimentation of spike burst for given static line input is aimed to mimick, while there is another experimentation of complex cell based on moving stimulus by Hubel and Wiesel.

The controlled conductance by CMOS transistors is an element of the proposed neuromorphic system, which have been studied for the biologically plausible analog-mixed neural networks [4, 5].

III. BIO-INSPIRED VISUAL INFORMATION PROCESSING AND APPLICATION TO OBJECT DETECTION

Hodgkin-Huxley (H-H) formalism is a widely adopted idea of neuron's biophysical characterisation and dynamics. The electrical equivalent circuit model of Fig. 2a is known as the empirical model of H-H formalism, which describes quantitatively the dynamics of the voltage-dependent conductance. Although the particular advantages of H-H formalism were not exhibited in neural network's tasks of

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

vision or recognition yet, asynchronous spikes based on H-H formalism are considered as a principle element of high level or large scale neural computing or application system. The H-H formalism is widely of interest for its biophysical dynamics, though its complexity in computation is prohibitively high. Hence, asynchronous dynamics of the H-H formalism is adopted as the idea of neuron model.

(b)

Figure 3. (a) The artificial primary visual cortex model with orientation selective synaptic weights to mimick the simple cell of visual cortex (b) the simulated spike burst of VLSI visual cortex to the stimulus in various orientations.

The tuning properties of orientation selectivity have been believed to play the key role for perception in visual cortex. As shown in Fig. 1, the tuning of specific neurons to the orientation of visual stimulus probably depends on the tuning features after passive or active learning for the earlier processing of natural image. To mimick this response, a simple model was implemented as illustrated in Fig. 3, though some modifications are likely necessary for being more plausible to the natural system. The tuned feature map (or connection) of 5 x 5 synaptic weights is used, based on the reference stimulus to match with the minor adjustment depending on the output. The tuned feature map of vertical orientation is illustrated in Fig. 3a, while the synaptic weights of Fig. 3a are in the ration of (1: -0.6: 0.1 for black : grey : white). The six types of input stimulus (50 x 50 pixels) are experimented with the feature map (as synaptic connections) and spiking neurons based on H-H formalism[4]. The spike burst output of Fig. 3b is observed through a SPICE simulation, where the neuromorphic visual cortex response mimics that of the biological spike burst of Fig. 1 from the experimentation work of Hubel and Wiesel.

The feasibility of bio-inspired neuromorphic system is demonstrated with its plausibility to primary simple cell function of visual cortex as exhibited in Fig. 3b. The tuned feature characteristics of other orientations (-45˚, 25˚) are evaluated with the consistent outcomes as expected in the original experimentation shown in Fig. 1.

The proposed bio-inspired neuromorphic system is applied to example cases for evaluating its feasibility in forming competent visual processing system with the robustness that is characteristic of animal or human vision. The previous research demonstrated the robustness to a certain application of object detection, i.e. the vehicle license plate detection. The license plate detection was investigated for the flexible detection based on the rectangle with the right angle, regardless of the aspect ratio or the whole size. It is based on the particular selective response to orientation at the right angle, i.e. presenting both components of horizontal and vertical orientation of the still image. It demonstrated the robust detection under some environmental challenges such as the shiny reflection from the nearby area of license plate, in addition to the different sizes from the various distance [5]. In this paper, the application of multi-directional selectivity on the video information is investigated further for the detection of human heads in the driving vehicle of changing background and illumination. The human torso template in Fig. 4 is applied to the head detection, as the property of rectangle was utilized in the license plate detection [5].

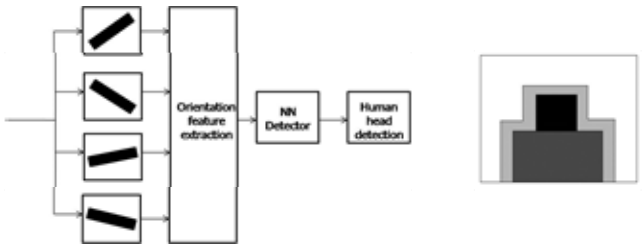

Figure 4. Neuromorphic vision for human detection, inspired by the visual cortex, and based on the neural network detector of head-torso shape.

Fig 5 shows the successful detection of the two passengers in the car. Since tests were done on an image sequence, slightly different approach could be made than when input data were still images. As seen in Fig. 5, the frame difference was made between current and previous bio-inspired directional selective processed image to decrease any orientation features that were stand-still. Although it is true that

passengers sitting in their seats rarely have any or no body movement, all human has slightest movement in their head whether that is tilting of head or changes in facial expression whereas other unwanted signals such as from the interior of car is decreased. For the orientation selectivity, the 6 simulated synaptic connections of 9 x 9 were used for the orientation feature extraction. Six were orientations were used as six different orientation, more or less, can describe the basic outline of human head while reducing the chance of other unwanted objects being detected. The orientation features extracted shows heavy density in the head area which yields the high lightened head area. And lastly, neural net detection were made resulting the yellow boxes of human heads detected, which was decided by performing 'winner takes all' approach to get strongest signal. Note that for the detection, number of human head in the input date is known, i.e. for the image shown in Fig. 5, two strongest signals were taken.

Figure 5. (from top left in anti-clockwise direction) Input image with resolution of 640 x 480, bio-inspired processing of current and previous image, torso template-based neural network detector of Fig. 4 and detection result where yellow box denotes the passenger head detected from the bio-inspired visual processing and green box denotes the detected passenger

The driving vehicle is subject to the wide range of changes in the illumination level and background. There is a difficulty of detecting every passenger due to the change in both the illumination and background when only gray image is used. Thus to improve robustness, color component of image was added during processing to improve the robustness reflecting on the fact that animals utilizes different color components to human when processing. In Fig. 6, red color component was taken to process to improve the robustness. There is a small difference; the head area became slightly lighter, and all passengers were successfully detected with the mixed combination of gray image and red-color component image. Other mixtures of color components were evaluated not suitable for the improvement of an example application, while the mixed gray image illustrated the better detection accuracy of 95% than the single red-color component image.

Figure 6. (from top left in anti-clockwise direction) The gray input image converted from the colour image, the image of red-color component extracted from the colour image, improved detection of passenger based on the combination of the gray image and the red-colour component image and imperfect detection of passenger based on the gray image converted from the colour image.

The bio-inspired processing is applied to pedestrian detection where the test image set was captured from a moving bus in London from a commericially available camera. Same approach was used for pedestrian detection such that the orientation features from the input image is extracted first and then neural network with human shape template was used to detect the human. For pedestrian detection application, especially for a vehicle, may require the detection of a pedestrian who is having certain amount of motion, e.g. running. Also there is more interest in a pedestrian moving across the field of vision as there is more likelihood of collision. Considering these points, frame differences were taken so that the detected pedestrians are those with more than certain motion as seen in Fig. 7. In Fig. 7, other pedestrians are seen other than the detected pedestrian but they were not detected since their motions were low.

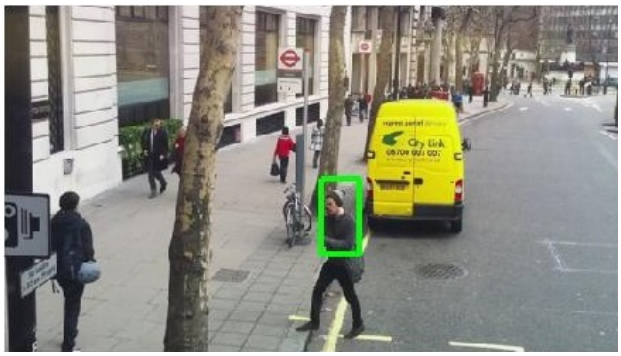

Figure 7. Pedestrian detection result where two previous frames were used in the process.

IV. FUZZY MEMBERSHIP FUNCTION TO ENHANCE DETECTION

There are some tasks demanding further processing, because of dynamic environmental changes or the limitation of template features for complex object. The detection of a presenter in the dark conference room is challenging, as there are not only the dynamic changes of illumination but also the confusing patterns from the displayed presentation. The recognition process in the neuromorphic vision is based on the winner neuron representing the regional summation after the template processing, however the exact winner location can be disturbed by multiple locations close to the maximum value (i.e. the winner). The membership function of Fig. 8 is

introduced to improve the cases of confusing illumination or complex situation of Fig. 9. The illustrated membership function is derived for 12 x 22 reference locations is based on the heuristic evaluation. The average of 12 x 22 elements from the local summation of saliency map is derived to accommodate the changes in the illumination or patterns, while the membership function of Fig. 11 is determined by four points of (average)x8, (average)x10, (average)x11, (average)x12. The action potential value is applied to the membership function, and the multiple candidate locations can be determined with revised value rather than a winner location of the maximum action potential. Several locations are suggested as the location of human head object with the processing of fuzzy membership function.

In Fig. 10, the application of fuzzy processing illustrates the improve detection of a presenter (head) than the case without the fuzzy processing, though the primitive fuzzy membership function is applied.

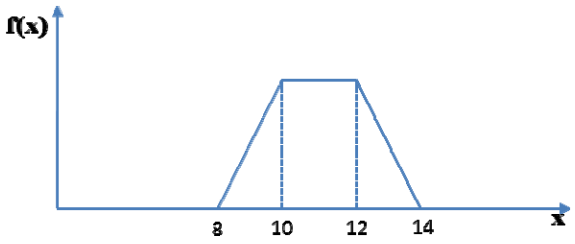

Figure 8. Membership function introduced to the neuromorphic vision

Figure 9. Effect of applying fuzzy function.

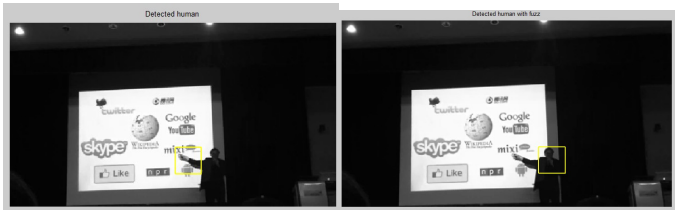

Figure 10. Enhanced human detection procedure with membership function is shown on the right and on the left shows the detection result without applying the mempership function.

V. CONCLUSION

The bio-inspired neuromorphic vision enhanced by fuzzy processing is proposed as a feasible way of mimicking the primitive function of visual cortex, with an application example of detecting human heads. The example cases successfully illustrate the bio-inspired processing with the neural network enhanced by fuzzy processing. The bio-inspired early vision is based on the neuromorphic processing of one-fourth scale of original images, while the gray-and-color mixed combination of input video image improved the robustness substantially.

The object detection in the moving vehicle or the conference room shows the successful human detection under the changing environment of illumination. The bio-inspired computing of human detection in the moving vehicle or the dark conference room demonstrated the robust vision, and the feasibility of neuromorphic vision is exhibited for various applications in the limited operation environment.

***Abstract*—In this paper we present an algorithm for detecting hyperintense regions in brain images acquired by Magnetic Resonance Imaging. The work is part of a more general research oriented to the design of support tools that assist the healthcare experts in their research activities on brain diseases. The algorithm has been focused on the detection of small multiple sclerosis lesions in PD- and T2-weighted images. In the design of the algorithm we have considered a fuzzy approach to deal with the uncertainty and vagueness characteristic of these lesions in magnetic resonance images. The core of the work is the introduction of a Mamdani type Fuzzy Rule-Based System to optimize the detection taking into account the necessary trade-off between true and false positives in this kind of problems. Results show a very good sensitivity of the algorithm in the detection of hyperintense regions associated with small multiple sclerosis lesions, and a low false positive rate with regard the number of pixels analyzed.**

Keywords-component; fuzzy rule-based systems; fuzzy reasoning; magnetic resonance imaging; multiple sclerosis

I. INTRODUCTION

Multiple Sclerosis (MS) is a disease of the central nervous system characterized by multifocal inflammation and destruction of the myelin that encases the axons. This demyelinating process results in an inhibition of neural transmission and causes the appearance of several clinical symptoms, such as motor and sensory disturbances, paralysis or visual alterations ([1], [2], [3]). These areas of demyelination, or lesions, can be observed by magnetic resonance imaging (MRI).

Magnetic resonance imaging (MRI) is the modality of choice for clinical evaluation of MS because it provides an objective and direct assessment of the evolving pathology in multiple sclerosis [4], and it has also been recognized as a diagnostic criterion of this disease [5]. Moreover, quantitative analysis of MR images to measure and monitor lesion load and tissue volumes has become invaluable for patient follow-up and evaluation of therapies [6].

In a MRI examination, MS lesions can be visualized using different sequences. Dual acquisition of proton density (PD-) and T2-weighted images is one of the most common sequences used to evaluate MS lesion volume ([4], [6]). In these weighted images pixels belonging to MS lesions show hyperintensity, a lighter gray level in relation to its surroundings. So, the detection of MS lesions in these weighted images is based on the location of the hyperintense regions.

However, segmentation of MS lesions in PD- and T2-weighted images is a challenging task which stems from several reasons. Among them it is worth to highlight the following: MS lesions are not the only regions presenting hyperintensity within the images; detection of MS lesions in MRI involves the analysis of several images with different anatomical features, and presents a high dependence of contrast-to-noise ratio in the images; the presence of noise, partial-volume effects and motion can have significant consequences on the performance of segmentation algorithms [7].

One of the main challenges in developing an automated MS segmentation algorithm within MRI images is the minimization of false-positive. Beside aforementioned drawbacks, the presence of small MS lesions is one of the main problems to avoid false detections. The size of small lesions gives a greater weight to the boundary pixels and, consequently, the detection

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

of small MS lesions without false detections is difficult due to the presence of factors such as noise or non-homogeneities of magnetic resonance images. Therefore, the greater the sensitivity for detecting small lesions, the greater the chance of false positives.

Moreover, MS lesions are inherently fuzzy with an uncertainty component mainly in the definition of their boundaries [4]. This consideration made that some authors ([8], [9]) introduced fuzzy techniques in the design of their MS detection and segmentation algorithms.

Although some authors, [10], [11], [12], [13], have developed crisp and fuzzy algorithms for detecting MS lesions, within them false detections must be manually removed or require that the detection excludes regions below a minimum size. Then, the design of an automatic algorithm for this purpose has the risk of removing small lesions.

Thus, in order that an automatic MS lesions detection algorithm can ensure high sensitivity in the detection of hyperintense pixels, while avoiding a large number of false positives, it seems necessary to introduce a trade-off between the number of true and false positives. This trade-off may also help in the selection of optimal parameters to combine the multiple features involved in an algorithm.

Taking into account previous considerations, our research is oriented to the development of automatic algorithms for detecting small MS lesions A successful detection of these lesions would be useful to avoid manual removing of false positives using an existing MS lesion segmentation algorithm, or to be used as an starting point in the design of a new automatic MS lesion segmentation algorithm.

In this paper, we present an approach based on a *Mamdani* type *Fuzzy Rule-Based System* (*MFRBS*) [14] to design the detection step of this kind of algorithms. In our approach, we start from an algorithm developed in previous works ([15], [16]), and we introduce this fuzzy scheme to improve the design of the previous detection step using also an MRI sequence more sensitive to the presence of small lesions.

The rest of the paper is organized as follows. Section II described the system proposed in [15] for detecting multiple sclerosis small lesions. The section III outlines the proposed algorithm. The results are presented in section IV, and the last section is devoted to presenting the conclusions and future research works.

II. An Approach to MS Small Lesions Detection

Present paper, as some previous works of the authors, is part of a more general research activity oriented to a general methodology for the development of automatic algorithms oriented to offer support tools that can assist to radiologists and other healthcare professionals in the diagnosis and research activity on neurological diseases that require medical imaging.

With this aim in [15] authors developed a fuzzy-based algorithm for detecting small MS lesions in whose design it was implemented the protocol followed by the experts for detecting MS lesions. With this in mind, lesions detection was based on the location of pixels showing hyperintense behavior regarding its local neighbouring pixels. However, since the hyperintensity may also appear in regions that do not correspond to lesions, fuzzy rules were introduced allowing differentiating lesions from other hyperintense regions.

The proposed algorithm consisted of four main stages: *Preprocessing, Fuzzy characterization and evaluation of hyperintensity characteristics, Defuzzification, and Filtering of false detections*. The image database considered for the development of the system was acquired with a Spin Echo sequence (TR / TE / matrix / FOV: 2200ms / 12-80ms / 192x256 / 250mm) that provided 5mm thick slices separated 1mm.

1) Fuzzy characterization and evaluation of hyperintensity characteristics: On the images obtained from the preprocessing step, the extraction of hyperintensity due to the presence of MS small lesions was based on next definitions:

Definition 2.1
A pixel, p_{ij}, presents hyperintensity if its gray level, $g(p_{ij})$ in PD- and T2-weighted images is high enough in relation to its near surrounding.

Definition 2.2
A region, R_k, is a small MS lesion if:
i.- R_k is located within the encephalic parenchyma,
ii.- $\forall\, p_{ij} \in R_k$, p_{ij} presents hyperintensity, and
iii.- R_k is contained within a 5x5 raster window with a minimum size of 3 pixels.

Then, the *hyperintensity characterization and evaluation* was carried out considering a 9x9 raster window centered on the pixels of the MS small lesions marked by the neuroradiologists, and applying next rules:

Rule 2.1
The higher the gray level of pixels in a region, the greater its hyperintense behavior.

Rule 2.2
A pixel has hyperintense behavior if its gray level is sufficiently distinguishable from the gray levels of two adjacent pixels for a sufficiently large number of radios within a 9x9 window centered at that pixel.

Rule 2.3
A region can be associated with MS lesion if its pixels present hyperintense behavior in both PD- and T2-weighted images.

The implementation of these rules provided the values $\mu_D^{rk}(p_{ij})$ and $\mu_{T2}^{rk}(p_{ij})$, or degrees with which the pixel p_{ij} is sufficiently differentiable at each radius r_k ($1 \le k \le 8$) of the 9x9 window in PD and T2-weighted images, respectively.

Figure 1 shows the 9x9 window, $W(p_{ij})$, used by the algorithm to study the local hyperintensity behaviour of the pixel p_{ij} (black square in the image). The black lines correspond to the eight considered radius, and the gray squares under them the pixels considered.

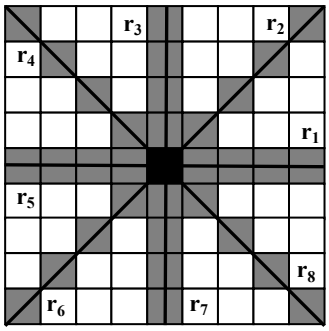

Figure 1. Example of 9x9 window considered for evaluating the hyperintensity. Gray-levels of the pixels under the eight radius (black lines), together with the gray-level of central pixel (black lines), are used for evaluating the hyperintensity of the last one.

Finally these degrees were aggregated for obtaining the membership degree of each pixel to the hyperintensity fuzzy set, $\mu_H(p_{ij})$.

2) Defuzzification and Filtering of false detections: To obtain the agrupations associated with small MS lesions we applied a defuzzification process to the membership functions previously obtained. Then, with the aim of eliminating false detections, due to hyperintense pixels do not associated with MS small lesions, a filtering process was carried out in which size, location and regional restrictions were applied:

III. Proposed Algorithm Description

The aim of the algorithm here presented is to increase lesion detection ratio obtained by our previous system, but maintaining both its general structure and the trade-off between true and false detections.

With this in mind, our approach takes into account the greater sensitivity to show small MS lesions of MRI sequences used at present in MS examinations. This greater sensitivity is mainly due to the acquisition of images with contiguous 3 mm thick sections. As Molyneux et al. showed [17], the reduction of the section thickness from 5 mm to 3 mm increases the MR-visible lesion volume by about 9%.

Next section presents the images considered in this paper. The differences introduced by the MRI acquisition parameters with regard to the previous works ([15], [16]) were taken into account in the design of the algorithm here proposed.

A. Images

The images were acquired in a Magnetom Vision 1.5T (Siemens, Erlangen, Germany) equipment using a Turbo Spin Echo (TSE) sequence that enables dual acquisition of PD and T2 weighted images with the same sequence. The acquisition was performed with interleaved contiguous 3mm-thick axial sections (TR /TE / matrix / FOV: 3000ms / 14-80ms / 256x256 / 250mm). Two blocks of 23 interleaved slices were required to cover the whole brain.

The data set considered for our study consisted of 8 T2-, PD-weighted couples of slices selected from the images obtained from two clinically definite MS patients. The selected images corresponded to axial slices associated with representative brain locations.

For having into account the aforementioned sources of problems, the half of the images showed low lesion volume and the other half high lesion load. For designing the algorithm we considered two out of the eight slices, one of a patient with reduced lesion volume, Im_R, and the other of a patient having high lesion load, Im_H

The images obtained by the TSE sequence showed some differences at contrast level regarding the images considered at previous approach. These differences were more noticeable at the PD weighted images, where the differentiation between the gray levels of parenchyma and fluid regions was lower than the appreciated at the images acquired with the SE sequence. Moreover, with the new acquisition in the case of T2-weighted images the differentiation between lesions and fluid regions is more complex in some locations due to the similarity of their gray levels.

B. Study Design

With the aim of facing up to the differentiating factors introduced by the new acquisition method, the algorithm was overhauled looking for the steps that should be modified. After the analysis carried out it was showed that, though the methodology applied for local assessment of hyperintensity should be preserved, was necessary to perform some modifications within the "*Fuzzy characterization and evaluation of hyperintensity*" stage developed at previous algorithm.

Specifically, the changes came about in the way the hyperintensity fuzzy set was obtaining throughout the radial analysis. Thus, following previous algorithm, after applying the rules 2.1 and 2.2, the degrees with which a pixel p_{ij} is sufficiently differentiable at each radius r_k ($1 \le k \le 8$) of the window $W(p_{ij})$ were obtained for PD- ($\mu_D^{r_k}(p_{ij})$) and T2- ($\mu_{T2}^{r_k}(p_{ij})$) weighted images.

Then, as shown in the gray shaded region of Figure 1, the new proposal for obtaining the hyperintensity fuzzy set was carried out by means of a *Mamdani* type *Fuzzy Rule-Based System* (*MFRBS*) which took into account previous membership functions, rules 2.1 and 2.2 and the knowledge of experts.

1) Obtaining the PD and T2 Hyperintensity Membership Functions $\mu_{H,D}$ and $\mu_{H,T2}$: According to rule 2.2, for determining the degree with which a pixel is hyperintense at both weighted images must be imposed that *for a high enough number of radii the pixel is sufficiently differentiable*. Our proposal for implementing this restriction consisted on aggregating the differentiability degrees of the pixel at each radius ($\mu_P^{r_k}(p_{ij})$ (P=PD, T2)) using an OWA operator [18], i.e.

$$\mu_{H,P}(p_{ij}) = f_{WP}\left(\mu_P^{r_1}(p_{ij}),\cdots,\mu_P^{r_8}(p_{ij})\right) \quad (1)$$

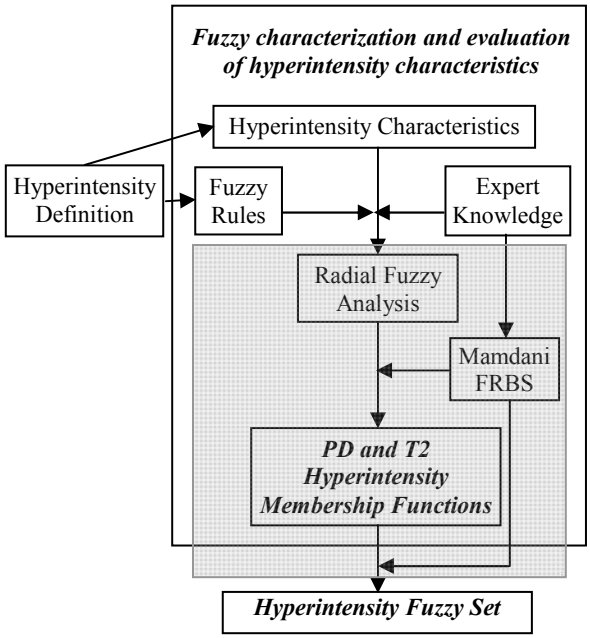

Figure 2. Gray-shaded region shows the step of the proposed algorithm that has been modified regarding the previous proposal.

To get the vectors w_P to be considered in the definition of $\mu_{H,PD}$ and $\mu_{H,T2}$ we followed the next two steps: *a) Sensitivity analysis* of $\mu_{H,PD}$ and $\mu_{H,T2}$ to the consideration of the vectors $w_P^1 = (1,0,\cdots,0)$, $w_P^2 = (0,1,0,\cdots,0)$, …, and $w_P^8 = (0,\cdots,0,1)$, which correspond to consider 1, 2, … and 8 radii respectively; *b)* Implementation of a *MFRBS* to the results of the *sensitivity analysis* to determine w_{PD} and w_{T2}.

a) Sensitivity analysis: To perform this analysis we considered the following quality indexes: Correction Factor associated with the detection level of small lesions, *CF*; Sensitivity to the Detection of pixels of small lesions, *SD*; and Efficiency for Avoiding False Positives; *EAFP*.

Since the minimum size for a region to be considered small lesion is of three pixels, if the number of pixels of a region R_k detected by the algorithm is greater or equal to 3 the region can be associated with lesion, otherwise, although it can not be considered as lesion, may be recovered as such at subsequent steps. However, a lesion would not be recovered if the algorithm did not detect any pixel of this lesion.

Taking into account previous considerations the first quality index was introduced as follows:

Definition 2.3
Let L be the set of lesions, l_i, marked by the experts at a given image I, $Alg(L)$ the set of lesions detected by the algorithm, and $N=\#(L)$. Then the *Correction factor associated with the detection level of small lesions* at I is given by

$$FC = \frac{1}{1+\sum_{i=1}^{N} \max(\overline{\chi}_{Alg(L)}(l_i), DP_{Alg(L)}(l_i))}. \quad (1)$$

where $\overline{\chi}_{Alg(L)}(l_i)$ is the complementary of the characteristic function of $Alg(L)$, and $DP_{Alg(L)}(l_i)$ is equal to 0.5 if the algorithm detects less than 3 pixels of lesion l_i and equal to 0 in other case.

This factor was considered as a weighting factor of the true positives fraction for defining the *Sensitivity to the Detection of pixels of small lesions,* as follows:

Definition 2.4
Let TP be the number of voxels in the image I detected as of lesion by experts and by our algorithm, and FN the number of image voxels detected as of lesion by experts but not by our algorithm. Then, the *Sensitivity to the Detection of pixels of small lesions* in I is given by:

$$SD = FC\,\frac{TP}{TP+FN}. \quad (3)$$

This Sensitivity index provides information regarding the possibility for detecting lesion pixels of an image and penalizes the cases of missed lesions, although some pixels of those lesions have been detected by the algorithm.

Whereas previous indexes are related to sensitivity and ability of the algorithm for correctly detecting lesion pixels, the third index focuses on its accuracy for avoiding false detections.

Definition 2.5
Given an image I, let *card* (*ICR*) be the number of pixels within the Intracraneal Region (*ICR*) of I, or number of image pixels analyzed by the algorithm. Then, the *Efficiency for Avoiding False Positives* in I is given by:

$$EAFP = 1 - \frac{FP}{card(ICR)} = 1 - \frac{FP}{TP+FN+TN+FP}. \quad (4)$$

where TN (true negatives) is the number of *ICR* image pixels neither marked by experts nor detected by the algorithm, and FP (false positives), is the number of *ICR* image pixels detected by the algorithm but unmarked by experts.

These quality indexes were evaluated on the PD- and T2-weighted images of the design database. To do it, for each pixel p_{ij} situated at position (i, j) on Im_R and Im_H, its hyperintensity values $\mu_{H,D}^k(p_{ij}) = f_{w_D^k}(\mu_D^{r1}(p_{ij}), \mu_D^{r2}(p_{ij}), \cdots, \mu_D^{r8}(p_{ij}))$ and $\mu_{H,T2}^k(p_{ij}) = f_{w_{T2}^k}(\mu_{T2}^{r1}(p_{ij}), \mu_{T2}^{r2}(p_{ij}), \cdots, \mu_{T2}^{r8}(p_{ij}))$ were obtained for the PD- and T2- weighted images, and the 8 weighting vectors, $1 \le k \le 8$. Then these values were defuzzified applying an α-cut with $\alpha = 0.5$, since for this value there is a balance between being and not be hyperintense.

The quality values obtained after the defuzzification process for the PD- and T2-weighted images are shown in tables I and II. Rows two to nine of these tables display the mean results obtained for the 8 weighting vectors for images Im_R (columns 2, 4 and 6) and Im_H (columns 3, 5 and 7).

w^3_{T2}	1.0	1.0	0.95	0.961	0.775	0.815
w^4_{T2}	1.0	1.0	0.850	0.824	0.875	0.892
w^5_{T2}	0.667	0.667	0.433	0.458	0.938	0.943
w^6_{T2}	0.5	0.4	0.275	0.235	0.974	0.973
w^7_{T2}	0.4	0.25	0.18	0.108	0.993	0.992
w^8_{T2}	0.286	0.154	0.071	0.024	0.999	0.999

In the analysis of these values was borne in mind that the best weighting vector for each weighted image ought: *1)* allow detecting a minimum of 3 pixels in all (or the maximum of) lesions, and *2)* furnish high detection level of lesion pixels but maintaining the number of false positives as small as possible.

From definitions 2.3, 2.4 and 2.5 it follows that the higher the value of *FC* the closer we will be to meet first condition, and the higher the values of *SD* and *EAFP* the more will be fulfilled condition *2)*. Moreover, the larger number of considered radii the more the restriction of lesion size will be satisfied, and the lower the possibility that correct and false detections show connectivity. As can be observed looking at tables I and II, these characteristics have significantly influence in the values of *SD* and *EAFP*, making that as the number of radii increases the first increases and the second decreases.

Given the above, the obtaining of the weighting vectors considered for defining $\mu_{H,PD}$ and $\mu_{H,T2}$ was performed using a *Mamdani type Fuzzy Rule system* because besides its high level of description, this type of system provides a natural framework for including expert knowledge in the form of linguistic rules, and possesses a high degree of freedom for selecting the most suitable fuzzification, defuzzification and inference components.

b) Application of the MFRBS for determining w_{PD} and w_{T2}: The *Knowledge Base* (*KB*) of the proposed system was obtained from experience and knowledge of experts. So, taking into account experts experience and the relationship between *FC* and *SD*, the *Data Base* (*DB*) was constituted by *SD* and *EAFP*, as input variables, and the *Adequacy* of the weighting vector as output variable. Moreover the linguistic terms, or labels, related to input and output variables were: L_{SD}={*High, Medium, Low*}, L_{EAFP}={*High, Medium, Low*} and $L_{Adequacy}$={*High, Medium, Low, Very Low*}.

For defining the membership functions associated with the linguistic labels considered for *SD* we studied the behavior of *FC* in cases where for some lesion the algorithm detected less than 3 pixels. From this study it appeared that there was a reverse proportionality factor between the increasing of lesions for which less than 3 pixels were detected by the algorithm and the value of *FC*. Furthermore, given the relationship between *FC* and *SD*, this factor made diminishing the *SD* value in the same proportion than *FC* if there are not false negatives, and at a higher rate in case of false negative detections.

In addition to previous considerations it was considered that the value of *EAFP* decreases as *FP* increases and, the greater the number of false positives the easier these pixels can present connectivity with the false positives, making that small lesions appear larger than their actual size. With the aim of avoiding this situation, we should be very restrictive in defining the membership functions associated with the variable *EAFP*

Given the above considerations, as well as the knowledge of the experts, the semantics of the linguistic variables were defined by the membership functions shown in the graphs of figure 3.

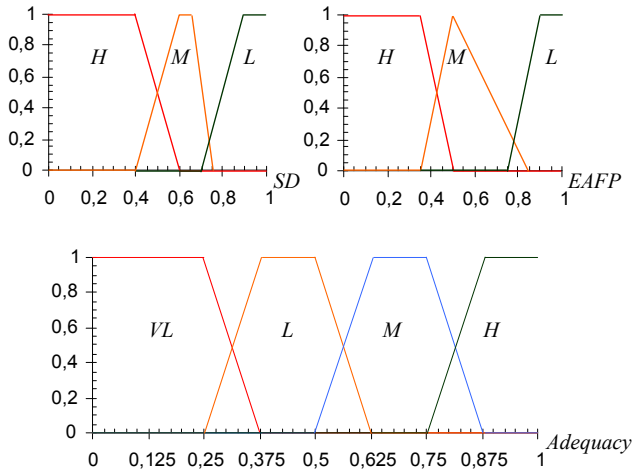

Figure 3. Membership functions of the labels associated with the input (*SD* and *ENDFP*) and output (*Adequacy*) variables.

The *Rule Base* (*RB*) considered in the *KB* was constituted by the nine linguistic rules represented by the *decision table* shown in table III.

TABLE III. DECISION TABLE OF THE KB CONSIDERED FOR DEFINING $\mu_{H,D}$ AND $\mu_{H,T2}$

Decision Table		SD		
		High	***Medium***	***Low***
EAFP	***High***	R_1:High (H)	R_4: Medium (M)	R_7: Low (L)
	Medium	R_2: Medium (M)	R_5: Low (L)	R_8: Very Low (VL)
	Low	R_3: Low (L)	R_6: Very Low (VL)	R_9: Very Low (VL)

Once the *KB* of the considered *MFRBS* was identified, we went on to define the *Inference Engine* (*IE*) which, by means of previous rules, put into effect the inference process on the system inputs.

The *IE* here considered was the classic of Mamdani, i. e. the t-norm minimum was used as conjunction and implication operators, and the mode A-FATI (first aggregate, then infer) as defuzzification interface. Finally in the *Defuzzification interface* the aggregation operator was modeled by the t-conorm maximum, while the defuzificación was carried out by the *Gravity Center* method, i.e. we considered the usually called *max-min-CG* inference engine

Tables IV and V show the results obtained by applying the proposed *MFRS* to the PD- and T2-weighted images, respectively. Having a look at these results it can be observed that for both weighted images the best performance is given for the weighting vectors that consider 4 radii (values highlighted in bold at both tables). This fact is better appreciated at figure 4 wherein blue triangles, red ellipses, green squares, black crosses, and brown triangles have been used for representing the *GC*s obtained for the weighting vectors w_P^1, w_P^2, w_P^3, w_P^4 and w_P^5, while the *GC*s obtained for the weighting vectors w_P^6, w_P^7 and w_P^8, are represented by purple ellipses. Therefore, the membership degrees of a pixel p_{ij} to the *PD* and *T2* hyperintense fuzzy sets are given by:

$$\mu_{H,P}(p_{ij}) = (0,0,0,1,0,0,0,0) \bullet \left(\mu_P^{r\sigma(1)}(p_{ij}),\ldots,\mu_P^{r\sigma(8)}(p_{ij})\right)^T . \quad (5)$$

	k=7	0.108	0.992	R_7	(0.437, 0.417)
	k=8	0.024	0.999	R_7	(0.437, 0.417)

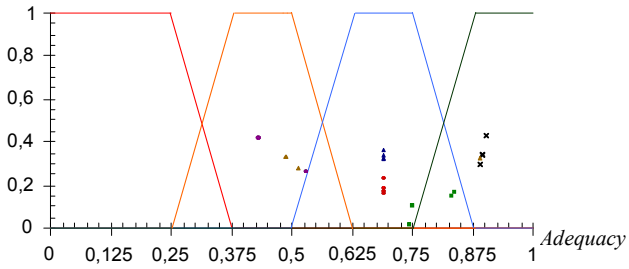

Figure 4. Gravity centers obtained applyinf¡g the proposed MFRBS. Black crosses, and brown triangles represent the GCs obtained for the weighting vectors w_P^4 and w_P^5, respectively.

2) Obtaining the Hyperintensity Membership Function μ_H: According to rule 2.3, a pixel is hyperintense if it presents hyperintense behavior at both PD- and T2-weighted images. So, for obtaining the membership degree of a pixel to the hyperintense fuzzy set, its membership degrees to the *PD* and *T2* hyperintense fuzzy sets had to be aggregated.

Given the characteristics of $\mu_{H,PD}$ and $\mu_{H,T2}$ it was considered that the aggregation operator used for defining μ_H should be a not too restrictive "logical and" (to provide similar importance to both membership functions), and ought take into account the process followed for obtaining the functions to be aggregated.

Bearing in mind the above restrictions as well as the characteristics of the lesions within the images, we studied the operators that could better adapt to them. After this study it was decided that the best operators were: the T-norms Minimum (Min) and Product (Prod), and Averaging Operator Geometric Mean (GM).

For determining which of these operators was better suited to our model we applied a *MFRBS* similar to the considered at previous step. The differences regarding previous system were at the *KB*. So, at the *DB* the linguistic variables and the membership functions associated to the output variable were modified. This change involved the modification of the *RB*.

The set of linguistic terms associated to the output variable was $L'_{Adequacy}$={High, Medium, Low}. The semantics associated with this variable, as well as the Rule Base, which were determined from the information provided by the experts, are shown at figure 5 and table VI, respectively.

The results obtained after applying the proposed *MFRBS* are shown at table VII. Moreover, for a better understanding of these results, the *GC*s obtained from the defuzzification step for the minimum, product, and geometric mean have been depicted as blue, red, and black points at figure 5.

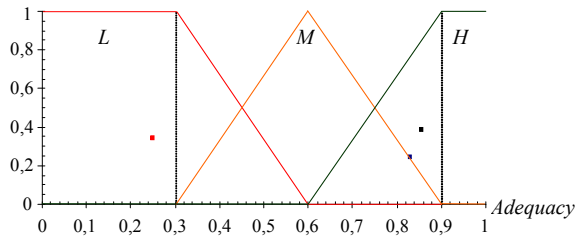

Figure 5. Membership functions of the output variable considered in the DB of the MFRBS designed for determining the aggregation operator used in the definition of the hyperintensity membership function. Blue, red and black points are the GCs obtained for the operators *Min, Prod* and *GM*, respectively.

TABLE VI. DECISION TABLE OF THE KB CONSIDERED FOR DEFINING μ_H

Decision Table		**SD**		
		High	***Medium***	***Low***
EAFP	***High***	R_1:High (H)	R_4: Medium (M)	R_7: Low (L)
	Medium	R_2: Medium (M)	R_5: Medium (M)	R_8: Low (L)
	Low	R_3: Low (L)	R_6: Low (L)	R_9: Low (L)

TABLE VII. RESULTS OBTAINED APPLYING THE PROPOSED MFRBS TO THE DESIGN DATABASE FOR OBTAINING μ_H

Operator	***FC***	***FSD***	***EAFP***	***Rules***	***GC***
Min	1	0.8	0.948	R_1	(0.835, 0.23)
Prod	0.667	0.433	0.964	R_4, R_7	(0.246, 0.345)
GM	1	0.88	0.924	R_1	(0.856, 0.376)

In analyzing the results it is appreciated that the product T-norm has clearly the worst fitting to the data, since its *Adequacy* is Low. As for the T-norm minimum, though its *Adequacy* is High, the *CG* obtained after the defuzzification is very close to *Adequacy* Medium. Therefore, since for the Geometric Mean aggregation Operator the Adequacy obtained was clearly High, the hyperintensity membership function (μ_H) was defined as:

$$\mu_H(p_{ij}) = \sqrt{\mu_{H,D}(p_{ij})\mu_{H,T2}(p_{ij})} \qquad (6)$$

IV. RESULTS

The proposed algorithm was evaluated on the 8 PD- and T2-weighted images of the data set. To do it, once the hyperintensity degrees of all the pixels were obtained using (6), we applied a 0.5-cut in order to maintain the balance between being and not be hyperintense. Then we evaluated the quality indexes *FC*, *SD*, and *EAFP*, obtaining the results shown at table VIII.

It must be emphasized that the algorithm showed a high sensitivity detecting hiperintensity regions associated with MS lesions, as can be inferred from the mean value of *SD* that appears at table VIII. In the evaluation of this value must be taken into consideration the hard penalization introduced by the *correction factor FC*. However this index showed also a high mean value (close to 1), and a minimum value of 0.5, what points out that the vast majority of pixels belonging to MS lesions were detected throughout the detection of hiperintensity within these images. Moreover, although we had a small number of false negatives, and the size of MS lesions can be very small, we checked out that all small lesions previously marked up by the experts were detected after applying the proposed algorithm.

On the other hand, the values obtained for *EAFP* indicate a low presence of false detections (*FP*) with regards to the number of pixels within the intracranial region (*card*(*ICR*)). The small difference between minimum and maximum values for this index, depicted at last column in fourth and fifth rows of table VIII, also allow us to infer that the detection of false positives showed no dependence of the different anatomical features that appear on different slides.

TABLE VIII. RESULTS OBTAINED TROUGH THE LOCAL ANALYSIS OF THE IMAGES DATABASE

	FC	***SD***	***EAFP***
Mean	0.94	0.85	0.93
σ	0.177	0.195	0.008
Minimum	0.5	0.43	0.92
Maximum	1.0	1.0	0.94

However, it must be taken into consideration that though a mean value obtained for this index is very high, this not implies necessarily that the number of FP were extremely low because *card*(*ICR*) is much greater than the possible number of *FP*. In this regard, should be noted that, although it would be desirable, in our implementation of the proposed trade-off it was not imposed that the results provided by the algorithm were free of false detections, instead it was decided to prioritize correct detections, as can be inferred from the definition of the semantic of the output linguistic variable shown in figure 3.

V. CONCLUSIONS AND FUTURE WORK

In conclusion, we have presented an algorithm to detect small hyperintense regions in PD- and T2-weighted MR images of the brain, and we have applied it to the detection of small multiple sclerosis lesions. The algorithm is designed based on a trade-off between true and false positive detections

that has been assessed by the introduction of quality indexes defined for this purpose. Then, a Mamdani type *FRBS* designed considering knowledge and experience of experts, and whose *KB* has fed on the results of the quality indexes obtained for the design images, has provided the aggregation operators defining the hyperintensity fuzzy set. Results have shown that the algorithm is very efficient detecting hyperintense regions associated with small MS lesions.

Future work will involve the introduction of new strategies for reducing false detections without removing true detections. Also the algorithm will be applied to a greater data set to achieve a better validation.

***Abstract*—Texture is one of the most used low-level feature for image analysis and, in addition, one of the most difficult to characterize due to its imprecision. It is usual for humans to describe visual textures according to some perceptual properties like coarseness-fineness, orientation or regularity. In this paper, we propose to model the fineness property, that is the most popular one, by means of a fuzzy partition on the domain of representative fineness measures. In our study, a wide variety of measures is studied, and the partitions are obtained by relating each measure (our reference set) with the human perception of fineness. Assessments about the perception of this property are collected from pools. This information is used to analyze the capability of each measure to discriminate different fineness categories, which imposes the number of fuzzy sets of the partition. Moreover, it is used to calculate the parameters of the membership function associated to each fuzzy set.**

***Index Terms*—Coarseness, fineness, fuzzy partition, fuzzy texture, image features, texture features.**

I. Introduction

Texture is, together with color and shape, one of the most important features for image analysis. However, it is also one of the most difficult to characterize due to its imprecission [1], [2]. In fact, there is not an accurate definition for the concept of texture but some intuitive ideas, as local changes in the intensity patterns or as a set of basic items arranged in a certain way [3]. Moreover, it is usual for humans to describe visual textures according to some vague textural properties like *coarseness/fineness*, *directionality* or *regularity* [4], [5]. Thus, coarseness is related to the spatial size of texture primitives, directionality reflects if they have a dominant orientation, and regularity refers to the variation of their placement. In this framework, visual textures are described by humans using linguistic terms as *fine* (e.g. the image in figure 1(J)), *very coarse* (figure 1(I)), *irregular* (figure 1(B)) or *very directional* (figure 1(I)).

There are many measures in the literature that, given an image, capture the presence of one of these perceptual properties in the sense that the greater the value given by the measure, the greater the perception of the property [3], [4]. However, there is no perceptual relationship between the value given by these measures and the degree in which the humans perceive the texture. Thus, given a certain value calculated by applying a measure to an image, we can not give a textural interpretation (e.g. for coarseness measures, there is not an immediate way to decide whether there is a fine texture, a coarse texture or something intermediate).

To face this problem, fuzzy logic has been recently employed for representing the imprecision related to texture. In many of these approaches, fuzzy logic is usually applied just during the process, being the output a crisp result [6], [7]. Other approaches try to model the texture and its semantic by means of fuzzy sets defined on the domain of a given texture measure. In this last framework, some proposals model the texture property by means of an unique fuzzy set [8], and other approaches define fuzzy partitions providing a set of linguistic terms [9], [10].

Focusing our study in the last type of approaches, two questions need to be faced for defining properly a fuzzy partition: (i) the number of linguistic labels to be used, and (ii) the parameters of the membership functions associated to each fuzzy set (and, consequently, the kernel localization). However, these question are not treat properly in the literature. Firstly, the number of fuzzy sets are often chosen arbitrarily, without take into account the capability of each measure to discriminate between different categories. Secondly, in many of the approaches, just an uniform distribution of the fuzzy sets is performed on the domain of the measures, although is wellknown that measure values corresponding to representative labels are not distributed uniformly. In addition, from our knowledge, none of the fuzzy approaches in the literature considers the relationship between the computational feature and the human perception of texture, so the labels and the membership degrees do not necessarily will match with the human assessments.

Among all the perceptual texture properties, the *coarseness-fineness* is the most popular one, being considered as the most fundamental feature in texture analysis by some authors [10]. In fact, the presence of fineness is usually associated to the presence of texture (from this point of view, texture is defined as local variations against the idea of homogeneity). In this sense, a *fine* texture contains small texture primitives with big gray tone differences between neighbor pixels (e.g. the image in Figure 1(A)), whereas a *coarse* texture corresponds to bigger primitives formed by several pixels (e.g. the image in Figure 1(I)). By considering the importance of the *coarseness-fineness* concept and in order to explain the methodology proposed in this paper, we will focus our study on this textural property (although other properties can be easily applied in a similar way).

In this paper, we propose to model the fineness property by means of a fuzzy partition on the domain of representative

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Figure 1. Some examples of images with different degrees of fineness

fineness measures. Firstly, in order to select the number of linguistic labels, we analyze the ability of each measure to discriminate different categories of the perceptual property. For this purpose, data about the human perception of fineness is collected by means of pools. This information is also used to localize the position and size of the kernel of each fuzzy set, obtaining a fuzzy partition adapted to the human perception of fineness.

The rest of the paper is organized as follows. In section II we present our methodology to obtain the fuzzy partition. Results are shown in section III, and the main conclusions and future work are sumarized in section IV.

II. Defining Fuzzy Partitions for Texture

Given a texture property (coarseness, directionality, regularity, etc), let $\mathcal{M}$ be a measure of that property and let $\mathcal{D}_{\mathcal{M}}$ be the measure domain. The notions of fuzzy texture and fuzzy texture space are introduced as follows:

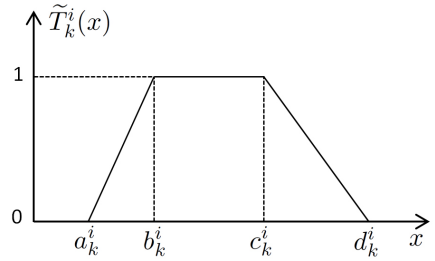

Figure 2. Trapezoidal function used for each fuzzy set $\widetilde{T}_k^i$

Definition 2.1: A fuzzy texture $\widetilde{T}$ is a linguistic label whose semantics is represented by a normalized fuzzy subset of $\mathcal{D}_{\mathcal{M}}$.

Definition 2.2: A fuzzy texture space Π is a set of fuzzy textures that defines a partition of $\mathcal{D}_{\mathcal{M}}$.

In this paper, we will focus our study on the *coarseness-fineness* property. Thus, we need to define the *coarseness-fineness* measures $\mathcal{M}$ that are used as the reference set (section II-A).

As it was pointed, there is not a clear perceptual interpretation of the value given by a coarseness-fineness measure. To face this problem, fuzzy partitions on the domain of the measures shown in section II-A are proposed. From now on, we will note Π_k the partition defined on the domain of a given fineness measure $\mathcal{M}_k$, N_k the number of fuzzy sets which compounds the partition Π_k, and $\widetilde{T}_k^i$ the i-th fuzzy set in Π_k.

In our approach, we propose to define the membership function $\widetilde{T}_k^i(x)$ for each fuzzy set $\widetilde{T}_k^i$ by using the trapezoidal function shown in Figure 2, that has the form

$$\widetilde{T}_k^i(x; a_k^i, b_k^i, c_k^i, d_k^i) = \begin{cases} 0 & x < a_k^i \quad or \quad x > d_k^i \\ \frac{x - a_k^i}{b_k^i - a_k^i} & a_k^i \leq x \leq b_k^i \\ 1 & b_k^i \leq x \leq c_k^i \\ \frac{d_k^i - x}{d_k^i - c_k^i} & c_k^i \leq x \leq d_k^i \end{cases} \tag{1}$$

This way, two questions need to be faced in order to define the fuzzy partition Π_k: (i) how many fuzzy sets will compound the partition, and (ii) how to obtain the parameter values of the membership function for each fuzzy set.

In order to answer both questions, we will analyze the ability of each measure to distinguish between different degrees of fineness. This analysis will be based on how the human perceives the fineness. To get information about human perception of fineness, a set of images covering different degrees of this property will be gathered. These images will be used to collect, by means of a pool, human assessments about the perceived fineness (section II-B)

Using the data about human perception, and the measure values obtained for each image, we will apply an iterative algorithm based on a set of multiple comparison tests, in order to obtain the number of classes (fineness degrees) that each measure can discriminate. Thus, we propose to set the number

Algorithm 1 Distinguishable clusters selection

Input:

$Part^0 = C_1, C_2, \ldots, C_n$: Initial Partition

δ: distance function between clusters

ϕ: Set of multiple comparison tests

NT: Number of positive tests to accept distinguishability

1.-Initialization

$k = 0$

$distinguishable = false$

2.- While (distinguishable = false) and (k < n)

Apply the multiple comparison tests ϕ to $Part^k$

If for each pair C_i, $C_j \in Part^k$ more than NT of the multiple comparison tests ϕ show distinguishability

$distinguishable = true$

Else

Search for the pair of clusters C_r, C_{r+1}, verifying $\delta(C_r, C_{r+1}) = \min\{\delta(C_i, C_{i+1}), C_i, C_{i+1} \in Part^k\}$

Join C_r and C_{r+1} on a cluster $C_u = C_r \cup C_{r+1}$

$Part^{k+1} = Part^k - C_r - C_{r+1} + C_u$

$k = k + 1$

3.- Output: $\widetilde{Part}_k = C_1, C_2, \ldots, C_{n-k}$

of fuzzy sets N_k in the partition Π_k as the number of classes that can be discriminated by the measure $\mathcal{M}_k$ (section II-C). In addition, the information given by the tests, will be used to define the parameter values of the membership function $\widetilde{T}_k^i(x)$ for each fuzzy set $\widetilde{T}_k^i$ (section II-D).

A. Texture measures

As mentioned in the introduction, there are many measures in the literature that, given an image, capture the fineness (or coarseness) presence in the sense that the greater the value given by the measure, the greater the perception of texture [4], [3]. In this paper, some of the most representative of these measures, that are listed in the first column of Table I, have been analyzed. It should be noticed that most of these measures were developed in the early nineties. However, they are still considered the state of the art in the characterization of the coarseness property of textures. In fact, they are achieving a growing interest due to applications in fields like image retrieval, where low level features like texture are the basis for the description of visual content (e.g. MPEG-7 descriptors) [11], [12], or for learning new concepts [13], [14]. All the coarseness-fineness measures analyzed in this paper are automatically computed from the texture image, obtaining a real value. Thus, the domain for all of them is $\mathcal{D}_{\mathcal{M}} = \mathbb{R}$.

B. Assessment collection

From now on, let $\mathcal{I} = \{I_1, \ldots, I_N\}$ be the set of N images representing fineness examples, and let $\Gamma = \{v^1, \ldots, v^N\}$ be the set of perceived fineness values associated to $\mathcal{I}$, with v^i being the value representing the degree of fineness perceived by humans in the image $I_i \in \mathcal{I}$. In this section, the way to obtain the set Γ will be described. For this purpose, firstly the image set $\mathcal{I}$ will be selected (section II-B1). After that, a poll for getting assessments about the perception of fineness will be designed (section II-B2). Finally, for a given image, the assessments of the different subjects will be aggregated (section II-B3).

1) The texture image set: A set $\mathcal{I} = \{I_1, \ldots, I_N\}$ of $N = 80$ images representative of the concept of *fineness* has been selected. Figure 1 shows some images extracted from the set $\mathcal{I}$. Such set has been selected satisfying the following properties:

1) It covers the different presence degrees of fineness.
2) The number of images for each presence degree is representative enough.
3) Each image shows, as far as possible, just one presence degree of fineness.

Due to the third property, each image can viewed as "homogeneous" respect to the fineness degree represented, i.e., if we select two random windows (with a dimension which does not "break" the original texture primitives and structure), the perceived fineness will be the same for each window (and also respect to the original image). In other words, we can see each image $I_i \in \mathcal{I}$ as a set of lower dimension images (windows) with the same fineness degree of the original one.

As we explained, given an image $I_i \in \mathcal{I}$, a fineness measure $\mathcal{M}_k$ will be applied on it. In fact, and thanks to the third property, we really can apply this measure for each subimage, assuming that the human assessment associated to that subimage will be the human assessment associated to the whole image. From now on, we will note as $m_k^{i,w}$ the result of applying the measure $\mathcal{M}_k$ to the w-th window of the image I_i.

2) The poll: Given the image set $\mathcal{I}$, the next step is to obtain assessments about the perception of fineness from a set of subjects. From now on we shall note as $\Theta^i = [o_1^i, \ldots, o_L^i]$ the vector of assessments obtained from L subjects for the image I_i. To get Θ^i, subjects will be asked to assign images to classes, so that each class has associated a perception degree of fineness. In particular, 20 subjects have participated in the poll and 9 classes have been considered. The first nine images in figure 1 show the nine representative images for each class used in this poll. It should be noticed that the images are decreasingly ordered according to the degree of fineness.

As result, a vector of 20 assessments $\Theta^i = [o_1^i, \ldots, o_{20}^i]$ is obtained for each image $I_i \in \mathcal{I}$. The degree o_j^i associated to the assessment given by the subject S_j to the image I_i is computed as $o_j^i = (9-k) * 0.125$, where $k \in \{1, \ldots, 9\}$ is the index of the class C_k to which the image is assigned by the subject.

3) Assessment aggregation: Our aim at this point is to obtain, for each image in the set $\mathcal{I}$, one assessment v^i that summarizes the assessments Θ^i given by the different subjects about the presence degree of fineness.

To aggregate opinions we have used an OWA operator guided by a quantifier [24]. Concretely, the quantifier "the most" has been employed, which allows to represent the opinion of the majority of the polled subjects. This quantifier is defined as

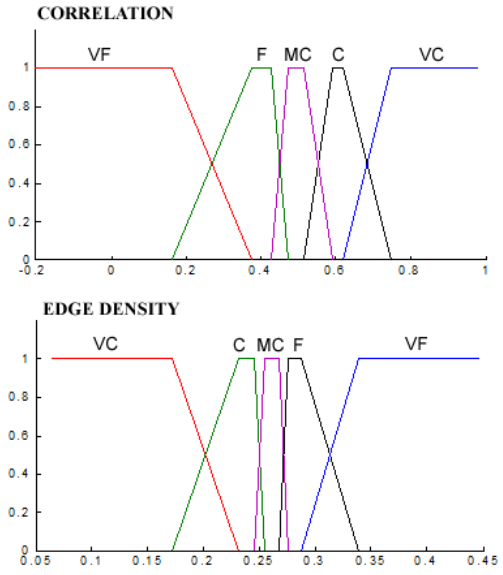

Figure 3. Fuzzy partitions for the measures Correlation and Edge Density. The linguistic labels are VC = very coarse, C = coarse, MC = medium coarse, F = fine, VF = very fine

$$Q(r) = \begin{cases} 0 & \text{if } r < a, \\ \frac{r-a}{b-a} & \text{if } a \leq r \leq b, \\ 1 & \text{if } r > b \end{cases} \quad (2)$$

with $r \in [0,1]$, $a = 0.3$ and $b = 0.8$. Once the quantifier Q has been chosen, the weighting vector of the OWA operator can be obtained following Yager [24] as $w_j = Q(j/L) - Q((j-1)/L), j = 1, 2, ..., L$. According to this, for each image $I_i \in \mathcal{I}$, the vector Θ^i obtained from L subjects will be aggregated into one assessment v^i as follows:

$$v^i = w_1 \hat{o}_1^i + w_2 \hat{o}_2^i + ... + w_L \hat{o}_L^i \quad (3)$$

where $[\hat{o}_1^i, \ldots, \hat{o}_L^i]$ is a vector obtained by ranking in nonincreasing order the values of the vector Θ^i.

C. Distinguishability Analysis of the Fineness Measures

As it was expected, some measures have better ability to represent fineness than the others. To study the ability of each measure to discriminate different degrees of fineness (i.e. how many classes can $\mathcal{M}_k$ actually discriminate), we propose to analyze each measure by applying a set of multiple comparison tests following the algorithm 1. This algorithm starts with an initial partition[1] and iteratively joins clusters until a partition in which all classes are distinguishable is achieved. In our proposal, the initial partition will be formed by the 9 classes used in our poll (where each class will contain the images assigned to it by the majority of the subjects), as δ the Euclidean distance between the centroids of the involved classes will be used, as ϕ a set of 5 multiple comparison tests will be considered (concretely, the tests of Scheffé, Bonferroni, Duncan, Tukey's least significant difference, and Tukey's honestly significant difference [25]), and finally the number of positive tests to accept distinguishability will be fixed to $NT = 3$.

From now on, we shall note as $\Upsilon_k = C_1^k, C_2^k, \ldots, C_{N_k}^k$ the N_k classes that can be discriminated by $\mathcal{M}_k$. For each C_i^k, we will note as $\bar{c}_i^k$ the class representative value. In this paper, we propose to compute $\bar{c}_i^k$ as the mean of the measure values in the class C_i^k.

Table I shows the parameters obtained by applying the proposed algorithm with the different measures considered in this paper. The second column of this table shows the N_k classes that can discriminate each measure and the third column shows how the initial classes have been grouped. The columns from fourth to eighth show the representative values $\bar{c}_r^k$ associated to each cluster.

D. The Fuzzy Partitions

In this section we will deal with the problem of defining the membership function $\mathcal{T}_k^i(x)$ for each fuzzy set $\mathcal{T}_k^i$ compounding the partition Π_k. As it was explained, the number of

[1]Let us remark that this partition is not the "fuzzy partition". In this case, the elements are measure values and the initial clusters the ones given by the pool.

Table II
PARAMETER VALUES THAT DEFINE THE MEMBERSHIP FUNCTIONS $\mathcal{T}_k^i(x)$ COMPOUNDING THE PARTITION FOR THE MEASURES OF CORRELATION AND EDGE DENSITY

(a) CORRELATION

i	a_k^i	b_k^i	c_k^i	d_k^i
1	$-\infty$	$-\infty$	0.1600	0.3758
2	0.1600	0.3758	0.4302	0.4725
3	0.4302	0.4725	0.5175	0.5937
4	0.5175	0.5937	0.6203	0.7480
5	0.6203	0.7480	∞	∞

(b) EDGE DENSITY

i	a_k^i	b_k^i	c_k^i	d_k^i
1	$-\infty$	$-\infty$	0.1711	0.2314
2	0.1711	0.2314	0.2446	0.2547
3	0.2446	0.2547	0.2673	0.2756
4	0.2673	0.2756	0.2884	0.3394
5	0.2884	0.3394	∞	∞

fuzzy sets will be given by the number of categories that each measure can discriminate (shown in Table I).

In this paper, the trapezoidal function given by equation (1) is used for defining each membership function $\widetilde{T}_k^i(x)$. In addition, a fuzzy partition in the sense of Ruspini is proposed. Figure 3 shows some examples of the type of fuzzy partition used.

To establish the value of the parameters b_k^i and c_k^i, that define the kernel of the trapezoidal membership function associated to the fuzzy set $\widetilde{T}_k^i$, we propose a solution based on the multiple comparison tests used in section II-C. As it is known, in these tests confidence intervals around the representative value of each class are calculated (being accomplished that these intervals do not overlap for distinguishable classes). All values in the interval are considered plausible values for the estimated mean. These confidence intervals are defined by the parameter $\Psi_i^k = 1.96\bar{\sigma}_i^k/\sqrt{||C_i^k||}$, with $\bar{c}_i^k$ and $\bar{\sigma}_i^k$ being the representative value and the estimated standard deviation for the class C_i^k, respectively. Table I shows the values Ψ_i^k for each measure and each class.

Based on this idea, we propose to set the center of the kernel of the membership function $\widetilde{T}_k^i(x)$ as the representative value $\bar{c}_i^k$ of the corresponding i-th class, using the information of the confidence interval to obtain the value of the parameters b_k^i and c_k^i:

$$b_k^i = \bar{c}_i^k - \Psi_i^k \qquad c_k^i = \bar{c}_i^k + \Psi_i^k \tag{4}$$

Since a fuzzy partition in the sense of Ruspini is proposed, the value of the parameters a_k^i and d_k^i is obtained as

$$a_k^i = c_k^{i-1} \qquad d_k^i = b_k^{i+1} \tag{5}$$

It should be noticed that $a_k^1 = b_k^1 = -\infty$ and $c_k^{N_k} = d_k^{N_k} = \infty$.

Figure 3 shows the graphical representation of the fuzzy partitions for the measures of correlation and ED (the ones with higher capacity to discriminate fineness classes), and Table II shows their corresponding parameters.

III. RESULTS

In this section, the fuzzy partition defined for the measure "Correlation" (showed in Figure 3) will be applied in order to analyze the performance of the proposed model.

Let's consider Figure 4(a) corresponding to a mosaic made by several images, each one with a different increasing degree of fineness. Figure 4(b-f) shows the membership degree to the fuzzy sets "very coarse", "coarse", "medium coarse", "fine" and "very fine", respectively, using the proposed model. For each pixel in the original image, a centered window of size 32×32 has been analyzed and its membership degree to each fuzzy set has been calculated. Thus, Figure 4(b) represents the degree in which the texture is perceived as "very coarse", with a white level meaning maximum degree, and a dark one meaning zero degree. It can be noticed that our model captures the evolution of the perception degrees of fineness.

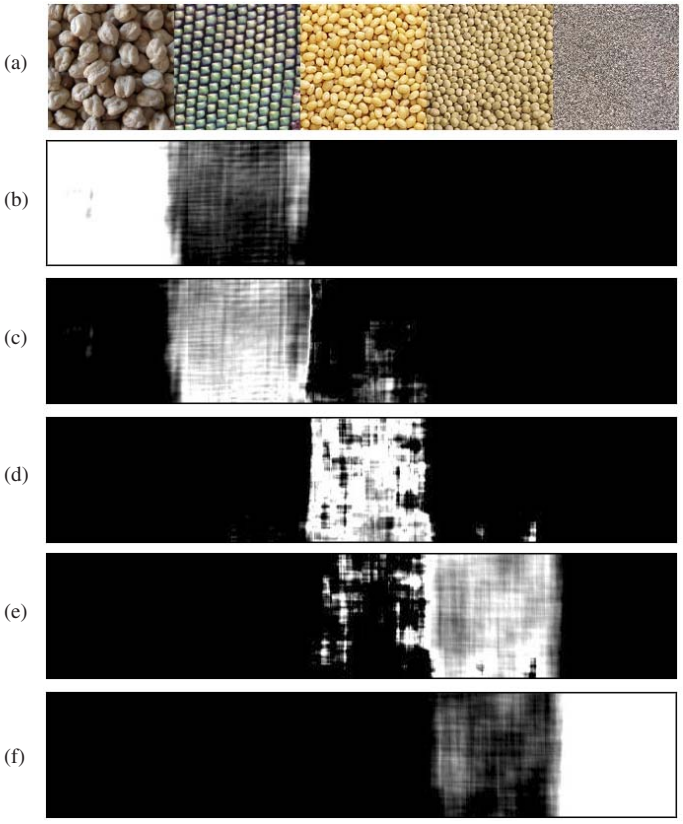

Figure 4. Results for a mosaic image. (a) Original image (b)(c)(d)(e)(f) Membership degree of each pixel to the sets "very coarse", "coarse", "medium coarse", "fine" and "very fine", respectively (the darker the pixel, the lower the membership degree).

Figure 5 presents an example where the proposed fuzzy partition has been employed for pattern recognition. In this case, Figure 5(a) shows a microscopy image corresponding to the microstructure of a metal sample. The lamellae indicates islands of eutectic, which are to be separated from the uniform light regions. The brightness values in regions of the original image are not distinct, so texture information is needed for extracting the uniform areas. This fact is showed in Figures 5(b) and 5(c), where a thersholding on the original image is displayed (homogeneous regions cannot be separated from the textured ones as they "share" brightness values). Figure 5(d) shows a mapping from the original image to its membership degree to the fuzzy set associated "very coarse". Thus, Figure 5(d) represents the degree in which the texture is perceived as "very coarse" and it can be noticed that uniform regions

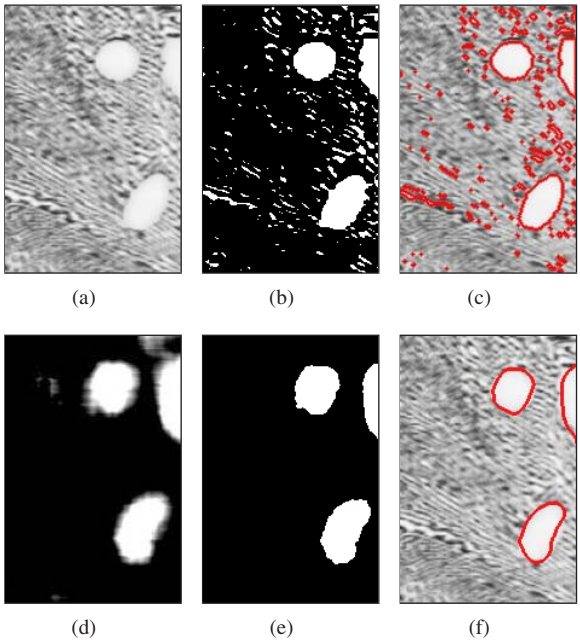

Figure 5. Example of pattern recognition (a) Original image (b) Binary image obtained by thresholding the original one (c) Region outlines of *b* superimposed on original image (d) Membership degrees to the set "very coarse" obtained with our model from the original image (e) Binary image obtained by thresholding *d* (f) Region outlines of *e* superimposed on original image.

correspond to areas with the maximum degree (bright grey levels), so if only the pixels with degree upper than 0.9 are selected (Figure 5(e)), the uniform light regions emerge with ease (Figure 5(f)).

Figure 6 presents another example of the application of the proposed fuzzy partition for pattern recognition. Figure 6(a) shows the natural image used in this example, that corresponds to a microscopic image of a Volvox (a colony of greencells). In this case, we want to separate the main colony from the background and the daughter colonies from the mother colony. As in the previous example, this can not be done by thresholding on the original image, as it is shown in Figure 6(b), so texture information is needed. Figures 6(c), 6(d) and 6(e) shows the mapping from the original image to its membership degree to the fuzzy sets "very fine", "medium coarse" and "very coarse", respectively. It can be noticed that daughter colonies in Figure 6(a) correspond to areas with high degrees of fineness, so they can be obtained by selecting the pixels with membership degree higher than 0.9 to the fuzzy set "very fine". On the other hand, the main colony can be separated from the uniform background as in the previous example (with a threshold of 0.9 in the membership degree to the fuzzy set "very coarse"), obtaining the region outlines shown in Figure 6(f)

IV. Conclusions and Future Works

In this paper, a fuzzy partition for representing the fineness concept have been proposed. The number of fuzzy sets and

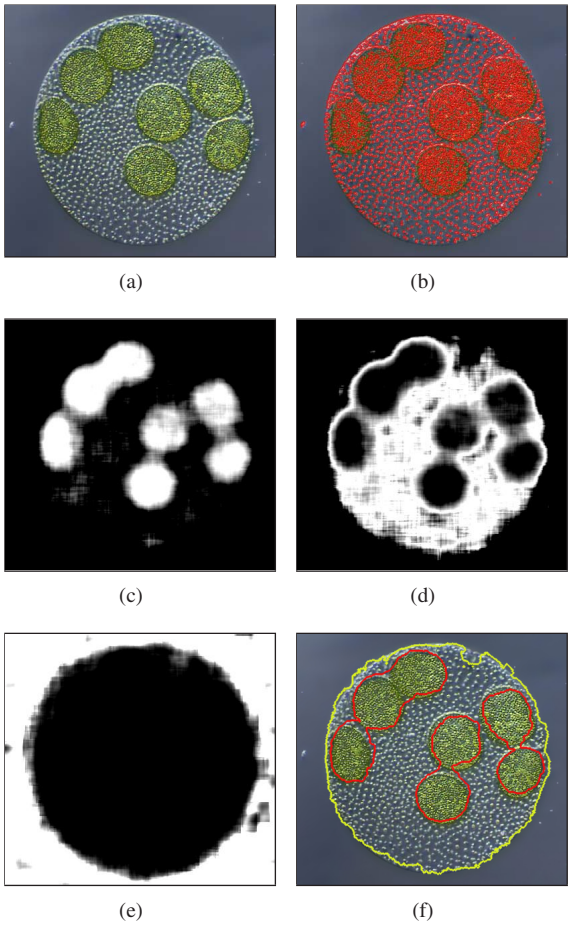

Figure 6. Results for a microscopy image. (a) Original image (b) Thresholding performed on *a* superimposed on original image (c)(d)(e) Membership degrees to the sets "very fine", "medium coarse" and "very coarse", respectively (f) Thresholding performed on *c* and *e* superimposed on original image.

the parameters of the membership functions have been defined relating fineness measures with the human perception of this texture property. Pools have been used for collecting data about the human perception of fineness, and the capability of each measure to discriminate different fineness degrees has been analyzed. The results given by our approach show a high level of connection with the human perception of fineness. As future work, the performance of the fuzzy partition will be analyzed in applications like textural classification or segmentation.

Abstract— **Communication robots are hard to interact with humans autonomously in everyday environment due to lack of intelligence even though robots can perform certainly only in limited environments and limited situations. However, since intelligence of robots is handled by an operator, tele-operated robots are useful to investigate functions required for robots and effects of robots in real-environment. This paper proposes an educational system with a tele-operated android robot that has human-like appearance. The developed android robot, named SAYA, is able to express human-like facial expressions and performs some communicative functions with its head and eye movements, and it is utilized as a roll of a teacher in the proposed educational system. In addition, SAYA's utterances and behaviors are controlled remotely by an operator so that it is able to not only conduct the class but also interact with students. A field trial was carried out at an elementary school, and SAYA conducted the class concerning the principle of leverage as a topic of science classes while interacting with students. Also, how it affected students' interest and motivation was investigated. As results, the trial verified that some students became interested in science class more than before the trial, and its positive effects in educational field, especially elementary schools, were verified.**

Keywords-android robot; remote class system; educational robot; field trial; human-robot interaction

I. INTRODUCTION

In the last decade, various kinds of robots which offer services in daily environment through interactions with humans have been developed and studied. In the near future, robots are expected to be able to offer not only physical supports but also informative and emotional supports. For that purpose, it is very interesting to investigate what kinds of functions, mechanisms, and intelligence are required for robots, and investigate how robots should interact with human in daily environment. Thus, many kinds of communication robots have been developed and applied to not only laboratories but also our daily lives [1]-[6]. For example, the pet-type robot, named AIBO [1], was commercialized around ten years ago, and it can act in our living space. A seal type robot was also developed as a mental therapy robot and its effectiveness for elderly people was verified by being utilized in nursing-care facilities [2]. These kinds of animal-type robots interact with humans emotionally by performing endearing movements. On the other hand, humanoid-type robots have been developed, which have human-like properties such as a head and arms to express more human-like behaviors. Thus, in humanoid-type robot researches, they utilize bodily movements such as gestures, nodding, eye-orientation, and facial expressions as non-verbal behaviors to interact with humans naturally [3]-[7]. For example, Robovie [3]-[5] interacts with humans and offers informative services by utilizing its human-like physical structure, and it was actually used at real-environment such as a train station, a museum, and an elementary school. However since intelligence technologies for robots are still impractical, robots cannot interact with human autonomously even though they can perform effectively in limited environments or limited situations. On the other hand, it is expected that tele-operated robots are applicative as an interface of telecommunication system rather than autonomous robots because their intelligence is handled by human operator. That is, in tele-operated robot, an operator enables a robot to interact with human by controlling robot's behaviors and utterances remotely without advanced intelligence technologies.

In this paper, a remote class support system is proposed as a one of applications of telecommunication system in which a robot is used as an interface. Especially, android type communication robot SAYA [8][9] which has human-like appearance is utilized in the proposed system, and it can interact with humans with human-like body movements such as facial expressions, head movements, and eye-orientation. Actually, Sakamoto et al. [10] verified effectiveness of the tele-operated android robot on conveying presence of a human who was in different place rather than existing media such as a speaker or a video-conference system. To investigate its effectiveness for children in elementary schools is also interesting, because children were interested in learning with a robot and they were motivated to learn a foreign language as shown in previous research [5] in which the robot interacted with children by speaking only English. Hence, the remote class support system with the android robot SAYA is also expected to contribute to children's motivation to learn. Thus, a science class is conducted for children at an elementary school with the proposed system to investigate its effectiveness on children's interest and motivation through this trial.

The structure of this paper is as follows. In Section 2, the android robot SAYA and its communicative functions are introduced. Section 3 describes the system structure of the

Japan Society for the Promotion of Science *(JSPS)*

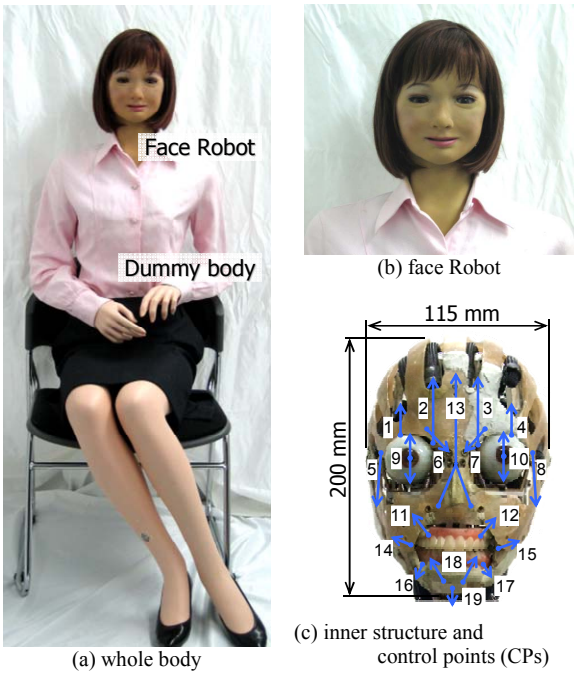

Figure 1. Android Robot SAYA

remote class support system with SAYA and the detailed content of the class. In section 4, detailed procedure of a field trial and its results are presented. In final section 5, the contributions of this research are discussed, and this paper is conluded.

II. ANDROID ROBOT SAYA

Fig. 1 shows SAYA which has been developed as one of android-type communication robots. The face robot [9][11] is mounted on a dummy body and it is highly realistic appearance. SAYA is also used as an interface of receptionist system at a university [8], which equips a speech dialogue function and some non-verbal communicative functions such as facial expressions, head movements, and eye-orientation.

A. Facial Expressions with the Face Robot

In human face-to-face communication, facial expressions are said to play a very important role as one of non-verbal communication [12]. Facial expressions are expected to contribute to realize smooth communication between humans and robots. Therefore highly realistic face robots that resembles to human-like face have been developed, and it can express facial expressions [9][11]. Almost all related studies of producing facial expressions are based on "action unit" that is defined in FACS (Facial Action Coding System) [13]. Action units express motions of mimic muscles as 44 kinds of basic motions, and there are 14 action units to express 6 typical facial expressions. Referring to these studies, 19 control points and their directions on the face robot are modeled as shown in Fig. 1(c). By combining movements of control points, various facial expressions are realized with the face robot. Fig. 2 shows examples of 6 typical facial expressions of the face robot, and the face robot succeeded in achieving high correct recognition rate of these facial expressions in previous study [9].

Figure 2. Examples of SAYA's facial expressions

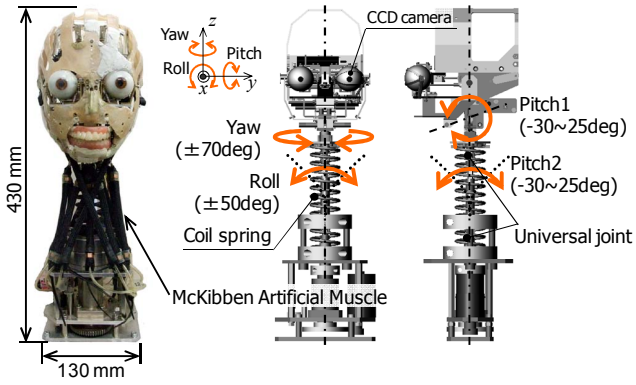

Figure 3. Mechanical structure of SAYA

In the face robot, McKibben artificial muscles are utilized to actuate control points. Since it is small, lightweight and flexible, it can be distributed to curved surfaces of the skull like human muscles.

The facial skin is formed with soft urethane resin to mimic the texture of human facial skin.

B. Eye and Head Movements

Figs. 1(b) and 3 show the internal structure of the face robot. There are 2 DOF for eye movements. Two eyeballs are linked mutually and two DC motors move both pitch and yaw rotations of eyeballs. In addition, a small CCD camera is mounted to the inside of an eyeball to obtain images of SAYA's view point. The eye orientation is also able to be controlled by extracting human skin color region from image of the CCD camera so that the face robot can track a human.

There are 4 DOF for head movements. In order to mimic flexible neck movements of a human cervical spine, we utilize a coil spring in the neck part. Furthermore, the center of rotations for pitch rotation ("Pitch1") and yaw rotation are set in the base of the head part. The forward and backward motions are realized by combining the head rotation ("Pitch1") and the neck bending ("Pitch2"). The roll-rotation, both pitch-rotations ("Pitch1" and "Pitch2") and the yaw-rotation are also actuated by McKibben artificial muscles as shown in Fig. 3.

We use electro-pneumatic regulators for controlling contraction of McKibben artificial muscle.

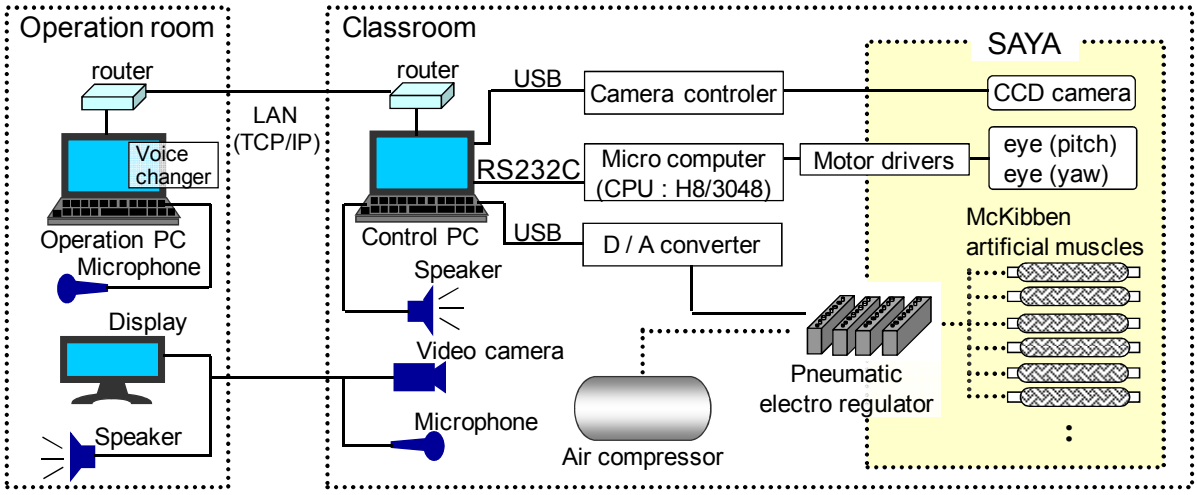

Figure 4. System configuration

III. Remote Class Support System with the Android Robot SAYA

A. System Configuration

Fig. 4 shows the system configuration of the developed remote class support system, and the android robot SAYA is utilized as the interface and it plays the role of a teacher.

In a classroom, there are SAYA, control PC, and some control equipment. An air compressor and an electro-pneumatic regulator are used to control contraction of McKibben artificial muscle. A microphone and a video camera are also used to obtain visual and sound information of a classroom.

In an operation room, one monitor is used for an operation, and the other one is used for an observation. The operator is able to monitor students' behaviors through observation monitor, and he can control SAYA's behaviors by sending commands to the control PC through the operation PC. Commands of the operation PC are delivered to the control PC through the LAN. Then, the control PC executes robot's behaviors based on received commands. For example, captured images of the SAYA's CCD camera and the video camera are transmitted to the operation PC, and the operator can observe the classroom from both viewpoints of the robot and the rearward. Then, the operator can move the SAYA's viewpoint by controlling its eye and head orientations using this visual information. As a result, SAYA is able to look around a classroom and look at a specific student.

The operator is also able to hear students from speakers and talk to students. Operator's voice is changed to women's voices through a voice-changer as SAYA's voice.

B. Interactive Behaviors

In this system, there are two operation modes that are "lecture mode" and "interaction mode".

In "lecture mode", the operator gives students explanations about slides displayed at the front of a classroom through SAYA. The operator speaks sentences that were prepared based on lecture content. SAYA's mouth is moved in synchronization with sound information of operator's voice, and SAYA looks around a classroom while talking.

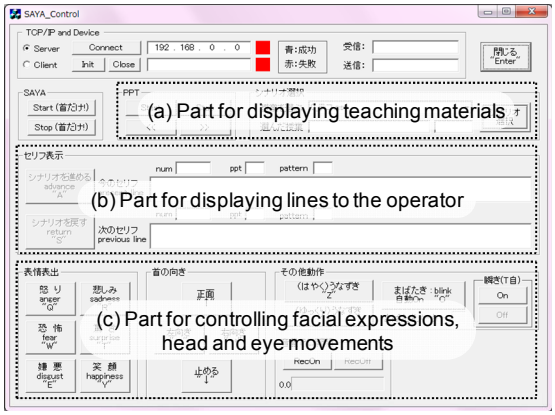

Figure 5. Operation interface

In "interaction mode", the operator controls SAYA's head and eye orientations to let SAYA look around a room and look at a student. The operator also talks to students through SAYA to answer students' talks and questions. In addition, he sometimes says short words to encourage students to concentrate on the class such as "do your best", "be quiet", "don't look away" and so on. The operator also executes to appropriate facial expressions according to its utterance. For example, when he says "be quiet", he executes facial expression "anger".

Since behaviors of SAYA consist of simple movements, the operator can execute these interactive behaviors easily. Additionally, SAYA is basically performed by tele-operation. As a result, it seems to apparently conduct the class and interact with students autonomously.

C. Operation Interface

Fig. 5 shows the operation interface for the operator. It mainly consist 3 parts: (a) part for displaying teaching materials, (b) part for displaying lines to the operator, (c) part for controlling facial expressions, head and eye movements. In

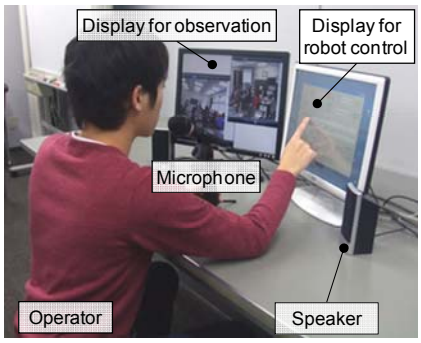

Figure 6. Operation room

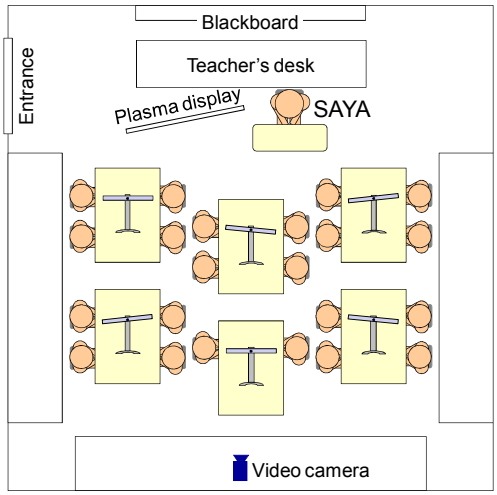

Figure 7. Experimental environment

part (a), there are some icons to change teaching materials that are displayed to a screen or a display. In part (b), lines that the operator should say are displayed in the text boxes. In part (c), there are many icons that are corresponding to robot's behaviors such as facial expressions, eye and head movements. An operator can easily control the robot by clicking these icons with a mouse or a touch panel as shown in Fig. 6.

D. *Content of Science Class*

The principle of leverage is adopted as a topic of the science class for elementary school students. This topic is said to be difficult for students because it contains both mathematical elements and experimental validations. In order to create teaching materials, science textbooks that are generally used in elementary schools are referred.

Table 1 shows the flow of the science class concerning the principle of leverage. First of all, self-introduction of the android robot SAYA is performed, and the class is opened. Then, SAYA explains the theory and mechanical advantages of leverage with some slides. In this scene, three important points of leverage are introduced. That is, a pivot point, a point of effort, and a point of load are explained. SAYA then shows familiar examples of leverage that are seen in our daily lives. For example, scissors, bottle-opener, tweezers, and so on are shown. After that, SAYA lets students experiment for discovering or confirming the principle of leverage with an experimental lever kit, and students are able to experience the

IV. FIELD TRIAL AT AN ELEMENTARY SCHOOL AND EVALUATION

A. *Setting*

A field trial at an elementary school was conducted to verify effectiveness of the developed educational system in actual educational fields. The trial was carried out after school, and it took about one hour. 22 students who were 10-11 years old and belonged to the fifth-grade class participated.

Fig. 7 shows experimental environment. We used a standard classroom, and we put SAYA on the front of the room as the role of a teacher. A plasma display was also put on the front of the room to display teaching-materials, and a video camera was put on the rearward to let the operator monitor the classroom. In addition, there was an experimental lever kit on each desk every four students as shown in Fig. 8.

Four students per a desk were made to sit on assigned positions. The position of each student had defined so that the operator could identify each student, and he could let SAYA look at a student and call a student's name individually.

B. *Experimental Procedure*

At the first, an experimenter let students sit down in assigned positions. He then explained the flow of this trial briefly and asked students to answer a brief questionnaire. After that, he exited the room and the operator began the science class by controlling SAYA. The science class was conducted along the scenario that had prepared based on content described in Table I. During the class, the operator sometimes talked to students. That is, the operator asked some questions or gave cautions and advices to students through

SAYA. After the class, the experimenter asked children to answer a questionnaire.

Fig. 9 shows scenes of the field trial in the elementary school. Fig. 9(a) shows the scene in which SAYA gave explanations about the leverage along the scenario, and students concentrated on hearing SAYA's talk and paid attention to the screen. SAYA sometimes looked at students and asked some questions as shown in Fig. 9(b). Fig. 9(c) shows the scene in which students raised their hand and attempted to answer a SAYA's question. In class, students experimented for discovering and confirming the principle of leverage with the experimental lever kit as shown in Fig. 9(d).

TABLE II. QUESTIONNAIRE AND RESULTS OF Q. 1 TO Q. 12

	Questionnaire	Result (ave. (s.d.))
Q.1	Are you interested in science and technology?	1.00 (0.87)
Q.5		1.36 (1.00)
Q.2	Do you prefer science classes?	0.73 (1.08)
Q.6		1.45 (0.74)
Q.3	Are you interested in robots?	1.09 (1.15)
Q.7		1.36 (1.09)
Q.4	Are you interested in a class conducted by robots?	1.27 (0.94)
Q.8		1.50 (0.96)
Q.9	Were you able to concentrate on the class more than usual?	0.55 (1.30)
Q.10	Was the class easy to understand?	1.45 (0.86)
Q.11	Do you want to participate in the class again if you have opportunity?	1.09 (1.23)
Q.12	Did SAYA answer you correctly? (yes / no)	yes: 17, no : 5

C. *Questionnaire Investigation for Evaluation*

In order to evaluate the developed educational system, the questionnaire was prepared to investigate how students' interest and motivation were affected through this experiment. Therefore, questionnaire investigations were conducted before and after the class. Tables II shows the questionnaire that consisted of 12 questions (Q.1 - Q.12). First 4 questions (Q.1 - Q.4) were used for the investigation before the class as the brief questionnaire, and last 8 questions (Q.5 - Q.12) were used after the class. Each question was evaluated on a scale of -2 to 2 except Q.12, where 2 is most positive evaluation. Only Q.12 was evaluated with "yes" or "no". Moreover, Q.1 and Q.5 (interest in science and technology), Q.2 and Q.6 (interest in science classes), Q.3 and Q.7 (interest in robots), Q.4 and Q.8 (interest in a class conducted by robots) are same question. Their results are compared to estimate the contrast of students' interest and motivation between before and after the experimental science class.

D. *Questionnaire Results*

Table II also shows averages (ave.) of Q.1 to Q.11, and numbers provided in parentheses are standard deviations (s.d.). The numbers of respondents who answered "yes" or "no" in Q.12 are also shown. In addition, Fig. 10 shows comparisons between Q.1 and Q.5, Q.2 and Q.6, Q.3 and Q.7, Q.4 and Q.8. In Tables II, we can find that students' interest and motivation were affected through this experiment. That is, evaluation

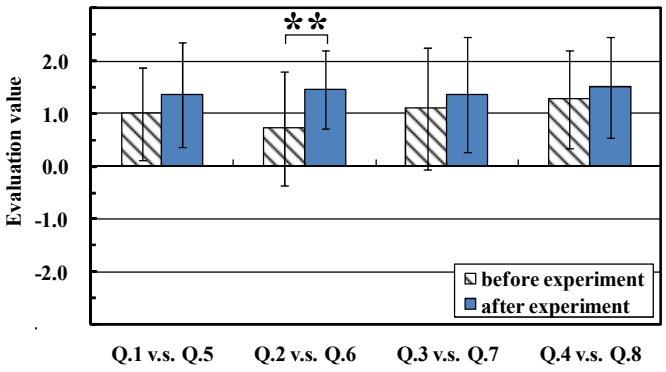

Figure 10. Comparisons between paired questions (Q.1 and Q.5, Q.2 and Q.6, Q.3 and Q.7, Q.4 and Q.8)

values of Q.1, Q.2, Q.3, and Q.4 are higher than values of Q.5, Q.6, Q.7, and Q.8 respectively. Wilcoxon signed-rank test was also applied to each pair, and its results are shown in Fig. 10. The results revealed a significant difference in the pair of Q. 2 and Q.6 ($p < .01$). Therefore, the class conducted with SAYA enhanced students' interest in science classes.

In addition, it is confirmed that concentration of students was low because evaluation value of Q.9 (concentration on the class) is relatively lower than those of other questions. The results of Q.10 and Q.11 indicate that students could understand SAYA's explanations and teaching materials easily, and students wanted to participate in the classes again. In Q.12, 17 of 22 students answered "Yes". That is, it is confirmed that the operator replied to them correctly through SAYA.

V. CONCLUSION

In this paper, a remote class support system was proposed as a one of applications of telecommunication system in which the android robot SAYA was used as an interface. SAYA has human-like appearance and can interact with humans with human-like body movements such as facial expressions, head movements, and eye-orientation. A remote control system of SAYA was also developed for the remote class support system, and this system allows an operator to control SAYA's behaviors and observe students' behaviors remotely. In addition, the principle of leverage was adopted as the topic of a science class, and the scenario of the class concerning that topic was made. Then, the science class with SAYA was carried out in an elementary school to investigate how the proposed educational system affects students' interest and motivation.

Results of field trial reveal that students came to like science class. That is, it is expected that this system enhanced students' interest in science classes. However, other students' interest and motivation (interest in science and technology, interest in robots, and interest in a class conducted by robots) were not affected significantly even though their evaluation values were higher than before the trial.

Our future work is to investigate how students' attributions (familiarity with robots, science classes, and science and technology) affect to changes of their interest and motivation through experience of the class conducted by SAYA. In addition, various topics of science classes will be prepared, and the proposed educational system should be compared with other existing media such as video-conference system. Also, it would be interesting to investigate contrasts between the proposed educational system and human teacher.

***Abstract*— A multimodal gesture recognition method is proposed based on Choquet integral by fusing information from camera and 3D accelerometer data. By calculating the optimal fuzzy measures for the camera recognition module and the accelerometer recognition module, the proposal obtains enough recognition rate 92.7% in average for 8 types of gestures by improving the recognition rate approximate 20% compared to that of each module. The proposed method aims to realize the casual communication from humans to robots by integrating nonverbal gesture messages and verbal messages.**

Keywords- Gesture Recognition; Sensor Fusion; Choquet Integral; Human-Robot Interaction; 3D Accelerometer

I. INTRODUCTION

Recognition of human motions is greatly needed for communication between humans and robots in social robot systems such as service robots, entertainment robots, and household robots, that need to assist human with hospitality attitude in daily life. The casual communication robotic system, e.g., mascot robot system [1, 2], has been proposed based on verbal information to assist human in living environment. As for nonverbal approaches, gesture recognition has recently become attractive research themes in the field of Human-Computer Interaction (HCI) for robotics [3], human behavior studies [4], emotion [5] and sign language [6] recognition, and virtual environment navigation [7]. Most works on the gesture recognition for HCI have been done based on visual information, in terms of Hidden Markov Models(HMM) [8], Dynamic Time Warping(DTW) [9], and Self Organizing Markov Map(SOMM) [10]. Camera based human gesture recognition system often gets moving information of body parts (hands and head) by applying skin color tracking method. It is, however, easy to have a noise effect by the object that has similar color of the skin [11]. On the other hand, application of accelerometer data to gesture recognition is an emerging technique to improve recognition performance. A wearable acceleration sensor based air writing system that recognizes the gestures of writing alphabets is proposed in [12].

A multimodal gesture recognition system is proposed in [13], where information of both 3D acceleration and image are combined based on fuzzy logic. In the study, when the similarity calculated from the acceleration recognition modules is greater than given threshold value, the recognition result from the accelerometer module is taken as the final result. In reverse, image recognition module processes the candidate gestures that come from acceleration module to get final result. They, however, have not discussed about how to decide the given threshold. So, it is difficult to use the method for other cases of gestures in general.

To improve the robustness of [13], a Choquet integral[14] based multimodal gesture recognition method is proposed, where human gestures are recognized based on the fusion of video images and 3D acceleration sensors. The Angular Metrics for Shape Similarity (AMSS) [15] algorithm is employed to evaluate the similarity between gesture templates and input data from above two modules separately. Next, the optimal fuzzy measures of Choquet integral are calculated from the training data by a hill climbing algorithm. In the fusion processing, the fused similarities are calculated from similarities of both modules by Choquet integral. Finally, the gesture with maximum fused similarity is chosen as the recognition result.

In II, the multimodal gesture recognition system based on camera and 3D accelerometers is proposed. The experiments to confirm the proposal and discussion are presented in III.

II. MULTIMODAL GESTURE RECOGNITION SYSTEM

The architecture of the proposed gesture recognition system is shown Fig. 1.

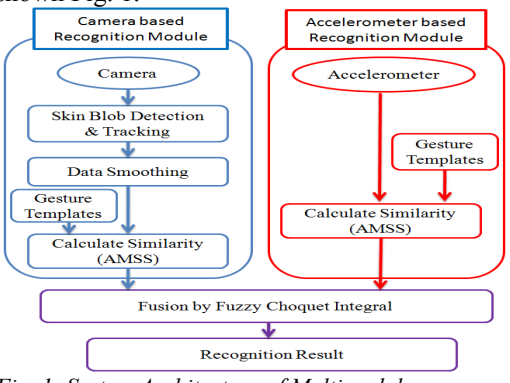

Fig. 1: System Architecture of Multimodal Gesture Recognition System

The system consists of two modules, i.e., camera based gesture recognition module and accelerometers based gesture recognition module.

A. Camera based Gesture Recognition Module

1) Skin Blob Detection and Tracking

The skin blob detection and tracking module uses the HSV color space because the HSV color space is suitable for detecting human's skin color. A pixel's color is identified as the skin color if the HSV value of this pixel exists in certain color ranges set in advance. The possible range of skin color, however, is changed according to the environment, and the final assigned range in the experiment is $2 \le H \le 14$, $65 \le S \le 180$, and $20 \le V \le 250$ by using OpenCV Library. It is confirmed that the three regions of the head and two hands parts are detected in the skin blob detection processing module.

The detected blobs are labeled from the first frame, i.e., the blobs in the left side and right side of the frame are labeled as hands, and the blob between two hands is labeled as head. From the second frame on, the nearest blob to the blob in the previous frame will be marked as the same label.

2) Feature Extraction and Data Smoothing

To recognize gestures, the 2D locations of blobs' centers are used as the features. The locations of left hand, head, and right hand are denoted as $\{x_l, y_l\}$, $\{x_h, y_h\}$, and $\{x_r, y_r\}$, respectively.

In the feature extractions part, the following two processes are done on the raw data:

a) Data Smoothing: Simple moving average of 3 adjacent points is used to smooth raw data, i.e.,

$$x_{smoothing} = (x_{i-1} + x_i + x_{i+1}) /3, \quad (1)$$

where xi stands for the raw locations of blobs.

b) Quantization: The DTW (Dynamic Time Warping) algorithm mentioned in 3.1.4 is used for recognizing gestures. The complexity of the DTW algorithm is dependent on the length of the input sequence and template sequence. The short length of sequences contributes to the performance improvement of recognition. If the distance between a point and its nearest point of the trajectory is shorter than 10 pixels, the point is ignored; otherwise the point is added to the points' sequence of trajectory.

3) Camera based Gesture Recognition by AMSS

The Dynamic Time Warping (DTW) is widely used for matching time series by calculating the optimal distance between two time series based on dynamic programming. The Angular Metrics for Shape Similarity (AMSS) [15] algorithm is used to calculate the similarity between gesture sequence and template sequence, which is a robust improvement of DTW algorithm. Instead of calculating the distance of elements in conventional DTW, the AMSS takes the cosine value of the intersection angular of two trend vectors, which is computed by neighboring element of each time series, as the distance measurement. The warping path is computed through the whole distance matrix. The similarity of two time series is calculated as the average value of accumulated value on optimal warping path.

The AMSS algorithm is based on trend vectors which are scale-invariant, so it has the power for recognizing user-independent gestures. Besides, due to its efficiency and simplicity, the AMSS algorithm is selected as the main recognition algorithm.

The recognition rate of DTW based system is greatly dependent on the quality of the reference template. Accordingly selecting reliable template is one of the important tasks in the training process. There are several methods for template selection such as random selection, minimum selection, normal selection, and multiple selection [16]. After checking from the cost performance viewpoint, minimum selection is used to select the appropriate template for the gesture recognition.

B. Accelerometer based Gesture Recognition Module

Two 3D acceleration sensors are used for capturing the motion of human's two hands.

The sequence of feature values are taken as the input of the accelerometers based gesture recognition module. The AMSS is used for measuring the similarity of input sequence and template sequences. The average similarity of the 3-axes is taken as the similarity of this module.

C. Proposed Fusion Method based on Choquet integral

The information obtained from two accelerometers and a camera is different in accuracies and frequencies. This information is processed by different preprocessing and recognition algorithms. The recognition result comes from accelerometers and camera is not additive. Thus, a Choquet integral based method is proposed for fusing the similarity of accelerometers and camera based recognition modules.

The Choquet integral is proposed by Murofushi and Sugeno[14]. Let $S^a_{i,g,t}$ denotes the similarity between the i-th training data of g-th gesture and the t-th template sequence by the accelerometers based module, and $S^c_{i,g,t}$ the similarity calculated from the camera based module. M^c_g and M^a_g stand for the fuzzy measure of camera module and the accelerometer module of g-th gesture template separately. Then, the fused similarity calculated by Choquet integral [14] is shown as

$$C_{i,g,t}\left(S^c_{i,g,t}, S^a_{i,g,t}, M^c_g, M^a_g\right) = \begin{cases} S^a_{i,g,t} + (S^c_{i,g,t} - S^a_{i,g,t}) \times M^c_g, if\,(S^c_{i,g,t} \ge S^a_{i,g,t}) \\ S^c_{i,g,t} + (S^a_{i,g,t} - S^c_{i,g,t}) \times M^a_g, if\,(S^c_{i,g,t} < S^a_{i,g,t}) \end{cases} . \quad (2)$$

The difference of similarity error between i-th training data of g-th gesture and the misrecognized gesture is calculated as

sponsor*(JSPS: Japan Society for the Promotion of Science)*

$$f\left(i,g,M_1^a,M_1^c,...,M_G^a,M_G^c\right) = \max_{k\in\{1,...,T\}}\{C_{i,g,k}\} - C_{i,g,g} \quad , \quad (3)$$

where G denotes the number of gesture, and T is the number of templates.

Then, the problem of finding the optimal fuzzy measure $\left({}^*M_1^a, {}^*M_1^c,..., {}^*M_G^a, {}^*M_G^c\right)$ from all training data can be modeled as

$$\min_{\left(M_1^a,M_1^c,...,M_G^a,M_G^c\right)} \sum_{g\in\{1,...,G\}}\sum_{i\in\{1,...,TN\}} f\left(i,g,M_1^a,M_1^c,...,M_G^a,M_G^c\right), \quad (4)$$

where TN is the number of training data for each gesture.

The optimal fuzzy measure value of both modules cannot be calculated exactly, but it can be found approximately. A hill climbing based algorithm is employed to find the optimal fuzzy measure. The algorithm is demonstrated as follows:

Step-0: Initialize $\left(M_1^a,M_1^c,M_2^a,M_2^c,...,M_G^a,M_G^c,\right)$ randomly in the range of between 0 and 1 by uniform distribution.

Step-1: Calculate the fused similarity from the two modules by equation (2), and then calculate the recognition rate from the training data.

Step-2: Preserve current parameters if the recognition rate in step 1 is better than the best training rate before.

Step-3: For each gesture *g* in {1, 2, ..., G}, similarity error of all training data is calculated by changing the parameters and one step forward and backward as in equation (3). And then the minimum of these similarity errors is found.

Step-4: If the minimum similarity error calculated in step 3 is greater than the similarity error before parameter adjustment, then it has reached to the local minimum similarity error, so exit the loop.

Step-5: Update the changes if it is less than the current error, and go back to step 1.

III. Experiment on Multimodal Gesture Recognition

A. Experimental Environment

To demonstrate the validity and applicability, the proposed method is confirmed by using the gestures from the mascot robot system. The experiments on the mascot robot system are complex and require a lot of time, therefore, the authors here did the offline experiments on eight types of gestures, which are used in the mascot robot system.

The proposed method is implemented on each of notebook PCs with Intel® Core2Duo 2.54GHz, 2GB of RAM by using Visual C++ 2008 and OpenCV 2.1 library for video processing on Windows system. Two 3D accelerometers and a web camera are used to track movements of parts of a body in experiments. The wearable accelerometers (W=45mm, D=45mm, H=20mm), manufactured by Microstone Inc.[17], are used to get three dimensional acceleration data of human body movements in (x, y, z) 3D space, and the accelerometer transmits these 3D movement data via a Bluetooth connection. Each human participant wears accelerometer on his/her wrists as shown in Fig. 5. The video sequences are captured by a Logicool Qcam(R) Connect camera mounted on a notebook PC with 30 fps rate and 320x240 pixels resolution.

Eight gestures are employed in the home party scenario experiments. Each name and description of the eight gestures is;

(G1) Toast: Raising a hand with a glass upwards from the waist level.

(G2) Throw dart: Moving a hand with a dart forward speedily from the head level.

(G3) Victory pose: From the relaxed position besides legs, the right hand is raised up to a level between the chest and the head. (This motion expresses happiness when the dart hits the target.)

(G4) Banzai pose: Both hands are first put down besides legs and then both are held right up. (This motion expresses happiness when the dart hits the target.)

(G5) Squatting with hands over the head: From the relaxed position the besides legs, both hands are put on the head and human participant squats. (This expresses disappointment when the dart loses the target.)(Fig. 2)

Fig. 2: G5 (Squatting with hands over the head). The blue, red, green lines are the trajectory of the three body parts.

(G6) Face covering: Both hands are first put down besides legs and then right hand is held at face. (This expresses sadness when the dart loses the target.) (Fig. 3)

Fig. 3: G6 (Face covering).

(G7) Guiding: From their relaxed position, the right hand beside legs is swung up to the point towards the right direction.

(G8) Bye-bye: Both hands are first put down besides legs and then right hand is waved iteratively at right side.

The eight types of gestures are performed by 6 experimenters for five times separately (240 gestures in total).

B. Training the value of fuzzy measure

The main task in the training phase is to select the proper template and to calculate the optimal fuzzy measure values for similarities fusion.

The dataset includes 240 data which is divided into a training set and a testing set for each gesture with the ratio of 3:2. As mentioned in 3.1.3, the minimum selection is used to choose the suitable template. To find the optimal fuzzy measure values, the following three steps are done;

(1) Similarity calculation: Calculate the similarities of camera and accelerometers modules separately for all of the training data.

(2) Similarity normalization: Each training data is compared to the eight templates. That is, it will get eight similarities for each input data. Then these eight similarities are normalized in the range of [0, 1], i.e., dividing by the maximum of the eight similarities.

(3) Finding optimal measure value: The algorithm illustrated in 3.3 is implemented for calculating the optimal fuzzy measures for each gesture.

Because the algorithm mentioned in 3.3 is the one relied on initial values, it is executed for many times to get the approximate global optimal fuzzy measures. The fuzzy measures which achieve best recognition rates from the training data are considered as the optimal fuzzy measures for evaluating test data.

In this experiment, the algorithm is applied for 100 times with step value of 0.05, which achieves the best recognition rate of 97.9% by the training data. Table 1 demonstrates the initial and calculated final fuzzy measures of the two modules in the training stage.

Table 1: The initial and final values of fuzzy measure

Gesture	Camera Module		Accelerometers module	
	Initial	Final	Initial	Final
G1	0.5	0.6	0.9	0.85
G2	0.3	0.4	0.9	0.6
G3	0.5	0.45	0.8	0.3
G4	0.5	0.8	0.4	0.3
G5	0.4	0.7	0.3	0.5
G6	0.4	0.25	0.1	0.75
G7	0.1	0.25	0.9	0.55
G8	0.5	0.5	0.9	0.75

C. Result of Multimodal Gesture Recognition and Discussion

The recognition result of the camera based and the accelerometers based modules are given in Table 2 and Table 3. According to Table 2, G1 (toast gesture) shows the worst result of the camera based recognition module. Because G7 (guide gesture) has the similar trajectory to G1 (Fig. 4), 10 data of G1 are misrecognized as G7 and 6 data of G7 are misrecognized as G1. For some gesture (i.e. G6) obtained better recognition result in the camera based recognition module, while some gestures (i.e. G7) got better recognition result in the accelerometers module.

Table 2: Gesture Recognition Results of camera based recognition module

Gesture	Gesture category								
	G1	G2	G3	G4	G5	G6	G7	G8	Total
G1	**18**	0	1	0	0	1	10	0	30
G2	2	**19**	0	0	0	0	9	0	30
G3	0	0	**20**	0	0	2	8	0	30

Fig. 4: The trajectories (shown in green) of G1 and G7

Table 3: Gesture Recognition Results of accelerometers based recognition module

Gestures	Gesture category								
	G1	G2	G3	G4	G5	G6	G7	G8	Total
G1	**14**	0	3	10	1	1	0	1	30
G2	0	**30**	0	0	0	0	0	0	30
G3	0	0	**9**	5	13	2	0	1	30
G4	0	0	0	**16**	14	0	0	0	30
G5	0	0	0	6	**24**	0	0	0	30
G6	0	0	4	4	7	**15**	0	0	30
G7	0	0	0	0	0	0	**30**	0	30
G8	0	0	0	0	0	0	0	**30**	30

The recognition rate of training data and test data is shown in Fig. 5. By calculating the optimal fuzzy measure of fuzzy

Choquet integral, the proposed fusion method achieves an average recognition rate of 92.7%, which is 19.4% higher than the average recognition rate of both modules. Seven of all eight gestures achieve higher recognition rate than the one of each modules. For the large difference of the both modules' recognition rate, the recognition result of G7 is affected by the recognition result of camera module so that it gets lower recognition rate than the rate of accelerometers modules. The proposed multi-modal recognition method obtains the average evaluation value of 92.7%, i.e., the highest recognition rate in the averages of all gestures.

	G1	G2	G3	G4	G5	G6	G7	G8	Avg
Camera Only	60.0%	63.3%	66.7%	80.0%	100.0%	83.3%	66.7%	93.3%	76.7%
Accelerometer Only	46.7%	100.0%	30.0%	53.3%	80.0%	50.0%	100.0%	100.0%	70.0%
Training(Proposal)	94.4%	100.0%	100.0%	100.0%	100.0%	94.4%	100.0%	94.4%	97.9%
Test(Proposal)	91.7%	100.0%	75.0%	100.0%	100.0%	83.3%	91.7%	100.0%	92.7%

Fig. 5: The recognition rate of training data and test data in proposed multimodal gesture recognition system

This result confirms the practical applicability of the proposed multi-modal recognition method compared with other the recognition methods which are based on a single sensor.

IV. CONCLUSION

A Choquet integral based multimodal gesture recognition method is proposed. The proposal achieves the highest recognition rate in the 8 types of gestures. More than 92.7% of gestures are recognized as for all types of gestures, which show the proposed multimodal gesture recognition method advances to the recognition methods based on single sensor.

The proposed multimodal gesture recognition provides casual communication abilities for the Mascot Robot System, where robots assist humans in view of the home party atmosphere based on recognitions of verbal and nonverbal messages from humans. Multimodal sensing based Emotion Spaces and Fuzzy Atmosfield [18] will enable robots to help humans according to the atmosphere in all social situations by integrating verbal and nonverbal communication cues from humans and robots, such as speech, gesture, and facial expression.

***Abstract*—Emotional states based three-dimensional (3-D) Fuzzy Atmosfield (FA) is proposed to express the feeling between humans and robots in communication, and is built with 3-D coordinates, i.e. "friendly-hostile", "lively-calm", and "casual-formal" axes. The FA aims to be an effective tool to proceed with the communication paying attention to the atmosphere generated by individual emotional state which is calculated from bimodal communication cues namely emotional-speech and emotional-gesture by using weighted fusion and fuzzy inference. A novel emotion recognition approach is presented which consists of two steps, i.e., classification of six basic emotions for initial emotional states in the Affinity-Pleasure-Arousal emotion space, and emotional transition from prior state by using fuzzy logic. Home party enjoying demonstration confirms FA's availability empirically by questionnaires from unrelated persons of authors' group, where smooth communication between four humans and five eye robots is realized in Mascot Robot System.**

Keywords- human-robot communication; emotion recognition; emotional state; communication atmosphere; fuzzy inference

I. INTRODUCTION

Affecting computing, playing a significant role in human-robot interactions, has been paid more and more attention, where how to identify atmosphere amongst communicators as well as attitude, mood, and emotion of interlocutors, and how to provide a comfortable environment to eliminate the barriers between humans and robots, have become the main objectives for the next generation of intelligent robots.

Emotion recognition, a popular topic in recent years, has attracted increasing attention from researchers involved in a variety of discipline e.g. psychology, computer science, linguistics, neuroscience, and related disciplines [1]. Multiple channels of information during communication are used to analyze emotional states of humans including speech, facial expression, body gesture, posture, and so on [2-5]. Few studies, however, concentrate on communication atmosphere which is easily felt but hard to define, and even more difficult to evaluate, and it is never finished, static or at rest [6, 7]. In [8], human expressive communication is analyzed by exploiting interrelation between speech and gestures. A 3-D communication atmosphere is built by using audio-visual modals, where only face-to-face communications between two participants are considered in recognition [7]. Most of previous researches concentrate on analysis of personal mood without understanding the atmosphere which is composed of all emotional states of humans in the communication.

Fuzzy Atmosfield is proposed to describe mood states among communicators being generated from not only the verbal and non-verbal information of speakers, but also background music or noise. Bimodal information based emotion recognition is carried out in two steps: 1. Emotion of the interlocutor is classified on the basis of six primary emotions, i.e. "happiness", "surprise", "fear", "anger", "disgust", and "sadness", which are predetermined as the initial emotional states in Affinity-Pleasure-Arousal emotion space; 2. Emotional state's transition is executed by using fuzzy logic on speech features including volume, average frequency, and interval time. Fuzzy inference and expert rules are employed to build Fuzzy Atmosfield from individual emotion spaces, and a 3-D space defined as "friendly-hostile", "lively-calm", and "casual-formal" axes is presented to express Fuzzy Atmosfield. Experiments for Fuzzy Atmosfield are performed with four humans and five eye robots in a household environment by using Mascot Robot System. The results based on questionnaires verify availability of proposed methods.

The emotion recognition based on bimodal communication cues is mentioned in II. In III, emotional states based Fuzzy Atmosfield by using fuzzy inference and expert rules is presented. The experiments for Fuzzy Atmosfield in Mascot Robot System are given in IV.

II. EMOTION RECOGNITION BASED ON BIMODAL COMMUNICATION CUES

A. Overview of the Model's Architecture

This work was supported by Japan Society for the Promotion of Science (JSPS) KAKENHI 21300080

Emotion recognition based on bimodal information, i.e. emotional speech and gesture, is proposed to express the emotional states of interlocutors in Affinity-Arousal-Pleasure space. Fig. 1 shows the procedure of the proposed emotion recognition method, where there are two steps.

- Initial states of emotion are determined by fusing semantic cues from speech and the gestures of communicators.
- Starting from the initial/previous state of emotion, transition of emotional states in the 3-D emotion space is executed by using fuzzy inference considering the influence from features of speech.

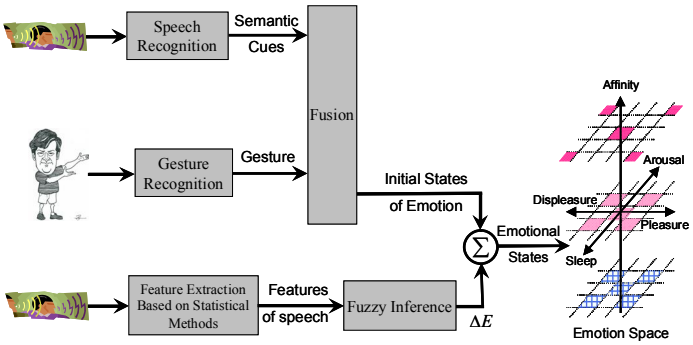

Figure 1. Emotion recognition based on bimodal information

B. *Affinity-Pleasure-Arousal Emotion Space*

A 3-D emotion space named Affinity-Pleasure-Arousal space is used to illustrate the mentality state of speakers during communication. By using the Affinity-Pleasure-Arousal plane, it is not only possible to express fixed mentality states but also to take into account rapid variations in the mentality state due to time involving communication [9], as shown in Fig. 2.

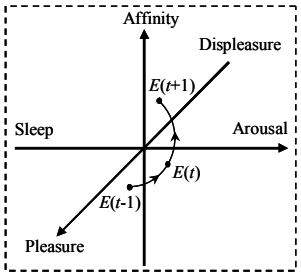

Figure 2. Emotion space expressed in 3-D axes

Affinity-Pleasure-Arousal emotion space is defined with fuzzy domains that can be indicated as

$$E = (e_{affinity},\ e_{pleasure},\ e_{arousal}),$$
$$\forall e_{affinity} \in [-1,\ 1],\ \forall e_{pleasure} \in [-1,\ 1],\ \forall e_{arousal} \in [-1,\ 1] \quad (1)$$

where $e_{affinity}$, $e_{pleasure}$, $e_{arousal}$ are the values in "affinity", "pleasure-displeasure", and "arousal-sleep" axes, respectively. The membership functions for these three axes are shown in Fig. 3.

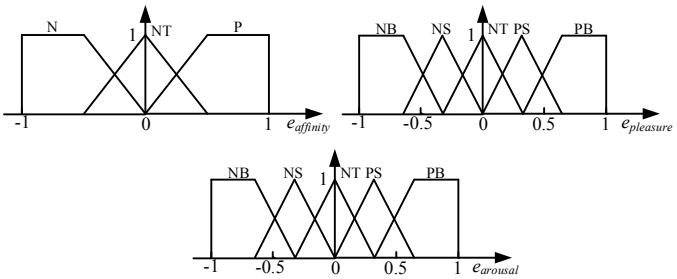

Figure 3. Membership functions for emotion space axes

C. *Semantic Cues from Emotional Speech*

Automatic speech recognition (ASR) system is developed for general robot systems by NEC Corporation in the Development Project for a Common Basis of Next-Generation Robots led by the NEDO organization. Its functions include single word speech recognition, noise canceller, sound source directional detection, speaker independent recognition and dictionary switching, i.e. it can select a specific dictionary fitting with current conversation topic. The speech recognition principle in the ASR is a word-matching search based on pre-defined dictionary.

Traditionally, research on the recognition of emotion from semantic cues of speech was focused on the discovery and utilization of emotional keywords, that is, specific words that express the speaker's emotional state [10]. To take advantage of the function of single word recognition in ASR, emotional keywords from speech are selected for emotion recognition.

Six primary emotions [11], i.e., "happiness", "surprise", "fear", "anger", "disgust", and "sadness", are employed as the initial state of emotion recognition. The contribution from any emotional keyword w to one of the six basic emotion e_i is defined as $P(e_i|w)$ which is calculated in a training phase by its frequency of occurrence under the observation of the emotion on the basis of large emotional speech corpus.

D. *Emotional Gesture Recognition*

Although semantic cues of speech, to some extent, could reflect emotional state, the variety and complexity of language makes it difficult for researchers to recognize emotional states from pure textual information. Emotional-gesture, another available modal in communication, is necessary adopted for emotion recognition, which can originate from any bodily motion or state but commonly originate from the hand or face.

A multi-modal information based hand gesture recognition system is developed by authors' group [12, 13], where emotional gestures are recognized based on multi-modal sensing, i.e., the combination of the 3-D acceleration sensor and web cameras. The gesture recognition system includes two modules, i.e. the acceleration sensor recognition module and the image recognition module. After fusing above two independent module's results, emotional gestures are recognized finally. In the same way as emotional keywords, the contribution from any gesture g to one of the six basic emotion e_i is defined as $P(e_i|g)$ which is calculated in the data training of a large gesture database.

E. Emotion Recognition by Weighted Fusion

Weighted fusion is one kind of techniques for decision-level fusion, which arrives at the final classification decision by combining the weights of individual recognition. The basic idea behind this approach is with the hypothesis that the overall recognition rate will be improved by combining pieces of evidence provided by independent sources.

Information fusion of bimodal communication cues, i.e., semantic cues of speech and gesture is executed by using weighted fusion. Through calculating the sum of each emotion probabilistic from keywords of speech and gestures, the emotion e_i, receiving the maximum of probabilistic contribution, will be output as the final recognition result of emotion, as shown in Fig. 4. If it fails to receive only one kind of emotion, then jump to the recalculate procedure.

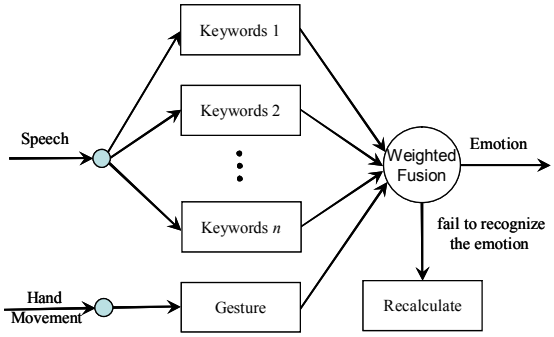

Figure 4. Emotion recognition by weighted fusion

Emotion recognition based on bimodal information outputs one of the six primary emotions as the initial coordinate in Affinity-Pleasure-Arousal emotion space, where is predetermined according to the relationship between six primary emotions and three axes of the emotion space.

F. Transition of Emotional States in Emotion Space

To recognize the real emotional states of communicators, features of speech such as volume, average frequency, and interval time are assigned to inputs for transition of emotional states. Fuzzy inference method is accepted to establish the relation-ship between voice features and the variation of three axes from previous position in Affinity-Pleasure-Arousal emotion space, as shown in Fig. 5.

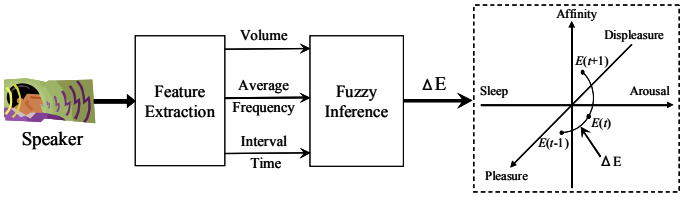

Figure 5. Emotion space of speaker using fuzzy inference

After completion of the feature extraction module, the ratio of two voices' volume, ratio of average frequency between speaker's and standard, and interval time between two utterances are used for fuzzy inference in transition of emotional states. The membership functions for these features are shown in Fig. 6.

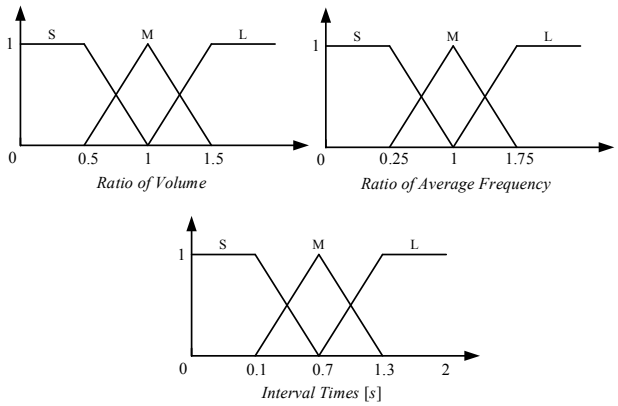

Figure 6. Membership functions for speech features

The fuzzy rules of ΔE, namely $\Delta e_{affinity}$, $\Delta e_{pleasure}$ and $\Delta e_{arousal}$ based on speech features are shown in Table I, Table II, and Table III, respectively.

TABLE I. FUZZY RULES OF $\Delta E_{AFFINITY}$

		Ratio of Average Frequency		
		S	M	L
Ratio of volume	S	N	P	P
	M	N	NT	P
	L	N	P	P

TABLE II. FUZZY RULES OF $\Delta E_{PLEASURE}$

		Ratio of Average Frequency		
		S	M	L
Ratio of volume	S	N	P	P
	M	N	NT	P
	L	N	P	P

TABLE III. FUZZY RULES OF $\Delta E_{AROUSAL}$

		Interval Time		
		S	M	L
Ratio of volume	S	NT	NT	N
	M	P	NT	N
	L	P	P	NT

To obtain the values of $\Delta e_{affinity}$, $\Delta e_{pleasure}$ and $\Delta e_{arousal}$ in Affinity-Pleasure-Arousal space, the center of gravity method is used as a defuzzification method, and then $E(t) = E(t-1) + \Delta E$.

The transfer of emotional states is one continuous process in the 3-D emotion space, as the smooth curve connecting $E(t-1)$, $E(t)$, and $E(t+1)$ in Fig 1. For instance, when the speaker stops talking, emotional state is in the process of diminishing but not at origin (neutral state).

III. FUZZY ATMOSFIELD BASED ON EMOTIONAL STATES

Fuzzy Atmosfield is invisible but it is supposed to exist by occupying space and containing energy. It reflects the mood states of communication between speakers, and affects the emotional states of humans as well. Thus, Fuzzy Atmosfield is not just a natural phenomenon, bus also one kind of "psychological field", associated with individual emotional states, background music, and noises, etc. In this paper, only emotional states are concerned.

A. *Fuzzy Atmosfield described in a 3-D Space*

Atmosfield (Atmosphere Field, i.e., atmos' field) exists in the space surrounding us. It is created in the process of communication between speakers, producing "psychological feeling" that can give influence to the process and results of humans' behavior. Due to its special characteristic of "psychological field", it could not be calculated as accurately as some physic's fields such as electrical field and magnetic field, and therefore, is defined as Fuzzy Atmosfield.

Fuzzy Atmosfield is illustrated in a 3-D space defined by "friendly-hostile", "lively-calm", and "casual-formal" axes, which is determined by questionnaires from 10 peoples on 20 different occasions [14], as shown in Fig. 7.

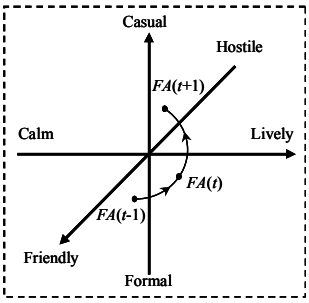

Figure 7. Fuzzy Atmosfield expressed in 3-D axes

To construct Fuzzy Atmosfield, the proposed 3-D space with fuzzy domains is described firstly as

$$FA = (a_{friendly},\ a_{lively},\ a_{casual}),$$
$$a_{friendly} \in [-1,\ 1],\ a_{lively} \in [-1,\ 1],\ a_{casual} \in [-1,\ 1] \tag{2}$$

where $a_{friendly}$, a_{lively}, a_{casual} are the values in "friendly-hostile", "lively-calm", and "casual-formal" axes, respectively. The membership functions for Fuzzy Atmosfield's axes are shown in Fig. 8.

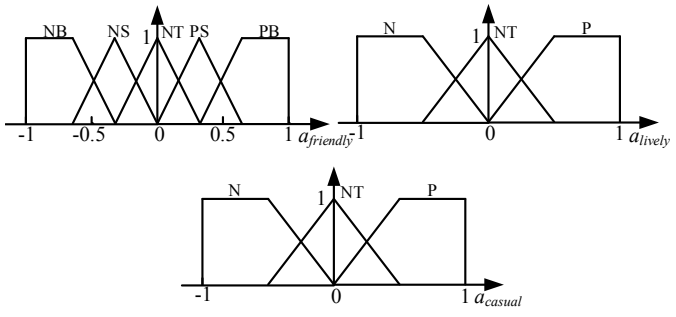

Figure 8. Membership functions for Fuzzy Atmosfield axes

B. *Scheme of Fuzzy Atmosfield*

The scheme of Fuzzy Atmosfield based on emotional states of communicators is presented as shown in Fig. 9. First of all, the emotional states of all participants in the conversation have been obtained in emotion recognition system (for humans) or emotion synthesis system (for robots). Secondly, information fusion module of emotional states is executed, where fuzzy inference is employed to express the relationship between Fuzzy Atmosfield and emotion space, and with the utilization of speaker's volume, some expert rules are arranged to realize the mapping from *n* emotion spaces to Fuzzy Atmosfield. At last, the atmosphere state is given in the 3-D Fuzzy Atmosfield.

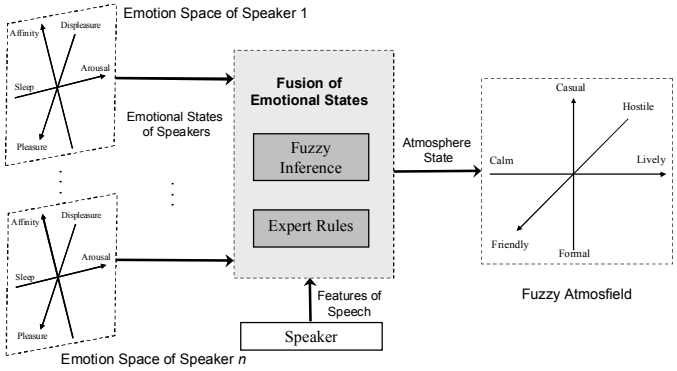

Figure 9. Scheme of Fuzzy Atmosfield

C. *Emotional states based Fuzzy Atmosfield*

As mentioned in II, Fuzzy Atmosfield is composed of individual emotion spaces. Meanwhile, the changing of atmosphere state is a continuous process as well as emotional state. In a word, at time *t*, the transfer of atmosphere state in Fuzzy Atmosfield is not only related to the atmosphere state at time *t*-1, but also the new emotional states of communicators stimulated from external environment. Therefore, the formula of Fuzzy Atmosfield can be defined as

$$FA(t) = \begin{cases} f(E_1(t),\ \cdots,\ E_n(t)),\ t = 1 \\ (1-\lambda)FA(t-1)\cdot\gamma + \lambda f(E_1(t),\ \cdots,\ E_n(t)),\ t > 1 \end{cases} \tag{3}$$

where FA is the atmosphere state in Fuzzy Atmosfield; f is the function of emotional states E at time *t*; *n* is the number of speakers involved in the communication; γ is the decreasing function of $FA(t-1)$, and γ is an undetermined function, $0 \le \gamma \le 1$; λ is the correlation factor, $0 \le \lambda \le 1$; When $t = 0$, FA is at initial state where is set beforehand.

Considering different contribution of individual emotional states to Fuzzy Atmosfield, weighted average method is accepted to construct function f in

$$f:\ \sum_{i=1}^{n} w_i \cdot defuzzy(\underset{\sim}{E}_i(t) \circ R),\ i = 1,\ 2,\ \ldots,\ n \tag{4}$$

where R is the relationship between emotion space and Fuzzy Atmosfield, which is obtained by using fuzzy inference, and 75

fuzzy rules are arranged to build R; $\underset{\sim}{E}_i(t)$ is fuzzy set of emotion space of ith communicator; the center of gravity method is used as a defuzzification method in *defuzzy*; w_i is the weight of ith emotion space contributing to the Fuzzy Atmosfield, $\forall w \in [0,\ 1]$, $\sum_{i=1}^{n} w_i = 1$. It can be illustrated as shown in Fig. 10.

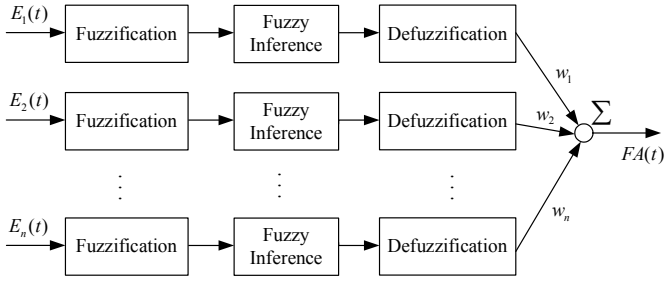

Figure 10. Flow chart from emotion spaces to Fuzzy Atmosfield

D. *The weights of* w_i

To analyze the contribution of each emotion space, the role of each participant for altering communication atmosphere should be considered, i.e., the actions such as speech, facial expression, and other body movements should be taken into account. In this paper, volume of speech is employed for computing the weights of each emotion space. At time t, w_i is calculated as

$$w_i = \frac{v_i}{\sum_{j=1}^{n} v_j},\ i = 1,2,\ \ldots,\ n,\ j = 1,2,\ \ldots,\ n \tag{5}$$

where v is the volume of speaker.

E. *The weight of* λ

Considering the influencing factors for communication atmosphere, volume of speech is used to determine the correlation factor λ in equation (3). Some expert rules are formulated by using ratio of volume $v(t)$ and $v(t-1)$ as

$$ra_{volume} = \frac{\sum_{i=1}^{n} v_i(t)}{\sum_{i=1}^{n} v_i(t-1)} \tag{6}$$

where ra_{volume} is the ratio of volume $v(t)$ and $v(t-1)$, and

$$\lambda = \begin{cases} 0, & if\ \sum_{i=1}^{n} v_i = 0 \\ \frac{1}{2} \cdot ra_{volume}, & if\ ra_{volume} < 1 \\ \frac{1}{2}, & if\ ra_{volume} = 1 \\ 1 - \frac{1}{2}\exp(-(\frac{ra_{volume} - 1}{\sigma})^2), & if\ ra_{volume} > 1 \end{cases} \tag{7}$$

where σ is an undetermined parameter.

IV. Experiments for Fuzzy Atmosfield

The proposed Fuzzy Atmosfield is evaluated by performing communication experiments with four humans and five eye robots in Mascot Robot System (MRS). The MRS is an information presentation system destined to be used mainly as an information terminal in a home environment for casual communication with humans [15]. The five eye robots include four fixed robots (placed on a TV, a darts game machine, an information terminal, and a mini-bar) and 1 mobile robot, as shown in Fig. 11.

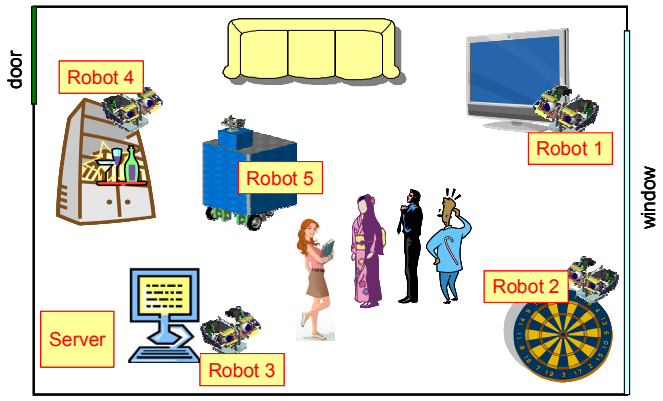

Figure 11. Household environment for humans and robots

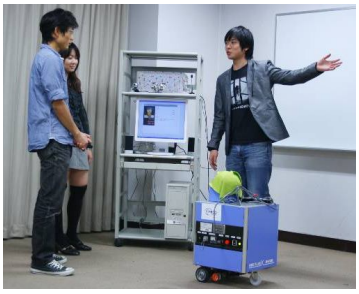
An ideal household environment is created that is a relatively quiet place without background music or noises. Six scenarios are performed in the experiment, i.e., Scenario 1: "Greeting guests at the door", Scenario 2: "Drinking at the bar", Scenario 3: "Playing dart game", Scenario 4: "Watching TV", Scenario 5: "Checking timetable of train at the terminal computer", Scenario 6: "Farewell with guests at the door". Each scenario is designed with dialog between humans and robots, where eight types of typical human emotional gestures [11], including "Toast", "Throw dart", "Victory pose", "Banzai pose", "Put both hands on head and squat", "Put hand on one's face", "Guiding", and "Goodbye", are performed as well. Fig. 12 shows the photo and dialog of Scenario 5, where a conversation is taken place between Host, Guest 1, Guest 2, and Robot 3 (the information terminal robot).



Robot 3: [Which station?]
Host: Shibuya.
Robot 3: [Trains heading out of the city?]
Host: Yamanote line. To Shinagawa.
[Display PC shows the timetable.]
Guest 1: That's just right.
Guest 2: Thank you.
Robot: You're welcome.
Host: So let's go to the door.

a) The photo of Scenario 5 b) The dialog of Scenario 5

Figure 12. The scenario 5 of "Checking timetable of train"

Emotional state of each person is obtained by proposed emotion recognition approach with high recognition rates, while robots' emotion spaces are established in expression synthesis system [9] which is developed by the authors' group.

To integrate individual emotional state of humans and robots, in the experiments, some parameters of Fuzzy Atmosfield's model are decided empirically, i.e., $\gamma = e^{0.1}$, $\sigma = 2$. The Fuzzy Atmosfield of Scenario 5 in home party is built by using proposed method, as shown in Fig. 13, where the coordinate of the sphere's center is $FA(t)$, and the diameter d which represents the variation of atmosphere state is calculated as

$$d = \min\{\frac{1}{\sqrt{3}}\sqrt{[a_{friendly}(t) - a_{friendly}(t-1)]^2 + [a_{lively}(t) - a_{lively}(t-1)]^2 + [a_{causal}(t) - a_{causal}(t-1)]^2}, 0.1\}. \quad (8)$$

The results of Fuzzy Atmosfield based on questionnaires by 10 peoples verify availability of proposed methods. Smooth communication between 4 humans and 5 eye robots in home party proceeds with harmonious atmosphere, where robots can recognize the atmosphere state in real time. And then, through classification, identification, and response, robots could adjust talking contents and tones to improve communication atmosphere.

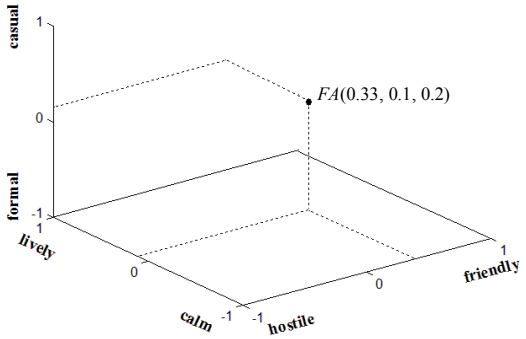


Figure 13. Fuzzy Atmosfield of Scenario 5 in home party

V. Conclusions

To express affective states during human-robot communication, the concept of Fuzzy Atmosfield is proposed, where it is composed of individual emotional states of humans and robots.

On the basis of bimodal communication cues including speech message and gesture message, first emotion classification is carried out in accordance with six basic emotions which are predetermined as the initial states in Affinity-Pleasure-Arousal emotion space; second transition of emotional state is executed by using fuzzy logic on some speech features. With the fusion idea of emotional states, Fuzzy Atmosfield is created by using fuzzy inference and expert rules. Being convenient to observe for users, a 3-D space with "friendly-hostile", "lively-calm", and "casual-formal" axes is introduced to express Fuzzy Atmosfield. Results of experiment demonstrate the availability of Fuzzy Atmosfield in a home party with smooth communication proceeded between 4 humans and 5 eye robots.

The proposed Fuzzy Atmosfield aims to realize casual communication in multi-human and multi-robot environments, not only integrating the mood expression of individuals, but also providing good guidance for robots to improve communication atmosphere by adjusting the content of speech, improving the way of communication, or playing harmonious music, and so on.

In-depth study on assignment of appropriate parameter in the model of Fuzzy Atmosfield will continue in the further researches. In addition, more verbal or non-verbal information except speech and hand gesture would be considered to construct Fuzzy Atmosfield, for example, facial expression, head movements, and other body languages. Furthermore, the background music or noise would be essential factors for Fuzzy Atmosfield.

***Abstract*— Friendly user interface is desired for robots and computer systems which support human in all areas of daily life, e.g., information service, educational system, support service for elderly, etc.. Presence expressions by eye robot is proposed, where the eye robot expressions help human to more deeply understand robot, and then effectively provide their service in its situation e.g., a personal learning program and an entertainment program. The proposed presence expression is applied a personal education system that involves the eye robot, learning contents on a laptop PC with a web camera, a wii remote (Nintendo Co.,Ltd.) for measuring attention span of a subject based on 3D accelerometer information. To estimate effects of presence expression by the eye robot, subjective questioner is performed in the personal education system. Three type of leaning programs are conducted by the system for 10 subjects with subjective questionnaires evaluated with the 3-poin scale. The results show that the proposed expressions by the eye robot help the subject to feel like one is watching and to have an uncanny impression. As a result, the system has enabled the subjects to take the program with feeling of tension. This research plans to apply computer go system, another personal educational and entertainment system, where the system realizes casual communication in the games.**

Keywords-component; communitation robotics, computer Go, presence expression, casual communication

I. INTRODUCTION

Computer systems with computational intelligence technique is helping supporting human in all areas of daily life, e.g., information service, games, educational system, support service for elderly, etc.. In these systems, e.g. e-learning system and computer game, intelligent agents are working to assess their situations and to decide actions according to personal actions and data [1] [2]. One thing these systems have in common is one-to-one interactive situations between system and human when these systems present information to human. For assisting inputs of these types of system, evolutionary robot vision approach has been proposed for face detection [3]. For assisting outputs of one-to-one interactive systems, friendly user interface is requested communication robots, interactive interfaces that can communicate with human in a natural way.

Presence expressions by eye robot is proposed, where the eye robot expressions help human to more deeply understand robot, and then effectively provide their service in its situation e.g., a individual learning program and an entertainment program. The proposed presence expression is applied a personal education system that involves the eye robot, learning contents on a laptop PC with a web camera, a wii remote (Nintendo Co.,Ltd.) for measuring attention span of a subject based on 3D accelerometer information. To estimate effects of presence expression by the eye robot, subjective questioner is performed in the personal education system. Three type of leaning programs are conducted by the system for 10 subjects with subjective questionnaires evaluated with the 3-poin scale.

II. COMUNICATION ROBOTIC SYSTEM

Friendly user interface is strongly desired for computer system that support human in all areas of daily life, e.g., information service, educational system, support service for elderly, etc.. Communication robots have been developed as interfaces that can communicate with human in a natural way. Human comprehend others including nonhuman, e.g., robots by constructing virtual model in their own mind through their interaction, where presence is important. Communication robots are media that mainly show their presence according to their own appearance. The android robot, Geminoid HI-1 that appears and behaves like a living person have represented specified personal presence by teleoperating [4]. Telenoid-R1 is designed to appear and to behave as a minimalistic human, where the Telenoid-R1 has expressed unspecified personal presence in the distance [5]. As a real application for group education system, the android SAYA is applied for a remote class system at an elementary school, where SAYA conduct the class with her effective presence by using her voice and eye contact [6].

As a casual communication interface, an eye robot have been proposed, where the eye robot interacts with human by friendly eye expressions. The eye robot is developed based on the mechanisms of the human eye [7]. Eye motions consist of eyelid motion and ocular motion. This motion set is one of the components of casual communication. The structure of the

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

eyelids part and the ocular part is shown in Fig. 1. The eye robot has 2 degrees of freedom (D.O.F) for the eyelids part and 3 D.O.F for the ocular part. The eye robot covers a wider range with each motion of the eye than is possible with human eyeballs. Therefore the eye robot can sufficiently simulate a human being's eye motions. The picture of the eye robot is shown in Fig.2, where the eye robot expresses representative motions. The size of the eye robot is 130 mm in width, 80 mm in height, and 75 mm in depth. This size is inspired by the size of a five-year-old child's head.

The eye motion of eye robot is defined as the combination of eyelid motion and ocular motion. Eyelid motion and ocular motion are independent in the pleasure-arousal plane. All motions of the eyelids and eyeballs have the tendency to change according to each axis of the pleasure-arousal plane. The motions are assigned to the 25 different partitions of the pleasure-arousal plane based on psychological knowledge and results from the questionnaire survey. The eye robot realizes casual communication between human and system by expressing mentality and intention according to human action based on affinity pleasure-arousal space.

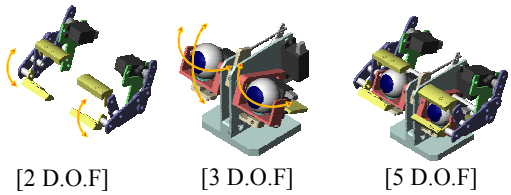

Figure 1. the structure of the robot

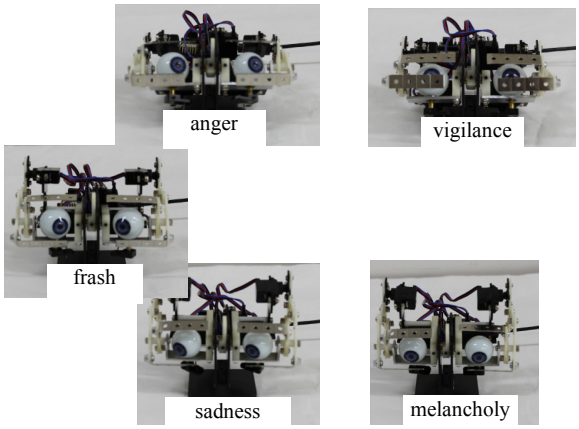

Figure 2. the representatiove motions of the eye robot

III. THE STRUCTURE OF THE ROBOTPRESENCE OF ROBOT FOR COMPUTER GO

In 2, communication robot systems are introduced, where robots assist human with expressing their presence. This type of robots can provide casual information system by combining with information system.

A. Presence expression using robotic agent for co-creation

Presence of communication robots works effectively in human-robot interaction. Presence of robots depends on their appearance, and the appropriate appearance should be selected on a case-by-case basis. In home environment, presence of robot should be restricted from the view point of size and expression manner, where space is limited and interpersonal distance is small. Presence expressions by the eye robot as a small and casual communication robot is proposed in home environment, where the presence expression encourage cooperation between human and robot system, and realize human-robot co-creation in home-use personal education system and entertainment system.

B. Individual learning system and Computer Go system

The presence expressions are applied individual learning systems and entertainment systems requiring individual learning. The presence by a robot has worked effectively in the group-learning situation [6]. In individual learning situations in home environment, robot's size and expression manner should be restricted considering the robot is on human side. In this research, the eye robot as a small and casual communication robot is used for assistant of human learner.

This individual learning system is able to be combined to entertainment systems requiring individual learning, that is computer Go system that has already developed on a CG basis [1].

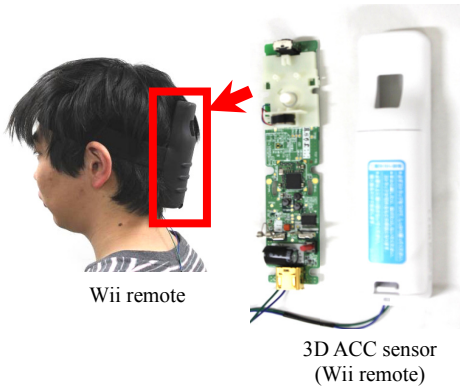

Figure 3. the 3D ACC sensor unit

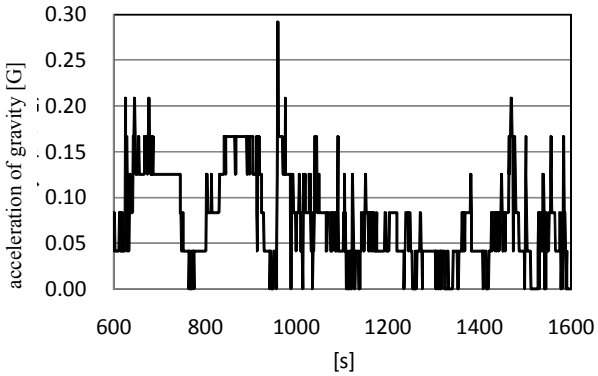

Figure 4. the sample data of ACC sensor

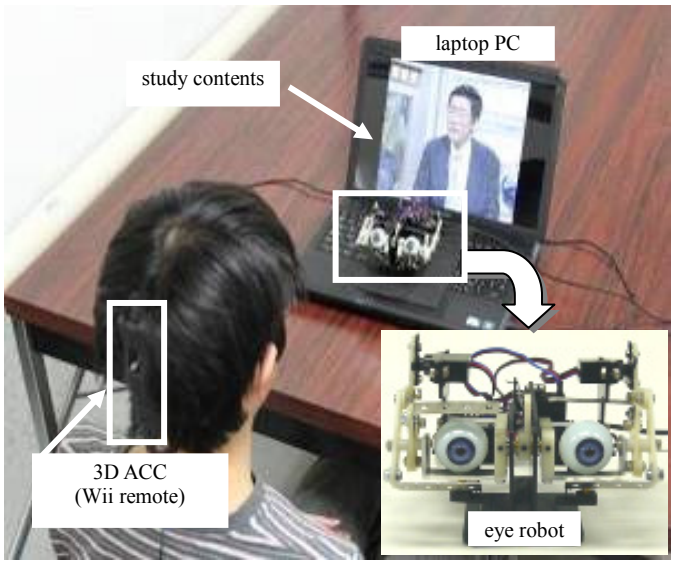

Figure 5. the expresimental situation by individual learning system

IV. INTERPERSONAL EXPERIMENTS FOR EVALUATING PRESENCE EXPRESSION

To estimate effects of presence expression by eye robot, subjective questioner is performed in personal education system. To perform effectively, memory experiments should be performed implicitly. At first psychological evaluation experiments are expressly performed in a mascot robot system environment. In the psychological evaluation experiments, memory experiments are performed implicitly.

A. Evaluation Experiments on Interactions based on Subjective Estimation

To estimate human impressions on the proposed presence expression by eye robot, interactive experiments are performed in individual learning situation by using a multimedia system. In the experiments, subjective estimations by questionnaires are conducted. In addition, attention spans are measured.

Experimental situation involves the learning contents on a laptop PC with a web camera, the eye robot, a subjective that wears wii remote (Nintendo Co.,Ltd.) for measuring his/her attention span based on 3D accelerometer information. The experiment's disposition is shown in Fig.3, and an obtained data example from accelerometer is shown in Fig.4.

To verify the influence of proposed presence expression, the following three types of action patterns are performed by the system according to the human behavior information, and compared to one another. The first pattern is that the eye robot expresses alert motion in incremental steps with voice (pattern 1: present expression with voice). The second is that the system alert with voice when a subject loses his/her consideration, but without eye robot (patter 2: voice). The third is that the system does not any alert without eye robot (pattern 3: nothing). In the experiments, these three patterns are performed in no particular order.

For the experiment, three types of the highschool-level learning contents (geography, earth science, and domestic science) are prepared, where the 30-minute learning movies are played on the PC. The procedure of the experiments is as follows;

Step1) the subject is informed about the experiment and the eye robot, and wears a wii remote on the head.

Step2) the subject start an individual learning program. The system behaves according to the attention of the subject in a predetermined one of three patterns.

Step3) after the learning program, the subject fills out a test on the learning contents. After that test, subjective questionnaires on nine items are conducted.

Step4) steps2) and 3) are repeated for the three action patterns in the same way.

The subjective questionnaires are evaluated with the 3-poin scale. The items of the subjective questionnaires are as follows;

1) Have you had the class about the learning contents?

2) Could you concentrate on the learning program?

3) Did you take the program with a feeling of tension?

4) Did you feel like one is being watched?

5) Did you feel friendly?

6) Did you feel the presence of human?

7) Did you have an uncanny impression?

8) Did you feel the learning contents interesting?

9) Was the alert done at the right time?

The subjects for the experiment are 10 engineering students.

B. Result of the Experiments

The results of the subjective estimations are shown in Fig.5. These figures show the mean values obtained for each question in the three action patterns. The subjective questionnaires are evaluated on a 3-poin scale of zero to two. Low values imply negative, and high values imply positive effect. Table I gives the average frequency of the head-nodding movement. Table II gives the average value of the attention span in the 30-minutes learning program. Table III gives the average score of the test on the learning contents, and this graph is shown in Fig. 7.

Fig. 2 shows that the pattern 1 is evaluated as the most positive on (3), (4), and (7), and the pattern 3 is the most positive on (2) and (8). Tab. I and Tab. II show the pattern 3 is the lowest, where the subject's head move less often than any others. Tab. III and Fig. 7 show that the pattern1 get most high score, but there is not so major deference.

These mean that first, the proposed expression by the eye robot shows the presence, and then the subject feel like one is watching and have an uncanny impression. As a result, the subject could take the program with feeling of tension.

On the other hand, the subjects feel no action is the fittest situation to concentrate the learning contents. And the frequency of the head movement is the lowest when the system dose nothing. But the "pattern 3: nothing" gets the lowest score in the memory test even though there is not so large deference. These result that the system has a possibility not to grasp the subject in foggy state, where the subject doesn't move his/her head, and spread his/her focus.

As all results, it have been confirmed that the proposed expression by the eye robot shows the presence in the individual learning system, and then the subject feel like the robot is watching and the subject have been able to take the program with feeling of tension.

V. CONCLUSION

The presence expressions by eye robot is proposed, where the eye robot expressions help human to more deeply understand robot, and then effectively provide their service in its situation e.g., a personal learning program and an entertainment program. The proposed presence expression is applied a personal education system that involves the eye robot, learning contents on a laptop PC with a web camera, a wii remote (Nintendo Co.,Ltd.) for measuring attention span of a subject based on 3D accelerometer information. To estimate effects of presence expression by the eye robot, subjective questioner is performed in the personal education system. Three type of leaning programs are conducted by the system for 10 subjects with subjective questionnaires evaluated with the 3-poin scale. The results show that the proposed expressions by the eye robot help the subject to feel like one is watching and to have an uncanny impression. As a result, the system has enabled the subjects to take the program with feeling of tension.

This research plans to apply computer go system, another personal educational and entertainment system, where the system realizes casual communication in the games.

Abstract— **A bi-modal emotion recognition approach is proposed for recognition of four emotions that integrate information from gestures and speech. The outputs from two uni-modal emotion recognition systems based on affective speech and expressive gesture are fused on a decision level fusion by using weight criterion fusion and best probability plus majority vote fusion methods, and the performance of classifier which performs better than each uni-modal and is helpful in recognizing suitable emotions for communication situations. To validate the proposal, fifty Japanese words (or phrases) and 8 types of gestures that are recorded from five participants are used, and the emotion recognition rate increases up to 85.39%. The proposal is able to extent to using more than other modalities and useful in automatic emotion recognition system for human-robot communication.**

Keywords- Emotion Recognition; Decision-level Fusion; Expressive Gesture; Affective Speech

I. INTRODUCTION

In the last years, emerging research in human-robot communication is daily life support robot system such as entertaintment robots system, service robot system, or household robot system. In such systems, robots communicate with humans friendlity by talking to humans and expressing the emotion [1,2] coresponding to the humans' speeches. The casual communication between humans and mutiple robots via both of humans' speech and gestures has proposed in mascot robot system [3, 4]. Recognition users' mood or emotional state is main key to determining the coressponding emotion of robots. Most of the work analizes the human emotion by verbal and non-verbal information. For instance, the emotion recognition using only speech by combining acoustic and semantic analyses [5], and the bi-modal emotion recognition using visual information from expressive face and body gestures [6]. Morerever, the most approach is fusion of both speech information and gesture information [7], also including the expressive faces [8,9].

In this work, the bi-modal emotion recognition is proposed by combining the information from speech, hands and simple body gestures. The motivation of the proposal is improve social communication between humans and robots in assist robot systems. Fisrt, the two uni-modal emotion recognition system for human's speech and gesture are performed separately. Then, at the decision-level fusion, the output of the two uni-modalities are fused by using weight criterion fusion and majority vote fusion methods. The 50 Japanese word or phrases and 8 type of gestures that are using in mascot robot system are used to perform the emotion recognition accuracy.

In II, the overview of mascot robot system is presented. In III, two uni-modal emotion recognitions based on speeches and gestures multimodal are presented; bi-modal emotion recognition on decision-level fusion is proposed. The experiments to confirm the proposal is presented in IV.

II. MASCOT ROBOT SYSTEM

The mascot robot system (MRS) is an information retrieval and recommendation system for household environments which is able to use casual communication between humans and robots through humans' speeches and gestures. In this system, the robots need to recognize human's speeches and give back the actions corresponding to semantic of requirements. Also, the emotional reactions are appeared to do friendly casual communication. The MRS is developed as a national project with the purpose of developing the Common Basis of Next-Generation Robots led by the New Energy and Industrial Technology Development Organization (NEDO 2005-2008), and now under the support from Japan Society for the Promotion of Science (JSPS 2009-2012). The construction of MRS is shown in Fig.1.

In the home environment such as living room, the fixed type robots are setup on furniture and appliances such as the TV, a dart, information retrieval monitor, drink bar, and a self-propelled type mobile robot. Each robot is controlled by a PC. The common server which controls whole system and the four fixed robots are connected using local area network, LAN cables, while the connection with the mobile robot is achieved via a wireless LAN. The overall management server controls and supervises the whole system, allowing it to coordinate the action of the whole group of robots.

In order to connect the system, the Robot Technology

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

middleware (RTM) [10] is used to construct the network system which is called RTM-Network as shown in Fig.2. In RTM-Network, each robot can be viewed as a network component and each function unit of every robot is called a robot technology component (RTC).

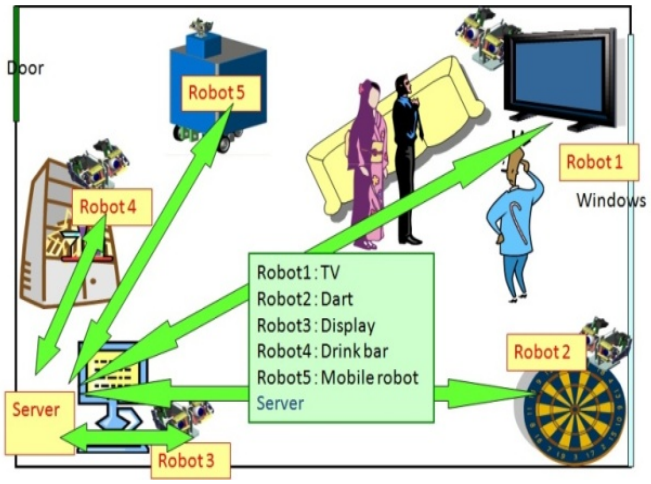

Figure 1. Mascot robot system in a home environment

Every robot is composed of a controlled PC, a microphone,a web camera, a Speech Recognition Module (SRM), a Gesture Recognition Module (GRM), and an Eye robot. The input speeches and gestures that are gotten from the microphone and web camera are processed and then indicated the recognition result on the PC display or written down the information in a log file through the RT Middleware network system. Depending on the recognition results, the eye robot expresses their corresponding emotions through designated actions, and the other actions or talking with people from five robots.

The eye robot on its part has a pair of eyeballs and eyelids. The eyeball movement is based on fuzzy control (up and down, left and right) and serves to express different emotions such as happiness, sadness, surprise, and anger. The eye robots are shown in Fig.2, the appearance of mobile eye robot is shown in Fig.3.

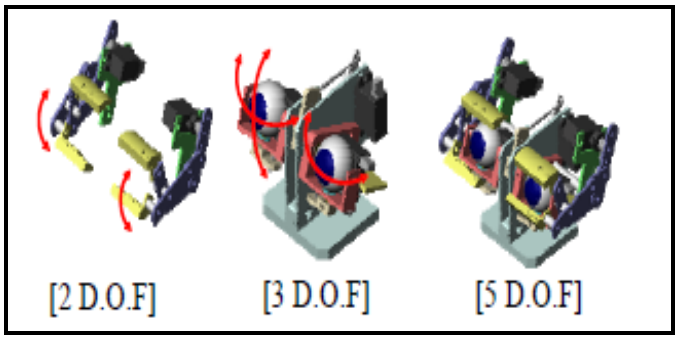

Figure 2. Structure of eye robot

Figure 3. Mobile type eye robot

A host and three guests are considered as users of the MRS. The MRS is ascertained the validity based on a typical situation scenario where the MRS performs representative function of the system. The specification of the scenario is as follows. When the users mention something to the robots that requires an affinity response (for example, "this is interesting", "we won the game", or doing banzai pose, etc...), the system searches for and subsequently provides information based on the user's speech and gestures. Communication between the user and the system is established by the user's speech and gestures to the robots and the robot's response as an emotional expression, as well as displaying information on a screen. For example, the MRS can propose cocktail recipes or provide companionship during a game of darts and reacting accordingly to the performance of the players. The MRS could also take cues from baseball games on TV and offer the user information about the players participating in the game. Futhermore, MRS presents the atmosphere of communications from emotion expresstions of humans and robots.

III. BI-MODAL EMOTION RECOGNITION

A. Uni-modal Emotion recognition

1) Uni-modal Emotion Recognition based on Speeches

To achieve the speakers' emotion based on their speeches, both acoustic analysis and semantic analysis are used in recently research. Here it is assumed that the speakers' expresstion of their emotion consists in meaningful talking words or phrases. Therefore, an approach in spotting for emotional information is needed. In order to reduce the complexity and reduce the cost of speech recognition module (SRM), in this work, free software Julius is used to recognize the human's speech under the RT middleware [10]. The RT-Middleware aims at establishing a common platform based on the distributed object technology and which would support the construction of various networked robotic systems by the integration of various network enabled robotic elements called RT-Components. The concept of the Julius based SRM is shown in Fig.4. There are two RT components to recognize humans' speech. The first component- PulseAudioInput is using a microphone to get the speech signal. The second component-pyJulius is using Python language to recognize the input speech signal. The speech based uni-modal emotion recognion is using the data that collect from 4 people using in

home party scenario in mascot robot system [3,4]. There are five emotion extract from the communicaiton in mascot robot system: happiness, sadness, supriseness, and neutral.

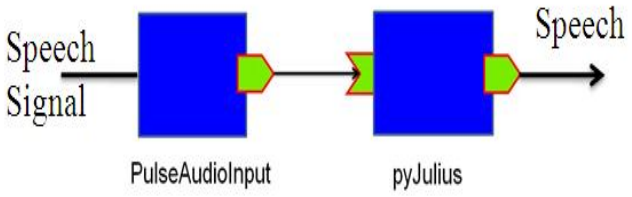

FigURE 4. RTM based speech recognition module

2) Uni-modal Emotion Recognition based on Gestures

Recognition of human emotion from body and hands movements is unresolved in non-verbal communication. In gesture based emotion recognition uni-modal, 8 types of gestures in mascot robot system [3, 4] are used to detect the corresponding emotions. Table 1 provides the list of gesture emotion categories recognized by the system.

The fuzzy Choquet integral [12] based multimodal gesture recognition method is used, where human gestures are recognized based on the fusion of video images and 3D acceleration sensors. The Angular Metrics for Shape Similarity (AMSS) [11] algorithm is employed to evaluate the similarity between gesture templates and input data from the two modules above separately. Next, the optimal fuzzy measures of the Choquet integral are calculated from the training data by a hill climbing algorithm. In the fusion processing, the fused similarities are calculated from similarities of both modules by Choquet integral. Finally, the gesture with maximum fused similarity is chosen as the recognition result. The architecture of the gesture recognition system is shown Fig.5.

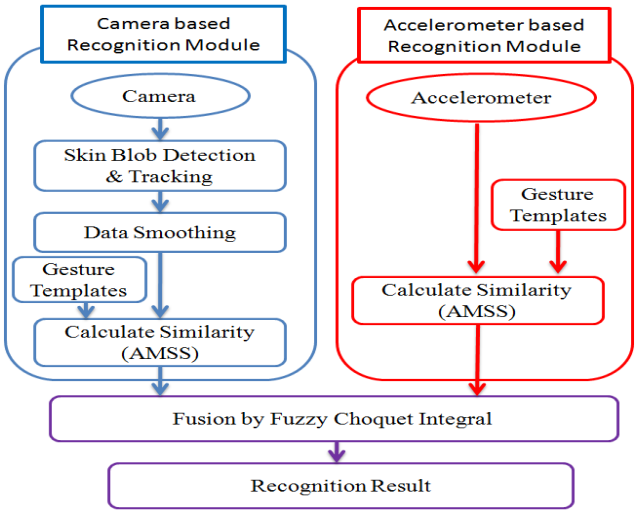

Figure 5. System Architecture of Multimodal Gesture Recognition System

a) Feature Extraction from Acceleration Data

With each gesture time series data, the maximum and minimum are calculated at first. Then the parameters of mean, variance, and mean crossing rate are calculated by:

$$mean = \sum_{k=1}^{N} sample_k / N \quad (1)$$

$$variance = \sum_{k=1}^{N} (sample_k - mean)^2 / N \quad (2)$$

$$mcr = \sum_{k}^{N-1} \mathrm{sgn}(sample_k - mean) - \mathrm{sgn}(sample_{k+1} - mean) \quad (3)$$

where N is the number of total samples of a gesture in the time series data. All of the parameters have be calculated on axis x, y, and z.

In order to indentify the gesture from the eight types of gestures, the Angular Metrics for Shape Similarity (AMSS) [11] is used for measuring the similarity of input sequence and template sequences. The average similarity of the 3-axes is taken as the similarity of this module.

b) Image Recognition Module

Gestures are also recognized by video image processing along with acceleration sensor recognition to help make decisions when the system cannot recognize the gestures from acceleration sensor which is the main part of algorithm. Video image sequences are captured while a web camera is put in front of the human within home environment background. The gesture is extracted from each frame in the stream by three main steps: skin-color detection, head and hands tracking and rules matching.

c) Skin Color Detection and Tracking

The skin detection algorithm is based on the HSV (Hue-Saturation-Value) color space with its robustness to the way that humans tend to perceive colors. Generally, a pixel's color can be considered as skin color if $h_{min} < H < h_{max}$ and $s_{min} < S < s_{max}$,where H,S, and V are the pixel's color components in the HSV color space and, h_{min}, h_{max}, s_{min}, s_{max} are the threshold values. From this operation, three regions including the head and two hands can be found as groups of skin color areas.

B. Bi-modal Emotion Recognition based on Speeches and Gestures

After describing the two uni-modal emotion recognition systems based on semantic information of speech and gestures separately, the effective bi-modal emotion recognition system based on both human's speech and gestures is proposed to do the casual communication between humans and robots. By fusing speech and gesture modalities at the decision level, the combined emotion is classified. The structure of the bi-modal emotion recognition is shown in Fig.6. In the decision level, the output is computed combining the probabilities of the two uni-modal modules. Various researches have been proposed such as sum rule, product rule, median rule, majority vote, etc.

In this work, two different approaches are used to get output emotions by combining the posterior probabilities of the two uni-modal systems. The first approach selects the emotion that received the best probabilities in the two uni-modal system. When each uni-modal system gives the output of different emotion with same probabilities, majority vote is used (in this case, the highest voting for speech based uni-modal system) to get suitable emotions. The second approach selects the emotion using the weight criterion rule. Suppose that, α is assigned as the weight of speech based uni-modal system, β is assigned as the weight of gesture based uni-modal system.

Then, the output emotion is defined by using the weight criterion rule is shown as

$$\text{Emotion (i)} = \arg\max_{i=1,2,\ldots,M} \{ \alpha p(e_i|S) + \beta p(e_i|G) \}, \quad (4)$$

where M denotes the maximum of possible emotions, $p(e_i|S)$ and $p(e_i|G)$ denote probabilities of i^{th} emotion that gotten from each speech based emotion recognition system and gesture based emotion recognition system. Cause of speech is still main language in daily communication, α and β are assigned 0.7 and 0.3 respectively.

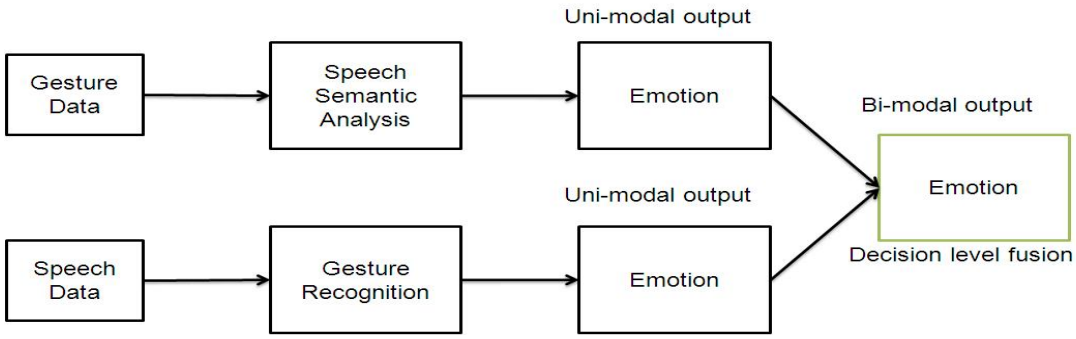

Figure 6. Bi-modal emotion recognition based on speech and gesture

Table 1. 8 types of emotional gestures recognized by the system

Happiness
(G1) **Victory pose**: From the relaxed position besides the legs, the right hand is raised up to a level between the chest and the head.
(G2) **Banzai pose**: Both hands are first put down besides legs and then both are held right up.
Sadness
(G3) **Face covering**: Both hands are first put down besides the legs and then the right hand is held at face.
(G4) **Bye-bye**: Both hands are first put down besides the legs and then the right hand is waved iteratively at right side.
Disappointment
(G5) **Squatting with hands over the head:** From the relaxed position hands besides the legs, both hands are put on the head and human participant squats.
Neutral
(G6) **Toast**: Raising a hand with a glass upwards from the waist level.
(G7) **Dart throwing**: Moving a hand with a dart forward speedily from the head level.
(G8) **Guiding**: From their relaxed position, the right hand beside legs is swung up to the point towards the right direction.

IV. EXPERIMENTS ON BI-MODAL EMOTION RECOGNITION

A. Data Collection

Five participants (4 male and 1 female) within the age range 22 - 30 took part in the recording. The participants are three different nationalities: Japanese, Chinese, and Vietnamese. Fifty (50) Japanese word and phrases, and 8 type of gestures that are used in home party scenario of mascot robot system are recorded. The sample frames of banzai pose gesture are shown in Fig.7.

Figure 7. Banzai pose gesture

B. *Emotion Recognition Results*

1) *Speech based emotion recognition*

Table 2 shows the performance of the uni-modal emotion recognition based on speech. The overall performance of this classifier is 70%. Happiness is recognized with high rate (87.67%). Sadness and Disappointment have lower rates (60.33% and 6.33% respectively).

Table 2. Confusion matrix of emotion recognition based on speeches

	Happiness	Sadness	Disappointment	Neutral
Happiness	87.67	3.33	3.33	5.67
Sadness	3.67	60.33	26.33	9.67
Disappointment	0	23.33	62.33	14.34
Neutral	7.33	13.33	11	68.34

2) *Gesture based emotion recognition*

Table 3 shows the performance of the uni-modal emotion recognition based on humans' gestures. The overall performance of this classifier is 88.5%. Disappointment is classified with the highest rate (96.67). Happiness has the lowest recognition rate of 83.33%.

Table 3. Confusion matrix of emotion recognition based on gestures

	Happiness	Sadness	Disappointment	Neutral
Happiness	83.33	0	0	16.67
Sadness	1.67	85	0	13.33
Disappointment	0	3.33	96.67	0
Neutral	5.55	5.55	0	88.89

3) *Decision-level fusion*

In daily communication, speech is still the main language to express meaningful moods and emotions. Then here the weight criterions are set 0.7 and 0.3 for speeches based uni-modal and gestures based uni-modal respectively. Table 4 shows the performance of the emotion recognition bi-modal based on both speech and gestures. The accuracy of majority vote approach is higher than that of weight criterion.

Table 4. Confusion matrix of emotion recognition based on decision-level fusion

	Weight Criterion	Majority Vote
Happiness	86.67	86.33
Sadness	63.34	80.22
Disappointment	76.63	90.67
Neutral	78.48	84.34
Overall	76.28	85.39

V. CONCLUSIONS

A bi-modal emotion recognition approach is proposed for recognition of four emotions (happiness, sadness, disappointment, and neutral) that integrates information from humans' speech and gestures. The outputs from two uni-modal emotion recognitions based on speech and gestures are fused on the decision level fusion by using weight criterion fusion and best probability plus majority vote fusion methods. The performance of the classifier was found to be better than each of the uni-modal recognition system and is more helpful in recognizing suitable emotions for communication situations. Firstly, two uni-modal emotion recognition are performed under the 50 Japanese word or phrases and 8 types of gestures that are recorded from five participants. Then, two approaches on the decision-level fusion are performed and obtained 76.28% and 85.39% respectively. The proposal is able to extent to using more than other modalities and useful in automatic emotion recognition system for human-robot communication.

***Abstract*—A linear fuzzy clustering model based on Fuzzy c-Medoids (FCMdd) was proposed for extracting intrinsic local linear substructures from relational data. In the same way with Non-Euclidean Relational Fuzzy (NERF) c-Means, β-spread transformation was also proved to be useful for handling non-Euclidean relational data in FCMdd-type linear clustering. In this paper, the FCMdd-type linear clustering model is further modified in order to handle incomplete data including missing values. In several numerical experiments, it is demonstrated that some pre-imputation strategies contribute to properly selecting representative medoids of each cluster.**

***Keywords*—relational clustering, linear fuzzy clustering, missing value.**

I. Introduction

Relational data analysis is an important technique for revealing intrinsic structure of relational data composed of mutual relations among objects. Besides the basic fuzzy clustering models for object-type data such as Fuzzy c-Means (FCM) [1], which is a fuzzy extension of k-Means [2], several relational fuzzy clustering models have been proposed for extracting cluster substructures from relational data. Relational Fuzzy c-Means (RFCM) [3] is the basic FCM-type relational clustering model, which can be identified with FCM when mutual relations are given by Euclidean distances. k-Medoids approach [5] is an alternative of FCM-type clustering where cluster prototypes are not given by mean vectors but are chosen from object sets. Krishnapuram *et al.* [4] extended (hard) k-Medoids to Fuzzy c-Medoids (FCMdd), in which the chosen object called "medoid" is the representative object of a cluster. FCMdd-type clustering models can easily be applied to relational data matrices without calculating cluster centroids in a intrinsic data space.

FCM-type linear fuzzy clustering models such as Fuzzy c-Lines (FCL) [6] and its variants [7] use linear-shape prototypes like lines, planes and linear varieties. Fitting lines or linear varieties to data sets, the linear clustering models perform fuzzy principal component analysis (fuzzy PCA) [8] in each cluster [9]. Haga et al. [10] proposed an FCMdd-type linear clustering model where each linear prototype is spanned by several representative "medoids".

This work was funded in part by the Ministry of Education, Culture, Sports, Science and Technology, Japan, under Grant-in-Aid for Scientific Research (20700214).

When relational data are not Euclidean, FCM-type and FCMdd-type clustering models cannot be directly applied because their algorithms are essentially designed for Euclidean data space. Hathaway and Bezdek [11] proposed non-Euclidean-type Relational Fuzzy (NERF) c-Means, in which a spreading transformation called β-spread transformation is performed in order to decrease the influences of non-Euclidean relations. Yamamoto *et al.* [12] applied the β-spread transformation to FCMdd-type linear clustering and demonstrated that a suitable data transformation is achieved by selecting proper parameter values automatically.

In [13], Hathaway and Bezdek demonstrated that the β-spread transformation is also useful for handling missing elements in relational data matrices, in which the bad influences of imputation errors are decreased by β-spread transformation. This paper demonstrates that the performance of FCMdd-type linear fuzzy clustering for incomplete relational data can also be improved by β-spread transformation through several experiments.

II. FCMdd-type Linear Clustering for Relational Data

A. FCM-type Linear Clustering

Assume that we have m dimensional observations of n samples $\boldsymbol{x}_i = (x_{i1}, \ldots, x_{im})^\top, i = 1, \ldots, n$ and that the goal is to partition the n samples into C clusters. The objective function for FCM-type clustering is defined as:

$$L_{fcm} = \sum_{c=1}^{C} \sum_{i=1}^{n} u_{ci}^{\theta} D_{ci} \tag{1}$$

where u_{ci} is the fuzzy membership degree of sample i to cluster c, and θ is the fuzzification parameter. The larger the θ, the fuzzier the membership assignment. The clustering criterion D_{ci} is the distance between sample i and the prototype of cluster c. Besides point-type prototypes in FCM, FCL used linear prototypes defined as:

$$Line_c(\boldsymbol{b}_c, \boldsymbol{a}_c) = \{\boldsymbol{x} | \boldsymbol{x} = \boldsymbol{b}_c + t\boldsymbol{a}_c; t \in R\}, \tag{2}$$

where $\boldsymbol{a}_c$ is the basis vector of the principal sub-space. The clustering criterion is calculated as:

$$D_{ci} = ||\boldsymbol{x}_i - \boldsymbol{b}_c||^2 - |\boldsymbol{a}_c^\top (\boldsymbol{x}_i - \boldsymbol{b}_c)|^2. \tag{3}$$

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

The updating rules for membership u_{ci} and the cluster center $\boldsymbol{b}_c$ are derived as:

$$u_{ci} = \left[\sum_{l=1}^{C} \left(\frac{D_{ci}}{D_{li}} \right)^{\frac{1}{\theta-1}} \right]^{-1}, \tag{4}$$

$$\boldsymbol{b}_c = \frac{\sum_{i=1}^{n} u_{ci}^{\theta} \boldsymbol{x}_i}{\sum_{i=1}^{n} u_{ci}^{\theta}}. \tag{5}$$

The basis vectors $\boldsymbol{a}_c$ are the principal eigenvectors of the generalized fuzzy scatter matrix:

$$S_{fc} = \sum_{i=1}^{n} u_{ci}^{\theta} (\boldsymbol{x}_i - \boldsymbol{b}_c)(\boldsymbol{x}_i - \boldsymbol{b}_c)^{\top}. \tag{6}$$

B. FCM-type Relational Clustering

When we have relational data composed of mutual relations among samples $D = \{d_{ij}\}$, the FCM-type objective function is redefined as [3]:

$$L_{rfcm} = \sum_{c=1}^{C} \sum_{i=1}^{n} \sum_{j=1}^{n} \frac{u_{ci}^{\theta} u_{cj}^{\theta} d_{ij}^2}{2 \sum_{t=1}^{n} u_{ct}^{\theta}}. \tag{7}$$

If the mutual relation d_{ij} is given by the Euclidean distance among samples i and j, the relational clustering model is equivalent to FCM with object-type data. However, the clustering model can derive only poor results if the relational information is not Euclidean.

In order to transform a non-Euclidean matrix to one of Euclidean form, Hathaway and Bezdek [11] considered the following β-spread transformation:

$$D_{\beta} = D + \beta \times (M - I), \tag{8}$$

where I is a unit matrix and β is a suitably chosen scalar. M is a matrix whose elements are all 1. It was shown that D_{β} is Euclidean if $PD_{\beta}P$ with $P = I - (1/n)M$ is negative semi-definite, i.e., β is greater than or equal to the largest eigenvalue of PDP. In NERF, β is gradually increased from 0 to a certain value by considering the negative elements of clustering criteria because negative values of the clustering criterion signal the non-existence of Euclidean space and indicate that the current value of β should be increased so that the basic RFCM iteration can be continued.

C. FCMdd-type Linear Clustering

Assume that d_{ij} is the mutual Euclidean distance such that

$$d_{ii} = 0, d_{ij} \geq 0, d_{ij} = d_{ji}, i, j = 0, \ldots, n. \tag{9}$$

FCMdd [4] is a fuzzy extension of k-Medoids, which performs an FCM-like clustering by selecting $\boldsymbol{b}_c$ from objects $\boldsymbol{x}_i$, $i = 1, \ldots, n$. The representative objects are called 'medoids'.

Haga et al. [10] applied the idea to linear fuzzy clustering, in which two representative medoids are selected in each cluster and the prototypical line is defined as:

$$Line_c(\boldsymbol{x}_{c1}, \boldsymbol{x}_{c2}) = \{\boldsymbol{x} | \boldsymbol{x} = \boldsymbol{x}_{c1} + t(\boldsymbol{x}_{c2} - \boldsymbol{x}_{c1}); t \in R\}. \tag{10}$$

The squared Euclidean distance between object i and the prototypical line $Line_c$ is given as:

$$D_{ci} = d_{i,c1}^2 - \frac{(d_{i,c1}^2 - d_{i,c2}^2 + d_{c1,c2}^2)^2}{4 d_{c1,c2}^2}. \tag{11}$$

With fixed fuzzy memberships u_{ci}, the optimal representative medoids $\boldsymbol{x}_{c1}$ and $\boldsymbol{x}_{c2}$ in cluster c are derived by $\boldsymbol{x}_{q1}$ and $\boldsymbol{x}_{q2}$ as follows:

$$(q1, q2) = \underset{(k1,k2)}{\arg} \min_{\substack{1 \leq k1,k2 \leq n \\ k1 \neq k2}} \sum_{i=1}^{n} u_{ci}^{\theta} D_{ci}. \tag{12}$$

In order to reduce the computational cost of the combinatorial optimization problem, a simplified medoid search process was also proposed such that medoids are selected from a subset X_c of objects having large memberships as follows:

$$(q1, q2) = \underset{(k1,k2)}{\arg} \min_{\substack{\boldsymbol{x}_{k1}, \boldsymbol{x}_{k2} \in X_c \\ k1 \neq k2}} \sum_{i=1}^{n} u_{ci}^{\theta} D_{ci}, \tag{13}$$

where $X_c = \{\boldsymbol{x}_i : u_{ci} > M_{min}\}$.

This linear fuzzy clustering model was also extended to the 2-D prototype case by spanning 2-D prototypical planes using three medoids [10].

When $D = d_{ij}$ is Non-Euclidean, the clustering criterion of Eq.(11) can be negative. From the practical view point, we have no trouble in operating the conventional FCMdd-type linear clustering algorithm if all clustering criteria are not negative. Yamamoto *et al.* [12] proposed a method for automatically transforming non-Euclidean relational data with β-spread transformation when clustering criteria have negative value in FCMdd-type linear clustering. If all relational data elements satisfy triangle inequality, clustering criteria are non-negative, i.e., if triangle inequality ($d_{c1,c2} \leq d_{i,c1} + d_{i,c2}$) is satisfied, the clustering criterion D_{ci} is positive. For all objects, the following triangle inequality transformed by β-spread transformation should be satisfied.

$$d_{c1,c2} + \beta \leq d_{i,c1} + \beta + d_{i,c2} + \beta. \tag{14}$$

Then, the β should satisfy the following relation:

$$\beta \geq d_{c1,c2} - d_{i,c1} - d_{i,c2}. \tag{15}$$

and, a plausible value of $\triangle\beta$ in a iteration step is obtained as:

$$\triangle\beta = \max\{d_{c1,c2} - d_{i,c1} - d_{i,c2} - \beta\}, \tag{16}$$

where $\triangle\beta = 0$ if $\triangle\beta < 0$. Then, β is monotonically increasing.

A sample procedure including the automated β-spread transformation can be summarized as follows:

Step.1 Set $\beta = 0$. Randomly initialize the prototypical medoids (two representative objects) of each cluster.
Step.2 Calculate the clustering criteria D_{ci} .
Step.3 If there are at least one object that has $D_{ci} < 0$, update $\beta = \beta + \triangle\beta$ by Eq.(16).
Step.4 Update fuzzy memberships.

Step.5 Search medoids in each cluster.

Step.6 Repeat Steps 2-5 until a certain stopping criterion is satisfied.

III. Application to Incomplete Relational Data Including Missing Elements

In real applications, relational data matrices may have missing elements. In such cases, the FCMdd-type linear clustering algorithm should be applied after imputing the missing elements. Hathaway and Bezdek [13] demonstrated that the β-spread transformation is also useful for handling missing elements in relational data matrices, in which β-spread transformation is responsible for decreasing the bad influences of imputation errors. This paper considers the applicability of several imputation techniques used in [13] in FCMdd-type linear clustering.

Hathaway and Bezdek [13] used three imputation technique based on triangle inequality-based approximation(TIBA).

A. minimax TIBA

The triangle inequality, which Euclidean relational data always satisfy, is represented as follows:

$$d_{ij} \leq d_{ik} + d_{kj}. \tag{17}$$

Assume that an element of relational matrix $\tilde{d_{ij}}$ is missing and that it brings

$$\tilde{d}_{ij} = \tilde{d}_{ji}. \tag{18}$$

Let K_{ij} as the corresponding index set as

$$K_{ij} = \{k | d_{ik} \text{ and } d_{kj} \text{ exist}\}. \tag{19}$$

Although it is very rare that K_{ij} is empty, $\tilde{d_{ij}}$ is defined as zero value if K_{ij} is empty. For each $k \in K_{ik}$, the triangle inequality Eq.(17) is given as upper bound of $\tilde{d_{ij}}$. In minimax TIBA, missing elements are replaced with the minimum upper bound of $\tilde{d_{ij}}$:

$$\tilde{d}_{ij} = \tilde{d}_{ji} = \min_k \{d_{ik} + d_{kj}\}. \tag{20}$$

B. maximin TIBA

The triangle inequality is also represented as follows:

$$d_{ik} \leq \tilde{d}_{ij} + d_{jk} \tag{21}$$

$$d_{jk} \leq \tilde{d}_{ji} + d_{ik}. \tag{22}$$

and brings the following inequalities:

$$\tilde{d}_{ij} \geq d_{ik} - d_{jk} \tag{23}$$

$$\tilde{d}_{ji} \geq d_{jk} - d_{ik} \tag{24}$$

So, the lower bound of $\tilde{d_{ij}}$ is given as:

$$\tilde{d}_{ij} \geq |d_{ik} - d_{jk}|. \tag{25}$$

In maximin TIBA, missing elements are replaced with the maximum lower bound of $\tilde{d_{ij}}$:

$$\tilde{d}_{ij} = \tilde{d}_{ji} = \max_k \{|d_{ik} - d_{jk}|\}. \tag{26}$$

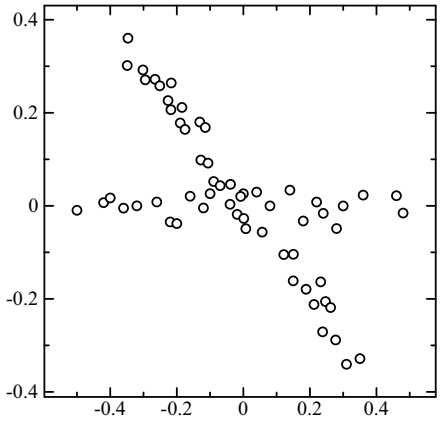

Fig. 1. 2-D plots of artificial data set

C. Average TIBA

It is also reasonable to use the complement value of the previous two imputation values. In average TIBA, the average values of minimax TIBA and maximin TIBA is used for imputing missing elements.

These imputation techniques based on triangle inequalities can be easily applied to relational clustering problems. In the next section, these three imputation approaches are compared in FCMdd-type linear clustering tasks in conjunction with β-spread transformation.

IV. Numerical Experiments

Several experimental results are shown in order to consider the applicability of the three TIBA imputation techniques in FCMdd-type linear clustering with β-spread transformation.

A. Artificial Data Set 1

First numerical experiment was performed using an artificially generated relational data set. The relational data set composed of 60 objects was generated from a 2-D data set shown in Fig. 1, in which objects form two line-shape clusters. The first relational data matrix was generated by Euclidean norm. The iterative algorithm was performed until the medoids become unchanged and the model parameters were set as $(C, \theta) = (2, 2)$. In order to demonstrate the characteristics of the algorithm, the initial memberships were given in a supervised manner, i.e., $(u_{1i}, u_{2i}) = (0.9, 0.1)$ for the first visual cluster and $(u_{1i}, u_{2i}) = (0.1, 0.9)$ for the second one.

Figure 2 shows the cluster partition (maximum membership partition) derived by FCMdd-based linear fuzzy clustering without missing elements, where objects were partitioned into two clusters of circles and times, smaller times has very fuzzy memberships, and the medoids and prototypical lines are indicated by black circles and lines, respectively. This Euclidean relational data can be successfully partitioned without β-spread transformation.

Next, incomplete relational data matrices were generated by removing a part of off-diagonal elements so that K_{ij} was not empty. In order to protect tridiagonal parts of relational

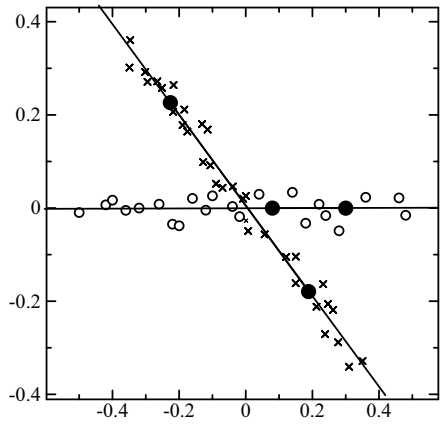

Fig. 2. Cluster partition of Euclidean data without missing elements

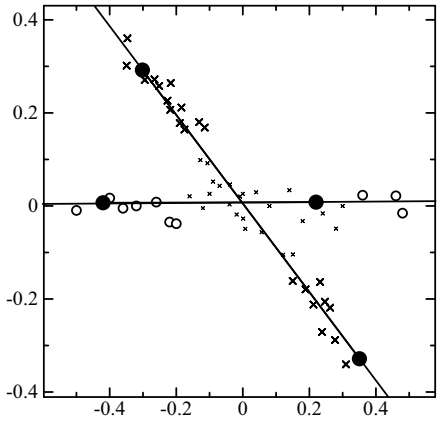
data, the maximum number of missing elements was set as $n^2 - 3n + 2$.

Clustering results are depicted in Fig. 3. Each approximation method could estimate cluster medoids for capturing the two visual linear prototypes until the numbers of missing elements are less than about 30%. Small crosses having ambiguous memberships increased more than complete relational data of Fig. 2. β-spread transformation performed on each approximation, e.g. minimax TIBA: $\beta = 0.04867$, maximin TIBA: $\beta = 0.044286$, average TIBA: $\beta = 0.051706$. The maximum eigenvalues of PDP were also calculated as minimax TIBA:0.053808, maximin TIBA:0.1711612, average TIBA:0.083694. This results imply that the FCMdd-type linear clustering can successfully extract linear substructures of incomplete Euclidean relational data using β-spread transformation although the three imputation technique could regenerate non-Euclidean relational matrices only.

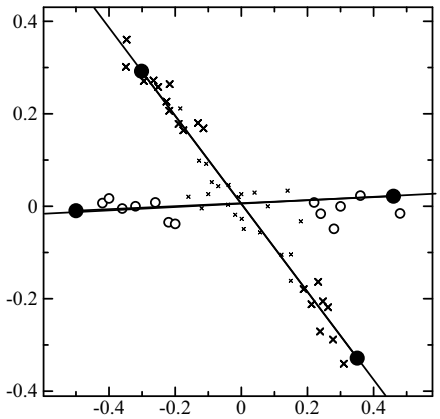
B. Artificial Data Set 2

The second relational data matrix was generated by using L1 norm from Fig. 1. Figure 4 shows the cluster partition derived without missing elements. The linear substructures were successfully estimated by using β-spread transformation with $\beta = 0.005808$, which is much smaller than the maximum eigenvalue of PDP 0.44933. In this way, β-spread transformation plays an important role for handling non-Euclidean relational data in FCMdd-type linear clustering.

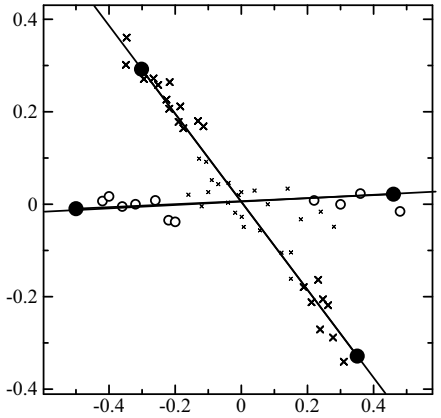
Next, incomplete relational data matrices were generated in a same manner with the Euclidean case. Clustering results were depicted in Fig. 5. Minimax TIBA and average TIBA could extract linear prototypes until the numbers of missing elements are less than about 60%, and maximin TIBA also could until about 40%. The parameters β in β-spread transformation were given as, minimax TIBA: $\beta = 0.23344$, maximin TIBA: $\beta = 0.137577$, average TIBA: $\beta = 0.165504$. The derived β values are still smaller than the maximum eigenvalues of PDP, minimax TIBA:0.655306, maximin TIBA:0.427750, average TIBA:0.619776. In this way, β-spread transformation also works well in incomplete situations.



(a) minimax TIBA (# missing: 500)



(b) maximin TIBA (# missing: 400)



(c) average TIBA (# missing: 500)

Fig. 3. Comparison of cluster partitions from relational data imputed by three TIBA (Euclid norm)

C. Ekman's Color Similarities Data

Third, the proposed algorithm is applied to the Ekman's color similarities data [14]. The 14×14 data matrix is composed of mutual similarities among 14 different colors. In this experiment, mutual similarities s_{ij} are first transformed

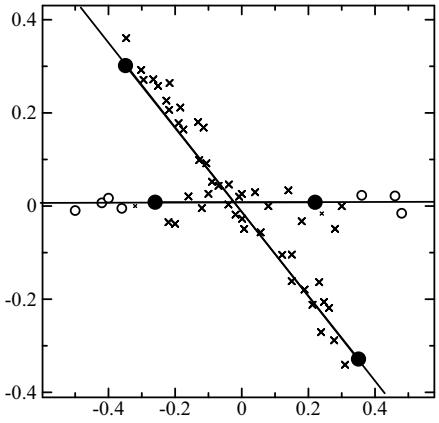


Fig. 4. Cluster partition of L1 norms without missing elements

into dis-similarity measure as follows:

$$d_{ij} = \max_{k,l} s_{kl} - s_{ij}. \tag{27}$$

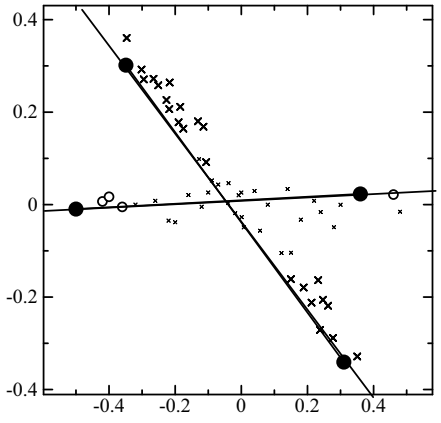
In the proposed algorithm, parameters were set as $C = 2$, $\theta = 2.0$. Figure 6 shows the derived cluster partitions on the 2-D plane constructed by multi-dimensional scaling (MDS) [15]. Minimax TIBA and average TIBA derived a same cluster partition, in which colors from purple to blue belonged to the first cluster while colors from yellow, green to red belonged to another cluster. Other colors equally belonged to both classes. This cluster partition is almost similar to the case without missing elements. Maximin TIBA also derived a similar partition to the other imputation technique, but this partition was more ambiguous. The parameters β in β-spread transformation were given as, minimax TIBA: $\beta = 275.085$, maximin TIBA: $\beta = 59.776$, average TIBA: $\beta = 134.000$. The derived β values are still smaller than the maximum eigenvalues of PDP, minimax TIBA:430.8659, maximin TIBA:150.667, average TIBA:192.596. Here, maximin TIBA gave a much smaller β value than the maximum eigenvalues of PDP. It may be the reason why it derived a very ambiguous partition.

D. Rothkopf Morse Code Confusion Data

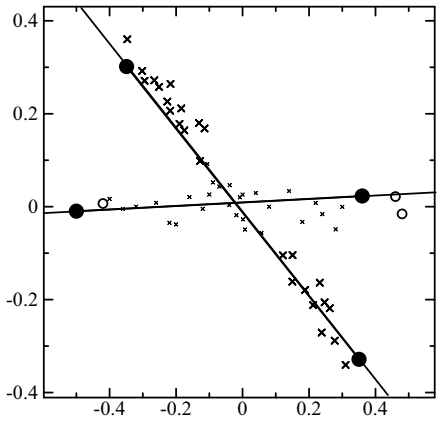
Fourth, the proposed approach is applied to the classical Rothkopf Morse code confusion data [16]. The (36 $\times$ 36) relational data is composed of confusion rates among 36 Morse code signals (26 letters and 10 digits). Before the experiment, the asymmetric relational data matrix, whose element s_{ij} represents the percentage of trials that i was identified as j, was transformed into a symmetric relational data matrix as follows:

$$d_{ij} = s_{ii} + s_{jj} - s_{ij} - s_{ji} \tag{28}$$

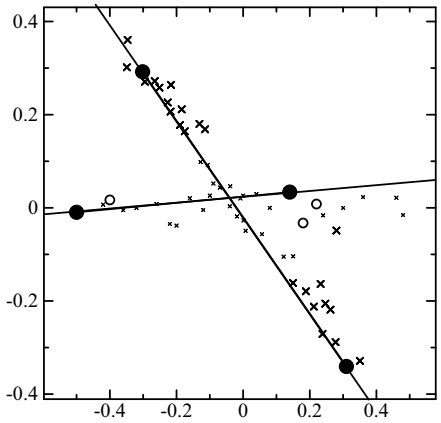
The model parameters were set as $C = 3$, $\theta = 2.0$. Clustering results are depicted in Fig. 7, which constructed on the 2-D plane by MDS. Minimax TIBA and average TIBA allowed with 30 % missing values or fewer. Maximin TIBA resulted in a good partition with 10 % missing values or



(a) minimax TIBA (# missing: 1000)



(b) maximin TIBA (# missing: 700)



(c) average TIBA (# missing: 1100)

Fig. 5. Comparison of cluster partition from relational data imputed by three TIBA (L1 norm)

fewer. The parameters β in β-spread transformation were given as, minimax TIBA: $\beta = 226.945$, maximin TIBA: $\beta = 91.523$, average TIBA: $\beta = 0.0$. The derived β values are still smaller than the maximum eigenvalues of PDP, minimax TIBA:460.808, maximin TIBA:173.284, average TIBA:132.503. In this experiment, average TIBA was the best imputation method of the three TIBA, because average

TIBA did not need β-spread transformation. However, a similar partition was derived with β-spread transformation even when missing values were imputed by other methods.

In this way, β-spread transformation also works well with incomplete real world data.

V. Conclusion

This paper considered the applicability of β-spread transformation for handling incomplete relational data in FCMdd-type linear clustering. In numerical experiments, three imputation techniques of minimax TIBA, maximin TIBA and average TIBA were compared using two artificially generated data sets and a real one. The experimental results indicated that β-spread transformation still works well for incomplete data while minimax TIBA and average TIBA seem to be better than maximin TIBA. It is because that relational data imputed by maximin TIBA were more non-Euclidean.

A potential future work is extension to the case of multi-dimensional prototype models.

***Abstract*—This paper proposes an FCM-type clustering method for capturing cross-shape fuzzy clusters in multi-dimensional data spaces. The proposed objective function is a combination of Fuzzy c-Varieties (FCV) and cross-shape cluster extraction in 2-D space, which is an extended linear fuzzy clustering model with local coordinate rotation. FCV is responsible for finding 2-D planes, on which cross-shape prototypes exist. Each prototypical cross is estimated on the FCV prototypes. Fuzzy memberships are updated using a combined clustering criterion of distances between data samples and FCV prototypes and measures for linear clustering on the FCV prototypes with local coordinate rotation.**

***Keywords*—co-clustering, collaborative filtering, principal component analysis.**

I. Introduction

Many variants of FCM-type clustering models [1], [2], [3] have been proposed by extending the original Fuzzy c-Means (FCM) algorithm [4], which is a fuzzy counterpart of k-Means clustering [5]. If we have some structural information on cluster prototypes, we can modify the point-type prototypes of FCM by replacing with other shapes. Fuzzy c-Lines (FCL) [6] is a linear fuzzy clustering model, in which cluster prototypes are defined by lines having infinite length. Fuzzy c-Varieties (FCV) [7] extended FCL, in which cluster prototypes are defined by linear varieties such as planes and hyper-plane. These linear clustering models have close connection with local principal component analysis (local PCA) [8], [9], in which fuzzy PCA [10] is performed in each cluster based on the FCM-type alternate optimization scheme [11], [12].

Using other non-linear-shape prototypes, many FCM variants such as Fuzzy c-Spherical Shells (FCSS) [13] with circular-shape prototypes, Fuzzy c-Quadric Shells (FCQS) [14] with quadric surfaces and Fuzzy c-Rectangular Shells (FCRS) [15] with rectangular-shape prototypes have been proposed. Yoshida *et al.* [16] proposed a technique for extracting cross-shape clusters in 2-D data space by introducing local coordinate rotation in linear fuzzy clustering. Each cross-shape cluster is composed of two linear sub-clusters and is captured in a single local minor component extraction context [17] by considering coordinate rotation of one sub-cluster around intersection of two linear sub-prototypes.

This work was funded in part by the Ministry of Education, Culture, Sports, Science and Technology, Japan, under Grant-in-Aid for Scientific Research (20700214).

In this paper, the cross-shape extraction model is extended to multi-dimensional cases. In the Gaussian mixture models (GMMs) field, a combined likelihood function was proposed for capturing 2-D non-linear manifolds [18]. In the same manner, this paper proposes a combined objective function of FCV and cross-shape cluster extraction. The objective function for FCV composed of distances between data samples and 2-D plane-like prototypes is responsible for capturing 2-D planes, on which each cross-shape exists. Each cross-shape prototype is estimated in the prototypical 2-D planes. The clustering criteria for updating fuzzy memberships are given by the two criteria.

The remaining parts of this paper are organized as follows. Section II briefly reviews the FCM-type linear fuzzy clustering models and the cross-shape prototype model. Section III proposes a combined objective function. Numerical experimental result is presented in Section IV. Finally, Section V gives conclusion.

II. FCM-type Linear Fuzzy Clustering and Cross-shape cluster extraction

A. Fuzzy c-Lines and Fuzzy c-Varieties

Assume that we have n samples with m dimensional observation $\boldsymbol{x}_i = (x_{i1}, \ldots, x_{im})$, $i = 1, \ldots, n$ and the goal is to partition the samples into C clusters. The FCM algorithm uses point-type prototypes given by mean vectors $\boldsymbol{b}_c = (b_{c1}, \ldots, b_{cm})$, $c = 1, \ldots, C$ and the clustering criterion for cluster c is the squared Euclidean distance d_{ci} between sample $\boldsymbol{x}_i$ and prototype $\boldsymbol{b}_c$. The objective function to be minimized is the weighted within-sum-of-distances.

$$\begin{aligned} L_{fcm} &= \sum_{c=1}^{C}\sum_{i=1}^{n} u_{ci}^{\theta} d_{ci} \\ &= \sum_{c=1}^{C}\sum_{i=1}^{n} u_{ci}^{\theta} ||\boldsymbol{x}_i - \boldsymbol{b}_c||^2. \end{aligned} \quad (1)$$

$u_{ci} \in [0, 1]$ is the fuzzy membership degree of sample i in cluster c and follows the probabilistic constraint of $\sum_{c=1}^{C} u_{ci} = 1$. θ is the fuzzification parameter called 'fuzzifier'. Membership assignment becomes fuzzy as θ becomes large, while $\theta = 1$ reduces a crisp partition of k-Means.

The optimal cluster center for each cluster with fixed memberships u_{ci} is derived as the membership-weighted mean

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

vector.

$$\boldsymbol{b}_c = \frac{\sum_{i=1}^{n} u_{ci}^{\theta} \boldsymbol{x}_i}{\sum_{i=1}^{n} u_{ci}^{\theta}}. \quad (2)$$

With fixed cluster prototypes $\boldsymbol{b}_c$, the optimal memberships satisfying the probabilistic constraint are given as

$$u_{ci} = \left[\sum_{\ell=1}^{C} \left(\frac{d_{ci}}{d_{\ell i}} \right)^{1/(\theta-1)} \right]^{-1}. \quad (3)$$

In the singular situation where some data samples are on prototypes (zero-distances), the data samples are crisply assigned to the prototypes and have zero-memberships to other clusters. These two phases of cluster prototype estimation and membership estimation are repeated until converge based on the alternate optimization scheme.

FCL replaces the point-type prototype with 1-dimensional lines defined as follows:

$$Line_c(\boldsymbol{b}_c, \boldsymbol{a}_c) = \{x | x = \boldsymbol{b}_c + \boldsymbol{a}_c t; t \subseteq R\}. \quad (4)$$

Each line is defined by two vectors of cluster center $\boldsymbol{b}_c$ and basis vector $\boldsymbol{a}_c$. The prototypical line of cluster c is to pass through its cluster center and to be spanned by basis vector $\boldsymbol{a}_c$. The clustering criteria are squared Euclidean distances between sample points and linear prototypes, and the objective function is defined as follows:

$$\begin{aligned} L_{fcl} &= \sum_{c=1}^{C} \sum_{i=1}^{n} u_{ci}^{\theta} D_{ci} \\ &= \sum_{c=1}^{C} \sum_{i=1}^{n} u_{ci}^{\theta} \left(||\boldsymbol{x}_i - \boldsymbol{b}_c||^2 - |\boldsymbol{a}_c^{\top} (\boldsymbol{x}_i - \boldsymbol{b}_c)|^2 \right). \quad (5) \end{aligned}$$

The optimal memberships u_{ci} with fixed cluster prototypes are calculated by Eq.(3) replacing the clustering criteria with $D_{ci} = ||\boldsymbol{x}_i - \boldsymbol{b}_c||^2 - |\boldsymbol{a}_c^{\top} (\boldsymbol{x}_i - \boldsymbol{b}_c)|^2$. With fixed memberships, optimal prototype estimation is achieved in a 2 step procedure. $\boldsymbol{b}_c$ is often updated in a same formula with Eq.(2). Next, basis vector estimation is reduced to fuzzy PCA [10], in which the conventional PCA procedure is performed in a fuzzy set where the fuzzy membership degree of each sample is given by u_{ci}^{θ}. The optimal basis vector of cluster c is the eigen vector corresponding to the largest eigenvalue of the following generalized fuzzy scatter matrix S_{fc}:

$$S_{fc} = \sum_{i=1}^{n} u_{ci}^{\theta} (\boldsymbol{x}_i - \boldsymbol{b}_c)(\boldsymbol{x}_i - \boldsymbol{b}_c)^{\top}. \quad (6)$$

FCV extended FCL into multi-dimensional case. Using p independent basis vectors $\boldsymbol{a}_{ck}, k = 1, \ldots, p$, p-dimensional linear varieties to be used as the prototype of cluster c is given as

$$V_c{}^p(\boldsymbol{b}_c; \boldsymbol{a}_{c1}, \boldsymbol{a}_{c2}, \ldots, \boldsymbol{a}_{cp}) = \{\boldsymbol{x} | \boldsymbol{x} = \boldsymbol{b}_c + \sum_{k=1}^{p} t_k \boldsymbol{a}_{ck}; t_k \in R\}, \quad (7)$$

and the clustering criteria are replaced with the distances between data samples and the linear varieties. The membership updating rule is Eq.(3) with the modified criteria. If cluster center $\boldsymbol{b}_c$ is also updated by Eq.(2), the basis vectors are given by the eigenvectors corresponding to the p largest eigenvalues of S_{fc}.

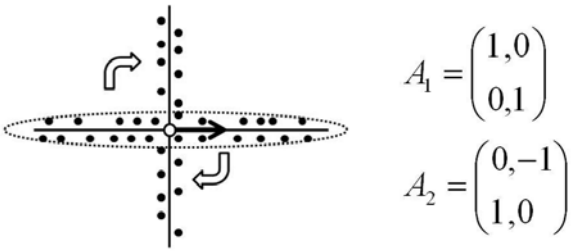

Fig. 1. Definition of prototypical cross-shape and rotation matrix

B. Cross-shape Cluster Extraction in 2-D Data Space

Yoshida *et al.* [16] proposed a technique for capturing the cross-shape substructure by using a single linear prototype. Assume that samples were drawn from a 2-D data space ($m = 2$). The cross-shape prototype of a cluster can be defined by two elements of center point and first normal vector as shown in Fig. 1 where the two lines cross at the center point.

In the model, each cross-shape cluster is further divided into two linear sub-clusters corresponding to the two component lines. The first sub-cluster memberships u_{c1i} represent the degree of belongingness to the first prototypical line whose normal vector is $\boldsymbol{a}_c$. The second ones u_{c2i} correspond to the second line whose basis vector is $\boldsymbol{a}_c$. The conventional membership value for cluster c is recovered by $u_{ci} = u_{c1i} + u_{c2i}$. In order to jointly estimate the two memberships of u_{c1i} and u_{c2i} in a single linear clustering-like procedure, vertical rotation of the second sub-cluster around the center point is considered. The local coordinate rotation matrix for the second sub-cluster is given as A_2 in Fig. 1. The distances between sample i and sub-cluster j in cluster c is given as follows:

$$D_{cji} = ||\boldsymbol{a}_c^{\top} \boldsymbol{A}_j (\boldsymbol{x}_i - \boldsymbol{b}_c)||^2 \quad (8)$$

The objective function is defined based on the minor component analysis concept [17], in which linear manifolds are formulated by normal vectors.

$$\begin{aligned} L_{cross} &= \sum_{c=1}^{C} \sum_{j=1}^{2} \sum_{i=1}^{n} u_{cji}^{\theta} D_{cji} \\ &= \sum_{c=1}^{C} \sum_{j=1}^{2} \sum_{i=1}^{n} u_{cji}^{\theta} |\boldsymbol{a}_c^{\top} \boldsymbol{A}_j (\boldsymbol{x}_i - \boldsymbol{b}_c)|^2, \quad (9) \end{aligned}$$

where the probabilistic constraint for memberships is modified as:

$$\sum_{c=1}^{C} \sum_{j=1}^{2} \sum_{i=1}^{n} u_{cji} = 1. \quad (10)$$

Fuzzy memberships for sub-clusters are given by

$$u_{cji} = \left[\sum_{\ell=1}^{C} \left(\frac{||\boldsymbol{a}_c^\top \boldsymbol{A}_j(\boldsymbol{x}_i - \boldsymbol{b}_c)||^2}{||\boldsymbol{a}_\ell^\top \boldsymbol{A}_j(\boldsymbol{x}_i - \boldsymbol{b}_\ell)||^2} \right)^{\frac{1}{\theta-1}} \right]^{-1}. \quad (11)$$

From the necessary condition for the optimality, center points of prototypical cross-shape are updated as

$$\boldsymbol{b}_c = \frac{\sum_{j=1}^{2}\sum_{i=1}^{n} u_{cji}^{\theta}(\boldsymbol{A}_j^\top \boldsymbol{a}_c \boldsymbol{a}_c^\top \boldsymbol{A}_j \boldsymbol{x}_i)}{\sum_{j=1}^{2}\sum_{i=1}^{n} u_{cji}^{\theta} \boldsymbol{A}_j^\top \boldsymbol{a}_c \boldsymbol{a}_c^\top \boldsymbol{A}_j}. \quad (12)$$

Normal vectors $\boldsymbol{a}_c$ is derived in a similar way to minor component analysis so that $\boldsymbol{a}_c$ corresponds to the smallest eigenvalue of the following modified scatter matrix:

$$\boldsymbol{S}_{fc} = \sum_{j=1}^{2}\sum_{i=1}^{n} u_{cji}^{\theta}(\boldsymbol{x}_{ci}^j - \boldsymbol{v}_c)(\boldsymbol{x}_{ci}^j - \boldsymbol{v}_c)^\top, \quad (13)$$

where x_{ci}^j and $\boldsymbol{v}_c$ are sample vector and cluster center after local coordinate rotation such that

$$\boldsymbol{x}_{ci}^j = \boldsymbol{A}_j(\boldsymbol{x}_i - \boldsymbol{b}_c), \quad (14)$$

$$\boldsymbol{v}_c = \frac{\sum_{j=1}^{2}\sum_{i=1}^{n} u_{cji}^{\theta}\boldsymbol{A}_j(\boldsymbol{x}_i - \boldsymbol{b}_c)}{\sum_{j=1}^{2}\sum_{i=1}^{n} u_{cji}^{\theta}}. \quad (15)$$

Because of coordinate rotation, samples are virtually duplicated and the scatter matrix is calculated using $2n$ objects.

III. Hybrid of FCV and Cross-shape Fuzzy Cluster Extraction

A. Active Curve Axis Gaussian Mixture Models

Zhang *et al.* [18] proposed a non-linear extension of Gaussian mixture models (GMMs) in order to deal with curve manifolds using a non-linear probability model called active curve axis Gaussian model. The non-linear Gaussian model is generated by bending the normal Gaussian model at the first principal axis in 2-D data space. Then, they modified the mixture models into multi-dimensional data space by assuming that the principal axis curves are located in 2-D planes determined by the first two eigenvectors. The modified likelihood function was defined by combining the two measures: deviations from 2-D planes and distances from principal axis on the 2-D planes. The model parameters are estimated by a generalized Expectation-Maximization (EM) algorithm.

In this paper, a similar idea of combining two criteria is performed in order to capture cross-shape clusters in multiple-dimensional data space.

B. Combination of Two Criteria and Generalized Algorithm

In this paper, FCV is combined with cross-shape cluster extraction in 2-D plane. Assume that we have n samples with m dimensional observation $\boldsymbol{x}_i = (x_{i1}, \ldots, x_{im})$, $i = 1, \ldots, n$ and the cluster prototypes are given by cross-shape composed of two lines on 2-D plane. In the FCV part, the prototypical 2-D plane in cluster c is defined by cluster center $\boldsymbol{q}_c$ and basis vectors $\boldsymbol{p}_{c1}$ and $\boldsymbol{p}_{c1}$. Then, the FCV criterion of distance between samples $\boldsymbol{x}_i$ and the 2-D plane is calculated as:

$$d_{ci}^{*} = ||\boldsymbol{x}_i - \boldsymbol{q}_c||^2 - \sum_{k=1}^{2} |(\boldsymbol{x}_i - \boldsymbol{q}_c)^\top \boldsymbol{p}_{ck}|^2. \quad (16)$$

Next, in order to consider the cross-shape cluster extraction in the 2-D plane, samples are projected on the 2-D plane as $\boldsymbol{y}_i = (y_{i1}, y_{i2})^\top$):

$$y_{ij} = \boldsymbol{p}_{cj}^\top(\boldsymbol{x}_i - \boldsymbol{q}_c), \quad j = 1, 2. \quad (17)$$

The cross-shape prototype on the 2-D plane is defined by cluster center (intersection of two lines) $\boldsymbol{b}_c$ and first normal vector $\boldsymbol{a}_c$. Then, the criterion of distance between the projected sample vector $\boldsymbol{y}_i$ and the prototypical cross is calculated as:

$$d_{ci}^{**} = ||\boldsymbol{a}_c^\top \boldsymbol{A}_j(\boldsymbol{y}_i - \boldsymbol{b}_c)||^2. \quad (18)$$

using the two criteria, the combined objective function is defined as:

$$\begin{aligned} L &= \sum_{c=1}^{C}\sum_{j=1}^{2}\sum_{i=1}^{n} u_{cji}^{\theta}(d_{ci}^{*} + d_{ci}^{**}) \\ &= \sum_{c=1}^{C}\sum_{j=1}^{2}\sum_{i=1}^{n} u_{cji}^{\theta}\Bigg(||\boldsymbol{x}_i - \boldsymbol{q}_c||^2 - \\ &\quad + \sum_{k=1}^{2} |(\boldsymbol{x}_i - \boldsymbol{q}_c)^\top \boldsymbol{p}_{ck}|^2 + ||\boldsymbol{a}_c^\top \boldsymbol{A}_j(\boldsymbol{y}_i - \boldsymbol{b}_c)||^2 \Bigg). \end{aligned} \quad (19)$$

The iterative algorithm is composed of three steps. In the first step, prototypical 2-D planes are estimated. Cluster centers $\boldsymbol{q}_c$ are calculated by Eq.(2) where $u_{ci}^{\theta} = u_{c1i}^{\theta} + u_{c2i}^{\theta}$. Basis vectors $\boldsymbol{p}_{ck}$ are given by the k-th principal eigenvector of Eq.(6) replacing $\boldsymbol{b}_c$ with $\boldsymbol{q}_c$.

In the second step, cross-shape prototypes are estimated on 2-D planes. Intersection vectors $\boldsymbol{b}_c$ are calculated by Eq.(12) replacing $\boldsymbol{x}_i$ with $\boldsymbol{y}_i$. Normal vectors $\boldsymbol{a}_c$ are given by the eigenvectors corresponding to the smallest eigenvalues of Eq.(13) replacing $\boldsymbol{x}_i$ with $\boldsymbol{y}_i$.

Then, in the third step, fuzzy memberships for sub-clusters u_{cji} are calculated as:

$$u_{cji} = \left[\sum_{\ell=1}^{C} \left(\frac{d_{ci}^{*} + d_{ci}^{**}}{d_{\ell i}^{*} + d_{\ell i}^{**}} \right)^{\frac{1}{\theta-1}} \right]^{-1}. \quad (20)$$

IV. Numerical Example

A numerical experiment was performed with an artificially generated data set composed of 80 samples. Figure 2 shows the 3-D plots of the data set including two separate cross-shape clusters. The two cross-shape clusters exist on two 2-D planes, which are mutually orthogonal as shown in Fig. 3, and the intersection areas of the two crosses have small distances for both two planes. The goal of the experiment is to capture the two cross-shape sub-structures by partitioning samples into two clusters ($C = 2$). The fuzzification parameter was set as $\theta = 2$. Figure 4 shows the clustering result derived by FCV

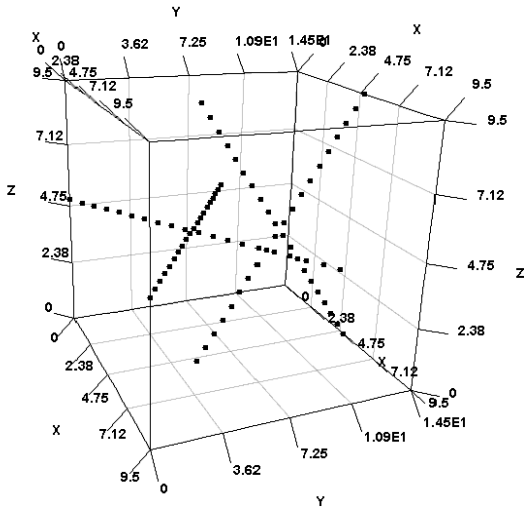

Fig. 2. 3-D plots of the data sets

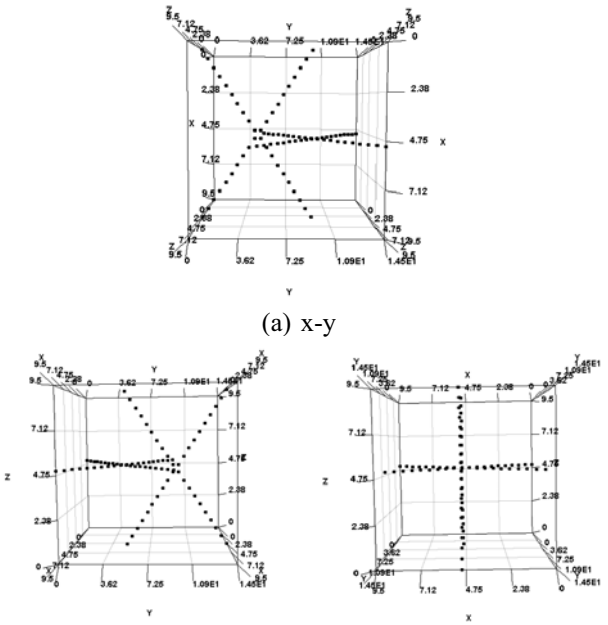

(a) x-y

(b) y-z (c) x-z

Fig. 3. Other views of Fig. 2

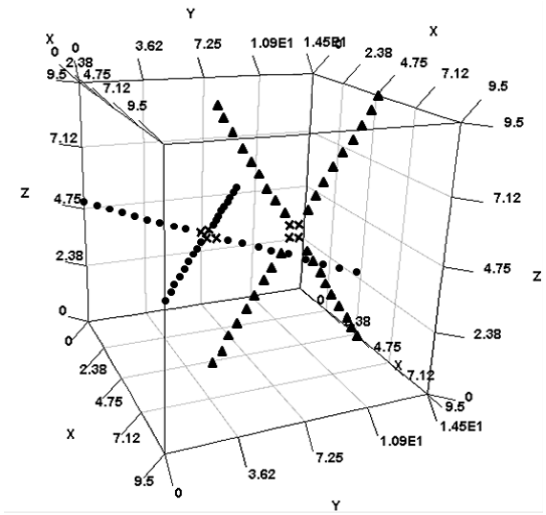

Fig. 4. Clustering result of FCV

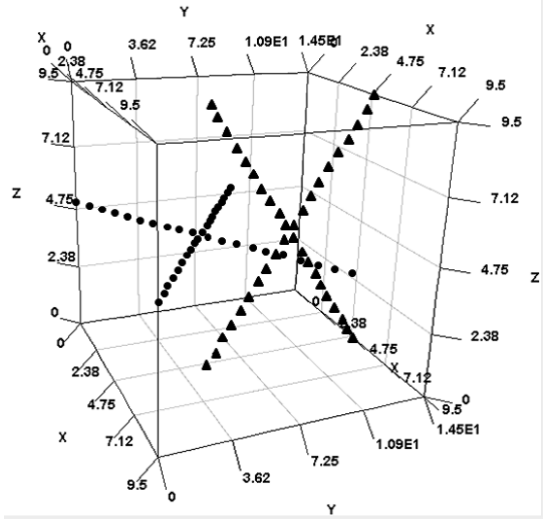

Fig. 5. Clustering result of proposed method

where circles and triangles indicate the maximum membership classification and times indicate the samples having very fuzzy memberships of $u_{ci} \in [0.4, 0.6]$. FCV is useful for capturing 2-D planes, on which cross-shape clusters exist, while it cannot reveal cross-shape substructure. Figure 5 shows the result by the proposed method where two cross-shape clusters were properly extracted. The intersection areas were also properly assigned to clusters by considering both two criteria.

Table I compares the membership degrees of the eight data points, which are described by $\times$ in the intersection of two cross-shapes in Fig. 4. The table indicates that the proposed hybrid approach made it possible to clarify the cross-shape cluster partitions by assgining more crisp memberships. In this way, the proposed hybrid objective function contributes to extraction of cross-shape substructures in multi-dimensional data space.

V. Conclusion

This paper proposed a hybrid objective function of FCV and cross-shape cluster extraction for extracting cross-shape substructures in multi-dimensional data space. The FCV part is responsible for capturing 2-D planes, on which cross-shape substructures exist, while cross-shape cluster extraction part performs linear sub-space learning with local coordinate rotation. Fuzzy memberships are estimated considering both criteria.

A possible future work is hybridization with FCM in such a way with Fuzzy c-Elliptotypes (FCE) [7] for avoiding the size problem of FCL-type linear clustering models. Another

***Abstract*—Recently, fuzzy c-means clustering with kernel functions is remarkable in the reason that these algorithms can handle datasets which consist of some clusters with nonlinear boundaries. However the algorithms have the following problems: (1) the cluster centers can not be calculated explicitly, (2) it takes long time to calculate clustering results. By the way, we have proposed the clustering algorithms using penalty-vector regularization to handle uncertain data. In this paper, we propose new clustering algorithms using quadratic penalty-vector regularization by introducing explicit mappings of kernel functions to solve the following problems. Moreover, we construct fuzzy classification functions for our proposed clustering methods.**

Keywords*— *clustering, kernel function, uncertain data, penalty-vector regularization, classification function, explicit mapping

I. Introduction

Clustering is one of the data classification techniques and we can classify data without any external criterion using clustering methods. One of most typical and useful clustering methods is fuzzy c-means clustering (FCM) [1] and we consider FCM in this paper.

Now, studies of clustering methods for detecting nonlinear boundary have been widely discussed and kernel trick [2], [3] is focused as a very useful tool to handle datasets which consist of some clusters with nonlinear boundaries. The kernel trick uses some function called "kernel function".

Here, we consider a mapping $\phi : \Re^p \to \Re^s$ $(p \ll s)$. The kernel function is an operator $K : \Re^p \times \Re^p \to \Re$ which satisfies $K(x, y) = \langle \phi(x), \phi(y) \rangle$. We can calculate the value of the inner product in the high-dimensional feature space with low-cost calculation by the kernel functions.

However, special problems frequently arise when we introduce kernel functions into FCM. First, the cluster centers can not be calculated directly. The reason is that the mapping ϕ can not be represented explicitly in general. The second problem is caused by the first one, that is, it takes long time to calculate clustering results. The procedure to calculate the belongingness or membership grades of each data to clusters becomes complicated. To solve the above problems, Miyamoto et al. introduced explicit mappings into kernel trick and succeeded to calculate the cluster centers directly [4].

By the way, the data we handle have uncertainties in many cases. Until now, we have two methodologies to analyze such data, deterministic and parametric ones.

In the deterministic methodology, the uncertainty introduced data is represented as an interval. Distances or dissimilarities are the most essential measures for data analysis and therefore, the measures between intervals must be defined when we handle uncertainty of data as interval. There are many kinds of such measures, e.g., Hausdorff distance. However, we have two problems when we try to classify the dataset of such data. First, we don't have any clear principle to select which measures to use. Second, we can't discuss clustering in the framework of optimization with such measures.

On the other hand, the uncertainty is represented by some probabilistic density function (PDF) in parametric methodology. In this methodology, the clustering is regarded as a method to determine some parameters of the PDF. However, the methodology have also at least one problem, that is, selection of types of PDFs.

Therefore, we have proposed and developed the concept of tolerance in Ref. [5], [6] to solve the above problems. In our concept, tolerance vectors [5] and penalty ones [6] play main role. Uncertain data is allowed to allocate any position by those vectors as far as the constraints for those vectors are satisfied and the position is derived as an optimal solution of a given objective function. Hence, we can say that this concept is in the framework of methodology of soft computing. Penalty vector is a similar concept to tolerance one and the methods using penalty vectors become more flexible than tolerance vectors because no constraint for the vectors is needed. Moreover, the concept has been developed by using kernel trick in Ref. [7]. The method can classify datasets which consist of clusters of uncertain data with nonlinear boundary.

In this paper, we try to construct new FCMs for uncertain data using quadratic penalty-vector regularization with explicit mappings of kernel functions. The proposed methods have the following advantages:

1) The method can classify datasets which consist of clusters of uncertain data with nonlinear boundaries because of kernel trick.
2) The methods can calculate clustering results at shorter

time than the conventional methods because of explicit mappings.

Moreover, we try to construct fuzzy classification functions for our proposed clustering. Fuzzy classification functions [10] calculate the values of membership grade of arbitrary points for any cluster by handling clustering results as prototypes of supervised classification. Therefore, the functions are very useful tools to give some principle to classify new observations and we can construct the functions because kernel functions can be described as explicit mapping.

II. FCM for Uncertain Data with Regularization Term of Penalty Vectors

A. Preliminaries

First of all, we define some symbols. Each data is denoted $x_k = (x_{k1}, \ldots, x_{kp})^T \in \Re^p$ and the dataset $X = \{x_1, \ldots, x_n\}$ is given. Each cluster $C_i (i = 1, \ldots, c)$ has a cluster center $v_i = (v_{i1}, \ldots, v_{ip})^T \in \Re^p$. V means a set of cluster centers $\{v_1, \ldots, v_c\}$. A membership grade for x_k to C_i, which means belongingness of x_k to C_i, is denoted by u_{ki}. U means a partition matrix $(u_{ki})_{1 \leq k \leq n, 1 \leq i \leq c}$. Moreover, $\delta_k = (\delta_{k1}, \ldots, \delta_{kp})^T \in \Re^p$ and $w_k \in [0, +\infty)$ mean a penalty vector and a weight of the penalty vector δ_k, respectively. Δ and W mean a set of penalty vectors $\{\delta_1, \ldots, \delta_n\}$ and a set of weights $\{w_1, \ldots, w_n\}$, respectively.

B. Objective Functions

As mentioned above, a method using quadratic penalty-vector regularization has been proposed in Ref. [6] as methodology of soft computing. Here, we show the objective function of FCM using quadratic penalty-vector regularization (FCMP).

$$J_{sp}(U, \Delta, V) = \sum_{k=1}^{n} \sum_{i=1}^{c} (u_{ki})^m d_{ki} + \sum_{k=1}^{n} w_k \|\delta_{kj}\|^2, \tag{1}$$

$$J_{ep}(U, \Delta, V) = \sum_{k=1}^{n} \sum_{i=1}^{c} u_{ki} d_{ki} + \lambda^{-1} \sum_{k=1}^{n} \sum_{i=1}^{c} u_{ki} \log u_{ki} + \sum_{k=1}^{n} w_k \|\delta_{kj}\|^2. \tag{2}$$

The dissimilarity d_{ki} is the square of the norm as follows.

$$\begin{aligned} d_{ki} &= d(x_k + \delta_k, v_i) \\ &= \|x_k + \delta_k - v_i\|^2 \\ &= \sum_{j=1}^{p} (x_{kj} + \delta_{kj} - v_{ij})^2. \end{aligned} \tag{3}$$

The constraint is as follows.

$$\sum_{i=1}^{c} u_{ki} = 1, \ u_{ki} \in [0, 1], \ ^\forall k. \tag{4}$$

J_{sp} and J_{ep} are objective functions for the standard FCMP (sFCMP) and the entropy based FCMP (eFCMP), respectively. The solutions can be derived by using Lagrange multiplier.

C. Optimal Solutions and Algorithms

The optimal solutions of sFCMP are as follows:

$$\begin{cases} u_{ki} = \dfrac{(1/d_{ki})^{\frac{1}{m-1}}}{\sum_{l=1}^{c} (1/d_{kl})^{\frac{1}{m-1}}}, & (5) \\ v_i = \dfrac{\sum_{k=1}^{n} (u_{ki})^m (x_k + \delta_k)}{\sum_{k=1}^{n} (u_{ki})^m}, & (6) \\ \delta_k = \dfrac{-\sum_{i=1}^{c} (u_{ki})^m (x_k - v_i)}{w_k + \sum_{i=1}^{c} (u_{ki})^m}. & (7) \end{cases}$$

The optimal solutions of sFCMP are as follows:

$$\begin{cases} u_{ki} = \dfrac{\exp(-\lambda d_{ki})}{\sum_{l=1}^{c} \exp(-\lambda d_{kl})}, & (8) \\ v_i = \dfrac{\sum_{k=1}^{n} u_{ki} (x_k + \delta_k)}{\sum_{k=1}^{n} u_{ki}}, & (9) \\ \delta_k = \dfrac{-\sum_{i=1}^{c} u_{ki} (x_k - v_i)}{w_k + 1}. & (10) \end{cases}$$

We can construct clustering algorithms using the above optimal solutions.

Algorithm 1 (sFCMP and eFCMP):

Step 1 Set the initial values U and Δ.

Step 2 Calculate V by the optimal solution on fixing U and Δ.

Step 3 Calculate U by the optimal solution on fixing Δ and V.

Step 4 Calculate Δ by the optimal solution on fixing V and U.

Step 5 Finish the algorithm if the solutions are convergent, else go back to Step 2.

III. Kernelized FCM for Uncertain Data with Quadratic Regularization Term of Penalty Vectors Using Explicit Mappings

In this section, we try to construct FCM for uncertain data using quadratic penalty-vector regularization with explicit mappings of kernel functions (EK-FCMP). First, we describe kernelized FCM for uncertain data using quadratic penalty-vector regularization (K-FCMP). Next, we introduce explicit mappings of kernel functions into K-FCMP to construct EK-FCMP. Last, we show an algorithm of EK-FCMP.

A. Kernel Functions

First, we define some symbols to introduce kernel functions. A mapping from the pattern space to the feature space is expressed as $\phi : \Re^p \to \Re^s$ $(p \ll s)$. Each data in the feature space is denoted $\phi(x_k) = x_k^\phi = (x_{k1}^\phi, \ldots, x_{ks}^\phi)^T \in \Re^s$ and the dataset $X^\phi = \left\{x_1^\phi, \ldots, x_n^\phi\right\}$ is given. Each cluster $C_i (i = 1, \ldots, c)$ has a cluster center $v_i^\phi = (v_{i1}^\phi, \ldots, v_{is}^\phi)^T \in \Re^s$. V^ϕ means a set of cluster centers $\left\{v_1^\phi, \ldots, v_c^\phi\right\}$. A membership grade for x_k^ϕ to C_i, which means belongingness of x_k^ϕ to C_i, is denoted by u_{ki}. U means a partition matrix $(u_{ki})_{1 \le k \le n, 1 \le i \le c}$. Moreover, $\delta_k^\phi = (\delta_{k1}^\phi, \ldots, \delta_{ks}^\phi)^T \in \Re^s$ and $w_k \in [0, +\infty)$ mean a penalty vector and a weight of the penalty vector δ_k^ϕ, respectively. Δ and W mean a set of penalty vectors $\{\delta_1^\phi, \ldots, \delta_n^\phi\}$ and a set of weights $\{w_1, \ldots, w_n\}$, respectively.

Now, a kernel function $K : \Re^p \times \Re^p \to \Re$ satisfies the following relation:

$$K(x, y) = \langle \phi(x), \phi(y) \rangle \tag{11}$$

From Mercer's theorem [9], K is a continuous symmetric non-negative definite kernel iff a mapping ϕ which satisfies the above relation exists. We should notice that ϕ is not explicit.

B. Objective Functions

Kernelized fuzzy c-means clustering (K-FCM) is FCM in which a kernel function is introduced into dissimilarity. An extended K-FCM by introducing penalty vectors have been proposed in Ref. [7]. We show the objective function of the standard model J_{ksp} and the one of the entropy based model J_{ksp} of K-FCM using quadratic penalty-vector regularization (K-FCMP) as follows:

$$J_{ksp}(U, \Delta^\phi, V^\phi) = \sum_{k=1}^{n} \sum_{i=1}^{c} (u_{ki})^m d_{ki} + \sum_{k=1}^{n} w_k \|\delta_{kj}^\phi\|^2, \tag{12}$$

$$J_{kep}(U, \Delta^\phi, V^\phi) = \sum_{k=1}^{n} \sum_{i=1}^{c} u_{ki} d_{ki} + \lambda^{-1} \sum_{k=1}^{n} \sum_{i=1}^{c} u_{ki} \log u_{ki} + \sum_{k=1}^{n} w_k \|\delta_{kj}^\phi\|^2. \tag{13}$$

The dissimilarity d_{ki} between the k-th uncertain data and the i-th cluster is the square of the norm on the feature space as follows:

$$\begin{aligned} d_{ki} &= d(x_k^\phi + \delta_k^\phi, v_i^\phi) \\ &= \|x_k^\phi + \delta_k^\phi - v_i^\phi\|^2 \\ &= \sum_{j=1}^{s} (x_{kj}^\phi + \delta_{kj}^\phi - v_{ij}^\phi)^2. \end{aligned} \tag{14}$$

The constraint is as follows:

$$\sum_{i=1}^{c} u_{ki} = 1, \ u_{ki} \in [0, 1], \ {}^\forall k. \tag{15}$$

C. Optimal Solutions

We can derive the optimal solutions by using Lagrange multiplier. The optimal solutions of standard K-FCMP are as follows:

$$\begin{cases} u_{ki} = \dfrac{(1/d_{ki})^{\frac{1}{m-1}}}{\sum_{l=1}^{c} (1/d_{kl})^{\frac{1}{m-1}}}, & (16) \\ v_i^\phi = \dfrac{\sum_{k=1}^{n} (u_{ki})^m (x_k^\phi + \delta_k^\phi)}{\sum_{k=1}^{n} (u_{ki})^m}, & (17) \\ \delta_k^\phi = \dfrac{-\sum_{i=1}^{c} (u_{ki})^m (x_k^\phi - v_i^\phi)}{w_k + \sum_{i=1}^{c} (u_{ki})^m}. & (18) \end{cases}$$

The optimal solutions of entropy based K-FCMP are as follows:

$$\begin{cases} u_{ki} = \dfrac{\exp(-\lambda d_{ki})}{\sum_{l=1}^{c} \exp(-\lambda d_{kl})}, & (19) \\ v_i^\phi = \dfrac{\sum_{k=1}^{n} u_{ki} (x_k^\phi + \delta_k^\phi)}{\sum_{k=1}^{n} u_{ki}}, & (20) \\ \delta_k^\phi = \dfrac{-\sum_{i=1}^{c} u_{ki} (x_k^\phi - v_i^\phi)}{w_k + 1}. & (21) \end{cases}$$

We can formally obtain the optimal solutions as above. However, we cannot calculate v_i^ϕ and δ_k^ϕ directly by this method. The reason is that the map ϕ is not explicit and we have to use x_k, not x_k^ϕ. Therefore, Algorithm 1 cannot be adapted and the procedure of K-FCMP becomes more complicated. Hence, We introduce explicit mappings into K-FCMP to calculate v_i^ϕ directly. It is expected that introducing the explicit mappings makes the procedure more simple and makes calculation time short.

D. Optimal Solutions with Explicit Mappings of Kernel Functions

In this paragraph, we introduce explicit mappings of kernel functions [4]. As above, the kernel function K satisfies $K(x, y) = \langle \phi(x), \phi(y) \rangle = \langle x^\phi, y^\phi \rangle$. Now, we consider a kernel function with the kernel matrix $K = (K_{kl}) = (K(x_k, x_l))$. As K is a positive symmetric matrix, we can introduce a inner product $\langle x, y \rangle_K = xKy$ into $\Re^s$. We assume that $\phi : X \to \Re^n$ and $\phi(x_k) = x_k^\phi = e_k$. Here e_k is a unit vector. Because ϕ can be represented explicitly, we call ϕ using the kernel matrix K explicit mapping. Therefore, the inner product is as follows:

$$\langle e_g, e_h \rangle_K = K_{gh}. \tag{22}$$

Thus, the dissimilarity d_{ki} can be calculated as follows:

$$\begin{aligned} d_{ki} &= d(x_k^\phi + \delta_k^\phi, v_i^\phi) \\ &= d(e_k + \delta_k^\phi, v_i^\phi) \\ &= \langle e_k + \delta_k^\phi - v_i^\phi, e_k + \delta_k^\phi - v_i^\phi \rangle_K \\ &= (e_k + \delta_k^\phi - v_i^\phi)^T K (e_k + \delta_k^\phi - v_i^\phi). \end{aligned} \tag{23}$$

We can calculate the optimal solutions by using the above inner product and dissimilarity. First, we show the solutions of standard EK-FCMP (sEK-FCMP) with the explicit mappings as follows:

$$\begin{cases} u_{ki} = \dfrac{(1/d_{ki})^{\frac{1}{m-1}}}{\sum_{l=1}^{c}(1/d_{kl})^{\frac{1}{m-1}}}, & (24) \\ v_i^\phi = \dfrac{\sum_{k=1}^{n}(u_{ki})^m (e_k + \delta_k^\phi)}{\sum_{k=1}^{n}(u_{ki})^m}, & (25) \\ \delta_k^\phi = \dfrac{-\sum_{i=1}^{c}(u_{ki})^m (e_k - v_i^\phi)}{w_k + \sum_{i=1}^{c}(u_{ki})^m}. & (26) \end{cases}$$

Next, we show the solutions of entropy based EK-FCMP (eEK-FCMP) with the explicit mappings as follows:

$$\begin{cases} u_{ki} = \dfrac{\exp(-\lambda d_{ki})}{\sum_{l=1}^{c}\exp(-\lambda d_{kl})}, & (27) \\ v_i^\phi = \dfrac{\sum_{k=1}^{n} u_{ki}(e_k + \delta_k^\phi)}{\sum_{k=1}^{n} u_{ki}}, & (28) \\ \delta_k^\phi = \dfrac{-\sum_{i=1}^{c} u_{ki}(e_k - v_i^\phi)}{w_k + 1}. & (29) \end{cases}$$

E. Algorithm

Here, we construct an algorithm for EK-FCMP using the above optimal solutions with the explicit mappings as follows.

Algorithm 2 (sEK-FCMP and eEK-FCMP):

Step 1 Set the initial values U and Δ^ϕ. Generate the kernel matrix K.

Step 2 Calculate V^ϕ by the optimal solutions with the explicit mappings on fixing U and Δ^ϕ.

Step 3 Calculate U by the optimal solutions with the explicit mappings on fixing Δ^ϕ and V^ϕ.

Step 4 Calculate Δ^ϕ by the optimal solutions with the explicit mapping on fixing V^ϕ and U.

Step 5 Finish if the solutions are convergent, else go back to Step 2.

F. Fuzzy Classification Functions

Fuzzy classification functions [10] calculate the value of membership grade of an arbitrary point for any cluster by handling the clustering result as a prototype of supervised classification. Therefore, The functions are very useful tools to give some indication to classify new observations and it is significant to discuss how to construct the functions in case of the work in this paper. However, it is difficult to construct the functions because the optimal solution of the membership grades includes the term of penalty vectors and the value cannot be calculated directly. Thus, we have to consider another way to calculate the values of membership grades and we try to obtain the values by iterative optimization for an arbitrary point on the pattern space. We show a standard model algorithm to calculate the value of membership grade $u_i(x) = u_i$ of an arbitrary point $x \in \Re^p$ for the i-th cluster.

Algorithm 3:

Step 1 Suppose that a new observation x is given. Derive a cluster center set V^ϕ by Algorithm 2. Introduce $\hat{V}^\phi = \left\{ \hat{v}_i^\phi \mid \hat{v}_i^\phi = (v_{i1}^\phi, \ldots, v_{is}^\phi, 0)^T \right\}$ and generate a kernel matrix $\hat{K} \in \Re^{(n+1)\times(n+1)}$ for the new dataset $\hat{X} = \{X, x\}$. Set an initial penalty vector $\hat{\delta}^\phi \in \Re^{n+1}$ for the observation x.

Step 2 Calculate u_i by the following equation on fixing $\hat{\delta}^\phi$

$$\begin{cases} u_i = \dfrac{(1/d_i)^{\frac{1}{m-1}}}{\sum_{l=1}^{c}(1/d_l)^{\frac{1}{m-1}}}, & (30) \\ d_i = (e_{n+1} + \hat{\delta}^\phi - \hat{v}_i^\phi)^T \hat{K} (e_{n+1} + \hat{\delta}^\phi - \hat{v}_i^\phi). & (31) \end{cases}$$

Step 3 Calculate $\hat{\delta}^\phi$ by the following equation on fixing u_i.

$$\hat{\delta}^\phi = \frac{-\sum_{i=1}^{c}(u_i)^m (e_{n+1} - \hat{v}_i^\phi)}{w(x) + \sum_{i=1}^{c}(u_i)^m}. \tag{32}$$

Step 4 Finish if the solutions are convergent, else go back to Step 2.

We omit the algorithm for eEK-FCMP.

IV. Numerical Examples

We show numerical examples in Fig. 1 $\sim$ Fig. 24. The pattern space is $[0, 1] \times [0, 1]$. We use the following Gaussian kernel:

$$K(x, y) = \exp(-\beta \|x - y\|^2).$$

The parameters are as follows: $m = 1.2$, $\beta = 70$, $\lambda = 1.2$ and $w_k = 3.0$ for all k. We use the same initial values at all case.

We apply the proposed methods to three types of datasets. First, we compare the conventional and the proposed methods through the nesting dataset. Fig. 1 $\sim$ Fig. 4, Fig. 5 $\sim$ Fig. 8, Fig. 9 $\sim$ Fig. 12 and Fig. 13 $\sim$ Fig. 16 are the results by K-sFCM, K-eFCM, sEK-FCMP and eEK-FCMP, respectively. We also show the cluster centers by using kernel principal component analysis (K-PCA) [11].

Next, we apply sEK-FCMP to other two types of datasets. The clustering results are shown in Fig. 17 (double-circle dataset) and Fig. 21 (double-mass dataset). Fig. 18 and Fig. 22 show the cluster centers in the feature space. The dimension of the feature space by Gaussian Kernel is infinite so that we use the kernel principal component analysis (K-PCA) [11] to show the two dimensional Euclidean space. It became possible to show the cluster centers explicitly by our proposed methods. Fig. 19 and Fig. 20, and Fig. 23 and Fig. 24 show the fuzzy classification functions of each cluster for three types of datasets. We can classify the new given data by the classification functions.

In Table I we show the range of w_k when desirable clustering results are obtained. In the range, the larger w_k gets, the faster the algorithm converges and the clearer the shape of the fuzzy classification functions becomes. EK-FCMP, in particular the entropy based model, with the adequate w_k gives more natural results than K-FCM.

TABLE I
THE RANGE OF w_k WHEN OBTAINING DESIRABLE CLUSTERING RESULTS

sEK-FCMP ($\beta = 70, m = 1.2$)	$1.62 \leq w_k \leq 4.96$
sEK-FCMP ($\beta = 40, m = 1.2$)	None
eEK-FCMP ($\beta = 70, \lambda = 10$)	$2.52 \leq w_k \leq 5.68$
eEK-FCMP ($\beta = 40, \lambda = 5.0$)	$13.2 \leq w_k$

V. CONCLUSION

In this paper, we developed FCM for uncertain data using quadratic penalty-vector regularization by introducing explicit mappings of kernel functions. The proposed algorithm has the following features:

1) The algorithm can handle datasets which consist of some clusters with nonlinear boundary.
2) Because of explicit mappings of kernel functions, we reduce the calculation time.
3) The algorithm becomes more simple than the conventional ones.

Moreover, we construct the fuzzy classification functions.

In the forthcoming paper, we will discuss how to find appropriate parameters and apply to real data.

***Abstract*—This paper presents Mahalanobis distance based fuzzy c-means clustering for uncertain data using penalty vector regularization. When we handle a set of data, data contains inherent uncertainty e.g., errors, ranges or some missing value of attributes. In order to handle such uncertain data as a point in a pattern space the concept of penalty vector has been proposed. Some significant clustering algorithms based on it have been also proposed. In conventional clustering algorithms, Mahalanobis distance have been used as dissimilarity as well as squared L_2 and L_1-norm. From the viewpoint of the guideline of dissimilarity, Mahalanobis distance based fuzzy c-means clustering for uncertain data should be considered. In this paper, we introduce fuzzy c-means clustering for uncertain data using penalty vector regularization as our conventional works. Next, we propose Mahalanobis distance based one. Moreover, we show the effectiveness of proposed method through numerical examples.**

***Index Terms*—fuzzy c-means clustering, penalty vector regularization, uncertain data, Mahalanobis distance.**

I. Introduction

Advanced data analysis methods are required in order to discover important properties from massive and complex databases. Data analysis method consists of supervised learning and unsupervised one. Data clustering simply called clustering is the most well-known unsupervised learning method. Clustering is a method which divides a set of objects into some groups which are referred to as clusters. Objects in same cluster are considered similar, while objects in different cluster are considered dissimilar. The method of K-means which referred to as hard c-means clustering (HCM) is the most popular clustering method [1]. Fuzzy c-means clustering (FCM) [2], [3] is an extension of HCM. In fuzzy c-means clustering, squared Euclidean distance [1]–[3], L_1-norm [4], [5] and Mahalanobis distance [6], [7] are used as dissimilarity.

By the way, each data is conventionally handled as a point in a pattern space and analyzed in clustering procedures. However, there are many cases that data contains inherent uncertainty such as errors, ranges or missing value of attributes. Typical examples of uncertain data are as follows:

- **Errors being introduced when the object is mapped from the real space to pattern space:**
  This kind of error is one of the most typical examples. A round-off error, a truncation error, and a reading error margin are introduced when we map a data from the real space to the pattern space.
- **Missing value of attributes:**
  When we handle data from the questionnaires, there are several questions which are not answered. This causes the missing value of attributes.

These uncertain data are represented by other form instead of a point [8], [9]. Even now, handling uncertain data have been actively studied in many researches [8]–[10]. This means handling uncertain data is one of the significant problems in the field of data mining.

From the viewpoint of handling uncertain data, a concept of tolerance has been proposed and formulated into clustering procedures as the constraint [11]. Moreover, clustering algorithms for data with tolerance have been also proposed [12]–[14]. In these clustering methods for data with tolerance, uncertain data is handled as data with tolerance.

In addition, the concept of penalty vector have been proposed to remove the constraint for tolerance [15], [16]. This concept is formulated on the basis of the concept of regularization such as L_2 or L_1 regularization terms. By introducing regularization terms, some fuzzy c-means clustering algorithms have been proposed [17], [18]. In these clustering algorithms, the L_1-norm [17] and the squared L_2-norm [18] are used as dissimilarity. However, Mahalanobis distance based fuzzy c-means clustering using penalty vector concept has not been discussed. From that sense, we propose Mahalanobis distance based fuzzy c-means clustering for uncertain data using penalty vector regularization.

The contents of this paper are the followings. In the second section, we denote some symbols, fuzzy c-means clustering (FCM). In the third section, we introduce the concept of penalty vector regularization. In the forth section, Mahalanobis distance based fuzzy c-means clustering for uncertain data using penalty vector regularization (FCMQS). In the fifth section, we show the effectiveness of proposed method through

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

numerical examples. In the last section, we conclude this paper.

II. Preliminaries

Let a data, a cluster and its cluster center be $x = (x_{k1}, \ldots, x_{kp})^T \in \Re^p$, $(k = 1, \ldots, n)$, $C_i (i = 1, \ldots, c)$ and $v_i = (v_{i1}, \ldots, v_{ip})^T \in \Re^p$, respectively. Moreover, u_{ki} is the membership grade of x_k belonging to C_i and we denote a partition matrix $U = (u_{ki})_{1 \leq k \leq n,\ 1 \leq i \leq c}$. Here, a set of data and a set of cluster center be $X = \{x_1, \ldots, x_n\}$, $V = \{v_1, \ldots, v_c\}$, respectively.

A. Fuzzy c-Means Clustering

Fuzzy c-means clustering is based on optimizing an objective function under the constraint for membership grade.

We consider following two objective functions J_s and J_e.

$$J_s(U, V) = \sum_{k=1}^{n} \sum_{i=1}^{c} (u_{ki})^m d_{ki},$$

$$J_e(U, V) = \sum_{k=1}^{n} \sum_{i=1}^{c} \left\{ u_{ki} d_{ki} + \lambda^{-1} u_{ki} \log u_{ki} \right\}.$$

here, m and λ is fuzzified parameters.

J_s is a well-known objective function as standard fuzzy c-means clustering (sFCM) proposed by Bezdek [2] and J_e is an entropy based fuzzy c-means clustering (eFCM) [3].

The constraint for u_{ki} is as follows:

$$\mathcal{U}_f = \left\{ (u_{ki}) : u_{ki} \in [0, 1], \ \sum_{i=1}^{c} u_{ki} = 1, \ {}^{\forall} k \right\}. \quad (1)$$

The dissimilarity for clustering is generally the squared L_2-norm between each data and a cluster center:

$$d_{ki} = \|x_k - v_i\|^2 = \sum_{j=1}^{p} (x_{kj} - v_{ij})^2.$$

In addition, the L_1-norm based FCM [4], [5] Mahalanobis distance based one [6], [7] are also considered. In Mahalanobis distance based FCM, the dissimilarity is as follows:

$$d_{ki} = (x_k - v_i)^T S_i (x_k - v_i).$$

where $S_i = (S_{ijl})_{1 \leq i \leq c, 1 \leq j, l \leq p}$ is a positive definite matrix having p^2 elements. In Mahalanobis distance based FCM, S_i is handled as a variable for optimization. The set of S_i is denoted by $S = \{S_1, \ldots, S_c\}$. The constraint for S_i is as follows:

$$|S_i| = \rho_i, \ (\rho_i > 0), {}^{\forall} i. \quad (2)$$

where ρ_i is a constant and $|S_i|$ is the determinant of S_i.

B. Concept of Tolerance

In general, each data is regarded as one point and classified into clusters. However, the uncertain data should be often represented in other form, instead of a point. In the concept of tolerance, data is handled as data with tolerance $x_k + \varepsilon_k$ [11]. A tolerance vector $\varepsilon_k = (\varepsilon_{k1}, \ldots, \varepsilon_{kp})^T \in \Re^p$ is within the tolerance κ_k. A set of tolerance vector is denoted as $E = \{\varepsilon_1, \ldots, \varepsilon_n\}$. By introducing this concept, clustering algorithms for data with tolerance have been proposed [12]–[14]. A constraint for tolerance vector is as follows:

$$(\varepsilon_{kj})^2 \leq (\kappa_{kj})^2, \ (\kappa_{kj} \geq 0), {}^{\forall} k, \ j. \quad (3)$$

III. Concept of Penalty Vector Regularization

Next, we introduce a concept of penalty vector. In the above-mentioned clustering algorithms for data with tolerance, the upper bound of ε_k is constrained by (3). Therefore, those clustering algorithms can not handle the data with unknown range. Thus, we have to consider another way to handle uncertain data with unknown range. From the viewpoint of handling uncertain data with unknown range, the concept of penalty vector has been proposed [15], [16]. A penalty vector is denoted as $\delta_k = (\delta_{k1}, \ldots, \delta_{kp})^T \in \Re^p$ and a set of δ_k is $\Delta = \{\delta_1, \ldots, \delta_n\}$. In clustering algorithms by using the concept of penalty vector, the data is represented as $x_k + \delta_k$ [17], [18]. The regularization terms for penalty vector are as follows:

$$\sum_{k=1}^{n} \sum_{j=1}^{p} \omega_{kj} (\delta_{kj})^2, \quad (4)$$

$$\sum_{k=1}^{n} \sum_{j=1}^{p} \omega_{kj} |\delta_{kj}|. \quad (5)$$

where, $\omega_{kj} > 0$ is a regularization parameter.

As the generalization of (4), the quadratic term for δ_k is considered as follows [18]:

$$\sum_{k=1}^{n} \delta_k^T W_k \delta_k. \quad (6)$$

where, $W_k = (\omega_{kjl})_{1 \leq k \leq n,\ 1 \leq j, l \leq p}$ is a positive definite matrix having p^2 elements. In case that W_k is a diagonal matrix, the second term of J_s is the same as (4). In particular, the diagonal elements ω_{kjj} affect d_{ki}. The bigger ω_{kjj} is, the smaller the optimal solution δ_{kj} is. Oppositely, the smaller ω_{kjj} is, the bigger the optimal solution δ_{kj} is. Hence, we know that W_k means the uncertainty of x_k.

By using this concept, fuzzy c-means clustering for uncertain data using penalty vector regularization (FCMQ) has been constructed [18].

IV. Mahalanobis Distance Based Fuzzy c-Means Clustering for Uncertain Data Using Penalty Vector Regularization

In this section, we propose Mahalanobis distance based fuzzy c-means clustering for uncertain data using penalty vector regularization (FCMQS). The dissimilarity for proposed method is Mahalanobis distance between $x_k + \delta_k$ and v_i written as follows:

$$d_{ki} = (x_k + \delta_k - v_i)^T S_i (x_k + \delta_k - v_i).$$

If we fix S_i with unit matrix, proposed method is equivalent to FCMQ.

A. Mahalanobis Distance Based Standard Fuzzy c-Means Clustering for Uncertain Data Using Penalty Vector Regularization

First of all, we propose Mahalanobis distance based standard fuzzy c-means clustering for uncertain data using penalty vector regularization (sFCMQS). The objective function of sFCMQS is as follows:

$$J_s(U,\Delta,V,S)=\sum_{k=1}^{n}\sum_{i=1}^{c}(u_{ki})^m d_{ki}+\sum_{k=1}^{n}\delta_k^T W_k\delta_k.$$

The constraints for u_{ki} and S_i remain the same as (1) and (2). From the convexity of objective function, the constraints (1) and (2), we introduce the following Lagrangian L_s as follows:

$$L_s=J_s(U,\Delta,V,S)+\sum_{k=1}^{n}\gamma_k\left(\sum_{i=1}^{c}u_{ki}-1\right)+\sum_{i=1}^{c}\psi_i\log\frac{|S_i|}{\rho_i}.$$

where, γ_k and ψ_i are Lagrange multiplier.

The optimal solutions for u_{ki} and v_i are derived from $\frac{\partial L_s}{\partial u_{ki}}=0$ and $\frac{\partial J_s}{\partial v_i}=0$ as follows:

$$u_{ki}=\frac{\left(\frac{1}{d_{ki}}\right)^{\frac{1}{m-1}}}{\sum_{l=1}^{c}\left(\frac{1}{d_{kl}}\right)^{\frac{1}{m-1}}},\tag{7}$$

$$v_i=\frac{\sum_{k=1}^{n}(u_{ki})^m(x_k+\delta_k)}{\sum_{k=1}^{n}(u_{ki})^m}.\tag{8}$$

Next, we consider δ_k. From $\frac{\partial J_s}{\partial \delta_k}=0$, we can get

$$\sum_{i=1}^{c}(u_{ki})^m S_i(x_k+\delta_k-v_i)+W_k\delta_k=0.\tag{9}$$

We put two symbols A_k and B_k are as follows:

$$A_k=\sum_{i=1}^{c}(u_{ki})^m S_i+W_k,$$

$$B_k=\sum_{i=1}^{c}(u_{ki})^m S_i(x_k-v_i)$$

Then,

$$A_k\delta_k=B_k.$$

From above, the optimal solution for δ_k is derived as follows:

$$\delta_k=-A_k^{-1}B_k.\tag{10}$$

Last, we consider S_i. From $\frac{\partial L_s}{\partial S_i}=0$, we can get

$$\sum_{k=1}^{n}(u_{ki})^m(x_k+\delta_k-v_i)(x_k+\delta_k-v_i)^T+\psi_i S_i^{-1}=0.$$

From above,

$$S_i=-\psi_i F_i^{-1}.$$

where F_i is following:

$$F_i=\sum_{k=1}^{n}(u_{ki})^m(x_k+\delta_k-v_i)(x_k+\delta_k-v_i)^T$$

From the constraint $|S_i|=\rho_i$,

$$(-\psi_i)^p\left|F_i^{-1}\right|=\rho_i.$$

Hence,

$$-\psi_i=\left(\frac{\rho_i}{\left|F_i^{-1}\right|}\right)^{\frac{1}{p}}.$$

Finally, the optimal solution for S_i is derived as follows:

$$S_i=\left(\frac{\rho_i}{\left|F_i^{-1}\right|}\right)^{\frac{1}{p}}F_i^{-1}.\tag{11}$$

B. Mahalanobis Distance Based Entropy Based Fuzzy c-Means Clustering for Uncertain Data Using Penalty Vector Regularization

Next, we propose entropy based FCMQS (eFCMQS). The objective function of eFCMQS J_e is as follows:

$$J_e(U,\Delta,V)=\sum_{k=1}^{n}\sum_{i=1}^{c}\left\{u_{ki}d_{ki}+\lambda^{-1}u_{ki}\log u_{ki}\right\}+\sum_{k=1}^{n}\delta_k^T W_k\delta_k.\tag{12}$$

The constraints for u_{ki} and S_i remain the same as (1) and (2). By the same procedures, the optimal solutions for u_{ki}, v_i, δ_k and S_i are derived as follows:

$$u_{ki}=\frac{\exp(-\lambda d_{ki})}{\sum_{l=1}^{c}\exp(-\lambda d_{kl})},\tag{13}$$

$$v_i=\frac{\sum_{k=1}^{n}u_{ki}(x_k+\varepsilon_k)}{\sum_{k=1}^{n}u_{ki}},\tag{14}$$

$$\delta_k=-A_k'^{-1}B_k',\tag{15}$$

$$S_i=\left(\frac{\rho_i}{\left|F_i'^{-1}\right|}\right)^{\frac{1}{p}}F_i'^{-1}.\tag{16}$$

where, A_k', B_k' and $F_i'$are as follows:

$$A_k'=\sum_{j=1}^{p}u_{ki}S_i+W_k,$$

$$B_k'=\sum_{i=1}^{c}u_{ki}S_i(x_k-v_i),$$

$$F_i'=\sum_{k=1}^{n}u_{ki}(x_k+\delta_k-v_i)(x_k+\delta_k-v_i)^T$$

C. Algorithm of Proposed Method

The algorithm of FCMQS is described as Algorithm 1. Eqs. **A**, **B**, **C** and **D** used in each algorithm follow Table I.

Algorithm 1 FCMQS

FCMQS1 Set initial values and parameters.
FCMQS2 Calculate $u_{ki} \in U$ by using Equation **A**.
FCMQS3 Calculate $v_i \in V$ by using Equation **B**.
FCMQS4 Calculate $\delta_k \in \Delta$ by using Equation **C**.
FCMQS5 Calculate $S_i \in S$ by using Equation **D**.
FCMQS6 If convergence criterion is satisfied, stop. Otherwise go back to **FCMQS2**.

V. NUMERICAL EXAMPLES

In this section, we show numerical examples of FCMQ and FCMQS with Polaris data set. This data set is the star chart of Polaris and its neighboring stars. This data set consists of 51 points which are allocated in two dimensional space and should be classified into three clusters. The fuzzified parameter $m = 2.0$ for sFCMQ and sFCMQS, while $\lambda = 1.0$ for eFCMQ and eFCMQS. Moreover, $\rho_i = 1.0$ in each algorithm.

We show classification results by sFCMQ, sFCMQS, eFCMQ and eFCMQS with some parameters W_k. In Figs. 1, 4, 7, 10, 2, 5, 8, 11 and 3, 6, 9, 12, W_k^1, W_k^2, and W_k^3 are used, respectively.

$$W_k^1 = \begin{pmatrix} 2.0 & 0.0 \\ 0.0 & 2.0 \end{pmatrix}, \ ^\forall k,$$

$$W_k^2 = \begin{pmatrix} 2.0 & 0.2 \\ 0.2 & 2.0 \end{pmatrix}, \ ^\forall k,$$

$$W_k^3 = \begin{pmatrix} 2.0 & 0.2 \\ 0.2 & 1.0 \end{pmatrix}, ^\forall k.$$

From these results, δ_k obtained by sFCMQ and eFCMQ indicate the belonging cluster center, while δ_k obtained by sFCMQS and eFCMQS indicate in the same straight line through the belonging cluster center. The reason is that A_k^{-1} and S_i work as rotation matrix for B_k.

This feature is typical difference between FCMQ and FCMQS. The effectiveness of proposed algorithm is shown from these classification results.

VI. CONCLUSIONS

In this paper, we have introduced the concept of penalty vector regularization in order to handle uncertain data. Moreover, we have proposed Mahalanobis distance based Fuzzy c-Means Clustering for uncertain data using penalty vector regularization (FCMQS). The proposed method is quite different from conventional clustering methods for uncertain data from the viewpoint of handling uncertain data as data with penalty vector. Furthermore, we have verified the effectiveness of proposed methods with numerical examples.

In future works, we will consider the relation and effect between S_i and W_k. Moreover, we will show the effectiveness of our proposed method and consider the features of our proposed methods in detail through various kinds of data set. In particular, it is an important problem to reveal the cluster shapes obtained by proposed method

***Abstract*—In this paper, we investigate three types of c-means clustering algorithms with a conditionally positive definite kernel. One is based on hard c-means, and the others are based on standard and entropy-regularized fuzzy c-means. First, based on a conditionally positive definite kernel describing a squared Euclidean distance between data in the feature space, these algorithms are derived from revised optimization problems of the conventional kernel c-means. Next, based on the relationship between the positive definite kernel and conditionally positive definite kernel, the revised dissimilarity between a datum and a cluster center in the feature space is shown. Finally, it is shown that a conditionally positive definite kernel c-means algorithm and a kernel c-means algorithm with a positive definite kernel derived from the conditionally positive definite kernel are essentially identical to each other. An explicit mapping for a conditionally positive definite kernel is also described geometrically.**

***Index Terms*—Clustering, Fuzzy c-means, Conditionally positive definite kernel**

I. Introduction

Fuzzy c-means (FCM) clustering [1] is a well-known fuzzy clustering technique, and many FCM variants have been proposed. One of the authors has proposed an FCM algorithm based on the concept of entropy regularization [2]; this algorithm is known as the entropy-regularized FCM (eFCM) algorithm. It is a useful algorithm that is mathematically related to other techniques.

Three algorithms [3], [4] have been proposed to cluster data with nonlinear borders via nonlinear transformation from the original pattern space into a higher dimensional feature space with support vector machine (SVM) kernel functions [5]. They are the K-HCM algorithm derived from the hard c-means (HCM) algorithm, the K-sFCM algorithm derived from the standard FCM (sFCM) algorithm, and the K-eFCM algorithm derived from the eFCM algorithm. These three algorithms are known as kernel c-means (K-CM) algorithms. For kernel data analysis, an explicit mapping is unknown, whereas the inner product is known. An explicit mapping has been introduced by one of the authors, and it is used to describe the situation of kernel fuzzy c-means in higher dimensional space via kernel principal component analysis [6], [7].

In kernel data analysis, the kernel must be positive definite so that it describes the inner product between the data in the feature space. On the other hand, there exists a class of conditionally positive definite (cpd) kernel [8]. In this paper, we investigate c-means clustering algorithms with cpd kernel. First, we develop three c-means clustering algorithms with cpd kernel by solving the revised optimization problem of K-HCM, K-sFCM, and K-eFCM. Accordingly, the cpd kernel is the squared Euclidean distance between the data in the feature space. We call these three algorithms cpdK-HCM, cdK-sFCM, and cpdK-eFCM, respectively; and sum up to cpdK-CM. Next, we show how the cpd kernel is used in K-CM algorithms, with the positive definite kernel obtained by arranging the cpd kernel. Furthermore, we show the connection between the cpdK-CM algorithms and the K-CM algorithms with the positive definite kernel obtained from the cpd kernel, and we interpret a mapping from the original data space to the feature space, which is latent in the cpdK-CM algorithms. Finally, we show a numerical example of the cpdK-CM algorithms.

II. Preliminaries

In this section, we introduce three K-CM clustering algorithms with an explicit mapping from the original data space to the feature space [6],[7]

The data set $X = \{x_i \mid x_i \in \mathbb{R}^p, i \in \{1, \ldots, N\}\}$ is given. The membership by which x_i belongs to the j-th cluster is denoted by $u_{i,j}$ $(i \in \{1, \cdots, N\}, j \in \{1, \cdots, C\})$, and the set of $u_{i,j}$, denoted by $u \in \mathbf{R}^{N \times C}$, is known as the partition matrix. The constraint on u is

$$\sum_{j=1}^{C} u_{i,j} = 1 \quad (0 \leq u_{i,j} \leq 1).$$

A high-dimensional feature space used in SVM is denoted by $\mathbb{H}$, whereas the original space, which is known as the data space, $\mathbb{R}^p$. $\mathbb{H}$ may be infinite dimensional. Let the inner product be denoted by $\langle \cdot, \cdot \rangle$. The norm of $\mathbb{H}$ for an element $g \in \mathbb{H}$ is given by

$$\|g\|_{\mathbb{H}} = \sqrt{\langle g, g \rangle}. \tag{1}$$

A transformation $\Phi : \mathbb{R}^p \to \mathbb{H}$ is employed, whereby x_i is mapped into $\Phi(x_i)$. In general, Φ is not usable; however, the inner product $\langle \Phi(x), \Phi(y) \rangle$ can be expressed by a kernel function

$$\mathcal{K}(x, y) = \langle \Phi(x), \Phi(y) \rangle. \tag{2}$$

The matrix whose (i, j)-element is $\mathcal{K}(x_i, x_j)$ is denoted by K. The cluster center set in $\mathbb{H}$ is denoted by $W = \{W_1, \cdots, W_C\}$.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

An explicit function Φ corresponding to an introduced kernel function has been proposed as

$$\Phi(x_i) = e_i \tag{3}$$

with

$$\langle e_i, e_j \rangle = e_i^{\mathsf{T}} K e_j, \tag{4}$$

where $\mathbb{H} = \mathbb{R}^N$ and e_i is the k-th unit vector whose i-th component is unity and remaining components are zero. Note that $\Phi : X \to \mathbb{R}^N$, i.e., Φ is not defined on $\mathbb{R}^p$ but on finite data X.

Three K-CM algorithms with explicit mapping are obtained by solving the following optimization problem:

$$\underset{u,W}{\text{minimize}} \sum_{i=1}^{N}\sum_{j=1}^{C} u_{i,j}\|\Phi(x_i) - W_j\|_{\mathbb{H}}^2, \tag{5}$$

$$\text{subject to } \sum_{j=1}^{C} u_{i,j} = 1, \quad u_{i,j} \in \{0,1\}, \tag{6}$$

for K-HCM,

$$\underset{u,W}{\text{minimize}} \sum_{i=1}^{N}\sum_{j=1}^{C} u_{i,j}^m\|\Phi(x_i) - W_j\|_{\mathbb{H}}^2, \tag{7}$$

$$\text{subject to } \sum_{j=1}^{C} u_{i,j} = 1, \tag{8}$$

for K-sFCM, and

$$\underset{u,W}{\text{minimize}} \sum_{i=1}^{N}\sum_{j=1}^{C} u_{i,j}\|\Phi(x_i) - W_j\|_{\mathbb{H}}^2 + \lambda^{-1}\sum_{i=1}^{N}\sum_{j=1}^{C} u_{i,j}\log(u_{i,j}), \tag{9}$$

$$\text{subject to } \sum_{j=1}^{C} u_{i,j} = 1. \tag{10}$$

for K-eFCM. These algorithms are described as follows:

Algorithm 1 (K-CM): [6] [7]

STEP 1. Set $m > 1$ for K-sFCM. Set $\lambda > 0$ for K-eFCM. Set the kernel matrix K and initial partition matrix.

STEP 2. Update the cluster centers W:

$$W_j = \left(\sum_{i=1}^{N} u_{i,j}\right)^{-1} (u_{1,j}, \ldots, u_{N,j})^{\mathsf{T}}, \tag{11}$$

for K-HCM and K-sFCM, and

$$W_j = \left(\sum_{i=1}^{N} u_{i,j}^m\right)^{-1} (u_{1,j}^m, \ldots, u_{N,j}^m)^{\mathsf{T}}, \tag{12}$$

for K-eFCM.

STEP 3. Update the squared Euclidean distance between the cluster center W_j and data $\Phi(x_i)$ in the feature space:

$$d_{i,j} = (e_i - W_j)^{\mathsf{T}} K (e_i - W_j). \tag{13}$$

STEP 4. Update the membership $u_{i,j}$:

$$u_{i,j} = \begin{cases} 1 & (i = \arg\ \min_k d_{k,j}), \\ 0 & (\text{otherwise}), \end{cases} \tag{14}$$

for K-HCM,

$$u_{i,j} = 1/\sum_{k=1}^{C}\left(\frac{d_{i,j}}{d_{i,k}}\right)^{1/(m-1)}, \tag{15}$$

for K-sFCM, and

$$u_{i,j} = \frac{\exp(-\lambda d_{i,j})}{\sum_{k=1}^{C}\exp(-\lambda d_{i,k})}, \tag{16}$$

for K-eFCM.

STEP 4. If (u, W, d) converge, terminate this algorithm. Otherwise, go to STEP 2.

III. Conditionally Positive Definite Kernel c-Means

In this section, we investigate K-CM clustering algorithms with a conditionally positive definite kernel. First, we derive conditionally positive definite K-CM algorithms; thus, the conditionally positive definite kernel is the squared Euclidean distance in a feature space. Next, we show how the cpd kernel is used in a K-CM algorithm with a positive definite kernel obtained by arranging the cpd kernel. Furthermore, we determine the relation between the cpdK-CM and K-CM algorithms with a positive definite kernel obtained from a cpd kernel, and we interpret a mapping from the original data space to the feature space, which is latent in cpdK-CM algorithms. Finally, we show a numerical example of the cpdK-CM algorithms.

A. c-Means algorithms with cpd kernel

In this subsection, we develop c-means clustering algorithms with a cpd kernel by solving the revised optimization problems of K-HCM, K-sFCM, and K-eFCM; thus, the cpd kernel is the squared Euclidean distance between the data in the feature space.

The cpd kernel is defined as follows:

Definition 1 (cpd matrix): [8]

A symmetric $N \times N$ matrix K ($N \geq 2$) taking values in $\mathbb{R}$ and satisfying

$$\sum_{i=1}^{N}\sum_{k=1}^{N} \zeta_i \zeta_k K_{i,k} \geq 0 \tag{17}$$

for all $\zeta_i \in \mathbb{R}$, with

$$\sum_{i=1}^{N} \zeta_i = 0, \tag{18}$$

is said to be conditionally positive definite (cpd).

Definition 2 (cpd kernel): [8]

Let $\mathcal{X}$ be a nonempty set. A function $\tilde{\mathcal{K}} : \mathcal{X} \times \mathcal{X} \to \mathbb{R}$, which yields a conditionally positive definite Gram matrix for all $N \geq 2$, $x_1, \cdots, x_N \in \mathcal{X}$, is known as a conditionally positive definite (cpd) kernel.

A cpd kernel describes the squared Euclidean distance in a feature space as follows:

Theorem 1 (Hilbert space representation of cpd kernels): [8]

Let $\tilde{\mathcal{K}}$ be a real-valued conditionally positive definite kernel on $\mathcal{X}$, satisfying $\tilde{\mathcal{K}}(x, x) = 0$ for all $x \in \mathcal{X}$. Then, there exists a Hilbert space $\mathbb{H}$ of real-valued functions on $\mathcal{X}$ and a mapping $\Phi : \mathcal{X} \to \mathbb{H}$ such that

$$\|\Phi(x) - \Phi(x')\|_{\mathbb{H}}^2 = -\tilde{\mathcal{K}}(x, x'). \tag{19}$$

If we drop the assumption $\tilde{\mathcal{K}}(x, x) = 0$, the Hilbert space representation reads

$$\|\Phi(x) - \Phi(x')\|_{\mathbb{H}}^2 = -\tilde{\mathcal{K}}(x, x') + \frac{1}{2}(\tilde{\mathcal{K}}(x, x) + \tilde{\mathcal{K}}(x', x')). \tag{20}$$

We cannot utilize the squared Euclidean distance between the data in the feature space for K-CM (Algorithm 1) because the optimization problems (5)–(10) include the squared Euclidean distance between the data and the cluster center in the feature space. Therefore, we reformulate the K-CM optimization problems (5)–(10) into the following problems:

$$\underset{u}{\text{minimize}} \sum_{j=1}^{C} \frac{\sum_{i=1}^{N}\sum_{k=1}^{N} u_{i,j}\|\Phi(x_i) - \Phi(x_k)\|_{\mathbb{H}}^2}{\left(\sum_{t=1}^{N} u_{t,j}\right)^2}, \tag{21}$$

$$\text{subject to } \sum_{j=1}^{C} u_{i,j} = 1, \quad u_{i,j} \in \{0, 1\}, \tag{22}$$

for K-HCM,

$$\underset{u}{\text{minimize}} \sum_{j=1}^{C} \frac{\sum_{i=1}^{N}\sum_{k=1}^{N} u_{i,j}^m\|\Phi(x_i) - \Phi(x_k)\|_{\mathbb{H}}^2}{\left(\sum_{t=1}^{N} u_{t,j}\right)^2}, \tag{23}$$

$$\text{subject to } \sum_{j=1}^{C} u_{i,j} = 1, \tag{24}$$

for K-sFCM, and

$$\underset{u}{\text{minimize}} \sum_{j=1}^{C} \frac{\sum_{i=1}^{N}\sum_{k=1}^{N} u_{i,j}\|\Phi(x_i) - \Phi(x_k)\|_{\mathbb{H}}^2}{\left(\sum_{t=1}^{N} u_{t,j}\right)^2} + \lambda^{-1}\sum_{i=1}^{N}\sum_{j=1}^{C} u_{i,j}\log(u_{i,j}), \tag{25}$$

$$\text{subject to } \sum_{j=1}^{C} u_{i,j} = 1. \tag{26}$$

for K-eFCM. The form $\|\Phi(x_i) - \Phi(x_k)\|_{\mathbb{H}}^2$ in the above objective functions can be translated into $-\tilde{K}_{i,k}$ if $\tilde{K}_{i,i} = 0$, and $-\tilde{K}_{i,k} + 1/2(\tilde{K}_{i,i} + \tilde{K}_{k,k})$ otherwise, with the cpd kernel matrix $\tilde{K}$. Such optimization problems are identical to those for RHCM and RFCM [9] if the corresponding relational data matrix is $\tilde{K}$, and they are solved using the following algorithms:

Algorithm 2 (cpdK-{H,sF,eF}CM):

STEP 1. Set the fuzzifier parameter m and λ for cpdK-sFCM and cpdK-eFCM, respectively. Set the cpd kernel matrix $\tilde{K}$ and the initial membership $u_{i,j}$. Set the N-dimensional squared matrix R as

$$R_{i,k} = -\tilde{K}_{i,k} + 1/2(\tilde{K}_{i,i} + \tilde{K}_{k,k}) \tag{27}$$

STEP 2. Update the intermediate variable $w_j \in \mathbb{R}^N$ as

$$w_j = \left(\sum_{i=1}^{N} u_{i,j}\right)^{-1} (u_{1,j}, \ldots, u_{N,j})^{\mathsf{T}}, \tag{28}$$

for cpdK-HCM,

$$w_j = \left(\sum_{i=1}^{N} u_{i,j}^m\right)^{-1} (u_{1,j}^m, \ldots, u_{N,j}^m)^{\mathsf{T}}, \tag{29}$$

for cpdK-sFCM, and

$$w_j = \left(\sum_{i=1}^{N} u_{i,j}\right)^{-1} (u_{1,j}, \ldots, u_{N,j})^{\mathsf{T}}. \tag{30}$$

for cpdK-eFCM.

STEP 3. Update the intermediate variable $\tilde{d}_{i,j}$ as

$$\tilde{d}_{i,j} = (Rw_j)_i - \frac{1}{2} w_j^{\mathsf{T}} R w_j. \tag{31}$$

STEP 4. Update the membership $u_{i,j}$ as

$$u_{i,j} = \begin{cases} 1 & (i = \arg\ \min_k \tilde{d}_{k,j}), \\ 0 & (\text{otherwise}), \end{cases} \tag{32}$$

for cpdK-HCM,

$$u_{i,j} = 1/\sum_{k=1}^{C} \left(\frac{\tilde{d}_{i,j}}{\tilde{d}_{i,k}}\right)^{1/(m-1)}, \tag{33}$$

for cpdK-sFCM, and

$$u_{i,j} = \frac{\exp(-\lambda \tilde{d}_{i,j})}{\sum_{k=1}^{C} \exp(-\lambda \tilde{d}_{i,k})}, \tag{34}$$

for cpdK-eFCM.

STEP 5. If a stopping criterion is satisfied, terminate this algorithm. Otherwise, go to STEP. 2.

B. c-Means with pd kernel obtained from cpd kernel

In this subsection, we show how the cpd kernel is used in K-CM algorithms with a positive definite kernel obtained by arranging the cpd kernel. First, we show the relation between the cpd kernel and the pd kernel. Next, for K-CM (Algorithm 1) with a pd kernel obtained by reformulating the cpd kernel, we show how the cpd kernel is used to calculate the squared Euclidean distance between the data and the cluster center in the feature space.

The cpd kernel and the pd kernel have the following relation:

Theorem 2 (Connection cpd — pd): [8]

Let K be an N-dimensional symmetric matrix; $\mathbf{1} \in \mathbb{R}^N$, an N-dimensional real-valued vector whose elements are all 1; $E \in \mathbb{R}^{N \times N}$, the identity matrix; and $\eta \in \mathbb{R}^N$, a vector satisfying

$$\mathbf{1}^\mathsf{T} \eta = 1. \tag{35}$$

Then,

$$K = (E - \mathbf{1}\eta^\mathsf{T})\tilde{K}(E - \eta \mathbf{1}^\mathsf{T}) \tag{36}$$

is positive definite if and only if $\tilde{K}$ is conditionally positive definite.

Given the cpd kernel $\tilde{K}$ for a data set X, we can obtain the pd kernel

$$K = (E - \mathbf{1}\mathbf{1}^\mathsf{T}/N)\tilde{K}(E - \mathbf{1}\mathbf{1}^\mathsf{T}/N) \tag{37}$$

from Theorem 2 and use it K-CM (Algorithm 1). Then, STEP 3 of Algorithm 1 is rewritten as

STEP 3. Update the intermediate variable $\tilde{d}_{i,j}$ as

$$d_{i,j} = (e_i - W_j)^\mathsf{T} \tilde{K}(e_i - W_j) \tag{38}$$

from that

$$(E - \eta \mathbf{1}^\mathsf{T})(e_i - W_j) = (e_i - W_j). \tag{39}$$

C. Discussion

In this subsection, we show the relation between the K-CM algorithm with a pd kernel obtained from the cpd kernel and the cpdK-CM algorithm, and we geometrically interpret the explicit mapping from the data space to the feature space, hiding in cpdK-CM.

First, the updating equations (28) and (29) of the intermediate variable w_j in cpdK-CM (Algorithm 2) and the updating equations (11) and (12) of the cluster center W_j in K-CM (Algorithm 1) are identical. Next, the updating equations (32), (33), and (34) of the membership $u_{i,j}$ in cpdK-CM (Algorithm 2) and the updating equations (14), (15), and (16) of the membership $u_{i,j}$ in K-CM (Algorithm 1) are also identical. Furthermore, the updating equation of $d_{i,j}$ in K-CM (Algorithm 1) with a pd kernel obtained by reformulating the cpd kernel is expressed as Eq. (38). On the other hand, the updating equation of $\tilde{d}_{i,j}$ in cpdK-CM (Algorithm 2) can be expressed as

$$\begin{aligned} \tilde{d}_{i,j} =& (Rw_j)_i - \frac{1}{2} w_j^\mathsf{T} R w_j \\ =& \frac{1}{2}(e_i - w_j)^\mathsf{T} \tilde{K}(e_i - w_j) \end{aligned} \tag{40}$$

from $R = -\tilde{K}$, with $\tilde{K}_{i,i} = 0$. Therefore, $\tilde{d}_{i,j}$ in cpdK-CM (Algorithm 2) and $d_{i,j}$ in K-CM (Algorithm 1) with a pd kernel obtained by reformulating the cpd kernel have the following relation:

$$\tilde{d}_{i,j} = \frac{1}{2} d_{i,j}. \tag{41}$$

Comparing these relations with that between the pd kernel and the cpd kernel, cpdK-CM (Algorithm 2) for the cpd kernel $\tilde{K}$ with $\tilde{K}_{i,i} = 0$ and K-CM (Algorithm 1) for the pd kernel K with

$$K = 2(E - \mathbf{1}\eta^\mathsf{T})\tilde{K}(E - \eta \mathbf{1}^\mathsf{T}) \tag{42}$$

are identical.

Next, we geometrically interpret the explicit mapping from the data space to the feature space, hiding in cpdK-CM. Since cpdK-CM (Algorithm 2) and K-CM (Algorithm 1) with a pd kernel obtained from the cpd kernel are identical, we interpret cpdK-CM (Algorithm 2) from the geometrical interpretation of K-CM (Algorithm 1) with a pd kernel obtained from the cpd kernel.

Fig. 1 shows the feature space $\mathbb{H}$ used in K-CM (Algorithm 1). The mapping $e_i = \Phi(x_i)$ from each data x_i by an explicit mapping Φ is expressed along the i-th axis. From the updating equation of the cluster center W_j in K-CM (Algorithm 1), every cluster center W_j is in the $N-1$-dimensional subspace spanned by each data e_i. Hence $e_i - W_j$ for all $i \in \{1, \cdots, N\}$ and $j \in \{1, \cdots, C\}$ is orthogonal to $\mathbf{1}$. Therefore, it is guaranteed that $d_{i,j}$ is non-negative, even if $\tilde{K}$ is conditionally positive definite (and not positive definite) in K-CM (Algorithm 1).

IV. NUMERICAL EXAMPLE

In this section, we present an example of cpdK-CM. Fig. 2 shows 147 data points in two-dimensional space, which form doughnut-shaped and ball-shaped clusters. Such data cannot be clustered correctly using the usual HCM, sFCM, and eFCM algorithms because these clusters have a nonlinear border. Introducing the cpd kernel

$$\tilde{\mathcal{K}}(x, x') = \log(1 + \|x - x'\|_2^{0.5}), \tag{43}$$

cpdK-sFCM (Algorithm 2) with the fuzzifier parameter $m = 1.1$ yielded a successful result, as shown in Fig. 3.

V. CONCLUSION

In this paper, we investigated a hard and two fuzzy c-means clustering algorithms with a conditionally positive definite

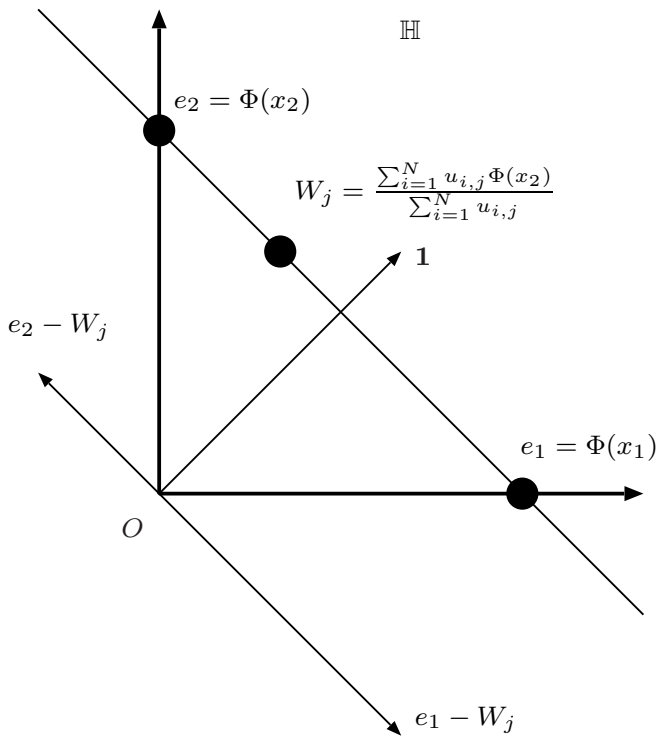

Fig. 1. Data and cluster centers in feature space $\mathbb{H}$

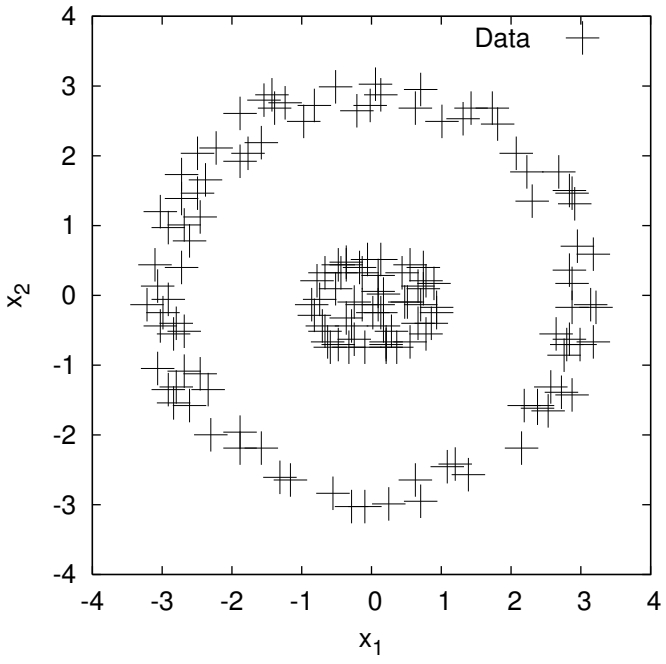

Fig. 2. Data

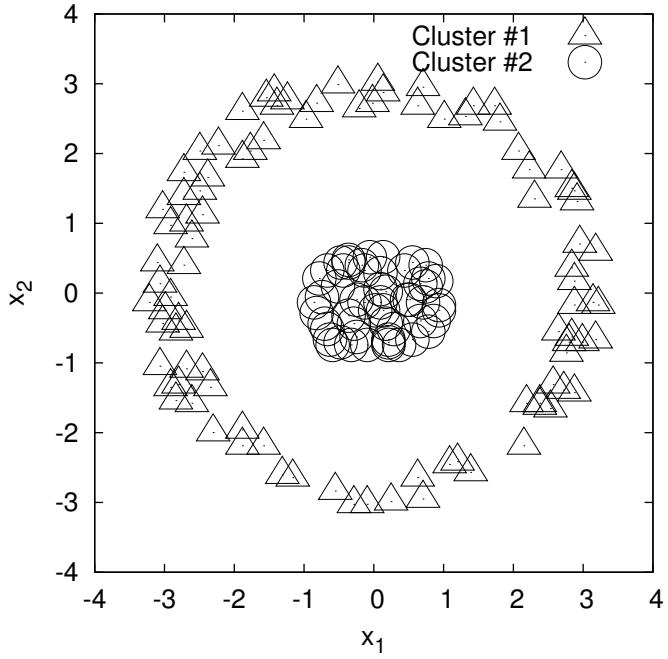

Fig. 3. Successful result ($\tilde{\mathcal{K}}(x, x') = \log(1 + \|x - x'\|_2^{0.5})$, $m = 1.1$

kernel. First, we developed c-means clustering algorithms using cpd kernel by solving the revised optimization problem of K-HCM, K-sFCM, and K-eFCM; thus, the cpd kernel is the squared Euclidean distance between the data in the feature space. Next, we showed how the cpd kernel is used in K-CM algorithms with a positive definite kernel obtained by arranging the cpd kernel. Furthermore, we showed the relation between the cpdK-CM algorithms and K-CM algorithms with a positive definite kernel obtained from the cpd kernel, and we interpreted a mapping from the original data space to the feature space, which is latent in cpdK-CM algorithms. Finally, we showed a numerical example of the cpdK-CM algorithms.

***Abstract*—Fuzzy cognitive maps have proven an exceptional means to reasoning for decision support. In this paper we propose a novel approach to hesitancy-aware reasoning based on cognitive maps and intuitionistic fuzzy logic. Intuitionistic fuzzy sets are considered for the linguistic representation of both the concepts of a cognitive map and the relations defined between them. A comparative advantage of this approach over the state of the art is an intrinsic mechanism of modeling human hesitancy, as introduced in the construction of a cognitive model, and propagated through the reasoning process to a final decision. A numerical example demonstrates its effectiveness which can extend to a variety of real-world applications.**

Keywords-fuzzy cognitive maps; intuitionistic fuzzy sets; reasoning; decision support

I. INTRODUCTION

Human decisions are commonly expressed with a degree of hesitation, originating from uncertain or imperfect facts and imprecise knowledge. The theory of intuitionistic fuzzy sets (IFSs) [1] offers a sound mathematical framework to modeling hesitation through a tradeoff between the membership and the non-membership of an element to such a set.

A pioneering approach to intuitionistic fuzzy reasoning for decision support have been proposed in [3], where different forms of fuzzy propositional expressions and their relations have been investigated. In [4] Sanchez's approach to fuzzy reasoning has been extended with IFSs and applied for medical diagnosis. As an alternative to that method, a distance-based method has been proposed in [5]. Recent advances in field include an intuitionistic fuzzy Petri net model and reasoning algorithm [6], and an extension of the fuzzy cognitive map (FCM) model for intuitionistic fuzzy reasoning [7].

FCMs are fuzzy directed graphs whose nodes represent concepts which can be causally interrelated through the graph edges and describe knowledge with fuzzy logic [8]-[9]. In [7] IFSs have been used to define fuzzy relations between the concepts including the hesitancy of the experts in defining such relations during the construction of an intuitionistic FCM (iFCM). Advantages of this approach include a) capability to model the expert's hesitation in the construction of the cognitive map b) coping with incomplete or even conflicting information, c) easy construction and parameterization.

The improved results obtained with the iFCM in comparison with the conventional FCM approach on a real application for medical decision support [7] motivated us to investigate an enhanced iFCM model for decision support. This model, presented in this paper, co-evaluates human hesitancy not only in the definition of the relations between the concepts but also in the definition of the concept values. It can be considered as a generalization of the original iFCM enabling the expression of hesitancy both in the construction of cognitive models by experts and in their application by users.

The rest of this paper consists of three sections. Section II briefly describes the previous iFCM approach [7], to which we will refer to as iFCM-I, and presents the novel iFCM approach for intuitionistic fuzzy reasoning. In order to differentiate it from the previous one, we will call it iFCM-II. A numerical example that demonstrates the effectiveness of the latter one is presented in Section III, whereas the conclusions of this study are summarized in Section IV.

II. INTUITIONISTIC FUZZY COGNITIVE MAPS

A. Intuitionistic Fuzzy Sets

Given a universe of discourse E an IFS is defined as [1]

$$A=\left\{\left\langle x,\mu_A(x),\gamma_A(x)\right\rangle \middle| x\in E\right\} \quad (1)$$

where $\mu_A : E\to[0,1]$ and $\gamma_A : E\to[0,1]$ define the degree of *membership* and *non-membership*, respectively, of the element $x\in E$ to the set $A\subset E$. For every element $x\in E$ it holds that $0\le\mu_A(x)\le 1 \quad 0\le\gamma_A(x)\le 1$ and $0\le\mu_A(x)+\gamma_A(x)\le 1$. For $x\in E$, if $\gamma_A(x)=1-\mu_A(x)$, A represents a fuzzy set. The *hesitancy* of the element $x\in E$ to the set $A\subset E$ is defined as

$$\pi_A(x)=1-\mu_A(x)-\gamma_A(x) \quad (2)$$

A variety of operations over IFSs have been defined [2]. These include the summation and the multiplication of two fuzzy sets, which are defined as

$$A\oplus B=\left\{\left\langle x,\mu_A(x)+\mu_B(x)-\mu_A(x)\cdot\mu_B(x),\gamma_A(x)\cdot\gamma_B(x)\right\rangle \middle| x\in E\right\} \quad (3)$$

$$A\otimes B=\left\{\left\langle x,\mu_A(x)\cdot\mu_B(x),\gamma_A(x)+\gamma_B(x)-\gamma_A(x)\cdot\gamma_B(x)\right\rangle \middle| x\in E\right\} \quad (4)$$

B. iFCM-I

Similarly to a conventional FCM [10], iFCM-I models a decision making task as a graph [7]. Its nodes represent N concepts that sufficiently describe this task. Each concept is

This work was realized in the framework of the project DebugIT which is co-funded by the EC FP7 grant agreement n° FP7–217139. The EC, DG INFSO, is not liable for any use that may be made of the information in this document. It reflects solely the views of the authors.

modeled as a *linguistic variable* C_i, i=1,2,…N that can take linguistic values represented by fuzzy sets $\widetilde{L}_n^{C_i}$, n=1,...,l, on U_i, where U_i represents the respective universe of discourse.

The experts describe the *relations* between the concepts by if-then *rules* of the form:

"**If** a *change X* occurs in the value of concept C_j **then** a *change Y* is caused in the value of concept C_i."

where X and Y are linguistic variables quantifying the respective *change* with a linguistic value represented by a fuzzy set $\widetilde{R}_n$, on E, from $\widetilde{R} = \{\widetilde{R}_r\}$, n=1,…,r.

From each rule the *influence* of concept C_j on concept C_i is inferred as a linguistic value represented by a fuzzy set $(\widetilde{I}_n)_{ji}$ on E, from $\widetilde{I} = \{\widetilde{I}_n\}$, n=1,...,g, according to [10]. These fuzzy sets express the degree to which a concept C_j influences another concept C_i, i=1,2,…N, j=1,2,…N.

Unlike a conventional FCM, iFCM-I can model the *hesitation* of the expert to express the rule and therefore the influence among two concepts, C_i and C_j, i=1,...N, j=1,...,N. This is represented by a fuzzy set $(\widetilde{H}_n)_{ij}$, on [0,1], from $\widetilde{H} = \{\widetilde{H}_n\}$, n=1,...,h, which is subsequently used to construct a set Ω of IFSs from $\widetilde{I} \times \widetilde{H}$, defined as

$$\Omega_n = \left\{ \left\langle x, \mu_{\Omega n}(x), \gamma_{\Omega n}(x) \right\rangle \middle| x \in E \right\}, n = 1,..., \omega \le m \cdot p \qquad (5)$$

with a membership function $\mu_{\Omega n}(x) = \mu_{\widetilde{I}m}(x)$, m=1,...,g, a non-membership function $\gamma_{\Omega n}(x) = 1 - \mu_{\widetilde{I}m}(x) - \mu_{\widetilde{H}p}(x)$, p=1,...,h, and a hesitancy function $\pi_{\Omega n}(x) = \mu_{\widetilde{H}p}(x)$ as Eq.(2), where $0 \le \mu_{\Omega n}(x) \le 1$, $0 \le \gamma_{\Omega n}(x) \le 1$, $0 \le \pi_{\Omega n}(x) \le 1$.

The reasoning process with iFCM-I involves iterative calculation of the following equation until a steady state is reached [7]:

$$s_i^{k+1} = f\left(\left(2s_i^k - 1\right) + \sum_{\substack{j=1 \\ j \ne i}}^{N} \left(\left(2s_j^k - 1\right) \cdot w_{ji}^{\mu} \cdot \left(1 - w_{ji}^{\pi}\right) \right) \right) \qquad (6)$$

where $s_i^k \in [0,1]$, i=1,2,…N represent real node values at an iteration k, $w_{ji}^{\mu} \in [-1,1]$ and $w_{ji}^{\pi} \in [0,1]$ represent the influence weight and the hesitancy weight corresponding to the edge directed from node j to node I. Function f is of sigmoid form and aims to keep the node values within [0, 1]. The initial weights are estimated by defuzzification of the aggregated, linguistically expressed, influences between the concepts [10].

C. iFCM-II

The previous iFCM approach considers only the hesitancy in expression of the influence between the concepts. However, in human decision making tasks hesitancy may also be introduced in the determination of concept values, and it may also be propagated through the reasoning process to the final decision. In order to incorporate such a consideration into a concise decision making model, we propose a more general, novel, formulation of the iFCM.

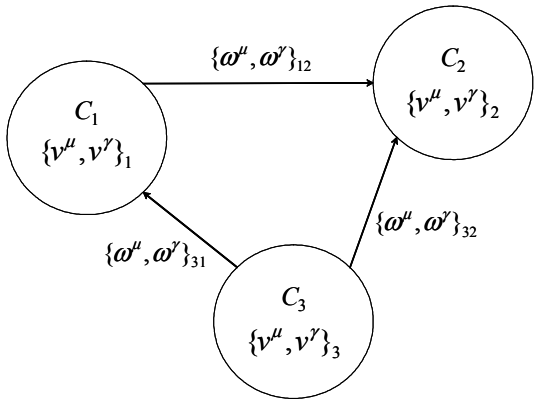

Figure 1. The proposed iFCM-II model.

The proposed approach considers that concepts C_i, i=1,2,…N are modeled as linguistic variables that can take linguistic values represented by IFSs of the form $L_n^{C_i} = \left\{ \left\langle x, v_i^{\mu}(x), v_i^{\gamma}(x) \right\rangle \middle| x \in U_i \right\}$, n=1,...,l, on U_i, where U_i represents the respective universe of discourse. Therefore, each concept is characterized by a pair $\{v^{\mu}, v^{\gamma}\}_i$ representing the membership and the non-membership to the respective IFS. Similarly, considering the use of IFSs in the description of the influence of a concept C_i to another concept C_j, a pair of membership and non-membership values $\{\omega^{\mu}, \omega^{\gamma}\}_{ji}$ can be used for the representation of this influence. This enhanced iFCM model is illustrated graphically in Fig.1. It should be noted that the pair $\{\omega^{\mu}, \omega^{\gamma}\}_{ji}$ defines an IFS as in Eq.(1), whereas in the case of iFCM-I which in turn results in $\left(w_{ji}^{\mu}, w_{ji}^{\pi}\right)$, represents a pair of weight values characterizing the influence between the concepts and not an IFS.

Having such an IFS-based representation of the concepts and the influences between the concepts, we reformulate the equation of the conventional FCM [10], which is

$$s_i^{k+1} = f\left(s_i^k + \sum_{\substack{j=1 \\ j \ne i}}^{N} s_j^k w_{ji} \right) \qquad (7)$$

so that it can be applied on IFSs, for i=1,2,…N

$$\{v^{\mu}, v^{\gamma}\}_i^{k+1} = F\left(\{v^{\mu}, v^{\gamma}\}_i^k \oplus \left(\bigoplus_{\substack{j=1 \\ j \ne i}}^{N} \left(\{v^{\mu}, v^{\gamma}\}_j^k \otimes \{\omega^{\mu}, \omega^{\gamma}\}_{ji} \right) \right) \right) \qquad (8)$$

where the arithmetic summation and multiplication of Eq.(7) have been replaced by the respective operations on IFSs defined by Eqs.(3-4), and $F(A)$ is a function defined on IFSs as

$$F(A) = \left\{ f_{\mu}(\mu_A), f_{\gamma}(\gamma_A) \right\} \qquad (9)$$

where A is an IFS, and f_{μ}, and f_{γ} are sigmoid functions such that $0 \le f_{\mu}(\mu_A) + f_{\gamma}(\gamma_A) \le 1$. In this work we consider

$$f_\mu(x) = f_\gamma(x) = \tanh(x) \tag{10}$$

It should be noted that function F is considered mainly as a means to push the system to converge to a steady state by deforming the real membership and non-membership values and not for the normalization of the real membership and the non-membership values, which by definition range in a standard interval i.e. [0, 1].

By using Eq.(4) on Eq.(8) for the calculation of the IFS multiplication, it is obtained:

$$\{v^\mu, v^\gamma\}_i^{k+1} = F\left(\{v^\mu, v^\gamma\}_i^k \oplus \left(\bigoplus_{\substack{j=1 \\ j\neq i}}^{N} \left(\{v_j^\mu \omega_{ji}^\mu, v_j^\gamma + \omega_{ji}^\gamma - v_j^\gamma \omega_{ji}^\gamma\}\right)\right)\right) \tag{11}$$

and by using Eq.(3) on the right-hand term of Eq.(9) it becomes

$$\{v^\mu, v^\gamma\}_i^{k+1} = F\left(\{v^\mu, v^\gamma\}_i^k \oplus \left\{m_{iN}, \prod_{\substack{j=1 \\ j\neq i}}^{N} \left(v_j^\gamma + \omega_{ji}^\gamma - v_j^\gamma \omega_{ji}^\gamma\right)\right\}^k\right)$$

which again due to Eq.(3) results in

$$\{v^\mu, v^\gamma\}_i^{k+1} = F\left(\left\{v_i^\mu + m_{iN} - v_i^\mu m_{iN}, v_i^\gamma \cdot \prod_{\substack{j=1 \\ j\neq i}}^{N} \left(v_j^\gamma + \omega_{ji}^\gamma - v_j^\gamma \omega_{ji}^\gamma\right)\right\}^k\right)$$

or

$$\{v^\mu, v^\gamma\}_i^{k+1} = F\left(\left\{v_i^\mu + \left(1 - v_i^\mu\right) \cdot m_{iN}, v_i^\gamma \cdot \prod_{\substack{j=1 \\ j\neq i}}^{N} \left(v_j^\gamma + \omega_{ji}^\gamma - v_j^\gamma \omega_{ji}^\gamma\right)\right\}^k\right) \tag{12}$$

where

$$m_{Ni} = \bigoplus_{\substack{j=1 \\ j\neq i}}^{N}{}^{\mu} v_j^\mu \omega_{ji}^\mu,\ i=1,2,\ldots N. \tag{13}$$

In this equation $\oplus^\mu$ represents the summation operator applied on the memberships of the IFSs in Eq.(3), i.e.

$$\mu_A \oplus^\mu \mu_B = \mu_A + \mu_B - \mu_A \mu_B. \tag{14}$$

Equation (12) can be calculated recursively for all j=1…N

$$m_{ij} = \begin{cases} v_1^\mu \omega_{1i}^\mu & j = 1 \\ m_{(j-1)i} \oplus^\mu v_j^\mu \omega_{ji}^\mu, & j > 1 \end{cases} \tag{15}$$

which due to Eq.(13) can also be expressed as

$$m_{ij} = \begin{cases} v_1^\mu \omega_{1i}^\mu & j = 1 \\ m_{(j-1)i} + v_j^\mu \omega_{ji}^\mu - m_{(j-1)i} v_j^\mu \omega_{ji}^\mu, & j > 1 \end{cases} \tag{16}$$

Obviously the complexity of Eq.(11) is higher than that of Eq.(6) and Eq.(7); however, the result obtained will be more informative since a propagated degree of hesitation will be quantifiable through the application of Eq.(2) on Eq.(11).

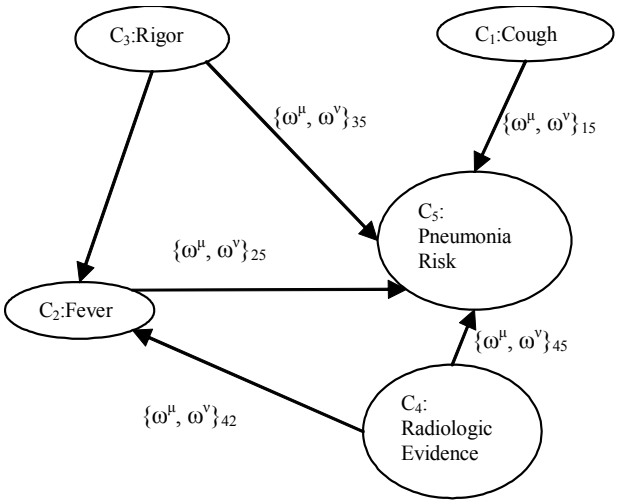

Figure 2. iFCM for pneumonia risk assessment.

The hesitancy of the proposed model at steady state is calculated from Eq.(2) by using the real membership and non-membership values. These are obtained by application of the inverse F on the decision concepts i.e. if c is a decision concept the real membership and non-membership values at the iteration K where convergence is met will be $F^{-1}\left(\{v^\mu, v^\gamma\}_c^K\right)$, which is defined as $\{f_\mu^{-1}(v^\mu), f_\gamma^{-1}(v^\gamma)\}_c^K$.

III. NUMERICAL EXAMPLE

The medical decision making task of pneumonia risk assessment, described in [11], has been considered for our case study. This is an important medical decision making task because of the serious, life threatening, adverse consequences that could occur in the critically ill patients if the pneumonia infection is misdiagnosed [12].

In order to present a numerical example that would be easily reproducible by other researchers, despite the complex IFS operations involved, we constructed a reduced version of the cognitive model presented in [11]. This iFCM model consists of only five concepts instead of 34 (Fig. 2). We demonstrate its construction and simulation for three cases, using both the iFCM-I and the iFCM-II approaches.

A. Model construction

The pneumonia risk assessment model was based on the knowledge of three expert physicians. The opinions of these experts were pooled to define the number and types of parameters/factors associated with the particular decision making task, as well as the interconnections among these parameters. The parameters have been considered as concepts of the FCM and include the symptoms of cough (C_1), fever (C2), rigor (C_3), the presence of radiological evidences of pneumonia in the patient's chest radiograph (C_4), and the risk

TABLE I. EXPERTS' OPINIONS ON INFLUENCES BETWEEN CONCEPTS

Relation ($C_i \rightarrow C_j$)	Experts' Opinions

$C_3 \rightarrow C_2$	0.300	0.600	0.100
$C_4 \rightarrow C_2$	0.700	0.070	0.220

TABLE III. DECISION RANGES FOR CONCEPT C_5

Decision Node Values	Ranges Proposed by Physicians			
	<0.50	**0.50-0.70**	**0.70-0.85**	**>0.85**
Infection Risk	Low	Moderate	High	Very high

of infection (C_5), which is the decision concept. These concepts are well documented in the literature [12]. They represent the main variables that play an important role in the final diagnostic decision about the risk of pneumonia. For this application, the concepts take two, three, four or five possible discrete or fuzzy values [7]. For example the symptom of cough takes three fuzzy values (no cough, moderate cough, serious cough state) according to the initial patient stage. The decision concept (C_5) represents the risk of pulmonary infection and takes four fuzzy values (low, moderate, high, very high).

According to the proposed methodology (Section II.C), the opinions of three experts were pooled together to assign new if-then rules that describe the influences from concepts C_i to concepts C_j, i=1…5, j=1…5. The inferences of the rules are linguistic weights described by IFSs $\{\omega^{\mu}, \omega^{\gamma}\}_{ji}$. The linguistic weights obtained by the experts for the construction of the iFCM model are apposed in Table I. For each influence (I-E_i) between two concepts, the expert E_i, i =1,2,3 expresses his/her hesitancy (H-E_i). The linguistic values of hesitancy vary from very low (v.low) to high. The respective membership, non-membership and hesitancy values derived from Table I are common for both the iFCM-I and iFCM-II models, and they are summarized in Table II. The interpretation of the numeric risk for pneumonia infection obtained from the output concept C_5 is performed according to Table III.

In what follows, we provide three example patient cases for which we would like to assess the pneumonia risk using the constructed model for both iFCM-I and iFCM-II approaches.

B. First Case

In the first case, we consider a patient with suspected pneumonia having moderate cough (C_1=0.6), high fever (C_2=0.7), and no other information is available. Based on these data, the experts assessed the infection risk as moderate.

In iFCM-I, as noted in [7], the concepts with unknown values are set to 0.5, i.e. C_3=C_4=0.5. In iFCM-II the membership values of the respective concepts are set to zero, i.e. C_3=C_4=0. The non-membership values of these concepts are initially set to 0.5. However, the initial non-membership values do practically affect the final decision, because, as it can be noticed by the obtained results, they reach zero at convergence.

The results of the reasoning process obtained with iFCM-I (Eq. 6), at each iteration k, till convergence at a steady state are apposed in Table IV. The first row includes the initial concept values, and the last row, in boldface, indicates the concept values at steady state. The respective results with the use of the proposed iFCM-II approach are presented in Tables V and VI. We provide all concept values for validation of the results of other researchers that would like to implement our iFCM models. Table V shows that iFCM-II reaches a steady state at a numerical value that is close to the membership value obtained with iFCM-II, whereas the decisions derived

by both iFCM approaches, according to Table III are in agreement with the aggregated fuzzy experts' opinion i.e. moderate. The non-membership values of all the concepts of iFCM-II are monotonically decreasing. The steepest decrease is observed at the output concept C_5, whose non-membership value reaches zero after converging at a steady state. Furthermore a real hesitancy estimation can be obtained from the decision concept, which according to Section II.C where $\tanh^{-1}(0.5842)=0.6688$, is 0.3312 using Eq.(2).

C. Second Case

The second case refers to a patient with suspected pulmonary infection having moderate cough (C_1=0.6), low fever (C_2=0.3), and rigor (C_3=1). Based only on these symptoms, the experts decided that the infection risk is moderate.

The convergence of both iFCM-I and iFCM-II follows a similar pattern with the first case, so we provide a condensed graphic representation of the values till steady state in Figs. 3 and 4. The respective values of the concepts are provided in Tables VII-IX. In these tables the first rows include the initial concept values, and the last rows, appearing in boldface, indicate the concept values at steady state. Both iFCM approaches are in accordance with the experts' opinion since they both evaluate to moderate risk according to Table III. The hesitancy at the output node is where $\tanh^{-1}(0.6874)=0.8430$, is 0.1581 using Eq. (2).

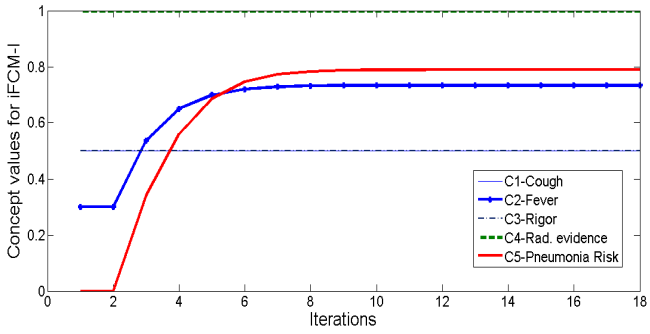

Figure 5. Convergence of iFCM-I for the third case.

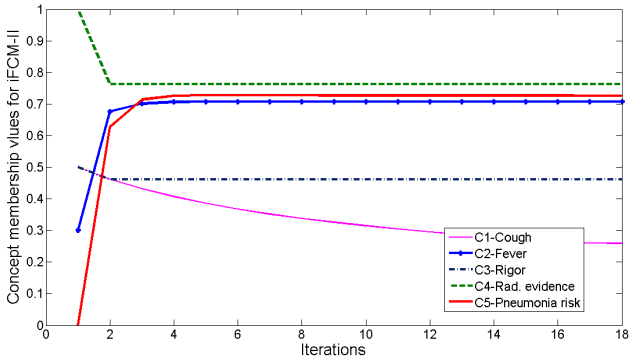

Figure 6. Convergence of iFCM-II for the third case.

There is no any information on other symptoms. According to the experts there is a high risk of this patient having pneumonia.

The convergence of both iFCM-I and iFCM-II is graphically represented in Figs. 5-6. The initial concept values and the concept values after converging at a steady state are apposed in Tables X-XII. According to Table III it can be noticed that both iFCM models result in a decision that is in agreement with the experts' opinion, i.e. high pneumonia risk. The hesitancy obtained at the decision node of iFCM-II is 0.0785 using Eq. (2), where $\tanh^{-1}(0.7266) = 0.9214$.

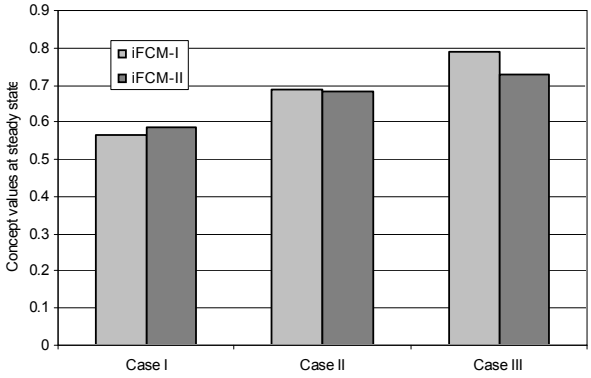

Figure 7. Comparison of the decision concept values at steady state with iFCM-I and iFCM-II for the three different patient cases presented in this study.

In the examined cases the results of both iFCM techniques are identical according to the calculated decision concepts (see Figure 7) and agree with the experts' opinion. But the advantageous point of iFCM-II technique is that it further assesses the hesitancy on concepts values and especially on decision nodes for which the physicians are interested.

IV. CONCLUSIONS

We presented a novel approach to intuitionistic fuzzy reasoning for decision support based on a novel iFCM model, which is referred to as iFCM-II. The proposed iFCM model is elegantly formulated using the mathematical formalism of IFS operations and exhibits several advantages over the previously proposed one. These include:

- It enables modelling of the uncertainty and imprecision introduced not only in the definition of the relations between the concepts of the cognitive map but also in the definition of the concept values.
- It is more general and could be used to closer approximate human decision making. It reduces to the previous iFCM model if the hesitancy in the determination of all concept values is zero.
- The output of the reasoning process may include a degree of hesitation expressed through IFS hesitancy.

The proposed iFCM-II model was applied for pneumonia risk assessment on three patient cases to demonstrate its functionality. The results showed that both iFCM-I and iFCM-II lead to decisions that are in accordance to the decisions of the experts. However, as illustrated in Fig. 7, the calculated decision concepts may exhibit differences.

Future research will focus on the application and the evolution of the proposed model towards an even improved modelling of uncertainty and human indecision.

Abstract— **This survey work tries to review the most recent applications and trends on fuzzy cognitive maps (FCMs) at the last ten years. FCMs are inference networks, using cyclic directed graphs, for knowledge representation and reasoning. In the past decade, FCMs have gained considerable research interest and are widely used to analyze causal systems such as system control, decision making, management, risk analysis, text categorization, prediction etc. Some example application domains, such as engineering, social and political sciences, business, information technology, medicine and environment, where the FCMs emerged a considerable degree of applicability were selected Their dynamic characteristics and learning methodologies make them essential for modeling, analysis, prediction and decision making tasks as they improve the performance of these systems. A survey on FCM studies concentrated on FCM applications on diverse scientific fields is elaborated during the last decade.**

Keywords-fuzzy cognitive maps; review; applications; styling; insert (key words)

I. INTRODUCTION

This study tries to gather the recent advances and trends on FCMs, their dynamic capabilities and application characteristics in diverse scientific areas. FCM represents a system in a form that corresponds closely to the way humans perceive it. Experts of each scientific area are used to express their knowledge by drawing weighted causal digraphs. The developed model is easily understandable, even by a non-technical audience and each parameter has a perceivable meaning [1,2].

In a graphical form, the FCMs are typically signed fuzzy weighted graphs, usually involving feedbacks, consisting of nodes and directed links connecting them. The nodes represent descriptive behavioral concepts of the system and the links represent cause-effect relations between the concepts. In the context of FCM theory, the fuzzy value of a concept denotes the degree in which the specific concept is active in the general system, usually bounded in a normalized range of [0, 1]. Furthermore, the weights of the system's interrelations reflect the degree of causal influence between two concepts and they are usually assigned linguistically by experts [3]. They work by capturing and representing cause and effect relationships.

According to Codara (1998) [4], FCMs can be used for various purposes, including:

• to reconstruct the premises behind the behavior of a given agent, to understand the reasons for their decisions and for the actions the take, highlighting any distortions and limits in their representation of the situation (explanatory function);

• to predict future decisions and actions, or the reasons that a given agent will use to justify any new occurrences (prediction function);

• to help decision-makers ponder over their representation of a given situation in order to ascertain its adequacy and possibly prompt the introduction of any necessary changes (reflective function);

• to generate a more accurate description of a difficult situation (strategic function).

Essentially, a Fuzzy Cognitive Map is developed by integrating the existing experience and knowledge regarding a system. This can be achieved by using a group of human experts to describe the system's structure and behavior in different conditions. With FCM it is usually easy to find which factor should be modified and how and by this sense, an FCM is a dynamic modeling tool in which the resolution of the system representation can be increased by applying further mapping [5,6]. As simple mathematical models, FCMs represent the structured causality knowledge for qualitative and quantitative inference. The resulting fuzzy model can be used to analyze, simulate, and test the influence of parameters and predict the behavior of the system.

The main reasons someone uses the FCM approach are [7]: easy of use, easy to construct and parameterize, flexibility in representation (as more concepts/phenomena can be added and interact), low time performing, easily understandable/transparent to non-experts and lay people [8], handle with complex issues related to knowledge elicitation and management, handle with dynamic effects due to the feedback structure of the modeled system.

Furthermore, individual FCMs pertaining to a particular domain can be combined mathematically [1,2]. This means that FCMs allow for different experts and/or stakeholder views to be incorporated [9], and can provide a useful mechanism for combining information drawn from many sources to create a rich body of knowledge [10-12]. Finally, vector-matrix operations allow an FCM to model dynamic systems [1,13],

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

allowing for the dynamic aspect of system behaviour to be captured [14]. Thus, FCMs have gained considerable research interest and accepted as useful methodology in many diverse scientific areas from knowledge modeling and decision making.

This work presents a survey on FCMs applications and trends in diverse scientific areas during the last decade exploring some of the most representative for each application study. The main aim of this study is to give an outline on how the FCMs increase their applications and more methodological efforts made by other researchers to enhance their applicability in different domains. It is difficult to present all the representative applications in each domain, as the number of FCM papers was extremely increased the last three years. Thus, we attempt to figure out only some of the most representative works of each domain, during the last decade.

II. FUZZY COGNITIVE MAPS AND APPLICATIONS

FCM is an efficient inference engine for modeling complex causal relationships easily, both qualitatively and quantitatively. Dickerson and Kosko (1994) used the FCM in a virtual world to model how sharks and fish hunt [15]. Parenthoen and his colleagues [16] successfully used the FCM to model the intentions and movements of a sheep dog and sheep in a virtual world.

During the past decade, FCMs played a vital role in the applications of diverse scientific areas, such as social and political sciences, engineering, information technology, robotics, expert systems, medicine, education, prediction, environment etc. Aguilar (2005) was the first who tried to gather the FCM applications in different scientific domains till 2004 [17]. In his work, most of the FCM applications were referred: administrative sciences, information analysis, popular political developments, engineering and technology management, prediction, education, cooperative man–machines, decision making and support, environmental management etc. After 2004, a large number of research studies related to methodologies for constructing or enhancing FCMs as well as innovative applications of FCMs were emerged. It is pinpointed that the number of research papers at 2010 is almost the double of the research papers presented till 2004 (see Table I). The recent applications are focused not only to the previous referred domains but to more others such as telecommunications, game theory, e-learning, virtual environments, ambient intelligence, collaborative systems. New methodologies engaged with dynamic construction of FCMs, learning procedures, fuzzy inference structures were explored to improve the performance of them.

In this work, we concentrate our effort on FCM research studies after 2000 and especially on the presentation of the main categories of them at the last ten years (2001 to 2010). In particular, we describe recent research studies after 2008 for most of the application domains.

From the number of FCM studies opposed in Table I (last access in scopus at 20 February 2011), it is observed that during the last decade (we consider the years 2000 till 2010), there is a large increase on the number of research papers related to FCMs.

TABLE I. RESEARCH STUDIES OF FCMS FOUND IN SCOPUS

Year	Number of FCM-related studies from scopus		
	Studies	*Journals & Book chapters*	*Conferences*
2000	18	8	10
2001	22	2	20
2002	7	4	3
2003	19	9	10
2004	53	15	38
2005	35	16	19
2006	50	11	39
2007	56	19	37
2008	81	21	60
2009	84	26	58
2010	(91+11 journals published in 2011) 102	50+11 Journals at 2011	41

Also, it is clearly shown that the last two years (2009-2010) the number of published papers in FCMs has been quadruple from the number of papers at the first years of decade (2000, 2001), and doubled from the papers published at 2004. Most of the research papers are related to FCMs applications and methodologies. 517 studies were accomplished during the past decade. A collection of papers with applications in various disciplines is presented in the book "Fuzzy Cognitive Maps: Advances in Theory, Methodologies, Applications and Tools edited by M. Glykas and prefaced by B. Kosko [6]. This is a significant index on FCM acceptability and applicability in research studies. Bar-chart in Figure 1 illustrates the FCM research studies for the last twenty years, including conference and journal papers, book chapters and technical reports, respectively for each year. It is clear from the chart that the FCMs have gained a considerable interest in research, which extremely increased during the last years. Furthermore, some types of typical problems solved by FCMs are modeling, prediction, interpreting, monitoring, decision making, classification, management. Paradigms of typical problems solved by FCMs are depicted in Table II.

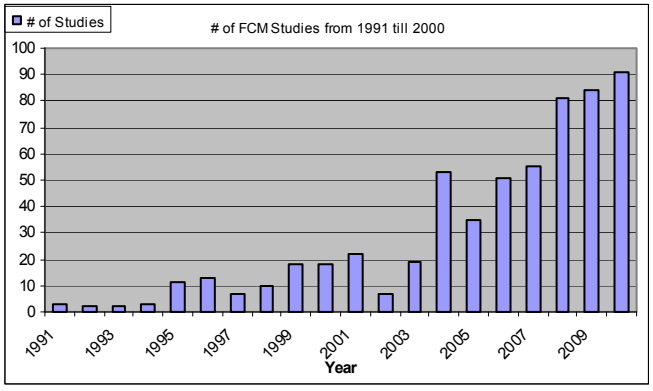

Figure 1. FCM papers during the last twenty years

TABLE II. PARADIGMS OF TYPICAL PROBLEMS SOLVED BY FCMS

Paradigm	Typical problems solved by FCMs
	Description
Control	Prediction interpreting, monitoring
Business	Planning, management, decision making, inference
medicine	Decision support, modeling, prediction, classification
robotics	Navigation, learning, prediction
environment	Knowledge representation, reasoning, stakeholders'analysis, policy making
Information technology	Modeling, analysis

A. FCM methodologies

In this section, a very short review is attempted to present the FCM methodologies and theories, depicting the estimation of their causal weights, the design and development process, the inference process etc.

As a generic model, the FCM relies on several assumptions. For example, the concepts' activation values are updated simultaneously at the same rate, and the causalities among the concepts are always in effect. However, these assumptions might not always hold, and the FCM isn't powerful or robust enough to model a dynamic, evolving virtual world. One other restriction is that use only simple monotonic and symmetric causal relations between concepts. But many real world causal relations are neither symmetric nor monotonic.

To solve these and other shortcomings and thus to improve the performance of FCMs, several methodologies were explored. Extensions to the FCMs theory are more than anything needed because of the feeble mathematical structure of FCMs and mostly the desire to assign advanced characteristics not met in other computational methodologies. Under this standpoint, some core issues are discussed and respective solutions are proposed in recent studies [18-25]; Pedryez (2010) presented the synergy of granular computing and evolutionary optimization to design efficiently FCMs, through a theoretic analysis [18]. Salmeron (2010) proposed the case of fuzzy grey cognitive maps, based on grey system theory, which is a very effective theory for solving problems within environments with high uncertainty, under discrete small and incomplete data sets [19]. Next, Iakovidis and Papageorgiou (2011) introduced the intuitionistic fuzzy sets and reasoning to handle the experts' hesitancy for decision making [20]. Also, more extensions of FCMs have been proposed, such as Rule-based FCMs [21,22], temporal FCMs [23], evolutionary multilayered FCMs [24,25] etc.

A dynamic version of FCMs, namely Dynamic Cognitive Networks, and a transformation process of cognitive maps, were proposed by Miao et al. [5,26] in order to explore the dynamic nature of concepts and to determine the strength of the cause and the cause-effect relationships as much as the degree of influence. Also, Fuzzy Cognitive Networks (FCNs) proposed as an operational extension of FCMs [27] that always reach equilibrium points in their operations especially to control unknown plants.

As another core task to design the FCMs, Song and his colleagues (2010) proposed a fuzzy neural network to enhance the learning ability of FCMs so that the automatic determination of membership functions and quantification of causalities can be incorporated with the inference mechanism of conventional FCMs. They employed mutual subsethood to define and describe the causalities in FCMs. It provides more explicit interpretation for causalities in FCMs and makes the inference process easier to understand. In this manner, FCM models of the investigated systems can be automatically constructed from data, and therefore are independent of the experts [28]. Next, Papageorgiou (2011) proposed a new methodology to design augmented FCMs combining knowledge from experts and knowledge from different data sources in the form of fuzzy rules [12].

It is worth noting that another important methodology for improving the performance of FCMs is learning algorithms. Learning methodologies for FCMs have been developed in order to update the initial knowledge of human experts and/or include any knowledge from historical data to produce learned weight matrices. The adaptive Hebbian-based learning algorithms, the evolutionary-based such as genetic algorithms and the hybrid approaches composed of Hebbian type and genetic algorithm were established to handle the task of FCM training [29,30-33]. These algorithms are the most efficient and widely used for training FCMs according to the existing literature [29,34].

B. Example Application Areas

Some example application areas were selected to present the way FCMs were applied and depicted in what follows. In Figure 2, the number of research studies accomplished in each one of the most common application domains during the last decade is depicted. At 2010, 13 application studies of FCMs were emerged in business, 12 in engineering and control, 8 in information technology, 5 in medical domain, and 6 in environment and agriculture.

1) Political and Social Sciences

FCMs emerged as a technique for modeling political and strategic issues situations and supporting the decision-making process in view of an imminent crisis. The research group of Andreou et al. proposed the use of the genetically evolved certainty neuron fuzzy cognitive map (GECNFCM) as an extension of CNFCMs aiming at overcoming the main

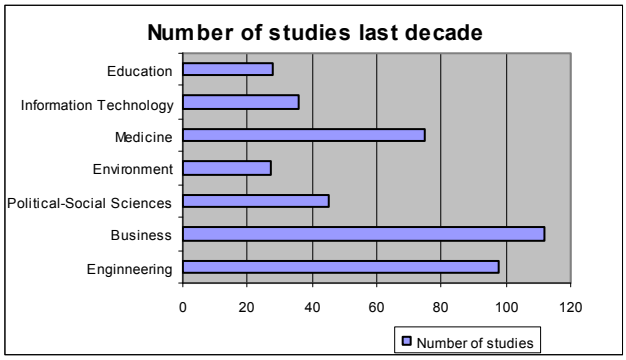

Figure 2. Number of FCM studies during the last decade (approximately +/- 5 studies per category).

weaknesses of the latter, namely the recalculation of the weights corresponding to each concept every time a new strategy is adopted [35]. That novel technique combined CNFCMs with genetic algorithms (GAs), the advantage of which lies with their ability to offer the optimal solution without a problem-solving strategy, once the requirements are defined. Using a multiple scenario analysis the value of the hybrid technique was demonstrated in the context of a model that reflects the political and strategic complexity of the Cyprus issue, as well as the uncertainties involved in it. Later, the same research group [24,36], presented the evolutionary FCMs for crisis management of the political problem of Cyprus.

An Ambient Intelligence (AmI) system, integrating aspects of psychology and social sciences, can be considered as a distributed cognitive framework composed by a collection of intelligent entities capable of modifying their behaviors by taking into account the user's cognitive status in a given time. Acampora et al. (2007), introduced a novel methodology of AmI systems' design that exploits multi-agent paradigm and a novel extension of FCMs theory benefiting on the theory of Timed Automata in order to create a collection of dynamical intelligent agents that use cognitive computing to define actions' patterns able to maximize environmental parameters as, for instance, user's comfort or energy saving [37].

Carvalho (2010) in his recent study, discussed the structure, the semantics and the possible use of FCM as tools to model and simulate complex social, economic and political systems, while clarifying some issues that have been recurrent in published FCM papers [38].

2) Medicine

At the last decade, FCMs have found important applicability in medical diagnosis and decision support [12, 39-45. In medical domain and in particular for medical decision support tasks, FCM based decision methodologies include an integrated structure for treatment planning management in radiotherapy [39], a model for specific language impairment [40], models for bladder and brain tumor characterization [41], an approach for the pneumonia severity assessment [42], and a model for the management of urinary tract infections [43]. Stylios et al. proposed FCM architectures for decision support in medicine [44].

Papakostas et al. (2007) implemented FCMs for pattern recognition tasks [45]. Froelich and Deja, 2009, proposed an FCM approach for mining temporal medical data [46]. Rodin et al. (2009) developed a fuzzy influence graph to model cell behavior in systems biology through the intracellular biochemical pathway [47]. Next, this model can be integrated in agents representing cells. Results indicate that despite individual variations, the average behavior of MAPK pathway in a cells group is close to results obtained by ordinary differential equations. The model was applied in multiple myeloma cells signaling.

3) Engineering

In this domain, FCMs found a large number of applications, especially in control and prediction. Particularly, FCMs have been used to model and support a plant control system, to construct a system for failure modes and effect analysis, to fine tune fuzzy logic controllers, to model the supervisor of a control system etc. Stylios and Groumpos, [2004] investigated the FCM for modeling complex systems and controlling supervisory control systems [48]. Papageorgiou et al. implemented learning approaches based on non-linear Hebbian rule to train FCMs that model industrial process control problems [29].

Recently, an integration of a cognitive map and a fuzzy inference engine was presented, as a cognitive–fuzzy model, targeting online fuzzy logic controller (FLC) design and self fine-tuning [49]. The proposed model was different than previous proposed FCMs in that it presents a hierarchical architecture in which the FCM process, available plant, and control objective data on represented knowledge to generate a complete FLC architecture and parameters description. Simulation results demonstrate model interpretability, which suggests that the model is scalable and offers robust capability to generate near optimal controller.

At 2010, Kottas et al. [27] presented basic theoretical results related to the existence and uniqueness of equilibrium points in FCN, the adaptive weight estimation based on system operation data, the fuzzy rule storage mechanism and the use of the entire framework to control unknown plants. The results are validated using well known control benchmarks. The same research team, at the same year, used FCN to construct a maximum power point tracker (MPPT), which may operate in cooperation with a fuzzy MPPT controller [50]. The proposed scheme outperforms other existing MPPT schemes of the literature giving very good maximum power operation of any PV array under different conditions such as changing insolation and temperature.

Beeson et al. (2010) proposed a factored approach to mobile robot map-building that handles qualitatively different types of uncertainty by combining the strengths of topological and metrical approaches [51]. This framework is based on a computational model of the human cognitive map and allows robust navigation and communication within several different spatial ontologies.

4) Business

In business, FCMs have found a great applicability. They can be used for product planning, for analysis and decision support. Some interested applications and worthy to be referred are illustrated. Jetter et al. (2006) used the concept of fuzzy front end for ideation, concept development and concept evaluation of new product development. This concept helped various problems managers who faced difficulty in early product development, as well as to systematic approaches to deal with them [52]. This approach helped in identification of market needs and technology potentials, detection and exploitation of idea sources, early stage assessment of ideas and product concepts, and successful management styles.

Yaman & Polat (2009) proposed the use of fuzzy cognitive maps (FCMs) as a technique for supporting the decision-making process in effect-based planning. With adequate consideration of the problem features and the constraints governing the method used, an FCM is developed to model effect-based operations (EBOs) [53]. In the mentioned study, the model was applied to an illustrative scenario involving military planning. Wei et al (2008) investigated the use of

fuzzy cognitive time maps for modeling and evaluating trust dynamics in the virtual enterprises [54]. Bueno & Salmeron (2008) proposed a tool for fuzzy modeling Enterprise Resource Planning selection [55]. Salmeron (2009) proposed the augmented fuzzy cognitive maps for modeling LMS critical success factors [56].

Kim and his coworkers (2008) developed a hybrid qualitative and quantitative approach, using FCMs and GAs, to evaluate forward-backward analysis of RFID supply chain [57]. The research group of Trappey et al (2010) used FCMs to model and evaluates the performance of RFID-enabled reverse logistic operations [58]. Radio frequency identification (RFID) complying with the EPCglobal (2004) Network architecture, i.e., a hardware- and software-integrated cross-platform IT framework, is adopted to better enable data collection and transmission in reverse logistic management. Inference analysis using genetic algorithms contributes to the performance forecasting and decision support for improving reverse logistic efficiency [58]. The study provided a method to predict future logistic operation states and to construct a decision support model to manage system performance based on the forecast.

Büyüközkan et al. (2009) proposed a systematic way of analyzing collaborative planning, forecasting and replenishment (CPFR) supporting factors using FCM approach [59]. Through their study, it was verified the application of FCM where interrelated variables like decision variables and uncontrollable variables were used. Xirogiannis et al. (2010) addressed the problem of designing an "intelligent" decision support methodology tool to act as a back end to financial planning [60].

One of the challenges in Risk Analysis and Management (RAM) is identifying the relationships between risk factors and risks. Lazzerini et al. (2010), proposed Extended Fuzzy Cognitive Maps (E-FCMs) to analyze the relationships between risk factors and risks [61]. The main differences between E-FCMs and conventional FCMs are the following: E-FCMs have non-linear membership functions, conditional weights, and time delay weights. Therefore E-FCMs are suitable for risk analysis as all features of E-FCMs are more informative and can fit the needs of Risk Analysis. Particularly, the work explores the Software Project Management (SPM) and discusses risk analysis of SPM applying E-FCMs.

5) Production Systems

FCM can provide an interesting solution to the issue of assessing the factors which are considered to affect the operator's reliability and can be investigated for human reliability in production systems [13]. Bertolini & Bevilacqua (2010) investigated the human reliability in production systems which act as an excellent means to study a production process and obtain useful indications on the consequences which can be determined by the variation of one or more variables in the system examined.

Lo Storto et al., (2010) presented a methodological framework to explore the cognitive processes implemented by members of a software development team to manage ambiguous situations at the stage of product requirements definition [62]. FCMs were used in the framework to elicit cognitive schemes and developed a measure of individual ambiguity tolerance. Moreover, FCMs were used to design game-based learning systems because it has the excellent ability of concept representation and reasoning [63]. A novel game-based learning model which includes a teacher submodel, a learner submodel and a set of learning mechanisms was established.

In computer vision, which is a new emerging area, there are demanding solutions for solving different problems. The data to be processed are bi-dimensional (2D) images captured from the tri-dimensional (3D) scene. The objects in 3D are generally composed of related parts that joined form the whole object. Fortunately, the relations in 3D are preserved in 2D. Hence, there are necessary ingredients to build a structure under the FCMs paradigm. FCMs have been satisfactorily used in several areas of computer vision including: pattern recognition, image change detection or stereo vision matching [64]. Pajares (2010) established a general framework of FCMs in the context of 2D images and described the performance of three applications in the three mentioned areas of computer vision.

6) Environment and Agriculture

FCMs were applied in ecology and environmental management for: modeling a generic shallow lake ecosystem by augmenting the individual cognitive maps [65], assessing local knowledge use in agroforestry management [66], modeling of interactions among sustainability components of an agro-ecosystem using local knowledge [67], predicting modeling a New Zealand dryland ecosystem to anticipate pest management outcomes [68], semi-quantitative scenario, with an example from Brazil [69]. Recently, van Vliet et al., (2010) used FCMs as a communication and learning tool for linking stakeholders and modelers in scenario studies [7]. In their recent work demonstrated the potential use of a highly participatory scenario development framework that involves a mix of qualitative, semi-quantitative and quantitative methods. Giordano, et al. (2010) proposed a methodology based on a FCM to support the elicitation and the analysis of stakeholders' perceptions of drought, and the analysis of potential conflicts [70]. The same year, Kafetzis et al. (2010) investigated two separate case studies concerned with water use and water use policy [71]. The documentation and analysis of such stakeholders' models will presumably offer insights into the use and limitations of local knowledge and management, while concurrently providing a current approach to developing appropriate strategies for process-oriented problem solving and decision making in an environmental pollution context.

In agricultrure, FCMs used to represent knowledge and assess cotton yield prediction in precision farming by connecting yield defining parameters with yield in Cotton Crop Production in Central Greece as a basis for a decision support system [72].

7) Information Technology (IT)

In information technology (IT) project management, a FCM-based methodology helps to success modeling. Current methodologies and tools used for identifying, classifying and evaluating the indicators of success in IT projects have several limitations. These could be overwhelmed by employing the FCMs for mapping success, modeling Critical Success Factors (CSFs) perceptions and the relations between them [8].

Rodriguez-Repiso et al (2007) demonstrated the applicability of the FCM methodology through a case study based on a new project idea, the Mobile Payment System (MPS) project, related to the fast evolving world of mobile telecommunications.

Xiangwei et al. (2009) analyzed and summarized common software's usability quality character system in order to find a software usability malfunction discovers and improve problems [73]. They used FCM to describe the software quality character relationship and give an integrated training arithmetic, syntax pruning arithmetic, semantic pruning arithmetic and quality relationship analysis arithmetic to the method.

An interesting tool for FCM development was presented in [74] where the FCM is defined by concepts and relationships that can change during the execution time. Using the tool, someone can design a FCM, follow the evolution of a given FCM, change FCM defined previously, etc. Furfaro et al. (2010) presented a novel method for the identification and interpretation of sites that yield the highest potential of cryovolcanic activity in Titan and introduced the theory of FCMs for the analysis of remotely collected data in planetary exploration [75].

In telecommunications, FCMs applied for distributed wireless P2P networks [76]. Peer-to-peer (P2P) technologies have raised great research interest due to a number of successful applications in wired networks. Popular commercial applications such as Skype and Napster have attracted millions of users worldwide. A novel team-centric peer selection scheme based on FCMs, which simultaneously considers multiple selection criteria in wireless P2P networks, was proposed. The main influential factors and their complex relationships for peer selection in wireless P2P networks were investigated.

TABLE III. FCM APPLICATIONS AT THE FIRST TWO MONTHS OF 2011

Research works published in 2011	**FCM applications at the first two months of 2011**	
	Application area	***Problem solving***
Kannappan et al. [80]	medicine	Classification, prediction
Papageorgiou [12]	medicine	Knowledge representation, decision making
Beena, & Ganguli [79]	Structural damage detection	learning
Song et al. [78]	Business	Classification and prediction
Hanafizadeh, P., Aliehyaei, R. [81]	Soft system	Modeling, analysis
Iakovidis & Papageorgiou [20]	medicine	Decision making, reasoning
Lee, N., Bae, J.K., Koo, C. [82]	Sales assessment	reasoning
Chytas, P., Glykas, M., Valiris, G. [834]	Business	Planning, analysis
Jetter, A., Schweinfort, W. [84]	Solar energy	Modeling, policy scenarios
A. Baykasoglu, Z.D.U. Durmusoglu, V. Kaplanoglu, [71]	Industial process control	Learning, control

Moreover, the participation of agents in FCM process [77] intends to a non-centralized detection of FCM stable state and to a modification process using asynchronous calculations. Stula et al. (2010) developed an agent-based fuzzy cognitive map (ABFCM) for injecting the concept of multi-agent system (MAS) into the FCM and the different inference algorithms in each node enabled the simulation of systems with diverse behavior concepts.

Of course, it was difficult in this study to present all the innovative and useful applications performed by FCMs and their extensions. We attempted to figure out some of the most mentioned applications emerged in the literature and to give the recent research directions of FCMs.

III. FCM APPLICATIONS AT 2011

During the first two months of year 2011, ten journal papers on FCM applications and modeling in different scientific fields were emerged. Table III includes these studies with the related application areas. So, the FCM has gradually emerged as a powerful paradigm for knowledge representation and a simulation mechanism that is applicable to numerous research and application fields. For example, Song et al. (2011) proposed a fuzzy neural network to enhance the learning ability of FCMs and incorporated the inference mechanism of conventional FCMs with the determination of membership functions. The effectiveness of this approach lies in handling the prediction of time series [78]. Beena et al. (2011) developed a new algorithmic approach for structural damage detection based on the use of FCM and Hebbian-based learning [79] and Baykasoglu et al. (2011) proposed a new training algorithm for FCMs, the Extended Great Deluge Algorithm (EGDA) [71]. Hanafizadeh and Aliehyaei applied FCMs in soft system methodology [81], Lee et al applied FCMs to sales opportunity assessment [82], Chytas et al applied FCMs to address the problems of proactive balanced scorecards [83], and Jetter et al. applied FCMs for scenario planning of solar energy [84]. Kanappan et al. [80] and Papageorgiou [12,20] applied FCMs in medical domain for classification and decision making.

IV. CONCLUSION

The Fuzzy Cognitive Map methodology has been proven through the literature a very useful approach and cognition tool to model and analyze complex dynamical systems. There is a considerable number of application studies of FCMs in different domains and the application of FCMs emerges a rapid continue. They are helpful to the decision-makers ponder over their representation of a given situation in order to ascertain its adequacy and possibly prompt the introduction of any necessary changes. It is a research challenge for applying FCMs in diverse scientific areas especially when efficient methods to quantify causalities, to adapt and learn FCMs, are proposed which might be handle with the complex tasks of each domain, thus to improve the FCM performance.

***Abstract*—Fuzzy Cognitive Maps (FCMs) have been widely used for a plethora of applications, exploiting its ability to represent the knowledge and the dynamics of a system. The diversity of inference mechanisms, which have been proposed until nowadays, discloses the effort for an effective concept value calculation methodology. In contrast with the most research efforts which consider a linear relation of the influence that a concept exercise to another concept, in this paper a nonlinear representation of that influence is introduced. The importance which is associated with the proposed methodology is that a nonlinear cause-effect relationship strengthens the behavior of an FCM through the simulation process. The analysis of this proposal through a progressive reasoning is followed by appropriately selected problems.**

***Index Terms*—Cognitive inference, Concept influence, Generalized logistic function, Cause-effect relationships.**

I. Introduction

Knowledge representation, in a complex system, is a demanding and composite procedure. Experts, from different fields of interest, are invited to offer their knowledge and experience for the modeling of the system. Conforming to market requirements, researchers systematically use qualitative approaches for the representation of the systems. The first attempt to represent knowledge through graphs was introduced by Alexrod [1]. Specifically, Alexrod in [1] proposed the technique of Cognitive Maps (CMs) as a tool of decision making in social and political systems. Kosko in [2] enriched the CMs with fuzzy logic and proposed Fuzzy Cognitive Maps (FCM). CM, a soft computing tool, constricts its contribution to system analysis because of the binary representation of cause-effect relationships. Kosko in [2] transformed the signed directed graphs to fuzzy signed directed graphs and overcame the issues related to systems' rules about knowledge-mining. Moreover, the reliability of causal relationship matrix is increased according to [3], which resulted from the synthesis of multiple experts' knowledge. The introduction of FCMs provoked the interest of the scientific community and challenged many researchers to notice the particular field. Taber and Siegel in [4] and Taber in [5] proposed a methodology of estimating experts' credibility weight, while Kosko and Burgess in [6] developed the inference mechanism of FCMs and applied the Differential Hebbian Law for unsupervised learning. The conception of combining different FCMs was inserted by Dickerson and Kosko [7] enhancing the architectural configuration of FCMs.

To continue with, Pelaez and Bowles [8] supported the idea that various factors, such as integrity constraints and time lag, should be taken into consideration during the inference process. The introduction of these constraints was the beginning of a race, in order for dynamic (non-linear) systems to be represented using FCM. Tsadiras and Margaritis in [9] introduced Certainty Neuron Fuzzy Cognitive Maps (CNFCM), which reveal the existence of concepts' memory related to its previous states and used for the computation of its current states. Andreou et al. [10] extended the previous model by combining CNFCM and genetic algorithms in order to surpass the weaknesses lie in the recalculation of a concept's weights every time a new strategy is applied.

A dynamic version of FCM proposed by Miao et al. [11] in order to explore the dynamic nature of concepts and to determine the strength of the cause and the cause-effect relationship as much as the degree of influence. Evolutionary strategies, combined with fuzzy cognitive maps, revealed efficiency and credibility increment when applied in ambiguous and multi-stimulus situations ([12], [13], [14], [15]). An integrated research, elaborated by Koulouriotis et al. [16], combines decay mechanisms, inertial forces, diminishing effects and biases, such as synergies and conditional effects ([17]), in order to describe and comprehend nonlinear and asymmetric cause-effect relationships, achieving simultaneously controllability. Fuzzy cognitive maps have several applications, either by implementing a learning procedure ([33], [18]) or not ([19], [20], [21], [23], [22]). Finally, the participation of agents in FCM process ([24], [25], [26]) intends to a non-centralized detection of FCM stable state and to a modification process using asynchronous calculations.

In the current article, an integrated inference mechanism is presented which is based on influence modification in order to meet the requirements of dynamic systems. In section II, a concise presentation of the theoretical background of FCM is quoted, offering an introductory view and the key points of inference mechanism development. The subsequent sections deal with the presentation of the proposed methodology and

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

the experimental analysis, while the concluding remarks are given in the last section.

II. Fuzzy Cognitive Maps: A theoretical background

Fuzzy Cognitive Maps (FCMs), proposed by Kosko [2], are fuzzy signed directed graphs with feedback, emphasizing both to the representation of the cause-effect relationships between concepts (i.e., positive, negative, zero) and the influence degree of this relationship expressed in linguistic values. Concretely, a FCM is a fuzzy graph which models a system and its behavior using the concepts and their relationships. A concept i indicates a state, a procedure, an event or a variable of the system and is represented with C_i $(i = 1, 2, \ldots, n)$. The directed edge between concepts C_i and C_j denotes the causality between concepts i and j and is represented with the weight w_{ij}, that can be a fuzzy value within $[-1, 1]$ or a trivalent logic within $\{-1, 0, 1\}$. There are three possible types that a weight (w_{ij}) can be distinguished in: a) positive $(w_{ij} > 0)$, which means that an increase (decrease) in the value of concept C_i leads to an increment (decrement) of value of C_j, b) negative $(w_{ij} < 0)$, which means that an increase (decrease) in the value of concept C_i leads to a decrement (increment) of value of C_j, and c) neutral $(w_{ij} = 0)$, which means that there is no relationship between C_i and C_j. The graphic illustration of the modeled system and the corresponding adjacency matrix is shown in Fig.1 and Fig.2.

A general rule for computing the value of a concept in each simulation step is the calculation of the influence caused by other concepts that are connected to the particular concept. The value A_i^{t+1} denotes the effect that concept C_i caused at time $t+1$ by other concepts [27] and is calculated by the following equation:

$$A_i^{t+1} = f\left(A_i^t + \sum_{j=1, j\neq i}^{n} A_j^t \cdot w_{ji}\right) \tag{1}$$

where, A_i^t is the value of concept C_i at time t, A_j^t is the value of concept C_j at time t, w_{ji} is the weight of the interconnection between concepts C_i and C_j, and f is a threshold function which limits the result of the multiplication in the interval [-1,1].

Tsadiras in [28] analyzed and compared different FCMs according to the type of threshold function which was implemented. After the initialization of the system by the experts and defuzzifying the inserted data, the concepts are ready to interact according to the determined relation network. The moment that a concept is activated, the other concepts, which are connected with, are influenced. The interaction between concepts continues until a fixed-point equilibrium is reached; a limit cycle is reached; or chaotic behavior is exhibited [9]. Tsadiras and Margaritis [9], developed a procedure by which the appropriate threshold function can be chosen according to concept's value and the effect influence field of definition. The interpretation of (2-4) is that a concept which is influenced by

Fig. 2. The Adjacency matrix of FCM

external effect can be activated to the degree that is not already activated.

$$f(A_i^t, S_i^t) = \begin{cases} A_i^t + S_i^t(1 - A_i^t), & A_i^t,\ S_i^t \geq 0 \\ A_i^t + S_i^t(1 + A_i^t), & A_i^t,\ S_i^t < 0,\ |A_i^t|, |S_i^t| \leq 1 \\ \frac{A_i^t + S_i^t}{1 - \min(|A_i^t|, |S_i^t|)}, & otherwise \end{cases} \tag{2}$$

$$A_i^{t+1} = f(S_i^t, A_i^t) \tag{3}$$

$$S_i^t = \sum_{j=1,\, j\neq i}^{n} A_j^t w_{ji} \tag{4}$$

where A_i^t is the value of concept C_i at the moment t, and S_i^t is the total influence which has applied from other concepts at moment t. The problem which arises from (4) is that S_i^t should belong within space $[-1, 1]$. The influence of the other concepts, S_i^t, has the maximum value when $|A_i^t| = 1$ and all $A_j^t,\ j = 1, \ldots, n$, have the same sign with the corresponding weight w_{ji}. So,

$$S_{i,\max} = \sum_{j=1}^{n} |A_j^t||w_{ji}| = \sum_{j=1}^{n} |w_{ji}|, \quad i = 1, \ldots, n \tag{5}$$

The maximum value of $S_{i,\max}$ can be calculated as follows:

$$S_{\max} = \max(S_{1,\max}, S_{2,\max}, \ldots, S_{n,\max}) \tag{6}$$

A new matrix w' is created which its elements w_{ji} can be calculated using the following equation:

$$w'_{ji} = \frac{w_{ji}}{S_{\max}} \tag{7}$$

Tsadiras and Margaritis [9], using (7), ensured that the influence value S_i^t will never be out of space $[-1, 1]$. Considering that the third part of (2) could possibly lead to division with

zero, Andreou et al. [29] proposed a transformation by which the absolute values of variables are replaced by their normal values. The third part of (2) transformed and acquired the form $\frac{A_i^t+S_i^t}{1-\min(A_i^t,S_i^t)}$.

Moreover, Yaman and Polat in [30] modified the third part of (2) and the one that Andreou et al. [29] proposed, inserting the mathematical expression $A_i^t + S_i^t$. In the case that the particular condition is satisfied, the sum of $A_i^t + S_i^t$ is impossible to be out of the continue space $[-1, 1]$. As it is obvious, (3) and (4) are also part of this proposition. Generally, the influence degrees are expected to be computed at the end of the determined influence durations. In the proposed methodology, links' influence duration is reduced by one unit and unit influence degree is recalculated for every step.

Finally, Koulouriotis et al. [16] proposed an enhancement on Dynamic Cognitive Networks (DCNs), combining adaptive characteristics which portraiture a dynamic system. These extensions are nonlinear and asymmetric cause-effect relationships, decaying mechanisms, inertial forces, diminishing effects and biases. Referring to nonlinear and asymmetric cause-effect relationships, Koulouriotis et al. [16] introduced a formula which is based on sigmoid function and is used for the computation of the effect that a concept A cause to a concept B (8).

$$\begin{array}{c} EFFECT = ef_{AB}\left(C_A\right) = \frac{2}{1+e^{-\alpha C_A}} - 1 \\ + \\ A \rightarrow B \end{array} \tag{8}$$

where α is a control parameter whose role is to adjust the rate of the impact that concept A exerts on B. The methodology by which authors [16] calculated the value of concept is given by (9):

$$A_i^{t+1} = \min\left(1, \max\left(\begin{array}{c} -1, A_i^t + \sum_{j=1, j\neq i, A_j^t>0}^{n} w_{ji}^{+} A_j^t \\ + \sum_{j=1, j\neq i, A_j^t<0}^{n} w_{ji}^{-} A_j^t \end{array}\right)\right) \tag{9}$$

Similarly, Koulouriotis et al. [16] imported decaying mechanisms, inertial forces, diminishing effects and biases in inference procedure, specifying the necessity of meticulously defined systems.

III. Proposed Methodology

Considering the above presentation of Fuzzy Cognitive Maps, we presume that A_j is the value of concept C_j and the weight w_{ji} indicates the relationship between concepts C_j and C_i, where $A_j, w_{ji} \in [-1, 1]$. The influence F_{ji} that a concept C_j causes to C_i is denoted with

$$F_{ji} = w_{ji} \cdot A_j, \qquad F_{ji} \in [-1, 1] \tag{10}$$

The graphic representation of (10) is illustrated in Fig.3 and reflects the linear function $y = a \cdot x$. Analytically, the vertical axis represents the influence F_{ji} that a concept C_j cause to concept C_i and the horizontal axis represents the value A_j of concept C_j. The line ϵ (red line in Fig.3) represents the linear

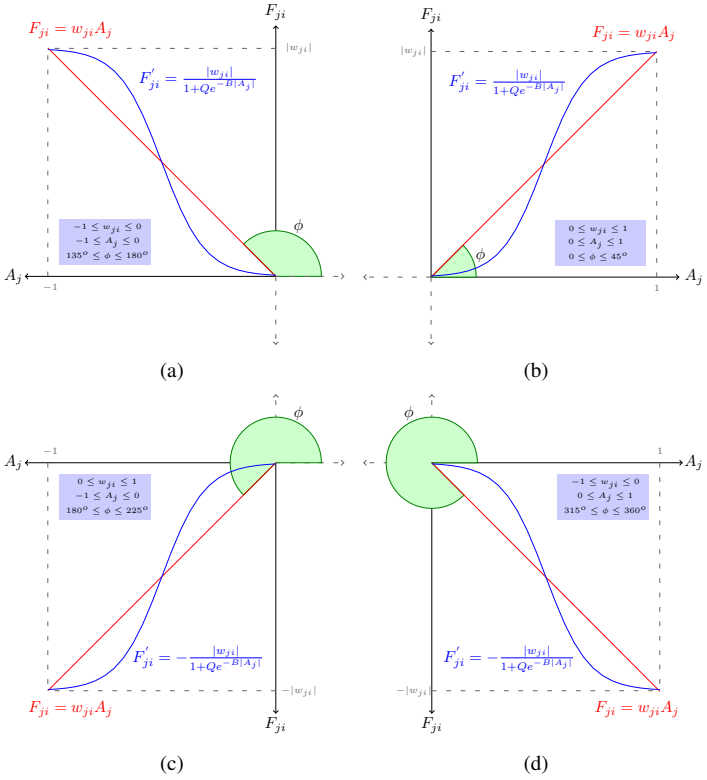

Fig. 3. The influence degree of concept C_j to C_i expressed with the generalized logistic function for a) $135^o \le \phi \le 180^o$, b) $0^o \le \phi \le 45^o$, c)$180^o \le \phi \le 225^o$, d)$315^o \le \phi \le 360^o$.

relation of F_{ji} and A_j. From the above statements, it can easily be deduced that w_{ji} is the slope of line ϵ.

$$w_{ji} = \tan(\phi) \tag{11}$$

In order for F_{ji} to belong within $[-1, 1]$, given that A_j, $w_{ji} \in [-1, 1]$, the field of definition of ϕ is $\phi \in \{[0^o, 45^o] \cup [135^o, 225^o] \cup [315^o, 360^o]\}$. Considering the current perception, the relation between influence F_{ji} and the value A_j is linear. In the present article, it is proposed a nonlinear representation of this relation, using the generalized logistic function.

$$f(x) = L + \frac{U - L}{(1 + Qe^{-B(x-M)})^{1/\nu}} \tag{12}$$

where, L is the lower asymptote, U is the upper asymptote, B is the growth rate, ν affects near which asymptote maximum growth occurs, Q depends on the value $f(0)$ and M is the time of maximum growth if $Q = \nu$.

According to the above considerations(11, 12), the influence F_{ji} that a concept C_j causes to a concept C_i, where A_j, $w_{ji} \in [-1, 1]$, can be formulated using the generalized

logistic function (12).

$$F_{ji}^{'} = \begin{cases} \frac{|w_{ji}|}{1+Qe^{-B|A_j|}}, & for \quad 0 \leq w_{ji},\, A_j \leq 1 \\ & \quad or \\ & -1 \leq w_{ji},\, A_j \leq 0 \\ -\frac{|w_{ji}|}{1+Qe^{-B|A_j|}}, & for \quad 0 \leq A_j \leq 1,\; -1 \leq w_{ji} \leq 0 \\ & \quad or \\ & -1 \leq A_j \leq 0,\; 0 \leq w_{ji} \leq 1 \end{cases} \tag{13}$$

where, $L = 0,\ U = |w_{ji}|,\ M = 0,\ \nu = 1$ and Q, B are two free parameters in order to adjust the shape of the sigmoid curve. The graphic illustration of influence $F_{ji}^{'}$, in relation to A_j, is shown in Fig.3. In the first quadrant Fig.3(a), the linear relation of F_{ji} and A_j is represented with the red line. The angle ϕ $(0 \leq \phi \leq 45^o)$ shows the space that line $F_{ji} = w_{ji}A_j$ can move in order to satisfy the limitation $0 \leq w_{ji} \leq 1$, considering (11). Moreover, the nonlinear relation of F_{ji} and A_j is represented with the generalized logistic function (sigmoid function), with upper limit $F_{ji_{max}} = |w_{ji}|$. Similarly, the other three quadrants are defined in Figs.3(b), 3(c) and 3(d), verifying the expression (13). Taking into consideration the above definitions in (13) and Fig.3, the value A_i^{t+1} of concept C_i at time $t+1$ can be computed using the following equation:

$$A_i^{t+1} = f\left(A_i^t + \sum_{j=1, j\neq i}^{n} F_{ji}^{'}(A_j^t, w_{ji})\right) \tag{14}$$

However, this methodology can be applied to every concept value computational methodology due to the fact that it not changes the methodology but the cause-effect relationship between two concepts.

The particular methodology proposes a nonlinear way to represent influence between concepts considering its appliance to dynamic systems. Essentially, the proposed methodology which is based on generalized sigmoid function, is a generalization of the concepts causal-effect relationship, which is reported in [16]. The nonlinear relationship between concepts transforms their values in such a way that results in a smoother convergence. However, this behavior might cause slower convergence to an equilibrium state. Furthermore, appropriately selected parameters (L, U, Q, B, M, ν) could lead the map to an equilibrium state even if a linear causal-effect relationship is not able to reach a stable state.

IV. Experimental Analysis

In order to apply, analyze and compare the proposed methodology, two different scenarios have been chosen which implement real-word and synthetic data.

A. Scenario 1

The first scenario [33] is referred to a simple control process in chemical industry. It comprises one tank and three valves that influence the amount of liquid in the tank. The particular procedure can be described as follows: Valves 1 and 2 pour two different liquids into the tank, producing a new liquid while a chemical reaction is triggered. When the new liquid produced reaches a specific level, measured by a sensor, valve 3 empties the tank. The FCM model is derived from the above control problem, according to a group of experts, and is illustrated in Fig.4. As we can assume from Fig.4, there are five concepts that constitute the FCM. The first concept (C_1) indicates that the amount of the liquid that Tank contains is dependent on the operational state of Valves 1, 2 and 3. Moreover, the state of Valves 1, 2 and 3 (C_1, C_2 and C_3 correspondingly) according to the predefined problem, could be closed, open or partially opened. Finally, the specific gravity of the liquid into the tank typifies the last concept (C_5). The initial values of concepts are given in matrix $A_{initial} = [0.4\ 0.7\ 0.6\ 0.7\ 0.3]$, the initial weight matrix ($W_{initial}$) is derived from the FCM of Fig.4 and the values of concepts C_1 and C_5 must be inside the ranges $0.68 \leq C_1 \leq 0.74$ and $0.74 \leq C_5 \leq 0.80$. In the current experimental analysis (Scenario 1, 2), the values of the free parameters Q and B (13) which are used in the procedure are $Q = 200$, $B = 10.5966$.

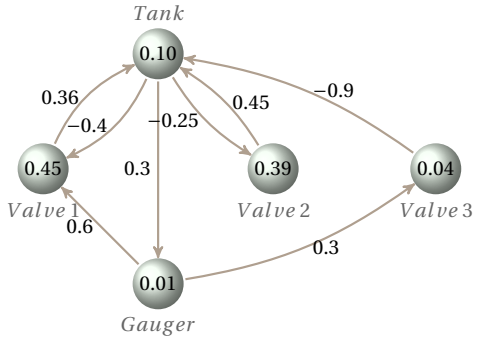

Fig. 4. The Fuzzy Cognitive Map derived from scenario 1

In [33], a linear cause-effect relationship between concepts (1) is used during the training process (Nonlinear Hebbian Learning - NHL) of the above FCM. In [33] the desired equilibrium state $A_{NHL}^1 = [0.683\ 0.7632\ 0.6538\ 0.7534\ 0.744]$ is reached and the NHL algorithm returns the updated weight matrix (W_{NHL}^1). In order for the proposed methodology to be compared with the common procedure, the above FCM is trained again with the difference that the NHL uses the proposed methodology (14) to compute the concepts values. In this case the equilibrium state $A_{prop} = [0.7108\ 0.7789\ 0.6480\ 0.7764\ 0.7660]$ is reached and the NHL algorithm returns the weight matrix W_{prop} (Fig.5). The values of concepts C_1 and C_5 which have been resulted from the aforementioned training processes are illustrated in Table I.

In order to evaluate the weight matrix W_{prop}, 1000 random initial vectors (A_{random}) are produced. These vectors are used as initial states of the FCM models which have as weighted matrices the W_{prop} and W_{NHL}^1 correspondingly. The minimum, maximum and mean values of concepts C_1 and C_5 as well as the standard deviations, which have been derived from the random examples, are presented in Table II.

By examining the mean values of Table II can be observed

TABLE I

$$\mathbf{W_{prop}} = \begin{array}{c} \\ \mathbf{C_1} \\ \mathbf{C_2} \\ \mathbf{C_3} \\ \mathbf{C_4} \\ \mathbf{C_5} \end{array} \begin{array}{c} \begin{array}{ccccc} \mathbf{C_1} & \mathbf{C_2} & \mathbf{C_3} & \mathbf{C_4} & \mathbf{C_5} \end{array} \\ \begin{pmatrix} 0 & -0.2112 & -0.0417 & 0 & 0.4649 \\ 0.5362 & 0 & 0 & 0 & 0 \\ 0.5617 & 0 & 0 & 0 & 0 \\ -0.8274 & 0 & 0 & 0 & 0 \\ 0 & 0.7110 & 0 & 0.4966 & 0 \end{pmatrix} \end{array}$$

Fig. 5. The weight matrix of FCM using the proposed methodology

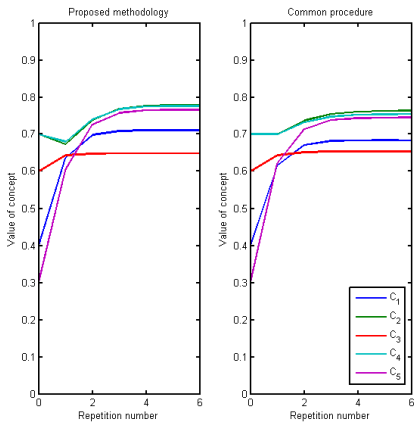

Fig. 6. Simulation process of Scenario 1

that the usage of the proposed methodology (nonlinear cause-effect relationships between concepts) in the NHL learning process leads to an equilibrium state for C_1 and C_5 very close to the midpoint of the desired bounds. It can further be concluded, from the minimum and maximum values as well as the standard deviations of 1000 random examples, that the consideration of a nonlinear cause-effect relationship between concepts leads to a FCM model as stable as the traditional methodology.

B. Scenario 2

An engine for producing scenarios with different properties (number of concepts, initial concept values, weight matrices) has been developed for the paper purposes. In order to investigate the simulation results, two different cases of the created scenarios have been selected. In the first case, the function $f(n) = \frac{1}{1+e^{-n}}$ is used as a threshold function (concept values inside the range $[0, 1]$), whereas in the second case the threshold function is $f(n) = \frac{2}{1+e^{-2n}} - 1$ (concept values inside the range $[-1, 1]$). The proposed methodology is compared with a common procedure in which (1) is used for calculating concepts values. Figures 8, 10 and 12 consist of two parts. The left part shows the simulation results of the proposed methodology while the right indicates the simulation results of (1).

In the first case, the proposed methodology presents very similar results with the common procedure (Fig.8). The initial weight matrix and the initial values of concepts which have been chosen for the simulation as much as the equilibrium state values (values of concepts) of the compared methodologies are illustrated in Fig.7 and Table III, respectively.

However, in the second case, the proposed methodology illustrates not only similar results with the common procedure, but also results which enhance its strength inference nature against the common procedure (Fig.12). The first example of the second case (when threshold function is $f(n) = \frac{2}{1+e^{-2n}} - 1$) is consisted of five concepts. The weight matrix, the initial concepts values as well as the equilibrium state of the two methodologies are presented in Fig.9 - Fig.10 and Table IV. It can be observed that although the two methodologies reach a similar equilibrium state, the proposed methodology needs more steps to finish the simulation process. Furthermore, the curves in Fig.10 follow a slightly different path to reach the final state.

Information about the initial and the equilibrium state of the second example of case two are given in Fig.11 - Fig.12 and Table V. By examining the aforementioned figures and

$$\mathbf{W_{initial}} = \begin{array}{c} \\ \mathbf{C_1} \\ \mathbf{C_2} \\ \mathbf{C_3} \\ \mathbf{C_4} \\ \mathbf{C_5} \\ \mathbf{C_6} \end{array} \begin{array}{c} \begin{array}{cccccc} \mathbf{C_1} & \mathbf{C_2} & \mathbf{C_3} & \mathbf{C_4} & \mathbf{C_5} & \mathbf{C_6} \end{array} \\ \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0.1764 & 0 & 0.3342 & 0 \\ 0 & 0 & 0 & -0.1011 & 0.1729 & -0.8323 \\ -0.3024 & 0 & 0 & 0 & 0 & 0.9496 \\ -0.0973 & -0.7245 & 0.0076 & 0 & 0 & 0.3027 \\ 0 & 0.6734 & -0.0208 & 0.9459 & 0.2406 & 0 \end{pmatrix} \end{array}$$

Fig. 7. Initial weight matrix for Scenario 2 - Case 1

TABLE III
INITIAL AND EQUILIBRIUM STATE VALUES OF CONCEPTS FOR SCENARIO 2 - CASE 1

Concepts	Initial state	Equilibrium state	
	$A_{Initial}$	$A_{Proposed}$	A_{Common}
C_1	0.3569	0.5372	0.5588
C_2	0.6627	0.6416	0.6439
C_3	0.2815	0.6959	0.6882

C_6	0.6246	0.7781	0.7699

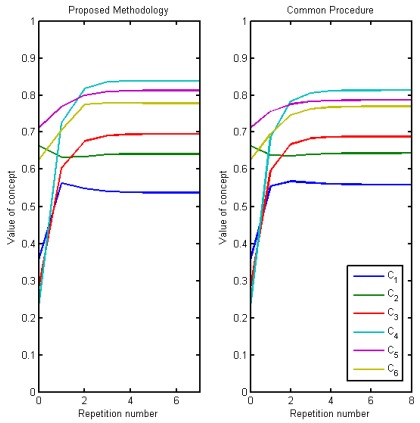

Fig. 8. Simulation process of Scenario 2 - Case 1

the corresponding table can be concluded that the selection of the threshold function leads to different results between the two methodologies. In Fig.12 can be observed that the proposed methodology reached an equilibrium fixed-point in contrast to the common procedure which reaches a limit cycle. This is feasible with an appropriate adjustment of the proposed methodology parameters (12-13). This fact, in combination with the first example of case two, highlights the enhanced, by the proposed methodology, dynamic behavior of the FCM. To continue with, the adjustable character (parameters Q, B) of the proposed influence mechanism introduce additional adaptability to similar situations.

V. CONCLUSIONS AND FUTURE WORK

Fuzzy cognitive maps are a remarkable simulation methodology primarily based on a linear cause-effect relationship between concepts. The subject of the particular research is the nonlinear representation of influence between concepts in order to achieve more effective simulation of real-world situations. The characteristics of the proposed methodology,

$$\mathbf{W_{prop}} = \begin{array}{c} \\ \mathbf{C_1} \\ \mathbf{C_2} \\ \mathbf{C_3} \\ \mathbf{C_4} \\ \mathbf{C_5} \end{array} \begin{array}{c} \begin{array}{ccccc} \mathbf{C_1} & \mathbf{C_2} & \mathbf{C_3} & \mathbf{C_4} & \mathbf{C_5} \end{array} \\ \begin{pmatrix} 0 & -0.0999 & -0.1133 & 0 & 0.9380 \\ -0.1444 & 0 & 0.1095 & 0 & 0.6938 \\ 0 & 0 & 0 & 0 & 0.0636 \\ 0 & 0 & 0.7425 & 0 & 0 \\ 0 & 0 & 0 & 0.3017 & 0 \end{pmatrix} \end{array}$$

which exploit experts' knowledge and experience, as well as its adjustability, highlight the enhanced inference mechanism.

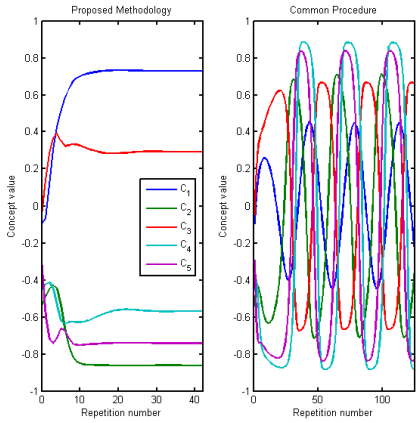

Fig. 12. Simulation process of Scenario 2 - Case 2 - Example 2

Improved learning results and randomly generated indicative examples, illustrate the ability of the proposed mechanism to converge into fixed states and efficiently manage realistic systems, even when the conventional approach falling into repeated cycle state. The proposed methodology stimulates the future research to a direction which is associated with the targeted and extensive analysis of real-world and other problems, especially when limit cycle or chaotic behavior is detected. Furthermore, the proposed methodology depends on a set of free parameters (L, U, Q, B, M, ν), thus a sensitivity analysis is going to be explored in a future work. Moreover, a thorough study of learning algorithms using the nonlinear influence mechanism in conjunction with its property of adjustability, could improve the whole process.

Abstract— **Doctor usually uses his experience from the clinical practice to confirm a diagnosis and to prescribe an appropriate treatment for a specific patient. The computerized medical reasoning should not only focus on existing medical knowledge but also on physician's previous experiences and new knowledge. Such knowledge and experience are vague and define uncertain relationships between facts and diagnosis. Case Based Fuzzy Cognitive Maps (CBFCM) are proposed as an evolution of Fuzzy Cognitive Maps (FCM) that allow more complete representation of knowledge since case-based fuzzy rules are introduced to improve FCM decision support systems. Semantic web is used to implement both FCM approaches. A database of 71 patients with urinary tract infections was used to perform the proposed approach. A comparative study between FCM (92%) and CBFCM (99%) was conducted and the results derived by CBFCM approach showed CBFCM to be superior to FCM.**

Keywords : Fuzzy Cognitive Maps, Rules, Decision Support Systems, Knowledge Representation, Clinical Guidelines, Semantic Web, case based reasoning.

I. INTRODUCTION

In medical practice, the doctor evokes several diagnoses but the differential diagnosis remains the major problem in medical decision making. It requires a several complementary examinations and experts review. Clinical Decision Support Systems (CDSS) are tools to improve patient safety and care processes [1,2]. Several studies and reviews have shown their effectiveness, i.e. [3,4,5,6] in the areas of diagnosis and therapy.

In a recent review, Peleg and others [7] claim that CDSS allow "*right knowledge to the right people in the right form at the right time*" [8]. The development of CDSS has two knowledge-management tasks: the possibility of integration into the care system workflow, and knowledge management for proper decision making.

CDSS models have to take into consideration issues related to patient data quality that is: incompleteness, poorly structured and sometimes unreliable data, problems associated with inaccuracies and uncertainties in Clinical Practice Guidelines (CPG). Many clinical diagnosis tasks involve reasoning under uncertainty [9]. Modeling a dynamic system can be hard in a computational sense.

The use of CDSS in urinary tract infections will reduce false diagnoses and establish a proper antibiotic regimen. FCMs have proved their efficiency in medical decision support and medical reasoning through the literature [10-14]. This paper describes and evaluates a new method to create a diagnosis model framework based on semantic web approach and Case Based Fuzzy Cognitive Maps (CBFCM). The produced results of the examined framework are compared with those obtained from FCM reasoning approach for 71 patients.

II. BACKGROUND

A. Clinical decision support system

CDSS form a significant part of the field of medical knowledge management technologies through their capacity to support the clinical process and use of knowledge, from diagnosis and investigation through treatment and long-term care. Their role and acceptance in daily clinical practice is increasing [15]. Recent studies [16] showed that CDSS can improve physician performance and accuracy, while the quality of each system may depend on the technical approach they use to model medical information.

CPG are structured documents that list a set of specific cases for which some diagnosis and therapeutic action plans are recommended with a given degree reflecting the strength of the recommendation corresponding to the level of scientific evidence. CPG include the description of the various

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

alternatives and the factors that would allow establishing decisions amongst them. However, because of the sheer volume of one such CPG and the rigid structure of such guidelines, it is very difficult for the physician to apply and strictly follow the workflow presented by guidelines. Our work is directed towards the creation of a computerised system that dynamically guides the physician through the workflow and assist physicians in diagnosis of clinical forms of UTI (Urinary Tract Infection).

An empirical antimicrobial therapy well suited to the patient requires consideration of the patient treatment parameters (treatment ongoing, drug allergies...) but above all a good first diagnosis is primarily based on a clinical approach. The diagnosis is based on a notion of causality between infectious disease and clinical signs that it generates light in the field of physiological and pathological patient. In order to solve the problem of modeling medical knowledge from guidelines and to assign UTI diagnosis by handling imprecision and uncertainty, the FCMs and their extension, namely CBFCMs, are investigated. The semantic web approach was used to implement the proposed approaches.

B. *Cognitive Maps*

Cognitive Maps were introduced by R. Axelrod in 1976 to represent political and social knowledge [17]. They are directed graphs with signed edges. The nodes represent variable concepts and the arrows interconnecting concepts represent the relations between concepts. The sign attached to the head of arrows indicates the polarity of the causal relations. A positive arrow from node (concept) C1 to node C2, means C1 causally increases C2. Cognitive maps have been used to model a number of areas (political, social, business, ...).

C. *Fuzzy Cognitive Maps (FCM)*

FCMs, as an extension of cognitive maps, were developed by R. Kosko [18] to represent the causal relationship between concepts and analyze inference patterns. FCM represents knowledge in a symbolic manner, encoding the relations between the elements of a mental landscape so that the impact of these elements can be assessed. FCMs have gained considerable research interest and have been applied to many areas [Papageorgiou & Arthi, 2010].

FCM inherits the fuzzy logic properties on cognitive maps that allow predicting the change of the concepts represented in Cognitive Maps. The graphical illustration of FCM is signed directed graph with feedback, consisting of nodes and weighted interconnections. Nodes stand for concepts, variables, states that are used to describe the behavior of the system and they are connected by weighted arcs representing the causal relationships among nodes. Each concept is characterized by a fuzzy value usually ranging from [0…1] or [-1…1].

The most important element in describing the system is the determination of which a concept influences which others and with which degrees. There are three possible types of causal relationships among concepts that express the type of influence from one concept to the others. The weight of the interconnection between concept *Ci* and concept *Cj*, denoted by Wij, could be positive Wij > 0 for positive causality or could be negative causality Wij < 0 or could be null when there is no relationship between concept Ci and concept Cj , thus Wij = 0.

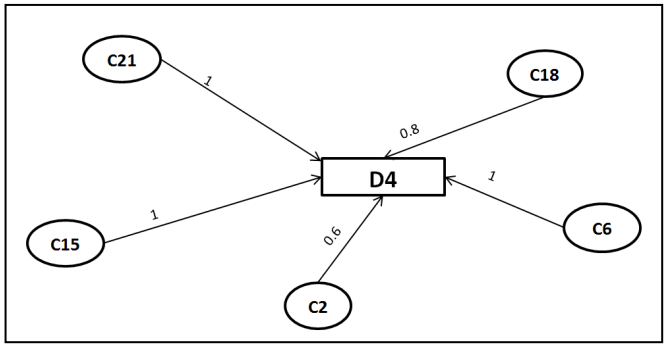

Figure 1. Representation of FCM model of acute prostatitis
(C2: Fever, C15: Vesical Uretral Reflux, C8: Vomitting, C18: Flank Pain, C19: Urine Dipstick Test, D8: Acute Prostatitis)

To get the value of a concept *Cj*, the value of each of its concepts inputs *Ci* is multiplied by the respective weight Wij which takes values in [-1..1]; then the results are added and passed by a non-linear function used to limit the range of possible output values.

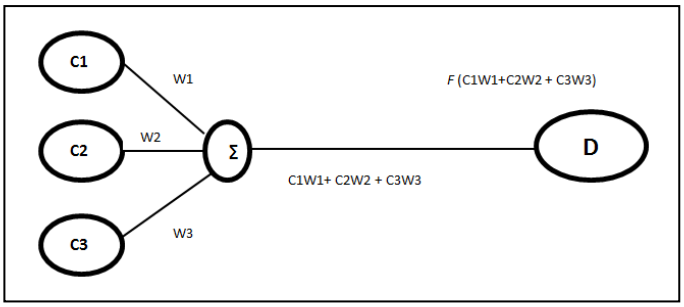

Figure 2. Graphical representation of calculating the value of the concepts of decision

So the value *Ai* for each concept *Ci* is calculated by the following rule:

$$A_i(k+1) = f(A_i(k) + \sum_{\substack{j \neq i \\ j=1}}^{N} (A_j(k) \cdot E_{ji}) \qquad (1)$$

where $A_i^{(k+1)}$ is the value of concept C_i at simulation step $k+1$, $A_j^{(k)}$ is the value of concept C_j at step k, E_{ji} is the weight of the interconnection between concept C_j and concept C_i and f is a threshold (activation) function that squashes the result of the multiplication in the interval [0, 1].

This equation indicates that a FCM is free to interact; at every step of interaction every concept has a new value. Several formulas can be used as threshold function [19], and as the interval of concept is bivalent (i.e., the concepts belong to the interval [0, 1]), we propose the function $f(x)$:

$$f(x)=1/(1+\exp(-cx)) \qquad (2)$$

where c is a real positive number and x is the value $A_i^{(k)}$ on the equilibrium point. In this work we use c=1, because this value showed best results in previous works [20].

Reasoning mechanism

The FCM inference algorithm is consisting of the following steps is used to simulate the process and give the necessary decisions about it.

(Step 1) Definition of the initial vector **A** that corresponds to the elements-concepts identified by experts' suggestions and available knowledge.

(Step 2) Multiply the initial vector **A** and the matrix **W** defined by experts by the eq. (1).

(Step 3) The resultant vector **A** at time step k is updating using Eqs. (1)–(2).

(Step 4) This new vector $\mathbf{A}^k$ is considered as an initial vector in the next iteration.

(Step 5) Steps 2–4 are repeated until $\mathbf{A}^k - \mathbf{A}^{k-1} \leq e$ = 0.001 (where e is a residual, describing the minimum error difference among the subsequent concepts) or $\mathbf{A}^k = \mathbf{A}^{k-1}$. Thus $\boldsymbol{A_f} = \mathbf{A}^k$.

In each of the case studies, an initial vector **A** is assigned (consisting of *Ai* values corresponding to each one concept *Ci*), representing the presented events at a given time of the process, and a final vector **A_f** is calculated at the steady state of the system, representing the last state that can be arrived at.

The iteration stops when a limit vector is reached, i.e., when $\mathbf{A}^k = \mathbf{A}^{k-1}$ or when $\mathbf{A}^k - \mathbf{A}^{k-1} \leq e$; where e is a residua, whose value depends on the application type (and in most applications is equal to 0.001).

1) Fuzzy Cognitive Maps extensions

FCMs are limited to the representation of simple monotonic causal relations between concepts and they do not handle the AND/OR relationships among the antecedent nodes, although they represent the causal relations between the antecedent and consequent nodes. Numerous works have been proposed to improve FCMs performances. Many extensions to the FCMs were developed, such as Extended Fuzzy Cognitive Maps (EFCMs), Rule Based Fuzzy Cognitive Maps (RBFCMs), Random Fuzzy Cognitive Maps (RFCMs), Intuitionistic FCMs, Fuzzy Grey Cognitive Maps and so on.

2) Case based reasoning:

Case-based reasoning (CBR) systems reason from experience: they solve new problems by retrieving relevant prior cases and adapting them to fit new situations. In 1988 the first case-based reasoning workshop identified theoretical foundations and fundamental issues for case-based reasoning research [20]. Case-based reasoning systems process new situations by retrieving a relevant prior case from memory, comparing that case to the new situation to determine important similarities and differences, and applying pertinent information from the old case to the new situation. Case-based reasoning has been applied to many tasks and domains, such as message classification, dispute mediation, explanation, language understanding, legal reasoning and planning.

Motivations for using case-based reasoning include: increasing efficiency in solving new problems, because relevant reasoning can be re-used rather than having to be re-derived; improving the quality of solutions; and simplifying knowledge acquisition. CBR facilitates the knowledge acquisition process because cases can be stored and used without having a perfect domain theory; case acquisition can be achieved without analyzing the interactions between individual factors in a case. Also, extensive pre-existing case libraries are available for many tasks, and those libraries can provide a starting point when building CBR systems [20].

D. Semantic web tools :

1) RDF / RDFS (Resource Description Framework / Schema)

RDF is a standard model for data interchange on the Web. RDF has features that facilitate data merging even if the underlying schemas differ, and it specifically supports the evolution of schemas over time without requiring all the data consumers to be changed. RDF extends the linking structure of the Web to use URIs (Url Resources Identifier) to name the relationship between things as well as the two ends of the link (this is usually referred to as a "triple"). The data are shown in triples:

Subject Verb/Predicate Object

These expressions are known as triples in RDF terminology. The subject denotes the resource, and the predicate denotes traits or aspects of the resource and expresses a relationship between the subject and the object. The subject is a resource identified by a URI (Uniform Resource Identifier), which is described by another resource (object) with a property (Word / Predicate). In the case problem of UTI, an example is given for the "pyelonephritis" diagnosis, where the subject "fever" has the property "symptom" for the object "pyelonephritis".

Exemple :

```
<rdf:Description about=
"http://www.spim.jussieu.fr/Pyelonephritis">
<prefixe:Symptom>Fever</prefixe:Symptom>
</rdf:Description>
```

Using this simple model, it allows structured and semi-structured data to be mixed, exposed, and shared across different applications.

2) Web Ontology Language (OWL):

The Web Ontology Language OWL is a semantic markup language for publishing and sharing ontologies on the World Wide Web. OWL is developed as an extension of RDF vocabulary. It is derived from the DAML + OIL Web Ontology Language. OWL is flexible, extendable, and decentralized because it's designed for use in the dynamic, global environment of the Web. OWL supports hierarchical relationships at their core, allowing for easy incorporation of subclasses and subproperty relationships that are essential for

managing and integrating complex data. We used in our project an ontology written in OWL, which will be described in the material.

3) Notation 3/ N3 logic:

The notation N3 is the format being developed by Tim Berners-Lee and others from the Semantic Web community. RDF / N3 is a rating given by Tim Berners Lee as an alternative to RDF / XML [30]. Notation3, or N3 is more compact and human readable than RDF / XML.

For example, the notion "The Fever is a symptom of Pyelonephritis" in RDF is represented as the triple: a subject denoting "Fever", a predicate denoting "Symptom", and an object denoting "Pyelonephritis". In N3, this is written as an RDF triple just like that:

```
:Fever :Symptom :Pyelonephritis
```

N3 language has been selected on purpose to represent medical knowledge due to its human readability and close relationship to the semantic web. Formalized medical information is represented with ontological concepts using Notation3 format. An example is given:

```
@prefix dco:
<http://www.debugit.eu/ontology/1.0/dco.owl#>.
dco:Fever dco:Symptom dco:Pyelonephritis.
```

N3 Logic is a logical platform that uses semantic web N3 as RDF syntax and expands the vocabulary of predicates. The goal of logic N3 is to give the possibility to integrate an RDF data model, logical rules and provide integrated functions that allow access and reason about data.

This allows expressing knowledge in N3 logic for a specific purpose [21]. In a rule, the premise is the subject and the conclusion is the complement (object). The sign "=>" is a common predicate expression log-rule namely implies.

An example of N3 rule is given:

If the patient is pregnant Then the diagnosis of "`PregnancyUrinaryTractInfection`" is inadequate for this patient. The main aspects of programming CBFCM approach in N3 are depicted :

```
{(?P dco:Pregnant) fl:mu 1} => {(?P
dco:PregnancyUrinaryTractInfection) fl:sigma 0}.
```

III. MATERIALS AND METHODS

A. Materials

In our project, we used 71 clinical cases to create a database of patient testing. We worked with domain ontology of Infectious Diseases DCO (DebugIT Core Ontology) [22]. DCO serve as the core component of the interoperability platform for the DebugIT project.

Inference engine:

As part of our project, we formalized the rules and we executed by an inference engine. EulerSharp [23] is an inference engine with backward-forward-backward chaining that allows the "loop-checking to ensure the processing of all data, to reason with data, queries and rules in N3". We choose Euler for historical performance[1], frequent updates[2], plugins & the ability to integrate new features[3] (built in).

B. Methods

1) Case Based Fuzzy Cognitive Maps (CBFCM)

One advantage of the FCM-based decision making is that it resembles human decision making, with its ability to perform approximate reasoning and handle incomplete information. But FCM seems to be limited to the representation of simple monotonic causal relations between concepts and could not handle the AND/OR relationships among the antecedent nodes.

In medical reasoning, many observables/factors such as painful, febrile, old, take the form of fuzzy concepts and used in FCM. These fuzzy concepts can be represented by fuzzy sets. Doctors use their academic knowledge and clinical cases already dealt with that imply a case-based reasoning and a heuristic approximate reasoning. A new method to improve results from the FCM approach is proposed by adding a system of rules based on cases. This method is developed using the tools of the semantic web. Fig3 is a graphical representation of CBFCM method:

A patient 01 represents a set of clinical parameters (C1, C2, and C3). These clinical parameters could be clinical signs, age, gender or biological results. They are used as input concepts in our CBFCM. These concepts are then processed by a set of fuzzy rules that are outcome of our case base. If the patient case is similarly of one of the cases already known then the diagnosis is confirmed by consensus; else we use our FCM algorithm to have a concept D1 for diagnosis decision.

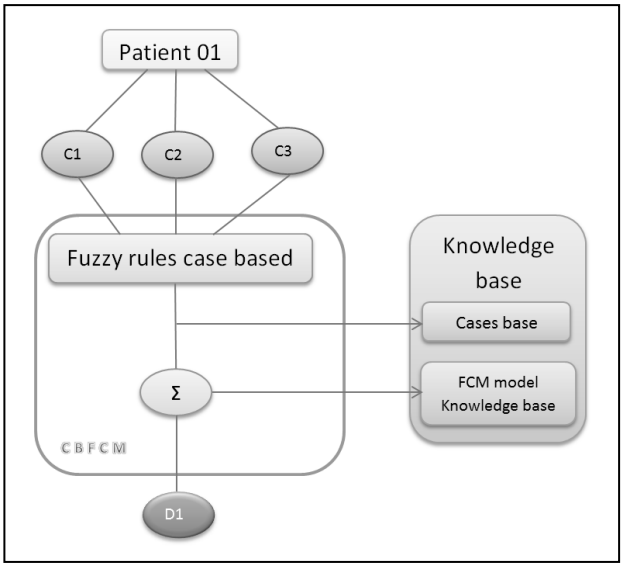

Figure 3. Diagram represents the CBFCM method

2) CBFCM Euler Plugin

To allow management of CBFCM fuzzy rules, FCM plugin for Eye[23] updated several times to change the value of a

[1] http://eulersharp.sourceforge.net/2003/03swap/dtb-2010.txt
[2] http://eulersharp.sourceforge.net/DONE
[3] http://eulersharp.sourceforge.net/2003/03swap/euler-builtins.html

fuzzy set membership (pi) and two decisions-conclusions can be arranged at the same rule.

We present in detail the steps followed for the design of our diagnosis model based CBFCM:

Extraction of clinical concepts and diagnostic:

From several CPG, we extracted clinical concepts and diagnostic concepts (all diagnoses).

Standardization of clinical concepts and diagnostic:

We have standardized, manually, concepts with the DebugIT ontology of Infectious Diseases (DCO).

Writing diagnostic rules:

The messages of CPG are as rules "*If Premise Then Conclusion*". The premise takes into account several patient parameters and it consists of several basic premises. Extracting Knowledge from CPG in fuzzy rules "If-Then". The rules are formalized as follows:

If the value of the concept *Ci* is X then the value of *Dj* is Y with a degree of influence (weight) Wij. Every relationship between a concept and a clinical diagnostic concept is defined by a membership function that determines the degree of causality between two concepts. Example, "If the urine dipstick test is negative then the diagnosis of UTI is wrong with a degree of 0.9".

In our approach, we use the knowledge from CPGs to build our cognitive maps that these rules represent the relationship between concepts and the weight of this relationship has a fuzzy value.

3) Construction of CBFCM diagnosis model

A number of medical guidelines for the diagnosis problem of UTI were formalized into CBFCM knowledge models using the approach presented in Fig.3. In order to construct our FCM model for medical decision support, the main concepts with their strengths of connections (causal influences) have to be assigned. Also a number of IF-THEN CBFCM rules were extracted to be used to improve the differential diagnosis and manage conflicts. The concepts and their relationships were extracted from CPG and each concept and clinical diagnosis contributes to a node represented in FCM.

All the concepts were defined. The relationships between these concepts and the clinical diagnosis concepts described in the CPG natural language were translated into formal language by defining the fuzzy weight of each concept. The fuzzy weights were determined using the methodology proposed in [24, 25]. These linguistic weights are initially used to describe the influence that exists between a clinical sign (concept) and a clinical diagnosis. Then, these weights are transferred to numerical weights in the range [-1,1] using the centroid defuzzification method of fuzzy logic[26].

a) CBFCM implementation in N3

To implement our algorithm for reasoning in N3, we use plugins of the inference engine EulerSharp developed in Prolog4. In Appendix B, the main aspects of programming CBFCM approach in N3 are depicted.

Our implementation method is to write rules in N3 logic for reasoning with standardized patients data using the FCM algorithm.

The CBFCM concepts are included in an ontology repository established for the project needs, namely DCO. DCO is updated continuously in order to contain all relevant clinical concepts. We worked with the DebugIT project ontologists to enrich the DCO ontology and can be used with our rules.

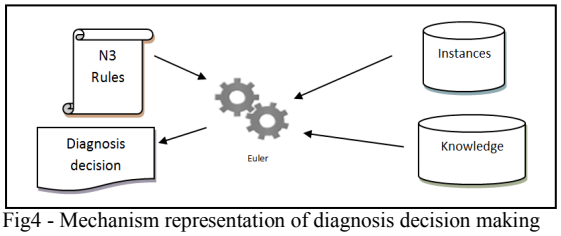

Fig4 - Mechanism representation of diagnosis decision making

Thus, based on this implementation technique, all the concepts, relationships and fuzzy rules for differential diagnosis are written in N3. Then, using the Euler plugin, the reasoning of the constructed model is accomplished, suggesting a differential diagnosis.

IV. RESULTS

The results presented here follow the steps of the methodology previously and the inference mechanism of CBFCMs (Eulersharp/plugin) [23]. The proposed methodology was validated with 71 patient cases derived from several European hospitals.

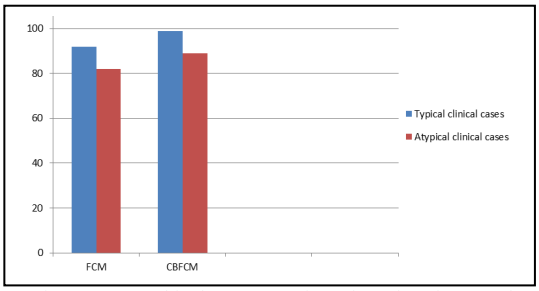

Figure 5 - Graphical representation of results of our study

Since this work is concerned by the modeling of diagnosis guidelines, the results are compared to the recommendations provided by the relevant clinical suggestions. Therefore, according to this approach, the rate of "correct" decisions, i.e. the decisions complying with the clinical diagnosis suggestions, is considered as the success rate of the compared models. The success rate of FCM approach was 92% and 99% of CBFCM approach for 71 examined patient cases. In 92%, and 99% of cases with FCM and CBFCM respectively, the answer given by our system was equivalent to the correct answers in cases involving clinical UTIs and 87%, 89% (FCM, CBFCM) in clinical cases involving other diseases (gynecological diseases, surgery ...) with urinary tract infection.

[4] http://eulersharp.sourceforge.net/2006/02swap/fcm-plugin.yap

Fig5 represent the results of corrects diagnosis given by our system.

V. DISCUSSION

The CBFCM approach allowed us to model medical knowledge of CPGs and to identify causal relationships in close as possible to the human reasoning. The use of CBFCM has enabled us to incorporate a second source of knowledge what we find beneficial to incorporate other types of knowledge. It allows us to model a simple knowledge of a medical field that is broad, complex and closely related to other areas.

The goal of our research study was threefold. First reasoning algorithms of Case Based fuzzy cognitive maps were established. Then, as a result the N3 notation and logic was used for the implementation of our cognitive maps for knowledge formalization of CPG and integration of others knowledge resources (others CPG). Finally, a patient database on which we applied the reasoning of our cognitive maps was created and tested for the model's validation.

We have implemented the knowledge bases, rules and databases in the same environment (RDF, N3, Euler..) without compatibility constraints, this is one of the advantages of using Semantic Web tools. The success rate of the proposed model giving UTI diagnosis was assigned to 99%, which shows the functionality of the model and its future usefulness in clinical practice.

CPG don't cover the whole field of community-acquired infections of the urinary tract in adults and we found a lot of information missing: the relationship between domain concepts. The rules, we have implemented, concern only the community urinary tract infections in adults. Integrating other GBPC, experts review, data mining results covering other areas of infectious diseases will allow us to improve our system.

Future work will be directed towards the construction of more dynamic systems based on the CBFCM methodology that could be integrating more sources of knowledge and data covering other areas of infectious diseases. Another part of the system is not yet developed that involves learning from the new case to enrich our knowledge base and enable close collaboration with practitioners on a daily basis.. The rules will be tested on a larger number of data and will be updated by integrating knowledge from more giuidelines/experts and data mining techniques.

VI. CONCLUSION

This under investigation study presents the results of comparison between the two reasoning methods: FCM and CBFCM. We explored the problem of modeling medical knowledge/guidelines and capturing the system's behavior for decision support of UTI diagnosis by using a new soft computing technology of CBFCMs implemented in semantic web. More specific, this work establishes a decision support tool based on CBFCM formalism for UTI diagnosis by proposing the appropriate diagnosis for each individual case.

The developed software tool calculates the diagnosis recommendations for UTIs. It receives the relevant patient state on input from the data store or a clinical information system (CIS). The simulations for test patients that are performed using the implementation of the proposed CBFCMs provide the differential diagnosis for these test patients.

The conducted study allowed us to test cognitive approaches for implementing CPG with Semantic Web tools. The advantage of this approach is to enable the sharing and reuse of knowledge from databases GBPC, experts and simplify maintenance.

This work represents a preliminary step in developing a methodology for the implementation of dynamic heterogeneous knowledge in the medical field and their use in decision support systems.

***Abstract*—A detailed analysis of the Hebbian-like learning algorithms applied to train Fuzzy Cognitive Maps (FCMs) is presented in this paper. These algorithms aim to find appropriate weights between the concepts of the FCM so the model equilibrates to a desired state. For this manner, four different types of Hebbian learning algorithms have been proposed in the past. Along with the theoretical description of these algorithms, their performance in system modeling problems is investigated in this work. The algorithms are studied in a comparative fashion by using appropriate performance indices and useful conclusions about their training capabilities are experimentally derived.**

Keywords-fuzzy cognitive maps; hebbian learning; training; system modeling

I. INTRODUCTION

An increased interest about the theory and application of the Fuzzy Cognitive Maps (FCMs) [1] in engineering science is noted recently. FCMs are characterized by their ability to model the dynamics of complex systems by incorporating the casual relationships between the main concepts that describe the system. They have been used initially to model complex social and financial systems [2,3], where analytical descriptions do not exist or can not be derived.

The design of the FCMs is highly dependent on the knowledge of the experts, which define the model's concepts and their interconnections among them. This dependency may significantly affect the modeling accuracy due to the imprecise expert's knowledge.

In order to enhance the knowledge storing capabilities of the FCM models, learning algorithms that search for the best weight values of the concepts' interconnections have been proposed. Mainly, there are two categories of learning algorithms: (1) algorithms that use the Hebbian adaptation rule (Hebbian-like) [5-11] and (2) algorithms that use evolutionary optimization mechanisms (Evolutionary-like) [12-14].

Although the algorithms of the second category ensure near-optimum solutions in the weights search space, the Hebbian-like algorithms of the first category are studied in this work, due to their popularity and quick convergence to desirable FCM states.

The first usage of the Hebbian rule in learning FCMs was performed by Dickerson and Kosko [5], who proposed the *Differential Hebbian Learning* (DHL) algorithm by using the generalized Hebbian rule introduced by Oja [15]. Since there, three other types of Hebbian learning algorithms were proposed, the *Nonlinear Hebbian Learning (NHL)* [7,8], *Data-Driven Nonlinear Hebbian Learning (DD-NHL)* [9] and *Active Hebbian Learning (AHL)* [10,11] ones.

Despite of the review of the Hebbian-like learning algorithms from the literature, the main contribution of this work is the comparison of these algorithms under the same conditions. On the author's best knowledge this kind of comparison is missing from the literature, although such an analysis has to be performed whether a new algorithm is proposed.

The paper is organized, by describing shortly the fundamental theory of the FCMs in section 2, by discussing the Hebbian-like learning algorithms in section 3, by comparing the learning capabilities of the algorithms in system modeling problems in section 4 and finally, by summarizing some to useful conclusions in section 5.

II. FUZZY COGNITIVE MAPS

Fuzzy Cognitive Maps (FCMs) are fuzzy signed directed graphs with feedback [4]. They were proposed by Kosko [6] as a modeling methodology of complex systems, able to describe the casual relationships between the main factors (concepts) that determine the dynamic behaviour of a system.

In their graphical presentation, FCMs have the form of a diagram with nodes having interconnections between them, as illustrated in the following Fig. 1.

As it can be seen from Fig. 1, a FCM consists of nodes (concepts), C_i, $i=1,2,3,...,N$, where N is the total number of concepts, which are characteristics, main factors, or properties of the system being modeled. The concepts are interconnected through arcs having weights that denote the cause and effect relationship that a concept has on the others. There are three possible types of casual relationships between two concepts C_i and C_j (i) positive, meaning that an increase or decrease in the value of a cause concept results in the effect concept moving in the same direction and it is described by a positive weight W_{ij}, (ii) negative, meaning that changes in the cause and effect

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

concepts take place in opposite directions, and the weight W_{ij} has negative sign and (iii) no relation, with the interconnection weight being zero. The weight value, e.g. W_{ij}, denotes the strength of how casual concept C_i causes C_j and takes values in the range [-1,1].

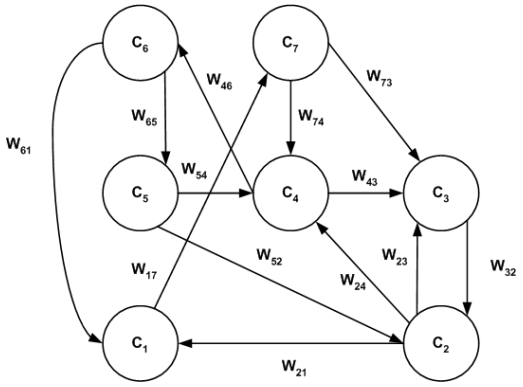

Figure 1. A simple Fuzzy Cognitive Maps

At each time, the value of each concept A_i is calculated, by summarizing the influences of all the other concepts to this and by squashing the overall impact using a barrier function f, according to the following rule

$$A_i^{(t+1)} = f\left(A_i^{(t)} + \sum_{i=1, i\neq j}^{N} W_{ji} A_j^{(t)} \right) \quad (1)$$

where A_i^{t+1} and A_i^t are the values of concept C_i at times t+1and t respectively, A_i^t the value of concept C_j at time t, W_{ji} the weight value of the interconnection with direction from concept C_j to concept C_i, and f the barrier function used to restrict the concept value into a specific range, usually in the range [0,1].

In each step, a new state of the concepts is derived according to (1) and after a number of iterations, the FCM may arrive in one of the following states: (1) a fixed equilibrium point, (2) a limited cycle and (3) a chaotic behaviour.

When the FCM arrives in a fixed equilibrium point, we can conclude that the FCM has converged and the final state corresponds to the actual system state in which the system concludes, when the initial values of concepts are applied.

The design of the FCMs is significantly based on the experience of some experts, who have the knowledge of the system being modeled and provide the weight values for the interconnection between concepts. In more flexible FCM structures these weights are being found during a learning procedure, in a similar way as in the case of neural networks training. For this reason many researchers have borrowed and adjusted algorithms from the neural network theory and proposed new learning procedures [5-9].

In the present paper, the Hebbian-like learning algorithms [5-11] is used in order to find the optimal weight set of the FCMs under investigation and their performance is compared to each other.

III. HEBBIAN LEARNING ALGORITHMS

Hebbian learning constitutes an unsupervised technique initially applied on the training of artificial neural networks [16]. The main feature of this learning rule is that the change of a synaptic is computed by taking into account the presynaptic and postsynaptic signals flow towards each processing unit (neuron) of a neural network and is defined by the following Eq.(2).

$$\Delta w_{ij} = \eta y_i(n) x_j(n) \quad (2)$$

where η is a positive constant that determines the *rate of learning* and x_j and y_i is the presynaptic and postsynaptic signals. The above rule has been modified by Oja [15] in order to solve the stability problems imposed in Eq.(2) by introducing a generalized form of the Hebbian rule called *Oja's rule*, having the following form:

$$\Delta w_{ij} = \eta y_i(n)\left(x_j(n) - y_i(n) w_{ij}(n) \right) \quad (3)$$

Based on the Oja's rule, several Hebbian like learning algorithms have been proposed in the literature, initially for the case of neural networks and recently, after appropriate modifications, for training FCMs.

A short description of the Hebbian like algorithms, having the form of Eq.(2), proposed as learning procedures that find an appropriate set of interconnection weights (connection matrix) subject to a system's requirements is presented hereafter.

A. Differential Hebbian Learning (DHL)

The DHL algorithm was the first Hebbian learning algorithm proposed by Dickerson and Kosko [5] in order to find better interconnection weights than those provided by the experts participated to the FCM design. This algorithm correlates the changes in the concept nodes of the model in order to modify their weights, according to the following Eq.(4).

$$w_{ij}^{(t+1)} = \begin{cases} w_{ij}^{(t)} + \mu_t \left(\Delta A_i^{(t)} \Delta A_j^{(t)} - w_{ij}^{(t)} \right), & \Delta A_i^{(t)} \neq 0 \\ w_{ij}^{(t)} , & \Delta A_i^{(t)} = 0 \end{cases} \quad (4)$$

where

$$\Delta A_i^{(t)} = A_i^{(t)} - A_i^{(t-1)} \quad (5)$$

Moreover, parameter μ_t refers to the learning rate which decreases with the algorithm's iteration as follows:

$$\mu_t = 0.1\left[1-\frac{t}{1.1N}\right] \quad (6)$$

where t is the current iteration and N is a constant that ensures the learning rate not to take negative values. An acceptable value of this constant is the maximum number of the algorithm's iterations.

B. Nonlinear Hebbian Learning (NHL)

The next Hebbian learning algorithm that mostly likes with the Oja's rule is the NHL proposed by Papageorgiou et al. [7], defined as:

$$w_{ij}^{(t+1)} = w_{ij}^{(t)} + \eta A_j^{(t)}\left(A_i^{(t)} - A_j^{(t)} w_{ij}^{(t)}\right) \quad (7)$$

where η is the learning rate. Besides the above basic formulation of the NHL algorithm two more extensions were introduced by Papageorgiou et al. [8], having the following forms:

$$w_{ij}^{(t+1)} = w_{ij}^{(t)} + \eta A_j^{(t)}\left(A_i^{(t)} - \mathrm{sgn}\left(w_{ij}^{(t)}\right) A_j^{(t)} w_{ij}^{(t)}\right) \quad (8)$$

where sgn(·) corresponds to the sign function that returns the sign of a quantity and it is used to maintain the sign of the corresponding weight. The last NHL form is derived by adding a weight decay parameter γ in the update rule, as follows:

$$w_{ij}^{(t+1)} = \gamma w_{ij}^{(t)} + \eta A_j^{(t)}\left(A_i^{(t)} - \mathrm{sgn}\left(w_{ij}^{(t)}\right) A_j^{(t)} w_{ij}^{(t)}\right) \quad (9)$$

In order to decrease the number of the free parameters, only the NHL version of Eq.(8) will be considered in the experimental section of the paper.

Despite of the new weight update rule of the NHL algorithm, the usage of two termination criteria [8] of the learning procedure was also a significant novel feature. These two criteria have the following form:

$$F_1 = \sqrt{\sum_{i=1}^{n}\left(OC_i^{(t)} - T_i\right)^2} \quad (10)$$

$$F_2 = \left|OC_i^{(t+1)} - OC_i^{(t)}\right| < e \quad (11)$$

where $OC_i^{(t)}$ is the i[th] output concept at iteration t and T_i the target value of the output concept, which for the case of a constrained concept lies in a range of $\left[T_i^{\min}, T_i^{\max}\right]$ takes the value $T_i = \frac{T_i^{\min} + T_i^{\max}}{2}$. The objective of the NHL learning algorithm is to find a set of interconnection weights that minimizes the cost functions F_1 and F_2 (subject to a tolerance e), so the FCM model can reach a desired state. While the first criterion shows the error of the output concepts from the desired values, the second one ensures that the FCM model equilibrates to a final state.

A short description of the processing steps of the algorithm is as follows [7]:

Step 1: For a given initial state $\mathbf{A}^o$ and weight set $\mathbf{W}^0$.

Step 2: For each iteration k.

Calculate the concept values $\mathbf{A^k}$ by using Eq.(1).

Update weights $\mathbf{W^k}$ by using Eq.(8).

Until the termination criteria F1 and F2 are met.

Step 3: Return the final weights $\mathbf{W^{final}}$.

C. Data-Drive Nonlinear Hebbian Learning (DD-NHL)

A modified version of the NHL algorithm was proposed by Stach et al. [9], which incorporated historical data of the model into the learning procedure. This algorithm called Data-Driven Nonlinerar Hebbian Learning (DD-NHL) and differs to the original NHL in two steps:

Difference 1: Instead of computing the concept values in each iteration by using Eq.(1), the concept values are provided by the historical data. These data is generated by applying the NHL algorithm [9] in a first stage.

Difference 2: The termination criterion F1 is replaced by the measuring the output concepts that lie inside the desired target values. More precisely, the candidate weight set is used to simulate the FCM model and if the output concepts equilibrated to a desired state the learning is completed (with simultaneously satisfaction of the F2 criterion), otherwise the procedure continues.

D. Active Hebbian Learning (AHL)

A common feature of the previous learning algorithms is that in each iteration the concepts of the FCM model are updated by using Eq.(1), synchronously.

The Active Hebbian Learning (AHL) algorithm considers that the concept nodes are activated asynchronously by a specific sequence. In this way the equilibrium point is reached by considering different times of nodes' activation, a mechanism that is useful in systems where the concepts are

activated based on a specific activation sequence. Moreover, unlike the previous algorithms where only the non-zero weights are being updated, in the case of the AHL algorithm all weights except those of the diagonal are updated.

Based on the AHL algorithm, the nodes of the FCM model is distinguished to *Activated* and *Activation* concepts, by the former ones being the nodes that firstly activated by causing the activation of the latter. In this case the activated concepts are updated through the following rule:

$$A_i^{(t+1)} = f\left(A_i^{(t)} + \sum_{i=1, i\neq j}^{N} W_{ji} A_j^{act(t)} \right) \quad (12)$$

where A_i are the value of the Ci activated concept and A_j^{act} the values of the activation concepts that influence the concept Ci. The weights are updated according to the following rule:

$$w_{ij}^{(t+1)} = \left(1-\gamma^{(t)}\right) w_{ij}^{(t)} + \eta^{(t)} A_i^{(t)} \left(A_j^{(t)} - w_{ij}^{(t)} A_i^{act(t)} \right) \quad (13)$$

where the learning rate η and the weight decay γ are decreased exponentially with the algorithm's iteration number (activation-simulation cycles) as follows:

$$\begin{aligned} \eta^{(t)} &= b_1 e^{(-\lambda_1 t)} \\ \gamma^{(t)} &= b_2 e^{(-\lambda_2 t)} \end{aligned} \quad (14)$$

where $0.01<b_1<0.09$, $0.1<\lambda_1<1$ and b_2, λ_2 are positive constants determined by trial and error. Furthermore, the two termination criterion of the NHL is also applied in the case of AHL in order to derive a desired equilibrium point of the FCM model.

The DHL, NHL, DD-NHL and AHL algorithms will be used to train the same FCM models that describe three different systems and their performance will be compared to each other, in the hereafter section.

IV. Comparative Study

In order to compare the performance of the previously described learning algorithms, in finding the appropriate weights set that give desired output concepts' values, two performance indices are used.

The first one (Mean Squared Error - MSE) measures the mean error between the values of the output concepts (OCs) and the desired values defined by the problem's specifications and is defined as:

$$MSE = \frac{1}{N} \sum_{n=1}^{N} \left(OC_n - T_n \right)^2 \quad (15)$$

where N is the number of the output concepts, OC_i and T_i the value the i^{th} simulated output concept and the corresponding desired value, respectively.

Furthermore, in order to measure the capability of the proposed weight set to converge to an acceptable output values when different initial states are applied (generalization capabilities), the following metric (Generalization Error – GE) is used.

$$GE = \frac{1}{NM} \sum_{k=1}^{M} \sum_{n=1}^{N} \left(OC_n^k - T_n \right)^2 \quad (16)$$

where M is the number of the different initial states.

A. Problem I

The first problem under study, is a benchmark system modeling problem commonly used in the literature [8,9]. It is a process control example consisting of one tank and three valves that control the amount of a liquid in the tank, as depicted in Fig.2.

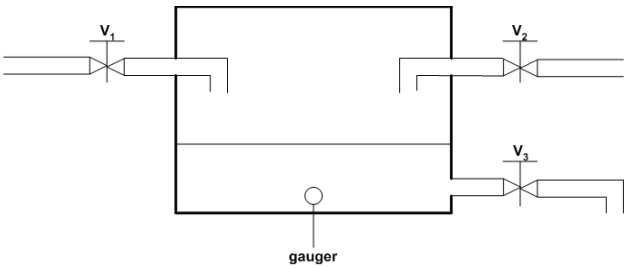

Figure 2. A simple process control problem

The main objective is to keep the height of the liquid and the specific gravity (measured by a sensor – gauger) of the liquid inside of predefined ranges. The FCM model for this process control problem consists of five concepts:

Concept 1 – C1: the amount of the liquid in the tank.

Concept 2 – C2: the state of valve 1

Concept 3 – C3: the state of valve 2

Concept 4 – C4: the state of valve 3

Concept 5 – C5: the specific gravity of the liquid in the tank

The initial weights provided by the experts are:

$$W^{initial} = \begin{bmatrix} 0 & -0.4 & -0.25 & 0 & 0.3 \\ 0.36 & 0 & 0 & 0 & 0 \\ 0.45 & 0 & 0 & 0 & 0 \\ -0.9 & 0 & 0 & 0 & 0 \\ 0 & 0.6 & 0 & 0.3 & 0 \end{bmatrix}$$

By taking into account that the constraints regarding the desired regions of the output concepts (C_1,C_5) are

$$0.68 \le A_1 \le 0.74$$
$$0.74 \le A_5 \le 0.80 \quad (17)$$

the four algorithms are applied with the settings of Table I and the following weight sets are derived in each case:

TABLE I. ALGORITHMS SETTINGS

Algorithms	Parameters
DHL	N=100, e=0.005
NHL	e=0.005, η=0.04
DD-NHL	e=0.005, η=0.04
AHL	e=0.005, b_1=0.02, b_2=0.04, λ_1=0.1, λ_2=1

$$W^{DHL} = \begin{bmatrix} 0 & -0.214 & -0.133 & 0 & 0.164 \\ 0.192 & 0 & 0 & 0 & 0 \\ 0.241 & 0 & 0 & 0 & 0 \\ -0.481 & 0 & 0 & 0 & 0 \\ 0 & 0.320 & 0 & 0.160 & 0 \end{bmatrix}$$

$$W^{NHL} = \begin{bmatrix} 0 & -0.197 & -0.017 & 0 & 0.477 \\ 0.547 & 0 & 0 & 0 & 0 \\ 0.578 & 0 & 0 & 0 & 0 \\ -0.825 & 0 & 0 & 0 & 0 \\ 0 & 0.710 & 0 & 0.5 & 0 \end{bmatrix}$$

$$W^{DD-NHL} = \begin{bmatrix} 0 & -0.244 & -0.068 & 0 & 0.445 \\ 0.515 & 0 & 0 & 0 & 0 \\ 0.557 & 0 & 0 & 0 & 0 \\ -0.839 & 0 & 0 & 0 & 0 \\ 0 & 0.690 & 0 & 0.467 & 0 \end{bmatrix}$$

$$W^{AHL} = \begin{bmatrix} 0 & -0.152 & -0.025 & 0.213 & 0.441 \\ 0.465 & 0 & 0.168 & 0.205 & 0.192 \\ 0.538 & 0.167 & 0 & 0.210 & 0.197 \\ -0.738 & 0.072 & 0.073 & 0 & 0.080 \\ 0.131 & 0.627 & 0.128 & 0.409 & 0 \end{bmatrix}$$

The initial values of the concepts used by the algorithms are A^0=[0.4 0.7 0.6 0.7 0.3], while the final state of the FCM model after applying each one of the above weight matrix is presented in the following Table II.

TABLE II. EXPERIMENTAL RESULTS – PROBLEM I

	Algorithms			
	DHL	***NHL***	***DD-NHL***	***AHL***
A1	0.645	**0.706**	**0.692**	**0.697**
A2	0.682	0.759	0.749	0.628
A3	0.634	0.656	0.645	0.654
A4	0.690	0.756	0.749	0.827
A5	0.689	**0.747**	**0.740**	**0.794**
Iterations	6	16	14	17
MSE	$5.42\text{x}10^{-3}$	$2.72\text{x}10^{-4}$	$6.05\text{x}10^{-4}$	$3.76\text{x}10^{-4}$
GE	$5.42\text{x}10^{-3}$	$2.72\text{x}10^{-4}$	$6.05\text{x}10^{-4}$	$3.76\text{x}10^{-4}$

The above table also includes some additional experimental results such as the algorithm's numbers of iterations needed to converge the algorithms, along with the two performance indices defined in Eq.(15) and Eq.(16).

In this table the bold faced concept values indicate that these outputs concepts lie inside the pre-defined range of desired values of Eq.(17). Comparing the equilibrium points of each algorithm it is deduced that only the DHL algorithm fails to converge in a desirable state, while the rest ones are behave desirable. Among those well converged algorithms the NHL shows the best performance since it equilibrates to a point that is closest to the desired central of the concept's range. This is also justified by examining the MSE value in each case. Moreover, the iterations of the algorithms are almost the same, but as the overall algorithms' execution time is concerned, it has to be mentioned that the DD-NHL algorithm is the most time consumed due to the historical data construction procedure.

Furthermore, it has to be noted that all the algorithms show a remarkable stability on the different initial concepts' state. This perceived from the GE index, which has been calculated by using 10 different random initial state vectors, which remains the same (in fact the final states are differ beyond the fifth decimal digit) with the corresponding MSE value for the case of all the algorithms.

B. Problem II

The second problem studied here, is a part of a chemical plant consisting of two tanks [10], three valves, a heating element and two thermometers and is depicted in the following Fig.3. The objective of the control system is to keep the height of the liquid in both tanks between some desired values, by simultaneously preserving the temperature of the two tanks between predefined limits.

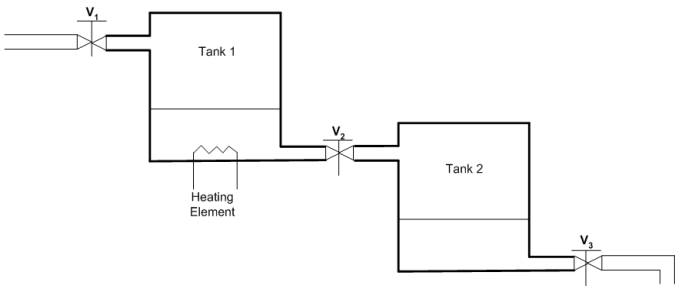

Figure 3. A chemical process control problem

The FCM model for this chemical process control problem consists of eight concepts:

Concept 1 – C1: the height of the liquid in tank 1

Concept 2 – C2: the height of the liquid in tank 2

Concept 3 – C3: the state of valve 1

Concept 4 – C4: the state of valve 2

Concept 5 – C5: the state of valve 3

Concept 6 – C6: the temperature of the liquid in tank 1

Concept 7 – C7: the temperature of the liquid in tank 2

Concept 8 – C8: the heating element operation

The initial weights provided by the experts are:

$$W^{initial} = \begin{bmatrix} 0 & 0 & 0.21 & 0.38 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0.70 & 0.60 & 0 & 0 & 0 \\ 0.75 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -0.80 & 0.70 & 0 & 0 & 0 & 0 & 0.09 & 0 \\ 0 & -0.42 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0.40 & 0 & 0 & 0 & 0 & 0.50 \\ 0 & 0 & 0 & 0.30 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0.40 & 0 \end{bmatrix}$$

By taking into account that the constraints regarding the desired regions of the output concepts (C_1,C_2,C_6,C_7) are

$$\begin{aligned} 0.55 \le A_1 \le 0.75 \\ 0.75 \le A_2 \le 0.80 \\ 0.75 \le A_6 \le 0.82 \\ 0.65 \le A_7 \le 0.75 \end{aligned} \quad (18)$$

the values of the algorithm's free parameters are determined by trial and error and the applied settings are summarized in the following Table III.

TABLE III. ALGORITHMS SETTINGS

Algorithms	Parameters
DHL	N=30, e=0.005
NHL	e=0.005, η=0.03
DD-NHL	e=0.005, η=0.03
AHL	e=0.005, η=0.005, γ=0 (constant)

The resulted weight sets provided by the four Hebbian-like learning algorithms are as follows:

$$W^{DHL} = \begin{bmatrix} 0 & 0 & 0.146 & 0.262 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0.483 & 0.414 & 0 & 0 & 0 \\ 0.517 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -0.549 & 0.551 & 0 & 0 & 0 & 0 & 0.063 & 0 \\ 0 & -0.287 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0.276 & 0 & 0 & 0 & 0 & 0.365 \\ 0 & 0 & 0 & 0.207 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0.276 & 0 & 0 \end{bmatrix}$$

$$W^{NHL} = \begin{bmatrix} 0 & 0 & 0.266 & 0.420 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0.720 & 0.635 & 0 & 0 & 0 \\ 0.780 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -0.762 & 0.831 & 0 & 0 & 0 & 0 & 0.177 & 0 \\ 0 & -0.362 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0.453 & 0 & 0 & 0 & 0 & 0.571 \\ 0 & 0 & 0 & 0.357 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0.454 & 0 & 0 \end{bmatrix}$$

$$W^{DD-NHL} = \begin{bmatrix} 0 & 0 & 0.272 & 0.424 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0.722 & 0.639 & 0 & 0 & 0 \\ 0.783 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -0.757 & 0.835 & 0 & 0 & 0 & 0 & 0.186 & 0 \\ 0 & -0.356 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0.458 & 0 & 0 & 0 & 0 & 0.575 \\ 0 & 0 & 0 & 0.363 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0.460 & 0 & 0 \end{bmatrix}$$

$$W^{AHL} = \begin{bmatrix} 0 & 0.020 & 0.224 & 0.392 & 0.019 & 0.017 & 0.017 & 0.017 \\ 0.020 & 0 & 0.022 & 0.705 & 0.609 & 0.021 & 0.021 & 0.021 \\ 0.753 & 0.021 & 0 & 0.020 & 0.021 & 0.018 & 0.018 & 0.018 \\ -0.765 & 0.805 & 0.020 & 0 & 0.022 & 0.019 & 0.107 & 0.019 \\ 0.020 & -0.385 & 0.021 & 0.022 & 0 & 0.020 & 0.020 & 0.020 \\ 0.017 & 0.021 & 0.411 & 0.019 & 0.021 & 0 & 0.018 & 0.538 \\ 0.018 & 0.022 & 0.019 & 0.314 & 0.021 & 0.018 & 0 & 0.018 \\ 0.017 & 0.021 & 0.018 & 0.019 & 0.021 & 0.411 & 0.018 & 0 \end{bmatrix}$$

The initial values of the concepts used by the algorithms are A^0=[0.480 0.570 0.580 0.680 0.580 0.590 0.520 0.580], while the final state of the FCM model after applying each one of the above weight matrix is presented in the following Table IV.

TABLE IV. EXPERIMENTAL RESULTS – PROBLEM II

	Algorithms			
	DHL	***NHL***	***DD-NHL***	***AHL***
A1	**0.640**	**0.643**	**0.645**	**0.670**
A2	0.723	**0.771**	**0.773**	0.806
A3	0.736	0.785	0.787	0.701
A4	0.813	0.876	0.877	0.730
A5	0.738	0.781	0.781	0.790
A6	0.714	**0.750**	**0.751**	0.679
A7	**0.674**	**0.702**	**0.704**	**0.703**
A8	0.729	0.768	0.768	0.679
Iterations	4	5	7	7
MSE	4.27×10^{-3}	6.46×10^{-4}	6.46×10^{-4}	6.28×10^{-3}
GE	4.27×10^{-3}	6.46×10^{-4}	6.46×10^{-4}	6.28×10^{-3}

The derived experimental results for the case of the second problem are almost the same with those of the first one. The NHL algorithm and its modified version DD-NHL, show the best performance by keeping the four output concepts inside the predefined ranges. The DHL and AHL algorithms have 50% accuracy, since they control satisfactory the two of the four outputs of the FCM model. Again, all the weight sets ensure robustness of the FCM model to the changes of the initial concepts' state as the GE index show.

C. Problem III

The third system that is being modeled by a FCM is a heat exchanger which constitutes a common part of the chemical and process industry [17]. The main objective in this case is the development of a model that simulates the behaviour of the system in order to control the water outlet temperature by adjusting the water flow rate.

The FCM model for this problem consists of five concepts:

Concept 1 – C1: the fan speed (S_f).

Concept 2 – C2: the water flow rate (F_w).

Concept 3 – C3: the water inlet temperature (T_{wi}).

Concept 4 – C4: the air inlet temperature (T_{ai}).

Concept 5 – C5: the water outlet temperature (T_{wo}).

The initial weights provided by the experts are:

$$W^{initial} = \begin{bmatrix} 0 & 0.625 & 0.75 & -0.25 & 0.625 \\ 0 & 0 & -0.75 & 0 & -0.75 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ -0.75 & 0.125 & 0.125 & -0.75 & 0 \end{bmatrix}$$

The output concept is the water outlet temperature (C_5) which for the experimental needs has to satisfy the following constraint

$$0.74 \le A_5 \le 0.75 \tag{19}$$

The corresponding values of the algorithms' free parameters are determined by trial and error and the applied settings are summarized in the following Table III.

TABLE V. ALGORITHMS SETTINGS

Algorithms	Parameters
DHL	N=30, e=0.005
NHL	e=0.001, η=0.06
DD-NHL	e=0.001, η=0.06
AHL	e=0.01, b_1=0.05, b_2=0.02, λ_1=0.1, λ_2=1

The resulted weight sets provided by the four Hebbian-like learning algorithms are as follows:

$$W^{DHL} = \begin{bmatrix} 0.107 & 0.133 & 0.160 & -0.052 & 0.134 \\ 0 & 0.106 & -0.159 & 0 & -0.159 \\ 0 & 0 & 0.106 & 0 & 0 \\ 0 & 0 & 0 & 0.108 & 0 \\ -0.158 & 0.027 & 0.027 & -0.158 & 0.107 \end{bmatrix}$$

$$W^{NHL} = \begin{bmatrix} 0 & 0.655 & 0.729 & 0.271 & 0.736 \\ 0 & 0 & 0.009 & 0 & -0.037 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ -0.380 & 0.651 & 0.646 & -0.368 & 0 \end{bmatrix}$$

$$W^{DD-NHL} = \begin{bmatrix} 0 & 0.653 & 0.734 & 0.241 & 0.734 \\ 0 & 0 & -0.071 & 0 & -0.106 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ -0.414 & 0.630 & 0.624 & -0.405 & 0 \end{bmatrix}$$

$$W^{AHL} = \begin{bmatrix} 0 & 0.602 & 0.692 & -0.047 & 0.594 \\ 0.139 & 0 & -0.402 & 0.135 & -0.410 \\ 0.138 & 0.144 & 0 & 0.134 & 0.136 \\ 0.130 & 0.136 & 0.135 & 0 & 0.128 \\ -0.404 & 0.236 & 0.235 & -0.416 & 0 \end{bmatrix}$$

The initial values of the concepts used by the algorithms are A^0=[0.300 0.650 0.450 0.150 0.300], while the final state of the FCM model after applying each one of the above weight matrix is presented in the following Table VI.

TABLE VI. EXPERIMENTAL RESULTS – PROBLEM II

	Algorithms			
	DHL	***NHL***	***DD-NHL***	***AHL***
A1	0.628	0.567	0.563	0.735
A2	0.687	0.844	0.843	0.712
A3	0.662	0.845	0.840	0.718
A4	0.619	0.614	0.609	0.675
A5	0.652	**0.750**	**0.744**	**0.745**
Iterations	33	36	34	18
MSE	$8.70\text{x}10^{-3}$	$2.04\text{x}10^{-5}$	$3.57\text{x}10^{-7}$	$5.71\text{x}10^{-8}$
GE	$8.56\text{x}10^{-4}$	$5.07\text{x}10^{-6}$	$4.51\text{x}10^{-10}$	$6.09\text{x}10^{-7}$

Based on the above table it is deduced that the DHL algorithm fails to equilibrate to a desired point since the final value of the output concept lies outside the desirable range Eq. (19). On the other hand, the rest algorithms give a satisfied equilibrium state of the FCM model, especially the AHL algorithm, which gives the best output value in a shorter time (18 iterations). As far as the GE performance index is concerned, the DD-NHL algorithm shoes better generalization capabilities, since it equilibrates to the same state independently of the initial state of the model. Moreover, although the performance of the NHL algorithm is accepted, it is quite marginal.

Generally, the NHL algorithm exhibits a satisfactory behaviour since it fully controls the output concepts variations by keeping them between the system's specifications. While the DD-NHL presents similar performance, its dependency on historical data, gives them high execution time without showing significant improvement of its performance. The remaining algorithms the DHL and AHL, seem to perform worst for the three and the two problems under study respectively, but the feature of the AHL algorithm to search for new interconnections between the concepts, can help to design more reliable FCM models.

Finally, it has to be mentioned that all the Hebbian-like learning algorithms studied in this work, are dependent on some free parameters *(η, γ, e, N)*, which significantly affect the convergence and termination of the algorithms to desired FCM model's states. Therefore special attention has to be paid to the selection of these parameters.

V. CONCLUSIONS

A detailed description of the Hebbian-like learning algorithms for training FCM models was presented in the previous sections. Appropriate experiments have been

conducted in order to analyze the performance of each algorithm under the same conditions. The results show that the NHL algorithm exhibits a satisfactory behaviour with low algorithmic complexity as compared with the other similar algorithms. While the comparison of the algorithms was realized by using some performance indices, there is a need to develop a methodology that permits the comparison of the different solutions in the real system's workspace.

The dependency of the Hebbian-like algorithms on some free parameters that significantly influence their performance is a disadvantage of these algorithms, since they control not only the final equilibrium point of the model but also the successfully termination of the algorithm. A novel algorithm with less sensitivity on such parameters and with high convergence rate on desirable states remains a major target of the scientists in this field.

***Abstract*—Due to global warming and climate changes, it is very important to use and conserve the power energy effectively. Monitoring the electrical consumption of consumers is one of the methods that can improve the energy usage efficiency. In this paper, a Non-Intrusive Load Monitoring (NILM) system, which applies a fuzzy classifier with the Fuzzy C-Means (FCM) clustering and optimization algorithms to identify the energizing and de-energizing statuses of each appliance, is proposed. Load energizing and de-energizing transient features are extracted, and the fuzzy classifier performs load identification based on these features. A two-stage fuzzy classifier is used in this paper. For the first stage, the FCM clustering is used to coarsely determine the parameters of the fuzzy classifier. Following this stage, two optimization algorithms, Error Back-Propagation Algorithm (EBPA) and Genetic Algorithm (GA), are employed to fine tune those parameters. As the classification results obtained from different realistic experimental environments, the proposed system is confirmed that it is able to identify the operational status of each appliance.**

Keywords- Fuzzy C-Means; Genetic Algorithm; Appliance Identification; Non-Intrusive Load Monitoring; Power Signatures

I. INTRODUCTION

Due to global warming and climate changes, effectively using and conserving the electricity has become a very important issue recently. One of the approaches for restraining the global warming is to improve the energy usage efficiency by monitoring the residential and commercial electrical consumption. If each appliance is efficiently operated and managed with respect to energy policies formulated by the government, the power energy can be used and conserved effectively. Further, as the energy usage efficiency is improved, the production of greenhouse gases, such as CO_2, CFCs, and so on, can also be reduced. In order to realize these goals, the operational information of each appliance must be understood first. Traditionally, loads are monitored by attaching "smart" sensors. These sensors are able to calculate the energy consumption and transmit the information to an energy management system. Although this approach is easy to implement, it has several disadvantages, e.g., a large amount of sensors, high installation cost. Therefore, to remedy the disadvantages of the traditional load monitoring approach, several *Non-Intrusive Load Monitoring* (NILM) systems were proposed [1-12]. The NILM approach requires a voltage and/or current sensor that is installed on the main electrical panel in a household. By analyzing the power signals, the NILM system is able to identify the energy consumption information of each appliance.

This paper aims to assess the feasibility of using fuzzy classification technique with the *Fuzzy c-Means* (FCM) clustering technique and two different optimization algorithms, *Error Back-Propagation Algorithm* (EBPA) and *Genetic Algorithm* (GA), for the NILM. In this paper, a two-stage fuzzy classifier is developed. At the first stage, the FCM clustering is used to coarsely determine the parameters of the antecedent and consequent of *fuzzy If-Then rules*. In this stage, the FCM clustering constructs fuzzy rules from a training dataset; each rule corresponds to a partition of feature space that is of *universes of discourse*. Also, this stage can be seen as embedding *heuristic* knowledge into the fuzzy classifier. After this stage, the EBPA and GA are adopted to fine tune the parameters of each fuzzy rule such that the classification accuracy can be improved. The load energizing and de-energizing transient features are extracted from current waveforms that are measured at the power entering point. The fuzzy classifier performs load identification based on the features. As the results, the proposed NILM system is capable of distinguishing the energizing and de-energizing statuses of each appliance. The organization of this paper is as follows: First, the existing NILM methods and power signatures used by the methods are surveyed in Sec. II. The proposed NILM method is discussed in Sec. III. The optimization strategies employed to fine tune the parameters are expressed in Sec. IV. The realistic experiments and their results are shown in Sec. V. The conclusions are summarized in Sec. VI.

II. EXISTING NON-INTRUSIVE LOAD MONITORING SYSTEMS

Two signal processing approaches, steady-state analysis and transient analysis, for NILM have been studied in the past.

An NILM system developed by the Electric Power Research Institute (EPRI) applied steady-state approach [1]. The system uses the variations of real and reactive power as the identification signatures. A five-stage algorithm was applied to detect the operation ON/OFF status of each load. Although the system with acceptable performance had been applied to some fields, several problems were pointed out by references [2-4]. For example, the system cannot distinguish the loads with similar real and reactive power consumption. In papers [5-6], the authors indicated that the nonlinear loads not only consume real and reactive power, they also introduce harmonics to the power lines. Hence, the harmonics can be used as the features for identifying different loads. In [7], nine time-domain steady-state features were used. Combinations of the features were sequentially inputted to a 1-Nearest-Neighbor Rule recognizer in order to find the best features that result the highest recognition rate. Besides the steady-state analysis, several studies shown that the transient waveforms for different types of loads are unique due to the differences of physical characteristics [2-3, 8-9]. These studies also found that the transient waveforms have completely or partially repeated profiles. Therefore, the transient properties can also be used as the features for load identification. In [10], a load recognition scheme that applied the notion of maximum approaching degree based on fuzzy logic theory was proposed. Since this scheme does not involve any training process, the NILM system is simple in implementation. In articles [4, 11-12], several steady-state features, such as real power, reactive power, and total harmonic distortion, with the turn-on transient energy are used as the features used by different Artificial Neural Network architectures for load identification. These articles also introduced the Coefficients of Variations to validate the repeatability of turn-on transient energy for each load.

III. Proposed Non-Intrusive Load Monitoring System

In this study, the proposed NILM system that integrates transient load current feature extraction methods with *soft-computing* techniques is used to identify the energizing and de-energizing statuses of each load. The flowchart of the proposed system is shown in Figure 1.

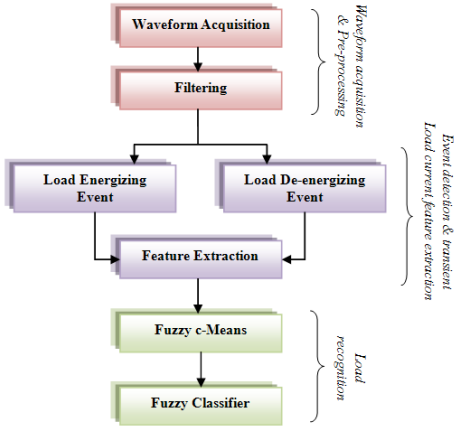

Figure 1. Flowchart of the proposed NILM System. The fuzzy classifier is optimized by optimization strategies.

Detailed descriptions of the system are described in the following sub-sections.

A. *Waveform Acquisition and Filtering*

The aim of waveform acquiring and filtering is to acquire load current waveforms and filter the high-frequency noise, respectively. The cut-off frequency of the low-pass filter of 500 Hz is used in this approach.

B. *Event Detection and Feature Extraction*

In the proposed system, the load energizing or de-energizing event of an appliance can be detected. The feature extraction process is triggered after the event is detected. Following descriptions deal with the processes of event detection and feature extraction.

1) Energizing event detection & Feature extraction:

When the *variation* of current intensity calculated using Eq. (1) is greater than a pre-specified positive threshold, α, a load energizing event is detected.

$$\Delta[I_{intensity}] = (I_{intensity})_{k+1} - (I_{intensity})_k \quad (1)$$

$$I_{intensity} = \frac{\sum_{j=1}^{N} |\, i(j) - \text{mean}(i) \,|}{N} \quad (2)$$

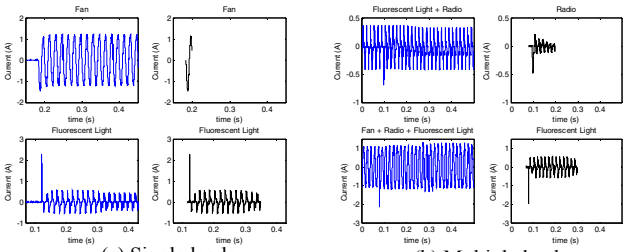
In Eq. (1), i(j) represents the j-th current sampling point; N is the total number of sampling points per cycle; k indicates the k-th sampling cycle; mean(i) denotes the average current value for each sampling cycle.

After the load energizing event is detected, the process for determination of transient period starts. Since the transient period may continue for certain cycles after a load is energized, a differential procedure based on the fundamental property of superposition is performed first. After this procedure, the *change rate* of current intensity is calculated using Eqs. (3) and (4). In Eq. (3), i'(t) represents a differential waveform that is obtained through the differential procedure. During this process, ΔI' is compared with a pre-specified threshold, γ. If ΔI' is less than γ for a pre-specified δ cycles, the determination of transient period terminates. Finally, the transient period, E_t, is defined as the total period of transient determination minus δ cycle time.

$$I'_{intensity} = \log\left(\sum_{j=1}^{N} (i'(j) - \text{mean}(i'))^2\right) \quad (3)$$

$$\Delta[I'_{intensity}] = \left| (I'_{intensity})_{k+1} - (I'_{intensity})_k \right| \quad (4)$$

Some load energizing current waveforms for different single and multiple load operation scenarios are shown in Figure 2. The acquired transient current waveform, i_{aq}(t), of an unidentified load is shown on the right column of these figures. In multiple load operation scenarios, all loads except the unidentified load were energized in advance.



(a) Single loads. (b) Multiple loads.

Figure 2. Load current waveforms for different operation scenarios.

Feature extraction is crucial for load identification. The feature extraction process transforms an observation space into a feature space. Generally, the feature space is of much lower dimensions than the observation space. In this paper, *Crest Factor* (*C.F.*) calculated using Eq. (5) and E_t are used as the features for load energizing identification. In Eq. (5), $i_{aq}(t)$ indicates the acquired transient waveform.

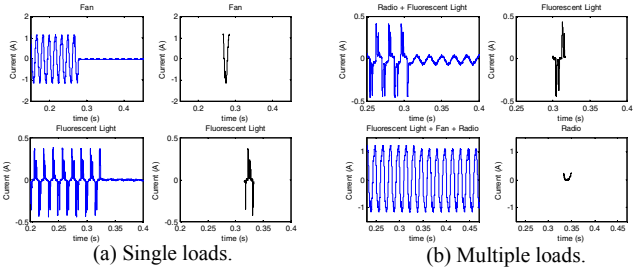
$$Crest\ Factor\ (C.F.) = \frac{\max|i_{aq}(t)|}{\sqrt{\int_{E_t} {i_{aq}}^2(t)dt \Big/ E_t}} \tag{5}$$

2) De-energizing event detection & Feature extraction:

When the variation of current intensity that is obtained from Eq. (1) is less than a pre-specified negative threshold, β, a load de-energizing event is detected. Following the detection of the event, the current waveforms before and after the event are subtracted. By doing so, the load de-energizing transient waveform of an undetermined load can be acquired. For the determination of load de-energizing transient period, the transient period, E_t, is defined as one cycle.

Figure 3 shows some load de-energizing current waveforms for different single and multiple load operation scenarios. The features, *C.F.* and I_{peak}, of an acquired de-energizing transient waveform are calculated using Eqs. (5) and (6). These features are used for load de-energizing identification.

$$I_{peak} = \max|i_{aq}(t)| \tag{6}$$



(a) Single loads. (b) Multiple loads.

Figure 3. Load current waveforms for different operation scenarios.

C. Fuzzy Classifier with Fuzzy C-Means Clustering

In this sub-section, the fuzzy classifier and the FCM clustering which is used to roughly construct the fuzzy classifier are discussed. The structure of the fuzzy classifier is shown in Figure 4. In Figure 4, the *fuzzifier* transforms the crisp input values calculated from the acquired current waveform into fuzzy sets. After this fuzzification process, the fuzzified inputs with fuzzy rules are passed to *inference engine* that combines them using a fuzzy *t*-norm operator to derive the *firing strength* of each fuzzy rule. When the firing strength of each rule is obtained, the crisp output can be calculated using a *de-fuzzifier*. Finally, this crisp output is delivered to the *decision-making unit* to determine the class of an unidentified appliance corresponding to the acquired current waveform.

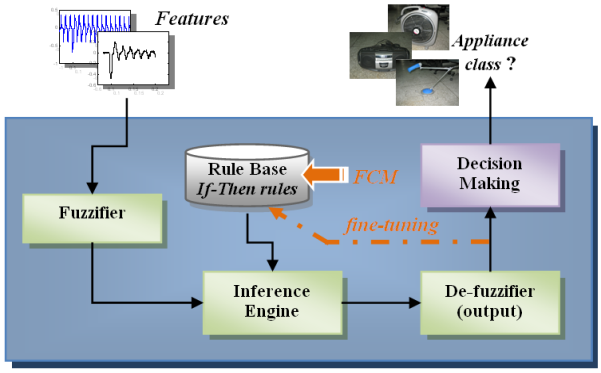


Figure 4. Structure of the fuzzy classifier.

1) Fuzzy Classifier:

A *fuzzy Rule Base* that consists of a set of fuzzy IF-THEN rules has the form shown in Eq. (7) [13]:

$$Ru^{(l)}: IF\ x_1\ is\ A_1^l\ and\ ...\ and\ x_n\ is\ A_n^l, THEN\ y\ is\ B^l \tag{7}$$

In Eq. (7), A_i^l and B^l are fuzzy sets in $U_i \subset R$ and $V \subset R$, respectively; $x=(x_1, x_2, \ldots, x_i, \ldots, x_n)^T \in U \subset R^n$ and $y \in V \subset R$ are the input and output linguistic variables of the fuzzy classifier, respectively; M is the total number of rules in the fuzzy rule base (i.e., l=1, 2, …, M).

a) Fuzzifier, Inference Engine, and De-fuzzifier:

Each fuzzy set in Eq. (7) is characterized as a *Gaussian membership function*. The center of the fuzzy set B^l in Eq. (7) is *singleton* with value of $\bar{y}^l$. By using *singleton fuzzifier*, *product inference engine* and *center average de-fuzzifier*, the fuzzy classifier can be formulated as Eq. (8). In Eq. (8), $f(x) \in V \subset R$ is the de-fuzzified output of the fuzzy classifier; $a_i^l \in$ (0, 1] are constants; $\sigma_i^l \in (0, \infty)$, $\bar{x}_i^l \in$ R, and $\bar{y}^l \in$ R are real-valued parameters.

$$f(x) = \frac{\sum_{l=1}^{M} \bar{y}^l [\prod_{i=1}^{n} a_i^l \exp(-(\frac{x_i - \bar{x}_i^l}{\sigma_i^l})^2)]}{\sum_{l=1}^{M} [\prod_{i=1}^{n} a_i^l \exp(-(\frac{x_i - \bar{x}_i^l}{\sigma_i^l})^2)]} \tag{8}$$

The Gaussian-type membership function rather than other types of membership functions is chosen in this paper for two reasons. Firstly, the total number of parameters to be tuned or evolved is small since each Gaussian membership function requires two parameters. Secondly, the Gaussian-type membership function ensures that the firing strength of each rule is always non-zero. In addition, the total number of universes of discourse for the input of the fuzzy classifier is

two. Each universe of discourse is further divided into three partitions using three Gaussian membership functions (because three-class energizing or de-energizing classification problem is considered). Thereby, the total number of fuzzy rules is nine. Thus, the feature space is partitioned into 3×3 decision regions. In this paper, the partition with the parameters of the fuzzy classifier is initialized using the FCM clustering, which will be discussed in the next sub-section.

b) Decision-Making Unit:

After the de-fuzzified output of the fuzzy classifier is calculated using Eq. (8), the output is passed to the decision-making unit to determine the class label of the input using Eq. (9). In Eq. (9), $Class^k$, an integer, denotes the pre-assigned class label of the k-th class; w is the total number of classes.

$$Class\ label = Class^j;\ j = \underset{k=1,2,\ldots,w}{\operatorname{argmin}}(|f(x) - Class^k|) \tag{9}$$

The recognition rate is one of the criteria for evaluating the performance of a classifier. In this paper, the recognition rate is defined as the number of correctly classifying the test data with the total data in the test dataset.

2) Fuzzy c-Means Clustering:

A 2-stage approach used to design the fuzzy classifier is proposed in this paper. These stages are described as follows:

- **Stage 1**. Apply the FCM clustering with the training dataset to coarsely determine the parameters of the fuzzy If-Then rules. This stage is a "heuristic" stage.
- **Stage 2**. Apply the optimization algorithms with the training dataset to fine tune the parameters determined in Stage 1.

After the fuzzy classifier with the acceptable performance is designed, it can be used to classify new patterns.

The FCM clustering is one of the partition clustering algorithms for data clustering [13, 14]. The FCM clustering algorithm allows each datum belonging to two or more clusters as the sense in *Fuzzy Logic*. The goal of the FCM clustering applied in this research is to find c *codebook prototypes*/*centroids*/*centers* in respect of the training dataset. These c cluster centers can be used to determine the parameters of each fuzzy If-Then rule. The FCM clustering procedure is summarized as follows:

- **Step 1**. For a dataset $X=\{\mathbf{x}_1, \mathbf{x}_2, \ldots, \mathbf{x}_k, \ldots, \mathbf{x}_n\}$, where $\{\mathbf{x}_k\}_{k=1}^n \in R^p$: fix $c \in \{2, 3, \ldots, (n\text{-}1)\}$, set $m \in (1, \infty)$, and initialize $U^{(0)} \in M_{fc}$. Here, $M_{fc} = \{U \in V_{cn} \mid u_{ik} \in [0, 1],\ 1 \le i \le c,\ 1 \le k \le n;\ \sum_{i=1}^{c} u_{ik} = 1, \forall k \in \{1,2,\ldots,n\}$ is true$\}$; V_{cn} is the set of real $c \times n$ matrices $U=[u_{ik}]$; u_{ik} is the membership value of $\mathbf{x}_k$ that belongs to cluster A_i.
- **Step 2**. At iteration l, where l=0, 1, 2, …: compute the c mean centers using

$$\mathbf{v}_i^{(l)} = \frac{\sum_{k=1}^{n} (u_{ik}^{(l)})^m \mathbf{x}_k}{\sum_{k=1}^{n} (u_{ik}^{(l)})^m}, 1 \le i \le c$$

.

- **Step 3**. Update $U^{(l)}$ to $U^{(l+1)}=[u_{ik}^{(l+1)}]$ using

$$u_{ik}^{(l)} = \frac{1}{\sum_{j=1}^{c} \left(\frac{\| \mathbf{x}_k - \mathbf{v}_i^{(l)} \|}{\| \mathbf{x}_k - \mathbf{v}_j^{(l)} \|}\right)^{\frac{2}{m-1}}}, 1 \le i \le c, 1 \le k \le n$$

.

- **Step 4**. If $\|U^{(l+1)} - U^{(l)}\|$ is less than or equal to a pre-determined tolerance, stop; otherwise, set l=l+1 and go to Step 2.

The cluster centers and the distribution of clusters are used in this paper. They are identified using the FCM clustering to roughly allocate the parameters of the fuzzy classifier. The *center* parameter of each Gaussian membership function, $\bar{x}_{x_i j}$, on each universe of discourse is set to the corresponding component of cluster center. Also, the *spread* parameter of each Gaussian membership function on each universe of discourse is determined using Eq. (10).

$$\sigma_{x_i j} = x'_i - \bar{x}_{x_i j};\ i=1, 2, \ldots, n, \text{ and } j=1, 2, \ldots, N_{MF} \tag{10}$$

In Eq. (10), n is the total number of universes of discourse (input variables); N_{MF} is the total number of membership functions (clusters) on each universe of discourse; x'_i is the component of a datum which belongs to cluster j with the approximate membership degree of e^{-1}. For the cases studied in this paper, n and N_{MF} are 2 and 3, respectively.

After the center and spread parameters are determined, the singleton parameters, $\{\bar{y}^l\}_{l=1}^M$, for the part of consequent of fuzzy rules can also be assigned based on the partitions and the labels of training data. After coarsely determining these parameters, they are further adjusted using the EBPA and GA.

IV. Optimizing of Fuzzy Classifier

In this section, two different types of optimization algorithms are applied to fine tune the parameters of fuzzy classifier. The gradient descent algorithm [13, 15-16] used to find the quasi-optimal structure of the fuzzy classifier of (8) according to the training dataset is discussed first.

A. Gradient Descent Algorithm Approach

Suppose that the following input-output pairs are collected: $\{(x_0^p, y_0^p)\}_{p=1}^N$, where $x_0^p \in U \subset R^n$ and $y_0^p \in V \subset R$. The goal is to design the fuzzy classifier based on these N input-output pairs. In Eq. (8), σ_i^l, $\bar{x}_i^l$, and $\bar{y}^l$ are roughly initialized based on the results of the FCM clustering. Once these parameters are specified, the quasi-optimal structure of the fuzzy classifier can be obtained. The gradient descent algorithm used for tuning the classifier's parameters is summarized as follows:

- **Step 1**. Initialize the parameters. Determine the initial parameters, $\bar{y}^l(0)$, $\bar{x}_i^l(0)$, and $\sigma_i^l(0)$, according to stage 1.
- **Step 2**. Present an input-output pair (x_0^p, y_0^p) and calculate the output associated with the inputs of the fuzzy classifier at the q-th iteration of tuning.
- **Step 3**. Update the parameters. The following updating equations are used to update the parameters:

$\bar{y}^l(q+1) = \bar{y}^l(q) - \eta \frac{f-y}{a} b^l$, where η is a tuning constant; f and y denote $f(x_0^p)$ and y_0^p, respectively; $a = \sum_{l=1}^{M} b^l$; $b^l = \prod_{i=1}^{n} \exp(-(\frac{x_i - \bar{x}_i^l}{\sigma_i^l})^2)$.

$$\bar{x}_i^l(q+1) = \bar{x}_i^l(q) - \eta \frac{f-y}{a}(\bar{y}^l(q) - f) b^l \frac{2(x_{0i}^p - \bar{x}_i^l(q))}{\sigma_i^{l2}(q)}$$

$$\sigma_i^l(q+1) = \sigma_i^l(q) - \eta \frac{f-y}{a}(\bar{y}^l(q) - f) b^l \frac{2(x_{0i}^p - \bar{x}_i^l(q))^2}{\sigma_i^{l3}(q)}.$$

- **Step 4**. Go to Step 2 with q=q+1, until $|f-y_0^p|$ is less than a pre-determined tolerance, or until the value of q equals to a pre-determined iteration.
- **Step 5**. Go to Step 2 with p=p+1 to update the parameters using next input-output pair, (x_0^{p+1}, y_0^{p+1}).
- **Step 6**. Set p=1 and re-do steps 2 to 5, until the result of the classifier is satisfactory.

B. Genetic Algorithm Approach

For the second approach, GA is used to globally search the optimal parameters. [16-18] The GA, which had been applied to different engineering optimization problems, is a global and stochastic search algorithm. Two types of operators for the GA are used: *genetic operators* and *evolution operator*. The genetic operators include *crossover* and *mutation* operators; the evolution operator comprises a *selection* operator. The flowchart of the GA used in this paper is shown in Figure 5.

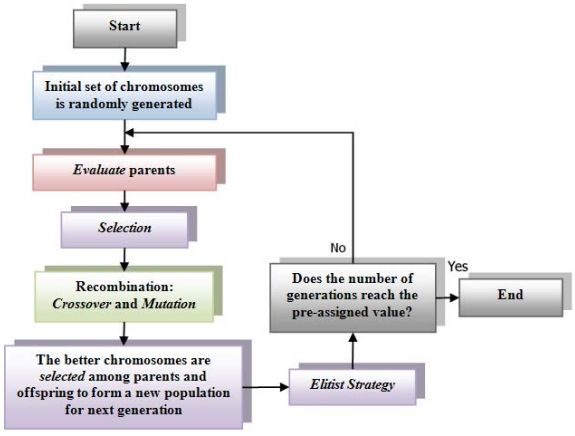

Figure 5. Flowchart of the GA.

With application of GA, the first important step is to *encode* the fuzzy classifier into the *chromosome* (*genotype* representation). In this paper, two universes of discourse are considered. Each universe of discourse is partitioned into three regions using three Gaussian membership functions. Hence, there are nine rules due to the 3×3 regions. As a result, a total of 21 parameters ($3_{\text{membership functions}} \times 2_{\text{parameters per function}} \times 2_{\text{inputs}} + 9_{\text{rules}}$) need to be adjusted. Each parameter is encoded into a binary string. The structure illustration of the chromosome is illustrated in Figure 6.

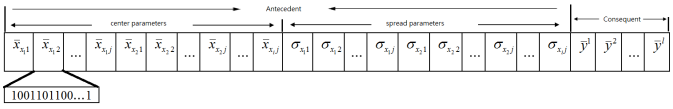

Figure 6. Representation of the chromosome.

In order to evaluate the quality of each chromosome, *fitness function* is needed. A good fitness function can gradually guide the GA to find the optimal solution. In this paper, the fitness function, the reciprocal of *mean-squared error* (MSE_{rror}), is defined as follows:

$$fitness = \frac{1}{MSError} = \frac{1}{\frac{1}{N}\sum_{p=1}^{N}[f(x_0^p) - y_0^p]^2}$$

s.t.

$$\bar{x}_{x_i(j-1)} \le \bar{x}_{x_i j} \le \bar{x}_{x_i(j+1)}$$

$$\bar{x}_{x_i j} - \rho \cdot \sigma_{x_i j} \le \sigma_{x_i j} \le \bar{x}_{x_i j} + \rho \cdot \sigma_{x_i j}$$

$$\bar{y}^l - 1 \le \bar{y}^l \le \bar{y}^l + 1$$

Note that, the boundaries of these constraints are determined based on the results of the FCM clustering; and ρ is a constant.

During *evaluation*, each chromosome must be *decoded* to the corresponding fuzzy classifier (*phenotype* representation). After each chromosome in current generation is evaluated, the *natural selection* process that mimics the process of Darwinian evolution to create populations from generation to generation is performed. In this paper, the *roulette wheel selection* is adopted; it belongs to the fitness-proportional selection. A new population with respect to the probability distribution based on fitness values is generated. The *enlarged* (μ+λ) *sampling space* is considered in this paper. With this sampling space, μ parents and λ offspring compete for survival. The μ best out of offspring and old parents are selected as the population for the next generation. The genetic operators facilitate an efficient search and guide the search into new regions. The crossover facilitates exploration, while the mutation facilitates exploitation of the search space [18]. In this paper, one-cut-point crossover and bit-wise flipping mutation operators are used. In addition, the *Elitist strategy* is also applied. This strategy ensures that the best chromosome is passed onto next generation if it is not selected via the selection process.

V. EXPERIMENTAL RESULTS

In this paper, the proposed NILM system is used to identify the operation status of each appliance. The appliances include *Fan*, *Fluorescent Light* (F.L.) and *Radio*. All the experiments in this study are executed at different realistic environments. During identification, no loads were energized or de-energized simultaneously. Experimental 1 describes the results of the appliance energizing identification; Experimental 2 describes the results of the appliance de-energizing identification. A circuit was designed to energize the appliance at different energizing phase angles. As the waveforms shown in Figures 2 and 7, the current waveforms for different types of loads are *unique* and *repeatable*.

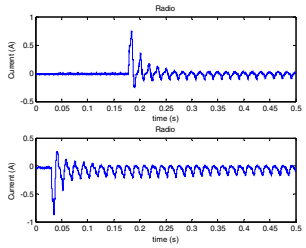

Figure 7. Current waveforms for different load energizing phase angles. The load, Radio, was energized at 73.5 degree (top) and 225 degree (bottom) at different measurement locations.

For all the experiments, 108 single load current measurements are performed. 69 of the measurements are used for training; while the remaining 39 measurements are used for testing. Additionally, 41 multiple load current measurements are used for testing as well.

A. Experimental 1: Load Energizing Classification

In this experiment, the proposed system is used to identify the energizing status of each load. The results of the fuzzy classifier with the two different optimization strategies for this load energizing classification are summarized below.

1) Fuzzy Classifier with the EBPA

In this experiment, the universes of discourse for the inputs are set to appropriate ranges according to the distribution of the training data. The feature space and the results of the FCM clustering are illustrated in Figure 8.

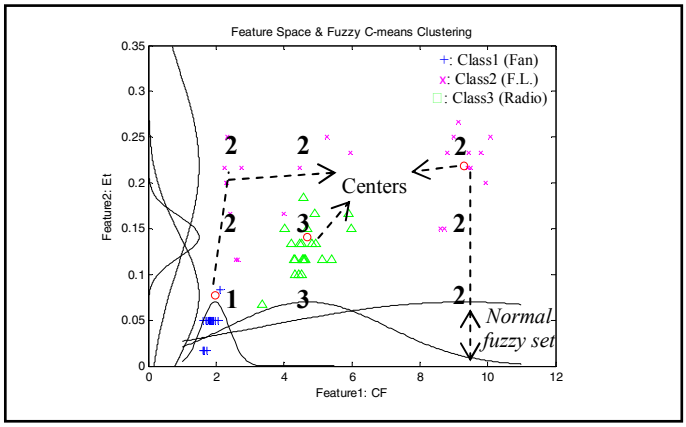

Figure 8. Feature space and fuzzy c-means clustering in Experimental 1.

In Figure 8, the interval of *CF* is [1, 11], whereas the interval of E_t is [0, 0.3]. The label of each partition is assigned according to the clusters and the training data. Analysis of the data shows that E_t has less ambiguity than *CF*. Hence, E_t is a better feature than *CF*.

The values of feature parameters, (α, γ, δ), used in this experiment are (0.03, 0.065, 10.0), respectively. These values are determined based on the past experience. The fuzziness constant, *m*, is 2; the value of *c* is 3 because this is a three-class problem. The tuning constant, η, is 0.003; the maximum training epoch is 500. The training and testing results of the fuzzy classifier with the gradient descent algorithm in this experiment are shown in Figure 9. The testing results are tabled in Table I.

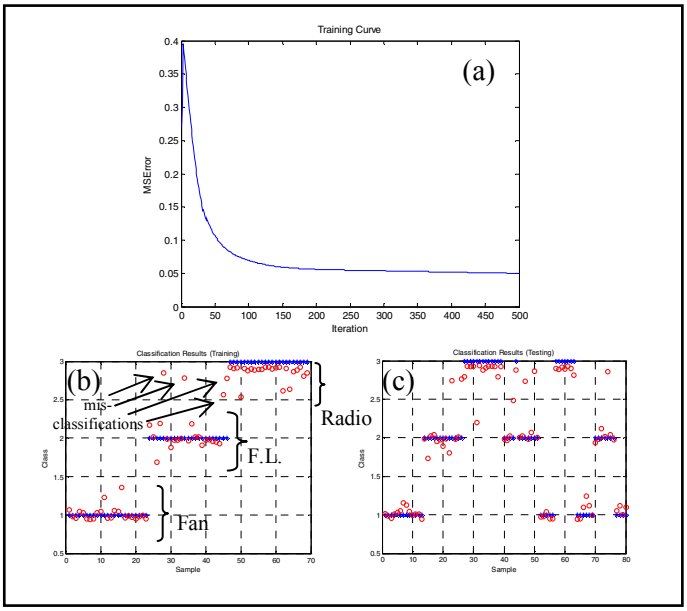

Figure 9. Training and testing results of the fuzzy classifier with the gradient descent algorithm in experimental 1. (a). Training curve. The final MSE_{rror}=0.04991; (b) Training result. The O.R.R.=94.2%; (c). Testing result. The O.R.R.=92.5%.

TABLE I. IDENTIFICATION RESULTS OF THE FUZZY CLASSIFIER WITH THE GRADIENT DESCENT ALGORITHM IN EXPERIMENTAL 1

C.M.	Single Load and Multiple Load operation		
	Fan	F.L.	Radio
Fan	28 (100%)	0 (0%)	0 (0%)
F.L.	0 (0%)	26 (83.87%)	5 (16.13%)
Radio	0 (0%)	1 (4.76%)	20 (95.24%)
O.R.R.[a] (%)	**92.5**		

O.R.R.[a]: Overall Recognition Rate

The units used in the Confusion Matrix (C.M.) table are the number of successful/unsuccessful recognizing count and percentage, respectively. From Table I, Fluorescent Light has the lowest recognition rate of 83.87%; Radio has the recognition rate of 95.24%; and Fan has the highest recognition rate of 100%. The overall recognition rate is 92.5%.

2) Fuzzy Classifier with the GA

The parameters used by the GA are as follows: The total length of each chromosome is 223. The population size and maximum generation are 50 and 200, respectively. For simplicity, the crossover and mutation rates during evolution are held constant; they are set to 0.63 and 0.07, respectively. The training and testing results of the fuzzy classifier with the GA in this experiment are shown in Figure 10. The testing results are shown in Table II.

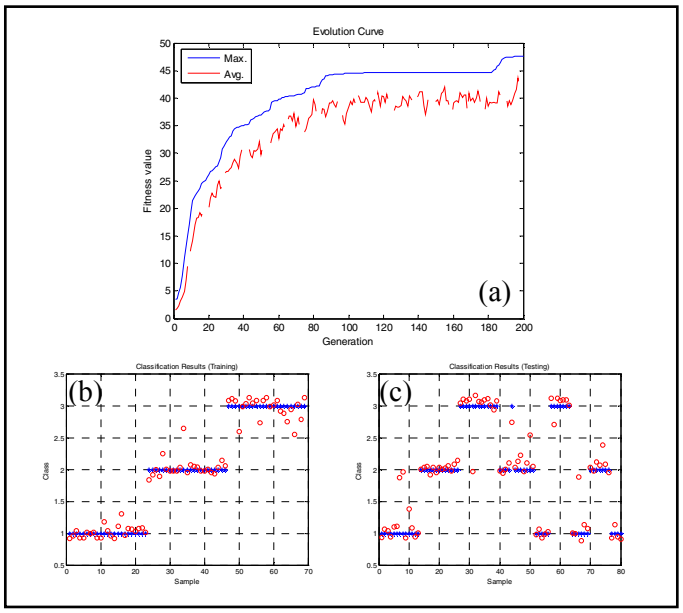

Figure 10. Training and testing results of the fuzzy classifier with the GA in experimental 1. (a). Evolution curves. The final f.v.=47.624; (b) Training result. The O.R.R.=98.55% (**+4.35%**); (c). Testing result. The O.R.R.=93.75% (**+1.25%**).

TABLE II. IDENTIFICATION RESULTS OF THE FUZZY CLASSIFIER WITH THE GA IN EXPERIMENTAL 1

C.M.	**Single Load and Multiple Load operation**		
	Fan	F.L.	Radio
Fan	25 (89.29%)	3 (10.71%)	0 (0%)
F.L.	0 (0%)	30 (96.77%)	1 (3.23%)
Radio	0 (0%)	1 (4.76%)	20 (95.24%)
O.R.R. (%)	**93.75**		

From Table II, Fan has the lowest recognition rate of 89.29%; Radio has the recognition rate of 95.24%; and Fluorescent Light has the highest recognition rate of 96.77%. The overall recognition rate is 93.75%.

B. Experimental 2: Load De-energizing Classification

In this experiment, the proposed system is used to identify the de-energizing status of each load. The feature space and the results of the FCM clustering are illustrated in Figure 11 (a). Analysis of the data shows that *CF* as well as I_{peak} is a good feature for classification. Based on the past experience, the β is set to 0.016. The tuning constant, η, is 0.01; the maximum training epoch is 500. The training and testing results of the fuzzy classifier with the gradient descent algorithm in this experiment are shown in Figure 11 (b) to (d). The testing results are tabled in Table III. The results show that he overall recognition rate is 100%.

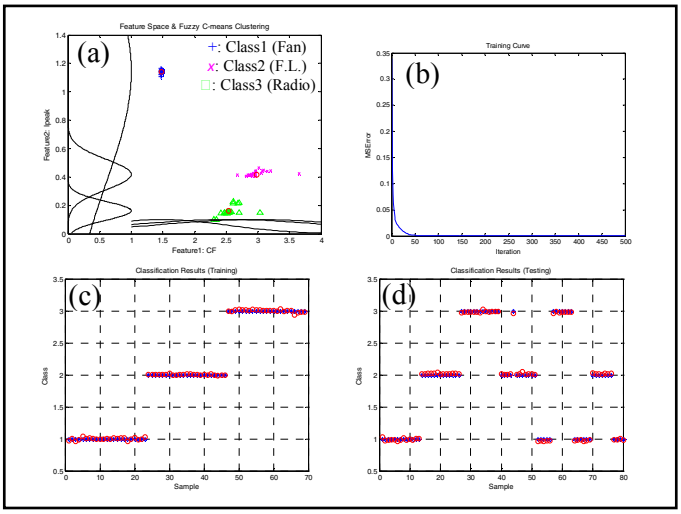

Figure 11. Training and testing results of the fuzzy classifier with the gradient descent algorithm in experimental 2. (a) Feature space and fuzzy c-means clustering in Experimental 2; (b). Training curve. The final MSE_{rror}=0.000268; (c) Training result. The O.R.R.=100%; (d). Testing result. The O.R.R.=100%.

TABLE III. IDENTIFICATION RESULTS OF THE FUZZY CLASSIFIER WITH THE GRADIENT DESCENT ALGORITHM IN EXPERIMENTAL 2

C.M.	**Single Load and Multiple Load operation**		
	Fan	F.L.	Radio
Fan	28 (100%)	0 (0%)	0 (0%)
F.L.	0 (0%)	31 (100%)	0 (0%)
Radio	0 (0%)	0 (0%)	21 (100%)
O.R.R. (%)	**100**		

VI. CONCLUSIONS

The NILM system acts an important role for effectively using and conserving the electricity. In this paper, an NILM system that integrates transient load current feature extraction methods and soft-computing techniques is proposed. The proposed system, which uses the fuzzy classifier with the FCM clustering and the two optimization algorithms as the load identifier, is capable of identifying energizing and de-energizing statuses of each load under single load and multiple load operation scenarios in different realistic environments. From the experimental results, the classification performance of the fuzzy classifier with the GA is better than the performance of the classifier with the conventional EBPA because the GA is a global search optimization algorithm. The overall recognition rates are above 92.5%. Additionally, the identification is not affected by different experimental locations. These results confirm that the proposed NILM system is able to identify the usage status of each appliance robustly.

***Abstract*—A fuzzy imbalanced force estimator and feed-forward controller designed by the knowledge of rotor dynamics for a single active magnetic bearing suspended rotor system was proposed to eliminate the unbalancing vibration of rotor in the paper. The variable parameters used in the fuzzy estimator are displacement and velocity of the rotor and control current of the magnetic bearing. Based on the estimating signal, a feed-forward control system is set to suppress the unbalancing vibration. The simulation and experiment results show that the proposed estimation system could accurately estimate the unbalance force and the feed-forward control system could restrain the unbalancing vibration to improving the rotational accuracy.**

Keywords-fuzzy imbalanced force estimator, single active magnetic bearing

I. INTRODUCTION

Active magnetic bearing (AMB) is the essential part of the non-contact rotor systems and have been widely developed in industrial application, i.e., the spindle of machine tool, the linear motor, the flywheel energy store system, and the compound molecular pump, etc. By the reference [1], we know the AMB can't work stably without a control system. Thus the control system which contains position sensors and a traditional proportional-integral-derivative (PID) controller is the standard control system for the industries. Parameters of the PID controller are based on the system's dynamic model. But the system model can't obtain accurately and always keep in the same condition. Thus, in order to optimize the controller to make the system more stable, there are many researches working for the controllers with the unknown parameters of the AMB system. For the unknown parameters of the AMB rotor system with vibrating base, an adaptive back stepping controller was proposed and the results showed the bearable acceleration disturbance level was higher than PID controller [2]. The model uncertainty of the AMB system changed with the operating rotor speed, a linear parameter-varying controller was proposed for the time-varying AMB parameters [3]. Mainly vibration source of the disturbance is the unbalance force from the rotor. The Sliding mode control was applied to increase the robustness of the AMB system to reduce the disturbance response [4].

From these researches, we can find in such a non-contact rotor system the unbalance force is usually the other factor which induced the rotor system being unstable as the rotor running to the critical speed of the system, consequently, the unbalance compensation is needed. Moreover, if the unbalance force can be predicted, the parameters of the controller can be modified to control the system operating more smoothly [5]. A model based force estimator with an adaptive tuner for a single AMB suspended rotor system was proposed to eliminate the imbalance vibration in our early research [6]. These methods are frequency dependent because the synchronous reference signal generator has parameters that are dependent on the rotor spin rate, thus requiring continual adaptation as the spin rate varies or they are built on the linear model of the AMB system that there are parameters uncertain problem must be resolved. Therefore, this problem was tried to be solved by a traditional PID controller and a fuzzy feed-forward force compensator.

In recent years, fuzzy controller has been found to be one of the most popular controllers. A well designed fuzzy logic controller can handle uncertain information and used in the control of the AMB system which are having a complex time-variable mathematical model.[7-10] The fuzzy logic control system contains sets of variable functions which are fuzzy rules and membership functions. Generally these variables can be adjusted by the experiment results and try and error. By continuing adjust the fuzzy variable functions, the fuzzy logic control system can be the most effective controller to control the AMB systems.

In this paper, a knowledge-based fuzzy imbalanced force compensator system is proposed. The compensator system is established by the measurement of the displacement of the rotor, control current of the magnetic bearing and rotor speed. And the fuzzy rules and membership functions was established by the previously research which showed the feed-forward compensator could meliorate the rotational accuracy in the operational range. After building the fuzzy compensator system, the feed-forward control system is established. To verify the compensator system and the feed-forward control system, the simulation and experiment results was carried out.

II. MODELING OF A SINGLE MAGNETIC BEARING SUSPENDED ROTOR SYSTEM

Fig.1 shows the basic structure of the single AMB system. The rotor is suspended horizontally by an AMB in the free end and a flexible coupling in the other end connected with the motor. The rotor positions in the free end are measured by two eddy-current type sensors at the magnetic bearing location. The spinning shaft is driven by the motor. Fig.2 shows the relative positions of the coupling, magnetic bearing and the mass center of rotor. Fig.2 also shows the directions of the four degrees of freedoms of the rotor and the action positions and directions of the magnetic forces (F_1 ~F_4) and the reacted forces (F_{xt}, F_{yt}) of the flexible coupling.

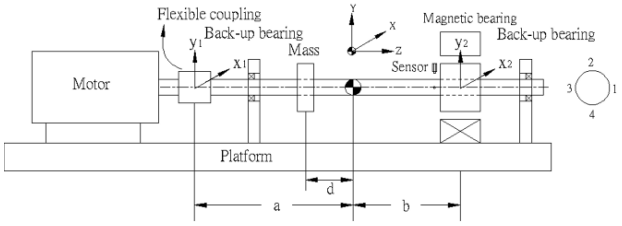

Fig.1 Structure of the single AMB system

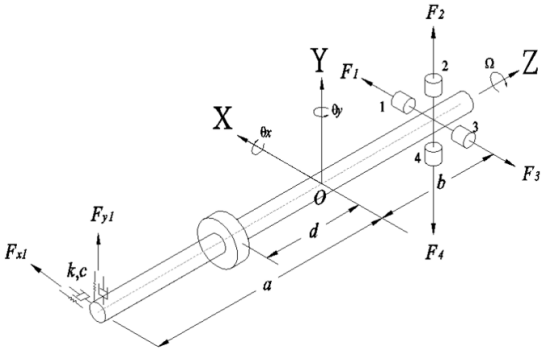

Fig.2 Geometric relationship of the single AMB system

According to the research[5], the magnetic force and the reacted forces of the flexible coupling can be expressed as:

$$F_1 - F_3 = k_i i_1 + k_{d1} x_2$$
$$F_2 - F_4 = k_i i_2 + k_{d1} y_2$$

where x_1, y_1, x_2, and y_2 are the radial displacements at the positions of flexible coupling and AMB; k_T and c_T are the equivalent stiffness and damping coefficients of the flexible coupling; k_i is the current-force coefficient and k_d is the displacement-force coefficient of AMB.

The dynamics of the system in terms of displacements in the flexible coupling and magnetic bearing locations, which can be written in matrix form as follows:

$$M\underline{\ddot{x}} + C\underline{\dot{x}} + K\underline{x} = B\underline{u} + E\underline{w} + F\underline{x}^3 + Dg$$

$$M = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}; C = \begin{bmatrix} c_T\beta_3 & 0 & \alpha_1 & -\alpha_1 \\ -c_T\beta_2 & 0 & -\alpha_2 & \alpha_2 \\ -\alpha_1 & \alpha_1 & c_T\beta_3 & 0 \\ \alpha_2 & -\alpha_2 & -c_T\beta_2 & 0 \end{bmatrix}$$

$$K = \begin{bmatrix} k_T\beta_3 & k_{d1}\beta_2 & 0 & 0 \\ -k_T\beta_2 & -k_{d1}\beta_1 & 0 & 0 \\ 0 & 0 & k_T\beta_3 & k_{d1}\beta_2 \\ 0 & 0 & -k_T\beta_2 & -k_{d1}\beta_1 \end{bmatrix}; B = \begin{bmatrix} -k_i\beta_2 & 0 \\ k_i\beta_1 & 0 \\ 0 & -k_i\beta_2 \\ 0 & k_i\beta_1 \end{bmatrix}; E = \begin{bmatrix} \gamma_2 & 0 \\ -\gamma_1 & 0 \\ 0 & \gamma_2 \\ 0 & -\gamma_1 \end{bmatrix};$$

$$D\begin{bmatrix} 0 \\ 0 \\ -1 \\ -1 \end{bmatrix}; \underline{x} = \begin{bmatrix} x_1 \\ x_2 \\ y_1 \\ y_2 \end{bmatrix}; \underline{u} = \begin{bmatrix} i_1 \\ i_2 \end{bmatrix}; \underline{w} = \begin{bmatrix} m_p r\Omega^2 \cos(\Omega t + \theta) \\ m_p r\Omega^2 \sin(\Omega t + \theta) \end{bmatrix};$$

$$\alpha_1 = \frac{I_p \Omega a}{IL}; \alpha_2 = \frac{I_p \Omega b}{IL};$$

$$\beta_1 = \left(\frac{b^2}{I} + \frac{1}{m}\right); \beta_2 = \left(\frac{ab}{I} - \frac{1}{m}\right); \beta_3 = \left(\frac{a^2}{I} + \frac{1}{m}\right);$$

$$\gamma_1 = \left(\frac{bd}{I} - \frac{1}{m}\right); \gamma_2 = \left(\frac{ad}{I} + \frac{1}{m}\right)$$

where m is the mass of the rotor; m_p is the eccentric mass of the rotor; θ is the angle between eccentricity and axis coordinate; I is the transverse moment inertia of the rotor; I_p is the polar moment inertia of the rotor; Ω is the rotating speed; r is the radius of the rotor; L is the length between the AMB and the flexible coupling.

The stability of the AMB system by using a PD controller and a force observer compensator was verified in the research. But the force observer design is based on the dynamic equations, and there are some model uncertainties of the flexible coupling and the nonlinearities of the magnetic bearing system, the observer would not work well for all the operation speed. And the phase of estimated force signal may be lag and the amplitude may be smaller than exact disturbance.

The control structure in this paper is showed as Fig.3. A fuzzy compensated system is used to estimate the imbalance force and disturbance and the control current is modified by the output of the fuzzy compensator. The fuzzy compensated system is built on the knowledge of rotor dynamics and doesn't need a precise mathematical model. The input signals of the proposed fuzzy mechanism are obtained from the position error and velocity of the rotor and the control current of the AMB system. And making use of the concept of the fuzzy set, the compensator signals are adjustable in varies with the response.

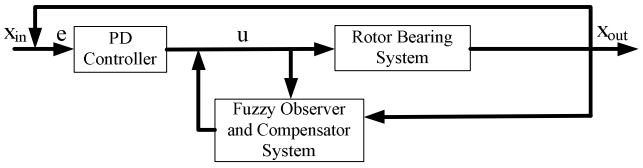

Fig.3 Control structure diagram of the single AMB system

III. DESIGN OF THE FUZZY MECHANISM

A fuzzy mechanism is constructed by the membership function and the fuzzy rules. Inputs of the fuzzy observer system proposed in this paper were established by the control current and the position of the rotor. In the fuzzy observer system, the control current and the displacement vibration signal are used to design fuzzy rules and membership functions to build up the fuzzy compensator.

The linguistic variable inputs for the fuzzy observer system are denoted as i_c and x. And the linguistic variable output is the observer force which is denoted as f. Membership functions of the input and output linguistic variables and the linguistic values for the input and output are showed as Fig.4, where the linguistic variables are labeled with "L," "M," and "S" to represent "large," "medium," and "small," respectively. The Mamdani method is used to design the membership functions of the fuzzy system. The membership bounds of the membership functions are modified from the results of the reference [5] and “try and error” results.

The fuzzy rules for the observer system are showed in table 1. There are six fuzzy linguistic values for the input linguistic variables, and three fuzzy linguistic values for the output linguistic variables. After the fuzzy observer system, the observer force is modified by a constant coefficient and feedback to the control current to make the system more stable.

IV. SIMULATION RESULTS

The simulation program of the single AMB system is established by MATLAB. The AMB system consists by a PD controller and the fuzzy compensator as the fig.5 shows. The gain value of the PD controller and the parameters of the AMB system are shown in table 2.

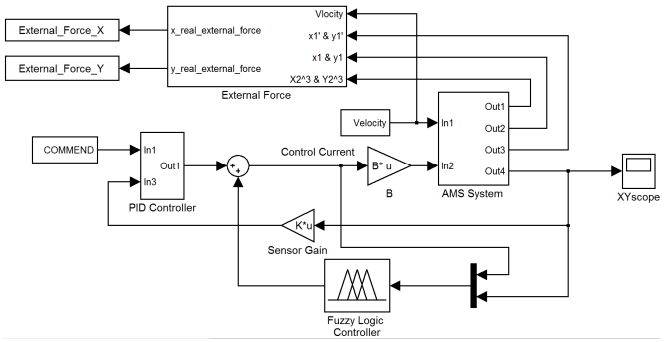

Fig.5 The AMB system established by the Simulink toolbox of the MATLAB

Table2. Parameters of the AMB system

M, the mass of the rotor	:	2.142 kg
L, length of the rotor	:	0.414 m
Mp, Eccentric mass	:	0.0013 kg
Ki, current parameter of the AMB	:	35.549
Kd, displacement parameter of the AMB:		1.423e5
Gs, Sensor gain	:	7000V/m

From the simulation of the AMB system, the disturbance force obtained by the fuzzy observer at various rotating speeds can be showed in fig. 6. With different rotating speeds of the rotor, we can see the disturbance is displayed like a harmonic signal with different magnitude and frequency. Thus, the simulation results shows the fuzzy observer system can observers the disturbance force, and the estimated results is close to the actual disturbance force of the system, even if we can’t demonstrate the system model very accurately.

Fig6. The observer force by the fuzzy observer system

Disturbance force from fuzzy observer will sent to the AMB system to be a compensated signal which is constructed by the disturbance force. Fig.6 shows the rotating orbits of the rotor with traditional PD controller, and fig.7 is the rotating orbits with the compensated signal. The limits of both horizontal and vertical axes in PD simulations are [100μm 100 μm]. The limits of both horizontal and vertical axes in simulations with fuzzy system are [10μm 1μm]. Simulation results show the fuzzy compensator can increase rotational accuracy in the operating range.

V. EXPERIMENT RESULTS

To validate the compensator, a single AMB system with a flexible bearing is constructed as shown in fig.9. The fuzzy

compensator is constructed in PC and is connecting with AMB system using the XPC system. The AMB system is connected to a rotor with a flexible coupling.

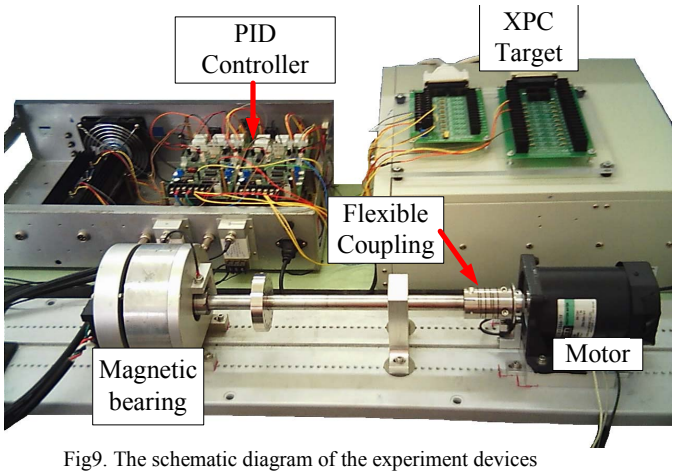

Fig9. The schematic diagram of the experiment devices

The vibrations of the shaft at the location of the AMB at several rotating speed are shown in fig.10. The rotor is controlled by a traditional PD controller with a fuzzy compensator being added to the system at 5 sec after. The blue lines in fig.10 are the average values of vibration of the shaft. The maximum peak to peak value of the vibration is approximately 5.7e-4 m ~ 7e-4 m when only using the PD controller. It demonstrates that the maximum vibration amplitude is reduced to 4.2e-4 m ~ 5.3e-4 m as the fuzzy compensator is added to the system. The average value is approximately 1.5e-4 m when only using the PD controller and is reduced to 0.9e-4 m as the fuzzy compensator added. It is obviously that the peak to peak values and the average values of the vibration are all suppressed after the fuzzy compensator is added. As the results, we can identify the valid of the fuzzy compensator system and it means that the fuzzy compensator system can make the system operating more smoothly, even if the system model is not accurate.

(c) 70Hz

Fig.10 The experiment results of the AMB system, fuzzy observer system is utilized after 5secs.

VI. CONCLUSION

This study demonstrates that the fuzzy force compensator applied to the single AMB system is useful for restraining the unbalancing vibration and to improve the rotational accuracy. From the results of the simulation and experiment, the fuzzy observer can works well at different operating speeds. And the fuzzy observer output can feed to the AMB system to make the system operating more smoothly. The whirling orbits of the rotor in the experiment showed it can be maintained in a small range than the traditional PD controller.

***Abstract*—A digital signal processor (DSP)-based cross-coupled functional link radial basis function network (FLRBFN) control is proposed in this study for the synchronous control of a dual linear motors servo system which is installed in a gantry position stage. The dual linear motors servo system comprises two parallel permanent magnet linear synchronous motors (PMLSMs). First, the dynamics of the field-oriented control PMLSM servo drive with a lumped uncertainty, which contains parameter variations, external disturbance and friction force, is introduced. Then, to achieve accurate trajectory tracking performance with robustness, an intelligent control approach using FLRBFN is proposed for the field-oriented control PMLSM servo drive system. The proposed FLRBFN is a radial basis function network (RBFN) embedded with a functional link neural network (FLNN). The network structure and its on-line learning algorithms for connective weights, means and standard derivations are described in detail. Moreover, since a cross-coupled technology is incorporated into the proposed intelligent control scheme for the gantry position stage, both of the position tracking errors and synchronous errors of dual linear motors will converge to zero, simultaneously. Finally, some experimental results are illustrated to depict the validity of the proposed control approach.**

Keywords- Dual linear motors servo system, gantry position stage, functional link neural network, radial basis function network, cross-coupled technology.

I. INTRODUCTION

The high precision motion control of gantry position stages has found numerous applications in the manufacturing industries including microelectronics, aerospace, solar cell, and flat panel manufacturing and inspection [1]. In the configuration of gantry position stage, two motors are mounted on two parallel linear guides to drive a moving stage. For the machining centers with heavy type high-speed gantry position stage, though the pillars of the two side of the gantry have the same drive mechanisms, the synchronous error between the two motors is unavoidable due to non-balanced forces adding to the cross gantry and other moving parts, mechanism assembly variations and various uncertainty disturbances during the working process. The synchronous error will influence the quality of the work-pieces and even lead to stop the working process due to the over current protection. Hence, the control of the synchronous error in the gantry configuration has become a challenge with increasing demands for high-speed and high accuracy manufacture and inspection.

Over the past decade, the cross-coupled technology was majorly used in machine tools and multiple axes motion applications for the reducing of contour tracking errors [2-3]. Recently, the cross-coupled technology was incorporated into some well-know adaptive control approaches to solve the synchronous control problem and improve the control performance [2-3]. In [3], an adaptive coupling control approach had been developed for the synchronous control of multiple motion axes systems. This approach was developed to stabilize the position tracking of each axis while synchronizing its motion with the motions of the other axes. However, a linear sliding mode control (SMC) has been adopted in this synchronous strategy.

In general, intelligent control approaches such as neural and fuzzy mechanisms are dynamic model-free control techniques [4]. Therefore, many studies on neuro-fuzzy approaches for controller developments and for describing the dynamic behaviors of complex systems have been published [5]. In these approaches, the RBFN method, which took local receptive field to perform function mappings, was investigated in [6]. Because the RBFN has a simple structure, the convergence speed of the RBFN is faster than a multilayer perceptron (MLP) network. Moreover, the RBFN has similar features in the following as the fuzzy system: (i) The output value is obtained by using a weighted sum method; (ii) The number of nodes in hidden layer in the RBFN is identical to the number of if-then rules in the fuzzy system; (iii) The receptive field functions in RBFN are similar to the membership functions of the premise part in the fuzzy system. As a result, the RBFN is one of the powerful tools for the systems control development [6].

The basic idea behind an FLNN is the use of the functional links. These functional links generate nonlinear transformations of the original input space before they are fed to the network which constructs the output layer. In other words, the input

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

variables can be enhanced and linear separability can be achieved in the extended space using the FLNN [7]. Moreover, the FLNN can capture nonlinear input-output relationship by the adequate set of polynomial inputs since the high order effects are incorporated in the input variables to increase the dimension of the input space. Thus, FLNN is suitable to be applied in system identifications or control applications [7].

II. Modeling of Dual Linear Motors Servo System

The dual linear motors servo system adopted in this study is composed of two 220V 5.0A 330N PMLSMs. The detailed machine model of the PMLSM, described in the synchronously rotating reference frame, can be found in [22, 23]. With the implementation of the field-oriented control, the electromagnetic force can be simplified as follows [23]:

$$F_{ei} = K_{fi} i_{qi}^{*} \tag{1}$$

$$K_{fi} = 3\pi n_{pi} \lambda_{PMi} / (2\tau_i) \tag{2}$$

where K_{fi} is the thrust coefficient; i_{qi}^{*} is the thrust current command; λ_{PMi} is the permanent magnet flux linkage; n_{pi}, which is 1, is the number of primary pole pairs; τ_i, which is 32mm, is the pole pitch; $i = y1, y2$ is to represent the y1-axis and y2-axis of the dual linear motors servo system.

The mover dynamic equation using the electromagnetic force shown in (1) is

$$F_{ei} = M_i \dot{v}_i + D_i v_i + F_{Li} + f_i(v) \tag{3}$$

where v_i is the linear velocity of the mover; M_i is the total mass of the mover; D_i is the viscous friction and iron-loss coefficient; F_{Li} is the external disturbances term; $f_i(v)$ is the friction force. Considering Coulomb friction, viscous friction and Stribeck effect, the friction force can be formulated as follows [24]:

$$f_i(v) = F_{Ci}\,\mathrm{sgn}(v_i) + (F_{Si} - F_{Ci}) e^{-(v_i / v_{si})^2}\,\mathrm{sgn}(v_i) + K_{vi} v_i \tag{4}$$

where F_{Ci} is the Coulomb friction; F_{Si} is the static friction; v_{Si} is the Stribeck velocity parameter; K_{vi} is the coefficient of viscous friction; $\mathrm{sgn}(\cdot)$ is a sign function. All the parameters in (4) are time-varying.

Curve-fitting technique based on step response of the mover position is applied here to find the model of the motor drive system. For the convenience of the controller design, the position and speed signals in the control loop are set at 1V=0.04963m and 1V=0.04963m/sec, respectively. The major system parameters are:

$$\begin{aligned} &\overline{K}_{fy1} = 195\ \text{N/A},\ \overline{M}_{y1} = 6.32\text{kg} = 0.4023\ \text{Nsec/V}, \\ &\overline{D}_{y1} = 819.4069\ \text{kg/sec} = 52.165\ \text{N/V} \end{aligned} \tag{5}$$

$$\begin{aligned} &\overline{K}_{fy2} = 195\ \text{N/A},\ \overline{M}_{y2} = 6.33\text{kg} = 0.4123\ \text{Nsec/V}, \\ &\overline{D}_{y2} = 821.4103\ \text{kg/sec} = 53.261\ \text{N/V} \end{aligned} \tag{6}$$

The overbar symbol represents the system parameter in the nominal condition. Though the electromagnetic force can be simplified as (1) via the field-oriented control mechanism, however, considering the variations of system parameters, external disturbances and friction force, the dual linear motors servo system is a nonlinear time-varying system in practical applications.

III. Proposed Cross-Coupled FLRBFN Control System

A. Strategy of Cross-Coupled Synchronous Control

Assuming that the system parameter variations, external disturbances and friction force are absent, each field-oriented control PMLSM servo drive can be formulated by rewriting (1) and (3) as follows:

$$\ddot{d}_i(t) = -\frac{\overline{D}_i}{\overline{M}_i}\dot{d}_i(t) + \frac{K_{fi}}{\overline{M}_i} i_{qi}^{*}(t) \triangleq A_{ni}\dot{d}_i(t) + B_{ni}\,u_i \tag{7}$$

where $d_i(t)$ is the position of the mover $A_{ni} = -\overline{D}_i / \overline{M}_i$; $B_{ni} = K_{fi} / \overline{M}_i > 0$; u_i is the control effort, i.e., the thrust current command. Now, considering the existence of parameter variations, external force disturbances and friction force for the single-axis field-oriented control PMLSM servo drive system, then (7) becomes

$$\begin{aligned} \ddot{d}_i(t) = {} & (A_{ni} + \Delta A_i)\dot{d}_i(t) + (B_{ni} + \Delta B_i)\,u_i + (C_{ni} + \Delta C_i)[F_{Li} \\ & + f_i(v)] = A_{ni}\dot{d}_i(t) + B_{ni}\,u_i + H_i \end{aligned} \tag{8}$$

where $C_{ni} = -1/\overline{M}_i$; ΔA_i, ΔB_i and ΔC_i denote the uncertainties introduced by system parameters M_i and D_i; H_i is named the lumped uncertainty and defined by

$$H_i \equiv \Delta A_i \dot{d}_i(t) + \Delta B_i\,u_i + (C_{ni} + \Delta C_i)[F_{Li} + f_i(v)] \tag{9}$$

Here, the lumped uncertainty is assumed to be bounded

$$|H_i| \le \rho_i \tag{10}$$

where ρ_i is a given positive constant.

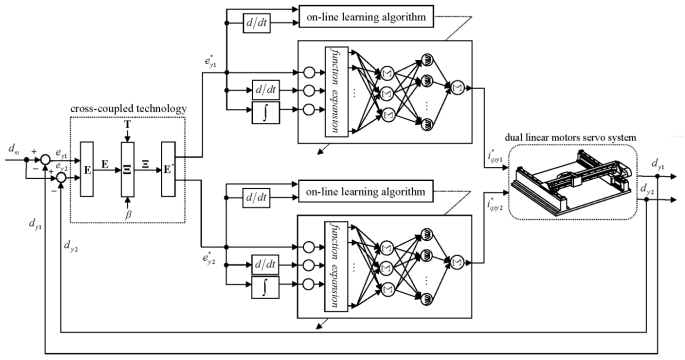

Figure 1. Configuration of cross-coupled FLRBFN control system.

In the proposed control approach, besides the position tracking of each axis, the position synchronization of two axes is considered simultaneously. First, define the position tracking error as

$$e_i = d_m - d_i \tag{11}$$

where d_m denotes the desired command. Then, the synchronous errors are defined as

$$\varepsilon_{y1} = e_{y1} - e_{y2},\ \varepsilon_{y2} = e_{y2} - e_{y1} \tag{12}$$

where ε_{y1} and ε_{y2} denote the synchronous errors of dual linear motors, respectively. If the synchronous errors show in (12) are zero, the goal of synchronous control, i.e., $e_{y1} = e_{y2}$, is achieved [3]. Rewrite (12) in the matrix form as

$$\boldsymbol{\Xi} = \mathbf{T}\mathbf{E} \tag{13}$$

where $\boldsymbol{\Xi} = \left[\varepsilon_{y1}\ \varepsilon_{y2}\right]^T$, $\mathbf{E} = \left[e_{y1}\ e_{y2}\right]^T$, and $\mathbf{T} = \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix}$ denotes the synchronous transformation matrix. Then, a cross-coupled position tacking error is defined as

$$\mathbf{E}^* = \mathbf{E} + \beta\boldsymbol{\Xi} \tag{14}$$

where $\mathbf{E}^* = \left[e_{y1}^*\ e_{y2}^*\right]^T$ and β is a positive coupled parameter. Substituting (13) into (14) yields

$$\mathbf{E}^* = \left(\mathbf{I} + \beta\mathbf{T}\right)\mathbf{E} \tag{15}$$

where $\mathbf{I}$ is a unit matrix and $\left(\mathbf{I} + \beta\mathbf{T}\right)$ is a positive defined matrix. In (15), $\mathbf{E} = \mathbf{0}$ if and only if $\mathbf{E}^* = \mathbf{0}$. It also implies that $\boldsymbol{\Xi} = \mathbf{0}$ [3]. Therefore, the control objective is to design a controller to guarantee the convergence of both the position tracking error e_i and the synchronous error ε_i to zero, simultaneously.

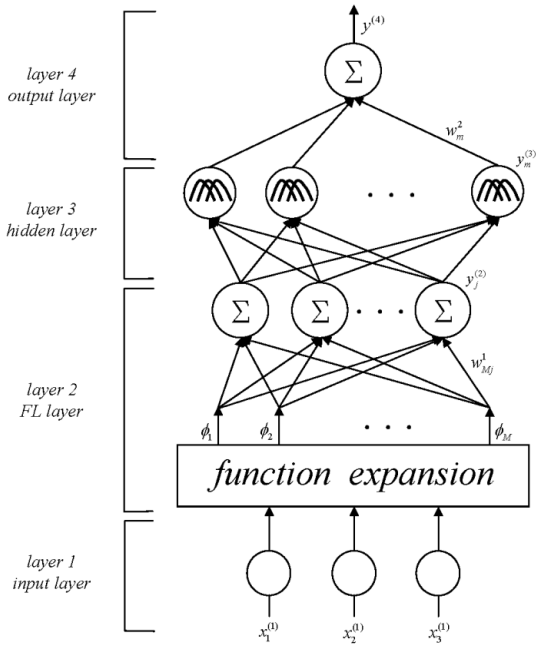

Figure 2. Structure of FLRBFN.

B. Proposed Cross-Coupled FLRBFN Control System

Not only to eliminate the synchronous error of the dual linear motors but also to guarantee the precision position tracking requirement in single axis motor, a cross-coupled FLRBFN control system shown in Fig. 1 is proposed. The four-layer neural network structure of the FLRBFN is shown in Fig. 2. Moreover, since the motions of the y1-axis and y2-axis are controlled separately, all the subscripts *i* are removed for simplicity in the following description.

1) Functional link neural network

To improve the accuracy of the function approximation, an FLNN is adopted to implement the function expansion for the proposed FLRBFN. In the function expansion of the FLNN, the basis functions such as trigonometric, Gaussian or other orthogonal polynomials are feasible. In this study, the trigonometric function is adopted since it forms a more compact representation than Gaussian function, and the sine and cosine functions can be computed more quickly. Therefore, for an input vector $\mathbf{X} = [x_1, x_2, x_3]^T$, the input variables can be separated in the enhanced space as $\boldsymbol{\Phi} = [\phi_1, \phi_2, ..., \phi_M]^T = \left[x_1, \cos(\pi x_1), \sin(\pi x_1), x_2 \cos(\pi x_2), \sin(\pi x_2), x_3, \cos(\pi x_3), \sin(\pi x_3)\right]^T$. Moreover, the output of the FLNN is given by a linear sum of the *j*th node as:

$$\hat{f}_j = \sum_M w_{Mj}^1 \phi_M(\mathbf{X}),\ M = 1, 2, \cdots, 9 \quad j = 1, 2, \cdots, k \tag{16}$$

where k is the number of the output nodes of the FLNN; $\hat{f}_j$ is the output of the FLNN; w_{Mj}^1 is the connective weight; ϕ_M is the output of function expansion.

2) Structure of FLRBFN

The structure of the FLRBFN is a three-layer RBFN embedded with an FLNN, including the input layer (layer 1), the functional link (FL) layer (layer 2), the hidden layer (layer 3) and the output layer (layer 4). To give a clear understanding, the signal propagation and the basic function of each layer are introduced in the following:

Layer 1 (input layer):

In this layer, the node output is represented as

$$y_l^{(1)} = x_l^{(1)}, \ l = 1, 2, 3 \tag{17}$$

where $x_l^{(1)}$ and $y_l^{(1)}$ are the input and output of the lth node in this layer. In this study, $x_1^{(1)}$, $x_2^{(1)}$ and $x_3^{(1)}$ are the cross-coupled position tacking error e^*, its integral $\int e^* d\tau$ and its derivative $\dot{e}^*$, respectively.

Layer 2 (FL layer):

In this layer, each node represents the outputs of the FLNN. The FLNN is designed to increase the dimensionality of the input variables and provide greater discrimination capability in the input variables space [7]. For the jth node

$$y_j^{(2)} = \hat{f}_j(y_l^{(1)}) \qquad j = 1, 2, \ldots, k \tag{18}$$

where $y_j^{(2)}$ is the output of the layer 2.

Layer 3 (hidden layer):

In this layer, the Gaussian function [8] is adopted as the receptive field function. The mathematical function of each node is

$$\Gamma_{jm}(y_j^{(2)}) = \exp\left[\frac{-\left(y_j^{(2)} - c_{jm}\right)^2}{\sigma_{jm}^2}\right], \ m = 1,2,\ldots,f \tag{19}$$

where f is the number of the hidden nodes; c_{jm} and σ_{jm} are the mean and standard derivation of the Gaussian function, respectively; $\Gamma_{jm}(y_j^{(2)})$ is the output of the receptive field function. Then, in this layer, the node output is represented as

$$y_m^{(3)} = \prod_{j=1}^{k} \Gamma_{jm}(y_j^{(2)}), \quad j = 1, 2, \ldots, k, \quad m = 1,2,\ldots,f \tag{20}$$

where $y_m^{(3)}$ is the output of the layer 3.

Layer 4 (output layer):

In the output layer, the weighted sum method is used to calculate the output of the FLRBFN. Then, the node output becomes

$$y^{(4)} = i_q = \sum_{m=1}^{f} y_m^{(3)} w_m^2 \quad m = 1,2,\ldots,f \tag{21}$$

where w_m^2 is the connective weight between the hidden layer and the output layer; $y^{(4)}$ is the output of the FLRBFN as the trust command current.

3) On-line learning algorithms

To describe the on-line learning algorithms of the FLRBFN using gradient decent method, first the energy function E is defined as

$$E = \frac{1}{2} e^{*2} \tag{22}$$

Then, the learning algorithms of connective weights, means and standard derivations are described as follows:

Layer 4:

The error term to be propagated is given by

$$\delta^{(4)} = -\frac{\partial E}{\partial y^{(4)}} = -\frac{\partial E}{\partial d}\frac{\partial d}{\partial y^{(4)}} \tag{23}$$

and the connective weight is updated by the amount

$$\Delta w_m^2 = -\eta_1 \frac{\partial E}{\partial w_m^2} = -\eta_1 \frac{\partial E}{\partial y^{(4)}}\frac{\partial y^{(4)}}{\partial w_m^2} = \eta_1 \delta^{(4)} y_m^{(3)} \tag{24}$$

The connective weight w_m^2 is updated according to the following equation:

$$w_m^2(n+1) = w_m^2(n) + \Delta w_m^2 \tag{25}$$

where the factor η_1 is the learning rate of the connective weight.

Layer 3:

The error term propagated in this layer is derived as

$$\delta_m^{(3)} = -\frac{\partial E}{\partial y_m^{(3)}} = -\frac{\partial E}{\partial y^{(4)}}\frac{\partial y^{(4)}}{\partial y_m^{(3)}} = \delta^{(4)} w_m^2 \tag{26}$$

and the update law of c_{jm} is

$$\begin{aligned} \Delta c_{jm} &= -\eta_m \frac{\partial E}{\partial c_{jm}} = -\eta_m \frac{\partial E}{\partial y^{(4)}}\frac{\partial y^{(4)}}{\partial y_m^{(3)}}\frac{\partial y_m^{(3)}}{\partial c_{jm}} \\ &= 2\eta_m \delta_m^{(3)} \frac{\left(y_j^{(2)} - c_{jm}\right)}{\sigma_{jm}^2} \prod_{j=1}^{k} \exp\left[\frac{-\left(y_j^{(2)} - c_{jm}\right)^2}{\sigma_{jm}^2}\right] \end{aligned} \tag{27}$$

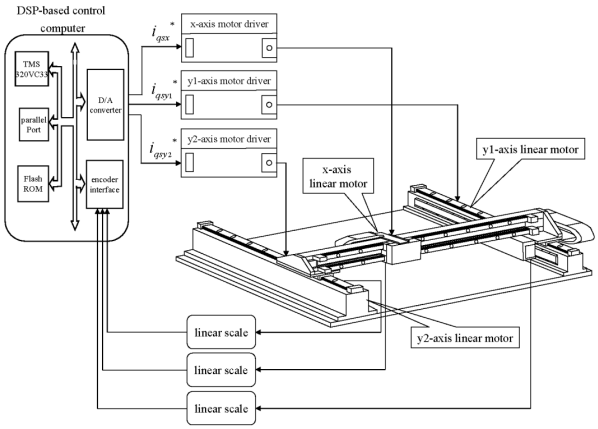

Figure 3. Block diagram of DSP-based control system.

where the factor η_m is the learning rate of the mean. The update law of σ_{jm} is

$$\begin{aligned}\Delta\sigma_{jm} &= -\eta_\sigma \frac{\partial E}{\partial c_{jm}} = -\eta_\sigma \frac{\partial E}{\partial y^{(4)}}\frac{\partial y^{(4)}}{\partial y_m^{(3)}}\frac{\partial y_m^{(3)}}{\partial \sigma_{jm}} \\ &= 2\eta_\sigma \delta_m^{(3)} \frac{\left(y_j^{(2)} - c_{jm}\right)^2}{\sigma_{jm}^3}\prod_{j=1}^{k}\exp\left[\frac{-\left(y_j^{(2)} - c_{jm}\right)^2}{\sigma_{jm}^2}\right]\end{aligned} \tag{28}$$

where the factor η_σ is the learning rate of the standard derivation. The mean c_{jm} and the standard derivation σ_{jm} of the Gaussian function are updated as follows:

$$c_{jm}(n+1) = c_{jm}(n) + \Delta c_{jm} \tag{29}$$

$$\sigma_{jm}(n+1) = \sigma_{jm}(n) + \Delta\sigma_{jm} \tag{30}$$

Layer 2:

The error term propagated in this layer is derived as

$$\begin{aligned}\delta_j^{(2)} &= -\frac{\partial E}{\partial y_j^{(2)}} = -\frac{\partial E}{\partial y^{(4)}}\frac{\partial y^{(4)}}{\partial y_m^{(3)}}\frac{\partial y_m^{(3)}}{\partial y_j^{(2)}} \\ &= \delta_m^{(3)} \frac{(-2)\left(y_j^{(2)} - c_{jm}\right)^2}{\sigma_{jm}^2}\prod_{j=1}^{k}\exp\left[\frac{-\left(y_j^{(2)} - c_{jm}\right)^2}{\sigma_{jm}^2}\right]\end{aligned} \tag{31}$$

According to (31), the connective weight is updated by the amount

$$\Delta w_{Mj}^1 = -\eta_2 \frac{\partial E}{\partial w_{Mj}^1} = -\eta_2 \frac{\partial E}{\partial y^{(4)}}\frac{\partial y^{(4)}}{\partial y_m^{(3)}}\frac{\partial y_m^{(3)}}{\partial y_j^{(2)}}\frac{\partial y_j^{(2)}}{\partial w_{Mj}^1} = \eta_2 \delta_j^{(2)} \phi_M \tag{32}$$

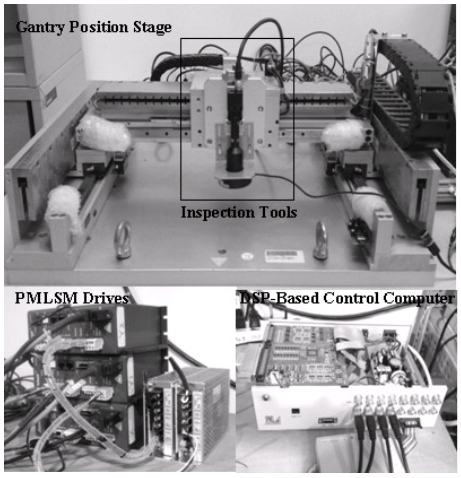

Figure 4. Photos of experimental setup.

TABLE I. EXPERIMENTAL CASES.

	reference trajectories				loads (add iron disk on the moving table)
	sinusoid		trapezoid		
	frequency	stroke	frequency	stroke	
Case 1	0.2Hz	±4*mm*	0.2Hz	4*mm*	0kg
Case 2	0.6Hz	±6*mm*	0.6Hz	6*mm*	7.32kg
Case 3	1Hz	±10*mm*	1Hz	10*mm*	10kg

where the factor η_2 is the learning rate of the connective weight in layer 2. The connective weight w_{Mj}^1 is updated according to the following equation:

$$w_{Mj}^1(n+1) = w_{Mj}^1(n) + \Delta w_{Mj}^1 \tag{33}$$

The exact calculation of the Jacobian of the system, $\partial d / \partial y^{(4)}$, is difficult to be determined due to the unknown dynamics of the PMLSM servo drive system. In this study, a linear combination of the cross-coupled position tracking error and its first derivative is adopted to approximate the Jacobian of the system in order to simplify the on-line adaption laws of the FLRBFN in practical applications as follows:

$$\delta^{(4)} \cong e^* + \dot{e}^* \tag{34}$$

IV. EXPERIMENTAL RESULTS

The block diagram of the DSP-based computer control dual linear motors servo system is shown in Fig. 3. A TMS320VC33 floating-point DSP is the core of the control computer. The photos of the experimental setup including the dual linear motors servo system installed in the gantry position stage, the motor drives and the control computer using DSP are shown in Fig. 4. To investigate the effectiveness of the proposed DSP-based control system with different test signals, strokes and load conditions, three cases as shown in Table I are

considered. The experimental results of the tracking response, control effort and tracking error of the three test conditions are shown in Fig. 5 and Fig. 6, respectively. From the results, the excellent control performance of the proposed cross-coupled FLRBFN control system under the occurrence of parameter variations and different trajectories are obvious owing to on-line learning.

V. CONCLUSIONS

The major contributions of this study are: (i) the successful development of an on-line trained FLRBFN which combines the merits of FLNN and RBFN; (ii) the successful implementation the intelligent control approach and the cross-coupled technology in a control computer which is based on a 32-bit floating-point DSP, TMS320VC33; (iii) the successful application of the cross-coupled FLRBFN control system to dual linear motors servo system to track different reference trajectories with robust control performance.

***Abstract*—This paper extends the defensive location problem (DLP), proposed by Uno and Katagiri, considering the situations that the defender locates defensive facilities for preventing invaders from reaching some important vertices in a network. Their DLPs assumed that invaders, with a given energy, exist on a given vertex in it. On the other hand, this paper considers a new DLP that invaders' sites and energies are given uncertainly. By representing their existing vertices and energies as random variables with scenarios, the new DLP can be formulated as a multiobjective bilevel stochastic programming problem. In order to find a satisficing solution of the decision maker for the multiobjective DLP, an interactive fuzzy satisficing method with tabu search algorithm based on strategic oscillation is proposed. The efficiency of the proposed method is shown by applying it to numerical examples of the DLPs.**

***Index Terms*—Facility location, Stackelberg equilibrium, stochastic programming, multiobjective programming, tabu search.**

I. Introduction

Defensive location problem (DLP), proposed by Uno and Katagiri [12], is one of the bilevel location problems in a competitive environment. Hakimi [4] considered a bilevel location problem of commercial facilities, e.g. shops and supermarkets, on a network. His problem deals with a type of competitiveness between two decision makers (DMs) locating their own facilities, with the aim of maximizing her/his profit obtaining from their customers. For the detail of Hakimi's problem and its applications, the readers can refer to the book of Miller et al. [8]. As an extension of Hakimi's location problem, Shiode and Drezner [11] considered a problem with random demands, Uno et al [13] considered a problem with fuzzy random demands, and Yang et al [14] considered a bilevel flow interception problem. Meanwhile, O'Hanley and Church [9] considered a bilevel maximum covering problem, which is a noncompetitive type of location problem.

On the other hand, the DLP deals with another type of competitiveness between two types of decision makers, called a defender and invader. Uno and Katagiri [12] considered the situation that the defender locates defensive facilities for preventing the invaders from reaching some important sites, called cores. Examples of their DLPs are "a government of a country locates self-defense bases to prevent her/his aggressors from reaching the capital of the country," "a coach of a succor/football team locates its players to defend goal from its opponent team," etc. By representing the location region as a network and the core is a vertex in the network and the defender and the invaders as an upper and a lower DM, their DLP can be formulated as a bilevel programming problem. An example of DLPs is illustrated in Fig. 1.

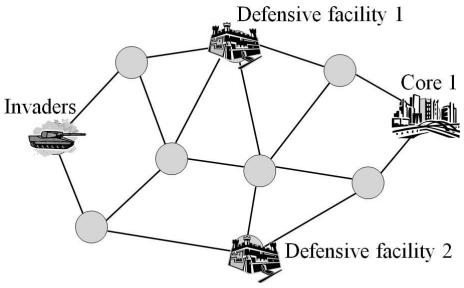

Fig. 1. An example of DLPs

Although the DLP can be expected for many situations that there are both a defender and invaders, their DLP assumed that the site of invaders is on a given vertex and their energy is a given value. This means that their DLP cannot deal with the situations that there are several vertices with several types of invaders given uncertainly, e.g., the defender locates fire stations for preventing that wildfire, which can be regarded as invaders, marching toward important sites. Then, in this paper, we consider a new DLP that invaders' sites and energies are given uncertainly. By representing their existing vertices and energies as random variables with scenarios, the new DLP can be formulated as a multiobjective bilevel stochastic programming problem. We define each objective function of the DLP as minimizing the degree of invasion for each core

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

under a probability given by the defender.

In order to find a satisficing solution for the defender, we apply an interactive fuzzy satisficing method in order to find a satisficing solution for multiobjective linear fractional programming problems. As other applications of the method, Katagiri et al [6] considered multiobjective fuzzy random linear programming problems whose objectives are possibility and probability, and Kato et al [7] considered fractile criterion optimization for multiobjective stochastic integer programming problems. For applying the method to the multiobjective DLP, we need to solve minimax problems for finding M-Pareto optimal solutions, which are candidates of satisficing solutions. We propose its solution method based upon tabu search algorithm proposed by Glover [3]; for the details of algorithm, the readers can refer to the book of Reeves [10]. Since there are many M-Pareto optimal solutions, in order to solve the problem efficiently, we introduce the algorithm to the idea of strategic oscillation, suggested by Hanafi and Freville [5], by utilizing characteristics of DLPs. We show an efficiency of the method by applying it to examples of the multiobjective DLPs.

The remaining structure of this article is organized as follows: In Section 2, we formulate an extended DLP as a multiobjective bilevel stochastic programming problem. We propose an interactive fuzzy satisficing method for finding a satisficing solution of the defender in Section 3. For solving minimax problems in the method, we propose a tabu search algorithm with strategic oscillation in Section 4. In Section 5, we show the efficiency of the interactive fuzzy satisficing method by applying it to examples of the DLPs. Finally, concluding comments and future extensions are summarized in Section 6.

II. Formulation of stochastic DLP

We represent a location region as network $N = (V, E)$, where $V = \{v_1, \ldots, v_n\}$ is a set of n vertices and E is a set of edges. For edge $e \in E$, let $d(e)$ be its weight, meaning the distance between vertices with e. In the network N, there are k core vertices, denoted by $c_1, \ldots, c_k \in V$. that the defender needs to defend from the invader.

In the new DLP, first the defender locates her/his defensive facilities before a scenario is determined., and then the invaders choose sets of paths with knowing a determined scenario. The defender can locate at most one defensive facility on each vertex in V. For i-th vertex, let $q_i \in \{0, 1\}$ denote the variable such that $q_i = 1$ if a defensive facility is located on v_i and $q_i = 0$ otherwise. Then the decision vector of the DLP for the defender can be represented as $\boldsymbol{q} := (q_1, \ldots, q_n)^T$.

On the other hand, sites of the invaders are given randomly with scenarios, whose set are denoted by S. For each scenario $s \in S$, the set of the invaders' sites and their energies are given as $\Xi(s) \subseteq V$ and $\gamma(\xi), \xi \in \Xi(s)$, respectively, Let p_h^ξ be the path ξ to h-th core c_h. Then, for scenario s and h-th core, the decision vector of the DLP for the invader can be represented as $\boldsymbol{p}_h(s) = \{p_h^\xi | \xi \in \Xi(s)\}$.

We define the degree of invasion for h-th core as the following function:

$$f_h(\boldsymbol{q}, \boldsymbol{p}_h(s)|s) := \\ 0 \vee \max_{\xi \in \Xi(s)} \{\gamma(\xi) - D(p_h^\xi) - \beta \cdot W(\boldsymbol{q}, p_h^\xi)\}, \tag{1}$$

where

$$D(\boldsymbol{p}_h(s)) := \sum_{e \in p_h^\xi} d(e), \tag{2}$$

β is a given positive number meaning the capacity that a defensive facility can reduce the energy of invaders on ξ, and $W(\boldsymbol{q}, p_h^\xi)$ is the number of facilities in p_h^ξ. Equation (1) is the objective function of the invader for scenario s and h-th core. Hence the invaders have k objective function for each scenario.

On the other hand, Since the defender needs to decide her/his location before a scenario is determined, an objective function value of the defender for h-th core can be represented as a random variable whose value for each scenario s is $f_h(\boldsymbol{q}, \boldsymbol{p}_h(s)|s)$. By integrating decision vectors of the invaders for all scenarios , we represent paths to h-th core as a random path as $\bar{\boldsymbol{p}}_h$. Then, the objective function of the defender for h-th core is denoted by $\bar{f}_h(\boldsymbol{q}, \bar{\boldsymbol{p}}_h)$, Hence the defender has k objective functions.

Next we represent feasible sets of the defender and the invaders. For the defender, we set m linear constraints represented as follows:

$$A\boldsymbol{q} \leq \boldsymbol{b}, \tag{3}$$

where

$$A := (\boldsymbol{a}_1, \ldots, \boldsymbol{a}_m)^T = \begin{pmatrix} a_{11} & \ldots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{m1} & \ldots & a_{mn} \end{pmatrix}, \tag{4}$$

$$\boldsymbol{b} := (b_1, \ldots, b_m)^T, \tag{5}$$

and $a_{ij}, b_i \geq 0$ for any $i = 1, \ldots, m, j = 1, \ldots, n$. Hence the feasible set of the defender can be represented as follows:

$$SD := \{\boldsymbol{q} \in \{0, 1\}^n | \boldsymbol{A}\boldsymbol{q} \leq \boldsymbol{b}\}. \tag{6}$$

On the other hand, the feasible set of the invader for scenario $s \in S$ and h-th core can be regarded as the family of sets of paths from all vertices in $\Xi(s)$ to c_h, denoted by $SI_h(s)$. Therefore, the extending DLP can be formulated as the following stochastic bilevel programming problem:

$$\left.\begin{array}{ll} \underset{\boldsymbol{q}}{\text{minimize}} & \left(\bar{f}_1(\boldsymbol{q}, \bar{\boldsymbol{p}}_1), \ldots, \bar{f}_k(\boldsymbol{q}, \bar{\boldsymbol{p}}_k)\right)^T \\ \text{where} & \bar{\boldsymbol{p}}_1, \ldots, \bar{\boldsymbol{p}}_k \text{ solve} \\ \underset{\boldsymbol{p}_h(s)}{\text{maximize}} & f_h(\boldsymbol{q}, \boldsymbol{p}_h(s)|s), \\ & \qquad \forall s \in S, \forall h = 1, \ldots, k \\ \text{subject to} & \boldsymbol{q} \in SD, \\ & \boldsymbol{p}_h(s) \in SI_h(s), \\ & \qquad \forall s \in S, \forall h = 1, \ldots, k. \end{array}\right\} \tag{7}$$

For solving (7), we give $\sigma_h \in (0, 1]$, $h = 1, \ldots, k$ for each core, meaning the probability that the defender wants to guarantee for invasion to each core. Then, we transform

(7) to the following bilevel programming problem by using k auxiliary variables $\alpha_1(\boldsymbol{q}), \ldots, \alpha_k(\boldsymbol{q})$:

$$\left.\begin{array}{ll} \underset{\boldsymbol{q}}{\text{minimize}} & (\alpha_1(\boldsymbol{q}), \ldots, \alpha_k(\boldsymbol{q}))^T \\ \text{subject to} & Pr\left(\bar{f}_1(\boldsymbol{q}, \bar{\boldsymbol{p}}_1) \leq \alpha_1(\boldsymbol{q})\right) \geq \sigma_1, \\ & \qquad \vdots \\ & Pr\left(\bar{f}_k(\boldsymbol{q}, \bar{\boldsymbol{p}}_k) \leq \alpha_k(\boldsymbol{q})\right) \geq \sigma_k, \\ \text{where} & \bar{\boldsymbol{p}}_1, \ldots, \bar{\boldsymbol{p}}_k \text{ solve} \\ \underset{\boldsymbol{p}_h(s)}{\text{maximize}} & f_h(\boldsymbol{q}, \boldsymbol{p}_h(s)|s), \\ & \qquad \forall s \in S, \forall h = 1, \ldots, k \\ \text{subject to} & \boldsymbol{q} \in SD, \\ & \boldsymbol{p}_h(s) \in SI_h(s), \\ & \qquad \forall s \in S, \forall h = 1, \ldots, k. \end{array}\right\} \quad (8)$$

III. Interactive fuzzy satisficing method

For h-th core, $h = 1, \ldots, k$, we provide a satisfaction level of the defender for each objective function as the following linear membership function:

$$\mu_h(\alpha_h(\boldsymbol{q})) = \begin{cases} 1, & \alpha_h(\boldsymbol{q}) \leq \alpha_h^1, \\ \dfrac{\alpha_h(\boldsymbol{q}) - \alpha_h^1}{\alpha_h^0 - \alpha_h^1}, & \alpha_h^1 \leq \alpha_h(\boldsymbol{q}) \leq \alpha_h^0, \\ 0, & \alpha_h^0 \leq \alpha_h(\boldsymbol{q}), \end{cases} \quad (9)$$

where α_h^1 means the infimum of k-th objective function value satisfying the defender sufficiently, and α_h^0 the supremum of that no satisfying her/him.

For estimating all satisfaction levels for objective functions simultaneously, we use the concept of M-Pareto optimal solutions.

Definition 1: $\boldsymbol{q}^*$ is called an M-Pareto optimal solution to (8) if and only if there does not exist another $\boldsymbol{q}$ such that $\mu_h(\alpha_h(\boldsymbol{q})) \geq \mu_h(\alpha_h(\boldsymbol{q}^*))$ for all $h = 1, \ldots, k$ and $\mu_{h'}(\alpha_{h'}(\boldsymbol{q})) \neq \mu_{h'}(\alpha_{h'}(\boldsymbol{q}^*))$ for at least one $h' \in \{1, \ldots, k\}$.

Interactive fuzzy satisficing method is a method to find a satisficing solution among a set of M-Pareto optimal solutions by utilizing information of M-Pareto optimal solutions computed on the way of this method. We propose the interactive fuzzy satisficing method to the multi-objective DLPs in order to find a satisficing solution for the defender among a set of M-Pareto optimal solutions. Let $(\bar{\mu}_1, \ldots, \bar{\mu}_k)$ be a k-tuple of reference membership levels of membership functions $\mu_1, \ldots, \mu_k$, respectively.

Interactive fuzzy satisficing method for the stochastic DLPs

Step 1: Set membership function (9) for each $h = 1, \ldots, k$ by giving α_h^1 and α_h^0.

Step 2: Set initial reference membership levels $(\bar{\mu}_1, \ldots, \bar{\mu}_k) = (1, \ldots, 1)$.

Step 3: For the given $(\bar{\mu}_1, \ldots, \bar{\mu}_k)$, solve the following corresponding minimax problem:

$$\left.\begin{array}{ll} \underset{\boldsymbol{q}}{\text{minimize}} & \max\limits_{h=1,\ldots,k}\{\bar{\mu}_h - \mu_h(\alpha_h(\boldsymbol{q})) \\ & \qquad + \rho \sum\limits_{l=1}^{k} (\bar{\mu}_l - \mu_l(\alpha_l(\boldsymbol{q})))\} \\ \text{subject to} & Pr\left(\bar{f}_1(\boldsymbol{q}, \bar{\boldsymbol{p}}_1) \leq \alpha_1(\boldsymbol{q})\right) \geq \sigma_1, \\ & \qquad \vdots \\ & Pr\left(\bar{f}_k(\boldsymbol{q}, \bar{\boldsymbol{p}}_k) \leq \alpha_k(\boldsymbol{q})\right) \geq \sigma_k, \\ \text{where} & \bar{\boldsymbol{p}}_1, \ldots, \bar{\boldsymbol{p}}_k \text{ solve} \\ \underset{\boldsymbol{p}_h(s)}{\text{maximize}} & f_h(\boldsymbol{q}, \boldsymbol{p}_h(s)|s), \\ & \qquad \forall s \in S, \forall h = 1, \ldots, k \\ \text{subject to} & \boldsymbol{q} \in SD, \\ & \boldsymbol{p}_h(s) \in SI_h(s), \\ & \qquad \forall s \in S, \forall h = 1, \ldots, k, \end{array}\right\} \quad (10)$$

where ρ is a sufficiently small positive number.

Step 4: If the defender is satisfied by the given solution of (10), then it is a satisficing solution of the defender. Otherwise, ask the defender to update $(\bar{\mu}_1, \ldots, \bar{\mu}_k)$ by considering the current membership function values, and return to Step 3.

The following theorem introduces an important relationship between (8) and (10).

Theorem 1: (i) If $\boldsymbol{q}^* \in SD$ is an optimal solution of (10) with some $(\bar{\mu}_1, \ldots, \bar{\mu}_k)$, then $\boldsymbol{q}^*$ is also an M-Pareto optimal solution of (8).
(ii) If $\boldsymbol{q}^* \in SD$ is an M-Pareto optimal solution of (8), then there exists $(\bar{\mu}_1, \ldots, \bar{\mu}_k)$ such that $\boldsymbol{q}^*$ is an optimal solution of (10).

Proof: (i) if $\boldsymbol{q}^*$ is not an M-Pareto optimal solution of (8), then there exist a solution $\boldsymbol{q}$ such that $\mu_h(\alpha_h(\boldsymbol{q})) \geq \mu_h(\alpha_h(\boldsymbol{q}^*))$ for all $h = 1, \ldots, k$ and $\mu_{h'}(\alpha_{h'}(\boldsymbol{q})) \neq \mu_{h'}(\alpha_{h'}(\boldsymbol{q}^*))$ for at least one $h' \in \{1, \ldots, k\}$. This means that $\boldsymbol{q}$ is better than $\boldsymbol{q}^*$ for (10) with any $(\bar{\mu}_1, \ldots, \bar{\mu}_k)$, and then this contradicts the optimality of $\boldsymbol{q}^*$.

(ii) if there does not exist $(\bar{\mu}_1, \ldots, \bar{\mu}_k)$ such that $\boldsymbol{q}^*$ is an optimal solution of (10), then for any $(\bar{\mu}_1, \ldots, \bar{\mu}_k)$, there exist a solution $\boldsymbol{q}$ such that $\bar{\mu}_h - \mu_h(\alpha_h(\boldsymbol{q})) \leq \bar{\mu}_h - \mu_h(\alpha_h(\boldsymbol{q}^*))$ for all $h = 1, \ldots, k$ and $\bar{\mu}_{h'} - \mu_{h'}(\alpha_{h'}(\boldsymbol{q})) \neq \bar{\mu}_{h'} - \mu_{h'}(\alpha_{h'}(\boldsymbol{q}^*))$ for at least one $h' \in \{1, \ldots, k\}$. This contradicts that $\boldsymbol{q}^* \in SD$ is an M-Pareto optimal solution of (8). ■

At Step 3 in the above method, we need to find an optimal solution of (10) for updated reference membership levels. In the next section, we propose an efficient solution method for (10).

IV. Tabu search based on strategic oscillation

First, we consider the complexity to solve (10) strictly. For each location $\boldsymbol{q} \in SD$, we need to compute its objective

function values. This means that for each scenario $s \in S$, we need to find the k sets of paths $\boldsymbol{p}_1(s), \ldots, \boldsymbol{p}_k(s)$ so as to minimize $f_1(\boldsymbol{q}, \boldsymbol{p}_1(s)|s), \ldots, f_k(\boldsymbol{q}, \boldsymbol{p}_k(s)|s)$ among all sets of paths from vertices in $\Xi(s)$ to cores $c_1, \ldots, c_k$. We can utilize a version of Warshall-Floyd Algorithm [1] to find such k sets of paths at a polynomial time. However, since the number of defensive locations is 2^n, solving (10) strictly needs enormous computational times for large-scale DLPs. Therefore, we propose an efficient solution method for (10) based upon tabu search algorithm with strategic oscillation.

The tabu search is one of local search methods, which replicates movement from a current solution $\boldsymbol{q}^{\mathrm{now}}$ to a next solution $\boldsymbol{q}^{\mathrm{next}}$. In the proposed method, we define a move as adding/subtracting one to/from an element of $\boldsymbol{q}^{\mathrm{now}}$, and a neighborhood of $\boldsymbol{q}^{\mathrm{now}}$, denoted by $\mathcal{N}(\boldsymbol{q}^{\mathrm{now}})$, as the set of all solutions that can be transferred by only one move from it. From $\mathcal{N}(\boldsymbol{q}^{\mathrm{now}})$, $\boldsymbol{q}^{\mathrm{next}}$ is chosen as the best solution in the sense of a given criterion, e.g. objective function value. However, without modification, a circulation of certain chosen moves may occur on the way of search, and then it only can examine a limited local area. Then, for cases that a move is chosen in the search, the tabu constraint for its opposite move is activated for given tenure, called the tabu tenure and denoted by T_1. Then the activated moves are forbidden to choose, called tabu, even if the moves make the objective function value of (10) best in $\mathcal{N}(\boldsymbol{q}^{\mathrm{now}})$. Tabu are memorized in a tabu list through the search.

Although the tabu search method has the advantage of finding several local optimal solutions efficiently, the feasible set of (10) is generally wide and there are many local optimal solutions in the feasible set. Then, we introduce the concept of strategic oscillation for finding various types of local optimal solutions. The following function, meaning the degree of feasibility for $\boldsymbol{q}$, plays an important role in the strategic oscillation:

$$r(\boldsymbol{q}) := \max_{i=1,\ldots,m} \{\boldsymbol{a}_i \cdot \boldsymbol{q} - b_i\} \tag{11}$$

Tabu search algorithm with strategic oscillation for the stochastic DLPs

- Step 0: Generate the initial searching matrix $\boldsymbol{q}^{\mathrm{now}}$, and initialize the tabu list and other parameters. If $\boldsymbol{q}^{\mathrm{now}} \in SD$, then go to Step 4.
- Step 1: Move $\boldsymbol{q}^{\mathrm{now}}$ to $\boldsymbol{q}^{\mathrm{next}}$ by decreasing an element of $\boldsymbol{q}^{\mathrm{now}}$ for the aim of increasing $r(\boldsymbol{q}^{\mathrm{next}})$ as much as possible. This step is repeated until it is satisfied $r(\boldsymbol{q}^{\mathrm{next}}) \geq 0$, that is $\boldsymbol{q}^{\mathrm{next}} \in SD$.
- Step 2: Move $\boldsymbol{q}^{\mathrm{now}}$ to $\boldsymbol{q}^{\mathrm{next}}$ for the aim of improving the objective function value of (10). This step is repeated at a given tenure, denoted by $T_2 > 0$.
- Step 3: Move $\boldsymbol{q}^{\mathrm{now}}$ to $\boldsymbol{q}^{\mathrm{next}}$ by decreasing an element of $\boldsymbol{q}^{\mathrm{now}}$ for the aim of increasing $r(\boldsymbol{q}^{\mathrm{next}})$ as much as possible. This step is repeated until $r(\boldsymbol{q}^{\mathrm{next}})$ is less than a given value, denoted by r_{low}.
- Step 4: Move $\boldsymbol{q}^{\mathrm{now}}$ to $\boldsymbol{q}^{\mathrm{next}}$ by increasing an element of $\boldsymbol{q}^{\mathrm{now}}$ for the aim of improving the objective function value of (10). This step is repeated until one step short of $r(\boldsymbol{q}^{\mathrm{next}}) < 0$.
- Step 5: Do the same operations as Step 2.
- Step 6: Move $\boldsymbol{q}^{\mathrm{now}}$ to $\boldsymbol{q}^{\mathrm{next}}$ by increasing an element of $\boldsymbol{q}^{\mathrm{now}}$ for the aim of improving the objective function value of (10) without the feasibility of (10). This step is repeated until $r(\boldsymbol{q}^{\mathrm{next}})$ is more than a given value, denoted by r_{upp}.
- Step 7: If the iteration count of the algorithm reaches a given number, denoted by T_3, then terminate. Otherwise, return to Step 1.

V. Numerical experiments

This section shows the efficiency of the method introduced in the previous sections by applying to a given numerical example of the stochastic multiobjective DLP. We consider the DLP on network $N = (V, E)$, where V and E have $n = 100$ vertices and 1000 edges, respectively, and there are $k = 3$ cores in V. For each edge $e \in E$, w_e is given a value in $\{1, \ldots, 100\}$ randomly.

For the defender, the capacity of the defensive facility is $\beta = 30$, and there are the following $m = 30$ constraints: for (4), each a_{ij}, $i = 1, \ldots, m$ and $j = 1, \ldots, n$, is given as a value in $\{1, \ldots, 100\}$ randomly, and

$$b_i = \theta_i \cdot \sum_{j=1}^{n} a_{ij}, \tag{12}$$

where θ_i, $i = 1, \ldots, m$ is a given value in $[0.1, 0.3]$ randomly. For (8), we set $\sigma_h = 0.7$, $h = 1, 2, 3$.

For the invaders, we give $s = 3$ scenarios each of whose possibilities is given randomly. For each scenario, their sites, number of vertices, and their initial energies are given in N, $\{1, \ldots, 3\}$, and $[100, 300]$, randomly and respectively.

For the tabu search algorithm in Section IV, we set $T_1 = 20$. In Steps 2 and 4 of the algorithm with strategic oscillation, we set $T_2 = 7$ and $T_3 = 100$, respectively.

For the interactive fuzzy satisficing method in Section III, at Step 0, we define three membership functions μ_1, μ_2, μ_3 whose parameters are $(\alpha_1^L, f_1^U) = (30, 90)$, $(\alpha_2^L, f_2^U) = (40, 120)$, and $(\alpha_3^L, f_3^U) = (60, 200)$, respectively. In this example of the DLP, we assume that the defender regards that c_3 is the most important, c_2 is the second, and c_1 is the last. Then, the defender thinks that she/he hopes to improve μ_3 even if μ_1 and μ_2 are worse, and similarly to improve μ_2 even if μ_1 is worse. TABLE I shows computational results for applying the method to the example of DLP, where we obtain them computed by Dell Studio XPS 8100 (CPU: Inter^R CORE^{TM} i7-860 2.80GHz $\times$ 2, RAM: 6.00GB).

In TABLE I, for the satisfaction levels of the M-Pareto optimal solution obtained at Iteration 1, the defender decreased $\bar{\mu}_1$ and $\bar{\mu}_2$ in order to improve the value of μ_3 at Iteration 2. Then, the defender can obtain the solution improving the value of $\bar{\mu}_3$. However, the solution did not satisfy the defender,

TABLE I
COMPUTATIONAL RESULTS

Iteration	1	2	3	4
$\bar{\mu}_1$	1.0	0.7	0.7	0.7
$\bar{\mu}_2$	1.0	0.9	0.8	0.8
$\bar{\mu}_3$	1.0	1.0	1.0	0.95
$\mu_1(f_1(\boldsymbol{q}^*, \boldsymbol{p}^*))$	0.564	0.356	0.475	0.501
$\mu_2(f_2(\boldsymbol{q}^*, \boldsymbol{p}^*))$	0.570	0.595	0.532	0.570
$\mu_3(f_3(\boldsymbol{q}^*, \boldsymbol{p}^*))$	0.558	0.680	0.747	0.727
CPU Time (seconds)	57.24	54.68	60.77	60.70

because the values of μ_1 for its solution is too bad. Then, at Iteration 3, the defender reduced $\bar{\mu}_2$ a little. Although the values of μ_1 for its solution is recovered, that of μ_2 is too bad. Then, the defender reduced $\bar{\mu}_3$ a little at Iteration 4. As a result, the defender obtained a satisficing solution and the method is terminated.

VI. CONCLUSION

In this paper, we have proposed a new location problem by considering a multiobjective DLP with invaders whose sites are given randomly. By representing a location region as a network, we have formulated the DLP as a stochastic multiobjective bilevel programming problem. For finding its satisficing solution of the defender, we have proposed an interactive fuzzy satisficing method with tabu search algorithm with strategic oscillation. Its efficiency has been shown by applying the proposed method for examples of the DLP.

For the proposed DLP, both the capacity of defensive facilities and the energy of invaders are given determinate values. However, it is often cases that these data include vagueness and ambiguity. Considering the DLP representing these data as fuzzy random variables [6], [13], which can be formulated as a fuzzy random programming problem, is an important future research.

***Abstract*—The Permanent Magnet (PM) Synchronous Motor is ideal in the field of the low power high performance servo, since it is controllable and its vigorous performance is excellent. However, the variations of moment inertia, load torque, and motor internal parameters have been a major difficulty to deal with speed control. This paper investigates the fuzzy logic controller based speed control for a vector-controlled PM synchronous motor drive. The fuzzy logic is based on the speed error and change of speed error measured between the actual motor speed and the reference speed. The robust control performance of the fuzzy logic controller is evaluated for various operating conditions using the parameters of a prototype PM synchronous motor and compared to that of conventional PI controller. The design and application of the fuzzy logic controller are considered and discussed.**

Keywords - fuzzy logic controller; permanent magnet synchronous motor; vector control ; robustness

I. INTRODUCTION

Fuzzy logic can be regarded as a mathematical approach based on intelligent reasoning, probability theory, and multi-valued logic to mimic the human nature in inferring problems. The theoretical development of fuzzy logic has gone through significantly and there have been numerous applications of this mathematical framework to a variety of fields [1]-[3]. In control system, fuzzy logic is considered as an alternative for classical control theory in the control of complex nonlinear plants where accurate mathematical modeling is difficult, if not impossible [2]. At present, fuzzy logic speed controller is renowned with its superior performance in the research community worldwide. It has been demonstrated by various publications with diversity of industrial drive applications such as high performance dc drives [4], vector controlled induction motor [5]-[7], permanent magnet (PM) Synchronous Motor [8]-[12], brushless dc motor [13] and switched reluctance motor [14]. It has been suggested that fuzzy controllers are more robust to plant parameter changes than classical PI controllers. The merit of fuzzy logic control as compared to conventional control approach resides in the fact that there is no need of mathematical models to deal with a problem, but skill is required to create the rules in a particular fuzzy logic controller [1].

Brushless ac servo drives using PM synchronous motor are increasingly utilized in high-performance positioning systems such as in robotics due to their excellent characteristics compared to dc motor or ac induction motor drives. Many researches have been studied the comparison between the operation of drive with speed control by fuzzy logic and PI techniques. Then the main conclusion verified that fuzzy logic control determines superior performance [6], [7], [12]. Vector control is typically used in these drives to improve the dynamic response. However, the papers are focused on the speed performance while only load torque varies. In this paper, a fuzzy logic controller for a vector-controlled PM synchronous motor drive is investigated. It is applied to the speed control with variation of moment inertia, stator resistance, and load torque. As in all variable-controlling schemes, the very ultimate goal is to minimize error between the desired and actual value. Therefore, the error and change of error measured between the actual motor speed and the reference speed are applied to a fuzzy logic adaptation mechanism. This intelligent behavior will force the system to behave a more satisfactory performance than that of conventional PI controller. The robustness to parameters variation of the fuzzy logic controller is evaluated by simulation for various operating conditions using the parameters of a prototype PM synchronous servo drive. The design and implementation of the fuzzy logic controller are considered and discussed.

II. MODELING OF PERMANENT MAGNET SYNCHRONOUS MOTOR DRIVE

A. Drive Configuration

Fig. 1 shows a block diagram of a typical vector-controlled PM synchronous motor drive. The PM synchronous motor is fed by a current-controlled voltage-source pulse width modulated (PWM) inverter. The motor phase currents waveforms are imposed by current controllers having reference input signals generated from rotor position sensor signals. The synchronous motor is thus fed with sinusoidal currents having phase and frequency locked to the rotor position. As a result, synchronism is obtained for all speeds. The motor currents are decomposed into i_d and i_q components which are respectively flux and torque components in the rotor-based d-q coordinates

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

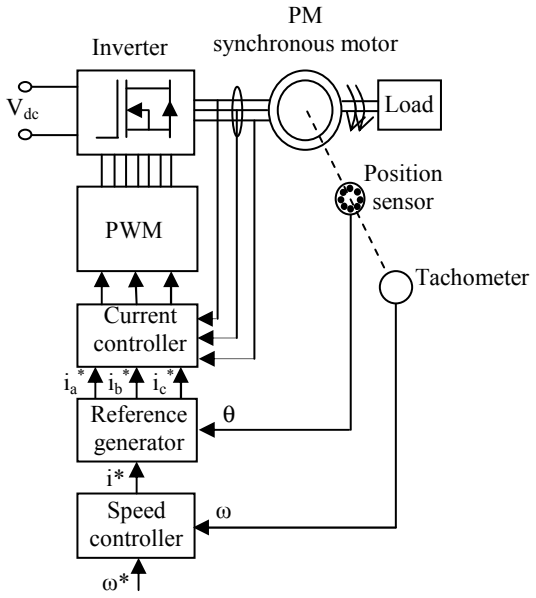

Fig.1 Vector-controlled PM synchronous motor drive

system. Maximum torque is obtained with i_d = 0 which corresponds to the case when the rotor and stator fluxes are perpendicular. The operation of the drive is then similar to that of a current-controlled dc motor.

B. Mathematical Model in d-q frame

In synchronous rotating d-q frame, one might decouple the flux-producing current (I_d) and torque-producing current (I_q). When I_{ds} constant, PM Synchronous Motor might be treated the same as dc motor. Hereafter, the modeling will be conducted in d-q frame. The electrical equation for the PM synchronous motor can be written as

$$V_d = R_s i_d + L_d \frac{\mathrm{d}i_d}{\mathrm{d}t} - \omega_s L_q i_q \quad (1)$$

$$V_q = R_s i_q + L_q \frac{\mathrm{d}i_q}{\mathrm{d}t} + \omega_s \left(L_d i_d + \psi_f\right) \quad (2)$$

By taking Laplace transformation, one might yield

$$\frac{i_d(s)}{V_d(s) + \omega_s L_q i_q(s)} = \frac{1}{(R_s + L_d s)} = \frac{1/R_s}{(\tau_s s + 1)} \quad (3)$$

$$\frac{i_q(s)}{V_q(s) - \omega_s \left(L_d i_d(s) + \psi_f\right)} = \frac{1}{\left(R_s + L_q s\right)} = \frac{1/R_s}{(\tau_s s + 1)} \quad (4)$$

where R_s is the stator resistance, L_d is the direct-axis inductance, L_q is the quadrature-axis inductance, ω_s is the electrical angular speed, ψ_f is the rotor-stator flux linkage, and $\tau_s = \frac{L_d}{R_s} = \frac{L_q}{R_s}$.

The electromechanical torque equation can be expressed as

$$T = \frac{3}{2} p\left[\psi_f i_q + \left(L_d - L_q\right) i_d i_q\right] \quad (5)$$

Since in the case of PM Synchronous Motor, L_d=L_q, (5) can be simplified as

$$T = \frac{3}{2} p \psi_f i_q = k_T i_q \quad (6)$$

The Laplace transformation of (6) is

$$\frac{T(s)}{i_q(s)} = \frac{3}{2} p \psi_f = k_T \quad (7)$$

where p = number of pole pairs.
The dynamic equation is

$$T - T_L = J \frac{d\omega}{dt} + B\omega \quad (8)$$

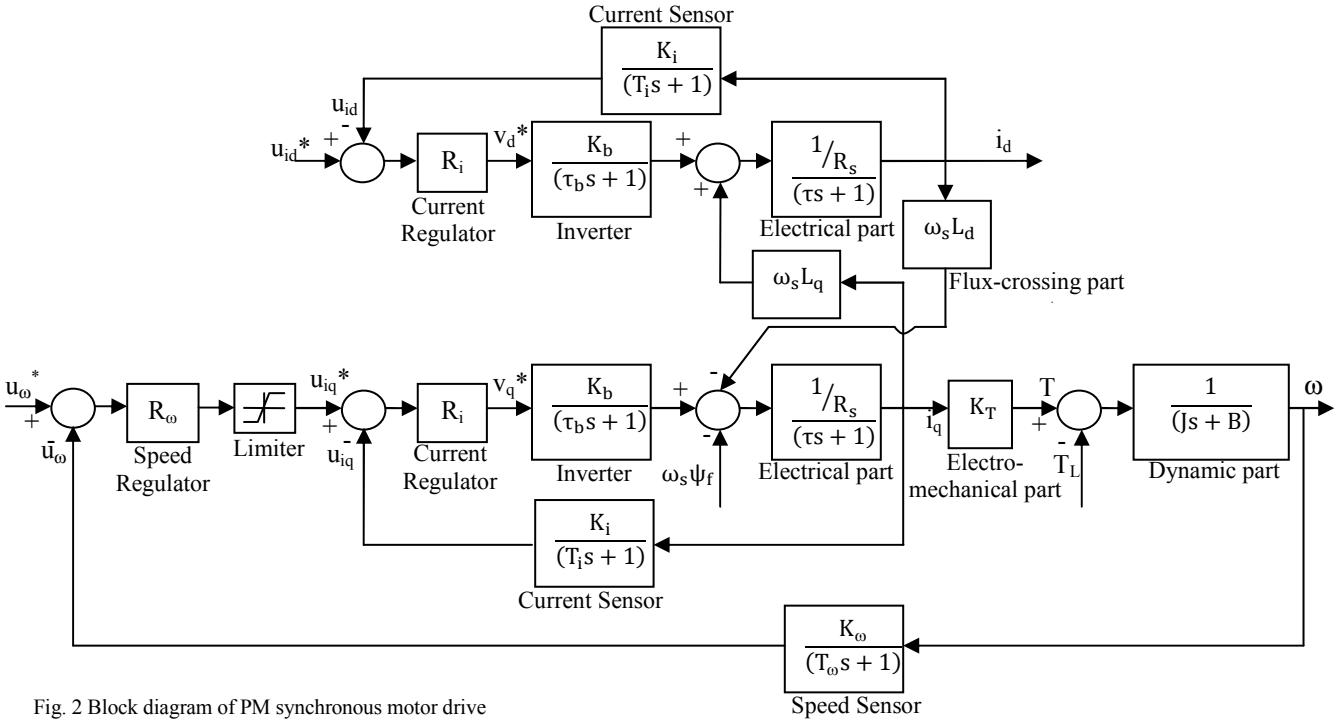

Fig. 2 Block diagram of PM synchronous motor drive

Laplace transformation is taken on (8), yield

$$\frac{\omega(s)}{T(s)-T_L} = \frac{1}{(Js+B)} \tag{9}$$

where, T_L is load torque, J = moment inertia, and B = friction coefficient

C. Block Diagram

An equivalent block diagram can be established according to (1)-(9) as shown in Fig. 2. This drive configuration also contains the transfer functions of speed sensor, current sensor, and inverter. A limiter is aimed to limit the maximum current fed to motor drive for safety concern.

III. Design of Fuzzy Logic Controller

Fig. 3 shows a simplified block diagram of speed control system based on a fuzzy logic controller. This controller has two inputs, namely speed error eω and change in speed error ceω, and one output ci_q* which represents the change in quadrature reference current i_q*.

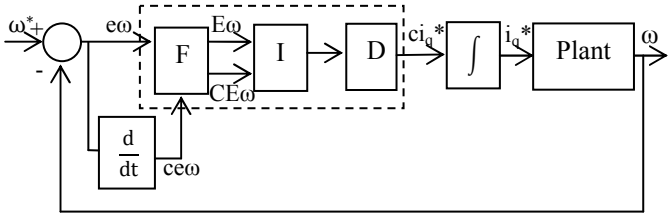

Fig. 3 Diagram block of fuzzy logic speed control scheme

The speed error and change of error are evaluated at instantaneous time as:

$$e\omega = \omega^* - \omega \tag{10}$$

$$ce\omega = \frac{de\omega}{dt} \tag{11}$$

where ω* is the reference speed, and ω is the actual speed. As shown in Fig. 3, the fuzzy logic controller consists of three phases: fuzzification (F), inference (I), and defuzzification (D).

In the first phase, the crisp variables eω and ceω are transformed into fuzzy variables Eω and CEω using triangular membership functions shown in Fig. 4. The universes of discourse of the input fuzzy variables, Eω and CEω, are respectively [-10,10] and [-1.2,1.2]. Whereas, the universe of discourse of the output variable CI_q^* is [-8,8]. For convenience, per-unit scaling factors are utilized to normalize all universe of discourse to [-1,1]. Each universe of discourse is then divided into seven fuzzy sets: NL (Negative Large), NM (Negative Medium), NS (Negative Small), Z (Nearly Zero), PS (Positive Small), PM (Positive Medium), PL (Positive Large). Each fuzzy variable is a member of the subsets with a degree of membership μ varying between 0 (nonmember) and 1 (full member). For example, the degree of membership of element x in fuzzy set Y of the universe of discourse X is expressed as $\mu_Y(x)$ with $0 \le \mu_Y(x) \le 1$

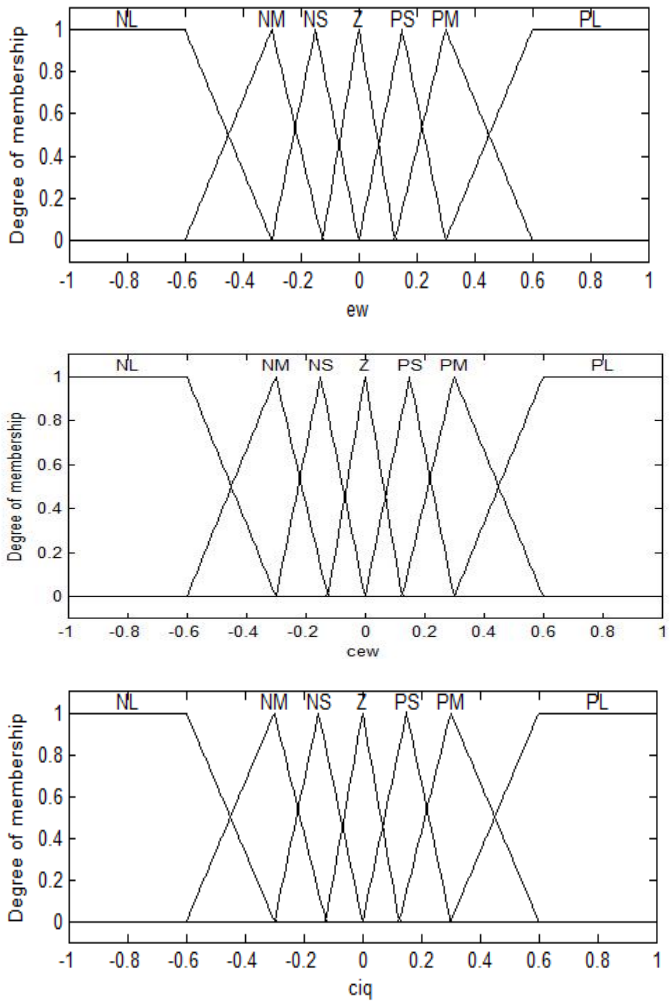

Fig. 4 Membership functions of Eω, CEω, and CI_q^*

In the second phase, in order to determine the controller output from the measured system variables, a fuzzy relation matrix is established. The fuzzy relation matrix gives a relationship between fuzzy set characterizing controller inputs and fuzzy set characterizing controller outputs. The fuzzy variables Eω and CEω are thus processed by an inference engine that performed a set of control rules contained in a (7x7) rule base as shown in Fig. 5.

CEω \ Eω	NL	NM	NS	Z	PS	PM	PL
NL	NL	NL	NL	NL	NM	NS	Z
NM	NL	NL	NL	NM	NS	Z	PS
NS	NL	NL	NM	NS	Z	PS	PM
Z	NL	NM	NS	Z	PS	PM	PL
PS	NM	NS	Z	PS	PM	PL	PL
PM	NS	Z	PS	PM	PL	PL	PL
PL	Z	PS	PM	PL	PL	PL	PL

Fig. 5 Fuzzy control rules

These 7 fuzzy sets of input and output have been chosen to give adaptability during the decision inference. The control rules are formulated using the knowledge of the PM synchronous motor behavior and the experience of control engineers. Each rule is assigned in the form shown in the following example: IF (Eω is Positive Medium) AND (CEω is Negative Large) THEN (CI_q^* is Negative Small). Different inference algorithms can be utilized to produce the fuzzy set values for the output fuzzy variable CI_q^*. In this study, the max-min inference algorithm is utilized in which the membership degree of CI_q^* is equal to the maximum of the minimum between Eω and CEω membership degrees:

$$\mu[(CIq*)_k] = max\,[min\,\{\mu(E\omega_i), \mu(CE\omega_j)\}] \qquad (12)$$

for $1 \le i \le n, 1 \le j \le n$

In the third phase, the inference output variable CI_q^* is transformed back into a crisp value ci_q^*. Various defuzzification algorithms have been proposed in many literatures. Here, the Mamdani centroid defuzzification algorithm is utilized in which the crisp value is calculated as the center gravity of the membership function of CI_q^*:

$$ci_q^* = \frac{\int \mu(CI_q^*) CI_q^* dCI_q^*}{\int \mu(CI_q^*) dCI_q^*} \qquad (13)$$

The reference current i_q^* for the vector control system is obtained by integrating ci_q^*:

$$i_q^* = \int ci_q^*\, dt \qquad (14)$$

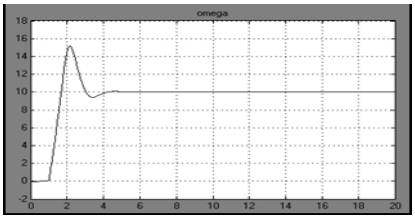
IV. Simulation Results

The control performance of the prescribed fuzzy logic controller was evaluated by simulation using a test drive system with the following parameters: P = 1 kW, V_d = 300 V, R_s = 1.4 Ω (including power switch equivalent resistance), L_s = 9.5 mH, J_{min} = 0.03 kgm^2, J_{max} = 0.23 kgm^2, B = 0.4E-3 kgm^2/s.

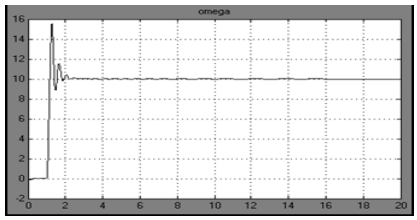
The parameters that vary are the system moment of inertia, stator resistance, and load torque. To evaluate the effectiveness of the proposed scheme, the step response of the speed control system is obtained for the varying parameters for two cases: (a) conventional PI controller, (b) fuzzy logic controller. All of the approaches described above were simulated in the Simulink environment.

A. Conventional PI Controller

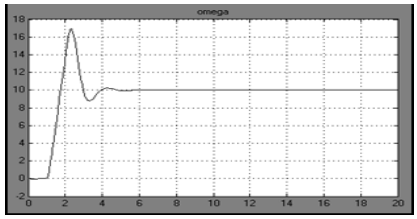
For this study, the PI coefficients for current controller and speed controller are K_p=1 T_i = 0.2, and K_p = 0.8 T_i =0.5, repectively. The obtained results for these cases are presented in Fig. 6.



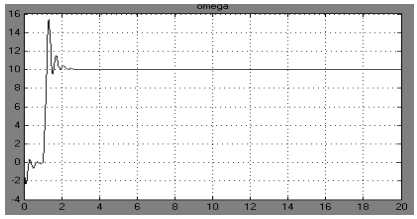
(a)



(b)



(c)



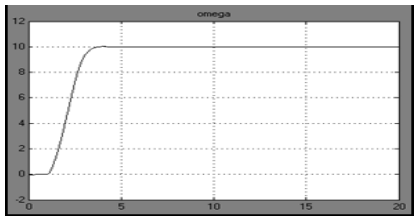
(d)

Fig. 6. Response of the system with PI speed controller
(a) J=0.03 kgm^2 (b) J=0.23 kgm^2 (c) R_s=2.8 Ω (d) T_L=3 Nm

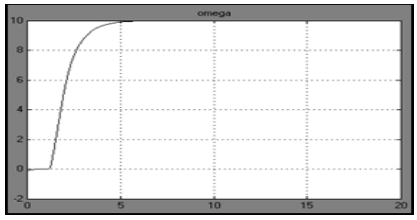
Fig. 6(a) and 6(b) demonstrate the system response with minimum and maximum moment inertia, respectively. It is obvious that the change of moment inertia influences greatly the system performance. As shown in Fig. 6(c), the variation of stator resistance also hurts the overall performance, particularly the extent of overshoot. Fig. 6(d) also shows undesirable ripples when an additional load torque is attached to the PM synchronous motor.

B. Fuzzy Logic Controller

The obtained results for the fuzzy logic based scheme are presented in Fig. 7.



(a)



(b)

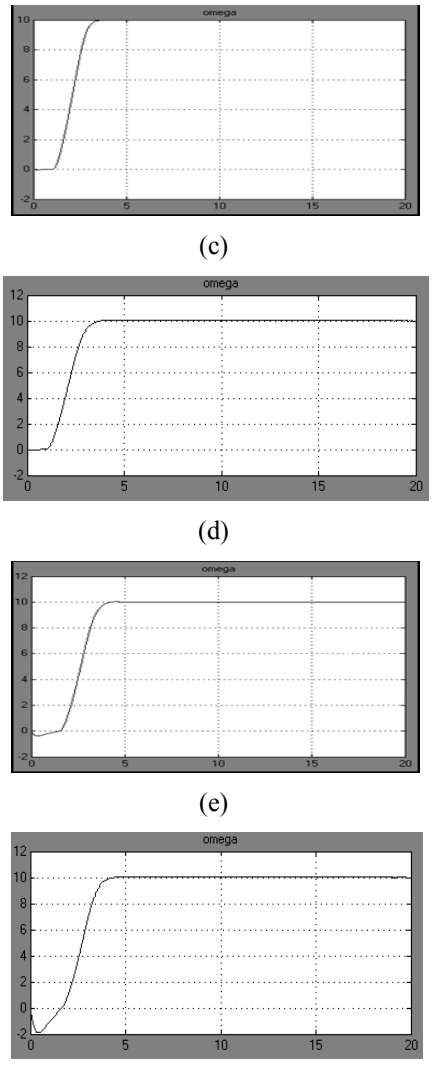


Fig. 7. Response of the system with fuzzy logic controller
(a) J=0.03 kgm^2 (b) J=0.23 kgm^2 (c) R_s=2.8 Ω (d) R_s=4.2 Ω
(e) T_L=3 Nm (f) T_L=6 Nm

Fig. 7(a) and 7(b) show the system response with minimum and maximum moment inertia, respectively. It is shown that the variation of moment inertia affects slightly in the fact that the system response in maximum moment inertia is a little bit more sluggish. However this influence does not hurt the overall performance. As shown in Fig. 7(c) and 7(d), the variation of stator resistance up to 200% is not an issue for fuzzy logic controller. And finally, Fig. 7(3) and 7(f) no longer shows undesirable ripples which occurs for that of PI controller.

V. CONCLUSION

A fuzzy logic control scheme has been studied for the speed control of a vector-controlled PM synchronous motor drive. Speed error and change of speed error measured between the actual motor speed and the reference speed were used as the fuzzy inputs. The simulation results have confirmed the efficiency and robustness of the fuzzy logic controller against the varying moment inertia, stator resistance, and load torque. Due to its simplicity and effortlessness, this scheme is applicable to industrial environment using conventional microprocessor.

Possibilistic Regression Analysis by Support Vector Machine

Pei-Yi Hao
Department of Information Management.
National Kaohsiung University of Applied Sciences, Kaohsiung, Taiwan, R.O.C.
e-mail: haupy@cc.kuas.edu.tw

***Abstract*—Support vector machines (SVMs) have been very successful in pattern recognition and function estimation problems for crisp data. This paper proposes a new method to evaluate interval linear and nonlinear regression models combining the possibility and necessity estimation formulation with the principle of SVM. For data sets with crisp inputs and interval outputs, the possibility and necessity models have been recently utilized, which are based on quadratic programming approach giving more diverse spread coefficients than a linear programming one. The SVM also uses quadratic programming approach whose advantage in interval regression analysis is to be able to perform interval nonlinear regression analysis by constructing an interval linear regression function in a high dimensional feature space. The proposed algorithm is a attractive approach to modeling nonlinear interval data, and is model-free method in the sense that we do not have to assume the underlying model function for interval nonlinear regression model with crisp inputs and interval output. Experimental results are then presented which indicate the performance of this algorithm.**

Keyword: Interval regression analysis, possibility and necessity models, Support vector machines (SVMs), Support vector regression machines, Quadratic programming.

I. INTRODUCTION

Regression analysis is to find a crisp relationship between the dependent and independent variables and to estimate a variance of measurement error. If a phenomenon under consideration is not governed by random variables but is governed by possibility variables, it is more natural to seek a fuzzy functional relationship for the given data being fuzzy or crisp. That is to say, the vague phenomenon where it is not assumed to follow randomness should be modeled by a fuzzy functional relationship. Fuzzy regression analysis can be classified into two categories; the first is possibilistic regression analysis based on possibility concepts and the second is least squares method for minimizing errors between the given outputs and the estimated outputs. Possibilistic regression derives new estimators by dealing directly with models formulated in a possibility context. Possibilistic regression analysis was first proposed by Tanaka et al. [1] where a fuzzy linear system was used as a regression model. Since membership functions of fuzzy sets are often described as possibility distributions, this approach is usually called possibilistic regression analysis [2,3].

Support vector machines (SVMs) have been very successful in pattern recognition and function estimation problems for crisp data [5,6]. Jeng *et al*. [7] first proposed the support vector interval regression networks (SVIRNs) for interval regression analysis by utilizing the ε -insensitive support vector regression (ε -SVR) in [5,6]. Hwang *et al*. [8] proposed the support vector interval regression machine (SVIRM) to evaluate the interval regression model combining the possibility estimation formulation and the property of central tendency with the principle of ε -SVR. Hao proposed a v-support vector interval regression network (v-SVIRN) to evaluate interval linear and nonlinear regression models for crisp input and output data [9]. As it is difficult to select an appropriate value of the insensitive tube width in ε -SVR, the v-SVIRN alleviates this problem by utilizing a new parametric-insensitive loss function. The v-SVIRN automatically adjusts a flexible parametric-insensitive zone of arbitrary shape and minimal size to include the given data. For a priori chosen v, v is an upper bound on the fraction of training errors and a lower bound on the fraction of support vectors. Hence, the selection of v is more intuitive.

In this paper, we propose a new method to evaluate interval linear and nonlinear regression models combining the possibility and necessity estimation formulation with the principle of support vector learning approach. The SVM approach allows us to perform interval nonlinear regression analysis by constructing an interval linear regression function in a high-dimensional feature space. Hence, the proposed algorithm is a very attractive approach to model nonlinear interval data. This algorithm is model-free method in the sense that we do not have to assume the underlying model function for interval nonlinear regression model with crisp inputs and interval output. This model-free method turns out to be a promissing method which has been attempted to treat interval nonlinear regression model.

II. A REVIEW OF PREVIOUS WORKS

A. Interval Regression Formulation Unifying the Possibility and Necessity Models

For a data set with crisp inputs and interval outputs, we can consider two interval regression models, i.e., the possibility and necessity models. In this section, we review the unified QP approach [4] to obtain the possibility and necessity models

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

simultaneously. In this unified approach, we assume for simplicity that the center coefficients of the possibility regression model and necessity regression model are same.

Suppose that we are given training data $\{(\mathbf{x}_1, Y_1),...,(\mathbf{x}_n, Y_n)\}$, where $\mathbf{x}_i = (1, x_{i1},..., x_{im})^t$ is the i-th input vector, $Y_i = (y_i, e_i)$ is the corresponding interval output that consists of a center y_i and a radius e_i. For this data set, the possibility and necessity estimation models are denoted as

$$Y^*(\mathbf{x}_i) = A_0^* + A_1^* x_{i1} + \cdots A_m^* x_{im} \qquad i = 1,..., n \tag{1}$$

$$Y_*(\mathbf{x}_i) = A_{*0} + A_{*1} x_{i1} + \cdots A_{*m} x_{im} \qquad i = 1,..., n \tag{2}$$

where the interval coefficients A_i^* and A_{*i} are denoted as $A_i^* = (a_i^*, c_i^*)$ and $A_{*i} = (a_{*i}, c_{*i})$, respectively. The estimated interval $Y^*(\mathbf{x}_i)$ by the possibility model always includes the observed interval Y_i, whereas the estimated interval $Y_*(\mathbf{x}_i)$ by the necessity model should be included in the observed interval Y_i. We can denote the interval coefficients and as

$$A_i^* = (a_i, c_i + d_i) \text{ and } A_{*i} = (a_i, c_i)$$

which satisfies the condition $A_{*i} \subseteq A_i^*$, $i = 0,1,...,m$, since c_i and d_i are assumed to be nonnegative. Therefore, by interval arithmetic the possibility model $Y^*(\mathbf{x}_i)$ and the necessity model $Y_*(\mathbf{x}_i)$ can be written as

$$Y^*(\mathbf{x}_i) = (\mathbf{a}^t \mathbf{x}_i, \mathbf{c}^t |\mathbf{x}_i| + \mathbf{d}^t |\mathbf{x}_i|) \tag{3}$$

$$Y_*(\mathbf{x}_i) = (\mathbf{a}^t \mathbf{x}_i, \mathbf{c}^t |\mathbf{x}_i|) \tag{4}$$

The two objective functions in the possibility and the necessity models are assumed as follows:

$$\min \ J_P = \sum_{i=1}^{n} (\mathbf{c}^t |\mathbf{x}_i| + \mathbf{d}^t |\mathbf{x}_i|) : \text{Possibility model} \tag{5}$$

$$\max \ J_N = \sum_{i=1}^{n} \mathbf{c}^t |\mathbf{x}_i| : \text{Necessity model} \tag{6}$$

The objective function of the unified model can be obtained by the combination of these two objective functions. The combination of two functions yields the following:

$$\min \ J_P - J_N = \sum_{i=1}^{n} \mathbf{d}^t |\mathbf{x}_i| . \tag{7}$$

Then, the objective function in the unified approach by QP can be assumed as the following quadratic function:

$$J = \sum_{i=1}^{n} \left(\mathbf{d}^t |\mathbf{x}_i|\right)^2 = \mathbf{d}^t \left(\sum_{i=1}^{n} |\mathbf{x}_i|^t |\mathbf{x}_i| \right) \mathbf{d} \tag{8}$$

Therefore, interval regression analysis [4] is to determine the interval coefficients A_i^* and A_{*i}, i=1,…,m that minimize the aforementioned objective function and satisfy inclusion relations $Y^*(\mathbf{x}_i) \subseteq Y_i \subseteq Y_*(\mathbf{x}_i)$. This problem can be described as the following QP problem:

$$\min_{\mathbf{a},\mathbf{c},\mathbf{d}} \quad J = \mathbf{d}^t \left(\sum_{i=1}^{n} |\mathbf{x}_i|^t |\mathbf{x}_i| \right) \mathbf{d} + \xi(\mathbf{a}^t \mathbf{a} + \mathbf{c}^t \mathbf{c})$$

$$\text{subject to} \begin{cases} \mathbf{a}^t x_i + \mathbf{c}^t |x_i| + \mathbf{d}^t |x_i| \geq y_i + e_i \\ \mathbf{a}^t x_i - \mathbf{c}^t |x_i| - \mathbf{d}^t |x_i| \leq y_i - e_i \\ \mathbf{a}^t x_i + \mathbf{c}^t |x_i| \leq y_i + e_i \\ \mathbf{a}^t x_i - \mathbf{c}^t |x_i| \geq y_i - e_i, \ i = 1,..., n \\ \mathbf{c} \geq 0, \ \mathbf{d} \geq 0 \end{cases} \tag{9}$$

where ξ is a significantly small positive number, and so leads the influence of $\xi(\mathbf{a}^t \mathbf{a} + \mathbf{c}^t \mathbf{c})$ to be negligible.

III. Estimization of Possibility and Necessity Models by Support Vector Machines

In this section, we propose a new method to evaluate interval linear and nonlinear regression models combining the possibility and necessity estimation formulation with the principle of SVM.

A. Interval Linear Regression

We first propose how to get solutions for interval linear regression models by implementing SVM approach for crisp-input interval-output data. Suppose that we are given training data $\{(\mathbf{x}_1, Y_1),...,(\mathbf{x}_N, Y_N)\}$, where $\mathbf{x}_i = (x_{i1},..., x_{im})^t$ is the i-th input vector, $Y_i = (y_i, e_i)$ is the corresponding interval output that consists of a center y_i and a radius e_i. For this data set, the possibility and necessity estimation models are denoted as

$$Y^*(\mathbf{x}_i) = B^* + W_1^* x_{i1} + \cdots W_m^* x_{im} \qquad i = 1,..., N \tag{10}$$

$$Y_*(\mathbf{x}_i) = B_* + W_{*1} x_{i1} + \cdots W_{*m} x_{im} \qquad i = 1,..., N \tag{11}$$

where the interval coefficients W_i^* and W_{*i} are denoted as $W_i^* = (w_i^*, c_i^*)$ and $W_{*i} = (w_{*i}, c_{*i})$, respectively. Besides, the interval bias coefficients B^* and B_* are denoted as $B^* = (b^*, d^*)$ and $B_* = (b_*, d_*)$, respectively. The estimated interval $Y^*(\mathbf{x}_i)$ by the possibility model always includes the observed interval Y_i, whereas the estimated interval $Y_*(\mathbf{x}_i)$ by the necessity model should be included in the observed interval Y_i. We can denote the interval coefficients as

$$W_i^* = (w_i, c_i + a_i) \text{ and } W_{*i} = (w_i, c_i) \tag{12}$$

which satisfies the condition $W_{*i} \subseteq W_i^*$, $i = 0,1,...,m$, since c_i and a_i are assumed to be nonnegative. Similarly, we can denote the interval bias coefficients as

$$B^* = (b, d + k) \text{ and } B_* = (b, d) \tag{13}$$

which satisfies the condition $B_* \subseteq B^*$, since d and k are assumed to be nonnegative. Therefore, by interval arithmetic the possibility model $Y^*(\mathbf{x}_i)$ and the necessity model $Y_*(\mathbf{x}_i)$ can be written as

$$\begin{aligned} Y^*(\mathbf{x}_i) &= W_1^* x_{i1} + \cdots W_m^* x_{im} + B^* \\ &= \left(\langle \mathbf{w} \cdot \mathbf{x} \rangle + b, \langle \mathbf{c} \cdot |\mathbf{x}| \rangle + d + \langle \mathbf{a} \cdot |\mathbf{x}| \rangle + k\right) \end{aligned} \tag{14}$$

and

$$\begin{aligned} Y_*(\mathbf{x}_i) &= W_{*1} x_{i1} + \cdots W_{*m} x_{im} + B_* \\ &= \left(\langle \mathbf{w} \cdot \mathbf{x} \rangle + b, \langle \mathbf{c} \cdot |\mathbf{x}| \rangle + d\right) \end{aligned} \tag{15}$$

The problem of finding the **w**, **c**, **a**, b, d and k that satisfies the inclusion relation $Y^*(\mathbf{x}_i) \supseteq Y_i \supseteq Y_*(\mathbf{x}_i)$ is equivalent to the following constrained optimization problem:

$$\min_{\mathbf{a},\mathbf{c},\mathbf{d}} \quad J = \frac{1}{2}\|\mathbf{w}\|^2 + \frac{C_1}{2}\left(\|\mathbf{c}\|^2 + d\right) + \frac{C_2}{2}\left(\|\mathbf{a}\|^2 + k\right)$$

$$\text{subject to} \begin{cases} \langle \mathbf{w} \cdot \mathbf{x}_i \rangle + b + \langle \mathbf{c} \cdot |\mathbf{x}_i| \rangle + d + \langle \mathbf{a} \cdot |\mathbf{x}_i| \rangle + k \geq y_i + e_i \\ \langle \mathbf{w} \cdot \mathbf{x}_i \rangle + b - \langle \mathbf{c} \cdot |\mathbf{x}_i| \rangle - d - \langle \mathbf{a} \cdot |\mathbf{x}_i| \rangle - k \leq y_i - e_i \\ \langle \mathbf{w} \cdot \mathbf{x}_i \rangle + b + \langle \mathbf{c} \cdot |\mathbf{x}_i| \rangle + d \leq y_i + e_i \\ \langle \mathbf{w} \cdot \mathbf{x}_i \rangle + b - \langle \mathbf{c} \cdot |\mathbf{x}_i| \rangle - d \geq y_i - e_i, \; i = 1, \ldots, n \\ k, d \geq 0 \end{cases} \tag{16}$$

The weight coefficient $C_1, C_2 > 0$ determines the tradeoff between model complexity, which is characterized by $\|\mathbf{w}\|^2$, and the vagueness of the possibility and the necessity models, which is characterized by $\left(\|\mathbf{c}\|^2 + d\right)$ and $\left(\|\mathbf{a}\|^2 + k\right)$, respectively. We can find the solution of this optimization problem given by Eq. (18) in dual variables by finding the saddle point of the Lagrangian:

$$\begin{aligned} L = {} & \frac{1}{2}\|\mathbf{w}\|^2 + \frac{C_1}{2}\left(\|\mathbf{c}\|^2 + d\right) + \frac{C_2}{2}\left(\|\mathbf{a}\|^2 + k\right) \\ & - \sum_{i=1}^{N} \alpha_{1i}\left(\langle \mathbf{w} \cdot \mathbf{x}_i \rangle + b + \langle \mathbf{c} \cdot |\mathbf{x}_i| \rangle + d + \langle \mathbf{a} \cdot |\mathbf{x}_i| \rangle + k - y_i - e_i\right) \\ & - \sum_{i=1}^{N} \alpha_{2i}\left(-\langle \mathbf{w} \cdot \mathbf{x}_i \rangle - b + \langle \mathbf{c} \cdot |\mathbf{x}_i| \rangle + d + \langle \mathbf{a} \cdot |\mathbf{x}_i| \rangle + k + y_i - e_i\right) \\ & - \sum_{i=1}^{N} \alpha_{3i}\left(-\langle \mathbf{w} \cdot \mathbf{x}_i \rangle - b - \langle \mathbf{c} \cdot |\mathbf{x}_i| \rangle - d + y_i + e_i\right) \\ & - \sum_{i=1}^{N} \alpha_{4i}\left(\langle \mathbf{w} \cdot \mathbf{x}_i \rangle + b - \langle \mathbf{c} \cdot |\mathbf{x}_i| \rangle - d - y_i + e_i\right) \\ & - \mu d - \gamma k \end{aligned} \tag{17}$$

where $\alpha_{1i}, \alpha_{2i}, \alpha_{3i}, \alpha_{4i}, \mu$, and γ are nonnegative Lagrange multipliers. Differentiating L with respect to **w**, **c**, **a**, b, d, and k, and setting the result to zero, we obtain:

$$\partial L / \partial \mathbf{w} = 0 \Rightarrow \mathbf{w} = \sum_{i=1}^{N} (\alpha_{1i} - \alpha_{2i} + \alpha_{3i} - \alpha_{4i}) \mathbf{x}_i \,, \tag{18}$$

$$\partial L / \partial \mathbf{c} = 0 \Rightarrow \mathbf{c} = \frac{1}{C_1} \sum_{i=1}^{N} (\alpha_{1i} + \alpha_{2i} - \alpha_{3i} - \alpha_{4i}) |\mathbf{x}_i| \,, \tag{19}$$

$$\partial L / \partial \mathbf{a} = 0 \Rightarrow \mathbf{a} = \frac{1}{C_2} \sum_{i=1}^{N} (\alpha_{1i} + \alpha_{2i}) |\mathbf{x}_i| \,, \tag{20}$$

$$\partial L / \partial b = 0 \Rightarrow \sum_{i=1}^{N} (\alpha_{1i} - \alpha_{2i} - \alpha_{3i} + \alpha_{4i}) = 0 \,, \tag{21}$$

$$\partial L / \partial d = 0 \Rightarrow \sum_{i=1}^{N} (\alpha_{1i} + \alpha_{2i} - \alpha_{3i} - \alpha_{4i}) = C_1 - \mu \leq C_1 \,, \tag{22}$$

$$\partial L / \partial k = 0 \Rightarrow \sum_{i=1}^{N} (\alpha_{1i} + \alpha_{2i}) = C_2 - \gamma \leq C_2 \,, \tag{23}$$

Substituting Eqs. (18)-(23) into (17), we obtain the following dual problem

$$\begin{aligned} \max \; & \frac{-1}{2} \sum_{i=1}^{N} \sum_{j=1}^{N} (\alpha_{1i} - \alpha_{2i} - \alpha_{3i} + \alpha_{4i})(\alpha_{1j} - \alpha_{2j} - \alpha_{3j} + \alpha_{4j}) \langle \mathbf{x}_i \cdot \mathbf{x}_j \rangle \\ & - \frac{1}{2C_1} \sum_{i=1}^{N} \sum_{j=1}^{N} (\alpha_{1i} + \alpha_{2i} - \alpha_{3i} - \alpha_{4i})(\alpha_{1j} + \alpha_{2j} - \alpha_{3j} - \alpha_{4j}) \langle |\mathbf{x}_i| \cdot |\mathbf{x}_j| \rangle \\ & - \frac{1}{2C_2} \sum_{i=1}^{N} \sum_{j=1}^{N} (\alpha_{1i} + \alpha_{2i})(\alpha_{1j} + \alpha_{2j}) \langle |\mathbf{x}_i| \cdot |\mathbf{x}_j| \rangle \\ & + \sum_{i=1}^{N} (\alpha_{1i} - \alpha_{2i} - \alpha_{3i} + \alpha_{4i}) y_i . + \sum_{i=1}^{N} (\alpha_{1i} + \alpha_{2i} - \alpha_{3i} - \alpha_{4i}) e_i . \end{aligned}$$

subject to (24)

$$\begin{aligned} & \sum_{i=1}^{N} (\alpha_{1i} - \alpha_{2i} - \alpha_{3i} + \alpha_{4i}) = 0 \,, \\ & \sum_{i=1}^{N} (\alpha_{1i} + \alpha_{2i} - \alpha_{3i} - \alpha_{4i}) \leq C_1 \\ & \sum_{i=1}^{N} (\alpha_{1i} + \alpha_{2i}) \leq C_2 \,, \\ & \alpha_{1i}, \alpha_{2i}, \alpha_{3i}, \alpha_{4i} \geq 0. \end{aligned}$$

As for the pair (**w**,**c**,**a**,b,d,p), it is easy to find that

$$\mathbf{w} = \sum_{i=1}^{N} (\alpha_{1i} - \alpha_{2i} + \alpha_{3i} - \alpha_{4i}) \mathbf{x}_i \,,$$

$$\mathbf{c} = \frac{1}{C_1} \sum_{i=1}^{N} (\alpha_{1i} + \alpha_{2i} - \alpha_{3i} - \alpha_{4i}) |\mathbf{x}_i| \,,$$

and $$\mathbf{a} = \frac{1}{C_2} \sum_{i=1}^{N} (\alpha_{1i} + \alpha_{2i}) |\mathbf{x}_i| \,.$$

While parameters b, d and k can be determined from the Karush-Kuhn-Tucker (KKT) conditions:

$$\alpha_{1i} \left| \left(\langle \mathbf{w} \cdot \mathbf{x}_i \rangle + b\right) + \left(\langle \mathbf{c} \cdot |\mathbf{x}_i| \rangle + d\right) + \left(\langle \mathbf{a} \cdot |\mathbf{x}_i| \rangle + p\right) - y_i - e_i \right| = 0 \tag{25}$$

$$\alpha_{2i} \left| -\left(\langle \mathbf{w} \cdot \mathbf{x}_i \rangle + b\right) + \left(\langle \mathbf{c} \cdot |\mathbf{x}_i| \rangle + d\right) + \left(\langle \mathbf{a} \cdot |\mathbf{x}_i| \rangle + p\right) + y_i - e_i \right| = 0 \tag{26}$$

$$\alpha_{3i} \left| -\left(\langle \mathbf{w} \cdot \mathbf{x}_i \rangle + b\right) - \left(\langle \mathbf{c} \cdot |\mathbf{x}_i| \rangle + d\right) + y_i + e_i \right| = 0 \tag{27}$$

$$\alpha_{4i} \left| \left(\langle \mathbf{w} \cdot \mathbf{x}_i \rangle + b\right) - \left(\langle \mathbf{c} \cdot |\mathbf{x}_i| \rangle + d\right) - y_i + e_i \right| = 0 \tag{28}$$

For some $\alpha_{3i}, \alpha_{4j} > 0$, the second factor in Eqs. (27) and (28) has to vanish. Hence, b and d can be computed as follows:

$$b=\frac{1}{2}\begin{pmatrix}-\langle \mathbf{w}\cdot\mathbf{x}_i\rangle-\langle \mathbf{w}\cdot\mathbf{x}_j\rangle-\langle \mathbf{c}\cdot|\mathbf{x}_i|\rangle+\langle \mathbf{c}\cdot|\mathbf{x}_j|\rangle\\ +y_i+y_j+e_i-e_j\end{pmatrix}, \tag{29}$$

$$d=\frac{1}{2}\begin{pmatrix}-\langle \mathbf{w}\cdot\mathbf{x}_i\rangle+\langle \mathbf{w}\cdot\mathbf{x}_j\rangle-\langle \mathbf{c}\cdot|\mathbf{x}_i|\rangle-\langle \mathbf{c}\cdot|\mathbf{x}_j|\rangle\\ +y_i-y_j+e_i+e_j\end{pmatrix}, \tag{30}$$

for some $\alpha_{3i},\alpha_{4j}>0$.

Once bias b and d is computed, we can determine the bias k from the Karush-Kuhn-Tucker (KKT) conditions. For some $\alpha_{1i},\alpha_{2j}>0$, the second factor in Eqs. (25) and (26) has to vanish. Hence, bias k can be computed as follows:

$$k=-\langle \mathbf{w}\cdot\mathbf{x}_i\rangle-b-\langle \mathbf{c}\cdot|\mathbf{x}_i|\rangle-d-\langle \mathbf{a}\cdot|\mathbf{x}_i|\rangle+y_i+e_i, \tag{31}$$

$$k=\langle \mathbf{w}\cdot\mathbf{x}_j\rangle+b-\langle \mathbf{c}\cdot|\mathbf{x}_j|\rangle-d-\langle \mathbf{a}\cdot|\mathbf{x}_j|\rangle-y_j+e_j, \tag{32}$$

for some $\alpha_{1i},\alpha_{2j}>0$.

Therefore, the possibility model $Y^*(\mathbf{x}_i)$ and the necessity model $Y_*(\mathbf{x}_i)$ constructed by the proposed approach are given as follows:

$$Y^*(\mathbf{x})=\begin{pmatrix}\sum_{i=1}^{N}(a_{1i}-\alpha_{2i}-\alpha_{3i}+\alpha_{4i})\langle \mathbf{x}\cdot\mathbf{x}_i\rangle+b,\\ \sum_{i=1}^{N}(a_{1i}+\alpha_{2i}-\alpha_{3i}-\alpha_{4i})\langle|\mathbf{x}|\cdot|\mathbf{x}_i|\rangle+d\\ +\sum_{i=1}^{N}(a_{1i}+\alpha_{2i})\langle|\mathbf{x}|\cdot|\mathbf{x}_i|\rangle+k\end{pmatrix} \tag{33}$$

$$Y_*(\mathbf{x})=\begin{pmatrix}\sum_{i=1}^{N}(a_{1i}-\alpha_{2i}-\alpha_{3i}+\alpha_{4i})\langle \mathbf{x}\cdot\mathbf{x}_i\rangle+b,\\ \sum_{i=1}^{N}(a_{1i}+\alpha_{2i}-\alpha_{3i}-\alpha_{4i})\langle|\mathbf{x}|\cdot|\mathbf{x}_i|\rangle+d\end{pmatrix} \tag{34}$$

B. Extension to the Interval Nonlinear Regression Model

Next, we will consider how to get solutions for interval nonlinear regression models. The basic idea is that an interval nonlinear regression function could be achieved by simply mapping the input patterns $\mathbf{x}_i$ by Φ: $R^n \rightarrow F$ into a high-dimensional feature space F, and then applying the interval linear regression algorithm in that space [5,6,12]. A key property of the proposed algorithm is that the only quantities that we need to compute are inner products, of the form $\langle \mathbf{x}_i\cdot\mathbf{x}_j\rangle$ and $\langle|\mathbf{x}_i|\cdot|\mathbf{x}_j|\rangle$. The algorithm would only depend on the data through inner products in F, i.e. on functions of the form $\langle \Phi(\mathbf{x}_i)\cdot\Phi(\mathbf{x}_j)\rangle$ and $\langle \Phi(|\mathbf{x}_i|)\cdot\Phi(|\mathbf{x}_j|)\rangle$. The functional form of mapping Φ does not need to be known since it is implicitly defined by the choice of kernel function $k(\mathbf{x},\mathbf{y})\equiv\langle \Phi(\mathbf{x})\cdot\Phi(\mathbf{y})\rangle$. Therefore, it is enough to know and use $k(\mathbf{x}_i,\mathbf{x}_j)=\langle \Phi(\mathbf{x}_i)\cdot\Phi(\mathbf{x}_j)\rangle$ and $k(|\mathbf{x}_i|,|\mathbf{x}_j|)=\langle \Phi(|\mathbf{x}_i|)\cdot\Phi(|\mathbf{x}_j|)\rangle$ instead of defining $\Phi(\bullet)$ explicitly. The well-used kernels for the regression problem are given as follows:

$k(\mathbf{x},\mathbf{y})=(\langle \mathbf{x}\cdot\mathbf{y}\rangle+1)^d$: Polynomial kernel of degree d;

$k(\mathbf{x},\mathbf{y})=\exp\left(\frac{-\|\mathbf{x}-\mathbf{y}\|^2}{2\sigma^2}\right)$: Gaussian RBF kernel;

$k(\mathbf{x},\mathbf{y})=\tanh(k\langle \mathbf{x}\cdot\mathbf{y}\rangle+\theta)$: Sigmoid kernel.

Hence, by replacing $\langle \mathbf{x}_i\cdot\mathbf{x}_j\rangle$ and $\langle|\mathbf{x}_i|\cdot|\mathbf{x}_j|\rangle$ with $k(\mathbf{x}_i,\mathbf{x}_j)$ and $k(|\mathbf{x}_i|,|\mathbf{x}_j|)$, respectively, we obtain the dual quadratic optimization problem given by Eq. (26). Here, we should note that the constraints are not changed.

$$\begin{aligned}\max\ & \frac{-1}{2}\sum_{i=1}^{N}\sum_{j=1}^{N}(\alpha_{1i}-\alpha_{2i}-\alpha_{3i}+\alpha_{4i})(\alpha_{1j}-\alpha_{2j}-\alpha_{3j}+\alpha_{4j})k(\mathbf{x}_i,\mathbf{x}_j)\\ &-\frac{1}{2C_1}\sum_{i=1}^{N}\sum_{j=1}^{N}(\alpha_{1i}+\alpha_{2i}-\alpha_{3i}-\alpha_{4i})(\alpha_{1j}+\alpha_{2j}-\alpha_{3j}-\alpha_{4j})k(|\mathbf{x}_i|,|\mathbf{x}_j|)\\ &-\frac{1}{2C_2}\sum_{i=1}^{N}\sum_{j=1}^{N}(\alpha_{1i}+\alpha_{2i})(\alpha_{1j}+\alpha_{2j})k(|\mathbf{x}_i|,|\mathbf{x}_j|)\\ &+\sum_{i=1}^{N}(\alpha_{1i}-\alpha_{2i}-\alpha_{3i}+\alpha_{4i})y_i.+\sum_{i=1}^{N}(\alpha_{1i}+\alpha_{2i}-\alpha_{3i}-\alpha_{4i})e_i.\end{aligned}$$

subject to (35)

$$\sum_{i=1}^{N}(\alpha_{1i}-\alpha_{2i}-\alpha_{3i}+\alpha_{4i})=0,$$

$$\sum_{i=1}^{N}(\alpha_{1i}+\alpha_{2i}-\alpha_{3i}-\alpha_{4i})\le C_1$$

$$\sum_{i=1}^{N}(\alpha_{1i}+\alpha_{2i})\le C_2,$$

$$\alpha_{1i},\alpha_{2i},\alpha_{3i},\alpha_{4i}\ge 0.$$

By using different kernel functions $k(\mathbf{x},\mathbf{y})$, one can construct different learning machines with arbitrary types of nonlinear regression functions in the input space [5,6,12]. Therefore, the possibility model $Y^*(\mathbf{x}_i)$ and the necessity model $Y_*(\mathbf{x}_i)$ constructed by the proposed approach are given as follows:

$$Y^*(\mathbf{x})=\begin{pmatrix}\sum_{i=1}^{N}(a_{1i}-\alpha_{2i}-\alpha_{3i}+\alpha_{4i})k(\mathbf{x},\mathbf{x}_i)+b,\\ \sum_{i=1}^{N}(a_{1i}+\alpha_{2i}-\alpha_{3i}-\alpha_{4i})k(|\mathbf{x}|,|\mathbf{x}_i|)+d\\ +\sum_{i=1}^{N}(a_{1i}+\alpha_{2i})k(|\mathbf{x}|,|\mathbf{x}_i|)+k\end{pmatrix} \tag{36}$$

and

$$Y_*(\mathbf{x})=\begin{pmatrix}\sum_{i=1}^{N}(a_{1i}-\alpha_{2i}-\alpha_{3i}+\alpha_{4i})k(\mathbf{x},\mathbf{x}_i)+b,\\ \sum_{i=1}^{N}(a_{1i}+\alpha_{2i}-\alpha_{3i}-\alpha_{4i})k(|\mathbf{x}|,|\mathbf{x}_i|)+d\end{pmatrix} \tag{37}$$

Kernel representations offer an alternative solution by projecting the data into a high dimensional feature space to increase the computational power of the interval linear regression algorithm. The use of interval linear regression model in the dual representation makes it possible to perform this step implicitly. By replacing the inner product with an appropriately chosen "kernel" function, one can implicitly perform a nonlinear mapping to a high dimensional feature space without increasing the number of tunable parameters [13,14]. Another attraction of the kernel method is that the learning algorithms can largely decoupled from the specifics of the application area, which must simply be encoded into the design of an appropriate kernel function. Hence, the problem of choosing an architecture for an interval regression model is replaced by the problem of choosing a suitable kernel. Several kernels have been developed by other researchers for discrete structures such as text and bio-sequences [15,16], indicating that the proposed approach is not restricted only to input spaces that are subsets of the Euclidean space.

IV. Numerical Example

In this section, we use one data set, crisp inputs-interval outputs shown in Table I. This data is taken from Tanaka and Lee [4]. The proposed SVM approaches are applied to this data set from an illustrative point of view.

TABLE I. Crisp Input-Interval Output Data

No.	1	2	3	4	5	6	7	8
x	1	2	3	4	5	6	7	8
Y	[15,30]	[20,37.5]	[15,35]	[25,60]	[25,55]	[40,65]	[55,95]	[70,100]

We first consider interval linear regression analysis. The interval linear model for this data is assumed as

$$Y(\mathbf{x}) = B + W \cdot \mathbf{x}$$

Applying the proposed SVM approach to the given data set, we obtain the possibility model $Y^*(\mathbf{x})$ and the necessity model $Y_*(\mathbf{x})$ as

$$Y^*(\mathbf{x}) = (10.7813,9.5833) + (7.9167,29.1667)x$$

$$Y_*(\mathbf{x}) = (10.7813,0.6250) + (7.9167,3.6458)x$$

Here, we set C_1=700 and C_2=400, respectively. We now introduce Tanaka and Lee's results to compare and evaluate both methods for the linear case

$$Y^*(\mathbf{x}) = (7.3111,11.856) + (8.371,2.462)x$$

$$Y_*(\mathbf{x}) = (7.311,0.168) + (8.371,0.514)x$$

We can see the interval coefficients are similar. A detailed comparison will be made later in Table II by using a measure of fitness. Fig. 1 illustrates the results for the proposed linear model. The solid line explains the fitted regression line for center. The two dash and dotted lines explain the fitted possibility and necessity models, respectively. As seen from Fig. 1, the proposed interval linear regression method works fairly well.

We now apply the proposed nonlinear method to analyze this data set. At first glance over Fig. 1, the nonlinear regression model looks appropriate for these data. Hence, we apply interval nonlinear regression method to this data set. Here, we use a Gaussian kernel for estimating the interval nonlinear model. Here, we set C_1=1, C_2=100000, and σ=0.08, respectively. Fig. 2 illustrates the results for the proposed nonlinear model.

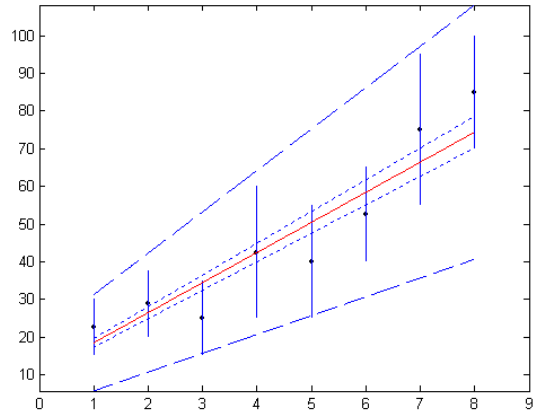

Figure 1. Linear interval regression model obtained by the proposed approach.

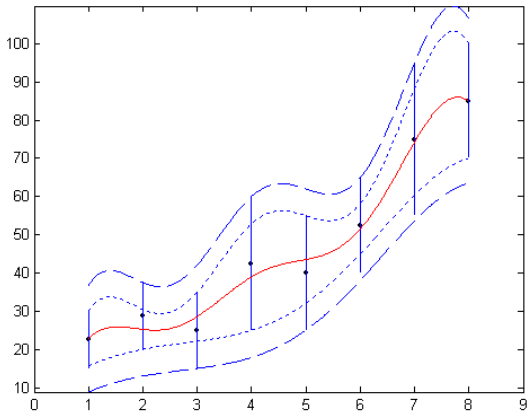

Figure 2. Linear interval regression model obtained by the proposed approach with Gaussian kernel.

As in Fig. 1, the solid line explains the fitted regression curve for center. The two dash and dotted curves explain the fitted possibility and necessity models, respectively. As seen from Fig. 2, we know that the interval nonlinear model looks more appropriate for this particular data set, and the proposed nonlinear algorithm performs well, too.

We now consider a measure of fitness to evaluate both the proposed methods and the methods of Tanaka and Lee's. We briefly review the measure of fitness (for details, see [4]). In the case of the linear model, the measure of fitness for the i-th data $\varphi_Y(\mathbf{x}_i)$ is defined as

$$\varphi_Y(\mathbf{x}_i) = \frac{\langle \mathbf{c} \cdot \mathbf{x}_i \rangle + d}{\langle \mathbf{c} \cdot \mathbf{x}_i \rangle + d + \langle \mathbf{a} \cdot \mathbf{x}_i \rangle + k}$$

which indicates how closely the possibility output for the i-th input approximates the necessity output for the ith input. Here, the denominator and the numerator represent the spreads of the estimated intervals $Y^*(\mathbf{x}_i)$ and $Y_*(\mathbf{x}_i)$, repectively. Then, the measure of fitness for all data φ_Y is defined as

$$\varphi_Y = \frac{1}{n}\sum_{i=1}^{n}\varphi_Y(\mathbf{x}_i) = \frac{1}{n}\sum_{i=1}^{n}\frac{\langle \mathbf{c} \cdot \mathbf{x}_i \rangle + d}{\langle \mathbf{c} \cdot \mathbf{x}_i \rangle + d + \langle \mathbf{a} \cdot \mathbf{x}_i \rangle + k}$$

Where n is a sample size and $0 \le \varphi_Y \le 1$. We can also define $\varphi_Y(\mathbf{x}_i)$ and φ_Y for nonlinear model by using the corresponding spreads of the estimated intervals $Y^*(\mathbf{x}_i)$ and $Y_*(\mathbf{x}_i)$. The larger the value of φ_Y, the better the model is fitting the data.

Table II shows the obtained $\varphi_Y(\mathbf{x}_i)$ and φ_Y for the linear model and the quadratic model of Tanaka and Lee's, and the proposed linear and nonlinear models. We can observe that the values of $\varphi_Y(\mathbf{x}_i)$ in the proposed nonlinear models are much larger than those in the linear and quadratic models of Tanaka and Lee's. Also, the summary measure of fit for all data φ_Y is greater for the nonlinear model as compared to the linear model. In particular, the nonlinear model with Gaussian kernel has the largest value $\varphi_Y = 0.5699$. Thus, the measure of fit indicates that the nonlinear model is providing the best fit to the given data compared to the other models. As a whole, the proposed interval regression and model selection methods work fairly well.

TABLE II. OBTAINED $\varphi_Y(\mathbf{x}_i)$ AND φ_Y FOR NUMERICAL DATA

V. CONCLUSION

Through numerical experiments, we realize that the proposed algorithms derive the satisfying solutions and are the attractive approaches to modeling the data with crisp inputs and interval output. In particular, we realize that we can use these algorithms successfully when a linear model is inappropriate. One of advantages of these algorithms is that we do not need to assume the underlying structure for the interval nonlinear regression model used in this paper. The algorithms combine generalization control with a technique to address the curse of dimmensionality. The main formulation results in solving a global quadratic optimization problem with linear constraints. Hence, this is not a computationally expensive way. In fact, this quadratic optimization problem can be solved easily by such computer software as Matlab, Mathematica, and so on.

In this paper, we deal with estimating interval nonlinear regression model combining the possibility and necessity estimation formulation with the principle of SVM for crisp inputs and interval output dataset. In future work, we intend to devise algorithms for estimating interval nonlinear regression model with interval inputs and interval output, without assuming the underlying structure. Furthermore, we will devise algorithms for estimating fuzzy nonlinear regression model with fuzzy inputs and fuzzy output.

***Abstract*—Discrete event systems (DES) theory has been developed and widely used to study the behavior of complex systems. In this paper, from a formalism based on this theory (DEVS), we propose to present a formal approach for taking into account the knowledge evolution. Indeed, knowledge is not static; it can evolve in time, or during the simulation. Few tools offer to take into account these developments, which may have a significant impact on the validity of results. To deal this knowledge, we suggest adding a lifespan to the modeled data, the latter is used to define the validity degree of knowledge; it is a kind of confidence measure.**

***Keywords*—DES; FDES; DEVS; fuzzy sets; knowledge; modeling; simulation**

I. Introduction

In this article we will present works that aim to improve the knowledge consideration in numerical models.

The process of modeling and simulation (M&S) can be divided into three phases (Figure 1):

(1) the acquisition of knowledge about the system, and proposing hypotheses;

(2) model the system based on the proposed assumptions to simplify it and make it executable by computer;

(3) simulate the model to validate and confirm the hypotheses.

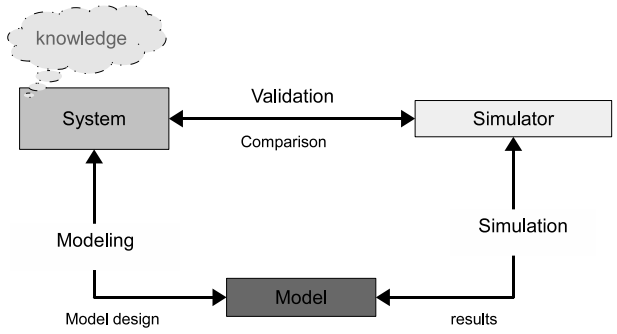

Figure 1. Modeling and simulation (MS) process

These three phases are more or less based on the need to correctly represent, i.e. in a legible and understandable, the knowledge. This knowledge can come from field observations and laboratory. They can be inferred or learned from an expert, etc. It is therefore important to identify any issues arising. What types of knowledge are needed to realize a good model? How to represent and express them? How to take into account their evolution?

Knowledge can be defined as a system for explaining the relationship between thoughts and objects. Knowledge representation amounts to establishing a correspondence between the studied system and a symbolic representation that can be processed by a computer: our model (see Figure 1). The cognitive sciences are the source of the work on knowledge; they have contributed to the development of multiple theoretical approaches [1]. Philosophers, psychologists, linguists, sociologists, computer scientists, mathematicians seek to analyze and represent knowledge. The ambition is to allow to the computer to use when calculating the same type of information that man. The difficulty of validating the information gained is the fact that we do not control the knowledge of an individual but an expression of that knowledge. The representation problem arises and causes problems of understanding, representation, expression and communication. This problem has led us to use fuzzy logic [2], [3], [4] because it allows to represent and manipulate imperfect knowledge (imprecise and uncertain). Methodological tools it offers can take into account the information so gradually, expressed in natural language, that is to say, very close to the mode of reasoning and expression of the human being. These properties are very interesting.

Recently, to deal imperfect knowledge in our models, we proposed several extensions that couple the computational intelligence methods with the DEVS formalism. iDEVS [5] is based on fuzzy set theory [2], it can simulate systems with imprecise parameters. DEVFIS to represent the FIS as a DEVS model [6]. Articles [7], [8] introduce a high-level language, based on the MDA approach and fuzzy logic for the specification of DEVS models. The experience gained during this work led us to think, and see, differently, some stages of the knowledge representation, and in particular the modeling phase. Generally modeling is defined as a step for creating a simplified representation (equation, experience, black box) of the studied system: a model (Figure 1). (1) A model is

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

an accurate or simplified description of the system in its environment. This definition is most commonly used. It is illustrated in Figure 1, which details the steps of modeling and simulation.

We want to propose an alternative definition, more focused on cognition: (2) "a model does not describe the system, but a state of knowledge, knowledge gained from the study or observation of system". This interpretation seems more consistent with the presented knowledge definition. The work presented thereafter, will be based on the definition (2). In this paper, our objectives are to introduce the concept of cognitive simulation, and explain and elaborate our modeling approach. We can define cognition as a process of complex information, such as reasoning, decision making, etc. A cognitive process is to acquire information about its environment, and relates everything to do with knowledge. Unlike a classical simulation, which evolves over time a model based on static knowledge, we propose the concept of cognitive simulation [9], [10], [11]: it aims to take into account the knowledge evolution over time. A state of knowledge may vary depending on the expert who utters (interpretability problem), it can also vary over time and become less relevant (temporality or confidence problems), it is knowledge that we can describe as dynamics.

In the first section, we present the general framework of the discrete event systems (DES) theory, then the DEVS formalism. In the second part, we detail the mechanisms to implement to apply our approach to cognitive simulation. Before concluding and presenting the limitations and perspectives of our work, in the last part, we will describe a sample application.

II. Discrete Event Modeling

Modeling and simulation (M&S) have emerged as essential tools for analyzing the behavior of complex systems. Several methods have been proposed to improve the analysis process. These proposals attempt to achieve more realistic models, relatively simple and highly flexible. Our interest focuses on DEVS (Discrete Event System Specification [12]) is a formalism for modeling systems based on the DES theory [13].

A. DES and FDES

A Discrete Event System (DES) is a discrete-state, event-driven dynamical system in which the state space is described by a discrete set, and states evolve in terms of asynchronous occurrence of discrete events over time [13]. In DES theory, states, events and transition functions have crisp values and they are defined as: a DES can be modeled by a five-tuple [13], [14], [15]:

$$G = (S, \Sigma, \delta, \lambda, s_0) \tag{1}$$

where:

- S: is the set of states;
- Σ: is the set of events containing detectable (i.e. an event is detectable if it produces a measurable change in the system output) and undetectable events, which are generally fired asynchronously;
- $\delta : S \times \Sigma \to S$ is the state transition function;
- $\lambda : S \times \Sigma \to \Sigma_d$ is the output function, where Σ_d and Σ_{ud} are the set of detectable and undetectable events, respectively $\Sigma = \Sigma_d \cup \Sigma_{ud}$;
- and, s_0 is the initial state vector whose elements are zero or one.

Actually, DESs represent many technological and engineering systems such as communication networks, computer networks, manufacturing systems, transportation systems, natural systems, and more. So far, many modeling approaches of DESs have been proposed and developed, including the notably finite automata [13], [16], fuzzy automata [17], [18], Petri nets [13], [19], DEVS formalism [12].

DES theory is used to model systems that cannot be described by differential or difference equations. However, dynamic models that cannot be easily represented by the ordinary and classical approaches might be modeled by sequences of events recording significant qualitative changes in the state of the system. Although DES theory has been applied in many engineering fields, it is not adequate for all fields. Recently, in order to make it possible to effectively represent deterministic uncertainties and vagueness as well as human subjective observation and judgment inherent to many real-world problems especially those in complex systems, several works introduce the concept of fuzzy states and fuzzy events, and generalize (crisp) discrete event systems (DES) to fuzzy DES (FDES). Fuzzy discrete event systems (FDESs) were proposed recently by [20], [14], [21], which may better cope with the real-world problems with fuzziness, impreciseness, and subjectivity such as those in biomedicine.

In summary in [20], [14], [21], a fuzzy DES is represented by a fuzzy automaton:

$$\widetilde{G} = (\widetilde{S}, \widetilde{\Sigma}, \widetilde{\delta}, \widetilde{s}_0) \tag{2}$$

where $\widetilde{S}$, $\widetilde{\Sigma}$, $\widetilde{\delta}$, $\widetilde{s}_0$ are fuzzy extensions of the crisp S, Σ, δ, s_0 respectively. Formally:

- $\widetilde{S}$ is a set of fuzzy states $\widetilde{s}$, where $\widetilde{s}$ is represented by a vector over $[0, 1]$;
- $\widetilde{\Sigma}$ is a set of fuzzy events $\widetilde{\alpha}$, where $\widetilde{\alpha}$ is represented by a matrix over $[0, 1]$;
- $\widetilde{\delta} : \widetilde{S} \times \widetilde{\Sigma} \to \widetilde{S}$ is a transition function, where $\widetilde{\delta}(\widetilde{s}, \widetilde{\alpha}) = \widetilde{s} \circ \widetilde{\alpha}$;
- and, $\widetilde{s}_0$ is the initial state.
