The integration of fuzzy information and the definition of FDES is a plus to improve the knowledge processing. This is a first step towards defining approaches to cognitive simulations. However, data to be processed (imprecise or uncertain) can occur at all levels of the system (see equation 1), their proper representation and their inclusion is a major issue. Despite this, most approaches only take into account that the vagueness or uncertainty of the states and/or system events. Inputs and the knowledge evolution over time are often omitted. We propose to extend the DEVS formalism for the inclusion of such information.

B. DEVS formalism

For several years our team working on the DEVS formalism [22], we work to develop and expand this M&S tool. This formalism provides a formal foundation to M&S that combines the advantages of a simulation-based approach with the rigor of a formal methodology. DEVS formalism is based on a mathematical paradigm with well-defined concepts of coupling of components, hierarchical, modular model construction, support for discrete event approximation of continuous systems and support of object-oriented paradigms. The DEVS formalism is based on the definition of two types of components: atomic models and coupled models.

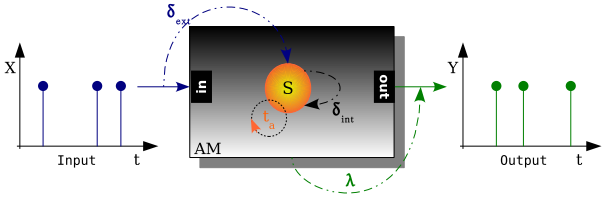

Figure 2. Behavior of atomic DEVS model

The atomic model (eq. 3) provides an autonomous description of the behavior of the system, defined by states, input/output functions and transition functions (see Figure 2). The coupled model is a composition of atomic models and/or coupled models. It is modular and presents a hierarchical structure which enables the creation of complex models from basic models.

Atomic DEVS model:

$$AM :< X, Y, S, t_a, \delta_{ext}, \lambda, \delta_{int} > \quad (3)$$

where:

- X: is the set of input events, is characterized by a couple (port, time, value), where the port means the input on which the event occurs, the time is the date of occurrence of the event, it is blank for internal events, and the value symbolizes the data from the event;
- Y: is the set of output events;
- S: is the set of partial or sequential states, which includes the state variables;
- $t_a : S \rightarrow \mathrm{T}^{\infty}$: is the time advance function which is used to determine the lifespan of a state;
- $\delta_{ext} : Q \times X \rightarrow S$: is the external transition function which defines how an input event X changes a state of the system, where $Q = \{(s, t_e) | s \in S,\ t_e \in (\mathrm{T} \cap [0, t_a(s)])\}$ is the set of total states, and t_e is the elapsed time since the last event;
- $\lambda : S \rightarrow Y^{\iota}$: is the output function where $Y^{\iota} = Y \cup \{\iota\}$ and $\iota \notin Y$ is a silent event or an unobserved event. This function defines how a state of the system generates an output event, when the elapsed time reaches to the lifetime of the state;
- $\delta_{int} : S \rightarrow S$: is the internal transition function which defines how a state of the system changes internally, when the elapsed time reaches to the lifetime of the state.

Every state S is associated with a lifetime t_a, which is defined by the time advance function. When an event receives an input event X, the external transition function δ_{ext} is triggered. This function uses the input event, the current state and the time elapsed since the last event in order to determine what the next model's state is. If no events occur before the time specified by the time advance function for that state, the model activates the output function λ (providing outputs Y), and changes to a new state determined by the internal transition function δ_{int}.

The DEVS models are executed by abstract simulators that are independent from the models themselves. Consequently, separated concerns between models and implementations of simulation can be achieved and enhance the verification of each layer independently. DEVS is a popular method to simulate a variety of systems. However, since its introduction by Zeigler in [12], significant efforts were taken to adapt this formalism to different fields and situations. The many proposed extensions [23], [24], [25], [26], [5], [6], proved its ability to extend and openness. In this large niche, we look towards the issue of knowledge evolution over time.

C. Proposal

As for the extension from DES to FDES, there are extensions to the DEVS formalism to deal fuzzy data, but they only address the uncertainty associated with events or states transitions [23], [26]. As used, the models are the result of the expression of imperfect knowledge and static over time. As we present them, they are not based on knowledge of an individual but on the expression of such knowledge, that is to say, on a state of knowledge, state variable over time.

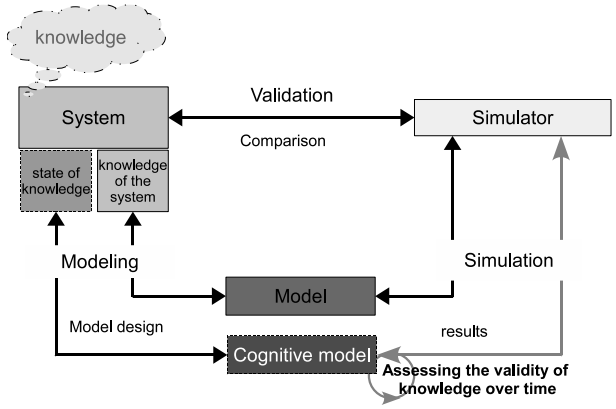

Figure 3. Integration of our cognitive model in MS process

Using Figure 3, we want to introduce the differences between the classic approach of M&S, presented in the introduction, and our approach. Between the cognitive model and the simulator, we added an evaluation mechanism that can evolve during the simulation the validity of the model parameters (eq. 3). Our approach makes sense, if we consider

that to give correct results must be taken into account in the models, the evolution and validity of data.

For example, a transport company that uses a predictive model to estimate the cost of its investments will not fix the price of a Brent barrel in advance. The evolution of the price of Brent is greatly influenced by complex factors: consumption, geopolitics, etc. Consider its price as imprecise can execute the model taking into account possible fluctuations in the price. Failing to have an accurate result, from our method, the company may have a tool for decision-making. Our proposal does not provide accurate results, it even adds to the imprecision of knowledge, but the results thus obtained allow having a broad estimate that has a good chance of being correct. We can consider this as a tool for decision support.

III. DEVS Cognitive approach

From the DEVS formalism, which is based on the DES theory, we propose a cognitive simulation approach to knowledge representation whose validity may decrease over time. Such data or information are not based on supposed knowledge of the expert, but are inferred from the knowledge expression. They are subjective, subject to human interpretation, and their relevance may vary. The information we want to take into account, can be likened to adding a confidence measure in the expert knowledge.

A. Cognitive DEVS models

We start from a simple observation, knowledge expressed and validated at a time t can, and is often the case; loses its relevance over time. To represent this loss of information, we propose to define a mechanism to data control and integrate it into the atomic DEVS model. Our goal is to extend the DEVS formalism to take into account what we call dynamic data. During the simulation, as data may lose their relevance and precision, we add a knowledge evaluation function called (Γ), during the simulation, it assessed the validity of data models and transforms some data to imprecise interval. This transformation, which can be seen as a fuzzification, will be performed by a new function added in the atomic DEVS model.

B. iDEVS method

The integration mechanism is based on our previous work, they aim to represent and manipulate imprecise data in DEVS models [27], [5]. The mechanism is simple and intuitive; we defined a new data type (a class), which allows to represent and to manipulate a fuzzy interval (Fuzzy Set) as an integer or a float. It is possible to perform calculations: basic operations (+, -, *, /) or implement functions (sin, cos, log). With the advantages of object-oriented programming (OOP), the use of our data type is transparent to the user. For example, let an integer A, and a fuzzy interval B, A+A = an integer, A+B = a fuzzy interval, B+A = a fuzzy interval, and B+B = a fuzzy interval. This is possible thanks to operator overloading to the right and left. Our data type is used to represent imprecision in various forms described in Figure 4.

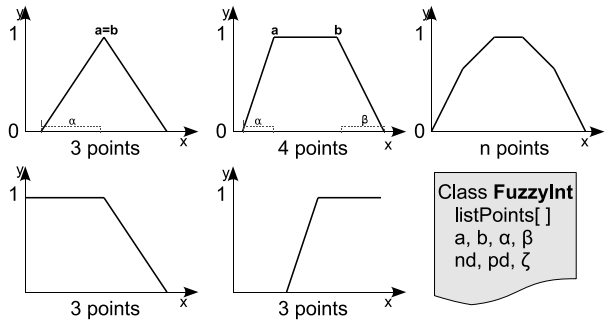

Figure 4. Example of imprecise data described from our class

Our data structure consists of a list of point (type (x, y)), 4 points defining the kernel (a and b) and the support (ψ and ω). We also added the left and right radius: $\alpha = a - \psi$ and $\beta = \omega - b$, and a linguistic label. Added to this, different coefficients to represent the validity of the information (pd), its necessity (nd), and so on. We also added a temporality variable (lifespan τ) which is evaluated and used to define the validity degree. The addition of this new information can describe the state of knowledge.

C. Operation method

We offer two application modes:

(1) a classic data (crisp) will be transformed into imprecise data (fuzzy interval), and we add a validity coefficient, a coefficient of necessity, and a lifespan. Interval support ($\omega - \psi$) or fuzzification coefficient (radius) is fixed by the user. All data are transformed into an object of $FuzzyInt$ type, in order to add our coefficients. During the first transformation, there is really no fuzzification, that is to say, that we do not add imprecision, the aim of the transformation is to add the coefficients, e.g. a value $A = 5$, will be transformed into interval $I_A = [5; 5; 5; 5]$, then depending on the validity degree and the simulation time, the bounds of the interval I_A will grow;

(2) imprecise data is tested and evaluated. Depending on its lifespan, its validity coefficient is decreased, and its support is increased (see Table I). In conclusion, we add the imprecision when data validity is low.

Table I
Proposed changes in the validity degree based on the simulation time

Simulation time (%)	0 to 40	50 to 60	70 to 100 %
Validity degree	1 to .6	.5 to .4	.3 to 0.0
Fuzzification data	$n \times 1$	$n \times 2$	$n \times 3$, a-1, b+1

D. Cognitive function

These two modes are grouped in a function added in our atomic DEVS model:

For state (S):

If S is imprecise, then we evaluate the lifespan of S compared to simulation time (lifespan equal simulation time minus current time), and we update the validity degree and the interval radius with the correlation table (Tab I).

Else, we transform S (fuzzification) using data from the user; the default fuzzification radius is 1.

For input (X):

If X is imprecise, then we evaluate the lifespan of X compared to simulation time, and we update the validity degree and the interval radius with the correlation table (Tab I).

Else, we transform X (fuzzification) using data from the user; the default fuzzification radius is 1.

Algorithm 1 Cognitive function algorithm

```
Γ(Q, X):
    N = Q (state) or X (input);
    if type(N) == fuzzy interval:
        N.update(N.listPoints = newList, N.to = SIM_TIME –
c_Time, N.pd = tab[N.to]) ;
    else
        N.fuzzification(data_user);
end;
```

In Table I we present an example of evolution of the state of knowledge. When the simulation advances of 10 %, decreases the validity degree of 0.1. Depending on the data validity, we increase the imprecision. It is the user to give the fuzzification data. By default, if the validity degree is above 0.7, we do not change; between 0.5 and 0.6 we double the interval radius, and under 0.4, we are tripling the interval radius and we are moving from a triangular representation ($a = b$) to a trapezoidal representation ($a \neq b$).

E. Integration into DEVS

Our cognitive function may be launched either in simulation algorithms, either directly in the atomic models. Its integration in the simulation part implies modification in the simulation algorithms. The method loses its genericity, because it will only work with a specific algorithm. In this case, add a line of code to run this function before launch the external transition function (δ_{ext}). We chose to integrate in the modeling part, at the level of atomic models. The function is called and then executed in the code of the external transition function. This is the first thing that must be δ_{ext}. Thus, it is not necessary to modify the simulation algorithms, and our method can be deployed in existing DEVS environments. So we keep the genericity of the approach.

F. Atomic Cognitive DEVS model

Our atomic cognitive model has the same features as the classic atomic DEVS model. Almost all functions have the same role, and the same behavior. Level simulation algorithms, their sequence is identical. The equation 4 describes our atomic model. The elements identified as being imprecise are described by a tilde. The additional element that appears is the function Γ, it defines the knowledge behavior over time.

Atomic cognitive model:

$$AcM := < \tilde{X}, \tilde{Y}, \tilde{S}, t_a, \delta_{ext}, \Gamma, \lambda, \delta_{int} > \quad (4)$$

with $\tilde{X}$, $\tilde{Y}$ and $\tilde{S}$ are a fuzzy extensions of the crisp X, Y, S, and where:

- $\tilde{X} \supset X$: is the set of input events, is characterized by a couple (port, $\widetilde{time}$, $\widetilde{value}$), where:
  - the $\widetilde{port}$ means the input on which the event occurs;
  - the $\widetilde{time}$ is the date of occurrence of the event, it can be imprecise, that is to say, defined as an object of $\widetilde{FuzzyInt}$ type. It is blank for internal events;
  - and, the $\widetilde{value}$ symbolizes the imprecise data from the event;
- $\tilde{Y} \supset Y$: is the set of output events, if one element of the model is imprecise, the outputs are imprecise;
- $\tilde{S} \supset S$: is the set of partial or sequential states, which includes the state variables. States are not directly imprecise, the state variables can be of $FuzzyInt$ type;
- $t_a : S \rightarrow \mathrm{T}^{\infty}$: is the time advance function which is used to determine the lifespan of a state. The lifetime of the state may not be accurate, in this case solutions have been proposed in [27], [28], [5];
- $\delta_{ext} : Q \times \tilde{X} \rightarrow \tilde{S}$: is the external transition function which defines how an input event $\tilde{X}$ changes a state of the system. In our model δ_{ext} has the same objectives and a new role, which is to trigger the function Γ;
- Γ : is our cognitive function, it allows to control and assess the confidence we have in information (see 1);
- $\lambda : \tilde{S} \rightarrow \tilde{Y}^{\iota}$: is the output function. This function defines how a state of the system generates an output event, when the elapsed time reaches to the lifetime of the state. In the case of imprecise data, it is used to send additional information such as membership degrees;
- $\delta_{int} : \tilde{S} \rightarrow \tilde{S}$: is the internal transition function which defines how a state of the system changes internally, when the elapsed time reaches to the lifetime of the state.

This model takes into account imprecise data, it is by no means a general proposal detailing the fuzzy DEVS model. To generalize it to fuzzy information (imprecision and uncertainty), one should take into account the uncertainties associated with the transition functions, the state changes, and events.

IV. Case study

To illustrate the interest of our approach, we propose to present a pedagogic example of application. We will present the difference in results between a traditional model and a model that performs our cognitive function.

The system is simple, a random generator (I) sends digital information (time, value) to two summer (adder) (A and B) responsible for adding the input value with a value stored in state variables. The summer A has a classical behavior, B run our cognition function. Two output models (O_1 and O_2) to print the results. In Model A, there is no distinction between knowledge of the system and state of knowledge. By cons, this is the case in Model B. For the latter, knowledge defined the

model behavior, that is to say, the addition of an input and a state variable. The state of the knowledge is characterized by the fuzzification of the value of state variable.

Table II
MODELS A AND B SIMULATION RESULTS

time	input	Output A	Output B
0	0	0	$[-2; 0; 0; 2]$
1	5	5	$[2; 5; 5; 8]$
8	2	7	$[2; 7; 7; 12]$
11	6	13	$[5; 13; 13; 21]$
27	3	16	$[4; 15; 17; 28]$
32	7	23	$[7; 21; 25; 39]$
40	2	25	$[5; 22; 28; 25]$
45	8	33	$[9; 29; 37; 57]$
50	5	38	$[10; 33; 43; 66]$

Table II presents the simulation results of the models A and B. We can see that the vagueness increases much during the simulation; this is due to the loss of data validity.

Model A makes only an addition of the input value with the value stored as a state variable. For example, at time 27: 13+3 = 16.

Before each addition, model B evaluates the lifespan of its state variable, and updates its validity degree, then it converts input value to imprecise variable and finally, adds its imprecise state variable with the imprecise input data. For example, at time 27: state model is [5;13;13;21], pd=1, τ=30, after its evaluation, we get [2;12;14;24], pd=0,3 and τ=3. The input data is transformed (fuzzification) [2;3;3;4] the lifespan is 23 (Simulation final time minus current time 50-27), validity degree is set at 1. The result is well [4;15;17;28], pd= 1 (max(0,3;1)) and τ=3 (min(3;23)).

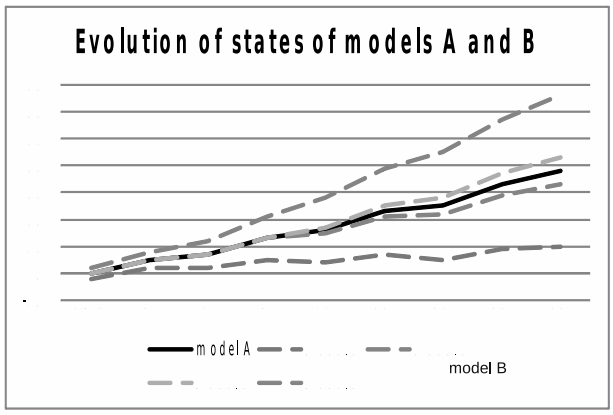

Figure 5. Models A and B state variables evolution

For this example, we chose to use the max operator for operations between validity degrees, and the min operator for the operations between lifespan. Curve 5 shows that the imprecision increases over time, and the results obtained from the classical model are bordered by the results of the cognitive model.

We are aware that the proposed case study is limited, its purpose is to validate the theoretical approach on a simple and concrete case. As shown by the example, and as one might expect, over time the imprecision of the data increases. All the advantages of this method are not clearly exposed from this application, we will soon propose other implementations. We can still highlight the originality of our approach, few studies focus on the impact of knowledge evolution over time, and therefore on the simulation results.

V. CONCLUSION

In this paper, from a formalism based on DES theory (DEVS) and a method for modeling imprecision (iDEVS), we presented a formal approach for taking into account the knowledge evolution: from our point of view, knowledge is not static, it can evolve in time, or during the simulation. To take into account this knowledge, we added a lifespan to the modeled data, the latter is used to define the validity degree of knowledge. It is a kind of confidence measure.

This work has as main objective to take into account the evolution over time of the knowledge validity, that is to say, a state of knowledge and a confidence measure. A mechanism of control and fuzzification was added at the atomic models of DEVS formalism (Atomic Cognitive DEVS model). The integration of this mechanism can respond to our problems while retaining all the properties of the DEVS formalism.

This work complements our research in the fields of FDES. They should be seen in a broader context, which aims to develop a multi-modeling framework for the study of complex systems, and more particularly a fuzzy toolbox for DES [29], [6].

Our approach is in validation phase, and it has to be improved to take into account to the problems of combinatorial explosion associated with the use of some mathematical operators in interval arithmetic. Another avenue of reflection is to study the impact of the operator used in operations between the validity degrees (pd). We propose three methods max, min, average, but we have not evaluated their impact in real situations. Finally, returning to Figure 3, and complete our reflection, we believe that the traditional model may be regarded as derived from necessary knowledge, and not necessarily sufficient. The cognitive model rather describes a possible behavior of the system. This reflection allows us to do a parallel with the possibility theory [30], [31], [32], and a link between possibility measure and necessity. We plan thus to complete our approach from the development of possibility theory.

Abstract **- Venture valuation is an essential technique in economics. Depending on the reason for a valuation, there are several methods applicable. It becomes even more complex when it comes to the valuation of companies that possess mainly intangible assets and whose success lies in the future. In this article a further step towards a Fuzzy Method is presented and discussed that allows the determination of a relevant parameter for a widely used valuation method. We focus on the application of a novel methodological framework to convert Fuzzy Cognitive Maps into Fuzzy rule-based Inference Systems. We demonstrate the principal feasibility and elucidate a method to optimize the functionality**.

Key Words *Fuzzy Cognitive Map, Fuzzy Inference Systems, Fuzzy Rules, High-Technology Ventures, Company Valuation, Risk-adequate Discount Rate*

I. INTRODUCTION

A. Background

There is a substantial need with key decision makers for support instruments that are robust, reliable, and above all, applicable in business real life. Particularly in the Venture Capital world, decisions that are based on unreliable or even wrong information can lead to significant losses of the invested money. This is particularly essential when it comes to valuing a young high-technology venture before an investment transaction. The inherent peculiarities of small high-technology ventures in venture capital transactions are analyzed exemplarily in [16].

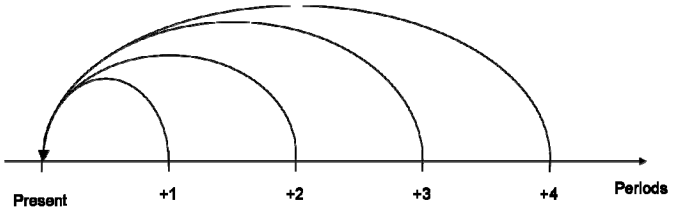

Figure 1: Principle of Future-Oriented Valuation Methods

Due to the lack of historic data, the existence of mainly tangible assets and the limited comparability to grown mature companies even in the same industry field, there is a need for specific valuation methods for young high-technology companies. A concept that has experienced a broad acceptance with practitioners in the recent years is based on the time-value-of-money concept. The main feature of Discounted Cash Flow Methods (DCF) is its future-oriented approach to valuation, i.e., prospective earnings determine the current value of the company (Fig. 1). The formal expression is shown in Equation 1. The present value *PV* of a company is the result of the added cash-flow *CF,* discounted by the discount rate *r,* the company is going to earn in the next *i* periods (Equation 1).

$$PV = \sum_{n=1}^{i} \frac{CF_i}{(1+r)^i}$$

Equation 1: Presented Value - Discounted Cash-Flow Method

The future development of a young high-technology company is, however, risky. Until now, no basic principle on how to consider the company or entrepreneurial risk in the context of company valuation has achieved acceptance.

One of the most popular methods with practioners is the so-called *Risk Premium Method*. This approach implies that the discount rate *r* consists of two components: the prime rate and an additive risk premium. The former can be relatively distinctly derived from, for example, the rate of return of risk-free fixed income assets (e.g. government bonds). The latter, however, is one the most disputed component in scientific literature on company valuation. In fact, there has not been a distinct, clear, and practicable method for exactly determining the risk premium, particularly when it comes to High-Technology Ventures. Usually, the chosen risk premia largely depends on subjective assessments of the valuer. Hence, an objective traceability is not fully given. Current research on this obvious deficit is agile, though; the aim of higher objectivity has not attained yet [3].

Obviously, the need for models and methods that can cope with uncertain prospective developments is big. Fuzzy techniques have already shown that they can be capable to

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

manage uncertainty and map it to formal computable structures. So, the application of Fuzzy techniques and concepts to this field is self-evident.

B. State-of-the-Art

The use of Fuzzy techniques to model relevant parameters in Finance has not been a major issue. Certain approaches have been presented, e.g., the use of fuzzy numbers to model uncertainty with investment decisions [4] or fuzzy interval methods in investment risk appraisal [5]. Takagi-Sugeno probabilistic fuzzy systems have also been used to identify relevant states of financial markets [19]. Modeling of risk has also been touched, for example when it comes to investment project risk appraisal [6]. The widely used *Capital Asset Pricing Model* (CAPM) was as well enhanced by Fuzzy concepts to model risk-return-relations under uncertainty [8], [9]. A further specific application of a Fuzzy CAPM in Insurance was presented in [7].

Besides adopting conventional Finance models with Fuzzy aspects, there have only been little advances in developing practical tools that play out the strengths of Fuzzy theory in modeling and making complex real-world systems manageable. Particularly, describing the relationship between risk and return in Venture Capital Investment has obviously been rarely touched by scientific literature. Hence, there is only a relatively small number of articles that directly deals with this issue. In [10] for example, a novel risk warning control method was presented that allows the comparison of different investment objects on the basis of risk-return-characteristics.

It becomes obvious that there is no explicit Fuzzy method that can help determine the relevant parameters for the DCF-model in the context of *High-Technology Venture* (HTV) Valuation.

C. Aim of this paper

In this article we want to discuss a novel approach to a risk-adequate company valuation. It shall allow a clear and traceable determination of the risk premium upon the basis of individual company characteristics. Essentially, our approach is based upon more realistic assumptions and does not demanding historic and comprehensive statistic data. To realize these ambitious goals, we make use of a novel method allowing the use of *Fuzzy Cognitive Maps* (FCM) as a knowledge capturing and representation tool and, in addition, as a starting point from which a rule-based *Fuzzy Inference System* (FIS) can be methodically clear derived from. As a result a crisp value for the parameter risk premium r_{rp} can be obtained.

D. Contribution

This article represents a significant further development of our original approach. The methodological fundament was presented and discussed in [1]. Therein, the initial model was established that uses verbal expert knowledge to assess the influence of specific factors on the risk of young HTVs. *Fuzzy Cognitive Maps* (FCM) were used for knowledge capturing and representation. Moreover, the FCMs can be used as the fundament for the development of rule-based *Fuzzy Inference Systems* (FIS). A first attempt to apply this technique in the context of high-technology venture valuation was presented in [2] and [3]. The aim was to obtain a crisp parameter upon the basis of qualitative expert knowledge. Besides the starting points for further research we showed the principal feasibility of this approach.

One of the major weak points of our method was the limited accuracy and efficacy of the initial model describing the relationship between the individual company's characteristics and the inherent risk. We primarily used not fully empirically proven factors. By founding our model on the findings of statistical meta-analysis, we could present in [11] a model that realistically maps the influence factors onto the company risk. Key to this enhancement is the number and the relevance of the factors that was statistically proven by 131 single quantitative studies on this issue.

In this article a further leap ahead is presented. Besides the enhanced economic model the focus is laid on the underlying Fuzzy Inference Systems and their rule bases. A particular focus is laid on the rule definition and rule base optimization of the final FIS. The result is a far more realistic behavior of the underlying model. Thus, our model provides the principal and technical fundament for a practicable decision making tool in venture capital investments, particularly focusing on high-technology ventures in the early stage.

E. Structure

After the introduction in Section 1, the preliminaries of the used methodological framework are presented in Section 2. The novel approach is elucidated in Section 3. Besides the basics of the underlying economic model, the rule base is being optimized. Simulation outputs before and after optimization are also depicted in this Section. Subsequently, the results and further research needs are discussed in Section 4.

II. PRELEMINARIES

The detailed presentation of the methodical framework in [1], [2] is used as a conceptual fundament. Hence, in this article, only the main features of the underlying method are cursorily presented.

A. Interpretation of Nodes and Edges

The shortages of conventional FCM are overcome by transformation using the specifically developed method presented in [1]. The major assumption of the novel framework is that there is no central rule base that represents the causal relations between the nodes. In contrast, it is assumed that each causal link can be represented by a standardized rule base. A causal link of the causal strength w_{ij} between two nodes C_i and C_j depicted by an arrow in an FCM is represented by a rule-based Fuzzy Inference System FIS_{ij} (see Figure 2). Hence, each causal link in an FCM can be translated into a corresponding single-input-single-output Fuzzy Inference System. By applying this procedure, every highly-individual FCM can be translated into a network of Fuzzy Inference Systems.

The authors thank *engage - Key Technology Ventures* for material and intellectual support.

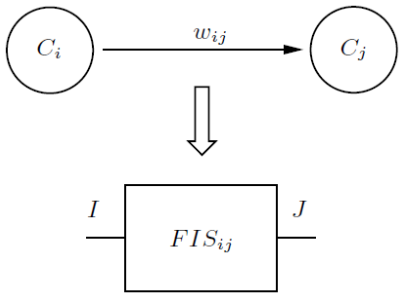

Figure 2: Representation of a single Causal Link by an FIS

B. *Multiple Causal Inputs*

To cope with multiple causal inputs, a method for combining multiple causal inputs is proposed being similar to the aggregation operator *A* proposed by Khan and Khor [17], [18]. Initially, all incoming edges are transformed to individual FIS according to the causal weight associated to them.

Thereby, the incoming signals can be weighted according to their (assumed) importance (Fig. 3). Usually, the signals are all treated equally. The outgoing signal represents the combined causal effect of the preceding cause nodes on the following effect node.

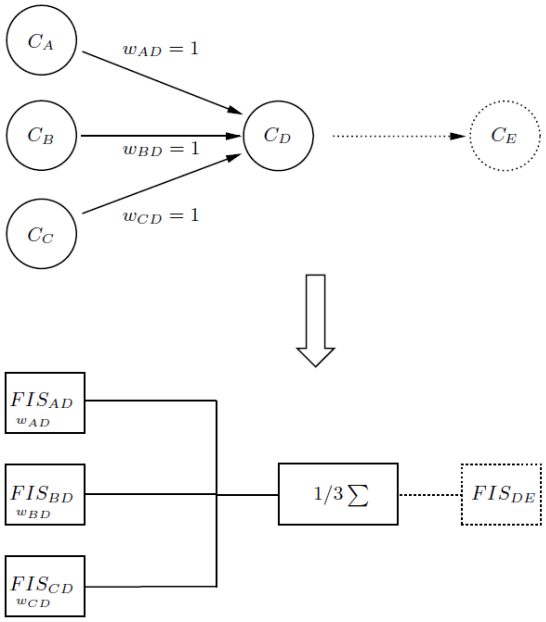

Figure 3: Interpretation of Multiple Causal Links

C. *Rule-Based Causality*

Each of these causalities is represented by a specific rule-based Fuzzy Inference System. The type of causality (positive or negative) as well as its strength is expressed by a specific rule base. The rule base is made for a single-input-single-output-Fuzzy Inference System. On the one hand, this decreases the calculation power needed to calculate a whole network of FIS. On the other hand, it reduces the risk of rule explosion.

The input and output parameters of the FIS correspond with the level of activation of the actual node. They are represented by *I*, whereas *J* denotes the output parameter level of activation of the effect node. Both parameters are defined on the basic set $X_{I,J} = [-1; 1] \in R$. An input signal $I = 1.0$ stands for the highest activation of the actual concept. It can correspond with the highest growth of the underlying concept. In contrast to that, an input value $I = -1.0$ expresses the highest activation of the node in the negative sense; it corresponds with the largest decline of the actual concept. The parameters *I* and *J* can take 21 parameter values each. Every step at 0.1 is represented by a parameter value. The output signal *J* equals the value of the concept node Cj and is, thus, possibly the input signal *I* of a successive FIS.

Each parameter is mapped onto a Fuzzy Set. The corresponding membership function is bell-shaped or Gaussian. This form of membership function provides a more realistic modeling of the underlying concept values and their corresponding membership degrees. At the outer borders of a fuzzy set, bell-shaped membership functions allow for a less harsh end and beginning of the membership. But, the closer the value gets to center c of the fuzzy number, the stronger the membership degree grows. This non-linearity corresponds with the real-world understanding of fuzzy observations (Fig. 4).

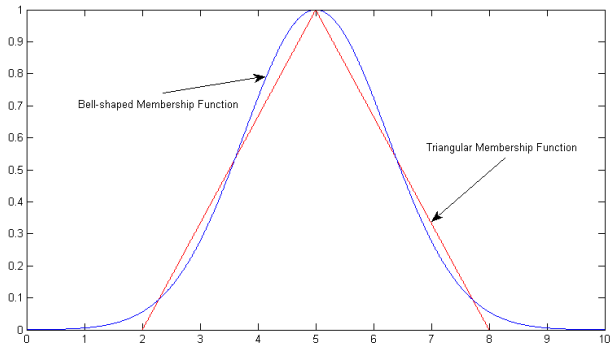

Figure 4: Triangular vs. Gaussian Membership Function

The set of membership functions representing the input and output parameter *I* and *J* is shown in Fig. 5.

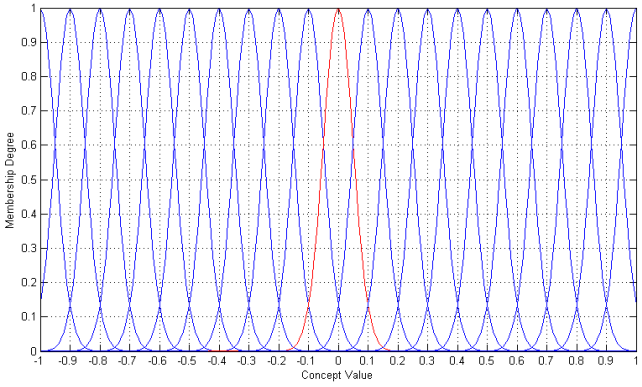

Figure 5: Membership Functions of the Parameters *I* and *J*

Next, the causal linkage between the two parameters has to be defined. To model (non-linear and non-symmetric) causality a specified rule base is designed. Each causality, and hence each causal strength is represented by a specific rule base. The IF-part of the rule consists of only one input *I*. This signal equals the fuzzy number of the concept node value C_i. Due to the discretization in steps of 0.1, the rule base is limited to a reasonable number of rules. Correspondingly, the THEN-part of the rule also consists of only one de-fuzzified output signal *J*. To determine the individual rule bases, the general understanding of the causal relationship between input and output parameter has to be highlighted. A positive causal relationship between C_i and C_j means that if C_i increases (less/ much) then C_j also increases (less/ much). A positive causal relation that has the causal strength $w_{ji} < 1$ leads, thus, to a weakened increase of C_j in case C_i increases. This weakening effect grows the lower the causal strength is.

For example, a concept value of $C_i = 1.0$ may lead only to a concept value $C_j = 0.2$. The same holds true for a decline when there is a positive causal relation. An exemplary rule base representing a positive causal strength $w = 1.0$ and the corresponding output profile is shown in Figure 5 and Figure 6, respectively. Analogue to this example there are specific rule bases for all possible causal weights *w*, $w \in [-1; 1]$. In the herein proposed methodological framework there is a total of 11 specific rule bases (increment of causality is 0.2, ranging from -1 to 1).

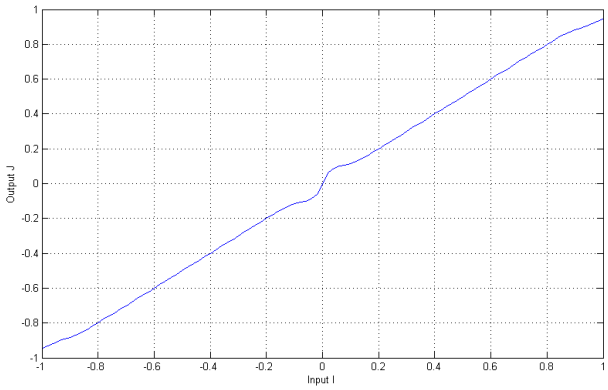

Figure 6: Output Profile of the FIS for Causality $w_{ij} = 1.0$

D. Crisp Output

To eventually obtain a crisp output, a specified component is needed: a final FIS_f. Its purpose is to take all directly preceding causal links and to 'calculate' a final output value. The input value is obtained by aggregating all incoming causal links (inputs) by using the aggregation operator (Figure 3). Its value ranges from +1 (highest increase) to -1 (highest decrease). The input value is mapped onto the corresponding output value by a specific rule base depending on the actual context. By applying this methodological framework it is possible to describe and model any complex system and its behavior by means of FCMs. Subsequently, this model of a complex system can be analyzed quantitatively, that means, a crisp value is returned.

Rule1:	IF	$I = -1.0$	THEN	$J = -1.0$
Rule2:	IF	$I = -0.9$	THEN	$J = -0.9$
Rule3:	IF	$I = -0.8$	THEN	$J = -0.8$
Rule4:	IF	$I = -0.7$	THEN	$J = -0.7$
Rule5:	IF	$I = -0.6$	THEN	$J = -0.6$
Rule6:	IF	$I = -0.5$	THEN	$J = -0.5$
Rule7:	IF	$I = -0.4$	THEN	$J = -0.4$
Rule8:	IF	$I = -0.3$	THEN	$J = -0.3$
Rule9:	IF	$I = -0.2$	THEN	$J = -0.3$
Rule10:	IF	$I = -0.1$	THEN	$J = -0.2$
Rule11:	IF	$I = 0$	THEN	$J = 0$
Rule12:	IF	$I = 0.1$	THEN	$J = 0.1$
Rule13:	IF	$I = 0.2$	THEN	$J = 0.2$
Rule14:	IF	$I = 0.3$	THEN	$J = 0.3$
Rule15:	IF	$I = 0.4$	THEN	$J = 0.4$
Rule16:	IF	$I = 0.5$	THEN	$J = 0.5$
Rule17:	IF	$I = 0.6$	THEN	$J = 0.6$
Rule18:	IF	$I = 0.7$	THEN	$J = 0.7$
Rule19:	IF	$I = 0.8$	THEN	$J = 0.8$
Rule20:	IF	$I = 0.9$	THEN	$J = 0.9$
Rule21:	IF	$I = 1.0$	THEN	$J = 1.0$

Figure 7: Rule Base for Causality $w_{ij} = 1.0$

III. Application

A. Basic Assumptions

For presenting a novel method to determine a relevant parameter for venture valuations, it is necessary to model the relationship between this parameter r_{rp} and the influencing factors. Referring to [4] and [12], the main factors are listed in Table 1.

Table 1: Significant Meta-Factors of Succes [12]

Metafactor	N	K	ρ	Expl. Var	X_S
Market Scope	1,046	10	0.21	100%	78
Industry Experience	423	4	0.11	100%	2
Marketing Experience	381	3	0.11	100%	2
Financial Resources	638	6	0.12	100%	14
Firm Age	1,890	15	0.16	87%	157
Patent Protection	453	5	0.11	100%	157
Size of Founding Team	332	5	0.13	100%	6
Supply Chain Integration	604	6	0.23	89%	41

N…aggregate sample size
K…number of correlation in the underlying studies that build the metafactor
ρ…estimate of the real population correlation
X_S…critical number of null-studies

Using these factors as the conceptual starting point, five experts were asked to construct an FCM upon these factors and weigh the causal interrelations between them. The result is depicted in Fig. 8.

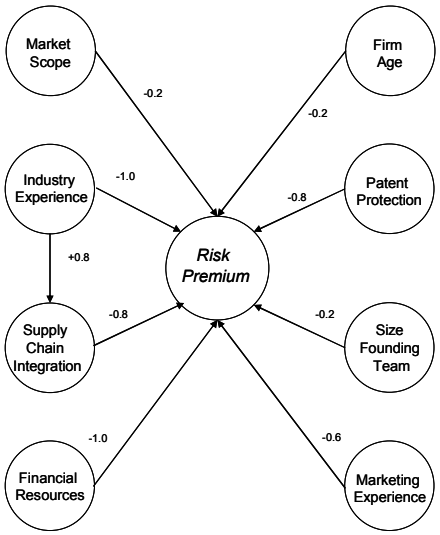

Figure 8: Expert FCM

The corresponding adjacency matrix E_{fin} is given by:

$$E_{fin} = \sum_{n=1}^{k} a_k E_{ij}^k = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -0.6 \\ 0 & 0 & 0.8 & 0 & 0 & 0 & 0 & 0 & -1.0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -0.8 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1.0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -0.2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -0.8 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -0.2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -0.6 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}$$

B. *Fuzzy Inference System and Rule Base*

According to the methodological framework discussed in [1], this FCM can be converted into a network of FIS. To eventually obtain a crisp value a final FIS is designed. Its position in the network of FIS is analogue to the configuration in Fig. 3. The final FIS maps the aggregated auxiliary parameter R onto the output parameter r_{rp} that is the crisp output. The design of the final FIS is of particular relevance as it transforms the model's causal relationships into one final crisp output. To obtain a realistic behavior the underlying relationship is modeled according to empirical findings on the relationship between risk and return rates and risk premia, respectively.

We conduct the process of Fuzzy Engineering as described by Kosko [14]. For constructing the rule base, we lean on the findings on different high technology ventures and corresponding return rates and risk premia that were observed in the recent past by Achleitner [13]. According to the used methodology, the input parameter of the final FIS_{f} consists of the aggregated antecedent causal inflows in the parameter *Risk Premium*. It integrates all impacting factors into one single figure.

Corresponding to the general understanding of nodes and their concept values the values R can take range in the interval -1 to 1. Thus, $X_R = [-1; 1] \subseteq R$. The observed risk premium r_{rp} in the Early-Stage sector scatters between 10% p.a. and 75% p.a. whereas about 50% of the values lie in the interval between 20% p.a. and 50% p.a. Thus, $X_{\text{rrp}} = [10; 75] \subseteq R$. Consequently, this distribution can be a guideline for determining the membership functions' form and position for representing the risk premia. The empirically observed risk premia concentrates in the interval [20; 45]. The borders of this interval represent the upper 75-quartile and the lower 25-quartile of the empirical distribution. This is modelled by using asymmetrically bell-shaped membership functions.

The modeling of the concentration of risk premia in the interval [25; 50] is supported by centring the membership functions stepwise at every five percent (20%, 25%, 30%, as well as, 40%, 45%, 50%). Outside this interval, the membership functions are centred at every ten percent (10%, 20% and 50%, 60%, 70%).

The median r_{rp} = 35% is depicted by a special form of the bell-shaped curve. It rather covers an interval than representing a single fuzzy value. Here, the Fuzzy Number $\tilde{r}_{\text{rp}}$ = 35 stands for the interval between r_{rp} = 30 and r_{rp} = 40. This should strengthen modelling the risk premia's concentration around the median. The lower and upper borders of the interval, namely the return rates r_{rpl} =10% and r_{rpu} = 75% are represented by triangular membership functions. Thus, a clear and distinct border is modelled guaranteeing that there are no risk premia smaller than 10% p.a. or greater than 75% p.a. The resulting membership functions are shown in Fig.9. A detailed description of this process can be found in [4].

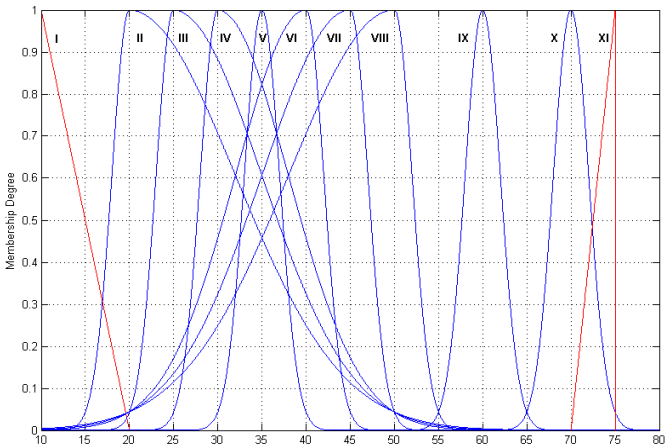

Figure 9: Membership Functions Representing the Empirically Observed Risk Premia

C. *First Results*

The simulation was carried out using the Fuzzy Logic Toolbox (Version V2.2.5 R2007a) for Matlab™(Version R 2007a). The Fuzzification is realized by singleton sets. The

Implication is carried out by using the *Min*-method. The *Max*-method is used as the aggregation operator. The *Center-of-Gravity*-method is used for de-fuzzification. In Fig. 10 the obtained preliminary output profile is depicted.

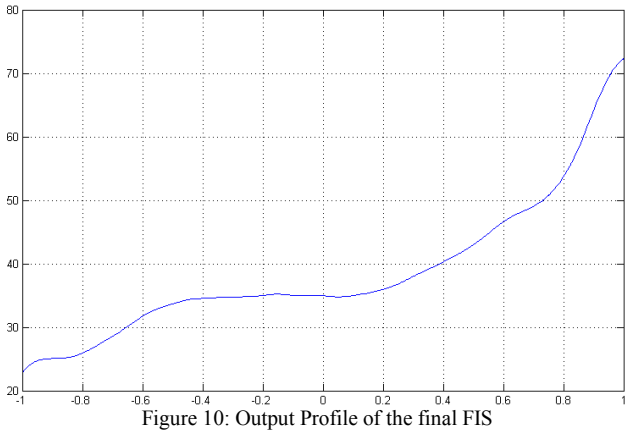

Figure 10: Output Profile of the final FIS

The depicted output profile fundamentally corresponds with the empirical findings of [12]. Below neutral point R = 0, the increase of the risk premium r_{rp} is rather slow. Beyond the point R = 0, the increase of r_{rp} is above-average denoting the tendency to increase the risk premia when the risk rises especially above a normal level. However, the mapping is still to be improved. Particularly, the peaks and unevenness of the output profile is to be bettered.

D. Rule Base Optimization

Not every rule is needed to approximate an arbitrary continuous function. The *Fuzzy Representation Theory* states that a Fuzzy Systems only needs to cover the extrema of the approximant *f* (Fig. 11).

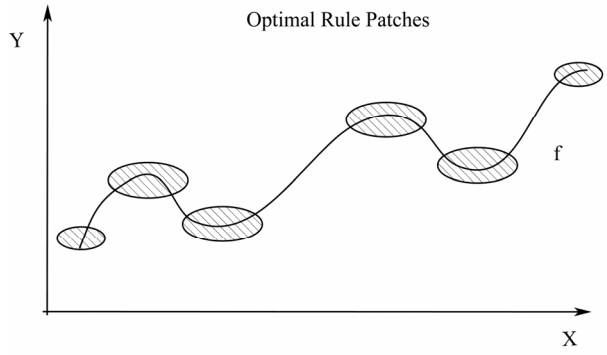

Figure 11: Rule Patches covering Extrema of the Approximant *f*

A proof of this theorem, made by Watkins [15], even states that two rules covering the turning points are sufficient to fully approximate the function. This, however, requires the exact knowledge about the function's shape. Despite of any theoretical limitations, this theorem gives a clear hint where to begin with rule optimization.

Table 2: Rule Base Covering the Extrema

Rule1	*IF*	R= -1.0	*THEN*	r_{rp} = 10%
Rule2	*IF*	R= 0	*THEN*	r_{rp} = 35%
Rule3	*IF*	R= 1.0	*THEN*	r_{rp} = 75%

1) Rules Covering the Extrema

The rule base optimization with the FIS rule base starts with a rule coverage at the extremes (-1.0; 10%), (1.0; 75%) and at the point (0; 35%) (Table 2). The resulting output profile can be seen in Fig. 12. However, the transitions are still too abrupt and the mapping is far too symmetrical. It does not yet possess the targeted shape and mapping compared to the preliminary output profile in Fig. 10.

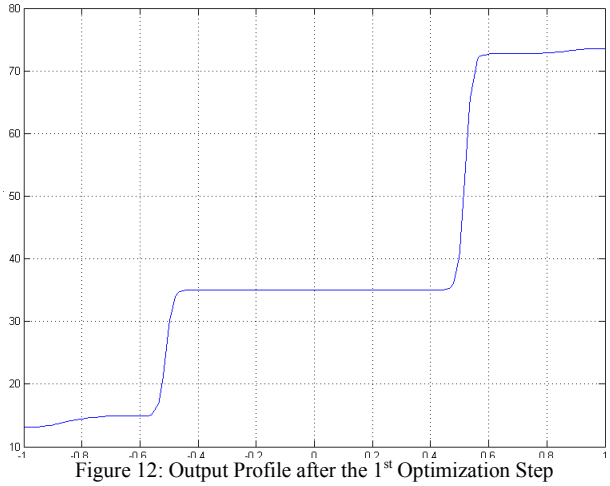

Figure 12: Output Profile after the 1st Optimization Step

2) Rules Covering the Extrema and the right-hand Side

($R > 0$). The rule base is enlarged by seven rules covering the right-hand side beyond $R = 0$ (Table 3). This results in a clearly smoother increase of r_{rp} when R rises over $R = 0$. The left-hand side $R < 0$ is still characterized by a too harsh, step-wise increase of r_{rp} (Fig. 13).

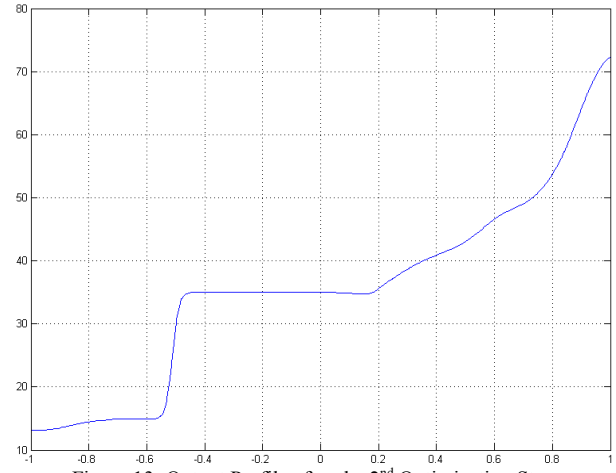

Figure 13: Output Profile after the 2nd Optimization Step

Table 3: Rule Base 2nd Optimization Step

Rule1	*IF*	R= -1.0	*THEN*	r_{rp} = 10%
Rule2	*IF*	R= 0	*THEN*	r_{rp} = 35%
Rule3	*IF*	R= 0.2	*THEN*	r_{rp} = 40%
Rule4	*IF*	R= 0.4	*THEN*	r_{rp} = 45%
Rule5	*IF*	R= 0.5	*THEN*	r_{rp} = 50%
Rule6	*IF*	R= 0.6	*THEN*	r_{rp} = 50%
Rule7	*IF*	R= 0.7	*THEN*	r_{rp} = 60%
Rule8	*IF*	R= 0.8	*THEN*	r_{rp} = 75%
Rule9	*IF*	R= 0.9	*THEN*	r_{rp} = 75%
Rule10	*IF*	R= 1.0	*THEN*	r_{rp} = 75%

3) Rule covering the Extrema and both Sides

Consequently, this next step mainly focuses on the rule coverage of the left-hand side (R < 0). Particularly, the peak at R = -0:2 and the slight trough at R ≈ 0.2 disrupt the continuity needed for the intended output profile. By deleting rules on the left-hand side of the mapping (R < 0) the peak at R ≈ -0.2 is lessened. The same holds true for the slight trough at R ≈ 0:2 which is mainly due to the added rule number seven (Fig. 14).

Table 4: Rule Base 3rd Optimization Step

Rule1	*IF*	R= -1.0	*THEN*	r_{rp} = 10%
Rule2	*IF*	R= -0.9	*THEN*	r_{rp} = 10%
Rule3	*IF*	R= -0.7	*THEN*	r_{rp} = 25%
Rule4	*IF*	R= -0.5	*THEN*	r_{rp} = 30%
Rule5	*IF*	R= -0.2	*THEN*	r_{rp} = 30%
Rule6	*IF*	R= 0	*THEN*	r_{rp} = 35%
Rule7	*IF*	R= 0.2	*THEN*	r_{rp} = 40%
Rule8	*IF*	R= 0.3	*THEN*	r_{rp} = 45%
Rule9	*IF*	R= 0.4	*THEN*	r_{rp} = 50%
Rule10	*IF*	R= 0.5	*THEN*	r_{rp} = 50%
Rule11	*IF*	R= 0.6	*THEN*	r_{rp} = 60%
Rule12	*IF*	R= 0.7	*THEN*	r_{rp} = 75%
Rule13	*IF*	R= 0.8	*THEN*	r_{rp} = 75%
Rule14	*IF*	R= 0.9	*THEN*	r_{rp} = 75%
Rule15	*IF*	R= 1.0	*THEN*	r_{rp} = 75%

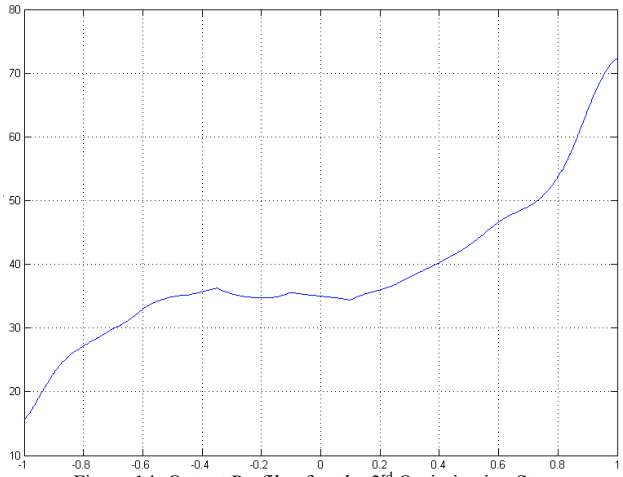

Figure 14: Output Profile after the 3rd Optimization Step

4) Optimal Rule Base

By reducing the rules on the left-hand side as well as on the right-hand side to finally twelve (Table 5), the behaviour of the mapping of R to r_{rp} is optimal. It is attained that there is a nearly monotonic growth of r_{rp} when R increases. But the increase of growth rate of r_{rp} depends on the actual value of R. The higher R grows, the stronger becomes the increase of r_{rp}

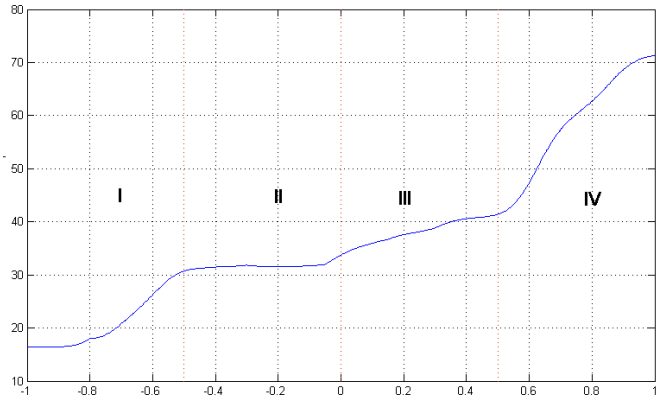

Figure 15: Simulation Results: Output Profile after Rule-Base Optimization

This optimal profile (Fig. 15) is the result of the optimized rule base (Table 5). This profile can be subdivided into four sections denoting the different behaviour of the FIS depending on the actual height of the aggregated risk R.

Table 5: Optimized Rule Base

Rule1	*IF*	R= -1.0	*THEN*	r_{rp} = 10%
Rule2	*IF*	R= -0.7	*THEN*	r_{rp} = 10%
Rule3	*IF*	R= -0.5	*THEN*	r_{rp} = 20%
Rule4	*IF*	R= -0.4	*THEN*	r_{rp} = 25%
Rule5	*IF*	R= -0.2	*THEN*	r_{rp} = 25%
Rule6	*IF*	R= -0.1	*THEN*	r_{rp} = 30%
Rule7	*IF*	R= 0	*THEN*	r_{rp} = 30%
Rule8	*IF*	R= 0.1	*THEN*	r_{rp} = 40%
Rule9	*IF*	R= 0.2	*THEN*	r_{rp} = 40%
Rule10	*IF*	R= 0.4	*THEN*	r_{rp} = 45%
Rule11	*IF*	R= 0.7	*THEN*	r_{rp} = 60%
Rule12	*IF*	R= 1.0	*THEN*	r_{rp} = 75%

Section I. In Section I, the risk parameter is below -0.5. Obviously, the risk is significantly smaller than usual. This is also expressed by a rather slow growth of the risk premium r_{rp} in the interval [-1; 0:8). In the range -0:8 < R ≤ -0:5, however, the risk premium r_{rp} grows stronger than in the preceding sector. This denotes the positive relationship between risk and risk premium even in cases that appear to be lesser risky than normal.

Section II. The second section is characterized by an almost constant mapping of the risk parameter R to the risk premium r_{rp}. This signifies the vague understanding of risk being only somewhat smaller than usually observed. The interval -0.5 < R < 0 stands for the wider range of high-

technology ventures whose risk is, at most, normal. But their risk profile not justifies yet a significant abatement of the risk premium r_{rp}.

Section III. Closely before *R* becomes zero or positive, the return rate r begins to grow steadily. This indicates that in case the high-technology venture appears to be more risky than average the required return rate r is used as a compensation for every unit risk that is taken more. This nearly linear relationship spans over the whole section III ($0 < R < 0{:}5$).

Section IV. After the risk parameter *R* has grown above 0.5, the growth of r_{rp} becomes above-average. This signifies that when a high-technology venture appears to be significantly riskier than the average ($R > 0{:}5$), the growth of the return rate r is no longer linear. It nearly becomes exponential. This is due to the fact that an investor only engages in a more-then-usual risky venture if there is an exceptional risk premium. Summing up, by optimizing the rule base, amore realistic behaviour of our model could be attained.

IV. DISCUSSION

In prior articles [1], [2], [3], [4], the principal feasibility of our approach was presented and discussed. In this article, we presented a further development of the approach. In detail, it comprises an enhanced economic model based upon statistically proven factors. Moreover, an optimized rule base was proposed. By these features, a way was demonstrated how to validate the risk premium, the most disputed component in DCF-valuation methods. Besides these promising results, there is still a lot of work to be done.

The herein proposed rule base is built and optimized manually. The conceptual basis for this is the theorem elaborated by Watkins [15]. Hence, future research will be focused on integrating learning algorithms to build the final rule base. This can lead to an even more objective rule base and even more realistically modeled system behavior. One suitable approach has already been identified: in [11] genetic algorithms are used to build and to optimize the rule base. The combination of our methodological framework with genetic algorithms for rule base building seems promising since genetic algorithm, as bio-inspired optimization methods in general, does not demand for an exact mathematical model. This feature significantly alleviates the application in the here presented context in which exact are intentionally avoided.

An improvement of the modeling of the economic relationships and the determination of the relevant factors is out of the scope of this article. The authors will look out for advancements on this topic. The herein used model provides the flexibility to adapt changing parameters and concepts.

Implementations are made according to speed requirements of the problem, for the case of critical real time systems hardware is the best choice. One important issue on fuzzy systems is the final step, defuzzifier, when computed fuzzy data is turned into crisp data. There are many different defuzzifier methods from which most used for hardware purposes are Center Of Gravity and Mean Of Maxima. This work presents hardware implementation for Center of Slice Area Average defuzzifier, for digital soft-core implementation; its main advantages are reduction on resource consumption and reduction of calculation time without loss of accuracy.**

Keywords: Soft Computing, Fuzzy Systems, Digital Systems, Discrete Numbers, Defuzzification

I. INTRODUCTION

Fuzzy systems are broad used for the decision making task given its capability of extract knowledge from an expert and translate it into rules that define described system providing better results than conventional controllers. Examples of successful implementations for fuzzy systems are: automatic parking car [1], nuclear reactors [2], robotics [3], function approximation [4], physics experiments [5], database Querying [6] among others.

A rule based fuzzy system is a special type of fuzzy systems that use fuzzy numbers as data for processing. It is constructed of four basic blocks known as: Fuzzifier, rule base, inference and defuzzifier. First and last blocks are used as interface between real world values and fuzzy values at input and output respectively. Rule base contains acquired knowledge from an expert that is managed by inference stage according to data retrieved from fuzzifier stage and delivers its result to defuzzifier stage.

Implementations for fuzzy systems are made according to speed requirements of the problem, for the case of critical real time systems where response time is crucial in order to keep a safe system operation, hardware is the best choice to provide high processing speed.

One important issue on fuzzy systems is the final step, defuzzifier, when computed fuzzy data is turned into crisp data. There are different forms for defuzzifiers satisfying different precision and speed requirements, even though, Center Of Gravity method COG and Mean Of Maxima MOM are the most used on hardware.

COG is proved to be more accurate than MOM, but it requires much more calculations [7], [10]. On this paper a defuzzifier method called Center of Slice Area Average Defuzzifier COSAA [8] is implemented in hardware, it is based on α-levels for membership functions representation and uses discrete numbers which make it fit better into digital computers. As results, it reduces execution time of Center Of Gravity COG, without loss of accuracy as Mean Of Maxima MOM and even with hardware resources reduction.

Paper is organized as follows: in order to implement efficient digital circuit is necessary to make some digital considerations as presented in Section II. Generalities for defuzzifiers are covered on Section III. Soft Core implementation for Center of Slice Area Average Defuzzifier is presented on Section IV. Results are shown in section V. Finally conclusions and future work are considered in Section VI.

II. CONSIDERATIONS FOR DIGITAL IMPLEMENTATION OF FUZZY SYSTEMS

Real world systems use precise units that can be grouped into a crisp universe where all elements are well defined. In contrast, fuzzy values are grouped into membership functions that belong to a linguistic variable where limits are defined, but not the elements.

Commonly in fuzzy systems, there is a range of values for result of operations that belongs to [0, 1] representing truth values, where 0 means no membership, and 1 is complete membership. Another form to represent membership values is using integer numbers, this case is best suited for digital implementations because floating point operations consume much more time and resources. For this case, results are considered on [0, *I*] interval, where *I* is an integer represented by equation 1, where *m* is the number of bits used for resolution [8].

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

$$I = 2^m - 1 \quad (1)$$

A. Linguistic Variables

Let us consider A be a linguistic variable, the k number of membership functions to define A is given by equation 2 and is graphically expressed on Figure 1.

$$A = \{A_0, A_1, A_2, \ldots, A_K\} \quad (2)$$

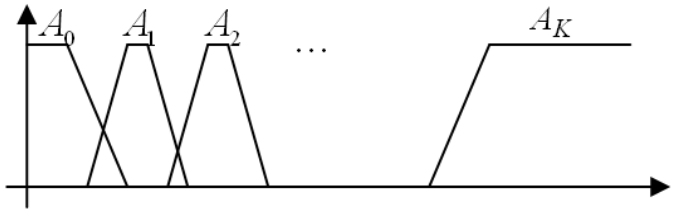

Figure 1. Membership functions for linguistic variable A

B. Membership Functions

To represent membership functions there are mainly two approaches, on the first, a membership function is represented trough a membership value for each element on input universe, it means that for a better output resolution is necessary to use a higher bit number, so while more resolution is gained, more values must be computed independently of the membership value number that modify truth universe.

The second approach is to use $\alpha - levels$ [9] or $\alpha - cuts$ [10] for membership values representation, on this case, a membership function is decomposed on a set of vectors that contain for each membership value, the interval on which the function is true. This approach allows the use of any shape for membership functions and does not take care of input resolution.

Let M be a membership function, with $x_i \in X; i = 0,1,\ldots,J$; where J is the number of points in x axis given by $J=2^n-1$, n is the number of bits used for input space representation.

Each $\alpha - level$ is defined by the following four parameters:

1. M is the name of the membership function;
2. i is the weight index, is at most equal to I and represents membership value in M;
3. α_0^i is the initial point for the interval with i as membership value.
4. α_f^i is the final point for the interval with i as membership value.

Figure 2 shows the representation of a membership function M represented by I number of $\alpha - levels$. The whole M membership function is now defined by the set of all its $\alpha - levels$ over input universe X, values for m and n depend on the number of bits used for each universe and can be different, better if $m<n$, usually 5 or 6 bits are suitable for membership universe m, and while more bits are used for crisp universe is a better resolution.

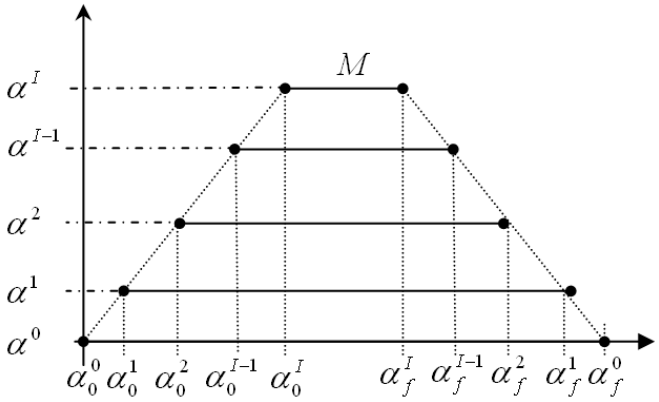

Figure 2. Discretization of a trapezoidal membership function into I number of $\alpha - levels$

C. Rule-base and Inference

The fuzzy system is dedicated to infer from fuzzy input data which is the most suitable fuzzy output it must deliver. Rule-base that contains knowledge acquired from an expert is expressed with rules in the form of Mamdani as on equation 3.

$$R_s: \text{IF x is } A_i \text{ AND y is } B_j \text{ THEN z is } C_k \quad (3)$$

where x and y are input variables, z is output variable, A_i, B_j and C_k are linguistic values for variables A and B at input and C at output.

Membership degree values for x and y inputs are used to calculate antecedent part of rule, realizing an intersection with both input membership values, commonly this is computed by some t-norm operation as on equation 4.

$$\mu_{C_k}(z) = T\left(\mu_{A_i}(x), \mu_{B_j}(y)\right) \quad (4)$$

When all rules are evaluated, only those membership functions that contribute to final result are joined by the use of an or t-conorm as on equation 5, obtaining a unified membership function made of those output membership functions whose maximum membership value is greater then zero, this resultant function is called aggregated membership function

$$\mu_C(z) = S((\mu_{C_0}(z)), \ldots, (\mu_{C_k}(z))) \quad (5)$$

An example for aggregated function is the one from Figure 3. There is a case for an $\alpha - level$ based fuzzy system with two inputs with four membership functions each, and one output with five membership functions, all trapezoidal. When two inputs $x=119$ and $y=374$ are evaluated, there are four activated rules, when they are aggregated, they turn into a unified shape represented with 512 values for universe of discourse and 32 membership values. Functions 0 and 5 do not contribute to final result, on behalf, functions 1, 2 and 3 do, with 13, 25 and 9 as membership values respectively.

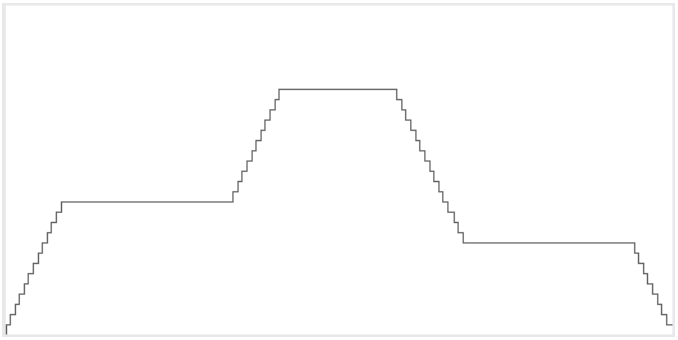

Figure 3. Aggregated membership function for *x=119* and *y=374*.

III. DIGITAL DEFUZZIFIERS

Final step on a fuzzy system is defuzzifier; it calculates the final result out of aggregated membership function, by computing only one crisp value that best represent desired output. There are many defuzzifier methods satisfying different precision and speed requirements, traditional methods are Center of Gravity COG and Mean of Maxima MOM, others are presented as Plateau Average PA [11], and Trapezoid Median Average [12].

As it has been proved on literature that COG is the best defuzzifier, many authors use it as ideal for testing, obtaining deviations from their methods with respect to COG [7], [10]. The intention then is to obtain a defuzzifier as good as COG but that is more suitable for digital implementations avoiding excessive calculation time elapsed by COG.

A. Mean of Maxima Defuzzifier

For calculation of Mean of Maxima defuzzifier MOM (equation 6), it is only necessary to know which was the highest membership value on aggregated function and obtain the middle point of that level as result, it is very simple, that is why it is fast, but does not consider rest of function so changes here are like big increases or decreases for final output, being unstable, but is well suited for many applications.

$$z_{MOM} = \sum_{j=1}^{l} \frac{w_j}{l} \tag{6}$$

B. Center of Gravity Defuzzifier

Center Of Gravity defuzzifier COG realization requires calculating the whole area and determining where its weighted midpoint is. As it uses all elements from input universe, it requires $r=2^n-1$ iterations according to number of bits used for input universe as on equation 7. This defuzzifier is preferred by most authors because of its accuracy and easiness for implementation.

$$z_{COG} = \frac{\sum_{i=1}^{k} x_i \times \mu(x_i)}{\sum_{i=1}^{k} \mu(x_i)} \tag{7}$$

C. Centre of Slice Area Average Defuzzifier

To work efficiently with a $\alpha - level$ based aggregated membership function Centre of Slice Area Average defuzzifier COSAA is used. On this case it requires at most *I* iterations according to membership values resolution as on (1).

COSAA is defined by 8, where upper part calculates summation of midpoints for all $\alpha - levels$, to calculate midpoint of each level do not require complex operations, it uses only addition, subtraction and right shift to realize division by 2. the only required division is made at endpoint with α_{MAX} . Operating description is graphically expressed on Figure 4 where *I* is equal to 4, i.e. two bits are used. Midpoints for each level are calculated and accumulated to finally obtain the average result indicated as COSAA.

$$z_{COSAA} = \frac{\sum_{i=0}^{\alpha_{\max}} \left(\frac{\left(x_f^{\alpha_i} - x_0^{\alpha_i} \right)}{2} + x_0^{\alpha_i} \right)}{\alpha_{\max}} \tag{8}$$

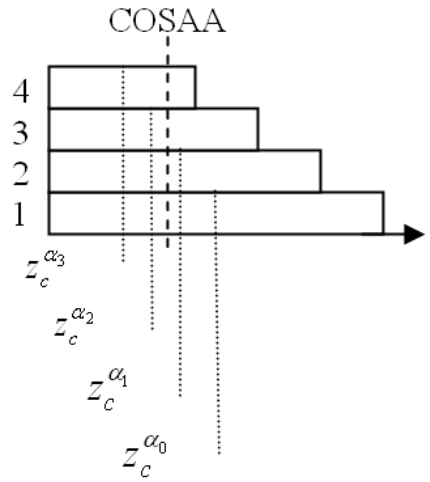

Figure 4. Center of Slice Area Average Defuzzifier operation.

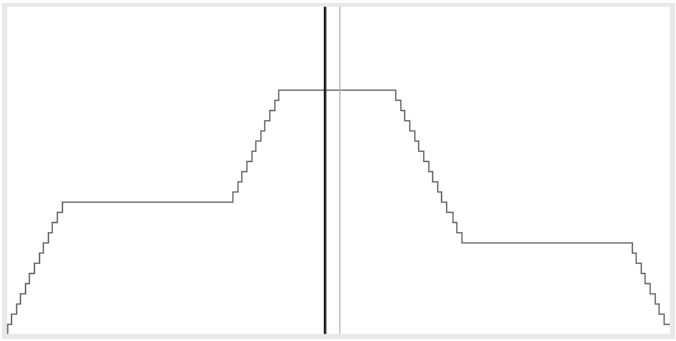

Figure 5. Defuzzifier results for inputs *x=119* and *y=374*, outputs are COG=243, MOM=255 and COSAA=244.

As example of defuzzifiers presented, there is a case for a $\alpha - level$ based fuzzy system with two inputs with four

membership functions each, and one output with five membership functions, all trapezoidal, represented on universes of 512 values (9-bit) for universe of discourse and 32 membership values (5-bit). Inputs are *x=119* and *y=374*, output results are COG=243, MOM=255 and COSAA=244 as on Figure 5.

IV. HARDWARE IMPLEMENTATION OF COSAA

Centre of Slice Area Average Defuzzifier Hardware implementation is based on equation (8) and is presented on Figure 8. Aggregated membership function resultant from previous stage is loaded into two ROM memories that contain the complete description of the function in terms of its $\alpha - levels$. Height index k for each $\alpha - level$ is given by memory address, and the contents are the initial point α_0^k on MEM_32x8 block, and final point α_f^k on MEM_32x8_FINAL. Five bits are used for membership resolution obtaining 32 levels, for that reason, memories are 32 deep, 8-bit wide.

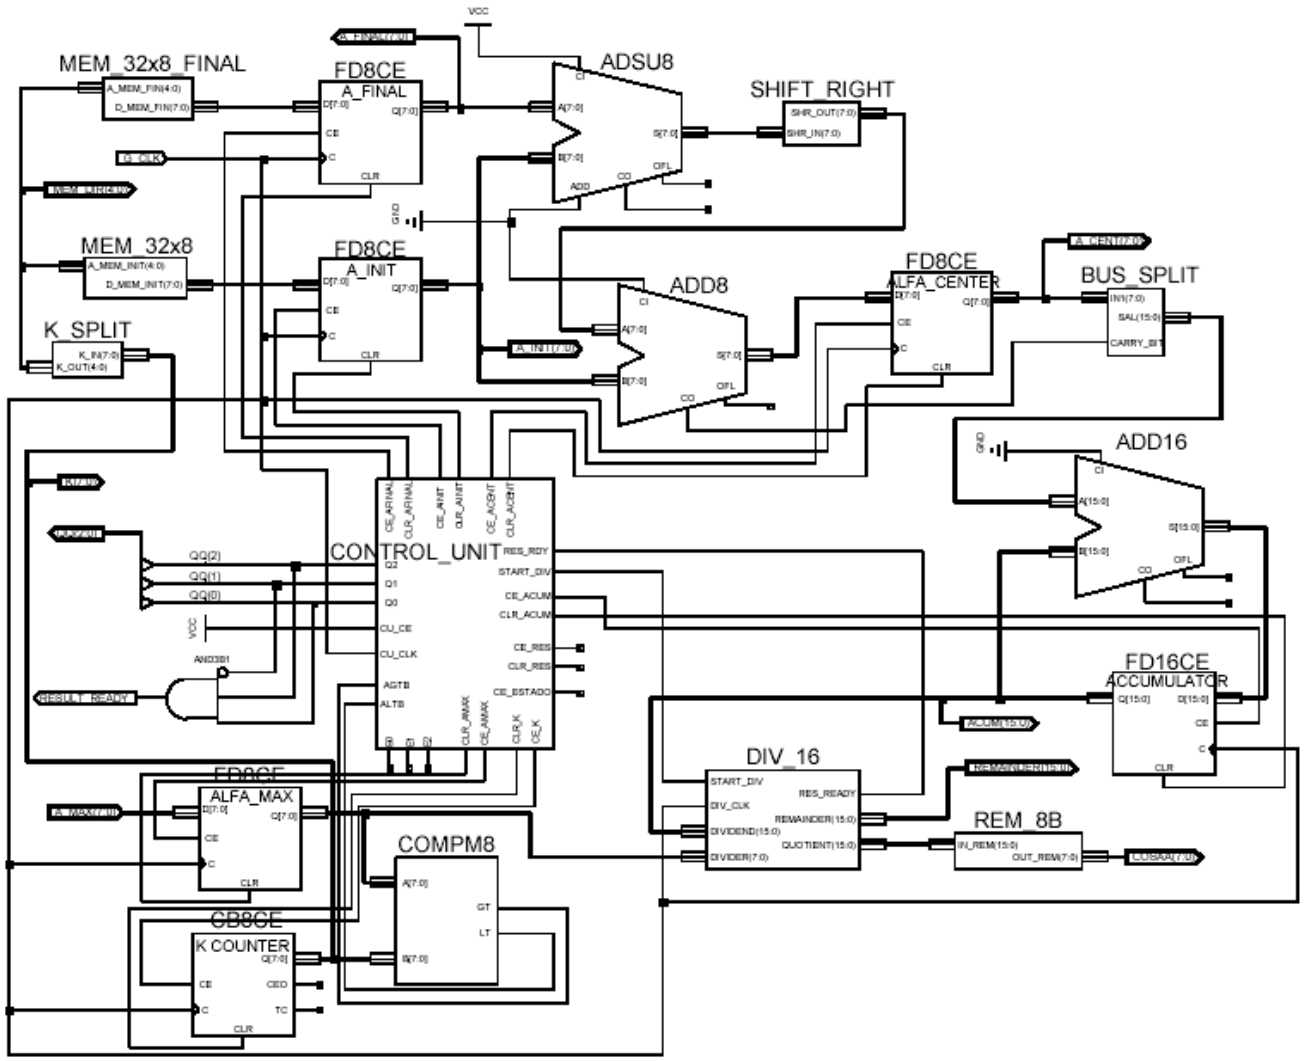

Figure 6. Hardware realization for Centre of Slice Area Average defuzzifier. There can be identified five 8-bit registers FD8CE that are D-type flip-flops and are used to store values of α_0^k (A_INIT), α_f^k (A_FINAL), α_C^k (ALFA_CENTER), α_{MAX} (ALFA_MAX) and Accumulator respectively labelled.

There can be identified four 8-bit registers (FD8CE) that are D-type flip-flops used to store values for α_0^k (A_INIT), α_f^k (A_FINAL), α_C^k (ALFA_CENTER), α_{MAX} (ALFA_MAX) and a 16 bit register for accumulator.

To calculate the center of a level as on upper part from Equation 8, ADSU8 is used as an 8-bit subtractor to realize the α_f^k - α_0^k part, division by two is performed by SHIFT_RIGHT unit; ADD8 realizes the summation of offset to obtain the center of evaluated level that will be now stored on its correspondent ALFA_CENTER register.

BUS_SPLIT is an 8 to 16 bit conversion block that drive α_C^k calculated value as input for ADD16 that is a 16 bit

adder used to realize summation among calculated value and previous values stored on accumulator register.

An 8-bit counter CB8CE labeled K_COUNTER, is used as pointer for each $\alpha - level$ address on both memories. COMPM8 is a magnitude comparator used for iteration control procedure between α_{MAX} and K. The procedure of calculate midpoints for all levels is repeated until *ALTB* signal from comparator goes high that is the moment when *k* is equal to α_{MAX} and is the appropriated moment to start division. The completion of division algorithm requires about 50 clock cycles to obtain a 16-bit result that is converted to 8-bit value trough REM_8B block. Result is available when RESULT_READY signal goes high and remains there until next COSAA calculation overwrite final value.

V. RESULTS

A. Simulation Results

This methodology was first implemented on a C++ Builder simulator on which every stage was constructed according to methodology presented. Simulation is realized for a fuzzy system with two inputs with four membership functions each, one output with five membership functions and 16 rules at rule base, for an easy visualization of universe spaces they are discretized at 32 $\alpha - levels$ i.e. 5 bits for *y* axis (membership universe), and 256 values, i.e. 8 bits for *x* axis (input universe).

Table I presents some test cases realized for three defuzzifiers, there is shown the result and elapsed time.

TABLE I. SOME TESTS REALIZED FOR THE SYSTEM.

x	y	Defuzz	Result	Time us
10	63	COSAA	23	2.23
10	63	COG	33	13.40
10	63	MOM	9	1.95
10	157	COSAA	65	2.23
10	157	COG	70	22.346
10	157	MOM	63	1.95
43	215	COSAA	128	2.23
43	215	COG	128	32.68
43	215	MOM	127	1.95
75	229	COSAA	176	2.79
75	229	COG	160	49.34
75	229	MOM	191	2.51
109	109	COSAA	86	3.35
109	109	COG	107	70.67
109	109	MOM	63	2.69
146	117	COSAA	132	3.07
146	117	COG	132	71.79
146	117	MOM	127	3.07

216	216	COG	204	18.15
216	216	MOM	245	2.23

B. Soft-Core Implementation Results

Hardware for COSAA was constructed from logical gate design using Xilinx tools for FPGA design over a Spartan 3 XC3S400-5FG320 device that has 400,000 logic gates. Execution results for COSAA hardware are shown on Figure 7 and Figure 8 using the set of $\alpha - levels$ that describes aggregated function.

G_CLK is the global clock signal for the system; *QQ* is the 3-bit state counter, it iterates from states1 to 3 until all levels are evaluated, this is controlled by *K* counter until its value reaches α_{MAX} (*A_MAX)* value as last level to evaluate. *MEM_DIR* is the current address index of the memory that contains α_0^k (*A_INIT)* and α_f^k (*A_FINAL)* values, the calculation of α_C^k is presented on *A_CENT* and its summation is stored on *ACUM*.

When all levels are calculated system goes to state 4 where it starts the final division between *ACUM* and *A_MAX* and wait there until division completion that is the moment to go to state 5 where result ready signal (*RESULT_READY)* is activated indicating that final result can be read from *COSAA* as integer and it will be available until next division is started on state 4.

On Table II there are resources consumed by final implementation of COSAA defuzzifier, it can be noticed that it uses few circuitry and delay times are considered for a combinatory array. Calculation of COSAA from an aggregated membership function requires 129 clock cycles to provide final result, considering that division uses almost 50 clock cycles, then it takes about 80 clock cycles to calculate the summation of all levels. To make this function more efficient it maybe must consider another type of division that is faster, but maybe hardware complexity increases.

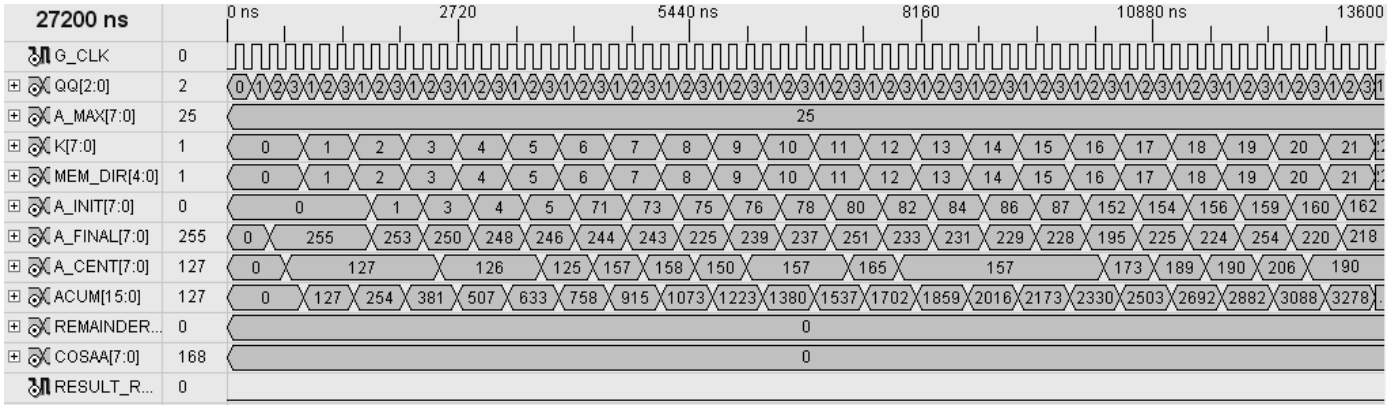

Figure 7. Simulation results for COSAA hardware implementation, the calculation of each level stored on memory is realized using *K* as index pointer until it is equal to *A_MAX* on state 4 where it starts to calculate final division for average. Final result is presented on state 5 where *RESULT_READY* signal is activated.

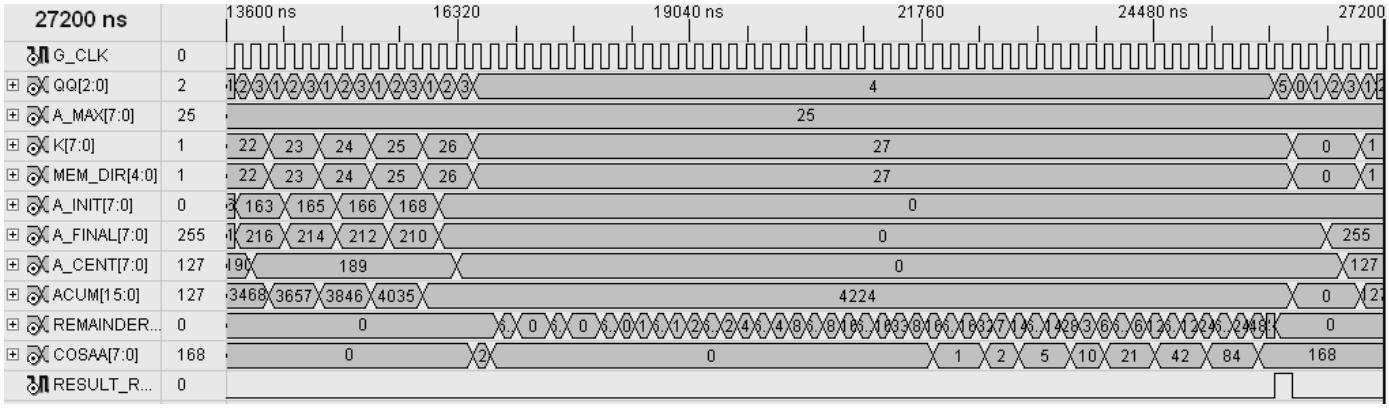

Figure 8. Simulation results for COSAA hardware implementation (Continued from Figure 17)

TABLE II. HARDWARE RESOURCES CONSUMED BY IMPLEMENTATION OF COSAA DEFUZZIFIER. TOTAL DELAY IS CONSIDERED JUST FOR A COMBINATORY CIRCUIT THAT DO NOT ITERATE.

Operation	Logic Gates	Logic Levels	I/O used	Total Delay us	Delay Logic	Delay Route
COSAA	972	14	124	26	41%	59%

VI. CONCLUSIONS

Center of Slice Area Average (COSAA) Defuzzification reduces considerably calculation time consumed by Center of Gravity (COG) that uses at least $2^n - 1$ iterations. The new method proposed has a maximum iteration number equal to the *I* number of $\alpha - levels$ and is proportional to the number of bits used to quantify membership space, being COSAA as fast as MOM.

About precision, COSAA competes with COG and is much better than MOM, versatility can be added by use of different aggregation methods.

The $\alpha - level$ method used for representing fuzzy systems with integer numbers, can be implemented easily over any binary computer system using simple operations such as additions and shifting, avoiding time consuming operations such as multiplications and divisions obtaining a reduction on calculation time, and a more flexible and efficient approach for fuzzy systems realization.

***Abstract*—Conventional methods produced composite facial expressions by interpolating the representative facial expressions under the assumption that the transitions between facial expressions are linear. Considering the nonlinear property, this paper proposes a fuzzy integral-based method for generating composite facial expressions. Fuzzy measures represent the relationship among emotions and the partial evaluation of current emotion state is obtained from a predefined error function of the ideal basic emotion states and the current emotion state. Fuzzy integral of the partial evaluation with respect to fuzzy measures is employed to globally evaluate the current emotion state for generating composite facial expressions. The effectiveness of the proposed method for generating composite facial expressions is demonstrated through the experiments with a robotic head with 19 degrees of freedom, developed in RIT Laboratory, KAIST.**

Keywords: Facial expression generation, choquet integral, λ-fuzzy measure, robotic head, diamond pairwise comparison method.

I. Introduction

Nowadays, robots have been used in many areas. Robots can guide people in a museum or play with children [1], [2]. It is expected that robot can be developed as a sociable partner in the future [3]. Considering the symbiosis between robots and humans, it is unavoidable for robots to interact with humans. In this sense, there have been many researches on human robot interaction (HRI) [4]- [6].

When robots interact with humans, robots should imitate the human's interaction because human can interact naturally with robots without additional education or knowledge. Facial expressions play an important role in human's interaction. According to Mehrabian, only 7% of information is delivered by language, 38% of information is delivered by paralanguage like voice and 55% of information is delivered by non-verbal communication like facial expressions and gestures [7], [8]. Therefore, facial expression is an important mean in communication.

There have been many researches on how to generate natural facial expressions. For example, linear dynamic affect-expression model and simple recurrent network were developed to generate facial expressions dynamically [9], [10]. Fuzzy rule based system was applied to generate facial expressions [11]. Grizard and Lisetti used three-levels architecture by adapting psychological theory and Lin and Huang used anatomical theory for generating facial expressions [12], [13].

However, researches on composite facial expressions have not been much progressed. To generate composite facial expressions, relationship among emotions should be considered. According to the psychologist Ekman, happiness is a positive emotion, surprise is a neutral emotion and anger, disgust, fear and sadness are negative emotions [14]. Therefore, both anger and disgust are very similar and they often appear together. However, being happy and disgust at the same time is highly unlikely produced. To generate more natural facial expressions, relationship between emotions should be considered. In addition, each emotion has its own main features in facial expressions. Happiness is chiefly expressed by stretching a mouth and surprise is mainly expressed by raising a forehead and eyebrows. When composite facial expressions are generated, each emotion is expressed separately in some parts of face such that they are produced in a big picture. Conventional methods for generating the composite facial expressions used the linear interpolation of the representative facial expressions under the assumption that the transitions between facial expressions are linear. Thus, linear interpolation method cannot generate natural facial expressions.

In this paper, fuzzy integral and fuzzy measure are used to generate natural composite facial expressions. The fuzzy measure deals with the ambiguity of the crisp set. Emotion state can be represented by the fuzzy measures because the relationship among them are ambiguous such that people cannot easily tell how much a subject is in a happy state, sad state, etc. Thus, the fuzzy measures are employed to represent the relationship among emotions. The partial evaluation of current emotion state is obtained from a predefined error function of the ideal basic emotion states and the current emotion state. Fuzzy integral of the partial evaluation with respect to fuzzy measures is employed to globally evaluate the current emotion state for generating composite facial expression by separately actuating the parts of a robotic face. The effectiveness of the proposed method for generating composite facial expressions is demonstrated through the experiments with a robotic head with 19 degrees of freedom, developed in RIT Laboratory, KAIST.

The rest of this paper is organized as follows. In Section II, the generation process of composite facial expressions is proposed based on the fuzzy measure and fuzzy integral.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Simulation and experimental results are presented in Section III. Finally, concluding remarks follow in Section IV.

II. Generation of Facial Expression

A. Composite Facial Expressions

According to the psychologist Ekman, human's basic emotions are anger, disgust, fear, happiness, sadness and surprise. Emotions are represented by facial expressions. When two emotions are mixed, facial expression is not produced with the average value. Each emotion is expressed separately in parts of face, and composite facial expressions are produced in a big picture [14]. Expressed parts in composite facial expressions are summarized in Table I. In several composite facial expressions, the expressed parts are exchangeable. For example, when fear and surprise are mixed, surprise can be expressed in a mouth and fear can be expressed in eyes, eye brows, and eye lids.

B. Fuzzy Measure and Fuzzy Integral

In this paper, Sugeno λ-fuzzy measure is used to reflect the relationship among emotions and the Choquet fuzzy integral is used to generate facial expressions. The fuzzy measure is defined in the following [15].

Definition 1: A fuzzy measure on the set X of symbols is a set function $g : P(X) \rightarrow [0,1]$ satisfying the following axioms;

i) $g(\varnothing) = 0, g(X) = 1$;

ii) $A \subset B \subset X$ implies $g(A) \leq g(B)$.

The Sugeno λ-fuzzy measure satisfies the following [16]:

$$g(A \cup B) = g(A) + g(B) + \lambda g(A)g(B). \tag{1}$$

TABLE II
Meaning of Fuzzy Measure

Fuzzy measure property	λ	ξ	Symbol relation
$g(A \cup B) > g(A) + g(B)$	$+\infty$	0	Negative correlation
	$\vdots$	$\vdots$	
$g(A \cup B) = g(A) + g(B)$	0	0.5	Independent
	$\vdots$	$\vdots$	
$g(A \cup B) < g(A) + g(B)$	-1	1	Positive correlation

In (1), g represents the fuzzy measure, λ represents the interaction degree, and ξ is a normalized value of λ. If λ is positive, $g(A \cup B) > g(A) + g(B)$, which means that $g(A \cup B)$ is overestimated and hence A and B have a negative correlation.

The Choquet fuzzy integral is defined in the following [17].

Definition 2: Let h be a mapping from finite set X to [0,1]. For $x_i \in X, i = 1, 2, \ldots, n$, assume $h(x_i) \leq h(x_{i+1})$ and $E_i = \{x_i, x_{i+1}, \ldots, x_n\}$. The Choquet fuzzy integral of h over X with respect to the fuzzy measure g is define as

$$\int_X h \circ g = \sum_{i=1}^{n} (h(x_i) - h(x_{i-1}))g(E_i), \; h(x_0) = 0. \tag{2}$$

In (2), fuzzy measure g should be calculated for all the power sets of X and partial evaluation values h are calculated from a predefined error function of the ideal basic emotion states and the current emotion state of a robot.

C. Diamond Pairwise Comparison

Six symbols are used because the number of human's basic emotions is six. Without fuzzy measure identification method, it is hard to identify $2^6 - 2 = 62$ fuzzy measures. Diamond pairwise comparison method is used to reflect the relationship among emotions [18]. Every two pair should be compared with the diamond pairwise comparison. In Fig. 1(a), one point in the diamond is marked. The Diamond can be translated to the coordinate axis on the right-hand side in Fig. 1(b) which X-axis represents sv_i and Y-axis represents I_{ij}. sv_i means the relative importance between two symbols. I_{ij} is the parameter to represent whether two symbols are positive relations or negative relations, which can be replaced with ξ_{ij}. ξ_{ij} is the normalized value and it can sufficiently express the relationship among emotions. The meaning of ξ is summarized in Table II. In this paper, ξ_{ij} is used instead of I_{ij}.

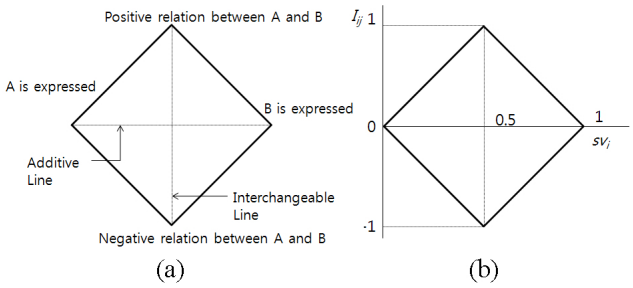

Fig. 1. Diamond pairwise comparison

$$sv_i + sv_j = 1, \; c_{ij} = sv_i / sv_j \tag{3}$$

c_{ij} is calculated from sv_i through (3). c_{ij} means the relative importance between two elements. If sv_i is more important, c_{ij} is greater than one and if sv_j is more important, c_{ij} is smaller than one. From C matrix in (4), the normalized eigenvector of maximum eigenvalue is the weight vector on each symbol. It will be changed by combining with information about relationship among emotions. Based on Table I, face consist of four parts, i.e. eye lids and eye brows, mouth and jaw, eyes, and neck. Each part has different weight so that there are four C matrices and four weight vectors.

$$C = \begin{pmatrix} c_{11} & c_{12} & \cdots & c_{16} \\ c_{21} & c_{22} & \cdots & c_{26} \\ \vdots & \vdots & \ddots & \vdots \\ c_{61} & c_{62} & \cdots & c_{66} \end{pmatrix} \tag{4}$$

D. Hierarchical Structure

A dissimilarity graph is obtained from the interaction degrees ξ_{ij}. Two closest clusters in the dissimilarity graph are merged through a step-by-step process until only one

TABLE I
EXPRESSED PARTS IN COMPOSITE FACIAL EXPRESSIONS

Emotion	expressed part	Emotion	expressed part
Anger	eyes, eye brows, eye lids	Disgust	mouth
Anger	eyes, eye brows, eye lids	Fear	mouth
Anger	eyes, eye brows, upper eye lids	Happiness	mouth, lower eye lids
Anger	eyes, eye brows, eye lids	Sadness	mouth
Anger	eyes, eye brows, eye lids	Surprise	mouth
Disgust	eyes, eye brows, upper eye lids	Fear	mouth, lower eye lids
Disgust	eyes, eye brows, eye lids	Happiness	mouth
Disgust	eyes, eye brows, upper eye lids	Sadness	mouth, lower eye lids
Disgust	eyes, eye brows, upper eye lids	Surprise	mouth, lower eye lids
Fear	eyes, eye brows, upper eye lids	Happiness	mouth, lower eye lids
Fear	mouth	Sadness	eyes, eye brows, eye lids
Fear	mouth	Surprise	eyes, eye brows, eye lids
Happiness	mouth	Sadness	eyes, eye brows, eye lids
Happiness	mouth	Surprise	eyes, eye brows, eye lids
Sadness	mouth	Surprise	eyes, eye brows, eye lids

cluster remains. Dissimilarity between two clusters, G_p and G_q, means the average distance in difference to the others except G_p and G_q, which is calculated as follows:

$$D_{G_p,G_q} = \frac{\Sigma_{G_r \in \mathfrak{G}, G_r \neq G_p, G_r \neq G_q} [\xi_{G_p,G_r} - \xi_{G_q,G_r}]^2}{|\mathfrak{G}| - 2} \quad (5)$$

where $\mathfrak{G}$ is the set of all clusters and $|\mathfrak{G}|$ is the number of clusters in that stage. If the difference of dissimilarity is smaller than a certain threshold, more than three symbols can be merged at the same time. Large threshold will generate a simplified hierarchical structure and small threshold will generate a complex but accurate hierarchical structure. Note that 0.1 is used as a threshold in this paper. The interaction degree graph from ξ_{ij} is shown in Fig. 2 and the dissimilarity graph from the interaction degree graph is shown in Fig. 3.

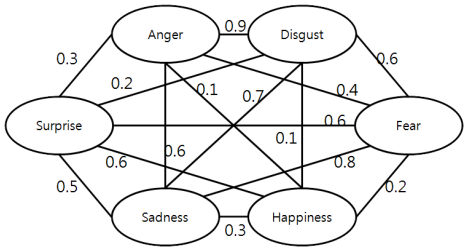

Fig. 2. Interaction degree graph

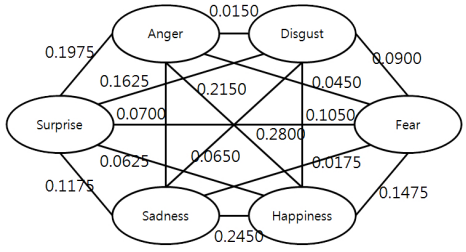

Fig. 3. Dissimilarity graph

In Fig. 4, the hierarchical structure from the dissimilarity graph and the four weight vectors from pairwise comparison matrices C are combined to produce the fuzzy measures of all sets.

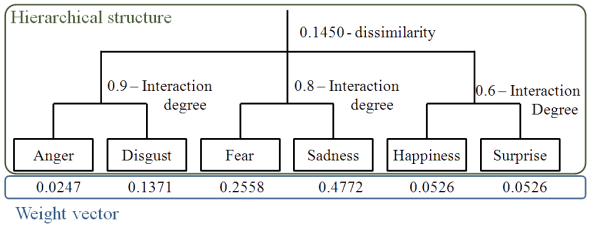

Fig. 4. A hierarchical structure

E. Fuzzy Measure Identification

ϕ_s transformation is used to get fuzzy measures $g(A)$. ϕ_s transformation is defined as follows [19]:

$$\phi_s : [0,1] \times [0,1] \rightarrow [0,1] \quad (6)$$

$$\phi_s(\xi, u) = \begin{cases} 1 & \text{if } \xi = 1 \text{ and } u > 0 \\ 0 & \text{if } \xi = 1 \text{ and } u = 0 \\ 1 & \text{if } \xi = 0 \text{ and } u = 1 \\ 0 & \text{if } \xi = 0 \text{ and } u < 1 \\ \frac{s^u - 1}{s - 1} & \text{other cases} \end{cases} \quad (7)$$

where $s = \frac{(1-\xi)^2}{\xi^2}$. Fuzzy measure $g(A)$, where $A \subset X$, is calculated as follows:

$$g(A) = \phi_s(\xi_R, \sum_{B \subset R} u_B^R) \quad (8)$$

where R means root level set and ξ_R is the dissimilarity degree in root level and B is upper level set. Weights in upper level are calculated as follows:

$$u_C^B = \begin{cases} w_i & \text{if } |C| = 1 \text{ and } i \in A \\ 0 & \text{if } |C| = 1 \text{ and } i \notin A \\ \phi_s^{-1}(\xi_B, \phi_s(\xi_C, \sum_{D \subset C} u_D^C) \times T_C^B) & \text{other cases} \end{cases} \quad (9)$$

where $w_i, i \in C$, is the weight in lower level and $\phi_s^{-1}(\xi, u)$ is the inverse function of $\phi_s(\xi, r)$. Weights in lower level should be changed to weights in upper level. In this paper, the hierarchical structure has only two levels so that ξ_C is an interaction degree in a lower level and ξ_B is a dissimilarity degree in an upper level. T_C^B is a conversion ratio from lower-level to upper-level which is defined as follows:

$$T_C^B = \frac{\phi_s(\xi_B, \sum_{D \in C} w_D^C)}{\phi_s(\xi_C, \sum_{D \in C} w_D^C)} \tag{10}$$

where

$$u_C^B = \begin{cases} w_i & \text{if } |C| = 1 \\ \sum_{D \in C} w_D^C & \text{other cases} \end{cases} \tag{11}$$

where $w_i, i \in C$, is a weight from pairwise comparison matrix C.

F. Partial Evaluation

Partial evaluation values are obtained from the emotion state of robot. Let the current emotion state vector $X = [x_1; x_2; \ldots; x_6]^T$, where each of $x_i, i = 1, 2, \ldots, 6$ is between 0 and 1. The emotion state is represented by six parameters and each parameter represents each emotion, i.e. $x_1, x_2, \ldots, x_6$ means anger, disgust, fear, happiness, sadness, and surprise, respectively.

Let $S_i = \{s_{i1}; s_{i2}; \ldots; s_{i6}\}^T, i = 1, 2, \ldots, 6$ be the ideal emotion state vector. The ideal emotion state means that the corresponding emotion is fully activated. Ideal emotion states parameter $s_{ij}, i = 1, 2, \ldots, 6$ and $j = 1, 2, \ldots, 6$ is calculated as follows:

$$s_{ij} = \begin{cases} 0 & \text{if } i \neq j \\ 1 & \text{if } i = j. \end{cases} \tag{12}$$

For example, anger is fully activated when emotion state is $S_1 = \{1; 0; 0; 0; 0; 0\}^T$. Current emotion state should be close to S_i to activate i-th emotion. $E = \{E_1; E_2; \ldots; E_6\}$ is a distance matrix containing the every distance from current emotion state vector to the ideal emotion state vectors, which is calculated as follows:

$$\begin{pmatrix} E_1 \\ E_2 \\ \vdots \\ E_5 \\ E_6 \end{pmatrix} = \begin{pmatrix} I - |S_1 - X| \\ I - |S_2 - X| \\ \vdots \\ I - |S_5 - X| \\ I - |S_6 - X| \end{pmatrix} \tag{13}$$

where $E_i = \{e_{i1}; e_{i2}; \ldots; e_{i6}\}^T$ is a size six matrix and $I = \{1; 1; 1; 1; 1; 1\}^T$.

Each e_{ij} has a different importance in E_i. For example, when anger expression is generated, anger parameter is more important than other parameters. Therefore, e_{ii} is multiplied to E_i to get partial evaluation vector H_i such that $H = \{H_1; H_2; \ldots; H_6\}$ is a calculated as follows:

$$\begin{pmatrix} H_1 \\ H_2 \\ \vdots \\ H_5 \\ H_6 \end{pmatrix} = \begin{pmatrix} e_{11} \times E_1 \\ e_{22} \times E_2 \\ \vdots \\ e_{55} \times E_5 \\ e_{66} \times E_6 \end{pmatrix} \tag{14}$$

where $H_i = \{h_{i1}; h_{i2}; \ldots; h_{i6}\}^T$ is a size six matrix. Every H_i and fuzzy measures from Fig. 4 are globally integrated by the Choquet integral. Each $H_i, i = 1, 2, \ldots, 6$ is evaluated and the largest output of the Choquet integral is selected with the Choquet integral output.

III. Simulation and Experimental Results

A. Parameter Setting

People see the relationship among emotions differently. 20 subjects were asked to fill out the interaction degree graphs. 20 types of hierarchical structures were produced and 5 subjects generated the same type of hierarchical structure as shown in Fig. 4, which was used in this experiment.

Based on Table I, pairwise comparison matrix C was produced. If i-th emotion was more important than j-th emotion, six times of relative weight was assigned to sv_i. Weight vectors in each part were shown in Table III.

TABLE III
Weight vectors on each part

	Mouth and jaw	Eye lids and eye brows	Eyes	Neck
Anger	0.0247	0.4771	0.2547	0.1666
Disgust	0.1371	0.0860	0.2069	0.1666
Fear	0.2558	0.0461	0.1059	0.1666
Happiness	0.4772	0.0247	0.2058	0.1666
Sadness	0.0526	0.1831	0.1569	0.1666
Surprise	0.0526	0.1831	0.0702	0.1666

B. Robotic Head

Robotic head's width, height, length, weight are 16cm, 26cm, 25cm, and 2.85kg, respectively. It can receive three-dimensional images through a stereo camera. Facial movements are controlled by 15 servo motors and neck's movements are controlled by 4 DC motors. Thus, it has 19 degrees of freedom. Three servo motors move jaw left and right, up and down, forward and backward. Four servo motors can push and pull the end of upper lip and lower lip. Two servo motors can move the eyes left and right, up and down. Four servo motors control the eye brows left and right, up and down, and two servo motors control the eye lids up and down. Neck is controlled by four DC motors. To sustain strong torque, harmonic drives are also used together with the DC motors. Each of the three DC motors rotates the head along the yaw, pitch and roll axes, respectively and the last one is to add one more degree of freedom to the pitch axis for nodding. Note that robotic head's movements are designed based on the facial action coding system (FACS) [20]. Normally, to maximize degrees of freedom, many robotic heads contains only mechanical structure in robotic heads and other modules

such as control module and motor module are placed near the robotic heads. Lots of wires are used to convey motors force from motor module to mechanical structure. However, the robotic head used in this experiment is designed to contain every module in its head. Thus, it does not have many degrees of freedom. However, it has good expandability.

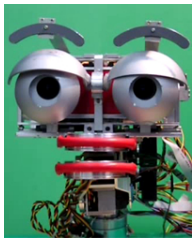

Fig. 5. Robotic head

The robotic head is controlled by digital signal processors (DSP) and electrically programmable logic devices (EPLD). Because DSP does not have enough counters, it is supported by EPLD to count the encoder's output.

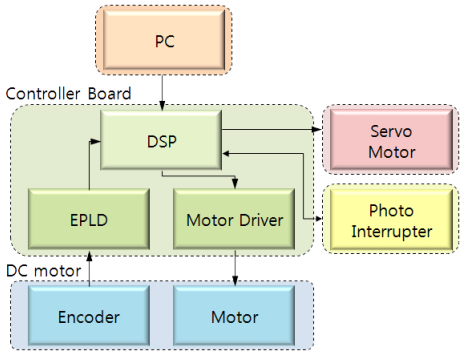

Fig. 6. Control circuit diagram

C. Simulation Results

Initial emotion state was set as $\{Anger, Disgust, Fear, Surprise, Sadness, Surprise\} = \{x_1, 0.09, 0.14, 0.10, 0.11, 0.65\}$ and the anger parameter x_1 was increased from zero to one to observe the variation of the composite facial expression. In the initial state, surprise was dominant.

In Fig. 7, X-axis is for the anger parameter and Y1-axis is for the normalized motor output value and Y2-axis shows the selected emotion. When the anger parameter was zero, surprise was selected in all the four parts because the surprise parameter value was much larger than the other parameter values. As the anger parameter value was increased, surprise was still selected in some initial time period but the normalized motor output value was decreased because the anger parameter moved far from zero to one. When the anger parameter value was continuously increased, eye brows and eye lids chose anger even though its value was smaller than that of the surprise parameter. When the anger parameter value was the same as the surprise parameter value, mouth, jaw and neck expressed

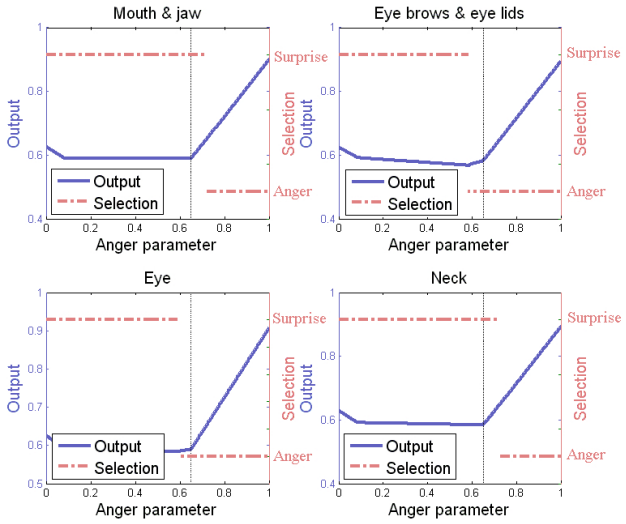

Fig. 7. Transition from surprise to anger

surprise and eyes, eye brows and eye lids expressed anger. Thus, the composite facial expression was generated. If the anger parameter value was increased more, all the four parts selected anger and the output became much larger. However, since the emotion state vector in this simulation could not be the ideal emotion state vector of anger S_1, the output could not reach the maximum value. Note that similar result for generating various composite facial expressions could be obtained for the other case, for example, by increasing the disgust parameter value when the anger was dominant.

D. Experiments

Ekman's six basic emotions were generated and shown to 12 subjects. Facial expressions were generated by random order and subjects who had not seen the robotic head before were surveyed. The result was shown in Table IV.

TABLE IV
A SURVEY ON BASIC EXPRESSIONS

	Correct	Wrong	Percentage
Anger	9	3	75%
Disgust	9	3	75%
Fear	10	2	83%
Happiness	12	0	100%
Sadness	12	0	100%
Surprise	12	0	100%

As the Table IV shows, most of people could distinguish every basic facial expression except anger and disgust. These two emotions were quite similar that some subjects got confused in distinguishing them.

Fifteen composite facial expressions were generated by random order and shown to 10 subjects. The result was shown in Table V. People could not easily distinguish composite facial expressions. The reason was that some composite facial expressions were not familiar and hard to be identified. For example, being disgust and happiness together was unlikely generated in

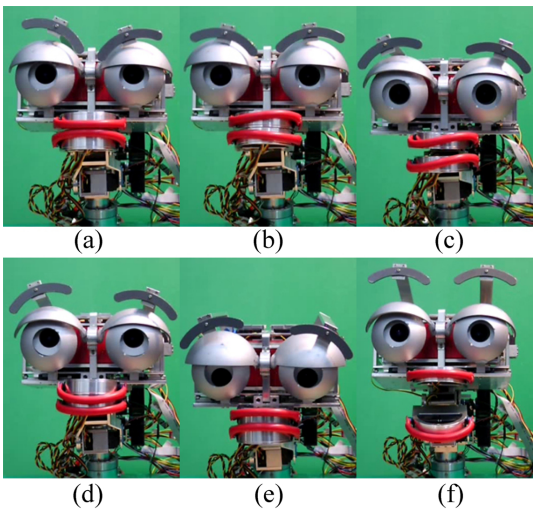

Fig. 8. Six basic emotions. (a) Angry (b) Disgust (c) Fear (d) Happiness (e) Sadness (f) Surprise

a normal life. Even if this facial expression was well generated, subjects could not easily recognize it. However, most subjects could identify familiar composite facial expressions easily, i.e. anger and disgust, happiness and surprise, etc.

TABLE V
A SURVEY ON COMPOSITE FACIAL EXPRESSIONS

	Anger	Disgust	Fear	Happiness	Sadness
Anger	x	x	x	x	x
Disgust	8	x	x	x	x
Fear	5	2	x	x	x
Happiness	5	3	2	x	x
Sadness	9	4	4	6	x
Surprise	4	7	3	9	4

Other reason was that some facial movements could not be generated by the developed robotic head. Happiness was mainly expressed by stretching a mouth and naso-labial folds. Robotic head did not have wrinkles so that it could not produce some facial movements. This point made subjects hard to identify the generated facial expressions. Easily and hardly recognizable facial expressions by the subjects are shown in Fig. 9 and Fig. 10, respectively.

Among the composite facial expressions, several familiar composite facial expressions were generated by the linear interpolation method and showed to 10 subjects. Only facial expressions with easily recognizable were generated because it is not important to generate facial expressions with unlikely produced in normal life. Table VI shows the result of comparison. The percentage of correct answers of linear interpolation method was lower than that of fuzzy integral-based method. Because characteristics of each emotion were disappeared by the linear interpolation, fewer people could recognize them.

Fig. 11 shows the composite facial expressions generated by the linear interpolation method. The linear interpolation method could generate continuous facial expressions transitions. However, it could not express the characteristics of each

TABLE VI
A COMPARISON WITH LINEAR INTERPOLATION METHOD AND FUZZY INTEGRAL-BASED METHOD

Facial expression	Anger and disgust	Anger and sadness	Happiness and surprise
Linear interpolation	6	5	5
Fuzzy integral-based	8	9	9

emotion in composite facial expressions. Thus, compared to Fig. 9(b) and Fig. 10(b), it become more difficult to identify which emotions are expressed in composite facial expressions.

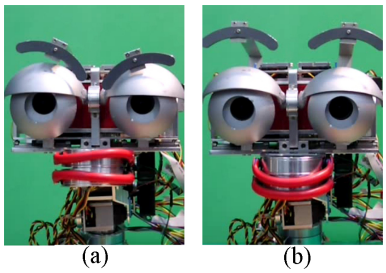

Fig. 9. Easily recognizable expressions. (a) Anger and disgust (b) Happiness and surprise

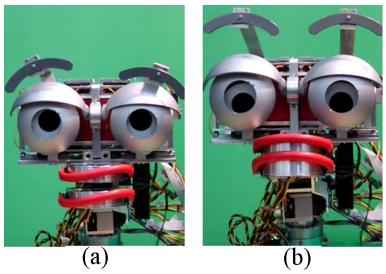

Fig. 10. Hardly recognizable expressions. (a) Happiness and fear (b) Surprise and sadness

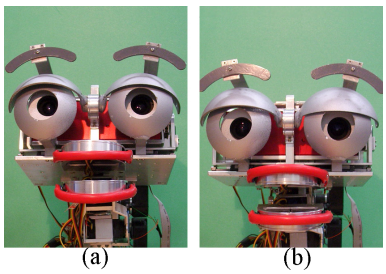

Fig. 11. Facial expressions from linear interpolation method. (a) Happiness and surprise (b) Surprise and sadness

IV. CONCLUSION

In this paper, a fuzzy integral-based generation method of composite facial expressions was proposed and demonstrated its effectiveness through the experiment with the developed robotic head. Fuzzy measures reflected the relationship among

emotions and the partial evaluation of current emotion state was obtained from a predefined error function. The Choquet fuzzy integral of the partial evaluation with respect to fuzzy measures was employed for generating composite facial expressions by separately actuating the parts of a robotic face. Experimental results showed that basic facial expressions were successfully generated and identified by the subjects. Composite facial expressions were also generated and some of them were hard to be identified, however, some familiar facial expressions were easily identified. It also showed that people could easily recognize the composite facial expressions generated by fuzzy integral-based method.

In future research, one microphone and one speaker will be added to the robotic head. Proper sound will be produced with the generation of facial expressions. Then people can recognize robot's facial expressions easily with sound.

***Abstract*—Previously, we presented a method for comparing soft partitions (i.e. crisp, probabilistic, fuzzy and possibilistic) to a known crisp reference partition. Many of the classical indices that have been used with outputs of crisp clustering algorithms were generalized so that they are applicable for candidate partitions of any type. In particular, focus was placed on generalizations of the Rand index. In this article, we extend our prior work by (1) investigating the behavior of the soft Rand for comparing non-crisp, specifically possibilistic, partitions and (2) we demonstrate how the possibilistic Rand and visual assessment of (cluster) tendency (VAT) algorithm can be used to discover the number of actual clusters and coincident clusters for outputs from the possibilistic c-means (PCM) algorithm.**

Keywords; cluster validity; possibilistic Rand index; comparing soft partitions; cluster correspondence.

I. INTRODUCTION

Let $O = \{o_1,\ldots,o_n\}$ denote n objects. When each object in O is represented by a (column) vector $\mathbf{x}$, the set $X = \{\mathbf{x}_1,\ldots,\mathbf{x}_n\} \subset \Re^p$ is an *object data representation* of O. When each object in $o_i \in O$ has a *physical label*, O is a set of *labeled data*; otherwise, O is unlabeled. Let integer c denote the number of classes, $1 < c < n$. Clustering in unlabeled data is the assignment of one of four types of labels to each object in O. The label vectors of the objects are the columns of c-partitions of O, which are sets of (cn) values $\{u_{ik}\}$ that can be conveniently arrayed as $(c \times n)$ matrices, say $U = [u_{ik}]$. The three sets are:

$$M_{pcn} = \left\{ U \in \Re^{cn} : u_{ik} \in [0,1] \forall\, i,k;\ 0 < \sum_{k=1}^{n} u_{ik}\ \forall\, i \right\}, \quad (1a)$$

$$M_{fcn} = \left\{ U \in M_{pcn} : \sum_{i=1}^{c} u_{ik} = 1 \forall\, k \right\}, \quad (1b)$$

$$M_{hcn} = \left\{ U \in M_{fcn} : u_{ik} \in \{0,1\} \forall i,k \right\}, \quad (1c)$$

where M_{pcn} (1a) are possibilistic c-partitions, M_{fcn} (1b) are fuzzy or probabilistic c-partitions, and M_{hcn} (1c) are crisp or hard c-partitions. It is convenient to have a single name for the set M_{pcn}-M_{hcn}, which contains the fuzzy, probabilistic, and possibilistic c-partitions of O. We call M_{pcn}-M_{hcn} the *soft c-partitions* of O.

Clustering algorithms map $X \subset \Re^p \mapsto M_{pcn}$. Let $CP = \{U_i: 1 \le i \le N\}$ denote N different *candidate partitions* of a fixed object set O that may arise as a result of clustering X with one algorithm at various values of its parameters; or more generally, with different algorithms, each with its own parameters. Which $U \in CP$ best explains and represents the (unknown) structure in O? In [1,2], we introduced one way to answer this question through the use of a *comparison index,* s(U,V). Applications of our prior approach include:

A1. s(U,V): V $(r \times n)$ is a *reference partition* that purports to represent the "true cluster structure" in O. s(U,V) measures the extent to which U's in CP recover or retrieve the true clusters in O, and hence, the sizes of U and V are equal. Retrieval rates are called *resubstitution error rates* when U and V are crisp, r = c, and s is a measure that counts matches between the columns in U and V.

A2. s(U,U'): U is a partition of O found with clustering algorithm A. Perturb each $\mathbf{x}_k$ or r_{ij} with zero mean, unit variance noise, and obtain U', a clustering of the perturbed data. s(U, U') measures the sensitivity of A to perturbations of the data.

A3. s(U,U'): U, U' are partitions of O found with clustering algorithms A and A'. s(U, U') measures the agreement between the two algorithms about clusters in O.

A4. s(U,U'): U, U' are partitions of O found by successive iterations of clustering algorithms. s(U, U') measures the change in similarity due to the next iteration, and hence, can be used as a stopping criterion for iterative methods.

A5. s(U,V): Prediction of V given U, or U given V (regression).

In [1,2], our experiments focused on A1. We <u>never</u> have an external reference partition in a real clustering situation which, by definition, involves unlabeled data. So, why do this at all? Well, the only way you can evaluate *any* clustering algorithm before using it in a real situation is to see how well it recovers "true but unknown" reference partitions. If nothing else, good recovery rates on data with "known" cluster structure at least provide some psychological reassurance that the clustering algorithm *can* sometimes recover "good clusters".

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

In this article, we extend our prior work by exploring the behavior of the soft Rand for comparing non-crisp, specifically possibilistic, partitions. We also demonstrate how the possibilistic Rand index and visual assessment of (cluster) tendency (VAT) algorithm can be coupled in order to estimate the number of clusters and identify coincident clusters found by the possibilistic c-means (PCM) algorithm [3,4]. This work supports the claim [4] that coincident clusters found by PCM can be advantageous. We demonstrate that by over specifying the number of clusters, one can address important different clustering tasks.

II. BACKGROUND

A. Prior Work

Let $U \in M_{hm}$ and $V \in M_{hcn}$ be crisp partitions of O. U and V need not possess the same number of clusters. The four classical combinations for pairs of objects from $O \times O$ in clusters of U and V are: (i) paired in U and V; (ii) not paired in U nor in V; (iii) paired in V but not in U; and (iv) paired in U but not in V [5]. The comparison of U to V with a similarity measure s begins with the $r \times c$ contingency matrix $N = UV^T$ shown in Table 1 that contains counts of the number of occurrences of each of the four types over the n(n-1)/2 distinct, unordered pairs in $O \times O$. Entry n_{ij} is the number of objects common to classes U_i and V_j.

Table 1. The contingency matrix N.

		Partition V (V_j = row j of V)				
	Class	V_1	V_2	…	V_c	Sums
Partition U (U_i = row i of U)	U_1	n_{11}	n_{12}	…	n_{1c}	$n_{1\bullet}$
	U_2	n_{21}	n_{22}	…	n_{2c}	$n_{2\bullet}$
	⋮	⋮	⋮		⋮	⋮
	U_r	n_{r1}	n_{r2}	…	n_{rc}	$n_{r\bullet}$
	Sums	$n_{\bullet 1}$	$n_{\bullet 2}$	…	$n_{\bullet c}$	$n_{\bullet\bullet} = n$

The building blocks of many similarity measures for s(U,V) are the four equations (2a)-(2d). These four equations simply count the number of occurrences among the n(n-1)/2 pairs of each of the four types of unordered pairs.

$$a = \frac{1}{2}\sum_{i=1}^{r}\sum_{j=1}^{c} n_{ij}(n_{ij}-1) \tag{2a}$$

$$b = \frac{1}{2}\left(\sum_{j=1}^{c} n_{\bullet j}^2 - \sum_{i=1}^{r}\sum_{j=1}^{c} n_{ij}^2\right) \tag{2b}$$

$$c = \frac{1}{2}\left(\sum_{i=1}^{r} n_{i\bullet}^2 - \sum_{i=1}^{r}\sum_{j=1}^{c} n_{ij}^2\right) \tag{2c}$$

$$d = \frac{1}{2}\left(n^2 + \sum_{i=1}^{r}\sum_{j=1}^{c} n_{ij}^2 - \left(\sum_{i=1}^{r} n_{i\bullet}^2 + \sum_{j=1}^{c} n_{\bullet j}^2\right)\right) \tag{2d}$$

Formula (2a) is the number paired in U and V, formula (2d) is the number paired in neither U nor V, formula (2b) is the number paired in V, not U, and formula (2c) is the number paired in U, not V.

The sums (a+d) and (b+c) are usually interpreted, respectively, as (the total number of) agreements and disagreements between U and V. In [1], we tabulate a [non-exhaustive] list of 14 coefficients that have been proposed for s(U,V) based on functions of a, b, c and d; Sokal and Sneath [6] list many others. In this note, the only index we consider is Rand's index [7], the classical form of which is

$$s_r(U,V) = (a+d)/(a+b+c+d). \tag{3}$$

B. Generalizing $s_r(U,V)$ when U and/or V are soft partitions

Rand's index first appeared in Sokal and Michener in 1958, where it was called a simple matching coefficient [8]. Rand reintroduced this function in 1971 [7], and the literature has consistently referred to it as "Rand's Index" since then. The resurgence of Rand's index in bioinformatics [9-12] has renewed interest in generalizing it, along with some of the other comparison indices based on the elements in Table 1, to various non-crisp cases. Specifically, we mention the papers (in chronological order) of Campello [13], Frigui et al. [14], Brower [15], Hullermeier and Rifqi [16], and Anderson et al. [1,2]. All of these papers generalize the Rand index to the case of U and/or V being fuzzy partitions of the n objects.

In [1,2], we provide generalizations for 14 comparison indices. It begins with the construction of the contingency matrix as $N = UV^T$. We showed that a modification is needed to accommodate the case when U and/or V are possibilistic. In the possibilistic case, we can have

$$\sum_{i=1}^{r} n_{i\bullet} > n, \text{ or } \sum_{j=1}^{c} n_{\bullet j} > n. \tag{4}$$

One or both of the terms $\sum_{i=1}^{r} n_{i\bullet}^2$ and $\sum_{j=1}^{c} n_{\bullet j}^2$ can make d in (2d) relatively large and negative. Depending on b in (2b) and c in (2c), the (soft) Rand index can result in $s_r(U,V) < 0$ or > 1. To remedy this, we scale N with

$$\phi = n/\sum_{i=1}^{r} n_{i\bullet} \tag{5}$$

or

$$\varphi = n/\sum_{j=1}^{c} n_{\bullet j}. \tag{6}$$

Since

$$\sum_{i=1}^{r} n_{i\bullet} = \sum_{j=1}^{c} n_{\bullet j}, \tag{7}$$

$\varphi = \phi$. Our normalized generalization [1] is

$$s_{r*}(U,V) = N^* = \phi UV^T = [n/\sum_{i=1}^{r} n_{i\bullet}]UV^T. \tag{8}$$

An advantage of this scaling is that when U and V are crisp, fuzzy or probabilistic partitions, ϕ=1, thus $N^* = N = UV^T$. This

shows that *ANY* index based on only the elements of Table 1 will reduce to the original index when U and V are both crisp partitions of the n objects; and otherwise, they will be valid soft generalizations of those indices. Moreover, for possibilistic partitions, the normalization produces index values in [0,1].

III. Comparing Non-Crisp Partitions

In [1,2], we explored A1, which measures the extent to which U's in CP recover or retrieve the true clusters in O. Our initial experiments did not contain any analysis of non-crisp to non-crisp partition comparison. In this section, we demonstrate non-crisp experiments, specifically for case A3, using the fuzzy c-means (FCM) algorithm [17] and the PCM [3,4]. We discuss the behavior of the measure.

Candidate fuzzy partitions are generated by the FCM using the *fcm* function from the MATLAB Fuzzy Logic Toolbox with the fuzzifier q = 2, maximum number of iterations MAXIT = 100, objective function error EPS = 1e-5 and random partition initialization. The PCM partitions are generated using our MATLAB implementation of the algorithm with the fuzzifier q = 2, MAXIT = 100, EPS = 0.001 and a FCM-based initialization. As discussed by Krishnapuram and Keller in [3,4], we re-estimated the parameters η_i (i.e. the value that determines the distance at which the membership value of a point in a cluster becomes 0.5) for each cluster at every iteration. The data sets are made up of different numbers of Gaussian clouds. The number of clouds and their parameters are provided with the discussion for each data set.

Example 1. Our analysis begins with data set 1 (D1), the scatterplot of which is shown in the uppermost view in figure 1. The images of the partition matrices shown in figure 1 are color coded, using a jet colormap, to assist visual interpretation. The value displayed, [0,1], ranges from blue to red, and passes through the colors cyan, yellow, and orange.

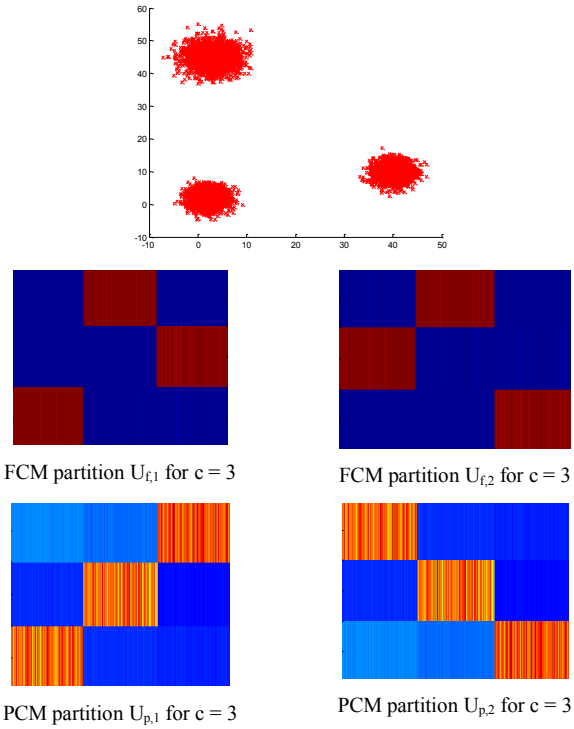
FCM is applied twice to D1 using different random initializations at c = 3, resulting in the terminal partitions $U_{f,1}$ and $U_{f,2}$. The images of these two fuzzy partitions in the middle views of figure 1 suggest that $U_{f,1} = U_{f,2}$, up to a relabeling (the data points are sorted by cluster to aid visual analysis, which is possible because we synthetically generated X). And this is the case. Putting U = V equation (8) we have

$$U = V \Rightarrow s_{r*}(U,U) = s_{r*}(V,V) = s_{r*}(U,V) \qquad (9)$$

In view of this, it is not surprising to find that $s_{r*}(U_{f,1},U_{f,1}) = s_{r*}(U_{f,2},U_{f,2}) = s_{r*}(U_{f,1},U_{f,2}) = 0.97$. The converse, which would be a useful result, does not follow. That is, we cannot conclude from $s_{r*}(U_{f,1},U_{f,1}) = s_{r*}(U_{f,2},U_{f,2}) = s_{r*}(U_{f,1},U_{f,2})$ that U = V.

Next, the PCM is applied twice with different random initializations and c = 3 ($U_{p,1}$ and $U_{p,2}$). The two partition matrices are shown in the bottom view of figure 1. We find $s_{r*}(U_{p,1},U_{p,1}) = s_{r*}(U_{p,2},U_{p,2}) = s_{r*}(U_{p,1},U_{p,2}) = 0.59$. We will explain why s_{r*} is considerably less than 1 after the next example.

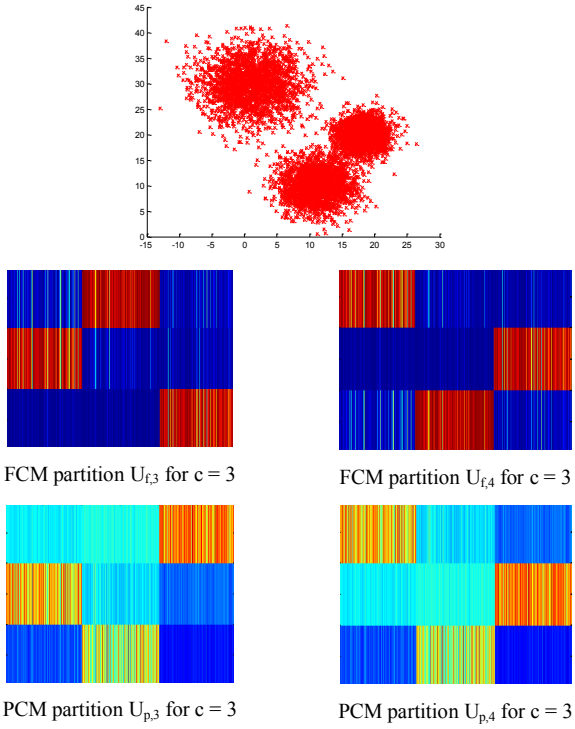
Example 2. Data set 2 (D2) is shown in figure 2. The main difference between D2 and D1 is that clusters in D1 are visually more compact and well separated. FCM and PCM are



FCM partition $U_{f,1}$ for c = 3 — FCM partition $U_{f,2}$ for c = 3

PCM partition $U_{p,1}$ for c = 3 — PCM partition $U_{p,2}$ for c = 3

Fig. 1. Data set 1 (D1) and corresponding FCM and PCM partitions. D1 is made up of three Gaussian clouds, each with 2000 samples, means of $[2\ 2]^T$, $[40\ 10]^T$, $[3\ 45]^T$ and standard deviations of 2, 2 and 3 respectively. The four candidate partitions are shown in order to visually compare and contrast D1 to data set 2 (D2), figure 2.



FCM partition $U_{f,3}$ for c = 3 — FCM partition $U_{f,4}$ for c = 3

PCM partition $U_{p,3}$ for c = 3 — PCM partition $U_{p,4}$ for c = 3

Fig. 2. Data set 2 (D2) and corresponding FCM and PCM partitions. D2 is made up of three Gaussian clouds, each with 2000 samples, means of $[10\ 10]^T$, $[18\ 20]^T$, $[1\ 30]^T$ and standard deviations of 3, 2 and 4 respectively.

each applied twice with random initialization for FCM (and hence, equal initializations for PCM) with c = 3. The images of the four terminal partitions discovered by these two algorithms again suggest that the fuzzy partitions are equal, and the PCM partitions are equal, and they are. Thus, in accordance with (9), $s_{r*}(U_{f,3},U_{f,4}) = s_{r*}(U_{f,3},U_{f,3}) = s_{r*}(U_{f,4},U_{f,4}) = 0.80$; and $s_{r*}(U_{p,3},U_{p,4}) = s_{r*}(U_{p,3},U_{p,3}) = s_{r*}(U_{p,4}, U_{p,4}) = 0.57$.

Examples 1 and 2 suggest that the *softer* the partition, the lower the $s_{r*}(U,V)$ value. For crisp partitions, Rand proved [7] that $s_r(U,U) = 1$, thus $s(V,V) = 1$ and $0 \le s(U,V) \le 1$. Entry n_{ij} in the contingency matrix is the number of objects common to clusters U_i and V_j. We calculated it as follows:

$$n_{ij} = \sum_{k=1}^{n} \left(U_{i,k} * V_{j,k} \right). \qquad (10)$$

If the partitions are crisp, then $U_{i,k} * V_{j,k}$ is in {0,1}, i.e. a value of 1 when the k^{th} data point belongs to the i^{th} cluster in U and the j^{th} cluster in V. When the values $U_{i,k}$ and $V_{j,k}$ are fuzzy and in particular less than 1, the membership values result in even smaller products. Our formulation of the contingency matrix leads to interesting behavior for the four counting formulae, (2a)-(2d), as well as the Rand ratio (a+d)/(a+b+c+d). The most interesting component is the effect on equations (2b) and (2c), i.e. the disagreements.

In order for the Rand to obtain a value of 1, the disagreement cases (2b) and (2c) must be zero. However, from equation (10), we see that as the partitions become *softer*, the support in agreements decreases and evidence in disagreements rises. This means that the Rand ratio will decrease because the value (2b)+(2c) is increasing. This is what we observe for FCM in D1 for U1 and U2 and in D2 for U5 and U6. In D1, the (2a)-(2d) values are: a=5747176, b=249975, c=249975 and d=11749871. In D2, we find that a=4039502, b=1997238, c=1997242 and d=9963017. What we observe is that the (2a) and (2d) values are less for D2 versus D1 (where D2 produces softer partitions than those for D1). We also notice that the (2b) and (2c) values are higher for D2 versus D1, making the ratio (a+d)/(b+c), i.e. (agreements)/(disagreements), for D1 (a+d)/(b+c) = 35 and (a+d)/(b+c) = 3.51 for D2.

The following normalization is proposed in order to address this behavior,

$$s'_{r*}(U,V) = s_{r*}(U,V) / \max(s_{r*}(U,U) , s_{r*}(V,V)) \qquad (11)$$

This normalization is proposed because $0 \le s_{r*}(U,V) \le \max(s_{r*}(U,U), s_{r*}(V,V))$. In the case of a crisp U or V, the normalization is 1 and the scaling reduces to Rand's result.

IV. Visual Assesment of (Cluster) Tendency

The problem of determining whether clusters are present as a step prior to *actual* clustering is called assessment of cluster tendency (algorithm 1).

The visual assessment of (cluster) tendency (VAT) algorithm [18] can be used to help discover if there are clusters in a given data set. The basic concept behind VAT (algorithm 1) is that objects are reordered and the reordered matrix of pair-wise object dissimilarities is displayed as an intensity image.

Algorithm 1: *Visual Assessment of (Cluster) Tendency (VAT)*

0. Input: An nxn matrix of dissimilarities $[R_{pq}]$

1. Set K = {1,2,…,n} ; I = J = Ø; P[0] = (0, …, 0).

2. Select $(i,j) \in \underset{p \in K, q \in K}{\arg\max} \{R_{pq}\}$.

   Set P(1) = i; I = {i}; and J = K – {i}.

3. For r=2,…,n:

   Select $(i,j) \in \underset{p \in I, q \in J}{\arg\min} \{R_{pq}\}$.

   Set P(r) = j;

   Replace $I \leftarrow I \cup \{j\}$ and $J \leftarrow J - \{j\}$.

   Next r.

4. Obtain the ordered dissimilarity matrix $\tilde{R}$ using the ordering array P as: $\tilde{R} = R_{P(i)P(j)}$, for $1 \le i,j \le n$.

5. Display the reordered matrix $\tilde{R}$.

Clusters may be indicated by dark blocks of pixels along the matrix diagonal. While VAT is used herein for analysis, clustering in ordered dissimilarity data (CLODD [19] and p-specVAT [20]) can be used to address the partitioning and validity questions by automatically creating partitions from the VAT image and providing a validity measure of each partition. In algorithm 1, R_{pq} is the dissimilarity of objects p and q and the vector P is the permuted indices of the n objects.

V. Comparing Possibilistic Partitions

In [21], Barni et al. remarked that the PCM has the undesirable tendency to produce coincidental clusters. In [4], Keller and Krishnapuram responded by providing additional insight into the inner workings of the PCM. In particular, they explained both the importance and behavior of the scaling parameters, η_i, and the fuzzifier, q. They also discussed how PCM can find c good clusters from a data set that may have more than c clusters. On the other hand, if the data set has less than c clusters, PCM can still potentially find c good clusters, some of which may be identical. However, how does one algorithmically discover the number of clusters in O as well as say that two clusters are equal?

Discovering the number of actual clusters. It is sometimes helpful to categorize clustering into three different tasks. In the previous section, the problem of *assessing cluster tendency* was briefly discussed. The FCM and PCM algorithms are examples of the second class of clustering problems, *actual clustering*. The third class is *cluster validity*. First, we may use a validity index, v(U), e.g. Dunn's index [22] or the Davies-Bouldin's index [23]. One generally varies an algorithm parameter, e.g. the number of clusters (c), the fuzzifier (q), etc., and v(U) is used to identify a trend such as the maximum or minimum or

Algorithm 2: *Simultaneous Discovery of the Number of Actual Clusters and Coincident Clusters Found by the PCM*

0. Overspecify the number of clusters (c) and obtain a terminal partition U from the PCM

1. Generate the similarity matrix S (c × c) from U

$$S_{pq} = s'_{r*}(V_p, V_q) \text{ for } \forall p,q \in \{1,\ldots,c\}$$

$$V_p = \begin{bmatrix} U_{p,1} & \cdots & U_{p,n} \\ \max_{k\neq p}\left(U_{k,1}\right) & \cdots & \max_{k\neq p}\left(U_{k,n}\right) \end{bmatrix} \quad (2\times n)$$

$$V_q = \begin{bmatrix} U_{q,1} & \cdots & U_{q,n} \\ \max_{k\neq q}\left(U_{k,1}\right) & \cdots & \max_{k\neq q}\left(U_{k,n}\right) \end{bmatrix} \quad (2\times n)$$

2. Generate the dissimilarity matrix D from S via 1 - S_{pq}

3. Run VAT on D

Visually identify the *actual* number of clusters

4. Clusters in D are coincident clusters in the PCM algorithm

"the big jump". The second group of methods use comparison indices, s(U,V), that compare pairs of partitions. Examples of this group include the crisp Rand [7] and our generalized Rand index [1-2]. If U and V are both in CP (and hence, both obtained by algorithmic means), s(U,V) is an internal criterion, and otherwise, we call it an external criterion.

Since c is unknown in real clustering situations, it is not generally possible to know that it has been overspecified. However, the problem domain often suggests a maximum plausible value for c, and this knowledge can be used to make a realistic overspecification. For example, if you are segmenting MRI images of the brain with c-means clustering, there will certainly not be more than 8 or 10 meaningful regions, so taking c at, say, 15, is a reasonable guess at overspecification.

However, each approach makes certain assumptions and therefore operates ideally for data sets with particular profiles, e.g. VAT and its relationship to single linkage [24]. Even more critical to PCM, these approaches do not solve the cluster correspondence problem. If one of the above methods is used to discover the number of *actual* clusters, there is no guarantee that PCM will find the c unique clusters (due to coincident clusters).

Since the inception of the PCM algorithm, a few extensions have been presented that attempt to avoid coincident clusters. In [25], Timm et al. add a penalizing term to the PCM objective function in order to help repel cluster prototypes. Additionally, de Caceres et al. present an improved way to estimate the cluster bandwidths, which in return appears to help keep prototypes from converging to similar spots [26].

Cluster correspondence (or registration) problem. A naive approach to cluster correspondence is to *directly* compare clusters, i.e. according to some distance of clustering algorithm parameters (i.e. prototypes, covariance matrices, etc.). It is

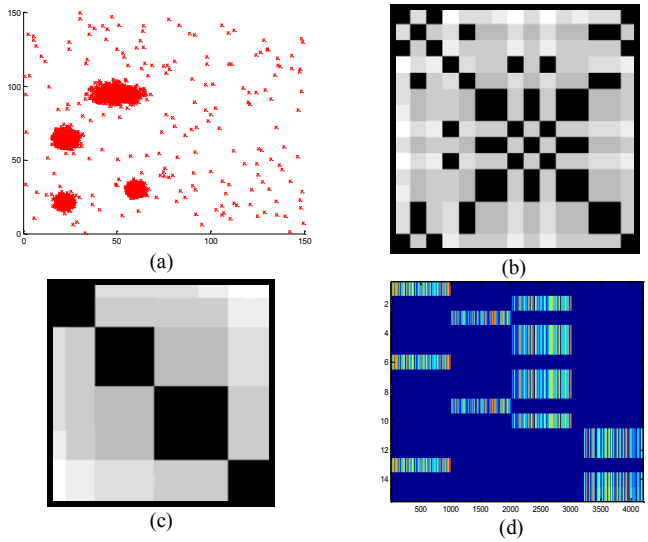


Fig. 3. Data set 3 (D3) and results from algorithm 2. D3 is four Gaussian clouds, each with 1000 samples, means of $[22\ 22]^T$, $[60\ 30]^T$, $[23\ 65]^T$, $[50\ 95]^T$ and standard deviations of 2, 2, 3 and (6,3) respectively. A set of 200 random points are included. (a) is the object data, (b) is the unordered dissimilarity matrix D for c = 15, (c) is the VAT reordering of D showing 4 clusters, and (d) is the possibilistic partition matrix (15 × n) that clearly shows which of the original clusters are coincident. We see that between 3,000 and 3,200 there are 200 objects (noise) that do not belong strongly to any particular cluster.

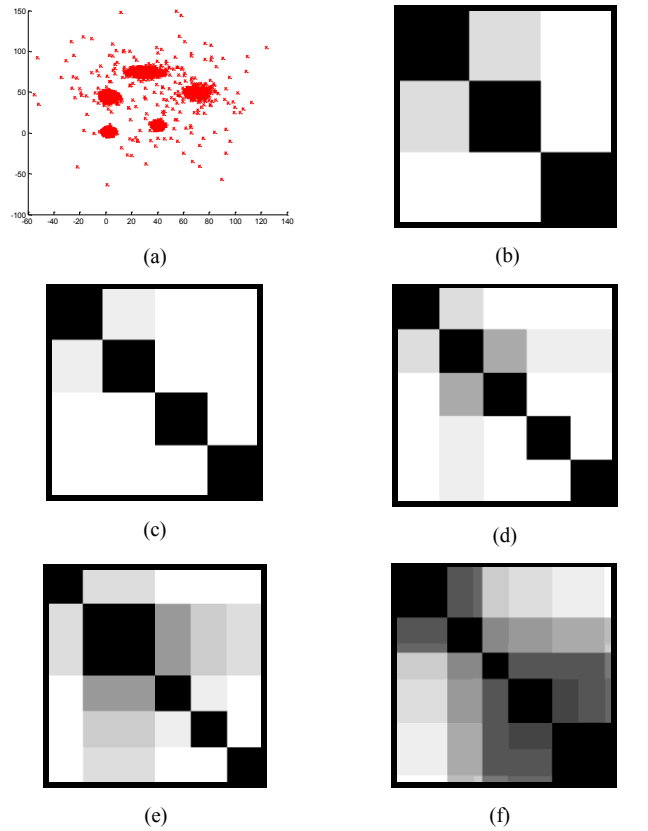

Fig. 4. Data set 4 (D4) and results from algorithm 2. D4 is five Gaussian clouds and noise; ($[2\ 2]^T$, 900, 2), ($[40\ 10]^T$, 500, 2), ($[3\ 45]^T$, 1000, 3), ($[30\ 75]^T$, 1200, (6,3)), and ($[70\ 50]^T$, 250, 6) for (mean, number of samples, standard deviation). There are 200 random noise points. In (b) c = 3, (c) c = 4, (d) c = 5, (e) c = 6, and in (e) c = 25.

possible that this approach might work for a limited number of scenarios. One example from the area of computer vision is the color space CIELAB. This space is designed around approximating human perception. Namely, this space makes it possible to interpret distance to a degree and therefore make reasonable working assumptions regarding merging criteria. An example of this is the mean shift clustering algorithm [27]. In [27], CIELAB space is exploited to *merge* mean shift prototypes for image region segmentation and filtering. However, this overly simplistic approach is not theoretically well founded and should not be relied upon in general.

Simultaneous discovery of the number of actual clusters and coincident clusters found by the PCM. Algorithm 2 begins with the overspecification of c. After PCM has terminated, the measure s'_{r*} is used to compare clusters and VAT is used in order to visually discover the number of *actual* clusters and coincident clusters simultaneously. This algorithm supports the claim [4] that coincident clusters are not a shortcoming of PCM. However, s'_{r*} is defined for partitions not clusters. How is it that cluster p can be compared to cluster q in the same partition?

In algorithm 2, a set of possibilistic partitions, $\{V_1, \ldots, V_c\}$, are built (where c is the number of clusters in U). The idea is to generate a possibilistic partition ($2 \times n$) for each cluster that contains the membership of every data point in cluster p ($1 \times n$) and the maximum membership value of each data point in the remaining set of clusters ($1 \times n$), i.e. for all $q \neq p$. The value S_{pq} is the similarity, [0,1], between clusters p and q based on the possibilistic partitions V_p and V_q. Next, VAT is used on the dissimilarity matrix D, $D_{pq} = 1 - S_{pq}$, to visually discover the *actual* number of clusters in O and subsequently coincident clusters. Figures 3 and 4 demonstrate this approach.

In figure 3(a), O contains four *actual* clusters and random noise. Figure 3(b) is the dissimilarity matrix D for c = 15. Figure 3(c) is the VAT reordering of D, $D_{pq} = 1 - S_{pq}$. Figure 3(c) indicates that there are four *actual* clusters in O and that each *actual* cluster is associated with multiple clusters found by the PCM. Figure 3(d) is the PCM partition matrix. In figure 3(d), rows are clusters and columns are data points (15×4200). The first 1,000 data points belong to clusters {1, 6, 13} and the second 1,000 data points belong to {3, 9}. The next 1,000 data points belong to clusters {2, 4, 5, 7, 8, 10}. The next 200 data points are the random noise and they do not have a strong membership in any cluster. Finally, the last 1,000 data points belong to clusters {11, 12, 14, 15}.

In figure 4, O contains five *actual* clusters. When the number of clusters is underspecified, i.e. c = 3 in figure 4(b) and c = 4 in figure 4(c), PCM finds a subset of the *actual* clusters. However, the VAT image shows that there are three and four clusters respectively and that there are no coincident clusters. The same story is true for figure 4(d), i.e. c = 5 and no coincident clusters. However, when the number of clusters is over specified to PCM (c > 5), e.g. figures 4(e) and 4(f), algorithm 2 identifies the correct answer, five *actual* clusters. We also discover that each *actual* cluster is accounted for by one or more clusters returned by PCM (coincident clusters). Even one step further, we know which clusters from the PCM map to an *actual* cluster in O.

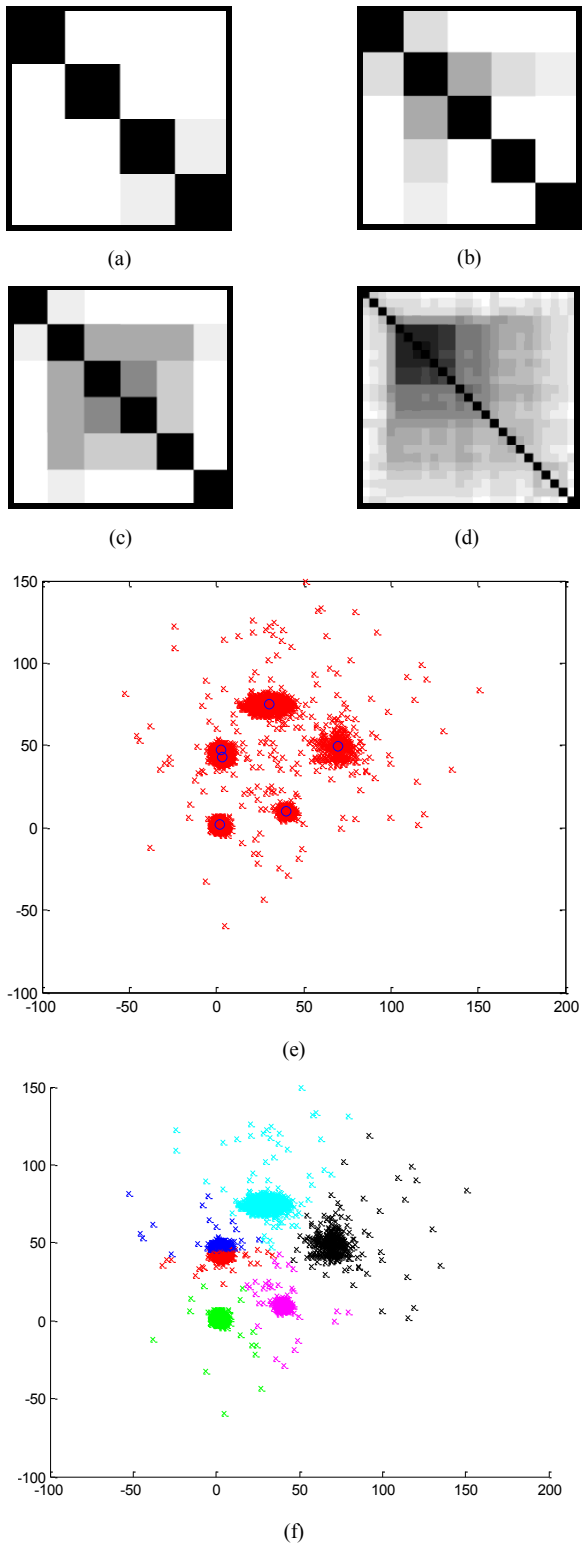

Fig. 5. Data set 5 (D5), which is generated using the same parameters used to generate D4 in figure 4, and the results from algorithm 2. However, in this experiment the FCM algorithm is used in place of the PCM. In (a) c = 4, (b) c = 5, (c) c = 6 and in (d) c = 25. In (e), the locations of the prototypes found in (c) are shown as blue circles. In (f), the FCM (c=6) membership matrix is hardened and each cluster is color coded.

These experiments demonstrate that when the number of clusters is underspecified to the PCM, algorithm 2 does not identify the correct *actual* number of clusters (instead some value smaller than it). The difficulty is that in a true clustering scenario, we do not know the answer. For example, in figure 4(b), c = 3, we would not know if the PCM found the correct number of clusters using algorithm 2. When we attempt c = 4, i.e. figure 4(c), we still are unaware if we have found the correct number of clusters. It is not until the specified c is greater than the *actual* number of clusters that we begin to get an indication of the correct number of *actual* clusters. This is the moment in which coincident clusters becomes an advantage. As c is steadily increased, i.e. algorithm 2 is run for c = 2, c = 3, etc., we eventually notice a *leveling off* in terms of the number of clusters discovered by algorithm 2. Therefore, we recommend testing a range of values for c in algorithm 2 in order to identify the *actual* number of clusters in O. In addition, different initializations can (and often do) lead to different clusterings. Therefore, we recommend running the PCM multiple times, e.g. 10, per c value. For each c, the user should select the largest value for the number of clusters found by algorithm 2.

On a final note, we demonstrate the result of algorithm 2 for FCM instead of PCM (figure 5). We see that when c is less than the number of *actual* clusters, i.e. figures 5(a) and 5(b), the VAT images show that the number of *actual* clusters is c. However, when c is overspecified, i.e. figures 5(c) and 5(d), the VAT image continues to indicate that the number of actual clusters is c. We are therefore unable to identify the *actual* number of clusters and the cluster correspondences via algorithm 2. Figure 5(e) is the scatterplot of D5 along with the locations of the prototypes. What we see is that when c is overspecified, the FCM tends to splits clusters. This is not the same behavior as the PCM, which produces coincident clusters. That is, coincident clusters in the PCM will have very similar rows in the membership matrix.

VI. CONCLUSIONS

In this article, we extended our prior work by exploring the behavior of the soft Rand for comparing non-crisp partitions. We also demonstrated how the possibilistic Rand and visual assessment of (cluster) tendency (VAT) algorithms can be used to simultaneously discover the number of *actual* clusters and coincident clusters found by the PCM. Our approach supports the claim [4] that coincident clusters are not a shortcoming of the PCM.

In future work, we will investigate how to extend the soft Rand to comparing partitions acquired across different data sets, e.g. samples drawn from the same underlying process. At the moment, our generalization of the Rand requires that U and V share the same object data set, O; however they need not possess the same number of clusters, $r \neq c$. We will explore next how to extend our approach to cases such as (1) temporal data sets, (2) clustering in unloadable data sets, and (3) the comparison of clustering discoveries found across potentially disjoint (sample) data sets. Namely, case (3) will investigate the question, "how similar are the clustering discoveries in data set A to data set B using clustering algorithms C and D"?

***Abstract*—Precise and effective prosthetic control is important for its applicability. Two desired objectives of the prosthetic control are finger position and force control. Variation in skeletal muscle force results in corresponding change of surface electromyographic (sEMG) signals. sEMG signals generated by skeletal muscles are temporal and spatially distributed that result in cross talk between adjacent sEMG signal sensors. To address this issue, an array of nine sEMG sensors is used with a force sensing resistor to capture muscle dynamics in terms of sEMG and skeletal muscle force. sEMG and skeletal muscle force are filtered with a nonlinear Teager–Kaiser Energy (TKE) operator based nonlinear spatial filter and Chebyshev type-II filter respectively. Multiple Takagi-Sugeno-Kang Adaptive Neuro Fuzzy Inference Systems (ANFIS) are obtained using sEMG as input and skeletal muscle force as output. Outputs of these ANFIS systems are fitted with smoothing spline curve fitting. To achieve better estimate of the skeletal muscle force, an adaptive probabilistic Kullback Information Criterion (KIC) for model selection based data fusion algorithm is applied to the smoothing spline curve fitting outputs. Final fusion based output of this approach results in improved skeletal muscle force estimates.**

Keywords – sEMG; TKE; ANFIS; KIC

I. INTRODUCTION

In the United States, 1.6 million people lived with amputations during 2005 [1]. This increase reflects on the war effects in Afghanistan and Iraq since 2003 [2]. During the same period of time, the fields of prosthetic design and development research for prosthesis has received increased attention. Precise and timely control of prosthesis is critical for its applicability, which necessitates the replacement of conventional algorithms by intelligent systems and decision methods. Therefore, a natural means of interface between the user and prosthesis is required. sEMG signals from skeletal muscles are a convenient means for users who do not want to deal with additional surgeries and regular hygiene problems. sEMG signals are simply electric voltages ranging between -5 and +5 [mV] which can be recorded on the skin surface of a hand amputee's forearm. Skeletal muscles generate a base sEMG even without a limb movement which changes with different movements and applied forces. This makes sEMG signals useful for position and force control of prosthesis. Presently available prosthetic hands have no tactile or proprioceptive feedback for grasping and only user's direct vision as a sensory feedback is available for its position control. Afore mentioned reasons cause 30–50% of the upper extremity amputees to choose not to use their prosthetic hand on a regular bases [3-4].

Effective grasping of any object requires the knowledge of force and its feedback. Since the hand amputee uses only sEMG signals collected from skeletal muscles, there is no hand force information directly available. sEMG is a measure of the nervous excitation that ultimately is responsible for activating the skeletal muscles, which in turn generate the finger forces with the help of the link kinematics of human hand. Therefore, a model or estimation scheme is needed for the dynamic estimation of skeletal muscle force from sEMG

signals. There have been numerous efforts in this direction and some of the recent are evident in the research work of [5-10].

The present work proposes a novel scheme of skeletal muscle force identification using sEMG signals. An array of nine sEMG sensors is used to record sEMG signals and skeletal muscle force signals recorded with a force sensing resistor from the arm of a healthy subject, which respectively is explained in detail in Section II and III. Eight Takagi-Sugeno-Kang ANFIS with different membership functions each with a rule base of ten are designed. The training of each ANFIS is done using a hybrid optimization method with zero error tolerance and 40 epochs. Each of the force signals simulated using these ANFIS and measured force signals are applied to a smoothing spline curve fitting method. Figure 1 shows the flow chart of the proposed approach. Final estimated force signal shows good match with the measured signal. This approach is tested on two different data sets of 45 and 60 seconds duration and the results seem promising. The paper is organized in eight sections. Present section follows the experimental set-up and then signal processing, ANFIS modeling, smoothing spline curve fitting, data fusion, results and discussion and conclusion and future work is presented respectively.

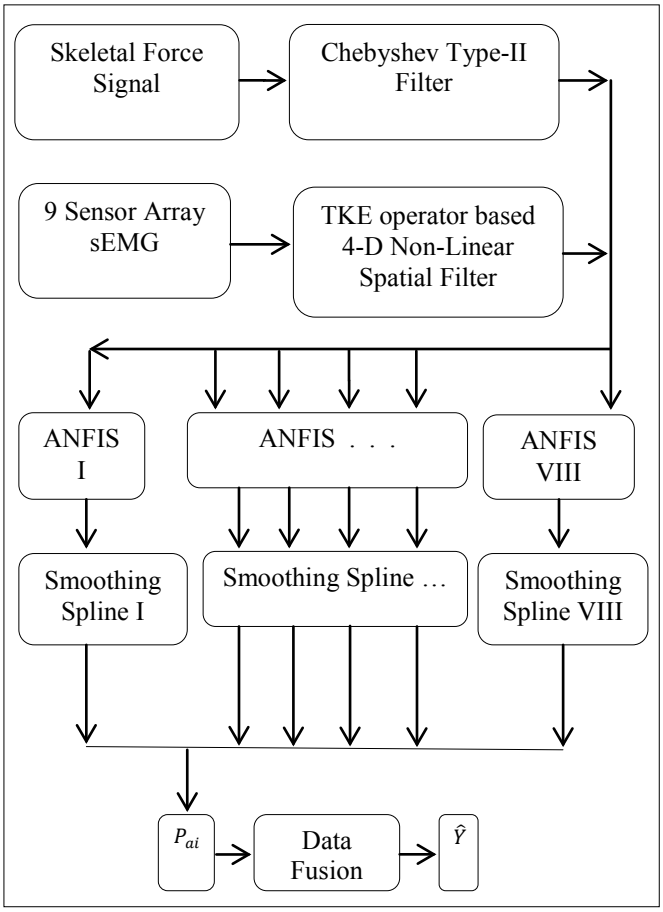

Figure 1. Flow chart of the approach used in this research work.

II. EXPERIMENTAL SET-UP

Based on the set-up of a sEMG sensor array in [11], an experiment set-up was developed using DELSYS® Bagnoli-16 EMG system with nine DE-3.1 sEMG sensors to capture sEMG signals from skeletal muscles. Here, the array involves nine sensors covering four directional spatial distributions of the sEMG signal. The middle three sEMG sensors were attached directly on the skin surface above the motor point of the flexor digitorum superficialis muscle (FDS) which controls the flexion of the ring finger. Appropriate sEMG electrode attachment point for the flexion of the ring finger was identified using a wet probe muscle stimulator at the FDS (RICH-MAR, HV 1000).

Prior to placing the sEMG sensors, the skin surface of the subject was prepared according to International Society of Electrophysiology and Kinesiology (ISEK) protocols. The thumb movement was restricted in this experiment using a thumb splint. However, the corresponding force data was captured using NI ELVIS™ with Interlink™ Electronics FSR 0.5" circular force sensor. Experimental set-up is shown in Figure 2, where 9 sensors are shown on a healthy subject forearm, holding a stress ball for force measurements. The sEMG and finger force data was collected at a sampling rate of 2000 Hz using LabVIEW™ in conjunction with DELSYS® Bagnoli-16 EMG and NI ELVIS™. With this experimental set-up we conducted several experiments of 30 seconds, 45 seconds and 60 seconds durations.

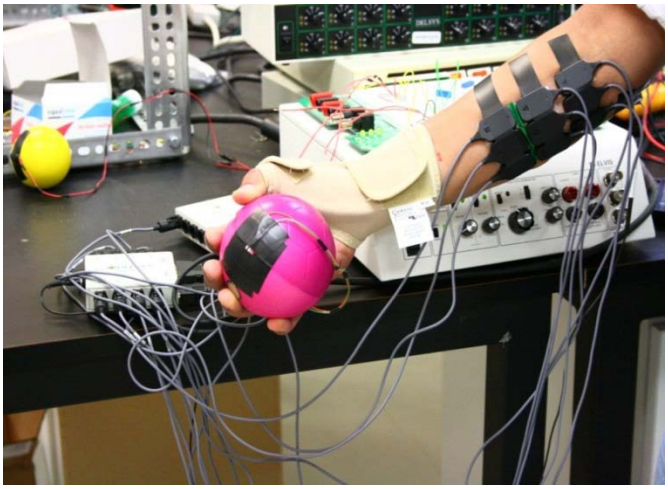

Figure 2. Experiment set-up.

III. SIGNAL PROCESSING

The recorded sEMG signal is filtered using nonlinear spatial filtering for multichannel surface EMG. As given in [12], this nonlinear spatial filter is derived from "Nonlinear Teager-Kaiser Energy (TKE) Operator." As given in [11], the

TKE operator in the time domain on sEMG signal is defined by Equation (1).

$$\Psi[x(n)] = x^2(n) - x(n+1) * x(n-1). \quad (1)$$

Here, Ψ is the TKE operator and $x(n)$ is the time domain sEMG signal. Based on the TKE operator, the four-dimensional nonlinear spatial filter is given by Equation (2).

$$\Psi_{d,4}[x(m,n)] = 4 * x^2(m,n) - x(m-1,n) * x(m+1,n) - x(m,n-1) * x(m,n+1) - x(m-1,n+1) * x(m+1,n-1) - x(m-1,n-1) * x(m+1,n+1). \quad (2)$$

Figure 3 shows a comparison between the measured and nonlinear spatial filtered sEMG signals.

A Chebyshev type II infinite impulse response (IIR) low pass filter with a 550 Hz pass band frequency is used to filter the skeletal muscle force signal. Figure 4 shows the comparison between the measured and Chebyshev type II filtered skeletal muscle force signal.

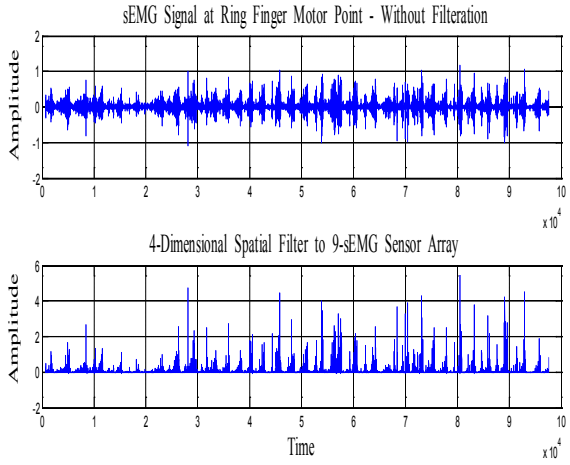

Figure 3. sEMG signal from ring finger.

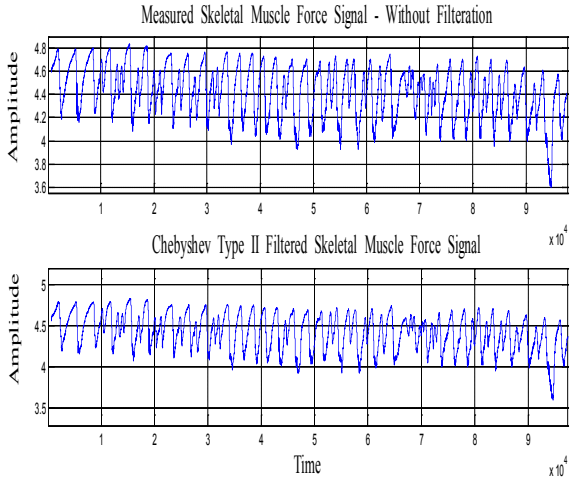

Figure 4. Skeletal muscle force signal from ring finger.

IV. ANFIS MODELING

In 1965 professor Lofti A. Zadeh introduced the concept of "*Fuzzy Sets*", which are sets with imprecise amplitudes [12]. Dr. Zadeh stated that the "*membership*" in a fuzzy set is a matter of degree and not a matter of affirmation or denial. For last four decades, this proposal has gained recognition as an important point in the evolution of modern concept of imprecision and uncertainty [12]. This innovation represents a paradigm shift from the classical sets or the crisp sets to "*Fuzzy Sets*" [12].

Fuzzy set and fuzzy logic theory can be used to capture the natural phenomenon of the imprecision and uncertainty [12]. The membership function is the characteristic of fuzzy set, which is a function whose range is an ordered membership set within the closed unit interval [12].

A crisp set which is a collection of distinct objects is defined in a way to partition objects in a given domain of discourse into two groups: members and non-members [12]. On the other hand, a fuzzy set can be formed by assigning a membership value (which represents the degree to which an object belongs to a fuzzy set) to each object in the interval of 0 to 1 [12]. Fuzzy membership functions can be of different forms such as triangular, trapezoidal, pi, bell and Gaussian form.

Fuzzy Inferance System (FIS) in fuzzy logic can be used to model a system which is an inference system based on empirical knowledge based linguistic rules [13]. The fuzzy inference system is composed of five steps: fuzzification of the input variables, application of the fuzzy operator (AND or OR) in the precedent, implication from the precedent to the subsequent, aggregation of the subsequents across the rules, and defuzzification. In the fuzzification process, the membership values coming from quantitative measurements are converted to linguistic values based on the membership functions [13].

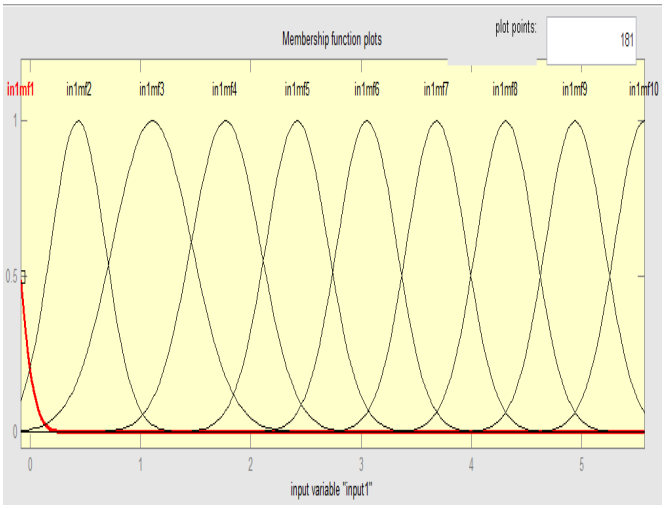

Figure 5. Gaussian membership functions for sEMG.

Figure 5 shows the plot of Gaussian membership functions for fuzzification of sEMG. The process of fuzzification followed by IF .. AND.. THEN ..OR ELSE type control or relation/estimation rules [13]. The output of the rules is computed as a max-min composition [13]. In the defuzzification process, the output of the rules has to be converted to a crisp value [13].

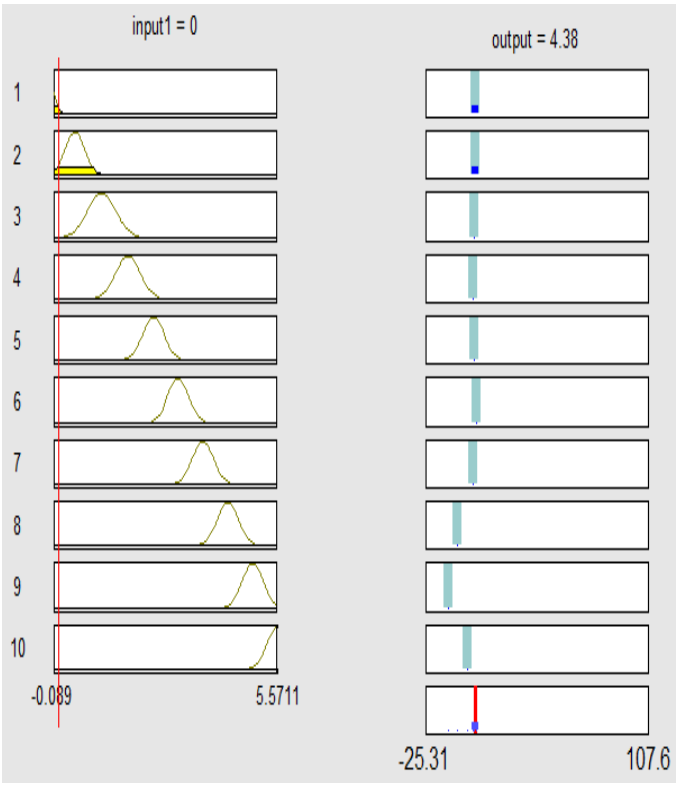

Figure 6. Illustration of ANFIS inference mechanism.

TABLE I. MEMBERSHIP FUNCTIONS

S. No.	Membership Function
1.	Gaussian (GAUSSMF)
2.	Gaussian combination (GAUSS2MF)
3.	Difference between two sigmoidal membership functions (DSIMF)
4.	Generalized bell-shaped (GBELLMF)
5.	Π-shaped (PIMF)
6.	Product of two sigmoidally shaped membership functions (PSIMF)
7.	Trapezoidal-shaped (TRAPMF)
8.	Triangular-shaped (TRIMF)

Using eight different membership functions types we designed eight single-output Sugeno-type adaptive neuro-fuzzy inference systems (ANFIS) using a grid partition on the data. The output membership function in each of these is linear. Each ANFIS has ten rules and connection type is 'And' with a weight of 1. For the 'And' method 'product' and for 'Or' method 'probabilistic' types are used for each ANFIS. Deffuzification is achieved using weighted average (wtaver) from each rule. Figure 6 shows the rules for ANFIS with Gaussian membership functions and illustrate the ANFIS inference mechanism. The membership functions used are tabulated in Table 1.

A Gaussian function is given by $f(x;\sigma,c) = e^{\frac{-(x-c)^2}{2\sigma^2}}$ for some real constants c and $\sigma > 0$, and $e = 2.718$. Gaussian combination membership function (GAUSS2MF) depends on the c and σ parameters [14]. The sigmoidal membership function is given as $f(x;a,c) = \frac{1}{1+e^{-a(x-c)}}$ and depends on the two parameters a and c. The difference between two sigmoidal membership function (DSIMF) which is the difference between two sigmoidal functions depends on the four parameters a_1, c_1, a_2, and c_2 [14]. Generalized bell-shaped membership function (GBELLMF) is given as $f(x;a,b,c) = \frac{1}{1+\left|\frac{x-c}{a}\right|^{2b}}$ and depends on three parameters a, b, and c where parameter a and b decide the width of the curve and parameter c locates the center, usually $b > 0$ [14]. Pi-shaped membership function (PIMF) is given by

$$f(x;a,b,c,d) = \begin{pmatrix} 0, & x \le a \\ 2\left(\frac{x-a}{b-a}\right)^2, & a \le x \le \frac{a+b}{2} \\ 1-2\left(\frac{x-b}{b-a}\right)^2, & \frac{a+b}{2} \le x \le b \\ 1, & b \le x \le c \\ 1-2\left(\frac{x-c}{d-c}\right)^2, & c \le x \le \frac{c+d}{2} \\ 2\left(\frac{x-d}{d-c}\right)^2, & \frac{c+d}{2} \le x \le d \\ 0, & x \ge d \end{pmatrix}, \quad \text{and}$$

evaluated at the points given by vector x. The "feet" of the curve is determined by parameters a and d whereas parameters b and c decides its "shoulders" [14]. The Product of two sigmoidally shaped membership functions (PSIMF) is simply the products of two sigmoidal functions as given before. The trapezoidal shaped membership function (TRAPMF) is given by

$$f(x;a,b,c,d) = \begin{pmatrix} 0, & x \le a \\ \frac{x-a}{b-a}, & a \le x \le b \\ 1, & b \le x \le c \\ \frac{d-x}{d-c}, & c \le x \le d \\ 0, & d \le x \end{pmatrix}$$ which depends on

four scalar parameters a, b, c, and d. The triangular shaped membership function (TRIMF) is given by

$$f(x;a,b,c) = \begin{pmatrix} 0, & x \le a \\ \frac{x-a}{b-a}, & a \le x \le b \\ \frac{c-x}{c-b}, & b \le x \le c \\ 0, & c \le x \end{pmatrix}$$ which depends on the scalar parameters a, b and c [14].

V. Smoothing Spline Curve Fitting

MATLAB® Curve Fitting Toolbox™ is a useful tool for fitting curves and surfaces to acquired data [15]. It can be used to do exploratory data analysis, preprocessing and post-processing of the data, comparing candidate models, and for removing outliers [15]. Weights for each smoothing spline curve fit are calculated by subtracting the ANFIS output from the measured skeletal muscle force output. A graphical user interface is used to fit the smoothing spline curve to each output from eight ANFIS with respective weights. Smoothing spline which is a piecewise polynomial computed from a smoothing parameter (p) of 0.92 is fitted to each of eight outputs of ANFIS. Smoothing parameter (p) is a number between 0 and 1. Change in the value of p from 0 to 1 results in the change in smoothing spline. For $p = 0$ the smoothing spline is a least-square straight-line approximation to the data whereas for $p = 1$ it gives the "natural" cubic spline interpolant to the data [15].

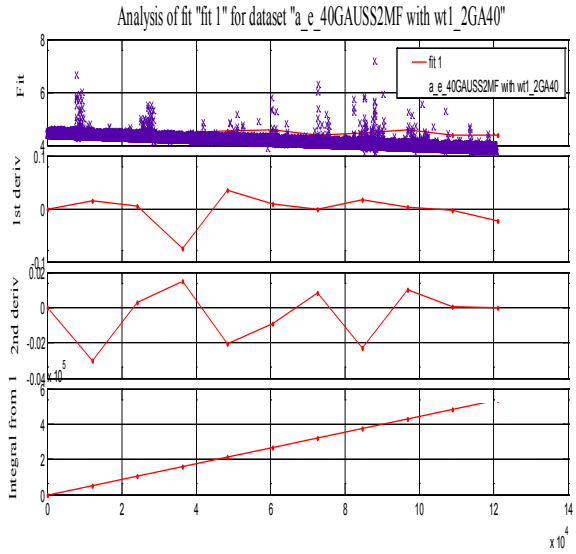

Figure 7. Analysis results for smoothing spline curve fitting to the output of ANFIS with Gaussian membership function.

For the specified weight (w_i) and smoothing parameter (p) a smoothing spline s is formed which minimizes the parameter J given by Equation (3).

$$J = p\sum_i w_i(y_i - s(x_i))^2 + (1-p)\int(\frac{d^2s}{dx^2})^2 dx, \qquad (3)$$

where x_i and y_i are predictor and response data respectively. The smoothing parameter p should be chosen to make the error $E(s) = \sum_i w_i(y_i - s(x_i))^2$ and roughness $\int(\frac{d^2s}{dx^2})^2 dx$ small. In this work the smoothing parameter p is chosen as 0.92 [15]. Figure 7 shows the analysis results for smoothing spline curve fitting to the output of ANFIS with Gaussian membership function.

VI. Data Fusion

Data fusion of multiple outputs of smoothing spline curve fittings is done by assigning a particular probability to each individual output [16]. This method gives good estimation of the skeletal muscle force. The goodness of the fit of each smoothing spline output can be measured using System Identification (SI) model fit value which is given by Equation (4).

$$FIT = [1 - |Y - \hat{Y}|/|Y - \bar{Y}|] * 100 \qquad (4)$$

In Equation (4) Y is measured, $\hat{Y}$ is estimated and $\bar{Y}$ is mean output signal. The model selection criterion used in this paper is Kullback Information Criterion (KIC) which has shown to perform well for sEMG sensor data fusion [7-10]. The sum of two directed divergences, which is the measure of the models dissimilarity, is known as Kullback's symmetric or J-divergence [17], as given by Equation (5).

$$KIC(p_i) = \frac{n}{2}logR_i + \frac{(p_i+1)n}{n-p_i-2} - n\psi\frac{(n-p_i)}{2}) + g(n), \qquad (5)$$

where $g(n) = n * log(n/2)$.

The fusion algorithm as given by [16] is applied for data fusion of the outputs of eight smoothing spline curve fit outputs which are obtained from eight different ANFIS models:

(I) Find smoothing spline curve fit outputs $M_1, M_2, \ldots, M_k$ for k number of outputs.

(II) Compute the residual square norm

$R_i = \|Y - \Phi_i\,\hat{\Theta}_i\|^2 = \|Y - \hat{Y}\|^2$,
where $\hat{\Theta}_i = \{\Phi_i{}^T\Phi_i\}^{-1}\Phi_i{}^T Y$, and

$$\Phi = \begin{bmatrix} Y_p^T & u_p^T & Y_{p-1}^T & \ldots & u_1^T \\ Y_{p+1}^T & u_{p+1}^T & Y_p^T & \ldots & u_2^T \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ Y_{n-1}^T & u_{n-1}^T & Y_{n-2}^T & \ldots & u_{n-p}^T \end{bmatrix}.$$

(III) Calculate the model criteria coefficient using Equation (5).

(IV) Compute the model probability $p(M_i|Z) = \frac{e^{-l_i}}{\sum_{j=1}^{k1} e^{-l_j}}$, where l is model selection criterion, i.e. $KIC(p_i)$.

(V) Compute the fused model output $\hat{Y}_f = \sum_{i=1}^{k1} p(M_i|Z)\hat{Y}_i$.

(VI) Compute the overall model from $\hat{Y}_f$ and skeletal muscle force data.

Here all the computation from step (II) to (VI) is adaptive i.e. the residual square norm, $KIC(p_i)$, model probability

$p(M_i|Z)$, and fused model output $\hat{Y}_f$ are being updated with time or for each data point. Figure 8 shows the flow chart for fusion of outputs and adaptive probability of KIC.

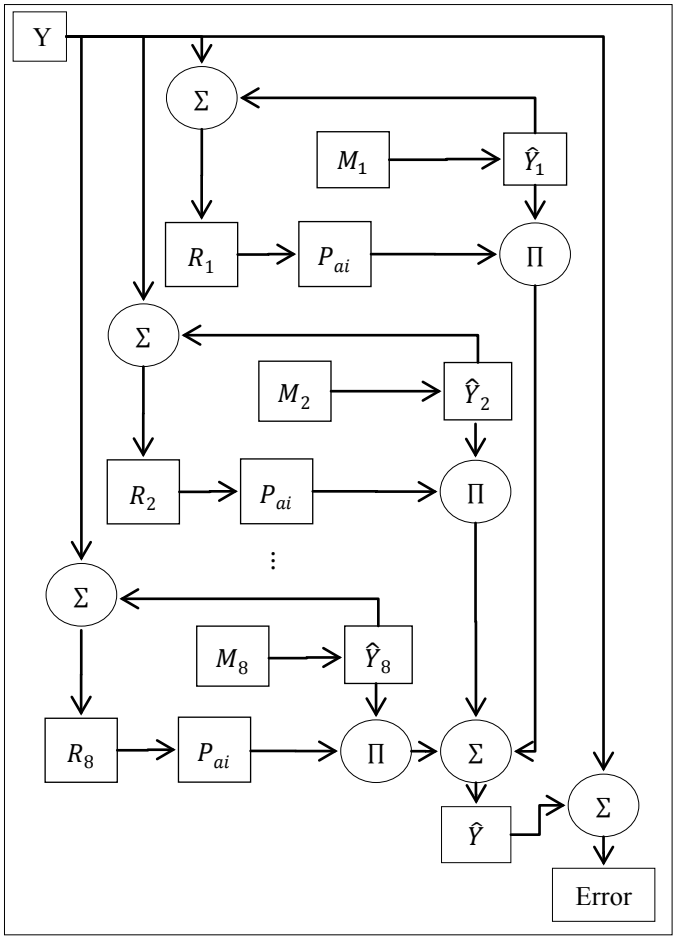

Figure 8. Flow chart for fusion of outputs and adaptive probability.

VII. Results and Discussion

The proposed method gives good estimation of the skeletal muscle force. A data set of 45 seconds is used to estimate the output. Figure 9 shows the measured and estimated skeletal muscle force using this method.

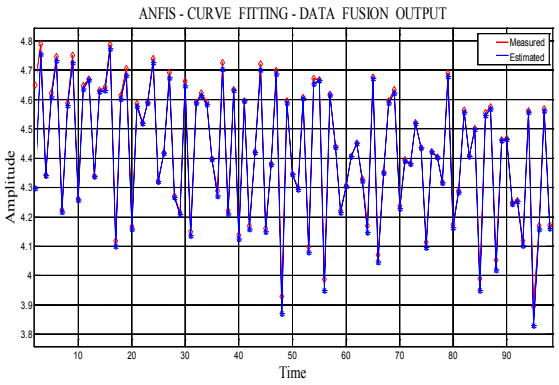

Figure 9. Plot of measured and proposed method estimated skeletal muscle force.

Figures 10 and 11 are the validation plots for 45 seconds and 60 seconds of data sets respectively. All of these three plots show a very close follow up of the measured signal by the estimated signal using this approach. Figure 12 shows the percentage error between the measured force signal and estimated finger force signal for 45 seconds of data set. The percentage error reduced to the lower values and the maximum percentage error value is 1.7 percent. The mean fit value between the measured and estimated output is 91.3 percent.

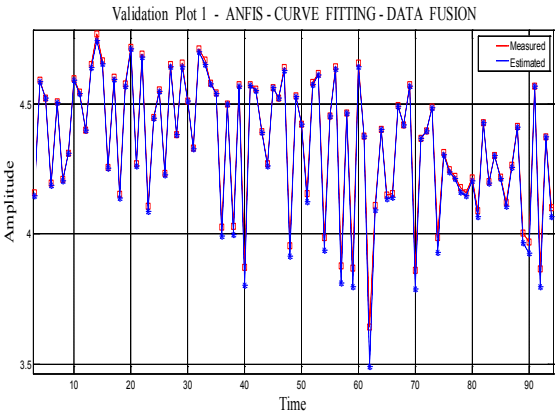

Figure 10. Validation plot 1 using different data set.

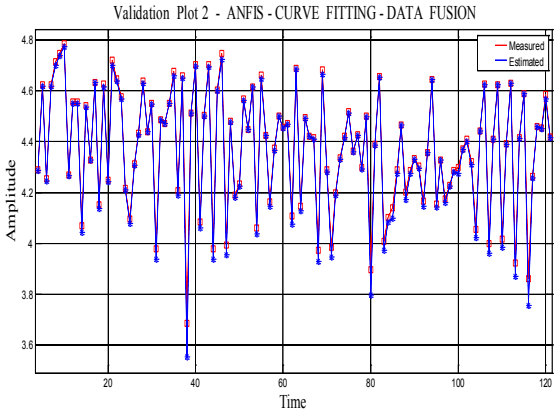

Figure 11. Validation plot 2 using different data set.

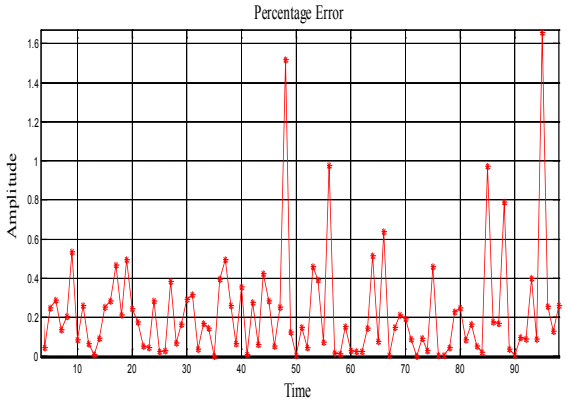

Figure 12. Percentage error plot.

Figure 13 shows the percentage error plot for different data set of 60 seconds duration. Percentage error reduced to lower values and the maximum percentage error value is 3.7 percent. The mean fit value between the measured and estimated output is 40 percent. The mean fit value for another 45 seconds of data set is 73 percent.

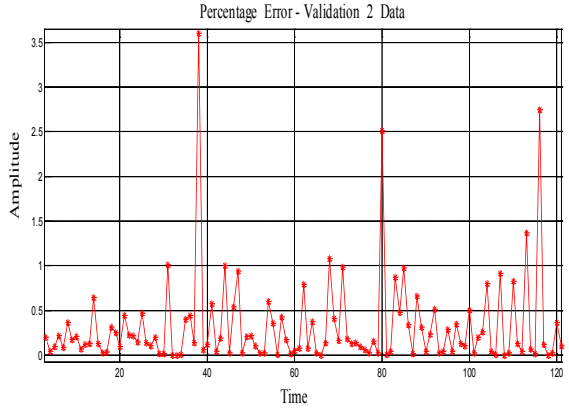

Figure 13. Percentage error plot for 60 seconds data set.

VIII. Conclusion and Future Work

Using sEMG and skeletal muscle force as input and output data, eight ANFIS were designed and tested. Output of these ANFIS were fitted with smoothing spline curve fit and resultant outputs were fused using a KIC based data fusion algorithm. This approach has been validated using two separate data sets. Results are promising and show good estimation of skeletal muscle force which can be applied to design, application and improvement of prosthetic hands for amputees.

Future work will address the improvement of data collection techniques, sEMG sensor design, use of this approach for finger angles and stiffness estimation from sEMG signals. Different modeling techniques with this approach and combined probability of different model selection criteria such as Akaike Information Criterion (AIC), Kullback Information Criterion (KIC) and the Bayesian Information Criterion (BIC) together will give improved results.

***Abstract*—In this paper, the Functional-Link based Interval Type-2 Compensatory Fuzzy Neural Network (FLIT2CFNN) is a six –layer structure, which combines compensatory fuzzy reasoning method, and the consequent part is combined the proposed functional-link neural network with interval weights. The compensatory fuzzy reasoning method uses adaptive fuzzy operations of neuro-fuzzy systems that can make the fuzzy logic system more adaptive and effective. Initially, there is no rule in the FLIT2CFNN. A FLIT2CFNN is constructed using concurrent structure and parameter learning. The advantages of this learning algorithm are that it converges quickly and the obtained fuzzy rules are more precise. All of the antecedent part parameters and compensatory degree values are learned by gradient descent algorithm. Several simulation results show that the FLIT2CFNN achieves better performance than other feedforword type-1 and type-2 FNNs.**

Keywords- type-2 fuzzy systems, Compensatory, structure learning, on-line fuzzy clustering.

I. INTRODUCTION

Fuzzy neural networks have been successful in a variety of area. However, most of fuzzy neural networks handle nonlinear system or time-varying modeling that its popular issue of research. In recent years, studies on dealing with optimize fuzzy membership function and defuzzification scheme have drawn attention [1-3], and adjust the parameter of fuzzy membership functions and defuzzification functions to adaptive network. Unfortunately, for optimize fuzzy logic reasoning and select optimal fuzzy operators, only static fuzzy operators are often used to make fuzzy reasoning. Such that the conventional neural fuzzy system can only adjust fuzzy membership functions by using fixed fuzzy operations such as Min and Max, the compensatory neural fuzzy system [4] with adaptive fuzzy reasoning is more effective and adaptive than the conventional neural fuzzy system with non-adaptive fuzzy reasoning.

In the typical TSK-type neural fuzzy network (TSK-type NFN), which is a linear polynomial of input variables. Nevertheless, the traditional TSK-type neural fuzzy network does not take full advantage of the mapping capabilities that may be offered by the consequent part. However, the multilayer neural network has such disadvantages as slower convergence and greater computational complexity. Therefore, this studied uses the functional link neural network (FLNN) [5-6] to the consequent part of the fuzzy rules. The consequent part of the proposed FLNN model is a nonlinear combination of input variables, which differs from the other existing models [1-3,7]. Moreover, using the functional expansion can effectively increase the dimensionality of the input vector, so the hyper-planes generated by the FLNN will provide a good discrimination capability in input data space.

All of the aforementioned FNNs only use type-1 fuzzy sets. Recently, studies on type-2 FLSs have paid close attention [8,9] and a complete theory of type-2 have been developed in [10]. Type-2 FLS are extensions of type-1 FLS, where the membership value of a type-2 fuzzy set is a type-1 fuzzy number. The type-1 fuzzy set cannot directly deal with these uncertainties. Because the membership functions of type-2 fuzzy systems are themselves fuzzy, they supply a powerful framework to represent and handle such types of uncertainties. Successful applications of type-2 FLS include area of signal processes [11] and control [12]. Therefore, the purpose of this paper is to develop a self –evolving type-2 FNN with compensatory-based fuzzy logic reasoning and functional-link-based in the consequent part. The network is called a Functional-Link based Interval Type-2 Compensatory Fuzzy Neural Network (FLIT2CFNN).

The rest of this paper is organized as follows. Section II describes the FLIT2CFNN structure. Section III introduces structure and parameter learning in a FLIT2CFNN. Section IV simulates nonlinear system identification problems. Finally, Section V draws conclusions.

II. FLIT2CFNN STRUCTURE

In this section, the structure of Functional-Link based Interval Type-2 Compensatory Fuzzy Neural Network (FLIT2CFNN) is introduced. Figure 1 shows the structure of FLT2CFNN, which has a six-layer. This six-layer network realizes an interval type-2 fuzzy system whose consequent part is a nonlinear combination of functional expansion of input variables, i.e., functional-link based. The detailed mathematical functions of FLT2CFNN are introduced as following below.

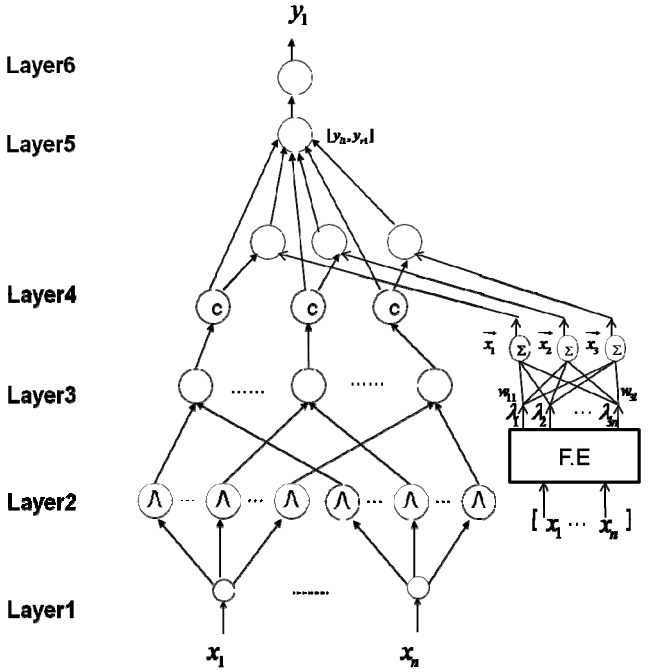

Fig.1. Structure of the FLIT2CFNN

Layer 1 (input layer): The inputs are crisp values. Only the current states $x(t)$ are fed as inputs to this layer. Note that there is no weights to be adjusted in this layer.

Layer 2 (MF Layer): Each node in this layer defines an interval type-2 membership function (MF). We use a Gaussian primary MF having a fixed standard deviation (STD) and an uncertain mean that takes on values in $[m_1, m_2]$ (Fig. 2), i.e., That is, the output $\tilde{A}_j^i$ of each node can be represented as an interval $[\overline{\mu}_j^i, \underline{\mu}_j^i]$.

$$\mu_{\tilde{A}_j^i} = \exp\{-\frac{1}{2}(\frac{x_j - m_j^i}{\sigma_j^i})^2\} \equiv N(m_j^i, \sigma_j^i; x_j),\ m_j^i \in [m_{j1}^i,\ m_{j2}^i] \quad (1)$$

The footprint of uncertainty (FOU) of this MF can be represented as a bounded interval in terms of upper MF, $\overline{\mu}_{\tilde{A}_j^i}$, and lower MF, $\underline{\mu}_{\tilde{A}_j^i}$,

where

$$\overline{\mu}_{\tilde{A}_j^i}(x_j) = \begin{cases} N(m_{j1}^i, \sigma_j^i; x_j), & x_j < m_{j1}^i \\ 1, & m_{j1}^i \le x_j \le m_{j2}^i \\ N(m_{j2}^i, \sigma_j^i; x_j), & x_j > m_{j2}^i \end{cases} \quad (2)$$

and

$$\underline{\mu}_{\tilde{A}_j^i}(x_j) = \begin{cases} N(m_{j2}^i, \sigma_j^i; x_j), & x_j \le \dfrac{m_{j1}^i + m_{j2}^i}{2} \\ N(m_{j1}^i, \sigma_j^i; x_j), & x_j > \dfrac{m_{j1}^i + m_{j2}^i}{2} \end{cases} \quad (3)$$

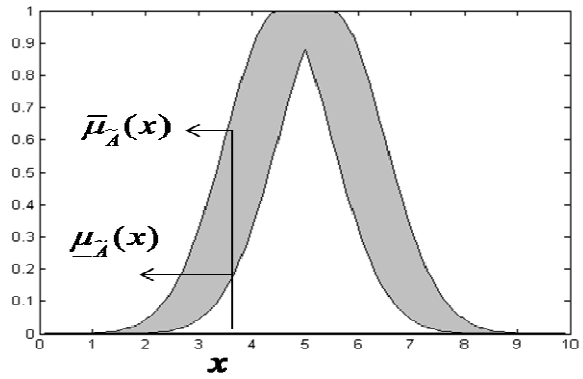

Fig.2. An interval type-2 fuzzy set with an uncertain mean.

Layer 3 (Spatial Firing layer): Each node performs a fuzzy meet operation on inputs from layer 2 using an algebraic product operation to obtain the spatial firing strength. The output of a rule node is a firing strength, F^i, which is an interval type-1 fuzzy set. The firing strength is computed as follows (Liang and Mendel,2000)

$$F^i = [\overline{f}, \underline{f}] \quad i = 1 \sim M, \quad (4)$$

where

$$\overline{f}_i = \prod_{j=1}^{n} \overline{\mu}_{\tilde{A}_j^i} \quad \text{and} \quad \underline{f}_i = \prod_{j=1}^{n} \underline{\mu}_{\tilde{A}_j^i} \quad (5)$$

and M is total number of rules.

Layer 4 (Compensatory Firing layer): Each node in this layer performs a compensatory fuzzy operation mentioned in [4], and derives if-condition matching of fuzzy rules. As a result, the compensatory firing function of inference node is

$$\varphi^i = [\overline{\varphi}, \underline{\varphi}], \quad i = 1, \cdots, M \quad (6)$$

where

$$\overline{\varphi}^i = \left(\prod_j^n \overline{f}_j^i\right)^{(1-\gamma_i + \frac{\gamma_i}{n})}, \quad \underline{\varphi}^i = \left(\prod_j^n \underline{f}_j^i\right)^{(1-\gamma_i + \frac{\gamma_i}{n})} \quad (7)$$

Here, the $\gamma_i \in [0,1]$ is called compensatory degree. The purpose of tuning γ_i is to increase the adaptability of fuzzy operation.

Layer 5(Consequent and Output processing layer): Each rule node in layer 3 has its own corresponding consequent node in layer 4.The output of each node is an interval type-1 fuzzy set , denoted by $[w_l^i\ ,\ w_r^i]$, if function-link neural network is used, then the link is existent.

$$[w_l^i\ ,\ w_r^i]=[c_0^i-s_0^i,\ c_0^i+s_0^i]+\sum_{k=1}^{L}[c_k^i-s_k^i,c_k^i+s_k^i]\cdot\lambda_k \quad (8)$$

That is,

$$w_l^i=\sum_{k=0}^{L}c_k^i\lambda_k-\sum_{k=0}^{L}|\lambda_k|s_k^i \quad (9)$$

where $\lambda_0=1$, and L=3n

$$w_r^i=\sum_{k=0}^{L}c_j^i\lambda_j+\sum_{k=0}^{L}|\lambda_k|s_k^i \quad (10)$$

Here λ_k is the functional expansion of input variables. The functional expansion uses a trigonometric polynomial basis function, given by $[x_1\ sin(\pi x_1)\ cos(\pi x_1)\ x_2\ sin(\pi x_2)\ cos(\pi x_2)]$ for two-dimensional input variables.

For output processing, the output y_l *and* y_r can be computed by using KM procedure [10]. In that procedure, the consequent part weights should be re-arranged in ascending order. According to [13], the relationship between $y_l\ , y_r, \tilde{y}_l,$ and $\tilde{y}_r$ is

$$\boldsymbol{y}_l=Q_l\tilde{\boldsymbol{y}}_l \text{ and } \boldsymbol{y}_r=Q_r\tilde{\boldsymbol{y}}_r \quad (11)$$

where Q_l and Q_r are $M\times M$ permutation matrices. Re-order the f^i accordingly and call them g^i. The outputs y_l and y_r can be computed as follows

$$y'_l=\frac{\sum_{i=1}^{L}\overline{g}^i y_l^i+\sum_{i=L+1}^{M}\underline{g}^i y_l^i}{\sum_{i=1}^{L}\overline{g}^i+\sum_{i=L+1}^{M}\underline{g}^i} \quad (12)$$

and

$$y'_r=\frac{\sum_{i=1}^{R}\underline{g}^i y_r^i+\sum_{i=R+1}^{M}\overline{g}^i y_r^i}{\sum_{i=1}^{R}\underline{g}^i+\sum_{i=R+1}^{M}\overline{g}^i} \quad (13)$$

Layer 6 (Output layer): The node in this layer computes the output linguistic variable y by defuzzification operation. The output of layer 5 is an interval set as a result of computing average of y'_l and y'_r. Hence, the defuzzified output is

$$y=\frac{y'_l+y'_r}{2} \quad (14)$$

III. FLIT2CFNN LEARNING

In this section, the FLIT2CFNN simultaneously uses on-line two types of learning algorithm, the structure and parameter learning. There are no rules in the FLIT2CFNN initially. The rules are created dynamically and automatically as learning proceeds upon receiving on-line incoming training data by performing the structure and parameter learning processes. All of free parameters are learned by following learning as a rule is generated. The details of structure learning and parameter learning are introduced in the rest of this section.

A. Structure learning

The first task in structure learning is conducted to decide whether or not to extract a new rule from training data as well as the number of fuzzy sets on the universal of discourse of each input variable. A previous study [2] used the rule firing strength as a criterion for type-1 fuzzy rule generation. This idea is extended to type-2 fuzzy rule generation criteria in a FLIT2CFNN. The firing strength is an interval in the FLIT2CFNN so that the center of interval is computed as

$$f_c^i=\frac{1}{2}(\overline{f}^i+\underline{f}_i) \quad (15)$$

The firing strength center then serves as a rule generation criterion. That is, for each piece of incoming data $\vec{x}=(x_1,\ldots,x_n)$, find

$$I=\arg\max_{1\le i\le M(t)} f_c^i(\vec{x}) \quad (16)$$

where $M(t)$ is the number of existing rules at time t. If $f_c^I(\vec{x})\le\phi_{th}$, then a new rule is generated, where $\phi_{th}\in(0,1)$ is a pre-specified threshold that decays during the learning process.. The threshold decides the number of input clusters generated in FLIT2CFNN.

Once a new fuzzy set is generated, the initial uncertain means and widths of the corresponding new type-2 fuzzy sets are assigned as

According to the notation in Eq. (1), the initial uncertain mean m_j^i and standard deviation σ_j^i for the new interval type-2 fuzzy set in input variable x_j are

$$m_j^i\in[x_j-0.1,\ x_j+0.1] \quad (17)$$

$$\sigma_j^i=\sigma_{fix} \quad (18)$$

B. Parameter Learning

The parameter learning phase occurs concurrently with the structure learning phase. For each incoming data, all of free parameters in the FLIT2CFNN are tuned, whether a newly generated rules or formerly existent. When we consider the single output case for clarity, our goal to minimize the error function is defined as

$$E(t)=\frac{1}{2}[y(t)-y^d(t)]^2=\frac{1}{2}e^2(t) \quad (19)$$

where $y(t)$ and $y_d(t)$ denote real and desired outputs, respectively. The Karnik-Mendel iterative procedure for computing y_l and y_r in Eqs. (12) and (13) has a premise that y_l^i and y_r^i are re-arranged in ascending order.

Since the FLIT2CFNN training process, the consequent part parameters change, and the corresponding rule orders change accordingly. It is necessary to know the specific site of antecedent and consequent parameters for updating the parameters. According to this mapping, (12) and (13) are expressed by $\tilde{\boldsymbol{y}}_l$ and $\tilde{\boldsymbol{y}}_r$, i.e., with the consequent values arranged in the original rule order despite their changes during the parameter learning process. Based on this original rule-ordered expression, the consequent part parameters are tuned using Kalman filter algorithm [14]. The compensatory degree weights and the antecedent part parameters are tuned using the gradient descent algorithm, and it is expressed as

$$w_i(t+1) = w_i(t) - \eta \frac{\partial E}{\partial w_i}, \tag{20}$$

where w can be expressed as $m_{j1}, m_{j2}, \sigma, \gamma$, *and* η is a learning coefficient. Details of the learning algorithm can be found in [13].

IV. SIMULATIONS

To demonstrate the ability of FLIT2CFNN to evolve, the following nonlinear system is described by the difference equation [1-2]

$$y_d(t+1) = \frac{y_d(t)}{1+y_d^2(t)} + u^3(t) \tag{21}$$

The training patterns are generated with $u(t) = \sin(2\pi t/100)$, $t = 1, \cdots, 200$. The inputs of FLIT2CFNN are $y_d(t)$ and $u(t)$, and the desired output is $y_d(t+1)$. Performance is evaluated using root-mean-square-error (RMSE)

$$RMSE = \sqrt{\frac{1}{200}\sum_{k=1}^{200}[y(t+1) - y^d(t+1)]^2} \tag{22}$$

where $y(t)$ is the output of FLIT2CFNN. Learning coefficient η is set to be 0.075. During the training process, the three rules are generated. Training is performed for 500 iterations. Table I shows that the performance of the FLIT2CFNN contains the network size, training and test RMSEs. Figure 3 shows the outputs of the plant and the IT2RFNN for these test inputs. The performance of FLIT2CFNN is compared with that of type-1and type-2 FNNs, including SONFIN[2] and Feedforward type-2 FNN, where the former parameter learning are learned by hybrid learning of Kalman filter algorithm and gradient descent, and the latter free parameters are tuned by gradient descent method. The results show that the FLIT2CFNN achieves smaller test errors than the other feedforward networks.

TABLE I. PERFORMANCE OF FLIT2CFNN AND OTHER FEEDFORWARD SYSTEM

Model	SONFIN	FEEDFORWARD TYPE-2 FNN	FLIT2CFNN
Rule number	10	6	3
Parameter number	70	72	66
Iterations	250	250	250
RMSE	0.0075	0.0082	0.0035

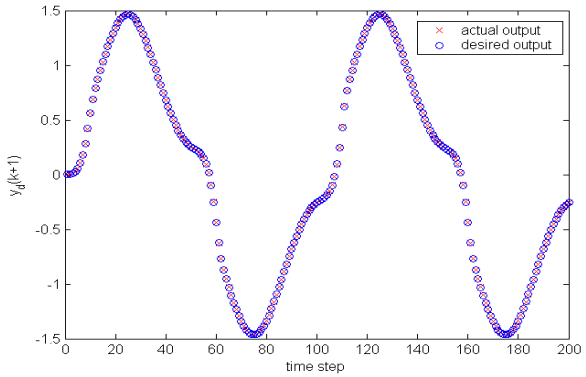

Fig.3. Output of the nonlinear system (O) and FLIT2CFNN (X).

This example is also considered the noise resistance ability of an FLIT2CFNN. Assumed that the measure y^d output contains noise. The added noise is artificially generated and is uniformly distributed in [-2.5, 2.5]. There are 20 Monte-Carlo realizations. On average, three rules are generated for the FLIT2CFNN. Fig. 4 shows one learning result of the 20 realizations, showing that the FLIT2CFNN output does not change as violently as the actual noisy output. This result verifies the FLIT2CFNN's noise resistance abilities. Table II shows the performance of FLIT2CFNN with noise. For comparison, the self-evolving type-1 system, SONFIN[2] and the Feedforward type-2 FNN are compared to the same problem. These results show that the FLIT2CFNN learning performance is better than the SONFIN and Feedforward type-2 FNN learning performance when there is noise.

TABLE II. PERFORMANCE OF FLIT2CFNN AND OTHER FEEDFORWARD SYSTEM WITH NOISE STATE

Model	SONFIN	FEEDFORWARD TYPE-2 FNN	FLIT2CFNN
Rule number	10	6	3
Parameter number	70	72	66
Train RMSE	0.13	0.142	0.128
Test RMSE	0.095	0.088	0.066

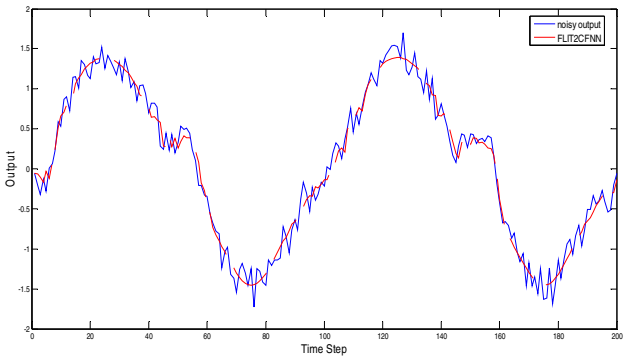

Fig.4. Online learning results of the FLIT2CFNN when noise appears in the measured data

V. CONCLUSIONS

This paper proposes a functional-link-based Interval Type-2 Compensatory Fuzzy Neural Network (FLIT2CFNN) structure for nonlinear system modeling and resistance noise ability. To achieve optimize type-2 fuzzy logic reasoning, the compensatory operation is chosen. The FLIT2CFNN model can automatically construct and adjust free parameters by performing online structure/parameter learning schemes concurrently. Moreover, the rule-ordered Kalman filter algorithm helps tune the consequent parameters online and improves learning accuracy. Except that the FoU in FLIT2CFNN helps handle the numerical uncertainty associated with system inputs and outputs. Therefore, the FLIT2CFNN has the potential to achieve better performance than type-1 fuzzy systems when dealing with noisy data. The proposed FLIT2CFNN can efficiently handle nonlinear system and good performance is achieved.

***Abstract*-This paper proposes Enhanced Fuzzy C-means technique (EFCM) based infrared image segmentation and its broad application in Automatic detection systems. The EFCM based image segmentation is able to approximate the exact number of clusters present in the image. EFCM based segmentation is applied on various infrared images that can be used for automatic detection systems and compared with widely used clustering techniques such as K-means and EM. Clustering performance has been compared in terms of well-proven and widely accepted validation indices, Global Silhouette Index and Separation Index. The segments or clusters obtained from above mentioned clustering methods have been assessed visually. Automatic Detection Systems based on EFCM can help in reducing complexities present in conventional systems.**

Keywords: EFCM, K-means, EM, GS, SI.

I. INTRODUCTION

Clusters are the collection of similar objects such that each group or cluster is homogeneous; that is, objects belonging to the same group are similar to each other. Each group or cluster should be different from other clusters; that is, objects belonging to one cluster should be different from the objects of other clusters. Clustering technique [1] can be hard or fuzzy. A hard clustering algorithm assigns each data point to a particular cluster during its operation and in its output. A fuzzy clustering method allocates a degree of membership to each data point depending on its association with several other clusters.

Automatic Detection Systems, on which proposed technique can be used, are those that can control any process, weather forecast or detect diseases with the help of infrared images. These systems are discussed in Section-4 of this paper.

This paper is organized in four sections. An overview of the existing clustering algorithms is given in Section-2. The proposed technique is explained in Section-3. In Section-4, we present the simulation results of all the clustering techniques, including the proposed EFCM technique. Moreover, a comparison between the cluster quality of all clustering techniques is made. Finally, we present our conclusion in the last section.

II. AN OVERVIEW OF SOME CLUSTERING BASED SEGMENTATION TECHNIQUES

Some of the widely used clustering techniques are K-means Clustering [2], FCM Clustering [3], Gath-Geva Clustering [4] and EM Clustering [5].

K-means clustering algorithm was proposed by Forgy and MacQueenin in 1967. It is one of the simplest unsupervised clustering algorithms, which has been widely used in various applications. It groups data into a fixed number of clusters where the centroid of one cluster is placed as far away as possible from another. Each data point in a cluster is associated to the nearest centroid. The Expectation Maximization (EM) clustering algorithm is based on the statistical model that uses the finite Gaussian mixtures model. This clustering algorithm utilizes the K-means initialization in which a fixed number of clusters are obtained through K-means clustering. Then the cluster parameters (weights, means and co-variances) are re-computed until a desired convergence value is achieved. In infinite mixture model, all attributes are assumed to be independent random variables. The Probabilistic Clustering technique [6] objects at fitting a fixed k-component Gaussian mixture model (GMM) to the data set. It assesses the probability of the components of a GMM such that whole data set can be categorized into components with high probability. This clustering algorithm employs the basic Expectation-Maximization Algorithm. Fuzzy C-Means (FCM) clustering was developed by Dunn in 1973 and later improved by J. C. Bezdek in 1981. FCM is frequently used in pattern recognition. In this technique, data points are bound to each cluster by means of membership functions, which give degree of association with each cluster. A data point is assigned to that cluster with which it is highly associated i.e. degree or membership is highest.

III. ENHANCED FUZZY C-MEANS CLUSTERING ALGORITHM (EFCM)

The FCM algorithm [3] could not identify the optimum number of clusters required, which is a major drawback. To overcome this drawback, a modified and improvised algorithm EFCM is presented in this paper. This algorithm has the capability to find the optimum number of clusters.

A. The Algorithm

The EFCM algorithm has four important steps:

1) Generation of subsets.
2) Estimation of optimum number of clusters.

1) Generation of subsets:

Fuzzy c-means (FCM) is a method of clustering which allows one piece of data to belong to two or more clusters. It is based on minimization of the following objective function:

$$J_m = \sum_{i=1}^{N}\sum_{j=1}^{C} u_{ij}^{m} \| x_i - c_j \|^2, \qquad 1 \le m \le \infty \quad (1)$$

where m is any real number greater than 1, u_{ij} is the degree of membership of x_i in the cluster j, x_i is the ith of d-dimensional measured data, c_j is the d-dimension center of the cluster, C is no. of cluster, and ||*|| is any norm expressing the similarity between any measured data and the center. Fuzzy partitioning is carried out through an iterative optimization of the objective function shown above, with the update of membership u_{ij} by:

$$u_{ij} = \frac{1}{\sum_{k=1}^{C}\left(\frac{\| x_i - c_j \|}{\| x_i - c_k \|}\right)^{\frac{2}{m-1}}} \quad (2)$$

and the cluster centers c_j are given by:

$$c_j = \frac{\sum_{i=1}^{N} u_{ij}^{m} x_i}{\sum_{i=1}^{N} u_{ij}^{m}} \quad (3)$$

This iteration will stop when $\max_{ij}\{| u_{ij}^{k+1} - u_{ij}^{k} |\} < \in$, where $\in$ is a termination criterion between 0 and 1, whereas k is the iteration step. This procedure converges to a local minimum or a saddle point of J_m.

The algorithm comprises of four steps:

1. Initialize the $U = [u_{ij}]$ matrix. It represents $U^{(0)}$.
2. At k-step: calculate the centers vectors $Ce^{(k)}=[c_j]$ with $U^{(k)}$ using equation 3 given above, assuming $C=2$ initially.
3. Update $U^{(k)}$, $U^{(k+1)}$ using equation 2 mentioned above.
4. *If* $|| U^{(k+1)} - U^{(k)} || < \in$ *then STOP; otherwise return to step 2.*

In this manner, the algorithm iteratively converges on the most optimum cluster centers.

2) Estimation of Optimum number of Clusters:

Determine the optimum number of clusters, C using validity measure Global Silhouette Index (GS) [7,8] defined in Section 3.2. GS value is calculated for various number of clusters (*n=1,2,...20*). Value of n for which GS is maximum is assigned to C . Form optimum number of clusters C using the Steps 2 to13. These are the required clusters for an infrared image.

B. Cluster Quality Measure

1) Global Silhouette Index

GS is calculated as shown below:

$$GS = \frac{1}{c}\sum_{m=1}^{c} S_m \quad (4)$$

S_m is calculated as:

$$S_m = \frac{1}{N_m}\sum_{i=1}^{N_m} s(i), \quad (5)$$

where N_m is number of data points in m^{th} cluster and $s(i)$ is :

$$s(i) = \frac{b(i) - a(i)}{\max\{a(i), b(i)\}}, \quad (6)$$

where $a(i)$ is the average distance between the i^{th} sample and all of the samples included in X_m (m^{th} cluster); '*max*' is the operator, and $b(i)$ is the minimum average distance between the i^{th} sample and all of the samples clustered in X_k ($k = 1,\ldots, c;\ k \neq m$). From this formula it follows that $-1 \le s(i) \le 1$. For a good cluster GS value should be near to 1.When $s(i)$ is close to 1, one may infer that the i^{th} sample has been "well-clustered ", i.e. it was assigned to an appropriate cluster. When $s(i)$ is close to zero, it suggests that the i^{th} sample could also be assigned to the nearest neighboring cluster.

2) Separation Index (SI) [9]

It uses a minimum-distance separation for partition validity. A lower value of *SI* indicates a better partition. For good quality clusters *SI* should have the least possible value.

$$SI = \frac{\sum_{m=1}^{c}\sum_{j=1}^{n}(\mu_{jm})^2 \| \overline{\mathbf{x}^j} - \bar{z}_m \|^2}{n.\min_{k,m} \| \bar{z}_k - \bar{z}_m \|^2} \quad (7)$$

where,

$\bar{z}_m$ is the m^{th} cluster center,

μ_{jm} is the membership of data point j in cluster m.

$$\mu_{jm} \in \{0,1\};\ 1 \le j \le n;\ 1 \le m \le c$$

$$\sum_{m=1}^{c} \mu_{jm} = 1$$

IV. RESULTS

The widely used clustering algorithms discussed above are tested on various synthetic and natural infrared images. Simulations are done using MATLAB on a PC with 2GB RAM, using a 2.00 GHz processor. Prior to the experiments, no pre-processing was done on these images. RGB features are used in clustering. The effectiveness of clusters is compared in terms of GS and SI values of cluster formed.

Example 1: In this example we deal with an infrared image of a boiler. Fig.1 shows why four is chosen as an optimum number of clusters. Table 1 shows the performance of different clustering techniques. Table 2 shows the clusters formed by different clustering techniques. From Table 2 we can easily visualize that the yellow part (1^{st} cluster) which shows the hot water part is segmented properly using EFCM.

Example 2: Here we are concerned with an infrared image showing breast cancer. Yellow part shows the cancer prone area in the breast. Fig. 2 shows how the optimum number of cluster is four. Table 3 shows the performance of different clustering techniques used in this paper. Table 4 shows the clusters formed by different clustering methods. From this table we can see that cancer prone part (3^{rd} cluster) is removed properly using EFCM. Validity of number of clusters can be assessed visually.

Example 3: In this example we consider segmentation of an infrared image taken at Tromso satellite station showing advancing of bloom. Yellow and red part shows warmer water and advancement of bloom. Here five is chosen as the optimum number of clusters. From Table 6 we can see that the red region (1^{st} cluster) is completely separated from the image.

A. Comparison of performance

The results of infrared image segmentation indicate that EFCM is successful in segmenting the image properly with optimum number of clusters. The Global Silhouette Index value of EFCM is the best in most of the cases. Results show that EFCM could retrieve most of the clusters properly. The cluster centers in case of Fuzzy C-means are widely separated. It is able to retrieve all the basic clusters, giving less redundant clusters. The disadvantage with Fuzzy C-Means is that it cannot find out the optimum number of clusters. K-means result is also good but the most important disadvantage of K-means is that it generally does not give proper clusters in the first run. This is due to random selection of cluster centers which results in consumption of more time while dealing in large images. EM results are not better than that of EFCM and K-means.

B. Practical Application

The main aim of the paper is to propose a technique which can be conveniently used in automatic detection systems. Here, the phrase "Detection Systems" is concerned with systems like detection of hot water level in boilers, detection of geographical features on any planet or even on unreachable areas of earth, weather forecasting systems and medical systems. Systems related to the examples mentioned above are described below:

1) Detection of water level in a boiler: Infrared images work on the principle of temperature sensing. They map a temperature range to various colors. This detection system takes the infrared image of the boiler and uses EFCM technique to segment the image properly for optimum number of clusters. For each cluster, average R, G, B value is calculated and corresponding temperature of that color is obtained from predefined scale. Then it compares the predefined temperature of water (i.e. 100^{o}C) with the temperature of various clusters and finds out the required cluster. Next step is to check the height of water level in boiler which is proportional to the height of color in the required cluster (1^{st} cluster) . Now water supply can be controlled on the basis of height of color. Real time implementation of this system can reduce the complexity of conventional boiler control system designs.

2) Detection of breast cancer: Medical thermal imaging (MII) can indicate life threatening diseases like breast cancer in their developing states, earlier than anatomical examinations. This type of detection system takes the infrared image, processes it for EFCM, calculates the average R, G, B values and obtains corresponding temperatures as described earlier. Subsequently, it checks for a predefined temperature region of the affected area to obtain the required cluster. From the cluster, affected area can be easily visualized. In Example 2 yellow color (3^{rd} cluster) shows the cancer prone area which is faithfully separated.

3) Detection of Geographical Features: Example 3 shows the infrared image taken at Tromso Satellite station. This image shows the bloom. Advancement of red color can give the information about direction of movement of bloom and its intensity. Usually satellite sends the whole image (very large data) to earth station. The large amount of data to be transmitted is very likely to be corrupted by noise. So it is better to send only required information which is depicted in red color (1^{st} cluster) in this case. If the satellite is equipped with EFCM processor then it will take the image, cluster it properly as shown in Table 6, and send only red color image to the earth station which is very small volume of data as compared to the amount of data required to represent the entire image. Continuous tracking of red color can give information about the advancement and intensity of bloom. This system can help in reducing the quantity of data transferred from the satellite to earth station because we can send only the required part of the image to earth.

V. CONCLUSION

In this paper, we present EFCM based infrared image segmentation. We have applied some well-known clustering techniques, viz., K-Means, EM for the segmentation of colored images and compared their performance in terms of Global Silhouette Index and Separation Index that they achieve. We have obtained that EFCM was able to estimate the number of clusters accurately. Its performance on the basis of GS and SI is better than other techniques used for comparison. Hence this technique can be preferably used for the Automatic Detection Systems. Automatic Detection Systems described in this paper can make data transfer much faster and easier (in Example 3), can reduce the size and complexity of conventional control systems for boiler (in Example 1) and can even detect the very dangerous and rare diseases that cannot be easily diagnosed in early stages.

ACKNOWLEDGMENT

***Abstract*—A data association technique for target tracking that uses image correlation is enhanced by incorporating uncertainty. The approach uses fuzzy logic to simplify the mapping of the uncertainty to a usable construct to adjust the image generation based on the uncertainty of the measurements. The application of the uncertainty mapping for two methods is developed. The first technique varies the size of the image based on uncertainty. The second modifies the phase variation range that is used to generate the elements in the tile. The techniques are compared to the baseline image correlation technique in a baseline target-tracking example.**

Keywords- Data fusion; data association; image correlation; fuzzy logic application; uncertainty.

I. INTRODUCTION

In data fusion applications, one of the most important steps in the process is the data association step [1, 2]. No matter the estimation algorithm or application, a technique to determine which measurements or observations are related to existing fusion estimates or each other is necessary. In target tracking, the standard method for data association is the chi-squared metric. This measure, based on the Mahalanobis distance, is a weighted measure that is used to compare two Gaussian random variables and is usually applied to kinematic distances. It is not easily applied to non-kinematic information, non-Gaussian distributions, or different data formats, e.g., classification and kinematics.

Another approach to data association was developed using image correlation [3]. In that effort, kinematic and classification over time was mapped to an image representation. Using this approach, a representation of the target track attributes over time, referred to as a tile, is generated. This windowed association technique, similar in concept of association to the ND-assignment problem [4], uses a phase-only filter (POF) image correlation score. While the technique of [3] had promise, it did not rely on the phase information that is the foundation of the POF. A better implementation using a phase-based tile was developed in [5, 6] that compared favorably when compared to the chi-squared metric. While the chi-square metric incorporates uncertainty, the phase-based tile approaches previously developed did not. In this work, two separate techniques to incorporate uncertainty into the association score are developed.

The first technique to incorporate uncertainty alters the size of the tile elements used for the image correlation based upon the uncertainty. Here, this is incorporated into the association and the effect on the resulting association of changing the size of the tile elements based on the uncertainty is observed. The second technique incorporates uncertainty by using phase variation mappings. Both techniques require the ability to map the variations based on the size of the uncertainties. A fuzzy logic process based the fuzzy data association technique of [7, 8] is employed by each of the two techniques in order to map the uncertainty. The application of the rescaling is global in that the entire tile is affected for each attribute based on all of the uncertainties in the time window. This is in contrast to techniques that change each measurement based on its uncertainty.

In Section 2, the image correlation technique using a phase-tile is presented. This is followed in Section 3 by an overview of tile generation. The development of the fuzzy logic used to map the uncertainty into the function that will vary the size of different attribute in the tile and the phase variation for each attribute is discussed in Section 4. Section 5 presents the technique to be used for tile size variation. The application of the fuzzy logic technique for the mapping of the phase variation is presented in Section 6. Section 7 provides a comparison of the techniques with two different tracking examples.

II. PHASE ONLY FILTER IMAGE CORRELATION

The 2-D image correlation problem has several approaches. The standard 2-dimensional image correlation function is defined by the 2-D convolution sequence

$$h(x,y)=\sum_{n=1}^{N}\sum_{m=1}^{M} g(m,n) f(x-n,y-m) \qquad (1)$$

As with most straightforward mathematical techniques, the function is a computational bottleneck and memory intensive. The operational computations are $O(n^4)$ flops where n is the number of pixels along an edge (assuming a square image). The resulting image will have four times the pixels. A more efficient approach is to utilize the frequency domain implementation. This requires three 2-D fast Fourier transforms

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

(FFTs) and one pixel-by-pixel multiplication of the two transformed images. The resulting algorithm is given as

$$\begin{aligned}&\sum\sum f^*(x,y) * f(x+X, y+Y) = \\ &\sum\sum F^*(k_x,k_y) F(k_x,k_y) e^{-j(k_x X + k_y Y)} \\ &= \mathbf{F}^{-1}\left\{\left|F(k_x,k_y)\right|^2\right\}\end{aligned} \tag{2}$$

for autocorrelation, and

$$\begin{aligned}&\sum\sum g^*(x,y) * f(x+X, y+Y) \\ &= \sum\sum G^*(k_x,k_y) F(k_x,k_y) e^{-j(k_x X + k_y Y)} \\ &= \mathrm{Re}\left\{\mathbf{F}^{-1}\left\{G^*(k_x,k_y) F(k_x,k_y)\right\}\right\}\end{aligned} \tag{3}$$

for cross-correlation.

Mathematically, the FFT was an improvement, but early implementers of image correlation used specific optical hardware, referred to as an optical correlator, to provide the calculations since large images could take significant computing power. Figure 1 shows the functional flow for such a device.

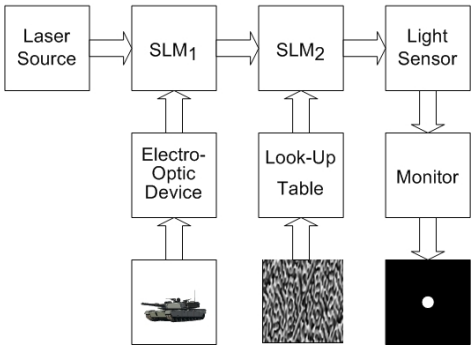

Figure 1. Function flow for optical correlator device providing image correlation

The physical limitations of the optical correlators did not exactly produce the correlation functions of Eqs. 2 and 3. Instead, the input signal became amplitude normalized such that primarily only the phase information was transmitted. The resulting equations became a phase-only filter (POF) given by

$$\begin{aligned}&\sum\sum G^*(k_x,k_y) \frac{F(k_x,k_y)}{\left|F(k_x,k_y)\right|} e^{-j(k_x X + k_y Y)} \\ &= \mathrm{Re}\left\{\mathbf{F}^{-1}\left\{G^*(k_x,k_y) \frac{F(k_x,k_y)}{\left|F(k_x,k_y)\right|}\right\}\right\}\end{aligned} . \tag{4}$$

As discussed in [10], the phase contained the most information of the image for comparison. As such the POF inadvertently became a powerful image correlation algorithm.

It is also worth noting that Eq. (4) is not commutative. Thus, if we change the order of the images in the cross-correlation problem, a different correlation will result.

III. Tile Generation

Each feature of a pattern for a given target report is comprised of an element of the tile comprised of a contiguous *n* x *n* pixel set. This set will be referred to as a sub-tile. In previous work [5], the size of the sub-tile for phase attribute matching has set to 20 pixels along each edge. This was determined to be a size that provided enough information in the frequency and phase based tiles for comparisons. These subtiles will not be fixed in size for one variant application. For the amplitude mapping approach, each attribute is assigned a region of interest or operational constraint. For example, a given pattern of data association is measured at two separate times. Position is given in terms of latitude and longitude. The third feature is the tracked altitude of the target. The fourth feature represents the measured vehicle speed. The final feature is the target heading. These values are tabulated in Table 1.

The POF correlation technique relies upon the majority of the image information being found within the phase components of the image. In contrast, the amplitude tile, first discussed in [3], uses amplitude variation to compare information. In [12], a phase representation was developed and compared well against the amplitude technique. Each attribute is mapped into a sub-tile that is defined as

$$f(x,y) = \sin(\omega x + \phi)\sin(\omega y + \phi). \tag{5}$$

TABLE I. Track Reports for Data Association

Feature	Lat. (deg.)	Long. (deg)	Altitude (m)	Speed (m/s)	Heading (deg.)
Scan 1	32	27	2500	100	45
Scan 2	32.6	25.6	3000	100	187

The frequency is different for each attribute or feature. For each frequency used, the value of each attribute is expressed by the phase component. The region of interest for the phase of each attribute value in Eq. (5) is mapped linearly between 0^o and 180^o. When the pattern from Table 1 is mapped into a phase tile, the result is a two-scan image that is depicted in Figure 2. The region of interest for the features is defined between 30^o and 35^o for latitude, 25^o and 28^o for the target's longitude, an altitude range between 0 and 4000 meters, a speed between 0 and 200 m/s, and a heading between 0^o and 360^o.

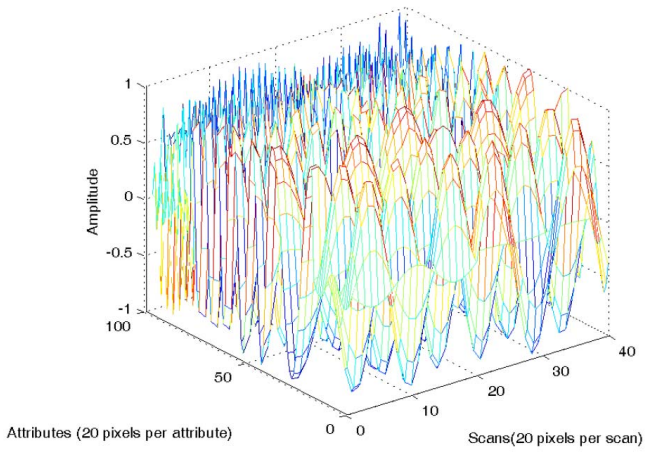

Figure 2. Two-scan image of phase tile for example data reports.

A. *Normalization*

The correlation function created by the POF provides a visual correlation peak that is easily understood. The function, however, does vary based on the amount of energy in the images. While this function is computationally complex, the optical correlator has it built-in via the physics and architecture. The energy variation means that comparisons require a normalization implementation. The approach used in this investigation is to compute the autocorrelation peaks of both images using the POF

$$\max\left(\max\left(POF(f(x,y),f(x,y)\right),\max(POF(g(x,y),g(x,y))\right) \quad (6)$$

and to find the maximum autocorrelation of both images. This value is used to divide the values of all of the points in the cross-correlation function.

IV. Fuzzy Logic Mapping of Uncertainty

In [7], a fuzzy logic approach to the data association problem was developed. There, the technique used multi-layered fuzzy logic to create a score by implementing a linguistic interpretation of the chi-squared metric. It looked at closeness based on the weighted distance between the two track elements. It also looked at the overlap of the error ellipses [11]. In this approach, a similar view of the error ellipses is used. Instead of using complex mathematical distances which would be adverse to the simplicity of the image correlation technique, a basic fuzzy logic approach is developed to adjust the tile creation based on the uncertainty ellipse size and orientation.

The first variable to be mapped is that of the orientation of the error ellipses. The fuzzy memberships are defined as five potential angles of the error ellipse relative to the longitude (x-axis). As seen in Figure 3, the memberships are 0^o, 45^o, 90^o, 135^o, 180^o. The alignments provide two inputs to the fuzzy decision process described in Figure 4. The first is a weighting factor that is generated using the crisp value of the antecedent functions. These weights are used in the defuzzification process of the second defuzzification step in Figure 4. The output of the first fuzzy logic function is used to modify the the range of values that defined the consequence membership functions in the defuzzification step of the second fuzzy logic function.

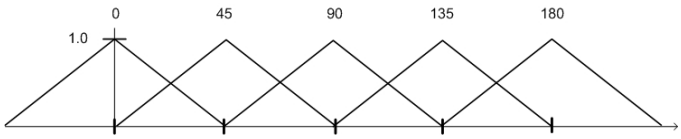

Figure 3. The antecedant triangular membership functions used to determine the alignment of the uncertainty ellipses

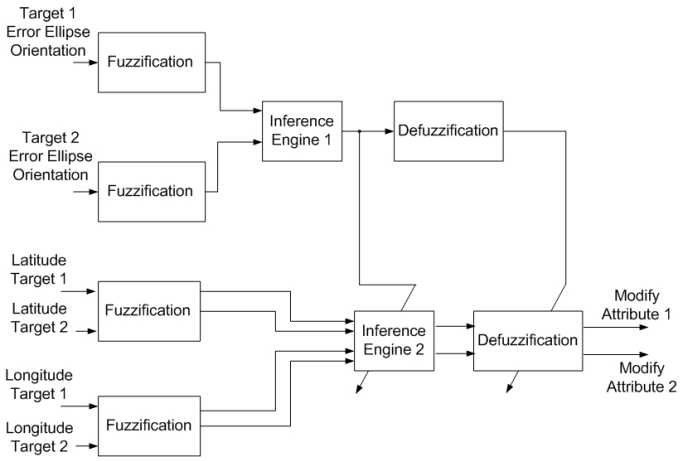

Figure 4. The fuzzy logic process to vary the tile generation used in image correlation track association process

The second input is the different rules that are activated from the inference engines in Tables 2 and 3 which relate to longitude component of the target track (or the x-axis) or the latitude component of the track (x-axis). These rules from the first stage determine vary the inputs to the inference engine the second stage (Table 4). The variations in the inputs are defined in Table 5. The input A indicates the average size of the minor or major axes of the uncertainty ellipse of Track 1 and B indicates the average of minor or major axes of Track 2. The table also indicates that multiple instantiations of the fuzzy inference engine are used in several cases.

The second process is based on the size of the axis of interest of the uncertainty ellipse. The actual uncertainty in the directions of latitude and longitude are mapped to membership functions in Figure 5. The elements of the membership functions are *small*, *medium_one*, *medium_two*, and *large*. Since the uncertainty measure is global, i.e., averaged over the entire time window, the results will affect all of the time subtiles of the entire attribute similarly. The proposed inference engine, defined in Table 4, varies depending on the alignment rule from the first step. If multiple instantiations are desired, then the output of each instantiation is weighted by the noted factor in Table 5. An NA indicates that those

rules are not used and result in a zero value for that component. The terms Maj and Min in the table refer to the major and minor axes of the uncertainty ellipses, respectively.

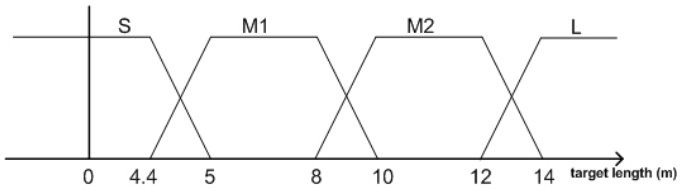

Figure 5. The antecedant triangular membership functions used to determine the size of the uncertainty ellipses axis

To simplify the development shown, the association score is generated on only the position data. The extension to include velocity would simply repeat the process on the velocity measures and uncertainties.

V. ATTRIBUTE PIXEL RESIZING BASED ON UNCERTAINTY

In image correlation, two images can have a noticeable difference, but, if the difference is a small percentage of the overall difference, then the images can still be highly correlated. In target tracking, if a component of the track has a large uncertainty, then the any effective difference between that component and the same component for a track or measurement to which it is being associated is reduced. The seven potential modifications will take the height of each subtile for a given attribute from 20 pixels down to 2 pixels. This is a reduction of 3 pixels for each rule. This means the consequence membership functions becomes as seen in Figure 6.

3	3	1	Min	Min	NA	NA	NA	NA	NA	NA

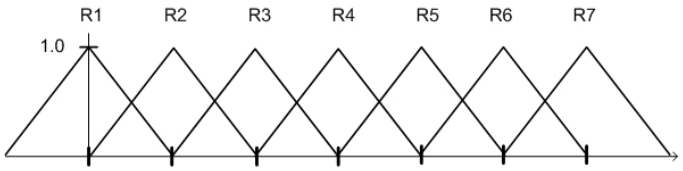

Figure 6. The consequence triangular membership functions used to determine the reduction in the attribute pixel size

The result of this approach is that large uncertainty has a lesser effect on the correlation score. This implies that the attributes (or elements of the track) with small differences relative to the uncertainty should be mapped into similar phases rather than different phases. Thus, rather than a linear mapping, the mapping should be non-linear in order to better represent attributes that effectively or near match, given the measurement uncertainty.

VI. INCORPORATING UNCERTAINTY AS A QUANTIZATION OF THE PHASE SEPARATION

The second approach to incorporating uncertainty is to vary the phase difference used in generating the subtiles. As seen in Figure 7, the linear range of values is reduced as the uncertainty becomes larger. This implies that the variation in the phase for small changes becomes less for very uncertain tracks than when the uncertainty is smaller. Thus, the association score in the former case would be greater as occurs in the chi-squared metric. The consequence function is the same as that seen in Figure 6. The defuzzified value is used to reduce the phase range.

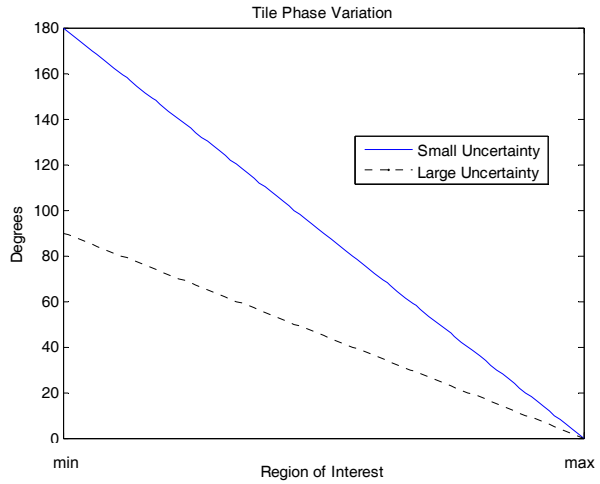

Figure 7. An example of the change in range of the phase variation based on track uncertainty

VII. EXAMPLE AND RESULTS

A scenario with two targets and three sensor systems was generated to compare the standard to the two techniques that incorporate uncertainty in a global manner. The two targets' trajectories are depicted in Figure 8 where the target on the bottom is considered Target 1 and that on top is considered Target 2. The sensor locations were chosen so that nearly parallel measurements (based on the uncertainty ellipses) were generated (Sensors 1 and 2) as the targets moved further along and nearly perpendicular target measurements were generated. These are considered extremes in target tracking and provide a good baseline.

The three sensors platforms, which are stationary throughout the scenario, are also shown in Figure 8. The three sensors are identical range-bearing sensors, i.e., a radar or active sonar, each with Kalman filter kinetic target tracking systems on them. As noted previously, the target tracks are associated with only the position data for this effort.

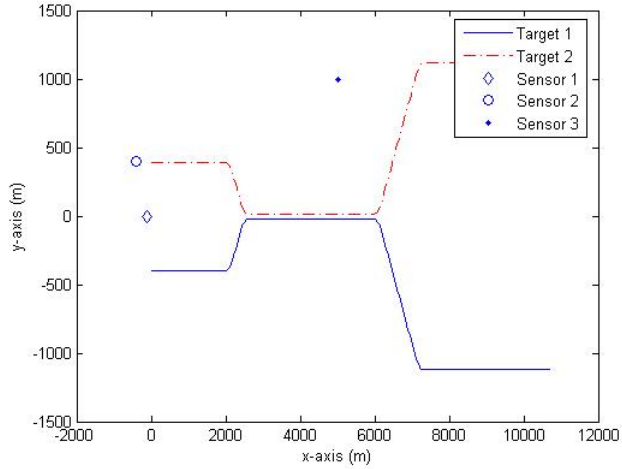

Figure 8. Example scenario with two targets and three sensors

The association scores of the track of Target 1 produced by the tracker of Sensor 1 compared to the two tracks of Sensor 2 are seen in Figures 9-11. Figure 9 depicts the association results of the original correlation technique without uncertainty. The results as in past efforts [7, 8] provide the ability to discern the two targets. In Figure 10, the uncertainty approach using the global resizing of the height of each attribute based on the average uncertainty is shown. In this case, the early portion of the track association does significantly better than without the uncertainty. At the end of the trajectory, the results are similar. This is due to the affects of the larger cross-range error of the sensor reports as the target gets further from the sensors. The cross-range error, especially for Sensor 1, is primarily in the direction of the y-axis. This is where the difference between the two targets exists in position. Figure 11 shows that the phase modification based uncertainty has a greater, and overall better, effect on the association scoring.

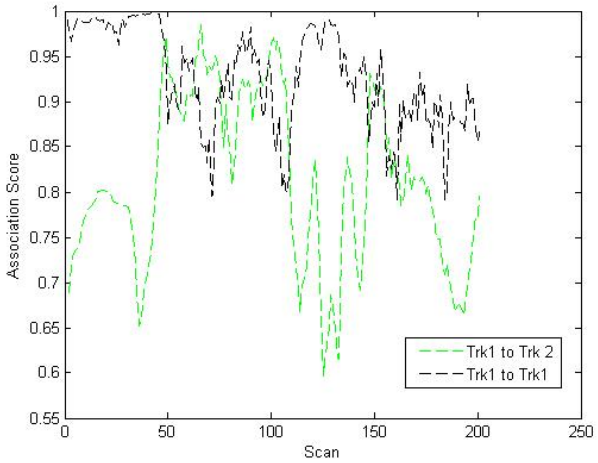

Figure 9. Association results for Sensor 1 and Sensor 2 without incorporating uncertainty

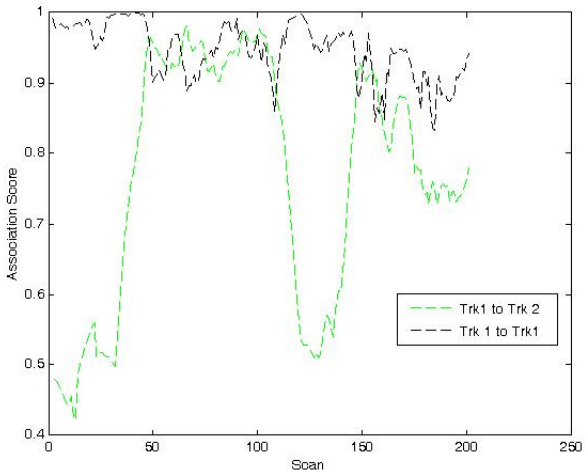

Figure 10. Association results for Sensor 1 and Sensor 2 incorporating global resizing

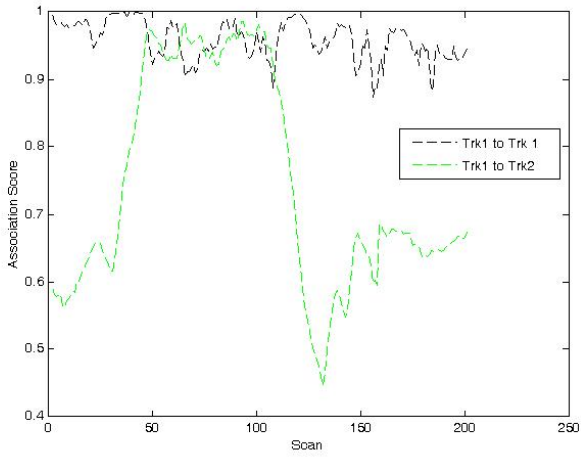

Figure 11. Association results for Sensor 1 and Sensor 2 incorporating phase modification based uncertainty

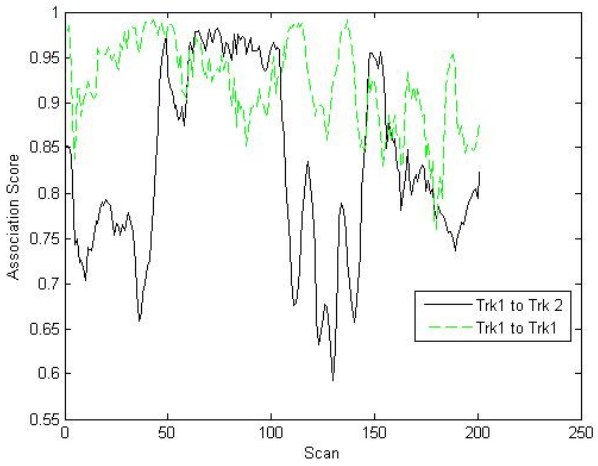

Figure 12. Association results for Sensor 1 and Sensor 3 without incorporating uncertainty

Figures 12-14 show the same comparisons as above but between Track 1 from Sensor 1 and both Tracks from Sensor 3. Similar results are obtained. The main differences that are seen are a result of the placement of the Sensor 3, which is perpendicular to Sensor 1 but closer to the end of the trajectory of the targets.

VIII. CONCLUSIONS

In this paper, two new approaches to incorporate uncertainty into the tile generation technique using fuzzy logic were introduced and demonstrated to provide significant improvement in the association scores. The use of fuzzy logic was able to provide the algorithm with less complex process to make the adjustments to the parameters used in the tile generation than if a full model of the process were developed.

Each technique was a global one in that the entire attribute component of the tile was changed based on the fuzzy system output. Future efforts are to show that by modifying only the input to the fuzzy system, the time component of each attribute can be changed with better results while allowing the fuzzy system to remain unchanged.

As this work continues, tracking system with different sensors types, e.g., bearing-only sensors, will be considered. This will demonstrate the total effectiveness of the uncertainty incorporation. Another adaptation to the techniques is to explore the incorporation of non-Gaussian uncertainties. By not limiting the association routine, it will become an effective tool with new tracking systems such as the particle filter.

***Abstract*—Removing Mixed Gaussian and Impulse Noise (MGIN) is considered to be very important in the domain of image restoration, but it is a somewhat more challenging topic than removing pure Gaussian or impulse noise. Therefore, relatively fewer works have been published in this area. This paper proposes a Non-Singleton Interval Type-2 (IT2) Fuzzy Logic System (FLS) for MGIN removal, explains how it can be designed based on a Quantum-behaved Particle Swarm Optimization algorithm, and shows that it provides both quantitatively and visually much better results compared to other often-used non-fuzzy techniques as well as its Type-1 and singleton IT2 counterparts.**

I. Introduction

Noises introduced into digital images during acquisition and/or transmission stages can be adequately modeled by either Additive Gaussian White Noise (AGWN), impulse noise, or Mixed Gaussian and Impulse Noise (MGIN) [28], [51].

AWGN, which is inadvertently introduced to an image during its acquisition stage, can be modeled as adding to each image pixel a value from a zero-mean Gaussian distribution. An ideal filter for removing AWGN would be able to smooth pixels within a distinct local region of an image without reducing the sharpness of the edges of that region. A Gaussian filter, which is a linear filter, can smooth noise out very efficiently; but, it does this at the price of significant edge blurring. To overcome this drawback, some nonlinear filters have been proposed [50], [64] that focus on using local measures of an image to detect the edges and smooth them less than other parts of the image.

Impulse noise, generally caused by transmission errors, can be modeled by randomly replacing a portion of the pixels with random pixels, while leaving the remaining pixels unchanged. The filters specifically developed for AWGN removal do not work well on impulse noise, because these filters consider the impulse noise pixels as edges, and preserve them. Different kinds of filters that aim at removing impulse noise have therefore been proposed, and were summarized by Yildirim et al. [74] as follows: 1) standard median filter [24], [65], which replaces the center pixel of a filtering window with the median value of all pixels in that window, has decent performance in terms of noise removal, but it also blurs image details like thin lines even at a low noise level; 2) modified versions of the median filter, e.g., weighted and center-weighted median filters [37], [75], [76], which give more weights to certain pixels in the filtering window, gain improved performance in terms of preserving image details at the cost of reduced noise removal capability; 3) approaches based on impulse detectors, which aim at deciding whether the center pixel of the filtering window has been corrupted by noise or not, e.g., [2], [7]–[12], [15], [19], [26], [36], [53], [59], [60], [63], [67], [72], [77], [80], [83]; 4) other mean-filter-based approaches [1], [29], [42] also exhibited good performance, but at the price of high computational expenses; 5) many different approaches based on soft computing methodologies [6], [13], [49], [55], [56], [58], [66], [74], [79], along with a number of nonlinear filters [39], [54], [57], [61], [68], [71], [78] that integrate the desired features of some of the aforementioned filters.

MGIN often occurs when an already corrupted image is transmitted over a noisy communication channel [25], [51]; and, is modeled by first adding AWGN and then impulse noise into the images. The study of MGIN removal is considered to be more general and challenging than that of pure AWGN or impulse noise removal; therefore, relatively fewer works have been published in this area, e.g., 1) Ma et al. developed a Structure-Adaptive Hybrid Vector Filter (SAHVF) [43] that employs a quad-tree decomposition to assess activities in different regions of the image, in order to choose a noise removal filter among a set of *ad hoc* approaches such as Peer Group Filter (PGF) [35], Adaptive Nearest Neighbor Filter (ANNF) [52], and Structure Weighted Average Filter (SWAF); 2) Garnett et al. [25] introduced a Rank Order Absolute Differences (ROAD) method that first focuses on impulse detection, and then uses a bilateral Gaussian filter to suppress noise; 3) Yang and Wu [73] first use an Impulse Proportion Adaptive Median Filter (IPAMF) to remove impulse noise, and then a Block-Matching 3-Dimensional (BM3D) DCT filter [16] to clean up AWGN.

Two types of criteria are often used to evaluate the performances of noise removal filters: quantitative measures, such as Mean Square Error (MSE) and Peak Signal-Noise Ratio

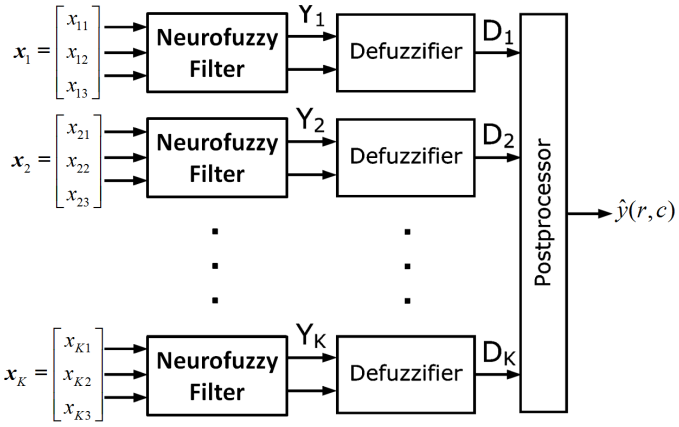

Fig. 1. Overview of the complete IT2 FLS composed by K neurofuzzy filters [74].

(PSNR), and visual quality of the restored image. It is generally very difficult for a filter to produce both quantitatively excellent and visually satisfactory outputs. Regarding MGIN removal, Yang and Wu's IPAMF+BM3D approach yields the best results from a visual quality perspective; while in the domain of pure impulse noise removal, an approach based on Interval Type-2 (IT2) TSK Fuzzy Logic System (FLS) [45], recently introduced by Yildirim et al. [74], has significantly exceeded all other filters in terms of quantitative measures.

Based on the framework proposed by Yildirim et al. [74], this paper develops a Non-Singleton (NS) IT2 FLS[1] [45], uses it jointly with the BM3D DCT filter, and shows that this new approach, referred to in the sequel as NS-IT2+BM3D, enables the highly corrupted images in MGIN environment to achieve excellent visual quality and exceptionally good quantitative results.

The rest of the paper is organized as follows: Section II presents the overview of the complete FLS, the detailed structure of its building blocks, namely, the neurofuzzy filters, and how a training image set can be generated and used by a Quantum-behaved Particle Swarm Optimization (QPSO) algorithm to find the "optimal" set of design parameters for each neurofuzzy filter; Section III demonstrates the improved performance of our NS-IT2 FLS by comparing it against several other techniques as well as its T1 and singleton IT2 counterparts; Section IV draws conclusions for the paper.

II. Noise Removal based on Fuzzy Logic System

A. Neurofuzzy filters

Our complete IT2 FLS has the general structure as depicted in Fig. 1. It is composed of K neurofuzzy filters, each of which can be viewed as a sub-FLS, and has the same structure,

[1]Compared to Singleton FLSs, NS FLSs allow users to account for the uncertainties associated with the input measurements. Note that NS FLSs based on Gradient Descend Methods have been well studied in [45], but were never widely applied due to their extremely complicated gradient formulas. This paper shows how Quantum-behaved Particle Swarm Optimization algorithm enables designers to achieve "optimal" NS IT2-FLSs without having to derive the gradient formulas.

$x(r-1,c-1)$	$x(r-1,c)$	$x(r-1,c+1)$
$x(r,c-1)$	$x(r,c)$	$x(r,c+1)$
$x(r+1,c-1)$	$x(r+1,c)$	$x(r+1,c+1)$

Fig. 2. Filtering window for neurofuzzy filters, where r and c are the indices of rows and columns, respectively, e.g., $x(r,c)$ is the luminance value of the pixel located at row r and column c [74].

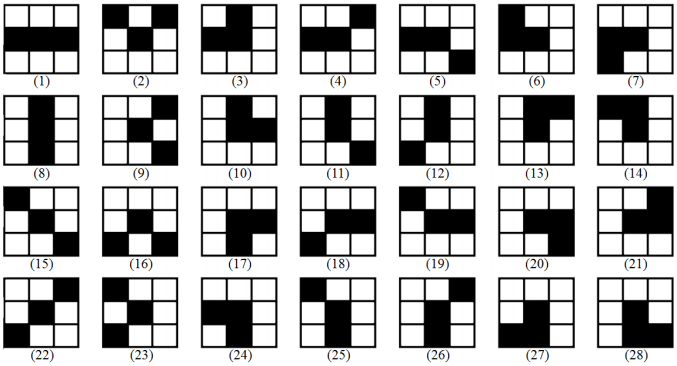

Fig. 3. 28 possible pixel topologies for the neurofuzzy filters [74].

i.e., the same number of antecedents, the same number of rules, and so on; but each uses a different input data set obtained from the given noisy image, and, therefore, has different design parameters. Each data set is obtained by shifting a 3×3 filtering window (see Fig. 2) through all pixels (excluding boundary pixels) in the image. Each time the window centers at a pixel, three of the nine pixels in the filtering window are selected to form an input vector, $\boldsymbol{x}_i = [x_{i1} \;\; x_{i2} \;\; x_{i3}]^T \; (i = 1, \ldots, K)$, for the i^{th} neurofuzzy filter.

Observe, in Fig. 3, that there are a total of 28 possible combinations of any three pixels in a filtering window, i.e., there can be at most $K = 28$ neurofuzzy filters. To give a specific example, assume we are focusing on the 7^{th} neurofuzzy filter that corresponds to pixel topology (7) in Fig. 3, and assume that the filtering window is centered at the pixel located at row r and column c (see Fig. 2), then the input vector for this neurofuzzy filter at this location is $\boldsymbol{x}_7 = [x_{71} \;\; x_{72} \;\; x_{73}]^T = [x(r+1,c-1) \;\; x(r,c-1) \;\; x(r,c)]^T$. The output of this neurofuzzy filter is an interval of numbers of the noise-free luminance value at location (r,c), $Y_7(r,c) = [\underline{y}_7(r,c), \bar{y}_7(r,c)]$. How the neurofuzzy filter actually obtains such an interval of numbers is described in details in Section II-B. A point-value for pixel (r,c), $D_7(r,c)$, is then computed, as:

$$D_7(r,c) = \frac{\underline{y}_7(r,c) + \bar{y}_7(r,c)}{2} \tag{1}$$

Similar operations are carried out by all other neurofuzzy filters, each using an input vector obtained based on the corresponding pixel topology. This leads to K defuzzified values, $D_1(r,c), D_2(r,c), \ldots, D_K(r,c)$. A post-processor block takes these defuzzified values and performs the following

computations to obtain the final estimation, $\hat{y}(r,c)$, of the noise-free luminance value at location (r,c):

$$D_{AV}(r,c) = \frac{1}{K}\sum_{i=1}^{K} D_i(r,c) \tag{2}$$

$$\hat{y}(r,c) = \begin{cases} 0 & \text{if } D_{AV}(r,c) < 0 \\ 255 & \text{if } D_{AV}(r,c) > 255 \\ \text{round}[D_{AV}(r,c)] & \text{otherwise} \end{cases} \tag{3}$$

It is worth of mentioning that all the neurofuzzy filters can be computed in parallel to save computation time.

B. Non-singleton Interval Type-2 Fuzzy Logic System

1) Structure: Type-2 (T2) FSs [46], [47], [81] have been shown to be more capable of modeling uncertainties than are T1 FSs. As a special case of T2 FSs, IT2 FSs have been widely used in FLS design for various applications [3], [4], [20], [44], [48]. On the other hand, a Non-Singleton (NS) FLS [45] allows users to take into consideration the uncertainties embedded in the input measurements, and gives the users more degree of design freedom by modeling input values as FSs instead of crisp numbers.

In this paper, we build each of the neurofuzzy filters mentioned in Section II-A as a T1 NS IT2 FLS, where the input values are modeled as T1 FSs[2]. Without loss of generality, assume we are focusing on the i^{th} $(i = 1, 2, \ldots, K)$ neurofuzzy filter, and want to use it to obtain an interval estimation, $Y_i(r,c)$, of the pixel value at location (r,c). Recall that the input vector is $\boldsymbol{x}_i = [x_{i1}\ \ x_{i2}\ \ x_{i3}]$, which is obtained by collecting three pixel values in the filtering window based on the corresponding topology. Our proposed NS IT2 FLS is based on N rules that take the following forms:

Rule 1: IF $\tilde{X}_{i1}$ is $\tilde{F}_{i1}^1$ and $\tilde{X}_{i2}$ is $\tilde{F}_{i2}^1$ and $\tilde{X}_{i3}$ is $\tilde{F}_{i3}^1$
THEN y_i is $\tilde{G}_i^1$

$\cdots$

Rule N: IF $\tilde{X}_{i1}$ is $\tilde{F}_{i1}^N$ and $\tilde{X}_{i2}$ is $\tilde{F}_{i2}^N$ and $\tilde{X}_{i3}$ is $\tilde{F}_{i3}^N$
THEN y_i is $\tilde{G}_i^N$

where the consequent of each rule, $\tilde{G}_i^k$ $(k = 1, \cdots, N)$, is an IT2 FS whose centroid [33], [45] is the interval $[y_{il}^k, y_{ir}^k]$; and each antecedent, $\tilde{F}_{ij}^k$ $(j = 1, 2, 3$ and $k = 1, \cdots, N)$, is an IT2 FS described by a *Lower Membership Function* (LMF) and an *Upper Membership Function* (UMF) that have the following forms, respectively $(u \in X)$:

$$\underline{\mu}_{ij}^k(u) = \begin{cases} N(\overline{m}_{ij}^k, \sigma_{ij}^k; u) & \text{if } u \le \frac{\underline{m}_{ij}^k + \overline{m}_{ij}^k}{2} \\ N(\underline{m}_{ij}^k, \sigma_{ij}^k; u) & \text{if } u > \frac{\underline{m}_{ij}^k + \overline{m}_{ij}^k}{2} \end{cases} \tag{4}$$

[2]The input values can be further modeled as IT2 FSs, which will give the system even more degrees of design freedom, and has the potential to gain additional improvements for the performance. Since this paper is the first attempt to develop a NS IT2 FLS in the domain of image processing, and only has limited space, we only focus on the T1 NS IT2 FLS here, and will study the IT2 NS IT2 FLS in the future.

$$\overline{\mu}_{ij}^k(u) = \begin{cases} N(\underline{m}_{ij}^k, \sigma_{ij}^k; u) & \text{if } u < \underline{m}_{ij}^k \\ 1 & \text{if } \underline{m}_{ij}^k \le u \le \overline{m}_{ij}^k \\ N(\overline{m}_{ij}^k, \sigma_{ij}^k; u) & \text{if } u > \overline{m}_{ij}^k \end{cases} \tag{5}$$

where, e.g., $N(\underline{m}_{ij}^k, \sigma_{ij}^k; u) = \exp[-\frac{1}{2}(u - \underline{m}_{ij}^k/\sigma_{ij}^k)^2]$. Examples of the three antecedent IT2 FSs of the k^{th} rule are depicted by the gray areas in Fig. 4, that are called *Footprints Of Uncertainty* (FOU).

The input T1 FS, $\tilde{X}_{ij}$ $(j = 1, 2, 3)$, for the corresponding antecedent has the following MF $(u \in X)$:

$$\mu_{ij}^k(u) = N(x_{ij}, \sigma_{\tilde{X}_{ij}}^k; u) \tag{6}$$

where the mean of the MF is the actual crisp input value x_{ij}. Examples of the three input T1 FSs are depicted by the dotted lines in Fig. 4.

2) Inference Engine: Details regarding the above rule-based inference system can be found in [45], Chapter 11. This section briefly reviews all the necessary steps of the computations.

First, the firing interval for every antecedent in each rule, $[\underline{f}_{ij}^k, \overline{f}_{ij}^k]$ $(j = 1, 2, 3$ and $k = 1, 2, \ldots, N)$, needs to be computed, where $\underline{f}_{ij}^k$ $(\overline{f}_{ij}^k)$ corresponds to the maximum value of the fuzzy intersections between the LMF (UMF) of $\tilde{F}_{ij}^k$ and the MF of X_{ij}, respectively:

$$\underline{f}_{ij}^k = \max_{u \in X} \left\{ \min \left[\underline{\mu}_{ij}^k(u), \mu_{ij}^k(u) \right] \right\} \tag{7}$$

$$\overline{f}_{ij}^k = \max_{u \in X} \left\{ \min \left[\overline{\mu}_{ij}^k(u), \mu_{ij}^k(u) \right] \right\} \tag{8}$$

An example of the fuzzy intersections between $\underline{\mu}_{ij}^k(u)$ $[\overline{\mu}_{ij}^k(u)]$ and μ_{ij}^k for the k^{th} rule are depicted by the heavy dashed (solid) lines in Fig. 4, where the corresponding $\underline{f}_{ij}^k$ and $\overline{f}_{ij}^k$ values are also labeled.

Once the firing interval of each antecedent becomes available, the firing interval for each rule, $[f_{il}^k, f_{ir}^k]$ $(k = 1, 2, \cdots, N)$, is obtained as follows:

$$f_{il}^k = \min_{j \in \{1,2,3\}} \underline{f}_{ij}^k \tag{9}$$

$$f_{ir}^k = \min_{j \in \{1,2,3\}} \overline{f}_{ij}^k \tag{10}$$

Finally, the Karnik-Mendel (KM) algorithm [33], [45] or the Enhanced KM (EKM) algorithm [69] is used to compute the following two values:

$$\underline{y}_i(r,c) = \min_{f^k \in [f_{il}^k, f_{ir}^k]} \frac{\sum_{k=1}^N f^k y_{il}^k}{\sum_{k=1}^N f^k} \tag{11}$$

$$\overline{y}_i(r,c) = \max_{f^k \in [f_{il}^k, f_{ir}^k]} \frac{\sum_{k=1}^N f^k y_{ir}^k}{\sum_{k=1}^N f^k} \tag{12}$$

which are the desired outputs of the i^{th} neurofuzzy filter, namely, $Y_i(r,c)$ at location (r,c).

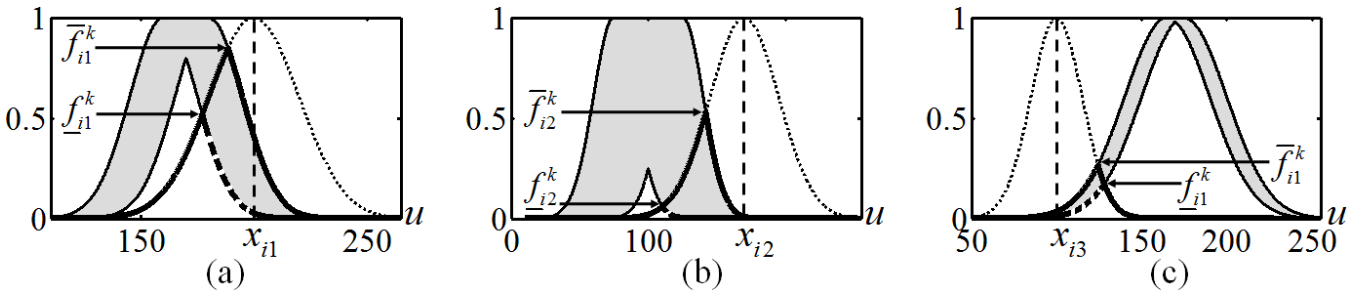

Fig. 4. An example of the LMFs and UMFs, $\underline{\mu}_{ij}^k(u)$ and $\overline{\mu}_{ij}^k(u)$, of the three antecedent IT2 FSs, $\tilde{F}_{ij}^k$ $(j = 1, 2, 3)$; the MFs, $\mu_{ij}^k(u)$, of the corresponding input T1 FSs , $\tilde{X}_{ij}$ $(j = 1, 2, 3)$; and, the fuzzy intersections between $\underline{\mu}_{ij}^k(u)$ $[\overline{\mu}_{ij}^k(u)]$ and μ_{ij}^k $(j = 1, 2, 3)$, where (a) $j = 1$; (b) $j = 2$; (c) $j = 3$.

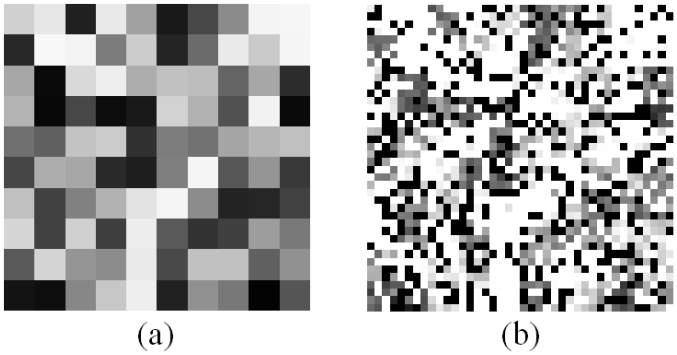

Fig. 5. Training image set: (a) original image, and (b) image corrupted by 30% AWGN and 50% impulse noise.

For the above i^{th} sub-system, each antecedent IT2 FS has three parameters, $\underline{m}_{ij}^k$, $\overline{m}_{ij}^k$ and σ_{ij}^k, each input T1 FS has one parameter, $\sigma_{\tilde{X}_{ij}}^k$, and each consequent has two parameters, y_{il}^k and y_{ir}^k; therefore, there are $3 \times (3 + 1) + 2 = 14$ parameters for each rule. We chose the number of rules[3] to be $N = 3^3 = 27$; consequently, the total number of parameters of each neurofuzzy filter is $N \times 14 = 378$.

C. Training Image Set

The training image set, which is used to tune the parameters of the neurofuzzy filters, consists of an original clean image and its corrupted version, and is artificially generated by a computer. The original image, depicted in Fig. 5(a), is 40×40 pixels and is divided into $10 \times 10 = 100$ boxes, i.e., each box contains $4 \times 4 = 16$ pixels. Pixels in each box have the same luminance value, an 8-bit integer uniformly distributed between 0 and 255.

The corrupted image was obtained by adding MGIN to the original one. The noise level was carefully chosen because it has important impact on the performance of the entire system. After extensive simulations, we used 30% AWGN and 50% impulse noise to contaminate the clean image, and depict the corrupted output in Fig. 5(b).

[3] N is chosen based on extensive simulations, where we tried to find an "optimal" number that provided satisfactory results and yet did not consume too much computation time.

To train the i^{th} neurofuzzy filter, the filtering window shifted through all pixel locations (excluding the boundary pixels), i.e., $r = 2, 3, \ldots, R-1$ and $c = 2, 3, \ldots, C-1$, where R and C are the total number of rows and columns of the pixels in the given image; and a set of input vectors, $\boldsymbol{x}_i$, is collected. Then the rule-based inference system produce a set of $D_i(r, c)$ values ($r = 2, 3, \ldots, R-1$ and $c = 2, 3, \ldots, C-1$), which can be viewed as the i^{th} neurofuzzy filter's estimation of the original pixel values at corresponding locations. Note that all the neurofuzzy filters were trained independently; therefore, the post-processer block was not involved in this stage. The "optimal" set of design parameters is obtained by optimizing the Mean Square Error (MSE) of the estimated pixel values:

$$MSE = \frac{1}{(R-2)(C-2)} \sum_{r=2}^{R-1} \sum_{c=2}^{C-1} [D_i(r, c) - y(r, c)]^2 \quad (13)$$

where $y(r, c)$ is the original noise-free pixel value at (r, c).

Comment: A reviewer of this paper suggested that it is not very clear whether different images would need different training images. In response, we want to point out that only one training image set (as shown in Fig. 5) is needed to obtain a NS IT2 FLS that is universally applicable to all different images.■

D. Particle Swarm Optimization

Different techniques can be employed to tune the parameters of the above neurofuzzy filters (NS IT2 FLSs), e.g., *gradient-based* methods [5], [21] proposed by Liang and Mendel [40], [45]. The analytical forms of the gradients of such a NS IT2 FLS that has this many parameters and nonlinear computations are quite complicated, making the computer implementation very difficult. In fact, this has been the main reason that has prevented NS T2 FLSs from becoming widely used. Also, the performance of the system can suffer significantly if the solution quickly falls into a local minimum, which can easily occur when gradient-based methods are used.

In recent years, *population-based random optimization* techniques, such as *Particle Swarm Optimization* (PSO) [34], *Genetic Algorithm* (GA) [27] and *evolutionary programming* (EP) [22], have been widely applied to T1 FLS designs [14], [18], [23], [30]–[32], [41]. In this paper, we utilize the PSO

algorithm, because it is computationally fast, is the easiest to implement; and, as will be seen in Section III, it enables our system to provide very good results.

1) Quick Review: The standard PSO algorithm, first introduced by Kennedy and Eberhart [34], is briefly reviewed in this section[4].

Let M denote the swarm (population) size, where each particle in the swarm represents a possible solution to the optimization problem; n denote the dimensionality of the search space; and, G denote the total number of generations (iterations) of the optimization process.

Each particle i ($i = 1, 2, \ldots, M$) has three inherent attributes: 1) a current position $\underline{X}_i = (X_{i,1}, X_{i,2}, \ldots, X_{i,n})$ in the search space; 2) a current velocity $\underline{V}_i = (V_{i,1}, V_{i,2}, \ldots, V_{i,n})$; and 3) a personal best (*pbest*) position (the position that produces the minimal value in the history of the particle) $\underline{P}_i = (P_{i,1}, P_{i,2}, \ldots, P_{i,n})$, i.e.:

$$\underline{P}_i(t+1) = \begin{cases} \underline{P}_i(t) & \text{if } f_{obj}(\underline{X}_i(t+1)) \geq f(\underline{P}_i(t)) \\ \underline{X}_i(t+1) & \text{if } f_{obj}(\underline{X}_i(t+1)) < f(\underline{P}_i(t)) \end{cases} \tag{14}$$

where $t = 1, 2, \ldots, G-1$ is the index of generation.

In each generation, each particle updates its velocity as follows ($j = 1, 2, \ldots, n$; $i = 1, 2, \ldots, M$):

$$V_{i,j}(t+1) = w \cdot V_{i,j}(t) + c_1 \cdot r_{1,i}(t)[P_{i,j}(t) - X_{i,j}(t)] + c_2 \cdot r_{2,i}(t)[P_{g,j}(t) - X_{i,j}(t)] \tag{15}$$

where, e.g., $X_{i,j}(t)$ is the j^{th} element of position of the i^{th} particle in the t^{th} generation; c_1 and c_2 are two constants called *acceleration coefficients*; $r_{1,i}(t)$ and $r_{2,i}(t)$ are two random variables uniformly distributed in the interval $[0, 1]$; w is called *inertia weight* that is usually set to decrease linearly from 0.9 to 0.4 during the course of the search process to help PSO reach convergence; and, $\underline{P}_g(t)$ denotes the global best (*gbest*) position found in the history of the entire swarm, i.e. ($i = 1, 2, \ldots, M$):

$$\underline{P}_g(t) = \arg\min_{\underline{P}_i(t)} f_{obj}(\underline{P}_i(t)) \tag{16}$$

At the end of each generation, a new position of a particle can be obtained, as:

$$\underline{X}_i(t+1) = \underline{X}_i(t) + \underline{V}_i(t) \tag{17}$$

2) Quantum-Behaved Particle Swarm Optimization: Despite its exceptionally good performance on many different problems, Van den Bergh [17] has shown that the PSO algorithm does not guarantee global optimization; therefore, ever since its debut in 1995, many variations and modifications of the PSO algorithm have been proposed to enhance its performance [38], [62], [82].

Recently, Sun et al [62], [70] proposed a Quantum-behaved PSO (QPSO) algorithm that, theoretically, guarantees optimal solution in the search space, and, they have shown that, in practice, the QPSO algorithm indeed provides better results for many widely-used benchmark tests than does the standard PSO algorithm. Therefore, this particular version of the PSO algorithm is our choice. Its pseudo-code is [70]:

initialize $\underline{X}_i(1)$ ($i = 1, \ldots, M$) randomly[5]
set $\underline{P}_i(1) = \underline{X}_i(1)$ ($i = 1, \ldots, M$)
for $t = 1$ to $G - 1$ **do**
  calculate $\underline{m}(t) = \frac{1}{M} \sum_{i=1}^{M} \underline{P}_i(t)$
  $\underline{P}_g(t) = \arg\min f_{obj}(\underline{P}_i(t))$
  for $i = 1$ to M **do**
    if $f(\underline{X}_i(t)) < f(\underline{P}_i(t))$ **then**
      $\underline{P}_i(t) = \underline{X}_i(t)$
    end if
    for $j = 1$ to n **do**
      η =rand(0,1)
      $\underline{P}_{i,j}(t+1) = \eta \times \underline{P}_{i,j}(t) + (1-\eta) \times \underline{P}_{g,j}(t)$
      u =rand(0,1)
      if rand(0,1)> 0.5 **then**
        $\underline{X}_{i,j}(t+1) = \underline{P}_{i,j}(t+1) - \beta |m_j(t) - \underline{X}_{i,j}(t)| \ln \frac{1}{u}$
      else
        $\underline{X}_{i,j}(t+1) = \underline{P}_{i,j}(t+1) + \beta |m_j(t) - \underline{X}_{i,j}(t)| \ln \frac{1}{u}$
      end if
    end for
  end for
end for

It can be seen that the QPSO algorithm differs from the PSO algorithm mainly in two ways: 1) instead of using (14), the best personal position of each particle is updated by taking a weighted average of its previous best personal and the global positions:

$$\underline{P}_{i,j}(t+1) = \eta \times \underline{P}_{i,j}(t) + (1-\eta) \times \underline{P}_{g,j}(t) \tag{18}$$

where η is a random variable uniformly distributed in $(0, 1]$; and 2) instead of using (17), the location of each particle is updated as:

$$\underline{X}_{i,j}(t+1) = \underline{P}_{i,j}(t+1) \pm \beta |m_j(t) - \underline{X}_{i,j}(t)| \ln \frac{1}{u} \tag{19}$$

where $m(t)$ is the average best personal positions of the entire swarm and u is also a random variable uniformly distributed in $(0, 1]$. Note that (19) was developed based on the solution of the Schrödinger equation, which is why the algorithm has the prefix "Quantum-behaved".

III. Benchmark Testing

Four widely used benchmark images (see Fig. 6) were chosen to test the performance of the above NS-IT2 FLS in comparison to median filter, Wiener filter, Gaussian filter, ROAD [25], and IPAMF+BM [73]. We also tested the T1 and singleton-IT2 counterparts of the proposed NS-IT2 FLS, as

[4]Please distinguish the notations and labeling in this section from those in the previous section, as they are completely independent and denote different things here.

[5]$\underline{X}_i(1)$ ($i = 1, 2, \ldots, M$) are randomly initialized, because extensive simulations [62] have shown that the initial values of the locations have little impact on the convergence of the QPSO algorithm.

TABLE I
MSEs OF DIFFERENT APPROACHES FOR THE FOUR BENCHMARK IMAGES (BABOON, PENTAGON, BOAT, AND BRIDGE) CORRUPTED BY 30% AWGN AND 30%, 50%, AND 70% IMPULSE NOISE, RESPECTIVELY

Approach	Baboon			Pentagon			Boat			Bridge		
	30%	50%	70%	30%	50%	70%	30%	50%	70%	30%	50%	70%
Median Filter	5943.3	7173.5	10269	6163.7	7241.8	9933.5	6042.5	7231.7	10330	5934.5	7260.2	10682

NS-IT2+BM3D	1362.2	1532.1	1847.1	854.63	757.72	771.88	1367.1	1518.1	1816.2	2157.4	2473.0	2885.8

an effort to see whether modeling the inputs as FSs is indeed helpful. Three different levels of MGIN were generated for the test: 30% AWGN with 30%, 50%, and 70% impulse noise, respectively[6].

The MSEs of the above techniques for the four images under different noise levels are summarized in Table I, where one can observe that, quantitatively, the fuzzy logic family (T1, singleton-IT2, and NS-IT2 FLSs) significantly out-performed the other techniques. In addition, after extensive simulations, it was found that the performance of the fuzzy logic family can be greatly enhanced when used jointly the with BM3D[7] DCT filter [16], which is a fast way to remove the residual AWGN after the FLS process. The MSEs of such joint approaches between fuzzy logic family and BM3D are also given in Table I, where one can observe that the NS-IT2+BM3D approach generally out-performs other techniques and its T1 and singleton-IT2 counterparts, with noticeable improvements, except in two cases, image "Baboon" with 70% impulse noise

[6]Due to page limit, we only tested a limited number of different noise levels; therefore, it remains as an open issue how much noise must be present before the NS IT2 FLS provides a significant improvement over the singleton IT2 FLS.

[7]The implementations of the BM3D filter has been generously made available online by its authors [16]. But since it is just a complement to our technique and is not the focus of this paper, the details of BM3D are not provided here.

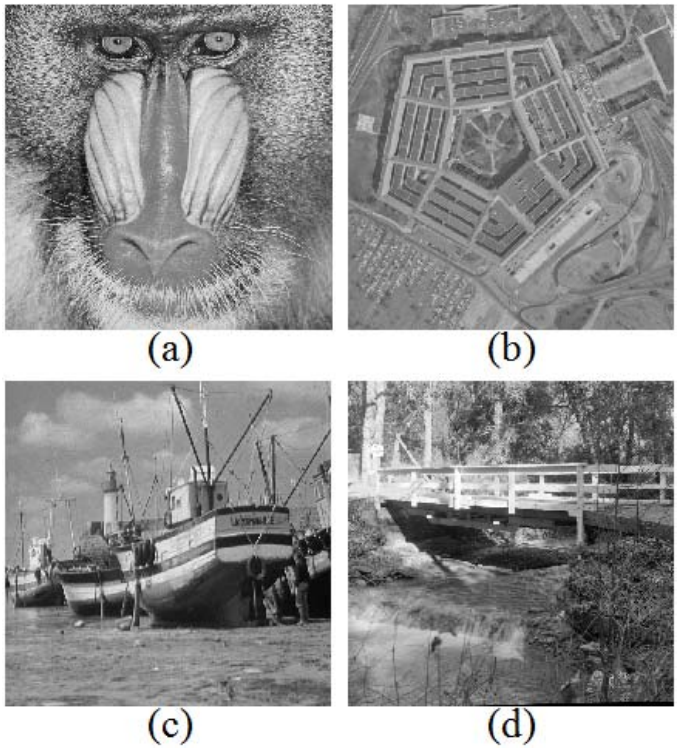

Fig. 6. Four benchmark test images: (a) baboon; (b) pentagon; (c) boat; (d) bridge.

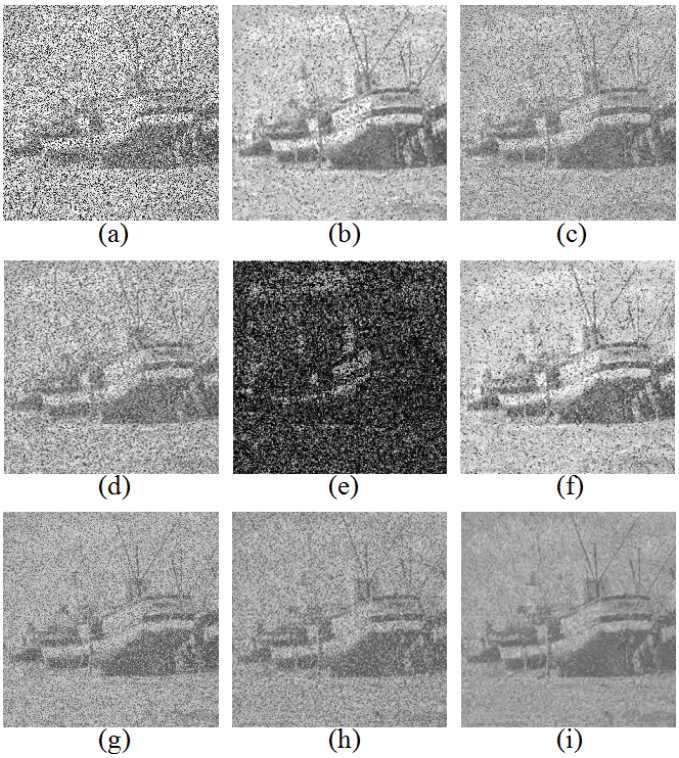

Fig. 7. (a) Image "boat" corrupted by 30% AWGN and 50% impulse noise; and its restored versions based on (b) median filter; (c) Wiener filter; (d) Gaussian filter; (e) ROAD; (f) IPAMF+BM3D; (g) T1+BM3D; (h) singleton-IT2+BM3D; (i) NS-IT2+BM3D

TABLE II
AVERAGE MSES OF THE FOUR BENCHMARK IMAGES FOR DIFFERENT APPROACHES UNDER 30% AWGN AND 30%, 50%, AND 70% IMPULSE NOISE, RESPECTIVELY

	30%	50%	70%
Median Filter	6021.0	7226.8	10303
Wiener Filter	4293.6	3580.1	3325.8
Gaussian Filter	5648.9	6153.7	6974.6
ROAD	3023.5	4243.3	5217.3
IPAMF+BM3D	6147.2	7277.9	9693.6
T1 FLS	2182.3	2434.0	2792.7
Singleton IT2	1871.4	2209.0	2618.3
NS IT2	1784.2	2128.7	2552.8
T1+BM3D	1861.8	1914.8	2111.7
Singleton-IT2+BM3D	1490.5	1641.0	1914.1
NS-IT2+BM3D	1435.4	1570.2	1830.2

and "Bridge" with 30% impulse noise, where the singleton-IT2+BM3D has slightly better results. To give an overview of these results, the average MSEs of the four images are summarized in Table II, where we can observe that the NS-IT2+BM3D always out-performs other techniques in terms quantitative measures.

Fig. 7 presents the image "boat" corrupted by 30% AWGN and 50% impulse noise and its restored versions based on the above techniques. Observe that the NS-IT2+BM3D appear to give the best visual restoration. Similar results were obtained for other images and under other noise levels.

IV. CONCLUSION

This paper presented a NS-IT2 FLS framework for removing MGIN from digital images. Using only one set of artificially generated training images, the design parameters of the system were tuned by a QPSO algorithm which allowed us to avoid using complex gradient-descent methods. The paper showed that the proposed technique yields both quantitatively and visually much better results compared to several widely-used non-fuzzy noise removal filters. Also, by introducing more degrees of design freedom into the system, the NS-IT2 FLS has also been shown to out-perform its T1 and singleton-IT2 counterparts.

***Abstract*—Due to the trend of individualization and adaptation of e-Learning, more and more SCORM-compliant teaching materials are developed by institutes and individuals in different sites. Also, cloud computing environments are emerging as powerful infrastructures to support e-Learning applications. Therefore, how to rapidly retrieve SCORM-compliant documents on cloud computing environments has become an important issue. Creating an index from folksonomies has been investigated in previous researches; however, the involved uncertainty has not been addressed. This paper focuses on the fuzzy index creation problem for learning content retrieval. A bottom-up approach to constructing the fuzzy index is proposed. The index creation method has been implemented, and a synthetic learning object repository has been built on a Hadoop cloud platform to evaluate the proposed approach. Experimental results show that this method can increase precision of retrieval.**

I. INTRODUCTION

Due to the advances in information technologies and the requirements of courseware, more and more teachers are able and willing to design their own teaching materials and make them accessible on the Web [1-3]. In addition, a growing number of large-scale projects aim to construct learning content repositories [4, 5]. For example, in 2002, the National Science Council of Taiwan approved a resolution on the "National Science and Technology Program for e-Learning," planning to spend $120 million within a five-year period [6]. These educational contents are mainly based on Sharable Content Object Reference Model (SCORM) [7], which has become a popular standard for creating sharable and reusable teaching materials for e-Learning. With the popularization of e-Learning, how to find and reuse these existing materials becomes an important issue.

Cloud computing systems [8, 9] are transparent resource-sharing infrastructures, which can overcome the limitations in traditional e-Learning platforms, such as scalability, interoperability, availability, etc. Also, Cloud computing technologies provide possibilities for supporting innovative applications of e-Learning. For example, a medical college can provide students with three-dimensional simulation of human body anatomy using high performance cloud computing systems, which is beyond the ability of traditional e-Learning platforms. Therefore, more and more effort has gone into the field of e-Learning cloud, using cloud technologies in the context of e-Learning.

With the promising development of e-Learning cloud, there will be a great demand to find desired teaching materials from multiple repositories in the e-Learning cloud. A traditional approach is to implement a meta-search engine on top of these distributed repositories [10]. When the meta-search engine receives a query, it distributes the query to the local repositories, and then collects the returned results and presents them to users. However, this traditional approach doesn't consider characteristics of SCORM and cloud computing to speed up the retrieval process. For example, SCORM-compliant documents are associated with nine categories of metadata. When processing a query with a restrictive filter, such as "documents about insects," the meta-searching approach will search the whole databases.

We classify the schemes of content retrieval into static and dynamic ones according to the adaptability of the retrieved results. For static CR, the retrieved result only depends on the query, independent of users and contexts. Dynamic CR can be further divided into personalized, context-aware and other schemes, according to the factors that are considered by the adaptive mechanisms of CR. To support context-aware CR, the teaching materials stored in the repositories have to be organized according to their contextual information, in order for efficient retrieval. However, it is almost impossible to request experts to annotate all these contents with suitable context-aware metadata. Therefore, content annotation based on folksonomies and automatic techniques in a collaborative way is a promising solution.

In well-known folksonomy applications, such as del.icio.us (http://del.icio.us/), Flickr (http://www.flickr.com), etc., folksonomies are organized into a flat structure, which consists of several catagories named by user-defined tags. This flat organization is suitable for users to manage their preferences. However, when the size of repositories gets larger and larger, a hierarchical organization becomes a better choice to organize the contents. To bridge the gap of the two structures, we formulate this index creation problem and

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

propose a bottom-up approach to constructing an index from existing folksonomies according to the similarity between tags, which considers metadata and structural information of the teaching materials annotated by the tags [11]. Furthermore, creating an index from folksonomies often involves uncertainty. For example, which tags are associated with which categories. Therefore, a fuzzy representation is proposed to address this issue. The index creation method has been implemented, and a synthetic learning object repository has been built to evaluate the proposed approach. Experimental results show that this method can increase precision of retrieval.

The contributions can be summarized as follows. First of all, we propose a fuzzy folksonomy-based method for index creation, which can reduce the effort required in subsequent work of location-aware content retrieval. With this method, the heavy burden of experts for manually developing concept hierarchy can be significantly alleviated. Second, a similarity function is proposed to increase the precision of folksonomy fusion, which considers more characteristics of learning contents, including metadata and structural information of the teaching materials annotated by the tags. Next, a self-organizing mechanism can designed to balance the number of documents annotated by the tags, which can increase the performance of indexing structures. Finally, the proposed method is implemented and the built index is evaluated. Experimental results reveal that this method can improve the performance of retrieval.

The rest of this work is organized as follows. In Section II, we review the preliminaries and previous work on related researches. Then, the problem is formulated in Section III. Next, the method of index creation is described in Section IV. Section V illustrates experimental results. Finally, the concluding remarks are given in Section VI.

II. PRELIMINARIES AND RELATED WORK

In this section, we review previous research related to this work. First, the SCORM model is introduced. Then, methods of information retrieval are described. Finally, we review methods of ontology building, which is related to index creation.

A. Sharable Content Object Reference Model (SCORM)

To share and reuse teaching materials, several standards have been proposed recently. Among these, SCORM (http://www.adlnet.org/) is the most popular standard for learning contents. It was proposed by the U.S. Department of Defense's Advanced Distributed Learning (ADL) organization in 1997. This standard consists of several specifications developed by IEEE LTSC (Learning Technology Standards Committee, http://ltsc.ieee.org/wg12/), IMS (Instructional Management System, http://www.imsproject.org/), AICC (Aviation Industry CBT Committee, http://www.aicc.org/), etc. The SCORM specifications are a composite of several specifications developed by international standards organizations. In a nutshell, SCORM is a set of specifications for developing, packaging and delivering high-quality education and training materials whenever and wherever they are needed [12, 13]. In SCORM, content packaging scheme is proposed to package the learning objects into standard teaching materials. The content packaging scheme defines a teaching materials package consisting of four components: 1) Metadata, which describes the characteristics or attributes of this learning content; 2) Organizations, which describe the structure of the teaching material; 3) Resources, which denote the physical files linked by each learning object within the teaching material; and 4) the (Sub) Manifest, which describes this teaching material, consisting of itself and other teaching materials. SCORM Metadata refers to the IEEE's Learning Object Metadata (LOM), and describes the attributes of teaching materials. IEEE LOM v1.0 includes nine categories: General, LifeCycle, Meta-Metadata, technical, educational, rights, relation, annotation, and classification.

Su et al. proposed a level-wise approach to SCORM content management [14]. In this two-phase scheme, structural information is considered. Also, both general and specific Learning Objects can be retrieved according to requests of users. However, the design of this structure doesn't consider its usability in ubiquitous learning environments.

There have been numerous studies on Structured Document Retrieval [15, 16]. Researches showed that structured searching can increase precision. Previous work mainly addresses XML and SGML documents. Besides, XML Query Languages, such as XIRQL, XQL, etc., were proposed. However, intra-document structural modeling is not suitable for SCORM-compliant documents.

B. Search Engine Technologies

Inverted file indexing has been widely used in information retrieval [17-20]. An inverted file is used for indexing a document collection to speed up the searching process. The structure of an inverted file consists of two components: the vocabulary and the posting list. The vocabulary is composed of all distinct terms in the document collection. For each term, a list of all the documents containing this term is stored. The set of all these lists is called the posting list. However, the structure of a document is not considered in this model.

Storage requirements of inverted indices [21] have been evaluated based on B+-tree and posting list. Five strategies of the index term replication were discussed. This approach is extended to analyze the storage requirement of the proposed approach in this proposal. In [22], 11 different implementations of ranking-based text retrieval systems using inverted indices were presented, and their time complexities were also investigated.

The meta-search approach has been studied in the context of distributed information retrieval [10]. This approach consists of Query Distribution and Result Merging phases. Furthermore, the Document Retrieval problem is divided into two sub-problems: Database Selection problem and Document Selection problem. However, Distributed indexing is not suitable for common cloud architectures. Also, distributed information retrieval is less efficient in searching.

The use of ontologies to overcome the limitations of keyword-based search has been put forward as one of the motivations of the Semantic Web since its emergence in the late 1990s. One way to view a semantic search engine is as a tool that gets formal ontology-based queries from a client,

executes them against a knowledge base, and returns tuples of ontology values that satisfy the query. In this view, the information retrieval problem is reduced to a data retrieval task. While this conception of semantic search brings key advantages already, our work aims at taking a step beyond.

A purely Boolean ontology-based retrieval model makes sense when the whole information corpus can be fully represented as an ontology-driven knowledge base. But, there are well-known limits to the extent to which knowledge can be formalized this way. Boolean search does not provide clear ranking criteria, without which the search system may become useless if the retrieval space is too big.

C. Ontology Building Approaches

We review ontology building approaches because its construction process is similar to index creation in concept. Traditionally, ontology building mainly depends on the contribution of domain experts in the knowledge creation activity. Metadata extraction and merging is carried out manually by domain experts. Many tools have been developed for ontology developers to access ontologies, browse them, edit them, and propose modifications. However, some drawbacks do exist. This process is time-consuming and arduously. For this reason, recent researches turned to automatic and semiautomatic (as opposed to manually) ontology construction and maintenance. Automatic techniques for building and integrating ontologies have been studied for many years by the artificial intelligence community. More recently, several techniques specifically aimed at learning ontologies from text corpora or database repositories were proposed. Well-known research approaches to ontology building include [23]:

- Dictionary-based approach [24]: constructs the hierarchy of concepts based on a traditional dictionary, which presents the related concepts of words, including synonyms, etymology, etc.
- Conceptual clustering [25]: Concepts are grouped according to a semantic distance between each other to generate hierarchical relations.
- Association rules mining [26]: The frequency of an association of terms is computed in the text repositories. If the frequency of the association is close to the occurrence of individual terms, the association is transformed in an ontological relation.
- Formal concept analysis [23]: is a method for representation, analysis and management of data and knowledge. It can be used to build a hierarchy of terms and associated relations.

In [8], a fuzzy ontology extraction algorithm was proposed for adaptive e-learning. Folksonomies have not been widely applied to the subject of index creation. Although folksonomies are not formal models for knowledge representation, the collaborative wisdom of resource categorization can be a good start point from which effective indices can be built.

III. Problem Formulation

Before the index creation problem is described, some concepts and models are introduced. First, a level-wise structural model of learning contents is presented, which is intended to model the semantic features of different levels of a structural learning content.

Definition. Content Package (CP)

A Content Package represents a structural learning content, such as a SCORM-compliant teaching material. It is a rooted tree. The leaf node represents textual content, which is characterized by a feature vector = $<w_1, w_2, \ldots, w_n>$, where n is the size of the vocabulary and the weighting scheme is the widely used TF-IDF (Term Frequency – Inverse Document Frequency) [17, 19]. Internal nodes represent structural information of this teaching material. Each Content Package is associated with two types of attributes:

- Level j feature vector, L_j, $(0 < j < Height)$

where L_j = Average of feature vectors of nodes at level j, and Height is the height of the rooted tree;

- Metadata, $\{M_k \mid k = 1 \text{ to } m, m \text{ is the number of metadata}\}$.

A folksonomy is a user generated taxonomy used to categorize and retrieve web content such as Web pages, photographs and Web links, using user-defined labels called tags. Typically, a folksonomy has a flat structure, which consists of several user-defined categories. The folksonomic tagging is intended to make a body of information increasingly easy to search, discover, and navigate over time. One well-known website using folksonomic tagging is del.icio.us. In this work, fuzzy folksonomies are modeled as follows. The proposed model is based on Zadeh's theory of fuzzy sets [27].

Definition. Fuzzy Folksonomy

A fuzzy folksonomy defined by a user is a triple of (T, I, R), where T is a fuzzy set of tags, I is a fuzzy set of content packages and R is a fuzzy relation on $T \times I$. We say that tag t is related to a content package i if i is annotated by t. Each tag is associated with two types of attributes, which are derived from content packages annotated by this tag.

- Level j feature vector, L_j, $(0 < j < Height)$

where L_j = the average of the level j feature vectors of content packages annotated by the tag, and *Height* is the height of the rooted tree;

- Metadata, $\{M_k \mid k = 1 \text{ to } m, m \text{ is the number of metadata}\}$

where the value of M_k is defined by the most frequent M_k value of the content packages annotated by the tag.

The following example illustrates this definition. Figure 1 depicts two folksonomies defined by users A and B, respectively. The folksonomy of user A can be represented by

$T = \{t_1, t_2\}$

$I = \{i_1, i_2, i_3, i_4\}$

$R = \{(t_1, i_1), (t_1, t_2), (t_1, i_3), (t_2, i_1), (t_2, i_4)\}$

where i_1, i_2, i_3 and i_4 are content packages.

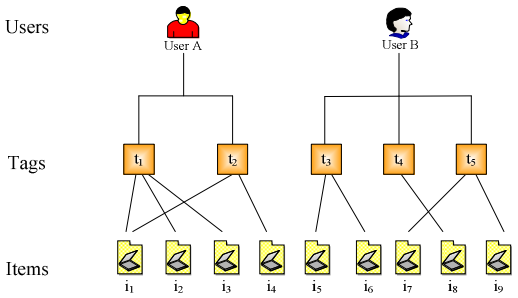

Figure 1. The folksonomy of user A

In the field of computer science, ontology is a data model that represents a set of concepts within a domain and the relationships between those concepts. It is used to understand the objects within that domain. However, there has not been a commonly acceptable definition for ontologies. The following definitions describe ontology-like indices referred to in this paper. First, the relations, general and specific, are stated.

Definition. General

A tag *a* is more general than a tag *b* if the set of teaching materials annotated by *a* includes those annotated by *b*.

Next, we define the index.

Definition. Index

An index is considered to be a rooted tree. The nodes represent concepts in the domain, and the edges represent relations between nodes. A parent node *p* is more general than its child node *c*. Each node is associated with a feature vector, which characterizes the semantic meaning of this concept.

Based on the definitions above, the index creation problem is stated as follows.

Definition. The Fuzzy Folksonomy-based Index Creation Problem (FICP)

Given a collection of content packages and corresponding folksonomies, generate an index. The objective is to improve performance of learning content retrieval.

IV. FUZZY FOLKSONOMY-BASED INDEX CREATION

Our idea to solve the FICP problem is based on the heuristic that existing folksonomies generated by users can be a good starting point from which to construct a location-aware index. While most folksonomies are organized into flat structures, we plan to build hierarchical indices to better organize the learning content. To bridge the gap of the two structures, folksonomies and indices, we propose a bottom-up approach to construct an index from existing folksonomies according to the similarity between tags, which considers metadata and structural information of the teaching materials annotated by the tags.

We design an algorithm to merge two folksonomies into one which is used for subsequent information retrieval. The idea is to make decisions of tag merging according to the similarity of the two tags. The main difficulty is how to choose a suitable similarity function for SCORM-compliant teaching materials, which are characterized by textual content, metadata and structural information. Here, a similarity measure for two tags, *a* and *b*, is proposed:

$$Sim(a,b) = (1-\beta)\sum_{i=0}^{Height}\alpha_i \times Sim_i(a,b) + \beta \times Sim_M(a,b) \quad (1)$$

where the sum of $_i$ is equal to one, and 0< <1. The parameter, $_i$, is used to adjust the weighting of level-wise content vector. The parameter is used to adjust the weighting of metadata similarity. The similarity function consists of two parts:

- Sim_i: level i similarity function, which is *cosine* function, 0< i < *Height*. The similarity between two vectors $v_k = <k_1, k_2, \ldots, k_{|V|}>$ and $v_p = <p_1, p_2, \ldots, p_{|V|}>$ is measured by the following formula:

$$sim_i = \frac{\sum_{i=1}^{|V|} k_i \times p_i}{\sqrt{\sum_{i=1}^{|V|} k_i^2} \times \sqrt{\sum_{i=1}^{|V|} p_i^2}} \quad (2)$$

- Sim_M: Metadata similarity function, which is (the number of matched attributes) / (the number of all attributes).

The Folksonomy-based Index Creation Algorithm consists of two steps: initializing the master folksonomy and iteratively merging tags of the other folksonomy into the master folksonomy, listed as follows.

Algorithm. Fuzzy Folksonomy-based Index Creation Algorithm (AlgFFIC)

Input:

F_1, F_2: the two folksonomies to be merged
Th_sim: the threshold for comparing similarity
sim: the similarity function

Output:

F: the merged folksonomy

Step 1. Initialization
  1.1 Each tag of F_1 and F_2 is represented by the average of its related teaching materials.
  1.2 F_1 is assigned as the Master folksonomy, M.
Step 2. for each tag t in F_2
  2.1 calculate the similarity of t and each tag of M.
  2.2 let *t_close* be the closest tag in M to t.
  2.3 if the *sim*(t, *t_close*) > *Th_sim* then
      add the tag t into *t_close*
    else
      add tag t into M as a new tag

Step 1 of the ***AlgFFIC*** algorithm evaluates attributes of the input folksonomies. Also, one of the input folksonomy is assigned as the Master folksonomy, which serves as the base for other tags to join. Next, tags of the other folksonomy are merged into the Master folksonomy one after another in Step 2. Finally, a merged folksonomy is generated.

In Step 2.3, a threshold, *Th_sim*, is set to decide whether to merge the tag or construct a new tag. When the similarity is greater than the threshold, the two tags are merged. Otherwise, a new tag is constructed in the master folksonomy for the dissimilar tag from the other folksonomy.

V. IMPLEMENTATION

In this experiment, we have implemented a cloud portal for query submission and results presentation. In addition, results are shown with estimated transmission time. The corpus is composed of synthetic SCORM-compliant documents. The experiments investigate searching performance in terms of query processing time.

A. Prototype Design

A folksonomy-based information retrieval system is implemented to evaluate the proposed method, as shown in Figure 2. The objective is to increase precision by folksonomy-based semantic search, and to reduce search time by folksonomy-based indexing. The phase of constructing a concept hierarchy is based on the proposed method, in order to alleviate the heavy burden of experts and knowledge engineers. This framework consists of three phases. In the concept hierarchy construction phase, users' folksonomies are merged into a hierarchy, which can be referred by the index creation phase. A bottom-up method is designed to organize teaching materials located in different repositories, according to the generated index. A global index is then created to facilitate semantic search. Finally, users' queries are submitted in the search phase, and desired teaching materials are retrieved fast and precisely.

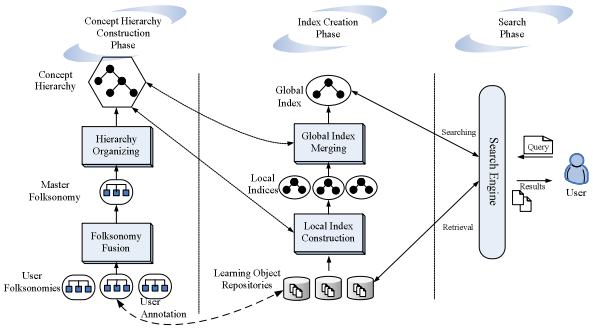

Figure 2. The overview of a folksonomy-based information retrieval system

A Cloud computing test-bed has been built by the High Performance Computing Lab. of Tunghai University, Taichung, Taiwan, using Hadoop. The summary of the nodes is shown in Figure 3.

B. Evaluation

Two synthetic LORs are used in this experiment. The first LOR contains 1,200,000 SCORM-compliant documents, which are converted from Web pages related to educational domains. After stop-word cleansing, there remains 2,570,623 distinct index terms. The size of this LOR is around 20 GB. The other LOR contains 2,400,000 SCORM-compliant documents, which are converted from technical papers related to computer science domains. After stop-word elimination, there remains 4,730,384 distinct index terms. The size of this LOR is around 40 GB. We have implemented two algorithms for this experiment. The first algorithm is a traditional meta-searching approach, named DIR (Distributed Information Retrieval). The other is the approach using the proposed approach, named CIR (Cloud Information Retrieval).

Figure 4 presents the running time of two implementations for different numbers of query terms on LOR 1. In the three cases, CIR performs better than DIR. Figure 5 presents similar results on LOR 2. The main reason may be that CIR using the proposed approach can effectively speed the searching processing.

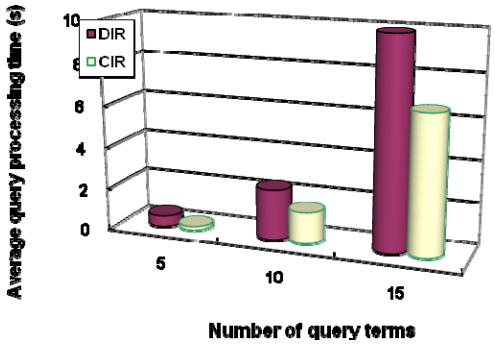

Figure 4. The running time for different numbers of query terms on LOR 1

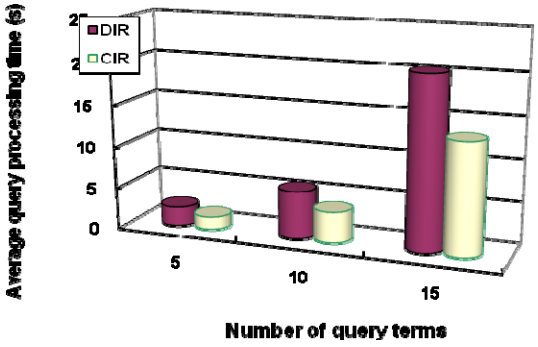

Figure 5. The running time for different numbers of query terms on LOR2

VI. CONCLUSIONS

This paper describes a fuzzy folksonomy-based approach to index creation for learning content retrieval. We divide the index creation problem into two sub-problems: folksonomy fusion and hierarchy organizing. The former problem is solved by merging tags according to a similarity function, which considers textual, metadata and structural information of teaching materials. Experimental results show the effectiveness of this approach. This folksonomy-based approach is characterized by a time-saving development process, minimal involvement of experts and high performance of information retrieval.

Learning content retrieval includes many important and challenging issues. After the study of this work, the future work will address the possibility of complementing traditional ontologies with folksonomies. In addition, it is a promising way to use Expert Systems technologies to facilitate the searching process.

***Abstract*—Numerous similarity measures between intuitionistic fuzzy sets are proposed in literature using different approaches. In this paper, relationship between some existing intuitionistic fuzzy similarity and distance measures are investigated. These relations are paramount for the choice of a similarity or a distance measure and its application for any research topic.**

***keywords*—Similarity measures, distance measures, intuitionistic fuzzy sets**

I. Introduction

Intuitionistic fuzzy set (IFSs) [1], [2] which are generalizations of fuzzy sets [3] are showed in [4] to be similar to vague sets proposed by Gau and Buehrer [5] and demonstrated in [6] to be equivalent to interval valued fuzzy sets [7]. These theories were the subject of operators' propositions. Similarity and distance measures between IFSs are widely studied and discussed. Chen [8], [9] proposed measures of similarity between vague sets. Hong and Kim [10] demonstrated that these measures are not effective in some cases and proposed to rectify them by giving another similarity measure. Fan and Zhangian [11] proposed an intuitionistic fuzzy similarity measure (IFSM) which resolves some problems of the precedent measures but still contains some counter intuitive cases [12]. Dengfeng and Chuntian [13] proposed some intuitionistic fuzzy similarity measures (IFSMs) and applied them to pattern recognition. However, Mitchell showed in [14] some counter intuitive cases of these measures and proposed an IFSM to solve their weakness by adopting a statistical viewpoint. Other IFSMs are proposed in [15], [16].

In addition to IFSMs, many measures of distances between IFSs are proposed. Szmidt and Kacprzyk [17] proposed Hamming and Euclidean distances based on a geometric interpretation of IFSs. Wang and Xin [18], proposed other distance measures and applied them to pattern recognition showing that the found results are similar to those proposed in [15]. Hung and Yung [19] proposed IFSMs based on Hausdorff distance. The same authors proposed some distance measures and IFSMs in [20] based on L_p metric. More details about IFSMs and distance measures between IFSs are presented in [21], [22].

In section two, we present IFSs definition followed by the definition of distance measures and similarity measures between IFSs from literature. Therefore, we provide relationship between them.

II. Intuitionistic Fuzzy Sets and Interval Valued Fuzzy Sets

A. Definition 1

An intuitionistic fuzzy set A in a discourse universe X is defined in [1] as:
$A = \{\langle x, \mu_A(x), \nu_A(x)\rangle \,|x \in X\}$ where $\mu_A(x) : X \to [0,1]$ and $\nu_A(x) : X \to [0,1]$ with the condition $0 \leq \mu_A(x) + \nu_A(x) \leq 1 \ \forall \ x \in X$.
The numbers $\mu_A(x)$, $\nu_A(x)$ denote respectively the degrees of membership and of non-membership of the element $x \in X$ to A. Also, μ_A and ν_A are called respectively truth membership function and false membership function.
In addition to membership and non-membership functions, a function of hesitancy or uncertainty of x to A denoted by $\pi_A(x)$ must be taken into consideration. $\pi_A(x)$ is computed as:
$\pi_A(x) = 1 - \mu_A(x) - \nu_A(x)$ with $0 \leq \pi_A(x) \leq 1$

B. Definition 2

In [7], an interval-valued fuzzy set in a universe X is a mapping $A : X \to$ Int([0,1])
$x \longmapsto [\underline{A}(x), \overline{A}(x)] \subseteq [0,1]. \ \forall x \in X.$
where Int([0, 1]) is the set of all closed subintervals of [0, 1].

C. Notations

We note IFSs(X) the set of all IFSs in X and we use μ_A , ν_A and π_A instead of $\mu_A(x_i)$, $\nu_A(x_i)$ and $\pi_A(x_i)$ respectively, $\forall x_i \ \in \ A$, $\forall A \ \in$ IFSs(X).

III. Intuitionistic Fuzzy Distance Measures Proposed in Literature

In this section, we present some distance measures, existing in literature, between tow IFSs A and B.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

A. Definition 1

Atanassov [2] proposed the following distance measures:

- Hamming Distance

$$H(A,B) = \frac{1}{2n}\sum_{i=1}^{n} |\mu_A - \mu_B| + |\nu_A - \nu_B| \quad (1)$$

- Euclidean Distance

$$E(A,B) = \sqrt{\frac{1}{2n}\sum_{i=1}^{n} (\mu_A - \mu_B)^2 + (\nu_A - \nu_B)^2} \quad (2)$$

- [2] present these distances using the max operator

$$J_1(A,B) = \max_i |\mu_A(x_i) - \mu_B(x_i)| \quad (3)$$

J_1 defines the Hamming distance between fuzzy sets

$$J_2(A,B) = \max_i |\nu_A(x_i) - \nu_B(x_i)| \quad (4)$$

$$J(A,B) = \frac{1}{2}(J_1(A,B) + J_2(A,B)) \quad (5)$$

B. Definition 2

Szmidt and Kacprzyk [17] interpreted the precedent measures (1, 2) by a geometric perspective. Thus, they concluded that the hesitation degree must be taken into consideration to compute Euclidean and hamming distances and proposed these measures.

- Hamming Distance

$$\begin{aligned} l_{IFS}(A,B) &= \frac{1}{2n}\sum_{i=1}^{n} |\mu_A - \mu_B| + |\nu_A - \nu_B| \\ &+ |\pi_A - \pi_B| \end{aligned} \quad (6)$$

- Euclidean Distance

$$q_{IFS}(A,B) = \frac{1}{\sqrt{2n}} \times \sqrt{\sum_{i=1}^{n} (\mu_A - \mu_B)^2 + (\nu_A - \nu_B)^2 + (\pi_A - \pi_B)^2} \quad (7)$$

C. Definition 3

In the real space $\mathbb{R}$, for any two intervals $A = [a_1, a_2]$ and $B = [b_1, b_2]$, the Hausdorff distance $H(A,B)$ is defined as:

$$Hd(A,B) = \max\{|a_1 - b_1|, |a_2 - b_2|\} \quad (8)$$

Based on the definition of $H(A,B)$, Hung and Yang [19] proposed Hausdorff distance between two subintervals $I_A(x_i) = [\mu_B(x_i), 1 - \nu_B(x_i)]$ and $I_B(x_i) = [\mu_B(x_i), 1 - \nu_B(x_i)]$, $i = 1, 2, \ldots, n$ of the IFSs A and B defined in [0,1] by this formula:

$$d_{Hd}(A,B) = \frac{1}{n}\sum_{i=1}^{n} max(|\mu_A - \mu_B|, |\nu_A - \nu_B|) \quad (9)$$

Using the $d_{Hd}(A,B)$ definition, the authors proposed some similarity measures between IFSs in [19].

D. Definition 4

Grzegorzewski [23] proposed the following formulas for Euclidean and hamming distances for IFSs based on Hausdorff metric.

- Hamming Distance

$$l_h(A,B) = \frac{1}{n}\sum_{i=1}^{n} max(|\mu_A - \mu_B|, |\nu_A - \nu_B|) \quad (10)$$

- Euclidean Distance

$$q_h(A,B) = \sqrt{\frac{1}{n}\sum_{i=1}^{n} max((\mu_A - \mu_B)^2, (\nu_A - \nu_B)^2)} \quad (11)$$

E. Definition 5

Wang and Xin [18] showed by examples, that the normalized Euclidean distance (7) may not classify patterns in some cases and proposed the following distance measures:

$$\begin{aligned} d_1(A,B) &= \frac{1}{n}\sum_{i=1}^{n}\left[\frac{|\mu_A - \mu_B| + |\nu_A - \nu_B|}{4}\right] \\ &+ \frac{1}{n}\sum_{i=1}^{n}\left[\frac{\max(|\mu_A - \mu_B|, |\nu_A - \nu_B|)}{2}\right] \end{aligned} \quad (12)$$

$$d_2^p(A,B) = \frac{1}{\sqrt[p]{n}}\sqrt[p]{\sum_{i=1}^{n} (\varphi_\mu(x_i) + \varphi_\nu(x_i))^p} \quad (13)$$

where $\varphi_\mu(x_i) = |\mu_A - \mu_B|/2$, $\varphi_\nu(x_i) = |\nu_A - \nu_B|/2$ and p is a positive integer.

IV. Intuitionistic Fuzzy Similarity Measures Proposed in Literature

In this section, we present similarity measures between two IFSs A and B from literature, we recall that similarity measures $s(A,B)$ and distance measures $d(A,B)$ are dual concepts, so, if $s(A,B)$ is a similarity measure between IFSs A and B, then $d(A,B) = 1 - s(A,B)$ and inversely $s(A,B) = 1 - d(A,B)$.

A. Definition 1

In their paper, Hong and Kim [10] proposed the following similarity measure:

$$S_H(A,B) = 1 - \frac{\sum_{i=1}^{n} |\mu_A - \mu_B| + |\nu_A - \nu_B|}{2n} \quad (14)$$

S_H can not distinguish positive difference from negative difference, so some counter cases exist for S_H [12]. For example, if $A = \{(x, 0, 0)\}$ and $B = \{(x, 0.3, 0.5)\}$ then $S_H(A,B) = 0.6$ which is not reasonable. An example of another type of counter intuitive is given in [12]: If $A = \{(x, 1, 0)\}$, $B = \{(x, 0, 0)\}$ and $C = \{(x, 0.5, 0.5)\}$ then, $S_H(A,B) = S_H(C,B) = 0.5$.

B. Definition 2

In [11] the following measure are presented:

$$S_L(A,B) = 1 - \frac{\sum_{i=1}^{n} |S_A(x_i) - S_B(x_i)|}{4n} - \frac{\sum_{i=1}^{n} |\mu_A - \mu_B| + |\nu_A - \nu_B|}{4n} \quad (15)$$

where $S_A(x_i) = \mu_A - \nu_A$ and $S_B(x_i) = \mu_B - \nu_B$.

C. Definition 3

Dengfeng and Chuntian [13] proposed the following similarity measure between IFSs.

$$S_d^p(A,B) = 1 - \frac{1}{\sqrt[p]{n}} \sqrt[p]{\sum_{i=1}^{n} |\varphi_A(x_i) - \varphi_B(x_i)|^p} \quad (16)$$

here:

$$\varphi_A(x_i) = \frac{\mu_A(x_i) + 1 - \nu_A(x_i)}{2}$$

and

$$\varphi_B(x_i) = \frac{\mu_B(x_i) + 1 - \nu_B(x_i)}{2}$$

with $1 \leq p < +\infty$

Mitchell [14], Liang and Shi [15] present some counter-intuitive cases for S_d^p which are existing because S_d^p does not verify the property condition (P2) of similarity measures defined as:

$(P2)$ $S(A,B) = 1$ if and only if $A = B$

As an example [12], the computed similarity S_d^p (16) using the sets $A = \{(x, 0.1, 0.1)\}$ and $B = \{(x, 0.5, 0.5)\}$ with $p = 1$, is $S_d^1(A,B) = 1$.

D. Definition 4

In [15] some similarity measures are given, we present below one of them.

$$S_e^p(A,B) = 1 - \frac{1}{\sqrt[p]{n}} \times \sqrt[p]{\sum_{i=1}^{n} (\varphi_{\mu_{AB}}(x_i) + \varphi_{\nu_{AB}}(x_i))^p} \quad (17)$$

where

$$\varphi_{\mu_{AB}}(x_i) = \frac{|\mu_A - \mu_B|}{2}$$

and

$$\varphi_{\nu_{AB}}(x_i) = \left| \frac{1 - \nu_A}{2} - \frac{1 - \nu_B}{2} \right|$$

make the use of two end points of the subintervals in IFSs.

E. Definition 5

Hung and Yang [20] defined the L_p distance between two intervals $I_A(x_i) = [\mu_A, 1-\nu_A]$ and $I_B(x_i) = [\mu_B, 1-\nu_B]$, $i = 1, 2, \ldots, n$ as:

$$d_p(I_A(x_i), I_B(x_i)) = (|\mu_A - \mu_B|^p + |\nu_A - \nu_B|^p)^{1/p},\ p \geq 1$$

In consequence, the distance $L_p(A,B)$ between A and B is defined as:

$$L_p(A,B) = \frac{1}{n} \sum_{i=1}^{n} d_p(I_A, I_B) \quad (18)$$

Then, the authors proposed some similarity measures based on L_p metric, we present the following measure from them:

$$S_l^p(A,B) = \frac{2^{\frac{1}{p}} - L_p(A,B)}{2^{\frac{1}{p}}} \quad (19)$$

F. Definition 6

In [24] the authors gave a generalization of measures between fuzzy sets proposed in [25] and presented the following measures between IFSs.

$$S_{pk2}(A,B) = 1 - \frac{1}{2} \left(\max_i |\mu_A - \mu_B| + \max_i |\nu_A - \nu_B| \right) \quad (20)$$

$$S_{pk3}(A,B) = 1 - \frac{\sum_{i=1}^{n} |\mu_A - \mu_B| + |\nu_A - \nu_B|}{\sum_{i=1}^{n} (|\mu_A + \mu_B| + |\nu_A + \nu_B|)} \quad (21)$$

V. Relationship between the Presented Measures

- The Hausdorff distance (9) is the same of the Hamming distance (10). So we have:

$$d_{Hd}(A,B) = l_h(A,B) \quad (22)$$

  We mention that this measure should be the Hausdorff distance because it is the generalization of the Hausdorff distance between crisp sets.

- If we replace $\pi_A(x_i)$ and $\pi_B(x_i)$ with their formulas in $l_{IFS}(A,B)$ (6) we find that $H(A,B) \leq l_{IFS}(A,B) \leq 2H(A,B)$ where H(A,B) has the equation (1). It is obvious that $H(A,B) \leq l_{IFS}(A,B)$, thus we show below that $l_{IFS}(A,B) \leq 2H(A,B)$

  Proof:

$$\begin{aligned} l_{IFS}(A,B) &= \frac{1}{2n} \sum_{i=1}^{n} |\mu_A - \mu_B| + |\nu_A - \nu_B| \quad (23) \\ &+ |1 - \mu_A - \nu_A - 1 + \mu_B + \nu_B| \\ &\leq \frac{1}{2n} \sum_{i=1}^{n} |\mu_A - \mu_B| + |\nu_A - \nu_B| \\ &+ |\mu_B - \mu_A| + |\nu_B - \nu_A| \\ &\leq \frac{1}{2n} \sum_{i=1}^{n} 2|\mu_A - \mu_B| + 2|\nu_A - \nu_B| \\ &\leq \frac{1}{n} \sum_{i=1}^{n} |\mu_A - \mu_B| + |\nu_A - \nu_B| \quad (24) \end{aligned}$$

Then

$$H(A,B) \leq l_{IFS}(A,B) \leq 2H(A,B) \tag{25}$$

■

If we examine the formulas (23, 25) we can remark that the measure definition l_{IFS} is very close to that of $H(A,B)$.

- In the sections (III-A, III-B, III-D), we presented three different definitions of Hamming and euclidean distance measures from literature. If we examine measures S_H (14), S_L (15) and d_1(12) we remark that they are related on intuitionistic fuzzy Hamming distance measure H (1), d_1 is on relation with Hamming distance l_h (10) in addition of H. In the same way, formulas d_2^p (13) and S_l^p (19) depend on the power p, if p=1, all these formulas can be written using Hamming distances H and l_h. So, we can write formulas S_H (14), S_L (15) as follows:
  - $S_H(A,B)$(14) is a dual concept of $H(A,B)$(1), so it can be written as:

$$S_H(A,B) = 1 - H(A,B) \tag{26}$$

  - $S_L(A,B)$ (15) is on relation with $H(A,B)$(1), we have:

$$\begin{aligned} S_L(A,B) &= 1 - \frac{\sum_{i=1}^{n} |S_A(x_i) - S_B(x_i)|}{4n} \\ &- \frac{1}{2} H(A,B) \end{aligned} \tag{27}$$

    where $S_A(x_i)$ and $S_B(x_i)$ are defined in section IV-B.
  - d_1 is on relation with Hamming distances H and l_h as:

$$d_1(A,B) = \frac{1}{2}\left(H(A,B) + l_h(A,B)\right) \tag{28}$$

  - if p=1 and from (22, 28), the similarity measures d_2^p(13), S_l^p(19) are written as:

    *

$$d_2^1(A,B) = \sqrt{H(A,B)} \tag{29}$$

    *

$$S_l^1(A,B) = 1 - H(A,B) \tag{30}$$

- The IFSM S_e^p (17) is the dual concept of the distance measure d_2^p(13). It is easy to find in (17) that:

$$\varphi_{\nu_{AB}}(x_i) = \left| \frac{1-\nu_A}{2} - \frac{1-\nu_B}{2} \right|$$

$$\varphi_{\nu_{AB}}(x_i) = \left| \frac{\nu_A - \nu_B}{2} \right|$$

Thus:

$$S_e^p(A,B) = 1 - \frac{1}{\sqrt[p]{n}} \sqrt[p]{\sum_{i=1}^{n} \left(\frac{|\mu_A - \mu_B|}{2} + \frac{|\nu_A - \nu_B|}{2} \right)^p}$$

So we have the equality:

$$S_e^p = 1 - d_2^p \tag{31}$$

Despite the different interpretations of the measures (17), (13), they lead to the same formula.
When p=1, from (31, 29) we have:

$$S_e^1(A,B) = 1 - \sqrt{H(A,B)} \tag{32}$$

- The IFSM S_d^p (16) can be written as:

$$\begin{aligned} S_d^p(A,B) &= 1 - \frac{1}{\sqrt[p]{n}} \sqrt[p]{\sum_{i=1}^{n} \frac{|\mu_A - \mu_B + \nu_B - \nu_A|}{2}} \\ &\leq 1 - \frac{1}{\sqrt[p]{n}} \sqrt[p]{\sum_{i=1}^{n} \frac{|\mu_A - \mu_B| + |\nu_B - \nu_A|}{2}} \\ &\leq S_e^p \\ &\leq 1 - d_2^p \end{aligned}$$

- The measure S_{pk2} (20) presented in section IV-F is the dual concept of the distance J (5), Thus:

$$S_{pk2}(A,B) = 1 - J(A,B) \tag{33}$$

- The measure S_{pk3} (21) presented in section IV-F is written as:

$$S_{pk3(A,B)} = 1 - \frac{2nH(A,B)}{\sum_{i=1}^{n} |\mu_A + \mu_B| + |\nu_A + \nu_B|} \tag{34}$$

VI. Concluding Remarks

We showed that some measures are on relationship with the Hamming distance. Despite the different interpretations of distance measures or similarity measures, some of them are equal such as S_e^p (17) and d_2^p (13). In addition, the similarity measure $S_H(A,B)$ (14) is demonstrated to have some counter intuitive cases. So, from the equality (26), we deduce that all the following formula measures having close relation with the Hamming distance $H(A,B)$ (1) have the same counter intuitive cases of S_H:
d_1 (12), d_2^p (13), S_e^p (17), S_d^p (16), l_{IFS} (6) and S_{pk3} (21).

Abstract— **Latent Semantic Indexing (LSI) is an information retrieval technique using a low-rank singular value decomposition (SVD) of term-document matrix. The aim of this method is to reduce the matrix dimension by finding a pattern in document collection with concurrently referring terms. The methods are implemented to calculate the weight of term-document in vector space model (VSM) for document clustering using fuzzy clustering algorithm. LSI is an attempt to exploit the underlying semantic structure of word usage in documents. During the query-matching phase of LSI, a user's query is first projected into the term-document space, and then compared to all terms and documents represented in the vector space. Using some similarity measure, the nearest (most relevant) terms and documents are identified and returned to the user. The current LSI query-matching method requires computing the similarity measure about the query of every term and document in the vector space. In this paper, the Maximal Tree Algorithm is used within a recent LSI implementation to mitigate the computational time and computational complexity of query matching. The Maximal Tree data structure stores the term and document vectors in such a way that only those terms and documents are most likely qualified as the nearest neighbor to the query will be examined and retrieved. In a word, this novel algorithm is suitable for improving the accuracy of data miners.**

Keywords-Fuzzy clustering; data mining; LSI; SVD.

I. INTRODUCTION

Data mining [1] is a technique to obtain some patterns of knowledge from a depository or a data base. This technique enables us to find and describe structural patterns in data collection as a tool for helping to explain the data patterns and make predictions from them. Generally, data mining tasks are divided into two major steps: (1) predictive tasks which aim to forecast the value of a particular attribute based on the values of other attributes and (2) descriptive tasks which aim to derive patterns (correlations, trends, clusters, trajectories, and anomalies) [2]. Clustering is a method to re-organize automatically a large data collection by partitioning a set data, so the objects in the same cluster are more similar to one another than to objects in other clusters. Especially, document clustering aims to re-organize a large text data collection. In the field of Information Retrieval (IR), document clustering is used to automatically group the document that belongs to the same topic in order to provide user's browsing of retrieval results [3]. Some experimental evidences show that IR application can benefit from the use of document clustering [4]. Document clustering has always been used as a tool to improve the performance of retrieving and navigating large data.

The clustering methods can be classified into two groups: hierarchical method and partitioning method. Partitioning clustering can be classified into hard clustering and overlapping clustering (fuzzy clustering). Any given document has a possibility to contain multiple subjects or categories. This issue aims to use a fuzzy clustering approach, which enables us to include a document in multiple clusters. The method is different from hard clustering method, which a document only belongs to one cluster, not more. The hard clustering assumes well defined boundary among the clusters.

While grouping or clustering of documents, the problem is a very huge number of terms or words are contained in the full text vector space. Many lexical matching at term grade are inaccurate. Sometimes, a word has ambiguously several meaning or some words have synonymously the same meaning, and these cause results in the selection of irrelevant documents. Therefore, this research uses an Information Retrieval approach of Latent Semantic Index (LSI). In this method, the documents are projected onto a small subspace of this vector space and are clustered. So, there is creation of new abstract vector space is capable of capturing contents of important documents in order [3].

The remaining of this paper is written as follows. Section 2 clarifies the research in the past. Section 3 is spent to give the preliminary knowledge on fuzzy clustering. In Section 4, a sufficient and necessary process is shown for the vector space model and LSI. In Section 5, we present an exemplified algorithm of this method. Finally, some concluding remarks are given in Section 6.

II. LITERATURE REVIEW

2.1 LSI Timeline

In 1964, H. Borko and M. Bernick [5] described and tested factor analysis technique first. They report the results of a series of experiments in the techniques of automatic document classifications. Two different classification schedules are compared along with two methods of automatically classifying documents into categories. It is concluded that, while there is no significant difference in the predictive efficiency between Bayesian and Factor Score methods. Automatic document classification is enhanced by the use of a factor-analytically-derived classification schedule. Approximately 55 percent of the documents was automatically and correctly classified. Their experiments provide the information on the effectiveness of techniques for automatic document classification. In the approach to the problem the authors' began by using the computer to help gather data about a representative set of technical documents. In the initial analysis all the content words used in the abstracts of the document were counted and arranged by frequency of occurrence. A limited number of high-frequency words were manually selected to constitute an authority list for use in automatically indexing documents. Every document in the sample was automatically indexed using these terms [5].

In 1988, Furnas *et al*. published a seminal paper on LSI technique. They introduced a new method for automatic indexing and retrieval, implicit higher-order structure in the association of terms with documents is modeled to improve estimates of term-document association, and therefore the detection of relevant documents on the basis of terms found in queries. Singular-value decomposition is used to decompose a large term by document matrix into 50 to 150 orthogonal factors from which the original matrix can be approximated by linear combination; both documents and terms are represented as vectors in a 50 to 150-dimensioal space. Queries are represented as pseudo-documents vectors formed from weighted combinations of terms, and documents are ordered by their similarity to the query. Initial tests find this automatic method very promising [6].

Dumais and Nielsen first used LSI to assign articles to reviewers in 1992. The 117 manuscripts submitted for the Hypertext'91 Conference were assigned to members of the review committee, using a variety of automated methods based on information retrieval principles and Latent Semantic Indexing. Fifteen reviewers provided exhaustive ratings for the submitted abstracts, indicating how well each abstract matched their interests. The automated methods do a fairly good job of assigning relevant papers for review, but they are still somewhat poorer than assignments made manually by human experts and substantially poorer than an assignment perfectly matching the reviewers' own ranking of the papers. A new automated assignment method called "n of 2 n" achieves better performance than human experts by sending reviewers more papers than they actually have to review and then allowing them to choose part of their review load themselves [7].

Landauer etc. got patent granted for the cross-lingual application of LSI in 1994. This search was stimulated by the earlier examples of thermodynamics which arose from the attempt to understand the limits of steam engines, and by Shannon's channel capacity theory. These examples suggested that the computer could be characterized in a similar way. The earlier prototypes had derived optimum performance limits in a way which transcended particular technologies and design choices. Scientists and engineers take pride in the ability to do back-of-the-envelope calculations, to quickly reach to the critical aspects without encumbering details. Yet, in this field of ultimate physical limits of information handling, the quick and dirty approaches have turned out to be wrong in a remarkably consistent way. All of the first answers have been misleading [8].

Foltz first use LSI for grading essays in 1995. While the CHI conference focuses on issues of the interactions between humans and computers, it also addresses issues of interactions between humans and more primitive information systems, such as conference proceedings. Over the past two years, the CHI conference committee has tried to improve the usability of the conference proceedings by improving the index. For CHI'92 and '93, the proceedings had no keyword index. This can be due to the fact that generating an index is both a time consuming process and difficult to do well. For CHI'94 and '95, an information retrieval method was used for indexing that permitted both automating the indexing and developing a better index to the CHI proceedings [9].

From 1998 through 2000, an R&D program was conducted to apply a key technology, Latent Semantic Indexing (LSI), to provide superior advanced search capabilities. During this period, several federal agencies were engaged to explore applications of this technology of particular interest to the US Intelligence Community. From 2001 through 2002, a complete software framework was implemented to facilitate the use of this technology in Text Analytics applications.

In 2005, EBSCO Publishing (EBSCO, Content Analyst Company) has announced the release of Executive Daily Brief (EDB), a result of a partnership with the Content Analyst Company. EDB combines Content Analyst's Concept Search with the variety of content offered by EBSCO, to create a customizable business information monitoring and alert service.

EDB is designed to enable users to search for conceptually-related content by entering phrases, paragraphs, or entire articles into a search box. EDB then intuitively finds and retrieves the relevant information. EDB actually "trains" itself as it operates, creating a more intelligent search with each use. Users set up customized folders on topics or projects of their own choosing. EDB monitors more than 10,000 business sources each day and automatically places relevant articles into the appropriate project folders for review, based upon example documents, emails, or articles that the user places in each folder.

EDB's content repository includes business journals, current articles, and real-time business news from a variety of information sources. Along with EDB's own content resources, users may customize EDB's content by exposing other sources of data to the Concept Search, such as pertinent company documents and intranet resources.

2.2 Challenges to LSI

Early challenges to LSI focused on scalability and performance. LSI requires relatively high computational performance and memory in comparison to other information retrieval techniques. However, with the implementation of modern high-speed processors and the availability of inexpensive memory, these considerations have been largely overcome. Real-world applications involving more than 30 million documents that were fully processed through the matrix and SVD computations are not uncommon in some LSI applications.

Another challenge to LSI has been the alleged difficulty in determining the optimal number of dimensions to use for performing the SVD. As a general rule, fewer dimensions allow for broader comparisons of the concepts contained in a collection of text, while a higher number of dimensions enable more specific (or more relevant) comparisons of concepts. The actual number of dimensions that can be used is limited by the number of documents in the collection. Research has demonstrated that around 300 dimensions will usually provide the best results with moderate-sized document collections (hundreds of thousands of documents) and perhaps 400 dimensions for larger document collections (millions of documents). However, recent studies indicate that 50-1000 dimensions are suitable depending on the size and nature of the document collection.

Checking the amount of variance in the data after computing the SVD can be used to determine the optimal number of dimensions to retain. The variance contained in the data can be viewed by plotting the singular values(SV) in a scree plot. Some LSI practitioners select the dimensionality associated with the knee of the curve as the cut-off point for the number of dimensions to retain. Others argue that some quantity of the variance must be retained, and the amount of variance in the data should dictate the proper dimensionality to retain. Seventy percent is often mentioned as the amount of variance in the data that should be used to select the optimal dimensionality for recomputing the SVD.

III. Clustering analysis

Clustering is useful in several exploratory pattern-analysis, grouping, decision-making, and machine-learning situations, including data mining, document retrieval, image segmentation, and pattern classification. However, in many such problems, there is little prior information (e.g., statistical models) available about the data, and the decision-maker must make as few assumptions about the data as possible. It is under these restrictions that clustering methodology is particularly appropriate for the exploration of interrelationships among the data points to make an assessment (perhaps preliminary) of their structure.

The term “clustering” is used in several research communities to describe methods for grouping of unlabeled data. These communities have different terminologies and assumptions for the components of the clustering process and the contexts in which clustering are used. Thus, we face a dilemma regarding the scope of this survey. The production of a truly comprehensive survey would be a monumental task given the sheer mass of literature in this area. The accessibility of the survey might also be questionable given the need to reconcile very different vocabularies and assumptions regarding clustering in the various communities.

Fuzzy clustering methods partition a set of data into a number of overlapping clusters based on the distance in a metric space between the data points and the cluster prototypes. Various clustering algorithms can be used depending on the assumed structure of the identification data and the model type one wants to obtain [11]. A clustering method that has proven suitable for the identification of TS fuzzy models is the GK fuzzy clustering algorithm [12]. Unlike the popular fuzzy -means algorithm [13], the GK algorithm employs an adaptive distance norm in order to detect clusters of different geometric shapes in the data set.

Each cluster in the product space of the input/output data represents a rule in the rule base. The goal is to establish the fuzzy antecedents $\boldsymbol{A_i}$. These are defined by the fuzzy clusters found in the data. If desired, univariate membership functions $\boldsymbol{u_{i,j}}$ can be obtained by projections onto the various input variables $\boldsymbol{x_j}$ spanning the cluster space. The details are described by [11] and [14].

IV. Vector Space Model and LSI

4.1 Latent Semantic Indexing

Latent Semantic Indexing(LSI) is an indexing and retrieval method that uses a mathematical technique called Singular Value Decomposition (SVD) to identify patterns in the relationships between the terms and concepts contained in an unstructured collection of texts. LSI is based on the principle that words tend to have similar meanings in the same context. It requires relatively high computational performance and large memory in comparison to other information retrieval techniques [15]. A key feature of LSI is its ability to extract the conceptual content of texts by establishing associations among those terms which occur in similar contexts.

Latent Semantic Indexing can be able to correlate semantically terms in a collection of texts. The method was first applied to texts at Bell Laboratories in the late 1980s, also called Latent Semantic Analysis (LSA), which can uncover the underlying latent semantic structure in the usage of words in a body of texts and extract the meaning of the text in response to user queries, commonly referred to as concept searches. Queries, or concept searches, depend on a set of documents which have undergone LSI will return results that are similar in meaning to the search criteria even if the results do not share specific words with the search criteria [16].

4.2 Singular Value Decomposition

In linear algebra, the singular value decomposition (SVD) is an important factorization of a rectangular real or complex matrix, with many applications in signal processing and statistics. Suppose **A** is an m×n matrix whose entries come from a space, which is either the space of real numbers or the space of complex numbers. Then there exists a factorization of the form

$$A = \mathrm{U}\sum\mathrm{V}^{\mathrm{T}} \qquad (1)$$

where **U** is an m×m unitary matrix, the matrix **A** is an m×n diagonal matrix with nonnegative real numbers on the diagonal, and $\mathbf{V}^{\mathbf{T}}$ is an n×n unitary matrix, denotes the conjugate transpose of **V**. Such a factorization is called the singular value decomposition of **A**. The diagonal entries $\mathbf{\Sigma_{ij}}$ of **Σ** are known as the singular values of **A**. It's shown in Figure 1:

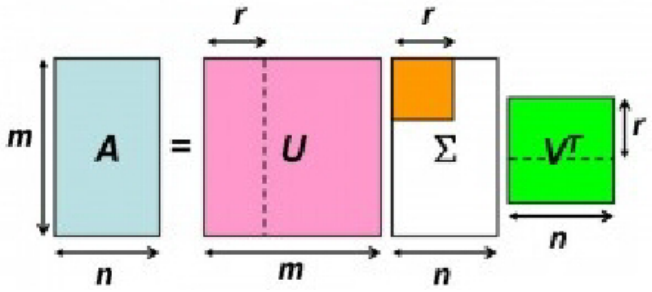

Figure 1. The singular value decomposition

For obtaining simplified vector space, we just need pick up the non-zero singular values of **Σ**. The rank-**r** is the amount of non-zero singular values of **Σ**.

A common usage is to place the singular values in descending order. In this case, the diagonal matrix **Σ** is uniquely determined by **A**.

So we obtain the followed new equation(2) and Figure 2:

$$A = \mathrm{U}_r \sum_r V_r^T \qquad (2)$$

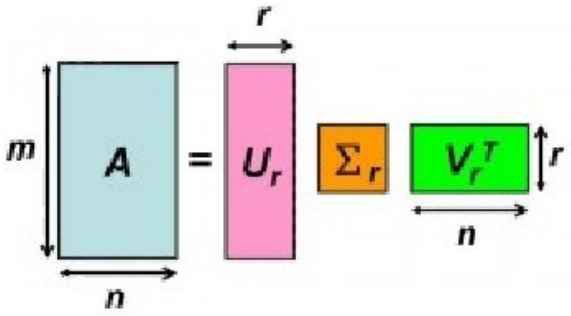

Figure 2. The simplified SVD

4.3 An Example of SVD

This example has terms 1, 2, 3, 4 and 5 as follows:
Term 1 appear 1, 0, 0, 0 times in document 1, 2, 3, 4;
Term 2 appear 0, 0, 0, 4 times in document 1, 2, 3, 4;
Term 3 appear 0, 3, 0, 0 times in document 1, 2, 3, 4;
Term 4 appear 0, 0, 0, 0 times in document 1, 2, 3, 4;
Term 5 appear 2, 0, 0, 0 times in document 1, 2, 3, 4.

Factor matrix A, that is, term-document matrix **A** is shown in matrix 3:

$$A = \begin{array}{c} \begin{matrix} t_1 & t_2 & t_3 & t_4 & t_5 \end{matrix} \\ \begin{pmatrix} 1 & 0 & 0 & 0 & 2 \\ 0 & 0 & 3 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 4 & 0 & 0 & 0 \end{pmatrix} \end{array} \begin{matrix} d_1 \\ d_2 \\ d_3 \\ d_4 \end{matrix} \qquad (3)$$

Step 1:

Calculate the interactive matrix (4).

$$A \cdot A^T = \begin{pmatrix} 1 & 0 & 0 & 0 & 2 \\ 0 & 0 & 3 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 4 & 0 & 0 & 0 \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 4 \\ 0 & 3 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 2 & 0 & 0 & 0 \end{pmatrix}$$

$$= \begin{pmatrix} 1 & 0 & 0 & 0 & 2 \\ 0 & 16 & 0 & 0 & 0 \\ 0 & 0 & 9 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 2 & 0 & 0 & 0 & 4 \end{pmatrix} \qquad (4)$$

Step 2:

We calculate the eigenvalues and singular vectors of $\boldsymbol{A \cdot A^T}$. The non-zero singular eigenvectors are shown by descending as:

λ_1=16, λ_2=9, λ_3=5.

The non-zero singular values are obtained in the following:

δ_1=4, δ_2=3, $\delta_3=\sqrt{5}$, the rank-**r** of non-zero singular matrix **Σ** is 3.

So, the eigenvectors are in the following:

$$v_1 = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \quad v_2 = \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \end{pmatrix}, \quad v_3 = \begin{pmatrix} \sqrt{0.2} \\ 0 \\ 0 \\ 0 \\ \sqrt{0.8} \end{pmatrix}.$$

So the singular value matrix **Σ** and the term decomposition matrix **V** are shown as:

$$\sum_r = \begin{pmatrix} 4 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & \sqrt{5} \end{pmatrix};$$

$$V^T{}_r = \begin{pmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ \sqrt{0.2} & 0 & 0 & 0 & \sqrt{0.8} \end{pmatrix}.$$

Step 3:

Calculating the document decomposition matrix U.

$$u_1 = \frac{1}{\delta_1} A v_1 = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix},$$

$$u_2 = \frac{1}{\delta_2} A v_2 = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \end{pmatrix},$$

$$u_3 = \frac{1}{\delta_3} A v_3 = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix},$$

$$U_r = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}.$$

So if we want to analyze the attribute of document, we just need calculate the document decomposition matrix U_r.

V. ACCIDENT CASE CLUSTERING BASED ON LSI

Latent semantic analysis employs information retrieval to explore latent semantics and attributes of accident cases. So, we use latent semantic method to analyze a large number of accidents data. This analysis has the following steps: build the primary matrix, execute singular value decomposition, purse similarity analysis of accident cases and obtain the results clustering.

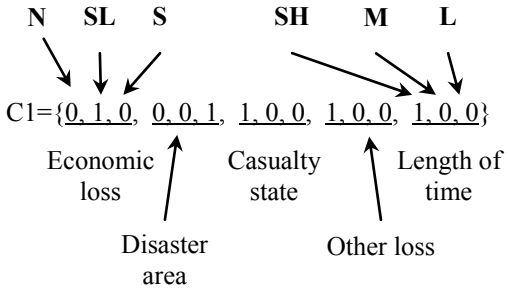

Figure 3. The description of accident attributes

TABLE I. SAMPLE DATA

No.	Attribute				
	Economic loss	*Disaster area*	*Casualty state*	*Other loss*	*Length of time*
C1	SL	S	N	N	SH
C2	N	N	S	S	SH
C3	SL	S	S	N	SH
C4	N	SL	S	S	SH
C5	S	S	S	N	SH
C6	S	SL	SL	SL	L
C7	SL	S	SL	N	M
C8	N	S	S	N	L

TABLE II. THE PRIMARY MATRIX

	C1	C2	C3	C4	C5	C6	C7	C8
Economic loss : N	0	1	0	1	0	0	0	1
Economic loss : SL	1	0	1	0	0	0	1	0
Economic loss : S	0	0	0	0	1	1	0	0
Disaster area : N	0	1	0	0	0	0	0	0
Disaster area : SL	0	0	0	1	0	1	0	0
Disaster area : S	1	0	1	0	1	0	1	1
Casualty state : N	1	0	0	0	0	0	0	0
Casualty state : SL	0	0	0	0	0	1	1	0
Casualty state : S	0	1	1	1	1	0	0	1
other loss : N	1	0	1	0	1	0	1	1
other loss : SL	0	0	0	0	0	1	0	0
other loss : S	0	1	0	1	0	0	0	0
Length of time : SH	1	1	1	1	1	0	0	0
Length of time : M	0	0	0	0	0	0	1	0
Length of time : L	0	0	0	0	0	1	0	1

5.1 Establishing Primary Matrix

In our accident database, all the data include 5 attributes: (1) economic loss, (2) disaster area, (3) casualty state, (4) other loss and (5) length of time. Every attribute has 3 serious grades which economic loss, disaster area, casualty state and other loss are **N**(nothing), **SL**(slight) and **S**(serious), and length of time is **SH**(short), **M**(middle) and **L**(long). For example, the accident case 1 has slight economic loss, serious disaster area, no casualty state, no other loss and short length of time. If the any attribute of an accident case has any grade, then this grade is "1", or else it is "0". It may denote the expression shown in Figure 3.

Table I recorded eight accident cases from the National Institute of Technology Evaluation (NITE). So we can transform it to a primary matrix as shown in Table II.

5.2 Singular Value Decomposition

In Table II, we have eight cases with five attributes. These create a 15x8 matrix, so we use Matlab to decompose singular value and obtain decomposed matrix **U**, **Σ** and $\mathbf{V^T}$. We chose the non-zero singular values of **Σ** to build $\mathbf{U_r}$, $\mathbf{\Sigma_r}$ and $\mathbf{V^T_r}$ which are shown in matrices 5, 6 and 7, respectively.

$$U_r = \begin{pmatrix} -0.39071 & 0.32158 \\ -0.29845 & -0.56435 \\ -0.46969 & 0.15712 \\ -0.30411 & -0.56933 \\ -0.43633 & 0.037314 \\ -0.10217 & -0.034567 \\ -0.30819 & 0.47413 \\ -0.38615 & -0.043407 \end{pmatrix} \quad (5)$$

$$\sum_r = \begin{pmatrix} 4.3642 & 0 \\ 0 & 2.8161 \end{pmatrix} \quad (6)$$

$$V_r = \begin{pmatrix} -0.22655 & -0.41799 \\ -0.26777 & 0.33835 \\ -0.12346 & 0.000975 \\ -0.068385 & -0.2004 \\ -0.093093 & -0.21445 \\ -0.4563 & 0.33619 \\ -0.089526 & 0.11419 \\ -0.094028 & 0.15609 \\ -0.43422 & -0.34894 \\ -0.4563 & 0.33619 \\ -0.02341 & -0.012275 \\ -0.13807 & -0.40257 \\ -0.43527 & -0.21933 \\ -0.070618 & 0.16837 \\ -0.11189 & -0.027689 \end{pmatrix} \quad (7)$$

5.3 The Clustering Of Accident Cases

At first, we calculate the cosine of any two accident cases in 2-Dimensional semantic space. If the cosine of these two cases is "1", the angle of two case vectors is 0-degree, that is, the two cases are the same else cosine is "0" these two cases are not the same. All of the values are shown in Table III.

From the data of Table III, we use the similarity measure data shown in Table III, to build the maximal tree. First, we pick all the vertices for which relation values are not less than 0.9. Thus, the vertices {1, 3}, {1, 7},{2, 4}, {3, 5}, {3, 8}, {5, 6}, {5, 8}, and {6, 8} are selected output. We connect these vertices by their similarity value to build the initial cluster tree, as shown in Figure 4.

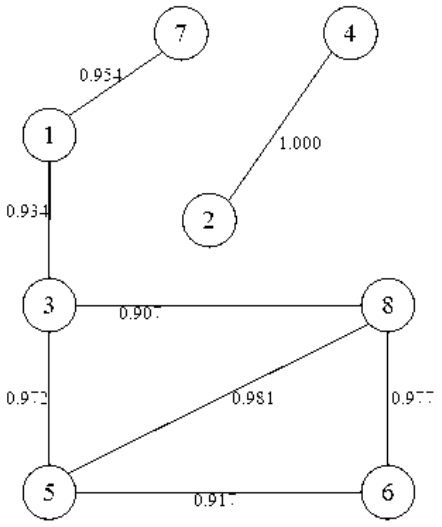

Figure 4. The initial cluster tree

The maximal tree cannot have a circuit because any two vertices have only one maximal relation. Thus, we must remove the edge of minimum value in a circuit. The edge {3, 8}, and {5, 6} should be removed. The next cluster tree is shown in Figure 5.

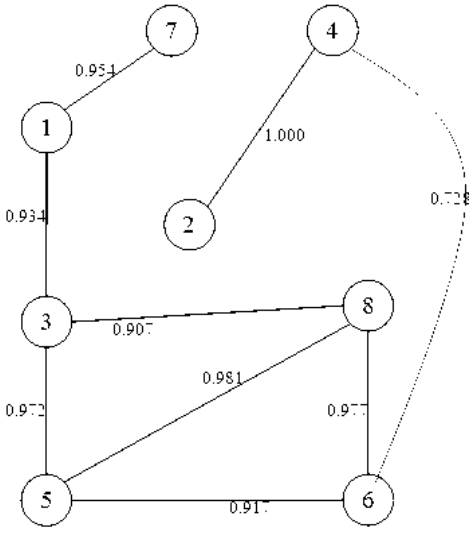

Figure 5. The clustering tree

TABLE III. FUZZY SIMILARITY DATA

	1	2	3	4	5	6	7	8
1	1							
2	-0.20082	1						
3	0.93383	0.16291	1					
4	-0.19676	0.99999	0.16699	1				
5	0.82342	0.39052	0.97192	0.39433	1			
6	0.52771	0.72615	0.79565	0.72899	0.91652	1		
7	0.95362	-0.4864	0.78282	-0.48278	0.61441	0.24753	1	
8	0.69629	0.56331	0.90698	0.56673	0.98062	0.97712	0.44792	1

However vertices 2 and 4 are not included in group{1, 3, 5, 6, 7, 8}. We thus need to connect add the two groups of vertices, {2,4} and {1,3,5,6,7,8} and connect vertices with maximum similarity value between the two groups. The similarity values are 0.782 for {4, 6}. So, all the vertices are connected. The cluster tree is shown in Figure 6.

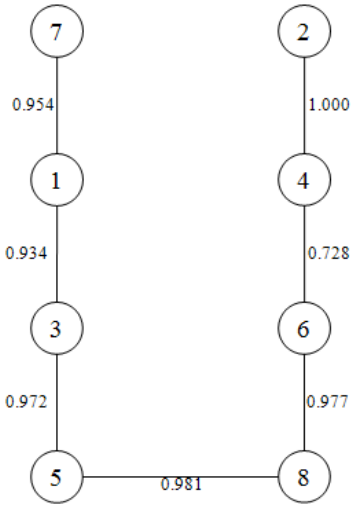

Figure 6. The Maximal Tree

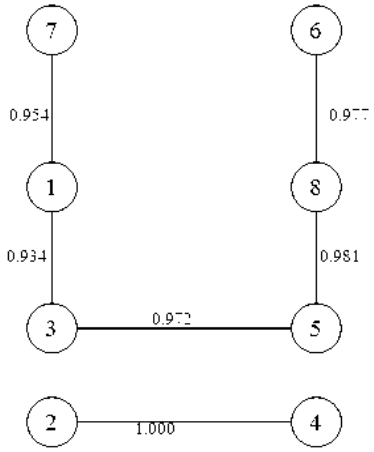

Figure 7. The clustering by λ=0.900

At last, we get a Maximal Tree, which each side has a weight "r_{ij}". By the Threshold-λ, we remove all the sides which have weight $r_{ij}<\lambda$. In the remaining vertexes, any connected vertexes are the same cluster [10].

If we select a high similarity value of λ=0.900, based on the clustering tree, we delete all the sides whose similarity value of λ blew 0.900. So the cases 1, 3, 5, 6, 7 and 8 are similar in the same group, and the Cases 2 and 4 are similar in the same group. It is shown in Figure 7. In addition, if we wish to extract some accident cases, we just need to embed the equivalent example data of these cases in the data set. If any ones can be clustered to a group with the equivalent example data according to the threshold λ, it must be a useful data element which we want [10].

VI. Application of LSI

LSI is used to realize automated document categorization. Several experiments have demonstrated a number of successful correlations between the way LSI and humans' process and effectively categorized text [17]. Document categorization is the assignment of documents to one or more predefined categories based on their similarity to the conceptual content of the categories [18]. LSI uses template documents to establish the conceptual basis for each category. During the process of categorization, the concepts contained in the documents categorized are compared to the concepts contained in the template items, and a category or categories are assigned to the documents based on the similarities between the concepts they contain and the concepts that are contained in the template documents.

LSI can realize effectively dynamic clustering based on the conceptual content of documents can also be accomplished using LSI. Clustering is a way to group documents based on their conceptual similarity to each other without using template documents to establish the conceptual basis for each cluster. This is useful when dealing with an unknown collection of unstructured text.

LSI is not restricted only to working with words. It can also process arbitrary character strings. Any object if it can be expressed in text can be represented in an LSI vector space. For example, texts with MEDLINE abstracts have shown that LSI is able to effectively classify genes based on conceptual modeling of the biological information contained in the titles and abstracts of the MEDLINE citations [19].

LSI has proven to be a useful solution to a number of conceptual matching problems [20][21]. The technique has been shown to capture key relationship information, including causal, goal-oriented, and taxonomic information [22].

VII. CONCLUSIONS

The latent semantic indexing (LSI) methodology for information retrieval has applied the singular value decomposition to identify an eigenfunction for a large matrix, whose cells represent the occurrence of terms(conditions) within documents. This methodology was used to rank text documents and data clustering, based on their relevance to a topic. In this paper, we proposed the method that integrated the Latent Semantic Indexing (LSI) concept to our document clustering. This involves the use of Singular Value Decomposition (SVD) which creates a new abstract and uses a way of finding simplified document collection in matrix representation, so that it could identify the terms and documents which are similar. The considered synthetic and real-world examples demonstrated the improved mining properties due to the befitting cluster and the algorithms capability of determining a suitable similarity degree of clusters in the data.

***Abstract*—This paper proposes an image-guided method for estimating the position of an AUH (autonomous unmanned helicopter) from one captured landmark image. The proposed method is intended for application as auxiliary information for the guidance of an AUH during approach of a landmark based landing. The relation between the camera position and landmark image can be analyzed by projective geometry with the provision of sufficient landmark features. ANFIS is utilized for establishing the mapping relation and establishing a fuzzy model for efficient camera position estimation. The proposed method provides a highly accurate method of AUH guidance during landmark approach.**

Keywords-camera position estimation; visual-based guiding; ANFIS; incomplete landmark image

I. INTRODUCTION

Unmanned aerial vehicles (UAVs) are very useful systems for aerial photography, gas pollution detection or military applications. UAVs could potentially replace human beings in the completion of many difficult tasks. Because of their ubiquitous uses, the theories and applications of UAV systems have become popular contemporary research topics. There are many types of UAVs with different functions. Generally UAVs can be divided into two major categories, fixed-wing type and rotary-wing type. The fixed-wing UAVs can carry out long-distance and high-altitude reconnaissance missions. However, flight control of fixed-wing UAVs is not easy in low-altitude conditions. Conversely, rotary-wing UAVs can hover in low-altitude while conducting surveys, photography or other investigations. Consequently in some applications, the rotary-wing type UAV is more useful than the fixed-wing UAV. One common type of rotary-wing type UAVs is the AUH (Autonomous Unmanned Helicopter). AUHs have characteristics that include of 6-DOF flight dynamics, VTOL (vertical taking-off and landing) and the ability to hover. These attributes make them ideal for aerial photography or investigation in areas that limit maneuverability.

In recent years, there has been a lot of research interested in a more intelligent design of autonomous controllers for controlling the basic flight modes of unmanned helicopters [1] – [3]. The controller design for AUHs requires multiple sensor feedback signals for sensing states of motion. One of the basic flight mode controls of unmanned helicopters is landing. The most commonly used sensors are IMU (Inertial Measurement Unit) and GPS (Global Positioning System). The IMU provides three-axis angular velocity, and the GPS provides three-axis position information. For landing control, the height and pose of an unmanned helicopter are very important. There is a statement in [4] that the desired downward velocity is proportional to the square of the height. However, GPS error can range up to 6 meters [5]. This is much larger than the size of small unmanned helicopters and the landmark, both of which are usually measured in centimeters. Such large erroneous GPS measurements weaken the accurately landing ability of small unmanned helicopters. This paper will focus on the development of a position estimation method for that provides greater accuracy of position information for the guidance of unmanned helicopters during the approach to the landmark. The schematic diagram is shown in Fig. 1.

One of the guiding sensors is an image system which is usually collocated with IMU and GPS in the outdoor environment. The image system has been used on vehicles for navigation, obstacle avoidance or position estimation. In [6], the algorithm to extract the edge of the runway for computing the position of airplane was proposed. In [7] – [9], the image-guided methods with two or more images for guiding the RC unmanned helicopter approaching to the landmark are discussed. It is obvious that multiple-camera measurement system is an effective and mature method. However, the

payload of the small unmanned helicopters has to be considered. Hence the image system is the smaller the better. In [10] and [11], image sequences are used to estimate the position of an unmanned helicopter. We developed a method for estimating the camera position from only a single image. Based on the estimated information, the unmanned helicopter can be guided to land autonomously.

The parking apron of a helicopter is in the shape of circle with an 'H' inside it. There are some recognition algorithms designed for recognizing the 'H' of the landmark [12], [13]. For the purpose of landing small unmanned helicopters autonomously and safely, the relative position between the small unmanned helicopter and the landmark has to be considered. Consequently, we propose a method for estimating the camera position from a single image. Referring to Fig. 1, when the unmanned helicopter is approaching the landmark, the camera position can be described by R, θ and Q.

Obviously, the measurement of spatial information from one image is very difficult. However, the relation between the camera position and landmark image can be analyzed by projective geometry. The proposed method for estimating the camera position from one image is illustrated in Fig. 2. In this method, we select sufficient features of the landmark image which can be related to the camera position. The mapping relation established by projective geometry is very complicated and the amount of data is substantial. Therefore the database is divided into four parts so as to reduce the size of the database by considering which quadrant the "center" of the landmark image is located in. The ANFIS is utilized for learning the database and establishing a fuzzy model of the mapping relation.

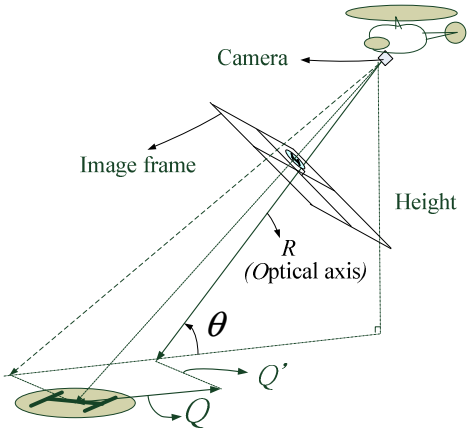

Fig. 1. The AUH approaching to landmark.

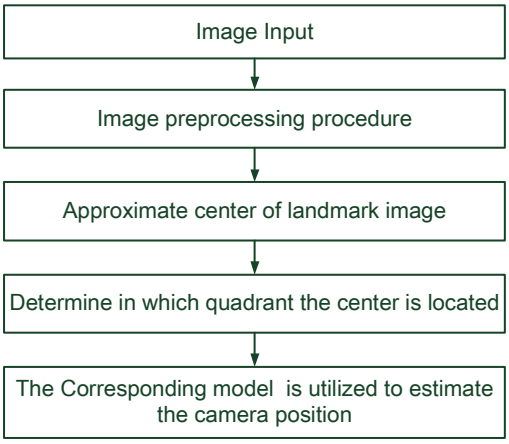

Fig. 2. The method of camera position estimation from landmark image.

In Fig. 2, the four major processes of the method are illustrated. The first step is "Image preprocessing procedure". In this procedure, the captured landmark picture is preprocessed into a clear and intact shape, and the binary image is computed to decrease the computation time. The second step is "Computing the approximate center of the landmark image". Since the landmark image is seriously deformed, the label 'H' on the landmark is employed for calculating the projection of the landmark center. The third step is "Determine in which quadrant the center is located". In this step, the approximate center is used to represent the location of landmark image. The last step is "Estimate the camera position with corresponding model". The camera position can be estimated quickly using the fuzzy model obtained by the ANFIS.

In the section of experimental results, different deformation cases of the landmark image are considered. Distortions that occur when the camera is at different shooting positions are simulated. The simulation is helpful for observing landmark image features. Moreover, the basic rectangle of the landmark image, corner detection, and the calculation of approximate center of landmark are demonstrated in the experimental results. The training results of ANFIS and camera position estimation results are demonstrated at the end of this paper.

II. Analysis of Image Features Via Projective Geometry

In this research, we consider the case of an unmanned helicopter approaching a landmark during landing. Fig. 3 illustrates the projection of the landmark diameter and the relation between the camera and the landmark. The landmark can be projected onto the image frame through the camera center [14]. The most obvious feature of the landmark is the diameter. The projection of the landmark diameter can be divided into vertical and horizontal directions. The projection cases specific to vertical direction and horizontal direction will be discussed in the following subsections.

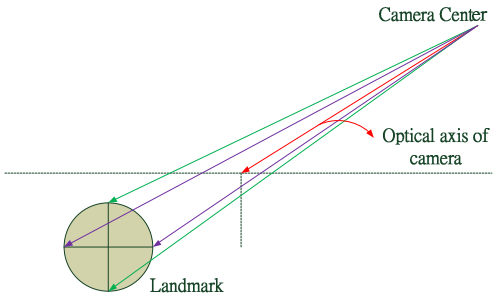

Fig. 3. The center projection of the landmark.

A. Landmark image features projection in the horizontal direction

We will first consider the projection case of the horizontal diameter. In Fig. 4, the plane π is perpendicular to the optical axis, and π is located somewhere on the optical axis. Here, π is equivalent to the image frame. In addition, form Fig. 4, the landmark diameter is projected onto π and the projection of the landmark radius r is $\hat{m}$ and $\hat{n}$ in the vertical and the horizontal directions, respectively. The geometric projection relation between landmark radius r and $\hat{m}$, $\hat{n}$ is shown as Fig. 4. The distance P and B are

$$P = \sqrt{R^2 + H^2}\ , \tag{1}$$

$$B = \sqrt{(Q+P)^2 + H^2}\ , \tag{2}$$

respectively. Where H is the altitude of camera and R is the distance from the camera center to the ground.

To analyze the projection relations in Fig. 4, three regions, named Ψ_1, Ψ_2 and Ψ_3, in the shape of triangle, are employed. They are shown as colored regions in Figs. 5, 6, and 7, respectively. Consider the case of Fig. 5, region Ψ_1 is a triangle with several angles in it. The angles could be computed with trigonometric functions. The derivation of the angles are (3) and (4) .

$$\begin{cases} \alpha_1 = \tan^{-1}\left((Q'+r)/B\right) \\ \alpha_2 = \tan^{-1}\left(Q'/B\right) \\ \alpha_3 = \tan^{-1}\left((Q'-r)/B\right) \end{cases} \tag{3}$$

$$\begin{cases} \beta_2 = \alpha_1 - \alpha_2 \\ \beta_1 = \alpha_1 - \alpha_2 - \beta_2 \end{cases} \tag{4}$$

Next, the region Ψ_2 is shown in Fig. 6. There are three angles γ_1, γ_2 and γ_3 in this region. The derivation of the angles is (5). Similarly, B' can be computed with trigonometric functions and γ_1, γ_2, γ_3.

$$\begin{cases} \gamma_1 = \tan^{-1}\left((Q+P)/H\right) \\ \gamma_2 = 90 - \theta \\ \gamma_3 = \gamma_1 - \gamma_2 \end{cases} \tag{5}$$

Finally, the third region Ψ_3 is illustrated in Fig. 7. In this figure, the projections of the landmark radius r are $\hat{m}$ and $\hat{n}$ which can be obtained by (6) and (7).

$$\begin{cases} Q'_{proj} = B' * \tan^{-1}(\alpha_2) \\ e = B' * \tan^{-1}(\alpha_3) \\ f = B' * \tan^{-1}(\alpha_1) \end{cases} . \tag{6}$$

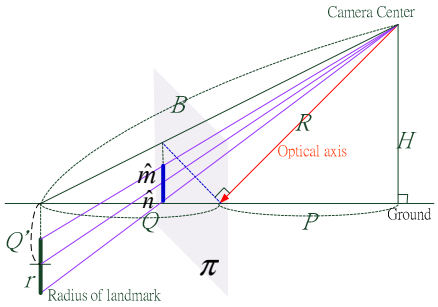

Fig. 4. The center projection of the landmark image features in horizontal direction.

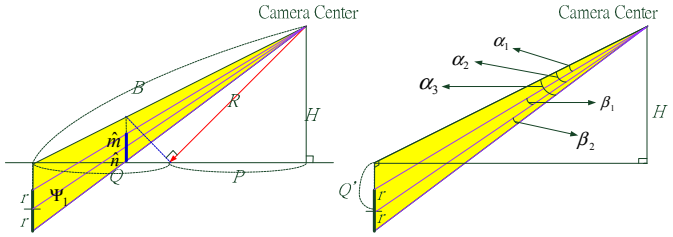

Fig. 5. Image features analysis in region Ψ_1. (a)The region Ψ_1 referring to Fig. 4. (b) The important angles α_1, α_2, α_3 and β_1, β_2 in region Ψ_1.

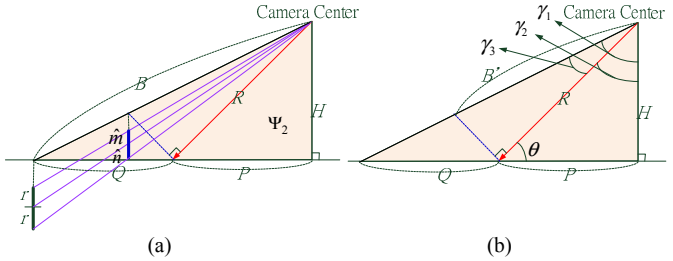

Fig. 6. Image features analysis in region Ψ_2. (a)The region Ψ_2 referring to Fig. 4. (b) The important angles γ_1, γ_2 and γ_3 in region Ψ_2.

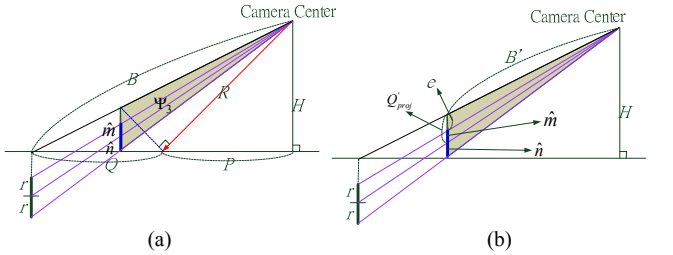

Fig. 7. Image features analysis in region Ψ_3. (a)The region Ψ_3 referring to Fig. 4. (b) The landmark radius r, and its projections $\hat{m}$ and $\hat{n}$.

$$\begin{cases} \hat{m} = Q'_{proj} - e \\ \hat{n} = f - Q'_{proj} \end{cases} . \quad (7)$$

B. Landmark image features projection in the vertical direction

In the case of landmark image features projections in the vertical direction, the geometric analyses will be more complicated than those of the horizontal case. However, the projection of the image features can be obtained by similar methods. In Fig. 8, the landmark radius is projected onto the plane π and form g_5, g_6.

The projective geometry illustrated in Fig. 8 will be discussed in terms of five distinct regions. One of them is named Ω_1, and as shown in Fig. 9, is a triangle. Three of them are triangles containing the vertical red lines individually, named Ω_2, Ω_3, and Ω_4, as shown in Fig. 10. And the last is a ladder-shaped region, named Ω_5, as shown in Fig. 11.

Consider the colored region Ω_1 shown in Fig. 9(a). Many useful quantities including angles and line segments can be computed from the region Ω_1. From Fig. 9(b), the angles obtained by (8) can be used to compute the line segments in Figs. 9(c) and 9(d) by equations (9)-(11).

$$\begin{cases} \omega_1 = \tan^{-1}\left((P+Q+r)/H\right) \\ \omega_2 = \omega_1 - \gamma_2 \\ \omega_6 = \tan^{-1}\left((P+Q-r)/H\right) \\ \omega_3 = \omega_1 - \omega_6 \\ \omega_7 = \tan^{-1}\left((P+Q)/H\right) \\ \omega_4 = \omega_1 - \omega_7 \\ \omega_5 = \omega_1 - \omega_6 - \omega_4 \\ \omega_8 = \omega_6 - \gamma_2 \end{cases} . \quad (8)$$

$$\begin{cases} e_3 = R * \tan(\omega_2) \\ e_4 = R * \tan(\omega_8) \\ e_5 = R * \tan(\omega_8 + \omega_5) \\ e_1 = e_5 - e_4 \\ e_2 = e_3 - e_5 \end{cases} . \quad (9)$$

$$\begin{cases} k_1 = \sqrt{(P+Q+r)^2 + H^2} \\ k_2 = \sqrt{(P+Q)^2 + H^2} \\ k_3 = \sqrt{(P+Q-r)^2 + H^2} \end{cases} \quad (10)$$

$$\begin{cases} u_1 = \sqrt{R^2 + e_3^2} \\ u_2 = \sqrt{R^2 + e_5^2} \\ u_3 = \sqrt{R^2 + e_4^2} \end{cases} . \quad (11)$$

From the triangles Ω_2, Ω_3, Ω_4 in Fig. 10 and the results obtained from equations (9)-(11), one can obtain q_1, q_2 and q_3 by (12).

III. IMAGE FEATURES EXTRACTION

The procedure of image feature extraction is illustrated in Fig. 12. There are three major parts in this procedure. They are "*Image preprocessing procedure*", "*Corner detection and approximate center computing*" and "*Landmark image feature extraction*". Details about the three parts are discussed below.

A. Image preprocessing procedure

The landmark image features can be obtained by image preprocessing [15]. There are three major parts in this algorithm. The first part is image segmentation, including thresholding and filtering for segmenting the approximate landmark image in the frame. Thresholding is a fundamental tool for segmentation of an image when objects and background pixels can be distinguished by their grey level values. When an image is segmented into a binary image, analysis and computing become far easier. The second technique used for image pre-processing is morphological image processing, which is utilized to obtain more complete and clear edges of the target image. Erosion and dilation are the commonly used operations of morphological image processing [16]. The third part is landmark image extraction, including "Recursive connected labeling algorithm", "Basic rectangle computing" and "Major axis and minor axis computing". A connected labeling algorithm is usually used for multiple

objects labeling in image. But this process is not necessary in this paper since only a signal landmark image is considered.

B. Corner detection and approximate center computing

A corner detection algorithm is utilized for detecting the four corners of the label 'H' of the landmark. There are many different corner detection algorithms developed for locating feature points. One of the common corner detection algorithms is Harris corner detector [17]. The main principle of Harris corner detector is to use the Gaussian filter to detect the corners response of each pixel in the image. Gaussian filter can not only enhance the significant corners, but also remove the undesirable corners. Moreover, it can reduce the probability of misjudgment. Although the Harris corner detector is a very useful tool, it requires a lot of computing time. Therefore the corner detection operations are applied only for the basic rectangle to reduce computation time.

Further, the procedure is developed to locate the approximate center of the landmark image. The procedure is described as follows.

STEP 1 Detect the corners of the image in the basic rectangle.

STEP 2 Detect the convex corners of the label 'H'.

STEP 3 Label the convex corners and extracted the four corners of the label 'H'.

STEP 4 Find the intersection of the diagonals, and designate these coordinates as the approximate center of the landmark image.

C. Landmark image feature extraction

From section II, we know that the deformation of a landmark image is unavoidable. Even so, the projection relation can be analyzed via the proposed method. The projections of the landmark radius in vertical and horizontal directions are g_5, g_6, $\hat{m}$, and $\hat{n}$, respectively. Fig. 13(a) is an example of the image of the landmark. The white part is obviously a deformed circle. Fig. 13(b) is a sketch map showing the features of the landmark image.

IV. Database Construction and ANFIS Structure

ANFIS (Adaptive Neuro-Fuzzy Inference Systems) is a very high efficiency learning algorithm. Its learning effect is equivalent to that of NNs (neural network), but the requisite learning time is substantially lower. Consequently, ANFIS is employed in this paper for learning the mapping relation between the landmark and camera position.

The input of the ANFIS are g_5, g_6, e_5, $\hat{m}$, $\hat{n}$, q_2, and d. The output of ANFIS are θ, R and Q. The amount of the training data is very large. Since the center of the landmark image will only appear in one of the quadrants, the database is then split into four parts depending on the quadrant location of the estimated center so to reduce the quantities of training data required. They are "the landmark image located at the first quadrant", "the landmark image located at the second quadrant", "the landmark image located at the third quadrant" and "the landmark image located at the fourth quadrant".

Four ANFIS named "$ANFIS_{First_Quadrant}$", "$ANFIS_{Second_Quadrant}$", "$ANFIS_{Third_Quadrant}$" and "$ANFIS_{Fourth_Quadrant}$" are established by the corresponding database. The ANFIS for all databases is called "$ANFIS_{cam_estimation}$" and its structure is illustrated in Fig. 14. The structure of any one of these ANFIS's is illustrated in Fig. 15.

V. Experimental Results

The experimental results of the proposed method for camera position estimation are discussed in this section. The features are not easily extracted from a deformed landmark image. Fig. 16 shows some simulation results of the projection of the landmark under different conditions. The intersection of optical axis of the camera system and ground is set to be at (0,

0). For example, Fig. 16(a) shows the relations of a randomly set camera system and the landmark, and the corresponding projection of the landmark and the center is shown in Fig. 16(b). Similarly, Fig.16(c) and (d) show the camera position at R=60 , θ =30° and the center of landmark at (10, -7). The deformation of the landmark image is obvious.

A. Image processing and feature extraction results

Consider the image shown in Fig. 17, in our simulations, the landmark diameter is 3cm and the size of the image is 320 by 240 pixels. For example, Fig. 17(a) is an obtained real image, and Fig. 17(b) is the binary image and the basic rectangle of landmark. The order statistics filter [18] is utilized for obtaining the clear landmark image. The computed major and minor axis of basic rectangle are 71.70 and 58.47, respectively. Fig. 17(c) shows the corner detection result and approximate center.

TABLE I. IMAGE FEATURES THAT EXTRACTED FROM FIG. 16

Image No.	Image Features					
	g_5	g_6	e_5	$\hat{m}$	$\hat{n}$	q_2
Test image1	32.55	22.70	37.33	28.41	37.83	77.29
Test image2	22.27	22.23	82.36	29.44	30.31	53.68
Test image3	20.64	21.11	80.48	28.50	29.00	60.38

Similarly, the other features in Fig. 17 are collated in TABLE I. By reviewing this data we can see that the simulation results demostrate that the proposed image proccess method can extract landmark image features. Furthermore the corner detection algorithm will not be affected by the rotation or deformation of a landmark image. The landmark image is clear therefore the features are easily extracted.

B. Camera position estimating results

The ANFIS training data is generated by geometric computation and then classified into four parts to reduce the training time and the structure of ANFIS. This paper considers the practical application of an AUH approaching a landmark. The research does not examine extreme situations. Therefore the training range of R is from 20cm to 300cm. The training range of θ is from 55° to 90°. The training RMSE (root mean squared error) of R, θ and Q in $ANFIS_{First_Quadrant}$ are 0.1325, 0.1433 and 0.1654, respectively. The training RMSE of R, θ

TABLE II. THE ESTIMATION RESULTS OF CAMERA POSITION

Data No.	Camera Position			Estimating Error		
	R (cm)	θ	Q (cm)	R (cm)	θ	Q (cm)
1	33	65	10	0.124	-0.145	0.216
2	45	78	19	0.217	0.204	0.145
3	59	57	21	-0.194	0.174	-0.164
4	65	81	45	-0.154	-0.134	0.201
5	106	84	50	0.198	0.165	0.169
6	124	59	54	-0.119	0.214	0.176
7	154	81	14	0.132	-0.175	0.203
8	169	71	35	0.211	0.132	-0.164
9	201	84	44	-0.209	-0.198	-0.170
10	284	65	95	-0.174	0.181	0.198

and Q in $ANFIS_{Second_Quadrant}$ are 0.1026, 0.2053 and 0.1461, respectively. The training RMSE of R, θ and Q in $ANFIS_{Third_Quadrant}$ are 0.1271, 0.0971 and 0.0745, respectively. The training RMSE of R, θ and Q in $ANFIS_{Fourth_Quadrant}$ are 0.0925, 0.1033 and 0.0754, respectively. Some of the estimation results of camera position are illustrated in TABLE II. In TABLE II, 10 data sets are employed to verify the fuzzy model. The average absolute error of R is 0.1732cm, the average absolute error of θ is 0.1722°, and the average absolute error of Q is 0.1806cm.

VI. CONCLUSIONS

For the guidance of an AUH during its landmark approach, we proposed a visual-based guidance method for camera position estimation. This method can estimate the camera position via select landmark features. The designed method can reduce the image process procedure. More importantly, the image features can be extracted from a deformed landmark image. The simulation results show that the basic rectangle and the label 'H' are very helpful for computing the image features.

In addition, the size of established database is very large. To reduce the quantities of training data and thereby speed up the ANFIS training the database is split into four parts. The ANFIS established an approximate fuzzy model to replace the complex projective relationship between the camera and landmark. In practical applications, this method can provide the position information required by an AUH for accurate guidance during approach to a landmark.

***Abstract*—The result of image thresholding is not always satisfactory due to the disturbing factors like vagueness, non-uniform illumination etc and to overcome these problems recently various researchers have proposed fuzzy image thresholding. The linear index of fuzziness for type-1 fuzzy sets by Zenzo et. al. and measure of ultrafuzziness for type-2 fuzzy sets by Tizhoosh has difficulties in handling MRI brain images with one level of gray value as background and other two levels of grayness as white matter and gray matter. Hence this paper proposes new modified thresholding measures for MRI brain images using type-1 and type-2 fuzzy sets. The results show the effectiveness of the proposed modified thresholding measures.**

***Index Terms*—type-1 fuzzy sets, type-2 fuzzy sets, thresholding, ultrafuzziness**

I. Introduction

Image thresholding, considered as the simplest form of segmentation, is an important task in most of the image processing applications. Lot of research work has already been appeared on robust thresholding techniques [1], [2], [3]. Recently fuzzy set theory have been used extensively in image thresholding [4], [7], [8], [9], [10], [11], [12], [13] due to the ability of fuzzy logic in handling ambiguity/vagueness in the presence of disturbing factors like non-uniform illumination, vagueness etc.

Fuzzy thresholding techniques can be classified into four categories [4] based on the way in which it is applied. They are namely (a) fuzzy clustering using fuzzy c-means, probabilistic c-means etc. (b) rule-based approaches (c) fuzzy geometrical approaches using spatial image information and geometrical measures(compactness, area coverage etc.) (d) information-theoretical approach by minimizing/maximizing measures of fuzziness (index of fuzziness, fuzzy entropy, fuzzy divergence etc.). Due to the simplicity and high speed of information-theoretical approach [7], [8], [9], [10], [11] it has been mostly used for image thresholding.

The linear index of fuzziness for type-1 fuzzy sets by Zenzo et. al. [11] and measure of ultrafuzziness for type-2 fuzzy sets by Tizhoosh [4] has difficulties in handling (we mean thresholding) MRI brain images. Here the difficulties in thresholding are due to the presence of 3 levels of grayness in MRI images, one level of gray value as background and other two levels of grayness as white matter and gray matter. Hence this paper proposes new modified thresholding measures for MRI brain images using type-1 and type-2 fuzzy sets. The results show the effectiveness of the proposed modified thresholding measures.

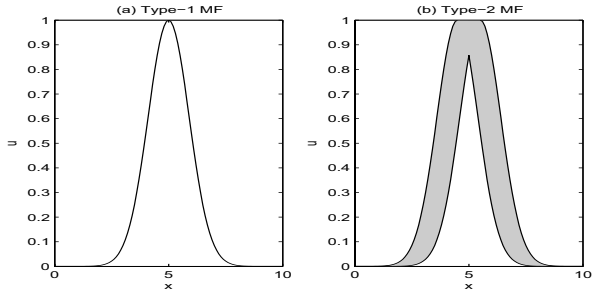

Fig. 1. Gaussian membership function with variance=0.9 of (a) type-1 with mean=5 (b) type-2 with uncertain means mean1=4.5, mean2=5.5

This paper is organized as follows. Section II deals with measure of fuzziness and section III introduces modified measures of fuzziness. Section IV presents the experimental results and section V concludes the paper.

II. Measure of fuzziness

A. Type-1 fuzzy sets

A type-1 fuzzy set A in X is defined by a type-1 membership function $\mu_A(x)$ given by

$$A = \{(x, \mu_A(x)) | x \in X\} \tag{1}$$

Figure 1a shows the Gaussian membership function of type-1 fuzzy set with variance = 0.9 and mean = 5.

The linear index of fuzziness [11] for an $M \times N$ image subset $A \subseteq X$ with L gray levels $g \in [0, L-1]$ can be given by

$$\gamma_l(A) = \frac{2}{MN} \sum_{g=0}^{L-1} h(g) \times \min[\mu_A(g), 1 - \mu_A(g)] \tag{2}$$

where h(g) is the histogram. $\mu_X(g)$ is the membership function and can be defined by the standard S-function, Huang & Wang function, triangular membership function, LR type fuzzy number etc..

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

B. Type-2 fuzzy sets

Even though the application of T1 FS has seen success in all applications[5], [6], since it introduction by Zadeh in 1965, it has limited capabilities to directly model and minimize the effect of uncertainties [14], [15], [16], [17], [18]. This is due to the fact that T1 FS does not have measure of dispersion to capture more about linguistic uncertainties as equivalent to that of probability density function (pdf) [1] having variance as a measure of dispersion about the mean. In late 1975, Zadeh introduced the concept of type-2 fuzzy sets (T2 FS). T2 FS are described by membership functions (MFs) that are characterized by more parameters than MFs for T1 FSs and hence T2 FSs provide more degrees of freedom to handle uncertain environments [14]. Type-2 fuzzy sets are characterized by fuzzy membership functions that are three-dimensional with membership grade as a fuzzy set in [0, 1] rather than two dimensional membership functions with crisp number in [0, 1] as membership grade as in the case of T1 FS.

A type-2 fuzzy set ($\tilde{A}$) is given by

$$\tilde{A} = \{((x,u), \mu_{\tilde{A}}(x,u))|\ \forall x \in X,\ \forall u \in J_x \subseteq [0,1]\} \quad (3)$$

where $0 \leq \mu_{\tilde{A}}(x,u) \leq 1$ is a type-2 membership function. $\tilde{A}$ can also be expressed as

$$\tilde{A} = \int_{x\in X} \int_{u\in J_x} \mu_{\tilde{A}}(x,u)/(x,u), \qquad J_x \subseteq [0,1] \quad (4)$$

A more practical definition for a type-2 fuzzy set can be given as

$$\begin{aligned} \tilde{A} \quad = \quad & \{(x, \mu_U(x), \mu_L(x))|\ \forall x \in X, \\ & \mu_L(x) \leq \mu(x) \leq \mu_U(x), \mu \in [0,1]\} \end{aligned} \quad (5)$$

Figure 1b shows the Gaussian membership function of type-2 fuzzy set with variance = 0.9 and uncertain means 4.5 & 5.5.

The ultrafuzziness [4] $\tilde{\gamma}$ for an $M \times N$ image subset $\tilde{A} \subseteq X$ with L gray levels $g \in [0, L-1]$ can be given by

$$\gamma_l(A) = \frac{2}{MN} \sum_{g=0}^{L-1} h(g) \times [\mu_U(g) - \mu_L(g)] \quad (6)$$

where h(g) is the histogram, $\mu_{\tilde{A}}(g)$ is the membership function, $\mu_U(g) = [\mu_A(g)]^{1/\alpha}$ is the upper membership values, $\mu_L(g) = [\mu_A(g)]^{\alpha}$ is the lower membership value and $\alpha \in (1,2]$.

III. Introducing Modified fuzziness measure

A. Modified index of fuzziness for type-1 fuzzy sets

The modified index of fuzziness for an $M \times N$ image subset $A \subseteq X$ with L gray levels $g \in [0, L-1]$ can be given by

$$\gamma_m(A) = \frac{2}{MN} \sum_{g=0}^{L-1} h(g) \times \mu_A(g) \times (1 - \mu_A(g)) \quad (7)$$

[1]pdfs usually require infinite number of moments. Since it is very difficult to determine all the moments, we make use of only first two moments namely mean and variance(measure of dispersion about mean)

where h(g) is the histogram. $\mu_A(g)$ is the membership function and can be defined by the standard S-function, Huang & Wang function, triangular membership function, LR type fuzzy number etc..

B. Modified measure of ultra fuzziness for type-2 fuzzy sets

The modified ultrafuzziness $\tilde{\gamma}$ for an $M \times N$ image subset $\tilde{A} \subseteq X$ with L gray levels $g \in [0, L-1]$ can be given by

$$\gamma_m(A) = \frac{2}{MN} \sum_{g=0}^{L-1} h(g) \times \mu_L(g) \times [\mu_U(g) - \mu_L(g)] \quad (8)$$

where h(g) is the histogram, $\mu_{\tilde{A}}(g)$ is the membership function, $\mu_U(g) = [\mu_A(g)]^{1/\alpha}$ is the upper membership values, $\mu_L(g) = [\mu_A(g)]^{\alpha}$ is the lower membership value and $\alpha \in (1,2]$.

IV. Experiments and results for thresholding brain images

Image thresholding using type-1 fuzzy sets is done by thresholding with the minimum/maximum fuzziness obtained by shifting the membership function, defined over the image histogram, along the grey level range. Similarly, image thresholding using type-2 fuzzy sets can be done by thresholding with the minimum/maximum ultrafuzziness obtained by shifting the membership function, defined over the image histogram, along the grey level range.

Magnetic resonance images have three levels of grayness inherent in it. One level of gray value can be seen as background and other two levels of grayness can be seen as white matter and gray matter. Fig. 2 shows the white and gray matter in the brain slice. Due to the presence of 3 levels of greyness in MRI images, it is very difficult to threshold. Normal thresholding for two levels of greyness (namely separating background and foreground) will not work properly for MRI images.

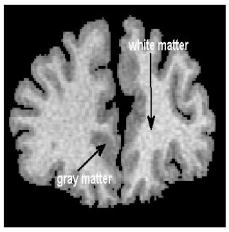

Fig. 2. White matter and gray matter corresponding to a brain slice

Several brain images have been experimented and here we show only the results of three slices of brain. Fig. 3 show the orginal brain slices and Fig. 4 show the corresponding preprocessed images.

Linear index of fuzziness (of type1) is calculated using eqn.2 and modified index of fuzziness (of type1) is calculated using eqn.7. Fig.5 show the plot of linear index of fuzziness and modified index of fuzziness corresponding to the preprocessed images (fig.4). It can be seen from the first image of Fig.5 that modified fuzziness index gives a threshold, $T_2 = 166$ for PImage1, which gives a much better thresolding result which can be seen from the first images

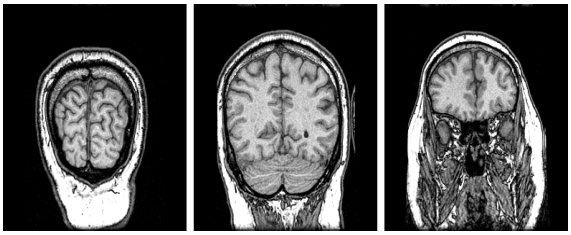

Fig. 3. Orginal images (from left) (a) Image1, (b) Image2, and (c) Image3

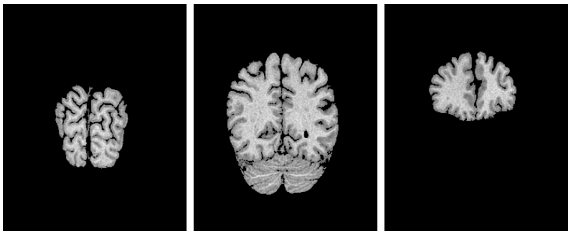

Fig. 4. Preprocessed images corresponding to Fig. 3 (from left) (a) PImage1, (b) PImage2, and (c) PImage3

of Fig.6 and Fig.7. Modified fuzziness index of PImage2 and PImage3, as seen in the second and third images of Fig.5, shows two twists corresponding to gray and white matter in the images. But such twists cannot be seen in the linear index of fuzziness of PImage2 and PImage3, as seen in the second and third images of Fig.5. The threshold values corresponding to the secondary twist helps to separate (and hence threshold) white matter. The thresholding results corresponding to the thresholds thus obtained (Fig.7) performs better than the linear thresholds (Fig.6) (Please see the second and third images of corresponding figures).

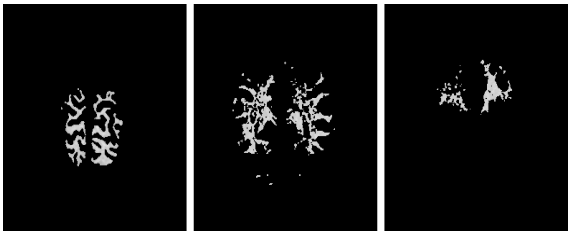

Fig. 6. Thresholded images with threshold obtained from fuzziness index of type1. Thresholded (a) PImage1 with T=176, (b) PImage2 with T=199, and (c) PImage3 with T=199

Ultrafuzziness (of type2) is calculated using eqn.6 and modified index of fuzziness (of type2) is calculated using eqn.8. Fig.8 show the plot of ultrafuzziness and modified ultrafuzziness corresponding to the preprocessed images (fig.4).

Modified ultrafuzziness shows two twists corresponding to

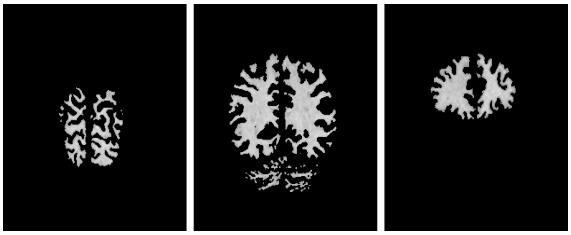

Fig. 7. Thresholded images with threshold obtained from modified fuzziness index of type1. Thresholded (a) PImage1 with T=166, (b) PImage2 with T=165, and (c) PImage3 with T=147

TABLE I
THRESHOLDS FOR THE IMAGES

	PImage1	PImage2	PImage3
Type-1	176	199	199
mType-1	166	165	147
Type-2	176	199	150
mType-2	156	150	133

gray and white matter in the images. The threshold values corresponding to the secondary twist helps to separate (and hence threshold) white matter. It can be seen from the figures that modified ultrafuzziness gives a thresholding result which is much better than the threshold of ultrafuzziness and it clear from the images of Fig.9 and Fig.10.

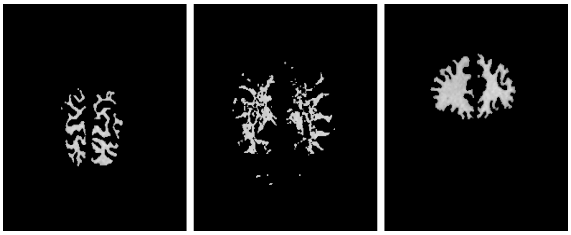

Fig. 9. Thresholded images with threshold obtained from ultrafuzziness of type2. Thresholded (a) PImage1 with T=176, (b) PImage2 with T=199, and (c) PImage3 with T=150

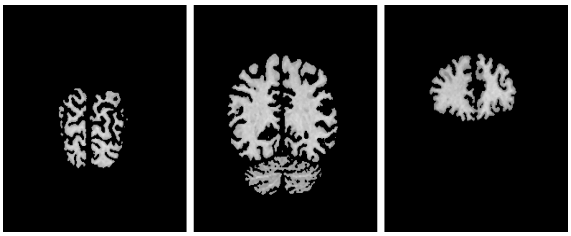

Fig. 10. Thresholded images with threshold obtained from modified ultrafuzziness of type2. Thresholded (a) PImage1 with T=156, (b) PImage2 with T=150, and (c) PImage3 with T=133

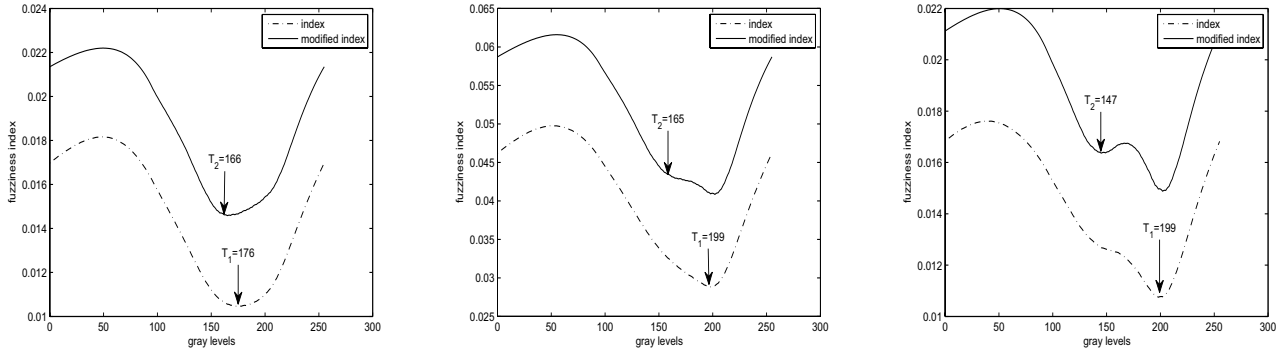

Fig. 5. Fuzziness index (of type1) and modified fuzziness index (of type1) for the images (from left) (a) PImage1, (b) PImage2, and (c) PImage3

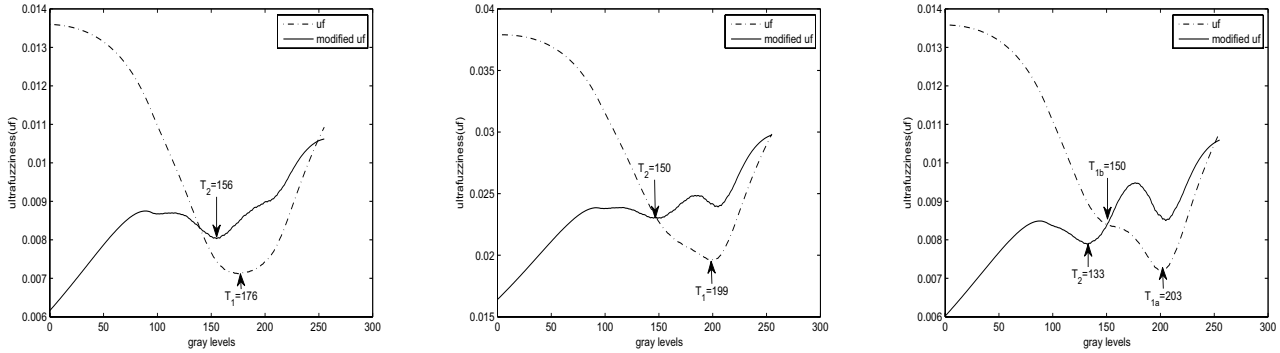

Fig. 8. Ultrafuzziness and modified ultrafuzziness for the images (from left) (a) PImage1, (b) PImage2, and (c) PImage3

V. Conclusion

Due to the difficulties in handling MRI brain images with one level of gray value as background and other two levels of grayness as white matter and gray matter, the paper has presented modified index of fuzziness for type1 fuzzy sets and modified ultrafuzziness for type2 fuzzy sets for thresolding brain images. The results have shown the effectiveness of the proposed modified thresholding measures.

***Abstract*—Mining frequent patterns refers to the discovery of the sets of items that frequently appear in a transaction database. Many approaches have been proposed for mining frequent itemsets from a large database, but a large number of frequent itemsets may be discovered. In order to present users fewer but more important patterns, researchers are interested in discovering frequent closed itemsets which is a well-known complete and condensed representation of frequent itemsets. In this paper, we propose an efficient algorithm for discovering frequent closed itemsets over a data stream. The previous approaches need to do a large number of searching operations and computations to maintain the closed itemsets when a transaction is added or deleted. Our approach only performs few intersection operations on the transaction and the closed itemsets related to the transaction without doing any searching operation on the previous closed itemsets. The experimental results show that our approach significantly outperforms the previous approaches.**

Keywords-frequent closed itemsets; data stream; sliding window; data mining;

I. INTRODUCTION

Mining frequent itemsets [1, 4, 8] from a transaction database is a fundamental task to several data mining applications. The problem of discovering frequent itemsets in database is stated as follows: Given a finite set of *items* $I = \{a_1, a_2, \ldots, a_m\}$, a *transaction* t is a set of items which were purchased by a customer at the same time. A *transaction database* D contains a set of transactions and each transaction is given a unique identifier (TID). An *itemset* $X = \{i_1, i_2, \ldots, i_k\}$ ($i_j \in I$, $1 \le j \le k$) is a set of k distinct items, where k is the *length of* X. The *support count* of X is denoted as $SC(X)$ and defined as the number of transactions which contain X. The *support* of X is defined as the ratio of $SC(X)$ to the total number of transactions in D. An itemset is said to be *frequent* if its support is no less than a user specified threshold *min_sup* which is called *minimum support*. The problem of mining frequent itemsets from a database D is to discover all the itemsets whose supports are no less than *min_sup*. For example, suppose the *min_sup* is set to be 40% for the transaction database in Table I, that is, the *minimum support count* is 40% × 5 = 2.

TABLE I. TRANSACTION DATABASE

TID	Item Bought
t_1	C,D
t_2	A,B
t_3	A,B,C
t_4	A,B,C
t_5	A,C,D

Therefore, the frequent itemsets and their support counts are {A}:4, {B}:3, {C}:4, {D}:2, {AB}:3, {AC}:3, {BC}:2, {CD}:2 and {ABC}:2.

Several algorithms [1, 4, 9] have been proposed for mining frequent itemsets from transaction databases. But they mainly focused on static database and did not consider applications that involve data streams. A *transaction data stream* is an ordered sequence of transactions that comes in a timely order. Mining frequent itemsets over data streams is an important technique which is essential to a wide range of applications such as network traffic analysis, web click stream mining, on-line transaction analysis and many other important tasks. However, mining frequent patterns from data streams poses many challenges because data comes continuously, unbounded and usually with high speed. Furthermore, data distribution in a stream usually changes with time such that the status of itemsets may be changed (from frequent to infrequent or from infrequent to frequent). Hence, how to efficiently capture all the frequent itemsets over a data stream without information loss is a big challenge.

There are lots of works [2] in developing efficient algorithms for mining frequent itemsets from a data stream. But they often discover a large number of frequent itemsets and present too many redundant patterns to users. It is widely recognized that the larger the set of frequent itemsets is, the more the processing cost is required. In other words, the performance of the algorithms may be degraded when a database contains lots of frequent itemsets or a low threshold is used. In order to present users fewer but more important patterns, one of the solutions is to mine only the *frequent closed itemsets* [6, 8, 10]. Closed itemsets are the itemsets that have no proper supersets with the same support. Non-closed itemsets are regarded as redundant [6, 8, 10]. A closed itemset

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

is said to be frequent if its support is no less than *min_sup*. For example, the frequent closed itemsets in Table I are {A}:4, {C}:4, {AB}:3, {AC}:3, {CD}:2 and {ABC}:2. In this example, itemset {B} is non-closed since its support is the same as {AB}. This implicitly indicates that {B} will not appear in a transaction without {A} and hence the whole information about {B} is included in {AB}.

It is well known that frequent closed itemset provides users not only condensed but also complete information about frequent itemsets. In general, the number of frequent closed itemsets is much less than the number of frequent itemsets, that is, the set of frequent closed itemsets is a small subset of the set of frequent itemsets. Besides, a complete set of frequent closed itemsets can be used to uniquely derive all frequent itemsets and supports without losing any information [8].

Recently, some methods for mining frequent closed itemsets over a data stream were presented. Chi et al. proposed the *Moment* algorithm [3] to incrementally update the frequent closed itemsets over a data stream. They use a tree like structure, called *CET Tree (Closed Enumerate Tree)*, to maintain a dynamically selected set of itemsets. Each node in the CET Tree represents an itemset with different node type. Whenever a transaction arrives or leaves, the nodes in the CET Tree are inserted, deleted or updated according to their node types. However, exploration of frequent closed itemsets and node type checking are time-consuming, especially when the minimum support is low. Furthermore, in order to maintain frequent closed itemsets, Moment needs to maintain a large number of nodes representing non-closed itemsets. A huge number of such non-closed nodes may require a lot of memory space when the transactions in a stream contain many frequent closed itemsets.

NewMoment [7] was recently proposed by Li et al.. It uses a tree structure, called *NewCET Tree*, to maintain the information of frequent closed itemsets. Each node in *NewCET Tree* consists of a frequent closed itemset and its support count. The search space and the memory consumption of NewMoment are much smaller than that of Moment, since there is no non-closed node in NewCET Tree. Besides, it adopts a bit-sequence technique to improve time efficiency for exploration of frequent closed itemsets. Both Moment and NewMoment relies on a depth-first, Apriori-like technique to construct their structures. When minimum support is low, the two algorithms may become inefficient, since they must enumerate a large number of candidate itemsets, which is very time-consuming.

Although Moment and NewMoment show good performance in [3, 7], they generally use a fixed support threshold to discover closed itemsets in data stream. In other words, the minimum support threshold needs to be pre-defined before mining and it cannot be changed during the mining process. However, in a data stream, data distribution of frequent closed itemsets usually changes with time such that users often need to alter support thresholds to obtain desired mining results.

To interactively present frequent closed itemsets to users online based on any minimum support threshold, Jing et al. proposed an algorithm *CFI-Stream* [5] to maintain the complete set of closed itemsets over data stream. The experiments in [5] show that CFI-Stream achieves a better performance than Moment in terms of time and space, particularly at lower minimum support. CFI-Stream uses a lexicographical ordered tree, called *DIU Tree* (*DIrect Update Tree*), to maintain all the closed itemsets and their supports such that any frequent closed itemset can be efficiently obtained based on any minimum support threshold. Comparing with Moment-based algorithm [3, 7], CFI-Stream is much more efficient and flexible when the minimum support is changed. However, the computational cost of CFI-Stream is very expensive since CFI-Stream uses a *candidate generate-and-test mechanism* to update closed itemsets. The mechanism is described as follows. When a transaction which contains k distinct items is added to (or deleted from) the database, CFI-Stream needs to *generate* $(2^k - 1)$ subsets (i.e., candidate closed itemsets) for the transaction. To *test* whether a candidate is closed or not, in the worst case, CFI-Stream needs to search all its supersets by traversing parts of DIU Tree. In other words, CFI-Stream requires to search from the DIU Tree $(2^k - 1)$ times for a transaction with k distinct items, which seriously degrades the performance of CFI-Stream.

II. PRELIMINARIES

In this section, we introduce some preliminaries for mining frequent closed itemsets over a data stream. A *data stream DS* = $<t_1, t_2,\ldots,t_t>$ is a continuous sequence of transactions in a timely order. A transaction-sensitive sliding window [2] is denoted as W, which captures the latest w transactions from a data stream. When a new transaction arrives to W, it would be added into W if the current number of transactions in W is less than w. Otherwise, if the current number of transactions in W is equal to w, then the oldest transaction would be expired from W and the new transaction would be added to W. The *support count* of an itemset X in W is denoted as $SC_W(X)$, and defined as the number of transactions which contain X in W. The *support* of X in W is defined as the ratio of $SC_W(X)$ to the total number of transactions in W. An itemset X in W is said to be *frequent* if $SC_W(X)$ is no less than $min_sup \times |W|$. The function f takes a set of transactions T in W as an input and returns an itemset which is the result of the intersection of all the transactions in T. The function g takes an itemset Y as an input and returns a set of transactions in W, which contain Y. The function $C_W(X)$ takes an itemset X as an input and returns an itemset which is the intersection of all the transactions in W belong to $g(X)$, that is, $f(g(X))$. For any itemset X, $C_W(X)$ is called *the closure of X* in W. The support of X in W is the same as the support of $C_W(X)$ since X and $C_W(X)$ in W appear in the same transactions.

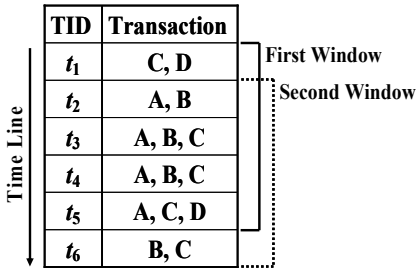

Figure 1. Transaction-sensitive sliding window

Definition 1. An itemset X is called a *closed itemset* in W if and only if $C_W(X) = X$.

$C_W(X) = X$ means that there is no proper superset of X with the same support as X. Therefore, X is a closed itemset. If $C_W(X) \neq X$, then the support of X is same as the support of its superset $C_W(X)$, that is, X is not a closed itemset. For example, Figure 1 shows a transaction-sensitive sliding window when the window size is set to 5. The first window W_1 consists of the transactions from t_1 to t_5. When a new transaction t_6 arrives to the window, the oldest transaction t_1 is expired from the window. The second window W_2 consists of the transactions from t_2 to t_6. In the first window W_1, $g(\{B\}) = \{t_2, t_3, t_4\}$ is a set of all the transactions which contain {B}. $C_{W1}(\{B\}) = f(g(\{B\})) = f(\{t_2, t_3, t_4\}) = t_2 \cap t_3 \cap t_4 = \{AB\} \cap \{ABC\} \cap \{ABC\} = \{AB\}$ is the closure of {B}. In the first window, {B} is not a closed itemset, since $C_{W1}(\{B\}) = \{AB\} \neq \{B\}$.

Definition 2. An itemset X is a *frequent closed itemset* in W if and only if $X = C_W(X)$ and $SC_W(X)$ is no less than *min_sup*.

Problem Statement. Given a transaction-sensitive sliding window size w, the problem is to efficiently find the complete set of frequent closed itemsets from the most recent w transactions over *a data stream* based on any user-specified *min_sup*.

In the following, we list some important properties about closed itemsets, which are intuitive and widely used in the previous literature [6, 8, 10].

Property 1. If $C_W(X) = Y$, then $SC_W(X) = SC_W(Y)$.

Rationale: If $C_W(X) = Y$, then $g(X) = g(Y)$. Therefore, $SC_W(X) = SC_W(Y)$.

Property 2. If $C_W(X) = Y$, then $C_W(Y) = Y$.

Rationale: Since $C_W(X) = Y$, $g(X) = g(Y)$. $C_W(Y) = f(g(Y)) = f(g(X)) = C_W(X) = Y$.

Property 3. X is closed if and only if $SC_W(X) > SC_W(Z)$, for all itemset Z, $Z \supset X$.

Rationale: If X is closed in W, then $C_W(X) = X$, that is, $C_W(X) \neq Z$ for all $Z \supset X$. Therefore, some transactions which contain X do not contain Z, that is, $SC_W(X) > SC_W(Z)$.

Property 4. If $X \subseteq Y$, then $g(Y) \subseteq g(X)$ and $C_W(X) \subseteq C_W(Y)$.

Property 5. $f(g(X)) \cap f(g(Y)) = f(g(X) \cup g(Y))$.

Theorem 1. For any two closed itemset X and Y, if $(X \cap Y) = S$ and $S \neq \varnothing$, then S is a closed itemset.

Rationale: To prove S is closed, we need to show that $C_W(S) = S$, that is, $C_W(S) \subseteq S$ and $S \subseteq C_W(S)$. If $X \cap Y = S$, then $g(X) \subseteq g(S)$ and $g(Y) \subseteq g(S)$ (Property 4). Therefore, $(g(X) \cup g(Y)) \subseteq g(S)$. According to Property 4 and Property 5, $C_W(S) = f(g(S)) \subseteq (f(g(X) \cup g(Y)) = (f(g(X) \cap f(g(Y)) = (C_W(X) \cap C_W(Y)) = (X \cap Y) = S$. That is, $C_W(S) \subseteq S$. According to Property 2, we have $S \subseteq C_W(S)$.

III. CLOSTREAM ALGORITHM

In this section, we first introduce our structures and then describe the CloStream algorithm in detail. The algorithm consists of two sub-procedures: CloStream+ and CloStream—. CloStream+ is used to update closed itemsets when a transaction arrives to the window, while deletion operation is used to update closed itemsets when a transaction leaves from the window. We use two data structures, called Closed Table and Cid List, to maintain the information of closed itemsets over a data stream. The details of the structures are described as follows.

Closed Table consists of three fields: *Cid*, *CItemset* and *SC*. Each closed itemset (CItemset) X is assigned a unique closed itemset identifier (Cid) which is a non-zero positive integer, and its support count (SC) is also recorded in a Closed Table. Each record in a Closed Table is denoted as (c, X, SC(X)), where c, X and SC(X) are the values of Cid, CItemset and SC. Given a Cid c of an itemset, the itemset and its support count can be directly retrieved from the Closed Table. Initially, the first record in a Closed Table is set to (0, *null*, 0).

Cid List consists of two fields: *Item* and *Cidset* field. The Cidset for an item i_p is denoted as *cidset*(i_p) which is a set of Cids of closed itemsets containing item i_p. Table II and Table III show the Closed Table and Cid List after the five transactions in Figure 1 arrive to the first window. In Table III, cidset(B) = {2, 3}, since item B is contained in the two closed itemsets {AB} and {ABC}, and their Cids are 2 and 3, respectively.

TABLE II. ORIGINAL CLOSED TABLE

A. *CloStream*$^+$

In this subsection, we describe the procedure *CloStream*$^+$. Let t_A be a new transaction, D_B be the set of the transactions in the current window, and $D_U = D_B \cup \{t_A\}$ be the set of the transactions in the next window after adding t_A. $SC_{DB}(X)$ and $SC_{DU}(X)$ are the support counts of the itemset X in D_B and D_U, respectively. $C_{DB}(X)$ and $C_{DU}(X)$ are the closures of X in D_B and D_U, respectively. The sets of all the closed itemsets in D_B and D_U are denoted as C_{DB} and C_{DU}, respectively.

When a transaction $t_A = \{i_1, i_2, ..., i_k\} (i_j \in I, 1 \leq j \leq k)$ arrives to D_B, we observe that the support count of t_A is increased by one

but the support count of t_A's supersets would not be increased. According to Property 3, t_A must be a closed itemset in D_U. Besides, only the supports of the subsets of t_A would be increased and thus only the subsets of t_A would be changed from non-closed to closed.

According to Theorem 1, the closed subsets of t_A in D_U can be obtained by performing intersection operations on t_A and all the closed itemsets in D_B. However, this process is very time-consuming, since the number of closed itemsets in D_B may be very large and there may be many closed itemsets without common items with t_A. In order to avoid performing a large number of invalid intersections, CloStream$^+$ uses a Cid List and a *SET function* to find those closed itemsets which at least have a common item with t_A, that is, the intersections of the closed itemsets and t_A are not empties.

The SET function is defined as follows: SET($\{t_A\}$) = cidset(i_1) $\cup$ ... $\cup$ cidset(i_k), where cidset(i_j) ($1 \leq j \leq k$) is the cidset for item i_j in Cid List. Each Cid in SET($\{t_A\}$) represents a closed itemset which has at least a common item with t_A. Therefore, a lot of intersection operations can be reduced, since CloStream$^+$ only performs intersection operations on t_A and those closed itemsets whose Cids are in SET($\{t_A\}$).

By performing intersection operations on t_A and every closed itemsets whose Cids are in SET($\{t_A\}$), we can obtain the closed subsets of t_A in D_U. In order to update the supports of the closed subsets of t_A in D_U, we can find their closures in D_B for each of them. The support counts of them in D_U are equal to the support counts of their closures in D_B increasing by one. CloStream$^+$ uses a temp table, which is denoted as $Temp_A$, to store the closed subsets of t_A and their closures in D_B when a transaction t_A is added. $Temp_A$ is a hash structure and consists of two fields: *UItemset* and *Closure_Id*. Each record in $Temp_A$ is denoted as (S, t), where S is a closed itemset which needs to be updated and t is the identifier of the closure of S. In the following, we describe the algorithm for CloStream$^+$ in details.

As t_A is added to the current window, t_A is closed in D_U and then we put t_A into $Temp_A$. Initially, the Closure_Id of t_A is set to 0. To obtain the closed itemsets which need to be updated, CloStream$^+$ performs intersection operations on t_A and each closed itemset whose Cid i is in SET($\{t_A\}$). Let an itemset whose Cid is i be denoted as CT[i]. For an itemset S = $t_A \cap$ CT[i] ($i \in$ SET($\{t_A\}$)), S is closed in D_U according to Theorem 1. If S is not in $Temp_A$, then S is put into Temp$_A$ and its current Closure_Id is i, since CT[i] is a superset of S and may be the closure of S. Otherwise, the current Closure_Id of S, say, t, is replaced with i if SC_{DB}(CT[i]) is greater than SC_{DB}(CT[t]). This is because CT[t] is not the closure of S and CT[i] may be the closure of S.

After performing intersection operations on t_A and each closed itemset whose Cid is in SET($\{t_A\}$), all closed itemsets which need to be updated and the Cids of their closures in D_B are stored in $Temp_A$. CloStream$^+$ uses the information in $Temp_A$ to update the Closed Table and Cid List. For each record (u, c) in Temp$_A$, if u equals to CT[c], then SC_{DU}(CT[c]) is increased by 1 since u is originally closed in D_B. Otherwise, u is a new closed itemset and assigned a unique Cid n.

TABLE IV. THE CLOSED TABLE AFTER AFTER ADDING t_6

Cid	CItemset	SC
0	null	0
1	{CD}	2
2	{AB}	3
3	{ABC}	2
4	{C}	5
5	{ACD}	1
6	{A}	4
7	{AC}	3
8	{BC}	3
9	{B}	4

TABLE V. THE CIDLIST AFTER ADDING t_6

Item	Cidset
A	{2, 3, 5, 6, 7}
B	{2, 3, 8, 9}
C	{1, 3, 4, 5, 7, 8}
D	{1, 5}

CloStream$^+$ adds a new record with Cid = n, CItemset = S, and SC_{DU} = (SC_{DB}(CT[c]) + 1) to the Closed Table. Besides, identifier n is also added into the cidsets for the items that contained in u in Cid List.

After dealing with all records in $Temp_A$, the information of all the closed itemsets in D_U are maintained in the Closed Table and Cid List, and the allocated memory space for $Temp_A$ can be released. All frequent closed itemsets can be obtained by scanning Closed Table once.

B. A Running Example for CloStream$^+$

After adding t_1, t_2, t_3, t_4 and t_5 into the first window in Figure 1, the Closed Table and Cid List are shown in Table II and III, respectively. As t_6 = {BC} arrives, ({BC}, 0) is put into $Temp_A$. Then CloStream$^+$ performs intersection operations on each closed itemset whose Cid is in SET({BC}) = {1, 2, 3, 4, 5, 7}. The intersection of t_6 and CT[1] = {CD} is {C}. Because {C} does not exist in $Temp_A$, the record ({C}, 1) is put into $Temp_A$. Next, the intersection of t_6 and CT[2] = {AB} is {B}. Because {BC} does not exist in $Temp_A$, the record ({BC}, 2) is also put into $Temp_A$. Next, the intersection of t_6 and CT[3] = {ABC} is {BC}. Since {BC} exists in $Temp_A$ along with its current Closure_Id 0, we compare SC_{DB}(CT[3]) with SC_{DB}(CT[0]). Because SC_{DB}(CT[3]) is greater than SC_{DB}(CT[0]), the Closure_Id of {BC} is replaced with 3. CloStream$^+$ uses the same way to deal with the other Cids which belong to SET({BC}). Finally, the content of $Temp_A$ is shown in Table VI, which includes all closed itemsets in t_6 after adding t_6 and the identifiers of their closures before adding t_6.

CloStream$^+$ uses $Temp_A$ to update Closed Table and Cid List. In $Temp_A$, the first record is ({BC}, 3), since {BC} is not equal to CT[3], CloStream$^+$ assigns 8 as a Cid for {BC} and SC_{DU}({BC}) = SC_{DB}(CT[3]) + 1. Cid 8 is then added into cidset(B) and cidset(C) respectively. The next record in $Temp_A$ is ({C}, 4). Because {C} equals to CT[4], which means that {C} is closed in the first window, the support count of CT[4]={C} is increased by 1. For the last record ({B}, 2), since {B} is not equal to CT[2], which means that {B} is a new closed itemset, CloStream$^+$ assigns 9 as a Cid for {B} and SC_{DU}({B}) = SC_{DB}(CT[2]) + 1.

TABLE VI. TEMP$_A$

UItemset	Closure_Id
{BC}	3
{C}	4
{B}	2

Besides, Cid 9 is added into the cidset(B). Finally, the updated Closed Table and Cid List are shown in Table IV and Table V, respectively.

C. CloStream⁻

In this subsection, we describe the procedure *CloStream*⁻. Let t_D be the oldest transaction in the current window W, D_B be the original set of transactions, and $D_D = D_B - \{t_D\}$ be the set of the transactions after deleting t_A from D_B. $SC_{DB}(X)$ and $SC_{DU}(X)$ are the support counts for the itemset X in D_B and D_D, respectively. The closures of X in D_B and D_D are denoted as $C_{DB}(X)$ and $C_{DD}(X)$, respectively. The sets of closed itemsets in D_B and D_D are denoted as C_{DB} and C_{DD}, respectively.

Whenever a transaction $t_D = \{i_1, i_2, ..., i_k\}(i_j \in I,\ 1 \le j \le k)$ is deleted from the database D_B, only the support counts of the subsets of t_D will be decreased by one, that is, only the subsets of t_D may be changed from closed to non-closed. Therefore, CloStream⁻ first find out the closed subsets of t_D in D_B and then determine which closed subsets of t_D will turn out to be non-closed. The closed subsets of t_D in D_B can be obtained by performing intersection operations on t_D and all the closed itemsets in C_{DB} according to Theorem 1.

However, it is very time-consuming to perform a large number of intersections, since there is a large number of closed itemsets in D_B. In order to avoid performing a lot of invalid intersections, CloStream⁻ also uses Cid List and computes the SET function to obtain the closed itemsets which have at least a common item with t_D.

CloStream⁻ uses a temp table, called $Temp_D$, to store the information about closed subsets of t_D in D_B, which consists of a triple: *DItemset*, *Closure_Id* and *HS*. Suppose that each record in $Temp_D$ is denoted as (S, c, h), in which S is a closed subsets of t_D, c is an identifier of the closure of S in D_B, and h is the identifier of a closed superset of S, which is not contained in t_D and whose support is the largest among the supports of all the supersets of S. HS is used to check if S is closed in D_D. If $SC_{DD}(S) = SC_{DD}(CT[h])$, then S is non-closed in D_D, since there is a superset CT[h] with the same support as S. For a closed superset Z of S ($Z \subset t_D$), $SC_{DD}(Z)$ must not be equal to $SC_{DD}(S)$, since the support counts of S and Z are decreased by one simultaneously after deleting t_D. In the following, we describe the algorithm for CloStream⁻ in details.

As t_D is deleted from the database, CloStream⁻ puts t_D into $Temp_D$ since t_D is a closed itemset in D_B. The Closure_Id and HS of t_D are set to zeros. To obtain the closed subsets of t_D in D_B, CloStream⁻ performs intersection operations on t_D and each closed itemset CT[i] whose cid i is in SET($\{t_D\}$). Suppose that $S = t_D \cap$ CT[i], then S is a closed subset in D_B according to Theorem 1. If S is not in $Temp_D$, then (S, i, *0*) is put into $Temp_D$, since CT[i] may be the closure of S. Otherwise, if S exists in $Temp_D$ with Closure_Id = c and HS = h, there are two cases need to be considered. Case 1: if $SC_{DB}(CT[i])$ is greater than $SC_{DB}(CT[c])$, then CT[i] may be the closure of S but CT[c] is not (Property 3). In this case, (S, c, h) is replaced with (S, i, c). Case 2: if $SC_{DB}(CT[i])$ is not greater than $SC_{DB}(CT[c])$ but greater than $SC_{DB}(CT[h])$, then (S, c, h) is replaced with (S, c, i). Otherwise, the record (S, c, i) remains unchanged.

After performing intersection operations on t_D and each closed itemset whose Cid is in SET($\{t_D\}$), each closed subset S of t_D which need to be updated and its closure c in D_B are stored in $Temp_D$. According to Definition 1, CT[c] = S. CloStream⁻ uses the identifier c to find S in Closed Table and decreases the support count of S by 1. After finding all the closed itemsets which need to be updated and updating their support counts, CloStream⁻ then determines which closed itemsets become non-closed.

For each record (S, c, h) in $Temp_D$, if $SC_{DD}(CT[c]) = SC_{DD}(CT[h])$, then S becomes non-closed in D_D since there is a superset CT[h] with the same support as S. CloStream⁻ removes the information of CT[c] from the Closed Table and Cid List. Notice that if $SC_{DD}(CT[c]) = 0$, the information of CT[c] is also be removed. After processing all the records in $Temp_D$, the information of the closed itemsets after deleting t_D is maintained in the updated Closed Table and Cid List, and the allocated memory space for $Temp_D$ can be released. By scanning Closed Table once, frequent closed itemsets and their supports in D_D can be obtained.

TABLE VII. THE CLOSED TABLE AFTER AFTER DELETING t_1

Cid	CItemset	SC
0	null	0
2	{AB}	3
3	{ABC}	2
4	{C}	4
5	{ACD}	1
6	{A}	4
7	{AC}	3
8	{BC}	3
9	{B}	4

TABLE VIII. THE CIDLIST AFTER DELETING t_1

Item	Cidset
A	{2, 3, 5, 6, 7}
B	{2, 3, 8, 9}
C	{3, 4, 5, 7, 8}
D	{5}

D. A Running Example for CloStream⁻

Suppose D_B is the set of the transactions after adding t_6 into Table I.The Closed Table and Cid List are shown in Table IV and Table V, respectively. When t_1 is deleted from D_B, t_1 is put into DItemset of $Temp_D$ since t_1 is a closed itemset in D_B. The values of Closure_Id and HS are set to zeros. In order to efficiently obtain all the closed subsets of t_1, CloStream⁻ performs intersection operations on t_1 = {CD} and each closed itemset whose cid is in SET({CD}) = {1, 3, 4, 5, 7, 9}.

The intersection of t_1 and CT[1] = {CD} is {CD}. We find that {CD} exists in $Temp_D$ with Closure_Id = 0 and HS = 0. The record ({CD}, 0, 0) is replaced with ({CD}, 1, 0) since $SC_{DB}(CT[1])$ is greater than $SC_{DB}(CT[0])$. Next, the intersection of t_1 and CT[3] = {ABC} is {C}. Since {C} does not exist in $Temp_D$, the record ({C}, 3, 0) is put into $Temp_D$.

The intersection of t_1 and CT[4] = {C} is {C}. We find that {C} exists in $Temp_D$ with Closure_Id = 3 and HS = 0. Because SC_{DB}(CT[4]) is greater than SC_{DB}(CT[3]), the Closure_Id of {C} is replaced with 4. Besides, the HS of {C} is replaced with 3, since C_{DB}(CT[3]) is greater than SC_{DB}(CT[0]). Therefore, the current Closure_Id and HS of {C} are 4 and 3, respectively.

The next Cid in SET({CD}) is 5. The intersection of t_1 and CT[5] = {ACD} is {CD}, and {CD} exists in $Temp_D$ with Closure_Id = 1 and HS = 0. Because SC_{DB}(CT[5]) is not greater than SC_{DB}(CT[1]) but greater than SC_{DB}(CT[0]), only the value of HS is updated as 5.

After performing intersection operations on t_1 and all the closed itemsets whose Cids are in SET({CD}), the content of $Temp_D$ is shown in Table IX. CloStream⁻ then decreases support counts of {CD}and {C} by one from Closed Table.

In Table IX, the first record is ({CD}, 1, 5). Since SC_{DD}(CT[1]) = SC_{DD}(CT[5]), CT[1] = {CD} turns out to be non-closed after deleting t_1. For the second record ({C}, 4, 7), CT[4] = {C} is still closed in D_D, since SC_{DD}(CT[4]) ≠ SC_{DD}(CT[7]). After processing all the records in $Temp_D$, the updated Closed Table and Cid List are shown in Table VII and Table VIII. By scanning Closed Table once, all the frequent closed itemsets in D_D and their support counts can be obtained.

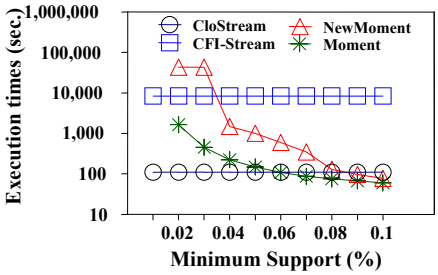
DItemset	Closure_Id	HS
{CD}	1	5
{C}	4	7

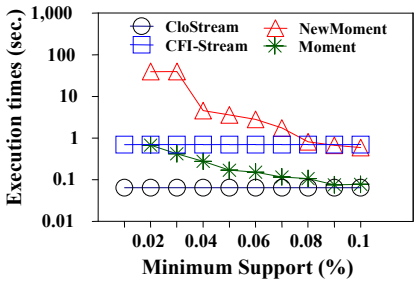
IV. EXPERIMENTAL RESULTS

In this section, we evaluate the performance of our CloStream algorithm and compare it with the three famous algorithms CFI-Stream, Moment and NewMoment. The experiments are performed on a 1.83 GHz Intel Core 2 Duo Processor with 2 Gigabyte memory, and running on Windows Vista. CloStream and CFI-Stream were coded in Java language. Moment [3] and NewMoment [7] are provided by their authors and coded in C++ language. To evaluate the performance of these algorithms, we generate a synthetic dataset T10I4D10100 from IBM data generator [1]. The parameters are described as follows: D is the total number of transactions; T is average transaction size; I is the average size of maximal potential frequent itemsets; N (=2000) is the number of distinct items. Besides, a real-world dataset BMS-Web-View-1 was downloaded from FIMI Repository [11], where I = 497, T = 2.5 and D = 59,602. The maximum length of the transactions in BMS-Web-View-1 is 267.

Fig. 2(a) shows the loading time of the first window for the four algorithms on the dataset T10I4D10100 under different minimum supports as the size of sliding window is set to 10K. From Fig. 2(a), we can see that the execution times for Moment and NewMoment increase as the minimum support decreases, since the lower the minimum support is, the larger the search space is for Moment and NewMoment. On the other hand, the execution times for CFI-Stream and CloStream are not affected by different minimum supports, since CFI-Stream and CloStream maintain all the closed itemsets in their structures. When *min_sup* is less than 0.06%, CloStream outperforms Moment and NewMoment, and the performance gap significantly increases as the minimum support decreases.



(a) Times for loading the first window



(b) Times for sliding 100 consecutive windows

Figure 2. Execution times on dataset T10I4D10100 for the four algorithms

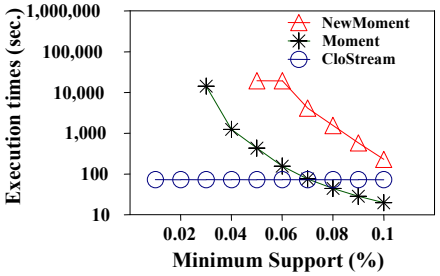
When *min_sup* is high, Moment and NewMoment run slightly faster than CloStream since they only generates frequent closed itemsets, but CloStream generates all the closed itemsets. In Fig. 2(a), CFI-Stream runs slower than CloStream about 100 times, since CFI-Stream needs to generate all the subsets (i. e., candidate closed itemsets) for each transaction and search all the supersets for each candidate from DIU Tree to check if the candidate is closed. In other words, a transaction of length k will lead CFI-Stream to generate (2^k - 1) candidates and search from DIU-Tree (2^k - 1) times. Therefore, CFI-Stream is unfavorable to deal with long transactions.

Fig. 2(b) shows the average execution times for the four algorithms after sliding 100 consecutive windows on the dataset T10I4D10100 under different minimum supports. From Fig. 2(b), we can see that CloStream runs faster than Moment and CFI-Stream about 10 times when *min_sup* = 0.02%, and outperforms NewMoment about 100 times when *min_sup* is less than 0.03%, since Moment, NewMoment and CFI-Stream need to search their structure to determine which itemsets are closed. However, whatever the transactions are added or deleted, our CloSream algorithm only needs to do some intersection operations without doing any searching operations on the previous closed itemsets.

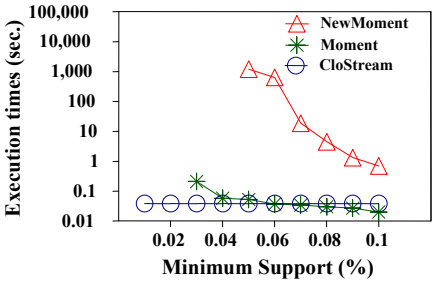
Fig. 3(a) shows the loading time of the first window for the algorithms Moment, NewMoment and CloStream on the real dataset BMS-Web-View-1 under different minimum supports as the size of sliding window is set to 10K. Since the maximum length of the transactions in this dataset is 267, CFI-Stream needs to enumerate (2^{267}-1) candidates and search from DIU Tree over 100 billion times. The performance for CFI-Stream is much worse than the three algorithms. Therefore, we only

compare the performance of our CloStream with Moment and NewMoment on this dataset. From Fig. 3(a), we can see that CloStream runs faster than Moment and NewMoment over 100 times when *min_sup* is less than 0.03% and 0.06%, respectively. Particularly, when *min_sup* is less than 0.03%, Moment runs out of memory, since it not only captures lots of non-closed nodes in CET-Tree but also maintains all frequent closed itemsets in CET-Tree and hash table. Although NewMoment is able to run when *min_sup* is less than 0.05%, it requires more than 2.5 hours.

Fig. 3(b) shows the average execution times for the three algorithms over 100 consecutive windows on dataset BMS-Web-View-1 under different minimum supports. From Fig. 3(b), we can see that CloStream significantly outperforms NewMoment and runs faster than Moment when *min_sup* is less than 0.04%. Although NewMoment uses less memory space than Moment, it requires a long execution time. Particularly, when *min_sup* = 0.05%, the total execution time of NewMoment for sliding 100 consecutive windows is over (100 × 1,000) = 100,000 seconds, while CloStream only takes about (0.1 × 100) = 10 seconds under the same threshold.



(a) Times for loading the first window



(b) Times for sliding 100 consecutive windows

Figure 3. Execution times on the real-world dataset BMS-Web-View-1 for the three algorithms

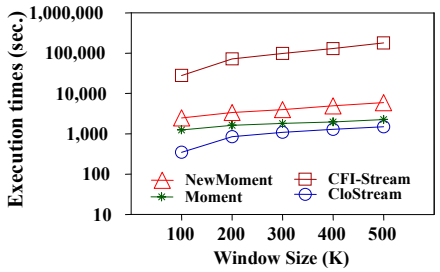


Figure 4. Scalability for the four algorithms under various sliding window sizes

Fig. 4 shows the execution times of the four algorithms for loading the first window under different sliding window sizes on dataset T5I4. In this experiment, the size of sliding window is increased from 100K to 500K and the minimum supports for Moment and NewMoment are set to 0.005%. From Fig 4 we can see that CloStream outperforms the other three algorithms and has a good scalability for large dataset.

V. CONCLUSIONS

In this paper, we propose a novel algorithm CloStream to discover frequent closed itemsets over stream sliding windows. We use Cid List and the SET function to find the closed itemsets which have the common items with the added or deleted transaction. Different from the previous approaches which need to take a lot of time to search from a tree structure, CloStream only needs to do the intersections on the closed itemsets which return from the SET function and the added or deleted transaction without searching from our proposed structures. Besides, all the frequent closed itemsets can be obtained online based on any user-specified thresholds. The experimental results also show that our CloStream algorithm outperforms the three famous algorithms CFI-Stream, Moment and NewMoment on both synthetic datasets and real-world dataset.

***Abstract*—This paper proposes a differential evolution with local information for TSK-type neuro-fuzzy system optimization. The differential evolution with local information consider neighborhood between each individual to keep the diversity of population. An adaptive parameter tuning based on 1/5th rule is used to trade off between local search and global search. For structure learning algorithm, the on-line clustering algorithm is used for rule generation. The structure learning algorithm generates a new rule which compares the firing strength. Initially, there is no rule in neuro-fuzzy system model. The rules are automatically generated by fuzzy measure. For parameter learning, the parameters are optimized by differential evolution algorithm. Finally, the proposed neuro-fuzzy system with novel differential evolution model is applied in chaotic sequence prediction problem. Results of this paper demonstrate the effectiveness of the proposed model.**

Keywords- Evolution Algorithm; Neuro-Fuzzy System; Fuzzy System; Differential Evolution Optimization.

I. INTRODUCTION

To train the parameters in designing a neuro-fuzzy system (NFS), many papers had used Backpropagation (BP). The BP is a powerful training technique that can be applied to networks with a forward structure. Since the steepest descent approach is used in BP training to minimize the error function, the algorithms may reach the local minima very quickly and never find the global solution. The aforementioned disadvantages lead to suboptimal performance, even with a favorable neural fuzzy network topology. One major optimization category as evolutionary algorithm (EA) [1-3] for global solution in NFS has been proposed. These algorithms are heuristic and stochastic. They involve populations of individuals with a specific behavior similar to a biological phenomenon, like crossover or mutation. Genetic NFS [4-7] is a well-known case which design FSs using genetic algorithms (GAs).

Another evolutionary algorithms category for FS design, called particle swarm optimization (PSO), appears to be better than the backpropagation algorithm. It is an evolutionary computation technique that was developed by Kennedy and Eberhart in 1995 [8]. The underlying motivation for the development of PSO algorithm is the social behavior of animals, such as bird flocking, fish schooling and swarm theory. PSO has been successfully applied to many optimization problems, such as feedforward neural network design [9-11] in control problems, with improved performance over GAs.

A differential evolution algorithm (DE), similar to GA, has emerged as a robust numerical optimization algorithm and has been successfully applied to solve various difficult optimization problems [12-14]. The basic strategy employs the difference of two randomly selected individuals as the source of random variations for a third individual. In [15-16], the researcher has proposed a modified differential evolution (MODE) for an adaptive neural fuzzy network (ANFN-MODE). This MODE provides a cluster-based mutation scheme to prevent the algorithm from being trapped in local optima of the search space. However, a DE that lacks the diversity and adaptive parameter tuning is often to affect the proformace[14].

This study proposes DE using local information (DELI) for TSK-type NFS optimization. The DELI consider neighborhood between each individual to keep the diversity of population. An adaptive parameter tuning based on 1/5th rule is used to tradeoff between local search and global search. An online learning algorithm, consisting of structure learning and parameter learning, is proposed to construct the NFS automatically. The structure learning algorithm generates a new rule which compares the fire strength. Initially, there is no rule in NFS model. The rules are automatically generated by fuzzy measure. The parameter learning algorithm is based on DELI to tune the free parameters in the NFS. To investigate the effectiveness of the proposed NFS-DELI, it is applied to dynamic system identification. The proposed NFS-DE model shows effectiveness results in simulations**.**

This paper is organized as follows. Section II describes the basic structure and function for NFS. Section III introduces the rule generation and parameter optimization algorithm in DELI. Section IV presents NFS design results of DELI and its performance comparisons with other evolutionary algorithms. Finally, Section V draws conclusions.

II. THE STRUCTURE OF NFS

A four-layered NFS is shown in Fig. 1, which is comprised of the input, membership function, rule, and output layers. The signal propagation and the basic functions in each layer are described as follows.

Layer 1—Input layer: No computation is done in this layer. Each node in this layer, which corresponds to one input

variable, only transmits input values to the next layer directly. That is

$$O^{(1)} = z_i . \tag{1}$$

Where i =1,2…*n* are the input variables of the NFS.

Layer 2—Membership function layer: Each node in this layer is a membership function that corresponds one linguistic label of one of the input variables in Layer 1. In other words, the membership value which specifies the degree to which an input value belongs to a fuzzy set is calculated in Layer 2

$$O^{(2)} = \mu_{ij} = \exp\left({-(z_i - m_{ij})^2} \Big/ {\sigma_{ij}^2} \right). \tag{2}$$

Where i =1,2…*n,* j=1,2…M, m_{ij} and σ_{ij} are respectively, the center (or mean) and the width (or variance) of the Gaussian membership function of input variable. M is number of rules.

Layer 3—Rule layer: A node in this layer represents a fuzzy logic rule and performs precondition matching of a rule. Here, we use the AND operation for each Layer 2 node

$$O^{(3)} = R_j = \prod_{i=1}^{n} \mu_{ij} . \tag{3}$$

The output of a layer 3 node represents the firing strength of the corresponding fuzzy rule.

Layer 4—Output layer: Each node in this layer corresponds to one output variable. The node integrates all of the actions recommended by layers 4 and acts as a defuzzifier with

$$O^{(4)} = y = \frac{\sum_{j=1}^{M} R_j \left(\sum_{i=1}^{l} s_{ij} z_i + s_{0j} \right)}{\sum_{j=1}^{M} R_j} . \tag{4}$$

In this paper, the consequent part use a TSK type which linear combination of TSK parameters S_{ij} and input variables.

III. Learning Algorithms of the NFS

This section describes the basic concepts of two types of learning algorithm. Section III-A describes the rule generation based on-line clustering algorithm for structure learning. Section III-B describes the DELI algorithm for parameter optimization.

A. Using on-line clustering algorithm for rule generation

The first task in structure learning is to decide when to generate a new rule. In many study, an on-line cluster algorithm is used to neuro-fuzzy system for generating fuzzy rule [2-5]. Fig.2. shows a detailed flow chart for this online procedure. Initially, there is no rule in NFS. For first incoming data, NFS generates a first fuzzy rule. The mean of membership function set the value of first incoming data, the variance of membership function set initial value. The weights set value randomly between the ranges. After first incoming data, the firing strength is calculated by Layer 3. A maximum firing strength in Layer 3 has to compare with a threshold which pre-specified threshold between 0 and 1. If the maximum firing strength is smaller than threshold, then a new rule is generated. Next step is to assign the value of mean, variance, and weights for the new rule. Repeating the above process for every incoming piece of training data generates new rules, until the iteration is termination.

B. Differential evolution with local information (DELI)

The DELI learning algorithm consists of three major phases: the initialization phase, the DE operator phase, and the parameter tuning phase.

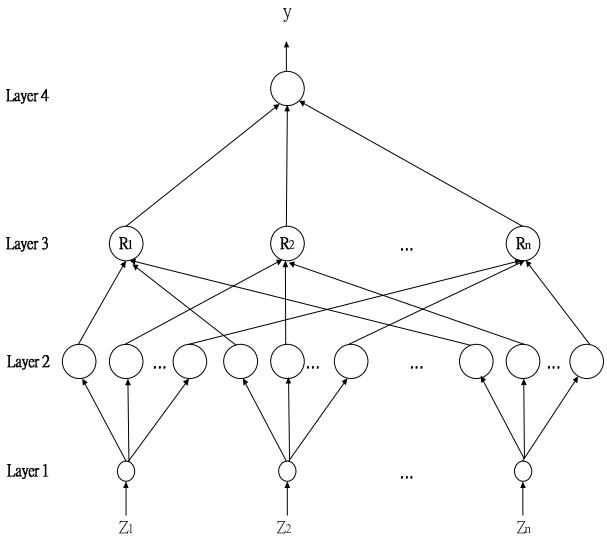

Fig. 1. Architecture of the NFS.

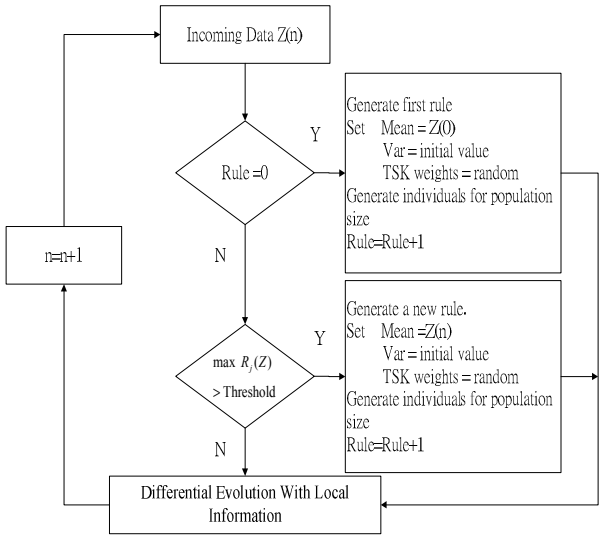

Fig. 2. The flow chart for on-line procedure.

In the initialization phase, every individual is consisted of mean, variance, and TSK weights. An individual is a neuro-fuzzy system in this paper. The detailed individual structure is shown in Fig.2. Before the DELI learning algorithm is applied, every individual must be created randomly. For evaluation of

performance, we adopt a fitness function to evaluate the performance of each individual as follows:

$$fitness = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(y_i - \bar{y}_i)^2}\ , \tag{5}$$

where y_i represents the model output of the ith data, $\bar{y}_i$ the desired output of the ith data, and N the number of the training data.

For DE operator phase, first operation is mutation operator. A mutated individual is generated according to the following equation:

$$\begin{aligned} v_g = &(1-\alpha)(x_1 + (1-F)(x_2 - x_3) + F(x_{local} - x_1)) \\ &+ \alpha(x_1 + (1-F)(x_2 - x_3) + F(x_{gbest} - x_1)) \end{aligned}, \tag{6}$$

where F, commonly known as the scaling factor, α is a control factor, x_{gbest} is the best fitness value up to now in the population and x_{local} is the local best fitness value that consider the neighborhood of individual. Three individuals (x_1, x_2, and x_3) are randomly selected in population for operation.

Second operation is crossover operator which mutated individual v_i and random individual x_i generate the offspring. If a random number smaller than crossover probability, the mutated individual v_i is selected for the element of offspring. Else, random individual x_i is selected. Finally, better individuals based on fitness function values are reserved to the next generation.

To prevent the DE from being trapped in the local optima of the search space, an adaptive parameter tuning is used in this paper. This scheme uses 1/5th rule to increase the search capability. The basic concept of 1/5th rule is derived from the Evolution Strategies [17-18]. The short description of the 1/5th rule is present in Figure 3.

1. perform the DELI for a number G of generations:
   - keep F constant during this period.
   - count the number N of better Gbest during this period.

2. determine an estimate of success probability P

   P = N/G

3. change F according to

$$F = \begin{cases} F/\beta & \text{if P>1/5} \\ F\cdot\beta & \text{if P<1/5} \\ F & \text{if P>1/5} \end{cases} \quad ,0 < \beta < 1$$

Fig. 3. The 1/5th code in DELI.

IV. Simulation Results

The time-series prediction problem used in this example is the chaotic Mackey–Glass time series, which is generated from the following differential equation:

$$\frac{dx(t)}{dt} = \frac{0.2x(t-\tau)}{1+x^{10}(t-\tau)} - 0.1x(t) \tag{7}$$

where τ > 17. In this paper, the parameter τ = 30, and x(0) = 1.2. Four past values are used to predict x(t), and the input–output data format is given by

$$[x(t-24), x(t-18), x(t-12), x(t-6) \mid x(t)]$$

A total of 1000 patterns are generated from t = 124 to 1123, where the first 500 patterns are used to train, and the last 500 are used to test. A total of 50 runs are performed for statistical analysis. As in the previous study [11], a first-order TSK-type FS is used. In DELI, the threshold μth is set to 0.011 α is set to 0.4, β is set to 0.9. Fig. 4 shows the average best-so-far training RMSE for each evaluation. DELI have better fitness value and learning capability. Table 1 shows the average training and test RMSEs over 50 runs. Comparison of GA, PSO , DE , MODE[15] , HGAPSO[11], DELI, the proposed DELI have a good performance. Fig. 5 shows the desired output (blue line) and actual output (red line) of DELI.

The result shows the best prediction output of DELI.

V. Conclusions

This paper proposed a DELI for dynamic system identification. The DELI is simple evolution algorithm with neighborhood information, and keeps the diversity in population. DELI with 1/5th rule parameter tuning scheme tradeoff between local search and global search during evolution to effectively find a good solution for parameter optimization. An online cluster algorithm is used for rule generation. The experimental results demonstrate that the DELI obtains a smaller RMSE value than other algorithm for dynamic system identification.

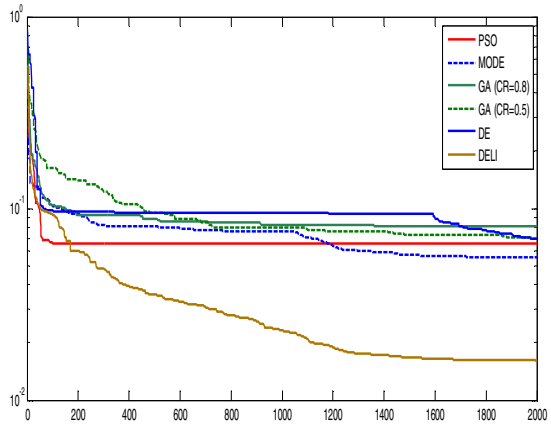

Fig. 4. Training RMSEs at each performance evaluation for DELI and other algorithms.

Table1. Performance of the DELI and other algorithms for the chaotic sequence prediction problem.

	GA	PSO	DE	HGAPSO[11]	MODE[15]	DELI
Rule number	4	4	4	4	4	4
Training RMSE	0.081	0.066	0.069	0.035	0.041	0.016
Testing RMSE	0.090	0.077	0.072	0.047	0.053	0.020

***Abstract*—This paper is concerned with exploring an extended approach for the stability analysis and synthesis for Markovian jump nonlinear systems (MJNLSs) with incomplete transition descriptions via fuzzy control. In this paper, not all the elements of the rate transition matrices (RTMs) are assumed to be known. By fully considering the properties of the RTMs and the convexity of the uncertain domains, sufficient criteria of stability and stabilization are obtained. The proposed stability conditions are much less conservative than most of the existing results and stabilization conditions with a mode-dependent fuzzy controller are derived for Markovian jump fuzzy systems (MJFSs) in terms of linear matrix inequalities (LMIs). Finally, illustrative numerical examples are provided to demonstrate the effectiveness of the proposed approach.**

***Index Terms*—Markovian fuzzy systems, partially known transition matrix, linear matrix inequality**

I. Introduction

Markovian jump nonlinear systems (MJNLSs) are a class of multi-modal systems in which the transitions among different modes are governed by a Markov chain. The studies of these systems are motivated by the powerful modeling capability of Markov chains in practical applications, and many useful results have been obtained, see [2]-[6] for instance. However, in most of the studies, complete knowledge of the mode transitions is required as a prerequisite for analysis and synthesis of MJNLSs. This means that the transition probabilities (TPs) of the underlying Markov chain are assumed to be completely known.

To relax the assumption that all the TPs are known, a new concept for Markovian jump linear systems (MJLSs) with partially unknown TPs was proposed in [17] and a series of studies have been carried out [18]-[20]. Meanwhile, as two extreme cases, the so-called switched systems under arbitrary switching [18]-[20] and the conventional Markov jump systems was covered in the framework. However, although the works laid a conceptual foundation for analysis and synthesis of MJLSs, the proposed approach still have room for improvement in terms of conservatism. In fact, the properties of the transition rate matrix (RTM) has not been fully used. And most of existing results are dedicated to the MJLSs, while few results are available for the control design of Markovian jump nonlinear systems (MJNLSs).

In this paper, a new approach will be explored for the analysis and synthesis of MJNLSs with incomplete description of their transitions via fuzzy control. The proposed systems are more general and because it includes the completely known or unknown transition probabilities. Using the properties that the sum of each row is zero in a RTM, together with the convexity of the uncertain domains, necessary and sufficient conditions for the stability analysis and stabilization synthesis problems are first derived. The stabilization condition is expressed in terms of linear matrix inequalities (LMIs), which can be solved efficiently via existing LMI-optimization techniques.

II. Problem Formulation and Preliminaries

Given the probability space $(\Omega, \mathbb{F}, \mathbb{P})$: and consider continuous-time and discrete-time MJLNS , which can be described by the following fuzzy models :

$$\begin{aligned} R_i\text{: IF } & z_1(t) \text{ is } \Gamma_{i1} \text{ and } \cdots \text{ and } z_p(t) \text{ is } \Gamma_{ip} \\ \text{THEN } & \dot{x}(t) = A_{0i}(\eta(t))x(t) + B_i(\eta(t))u(t) \end{aligned} \quad (1)$$

where $x(t) \in \mathbb{R}^n$ constitutes the state vector, $u(t) \in \mathbb{R}^m$ is the control input, $R_i, i \in \mathcal{I}_R = \{1, 2, \cdots, r\}$, denotes the ith fuzzy rule, $z_h(t), h \in \mathcal{I}_P = \{1, 2, \cdots, p\}$, is the hth premise variable, Γ_{ih}, $(i, h) \in \mathcal{I}_R \times \mathcal{I}_P$, is the fuzzy set of $z_h(t)$ in R_i, the system matrices of the ith rule are denoted by $(A_{0i}, B_i$, which are assumed known and some constant matrices of compatible dimensions. The stochastic process $\{\eta(t), t \geq 0\}$(respectively, the Markovian chain $\eta(k), k \geq 0$), taking values in a finite space state denoted by $\mathbb{T} = \{1, 2, \cdots, \mathcal{N}\}$. The random form process $\eta(t)$ is a continuous-time has the following mode transition probabilities :

$$\mathbf{Pr}(\eta(t + \Delta t) = s | \eta(t) = l) = \begin{cases} \lambda_{ls}\delta + o(\Delta), s \neq l \\ 1 + \lambda_{ls}\delta + o(\Delta), s = l \end{cases}$$

where $\Delta > 0$, $\lim_{\Delta \to 0}(o(\Delta t)/\Delta t) = 0$ $(l, s \in \mathbb{T}, l \neq s)$ denotes the switching rate from mode l at time t to mode s at

time $t+\Delta t$, and $\lambda_{ll}=-\sum_{s=1,s\neq l}\lambda_{ls}$ for all $l\in\mathbb{T}$. Hence, the rate transition matrix (RTM) in the Markov process is given by

$$\Lambda=\begin{bmatrix}\lambda_{11} & \lambda_{12} & \cdots & \lambda_{1\mathcal{N}}\\ \lambda_{21} & \lambda_{22} & \cdots & \lambda_{2\mathcal{N}}\\ & & \ddots & \\ \lambda_{\mathcal{N}1} & \lambda_{\mathcal{N}2} & \cdots & \lambda_{\mathcal{N}\mathcal{N}}\end{bmatrix} \tag{2}$$

The set $\mathbb{T}$ contains $\mathcal{N}$ modes of system (1) for $\eta(t)=l\in\mathbb{T}$, the system matrices of the lth modes are denoted by $(A_{0i,l},B_{i,l})$, which are real known with appropriate dimensions.

In addition, the transition rates or probabilities of the Markov chain in this paper are considered to be partially known, namely, some elements in matrix Λ or 1 are time-invariant but unknown. We denote

$$\mathbb{T}_{\mathbb{K}}^{l}=\{s:\text{if }\lambda_{ls}\text{ is known}\} \tag{3}$$

$$\mathbb{T}_{\mathbb{UK}}^{l}=\{s:\text{if }\lambda_{ls}\text{ is unknown}\} \tag{4}$$

Moreover, if $\mathbb{T}_{\mathbb{K}}^{l}\neq 0$, it is described as

$$\mathbb{T}_{\mathbb{K}}^{l}=\left\{\mathbb{E}_{1}^{l},\cdots,\mathbb{E}_{m}^{l}\right\},\quad 1\leq m\leq\mathbb{N} \tag{5}$$

where $\mathbb{E}_{m}^{l}$ represents the mth element with the index $\mathbb{E}_{m}^{l}$ in the lth row of matrix Λ. In the continuous-time case, when λ_{ll} is unknown, it is necessary to provide a lower bound $\lambda_{d}^{(l)}$ for it and we have $\lambda_{d}^{(l)}<-\lambda_{\mathbb{E}}^{(l)}$. Let the mode at t be l. Using the center-average defuzzifer, product inference, and singleton fuzzifier, (1) is inferred as

$$\dot{x}(t)=\sum_{i=1}^{r}\theta_{i}(z(t))\left(A_{0i}\left(\eta(t)\right)x(t)+B_{i}(\eta(t))u(t)\right) \tag{6}$$

where $\theta_{i}(z(t))=w_{i}(z(t))/\sum_{i=1}^{r}w_{i}(z(t))$, $w_{i}(z(t))=\prod_{h=1}^{p}\mu_{\Gamma_{ih}}(z_{h}(t))$, and $\mu_{\Gamma_{ih}}(z_{h}(t))$: $U_{z_{h}}\subset\mathbb{R}\rightarrow\mathbb{R}_{[0,1]}$ is the membership function of $z_{h}(t)$ on the compact set $U_{z_{h}}$. Some basic properties are $\theta_{i}(z(t))\geq 0$ and $\sum_{i=1}^{r}\theta_{i}(z(t))=1$.

Throughout this paper, it is assumed that state $x(t)$ or $x(k)$ are available and the mode $\eta(t)$ or $\eta(k)$ are not available for feedback control. For each possible value of $\eta(t)=l$ or $\eta(k)=l,l\in\mathbb{T}$ in the succeeding discussion, for the convenience of notations, we will denote

$$A_{0i,l}(t)=\sum_{i=1}^{r}\theta_{i}(z(t))A_{0i}(\eta(t))$$

$$B_{i,l}(t)=\sum_{i=1}^{r}\theta_{i}(z(t))B_{i}(\eta(t))$$

In this paper, we will derive the stochastic stability criteria for system (1) when the transition rates or probabilities are partially known, and to determine the feedback gains $K_{j}(j\in\mathcal{I}_{r})$ such that the resulting closed-loop system is stochastically stable via the mode-independent fuzzy controller

$$\begin{aligned}R_{i}&\text{: IF }z_{1}(t)\text{ is }\Gamma_{i1}\text{ and }\cdots\text{ and }z_{p}(t)\text{ is }\Gamma_{ip}\\ &\text{THEN }u(t)=K_{j}(\eta(t))x(t),\quad j\in\mathcal{I}_{R}\end{aligned}$$

whose defuzzified output is given by

$$\begin{aligned}u(t)&=\sum_{j=1}^{r}\theta_{j}(z(t))K_{j}(\eta(t))x(t)\\ &=K_{j,l}(t)x(t)\end{aligned} \tag{7}$$

With the mode-independent fuzzy control law (7), the overall closed-loop MJFS when $\eta(t)=l$, $l\in\mathbb{T}$ can be written as

$$\dot{x}(t)=\left(A_{0i,l}\left(t\right)+B_{i,l}(t)K_{j,l}(t)\right)x(t) \tag{8}$$

Let $x(t,x_{0},\eta_{0})$ denote the trajectory of the state $x(t)$ from the initial state $x(0)=x_{0}$ and the initial mode $\eta(0)=\eta_{0}$.

III. Stability analysis and Stabilization

In this section, a stochastic stability condition for system (1) will be developed when the transition rates or probabilities are partially unknown, and a state feedback fuzzy controller will be designed for the MJFSs (8) such that the closed-loop systems are stochastically stable. First, we provide the following previous stability results for MJFSs when the transition rates or probabilities are partially unknown:

Lemma 1: System (1) is stochastically stable if and only if there exist matrices $Q_{l}=Q_{l}^{T}\succ 0$, $Q_{s}=Q_{s}^{T}\succ 0$, $l,s\in\mathbb{T}$ such that

$$A_{0i,l}^{T}(t)Q_{l}+Q_{l}A_{0i,l}(t)+\sum_{s=1}^{\mathbb{N}}\lambda_{ls}Q_{s}<0 \tag{9}$$

Let us first give the stability result for the unforced system ($u(t)\equiv 0$). The following theorem presents a necessary and sufficient condition on the stochastic stability of the considered system with partially known transition rates.

Theorem 1: Consider the unforced MJFS (1) with $u(k)=0$ and known transition probabilities. The corresponding system is stochastically stable if there exist matrices $P_{i,l}\succ 0$, $i\in\mathcal{I}_{r}$, $l,s\in\mathbb{T}$,

$$\begin{aligned}&A_{0i,l}^{T}P_{i,l}+P_{i,l}A_{0i,l}+\mathcal{P}_{\mathbb{K}}^{l}-\sum_{s\in\mathbb{T}_{\mathbb{K}}^{l}}\lambda_{ls}P_{i,s}<0\\ &\qquad\forall s\in\mathbb{T}_{\mathbb{UK}}^{l},\text{if }\ l\in\mathbb{T}_{\mathbb{K}}^{l}\end{aligned} \tag{10}$$

$$\begin{aligned}&A_{0i,l}^{T}P_{i,l}+P_{i,l}A_{0i,l}+\mathcal{P}_{\mathbb{K}}^{l}+\lambda_{d}^{l}P_{i,l}\\ &-\lambda_{d}^{s}P_{i,s}-\sum_{s\in\mathbb{T}_{\mathbb{K}}^{l}}\lambda_{ls}P_{i,s}<0\\ &\qquad\forall s\in\mathbb{T}_{\mathbb{UK}}^{l},\text{if }\ l\in\mathbb{T}_{\mathbb{UK}}^{l}\end{aligned} \tag{11}$$

where λ_{d}^{l} is a given lower bound for the unknown diagonal element.

Proof: We consider the proof into two cases, that is $l\in\mathbb{T}_{\mathbb{K}}^{l}$ and $l\in\mathbb{T}_{\mathbb{UK}}^{l}$.

1) Case I: $l\in\mathbb{T}_{\mathbb{K}}^{l}$ It should be noted that one has $\sum_{s\in\mathbb{T}_{\mathbb{K}}^{l}}\lambda_{ls}\leq 0$. Since $\sum_{s\in\mathbb{T}_{\mathbb{K}}^{l}}\lambda_{ls}=0$ measn the elements in the i^{th} row of the transition rates are known, we only need to consider $\sum_{s\in\mathbb{T}_{\mathbb{K}}^{l}}\lambda_{ls}<0$ here. Now we rewrite the left-hand side of (9) as

$$\begin{aligned}\Theta_l &= A_{0i,l}^T P_{i,l} + P_{i,l} A_{0i,l} + \mathcal{P}^l \\ &= A_{0i,l}^T P_{i,l} + P_{i,l} A_{0i,l} + \mathcal{P}_{\mathbb{K}}^l + \sum_{s\in\mathbb{T}_{\mathbb{UK}}^l} \hat{\lambda}_{ls} P_{i,s} \\ &= A_{0i,l}^T P_{i,l} + P_{i,l} A_{0i,l} + \mathcal{P}_{\mathbb{K}}^l - \lambda_{\mathbb{K}}^l \sum_{s\in\mathbb{T}_{\mathbb{UK}}^l} \frac{\hat{\lambda}_{ls}}{-\lambda_{\mathbb{K}}^l} P_{i,s}\end{aligned}$$

where $\mathcal{P}^l = \sum_{s=1}^{\mathcal{N}} \lambda_{ls} P_s$ and the elements $\hat{\lambda_{ls}}$, $s \in \mathbb{T}_{\mathbb{UK}}^l$ are unknown. Since we have $0 \leq \frac{\hat{\lambda}_{ls}}{-\lambda_{\mathbb{K}}^l} \leq 1$ and $\sum_{s\in\mathbb{T}_{\mathbb{UK}}^l} \frac{\hat{\lambda}_{ls}}{\lambda_{\mathbb{K}}^l} = 1$, we know that

$$\Theta_l = \sum_{s\in\mathbb{T}_{\mathbb{UK}}^l} \frac{\hat{\lambda}_{ls}}{-\lambda_{\mathbb{K}}^l} \left[A_{0i,l}^T P_{i,l} + P_{i,l} A_{0i,l} + \mathcal{P}_{\mathbb{K}}^l - \lambda_{\mathbb{K}}^l P_{i,s}\right]$$

Therefore, for $0 \leq \hat{\lambda}_{ls} \leq -\lambda_{\mathbb{K}}^l$, $\Theta_l < 0$ is equivalent to $A_{0i,l}^T P_{i,l} + P_{i,l} A_{0i,l} + \mathcal{P}_{\mathbb{K}}^l - \lambda_{\mathbb{K}}^l P_{i,s} < 0$, $\forall s \in \mathbb{T}_{\mathbb{UK}}^l$, which implies that, in the presence of unknown elements $\hat{\lambda}_{ls}$, the system stability is ensured if and only if (10) holds.

2) CaseII : $\hat{\lambda}_{ii}$ is unknown, $\hat{\lambda}_{\mathbb{K}}^l \geq 0$ and $\hat{\lambda}_{ll} \leq -\lambda_{\mathbb{K}}^l$. Also, we consider $\hat{\lambda}_{ll} < -\lambda_{\mathbb{K}}^l$ since if $\hat{\lambda}_{ll} = -\lambda_{\mathbb{K}}^l$, then the i_{th} row of the transition rates matrix is completely known. Now, the left-hand side of the stability condition in (9) can be rewritten as

$$\begin{aligned}\Theta_l &= A_{0i,l}^T P_{i,l} + P_{i,l} A_{0i,l} + \mathcal{P}^l \\ &= A_{0i,l}^T P_{i,l} + P_{i,l} A_{0i,l} + \mathcal{P}_{\mathbb{K}}^l + \hat{\lambda}_{ii} P_{i,l} + \sum_{s\in\mathbb{T}_{\mathbb{UK}}^l, s\neq l} \hat{\lambda}_{ls} P_{i,s} \\ &= A_{0i,l}^T P_{i,l} + P_{i,l} A_{0i,l} + \mathcal{P}_{\mathbb{K}}^l + \hat{\lambda}_{ii} P_{i,l} \\ &+ \left(-\hat{\lambda}_{ll} - \lambda_{\mathbb{K}}^l\right) \sum_{s\in\mathbb{T}_{\mathbb{UK}}^l, s\neq l} \frac{\hat{\lambda}_{ls}}{-\hat{\lambda}_{ll} - \lambda_{\mathbb{K}}^l} P_{i,s}\end{aligned}$$

Likewise, since we have $0 \leq \hat{\lambda}_{ls}/(-\hat{\lambda}_{ll} - \lambda_{\mathbb{K}}^l) \leq 1$ and $\sum_{s\in\mathbb{T}_{\mathbb{UK}}^l, s\neq l} \frac{\hat{\lambda}_{ls}}{(-\hat{\lambda}_{ll} - \lambda_{\mathbb{K}}^l)} = 1$, we know that

$$\begin{aligned}\Theta_l = \sum_{s\in\mathbb{T}_{\mathbb{UK}}^l, s\neq l} \frac{\hat{\lambda}_{ls}}{-\hat{\lambda}_{ll} - \lambda_{\mathbb{K}}^l} &\left[A_{0i,l}^T P_{i,l} + P_{i,l} A_{0i,l} + \mathcal{P}_{\mathbb{K}}^l \right. \\ &\left. + \hat{\lambda}_{ii} P_{i,l} - \hat{\lambda}_{ii} P_{i,s} - \lambda_{\mathbb{K}}^l P_{i,s}\right]\end{aligned}$$

which means that $\Theta_l \leq 0$ is equivalent to $\forall s \in \mathbb{T}_{\mathbb{UK}}^l$, $s \neq l$

$$A_{0i,l}^T P_{i,l} + P_{i,l} A_{0i,l} + \mathcal{P}_{\mathbb{K}}^l + \hat{\lambda}_{ii} P_{i,l} - \hat{\lambda}_{ii} P_{i,s} - \lambda_{\mathbb{K}}^l P_{i,s} \quad (12)$$

As $\hat{\lambda}_{ll}$ is lower bounded by λ_d^l, we have

$$\lambda_d^l \leq \hat{\lambda}_{ll} \leq -\lambda_{\mathbb{K}}^l$$

which implies that $\hat{\lambda}_{ll}$ may take any value between $[\lambda_d^l, -\lambda_{\mathbb{K}}^l + \epsilon]$ for some $\epsilon < 0$ arbitrarily small. Then $\hat{\lambda}_{ll}$ can be further written as a convex combination

$$\hat{\lambda}_{ll} = -\alpha\lambda_{\mathbb{K}}^l + \alpha\epsilon + (1-\alpha)\lambda_d^l$$

where α takes values arbitrarily in $[0, 1]$. Thus (12) holds if and only if $\forall s \in \mathbb{T}_{\mathbb{UK}}^l$, $s \neq l$

$$A_{0i,l}^T P_{i,l} + P_{i,l} A_{0i,l} + \mathcal{P}_{\mathbb{K}}^l - \lambda_{\mathbb{K}}^l P_{i,l} + \lambda_{\mathbb{K}}^l P_{i,s} - \lambda_{\mathbb{K}}^l P_{i,s} + \epsilon(P_{i,l} - P_{i,s}) \leq 0 \quad (13)$$

and

$$A_{0i,l}^T P_{i,l} + P_{i,l} A_{0i,l} + \mathcal{P}_{\mathbb{K}}^l + \lambda_d^l P_{i,l} - \lambda_d^l P_{i,s} - \lambda_{\mathbb{K}}^l P_{i,s} < 0 \quad (14)$$

simultaneously hold. Since ϵ is arbitrarily small, (13) holds if and only if

$$A_{0i,l}^T P_{i,l} + P_{i,l} A_{0i,l} + \mathcal{P}_{\mathbb{K}}^l - \lambda_{\mathbb{K}}^l P_{i,l} < 0 \quad (15)$$

which is the case in (14) when $s = l$, $s \in \mathbb{T}_{\mathbb{UK}}^l$. Hence (12) is equivalent to (11). Therefore, in the presence of unknown elements in the transition rates matrix, one can readily conclude that the system is stable if and only if (10) and (11) hold for $l \in \mathbb{T}_{\mathbb{K}}^l$ and $l \in \mathbb{T}_{\mathbb{UK}}^l$, respectively. ■

Now let us consider the stabilizing controller design in the presence of unknown elements in the transition rates matrix. The following theorem presents a sufficient criterion for the existence of a mode-dependent stabilizing controller of the form in (7).

Theorem 2: Consider the system (1) with partially known transition rates. If there exist matrices $X_{i,l} > 0$ and $Y_{i,l}$, $i, j \in \mathcal{T}_r$ $l \in \mathbb{T}$, Z and a positive scalar μ such that

$$\Upsilon_{ii,ls} < 0, \quad i \in \mathcal{I}_r, \forall s \in \mathbb{T}_{\mathbb{UK}}^l, \text{ if } l \in \mathbb{T}_{\mathbb{K}}^l \quad (16)$$

$$\frac{1}{r-1}\Upsilon_{ij,ls} + \frac{1}{2}\left(\Upsilon_{ij,ls} + \Upsilon_{ji,ls}\right) < 0 \quad (17)$$
$$i \neq j \in \mathcal{I}_r, \forall s \in \mathbb{T}_{\mathbb{UK}}^l, \text{ if } l \in \mathbb{T}_{\mathbb{K}}^l$$

$$\Xi_{ii,ls} < 0 \quad i \in \mathcal{I}_r, \forall s \in \mathbb{T}_{\mathbb{UK}}^l, \text{ if } l \in \mathbb{T}_{\mathbb{UK}}^l \quad (18)$$

$$\frac{1}{r-1}\Xi_{ii,ls} + \frac{1}{2}\left(\Xi_{ij,ls} + \Xi_{ji,ls}\right) < 0 \quad (19)$$
$$i \neq j \in \mathcal{I}_r, \forall s \in \mathbb{T}_{\mathbb{UK}}^l, \text{ if } l \in \mathbb{T}_{\mathbb{UK}}^l$$

where, $\Upsilon_{ij,ls}, \Xi_{ij,ls}$ are shown at the top of the next page,

$$\mathcal{X}_{\mathbb{K}}^l = \text{diag}\left[X_{\mathbb{K}_1}, \cdots, X_{\mathbb{K}_{m_l}}\right] \quad (20)$$

$$\mathcal{T}_{\mathbb{K}}^l = \left[\sqrt{-\lambda_{l\mathbb{K}_1}} X_{i,l}, \cdots, \sqrt{-\lambda_{l\mathbb{K}_{m_l}}} X_{i,l}\right] \quad (21)$$

and $\forall e \in \{1, 2, \cdots, m_l\}$, K_e is described in (7), $K_e \neq l$, then there exists a mode-dependent stabilizing controller of the form in (7) such that the closed-loop system is stochastically stable. Moreover, if the LMIs in (16)- (19) have solutions, a fuzzy controller gain is give by

$$K_j = Y_{j,l} Z^{-1} \quad (22)$$

Proof: Consider the system (1) with the control input (7) and replace $A_{0i,l}$ by $A_{0i,l} + B_{i,l}K_{j,l}$ in (10) and (11), respectively. Then if $l \in \mathbb{T}_{\mathbb{K}}^l$, performing a congruence transformation to (10) by $P_{i,l}^{-1}$, we can obtain

$$\begin{aligned}&\left(A_{0i,l} + B_{i,l}K_{j,l}\right) P_{i,l}^{-1} + P_{i,l}^{-1} \left(A_{0i,l} + B_{i,l}K_{j,l}\right)^T \\ &+ P_{i,l}^{-T} \mathcal{P}_{\mathbb{K}}^l P_{i,l}^{-1} - P_{i,l}^{-T} \left(\sum_{s\in\mathbb{T}_{\mathbb{K}}^l} \lambda_{ls} P_{i,s}\right) P_{i,l}^{-1}\end{aligned} \quad (25)$$

Setting $X_{i,l} = P_{i,l}^{-1}$, $Y_{i,l} = K_{j,l}Z$ and considering (21). Applying the lemma 3, one can obtain that (25), then the lth

$$\Upsilon_{ij,ls}=\begin{bmatrix} -Z-Z^T & Z^TA_{0i,l}^T+Y_{j,l}^TB_{i,l}^T+X_{i,l} & Z^T & 0 & 0 \\ * & -\mu^{-1}X_{i,l}+\pi_{ll}X_{i,l} & 0 & \mathcal{T}_{\mathbb{K}}^l & \sqrt{-\lambda_{\mathbb{K}}^l}X_{i,l} \\ * & * & -\mu X_{i,l} & 0 & 0 \\ * & * & * & -\mathcal{X}_{\mathbb{K}}^l & 0 \\ * & * & * & * & -X_{i,s} \end{bmatrix} \tag{23}$$

$$\Xi_{ij,ls}=\begin{bmatrix} -Z-Z^T & Z^TA_{0i,l}^T+Y_{j,l}^TB_{i,l}^T+X_{i,l} & Z^T & 0 & 0 \\ * & -\mu^{-1}X_{i,l}+\pi_{d}X_{i,l} & 0 & \mathcal{T}_{\mathbb{K}}^l & \sqrt{-\lambda_{d}^l-\lambda_{\mathbb{K}}^l}X_{i,l} \\ * & * & -\mu X_{i,l} & 0 & 0 \\ * & * & * & -\mathcal{X}_{\mathbb{K}}^l & 0 \\ * & * & * & * & -X_{i,s} \end{bmatrix} \tag{24}$$

inequality of (10) holds for some matrices $X_{i,l}=X_{i,l}^T>0$ if and only if there exist a scalar $\mu>0$ and a matrix Z such that (26), at the top of page.

By Schur complement, we can obtain that (26) is equivalent to (27). In a similar way, if $s\in\mathbb{T}_{\mathbb{UK}}^l$, (18) and (19) can be worked out from (11). (10)-(11) will be satisfied in Theorem 1 such that the closed-loop system (8) is stochastically stable. Meanwhile, due to $Y_{i,l}=K_{j,l}Z$, the desire controller gain is given by (22). ■

IV. SIMULATIONS

In this section, we present an numerical example to demonstrate the effectiveness of the proposed results. Consider a single-link robot arm in, in which the dynamic equation is given by

$$\ddot{\theta}(t)=-\frac{MgL}{J}\sin(\theta(t))-\frac{D(t)}{J}\dot{\theta}(t)+\frac{1}{J}u(t) \tag{28}$$

where $\theta(t)$ is the angle position of the arm, and $u(t)$ is the control input. M is the mass of the payload. J is the moment of inertia, g is the acceleration of gravity, L is the length of the arm, and $d(t)$ is the coefficient of viscous friction. The values of parameters g and L are given by $g=9.81$ and $L=0.5$. It is assumed that the parameter $D(t)=D=2$ is time invariant, and the parameters M and J have four different modes at shown in Table 1. Let $x_1(t)=\theta(t)$ and $x_2(t)=\dot{\theta}(t)$. Under the condition $-179.4270<\theta(t)<179.4270$, the nonlinear term $\sin(\theta(t))$ can be exactly represented as

$$\sin(\theta(t))=h_1(x_1(t))\cdot x_1(t)+h_2(t)(x_1(t))\cdot\beta\cdot x_1(t) \tag{29}$$

with $\beta=10^{-2}/\pi$, where $h_1(x_1(t))$, $h_2(x_1(t))\in[0,1]$, and $h_1(x_1(t))+h_2(x_1(t))=1$. By solving the equations, the membership functions $h_1(x_1(t))$ and $h_2(x_1(t))$ are obtained as follows:

$$h_1(x_1(t))=\begin{cases}\frac{\sin(x_1(t))-\beta\cdot x_1(t)}{x_1(t)\cdot(1-\beta)}, x_1(t)\neq 0\\ 1, x_1(t)=0.\end{cases} \tag{30}$$

$$h_2(x_1(t))=\begin{cases}\frac{x_1(t)-\sin(x_1(t))}{x_1(t)\cdot(1-\beta)}, x_1(t)\neq 0\\ 0, x_1(t)=0.\end{cases} \tag{31}$$

It can be seen from the above equations that $h_1(x_1(t))=1$ and $h_2(x_1(t))=0$, when $x_1(t)$ is about 0 rad, and $h_1(x_1(t))=0$ and $h_2(x_1(t))=1$, when $x_1(t)$ is about π rad or $-\pi$ rad. Then the nonlinear Markovian system (28) can be represented by the following T–S fuzzy model:

Plant Rule 1 :
IF $x_1(t)$ is "about 0 rad," THEN
$\dot{x}(t)=A_{1,l}x(t)+B_{1,l}u(t)$
Plant Rule 2 :
IF $x_1(t)$ is "about π rad or $-\pi$ rad," THEN
$\dot{x}(t)=A_{2,l}x(t)+B_{2,l}u(t)$

where

$$x(t)=\begin{bmatrix}x_1(t)\\x_2(t)\end{bmatrix}, A_{1,1}=\begin{bmatrix}0 & 1\\ -gl & -D\end{bmatrix},$$
$$A_{1,2}=\begin{bmatrix}0 & 1\\ -gL & -0.8D\end{bmatrix}, A_{1,3}=\begin{bmatrix}0 & 1\\ -gL & -0.5D\end{bmatrix},$$
$$A_{1,4}=\begin{bmatrix}0 & 1\\ -gL & -0.4D\end{bmatrix}, A_{2,1}=\begin{bmatrix}0 & 1\\ -\beta gL & -D\end{bmatrix}$$
$$A_{2,2}=\begin{bmatrix}0 & 1\\ -\beta gL & -0.8D\end{bmatrix}, A_{2,3}=\begin{bmatrix}0 & 1\\ -\beta gL & -0.5D\end{bmatrix},$$
$$A_{2,4}=\begin{bmatrix}0 & 1\\ -\beta gL & -0.4D\end{bmatrix},$$
$$B_{1,1}=B_{2,1}=\begin{bmatrix}0\\1\end{bmatrix}, B_{1,2}=B_{2,2}=\begin{bmatrix}0\\0.8\end{bmatrix}$$
$$B_{1,3}=B_{2,3}=\begin{bmatrix}0\\0.5\end{bmatrix} B_{1,4}=B_{2,4}=\begin{bmatrix}0\\0.4\end{bmatrix}$$

TABLE I
MODES OF THE PARAMETERS M, AND J

Mode l	M	J
1	1	1
2	1.25	1.25
3	2	2
4	2.5	2.5

The two cases for the transition rates matrix are considered in Table 2. The proposed theorem 2 is to design a mode-independent fuzzy controller such that the closed-loop system is stochastically stable with partially unknown transition

$$\begin{bmatrix} -Z-Z^T & Z^T\left(A_{0i,l}+B_{i,l}K_{j,l}\right)^T+X_{i,l} & Z^T \\ * & -\mu^{-1}X_{i,l}+X_{i,l}^T\mathcal{P}_{\mathbb{K}}^l X_{i,l}-X_{i,l}^T\left(\sum_{s\in\mathbb{T}_{\mathbb{K}}^l}\lambda_{ls}P_{i,s}\right)X_{i,l} & 0 \\ * & * & -\mu X_{i,l} \end{bmatrix}<0 \tag{26}$$

$$\Upsilon_{ij,ls}=\begin{bmatrix} -Z-Z^T & Z^TA_{0i,l}^T+Y_{j,l}^TB_{i,l}^T+X_{i,l} & Z^T & 0 & 0 \\ * & -\mu^{-1}X_{i,l}+\pi_{ll}X_{i,l} & 0 & \mathcal{T}_{\mathbb{K}}^l & \sqrt{-\lambda_{\mathbb{K}}^l}X_{i,l} \\ * & * & -\mu X_{i,l} & 0 & 0 \\ * & * & * & -\mathcal{X}_{\mathbb{K}}^l & 0 \\ * & * & * & * & -X_{i,s} \end{bmatrix}<0 \tag{27}$$

probabilities. With the choice of $\mu = 0.2$, we can obtain the following controller gain matrices by solving (16)-(19) in Theorem 2:

Case I

$$K_{1,1}=\begin{bmatrix}-4.7256\\-6.2890\end{bmatrix}^T, K_{1,2}=\begin{bmatrix}-4.8434\\-6.1849\end{bmatrix}^T$$
$$K_{2,1}=\begin{bmatrix}-7.1346\\-93.1655\end{bmatrix}^T, K_{2,2}=\begin{bmatrix}-7.1646\\-8.8974\end{bmatrix}^T$$
$$K_{3,1}=\begin{bmatrix}-5.4878\\-10.0789\end{bmatrix}^T, K_{3,2}=\begin{bmatrix}-5.4967\\-10.1987\end{bmatrix}^T$$
$$K_{4,1}=\begin{bmatrix}-7.1648\\-13.1846\end{bmatrix}^T, K_{4,2}=\begin{bmatrix}-7.1649\\-14.7868\end{bmatrix}^T$$

Case II

$$K_{1,1}=\begin{bmatrix}-3.1648\\-5.1464\end{bmatrix}^T, K_{1,2}=\begin{bmatrix}-3.1684\\-6.1879\end{bmatrix}^T$$
$$K_{2,1}=\begin{bmatrix}-0.7978\\-2.4798\end{bmatrix}^T, K_{2,2}=\begin{bmatrix}-0.4798\\-2.4987\end{bmatrix}^T$$
$$K_{3,1}=\begin{bmatrix}-14.1654\\-19.7934\end{bmatrix}^T, K_{3,2}=\begin{bmatrix}-14.4684\\-21.4987\end{bmatrix}^T$$
$$K_{4,1}=\begin{bmatrix}-6.7913\\-13.2890\end{bmatrix}^T, K_{4,2}=\begin{bmatrix}-5.8434\\-13.1201\end{bmatrix}^T$$

Figures 1-2 show the result of the changing between modes during the simulation with the initial mode at mode 1. Applying the fuzzy controller (7) with the above gain matrices, the state response and control inputs of the closed-loop system are shown in figures under given initial condition

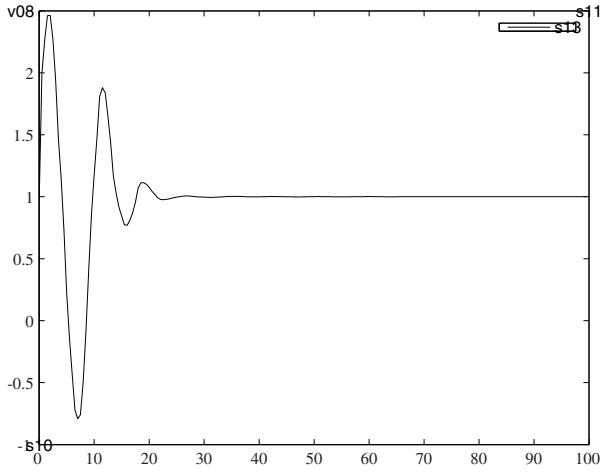

Fig. 1. The trajectories of states x_1

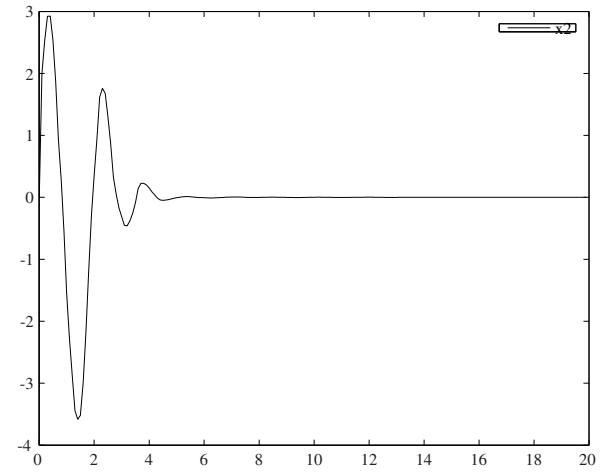

Fig. 2. The trajectories of states x_2

$x_0 = [0.5\pi, -2]^T$. It is seen from the curves in Figures 1-2 that, despite the partially unknown transition rates, the designed controllers stabilize the system (28) effectively.

V. Conclusion

In this paper, we have revisited the analysis and synthesis problems of Markov jump nonlinear system with incomplete transition descriptions via fuzzy control. Necessary and sufficient criteria are obtained for MJFSs by fully exploiting the properties of the transition rates matrix and the transition probabilities matrix. The conservatism of the approach developed previously, which only leads to sufficient conditions for the system, is reduced by the newly developed approach. The proposed stabilization conditions with a mode-dependent fuzzy controller are derived for Markovian jump fuzzy systems in terms of LMIs, which can be solved readily by using existing LMI optimization techniques. Finally, numerical examples have verified the theoretical results given in the paper.

Abstract— **This paper describes a testicular tubules evaluation using 1.0MHz ultrasonic array probe. In this system, we evaluate a diameter of testicular tubules. We employ an ultrasonic array probe with the center frequency of 1.0MHz. We employ evaluation index that cumulative relative frequency of amplitude values. In the experiment, we employ 24 nylon lines as the testicular tubules. Amplitude of large nylon line echo is larger than that of small nylon echo. For the evaluation, we calculate cumulative relative frequency amplitude of acquisition data. Fuzzy if-then rules are made by the cumulative relative frequency of large and small lines. We evaluate a rate of large lines among all lines by using the fuzzy MIN-MAX center-of-gravity method. In this experiment, the proposed method successfully evaluated the rate of the large lines. We changed the rate of large lines in 24 nylon lines, and tested our method 20 times for each rate. We evaluated the rate with 5.77 % in mean absolute error.**

Keywords-medical system; ultrasonic; cumulative relative frequency; azoospermia; testicular tubule.

I. INTRODUCTION

Azoospermia is the term used when there is a complete absence of sperm in the ejaculate. Fifteen-20% of infertile men turn out to be azoospermia. Azoospermia is caused by two problems; a production problem which is called non-obstructive azoospermia (NOA) and a deliver problem which is called obstructive azoospermia (OA). The development of intracytoplasmic sperm injection (ICSI) opened a new era in the field of assisted reproduction and revolutionized the assisted reproductive technique protocols of couples with male factor infertility [1]. Fertilization and pregnancies can be obtained with spermatozoa recovered not only from the ejaculate, but seminiferous tubules.

The ideal technique of sperm extraction from testicle for NOA would be minimally invasive and avoid destruction of testicular function without compromising the chance of retrieval adequate numbers of spermatozoa to perform ISCI. Schlegel et al. have successfully developed the techniques with the assistance of an operating microscope as Micro-TESE [2]. The testicle can be inspected for the presence of a spermatogenically active region of normal seminiferous tubules (Diameter: 0.250mm~0.300mm), which containing many developing germ cells. Those tubules are usually larger and more opaque than tubules without sperm production, and therefore easily distinguishable from sclerotic tubules that are much smaller in diameter (Diameter: <0.150mm). In almost all patients in whom micro-TESE was successful we could identify focal spermatogenesis in dilated and opaque seminiferous tubules surrounded by shrunken tubules or fibrous tissue [3], [4].

The determination of factors that can predict successful sperm retrieval (SR) procedure can offer realistic expectations for both the couple and the physician because SR rate is at most 50% even after the introduction of micro-TESE. Additionally, the operation is high cost and physically large burden for patients. Retrospectively, we examined the differences between SR success and failure group in FSH, LH, testosterone, testicular volume and age. So far, no one could foretell about the presence of a spermatogenic focus inside an NOA testis. Therefore, we request the system that noninvasive measures the tubules heterogeneity in the testicle before micro-TESE procedure [5], [6].

In our study, we propose a testicular tubule evaluation system with a 1.0MHz ultrasonic array probe. We can noninvasively evaluate it by the ultrasonic array probe. We employ two different diameter nylon fishing lines as a small tubule and large tubule. We calculate the cumulative relative frequency of amplitude values. From the difference of the frequency of amplitude values, we derive fuzzy IF-THEN rules and make a fuzzy MIN-MAX center-of-gravity method. We then evaluate the rate of large line among all lines by the method. In our experimental results, mean absolute error was 5.77 %.

II. PRELIMINARIES

In this section, we describe the ultrasonic array probe and the experimental system used here. Fig. 1 shows the system of our ultrasonic array probe (ISL Inc., ISL1938). It consists of 32 elements in line. Center frequency of the array probe is 1.0 MHz, and each element interval is 1.5 mm. As shown in Fig. 1, a combination ultrasonic is generated by applying a voltage to several elements. The applied voltage shifts for 1 element distance [7].

Figure 1. The system of 1.0MHz ultrasonic array probe.

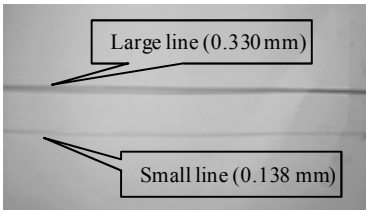

Figure 2. Large fishing line and small fishing line.

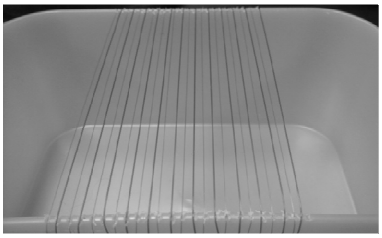

Figure 3. Object that line up 24 fishing line.

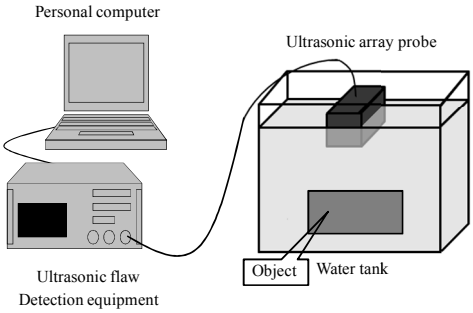

Figure 4. Ultrasonic data acquisition system.

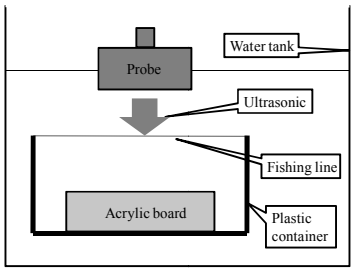
In our experiment, we employ two different diameter nylon fishing lines as shown in Fig. 2, we employ these lines as the object. The diameter of small line is 0.138 mm and that of large line is 0.330 mm. Here, it is noted that testicular larger diameter ranged fro m 0.25 to 0.30 mm and smaller one is 0.15 mm. Fig. 3 shows the phantom of it. It line up 24 fishing lines in parallelism. The ultrasonic data acquisition system is shown in Fig. 4. Fig. 5 shows the data acquisition method. The sampling interval is 500 ms. The ultrasonic data are provided to a personal computer through the ultrasonic array probe.

III. LARGE LINE EVALUATION

A. *Outline of the procedure*

Our method consists of five steps. Firstly, we acquire the waveforms from the probes, and extract the data in the nylon lines. Secondly, we calculate the amplitude values. Thirdly, we calculate cumulative relative frequency of amplitude values. Fourthly, we apply the fuzzy-if then rules from cumulative



(a) Slice view

Figure 6. Examples of ultrasonic data (B-mode).

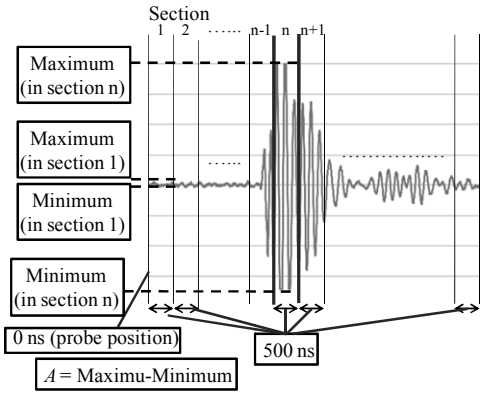

Figure 7. Calculation Amplitude

relative frequency of particular amplitude. Finally, we calculate the rate of large line among all lines by the fuzzy MIN-MAX center-of-gravity method.

B. *Calculation of cumulative relative frequency of amplitude*

Fig. 6 shows an example of ultrasonic data. As shown in Fig. 6, the rate of big amplitudes in the large lines is larger than that of the small lines. We use the difference of the distribution of the amplitude values for evaluating the rate of large line.

We employ the cumulative relative frequency of amplitude to compare the rate of the big amplitudes. We extract the waves of the interval 500 ns as shown in Fig. 7. We then calculate

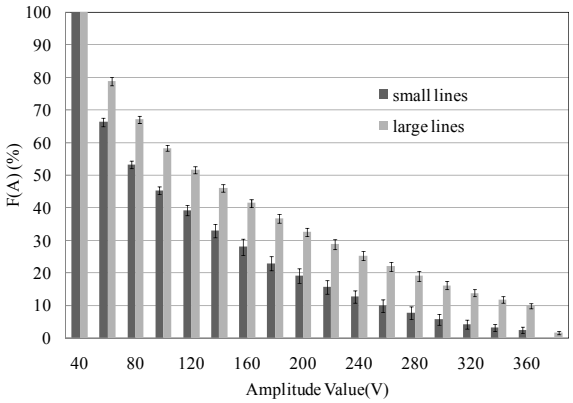

Figure 8. Average of cumulative relative frequency

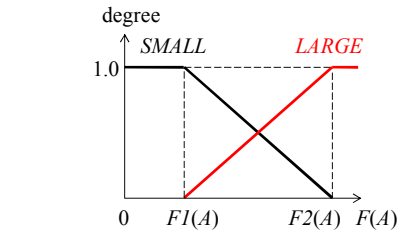
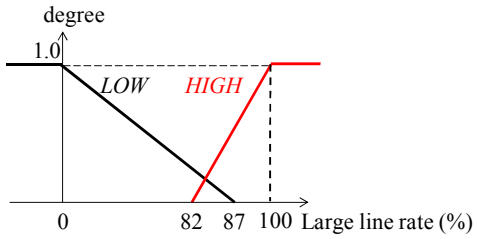


(a) Input membership functions.



(b) Output membership functions.

Figure 9. Fuzzy membership functions.

peak to peak value in amplitude in every interval. In Fig. 7, the notation A denotes peak to peak value. We calculate cumulative relative frequency from relative frequency from 40 V to 400 V at the interval of 20 V. The cumulative relative frequency is calculated by (1).

$$F(A) = \sum_{X=A}^{400} f(X) \tag{1}$$

Here, the notation $F(A)$ denotes cumulative relative frequency of amplitude of A, and $f(A)$ denotes relative frequency. We show the average of $F(A)$ of 20 times of 24 small and 24 large lines in Fig. 8. As shown in Fig. 8, cumulative relative frequency of large lines is larger than that of small lines.

C. Evaluation of rate of large line

We evaluate a rate of large line in mixed lines using fuzzy inference. From Fig. 8, we obtain knowledge of the cumulative relative frequency of amplitude as follows.

Knowledge 1: The cumulative relative frequency of large line is larger than that of small lines at same amplitude value.

TABLE I. Fuzzy IF-THEN Rules

Input			Output
$F(80)$	$F(180)$	$F(200)$	Large line rate
SMALL	*SMALL*	*SMALL*	*LOW*
SMALL	*SMALL*	*LARGE*	*LOW*
SMALL	*LARGE*	*SMALL*	*LOW*
SMALL	*LARGE*	*LARGE*	*HIGH*
LARGE	*SMALL*	*SMALL*	*LOW*
LARGE	*SMALL*	*LARGE*	*HIGH*
LARGE	*LARGE*	*SMALL*	*HIGH*
LARGE	*LARGE*	*LARGE*	*HIGH*

TABLE II. Values of $F1(A)$ and $F2(A)$.

$A(V)$	$F1(A)$	$F2(A)$
80	53.22	66.98
180	22.85	36.75
200	19.02	32.51

Knowledge 2: When amplitude value is 180, the cumulative relative frequency has the largest difference between small lines and large lines.

Knowledge 3: When amplitude value is 80, the cumulative relative frequency has the 2nd largest difference between small lines and large lines.

Knowledge 4: When amplitude value is 200, the cumulative relative frequency has the 3rd largest difference between small lines and large lines.

These knowledge are converted into eight fuzzy IF-THEN rules. The fuzzy IF-THEN rules are derived as shown in Table I. "*LOW*", "*HIGH*", "*SMALL*" and "*LARGE*" are fuzzy linguistic values, and these values are defined by fuzzy membership functions as shown in Fig. 9. The notations $F1(A)$ and $F2(A)$ denote $F(A)$ of 24 large lines and $F(A)$ of 24 small lines, respectively. To determine these values, we acquire ultrasonic data 20 times for each line set, and we calculate the average values. We show the values of $F1(A)$ and $F2(A)$ in Table II. The fuzzy IF-THEN rules are expressed by fuzzy MIN-MAX center-of-gravity method [8]. We determine a value of center of gravity as the rate of large line among all lines.

IV. Experimental Results

We acquired ultrasonic waves by 32 elements of the ultrasonic array probe. We used eight kinds of phantoms. These are lined up from large and small lines in total 24. We acquired 20 times ultrasonic waveforms for each object. Table III shows average of the calculated large line rate and truth large line rate

TABLE III. Object and evaluation result

Object		Large line rate(%)	
N_S	N_L	evaluation result	truth
24	0	2.84	0.00
23	1	14.33	4.17
20	4	19.55	16.67
16	8	27.99	33.33
12	12	49.33	50.00
8	16	66.94	66.67
4	20	93.60	83.33
0	24	86.25	100.00

(*truth* = N_L / (N_S + N_L) × 100 %). The notation N_S denotes number of small lines, and N_L denotes number of large lines.

Fig. 10 shows the result. The continuous line shows our evaluation result, and the dotted line shows the true value. As shown in this figure, the rate of large line is increased by the increment of the number of large line and our result accords with the truth value. The mean absolute error was then 5.77 %. The correlation coefficient the obtained was 0.98.

V. CONCLUSION

In our study, we proposed a testicular tubules evaluation system with a 1.0MHz ultrasonic array probe. We employed two different diameter nylon fishing lines as a small tubule and large tubule. In the preliminary experiment, we analyzed the difference of cumulative relative frequency of amplitude from the obtained ultrasonic data, and we found the difference of the distribution of the amplitude values. From these results, eight fuzzy IF-THEN rules were derived. The rate of large line was evaluated by fuzzy MIN-MAX center of gravity method. As the result, the evaluated rate of large line increases according to the increment of the number of large line. Then the correlation coefficient was 0.98. The experiments were done with 1.0 MHz ultrasonic waves. This experimental results suggested the high possibility to determine the larger diameter testicular tubule under the assumption that the characteristics of human testicular tubule is similar to that of the fishing line.

In the future, we will add the other indexes for optimize the fuzzy membership functions. Additionally we do experiment with the model being nearer to the living body and we experiment with the higher frequency ultrasonic waves than 1.0 MHz ultrasonic waves.

***Abstract*—This paper describes an effective system of selecting most suitable rasp for the patients. We suggest the ultrasonic system with a single ultrasonic probe. Firstly, we make a knock to the upper point of the rasp inserted with a hammer which has the trigger signals. We detected the acoustic signals with the knocking signals. An ultrasonic probe is fixed in the upper side of the rasp with a built-in magnet. A personal computer got the acoustic data. In the surgery, the surgeon tries to adapt for the patient from the small size rasp to the larger size rasp in turn. There is a correlation between the degree of tightening and the attenuation time of acoustic signal for the knocked sound by a hammer when inserting the rasp. The higher tightened degree implies shorter attenuation period. At the present time, the surgeon's experience chooses the suitable rasp. Therefore, we suggest the rasp determination system which selects the suitable rasp by fuzzy inference which dynamically corresponds for each patient. As the result, we successfully determined the suitable rasp in comparison to the results obtained from the practical surgery. We could indicate the indexes in order to judge how degree the rasp fits in the clinical treatment.**

Keywords— fuzzy inference, ultrasonic system, suitable rasp, total hip Arthroplasty (THA)

I. INTRODUCTION

A joint replacement consists in replacing a damaged joint with a prosthesis. In the orthopedic surgery, the arthritic or dysfunctional joint surface is replaced with an orthopaedic prosthesis [1]. Total hip arthroplasty (THA), which rebuilds the damaged hip joint with some implants, is operated to treat the hip joint diseases such as osteoarthritis, etc. The THA implants mainly consist of cup, liner, head and stem that play a role of acetabulum, hip cartilage, head of femur, and femur, respectively. The principal complication after THA is dislocation [2]. The primal mechanisms of dislocation are impingement of the femoral heck on the cup liner, impingement of the femur on the pelvis, and spontaneous dislocation due to excessive external force against muscular force. For example a hip joint that is affected by osteoarthritis may be replaced entirely with a prosthetic hip. This would involve replacing both the acetabulum, hip socket, and the head and neck of the femur. The purpose of this procedure is to relieve pain, to restore range of motion and to improve walking ability, thus leading to the improvement of muscle strength.

Joint replacement surgery is becoming a more common practice [3] [4]. The prosthetic implant used in hip replacement consists of different parts, the acetabular cup, the femoral component and the articular interface. The femoral component is the component that fits in the femur. The use of cementless femoral implants for total hip arthroplasty has increased in popularity over the last few decades [5]. Numerous implant designs based on different views concerning implant fixation are currently available. Bone is removed and the femur is shaped to accept the femoral stem with attached prosthetic femoral head or ball. Options exist for different patients and indications. Correct selection of the prosthesis is important [6], [7]. The selection of the optimum size and type of implant to fit the anatomical characteristics of the individual patient is important in order to avoid postoperative complications such as dislocation or loosening [8]-[10]. Regardless of implant design, primary stability of the cementless femoral implants in the femoral canal must be achieved at the time of operation and is really important for osseointegration, long-term fixation and clinical success [11]-[13].

The surgeon's experience in choosing the rasp size to be implanted is fundamental to achieve good fixation. However, especially for complicated cases, there is still the risk that the stem size chosen might be unsuitable. To solve the problem, References [14] and [15] described the mechanical stability at the time of implantation. Moreover, in order to do more quantitative evaluation and analysis, we propose how to select the most suitable stem for the patients by using the ultrasonic system in our study. The fuzzy inference which dynamically

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

corresponds for each patient is able to solve the problem of the Individual difference. As the results, we were able to select the suitable rasp with higher accuracy.

II. Total Hip Arthroplasty

Hip fractures occur as a result of major or minor trauma. In elderly patients with bones weakened by osteoporosis, relatively little trauma, even walking, may result in a hip fracture. The hip is made of a ball and a socket joint, linking the dome at the head of the femur and the cup in the pelvic bone. A total hip prosthesis is surgically implanted to replace the damaged bone within the hip joint.

Then a metal ball and a metal stem are inserted in the femur and a plastic socket is placed in the enlarged pelvis cup as shown in Fig. 1. The artificial components are fixed in place. The muscles and tendons are then replaced against the bones and the incision is closed.

Figure 1. Total Hip Arthroplasty

Each patient has each various bone in the hip. So the surgeon has to find the most suitable rasp for the patient while operating. In the present situation, there are some differences of selecting the suitable rasp. Therefore, we propose the determination system of selecting the suitable rasp for the patient.

III. Measurement System

We show our system in Fig. 2. The center frequency of the single ultrasonic probe is 1,000Hz. The acquired ultrasonic waveform is analyzed by a personal computer.

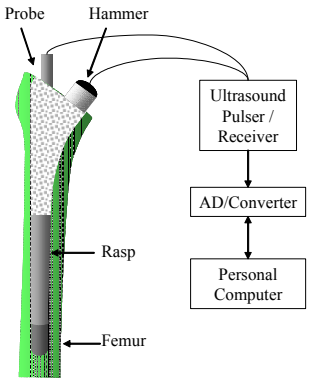

Figure 2. Measument System

At first, we make a knock to the upper point of the rasp inserted with a hammer which has the trigger signals. By using the knocking signals, we measured the acoustic signals. The microphone for measuring (10mmΦ) is fixed in the upper side of the rasp with a built-in magnet. The acoustic data is changed to the digital data by the AD converter (Picoscope ADC-212/100), and is sent to the personal computer.

A. Experimental Materials

In the clinical treatment, one of the indexes to judge how degree the rasp fits for the patient is the knocked sound by a hammer when inserting the rasp. The surgeon recognizes that the dull knocked sound means the loose fixed. From the physical opinion, in the case of loose fixing, the attenuation time of amplitude is long because the acoustic energy continues to transmit into the rasp. On the other side, in the case of tight fixing, the attenuation time of amplitude is short because the acoustic energy transmits from the rasp to the external fixed object and is absorbed on the early stage.

At first, we do envelope processing to the positive area of the acoustic wave as shown in Fig. 3. In this figure, we define the maximum of the attenuation value as A_{max} and the time at that time as T_{max}. A_{10} is A_{max} / 10. After the time of T_{max}, we define the time as T_{10} when the value is less than A_{10}.The attenuation time is obtained by (1). We estimate the degree of fixing by using this derived attenuation time.

$$T_{ATT} = T_{10} - T_{max} \quad (1)$$

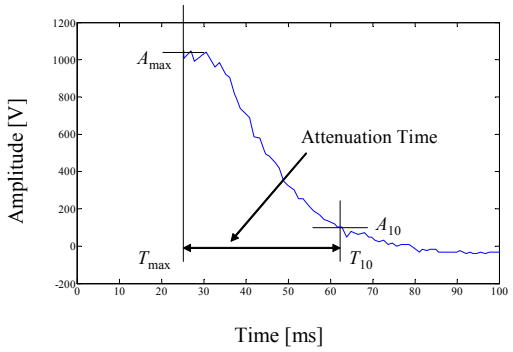

Figure 3. Measument System

B. Fuzzy Inference

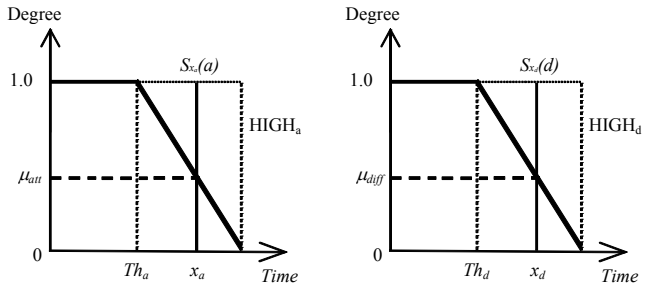
We propose a fuzzy evaluation system with two features, the attenuation time and the difference time. The difference time defines as the time between the attenuation time of the rasp and that of the one size smaller rasp. From the obtained coefficients, Knowledge 1, 2, 3 and 4 are derived.

Knowledge 1: The tight fixing has the short attenuation time.
Knowledge 2: The tight fixing has the short difference time.
Knowledge 3: The attenuation time depends on the fixed degree.
Knowledge 4: The difference time depends on the fixed degree.

These are converted to the following fuzzy if-then rules.

Rule 1: IF *Attenuation time* is *Short* THEN the degree of fixing is High.
Rule 2: IF *Difference time* is *Short* THEN the degree of fixing is High.

The fuzzy if-then rules are represented by the fuzzy membership functions as shown in Fig. 4.



(a) Attenuation Time (b) Difference Time

Figure 4. Fuzzy membership function

In this figure, the notations, Th_a and Th_d denote thresholds of *Attenuation Time* and *Difference Time*, respectively. The notation Th_a is determined as the time which is the standard deviation being shorter than the mean of the attenuation time. The notation Th_d is determined as the time which is the standard deviation being shorter than the mean of the difference time. Two fuzzy degrees, μ_{att} and μ_{diff} are calculated by (3) and (4).

$$\mu_{att}(x,y) = \min(S_{x_a}(a), HIGH_a) \quad (3)$$

$$\mu_{diff}(x,y) = \min(S_{x_d}(d), HIGH_d) \quad (4)$$

The fuzzy singleton functions $S_{x_a}(a)$ and $S_{x_d}(d)$ are defined by (5) and (6).

$$S_{x_a}(a) = \begin{cases} 1 & \text{if } a = x_a \\ 0 & \text{otherwise} \end{cases} \quad (5)$$

$$S_{x_d}(d) = \begin{cases} 1 & \text{if d} = x_d \\ 0 & \text{otherwise} \end{cases} \quad (6)$$

After consideration of the thresholds on these tables above, the threshold of the attenuation time MF Th_a is more adaptable than that of the difference time MF Th_d. Therefore, we calculate the adaptable ratio (=0.823) and put the adaptable ratio to the fuzzy membership functions. The total degree μ_{fix} is calculated by (7).

$$\mu_{fix} = \mu_{att}(x) * ratio + \mu_{diff}(x) * (1 - ratio) \qquad (7)$$

IV. EXPERIMENTAL RESULTS

We applied our proposed system to 8 total hip arthroplasty patients. The result of the fixed rasp size and the analyzed rasp size was shown in TABLE IX. The attenuation time measured in the practical surgery is showed in Fig. 5. In this figure, the horizontal-axis means the size of the rasp and the vertical-axis means the attenuation time.

By using our proposed method, we were able to select the suitable rasp of 7 patients. As concerns Subjects 1 and 7, there are two sizes of the determined rasp. Because these subjects have the fixed rasp which is one size larger than the rasp with the shortest attenuation time, it is left out of consideration that the determined rasp has two types which are the fixed size rasp and the one size smaller rasp. As concerns Subjects 2 and 5, we were not able to select the suitable rasp because the difference time is relatively large as shown in Fig. 5. As the result, the effectiveness of selecting the suitable rasp is 87.5%.

V. CONCLUSIONS

In this paper, we have proposed a rasp determination system for total hip arthroplasty patients. The acquired ultrasonic waveform with the single ultrasonic probe with the center frequency 1,000Hz is analyzed by a personal computer. At first, we make a knock to the upper point of the rasp inserted with a hammer which has the trigger signals. By using the knocking signals, we measured the acoustic signals. The ultrasonic probe for measuring is fixed in the upper side of the rasp with a built-in magnet. The acoustic data is changed to the digital data by the AD converter and is sent to the personal computer. In the surgery, the surgeon tries to adapt for the patient from the small size rasp to the larger size rasp in turn. Therefore, our system which selects the best suitable rasp by using the attenuation time is superior for surgeons and patients of total hip arthroplasty.

As the result, we successfully determined the suitable rasp in comparison to the results obtained from the practical surgery.

It is thought the indexes in order to judge how degree the rasp fits in the clinical treatment.

It remains as future works to consider the much better effective method and to apply the method to total hip arthroplasty patients.

***Abstract*—This paper proposes a body weight prediction method using autoregressive (AR) model and Fuzzy-AR model. First, we employ 6 persons body weight change data of 365 days. AR model predicts body weight of a day from these time-series data. We calculate an order of AR model for each person by Akaike's Information Criterion. In the experiment, we predicted body weight change of next day for those subjects. The AR model obtained 0.798 in correlation coefficient between predicted and truth values. Second, we propose a Fuzzy-AR model that predicts body weight of next *p* days from last *p* days, where *p* is the order of AR model. In this method, we propose a Fuzzy-AR model with the fuzzy membership function using last *p* days data. In the experiment, the Fuzzy-AR model obtained 0.558 in correlation coefficient on 2 subjects.**

Keywords- healthcare system; autoregressive model; prediction model; time-series data; body weight.

I. INTRODUCTION

Generally, the health care system provides healthcare services, including screening examinations, prenatal care and infectious disease control. Currently, busy lifestyles including hard work in daily business rise in chronic disease. In this situation, health care system for healthy people receives much considerable attentions. Reference [1] pointed that *"More than 1 billion people in the world are overweight, and at least 300 million of those are clinically obese. Without action, more than 1.5 billion people are expected to be overweight by 2015."* Thus, human body weight control is very important in the world.

In this paper, we consider a personal telehealth system to control body weight of the individual. In this system, it collects the daily weight data and analyzes them. It finally gives an advice to control it. In Ref. [1], this system is the following goal, i.e., *"Empower individuals and patients to better manage their health by providing them with information regarding their fitness and health through personal medical devices and services."*

In this paper, we propose a prediction method of body weight of next day using autoregressive (AR) model [2]-[4]. Next, we predict body weight change for next plural days using Fuzzy-AR model [5]-[8]. Thus, we predict body weight change using AR model and Fuzzy-AR model. We employ 6 subjects the body weight change data. The 6 subjects of AR parameters are calculated from Yule-Walker equation, and the order of AR model is determined by Akaike's Information Criterion. As the result, the correlation coefficient between the predicted and truth values is 0.798 on the 6 subjects. Next, using the order of AR model, we find the cycle of body weight change. The cycle is used as the order, *p*, of the Fuzzy-AR model proposed here. Fuzzy-AR model with fuzzy membership function predicts body weights of next *p* days from the time-series data of last *p* days. We compare the prediction accuracy using AR model with that using Fuzzy-AR model. As the result, Fuzzy-AR model obtained higher correlation coefficient.

II. PREDICTION METHOD BY AR MODEL

We predict body weight change of a day by AR model. The AR model is defined by (1).

$$y(t) = \sum_{i=1}^{p} a(i)x(t-i) + u(t) \tag{1}$$

Here, the notation $y(t)$ denotes a predicted value of time t, $x(t)$ does a measured value, $a(i)$ does AR parameter, u (t) does white noise, and p does the order. AR parameter, $a(i)$, is calculated by using Yule-Walker equation defined by (2).

$$\begin{pmatrix} R(0) & R(1) & \cdots & R(p-1) \\ R(1) & R(0) & \cdots & R(p-2) \\ \vdots & \vdots & \ddots & \vdots \\ R(p-1) & R(p-2) & \cdots & R(0) \end{pmatrix} \begin{pmatrix} a(1) \\ a(2) \\ \vdots \\ a(p) \end{pmatrix} = \begin{pmatrix} R(1) \\ R(2) \\ \vdots \\ R(p) \end{pmatrix} \tag{2}$$

Here, the notation $R(i)$ denotes auto covariance function. Moreover, the order, p, is determined on the basis of Akaike's Information Criterion (*AIC*) [9], [10]. In our experiment, the order, p, is determined from the time-series data of 365 days. That is, we vary p from 1 to 365, and then calculate the value of *AIC* by (3).

$$AIC = -2\ln(L) + 2k \tag{3}$$

Table I
Subjects Data

Subject	Sex	Age	Range of body weight change (kg)	Height (cm)
A	Male	35	66.6 ~ 71.1	180.0
B	Male	35	68.7 ~ 79.4	173.0
C	Male	39	74.8 ~ 88.3	176.0
D	Male	36	60.6 ~ 65.2	157.0
E	Male	41	95.6 ~ 105.0	175.0
F	Male	36	65.3 ~ 69.1	174.5

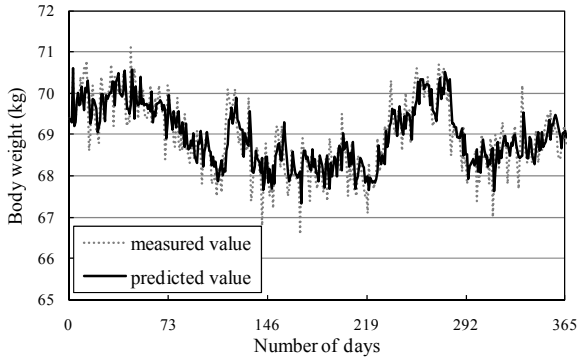

Figure. 1 Prediction result in subject A

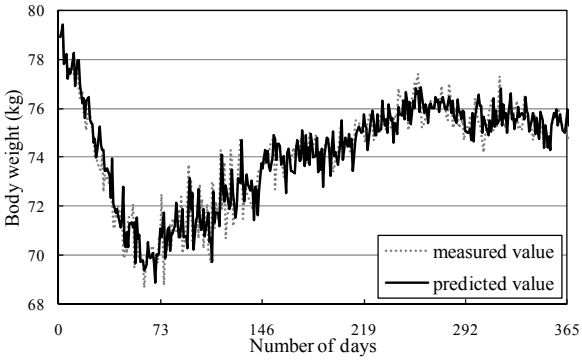

Figure. 2 Prediction result in subject B

Here, L denotes maximum likelihood and k does number of free parameter. Maximum likelihood, L, is changed by p. The order of AR model is determined as p with the minimum AIC during [1, 365]. We predict body weight of next day from time-series data of last p days.

III. Prediction Results of One Day

In our experiment, we employed body weight data while 365 days of 6 subjects in Table I. We predicted their body weight change by AR model. We evaluated our prediction results by using correlation coefficient between predicted values and truth values. We tested AR model 5 times and calculated the mean and the standard deviation (SD).

Fig. 1 shows prediction result of subject A. Subject A has rapid body weight change during [109, 117]. From Fig. 1, we can see that AR model predicted this rapid change. Fig. 2 shows prediction result of subject B. Subject B has body weight change of about 10 kg during about 2 months. From Fig. 2, we can see that AR model predicted this change. Fig. 3 shows the prediction result of subject C. Subject C has slowly decreasing body weight data. In Fig. 3, AR model predicted this slow change. Fig.4 shows the prediction result of subject D. Subject D has decreasing body weight data in short term. From

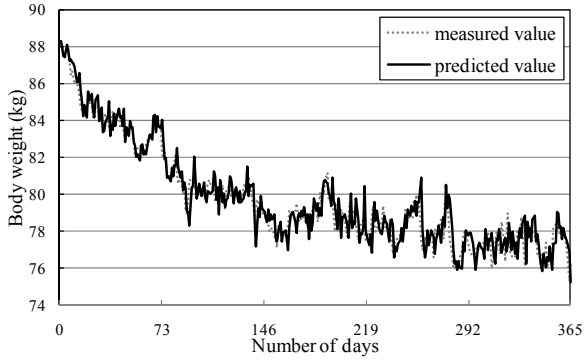

Figure. 3 Prediction result in subject C

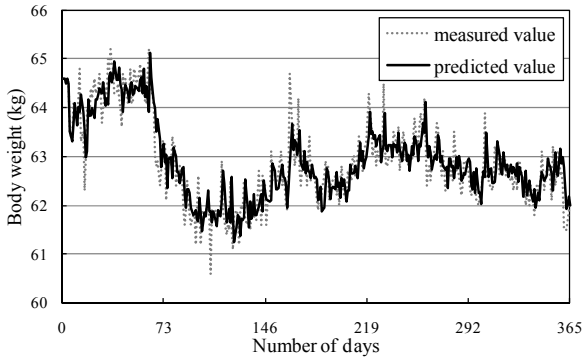

Figure. 4 Prediction result in subject D

Fig. 4, we can see that AR model predicted this change in short term. Fig.5 shows the prediction result of subject E. Subject E has rapidly body weight change during about 10 days. From Fig. 5, we can see that AR model predicted this change during about 10 days. Fig.6 shows prediction result of subject F. Subject F has rapid body weight change during a few days. From Fig. 6, AR model then did not predict this rapid change during a few days.

Table II shows the mean ± SD of correlation coefficient and the determined order of AR model. We obtained 0.798 ± 0.073 in the average.

IV. Prediction Method by Fuzzy-AR Model

The orders of AR model are different from person to person. The order would represent a cycle of body weight of individuals. By calculating the order, p, we will predict body weight change of next p days.

To find the weight cycle, we employ 100 subjects and determine the order for each subject. All subjects are ranged from 24 to 79 years old (male: 87 and female: 13). Fig. 7 shows histogram of the orders. In Fig.7, the peak frequency is 3 or 7 and their neighbors. Also, 14 is larger than its neighbors. From these results, we consider that the frequency is 7 days as the highest peak and 3 days as the second. Especially some persons have 14 days. We propose a Fuzzy-AR model with a fuzzy membership function. The fuzzy membership function defined from the order, p, where the order is individually determined as the highest frequency of the AR model. The notation t_x denotes the current point. Fuzzy-AR model is defined by (4).

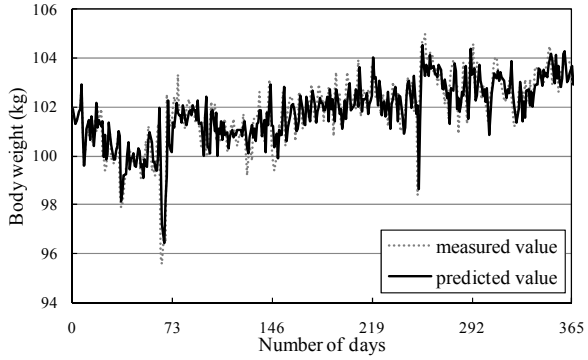

Figure. 5 Prediction result in subject E

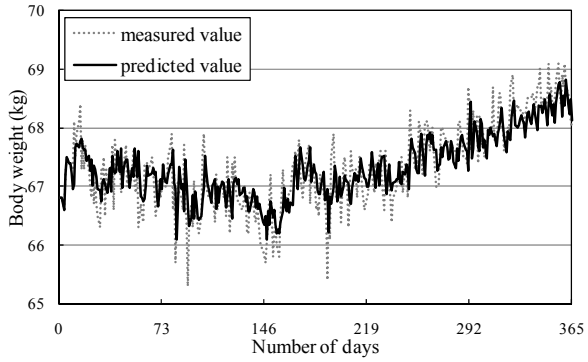

Figure. 6 Prediction result in subject F

Table II
Prediction Results

Subject	Order of AR model *p*	Correlation coefficient
A	8	0.734 ± 0.014
B	9	0.872 ± 0.015
C	3	0.906 ± 0.013
D	7	0.807 ± 0.013
E	10	0.734 ± 0.033
F	8	0.733 ± 0.013
Average	-	0.798 ± 0.073

$$y(t_x + d) = \sum_{i=1}^{p} a(i)x(t_x + d - i) + u(t) + \mu_w(d) \qquad (4)$$

Here, $x(t)$ means the measured values when $t < t_x$, and does the predicted values when $t \geq t_x$. The notation d denotes a predicted day parameter during $1 \leq d \leq p$. The notation $\mu_w(d)$ is fuzzy membership function defined by (5). We calculate minimal (W_{min}) and maximal (W_{max}) weights from the last p days data from t_x.

$$\mu_w(d) = \frac{x(t_x - p + d) - W_{\min}}{W_{\max} - W_{\min}} \qquad (5)$$

Fig. 8 shows an example of fuzzy membership function with p = 3. Also, Fig. 9 shows an example of fuzzy membership function with p = 7.

V. Prediction Results of *P* Days

In this experiment, we first employed subject C and subject D in Table I. We consider 6 days body weight change data of subject C because the order is 3. Fuzzy membership function was made by body weight data from 1st to 3rd days, and we predicted those from 4th to 6th days. We compare the prediction results of Fuzzy-AR model with AR model. In AR model, we use body weights from 1st to 3rd days. Furthermore, we extracted 14 days body weight change data of subject D because the order is 7. Fuzzy membership function was made by body weight data from 1st day to 7th day, and we predicted next 7 days. We compare the prediction results of Fuzzy-AR model with AR model. In AR model, we use body weight of last 7 days. We evaluated these prediction results by correlation coefficient between predicted values and truth values. We tested these models 100 times and calculated the mean and SD.

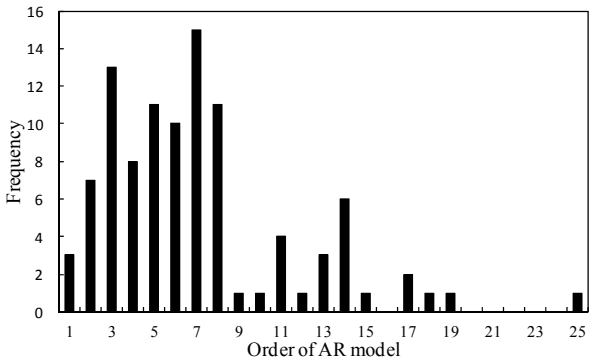

Figure. 7 Histogram of order of AR model

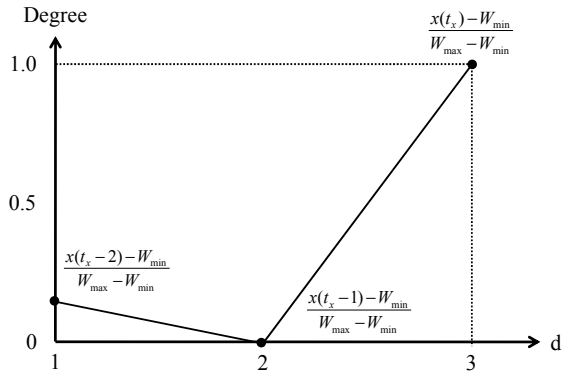

Figure. 8 Example of fuzzy membership function (p = 3)

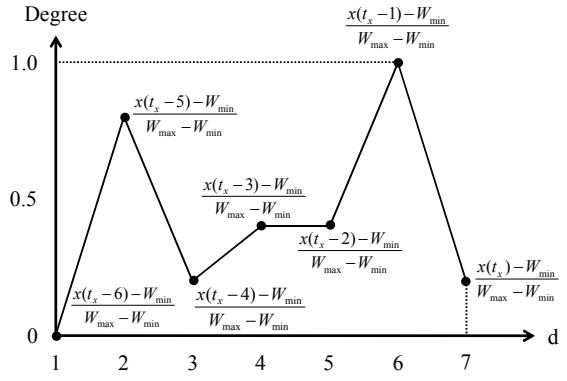

Figure. 9 Example of fuzzy membership function (p = 7)

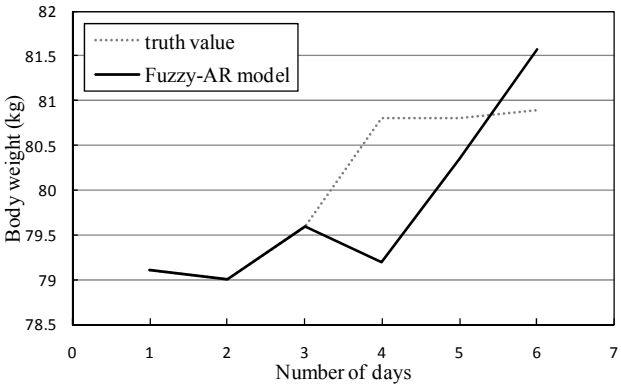

Figure. 9 Prediction result using Fuzzy-AR model in subject C

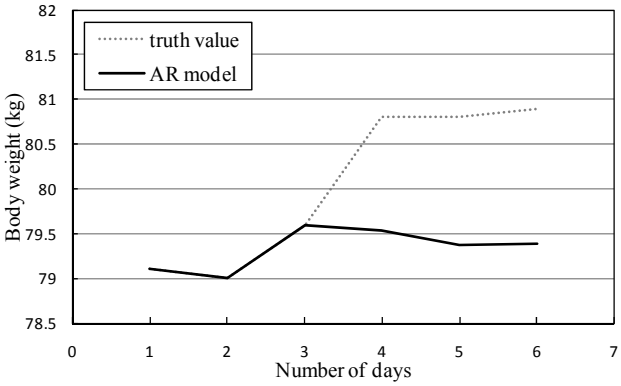

Figure. 10 Prediction result without using AR model in subject C

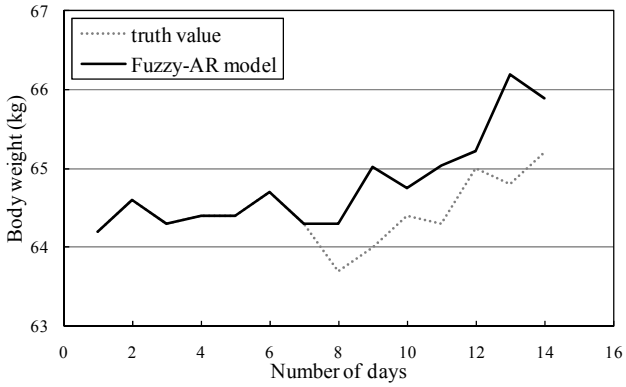

Figure. 11 Prediction result using Fuzzy-AR model in subject D

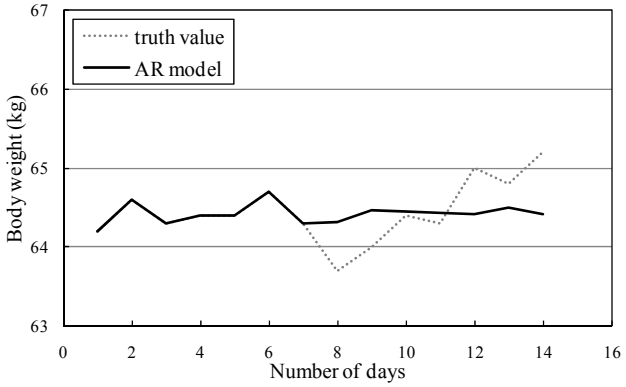

Figure. 12 Prediction result without using AR model in subject D

Fig. 9 shows prediction result using Fuzzy-AR model in subject C. The correlation coefficient was 0.571 ± 0.413. Fig. 10 shows prediction result using AR model in subject C. The correlation coefficient was 0.232 ± 0.615. Fig. 10 shows prediction result using Fuzzy-AR model in subject D. The correlation coefficient was 0.542 ± 0.187. Fig. 11 shows prediction result using AR model in subject D. The correlation coefficient was 0.176 ± 0.341. Thus, the accuracy using Fuzzy-AR model is higher than that using AR model.

VI. CONCLUSIONS

In our study, we predicted body weight change based on AR model. We predicted body weight change of 6 subjects by AR model. We tested AR model 5 times and calculated the mean of correlation coefficient. As a result, the AR model obtained 0.798 ± 0.073 in correlation coefficient between predicted and measured values. Next, we determined body weight change cycle from 100 persons data. Then, the peak frequency is 7 days. Next, we propose a Fuzzy-AR model for body weight data from last p days, where p is the order of AR model, and we predicted next p days. As a result of 2 subjects, Fuzzy-AR model obtained 0.558 ± 0.317 in correlation coefficient. This value was higher than AR model (0.204 ± 0.497). Thus, Fuzzy-AR model accurately predicted body weight change of next 3 or 7days than AR model.

In the future, we will improve prediction accuracy by considering the other attributes such as calories and athletics.

Abstract— **Both burden of human and performance of sensing technology should be carefully considered in bioinstrumentation. The article proposes the ideas of invasion, intrusion, and consciousness in biomedical sensing to improve its comfort and performance. Consideration of the three concepts is very important to realize burden-reduction of human. They also save sensing accuracy when sensing targets and sensor heads are influenced by invasion, intrusion, or consciousness during sensing. Realizing noninvasive, nonintrusive, and unconscious sensing requires solutions against uncertainty in sensory signals and estimation models. Sensory signals from these sensing methods might superimpose various types of signals besides target one. Target signals would be appropriately extracted by the causal analysis-based model. Case studies were investigated by considering the method and experimental results were reported in the article.**

Keywords-component; Biomedical sensing, Fuzzy Logic, Noninvasive, Nonintrusive, Unconscious, Uncertainty information processing, Causal Analysis, Hierarchical Knowledge Representation

I. INTRODUCTION

There have been noticed many kinds of problems related to our healthy, social, and environmental issues during the new decades of 21st century. Among them, aging society will make rapid progress especially in advanced nations. Medical crisis has also become clear. Environmental issues centering global warming would have some impacts on our live body. Through these rapid changes close to our daily life and health, it has been much more important for us to know about our human body by bioinstrumentation than ever.

For instance, metabolic syndrome which is caused by life style habit has been immediately paid attention to. Even though the cause would be individual's life style, the result is quite serious from obesity through hypertension and diabetes to cardiovascular events like brain and cardiac infraction and complication [1][2]. The most important and effective against the disease is to change the life style of diet, exercise, and sleep. However, it is very hard for the patients and the preliminary group of the disease to change their life styles which have been continued for a long time. In order to change the life style, it is effective for them to notice the status of their body condition based on the measurements of their vital signs and life styles. Continuation of the measurements would be the key to success in changing lifestyle habit. For this reason, bioinstrumentation and lifestyle measurement without invasion, intrusion and consciousness in daily life would be required besides the indices such as Electrocardiograph (ECG) and blood pressure (BP) sensed in the medical field.

In the article, the importance of idea of invasion, intrusion, and consciousness in bioinstrumentation is studied and discussed. The realized biomedical sensing methods which consider the idea are introduced and surveyed for considering the uncertainty in the sensing methods.

The rest of the article is organized as follows; Section II studies the bioinstrumentation from the views of invasion, intrusion, and consciousness. Section III introduces the biomedical sensing methods which are for visceral fat estimation and heart rate monitoring as the case studies. The methods employ the causal analysis with hierarchical knowledge against uncertainty which is caused by restrictions of reducing invasion, intrusion, and consciousness. Discussions follow the introductions and experimental results. Section IV concludes the article with summaries.

II. RELATIONSHIP BETWEEN LIVING BODY AND SENSING

Physical and mental pain and restraint of patients should be eliminated or minimized during bioinstrumentation with accurate sensing results. It is the motif of reducing invasion, intrusion, and consciousness. Fig. 1 shows the overview of bioinstrumentation. Various types of sensory signals from the living body are obtained via sensory head. The signals are accumulated into the database to put them to practical use of medical and healthcare by feeding back some effects the patients. Besides them, the database is used in the medical science and engineering to develop the new evidences and the new solutions.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

In this section, invasion, intrusion, and consciousness in biomedical sensing are studied and discussed from the views of both human burden and technology performance. Invasion has been studied more than intrusion and consciousness so far. However, latter two issues are also important idea to provide different meanings and values from invasion to realize comfortable and accurate biomedical sensing method.

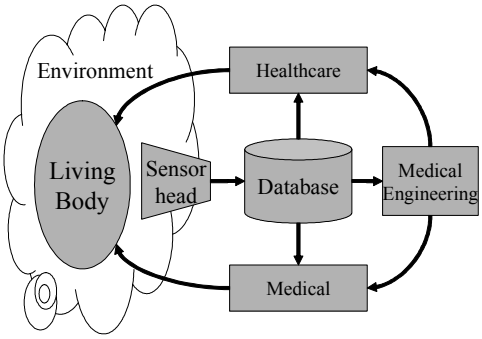

Figure 1. Overview of Bioinstrumentation

A. Invasion

Invasion levels can be defined by distance between sensory head and sensing target or location of them. According to [3], there are five invasion level of biomedical sensing as follows;

1. A catheter is inserted into body to send transmitter to a sensor head.
2. A sensor head is implanted to send sensory signals via fixed line.
3. A sensor head is implanted to send sensory signals via wireless communication.
4. A sensor head is contacted on skin of the body to detect signals.
5. A sensor head is not contacted on skin of the body to detect signals.

As mentioned above, the invasion levels are defined by the positional relationship between sensory head and live body. Even though the invasion level is low according to the definitions above, a CT scan that is non contact sensing requires X-ray exposure which is serious invasive. This case should be treated as high invasion. Thus, definition could be changed according to the development of sensing technology and consideration of influence to human body.

Compared with invasion, intrusion and consciousness sensing are new ideas in biomedical but important for both of sensing accuracy and human comfort.

B. Intrusion

Nonintrusion is important idea for sensing daily life activity. ECG and BP are very important physical indices used in medical and healthcare. The indices can be measured in just in hospital and clinic. It is strongly required to monitor for 24 hours to detect defect condition of body in daily life. However, it is impossible to monitor ECG in daily life in the case of using ordinary ECG equipment. A Holter electrocardiographic monitor has been realized for gathering the ECG signals and an ambulatory blood pressure monitor for accumulating blood pressure signals for 24 hours. Although the equipment could be used for sensing live body, it is far from non-intrusion. The user has to use contacted sensory head and to carry on the equipment. There has not been clearly defined but some levels would be discussed on intrusion.

C. Consciousness

Consciousness or realization to be sensed would have some influence to the sensing signals. White coat hypertension and masked hypertension [4] are examples for understating the importance of unconsciousness sensing. Not just for these serious cases, other examples can be easily pointed out with considering consciousness such as video and image sensing. Long and continuous sensing for 24 hours requires unconsciousness. Besides them, unconsciousness helps for users not to forget the measurement.

Through these definitions and observations on invasion, intrusion, and unconsciousness, some discussions on influences to patients and live bodies and to measurements.

D. To Living Body

It is strongly required to reduce and to eliminate burden, pain, and damage both physically and mentally to live bodies and patients. According to the definitions of invasion level, the level is decided by distance and location between sensor head and body. However, even though X-ray CT scan is non contact sensing, it gives serious impact of X-ray exposure on a living body. Implant sensing requires surgery whose invasion level is quite high, but intrusion is very low when the sensor could be used for a long time without any invasion. Additionally, a patient who is implanted a sensor into could feel unconscious with the sensor. As these discussions, invasion is not the only perfect prerequisite in biomedical sensing. Intrusion and consciousness should be also considered for realizing the effective and efficient bioinstrumentation.

E. To Measurements

Sensing performance would be generally sophisticated according to higher invasion level. However, invasion sometimes brings negative results in sensing. Contact between a sensor head and live body makes energy exchange among them to possibly cause unstable sensing. For example, huge sensor head of clinical thermometer realizes good fitting with body however it takes body temperature. Like the examples pointed out in intrusion section, it would be very hard to keep the ideal situation of the patient such as in daily life activities with high intrusion. Besides, unconscious sensing might bring good results with the sensing performance as discussed in consciousness section.

F. Uncertainty

Realization of biomedical sensing without invasion, intrusion, and consciousness would bring some uncertainty in the sensing mechanism. Sensor signals superimpose not just target but other kinds or noises. Besides extraction of target

signal, it is also required to compose causal structures which explain sensing principles well.

The article proposes causal analysis method against the problems to be solved discussed above. Causality plays an important role for solving the uncertainty discussed above because it is the basis of human's understandings and also machine could handle with it; i.e., it is transparent among humans and machines mutually. It brings powerful solution which improves observability and controllability of the target system.

III. CASE STUDIES

In this section, two applications to biomedical sensing with considering the sensing issues described in the previous section are described.

A. Visceral Fat Area Estimation

Entering the 21st century, declining birthrate and a growing proportion of elderly people have developed into more serious social problems especially in advanced nations. Not only solving the problem of labor power reduction but also extending healthy life expectancy is the important challenge which should be socially addressed. In terms of the issues, primary prophylaxis has been recognized as an important activity to prevent life style related diseases. Currently, the waist circumference and blood sugar, neutral fat or quantities of cholesterol in the blood are measured for the primary screening whether the person is metabolic syndrome at the medical checkup. Generally, it has been clarified that over-accumulation of visceral fat causes several life-style related diseases. X-ray CT or MRI is currently the gold standard in medical field but it causes serious invasion of X-ray exposure. An accurate and safe measurement of the visceral fat accumulation status is desired in medical field. In responding to the invasion problem, simple, accurate, and safe equipment of visceral fat estimation has been proposed based on bioelectrical impedance analysis (BIA) [5-7, 14] with considering low invasion. As shown in Fig. 2 and 3, body compositions depend on individuals and have complicated mixture. A patient in Fig. 2 accumulates much visceral fat and low subcutaneous one. On the other hand, we can see much subcutaneous fat and low visceral one in Fig. 3.

1) Measurement Principles and sensing

There are three types of composition which are visceral fat, subcutaneous fat, and lean body. Lean body is not fat and internal organs, muscles, and bones. Each area can be calculated by image processing technology applied to the image of cross sectional area gotten by a CT scan or an MRI as shown in Fig. 2.

Visceral fat area can be calculated by (1) which is the measurement principle of VF.

$$VFA = CSA - SFA - LBA \tag{1}$$

where *VFA* is visceral fat area, *CSA* all cross sectional area, *SFA* subcutaneous area, and *LBA* lean body area. In the sensing, two types of bioelectrical impedance and the abdominal shape at umbilical level are measured. As in (1), each area of *CSA*, *SFA*, and *LBA* will derive *VFA*. The strategy of the measurement is as follows;

1. *CSA* could have high correlation with the abdominal shape information.
2. SFA could be estimated by the abdominal shape and the internal abdominal impedance.
3. LBA could have inverse correlation with the total body impedance.

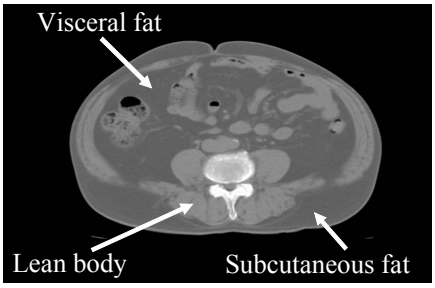

Figure 2. Cross sectional area image at umbilical level

Firstly, let us consider about the abdominal shape information. In a medical checkup, waist circumference is used to diagnose metabolic syndrome. However, it brings less information about the abdominal shape. The shape estimation performance could be improved by using the measurements of the width *a* and the depth *b* at abdominal level as shown in Fig. 3, instead of waist circumference. These variables are used in calculating *CSA* and *SFA*.

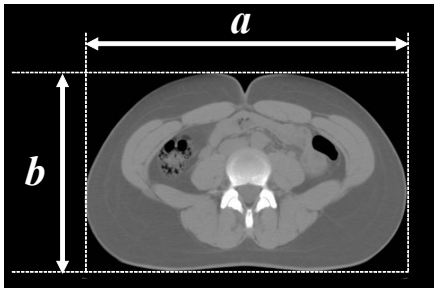

Figure 3. Body shape measurement

In order to measure the total body impedance, the electrodes for turning on electricity are placed on the back of both hands and the instep of both feet with the subjects lying on their back. Eight electrodes for the measurement are placed on surroundings of the waist circumference at umbilical level. These electrodes are placed on the trunk, paired in intervals of 9 cm, centered at the umbilicus with *250 μA* with *50 kHz*. The total body impedance can be obtained as Z_T. Regarding the abdominal surface impedance, the eight electrodes are classified into groups of four. In each group, the electricity is impressed using one electrode, and the impedances of the abdominal surface are obtained by the other electrode as Z_S.

2) Causal Structure Design

Fig. 4 illustrates the causality of *VFA* estimation considering the relationship between the sensory variables and the measurement principle. The left and the right are the sensory variables and the principle measurement respectively. According to the causal structure, we prepare the variables which are the candidates for constructing the causality. By using the selected variables, multi linear regression was employed to acquire the estimation model. In this step, we carefully considered about nature of the model without over-fitting, multicollinearity, and some other difficulties; especially keeping the notion of the measurement principle. We finally derived the estimation model denoted by the equation (2).

$$\widetilde{A}_{VF4} = \alpha_1 a + \alpha_2 b^2 + \alpha_3 Z_S \sqrt{a^2 + b^2} + \alpha_4 / Z_T + \varepsilon \quad (2)$$

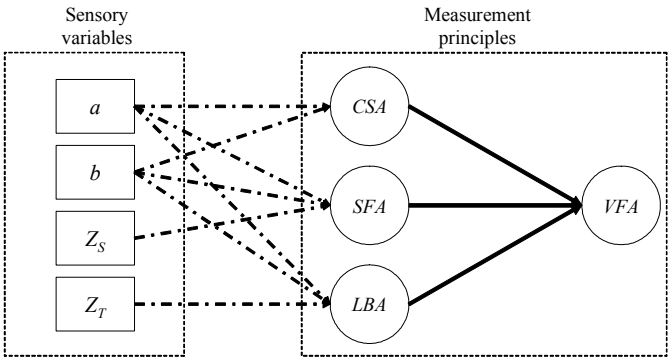

Figure 4. Causality between the sensory variables and the measurement principle

In order to extract the causality for estimating VFA, we designed the following development steps;

1. Preparation of variables according to the measurement principles
2. Selection of the variables by applying AIC and VIF on the sample dataset

In the first step, we prepared the candidates of the variables as possible as used in the estimation equation. The idea here is that the candidates should bring some information about VFA estimation and be understandable from the point view of the measurement principles shown in the Fig. 4. The prepared variables are listed in the table 1.

The second step is the suitable variables selection as a set of them. We employed two different criteria to realize the legitimate model for VFA estimation. Our consideration was to realize both promised performance and transparency according to the measurement principle. The first is the accuracy and simplification of the model without over-fitting to the sample dataset. The second is multicollinearity which causes some difficulties in the estimation results. The problem is caused by an almost linear relationship among dependent variables in the regression model. Akaike Information Criterion (AIC) [8] and Variance Inflation Factor (VIF) [9] are the employed criteria for former and later considerations. The criteria are given by the (3) and (4), respectively.

$$AIC = n\log(2\pi\hat{\sigma}_e^{\,2}) + \frac{1}{\hat{\sigma}^2}\sum_{i=1}^{n}\{y - (\alpha_1 x_1 + \cdots + \alpha_m x_m + \varepsilon)\}^2 + 2(m+2) \quad (3)$$

where m and n is the numbers of independent variables and data respectively, y a dependent variable, $x_i (i = 1,2,...,m)$ independent variables, $\alpha_i (i = 1,2,...,m)$ coefficient terms, ε error term, $\hat{\sigma}_e$ the standard deviation of estimation errors.

$$VIF_i = 1/(1 - R^2{}_i) \quad (4)$$

where R_i is the multiple correlation coefficient between the independent variable $x_i (i = 1,2,...n)$ and the rest of $(n-1)$ variables.

3) Experimental Dataset

We designed the experimental data set by using the three variables of gender, age, and waist circumference which is substituted to for VFA because it could not be used in the recruiting phase. The number of subject is 180 (90 males + 90 females) who were 22 to 80 years old (mean is 49.95) and had from 65.8 to 120 cm of their waist circumferences (the mean 90.09). All of the subjects are measured by both the proposed method and a CT scan as reference values.

4) Experimental Results and Discussions

The results were as follows; the correlation coefficient 0.88, the errors mean -1.38, and the errors standard deviation 27.28. The scatter diagrams of the proposed instrument and the CT scan and waist circumferences and the CT scan are shown in Fig. 5 and 6, respectively. The correlation coefficient between waist circumferences and CT scans is 0.77.

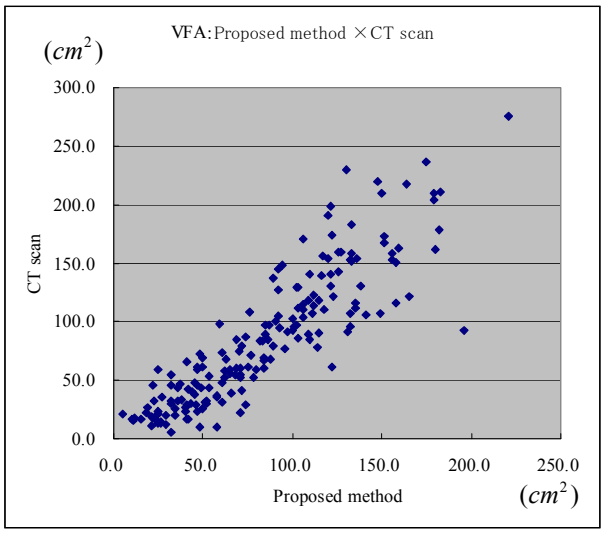

Figure 5. VFA: the proposed method vs. CT scan

As the results, visceral fat areas estimated by the proposed method achieved high correlation with ones by the CT scan. Waist circumference which is used in a medical checkup works

well but the estimation accuracy is lower than the proposed method. Besides, it cannot differentiate VF from subcutaneous one and lean body in principle. According to the scatter diagrams, the method estimates stably from small to huge size of visceral fat volume. Difference plot shown in Fig. 7 would also suggest this nature but is has a tendency of slightly lower estimation as VF goes large. The correlation coefficients of females' VFA and males' are 0.913 and 0.862 respectively. The difference between them is statistically non significance ($p = 0.114$).

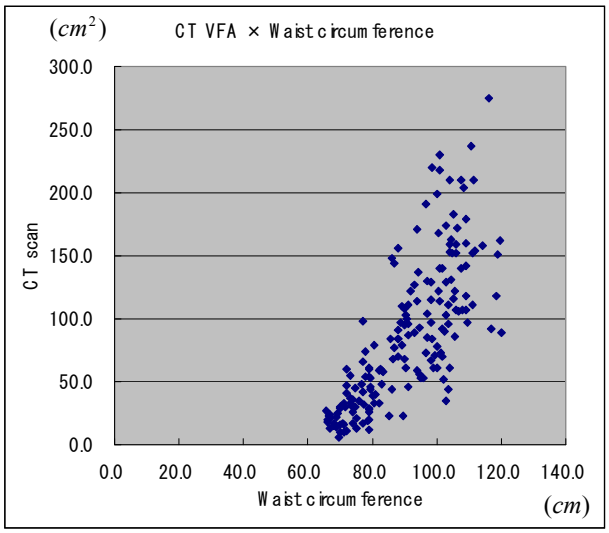

Figure 6. Waist circumference vs. CT scan

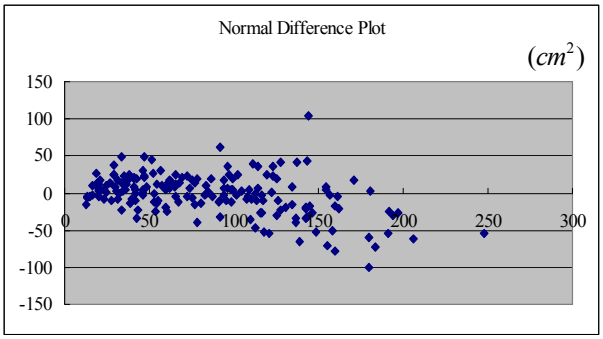

Figure 7. Normal difference plot

B. Heart Rate Estimation

Among vital-signals, heart rate (HR) provides important information of humans' health transit [10] such as an early stage of cardiac disease. It would be pretty important for us to continuously measure our heart rate to know the changes in our daily life. In addition, the variability of heart rate transit provides information of autonomic nerve activity [11]. Through these discussions, it might be clarified that continuous heart rate monitoring in daily life is quite important.

Currently, in a medical domain, an electrocardiography (ECG) is the gold standard system for measuring heart rate transit correctly. However, ECG requires subjects to be put electrodes on and is high intrusive. It is strongly preferred to be sensed in daily life without invasion, intrusion, and unconsciousness. In response to the requirements, heart rate monitoring equipment by using an air pressure sensor (APS) has been developed [11-13].

1) System Configuration

The equipment measures body pressure variability via an air pressure sensor, and extracts heart rate variability from the obtained pressure variability. Fig. 8 shows the system architecture of the equipment. Heart beats are detected and the heart rate variability is calculated by using detected heart beat intervals.

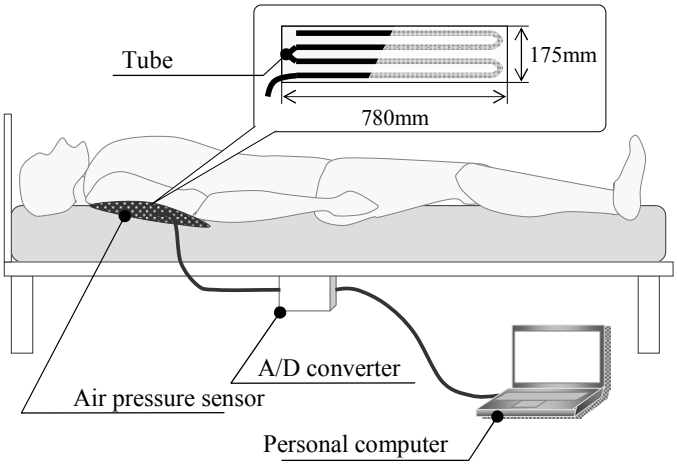

Figure 8. Heart rate extraction equipment

2) Causal Structure Transformation

Heart rate will be estimated as follows; heart beat locations which are R-waves are decided from the changes of the signal caused by heart beat, R-R interval can be calculated by using the R-waves, then heart rate is calculated by using R-R intervals. The causality is designed by considering the similarity between electrocardiograms and air pressure sensors.

Firstly, the conceptual causality by using ECG was designed as shown in Fig. 9. ECG extracts R-waves τ_R from the electrical change caused by heart rate *HR* and calculate heart rate from their RR intervals τ_{RR}.

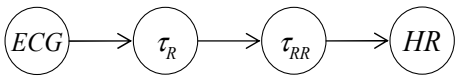

Figure 9. The conceptual causality for HR extraction via ECG

In the next step, the causality was divided into two parts. Because the process of calculating heart rate from RR interval τ_{RR} can be generalized, it was considered as independent causality, which allows the decomposition of the causality as shown in Fig. 10.

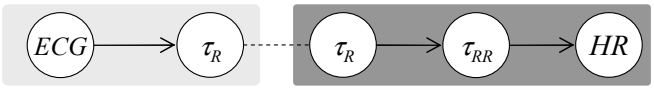

Figure 10. Decomposition of conceptual causality for ECG

Then, the original causality should be modified according to the development equipment. The aforementioned heart rate extraction equipment using an air pressure sensor measures pressure change caused by body movement *MV* and respiration *RSP* as well as heart beat *HB*. The conceptual causality considering the nature is depicted as shown in Fig. 11, which indicates that only *HB* is extracted from the pressure change, and *HR* is calculated by τ_{RR} in the same manner as ECG.

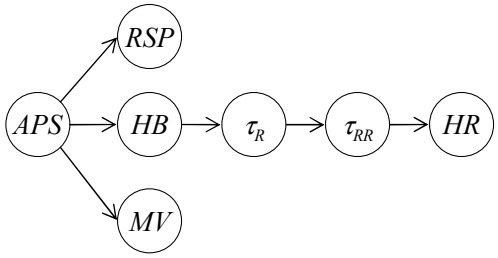

Figure 11. The conceptual causality for HR extraction via APS

The causality shown in Fig. 11 will be decomposed to the partial causalities as shown in Fig. 12 because in the structure, the process of calculating *HR* from τ_{RR} can be generalized. That is, the causality modification caused by the equipment replacement is limited to the process of extracting τ_R from the air pressure sensor.

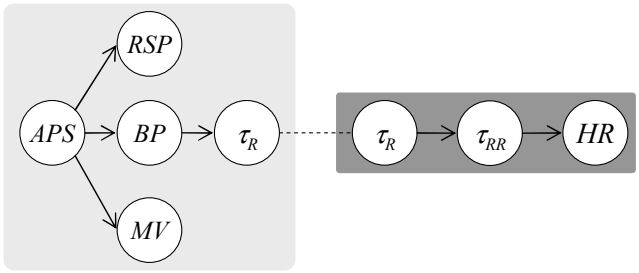

Figure 12. Decomposition of conceptual causality for HR extraction equipment via APS

As shown in Fig.12, τ_R should be extracted according to the changes of waves from the signals which superimpose not only *BP*, but *RSP* and *MV*. It is difficult to determine the precise position of R-waves τ_R by autocorrelation function and peak detection method. We developed formulate knowledge about heart beat by using fuzzy logic [12-14]. In the method, moving averages of pressure changes are calculated and smoothened. Then, the fuzzy logic based on the knowledge about τ_{RR} is applied to the smoothened pressure changes to extract *BP*.

3) Experimental Dataset

In the study, we use the dataset which is obtained from seven healthy male subjects by concurrently measuring pressure changes in body with the equipment shown in Fig 8 and the electrocardiogram from an ECG.

4) Experimental Results and Discussions

In this experiment, we compare the method with autocorrelation functions and peak detection and one with fuzzy logic. TABLE I shows correlations between heart rate changes that obtained from the ECG and those that obtained from the heart rate extraction equipment with an air pressure sensor.

The result indicates that the method with fuzzy logic achieved higher performance for all of the subjects. In particular, the correlation to ECG for the subject *E* is 0.991, which is extremely high. The improvement of the performance is realized by conducting minimum arrangement via consideration for sensors' characteristics based on experts' knowledge.

TABLE I. HR EXTRACTION PERFORMANCE VIA APS

Subjects	**Attributes**		**Correlation coefficient**	
	Height [cm]	***Weight [kg]***	***Developed method***	***AC function***
A	**175**	**76**	**0.973**	**0.703**
B	**171**	**68**	**0.807**	**0.389**
C	**165**	**50**	**0.754**	**0.621**
D	**171**	**56**	**0.872**	**0.699**
E	**180**	**92**	**0.972**	**0.658**
F	**172**	**55**	**0.844**	**0.677**
G	**170**	**62**	**0.737**	**0.346**
Mean	**172**	**65.6**	**0.851**	**0.585**

C. Discussions on both studies

In the case of visceral fat estimation, the sensing requires intrusion but invasion level is quite low compared with X-ray CT scan which is used in medical field as the gold standard. According to the causality development, the method used knowledge and statistical approach for realizing good performance.

As the case in heart rate estimation, it realizes noninvasive, nonintrusive, and unconscious sensing for heart rate monitoring of body on the bed. The method requires highly sophisticated signal extraction from multiple superimposed original sensory data.

Both cases prove that the causal analysis with hierarchical knowledge and causal analysis method works well against uncertainty in biomedical sensing.

IV. SUMMARIES AND CONCLUSIONS

This article discusses the importance of the ideas of intrusion and consciousness besides invasion in biomedical sensing. The problems to be solved in such noninvasive, nonintrusive, and unconscious sensing is to extract target signals and estimation model from uncertainty information.

Hierarchical knowledge and causal analysis methods are studied and applied to the two biomedical sensing case studies of visceral fat estimation and heart rate monitoring. The former considers noninvasive but intrusive and conscious and the latter realized noninvasive, nonitrusive, and unconscious biomedical sensing. Uncertainties in the both applications are investigated with the knowledge and causal analysis. The article has discussed on the ideas of invasion, intrusion, and consciousness in the biomedical sensing with considering uncertainty and provided the case studies and their experimental results. Biomedical sensing methods would be more sophisticated by considering the notions of the three points in the future.

Abstract—Load forecasting is an important component for power system energy management system. Precise load forecasting helps the electric utility to make unit commitment decisions, reduce spinning reserve capacity and schedule device maintenance plan properly. This paper presents the development of a novel fuzzy wavelet neural network model and validates its prediction on the short-term electric load forecasting of the Power System of the Greek Island of Crete. In the proposed scheme, a wavelet neural network has replaced the classic TSK model in the consequent part, while subtractive clustering has been applied to the definition of fuzzy rules. The forecasting error statistical results, corresponding to the minimum and maximum load time-series, indicate that the proposed load forecasting model provides more accurate forecasts, compared to conventional neural networks models.

Keywords- Load forecasting; power systems, fuzzy wavelet networks neural networks.

I. INTRODUCTION

Load forecasting is an important component for power system energy management system. Precise load forecasting helps the electric utility to make unit commitment decisions, reduce spinning reserve capacity and schedule device maintenance plan properly. Besides playing a key role in reducing the generation cost, it is also essential to the reliability of power systems. The system operators use the load forecasting result as a basis of off-line network analysis to determine if the system might be vulnerable. If so, corrective actions should be prepared, such as load shedding, power purchases and bringing peaking units on line. Since in power systems the next days' power generation must be scheduled every day, day-ahead short-term load forecasting (STLF) is a necessary daily task for power dispatch. Its accuracy affects the economic operation and reliability of the system greatly. Under-prediction of STLF leads to insufficient reserve capacity preparation and, in turn, increases the operating cost by using expensive peaking units. On the other hand, over-prediction of STLF leads to the unnecessarily large reserve capacity, which is also related to high operating cost.

In spite of the numerous literatures on STLF published since 1960s, the research work in this area is still a challenge to the electrical engineering scholars because of its high complexity. How to estimate the future load with the historical data has remained a difficulty up to now, especially for the load forecasting of holidays, days with extreme weather and other anomalous days. With the recent development of new mathematical, data mining and artificial intelligence tools, it is potentially possible to improve the forecasting result. With the recent trend of deregulation of electricity markets, STLF has gained more importance and greater challenges [1].

The research approaches of short-term load forecasting can be mainly divided into two categories: statistical methods and computational intelligence (CI) methods. In statistical methods, equations can be obtained showing the relationship between load and its relative factors after training the historical data, while CI methods try to imitate human beings' way of thinking and reasoning to get knowledge from the past experience and forecast the future load. Regression is one of most widely used statistical techniques. For load forecasting regression methods are usually employed to model the relationship of load consumption and other factors such as weather, day type and customer class. Engle *et al.* [2] presented several regression models for the next day load forecasting. Their models incorporate deterministic influences such as holidays, stochastic influences such as average loads, and exogenous influences such as weather. Time series approach is based upon the assumption that the data has some internal structure such as autocorrelation, trend or seasonal variation. Most commonly used classical time series methods are ARMA (autoregressive moving average), ARIMA (autoregressive integrated moving average), ARMAX (autoregressive moving average with exogenous variables), and ARIMAX (autoregressive integrated moving average with exogenous variables). Fan and McDonald [3] and Cho *et al.* [4] described implementations of ARIMAX models for load forecasting.

The interest in applying neural networks to electric load forecasting began in 1990. Neural Networks (NN) have parallel and distributed processing structures. As for the STLF problem, the multilayer perceptron (MLP) network is the most widely used one. With the ability to approximate any continuous nonlinear function, the MLP network has very good mapping (forecasting) abilities. Peng *et al*. presented a search procedure for selecting the training cases for ANNs to recognize the relationship between the weather changes and load shape. It utilizes a neural network algorithm that includes a combination of linear and non-linear terms which map past load and temperature inputs to the load forecast output. The single forecast output is the total daily load [5]. Lu *et al*. used a similar feed-forward neural network incorporating the previous

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

load demands, day of week, hour of day and temperature information for load forecasting [6]. Papalexopoulos *et al.* proposed the inclusion of additional input variables such as a seasonal factor and a cooling/heating degree into a single neural network [7]. An alternative technique for load forecasting using recurrent high order neural networks was considered in Kariniotakis *et al.* [8]. This type of neural network is supposed, in theory, to approximate very accurately any non-linear function, with exponential error convergence to zero [9]. Based on an interpolation procedure, the method gives superb results in training; in testing, however, the results are rather disappointing. The lack of generalization can be explained by the fact that the specific method needs an enormous number of training patterns in order to create a satisfactory input/output mapping. In this work, the training data set was created from the whole year of 1994 and the testing set for the first four months of 1995. The relatively small training data set had, as a consequence, the poor performance of the recurrent high order neural network model, despite its perfect training phase.

Many attempts by researchers have been made to improve load-forecasting process in many worldwide regions. Khan and Abraham [10] used a hybrid of neural network and fuzzy logic to forecast the load in Czech Republic. They found that hybrid fuzzy neural network and radial basis function networks are the best candidates for the analysis of the load in Czech Republic. Another study by Kodogiannis and Anagnostakis [11] discussed the development of improved neural-network-based short-term electric load-forecasting models for the power system of the Greek island of Crete. The performance was evaluated through a simulation study, using metered data provided by the Greek Public Power Corporation. Their results indicated that the load-forecasting models developed provided more accurate forecasts than the conventional methods.

NN models basically use the sigmoid activation function in neurons. However, the sigmoid function is not orthogonal, and the energy of the sigmoid function is limitless, and this leads to slow convergence. Wavelet function is a waveform that has limited duration and an average value of zero. The integration of the localization properties of wavelets and the learning abilities of NN shows advantages of Wavelet neural networks (WNN) over NN in complex nonlinear system modeling. A WNN that uses wavelet functions have been proposed by researchers for solving approximation and classification problems [12]. In this paper we present a methodology that follows the time series approach. In our case a novel fuzzy wavelet neural network traces previous load patterns and predicts a load pattern using recent load data without using weather information for modeling. The developed system identifies the load model, which reflects the stochastic behavior of the hourly load demand for the island of Crete in Greece. The balance of this paper contains also a comparative study of various other prediction techniques used to develop the STLF for the power system of Crete.

II. THE SHORT-TERM LOAD FORECASTING PROBLEM

This section is dealing with the application of the developed STLF models on the power system of the island of Crete. Public Power Corporation of Greece is the main provider of the electric power in Crete. Although the island has a population of around 600.000, during summer its total population is almost doubled due to the high tourist season. The island's electric system can be considered as small-scale one; hence serious damages could be suffered by small disturbances-overload. Thermoelectric power stations in two areas, Chania and Heraklion provide the necessary power. The later in Chania is composed of 4 (wind-turbine) units with total power of 202.5 MW. The former in Heraklion is composed of 12 (gas-turbine) units with total power of 192.9 MW. The objective of STLF is to predict the 24 hourly loads of the next day. Here, a modular-constructed forecasting system is proposed, where 24 neural blocks with a single output have to be developed and trained separately to represent the 24 hourly loads respectively. The outline of the proposed architecture is illustrated in Fig. 1.

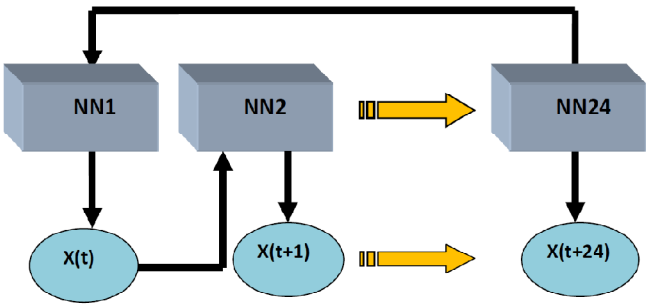

Figure 1. Proposed modular architecture for the STLF problem

Each neural block is fed by its previous. Hence, step-by-step, 24-hour load prediction can be obtained. In this work, the training data set was created from the whole year of 1994 and the testing one for the first four months of 1995. Both training and testing sets were classified into 24 time series, each one corresponds to a different daily hour. Therefore, for each neural block, the following non-linear load model is proposed for one-hour ahead forecasting:

$$x(t) = F\{ x(t-24l), x(t-k), x(t-24l - k) \}$$
$$l = 1,...,p \qquad k = 1,...,q \tag{1}$$

where p and q indicate the number of previous days and hours respectively. The main objective of the proposed system is the development of sufficiently accurate blocks representing the individual hourly loads. The investigation of a novel fuzzy wavelet neural network (FWNN) for system modelling has been carried out for the prediction of all 24h, each one trained separately, one for each hour. In the proposed scheme, a wavelet neural network has replaced the classic TSK model in the consequent part usually found in neuro-fuzzy schemes, while subtractive clustering has been applied to the definition of fuzzy rules. An assumption has been made in the case of black-outs, which occurred during the whole year. All the zero load values have been removed from both training and testing sets, and were replaced by the mean value of the preceding and subsequent load value. Eq. (1) is used to provide the input variables to the individual blocks. According to Eq. (1), the

requested load is forecast using not only the load data of previous days, but also the forecast load data for the same day at previous time steps. In the following sections, only results that correspond to hours with the maximum (14:00 h) and minimum (02:00 h) load consumption are illustrated.

III. MODELLING USING FWNN

A. Wavelet Neural Networks

Wavelet techniques can offer added insight and performance in data analysis situations where Fourier techniques have previously been used. The idea of using wavelets in neural networks has been proposed by Zhang and Benveniste [13]. The fundamental of WNN is looking for a series of appropriate wavelet basis functions in wavelet space. This process can be realised by iteration computation of wavelet basis function, which is to make the energy function minimized. To design a WNN, the main work is to design network structure, to determine the number of nodes in the middle layer, and to choose the wavelet basis function and the learning algorithm of weights training. Compared to the multilayer perceptron neural network (MLP), WNNs provide some advantages, such as the learning efficiency and the structure transparency. However, the problem of basis function networks is also led by it. Due to the crudeness of the local approximation, a large number of basis function units have to be employed to approximate a given system. In order to take advantage of the local capacity of the wavelet basis functions while not having too many hidden units, in this paper we propose an alternative type of WNN which has been influenced from related neuro-fuzzy architectures. The architecture of the proposed multiplication wavelet neural network-linear coefficients weights (LCW-MWNN) is shown in Fig. 2 [14].

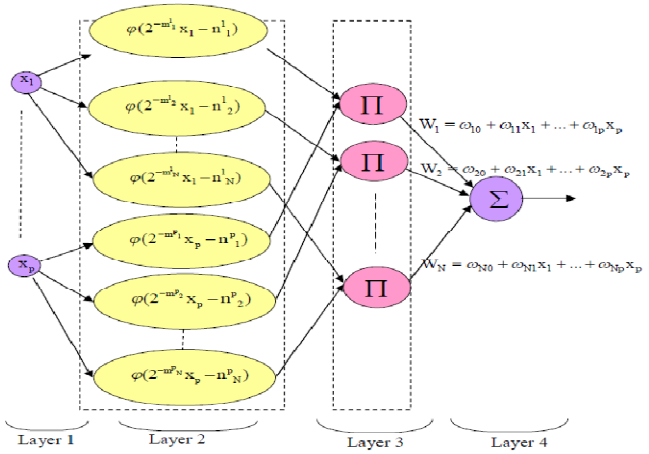

Figure 2. LCW-MWWN architecture

Referring to Fig. 2, Layer 1 accepts the input variables which are in form of $X_j = [x_{j1}, x_{j2}, ..., x_{jp}]^T$, while Layer 2 is used to calculate the wavelet "membership" values. In this layer, each node performs a membership function and acts as an element for membership degree calculation, where a wavelet function is adopted as the membership function. Generally, a WNN approximates any desired signal $y(t)$ by generalising a linear combination of a set of daughter wavelets $\varphi_{m,n}(t)$ which are generated by step sizes dilation and translation m and n from a mother wavelet with either of the forms below:

$$\varphi_{m,n} = \varphi\left(\frac{t-n}{m}\right) \qquad (2)$$
$$\varphi_{m,n} = \varphi(2^{-m}t - n)$$

where $m > 0$. The mother wavelet in the proposed Layer 2 is in the form of $\varphi_{m,n} = \varphi\left(\frac{t-n}{m}\right)$. The wavelet function adopted in this layer, is a modified differentiable version of Morlet wavelet

$$\varphi(x) = \cos(2\pi\beta x)e^{-\frac{x^2}{\upsilon}} \qquad (3)$$

Therefore, the mother wavelet of Eq. 2 from the i^{th} wavelet node connection to the p^{th} input data is expressed as

$$\varphi_{m^p_i, n^p_i}(x^p_j) = 2\pi\beta\left(\frac{x^p_j - n^p_i}{m^p_i}\right)e^{\frac{-\left(\frac{x^p_j - n^p_i}{m^p_i}\right)^2}{\upsilon}} \qquad (4)$$

This wavelet is derived from a function that is proportional to the cosine function and Gaussian probability density function. The nodes of Layer 3 are regarded as the "wavelet" rules in association to the fuzzy rules in a neuro-fuzzy architecture. The number of the "wavelet" membership functions for each input variable is equal to the number of "wavelet" inference rules. These units are fixed, meaning that no modifiable parameter is associated with them. The multiplicative inference (Larsen product operator) has been used, thus the output of this inference layer is given by

$$\phi_i(x_j) = \prod_{p=1}^{P} \varphi_{m^p_i, n^p_i}(x_j), \qquad p=1,2,..P \;\; j=1,2,..N \;\; i=1,2,..C \qquad (5)$$

The proposed approach differs from the conventional fuzzy rule table approaches. In those models, an input space is divided into $K_1 \times K_2 \times .... \times K_n$ fuzzy subspaces, where K_p, $p = 1,2,..,n$ is the number of fuzzy subsets for the p^{th} input variable. There is a fuzzy rule for each of these subspaces. The main drawback of that approach is that the number of fuzzy rules increases exponentially with respect to the number of inputs n. The structure of the output Layer 4, has been designed in the form of a local model $f(x_1, x_2, ..x_p)$, identical to the output layer appeared in *Takagi-Sugeno-Kang* (TSK) defuzzification schemes. For modelling of dynamic processes, TSK schemes possess an excellent interpretation, which is superior to most, if not all, alternative approaches. Usually $f(x_1, x_2, ..x_p)$ is a polynomial in the input variables x_p but it can be any function as long as it can appropriately describe the output of the model within the fuzzy region specified by the antecedent of the rule. When $f(x_1, x_2, ..x_p)$ is a first-order polynomial, the resulting fuzzy inference system is called a

first-order Sugeno fuzzy model. Thus, the output of Layer 4 is given as

$$y = \sum_{i=1}^{C} \left(w_{i0} + w_{i1} x_1 + \ldots + w_{ip} x_p \right) \phi_i(x) \qquad (6)$$

where, the network output is calculated as a weighted sum of the outputs of the local linear models and ϕ_i is interpreted as the operating point dependent weighting factor (i.e. output of Layer 3). Low time consumption is an advantage of this system. The Sugeno-type system is usually used when we operate on numerical (crisp) data. This system can be viewed as switching regression model or mixture of local experts. The scale and translation parameters and local linear model parameters are randomly initialised at the beginning and are optimized by using the Extended Kalman Filter algorithm.

B. Fuzzy EM-based Clustering

An effective approach to the identification of complex non-linear systems is the partitioning of the available data into subsets and approximation each subset by a simple model. This aim is furnished by gathering the objects are more similar to each other in one cluster. The term "similarity" in many cases considered as a *distance norm* from a data vector to a prototype object called as centre. While most classical clustering algorithms assign each datum to exactly one cluster, thus forming a crisp partition of the given data, fuzzy clustering allows for degrees of membership, to which the transitions of the subsets are gradual rather than abrupt (soft membership). Here clustering is based on Expectation Maximization in which the similarity should be understood as the probability that a data belongs to a specific Density. The Density parameter estimation is sought by the algorithm along with partitioning of the data.

Clustering algorithms typically require the user to pre-specify the number of cluster centers and their initial locations; the locations of the cluster centers are then adapted in a way such that these can better represent a set of data points covering the range of data behavior. Fuzzy Subtractive approach is a fast, one pass algorithm for estimating the number of clusters and clusters centers in a set of data. The subtractive clustering method assumes each data point is a potential cluster centre and calculates a measure of the likelihood that each data point would define the cluster centre, based on the density of surrounding data points. For better results it is recommended that normalization of each point into a unit hyper-box would make each dimension to be identical. The algorithm starts by finding the first large cluster, and then goes to find the second, etc [15]. The algorithm is represented in the following lines:

• *Selects the data point with the highest potential to be the first cluster centre. It is done by introducing a potential measure at data point* x_j *, defined as*

$$Pot_j = \sum_{k=1}^{N} \exp\left(-\frac{\left\| x_j - x_k \right\|^2}{(r_a / 2)^2}\right) \quad j = 1,\ldots,N \qquad (7)$$

Where r_a *is a positive constant representing a neighborhood radius and* $\left\| x_j - x_k \right\|^2$ *is the square of Euclidean distance between* x_j *and* x_k *. Hence, a data point will have a high density value if it has many neighbouring data points. After calculating the potential for each vector, the one with the higher potential is selected as the first cluster centre* x_{c1} *.*

• *Removes all data points in the vicinity of the first cluster centre (as determined by radii of all data points to the newly selected cluster centre), in order to determine the next data cluster and its centre location. The first cluster centre* x_{c1} *is chosen as the point having the largest density value* Pot_{c1} *. Next, the density measure of each data point* x_j *is revised as follows:*

$$Pot_j = Pot_j - Pot_{c1} \exp\left(\frac{\left\| x_j - x_{c1} \right\|^2}{(r_b / 2)^2}\right) \qquad (8)$$

Usually the r_b *variable is taken to be as* $1.5 r_a$ *. The process of acquiring new cluster centre is based on potential value in relation to an acceptance threshold* $\overline{\varepsilon}$ *, rejection threshold* $\underline{\varepsilon}$ *, and the relative distance criterion. A data point with the potential greater than the acceptance threshold is directly accepted as a cluster centre. The acceptance of a data point with a potential between the upper and the lower thresholds depends on the relative distance equation, defined as*

$$\frac{d_{min}}{r_a} + \frac{Pot_k}{Pot_1} \geq 1 \qquad (9)$$

where d_{min} *is the shortest distance between the candidate cluster centre and all previously found cluster centers. If Eq. 9 is greater than 1, then the associated x will be considered as a new cluster centre.*

• *Iterates on this process until a sufficient number of clusters is attainted. Since the algorithm is fixed and does not rely on any randomness, the results are fixed. However, we can test the effect of the four parameters, namely, acceptance ratio* $\overline{\varepsilon}$ *, reject ratio* $\underline{\varepsilon}$ *, cluster radius* r_a *and squash factor* r_b *These parameters have influence on the number of clusters and error performance measures. Large values of* $\overline{\varepsilon}$ *and* $\underline{\varepsilon}$ *will result in small number of rules. Conversely small values of* $\overline{\varepsilon}$ *and* $\underline{\varepsilon}$ *will increase the number of clusters. A large value of* r_a *generally result in fewer clusters that lead to a coarse model. A small value of* r_a *can produce excessive number of clusters that may result in an over-defined system.*

IV. CB-FWNN SCHEME

This paper presents a clustering based FWNN (CB-FWNN) that follows an "ANFIS structure" and its details are illustrated in Fig. 3. However significant differences against ANFIS have been considered in the proposed modeling structure. In many fuzzy and neuro-fuzzy models, the kernel of the fuzzy system

is the fuzzy knowledge base that consists of the input–output data points of the system interpreted into linguistic fuzzy rules. The consequent parts of TSK-type fuzzy IF–THEN rules are represented by either a constant or a function. Generally, the function is a linear combination of the input variables plus a constant term. TSK-type systems cannot, in general, model complex processes with desired accuracy using a certain number of rules. These systems do not have localizability; instead model the global features of the process, and their convergence is generally slow. The consequent part of these TSK-types fuzzy networks do not provide full mapping capabilities, and, in the case of modeling of complex nonlinear processes, may require a high number of rules in order to achieve the desired accuracy. Increasing the number of the rules leads to an increase in the number of neurons in the hidden layer of the network. In addition, in such TSK-schemes, the gradient decent method is usually used to train the non-linear antecedent parameters. However in the proposed structure instead of a linear function, a novel Linear Combination Multiplication Weight Wavelet Neural Network (LCW-MWNN) has been utilized. The specific model integrated two learning schemes; Weighted Least Square as well as the classic gradient descent (GD) learning algorithms. However, GD scheme is characterized by slow convergence training speed. Hence, in this study, the scale and translation parameters and local linear model parameters which have been randomly initialized at the beginning are optimized by using the Extended Kalman Filter algorithm.

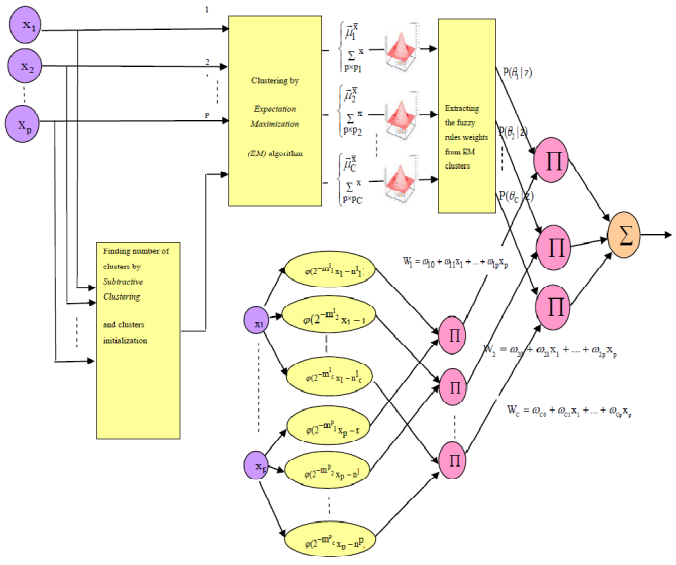

Figure 3. CB-FWNN proposed structure

In order to design the CB-FWNN structure, we assume initially, that one cluster in the input-output space corresponds to one potential fuzzy logic rule. Then the first step in structure learning is the determination of the number of fuzzy sets in the universal of discourse of each input variable [16]. In this research, the number of clusters are determined by subtractive clustering based on the training data as described earlier and remain constant throughout. Once the number of clusters defined, then the layout of the desired CB-FWNN can be sketched. At the consequence section, different scales of wavelet-neurons $\varphi_{x^p}(m_i^p, n_i^p)$ assigned for every dimension of the input. Although the number of different scales/ translation allocated to each dimension is fixed, each of inputs can be associated with different scales/translations. Knowing the optimum number of clusters, the number of different scales which each input dimension is going to be decomposed then can be determined, while the known number of clusters could assist in the determination of the number of fuzzy rules c as well as to the number of unknown parameters at the antecedent section. CB-FWNN's output is formulated as,

$$\begin{aligned}\hat{y}_j &= \sum_{i=1}^{C} \gamma_i(X_j) W_i(X_j) \phi_i(X_j) \\ &= \sum_{i=1}^{C} \gamma_i(X_j) W_i(X_j) \prod_{p=1}^{P} \varphi_{m_i^p, n_i^p}(x_j) \\ &= \sum_{i=1}^{C} W_i(X_j) \gamma_i(X_j) \left(\prod_{p=1}^{P} \cos\left(2\pi\beta\left(\frac{x_j^p - n_i^p}{m_i^p}\right)\right) e^{\frac{-\left(\frac{x_j^p - n_i^p}{m_i^p}\right)^2}{\upsilon}}\right)\end{aligned} \tag{10}$$

The conditional density $p(y \mid x)$ is a mixture of Gaussians functions at the output of clustering sub-unit therefore the regression problem is re-formulated also as

$$\begin{aligned}\hat{y}_j &= f(x) = E[y_j \mid x_j] \\ &= \int_y y_j p(y_j \mid x_j) dy = \frac{\int y_j p(x_j, y_j) dy}{p(x_j)} \\ &= \sum_{i=1}^{C} \frac{[W_i \phi_i(x_j)] p(x_j \mid \theta_i) p(\theta_i)}{p(x_j)} = \sum_{i=1}^{C} W_i \times P(\theta_i \mid x_j)[\phi_i(x_j)]\end{aligned} \tag{11}$$

where $\phi_i(x_j)$ is related to the i^{th} from c LCW-MWNN outputs, and the j^{th} input vector. $W_i(X_j)$ is the linear combination weight and $P(\theta_i \mid X_j)$ is the probability that the i^{th} Gaussian component is generated by the input vector X_j as depicted in the following equation, which replaces γ in eq. 10.

$$P(\theta_i \mid x_j) = \frac{\frac{P(\theta_i)}{(2\pi)^{p/2}\sqrt{|\Sigma_i|}} \exp\left(-\frac{1}{2}(x_j - \mu_i)^T (\Sigma_i)^{-1} (x_j - \mu_i)\right)}{\sum_{i=1}^{C} \frac{P(\theta_i)}{(2\pi)^{p/2}\sqrt{|\Sigma_i|}} \exp\left(-\frac{1}{2}(x_j - \mu_i)^T (\Sigma_i)^{-1} (x_j - \mu_i)\right)} \tag{12}$$

The final output based on dynamics of the proposed structure is derived by merging Eqs. 10 and 11 and have the following form

$$\hat{y}_j = \sum_{i=1}^{C} W_i(X_j) \times P(\theta_i \mid X_j) \left(\prod_{p=1}^{P} \cos\left(2\pi\beta\left(\frac{x_j^p - n_i^p}{m_i^p}\right)\right) e^{\frac{-\left(\frac{x_j^p - n_i^p}{m_i^p}\right)^2}{\upsilon}}\right) \tag{13}$$

The cluster parameters in this proposed scheme are estimated with the use of Expectation Maximization algorithm, while the Wavelet Neural Network parameters have been modified by Extended Kalman Filter and Weighted Least Square. The

choice of EM algorithm is justified by the fact that this approach avoids numerical instabilities encountered in Gradient Decent algorithm and presents an improved learning convergence.

V. RESULTS

This section presents the results and the statistics of forecasts obtained from the application of the developed STLF models on the power system of the island of Crete. Case studies for the proposed methods were carried out for a 24-hour load forecasting. The complete results for the STLF problem, for the hours with minimum and maximum load consumption, are illustrated in Table 1. Training has been conducted using power load data for 1994 (365 data points), while testing has been evaluated using data from the 4 first months of 1995.

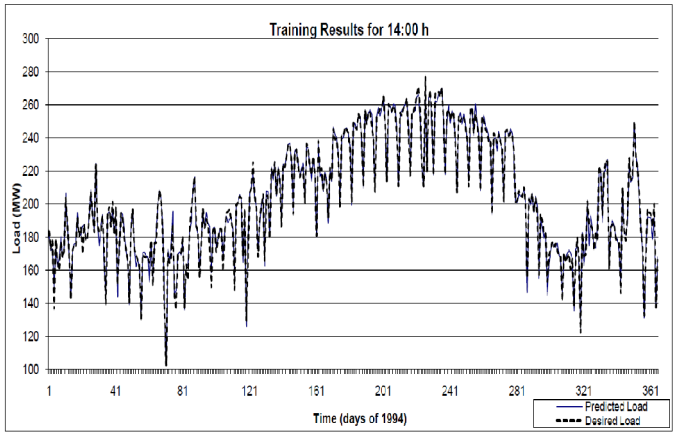

Figure 4. Training performance for max load

An obvious advantage of the proposed modular architecture is that, since the complete system consists of 24 neural blocks, each one with a single output, training is easier and faster compared to traditional neural approaches, which treat the output as a 24x1 vector. After many trials, it has been found that only two previous time load parameters are necessary for the proposed CB-FWNN to achieve an acceptable performance.

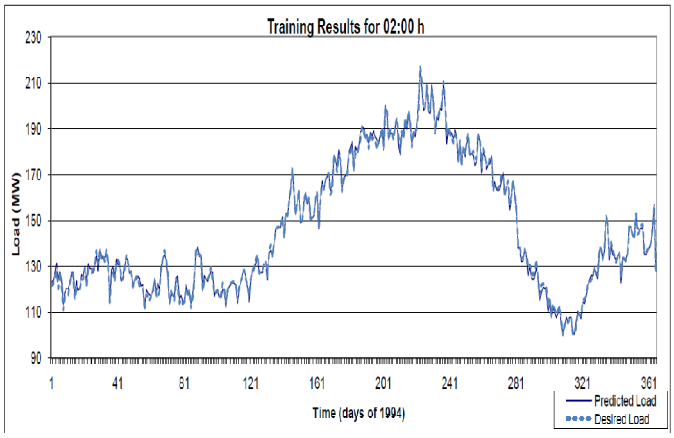

Figure 5. Training performance for min load

Fig. 4 and 5 illustrate the training performances on both minimum and maximum power consumption cases. Table I summarizes the various performance indices. The regression coefficient (R^2) is often used as an overall measure of the prediction attained. It measures the fraction of the variation about the mean that is explained by a model. The higher the value ($0 \le R^2 \le 1$), the better is the prediction by the model. The FWNN scheme developed herein was found to yield high level agreement with experimental observations for the test data set. The values of the coefficient of determination (R^2), as shown in Table I, indicate a very good fit of the experimental data from the FWNN-based approach.

TABLE I PERFORMANCE INDICES

Statistical index	Testing Data sets	
	14:00	02:00
Coefficient of determination (R^2)	0.9804	0.9654
Root mean square error (RMSE)	4.9492	2.6664
Mean absolute relative error (MARE) (%)	2.0481	1.3029
Mean Square Error	24.4943	7.1099
Standard error of prediction (SEP) (%)	2.7021	2.0324
Bias factor (B_f)	1.0089	1.0052
Accuracy factor (A_f)	1.0205	1.0131
Deviation	4.9492	2.6664

However, R^2 is a suitable criterion for model comparison on the assumption that the error is normally distributed and not dependent on the mean value. In fact, the distribution of the error is not clearly known, so this term must be used with caution, particularly in non-linear regression models and hence additional indices must be employed for model comparison.

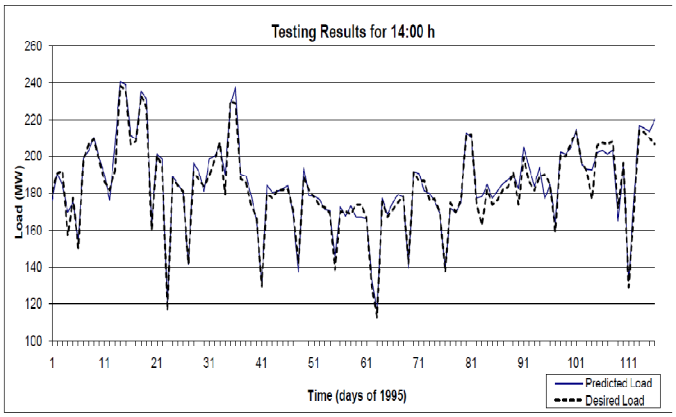

Figure 6. Testing performance for max load

The RMSE index is calculated between the desired and output values and then averaged across all data and it can be used as an estimation of the goodness of fit of the models. It can also provide information about how consistent the model would be in the long run. The MARE term provides information on how close forecasts or predictions are to the eventual outcomes. The SEP index is determined as the relative deviation of the

mean prediction values and it has the advantage of being independent on the magnitude of the measurements. Based on this index, the FWNN scheme achieved again a very good performance. The usual measures of goodness-of-fit for model comparison in many applications is performed by calculating in addition to squared correlation coefficient (R^2) the bias (B_f) and accuracy (A_f) indices [17]. Models describing predictions with B_f in the range of $\{0.9-1.05\}$ could be considered good, in the range of $\{0.7-0.9\} || \{1.06-1.15\}$ are considered acceptable, while for $\{<0.7 \;||\; >1.15\}$ are considered unacceptable. Bias factor is a multiplicative factor that compares model predictions and is used to determine whether the model over- or under-predicts the power consumption. A B_f greater than 1.0 indicates that a growth model is fail-dangerous.

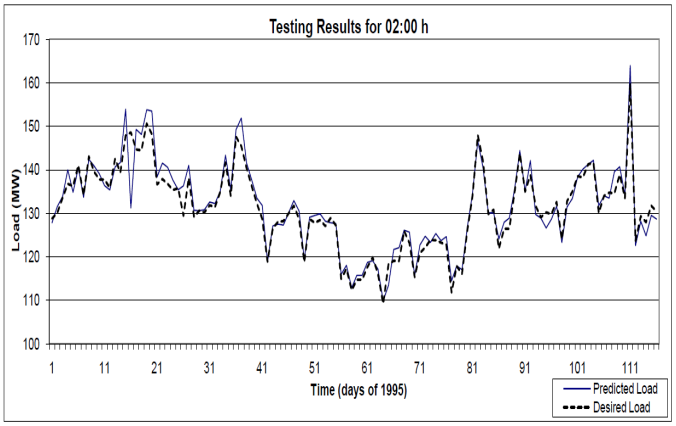

Figure 7. Testing performance for min load

Conversely, a B_f less than 1.0 generally indicates that a growth model is fail-safe, i.e. observed generation times were larger than predicted values, so that predicted values give a margin of safety. Perfect agreement between predictions and observations would lead to B_f of 1. The accuracy factor (A_f), is a simple multiplicative factor indicates the spread of results about the prediction. A value of 1 indicates that there is perfect agreement between all the predicted and measured values. Table I also shows the bias and accuracy factor values obtained for the two testing cases. Figs. 6 and 7 illustrate the testing performances for both cases. In order to evaluate the goodness of the current performance of the proposed FWNN scheme, a comparison against traditional neural networks using the same datasets has been made [11]. For the maximum load consumption, the MARE indices for MLP and RBF networks were 11.967 and 2.792 respectively, while for the minimum load case, the relevant values were 2.734 and 1.35. This comparison reveals the superiority of the proposed CB-FWNN scheme.

VI. CONCLUSIONS

This paper presented the development of a novel fuzzy wavelet neural network model and validated its prediction on the short-term electric load forecasting of the Power System of the Greek Island of Crete. In the proposed scheme, a wavelet neural network has replaced the classic TSK model in the consequent part, while subtractive clustering has been applied to the definition of fuzzy rules. The forecasting error statistical results, corresponding to the minimum and maximum load time-series, indicate that the proposed load forecasting model provides more accurate forecasts, compared to conventional neural networks models such as MLP and RBF. It should be noted that the proposed structures differ from the usual time-series prediction models since they include only loads for both previous times and previous days for hourly load forecasting. In a future work, the present approach will be enhanced by using additional load and weather information such as illuminations level, temperature, humidity, wind direction and industrial load.

Sheffield, UK
qian.zhang@sheffield.ac.uk, m.mahfouf@sheffield.ac.uk

***Abstract*—In high-dimensional modelling cases, a fuzzy modelling approach based on the grid-partitioning of fuzzy sets always meets great challenges, as it cannot avoid the problem of introducing a huge number of fuzzy rules. To tackle this issue, a new grid-partitioning based fuzzy modelling paradigm is proposed in this paper to construct a compact fuzzy system by including 'short fuzzy rules', in which only a few but strategic premises are used. In the proposed approach, the generation of fuzzy rules is data-orientated, a consideration which can greatly reduce the computational complexity. A new framework for fuzzy reasoning and defuzzification is also devised, which employs some archived reference data to help choose the most suitable fuzzy rules. In material engineering, describing the behaviour of mechanical properties of alloys is often a high-dimensional modelling problem, which involves the complexity of materials' chemical composites and their underlying physical processing mechanisms. In this paper, the proposed approach was successfully applied to generate models of ultimate tensile strength of alloy steel. Compared with the standard grid-partitioning based fuzzy modelling paradigms, the new method shows an improvement in both complexity and interpretability. Compared with the clustering-based fuzzy modelling approaches, the proposed method can achieve the same accuracy level and is more transparent.**

Keywords-fuzzy; high-dimensional modelling; grid partitioning; interpretability; short fuzzy rule; alloy steel; mechanical property

I. INTRODUCTION

There are many complex real-life modelling problems for which precise physical models do not currently exist, while abundant data that represent the input-output relationships can be collected. In this situation, some forms of intelligent systems associated with data-driven techniques, such as fuzzy rule-based systems and artificial neural networks (ANNs), appear to be suitable for model construction.

The fundamental concepts related to fuzzy rule-based systems were first introduced by Zadeh [1], [2]. They are known as robust universal approximators and allow a system to be represented using an explicit knowledge representation (linguistic 'IF-THEN' rules), which can easily be understood and explained by humans to allow them to gain a deeper insight into uncertain, complex, and ill-defined systems [3]. Compared with artificial neural networks, fuzzy systems are more transparent to humans to interpret. This is the most attractive property that distinguishes fuzzy systems from other black-box modelling approaches.

Normally, data-driven fuzzy modelling can be realised via two different routes: the grid-partitioning based method or the data-clustering based method. In the first method, the grid-partitioning initially defines a number of well-distributed fuzzy sets for each variable. The corresponding fuzzy rules are then elicited based on the fixed partitioning of fuzzy sets. In this approach, the fuzzy sets are also shared by all the fuzzy rules. In contrast, the second method employs data clustering (grouping) [4] information to define both the fuzzy sets and the fuzzy rules simultaneously. In this method, one cluster is associated to one fuzzy rule; the fuzzy sets are not shared by all the rules, but each set is only mapped into one particular fuzzy rule.

Compared with the grid-partitioning based method, the data-clustering based method needs less fuzzy rules to achieve a certain accuracy level; nevertheless its fuzzy sets are not evenly and well distributed and are not consistent with human knowledge and understanding. The grid-partitioning based method produces more interpretable systems, but it cannot avoid the problem of introducing a huge number of fuzzy rules for high-dimensional modelling problems. Another problem lies in high-dimensional modelling cases where a fuzzy rule may include too many antecedent conditions, a fact that defeats the interpretability property.

In this paper, a modelling paradigm using 'short fuzzy rules' is proposed to solve the above problems, where only a few but strategic antecedent conditions (premises) are included in a 'short fuzzy rule'. This remarkably decreases the number of fuzzy rules, as one short fuzzy rule possesses more powerful generalisation ability and can cover a wider input space. On the other hand, the short expression of fuzzy rules is much easier to be understood by a human. Table 1 illustrates the comparison among different fuzzy modelling paradigms.

TABLE I. COMPARISON OF THE PROPOSED APPROACH OF 'SHORT FUZZY RULES' WITH OTHER FUZZY MODELLING PARADIGMS

		Clustering based methods	*Grid-partitioning based methods*	*The proposed method*
Interpretability	*Number of fuzzy rules*	Good	Bad	Medium
	The length of fuzzy rules	Bad	Bad	Good
	The number of fuzzy sets	Medium	Good	Good
	The distribution of fuzzy sets	Bad	Good	Good
	General performance	Medium	Medium	Good
Accuracy		Good	Medium	Medium

The remaining parts of this paper are organised as follows. Section II introduces the fuzzy systems with short fuzzy rules. Section III describes the proposed method to generate the compact fuzzy system. In Sections IV and V, a modified fuzzy reasoning and defuzzification mechanisms and a new framework for the proposed fuzzy system are proposed. Section VI presents an experimental study relating to the modelling of the mechanical property of the alloy steel. Finally, concluding remarks are drawn in Section VII.

II. FUZZY SYSTEMS WITH SHORT FUZZY RULES

Generally, a fuzzy rule-based system consists of four fundamental components: a fuzzy rule-base, a fuzzy inference engine, a fuzzifier, and a defuzzifier. Fig. 1 shows the diagram of a fuzzy system. The central part of a fuzzy system is the knowledge-base (rule-base) consisting of fuzzy rules. A fuzzy rule is an IF-THEN statement in which some words are characterised by continuous membership functions. All other components are used to implement these rules in a reasonable and in an efficient manner. The fuzzifier represents a mapping from a real-valued point $\boldsymbol{x} \in U \subset R^i$ to a fuzzy set $\boldsymbol{A}$ in U, which is defined by a membership function $\mu_A(\boldsymbol{x})$: $\boldsymbol{A} \rightarrow [0, 1]$. In a fuzzy inference engine, fuzzy logic principles direct how to employ the fuzzy rules into a mapping from an input fuzzy set $\boldsymbol{A}$ to an output fuzzy set B. The defuzzifier is a mapping from the output fuzzy set B in $V \subset R$ to a real-valued point $y \in V$. Conceptually, the purpose of the defuzzifier is to specify a point in V that best represents B [5].

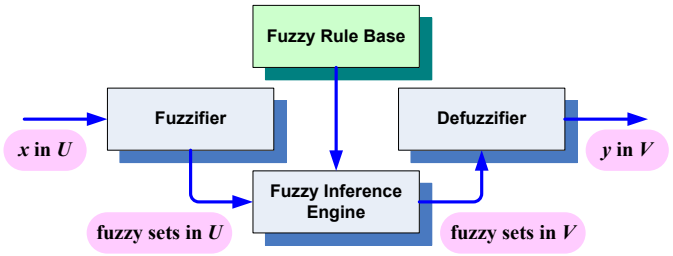

Figure 1. The basic configuration of fuzzy systems.

For an i-input 1-output system, a fuzzy rule-base could comprise the following Mamdani fuzzy rules:

Rule$_j$: IF x_1 is A_{1j} AND x_2 is A_{2j} AND … AND x_i is A_{ij}, THEN y is B_i.

where $\boldsymbol{x} = (x_1, x_2, \ldots, x_i)^T \in U$ and $y \in V$ are the input and output (linguistic) variables of the fuzzy system; A_{ij} and B_i are fuzzy sets in $U_i \subset R$ and $V \subset R$, respectively.

In some literatures [6], '*don't care*' is employed as an additional antecedent fuzzy set, which is fully compatible with any input value. Its membership function is defined as follows:

$$\forall x: \ \mu_{don't\ care}(x) = 1. \tag{1}$$

Since '*don't care*' conditions are usually omitted from the antecedent part, fuzzy rules with many '*don't care*' conditions are short and interpretable. The following shows an example of a fuzzy rule with '*don't care*' conditions:

IF x_1 is *don't care* AND x_2 is *medium* AND x_3 is *don't care*, THEN y is *large*.

If two '*don't care*' conditions are omitted, the above fuzzy rule can be shortened as follows:

IF x_2 is *medium*, THEN y is *large*.

In this paper, the number of antecedent conditions (premises) of each fuzzy rule is referred to as the rule length. In the above case, the rule length is reduced from 3 to 1 by using the '*don't care*' label.

III. GENERATION OF THE 'COMPACT FUZZY SYSTEM'

Generally, when constructing a fuzzy system, the fuzzy inference engine and the defuzzifiers are predefined. In the grid-partitioning based method, the uniformly-distributed fuzzy sets are also predefined for each variable. Thus, the primary work becomes to generating appropriate fuzzy rule-base.

In this work, the following steps are executed to elicit short fuzzy rules for the 'compact fuzzy system':

A. *Find candidate short fuzzy rules from all possible fuzzy rules*

The possible fuzzy rules include every combination of linguistic terms, although they are too many to be comprehensively evaluated. Suppose an i-input 1-output system has k linguistic terms (excluding '*don't care*') for every input variable and l linguistic terms for the output variable, the number of possible fuzzy rules could be $(k+1)^i * l$. The number of possible short fuzzy rules with rule length being 1 is $i*k*l$ and the number of possible short fuzzy rules with rule length being 2 is $\frac{i*(i-1)}{2} * k^2 * l$. In this paper, only the fuzzy rules no longer than 2 are considered.

As stated above, for a high-dimensional modelling problem, the possible short fuzzy rules may even be too many to be evaluated. In order to further decrease the number of candidate rules, it is required that only the rule that covers at least one training data point is considered as a candidate fuzzy rule.

Let $\boldsymbol{C}$ be a set of m training data $\boldsymbol{c}_n$, where $\boldsymbol{c}_n = [\boldsymbol{x}_n, y_n]^T = [x_{1n}, x_{2n}, \ldots, x_{in}, y_n]^T$ and $n = 1, 2, \ldots, m$. $Rule_j$ is regarded as a candidate short fuzzy rule, if

$$\exists n: \min\left(\mu_{A_{1j}}(x_{1n}), \mu_{A_{2j}}(x_{2n}), \ldots, \mu_{A_{ij}}(x_{in}), \mu_{B_j}(y_n)\right) > Th_1, \tag{2}$$

where 'Th_1' is a threshold value and it is set to 0.5 in this work without any loss of generality.

B. Calculate the 'confidence' value for each candidate short fuzzy rule

To estimate whether a fuzzy rule is redundant or not, an evaluation measure '*confidence*' is applied [7], [8]. In the area of data mining, it has been used for evaluating association rules in the pattern classification problem. The *confidence* of rule $\boldsymbol{A} \rightarrow B$ is defined as follows:

$$conf(\boldsymbol{A} \rightarrow B) = \frac{|C(\boldsymbol{A}) \cap C(B)|}{|C(\boldsymbol{A})|} \tag{3}$$

where $|C(\boldsymbol{A})|$ is the number of training patterns that are compatible with the antecedent $\boldsymbol{A}$, and $|C(\boldsymbol{A}) \cap C(B)|$ is the number of training patterns that are compatible with both the antecedent $\boldsymbol{A}$ and the consequent B. This *confidence* measure indicates that *conf*×100% of the training patterns that are compatible with the antecedent $\boldsymbol{A}$ are also compatible with the consequent B. In [7, 8], the *confidence* measure is extended to the fuzzy case and can be rewritten as follows:

$$conf(\boldsymbol{A} \rightarrow B) = \frac{|C(\boldsymbol{A}) \cap C(B)|}{|C(\boldsymbol{A})|} = \frac{\sum_{n=1}^{m}\left(\mathrm{N}_{\boldsymbol{A}}(\boldsymbol{x}_n) \times \mu_B(y_n)\right)}{\sum_{n=1}^{m}\mathrm{N}_{\boldsymbol{A}}(\boldsymbol{x}_n)} \tag{4}$$

where $\mathrm{N}_{\boldsymbol{A}}(\boldsymbol{x}_n)$ is the compatibility grade of the input vector $\boldsymbol{x}_n$ with the antecedent part $\boldsymbol{A} = [A_1, A_2, \ldots, A_i]^T$ of the fuzzy rule, and $\mu_B(y_n)$ is the compatibility grade of the output value y_n with the consequent part B of the rule. $\mathrm{N}_{\boldsymbol{A}}(\boldsymbol{x}_n)$ is usually defined by the minimum operator or the product operator. Such as:

$$\mathrm{N}_{\boldsymbol{A}}(\boldsymbol{x}_n) = \min\left(\mu_{A_{1j}}(x_{1n}), \mu_{A_{2j}}(x_{2n}), \ldots, \mu_{A_{ij}}(x_{in})\right) \text{ or} \tag{5}$$

$$\mathrm{N}_{\boldsymbol{A}}(\boldsymbol{x}_n) = \mu_{A_{1j}}(x_{1n}) \times \mu_{A_{2j}}(x_{2n}) \times \ldots \times \mu_{A_{ij}}(x_{in}). \tag{6}$$

In this work, these *confidence* values are also saved as the rule weights and will be further used in the defuzzification stage, as will be seen in Section IV.

C. Determine the final short fuzzy rule-base

A subset of candidate short fuzzy rules is selected as the active rule-base by taking into account the obtained *confidence* values. It is designed as the minimum subset of candidate rules which have the largest *confidence* values and can also cover all the training data. Specifically, if RS_p represent the selected rules and RU_q represent those unselected rules,

$$\min_p conf(RS_p) \geq \max_q conf(RU_q), \tag{7}$$

$$\forall n, \exists p: \min\left(\mu_{A_{ip}}(x_{1n}), \mu_{A_{2p}}(x_{2n}), \ldots, \mu_{A_{ip}}(x_{in}), \mu_{B_p}(y_n)\right) > Th_2 \tag{8}$$

where $conf(RS_p)$ is the *confidence* value of the pth short fuzzy rule RS_p; Th_2 is a threshold and a value 0.5 is used in this work without any loss of generality.

IV. Fuzzy Reasoning and Defuzzification

Because of the different rule structures of the compact fuzzy system and standard fuzzy systems, it is not appropriate to implement the traditional fuzzy reasoning and defuzzification methods directly. For a compact fuzzy system with short fuzzy rules, the following two issues should be addressed. First, a shorter rule describes a more general circumstance and a longer rule reflects a more specific situation. In a system including various rule lengths, longer rules should have higher priority to take effect. Second, among the rules with the same rule length, each makes a different level of impact on the system. This can be observed from a variety of *confidence* values for different fuzzy rules. In this work, both of the above issues are taken into account in the proposed fuzzy reasoning and defuzzification mechanism.

Suppose the product inference engine and the centre average defuzzifier [5] are employed, the system output $y(\boldsymbol{x})$ is calculated as follows:

$$y(\boldsymbol{x}) = \frac{\sum_p \mathrm{N}_{\boldsymbol{A}_p}(\boldsymbol{x}) \times b_p}{\sum_p \mathrm{N}_{\boldsymbol{A}_p}(\boldsymbol{x})} \tag{9}$$

where $\mathrm{N}_{\boldsymbol{A}p}(\boldsymbol{x})$ is the compatibility grade of the input vector $\boldsymbol{x}$ with the antecedent part $\boldsymbol{A}_p = [A_{1p}, A_{2p}, \ldots, A_{ip}]^T$ of the fuzzy rule RS_p; b_p is a representative real number of the consequent fuzzy set B_p (the centre of its membership function). $\mathrm{N}_{\boldsymbol{A}p}(\boldsymbol{x})$ is usually defined by the minimum operator or the product operator. Such as:

$$\mathrm{N}_{\boldsymbol{A}_p}(\boldsymbol{x}) = \min\left(\mu_{A_{1p}}(x_1), \mu_{A_{2p}}(x_2), \ldots, \mu_{A_{ip}}(x_i)\right) \text{ or} \tag{10}$$

$$\mathrm{N}_{\boldsymbol{A}_p}(\boldsymbol{x}) = \mu_{A_{1p}}(x_1) \times \mu_{A_{2p}}(x_2) \times \ldots \times \mu_{A_{ip}}(x_i). \tag{11}$$

By considering both the rule length and the rule weight, the above equation can be amended as follows:

$$y(\boldsymbol{x}) = \frac{\sum_p (l_{RS_p})^{conf_{RS_p}} \times \mathrm{N}_{\boldsymbol{A}_p}(\boldsymbol{x}) \times b_p}{\sum_p (l_{RS_p})^{conf_{RS_p}} \times \mathrm{N}_{\boldsymbol{A}_p}(\boldsymbol{x})}. \tag{12}$$

where l_{RSp} is the rule length of the pth short fuzzy rule RS_p, and $conf_{RSp}$ is the rule weight (*confidence* value) of RS_p.

V. A New Framework for the Compact Fuzzy System

After some initial experimental tests, it was found that the above compact fuzzy system always tends to yield a moderate prediction. The reason behind this may lie in the existing parallel fuzzy rules, which have similar or the same antecedent conditions but dissimilar consequent parts. To distinguish which rules should be applied in a certain situation, a new framework for the compact fuzzy system is proposed, as shown in Fig. 2.

The modified system will not use all the fuzzy rules including in the rule-based in the fuzzy inference engine. Only a set of relevant fuzzy rules, which is carefully selected by comparing their compatibility with the relevant reference data, will be employed into the fuzzy reasoning.

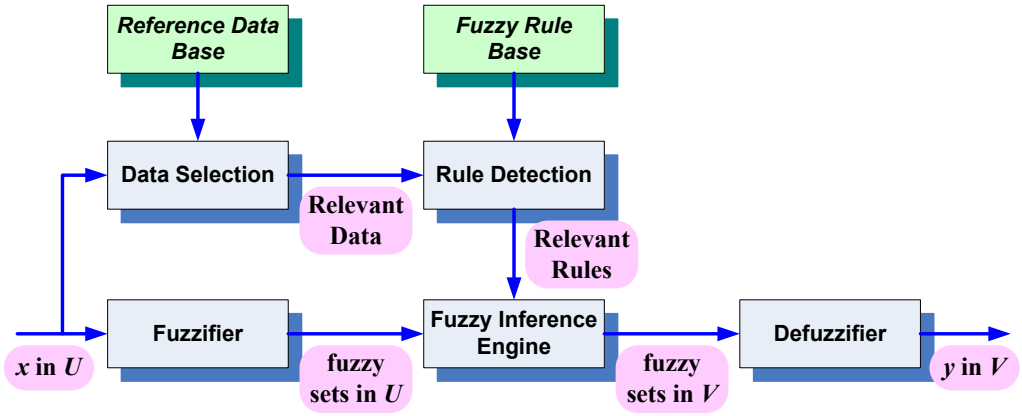

Figure 2. The diagram of the proposed fuzzy system.

Specifically, when a set of inputs $\boldsymbol{x} = [x_1, x_2, \ldots, x_i]^T$ goes into the system, it will be compared with the archived reference data set $\boldsymbol{C}_R = [\boldsymbol{c}_{R1}, \boldsymbol{c}_{R2}, \ldots, \boldsymbol{c}_{Rr}]$, where $\boldsymbol{c}_{Rr} = [\boldsymbol{x}_{Rr}, y_{Rr}]^T = [x_{1Rr}, x_{2Rr}, \ldots, x_{iRr}, y_{Rr}]^T$ and r is the number of all the reference data, and the most similar data $\boldsymbol{C}_S = [\boldsymbol{c}_{S1}, \boldsymbol{c}_{S2}, \ldots, \boldsymbol{c}_{Ss}]$ will be selected, where $\boldsymbol{c}_{Ss} = [\boldsymbol{x}_{Ss}, y_{Ss}]^T = [x_{1Ss}, x_{2Ss}, \ldots, x_{iSs}, y_{Ss}]^T$ and s is the number of the selected reference data. To estimate the similarity between $\boldsymbol{x}$ and a reference data, the Euclidean distance in the input space is calculated. If it is less than a threshold 'Th_3', the reference data are regarded as close to $\boldsymbol{x}$ and they will be selected to be used in the further fuzzy rule detection. This can be described as follows:

$$\boldsymbol{c}_R \subset \boldsymbol{C}_S, \text{ if } \sqrt{\sum_{t=1}^{i}(x_t - x_{tR})^2} < Th_3. \tag{13}$$

In general, 'Th_3' is recommended to be set as follows, without any loss of generality:

$$Th_3 = 0.15 \times \sqrt{\sum_{t=1}^{i}(x_{t\max} - x_{t\min})^2} \tag{14}$$

where $x_{t\max}$ and $x_{t\min}$ represent the maximum value and the minimum value of all the reference data in their tth dimension, respectively.

In the subsequent rule detection, the obtained relevant reference data are employed to identify the most relevant fuzzy rules $\boldsymbol{R}_S$. If a fuzzy rule R is compatible with at least one reference data to some extent, the fuzzy rule is reckoned as relevant and will be passed through fuzzy reasoning phase. This can be described as follows:

$R \subset \boldsymbol{R}_S$, if $\exists n \in [1, 2, \ldots, s]$:

$$\min\left(\mu_{A_1}(x_{1n}), \mu_{A_2}(x_{2n}), \ldots, \mu_{A_i}(x_{in}), \mu_B(y_n)\right) > Th_4, \tag{15}$$

where 'Th_4' is a threshold value and it is set to be 0.5 in this work without any loss of generality.

VI. Prediction of Mechanical Properties

In material engineering, it is crucial to establish transparent and reliable mechanical property prediction models for materials design and development [9]-[11]. But it may be 'tricky' to precisely describe the behaviour of mechanical properties using mathematical models alone due to the complexity of materials' chemical composites and their underlying physical processing mechanisms, such as hot rolling and heat treatment. Thus, developing a fast, efficient and transparent data-driven modelling framework for material property prediction is still a priority.

In the past, some prediction models relating to mechanical properties have been developed, which were mainly based on linear regression methods, artificial neural networks [12], and fuzzy systems [13]-[15]. Such linear models were only designed for specific classes of steels and specific processing routes, and are not sophisticated enough to account for more complex interactions, while neural networks are black-box techniques and the knowledge behind this kind of models cannot be understood fully. The fuzzy modelling techniques included in [13]-[15] employed data clustering information, which lead to a fuzzy rule-base which was not interpretable enough.

Particularly in this work, one of the studied mechanical properties of heat-treated alloy steels, is the Ultimate Tensile Strength (UTS), which represents a measure of the maximum load that a material can withstand. This problem is a high-dimension modelling problem and includes fifteen (15) input variables, which include the weight percentages for various chemical composites as well as the processing parameters of the heat treatment, consisting of the weight percentages for the chemical composites, namely carbon (C), silica (Si), manganese (Mn), sulphur (S), chromium (Cr), molybdenum (Mo), nickel (Ni), aluminium (Al) and vanadium (V), the test depth, the bar size, the treatment site, the quenching medium, as well as the hardening and tempering temperatures. Moreover, this problem is associated with a large amount of industrial data (3760 UTS data), which are not well-distributed and may be quantitatively redundant for training purposes. All the data are provided by Tata Steel Europe. In the following experiment, 60% of the data were used for training, and the remaining 40% were used for final testing. This experiment was repeated 20 times. Only one set of typical results out of the 20 runs is chosen and shown in the following.

For configurations, the number of fuzzy sets for each input variable was set to be 7 and the number of fuzzy sets for the output variable was set to be 15. In such a grid partitioning of input space, the number of all the possible fuzzy rules is $5.28*10^{14}$, the number of possible short fuzzy rules with rule length being 1 is 1575, and the number of possible short fuzzy

rules with rule length being 2 is 77175. By employing the proposed approach, only 214 'short fuzzy rules' were elicited.

Fig. 3 shows the prediction performance (predicted outputs against measured outputs) of the compact fuzzy model using standard fuzzy reasoning and defuzzification. It can be seen that the predictions tend to be of moderate values. Fig. 4 shows the prediction performance of the same model with the new framework introduced in Section IV and the modified reasoning and defuzzification methods proposed in Section V. For this case, the Root Mean Square Error (RMSE) based on the training data and the testing data are 40.05 MPa and 47.92 MPa, respectively. This accuracy is as good as those reported in [14], [15], which established fuzzy models via data-clustering based methods with rules including many antecedents unnecessarily.

For more details about the developed UTS model, Fig. 5 compares the fuzzy rules between a full-length one generated using data clustering techniques [14], [15] and the short ones obtained in this work. It can be seen that the full-length fuzzy rule is too complicated to be interpreted. One can also observe another disadvantage of the fuzzy system elicited from data clustering that the fuzzy sets are not evenly and well distributed. For these fuzzy rules, they can be rewritten as the following approximate linguistic rules using the linguistic hedges approach [16]:

R_1: IF Test Depth is *small* AND Size is *small medium* AND Site Number is *large* AND C is *large medium* AND Si is *medium* AND Mn is *medium small* AND S is *small* AND Cr is *medium small* AND Mo is *medium* AND Ni is *large medium* AND Al is *very small* AND V is *very small* AND Hardening Temperature is *small* AND Cooling Medium Number is *more or less large* AND Tempering Temperature is *medium large*, THEN UTS is *large medium*.

R_2: IF Mn is *large medium*, THEN UTS is *small medium*.

R_3: IF V is *small medium*, THEN UTS is *medium small*.

R_4: IF Ni is *medium* AND Hardening Temperature is *small*, THEN UTS is *small medium*.

It is clear that the linguistic fuzzy rules as R_2, R_3, and R_4, allow for a better insight into the heat-treated alloy steels process.

To verify the physical interpretation of the obtained models, Fig. 6 shows the three-dimensional response surfaces of the compact model. These surfaces are achieved by plotting two varying input variables against the output while keeping other input variables constant. The constant variables are set to the average values of the dominant steel grade, which is the 1%CrMo steel grade [17]. These plots in Fig. 6 are consistent with those variable effect plots in [17], which have been verified to follow the expected behaviour as predicted by theory and knowledge experts.

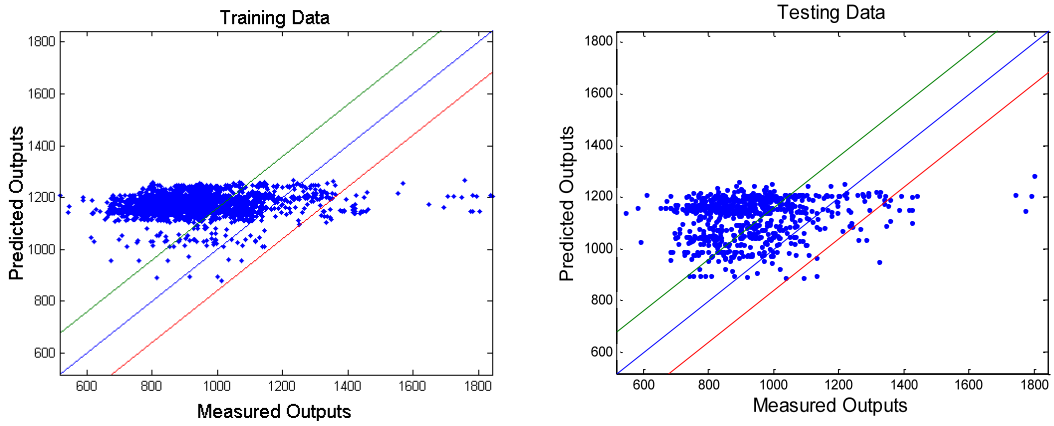

Figure 3. The UTS model's predicted outputs versus the measured outputs with the standard fuzzy reasoning and defuzzification methods.

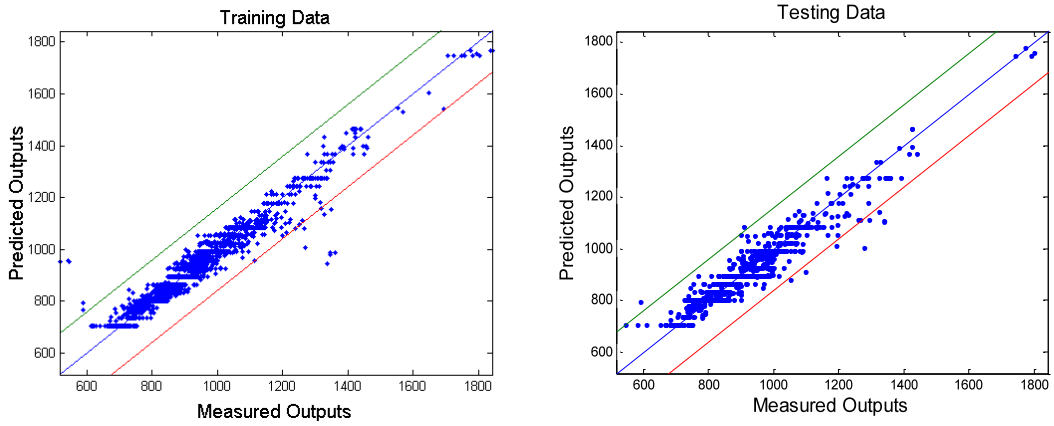

Figure 4. The UTS model's predicted outputs versus the measured outputs with the proposed system structure.

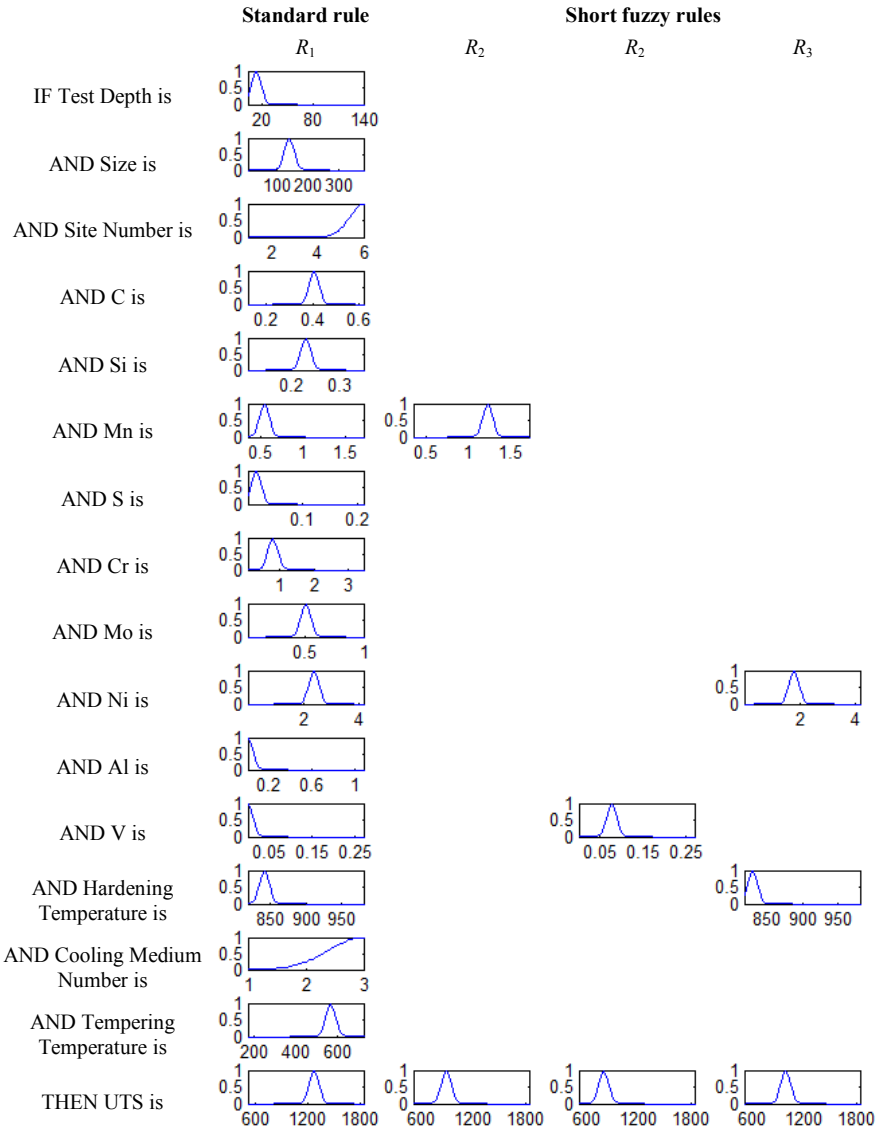

Figure 5. A comparison between a full-length and short fuzzy rules.

VII. CONCLUSION

For modelling problems, the most attractive advantage of fuzzy rule-based systems lies in their interpretability, which means that users should be able to understand a fuzzy system's behaviour by inspecting its associated rule-base. Normally, the interpretability issue involves the following widely accepted aspects: First, the number of fuzzy rules should be small enough to be comprehensible. Second, the rule premises should be simple in structure and contain only a few features (input variables). Third, the linguistic terms should be intuitively comprehensible. The form and parameters of the membership functions should correspond to the understanding of the linguistic expressions.

The grid-partitioning based fuzzy modelling approaches are considered to be more interpretable than data-clustering based ones since they include a set of well-distribution fuzzy sets. In the traditional grid-partitioning based methods, all the possible fuzzy rules in every partition are evaluated, which is time-consuming and cannot be achieved in high-dimensional modelling cases. In this work, the generation of fuzzy rules is data-orientated using 'short fuzzy rules', which can greatly reduce the number of fuzzy rules as well as the computational complexity. Among the fuzzy rules with various rule length, the shorter ones represent more general status and the longer ones deal with more specific situation. This has been fully taken into account in the reasoning and defuzzification. To identify the most appropriate fuzzy rules in a certain circumstance, a new mechanism of reference rules detection has also been developed.

The proposed approach was then successfully applied to generate models of the mechanical properties (in our case one) of alloy steels. Compared with the standard grid-partitioning based fuzzy modelling paradigms, the new method reveals an improvement in both the computational complexity and the interpretability. Compared with the clustering-based fuzzy modelling approaches, the proposed method can achieve the same accuracy level with a more transparent rule-base.

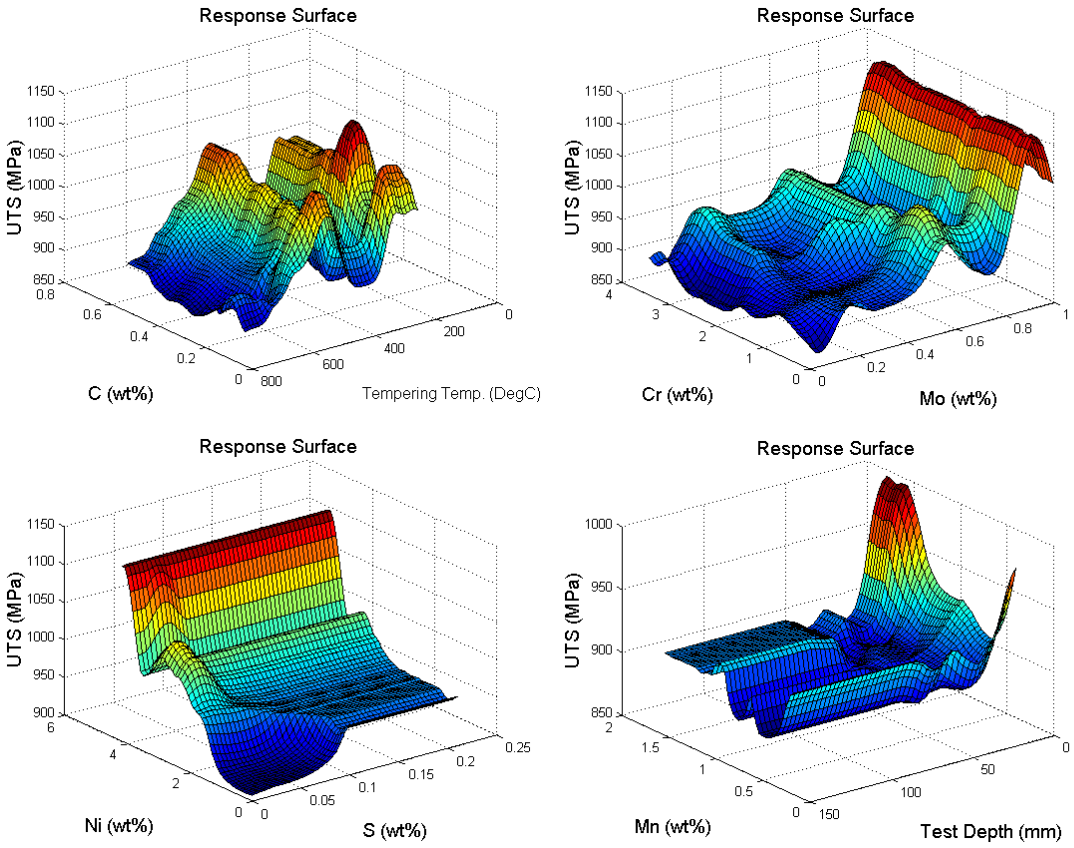

Figure 6. Response surfaces of the obtained UTS model.

In this paper, only the Mamdani-type fuzzy systems [18], which use linguistic expressions in both the antecedent and consequent parts, are considered. In the near future, the design could be extended to TSK-type fuzzy systems [19], which would replace the linguistic consequent parts of the Mamdani-type fuzzy system with deterministic forms. The authors will, also explore the possibility of extending the idea of employing short fuzzy rules within the framework of data-clustering based fuzzy modelling. It is also worth noting that the proposed framework does not include any optimisation strategy. In future, learning via effective optimisation could be embedded into the system to further improve overall accuracy while maintaining the same level of interpretability.

***Abstract*—To construct an appropriate e-learning system, it is inevitable to evaluate it by testing it with real human learners, but it naturally implies some sacrifices on the part of learners. To minimize the risk, some computational simulative evaluations are desirable. In this paper, we propose a multi-layered multi-agent simulation model for learner's growth through using an e-learning system. As a typical example of complex learning objects, we employ the task of learning presentation skills for which we are constructing a comprehensive learner support system and learners' data, and the knowledge model and learner growth model are prototypically proposed. By a preparatory experiment, our attempt, though it is still in its fancy, is shown to be on the right track.**

Keywords- contents evaluation; agent simulation; multi-layered knowledge model; hierarchical knowledge relations; awareness promotion

I. INTRODUCTION

With more need for customized tutoring or learning support with information and communication technology, more and more e-learning systems have been developed and utilized for various types of topics. They are supposedly developed deliberately with preceding analyses of the topic, the targeted learners, and the expected functions and user interfaces, but their effectiveness has been measured only when they are used by real human learners. It is true that the real value of any system is known only in the real situations, but as much risk of inappropriateness or failure should be avoided as possible, though we admit that the complete displacement of human trials is impossible.

To evaluate e-learning systems without real human learners, it may well be useful to employ an agent simulation. However, we face at least three fundamental issues:

- Knowledge and skill of many complicated, and often very abstract, tasks to be learned by human learners contains different levels of knowledges. Thus modeling such a complex system is not trivial, let alone implementing an agent system.
- Learner's knowledge and skill is in definition incomplete and often contains incorrect parts, which has also to be modeled.
- Learning steps contains continuous revisions, corrections, and refinements of prior knowledge and skill. So adequate model of growth has also to be modeled.

To tackle these issues, we will take a synthetic approach with an inter-related knowledge structure of complex tasks. As a typical example of complex learning objects, we employ the task of learning presentation skills for which we are constructing a comprehensive learner support system and learners' data, and we propose a multi-layered multi-agent simulation model for learner's growth through using an e-learning system. Though our attempt is still in its infancy, a preparatory experiment seems to show our attempt to be on the right track.

The organization of this paper is as follows. In section II, we describe our ongoing project to construct a comprehensive learner support system for English presentation, particularly for the purpose of presenting knowledge models assumed in the system. In section III, we propose a prototypical multi-layered multi-agent simulation model, and in section IV we conduct a preparatory experiment to evaluate our model.

II. PRESENTATION LEARNING SUPPORT

A. Overview of the relevant system

Based on the recognition above, we are currently developing a comprehensive learner support system for basic presentation in English [1]. It consists of several modules including digital contents of preliminary tutorials, an interactive aide for organizing a presentation and its corresponding slides, semi-automatic evaluation estimation, and a online review of recorded presentations, with a multimedia learner corpus of presentation. The overview of our system is shown in Fig.1.

B. Underlying Learner Model

As a learner support system, our system assumes a basic meta-cognitive model of presentation preparation and exercise similar to that of writing process designed by Hayes and Flower [2], and our model is shown in Fig. 2.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

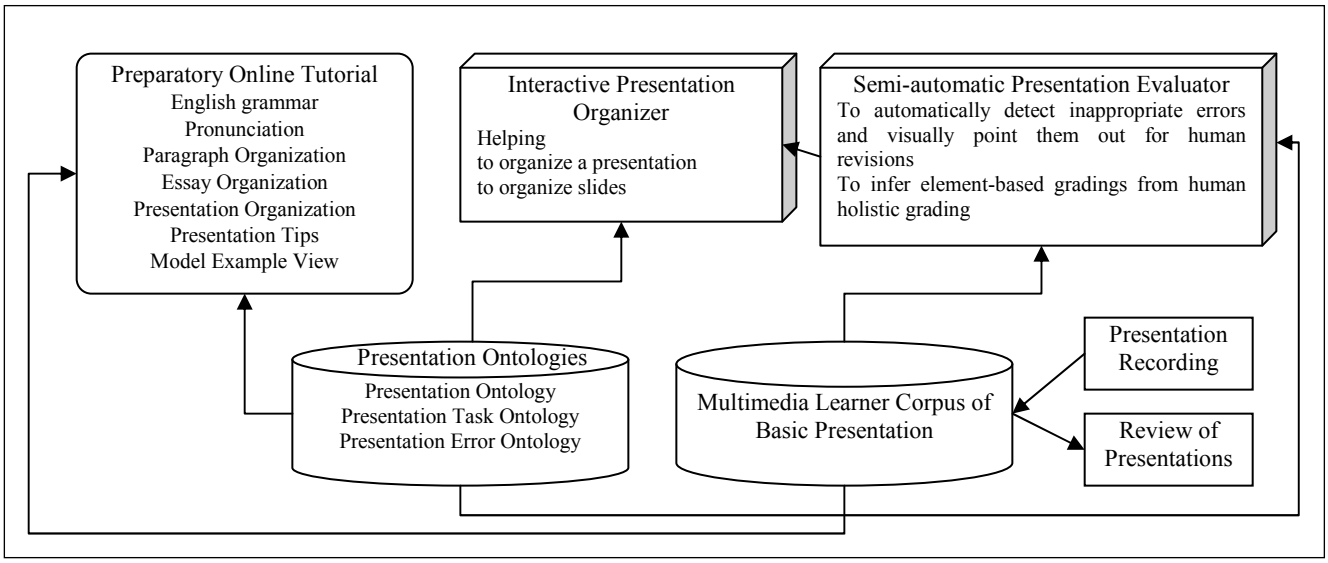

Figure.1 Overview of our prototypical learning support system of Basic Presentation

Based on the Hayes and Flower model, we added a performance section and clarified the status of strategies in the long-term memory. With this model, what any learner support system for presentation should promote is clear. In order for learners to acquire presentation strategies in their long-term memory, the skill choosing the proper writing style, speaking style, visual aids, and performance style, together with the feature of the chosen topic and the tendency of the audience, should be fostered in the way to stimulate their self-awareness. When preparing the presentation itself, three processes are to be effectively supported again by letting them be aware of what they are doing and what are to be improved.

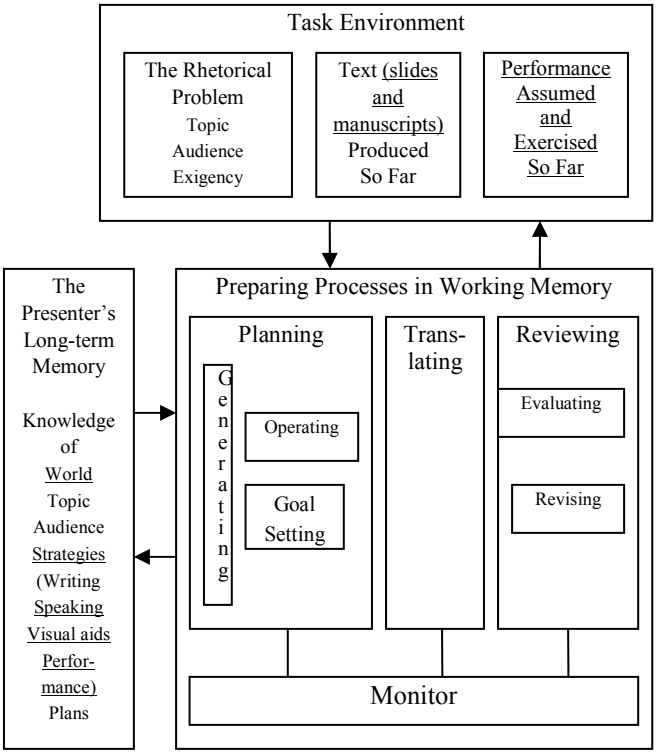

Figure 2 Our tentative model of the presentation preparation process

C. *Presentation Style Factors*

Presentation, whether it is oral or written, is delivered for a particular communicative purpose, which is to determine what and how to be delivered—content and style. A communicative purpose can be analyzed into different aspects. Let us call these aspects style factors. As each style factor affects what and how to be delivered, they have to be deliberately considered. Numerous books on presentation preparation emphasize the consideration of style factors, though each calls style factors differently, and we classify them as in Table 1.

With the decisions on style factors, oral and slide contents are to made not only on what to be delivered but also how to

TABLE 1 STYLE FACTORS

Factors	Examples
Topical (Genre)	inorganic chemistry, English literature ... (Note that the topical factor can be very much specific.)
Media	newspaper, textbook, oral presentation...
Targeted reader/ audience	laypeople, professionals ...
Purpose	persuasion, explanation ...
Intention	formal, informal or friendly ...
Time	the length of presentation

deliver it. Preparation for discussion is also affected. In other words, all the other aspects of presentation preparation and delivery are decided along the line of the choices of the appropriate style factors for the presentation. Particularly, all the linguistic style elements like shown in Figure 3 which manifest the choices are heavily affected.

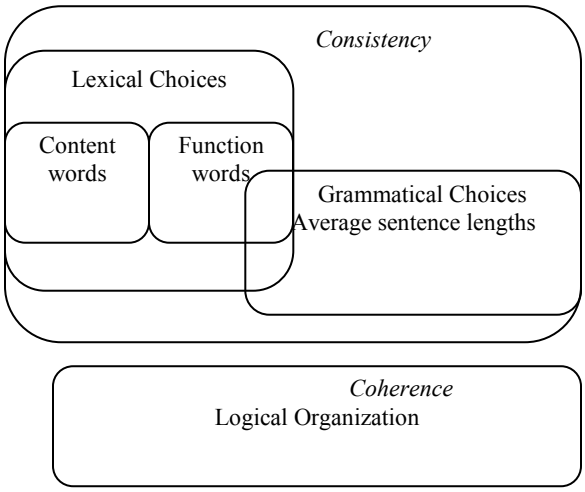

Figure 3 Linguistic Style Elements

D. Rhetorical Structure

The actual content of a presentation is then represented as a series of spoken sentences constituting a logical organization. One of the best known logical organization is that of paragraph, but a more fine-grained relation between sentences is needed, and a number of theories and frameworks have been proposed [4], of which Rhetorical Structure Theory, originally proposed by Mann and Thompson [5-9] is the most popular.

In the RST framework, the discourse structure of a text is considered to be coherent and thus capable of being be basically represented as a single-rooted tree with a set of directed graphs. Each directed graph is labeled for its rhetorical relation. Originally 23 relations were proposed [10], but the exact number proposed varies among researchers. Based on various proposals, we constructed a revised rhetorical relations of RST for presentation as shown in Table 2 [11].

It is important to note that the adequate sequence of rhetorical relations varies according to the purpose, targeted audience, and intention of the presentation. So, though it is difficult at this stage to reveal an quantitative correspondence between them, styles factors and rhetorical relations are related.

E. Learners' Presentation Samples

We have been constructing a multimedia learner corpus of English basic presentation (MLCP), part of which is to be employed as learning data in this paper. MLCP contains more than three hundred English presentations by learners [12]. The collected presentations vary in topic and in purpose, but all have common structure of five paragraphs, and common targeted audience, i.e. peer learners. The common structure is schematized as in Fig. 4, which is originally hinted by the idea of basic five paragraph essays. As shown, each slide roughly corresponds to a paragraph.

- Title and its corresponding slide
- Introduction and its corresponding slide
- Three supports and their corresponding slide
- Conclusion and its corresponding slide

As learning data for the experiment to be described later, we manually tagged rhetorical structure relations to the transcribed oral speech for 100 presentations. To facilitate the experiment, however, we manually added the style factors to them, which is not included in MLCP.

MLCP contains human evaluations of each presentations, which is considered to represent the growth level of the presenter.

TABLE 2 OUR REVISED RHETORICAL RELATIONS OF RST

EDU(Elementary Discourse Unit): Semantically clausal segments

A rhetorical relation is basically based on the surface structure and is assigned 0 or 1 according to the logical validity.

The Set of Rhetorical Relations for our purpose

Name	Description	Order of N&S
Background	Satellite provides background information to the nucleus	S before N
Contrast	Applies to two nuclei that contrast each other	
Elaboration	Satellite elaborates the information in the nucleus	N before S
*Elaborative Example	Satellite exemplifies the information in the nucleus	N before S
Enablement	Information in the satellite enables the audience to perform action in nucleus	N before S
Evidence	Satellite provides evidence to the statement in the nucleus	N before S
Justify	Satellite justifies the nucleus	
Motivation	Satellites motivates the reader to perform the action in the nucleus	
List	Listed nuclei	S before N
Sequence	Multiple nuclei that follow each other in sequence	
Solutionhood	Satellite is the problem; Nucleus provides the solution.	N before S
Summary	Short summary or paraphrase of the previous span	
*Supra-textual Cue	Cue for an action on the part of the audience.	
*Orphaned	Any other orphaned nucleus, to be connected to the nearest dominating nucleus (* indicates that the item is newly introduced here)	

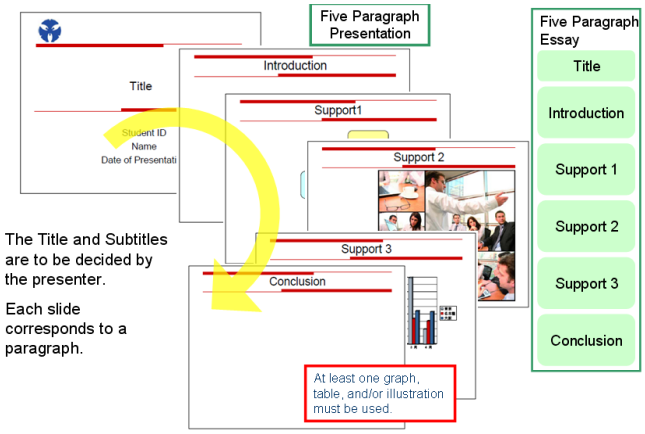

Figure 4 Correspondence between presentation slides and basic five paragraph essay

III. MULTI-LAYERED MULTI-AGENT MODEL OF LEARNER

According to our developing e-learning system for English presentation and learners' data described in the previous section, we constructed a multi-layered multi-agent model of learner in learning English presentation skills.

A. A Multi-Layered Model of Relevant Knowledges

When preparing a presentation, one should first analyze and determine style factors. According to style factors, he constructs what is to be presented, i.e. contents, and it is constructed as oral speech and slides. As noted previously, style factors do affect contents. For example, if the topic is technical while the audience is assumed to have little prior knowledge on the topic, then it should be supposed that the contents should contain comprehensible definitions and a fair amount of examples for easy understanding. Then, the actual speech and slides reflects the determination of style factors and the construction of contents. It is difficult to make a rigorous model for this kind of relationship, but a restricted part of the relationship can be stated fairly simply. In this paper, as a prototypical restricted model, we prepared a set of simple relations between the technical complexity of topics and the knowledge level of the targeted audience like the following.

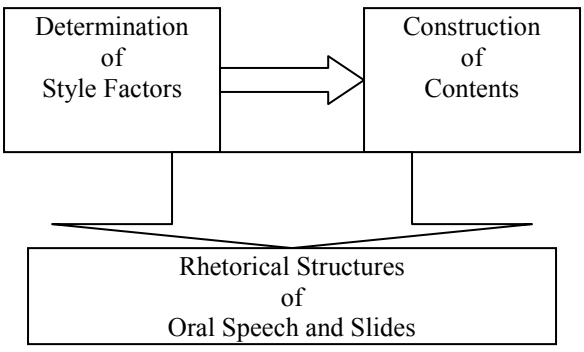

Figure 5 Primitive Multi-Layered Model

- The more technical the topic is, the more comprehensible definitions and examples (including metaphorical ones) are needed.
- The more abstract the topic is, the more metaphorical elaborations are needed.
- If the targeted audience have some prior knowledge, then the definitions usually come first. On the contrary, if not, then they may not.

At the same time, some style factors like purpose and intention both directly and indirectly (i.e., through the determination of contents) affect the sequence of rhetorical relations.

Note here that humans have each knowledge on style factors, contents, and rhetorical relations at different levels, and have additional knowledge on relations among them, which is why the model adopted here, roughly shown in Fig. 5, is called a multi-layered model of relevant knowledges.

B. A Multi-Agent Model

Each pieces of knowledges in the multi-layered model can be considered to an agent with a limited knowledge and reasoning rules. In other words, The body of knowledges of a human can be considered to a set of agents.

As for the relationship between style factors and contents, we only focus on the degree of necessity of definitions and examples, and the *style factor agents* are supposed to have one reasoning that require the corresponding construction of contents. Because it is beyond the scope of this paper, we assume that the construction of contents is the mere reflection of the determination by style factor agents; in other words, we do not deal with the actual contents, and the construction of contents is a set of the number of words (expressions, to be more exact) with definitions and the number of examples, both of which are determined by style factor agents, together with some other pieces of contents like causes and conclusions.

As for the rhetorical relations, we assume each rhetorical relation is implemented as an agent with simple reasoning of the order between nucleus and satellites.

C. A Learner Model Reflecting Growth Stages

The two notions of "multi-layered" and "multi-agent" are considered to constitute a human knowledge of a complex skill, and if they are constructed idealistically, it is a model of the perfected body of related knowledges. We assume as a zero hypothesis that the perfected body of related knowledges can in fact be constructed for some types of e-learning systems including that for English presentation, though we admit that it is not the case with every kind of possible e-learning systems. If we have a perfected body of related knowledges, then *a learner model at a particular growth stage* is to be constructed as an imperfect, often incorrect, body of related knowledges, and let's suppose so.

Then, a model for a particular growth stage constitute a set of agents at multi-layers whose reasoning is unstably probabilistic or just inert as shown in Fig. 6.

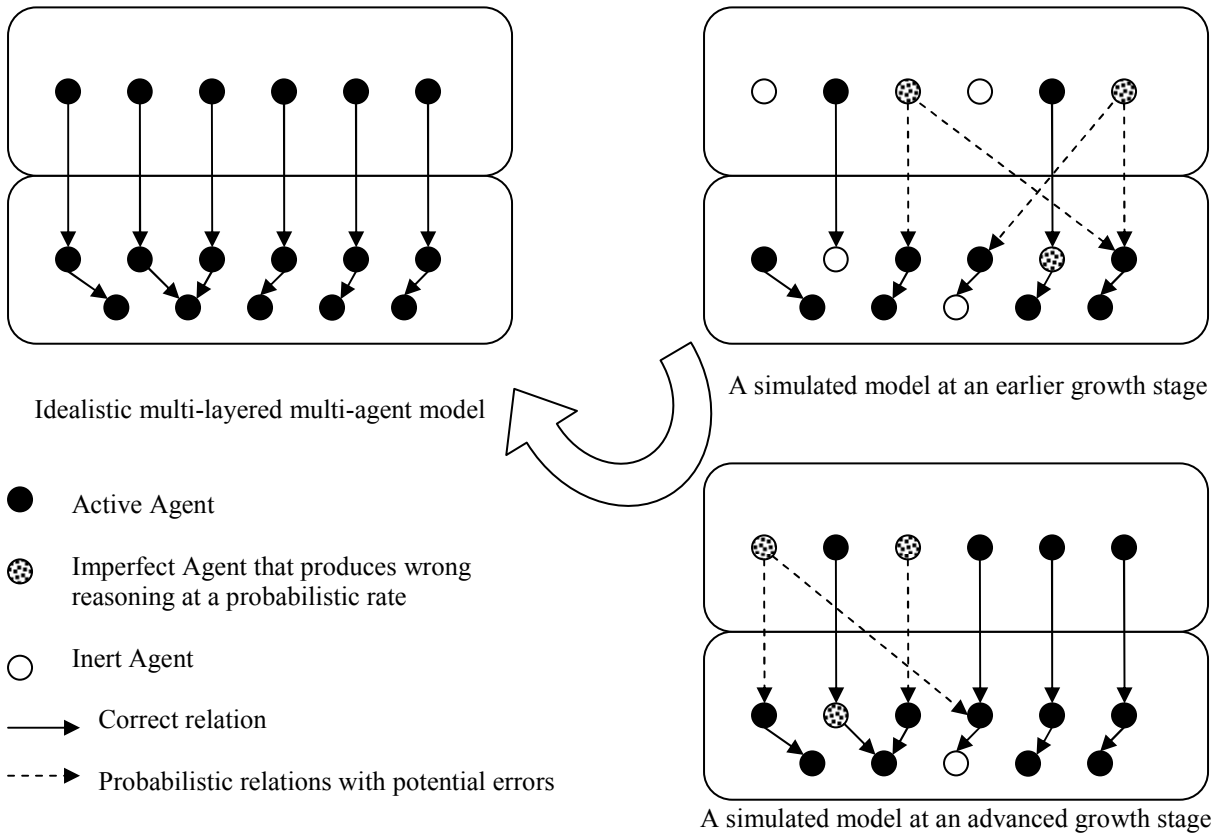

Figure 6 A Multi-Layered Multi-Agent Learner Model at Different Growth Stages

For convenience, each agent belongs to one of the two layers in Fig. 6, and in learner's model, agents are categorized as one of the three conditions.

- Active Agent
- Imperfect Agent that produces wrong reasoning at a probabilistic rate
- Inert Agent

Active agents requires other agents related to it to make a particular action, while imperfect agents may or may not do so to other agents that may or may not be related to it. Inert Agent does nothing. Then growth is considered to have more active agents than the previous stage.

IV. PROTOTYPICAL EXPERIMENT

Based on the model we described in the previous section, we conducted a prototypical experiment to evaluate our model.

Each agent has a set of two rules, one of which is inherent reasoning and the other of which is the request to other agents to a particular action. At the rhetorical relation layer, actions are categorized into the following two actions:

- To require another rhetorical relation agent to follow
- To require a particular type of sentence.

The experiment consists of two phases. The first phase is the stage to statistically learn the condition of each agent and the relations between agents from the data that represent a particular growth stage. A growth stage is judged with the evaluation value of presentations in MLCP. In this paper, we set four growth stages according to the evaluation value. So we will obtain (at least) four models each of which represents one of the four growth stage. Let us call each g_1, g_2, g_3, g_4. The second phase is the stage in which the set of agents whose conditions are learned for a particular growth stage re-learn for the next growth stage. Let us call each g_i^{i+1}. Then compare g_i^{i+1} with g_{i+1}. If g_i^{i+1} is the same or very similar to g_{i+1}, then it may well be considered that our model represents a growth stage from which it can learn to the next stage.

In average, each presentation consists of 15 sentences, and each learning set consists of 50 presentations. We admit that this size of the learning sets is not so large, and so we employed an SVM method, due to its perseverance to the small size of learning data sets.

As for style factor agents, we just implemented four, each of which may send their requests to the rhetorical relation layer. In this paper, we skipped the contents layer, simply because there is no data dedicated to the contents layer in the current MLCP while the data of leaner's speeches can be considered to

be the result of the construction of the contents at least for our experiment here.

Each style factor agents get an input from the meta data of each presentation whether its targeted audience is prepared or not, and whether the topic is technical or not. Then they may make inherent reasoning to send the preset request, and look for another agent to receive their request.

As for rhetorical relation agents, we just picked up four: background, elaboration, elaborative example, and solutionhood. Because the prepared style factor agents have to do with background and elaborative example, the expected result is that only the relations between style factor agents and *background* and *elaborative example* rhetorical relation agents are related.

The learning process has two stages: one for distinguishing the existence of relations from no relation, which distinguishes active and imperfect agents from inert agents, and the other for distinguishing the high probability of relations and the low probability of relations, which distinguishes active from imperfect agents.

The results of the second phase is shown in Table 3.

TABLE 3 THE RESULTS OF THE SECOND PHASE LEARNING RATE

	○ v. ●	○ v ⊛	⊛ v. ●
g_1^2 v. g_2	83.4%	75.8%	82.3%
g_2^3 v. g_3	52%	37.4%	64.7%
g_3^4 v. g_4	91.2%	62.3%	86.1%

As Table 3 shows, the comparison between g_2^3 and g_3 is low. This is because the third level is inherently intermediate and such an intermediate level of learners have relatively unstable conditions with unstable tendencies to use correct patterns. However, the comparisons between g_1^2 and g_2 and between g_3^4 and g_4 are relatively high, which indicates that our multi-layered multi-agent learner model can represent growth stages.

V. CONCLUDING REMARKS

In this paper, for the purpose of computational evaluation of e-learning systems for complex skills, we proposed a multi-layered multi-agent learner model which can trace growth stages. The result of the prototypical experiment indicates that our model in fact represents growth stages. It is quite primitive, but this model opens up a possibility to computational learner simulation, and it leads to minimize the risk of learner's sacrifice to be exposed to imperfect e-learning systems.

***Abstract*—Based on knowledge management and the spiral learning model for E-Learning, this paper proposes an interactive system, SPIral Capability Enhancement (SPICE) support system, to define two subjects: *Human Education* and *Information Security.* A student can review his situation on the subject to get feedback to evaluate his own capabilities based on comparisons. Basic idea of the proposed system originates in the pineapples of Capability Maturity Model Integration (CMMI) to allow the organizations and the systems to do the personal learning. This paper also discusses the possibility to adopt fuzzy markup language (FML) to infer the capability of maturity model which let the teachers as well as students know their capability of maturity model.**

Keywords: E-Learning; Knowledge Management; CMMI; FML

I. INTRODUCTION

The present education system not only achieves the goal of education but also promotes student's study level. During learning process, we first have to clarify our sub-goal as well as final goal to learn and then achieve the pre-defined goals. However, teachers and learners cannot discuss with each other in any time after class, so students have sometimes difficulties in clearly finding their achievement level to the met final goal. For instance, currently teachers cannot fully obtain the level that students have learned in the class. On the other hand, students cannot share their own advices on the subject with each other. In order to make teachers much understand students' performance level, developing a computerized assessment system is important to not only provide students with after-school teaching aid but also to facilitate teachers and officials to entirely track the students' learning process [4]. If there is a system which can achieve the above-mentioned purposes, students with the low-level understanding on the subject can learn more from such as a system. Therefore, such a system with the function of sharing learning feedback with each other is highly expected to make teachers save their reviewing time assisting students after class.

This paper proposes a spiral capability enhancement learning model to solve the above-mentioned problems. In this proposed model, the steps about how to use the developed system for students are as follows: Students (1) select the subject that they studies, (2) review themselves what they are able to do or what they understands, (3) and input their advices via the learning system to be able to share with other students. After that, the developed system shows students' learning level which have been achieved. According to the proposed model, students are able to not only review but also improve themselves through the feedback of the developed system. In this way, the involved students are capable of assisting with other students with lower maturity level and promoting their learning maturity level to the next higher one.

In this paper, the principles of Capability Maturity Model Integration (CMMI) are introduced to the SPICE [5, 6], and we called the CMMI-based spiral capability enhancement support. The main topic of this paper focuses on two SPICE applications, including human education management and information security management. Additionally, this paper also introduces the fuzzy inference mechanism to the developed system. From the simple simulation results, the proposed approach is feasible for students and teachers to understand the maturity level via the proposed CMMI-based SPICE system.

The remainder of the paper is organized as follows. Section II describes the spiral capability enhancement support system (SPICE). Section III introduces the application for human education management of SPICE system. Section IV introduces another application for the information security management of SPICE system. The simulation results of fuzzy markup language (FML) are demonstrated in Section V. Finally, conclusions are drawn in Section VI.

II. WHAT IS SPICE

A. Overview of SPICE

Fig. 1 shows the overview of the SPICE. In the model, first, a teacher analyzes the purposes of the course and divides to some circumstantial capabilities. Then he defines some maturity with them and registers to the learning system. On the other hand, a student who reviews his learning and inputs his situation with defined capabilities. At the same time, he also discloses know-how, means how he did or what he did, to the system in order to share among students. Then, the learning system judges his maturity with his inputs and defines maturity, and shows him it with what has been failed to achieve upper level and know-how given by other students. According to SPICE message, he has chance to improve himself to skill-up with these feedbacks. In this model, students repeat these three steps and can spiral up themselves

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

step by step. To efficiently enhance students' maturity level, it is needed to notify them their own current learning state to make students know how to do next in order to step into the next maturity level. Therefore, in this section, based on our previous work [5], the CMMI-based SPICE is introduced.

CMMI is an evaluating process method for software developing organizations [1]. It is specialized in software developing process, and currently it has been used in various fields, including national projects [2], corporate governance, and security policy. Table I shows the maturity level of CMMI is quantified with five levels. According to the definition of five maturity levels of CMMI, organizations can realize what is needed to further improve the organizational maturity. By introducing these five maturity levels to the CMMI-based SPICE, the students can promote their learning maturity level by following the defined maturity levels. The CMMI-based SPICE is an improved version of SPICE and it is easy to customize evaluation items and questions.

TABLE I. MATURITY LEVEL IN CMMI

Maturity	Stage meaning
1	Initial
2	Managed
3	Defined
4	Quantitatively Managed
5	Optimizing

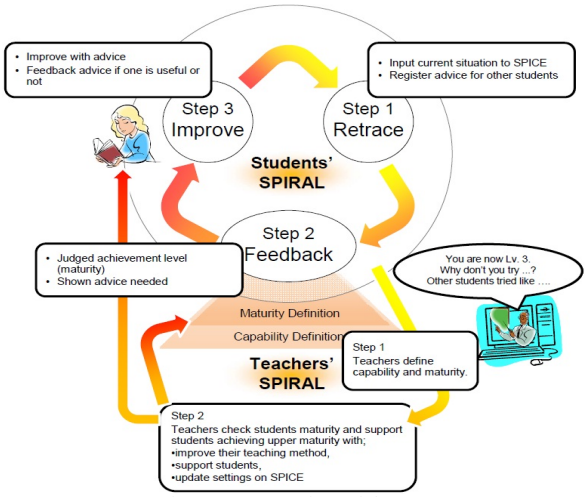

Figure 1. Overview of the SPICE.

B. *Structure of SPICE*

The SPICE is developed based on the maturity model of the knowledge management engineering, which is shown in Fig. 3. It operates as follows: (1) The manager extracts, defines, classifies, and then systemizes the process in order to further define the knowledge base for each application domain; (2) The defined and classified data are stored into the maturity model knowledge base to make manager acquire them; (3) The organizations and users can supervise and evaluate the current process of the activities via the system, and then stored the current activities' situation into the organization present condition management database; (4) The system also can diagnose the users' learning maturity level and how to promote to the next level, and then the diagnosis is stored into the practice know-how advice base. With the help of the SPICE, the manager and staff of the organizations can understand their own learning maturity level.

Take Fig. 2 for an example to describe the system. It is the system's screenshot to describe that there are two subjects, including human education and information security. In this figure, it indicates that the system can provide the taking-course students' list, analysis of the students' learning, and the learning maturity level of the students for the teachers.

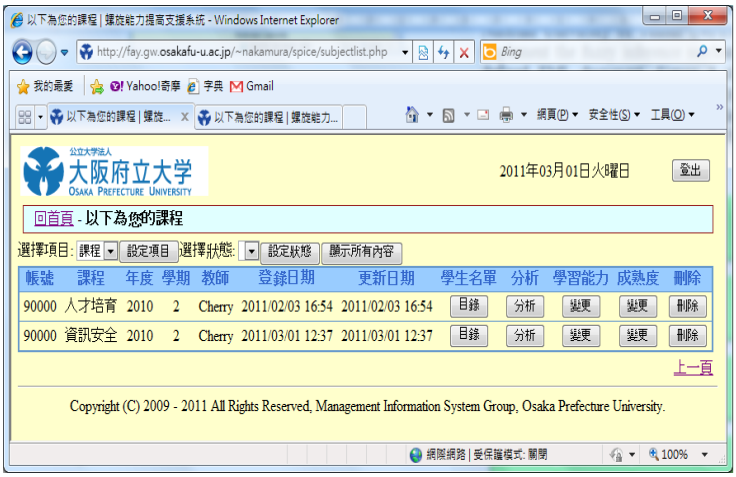

Figure 2. Screeshot showing teachers' courses.

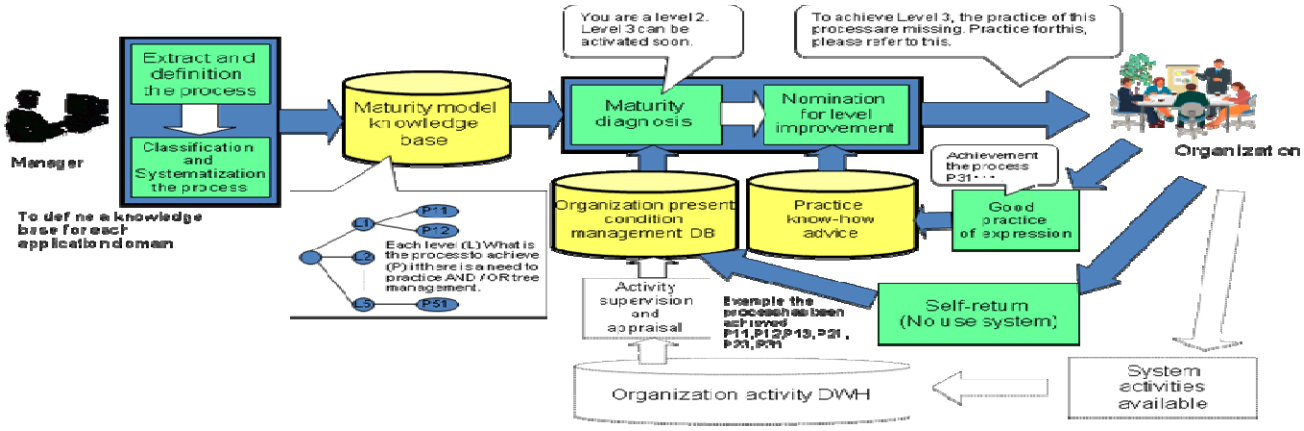

Figure 3. Process of developing the SPICE.

III. APPLICATION FOR HUMAN EDUCATION MANAGEMENT

A. Goal

The present education system should not only achieve the goal of education but also promote students' themselves study. It is necessary to clarify the achieving goal and then further attain the pre-defined goal. Therefore, five definitions of the subject human education, including technical capabilities, leadership, autonomy, cooperativeness, and responsibility, are defined in the SPICE system. With these definitions provided by the system, the teachers and students can continuously learn and share achieved goal. It is hoped that the proposed system will make as a reference for other education units in the future.

B. CMMI-based Human Education Definitions

In this application domain, according to the principles of CMMI [1], five definitions for the human education, including technical capability, leadership, autonomy, cooperativeness, and responsibility, from level 1 to level 5 are set up. Table II lists the detailed information of each definition for each level.

Following the five capability lists, we define five levels for each capability, for instance, in the technical capabilities: (L1) new technology is studied; (L2) one or more new technology is studied; (L3) new technology can by guided to others; (L4) the technology which represents the company has been developed; (L5) it continues to develop the new technology which represents the company.

Defining maturity levels as mentioned above enables teachers to understand the students learn capability and how many students on the level. Following the capability list that we define in human education subject, the students are easy to know how to achieve the level and how to step up. In addition, it is possible to refer other high-level student's advice to enhance the learn capability, the student can share knowledge with each other. Until now, we have already proposed 50 advices of human education subject. The other hand, teacher can reduce the time to educate student after school. Example interfaces are shown in Figure 4 and Figure 5.

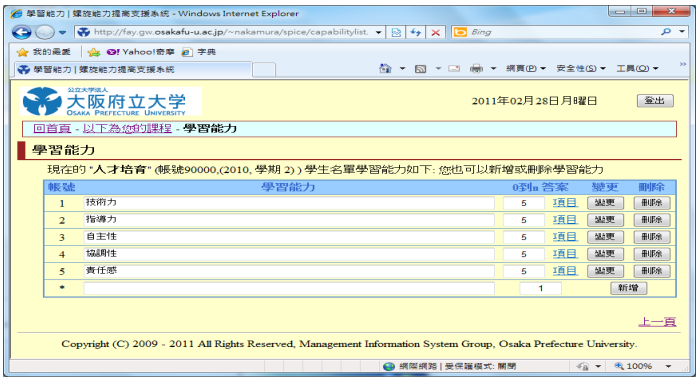

Figure 4. Form for defining questions to evaluate human education.

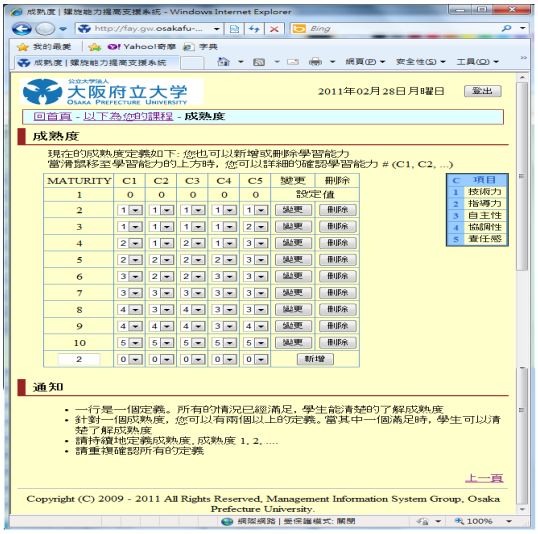

Figure 5. Form for defining maturity of human education.

We also set up the ten maturities for the subject. *Maturity 1* means that students do not register the subject, so each capability value is 0. When students register the subject, they can input their learn capability and advice how they achieve to next level, that can be the advice to other students.

TABLE II. EXAMPLE OF MATURITY MODEL: HUMAN EDUCATION

Level	Technical Capabilities	Leadership	Autonomy	Cooperativeness	Responsibility
L5	The new technologies have been continuously developed by the people in the organizations.	The guided people in the organization could become one truly leader.	The people in the organization could train their employees to have the autonomy in the organization.	The imitation person it negotiates, can adjust work	The action which is responsibility social natural environment is taken
L4	The new technologies have been developed by the people in the organizations.	The guided people in the organization could propose to organize one new team and recombine the teams.	The people in the organization could check the risk of the organization in advance and take all of the possible measures.	Can do the adjustment of work also the company internal some post	The internal policy of company, it plans the conduct which is responsibility, it is possible to execute
L3	New technologies could be guided other involved people in the organizations.	The guided people in the organization could become the leadership of other more than two teams.	The people in the organization could negotiate with the people in other organizations and plan a new proposal.	You can adjust work between the team	It is possible to carry out responsibility of the team
L2	One or more new technologies are studied by the people in the organizations.	The guided people in the organization could become a leader of their own teams.	The people in the organization could set the goal to evaluate themselves each half of year.	It can adjust work inside the team	It has responsibility for own speech
L1	New technology is studied by the people in the organizations.	The people in the organization are under the guided stage.	The people in the organization could accomplish the delivered jobs automatically.	The people in the organization could finish the assigned jobs under guidance.	Still, it is rearing stage

IV. APPLICATION FOR INFORMATION SECURITY MANAGEMENT

A. Goal

Information security has gradually become one of the most important factors in the current organizations. If the internal and external information of the organizations can work well and effectively, it will enhance the whole organizations' information security to increase the organizations' work efficiency and employees' work performance [10].

Defining some capability for information security subject of SPICE system, we hope that the paper's performance will make as a reference case for other administrative units to introduce the information security in the future.

B. CMMI-based Security Management Definition

As example, we set up five maturity levels and seven capability list in information security subject shown in Table III. The basic idea is referred from Capability Maturity Model Integration (CMMI) for software developing organization [1] is an evaluating method of progress.

We set up seven capability lists for the maturity model, such as information security, personal information, data encryption, data backup, idle machinery, antivirus software, and private information. Following the seven capability list, we define five levels for each capability, for instance, in the information security: (L1) organizations don't have any information security, (L2) organization conclude the information security, but never to implement, (L3) organization conclude the information security and to implement, (L4) organization conclude the information security by themselves, and regularly to self-criticism, (L5) provide other organization to instruct the information security. Until now, we have already collected 70 advices of information security subject.

The SPICE system interfaces of information security subject are shown in Figure 6 and Figure 7.

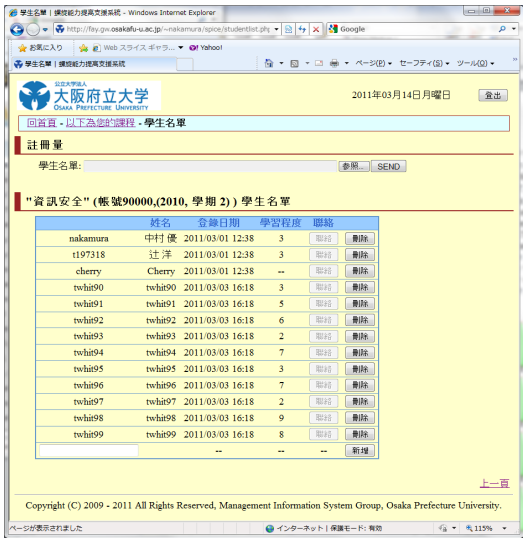

Figure 6. Form for student list of information security.

Figure 7. Form for subject analysis of information security.

TABLE III. EXAMPLE OF MATURITY MODEL: INFORMATION SECURITUY

Level	Information Security	Personal Information	Data Encryption	Data Backup	Idle Machinery	Antivirus Software	Private Information
L5	Provide other organization to instruct the information security	The computer is automaticity to turn off, when leave the computer for a long time	Use SSL(Secure Sockets Layer) to data encryption, and turn off computer when leave the seat	Regularly copy the date into CD	Don't have any idle machinery of company	Keep on the best condition everyday	Data Encryption the private information
L4	Organization conclude the information security by themselves, and regularly to self-criticism	The password is not easy to guess(Not name, birthday, phone, number plate)	Use SSL(Secure Sockets Layer) to data encryption	Regularly data backup of memory, USB drive and hard discs	Before sell and recycle, the data already delete of the idle machinery	Drawing off the web line immediately, when the computer is poisoned, and delete it	Never send the private information by e-mail
L3	Organization conclude the information security and to implement	The employee autonomy and regularly to change the password	Before mail, any information are encryption	The employee autonomy to data backup	Follow the regulation to sell and recycle the idle machinery	Buy the antivirus software to set up	Never open the private information on public computer
L2	Organization conclude the information security, but never to implement	The boss required to change the password	Mail the personal information are encryption	The boss required to data backup	Sell and recycle the idle machinery	Set up the antivirus software from internet	Security to store up the private information
L1	Organizations don't have any information security	Never change personal password	Mail the information that no be encryption	Never data backup	No properly to deal with the idle machinery	No antivirus software to set up of computer	No security to store up the private information

V. FUTURE PERSPECTIVE BASED ON FUZZY MARKUP LANGUAGE

As future perspective, let us combine our previous fuzzy inference model with FML to describe the knowledge base and rule base of the Spiral Capability Enhancement Support System. Figure 8 shows the structure for Human Education of the Spiral Capability Enhancement Support System.

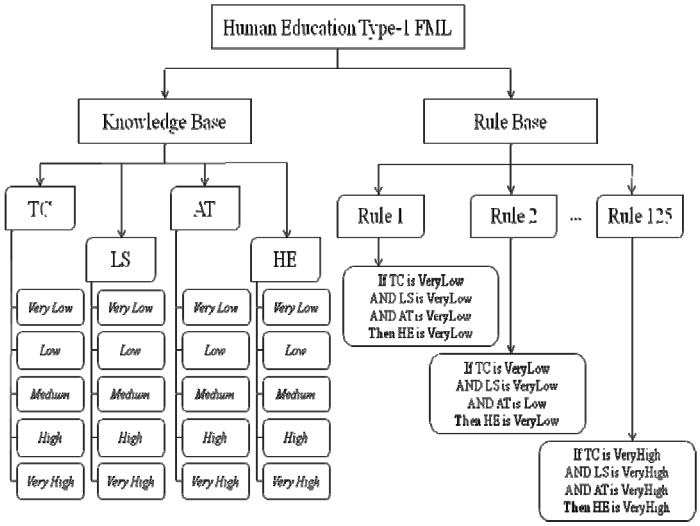

Figure 8. Membership functions of the fuzzy variables TC, LS, AT, and HE.

FML is a fuzzy-based markup language that manages fuzzy concepts, fuzzy rules, and a fuzzy inference engine [3, 8, 9].

There are three input fuzzy variables Technical Capabilities (TC), Leadership (LS), and Autonomy (AT) as well as one output fuzzy variable Human Education (HE) defined for the fuzzy reasoning mechanism. For fuzzy variable TC, LS, AT and HE, there are five linguistic terms are defined, including VeryLow, Low, Medium, High and VeryHigh. The brief descriptions of TC, LS, AT and HE are mentioned as follows:

- *TC:* The Technical Capabilities of company that develops new technology.
- *LS*: Leadership capabilities of team, including responsibility.
- *AT*: To accomplish the schedule of team, including negotiation with other company.
- *HE*: It represents the term relation strength. Based on the values of the *TC*, *LS*, and *AT*. *HE* is the inferred term relation strength of the term pair.

Herein, a FML editor, developed by the Ontology Application & Software Engineering (OASE) Laboratory, National University of Tainan (NUTN), Taiwan, will be used to implement the fuzzy inference mechanism based on the pre-defined FML document. Figure 9 shows the example membership functions of the fuzzy variables TC, LS, AT and HE. Figure 10 shows the structure of the adopted rule-based fuzzy inference mechanism. Table IV lists the adopted fuzzy rules.

Figure 9. Membership functions of the fuzzy variables TC, LS, AT, and HE.

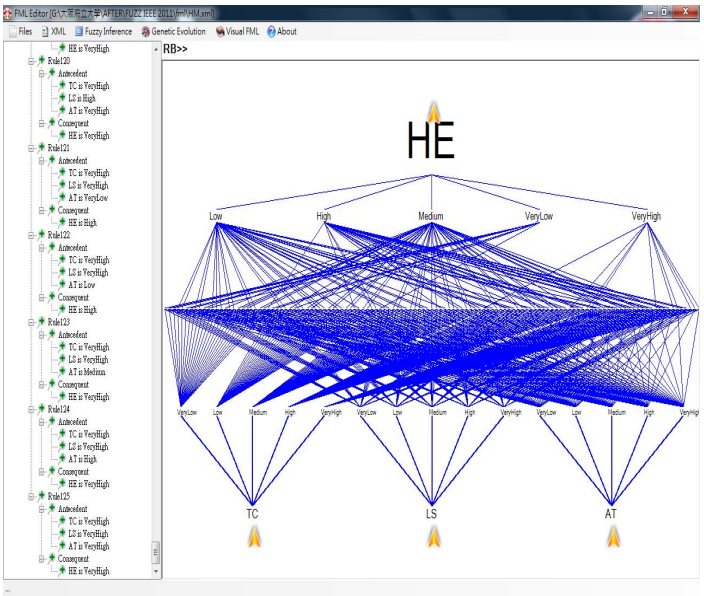

Figure 10. Structure of the adopted rule-based fuzzy inference mechanism.

TABLE IV. ADOPTED FUZZY RULES

Rule No	Fuzzy Variable				Rule No	Fuzzy Variable			
	TC	LS	AT	HE		TC	LS	AT	HE
1	VL	VL	VL	VL	69	M	H	H	H
2	VL	VL	L	VL	70	M	H	VH	H
3	VL	VL	M	VL			…		
4	VL	VL	H	L	96	H	VH	VL	M
5	VL	VL	VH	L	97	H	VH	L	H
		…			98	H	VH	M	H
36	L	M	VL	L	99	H	VH	H	VH
37	L	M	L	L	100	H	VH	VH	VH
38	L	M	M	L			…		
39	L	M	H	M	121	VH	VH	VL	H
40	L	M	VH	M	122	VH	VH	L	H
		…			123	VH	VH	M	VH
66	M	H	VL	L	124	VH	VH	H	VH
67	M	H	L	M	125	VH	VH	VH	VH
68	M	H	M	M					

VL: VeryLow, L: Low, M: Medium, H: High, VH: VeryHigh

VI. CONCLUSION

In this paper, a CMM-based E-Learning system has been proposed and applied spiral capability enhancement learning model as a new learning model. In this model, a student has chance to review himself what or how he learned, to get feedbacks from the learning system, and to improve himself with these feedbacks to enhance his capability. At the same time, a teacher is allowed to check students' achievement level and can ameliorate a way to teach.

This paper proposes the fuzzy markup language (FML) to apply to apply to human education and information security. In the future, we hope to refer the method of expert to define the genetic fuzzy markup language (GFML), and to devise the distinct rules that refer to other organizations.

ACKNOWLEDGMENT

***Abstract*— In order to reveal disparity and its cause in medical care among Japanese prefectures, this paper describes how DEA works as follows: (1) DEA/BCC model estimates the disparity between prefectures, (2) "RM-DEA using Cone-Ratio approach" estimates the cause of the disparity, and (3) Improved MF-DEA (Multi-Frontier based DEA) model estimates the disparity between eastern and western Japan. This paper also illustrates three numerical experiments.**

Keywords; Data Envelopment Analysis, Medical Service.

I. INTRODUCTION

Nowadays the shortage of medical employees connects with the regional and medical disparity, and it becomes a bigger problem. Especially the shortage of medical doctor is reported by Ministry of Health [1], and that of nurse is done by Japan Medical Association [2]. As these countermeasures, the analysis is done in Japan Medical Association Research Institute [3] (JMARI), and the committee relating to the medical employees is held also by the organization in the Japan[4]. Thus, the concern about the shortage of medical employees is higher and higher.

However, not only the number of employees but also the enhancement of equipment is critical to offer the better medical service. Therefore, the above-mentioned evaluation by only employee's data is insufficient in order to consider "anytime, anywhere, anyone, equally [5]" which is the medical ideal in Japan. And the regional and medical disparity should be considered by data including employees' and equipment's information. There is a similar analysis in JMAR, while the analysis is not carried out by the overall evaluation used multiple data items, and which item is prime cause of the disparity is not investigated. Then this paper intends to examine these disparity and its cause by using the multiple data, the number of medical employees and that of medical equipment. In this case, a relative evaluation method corresponding to the multiple inputs and outputs is necessary.

Recent years, in order to examine the efficiency of medical and other public services, a nonparametric method, Data Envelopment Analysis (DEA), is often used [5]. DEA is a method that can relatively compare ratios of the input and the output. This relative comparison and the comparative evaluation are basis in DEA.

Then the purpose of this paper is to evaluate the medical care system of prefecture in Japan and to reveal the regional and medical disparity by BCC (Banker-Charnes-Cooper) model. And "Restricted Multipliers DEA model using Cone-Ratio approach (RM-DEA) [6]" is applied in order to find out the weakness and the strength of prefecture. In addition, the medical disparity between western and eastern Japan is examined by the improved Multi-Frontier based DEA (MF-DEA) [7].

II. THE PROBLEM OF MEDICAL CARE SYSTEM EVALUATION IN CONVENSIONAL METHOD

Medical care system is evaluated by one ratio in a lot of researches. And most researches use the ratio to the number of patients. Hereafter, this method is regarded as the conventional method. Now, there are the following six data items: the number of doctors, nurses, high priced medical equipment, beds, ICU beds, and hospitals in inhabitable area (Hospital density). Then doctor and nurse items indicate medical employees. Bed, ICU bed, and high priced medical equipment item indicate equipment. The data item of hospital density shows geographical factor. For example, this factor indicates time to go to hospital. Here, prefectures can be evaluated in each data compared with the ratio value.

TABLE I. EXAMPLE:THE RATIO OF EACH ITEM

Prefecture	Ratio value per 100,000 patients		
	Doctor	Nurse	Bed
Hokkaido	208.8	947.4	1830.7
Aomori	150.2	709.2	1286.6
Iwate	185.2	735.1	1382.3
Miyagi	190.8	661.1	1162.1
Akita	187.6	728.7	1394.1
Yamagata	179.2	718.6	1161.1
:	:	:	:

However, there is not evaluation reached by all six items. Medical service can not be evaluated by one data item such as the number of doctors. The number of the doctors and nurses may be the most important in the hospital management but no medical employees can work in the place where there are no

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

medical facilities. Conversely, even if there are some medical employees, a necessary medical service cannot be offered without the necessary equipment. Therefore, medical service should be evaluated by multiple data items which show the number of medical employees and the enhancement of medical facilities equipment.

TABLE II. DATA SET

Data items	Data sources
The number of doctors	Hospital Report
The number of nurses	Hospital Report
The number of expensive equipments	Survey of Medical Institutions
The number of beds	Survey of Medical Institutions
The number of Icu beds	Survey of Medical Institutions
The number of hospitals	Survey of Medical Institutions
Inhabitable area	Social life statistics index
The numberof patients	Survey of Medical Institutions

III. OUTLINE OF DATA ENVELOPMENT ANALYSIS

DEA was proposed by A. Charnes et al. in 1978 as a method for management analysis. It is applied in various fields such as data mining, prospect for bankruptcy or so.

Evaluated objects, namely DMUs (Decision Making Units) are hospital, bank, electricity company or prefecture, for example. And each DMU is characterized by multi-inputs and multi-outputs. Then DMU which have smaller inputs and larger outputs is regarded as more efficient. Management efficiency is evaluated by efficiency value. Then efficient DMU has efficiency value as 1, inefficient DMU has it as less than 1. Efficiency value is calculated based on line called efficiency frontier which is formed by efficient DMUs [8, 9].

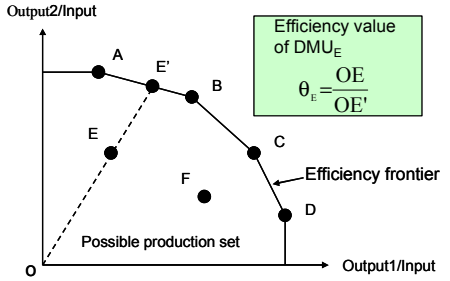

Fig. 1. Efficiency frontier and efficiency value of DMU_E

Here, Fig. 1 is prepared to signify how to evaluate DMU. Each axis indicates outputs divided by input. Therefore, DMU which is far from origin is more efficient. Four $DMU_{A,B,C,D}$ have no difference of superiority or inferiority, and they are equally efficient. The efficient frontier is formed with these efficient DMUs. Moreover, four $DMU_{A,B,C,D}$ get efficiency value 1 since they are located on the efficiency frontier. And other DMU $DMU_{E,F}$ is judged to be inefficient, their efficiency values are calculated at ratio of distance to the efficient frontier. As an example, the way to calculate the efficiency value of inefficient DMU_E is described. This time, the efficiency value of DMU_E is calculated by distance to efficiency frontier. In a word, the efficiency value is calculated from OE / OE' by ratio of the distance from origin to Point E' and origin to point E. Here, E' shows ideal state that DMU_E can reach by improvement of production activity.

IV. ANALYSIS METHODS

A. BCC Model

There are some models in DEA as the analytic model. And there are two analytic types called input-oriented type and output-oriented type. Here, output-oriented BCC model is explained since it is utilized in this paper. BCC model assumes the harvest variable of the scale. Moreover, the output-oriented type premises the current input, and obtains maximum output which is expected.

Assuming that there are *n DMUs* (DMU_1, DMU_2, ..., DMU_k, ..., DMU_n), and DMU_k is characterized by *m* inputs and *s* outputs. Then DMU_k has input expressed as $x_{1k},\ldots,x_{mk}$ and output expressed as $y_{1k},\ldots, y_{sk}$. Here the efficiency value is shown by calculating following linear algorithm.

$$\begin{aligned} \max \quad & \theta_k \\ s.t. \quad & \sum_{j=1}^{n} x_{ij}\lambda_{jk} \le x_{ik} \qquad (i = 1,2,\ldots, m) \\ & -\sum_{j=1}^{n} y_{rj}\lambda_{jk} + \theta_k y_{rk} \le 0 \quad (r = 1,2,\ldots, s) \\ & \sum_{j=1}^{n} \lambda_{jk} = 1 \\ & \lambda_{jk} \ge 0 \ , \ \theta : free \ , \ j = 1,2,\ldots, n \end{aligned}$$

About the optimal solution θ_k^* calculated by the formula (1), there is $\theta_k^* \ge 1$ and an efficiency value is expressed as $1/\theta_k^*$ at this time. When $1/\theta_k^* = 1$, DMU_k is evaluated to be efficient. And when $\theta_k^* \le 1$, DMU_k is evaluated to be inefficient.

B. RM-DEA model using Cone-Ratio approach

RM-DEA limits input and output items in an evaluation axis by restricting the variable weights, then the method can include subjective information. However, this method has the problem that the optimal solution cannot be obtained when the restricting condition is strong.

Therfore, in order to avoid this problem in the previous study, the evaluation method which gives distortion in the search direction by using a valuing level $0<\alpha_r \le 1$ (r=1,2;·;s) is proposed.

At this time, the formula is shown below. And α_r is any number decided by the evaluator and shows valuing level to the *r*-th output item.

$$\begin{aligned} \max \quad & \theta_k \\ s.t. \quad & \sum_{j=1}^{n} x_{ij}\lambda_{jk} \le x_{ik} \qquad (i = 1,2,\ldots, m) \\ & -\sum_{j=1}^{n} \frac{1}{\alpha_r} y_{rj}\lambda_{jk} + \theta_k y_{rk} \le 0 \quad (r = 1,2,\ldots, s) \\ & \sum_{j=1}^{n} \lambda_{jk} = 1 \\ & \lambda_{jk} \ge 0 \ , \ \theta : free \ , \ j = 1,2,\ldots, n \end{aligned}$$

The *r*-th output item is evaluated most at $\alpha_r = 1$, and the more α_r approaches *0*, the more the *r*-th output item is disregarded. Therefore, the efficiency value can be calculated when α of the item that the evaluator wants to value is set as 1 and α of other items is set as any value in the range of *0* and *1*. As a result in the previous study, the items which are the strength and weakness in DMU are able to be found by the change of the efficiency value when valuing level of the item is changed.

Next, Above-mentioned way to find is concretely explained by using 5 as sample data. When valuing level is given to the output item y_3, Table 3 shows the results. And the strength and weakness of each DMU are found.

TABLE III. RESULT IN VALUING Y_3

DMU	Efficiency value			
	α=1.0	α=0.8	α=0.5	α=0.3
1	0.86	0.73	0.70	0.70
2	0.92	0.74	0.46	0.39
3	1.00	0.95	0.91	0.91
4	1.00	1.00	1.00	1.00
5	1.00	0.94	0.93	0.93

Table 3 shows efficiency value when the valuing level of y_3 is set to 1, and the valuing level of other output items is set as 1, 0.8, 0.5, and 0.3. At this time the valuing level of the output item other than y_3 is α in this table.

In Table 3, DMU_4 did not show a decrease in the efficiency value even if the valuing level of the output item other than y_3 becomes small. The output item y_3 is the strength of DMU_4.

On the other hand, DMU_2 show a great decrease in the efficiency value, when the valuing level of the output item other than y_3 becomes small. Therefore, the output item y_3 is the extreme weakness of DMU_2.

Thus this paper finds out the strong and weak items in each prefecture by the change of the efficiency value when valuing level of the item is changed.

C. *Improved MF-DEA*

The previous study proposed MF-DEA which assigns frontier to each group, and gathering evaluation based on each frontier leads to multi-evaluation. Moreover, position in the group or relation with other groups can be considered if multiple efficiency values are compared. Fig. 2 shows the frontier formed by MF-DEA in the case of two groups.

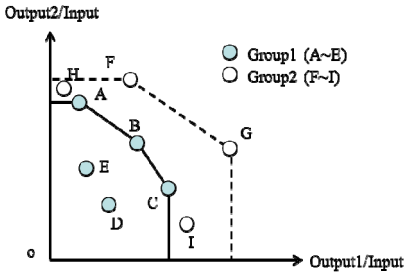

Fig. 2. Frontier formed by MF-DEA

Next, the formula of MF-DEA is described. There are *p* groups here. Group1 consists of α DMUs chosen optionally, group2 consists of β DMUs chosen optionally, and group p consists of γ DMUs.

$$\min \quad \theta_k$$

$$s.t. \quad \theta_k x_{ik} \geq \sum_{a=1}^{\alpha} x_{ia}\lambda_a^1 + \sum_{b=1}^{\beta} x_{ib}\lambda_b^2 + \cdots + \sum_{p=1}^{\gamma} x_{ip}\lambda_p^p \qquad (i = 1,2,\ldots,m)$$

$$y_{rk} \leq \sum_{a=1}^{\alpha} y_{ra}\lambda_a^1 + \sum_{b=1}^{\beta} y_{rb}\lambda_b^2 + \cdots + \sum_{p=1}^{\gamma} y_{rp}\lambda_p^p \qquad (r = 1,2,\ldots,s)$$

$$\theta_k = \theta_k^1 + \theta_k^2 + \cdots + \theta_k^p$$

$$\theta_k^a x_{ik} \geq \sum_{a=1}^{\alpha} x_{ia}\lambda_a^1 \qquad \theta_k^b x_{ik} \geq \sum_{b=1}^{\beta} x_{ib}\lambda_b^2 \qquad \cdots \qquad \theta_k^p x_{ik} \geq \sum_{p=1}^{\gamma} x_{ip}\lambda_p^p$$

$$y_{rk} \leq \sum_{a=1}^{\alpha} y_{ra}\lambda_a^1 \qquad y_{rk} \leq \sum_{b=1}^{\beta} y_{rb}\lambda_b^2 \qquad \cdots \qquad y_{rk} \leq \sum_{p=1}^{\gamma} y_{rp}\lambda_p^p$$

$$\sum_{a=1}^{\alpha} \lambda_a^1 = \sum_{b=1}^{\beta} \lambda_b^2 = \quad \cdots \quad = \sum_{p=1}^{\gamma} \lambda_p^p = 1$$

$$\theta \ : \ free \qquad \lambda_a^1 \geq 0 \qquad \lambda_b^2 \geq 0 \qquad \cdots \qquad \lambda_p^p \geq 0$$

Here, θ_k^p indicates efficiency value based on group *p*, and then DMU_k is evaluated from *p* viewpoints. Objective function θ_k which is sum of the efficiency value based on each viewpoint does not have any particular meaning. Here, efficiency value based on each group is shown in Table 4 by 9 DMUs data in Fig. 2.

TABLE IV. RESULT IN MF-DEA

Group	DMU	Efficiency value based on each frontier	
		Group1	Group2
1	A	1	0.85
	B	1	0.8
	C	1	0.7
	D	0.55	0.4
	E	0.7	0.45
2	F	1.2	1
	G	1.3	1
	H	1.05	0.9
	I	1.1	0.7

Then all group1's efficiency value based on group2 and all group2's efficiency value based on group1 are remarkable. The former values are less than 1 and the latter values are over 1. This means that DMUs in group1 exists outside the frontier of group 2 and DMUs in group2 exists inside the frontier of group1. In other words, the frontier of group2 covers that of group1. The relation between frontiers can also be considered by an efficiency value in Table 4. When the former and latter values are various, they have relation as union of set. This means that these frontiers cross.

However, relation between frontiers cannot completely be considered by efficiency values. As an example, there are six DMUs which have one input and two outputs. And Table 5 shows the result. Then, all group1's efficiency value based on group2 and all group2's efficiency value based on group1 are remarkable. Because the former and latter values are various, they have relation as union of set. Therefore these frontiers cross. However, the figure cannot be uniquely determined because there are two possible cases shown in Fig. 3 and Fig. 4.

The relation between frontiers can be almost considered by only efficiency values of efficient DMUs in belonging group. However, in the case of Table 5, the relation between frontiers cannot be uniquely determined due to different interpretations on inefficient DMU_D.

TABLE V. EXAMPLE:RESULT IN MF-DEA

Group	DMU	Efficiency value based	
		Group1	Group2
1	A	1	1.1
	B	1	1.25
	C	1	1.5
	D	0.6	0.8
2	E	1.2	1
	F	1.3	1

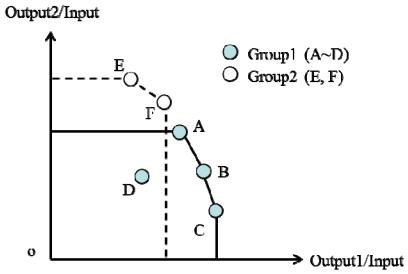

Fig. 3. Case1

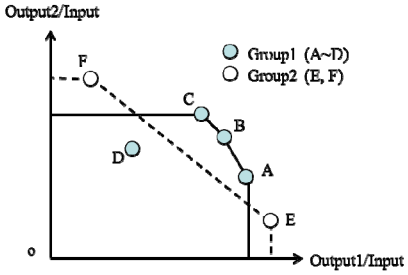

Fig. 4. Case2

Then, this paper pushes up inefficient DMUs to the frontier of its own group intentionally in order to solve this problem. Now, DMU_D moves to the frontier and then the arrival point is regarded as point D'. Here, the correction data is shown below. θ_k^* is the optimal solution calculated by BCC model.

$$x_{ik}^{+} = x_{ik} \qquad (i = 1,2,..m)$$
$$y_{rk}^{+} = \theta_k^* y_{rk} \quad (r = 1,2,..s)$$

And when MF-DEA is applied to these correction data in Fig. 5, Table 6 shows the result. Hereafter, improved MF-DEA indicates what MF-DEA is applied to these correction data.

$DMU_{D'}$'s efficiency value based on group2 is remarkable, and then this value is more than 1. $DMU_{D'}$ in group 1 exists outside the frontier of group2. Therefore the relation between frontiers is shown as Fig. 5. Finally, the figure can be uniquely determined from Table 5.

TABLE VI. EXAMPLE:RESULT IN IMPROVED MF-DEA

Group	DMU	Efficiency value based	
		Group1	Group2
1	A	1	1.1
	B	1	1.25
	C	1	1.5
	D'	1	1.2
2	E	1.2	1
	F	1.3	1

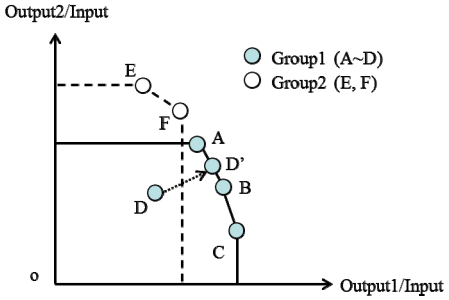

Fig. 5. Relation between frontiers in TABLE V

Thus this paper examines the relation between frontiers by using improved MF-DEA. This time position in the group is not considered. The frontier is regarded as the characteristics of its own group, and the difference between groups is described from the relation.

V. NUMERICAL EXPERIMENTS

A. Experimental conditions

Then this paper evaluates the medical care system by the following three experiments:

I. Experiment1 evaluates the medical care system based on the efficiency value, which is calculated by DEA. This time, BCC model is applied in order to notice output items. Finally, the result in this experiment compares with that in the conventional method.

II. "RM-DEA using Cone-Ratio approach" is able to find out data items which show strength and weakness. For that, there are the following three patterns in the previous study:

a) The valuing level α of one output item is set as 1, and those of other output items are set as 0.8.

b) The valuing level α of one output item is set as 1, and those of other output items are set as 0.5.

c) The valuing level α of one output item is set as 1, and those of other output items are set as 0.3.

Experiment2 applies these patterns to every six output items and especially examines the cause of medical disparity. Here, the cause indicates data items which show the weakness of prefecture. conventional method.

III. Experiment3 makes the analysis by improved MF-DEA in order to examine medical disparity between two big regions named western and eastern Japan. Eastern Japan has total 18 prefectures including Hokkaido, Tohoku region, Kanto region and four prefectures (Niigata, Yamanashi, Nagano and Shizuoka). Western Japan has 29 prefectures of the rest. Moreover, the result in MF-DEA is not placed due to the limitation of the page space. Therefore, the comparison between the result in MF-DEA and improved MF-DEA is performed in this paper.

B. Experimental data

Data set (Table 2) in II is used. The number of DMUs is forty-seven, and each DMU has the following two inputs and six outputs:

◆Inputs

Input1 : The number of patients

Input2 : The amount of investment

◆Output

Output1 : The number of doctors

Output2 : The number of nurses

Output3 : The number of expensive equipment

Output4 : The number of beds

Output5 : The number of ICU beds

Output6 : Hospital density.

C. Experimental Result

1) Experiment 1

Table 7 shows the result in BCC model and the conventional method. Here, "The ranking of rate per 100,000 patients" indicates the results in the conventional method, and the value indicates ranking in each item. Then "score" indicates the efficiency value in BCC model, "rank" indicates the ranking in "score".

TABLE VII. RESULT IN EXPERIMENT1

D. Discussion

1) Experiment 1

BCC model and conventional method evaluate the medical care system. And these results are compared. As mentioned in II, it is difficult to apply superiority or inferiority to prefectures in consideration of plural items. For example, Kagawa and Toyama of "Ranking of rate value per 100,000 patients" in Table 7 are remarkable. Toyama's ranking in items other than the hospital density and ICU bed item is higher place than Kagawa's ranking. However, Toyama's ranking is the lowest place in ICU beds item. Then, superiority or inferiority between these prefectures is not able to be evaluated. Thus, the difference between prefectures cannot be examined because there are no absolute standards in medical fields. Then according to score in Table 7, 18 prefectures are judged to be efficient because these efficiency values are 1. Therefore, these prefectures have the better medical care system.

Next, efficient prefectures are shown by using the map of Japan as Fig 6. At this time, the tracery indicates efficient prefectures. Then, because there are a lot of efficient prefectures in Kyushu and Shikoku region, these regions have the better medical care system in the whole region.

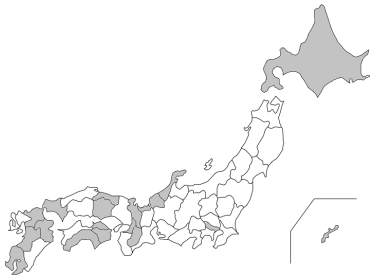

Fig. 6. Result in BCC model

On the other hand, Table 7 shows that Tohoku region has a lot of prefectures, such as Yamagata, Aomori, Miyagi, Akita, Fukushima, and Iwate whose efficiency value is low. In Fig. 6, while the other regions have at least one efficient prefecture, there is no efficient prefecture in Tohoku region. Therefore, the medical care system in Tohoku region is inferior to that in other region.

2) Experiment 2

When "valuing level α" is given to each item, the efficiency value almost is changed. If a DMU shows great decrease in the efficiency value when the valuing level of an output item is given, the output item is the weakness. However, this great decrease is clearly not defined. Therefore, this paper evaluates the weakness from "Change of ranking" in table 9. Here, "Change of ranking" indicates "±rank" of "Change from BCC" in table 8. Moreover, the strength is evaluated by "change of ranking", too.

In Table 9, let us focus on Tokyo, Tottori, and Kagawa. These prefectures did not show a decrease in the ranking, if the valuing level is given to every six output items. Here it is said that the medical care system is offered to the patient because these three prefectures do not have the weakness in any output item.

Next, Hokkaido prefecture is remarkable. When ICU bed item and hospital density item are strongly valued, these ranking decreased. Especially, 28 places are dropped in doctor item and 35 places are dropped in the hospital density item. This means that these items are weakness in this prefecture compared with other prefectures. Therefore, firstly hospital density item should be improved from the degree of ranking drop and secondly doctor item should be improved. Conversely, there was no change from 1st place when nurse, bed, and the high priced medical equipment item are strongly valued. This means that these items are the strength in this prefecture compared with other prefectures. In this way, while experiment1 is not able to find out the weakness and the strength, experiment2 is able to do those.

Miyagi is remarkable. In this case, the up of ranking happens in all items. In these ranking up, the degree of the up is the smallest in bed item. Subsequently, the degree is the second in nurse item. This means that there are a lot of prefectures where these two items are the strength compared with other items. In other word, these items are the weakness of Miyagi. Therefore, firstly bed item should be improved from the degree of ranking up and then nurse item should be improved.

3) Experiment 3

The medical disparity between western and eastern Japan is described by the relation between frontiers. Let us denote efficiency value based on each criterion as follows to simplify the discussion.

Efficiency value based on All Japan : θ

Efficiency value based on Eastern Japan : θ^E

Efficiency value based on Western Japan: θ^W

In Table 10, all prefectures in western Japan are remarkable, then θ^E is higher than θ^W . From this result, the prefectures in western Japan exist outside the frontier of eastern Japan. Therefore, the frontier of western Japan exists outside that of eastern Japan.

Next, all prefectures in eastern Japan are remarkable. θ^W is higher than θ^E in most prefectures, while θ^E is higher than θ^W in the following five prefectures: Hokkaido, Saitama, Chiba, Tokyo and Niigata prefectures. This result shows that most prefectures in western Japan exist outside the frontier of eastern Japan, these five prefectures exist outside the frontier of western Japan and these frontiers cross here.

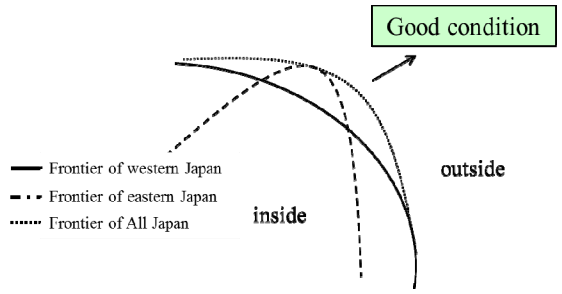

Fig. 7. Image of frontiers

As the result, the relation among frontiers is shown as Fig. 7. Therefore, western Japan has better medical care system than eastern Japan because the frontier of western Japan almost covers that of eastern Japan except for a part. Conversely, the medical care system of eastern Japan almost is inferior to that of western Japan, and there are few efficient prefectures in eastern Japan as shown Table 7. That is why, it is necessary to improve the medical care system in the entire eastern Japan.

VI. CONCLUSION

In order to evaluate the medical care system and to reveal the regional and medical disparity, this paper has applied three kinds of methods to the data published by Ministry of Health. The conventional method, ratio-comparison per 100,000 patients, could not evaluate the medical care system in each prefecture. However, the medical disparity between prefectures can have been examined by BCC model this time. And its cause has been found out by "Restricted Multipliers DEA model using Cone-Ratio approach". In addition, the regional relation between western and eastern Japan has been examined by the improved MF-DEA.

As future works, it is necessary to examine the medical disparity in a smaller region, secondary medical region, than prefecture and to reveal the disparity in a prefecture. In addition, the selection of input and output items needs to be rethought because there are a lot of data which show medical employees and equipment else.

***Abstract*- Data Envelop Analysis (DEA) is method for evaluating management efficiency of DMU (Decision Making Unit). DEA can analyze DMU's characteristic of data by assigning variable weight to each input and output elements. However the more the number of input and output elements is, the more complex assigning weight is. So, there is a problem that when the number of input and output elements is so large, it is difficult to analyze DMU's characteristics. This paper proposed new DEA model considering relation among input and output elements in order to analyze DMU's characteristics more easily. This model can limit assigned weights. Therefore, above problem can be solved. The power of the proposed method is examined by applying data set of Japanese professional baseball player's result in 2010.**

Keywords*. *Data Envelop Analysis, Linear Programming, Decision Making Unit,

I. INTRODUCTION

Data Envelopment Analysis (DEA) is a method for evaluating management efficiency of DMU (Decision Making Unit). Now Application of DEA is spreading, for example Universities, hospital, professional sport player and so on[1]. And it is expected that DEA will develop further. DEA has two characteristic as follows. (1) evaluates DMU by using multi-input and multi-output data. (2) can analyze DMU's characteristic of data by assigning variable weights to each element of input and output elements. However, the more the number of input and output elements is, the more non-zero weights are[2]. So, if the number of input and output elements are so large, it is difficult to analyze characteristics of DMU[3]. There is another problem of DEA. DMU is evaluated without considering relation among input and output elements. Therefore, the efficiency value of DMU is not necessarily correct.

This study proposes structured DEA method that is considering relation among input and output elements to solve above problems. Then the power of the proposed method is examined by applying data set of Japanese professional baseball player's result in 2010.

II. DATA ENVELOPMENT ANALYSIS

A. Outline of DEA

DEA was proposed by A. Charnes et al. in 1978 as a method for management analysis. The applicable field of DEA is wide such as data mining or prospect of bankruptcy[4][5].

DEA regards each DMU as production function that produces output by input. Then the efficiency of DMU is calculated compared with other DMUs relatively[6]. There are two characteristics DEA has; (1) weights are assigned to each input and output data and virtual input and output are generated. These weights are not fix but variable so that each DMU can employ suitable weight to be evaluated better. (2) common index for evaluation is shown as efficiency value. The efficient DMU gets efficiency value as one. On the other hand, inefficient DMU gets efficiency value less than one.

Assuming that there are n DMUs and each DMU is characterized by m input and s output. Then the DMU K has input expressed as x_{1k}, K, x_{mk} and output expressed as y_{1k}, y_{sk}. Here the efficiency value is shown by calculating following linear programming .

$$\begin{aligned} \max \quad & \sum_{r=1}^{s} u_r y_{rk} \\ \text{S.t} \quad & -\sum_{r=1}^{s} v_i x_{ij} + \sum_{r=1}^{s} u_r y_{rj} \le 0 \ (j = 1,2,3...,n) \\ & \sum_{r=1}^{s} v_i x_{ij} = 1 \\ & v_i \ge 0 \ (i = 1,2,3...,n) \quad u_r \ge 0 \ (r = 1,2,3...,n) \end{aligned} \tag{1}$$

Above formula signifies that weights are assigned to input of DMU K to make it as one. Then DEA controls the efficiency value of other DMUs does not exceed over one based on the weights for DMU K. Objective function has the role for maximizing output of remarkable DMU. Moreover, it is possible to analyze strong points of each DMU by weights. That is because input and output are considered in evaluation when the weights have value.

B. Problem of DEA

1) Problem of increasing input and output elements

DEA can analyze characteristics of DMU more multipronged from optimal weights as the number of input and output elements increase. However, increase of them causes

problem about analyzing characteristics of DMU. Generally, if input and output elements are so large, the number of DMU evaluated efficiency is also large. In this case, it is difficult to compare DMUs from their efficiency values. Moreover, non-zero weights which are actually used for evaluation increases. In other words, input and output elements which are characteristic of DMU increase. Then, it is difficult to understand strong characteristics of DMU.

Table I shows example of a result when input and output elements are so large (DMU:10 input:6 output:9). All DMU in this result are evaluated efficiency. So, it is impossible to compare DMUs by efficiency values. Moreover, Non-zero weights of DMU10 are 14 in 15. Because non-zero weights are too large, analyst can't understand strong characteristics of DMU3.

2) Problem of relation among inputs and outputs elements

Generally, analyst considers relation among input and output elements when he evaluates DMUs. However, DEA evaluates DMU regarding input and output elements as not having relation each other at all. So, the relation doesn't reflect in calculation even if there are strong relations among input and output elements. efficiency value of DMU is not necessarily correct.

Ⅲ. PROPOSED METHOD

This paper points out two problems of DEA in section Ⅱ. Then, this paper proposes structured DEA for solving them. This model makes structure of DMU and defined component of structure as group of related input and output elements. Structure shows relation among components and total efficiency of DMU. It is possible to evaluate each component by calculating efficiency value. And total efficiency value is calculated by efficiency value of components.

A. Structure of DMU

The structure of this study is constructed according to the following procedure.

Step1 is "Making component". Component is evaluated aspect of DMU and made by making input and output elements which related to an evaluated aspect to same group. It is defined that input elements set of Component K is X_k, output elements set is Y_k. And its efficiency value is θ_k. θ_k is calculating by (1) formula.

Step2 is "Adding middle layer and connecting components". If there is evaluated aspect that is composed of some component which are made in Step1, new component that is called middle layer added to the structure. Middle layer has some outputs which are efficient values of some component that compose middle layer. At the end, connect middle layer and total efficiency are connected based on their relation.

The example of the structure is shown as Figure 1. Now, there are four components, Component A ~ Component D and Middle Layer1. Arrow in Figure 1 shows that a middle layer at arrow's head is composed of component at arrow's tail. For example, Middle Layer 2 is composed of Component C, and Component D.

B. Calculating efficiency

Efficiency value of component is calculated by formula (1). It is impossible to calculate efficiency value of middle layer and total efficiency, because they don't have input elements. Then their efficiency value is calculated by formula (2) as follows.

$$\begin{aligned} \max \quad & \sum_{r=1}^{s} u_r y_{rk} \\ \text{S.t} \quad & \sum_{r=1}^{s} u_r y_{rj} \le 0 \ (j = 1,2,3...,n) \\ & x_i = 1 \ (i = 1,2,3...,n) \\ & v_i \ge 0 \ (i = 1,2,3...,n) \quad u_r \ge 0 \ (r = 1,2,3...,n) \end{aligned} \tag{2}$$

This formula is based on formula (1) and different point is that formula(2) assumes input value is 1. Therefore, all DMU's input value is equal. So, formula (2) calculates efficiency value by only relative comparison of output. Output elements of the middle layer are efficiency values of components that compose the middle layer. Equally, Efficiency value of total efficiency is calculated by formula (2).

Proposed method can overcome the problem of relation among inputs and outputs elements by calculating efficiency value in each component. Efficiency value of each component is calculated with only inputs and outputs which have relation. And, inputs and outputs which don't have relation aren't used for calculation together. Therefore, proposed method can evaluate as considering relation among inputs and outputs elements.

Table I Example of result when inputs and outputs elements are so large

DMU	effieicincy value	weights						weights								
		input1	input2	input3	input4	input5	input6	output1	output2	output3	output4	output5	output6	output7	output8	output9
DMU1	1	0.779	0.802	0.095	0.401	0	0.275	0.584	0	0.153	0	0.014	0.181	0.000	0	0
DMU2	1	0.990	0	0	0.509	0	0.656	1.244	0	0	0	0	0	0	0	0
DMU3	0.9242011	1.291	0.036	0.007	0	0.142	0.696	0.962	0.038	0.157	0.214	0.254	0.657	0.081	0.000	0
DMU4	1	0.662	0.892	0.041	0	0.173	0.378	0.705	0.202	0.043	0	0.007	0.367	0.000	0.00104	0.001
DMU5	1	0.701	1.125	0	0.225	0.041	0.240	0.753	0.253	0	0.059	0	0.216	0.000	0	0
DMU6	1	1.209	0.644	0	0.108	0.022	0.314	0.894	0.278	0	0.231	0.103	0.267	0.083	0.000	0
DMU7	1	0.625	0.191	2.546	0	0	0.026	1.373	0.571	0	0	0	0	0	0	0
DMU8	1	0.269	0.400	1.966	0	0.164	0	0.829	0.546	0.079	0	0.216	0	0	0	0
DMU9	1	0.979	0.400	0	0	0	0	1.024	0	0	0	0	0	0	0	0
DMU10	1	0.524	0.680	0.030	0.071	0.188	0.710	0.583	0.201	0	0.037	0.168	0.548	0.20663	0.140	0.140

Now, calculation example by using Figure1 is shown as follow. First, efficiency value of Component A ~ Component D is calculated by formula (1). Next, efficiency value of Middle Layer1 is calculated by formula (2) using $\theta_A, \theta_B, \theta_C$ as outputs. Middle Layer2 calculated as well as Middle Layer1 using θ_C, θ_D. At the end, Total Efficiency value is calculated by formula (2) using θ_1, θ_2.

C. *Analyzing result*

Analyzing result in traditional method is done with optimal weights. On the other hand, proposed method can overcome the problem that it is difficult to understand strong characteristics of DMU by using efficiency values of components and middle layers for analyzing result.

In proposed method, if efficiency value of Component K is 1, the evaluation of Component K is superior to the other DMUs. So, Component K is considered to be characteristic of the DMU. Oppositely, if efficiency value of Component K is low, Component K isn't considered to be characteristic of the DMU.

In analyzing DMUs as stated above, analyst can get characteristics of each DEA without using optimal weights. Therefore, it isn't caused problem in proposed method, when the input and output elements are so large. Moreover, proposed method can compare DMUs whose efficiency values are 1 by efficiency values of each component.

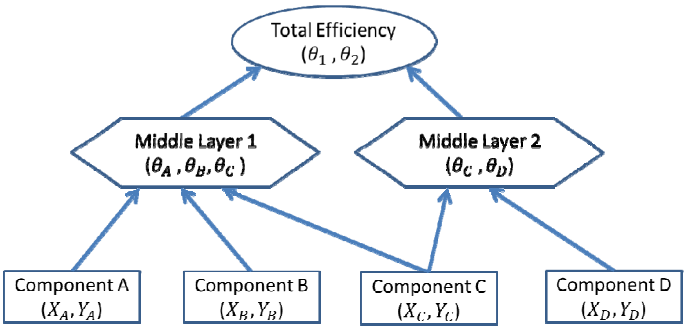

Fig. 1 Example of the structure

IV. NUMERICAL EXPERIMENTS

A. *Experimental conditions and data*

In order to examine utility of proposed method, Proposed method is applied to data set of 61 Japanese professional baseball player's result in 2010. There are 6 input and 9output elements as follows.

- Input
  (1) Total plate appearance
  (2) Number of strikeout
  (3) Number of failing stolen bases
  (4) Number of ground into double plays
  (5) Number of error
  (6) Total Defense opportunity

- Output
  (1) Number of hits
  (2) Number of caught stealing
  (3) Number of homerun
  (4) Number of run batted in
  (5) Number of Stolen Bases
  (6) Number of assists
  (7) Number of putouts
  (8) Number of double plays
  (9) Number of sacrifice bunts

From above input and output elements, considering input and output elements, we made five components and two middle layers as follows.

<Component 1> Bat Control

Input: (1),(2),(4) Output:(1)

<Component 2> Stolen Bases

Input: (3) Output :(5)

<Component 3> Sacrifice Bunts

Input: (1),(2),(4) Output:(9)

<Component 4> Slugging

Input: (1),(2),(4) Output:(3) (4)

<Component 5> Defense

Input: (5),(6) Output:(2) (6) (7) (8)

<Middle Layer 1>Technique of hitting

Input : 1 Output: efficiency of Component_1,2,3.

<Middle Layer 2>Offense

Input : 1 Output: efficiency of Middle Layer_1,
efficiency of Component_4

From above component and middle layer, the structure of Baseball player is constructed as Fig. 2.

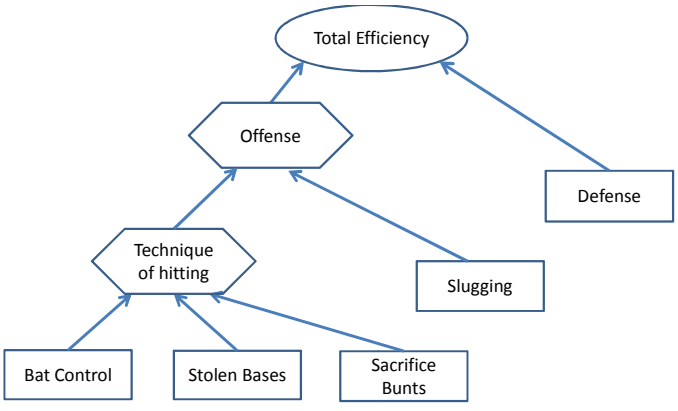

Fig. 2 Structure of Baseball Player

B. *Results*

The results is shown in Table Ⅱ. For example, DMU1 has efficiency as 0.918 in Total Efficiency, 0.918 in Technique of hitting and 0.537 in Defense.

C. *Disucussion*

1) Result of Traditional and Proposed methods

The efficiency value of the traditional method is calculated by formula(1). Table Ⅲ shows a part of the result of traditional method. It is shown that all DMU exclude only DMU60 have the efficiency value as 1 by traditional method. In this case, it is difficult for analyst to understand difference of DMUs by the efficiency value.

One of the reasons of it is increasing input and output elements. The other is assigning weights without considering relation among input and output elements. For example, DMU1's weight of input(3) is non-zero value, but weight of output(5) is zero. Input(3) and output(5) should be calculated together, because they have relation. Thus, calculation without considering relations makes DMU efficiency in the appearance, but analyst doesn't know whether DMU1 is real efficiency or inefficiency.

In proposed method, assigning weights are limited by making component. So, proposed method can evaluate considering relation among input and output elements. In the result of proposed method, number of DMU which has the efficiency value as 1 is fewer than the result of the traditional method. DMU1 has efficiency as 1 in traditional method but in proposed method efficiency as 0.918. Proposed method could find DMU1 is inefficiency, though analyst doesn't know in traditional method.

Weights have value 13 of 15 input and output elements in DMU3. Therefore, DMU3 is analyzed that it has characteristics overall. However, it is difficult for analyst to understand detail of characteristics, for example which elements is most superior or inferior. Proposed method can analyze detail of characteristics by the efficiency of each Component or Middle Layer. If DMU has high efficiency value of Component or Middle Layer, it is superiority. Oppositely, if DMU has low efficiency value of Component or Middle Layer , it is inferiority.

In this case, it is easy for analyst to understand characteristics of DMU3 by proposed method. Fig. 3 shows the structure and efficiency value of DMU3. The result based on

proposed method writes in structure figure like Fig.3, it is possible to understand characteristics of DMU just one look.

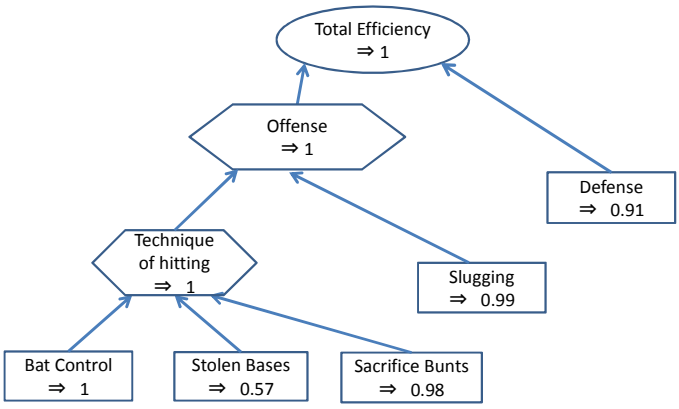

Fig. 3 Structure and Efficiency Value of DMU 3

For instance in Fig. 3, the efficiency value of Offense is 1, so DMU3 has superiority on Offense. The reason why Offense is superiority is found by the efficiency of its lower component. In this case, the reason is that the efficiency value of Technique of hitting is 1. Moreover, DMU3 has high efficiency value of Sacrifice Bunts and Slugging. So, Sacrifice Bunts and Slugging is also characteristics of DMU3. Like this, proposed method can analyzes characteristics of DMU which is difficult to understand by weights based traditional methods.

Table II a part of the result of proposed method

DMU	Total effieicincy value	efficiency value of component						
		Offense	Slugging	Technique of hitting	Stolen Bases	Sacrifice Bunts	Bat Control	Deffense
DMU1	0.918	0.918	0.894	0.918	0.476	0.761	0.918	0.537
DMU2	1	1	1	0.94	0.500	0.743	0.940	0.905
DMU3	1	1	0.987	1.000	0.571	0.985	1	0.905
DMU4	1	1	1	0.887	0.476	0.793	0.887	1
DMU5	1	1	1	0.863	0.643	0.680	0.863	0.748
DMU6	1	1	1	1	1	0.993	1	0.834
DMU7	1	1	0.875	1	0.5	0.905	1	0.666
DMU8	1	0.885	0.706	0.885	0.286	0.777	0.885	1.000
DMU9	1	1	0.686	1	0.841	0.675	1	0.879
DMU10	1	0.991	0.961	0.991	0.476	0.962	0.991	1

Table III a part of the result of traditional method

DMU	effieicincy value	weights						weights								
		Input(1)	Input(2)	Input(3)	Input(4)	Input(5)	Input(6)	Output(1)	Output(2)	Output(3)	Output(4)	Output(5)	Output(6)	Output(7)	Output(8)	Output(9)
DMU1	1	0.779	0.802	0.095	0.401	0	0.275	0.584	0	0.153	0	0.014	0.181	0.197	0	0
DMU2	1	0.990	0	0	0.509	0	0.656	1.244	0	0	0	0	0	0	0	0
DMU3	1	1.291	0.036	0.007	0	0.142	0.696	0.962	0.038	0.157	0.214	0.254	0.657	0.078	0.081	0
DMU4	1	0.662	0.892	0.041	0	0.173	0.378	0.705	0.202	0.043	0	0.007	0.367	0.235	0	0.001
DMU5	1	0.701	1.125	0	0.225	0.041	0.240	0.753	0.253	0	0.059	0	0.216	0.178	0	0
DMU6	1	1.209	0.644	0	0.108	0.022	0.314	0.894	0.278	0	0.231	0.103	0.267	0.060	0.083	0
DMU7	1	0.625	0.191	2.546	0	0	0.026	1.373	0.571	0	0	0	0	0	0	0
DMU8	1	0.269	0.400	1.966	0	0.164	0	0.829	0.546	0.079	0	0.216	0	0	0	0
DMU9	1	0.979	0.400	0	0	0	0	1.024	0	0	0	0	0	0	0	0
DMU10	1	0.524	0.680	0.030	0.071	0.188	0.710	0.583	0.201	0	0.037	0.168	0.548	0	0.207	0.140

2) Comparison characteristics between DMUs

When the number of DMU which has efficiency value as 1 is so large, it is difficult for analyst to compare DMUs by efficiency value based traditional method. Proposed method can compare the efficiency values of same component between DMUs. So, proposed method can compare DMUs that have efficiency value as 1. For example, it is shown Comparison between DMU2 and DMU4. DMU2 and DMU4 have total efficiency value as 1.Therefore, it is impossible to compare total efficiency value. DMU4 has the efficiency value as 1 in Defense, on the contrary DMU2 has efficiency value as 0.905. From this, DMU2 is superior to DMU4 in Defense. Similarly, it is compared the efficiency value in Technique of hitting, it is found that DMU2 is inferior to DMU4 in Technique of hitting. It is possible to compare each component or middle layer. As a result, it is shown that the proposed method can compare DMUs which have efficiency value as 1.

V. CONCULUTION

This study pointed out two problems of DEA. In order to solve them, this paper proposes Structured DEA. Two problems are as follows: (1) Difficulty to understand characteristics of DMU from the optimal weights calculated by the traditional DEA, (2) DEA can't consider relation among input and output elements. Structured DEA calculates partial evaluation of DMU by input and output elements which have relation. Total evaluation is calculated by the result of partial evaluation.

The proposed method is examined by applying 61 data of Japanese baseball players. From the numerical experiments, it is found that proposed method can analyzes characteristics of DMU which is difficult to understand by weights based traditional methods and can evaluate considering relation among input and output elements.

***Abstract*—A wrapper is a program that selectively extracts a necessary part (component) from Web pages. Automatic or semi-automatic wrapper construction is crucial to achieve a fine grained search engine for Web pages. However, this is not an easy task to achieve. This paper proposes a component-based search engine in which the content components gain a high score in the search results. Thus, the required segments for a query can be obtained without using a wrapper.**

***Index Terms*—search engine; blogs; ranking; semi-structured document**

I. INTRODUCTION

Information extraction is a necessary step for developing a Web search engine. However, web pages contain information which is not main content, for instance, online advertising, related information, website menu, navigation links, and so on. This kind of information has become the noise of creating Web search engine and decreases the accuracy of search result. Therefore, extraction of the main contents is crucial to improve the quality of blog search. A wrapper is a program that selectively extracts a necessary part (component) from Web pages. By ranking the importance of the components, we propose a component-based search engine in which the content components gain a high score in the search results. Thus, the required segments for a query can be obtained without using a wrapper.

The authors of the present paper have been working on a new search model [1], [2]. Tourism information was chosen to explain the effectiveness of the model. The blog site "Kyushu seifuku Blog" was chosen as analysis target of this research. This blog site is about the tourism information on the Kyushu area, which is published by Kyushu Tourism Promotion Organization [1]. Every blog entity on the site is composed of simple introduction and link. The details of the blog entities are open to the public on other external sites which are independent to the Kyushu Tourism Promotion Organization. We collected 1,303 blog entities and saved as html files and extracted 136,368 components from these blog.

II. RELATED WORK

A. Keyword Search for Semi-Structured Documents

There are two kinds of search engines – a vector space model based keywords search engine and semi-structured documents search engine. The vector space model is an algebraic model for representing text documents as vectors of identifiers. The first use was in the SMART Information Retrieval System [3]. According to the increase of HTML documents and XML documents, search engine for semi-structured documents are gaining attention. Moreover, it has been a big issue to integrate structure search and keyword search. For example, Seki et.al. [4] realised a faceted search for sub-structures using multiple vector space model search engines. It has become very popular to utilize vector space model to extract contents from semi-structured documents. Chidlovskii [5] described a method about information extraction from HTML/XML trees. Hu and his colleagues tried to formulate the semi-automatic construction parts as an algorithm [6]. Cooper and his colleagues proposed an indexing structure in order to achieve high query performance using semi-structured data repositories [7]. Moreover, Zhang, Ohmori and Hoshi analyzed the efficiency of keyword-based search for Hybrid XML-relational databases [8]. In order to improve the retrieval efficiency, Hatano and his colleagues proposed a method for determining fine grained results for keyword-based XML document retrieval [9].

All of these papers demonstrate how to integrate efficiently semi-structured document search into keyword document search. However, most of these approaches consider fixed XML formats which cannot deal with a variety of structures often seen in various blog sites. Each blog site provides completely different structures. Sometimes, bloggers can settle their own favorite format. So, we need structure-independent methods for blog search.

B. Blog Spams and Content Extraction

Blog sites are written in HTML. They are typical semi-structured documents. However, blog sites are not official sites. Official sites have documents with specific and clear purpose. Blogs are mixed by different purpose information such as the comments of blogger and company online advertising. Therefore it is difficult to evaluate the importance of a blog page as a single entity. We focus on the smallest plain text areas, which we call components, by which the pager is evaluated as s single entity.

One of the main difficulties in dealing with blogs is the increase of spams. There are a lot of researches about detection and the removal of the blog spam to improve the quality of search [10]. Even if we would succeed in choosing non-spam blogs, there remains a difficulty in extracting the real contents from the blog pages. Indeed, the target 1303 web pages, the present paper is analyzing, are chosen by experts of the tourism

[1] http://www.welcomekyushu.jp/

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

organization. They are not spam at all. However they still contain many navigational contents and advertisements in the pages. So, we will lose the feature of the page if we use all the words that appear in the page as the index words. To separate the real contents and other is a big problem we have to face. There are a few researches in extracting the pure contents using shallow features [11], [12].

III. Component Index

In order to create a blog search engine, it is necessary to extract the useful and valuable information from that blog. A large number of blog entries are written by the blog authors, and these constitute the main contents of the blog, and represent useful and valuable information. However, the main contents are often accompanied by a large amount of noise such as online advertisements, links to other blogs, copyright notices or the comments of readers. These noise data seriously harm the extraction of the blog's primary content. The top-ranked search results might not be pertinent for the query due to these noise. This is a big problem we must overcome to realise an ideal blog search engine. If all blogs were written in the same uniform template, it would be very easy separate contents and noise. However, there are a large number of blog sites, which have different templates. Moreover, blog authors can set up personalized templates according to their individual preferences. If we cannot distinguish the main contents and other noise, all the words in the HTML page will be recognized and indexed as feature words by which search is performed. In the end, the top ranked search results might be irrelevant.

The present paper considers a different approach to realise a high quality blog search. We believe that we can distinguish enhanced blogs and thin blogs even if we do not have a complete extraction program for article contents.

In the present paper, a web page is caught as a set in a lot of small text parts, which contain no tags. In other words, we focus on the leaves of HTML-trees. We do not try to separate the contents and other parts. Instead, we introduce a score for all these components. According to this score, the weight of words in the article become high and those in other parts become low. As the result, the rich content blogs appear at the top ranking in the search result.

Fig. 1 is an article in a tourism blog. It contains the navigational links of the site ①, links to the archives ②, links to the latest contents ③, the title of the article ④, and the main contents of the article ⑤. Fig. 2 shows the web page as an html-tree, where the square boxes highlight the main contents, where square boxes represents those content text areas. We call these small text areas as "components" and realised a search engine for these components by indexing them. We used GETA system [2] to realise the search engine. Fig. 3 displays the index file of the search engine. The lines starting with "@" symbol show the indexed objects, i.e. components. For example, "@1-1" and "@1-2" represents the first and the second test area of the first HTML file (Fig. 1). Other lines display index keywords and their frequencies in the text area. The keywords with "h:" represents the id of the HTML file. The keywords with "p:" represents the X-path by which the component can be reached from the root of the HTML-tree structure. For example, the keyword "p:/html[2]/body[4]/div[1]/div[1]/h3[1]/" in the second component "@1-2" represents the X-path to the text area ④, in Fig. 1, which is the headline of the article "Huis Ten Bosh is now blooging with roses!".

[2]http://geta.ex.nii.ac.jp

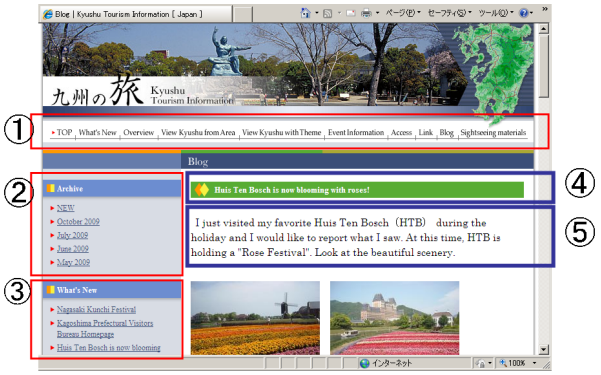

Fig. 1. A Tourism Blog

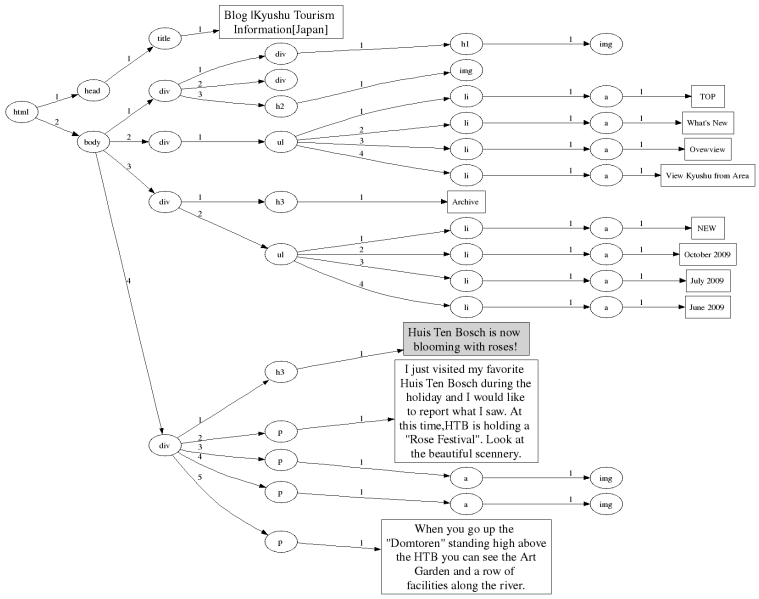

Fig. 2. HTML Tree

The anchor text that appears under the anchor tag is excluded from the components. Because the linked text is usually relevant to the other web pages, it is not useful contents to the search engine. Actually, most of them were displayed in the top, bottom, left and right of a blog page, what are links to top page, other blogs, or links to the online advertisement. Some anchor texts might correspond to internal link within the page. However, these anchor text usually contain only oe or two words. Moreover, these words appear in the text area which is the target of the link. Therefore, eliminating these

Fig. 3. Component Index

internal link anchor texts does not loose any information from the page.

IV. Component Scores

Lots of calculation methods were proposed to evaluate how important a word is to a document in a collection, such as "tf*idf" and the calculation method of SMART system [3], which are suitable long document. Comparing with the generic document, the sizes of the most of the components in this paper are a lot smaller. Therefore, "tf*idf" is not suitable these components.

We introduce the following formula for calculating the score of the components.

$$score(C_i) = NW(C_i) * depth(C_i),$$

where $NW(C_i)$ is the number of the distinct words in the component C_i and the depth $depth(C_i)$ is the length of the path to HTML tree's root. We found that the individual and detailed content is always put on the deeper nodes of the HTML tree, therefore, we use the depth to calculate the SC. On the other hand, the noise such as online advertisements is always put on the shallow nodes, which have common templates. Moreover, individual entities are written in original contents, which have rich vocabulary. The score of a web page is defined as the total scores of all the components in the page.

V. Search Results for "noodle"

We compared the SMART base standard score $S(D)$ and the component score $C(D)$ of html files D. Considering

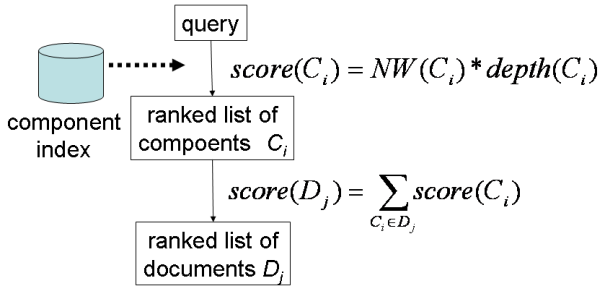

Fig. 4. Score of Components and Documents

practical situation, we conducted empirical evaluation using the following 22 keywords which are often seen in blog articles. These keywords are related to food, restaurant and gourmet.

noodle, soup, "ramen", dish, lunch, "chaashuu", vegetable, meat, pork, onion, 'sake", "udon", gourmet, chicken, fish, "soy sauce", egg, restaurant, meal, beef, rice, "tonkotsu"

For each 22 keyword w_i, firstly, we retrieved all the blog articles $D_{i,1}, \cdots, D_{i,N_i}$ that contain the keyword w_i. Secondly, we calculated the scores S-score(D_i) and C-score(D_i) together with their ranking S-rank(D_i) and C-rank(D_i). Then, we manually checked each pages $D_{i,j}$ when they have a large difference between S-rank(D_i) and C-rank(D_i). According to the limit fo space, we explain the analysis for the word "food" and 121 articles that contains the word.

Fig. 5 displays the scores of the 121 pages, where the x-axis represents the standard ranking (S-rank) and the y-axis represents the component-based ranking (C-rank) of each page. Most pages locate on the diagonal line and have almost similar rankings in S-rank and C-rank. However, there are some pages whose rankings are greatly changed. We selected top 12 pages among those pages and marked by square points. Table II displays the original data of those pages.

In the page where the ranking falls down, C-score is small. On the other hand, C-score is large for the page where the order went up. TableII displays typical components of each page which contain the query word (noodle). We see that the page where the ranking falls down (rank-descending page) contains a short sentence. We see that the page where the ranking went up is an article which contains given keyword and is written by a detailed content. It is worth-while to note that the rank-descending pages contain the query word, as shown in TableII, and that their C-score are small. This implies that short sentences shown as the snippets in TableII are the reason why those pages matches the query, as long as the components are concerned. The reason why those rank-descending pages gained high ranking in the standard ranking is not that their main contents contain the keyword but that they contain the keyword in navigation area or in left or right frames. On the other hand, the rank-ascending pages gained the high ranking because they are written with detailed contents as we can see Table II.

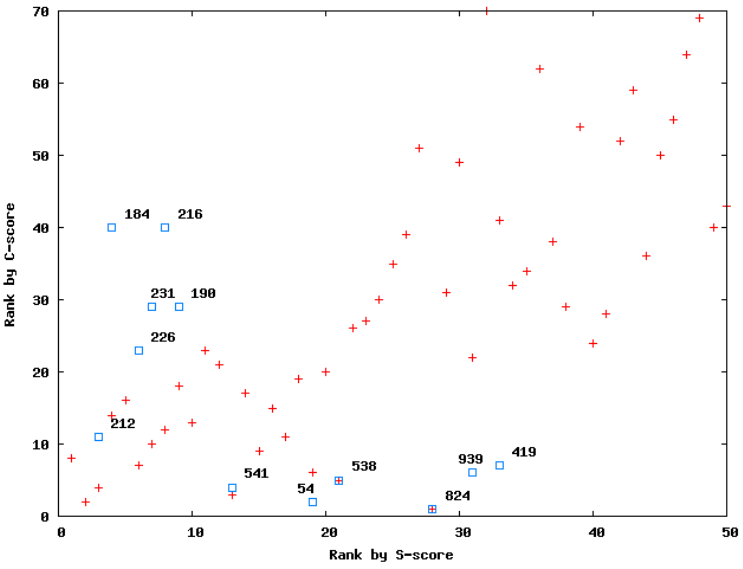

Fig. 5. Comparison of S-rank and C-rank

TABLE I
SCORE AND RANKING

HTML	S-rank	C-rank	Rank Diff	S-score	C-score
184.html	4	40	-36	0.0406	153
216.html	8	40	-32	0.0367	153
231.html	7	29	-22	0.0374	207
190.html	9	29	-20	0.0366	207
226.html	6	23	-17	0.0389	252
212.html	3	11	-8	0.0420	476
541.html	13	4	9	0.0348	880
538.html	21	5	16	0.0295	868
54.html	19	2	17	0.0309	1125
939.html	31	6	25	0.0260	830
419.html	33	7	26	0.0252	793
824.html	28	1	27	0.0272	1249

We displayed only one component in Table II. But the system already has all the components of the page and the scores of those components. So, we can display other appropriate components as snippets, which helps users to grasp the contents of the page before they actually read.

Top 6 pages (184.html, 216.html, 231.html, 190.html, 226.html, 212.html) that gained a big loss in the ranking, are in a private blog [3]. Their main articles are very short. However, they use a large area in the page for the pictures and for the links to related articles and to advertisement of affiliate (See Fig. 6).

A rank-ascending page, for example 419.html [4], contains a long sentence with the keyword and most of other contents concern personal experience and reproof of the blogger (See Fig. 7).

According to this case study, we observe that the pages which contain enhanced contents gained high ranks in the component-based ranking, while the pages whose related information is more than the article itself becomes a subordinate

Fig. 6. Page with Navigational Contents(184.html)

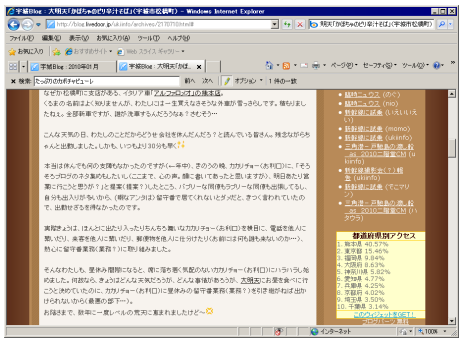

Fig. 7. Page with Rich Contents(419.html)

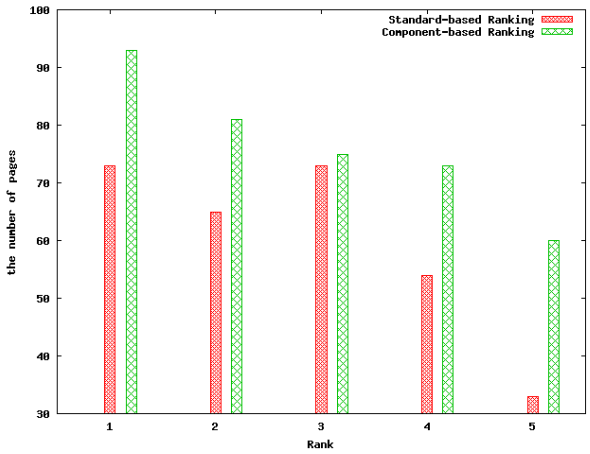

Fig. 8. User Preference of Standard Ranking and Component-based Ranking

position. This case study can be a clue for the effectiveness of the proposed ranking for detecting rich content blogs. We observed the similar pattern for other 21 cases of the keywords.

VI. Quantitative evaluation of ranking

We realised a standard search engine and a component-based search engine for 1303 blogs using GETA. We performed a quantitative evaluation of rankings using the 22 keywords as queries.

We compare the ranking of the pages in S-rank and C-rank. Actually, we constructed an experiment system for testee to select appropriate pages among

(A) top 5 pages in S-rank and

(B) top 5 pages in C-rank.

These pages are shuffled random and displayed as a search result for each query word for 22 keywords. We hide the rank of each search result. The testees do not know which page is chosen by S-rank or by C-rank. We displayed the components of the highest score as snippets in (A) and (B). Testees read the snippets and view the page, if they are interested, to choose the pages according to their preference. Fig. 8 shows the result. Component-based ranking obtained a better preference by testees in all ranks.

The total number of articles is not so large. But, those blog articles are collected from 144 sites and written different format. So, we think that this diversity supports our observation of the effectiveness of the proposed method.

VII. Conclusion and Further Work

Many people are using blogs as a means for publishing their opinions and recognize them as useful informal information sources to be searched for. However, a blog page contains various information besides the article itself. It is difficult to extract only the contents and utilize these contents, since there is no general rule to describe blog pages. In fact, blog pages have different format even if they are written in the same site. The present paper introduced a novel scoring method for a blog page focused on their components. This score and the ranking by this score succeeds to distinguish pages with enhanced articles from thin pages. Empirical evaluation are shown by constructing a search engine for tourism blogs. Effectiveness of the proposed method is confirmed through a detailed comparison of rankings of search result as well as quantitative evaluation.

We considered the leaves of an HTML-tree as components in the present paper. We excluded the anchor texts from components, since they do not contain the actual content of the page, but are links to external information. There may be other possibilities to formalize components. Inline tags, such as BR tag, and punctuation marks will be useful to characterize the real article area. Such shallow feature will improve the score as indicated in [12].

The authors appreciate the valuable comments from reviewers.

***Abstract*—We performed a single pendulum simulation and observed the influence of the situation space segmentation pattern in reinforcement learning processes in order to propose a new adaptive automation for situation space segmentation. Usually, in real-world reinforcement learning processes, infinite states and actions and the uncertainty of the optimum solution make the learning process more difficult than the finite Markov decision process. In a numerical experiment, a single pendulum simulation is performed in order to demonstrate the influence and adaptability of the proposed method.**

***Index Terms*—reinforcement learning, space segmentation.**

I. Introduction

Reinforcement learning is a framework for a strategy to learn through trial and error according to the reward provided by the environment[1]. In reinforcement learning, if the purpose of study is set, the agent automatically determines the best way to achieve the goal.

Reinforcement learning is chiefly applied to problems in the finite Markov decision process with a finite state and a finite action. However, recently, research on methods of expressing a continuous state and a continuous action, which is more similar to the real-world situation, has progressed. Research on motion control and autonomous control of the robot has been extensive. For example, studies have examined a control problem in order to enable the robot to walk. However, in the real world, this problem is difficult, as compared with the problem in the Markov decision process, because there are an infinite number of states and actions, and it is unclear as to whether an optimum solution exists.

Q-learning[2], [3] and SARSA are typical reinforced study methods that target discrete actions. Solving a problem that has a continuous state and a continuous action requires discrimination of the continuous state and continuous action.

In the present thesis, we investigate the method of this discretization, how to divide in order to find the optimum solution faster, and the technique by which an agent can acquire the best approach to automatically divide states, and the headstand stabilization problem of the pendulum was considered.

II. Reinforcement learning

Reinforcement learning assumes that agents can visit only a finite number of states, and that when visiting a state, they will collect a numerical reward (which can be interpreted as a punishment in the case of a negative reward). Each state has a different value associated with it. Given an initial state, subsequent states are reached according to actions. The value of a given state is defined as the average reward that can be collected by selecting actions available in that state.

A. Q-learning

Q-learning is a well-known reinforcement learning technique that works by learning an action-value function that gives the expected utility of taking given action a in given state s and following a fixed policy thereafter. One advantage of Q-learning is that Q-learning can compare the expected utility Q of available actions without requiring a model of the environment (usually, the agent selects the action with the maximum expected utility).

Expected utility Q is updated iteratively. For each state s from state set S, and for each action a from action set A, we update Q-value Q that depends on current state s of the agent, action a selected by the agent, the next state s of the agent after taking action a, and reward r received by the agent after taking the action. An update is calculated by the following expression:

$$Q(s,a) \leftarrow Q(s,a) + \alpha \left[r + \gamma \max_{\acute{a} \in A(\acute{x})} Q(\acute{s},\acute{a}) - Q(s,a) \right], \tag{1}$$

where α is the learning rate and γ is the discount factor. Once Q-learning has finished, the optimal policy and the optimal value function have been found without continuously updating the policy during learning.

Q-learning algorithm:

```
procedure Q-learning
begin
  initialize Q-table Q, ∀s ∈ S, ∀a ∈ A;
  set initial state s_0 and goal state s_n;
  for cycle := 1 to MAXCYCLE do s := s_0
    while s ≠ s_n do
      a := ActionSelect(Q, s);
      r := GetReward(s, a);
      s' := GotoNextState(s, a);
      Q := UpdateQ(Q, s, a, trace);
      s := s';
    end
  end
end
```

B. State and action space segmentation

A high-performance agent usually requires appropriately segmented state set S and action set A due to the state-space explosion of an agent. Generally, a genetic algorithm is used to search for appropriate segmentation in such individual double-loop learning. In other words, the particle swarm is a classification system in which we consider the minimization of (3) under the following condition:

$$\sum_{i=1}^{c} u_{ki} = 1, \tag{2}$$

where c is the number of clusters, and u_{ki} is called a membership function.

$$L = \sum_{i=1}^{c} \sum_{k=1}^{N} u_{ki} D\left(x_k, v_i\right), , \tag{3}$$

where N is the amount of data, c is the number of clusters, and $D\left(x_k, v_i\right)$ denotes the distance between data vector x_k and cluster center v_i, which is the difference between expected utility V and observed utility V' in the learning process.

C. Softmax Action Selection

In the present simulation, we use softmax action selection rules as an action selection policy. Softmax action selection rules rank and weight according to Q-value Q. The most common softmax method uses a Gibbs or Boltzmann distribution. This method chooses an action on the play with probability.

$$P(s,a) = \frac{\exp^{Q(s,a)/\tau}}{\sum_{\grave{a} \in A} \exp^{Q(s,\grave{a})/\tau}} \tag{4}$$

where τ is the temperature parameter. High temperatures cause (almost) all of the actions to be equiprobable, and low temperatures cause a greater difference in selection probability for actions that differ in their value estimates. If $\tau \to$ inf, then softmax action selection becomes the same as greedy action selection.

III. Single pendulum simulation

We simulated the single pendulum standing task (fig. 1). This physical calculation is performed by Runge-Kutta 4th order method.

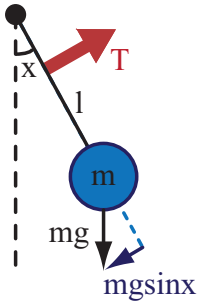

Fig. 1. Single pendulum

The following motion equation is simulated in increments of 0.05 seconds[4]:

$$m\ddot{x} = -mgl\sin x - k\dot{x} + T \tag{5}$$

where the parameters and variables are defined as follows:

- $m = 1(kg)$
- $l = 1(m)$
- $k = 0$
- $g = 9.8(m/s^2)$
- $-\pi < \theta \leq \pi$
- $-3\pi \leq \dot{\theta} \leq 3\pi$
- $-20 \leq T \leq 20$
- 1 iteration = 20 seconds
- 1 learning cycle = 0.2 seconds
- $\theta = \pi, \dot{\theta} = 0$, in the initial state
- $r_t = \frac{|x|}{\pi} - 0.5\frac{|T|}{20}$
- $\alpha = 0.25$
- $\gamma = 0.9$
- $\tau = 1$ at the first learning cycle, $\tau = 0.001$ at the last learning cycle (linearly decreasing)

A. Segmentation pattern in the state

First, we generated some patterns by dividing the state space, and a simulation was conducted.

```
procedure Q-learning with segmentation pattern
begin
  initialize Q-table Q, ∀s ∈ S, ∀a ∈ A;
  set initial state s_0;
  select dividing methods;
  for cycle := 1 to MAXCYCLE do s := s_0
    for time := 0 : 0.05 : 20
      s' := GetNextState(s, a);
      if mod(time, 0.2)==0;
        s'_r := s';
        r := GetReward(s'_r, a);
        Q := UpdateQ(Q, s_r, s'_r, a);
        a := ActionSelect(Q, s'_r);
        s_r := s'_r;
      end
      s = s';
    end
  end
end
```

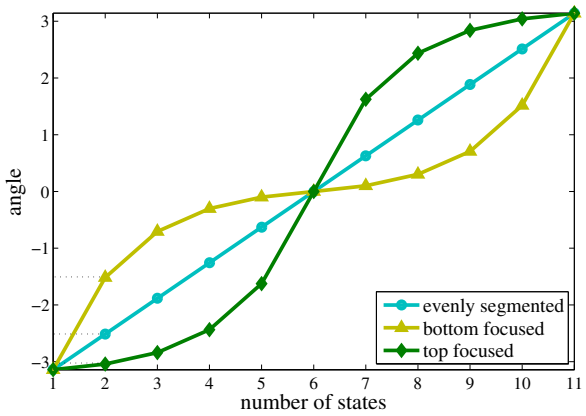

Fig. 2. dividing methods

Fig. 2 show the rate of the space segmentation. Vertical axes show the rate of the angle width (width of each segment) and horizontal axes show the angle of each segment.

For example, for "evenly segmented," the space is evenly segmented to 10 parts. for "bottom focused," the space is segmented larger around the bottom, and smaller around the top. In other words, the bottom is segmented to many parts and the agent can find difference of angle even small difference compared with the top. for "top focused," on the contrary, the top is segmented to many parts.

Other parameters and variables are defined as follows:

- 1000 episodes × 30
- θ and $\dot{\theta}$ are segmented into 10 segments
- T is segmented into six segments
- $\dot{\theta}$ and T are segmented evenly

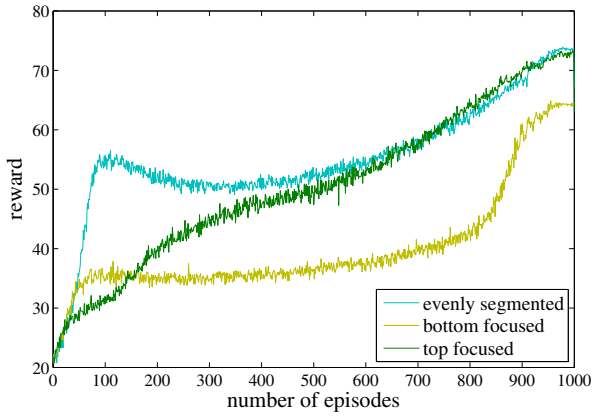

Fig. 3. comparison of the three methods

The results indicate that "evenly segmented" and "top focused" eventually provided good rewards, whereas "bottom focused" provided smaller rewards. In addition, the "bottom focused" requires more iterations than the first method in order to provide good rewards.

B. Segmentation and integration method

We investigated an automatic segmentation and integration method through simulation.

```
procedure Q-learning with segmentation and integration
begin
  initialize Q-table Q, ∀s ∈ S, ∀a ∈ A;
  set initial state s_0;
  for cycle := 1 to MAXCYCLE do s := s_0
    for time := 0 : 0.05 : 20
      s' := GetNextState(s, a);
      if mod(time, 0.2)==0;
        s'_r := s';
        r := GetReward(s'_r, a);
        Q := UpdateQ(Q, s_r, s'_r, a);
        a := ActionSelect(Q, s'_r);
        s_r := s'_r;
      end
      s = s';
    end
    if mod(cycle, FREQUENCY)==0;
      (S, Q) := Combine(S, Q);
      (S, Q) := Divide(S, Q);
  end
end
```

In this method, the space is initially evenly segmented, segmentation and integration is performed at regular cycles by the Combine(S, Q) and Divide(S, Q) functions.

The neighboring states that an average of the visited frequency is the least are integrated into a single state that has an average expected utility of the states by the Combine(S, Q) function. And the state that the visited frequency is the most is equally segmented into two states that have the same expected utility by the Divide(S, Q) function. Other expected utilities are undisturbed.

Other parameters and variables are defined as follows:

- 1000 episodes × 30
- θ and $\dot{\theta}$ are segmented into 10 segments
- T is segmented into six segments
- θ is segmented evenly, in the initial state
- $\dot{\theta}$ and T are segmented evenly

First of all, to decide how often states are combined and divided, each various episodes was combined and divided. These average rewards from 951 episodes to 1000 episodes were shown in TABLE I.

As a result, "every 200 episodes" had the best reward. So after this, we chose that the states were combined and divided every 200 episodes.

The proposed method eventually provides the best reward and the reward was increasing especially every 200 episodes, which indicates that the proposed method can be used to determine an appropriate segmentation method automatically over time.

Next, how to divide the states after the learning of "proposed method" was checked and the states were shown in fig.

TABLE I
HOW OFTEN COMBINE AND DIVIDE AND THE AVERAGE REWARD

how often combine and divide	the average reward
every 50 episodes	73.7279
every 100 episodes	77.3704
every 200 episodes	**78.3863**
every 300 episodes	76.4497
every 400 episodes	75.4669
every 500 episodes	74.6121
not combine and divide	73.2671

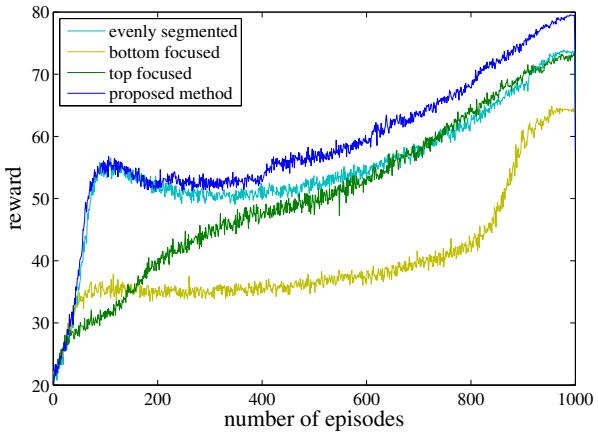

Fig. 4. comparison of the four methods

5. The result was got by average of 100 times.

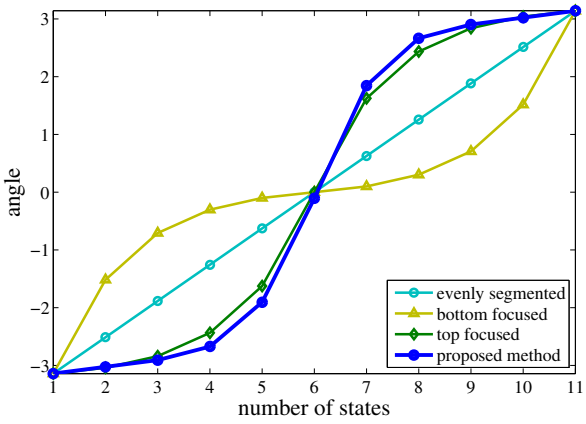

Fig. 5. final dividing methods

Following results were observed in fig. 5, "proposed method" had feature which was emphasized the feature of "top focused." In short, the top was segmented to many parts and the bottom was segmented to few parts.

Finally, the experiments with the finally segmented states of the proposed method were done from the beginning. In the experiments, the states were not combined and divided. The results were following fig. 6, 7.

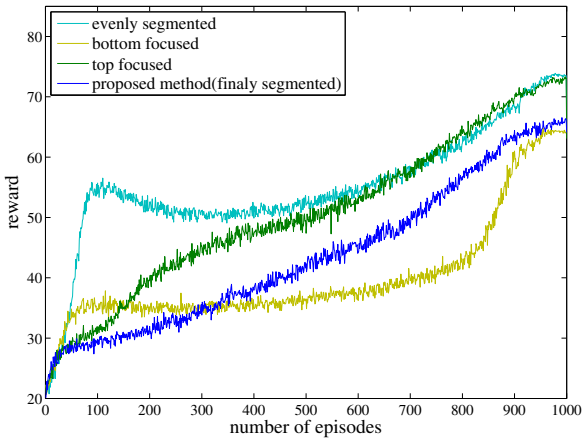

Fig. 6. results in 1000 episodes

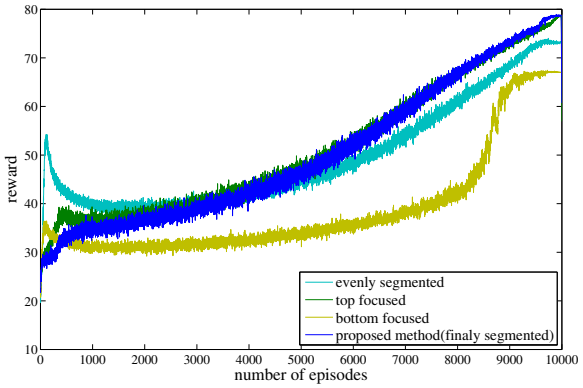

Fig. 7. results in 10000 episodes

Figures show that "1000 episodes" was not enough and "10000 episodes" was enough to get good rewards. This means the dividing way needs much time than the proposed method.

IV. Conclusion

We simulated a single pendulum simulation and observed the influence of the space segmentation and its adaptive automation for reinforcement learning. In order to divide state space, three methods were proposed, and "evenly segmented" and "top focused" got good rewards in the end episode.

The proposed method eventually provides the best reward and the reward was increasing especially every 200 episodes, which indicates that the proposed method can be used to determine an appropriate segmentation method automatically over time.

But, when the experiments with the state which were gotten by simulation were done from the beginning, the experiments needed much episodes than the proposed method to get reward at the same level. This shows that an appropriate division method is different depending on the advancement condition of study.

In the future, it is needed that a technique for integrating non-adjacent states, and expressed state space by using a function and particles, etc. In addition, more complicated experiments are also needed. For example, double pendulum simulation.

***Abstract*—One of the main difficulties in real-world data classification and analysis tasks is that the data distribution can be imbalanced. In this paper, a variant of the supervised learning neural network from the Adaptive Resonance Theory (ART) family, i.e., Fuzzy ARTMAP (FAM) which is equipped with a conflict-resolving facility, is proposed to classify an imbalanced dataset that represents a real problem in the semiconductor industry. The FAM model is combined with the Dynamic Decay Adjustment (DDA) algorithm to form a hybrid FAMDDA network. The classification results of FAM and FAMDDA are presented, compared, and analyzed using several classification metrics. The outcomes positively indicate the effectiveness of the proposed FAMDDA network in undertaking classification problems with imbalanced datasets.**

Keywords-Data classification; imbalanced data; Adaptive Resonance Theory Neural Networks; supervised learning

I. INTRODUCTION

Many problems in modern engineering applications can be undertaken as a classification task. Over the years, various machine learning techniques have been investigated and applied to process and analyze real databases from industries. In particular, data classification is an active research field in machine learning. A classification model can be constructed by capturing associations between the input and the output variables of a dataset through a supervised learning procedure. The effectiveness of the classification model can be affected by an imbalanced dataset in which its data samples from one class exist in a large quantity (i.e., the majority class) whereas data samples with other classes are available in small quantities (i.e., the minority classes). Imbalanced datasets are commonly observed in real applications. Many real-world datasets exhibit such characteristics, for examples, in medical prognosis and diagnosis [1], vision recognition [2], credit card fraud detection [3], and bioinformatics [4]. In these applications, the occurrence of minority/rare cases is occasionally given more attention than that of the majority.

Learning with an imbalanced dataset is never an easy task. One of the main challenges is how a classification model, whereby its knowledge base is dominated by information from the majority class, is able to learn information of the minority classes accurately. The reason is that a classification model may tend to neglect information acquired from data samples with the minority classes owing to overwhelming information of the majority class. The situation becomes worse if the imbalanced dataset is large in size and has an arbitrary high complexity. From the literature, data mining and machine learning techniques such as decision trees, *k*-nearest neighbor and naïve Bayesian [5] have been employed as classification models for handling imbalanced datasets. Nevertheless, they are unable to yield satisfactory results [5]. Modifications made on these techniques (e.g., [6, 7]) are able to improve the classification performances in dealing with imbalanced datasets. In this regard, two common approaches have been adopted to construct a more effective classification model for tackling imbalanced datasets, i.e., modifications are at either the data level [6] or the algorithm level [7]. At the data level, re-sampling methods, which include methods for under sampling the instances from the majority class, over sampling the instances from the minority classes, and the use of these two methods, have been introduced. The re-sampling methods are applied to determine a good mix of samples belonging to different classes from the imbalanced dataset for achieving good classification performances. On the other hand, at the algorithm level, the learning algorithm of the classification model is modified so as to learn the characteristics of samples from the minority classes more effectively.

In this research, a supervised Adaptive Resonance Theory (ART) neural network, namely Fuzzy ARTMAP (FAM) [8], is proposed as a base classifier to handle imbalanced datasets. FAM, an incremental learning model, is able to overcome the

The Matsumae International Foundation and the Watada Lab

stability-plasticity dilemma [9]. The FAM network is *plastic* enough to absorb new information from new samples and, at the same time, is *stable* enough to retain previously learned information from being corrupted by newly learned information. An interesting feature of FAM is that it integrates fuzzy set theory [10] and the stability-plasticity characteristic of ART into a common framework, and this allows the network to encode both analog and binary input patterns (i.e., information) in the form of rectangular prototypes. The focus of this research is on evaluating the effectiveness of a variant of FAM in dealing with a large imbalanced dataset collected from a manufacturing industry. Original FAM does not have the conflict resolving capability for handling overlaps among prototypes of different classes. In this case, a Dynamic Decay Adjustment (DDA) algorithm [11] can be integrated within the supervised learning mechanism of FAM, and the resulting network is known as FAMDDA. As far as imbalanced datasets are concerned, such additional facility is helpful for FAM to adapt and distinguish information of the minority classes from those of the majority class more accurately; hence, the network is able to provide a better solution to problem under scrutiny.

The organization of this paper is as follows. Section II explains the classification models (i.e., FAM and FAMDDA) used for learning imbalanced datasets. Section III describes the indicators for assessing the performance of a classification model with imbalanced datasets. In Section IV, a case study with a large imbalanced dataset from a semiconductor manufacturing plant is carried out. The results and the associated discussion are presented. Concluding remarks are given in Section V.

II. Fuzzy ARTMAP-based Neural Networks

A. Fuzzy ARTMAP (FAM)

FAM [8] is an incremental learning neural network from the ART family. The network is capable of self-organizing and self-stabilizing information gained from training samples during supervised learning. The structure of FAM is depicted in Fig. 1. The network is constructed by a pair of fuzzy ART modules (i.e., ART_a and ART_b) that are interconnected through a map field, F^{ab}. Each ART module consists of three layers of nodes, i.e., $F_0^a(F_0^b)$ is the normalization layer wherein an $M-$dimensional input vector, $\boldsymbol{a}$, is complement-coded [8] to a $2M-$dimensional vector $\boldsymbol{A}$; $F_1^a(F_1^b)$ is the input layer wherein the nodes receive the complement-coded input vectors; $F_2^a(F_2^b)$ is the recognition layer containing recognition nodes that encode prototypes of input patterns. Note that new nodes can be created in $F_2^a(F_2^b)$ when necessary to include new information.

The learning procedure of FAM is as follows. During supervised learning, an input pattern is presented to ART_a whereas its corresponding target output is presented to ART_b. At ART_a, the input pattern is complement-coded as pattern $\boldsymbol{A}$ and then propagated to F_2^a through F_1^a. The activation of each node j in F_2^a is measured by a choice function [8]

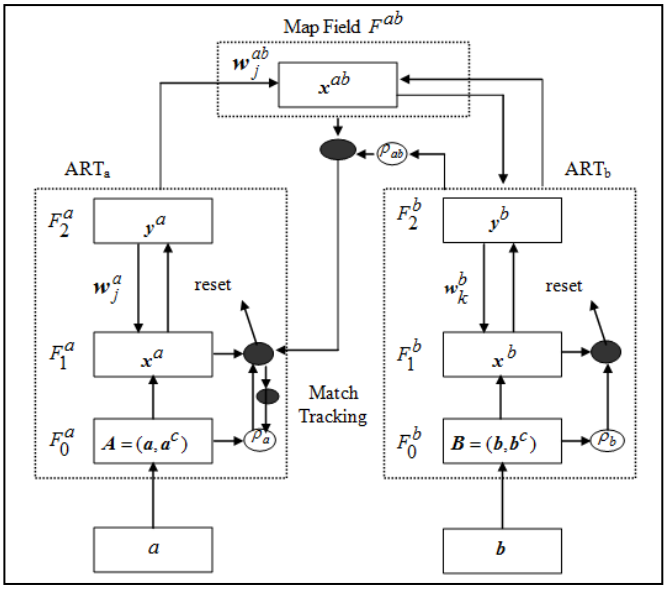

Figure 1. The network structure of Fuzzy ARTMAP.

$$T_j = \frac{\left|\boldsymbol{A} \wedge \boldsymbol{w}_j^a\right|}{\chi_a + \left|\boldsymbol{w}_j^a\right|} \tag{1}$$

where χ_a is the choice parameter and is set close to zero [8]; $\boldsymbol{w}_j^a$ the weight of node j. Based on the *winner-take-all* competition scheme, the node with the largest activation is selected as the winning node, and is denoted as node J. FAM imposes a vigilance test that measures the similarity between the winning prototype patterns, $\boldsymbol{w}_J^a$, and $\boldsymbol{A}$ against a threshold (vigilance parameter, ρ_a), as follows [8]

$$\frac{\left|\boldsymbol{A} \wedge \boldsymbol{w}_J^a\right|}{\left|\boldsymbol{A}\right|} \geq \rho_a \tag{2}$$

If the winning node fails in the vigilance test, a new search cycle for another winning node is exercised. The process of searching for a winning node is continued until the selected node is able to satisfy the vigilance test. If no such node exists, a new node is created in F_2^a to encode the input pattern. The same pattern-matching cycle takes place in ART_b using the target vector to find a winning node that encodes the target class.

Upon the identification of the winning nodes in F_2^a and F_2^b, a prediction is sent from F_2^a to F_2^b via F^{ab}. A map-field vigilance test is conducted to ascertain the prediction, i.e., [8]

$$\frac{\left|\boldsymbol{y}^b \wedge \boldsymbol{w}_J^{ab}\right|}{\left|\boldsymbol{y}^b\right|} \geq \rho_{ab} \tag{3}$$

where $\boldsymbol{y}^b$ denotes the output vector of $\boldsymbol{y}^b$; $\boldsymbol{w}_J^{ab}$ denotes the weight vector from F_2^a to F^{ab}; and ρ_{ab} is the map-field

vigilance parameter. If the map field vigilance test fails, this indicates that the winning node in F_2^a has made a wrong prediction of the target class in F_2^b; hence, a matching-tracking process [8] ensues. Parameter ρ_a, which is initially set to a user-defined baseline vigilance parameter $\overline{\rho}_a$, is now increased to

$$\rho_a = \frac{\left|\boldsymbol{A} \wedge \boldsymbol{w}_J^a\right|}{\left|\boldsymbol{A}\right|} + \delta \tag{4}$$

where δ is a small positive value. By increasing ρ_a, the current winning node in F_2^a will fail in the ART$_a$ vigilance test. A new search cycle in ART$_a$ is initiated again with a new level of ρ_a. This process is repeated until a correct prediction is made between the winning nodes in F_2^a and F_2^b. Then, FAM enters a learning phase, whereby the weight vector of the winning node in F_2^a is updated as [8]

$$\boldsymbol{w}_J^{a(new)} = \beta_a\left(\boldsymbol{A} \wedge \boldsymbol{w}_J^{a(old)}\right) + \left(1-\beta_a\right)\boldsymbol{w}_J^{a(old)} \tag{5}$$

where β_a is the learning rate of ART$_a$. The same learning process as in ART$_a$ also takes place in ART$_b$. Note that all equations in ART$_a$ are applicable to ART$_b$, but with superscript or subscript *a* replaced by *b*.

B. Fuzzy ARTMAP with the Dynamic Decay Adjustment (FAMDDA) Algorithm

The architecture of FAMDDA is the same as that of FAM. However, FAMDDA is equipped with an additional conflict-resolving facility contributed by the DDA algorithm. In this regard, the FAM learning procedure, specifically in its ART$_a$ module, is modified for resolving overlaps (conflicts) among prototypes of different classes.

In order to include the idea of infinite/finite volume as in [11] within the FAM framework, each dimension d of prototype p in the recognition layer (i.e., F_2^a) of the ART$_a$ module is given a status of S_{pd}=0 (i.e., infinite dimension) or S_{pd}=1 (i.e., finite dimension). All dimensions of a newly committed F_2^a prototype are initialized as 0. When the prototype is involved in width shrinking, the status of the selected dimension is changed to 1. In addition, a new set of *reference vector*, $\boldsymbol{w}_j^r$, is introduced to each prototype in F_2^a. Each reference vector is initialized as a zero vector. When learning takes place, besides the weight vector $\boldsymbol{w}_J^a$ [8], the reference vector of the *J*-th F_2^a winning node is also updated according to a recursive center estimation procedure [12], as follows.

$$\left(\boldsymbol{w}_J^r\right)^{new} = \left(\boldsymbol{w}_J^r\right)^{old} + \frac{1}{N_J}\left(\boldsymbol{A} - \left(\boldsymbol{w}_J^r\right)^{old}\right) \tag{6}$$

where N_J is the number of input patterns of the J-th node, $N_J = N_J + 1$.

If $\boldsymbol{x}$, which represents the weights of the $M-$dimension (or $2M-$ dimension with complement coding) winning prototype falls in the region formed by the prototype of different classes (i.e., λ), a conflict is said to occur. As such, a width shrinking procedure is executed to avoid the conflict. The width of the conflicting prototypical region is shrunk. The shrinking procedure is applied successively between the winning prototype and other conflicting prototypes. In general, three cases of width shrinking are considered [11]. First, if the existing finite dimensions of the conflicting prototype q can be shrunk without falling below a pre-set $\varepsilon_{\min}$, the one with the smallest loss in volume ($\gamma_{best,k}$) is chosen, as follows [11].

$$\gamma_{best,k} = \min\{\left|w_{qk}^r - x_k\right| : \forall 1 \le i \le n, i \ne k : \left(\frac{\lambda_{qk} - \left|w_{qk}^r - x_k\right|}{\lambda_{qk}} \le \frac{\lambda_{qi} - \left|w_{qi}^r - x_i\right|}{\lambda_{qi}}\right) \wedge \left(\lambda_{qk} \ge \varepsilon_{k,min}\right) : S_{qi}, S_{qk} = 1\} \tag{7}$$

where $\lambda_{qj} = \left|w_{qj} - w_{qj}^r\right|$ and w_{qj} represents the weight of the prototype q at dimension j. Equation (7) indicates that shrinking of an existing finite dimension is preferred for not losing the "infinite volume" of other infinite dimensions. Such idea also complies with the learning paradigm of FAM, which supports the stability property; i.e., it helps protect previously learned knowledge of FAMDDA from being washed away. However, if the first option is not satisfied, the following options are considered, i.e., either one of the remaining infinite dimensions is shrunk ($\gamma_{\max,l}$),

$$\gamma_{\max,l} = \max\left\{\left|w_{ql}^r - x_l\right| : S_{ql} = 0\right\} \tag{8}$$

or, the width of the finite dimension of the prototype q is shrunk

$$\gamma_{min,m} = \min\{\left|w_{qm}^r - x_{qm}\right| : \forall 1 \le i \le n, i \ne m : \left(\frac{\lambda_{qm} - \left|w_{qm}^r - x_{qm}\right|}{\lambda_{qm}} \le \frac{\lambda_{qi} - \left|w_{qi}^r - x_{qi}\right|}{\lambda_{qi}}\right) : S_{qi}, S_{qk} = 1\} \tag{9}$$

Equation (8) is selected if $\gamma_{\max,l} > \gamma_{\min,m}$. Upon the selection of γ_z from (7)–(9), region λ_{qk} is reduced by adjusting w_{qz}, as follows.

$$w_{qz}^{new} = \begin{cases} w_{qz}^{old} + \gamma_z & \text{if } w_{qz}^{old} < w_{qz}^r \\ w_{qz}^{old} - \gamma_z & \text{if } w_{qz}^{old} > w_{qz}^r \end{cases} \tag{10}$$

If $w_{qz} > 1$ or $w_{qz} < 0$, it is rounded as $w_{qz} = 1$ or $w_{qz} = 0$, respectively. For clarity, FAMDDA undergoes sequential learning which synchronizes the operation of the DDA algorithm with the learning process of FAM in a fast manner. In this situation, the DDA algorithm is not possible to find an optimum solution which can eliminate all conflicts within reasonable time in this sequential learning paradigm. Instead,

the proposed FAMDDA network attempts to reduce and/or avoid overlapping among prototypes of conflicting classes during its training session. The conflict-resolved prototypes and their associations obtained in the training phase are used, during the test phase, to recall a prediction when an unseen pattern is presented to ART_a.

In general, the training procedure of FAMDDA can be summarized as follows.

1. An M-dimensional input pattern $\boldsymbol{a} \in [0,1]^M$ in F_0^a is complement-coded to a $2M$-dimensional vector $\boldsymbol{A}$.
2. The input vector $\boldsymbol{A}$ is propagated from F_1^a to F_2^a through the weight vector, $\boldsymbol{w}^a$. The response of each node is computed according to the match function as in (1).
3. The prototype of node J is propagated back from F_2^a to F_1^a to participate in the vigilance test as in (2).
4. If the vigilance test fails, a new search cycle is initiated by re-visiting step 3. (The above cycle runs simultaneously in ART_b).
5. A prediction is sent from F_2^a (i.e., $\boldsymbol{w}_J^{ab}$) and from F_2^b (i.e., $\boldsymbol{y}^b$), respectively, to F^{ab}, where the map-field vigilance test as in (3) is performed.
6. If the map-field vigilance test fails, a matching-tracking procedure as in (4) is triggered. Similar to FAM, the matching-tracking procedure only affects the ART_a module of FAMDDA, and step 3 is re-visited.
7. The weight vectors $\boldsymbol{w}_J^a$ and $\boldsymbol{w}^r$ are updated according to (5)–(6). The weight vector $\boldsymbol{w}_J^b$ of the winning node in ART_b is updated using (5) by replacing superscript or subscript a with b.
8. The F_2^a nodes with different class from that of the winning node J are identified. Width shrinking of the existing conflicting nodes is initiated by considering one of the three cases as in (7)–(9).

The training session is completed when all training patterns have been presented to the network. Otherwise, the training session is continued by presenting the next pattern to the network, and step 1 is re-visited.

III. LEARNING WITH IMBALANCED DATASETS

The class distributions of an imbalanced dataset are uneven whereby most of the data samples belong to the majority class and very few data samples belong to the minority classes. Learning from such an imbalanced dataset is a challenging task especially when the database is huge and complex. For a binary classification problem, many performance indicators have been introduced, and they are based on a confusion matrix as shown in Table I.

A popular metric in pattern classification is the overall accuracy, which is the *correctly classified rate* (CCR) as shown in (11). Indeed, the CCR is suitable for assessing the performance of a classification model with balanced datasets. A tendency of a typical classification model when dealing with imbalanced datasets is that the model can be biased to classify

TABLE I. CONFUSION MATRIX

	Predicted Positive (Label=0)	**Predicted Negative (Label=1)**
Actual Positive (Label=0)	True Positive (TP)	False Negative (FN)
Actual Negative (Label=1)	False Positive (FP)	True Negative (TN)

all data samples as belonging to the majority class. In this regard, the model is likely to classify data samples from the majority class well (i.e., very high TP) but unlikely to classify data samples from the minority class efficiently (i.e., very low TN). Under this circumstance, a high CCR value can be contributed by a very high value of TP and a very low value of TN. As such the CCR is not an appropriate measure for classification performance when dealing with imbalanced datasets.

$$\mathrm{CCR} = \frac{\mathrm{TP} + \mathrm{TN}}{\mathrm{TP} + \mathrm{FP} + \mathrm{FN} + \mathrm{TN}} \tag{11}$$

From the literature, geometric mean, G-mean, is a more feasible performance indicator for imbalanced data classification. It is a nonlinear measurement, and is independent of the distribution of data samples among different classes [13]. G-mean evaluates the performance of a classification model in a fair way by considering the results of both the majority and minority classes. G-mean is expressed as follows:

$$\mathrm{G\text{-}mean} = \sqrt{\mathrm{TPR} \times \mathrm{TNR}} \tag{12}$$

where

$$\mathrm{TPR} = \frac{\mathrm{TP}}{\mathrm{TP} + \mathrm{FN}}, \ \mathrm{TNR} = \frac{\mathrm{TN}}{\mathrm{TN} + \mathrm{FP}} \tag{13}$$

TPR and TNR are the rates of TP and TN, respectively. TPR and TNP, respectively, represent the rates of the majority and minority classes being predicted correctly.

IV. CLASSIFICATION WITH A LARGE IMBALANCED DATASET

In the manufacturing industry, finished goods are normally produced in large quantities. The volume of production is a key performance index to indicate processing capacity and quality. In semiconductor as well as in other manufacturing industries, production growth from the mass production of one finished good is a target to achieve because it could bring a reduction in cost and also an increase in revenue. If the volume of production could be estimated by analyzing data from an upstream process with an intelligent system, then it could assist the production unit to identify impending yield or quality issues related to the final product. In this case, the undesirable variations from the upstream process could be identified to make improvements, and this helps to assure high product quality and efficient supply line management. Indeed, as pointed out in [14], classification is a useful way to help understand complex manufacturing processes.

A. Data Background

In this research, a case study involving the use of an encrypted dataset collected from a semiconductor company. The input and output features of the dataset are shown in Table II. The dataset comprises three input attributes where one of them is a categorical attribute whereas the other two are numerical attributes. The categorical attribute has a record of

215 values, ranging from 1A to 215A. Both numerical attributes have discrete values; the first has a range from 174610 to 299370 whereas the second from 174650 to 301770. The output class a binary number.

The dataset consists of 169910 samples, and they were divided into training and test sets. Table III summarizes the distributions of the data samples in the training and test sets. As can be seen from Table III, the data distribution in training and test sets was highly skewed. This is because in both training and test sets, the number of samples with label 0 is more than those with label 1. Indeed, the dataset exhibits a property of data imbalance, i.e., relative imbalance [15]. Thus, it was a challenging task to predict the samples from the minority class accurately.

B. Experimental Setups

Data normalization is required for use with FAM so as to mitigate the effect of category proliferation [8] during its learning process. In this case, the value of an attribute is normalized between 0 and 1 using

$$(x - \min(x))/(\max(x) - \min(x)) \qquad (14)$$

where $\min(x)$ and $\max(x)$ are respectively the lowest and the highest values of the attribute, x, in the dataset.

Data re-sampling techniques are useful for assisting a classification model in learning imbalanced datasets [15]. As such, an under sampling technique [6] was applied to select randomly a portion of training samples from the majority class in this experiment. The FAM-based networks were trained with the selected samples from the majority class together with all samples from the minority class. In this case, the numbers of samples selected from the majority class were respectively 10%, 30%, 50% and 100% of number of the samples from minority class (i.e., four ratios, namely 1:10, 3:10, 5:10 and 10:10).

The parameter settings of FAM-based networks are as follows. Original FAM used a fast training approach with $\beta = 1$; baseline vigilance of ART_a, $\bar{\rho}_a = 0.0$; choice parameter $\chi \approx 0$. As for FAMDDA, it was trained with the same parameter settings as original FAM in addition to a minimum width value, $\varepsilon_{\min} = 0.1$. In order to ascertain the stability of the classification performance, the experiment was repeated 10 times. The average results were computed using the bootstrap method [16], with the 95% confidence intervals estimated. The bootstrap method was employed because it did not rely on the assumption that the samples must be drawn from a normal distribution. In order to compare the average results between FAM and FAMDDA, a bootstrap hypothesis testing was conducted. In this case, the null hypothesis assumes the average results of FAM and FAMDDA were the same whereas the alternative hypothesis stated that the average result of FAM is lower than that of FAMDDA. The significance level α is set at 0.05. If the probability value (p-value) is lower than α, then the null hypothesis is rejected.

C. Results and Discussion

Fig. 2 compares graphically the G-mean results of the trained networks on the test set. Note that the networks were trained with samples from majority and minority classes in four different ratios. By observing Fig. 2, the FAM and FAMDDA, which were trained with a combination of majority and minority samples with a ratio 3:10, could give the highest G-mean results. Such classification results of the trained networks on the test set are presented in more details in Table IV. Even though 55% of the test samples recorded by attribute 2 (and a small portion of the test samples recorded by attribute 3) are extrapolated, both FAM and FAMDDA are able to classify the samples with good performances that exceed the extrapolation rates. In particular, the performances of FAM in terms of CCR, TPR, and G-mean are significantly lower than those from FAMDDA statistically (at the 95% confidence level). The performances of FAM and FAMDDA in terms of TNR are statistically similar. However, the latter is able to yield a slightly higher TNR by predicting more test samples from the minority class correctly. Overall, FAMDDA is able to outperform FAM in dealing with the imbalanced dataset from this problem.

In addition, despite the presence of a substantially large number of unseen samples that are different from those in the training set, the learned FAMDDA model is able to classify the unseen samples with very similar TPR (i.e., 77.57%) and TNR (i.e., 74.96%). This observation indicates that FAMDDA is able to predict equally well samples from the majority and minority classes, whereby it does not show a bias to the majority class that contains more samples.

TABLE II. AN OVERVIEW OF AN ENCRYPTED SEMICONDUCTOR DATASET

Dataset	Attribute 1 (categorical)	Attribute 2 (numerical)	Attribute 3 (numerical)	Output (numerical)
Training Set	1A to 215A	174610–261970	174650–278140	0/1
Test Set	1A to 215A	180800–299370	176670–301770	0/1
Interpolate Rate of Test Data (%)	100	44.66	93.06	100
Extrapolate Rate of Test Data (%)	0	55.34	6.94	0

TABLE III. CLASS DISTRIBUTIONS OF THE SAMPLES IN TRAINING AND TEST SETS

Dataset	Samples of the Majority Class	Samples of the Minority Class	Total Samples	Minority Rate (Minority/Total)
Training Set	44924	7469	52393	0.166
Test Set	108622	8895	117517	0.076

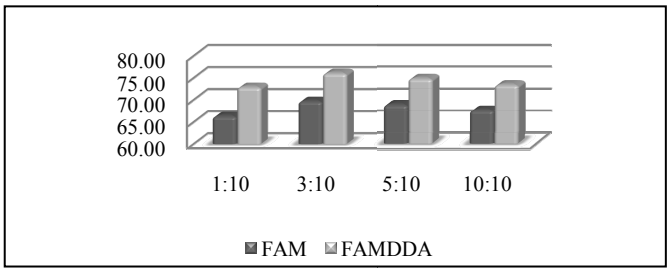

Figure 2. The G-mean results of the trained networks on the test set.

TABLE IV. PERFORMANCE COMPARISON BETWEEN FAM AND FAMDDA

Metric (%)	FAM			FAMDDA			*p*-value
	Average	Highest	Lowest	Average	Highest	Lowest	
CCR	66.04	72.62	60.85	77.36	84.02	70.74	0.000
TPR	65.31	72.42	59.53	77.57	84.92	70.06	0.000
TNR	74.70	78.25	70.13	74.96	79.07	71.05	0.425
G-Mean	69.78	73.71	66.47	76.14	78.73	74.43	0.000

TABLE V. PERFORMANCE COMPARISON WITH OTHER CLASSIFICATION METHODS

Model	CRR	TPR	TNR	G-mean
KNN	0.91	0.95	0.43	0.64
SVM-RBF	0.75	0.74	0.83	0.79
FAM (best)	0.7262	0.7242	0.7503	0.7371
FAMDDA (best)	0.8402	0.8492	0.7300	0.7873

The classification performances of FAM and FAMDDA are also compared with those results of other methods, which include K-nearest neighborhood (KNN) algorithm and support vector machines with radial basis function kernels (SVM-RBF) [17]. In this regard, the best individual classification performances of FAM and FAMDDA, which are based on the highest G-mean, are listed in Table V for comparison. KNN represents an instance-based learning algorithm whereas SVM-RBF is a kernel-based model making use of selected instances (i.e., support vectors, for which the margins between their locations and the concept boundary (hyperplane) have been maximally optimized) for performing pattern classification. Both FAM and FAMDDA could give more *balanced* results in terms of TPR and TNR as compared to KNN and thus, they could contribute to higher G-mean than the latter. The classification results of FAM are not better than SVM-RBF in terms of G-mean and CRR. On the other hand, FAMDDA could give G-mean that is compatible with that of SVM-RBF and the former has a slight advantage in performing with a higher CRR. This finding indicates the potential of FAMDDA as a useful model for learning and classifying imbalanced dataset from the semiconductor industry.

V. SUMMARY

In this paper, a variant of FAM, which has been equipped with a conflict-resolving facility, i.e., fuzzy ARTMAP with Dynamic Decay Adjustment algorithm (FAMDDA), has been proposed for undertaking learning with imbalanced datasets. It is used together with a data re-sampling technique for learning and classifying a large imbalanced dataset collected from a semiconductor company. The results and analysis showed that the proposed FAMDDA network can identify the samples from both the minority and majority classes more accurately than FAM. A benchmark study was also conducted to check on the classification performances of FAM and FAMDDA with other methods. The finding indicated that FAMDDA could serve as one of the favorable classification models in handling the imbalanced dataset problem from the semiconductor industry.

As for future work, additional experimentation should be conducted to evaluate the applicability of the proposed FAMDDA model in dealing with imbalanced datasets from different application domains. This allows validation of FAMDDA as a useful classification model for imbalanced datasets from different application domains. Besides, a long-term target in this research is to improve the classification performances, especially in terms of TPR and TNR. Hence, additional research effort will be devoted to devise more effective learning algorithms based on the existing framework for achieving this target.

ACKNOWLEDGMENT

***Abstract*—The conventional prediction of future power demands are always made based on the historical data. However, the real power demands are affected by many other factors as weather, temperature and unexpected emergencies. The use of historical information alone cannot well predict real future demands. In this study, the experts' opinions from related fields are taken into consideration. To deal the uncertainty of historical data and imprecise experts' opinions, we employ fuzzy variables to better characterize the forecasted future power loads. The conventional unit commitment problem (UCP) is updated here by considering the spinning reserve costs in a fuzzy environment. As the solution, we proposed a heuristic algorithm called local convergence averse binary particle swarm optimization (LCA-PSO) to solve the UCP. The proposed model and algorithm are used to analyze several test systems. The comparisons between the proposed algorithm and the conventional approaches show that the LCA-PSO performs better in finding the optimal solutions.**

***Index Terms*—Power supply reliability, Fuzzy set theory, Unit commitment problem, Fuzzy Value-at-Risk, Local convergence averse binary particle swarm optimization, Test systems.**

I. Introduction

Most previous studies have evaluated power loads forecasted using sufficient historical data. Nevertheless, these studies have the disadvantage that: there are many factors that must be simulated or determined in order to find which factors will affect the real power loads. For example, weather, temperature and unexpected emergencies influence power consumption. As a result, the power systems are suffering from the uncertainty associated with the fact that the real power demands always deviate from forecasts [1]. Consequently, the use of historical information alone cannot predict real future demands.

In this study, the conventional methods are improved to mitigate the above shortcoming. The experts' opinions from related fields are taken into consideration to better describe the future power loads. To handle the uncertainty that arises from the use of historical data and expert opinions, it is better to treat the forecasted power loads as variables with imprecise distributions, i.e., fuzzy variables.

In actuality, fuzzy set theory is a fundamental mathematical system that describes uncertainty, and various researchers have applied it to solve power system problems. To minimize real power losses and improve the voltage profile of a given system, Rahman [4] mathematically formulated an optimal reactive power control problem in which the objective function and constraints are expressed by fuzzy sets when modeled. In Khare's paper [5], fuzzy set theory was used to capture the subjective preferences of human operators in order to model their decision-making and generate a prioritized list of emergency problems that is more acceptable to the operator. Using a multi-objective fuzzy linear programming technique, Abou El-Ela [6] proposed a multi-stage procedure that lessens the influence of different emergency conditions. The results of their experiments showed that the proposed fuzzy procedure can reduce the influence of different emergency conditions.

Employing fuzzy set theory, we take the forecasted loads as fuzzy variables. The conventional unit commitment problem (UCP) which has been commonly formulated as a complex, nonlinear, mixed-integer optimization problem [1], [2], [3] is improved here to take the spinning reserve costs in a fuzzy environment into consideration. To handle this improved UCP, we propose a local convergence averse binary particle swarm optimization (LCA-PSO), which outperforms existing algorithms.

The remainder of this paper is organized as follows: in Section 2, we briefly review previous fuzzy power system problems and introduce some basic background regarding fuzzy variables; Section 3 illustrates the improved UCP; then, Section 4 provides the LCA-PSO as the solution; the model and algorithm are exemplified by some test systems in Section 5; finally, Section 6 summarizes the conclusions.

II. Preliminaries

In this section, we preliminarily provide some basic concepts and features of fuzzy variables.

Suppose ξ is a fuzzy variable whose membership function is μ_ξ, and r is a real number. Then, the possibility, necessity and credibility of event $\xi \le r$ are expressed, respectively, as follows:

$$\mathrm{Pos}\{\xi \le r\} = \sup_{t \le r} \mu_\xi(t), \tag{1}$$

$$\mathrm{Nec}\{\xi \le r\} = 1 - \sup_{t > r} \mu_\xi(t), \tag{2}$$

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

$$\mathrm{Cr}\{\xi \le r\} = \frac{1}{2}\left[\mathrm{Pos}\{\xi \le r\} + \mathrm{Nec}\{\xi \le r\}\right]. \tag{3}$$

The credibility measure is formed on the basis of the possibility and necessity measures, and in the simplest case, it is taken as their average. The credibility measure is a self-dual set function [7], *i.e.* $\mathrm{Cr}\{\xi \le r\} = 1 - \mathrm{Cr}\{\xi > r\}$. Equation (3) also results in the following:

$$\mathrm{Cr}\{\xi \le r\} = \frac{1}{2}\left[\sup_{t\le r}\mu_\xi(t) + 1 - \sup_{t>r}\mu_\xi(t)\right]. \tag{4}$$

For further information on fuzzy variables, one may refer to [7], [8] and [9].

According to [10], the VaR of an investment can be considered as the greatest value under a given confidence level. Following [11], if $\widetilde{L}_t$ denotes the fuzzy power demand of period t, in a fuzzy environment, the VaR of L_t with a confidence of $(1-\beta)$ can be written as:

$$\mathrm{VaR}_{1-\beta} = \sup\{\lambda | \mathrm{Cr}(\widetilde{L}_t \ge \lambda) \ge \beta\}, \tag{5}$$

where $\beta \in (0, 1)$.

Equation (5) tells us that the greatest value of $\widetilde{L}_t$ under confidence level $(1-\beta)$ is the largest λ.

The following numerical example illustrates the calculation of the VaR.

Example 1. *Supposing fuzzy variable* $\widetilde{L}$*=FN(1.0, 2.0), its membership function is normally distributed as* $\mu_{\widetilde{L}}(r) = \mathrm{Exp}\{-[(r-1.0)/2]^2\}$*, then let us calculate* $\mathrm{VaR}_{0.9}$.

At first, we need to calculate the credibility function of $\widetilde{L} \ge r$*. From Equation (1) and (2), we can compute the possibility and the necessity of* $\widetilde{L} \ge r$ *in the following*:

$$\begin{aligned}
\mathrm{Pos}\{\widetilde{L} \ge r\} &= \begin{cases} 1 & \mathrm{r}\le 1.0 \\ \mathrm{Exp}\{-[(r-1.0)/2]^2\}, & \mathrm{r}>1.0 \end{cases} \\
\mathrm{Nec}\{\widetilde{L} \ge r\} &= \begin{cases} 1-\mathrm{Exp}\{-[(r-1.0)/2]^2\} & \mathrm{r}\le 1.0 \\ 0 & \mathrm{r}>1.0. \end{cases}
\end{aligned} \tag{6}$$

Hence, according to Equation (3), the credibility of $\widetilde{L} \ge r$ *is written as:*

$$\mathrm{Cr}\{\widetilde{L} \ge r\} = \begin{cases} 1 - \frac{1}{2}\mathrm{Exp}\{-[(r-1.0)/2]^2\} & \mathrm{r}\le 1.0 \\ \frac{1}{2}\mathrm{Exp}\{-[(r-1.0)/2]^2\} & \mathrm{r}>1.0. \end{cases} \tag{7}$$

Therefore, making use of Equation (5), we have,

$$\mathrm{VaR}_{0.9} = \sup\{\lambda | \mathrm{Cr}(\widetilde{L} \ge \lambda) \ge 0.1\} = 2.91.$$

Recently, the measure of Value-at-Risk has been applied to many engineering problems to build fuzzy optimization models [11], [12], [13], [14], [15].

III. Modeling

From the literatures, with the purpose of providing sufficient electricity and reducing the generation cost, the UCP is solved by determining the power generation unit schedule. It is necessary to provide sufficient real power and spinning reserve in each period. However, in a market environment, the profit is also important. Therefore, the majority of the previous studies summarized the UCP as minimizing the cost function without violating the constraints.

A. The conventional UCP

1) Objective function:

$$\min F = \sum_{t=1}^{T}\sum_{i=1}^{N} u_i^t \cdot [f_i(P_i^t) + SC_i(1 - u_i^{t-1})]. \tag{8}$$

Respectively, F denotes the total cost of the power plant over the scheduling periods; T and N denote the number of considered system periods and the number of generation units, P_i^t is the power generation of unit i at time t; SC_i is the start cost of unit i; u_i^t denotes the status of unit i at time t. $f_i(P_i^t)$ is the cost function of unit i at time t, which is normally expressed by the following equation:

$$f_i(P_i^t) = a_i + b_i P_i^t + c_i (P_i^t)^2, \tag{9}$$

where, a_i, b_i and c_i are the coefficients determined by the attributes of each generation unit.

B. The improved UCP

1) Objective function: This study takes the spinning reserve cost into consideration. Then, in a fuzzy environment, the objective function is modified as follows:

$$\begin{aligned}
\min F = \sum_{t=1}^{T}\sum_{i=1}^{N} u_i^t \cdot \{&[1 - \mathrm{Pos}(Q_t > P_t)] f_i(P_i^t) \\
&+ \mathrm{Pos}(Q_t > P_t) f_i(P_i^t + R_i^t) + SC_i(1 - u_i^{t-1})\}.
\end{aligned} \tag{10}$$

P_t is the forecasted power demand of period t. If we assign a suitable value to the confidence level β, then, P_t can be calculated by Equation (5). Q_t is the real load in period t, $\mathrm{Pos}(Q_t \ge P_t)$ is the possibility that the real demand is larger than the forecasted value P_t, R_i^t is the spinning reserve of unit i at time t, and $\sum_{i=1}^{N} R_i^t = R_t$, respectively.

Remarks:

□ Supposing $\triangle P = Q_t - P_t$, if and only if $\triangle P > 0$(that is to say the real load is larger than the forecasted value), the reserve is considered to be called (even though the $\triangle P$ is sufficiently small).

□ In an uncertain environment, the power loads are fuzzy variables, and subsequently, the possibility theory can be applied to measure the chance that the spinning reserve will be called:

$$\mathrm{Pos}\{Q_t > P_t\} = \sup_{t>P_t}\mu_{\widetilde{L}_t}(t). \tag{11}$$

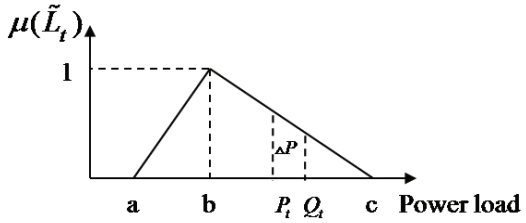

Fig. 1. The situation that spinning reserve is called

2) Constraints: The constraints are forwarded on the basis of system objective environmental demands. From the literature, they can be summarized as follows:
a). Power demand balance

$$\sum_{i=1}^{N} P_i^t u_i^t = P_t, \tag{12}$$

where P_t is the total power demand in period t.
b). Spinning reserve balance

$$\sum_{i=1}^{N} P_{max} u_i^t \geq P_t + R_t, \tag{13}$$

where R_t is the spinning reserve in period t.
c). Interval of each generation unit

$$P_{min}^i \leq P_i^t \leq P_{max}^i, \tag{14}$$

where P_{max}^i and P_{min}^i are the maximum and minimum generation capacity of unit i, respectively.
d). Unit on/off limitations

Usually, the unit state should be kept on for certain hours before it can be changed.

$$\begin{cases} T_{i,on}^t \geq T_{i,up} \\ T_{i,off}^t \geq T_{i,down} \end{cases}. \tag{15}$$

where, respectively, $T_{i,on}^t$ and $T_{i,off}^t$ are the time periods that unit i has been turned on or off. $T_{i,up}$ and $T_{i,down}$ are the minimum unit on time and maximum off time which are determined by the property of each unit.
e). Initial status of each unit

Before arranging the schedule, the unit initial status needs to be taken into consideration. That is, it is necessary to decide how many hours each unit has been committed or decommitted.

IV. The Solution

In this section, we provide the solution for the improved UCP in fuzzy environment.

UCP has been solved using various kinds of heuristic algorithm, such as genetic algorithm (GA) [16], evolutionary programming (EP) [17] and lagrangian relaxation based PSO (LRPSO) [18]. Based on these methods, Yuan [3] proposed an improved binary PSO (IPSO) algorithm, which has proven to be more effective than other approaches.

In this research, based on original PSO [19], an LCA-PSO is proposed to better solve the problem. The following is a preliminary explanation of the proposed method.
A. The fitness function of the improved UCP

Considering the spinning reserve cost and fuzzy power load, the objective function is updated as Equation (10), which is considered as the fitness function of LCA-PSO.
B. The equations update particle's position and velocity

The equations proposed in classic binary PSO [20] are employed here. The particle position is updated by the following equations:

$$v_i = w \cdot v_i + c_1 \cdot rand() \cdot (P_{best,i} - x_i) + c_2 \cdot rand() \cdot (G_{best} - x_i),$$

$$x_i = x_i + v_i, \tag{16}$$

where, v_i is the velocity of i, ω is the inertia weight, c_1 and c_2 are the learning rates generated in the interval $[0, 4]$. $rand()$ is a random number distributed in the interval $[0, 1]$. $P_{best,i}$ and G_{best} are the personal and global best among the iterations of particles, respectively. Subsequently, the position of particle i is updated by Equation (16).

Finally, the particles 0/1 states are determined by a sigmoid function $S(x)$:

$$S(x) = \frac{1}{1 + e^{-x_i}}. \tag{17}$$

C. The local convergence of PSO

It is well known that the PSO algorithm can find the optimal solution in fewer iterations than other algorithms, but may suffer from the local convergence problem. In particular, when the selection problem contains a large number of objectives, this defect of the PSO becomes more obvious. To solve this problem, Yuan [3] performed 10 trials from different initial populations and selected the smallest cost as the result. Lee [21] proposed a mutation-based PSO (MPSO) where mutations occur with given possibility. In this paper, we design the LCA-PSO by employing the escape speed (ES) and velocity modification (VM).

Escape speed: If the optimal solution cannot be updated after a specified number of time iterations, it will be considered as having fallen into local convergence. Then, each particle speed will be modified by the escape speed. The value of ES should be determined by the experiments' performances: on one hand, if the escape speed is sufficiently large, all of the particles can jump out of the current loop and resume searching in different areas; on the other hand, if the escape speed is smaller, the new optimal solution can be obtained more quickly.

Velocity modification: After the above step, each particle's velocity has been modified to an opposite direction with a random value. This is inappropriate for the future search.

Therefore, the VM is used to modify the velocity to a suitable value and in direction. In this case, a potential global optimal solution will be found.

We use the following two-dimensional Figure 2 to approximate the LCA-PSO.

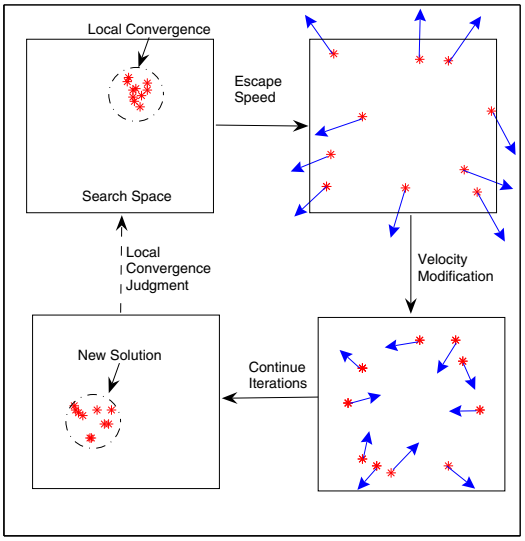

Fig. 2. Local convergence averse BPSO

Based on the above analysis, we summarize the LCA-PSO algorithm as follows:

[Step 1]. Initialize particles: Each particle contains $T \times N$ generator states, as:

$$x_i = \begin{bmatrix} u_1^1 & u_1^2 & \cdots & u_1^T \\ u_2^1 & u_2^2 & \cdots & u_2^T \\ \cdots & \cdots & \cdots & \cdots \\ u_N^1 & u_N^2 & \cdots & u_N^T \end{bmatrix}.$$

[Step 2]. Check the constraints of UCP, as mentioned in Subsection 3.2.2, part B.

[Step 3]. Solve the economic load dispatch (ELD) problem and update gray zone states for start-up cost. The concepts of ELD and gray zone have been well described in previous studies. One may refer to [3] and [22] for further information regarding these topics.

[Step 4]. Initialize personal best and global best: The personal best and global best are determined by the fitness function (10).

[Step 5]. Particle iterations: The particle positions are updated by Equation (16), and Step 2 is repeated to modify the unit states, then, new P_{best} and G_{best} are calculated.

[Step 6]. Solve the local convergence problem: If the global best cannot be improved in a given number of iterations, we consider the program to have fallen into the local convergence. Then, the aforementioned approach is used to cause the particles to jump out of current loop and to revise the particle's velocity.

[Step 7]. Following the completion of all iterations, the final global best is returned as the optimal result.

V. Exemplification using Test Systems

A. The performances of the proposed model and LCA-PSO

In this section, the proposed model and algorithm are exemplified using test systems. The 24-hour power loads are fuzzy variables evaluated from previous data and experts' opinions, as listed in Table 1. (a, b, c) denotes the triangular fuzzy variable, and FN(a, σ^2) represents a normally distributed fuzzy variable. The power demand here are measured in megawatt (MW).

TABLE I
24 Hours forecasted fuzzy power demands

Period	Power Demands	Period	Power Demands
1	(650, 700, 750)	13	(1350, 1400, 1450)
2	(700, 750, 800)	14	(1250, 1300, 1350)
3	(800, 850, 900)	15	(1150, 1200, 1250)
4	(900, 950, 1000)	16	(1000, 1050, 1100)
5	(950, 1000, 1050)	17	FN(1000, 400)
6	(1050, 1100, 1150)	18	FN(1100, 410)
7	(1100, 1150, 1200)	19	FN(1200, 410)
8	FN(1200, 440)	20	FN(1400, 430)
9	FN(1300, 420)	21	FN(1300, 400)
10	FN(1400, 400)	22	(1050, 1100, 1150)
11	FN(1450, 400)	23	(850, 900, 950)
12	FN(1500, 390)	24	(750, 800, 850)

Supposedly, the lowest and highest confidence levels provided by the grid company of VaR is 80% and 95%, respectively. Then, using Equation(5), we get the demands and reserves in real values, as listed in the following Table 2.

TABLE II
24 Hours evaluated power demands and reserves

Period	Demands	Reserves	Period	Demands	Reserves
1	730.0	15.0	13	1430.0	15.0
2	780.0	15.0	14	1330.0	15.0
3	880.0	15.0	15	1230.0	15.0
4	980.0	15.0	16	1080.0	15.0
5	1030.0	15.0	17	1019.1	11.2
6	1130.0	15.0	18	1119.4	11.3
7	1180.0	15.0	19	1219.4	11.3
8	1220.1	11.7	20	1419.4	12.1
9	1319.6	11.5	21	1319.1	11.2
10	1419.1	11.2	22	1130.0	15.0
11	1469.1	11.2	23	930.0	15.0
12	1518.9	11.1	24	830.0	15.0

Based on the above analysis, the proposed LCA-PSO is evaluated through the use of different-sized test systems (10, 20, 40, 60, 80 and 100 units), which are expanded from a 10-unit based system [17]. All of the experiments are implemented on a Dell E8500 3.16 GHz CPU with 2.96 GB of RAM.

We first tested the LCA-PSO in different systems of various unit sizes. The parameters were selected as follows: 20 particles, 500 iterations, $c_1 = 2.8$, $c_2 = 1.2$, $\omega = 1$, a maximum speed of 4.0 and a minimum speed of -7.0. For LCA-PSO, the given time iteration mentioned in Section IV was set at 20,

and this was used to evaluate whether the local convergence occurs.

Table 3 illustrates the performance of LCA-PSO by comparing the initial cost and the cost after 1000 iterations in different-sized systems. The savings are calculated as $(InitialCost - FinalCost)/InitialCost * 100\%$.

TABLE III
THE PERFORMANCE OF LCA-PSO

Unit No.	Initial Cost	Final Cost	Savings
10	602,270	570,006	5.36%
20	1,208,507	1,139,005	5.75%
40	2,420,321	2,277,396	5.91%
60	3,625,509	3,420,438	5.67%
80	4,827,049	4,554,346	5.65%
100	6,036,371	5,706,201	5.46%

From Table 3, we can find that, the LCA-PSO could result in a cost-saving of more than 5.3% amongst all of the test systems.

In Tables 4 and 5, we show an example of initial and final schedules as found by the LCA-PSO for the 10-unit test model. This illustrates the number of start-up and shut-down decisions made through the LCA-PSO optimization process.

B. Comparisons between LCA-PSO and other improved PSO algorithms

In this subsection, we compare the LCA-PSO with IPSO (*the best result of 10 trails was selected*) [3] and MPSO [21]. For MPSO, the mutation probability was 0.1. After 1000 iterations, the total costs and CPU time of each algorithm are listed in Tables 6 and 7.

TABLE VI
OPTIMAL RESULTS OF DIFFERENT ALGORITHMS

Unit No. \ Methods	LCA-PSO	MPSO	IPSO
10	570,006	574,905	599,782
20	1,139,005	1,152,966	1,196,029
40	2,277,396	2,323,435	2,401,728
60	3,420,438	3,451,762	3,592,585
80	4,554,346	4,691,481	4,798,427
100	5,706,201	5,864,719	5,988,264

We found that, in most of the test systems, the LCA-PSO was able to obtain better optimal solutions with less runtime cost than other approaches.

Nevertheless, compared with the CPU time used in prior work, more computation time is required to reach the final optimal solutions in this study. The reason for this could be that the objective function here is modified from Equations (8) to (10). Therefore, during each iteration, the cost was computed with respect to two options: 1. The reserve was not called (as in the conventional UC models); 2. The reserve was called. We must re-arrange different unit on/off schedules for each situation. Therefore, more time was required to obtain the optimal result.

To prove the effectiveness of LCA-PSO, we employed a 100-units test system, and Figure 3 shows the performance of each method during the 1000 iterations.

Finally, in Figure 3, it should be noted that, in the 100 units test system, the IPSO and MPSO are suffering from the local convergence problem. However, the proposed LCA-PSO could overcome the local convergence effectively, the ES and VM were quite effective in solving such unit commitment

optimization problem.

VI. CONCLUSION

In this study, the fuzzy variable is used to more accurately describe the future power load while the fuzzy Value-at-Risk is employed as a technique to evaluate the power demand and reserve for each period. The conventional unit commitment model is improved by considering the possibility that the reserve is called in uncertain environment. This model can minimize the system cost by considering various constraints. To solve the problem, we proposed an LCA-PSO as the solution that has been proved to be most useful and effective by the test systems. Furthermore, comparisons with existing algorithms show that the LCA-PSO has higher performance. In addition, the proposed model can be applied to various engineering reliability control problems.

***Abstract*—Based on portfolio selection theory, this study proposes an improved fuzzy multi-objective model that can evaluate the invest risk exactly and increase the probability of obtaining the expected return. In building the model, fuzzy Value-at-Risk (VaR) is used to evaluate the exact future risk, in term of loss. The VaR can directly reflect the greatest loss of a selection case under a given confidence level. On the other hand, variance is utilized to make the selection more stable. This model can provide investors with more significant information in decision-making. To better solve this model, an improved particle swarm optimization algorithm is designed to mitigate the conventional local convergence problem. Finally, the proposed model and algorithm are exemplified by some numerical examples. Experiment results show that the model and algorithm are effective in solving the multi-objective portfolio selection problem.**

***Index Terms*—Fuzzy multi-objective portfolio selection model, fuzzy variable, fuzzy Value-at-Risk, fuzzy simulation, improved particle swarm optimization.**

I. Introduction

In finance, portfolio selection theory plays a pivotal role in decision-making for portfolio investors. As an early adopter, Markowitz [1] proposed a significant portfolio selection theory in 1952. He used the single period variance of returns as a risk measure to develop techniques for portfolio optimization. From then on, various researches have been carried on.

Security returns in conventional models are always determined by precise historical data. However, such data are not always available. On the other hand, securities are always affected by infinitive factors. It is impossible to simulate the influence of all factors well. Therefore, in today's stock markets, it is not reasonable to evaluate future security returns only based on the historical data. To make the forecasting more accuracy, the expert's opinions from related fields need to be considered. In prediction, to handle the uncertain factors wthat affect the security return and the imprecise expert's opinions, it is in reason to treat security returns as variables with imprecise distributions, i.e., fuzzy variables.

Based on fuzzy set theory, recently, various fuzzy portfolio selection models are proposed [2-9]. Among these fuzzy portfolio selection models, the most important distinction could be the risk measure method. Different techniques provide different criteria to select a portfolio. Huang [8] employed the variance of fuzzy variables as a risk measurement. As an extension of conventional variance theory, the variance of fuzzy variables can reflect an average deviation level of a selection case to the expected value in fuzzy environment. Huang [3] also developed a mean-entropy model. As a physics concept, entropy was utilized here to reduce the uncertainty of a portfolio and make the prediction easily. Li *et al.* [4] proposed a mean-variance-skewness portfolio selection model. Being combined with variance, the skewness was taken for a new risk measurement which can evaluate an average deviation level from the expected value with asymmetry fuzzy returns. Recently, Wang *et al.* [9] introduced fuzzy Value-at-Risk (VaR) to this field. The VaR can directly reflect the loss of one selection case under given confidence level. It was used as a novel risk measurement. Different from previous methods which try to make the portfolio stable, the VaR can tell investors the exact future risk in term of loss.

Nevertheless, the above [2-9] are all single-objective models based on Markowitz's principle. That is, the return and risk are compensated by each other. Some decision makers do not want to set a fixed level to return or the risk as the constraints. They want to choose the investment scheme which can maximize the profit and minimize the potential risk together. Therefore, a single optimized portfolio cannot satisfy all investors. On the other hand, sometimes portfolio optimization models are required to consider more criteria than the standard mean-variance model. Therefore, to provide comprehensive selection information for investors, recently multi-objective portfolio selections models (MOPSM) were built. From the literatures, some studies on MOPSM have been investigated. Jana *et al.* [10] proposed a multi-objective portfolio based model and added another entropy objective function to generate a well diversified asset portfolio within optimal asset allocation. In this research, a fuzzy programming technique is utilized as the solution of the multi-objective non-linear programming model. Steuer *et al.* [11] took some additional arguments of portfolio selection theory into consideration, such as: dividends, liquidity, social responsibility, amount of short selling, and so forth. This study is significant for non-standard investors to make decisions. Zhang *et al.* [12] presented a fuzzy multi-objective mean-variance-skewness model with transaction costs. The skewness of portfolio return is considered as a critical factor

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

in selecting a portfolio. In order to solve the above model, a hybrid intelligent algorithm was designed by integrating simulated annealing algorithm, relevance vector machine and fuzzy simulation.

In this study, based on the property of fuzzy Value-at-Risk, we propose a mean-variance-VaR multi-objective portfolio selection model (VaR-MOPSM).

The remainder of this paper is organized as follows: Section 2 introduces some basic information on fuzzy variables. We also explain the concepts and calculations of the variance and fuzzy VaR. Section 3 illustrates the motivations behind our research. In Section 4, we briefly review previous MOPSM and build the VaR-MOPSM. The model can be solved by an improved particle swarm optimization (IPSO) introduced in Section 5. In Section 6, we apply the proposed algorithm to solve a numerical example. In order to demonstrate the effectiveness of the IPSO, we also compare it with existing methods in this Section. Finally Section 7 summarizes our conclusions.

II. Preliminaries

To make a better prediction of security returns, fuzzy set theory is employed to portfolio selection problem. In this section, we briefly review some features on fuzzy variables. The fuzzy variable is a fundamental mathematical tool to describe fuzzy uncertainty, and there are mainly three types of fuzzy variables frequently used: triangular, trapezoidal and normal distributions. Before introducing the variance and fuzzy VaR, it is necessary to review some basic knowledge on the credibility theory of fuzzy variables.

Suppose ξ is a fuzzy variable whose membership function is μ_ξ, and r is a real number. Then, the possibility, necessity and credibility of event $\xi \leq r$ are expressed, respectively, as follows:

$$\mathrm{Pos}\{\xi \leq r\} = \sup_{t \leq r} \mu_\xi(t), \tag{1}$$

$$\mathrm{Nec}\{\xi \leq r\} = 1 - \sup_{t > r} \mu_\xi(t), \tag{2}$$

$$\mathrm{Cr}\{\xi \leq r\} = \frac{1}{2}\left[\mathrm{Pos}\{\xi \leq r\} + \mathrm{Nec}\{\xi \leq r\}\right]. \tag{3}$$

The credibility measure is formed on the basis of the possibility and necessity measures, and in the simplest case, it is taken as their average. The credibility measure is a self-dual set function [13], *i.e.* $\mathrm{Cr}\{\xi \leq r\} = 1 - \mathrm{Cr}\{\xi > r\}$. Equation (3) also results in the following:

$$\mathrm{Cr}\{\xi \leq r\} = \frac{1}{2}\left[\sup_{t \leq r} \mu_\xi(t) + 1 - \sup_{t > r} \mu_\xi(t)\right]. \tag{4}$$

For further information on fuzzy variables, one may refer to [13], [14] and [15].

A. Expected value

The most general definition of expected value of fuzzy variable was given by Liu and Liu [13].

Let ξ be a fuzzy variable. Then the expected value of ξ is defined by:

$$\mathrm{E}[\xi] = \int_0^{+\infty} \mathrm{Cr}\{\xi \geq r\}\mathrm{d}r - \int_{-\infty}^{0} \mathrm{Cr}\{\xi \leq r\}\mathrm{d}r. \tag{5}$$

B. Variance

The variance of a fuzzy variable provides a measure of the spread of the distribution around its expected value. A small value of variance indicates that the fuzzy variable is tightly concentrated around its expected value; and a large value of variance indicates that the fuzzy variable has a wide spread around its expected value. Therefore, the variance can be used to represent the level of risk in a fuzzy system.

If the fuzzy variable has a finite expected value, according to Liu and Liu [13], its variance is defined as:

$$\mathrm{V}[\xi] = \mathrm{E}[(\xi - e)^2] \tag{6}$$

C. Value-at-Risk

The Value-at-Risk (VaR) of an investment is the likelihood of the greatest loss with a given confidence level [17], [18]. Following Wang *et al.* [16], if $\widetilde{L_t}$ denotes the fuzzy power demand of period t, then, in a fuzzy environment, the VaR of L_t with a confidence of $(1-\beta)$ can be written as:

$$\mathrm{VaR}_{1-\beta} = \sup\{\lambda | \mathrm{Cr}(\widetilde{L_t} \geq \lambda) \geq \beta\}, \tag{7}$$

where $\beta \in (0, 1)$.

Equation (7) tells us that the greatest value of $\widetilde{L_t}$ under confidence level $(1-\beta)$ is the largest λ.

Recently, the measure of Value-at-Risk has been applied to many engineering problems to build fuzzy optimization models [19], [20], [21], [22].

III. Motivations

As we mentioned in Section I, the most important distinction of the portfolio selection models could be the risk measure methods. Investor probability obtains quite different optimal results with different methods. In Table I below, we list the risk measurements in detail which have been applied to fuzzy portfolio selection problem.

The risk measurements listed in Table I can be sorted into two types. The first type includes mean-risk, mean-variance, mean-semivariance, entropy and mean-variance-skewness which find the optimal solutions by minimizing the risk measure functions, thus maximizing the stability of a portfolio. However, these evaluation methods do not focus on the exact risk of future loss, which is significant to investors. The second type is fuzzy VaR. Using fuzzy VaR as the risk measurement, investors can assign different confidence levels and then use the model to gain how much return they can

TABLE I
THE COMPARISONS OF THE FUZZY VAR AND EXISTING RISK MEASUREMENTS

Methods Name	Risk Measure Function	Purpose
Mean-risk [23]	$\mathrm{Cr}\{b - (x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n) \geq r\} \leq \alpha(r)$	Describe the credibility values of the bad events,which should lower than the given tolerance levels
Mean-variance [2]	$\mathrm{V}[x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n] \leq r$	Reflects an average deviation level from the expected value, which is limited by the given vale
Mean-semivariance [5]	$\mathrm{H}[x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n] \leq r$	Measures only the lower deviation from the expected return
Entropy optimization [3]	$\mathrm{SV}[x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n] \leq r$	Minimize the entropy can reduce the uncertainty of a portfolio and make the prediction easily
Mean-variance-skewness [4]	$\mathrm{V}[x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n] \leq \alpha$ $\mathrm{S}[x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n] \geq \beta$	Reflects an average deviation level from the expected value with asymmetry fuzzy returns
Fuzzy Value-at-Risk [9]	$\mathrm{VaR}_{1-\beta} = \sup\{\lambda \mid \mathrm{Cr}(\mathcal{L} \geq \lambda) \geq \beta\}$	Directly reflect the loss of one selection case under given confidence level

expect and how much future loss they may suffer in the worst case scenario. Nevertheless, the VaR cannot enhance the stability of a portfolio which may not make the selection case trusted.

To the best of our knowledge, the conventional multi-objective portfolio selection models were built based on the first type of risk measurements. That is to say, all of the existing MOPSMs only focus on enhancing the stability of a selection case from different aspects, but the exact risk in term of loss is not considered.

In this study, we proposed a MOPSM based on both types risk measure methods: variance is utilized to evaluate the portfolio stability while fuzzy VaR is applied to measure the exact future risk. Therefore, the obtained selection result could be more helpful in decision making.

IV. Modeling

In this Section, we briefly review the existing multi-objective portfolio selection models and then provide our model. Some notations are given as follows:

x_i: Proportion invested on security i, $i = 1, 2, ..., n$.

ξ_i: The fuzzy return of security i.

E: The expected return of a selection case.

V: The variance of a selection case.

S: The skewness of a selection case.

$(1 - \beta)$: The confidence level of Value-at-Risk.

$\mathrm{VaR}_{1-\beta}$: The VaR of a selection case under confidence level $(1 - \beta)$.

Cr: The credibility functions of fuzzy variables.

L: The loss functions of selection cases, defined as $L = -(x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n)$.

In the conventional MOPSM, the objective considered was to maximize the investment return and minimize several risk measure functions at the same time. Thus, it can be summarized as:

$$\begin{cases} \max\ \mathrm{E}[x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n] \\ \min\ \mathrm{V}[x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n] \\ \min\ \text{-S}[x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n] \\ \text{Subject to} \\ \quad x_1 + x_2 + ... + x_n = 1; \\ \quad x_i \geq 0,\ i = 1, 2, ..., n. \end{cases} \tag{8}$$

If we quantify the skewness function of model (8) by risk measurements mentioned in Table I, some other existing fuzzy portfolio selection models can be obtained.

In this study, we retain the Markowitz mean-variance selection principle; however, the fuzzy VaR is considered as another risk measure method. In this case, the proposed VaR-MOPSM can be described as:

$$\begin{cases} \max\ \mathrm{E}[x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n] \\ \min\ \mathrm{V}[x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n] \\ \min\ \mathrm{VaR}_{1-\beta} = \sup\{\lambda \mid \mathrm{Cr}(\mathcal{L} \geq \lambda) \geq \beta\} \\ \text{Subject to} \\ \quad x_1 + x_2 + ... + x_n = 1; \\ \quad x_i \geq 0,\ i = 1, 2, ..., n. \end{cases} \tag{9}$$

V. Solution

The VaR-MOPSM is a complex nonlinear optimization problem which cannot be solved by linear programming methods or simplex algorithms. Therefore, in this section, we provide a fuzzy simulation based multi-objective PSO algorithm to get the solutions.

A. Fuzzy simulation

In Section II, we have introduced the calculation of expected value, fuzzy variance and VaR of single fuzzy variable. However, we are required to deal with a series of different distributed fuzzy variables, such as $\xi = (\xi_1, \xi_2 ... \xi_n)$. It is impossible to solve the problem as $\mathrm{V}[x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n]$ or $\mathrm{VaR}_{1-\beta} = \sup\{\lambda | \mathrm{Cr}(\xi \geq \lambda) \geq \beta\}$ from the above definitions. The fuzzy simulation developed by Liu and Liu [13] plays a pivotal role in solving the above problem. Employing this technique, the theoretical calculation of fuzzy VaR can be briefly summarized as follows:

Suppose $\xi_i = (\xi_1, \xi_2, ..., \xi_n)$ is a continuous fuzzy variables with support $\prod_{i=1}^{n}[a_i^L, a_i^U]$, where a_i^L and a_i^U are the lower and upper supports of ξ_i. We first divide each fuzzy variable into l parts and then approximate the membership function μ_{ξ_i} by a sequence of discrete fuzzy vectors ζ_i^r which can be constructed as:

$$\zeta_i^r = a_i^L + \frac{r}{l}(a_i^U - a_i^L), \tag{10}$$

where, l and r are integers, and $0 \leq r \leq l$.

Second, the loss variable $\mathcal{L} = -(x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n)$ can be simulated by the fuzzy vectors ζ_i^r.

Third, on the basis of the approximate membership function of $\mathcal{L}$, the credibility function $\mathrm{Cr}\{\mathcal{L} \geq \lambda\}$ can be calculated by equation (4).

Finally, we can obtain an approximate values of variance and fuzzy VaR by equation (6) and (7) .

Therefore, the larger the value of l, the more exact the result will be, but the longer the computation time will be. We can conclude that the value of l should be set specially to different optimization problems. For more about this methods, you may refer to [4], [16] and [28].

B. Improved particle swarm optimization algorithm

The PSO algorithm was initially proposed by Kennedy [24] in 1995. It has been widely used and demonstrated its effectiveness in a variety of fields; refer to [9], [25], [26] and [27] for details.

1) Improving conventional PSO to mitigate the local convergence problem: It is well known that the PSO algorithm can find the optimal solution in fewer iterations than other algorithms, but may suffer from the local convergence problem. To overcome the above problem and better solve the multi-objective model, we improve the original PSO algorithm by the escape speed (ES) and particle restart position (PRP).

ES: If the optimal solution cannot be updated after a fixed number of iterations, then it will be considered as having fallen into local convergence. Then, each particle's speed will be modified by the escape speed. If the escape speed is sufficiently large, all the particles can jump out of their current loops and restart searching in different areas.

PRP: After the particle speed has been modified by the escape speed, the particles will be distributed randomly. For most of the selection problems, there should be a constraint on the search space; for example, in our problem, each position value belongs to the range (0,1). Then, the particle restart position is generated by the edge value of the search space.

2) The evaluation method of the multi-objective problem: To solve the multi-objective model, the following researches have been done:

Find the ideal Pareto solution. Pareto solutions are those for which improvement in one object can only occur with the worsening of at least one other objective. If we optimize each object (expected value or variance or VaR) without considering others, the ideal Pareto solution can be created. Such processes can be summarized as follows:

Scenario I: the expected return is considered as the unique object, then, the proposed model (9) degenerate to the following:

$$\begin{cases} \max\ \mathrm{E}[x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n] \\ \text{Subject to} \\ \quad x_1 + x_2 + ... + x_n = 1; \\ \quad x_i \geq 0,\ i = 1, 2, ..., n. \end{cases} \tag{11}$$

Scenario II: the variance is considered as the unique object, then, model (9) is revised to:

$$\begin{cases} \min\ \mathrm{V}[x_1\xi_1 + x_2\xi_2 + ... + x_n\xi_n] \\ \text{Subject to} \\ \quad x_1 + x_2 + ... + x_n = 1; \\ \quad x_i \geq 0,\ i = 1, 2, ..., n. \end{cases} \tag{12}$$

Scenario III: the fuzzy VaR is considered as the unique objective, then,

$$\begin{cases} \min\ \mathrm{VaR}_{1-\beta} = \sup\{\lambda | \mathrm{Cr}(\mathcal{L} \geq \lambda) \geq \beta\} \\ \text{Subject to} \\ \quad x_1 + x_2 + ... + x_n = 1; \\ \quad x_i \geq 0,\ i = 1, 2, ..., n. \end{cases} \tag{13}$$

The revised models (11), (12), (13) are single object optimization problem which can be easily solved by simplex methods. Supposedly, these models results in E_{max}, V_{min} and VaR_{min}, then, the ideal Pareto solution is considered as (E_{max}, V_{min}, VaR_{min}).

In model (7), if one selection case i produces the result of (E_i, V_i, VaR_i), the fitness value (FV) of portfolio i is considered as the distance between the ideal Pareto solution and optimal solution i, which can be obtained by the following equation (14).

$$\mathrm{FV}(i) = \sqrt{(\mathrm{E}_{max} - \mathrm{E}_i)^2 + (\mathrm{V}_{min} - \mathrm{V}_i)^2 + (\mathrm{VaR}_{min} - \mathrm{VaR}_i)^2} \tag{14}$$

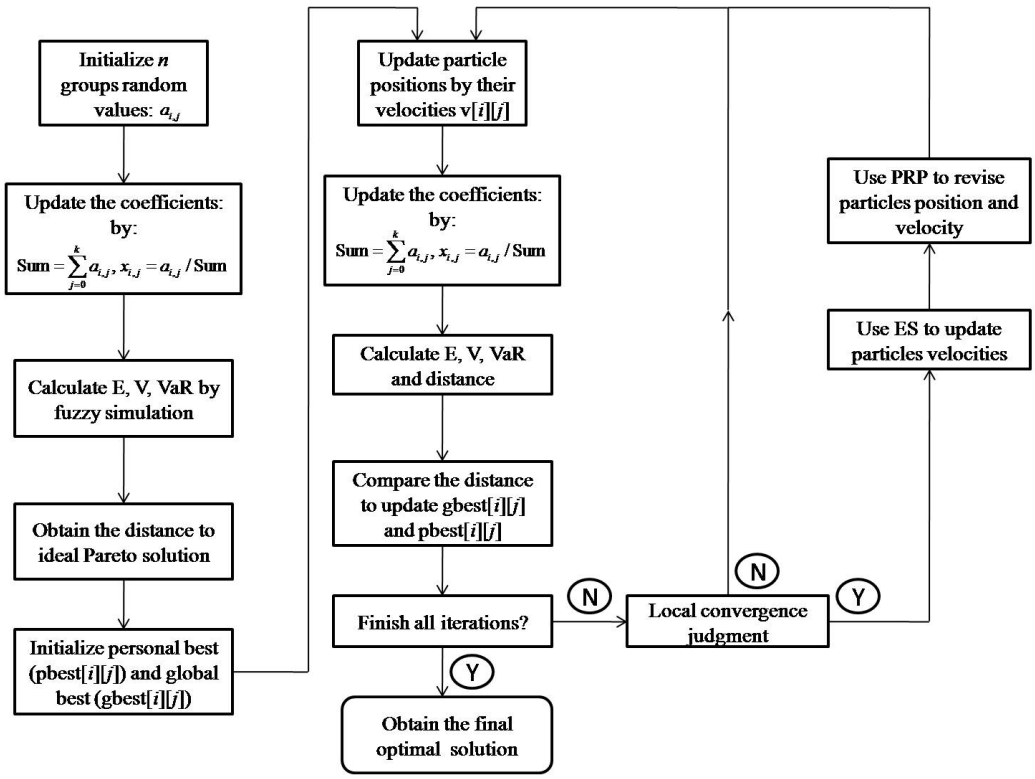

Fig. 1. The flow chart of IPSO

Therefore, the smaller the distance is, the better the optimal solution will be.

We use Figure 1 above to illustrate the IPSO.

VI. Numerical example

In this section, the proposed model and algorithm are exemplified by the following numerical example.

Example: Suppose that there are ten securities whose returns are independent triangular or normally distributed fuzzy variables, as given in Table II. The confidence level of fuzzy Value-at-Risk is set as 0.9, that is $\beta = 0.1$.

TABLE II
Security returns

Security No.	Return	Security No.	Return
1	(-0.8, 0.4, 2.0)	6	$N(0.9, 1.7^2)$
2	(-0.7, 0.6, 1.8)	7	$N(0.6, 1.0^2)$
3	(-1.1, 0.6, 2.8)	8	$N(0.8, 1.4^2)$
4	(-1.6, 0.9, 3.2)	9	$N(0.7, 1.1^2)$
5	(-1.4, 0.8, 3.9)	10	$N(1.1, 1.9^2)$

Then, apply these data to model (9), we get the following selection problem.

$$\begin{cases} \max \ \mathrm{E}[x_1\xi_1 + x_2\xi_2 + ... + x_{10}\xi_{10}] \\ \min \ \mathrm{V}[x_1\xi_1 + x_2\xi_2 + ... + x_{10}\xi_{10}] \\ \min \ \mathrm{VaR}_{0.9} = \sup\{\lambda | \mathrm{Cr}(\mathcal{L} \geq \lambda) \geq 0.1\} \\ \text{Subject to} \\ \quad x_1 + x_2 + ... + x_{10} = 1; \\ \quad x_i \geq 0, \ i = 1, 2, ..., 10. \end{cases} \tag{15}$$

Now, we use the IPSO algorithm to get the optimal solutions. All of the following experiments were implemented on a personal computer: Dell E8500 3.16 GHz CPU with RAM 2.96 GB.

A. The performance of IPSO

We first applied IPSO to solve model (15). After 100 iterations, the optimal fitness value (FV) is 0.146, and the capital should be allocated as Figure 2 shows, the numerical value of the selection is (0.00; 0.47; 0.00; 0.00; 0.52; 0.00; 0.00; 0.01; 0.00; 0.00).

From the numerical data provided in this Example, we may find security 2 is overlapped by security 3. However, from the selection result, only security 2 is considered as an invest proportion. The reason is: The VaR and variance of security 2 is smaller than those of security 3, when compute the distance to ideal Pareto solution, security 2 performs better.

B. Comparisons with other algorithms

Some existing approaches have been proposed to solve fuzzy portfolio optimization problems, such as genetic algorithms (GA) [3], [4] and simulated annealing algorithm

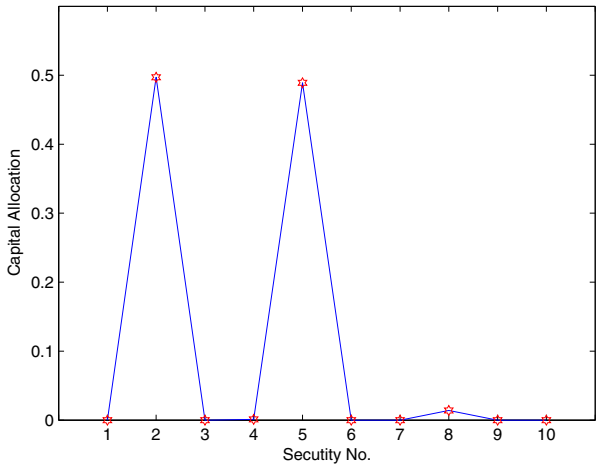

Fig. 2. Optimal solution of IPSO (Capital allocations)

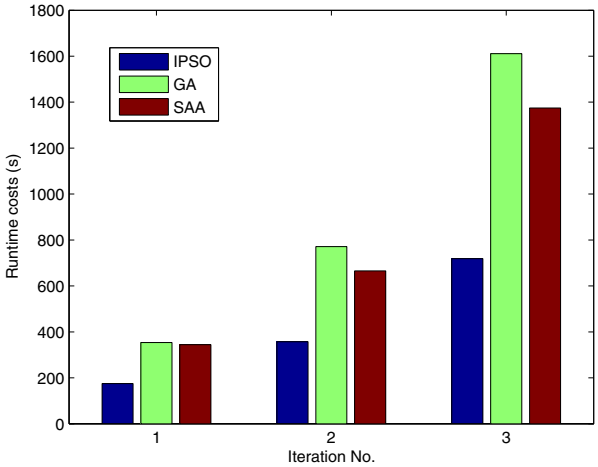

Fig. 4. Optimal solutions of different approaches

(SAA) [7]. In this study, we first revised the fitness functions of GA and SAA to solve the multi-objective portfolio selection problem. Then, the proposed IPSO is compared with other approaches from two aspects: the optimal solutions and runtime cost.

1) Solutions comparisons: The IPSO, GA and SAA are applied to solve the above numerical example. For GA, the crossover and mutation probability is set as 0.8 and 0.05, the Chromosome number is 20. The temperature reduction coefficient of SAA is selected as 0.984. The following Figure 3 shows the optimal process of each method during the 100 times iterations.

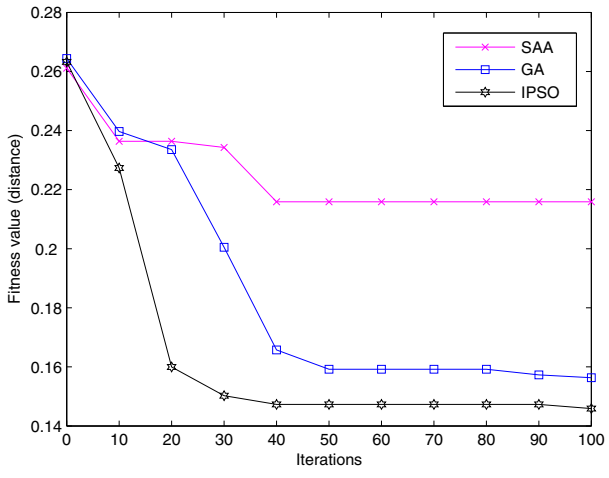

Fig. 3. Optimal solutions of different approaches

From the Figure 3, we can conclude that: the proposed IPSO can mitigate the local convergence problem very well and find better solutions than other methods.

2) Runtime comparisons: The runtime costs (50, 100, 200 iterations) of each algorithm are depicted in Figure 4.

From the comparisons results in Figures 3 and 4, we can conclude that the proposed IPSO has better performance than GA and SA for our VaR-MOPSM.

C. Discussion on the optimal results of VaR-MOPSM with previous MOPSMs

Here, we provide more explanations on the effectiveness of VaR-MOPSM by linguistic analysis.

Because the risk measurements of the existing portfolio selection models are quite different, each method produces varying criteria to select a portfolio, so comparisons among the selection results of different models may not be very meaningful. However, it is important to note that, investors clearly understand the purposes of the first type risk measurements (provided in Section III), such as mean-variance, mean-semivariance or entropy; minimize these values can improve the selection. However, they cannot identify the potential risk included in these numerical values. For instance, in the conventional MOPSM, if the risk level r is modified from 1.6 to 1.7, then the investors will obtain a selection case with higher expected return and risk. However, it is quite difficult for them to determine how much higher the future risk becomes, so they cannot balance the higher expected return with the higher risk. As a result, investors cannot clearly determine the parameters and evaluate the results of these models. Based on the above analysis, the existing MOPSMs are not sensitive in measuring the future risk. In our VaR-MOPSM, on the other hand, investors can determine the confidence levels as they wish, and any change in these values will be directly reflected by the greatest loss obtained from the fuzzy VaR. Therefore, from this perspective, the multi-objective portfolio selection model with the fuzzy VaR can provide more effective information for investors and help them make decisions more easily.

VII. Conclusion

In this paper, we built a novel multi-objective fuzzy portfolio selection model (VaR-MOPSM) which takes the expected value, Value-at-Risk and variance as the criteria to evaluate a selection case. Applying this model, investors can well balance the future return with the potential loss, and therefore make more proper decisions. The model is formed as a non-linear complicated multi-objective optimization problem, which cannot be solved by linear programming methods or simplex algorithms. To solve the VaR-MOPSM, a fuzzy simulation based improved particle swarm optimization algorithm (IPSO) was designed as the solution. The proposed model and algorithm were exemplified by some numerical experiments. From the experiments' results and discussion on the optimal results of VaR-MOPSM with previous approaches, we concluded that: 1. the VaR-MOPSM is more helpful for general investors in decision-making; 2. the IPSO can mitigate the local convergence very well; 3. IPSO is more effective in solving the multi-objective than other existing approaches. The VaR-MOPSM model proposed in this paper is also applicable to various investment or engineering problems.

***Abstract*—Markowitz's mean-variance model is based on probability distribution functions which have known or were assumed as some kinds of probability distribution functions. When our data are vague, we can't know the underlying distribution functions. The objective of our research was to develop a method of decision making to solve portfolio selection model by statistic test. We used central point and radius to determine the fuzzy portfolio selection model and statistic test. Empirical studies were presented to illustrate the risk of fuzzy portfolio selection model with interval values. We can conclude that it is more explicit to know the risk of portfolio selection model. According to statistic test, we can get a stable expected return and low risk investment in different choose *K*.**

Keywords-*Portfolio selection, Optimization, fuzzy probability distributions, fuzzy statistics and data analysis*

I. INTRODUCTION

Portfolio selection model has been well developed on the basis of a mean-variance approach proposed by Markowitz [10, 11, 13], who combines probability theory and optimization theory to analyze the behavior of economic agents. The key principle of the mean-variance model is to use the expected return of a portfolio as the investment return and the variance of the expected returns of the portfolio as the investment risk. Most of existing portfolio selection models is based on probability theory. Also some researches on the mean-variance portfolio selection problem have been studied by Sharpe [17], Merton [12], Perold [15], Pang [14], Voros [20] and Best [1, 2]. In order to analyze uncertain phenomena in real world, research works have applied multivariate data analysis to investigate some portfolio selection problems such as Wang et al.[29] propose a new real options analysis approach by combing binomial lattice-based model with fuzzy random variable. Zhang et al. [32] proposed a model to transform the forecasted uncertain values evaluated by experts into some normal fuzzy numbers. Tanaka and Guo [18, 19] proposed two kinds of portfolio selection models based on fuzzy probabilities and exponential possibility distributions, respectively. Wang and Zhu [28], Lai et al. [6] constructed interval programming models of portfolio selection. Zhang and Wang [30] and Zhang et al. [31] discussed the portfolio selection problem based on the (crisp) possibilistic mean and variance when short sales are not allowed on all risky assets. Watada [24], Ramaswamy [16] and Leon et al. [7] discussed portfolio selection using fuzzy decision theory. Usually the works did not consider any kind of probability distribution function with fuzzy random variables. From this point of view, the objective of this paper is to apply the concept of distribution function and fuzzy random variables in the portfolio selection model.

In order to find the probability distribution function in continuous fuzzy data, we have to take the concept of fuzzy statistic into consideration. Such fundamental statistics as mean, median and mode are useful measurements in illustrating some characteristics of a sample distribution. More research works should place focus on the fuzzy statistical analysis and applications in engineering, medical and social science fields. Wu and Hwang [22] proposed fuzzy statistical testing method to discuss the stationary of Taiwan short-term money demand function; Wu and Cheng [25] identified a model structure through qualitative simulation; Casalino, et al. [3], Esogbue and Song [5], Wu [23], and Wu and Sun [26] demonstrated the concepts of fuzzy statistic and applied them to social survey; Wu and Tseng [27] use fuzzy regression method of coefficient estimation to analyze Taiwan monitoring index of economic. All above-mentioned studies dealt with problems by means of central point values. Pei-Chun Lin, et al. [8] defined a new weight function, by means of fuzzy numbers defined with central point and radius. Moreover, Pei-Chun Lin, et al. [9] also purposes a method to recognize the underlying distribution function using central point and radius. It gives us more information about original fuzzy data.

The objective of this paper is to define a fuzzy portfolio selection model and decision by statistic test. In the first step, we need to find out the probability distribution function for each parameter. When we know the distribution function of each parameter, we can easily calculate the expected return and variance. Those values can enable us to define a fuzzy portfolio selection model. Moreover, we give a decision by statistic test. It give us a explicit risk in investment.

The rest of the paper consists of the following. Section 2 gives the brief review of related studies. The main method is described in section 3. Section 4 illustrates empirical studies with interval values to show that fuzzy portfolio selection model with statistic test. Finally, the concluding remarks and the topics of further studies are addressed in Section 5.

II. NOTATIONS AND PRELIMINARY DEFINITIONS

A. Fuzzy Numbers

In a standard formulation of the portfolio selection, literatures revealed that the authors pervert to use LR-type fuzzy numbers [4] to deal with problems.

Definition 1 A fuzzy number $A = [a, b, c, d]$ is called trapezoidal with tolerance interval $[b, c]$, left width $L = b - a$ and right width $U = d - c$ if its membership function has the following form:

$$\mu_A(x) = \begin{cases} 1 - \dfrac{b-t}{L} & if \;\; b - L \le t \le b, \\ 1 & if \;\; b \le t \le c, \\ 1 - \dfrac{t-c}{U} & if \;\; c \le t \le c + U, \\ 0 & otherwise \end{cases}$$

and we give the notation as $A \equiv (b, c, L, U)$.

Definition 2 Especially, if $b = c$, we have a triangular fuzzy number $B = [a, b, d]$, the left width $L = b - a$ and right width $U = d - b$. Its membership function is written in the following form:

$$\mu_B(x) = \begin{cases} 1 - \dfrac{b-t}{L} & if \;\; b - L \le t \le b, \\ 1 & if \;\; t = b, \\ 1 - \dfrac{t-b}{U} & if \;\; b \le t \le b + U, \\ 0 & otherwise \end{cases}$$

and we give the notation as $B \equiv (b, L, U)$.

Definition 3 An interval value is denoted as $A = [a, b]$ with central point $o = \frac{a+b}{2}$ and radius $l = \frac{b-a}{2}$. We give the notation as $A \equiv (o, l)$.

Moreover, two operations on LR-type fuzzy numbers, namely fuzzy addition and scalar multiplication, are given as follows.

Definition 4 Let $A_1 = (a, b, c, d)$ and $A_2 = (\bar{a}, \bar{b}, \bar{c}, \bar{d})$ be any two fuzzy numbers and λ be any real number. Then

(a) $A_1 + A_2 = (a + \bar{a}, b + \bar{b}, c + \bar{c}, d + \bar{d})$.

(b) $\lambda A_1 = (\lambda a, \lambda b, \lambda c, \lambda d)$, $\forall\, \lambda \ge 0$.

When we have those fuzzy numbers, we need some statistic methods to deal with those data. We introduce a statistic test in the following subsection.

B. Statisitc Analysis

In statistics often functions of observations are important [21]. An example is the sample mean $\overline{x}_n$ of n observations $x_1, x_2, \dots, x_n$ of a stochastic quantity.

For a sample $X_1, X_2, \dots, X_n$ of a normally distributed stochastic quantity $X \sim N(\mu, \sigma^2)$ a statistic for the hypothesis $H_0: \mu = \mu_0$ is

$$T = \frac{\overline{X}_n - \mu_0}{\frac{S_n}{\sqrt{n}}} \tag{1}$$

and the acceptance region A for T under probability δ for an error of the first type is

$$A = \left\{ t \in \mathbb{R} : \; |t| = \left| \frac{\overline{X}_n - \mu_0}{\frac{S_n}{\sqrt{n}}} \right| \le t_{n-1;1-\frac{\delta}{2}} \right\}, \tag{2}$$

where $\overline{X}_n$ is the sample mean of data, S_n is the sample standard deviation of data and $t_{n-1;1-\frac{\delta}{2}}$ is the $(1 - \frac{\delta}{2})$-fractile of the *t*-distribution with *n-1* degrees of freedom.

When we have those information above, we have prepare all prior knowledge for dealing with portfolio selection problem. Now, we give a briefly statement with Markwitz's portfolio selection model in the following subsection.

C. Markwitz's Portfolio Selection Model

Markowitz's mean-variance model is based on probability distribution where uncertainty is equated with randomness [10, 11, 13]. That is, the rate of return on the ith asset, r_i, will be regarded as a random variable.

Consider a market with n risky assets. An investor's position in this market is described by a portfolio $\mathbf{x} = (x_1, x_2, \dots, x_n)'$, where the ith component x_i represents the proportion invested in asset i. The return vector on portfolio $\mathbf{x}$ is described by $\mathbf{r} = (r_1, r_2, \dots, r_n)'$, where r_i represents the return rate of asset i. In conventional mean-variance methodology for portfolio selection, r_i is regarded as a random variable, $\forall\, i = 1,2, \dots, n$. Assume $\bar{\mathbf{r}} = (\overline{r_1}, \overline{r_2}, \dots, \overline{r_n})'$ and $V = (\sigma_{ij})_{n \times n}$ be the expected return vector and covariance matrix, respectively. The return R on the portfolio $\mathbf{x}$ is given by $R = \sum_{i=1}^{n} r_i x_i$. Set $F = (1, 1, \dots, 1)'$. The objective of the investor is to choose a portfolio that maximizes the return on the investment subject to some constraints on the risk of the investment.

A mean-variance model for portfolio selection can be formulated mathematically as:

$$\left.\begin{array}{c} \max \quad \bar{\mathrm{r}}\mathrm{x} \\ \text{s.t.} \quad \sqrt{\mathrm{x}'\mathrm{V}\mathrm{x}} \le \sigma \\ \mathrm{F}'\mathrm{x} \le 1 \\ x_i \ge 0 \quad \forall\, i = 1,2, \dots, n \end{array}\right\} \tag{3}$$

where σ ($\sigma \ge 0$) represents the risk level, $\mathrm{x}'\mathrm{V}\mathrm{x} = \sum_{i=1}^{n} \sigma_{ii}{}^2 x_i{}^2 + \sum_{j=1}^{n} \sum_{i=1, i \ne j}^{n} \sigma_{ij} x_i x_j$, $\sigma_{ij} = cov(a_i, a_j)$ is covariance, a_i and a_j are random variables, $\forall\, i, j = 1,2, \dots, n$.

Here, we rewrite formula (3) clearly as following formula.

$$\left.\begin{array}{c} \max \quad \mathrm{E}(\sum_{i=1}^{n} r_i x_i) \\ \text{s.t.} \quad \sqrt{\mathrm{x}'\mathrm{V}\mathrm{x}} \le \sigma \\ \sum_{i=1}^{n} x_i \le 1 \\ x_i \ge 0 \quad \forall\, i = 1,2, \dots, n \end{array}\right\} \tag{4}$$

i.e. We need to solve the programming problem as follows.

$$\left.\begin{array}{c} \max \quad \sum_{i=1}^{n} E(r_i) x_i \\ \text{s.t.} \quad \sqrt{\mathrm{x}'\mathrm{V}\mathrm{x}} \le \sigma \\ \sum_{i=1}^{n} x_i \le 1 \\ x_i \ge 0 \quad \forall\, i = 1,2, \dots, n \end{array}\right\} \tag{5}$$

In the next section, we will give definitions of fuzzy expected return and fuzzy portfolio variance. Moreover, we will give the procedure about how to solve the fuzzy portfolio selection model by statistic test.

III. Statistic Test on Fuzzy Portfolio Selection Model

A. Fuzzy Expeced Return and Fuzzy Portfolio Variance

Suppose that there are n distinct tradable assets in the market. The terminal rate of return for asset i, denoted as r_i, $\forall\, i = 1,2,\dots,n$, is assumed as a fuzzy random variable. By the widely accepted definition, the expectation of a fuzzy random variable is a fuzzy variable. We give the following combination to express the total fuzzy return R on a portfolio $\mathbf{x}$, where $\mathbf{x} = [\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_m]$ is a $n \times m$ matrix and $\mathbf{x}_1 = (x_{1_1}, x_{1_2}, \dots, x_{1_n})'$, $\mathbf{x_2} = (x_{2_1}, x_{2_2}, \dots, x_{2_n})'$, ..., $\mathbf{x}_m = (x_{m_1}, x_{m_2}, \dots, x_{m_n})'$ are $n \times 1$ vectors.

Definition 5 Fuzzy Expected Return

Let $A_i \equiv (o_i, l_i), \forall\, i = 1,2,\dots,n$, are interval values on the probability space $(\Omega, \mathcal{F}, P)$, where o_i is random variables of central point of A_i and l_i is random variables of radius of A_i, $\forall\, i = 1,2,\dots,n$. Then the fuzzy expected returns of A_i defined as follows.

For the proportion invested in asset k_i, i.e $k = o, l$ and $i = 1,2,\dots,n$. We have $\mathbf{x} = [\mathbf{x}_o, \mathbf{x}_l]$, where $\mathbf{x}_o = (x_{o_1}, x_{o_2}, \dots, x_{o_n})'$ and $\mathbf{x}_l = (x_{l_1}, x_{l_2}, \dots, x_{l_n})'$. Hence,

$$E[R(\mathbf{x})] = diag\left(\sum_{i=1}^{n} E(o_i)x_{o_i}, \sum_{i=1}^{n} E(l_i)x_{l_i}\right).$$

Note that $\sum_{i=1}^{n} E(k_i)x_{j_i} = 0$, for $k \neq j$.

Definition 6 Fuzzy Portfolio Variance

Let $A_i \equiv (o_i, l_i), \forall\, i = 1,2,\dots,n$, are interval values on the probability space $(\Omega, \mathcal{F}, P)$. Then the fuzzy portfolio variance of $A_i, \forall\, i = 1,2,\dots,n$, are defined as follows.

$$var[R(\mathbf{x})] = diag\left(var(\sum_{i=1}^{n} o_i x_{o_i}), var(\sum_{i=1}^{n} l_i x_{l_i})\right),$$

where
$var(\sum_{i=1}^{n} o_i x_{o_i}) = \sum_{i=1}^{n} {\sigma_{o_{ii}}}^2 {x_{o_i}}^2 + \sum_{j=1}^{n}\sum_{i=1,i\neq j}^{n} \sigma_{o_{ij}} x_{o_i} x_{o_j}$, $\sigma_{o_{ij}} = cov(o_i, o_j)$, and $var(\sum_{i=1}^{n} l_i x_{l_i}) = \sum_{i=1}^{n} {\sigma_{l_{ii}}}^2 {x_{l_i}}^2 + \sum_{j=1}^{n}\sum_{i=1,i\neq j}^{n} \sigma_{l_{ij}} x_{l_i} x_{l_j}$, $\sigma_{l_{ij}} = cov(l_i, l_j), \forall\, i = 1,2,\dots,n$.

Now, let us give the models of fuzzy portfolio selection model in the following subsection.

B. Fuzzy Portfolio Selection Model

Model 1 Fuzzy Portfolio Selection Model with Interval Values

Let $A_i \equiv (o_i, l_i), \forall\, i = 1,2,\dots,n$, is interval values. The portfolio selection model with interval values is as follows.

$$\left.\begin{array}{c} \max \quad \sum_{i=1}^{n} E(o_i)x_{o_i} \\ \text{s.t.} \quad \mathbf{x}_o{}'\mathbf{V}_o\mathbf{x}_o \leq {k_1}^2 \\ \sum_{i=1}^{n} x_{o_i} \leq 1 \\ x_{o_i} \geq 0 \quad \forall\, i = 1,2,\dots,n \end{array}\right\} \tag{6}$$

$$\left.\begin{array}{c} \min \quad \sum_{i=1}^{n} E(l_i)x_{l_i} \\ \text{s.t.} \quad \mathbf{x}_l{}'\mathbf{V}_l\mathbf{x}_l \leq {k_2}^2 \\ \sum_{i=1}^{n} x_{l_i} \leq 1 \\ x_{l_i} \geq 0 \quad \forall\, i = 1,2,\dots,n \end{array}\right\} \tag{7}$$

where $\mathbf{x}_o{}'\mathbf{V}_o\mathbf{x}_o = \sum_{i=1}^{n} {\sigma_{o_{ii}}}^2 {x_{o_i}}^2 + \sum_{j=1}^{n}\sum_{i=1,i\neq j}^{n} \sigma_{o_{ij}} x_{o_i} x_{o_j}$, $\sigma_{o_{ij}} = cov(o_i, o_j)$, and $\mathbf{x}_l{}'\mathbf{V}_l\mathbf{x}_l = \sum_{i=1}^{n} {\sigma_{l_{ii}}}^2 {x_{l_i}}^2 + \sum_{j=1}^{n}\sum_{i=1,i\neq j}^{n} \sigma_{l_{ij}} x_{l_i} x_{l_j}$, $\sigma_{l_{ij}} = cov(l_i, l_j), \forall\, i = 1,2,\dots,n$.

We can solve the optimal solution for each model in (6) and (7) by choosing different values for k_i ($k_i \geq 0$), $\forall\, i = 1,2$, which is presented the tolerated risk level. We get the optimal solution vector $\mathbf{x}^* = [\mathbf{x}_o{}^*, \mathbf{x}_l{}^*]'$, where $\mathbf{x}_o{}^*$ is the optimal solution for model in (6) and $\mathbf{x}_l{}^*$ is the optimal solution for model in (7).

Moreover, when we have the solution $\mathbf{x}^* = [\mathbf{x}_o{}^*, \mathbf{x}_l{}^*]'$, we can get the total expected return

$$\mathrm{E}\big(R(\mathbf{x}^*)\big) = diag\left(\sum_{i=1}^{n} E(o_i)\mathbf{x}_o{}^*, \sum_{i=1}^{n} E(l_i)\mathbf{x}_l{}^*\right).$$

Now, we have defined the fuzzy portfolio selection model with interval values. There are many solutions in the model. It is depended on choosing the k_i, $\forall\, i = 1,2$. We give a description about how to choose the k_i, $\forall\, i = 1,2$, in the following subsection.

C. Statistic Test on Fuzzy Portfolio Selection Model

First, we give a definition of T-test with interval data.

Definition 7 T-test with interval value

For interval value $A = [a, b] \equiv (o, l)$, sample $o_1, o_2, \dots, o_n$ can be approximated as a normally distributed stochastic quantity $X_o \sim N(\mu, \sigma^2)$ and sample $l_1, l_2, \dots, l_n$ can be approximated as a normally distributed stochastic quantity $X_l \sim N(\mu, \sigma^2)$.

Statistics for each hypothesis is as follows.

$$H_0^o: \mu_o = \mu_{o_0}, \text{ for statistic } T_o = \frac{\overline{X}_{o_n} - \mu_{o_0}}{\frac{S_{o_n}}{\sqrt{n}}}, \tag{8}$$

$$H_0^l: \mu_l = \mu_{l_0}, \text{ for statistic } T_l = \frac{\overline{X}_{l_n} - \mu_{l_0}}{\frac{S_{l_n}}{\sqrt{n}}}. \tag{9}$$

The acceptance region $A_i, \forall\, i = o, l$, for T under probability δ for an error of the first type are

$$A_o = \left\{ t_o \in \mathbb{R} \middle| |t_o| = \left| \frac{\overline{X}_{o_n} - \mu_{o_0}}{\frac{S_{o_n}}{\sqrt{n}}} \right| \leq t_{n-1;1-\frac{\delta}{2}} \right\}, \tag{10}$$

$$A_l = \left\{ t_l \in \mathbb{R} \middle| |t_l| = \left| \frac{\overline{X}_{l_n} - \mu_{l_0}}{\frac{S_{l_n}}{\sqrt{n}}} \right| \leq t_{n-1;1-\frac{\delta}{2}} \right\}. \tag{11}$$

Where $t_{n-1;1-\frac{\delta}{2}}$ is the $(1-\frac{\delta}{2})$-fractile of the *t*-distribution with *n-1* degrees of freedom.

Now, we give the decision making for the fuzzy portfolio selection model by statistic test.

Definition 8 Statistic test on Fuzzy Portfolio Selection Model with interval values

According to Definition 7 and Model 1, we set up

$$K_o = \left\{ k_1 \middle| k_1 \geq 0 \text{ such that } \mu_{o_0} = \sum_{i=1}^{n} E(o_i)\mathbf{x}_o{}^* \in A_o, \text{we don't reject } H_0^o \right\},$$

$$K_l = \left\{ k_2 \middle| k_2 \geq 0 \text{ such that } \mu_{l_0} = \sum_{i=1}^{n} E(l_i)\mathbf{x}_l{}^* \in A_l, \text{we don't reject } H_0^l \right\}.$$

Moreover, we choose $K = K_o \cap K_l$, for $K_o \cap K_l \neq \emptyset$.

Hence, we get the solution of Model 1.

Now, we give the procedure of solving fuzzy portfolio selection model by statistic test in the following.

Procedure of Solving Fuzzy Portfolio Selection Model with Interval Values

Step 1. Collect the fuzzy data.

Step 2. Compute o_i *and* l_i, $\forall\, i = 1,2,\dots,n$.

Step 3. Identify the underlying distribution by simulating o_i *and* l_i.

Step 4. Calculate the parameters for the expected value, variance and covariance in model (6) and (7).

Step 5. Solve the optimization model (6) and (7) with different values for k_i, $\forall\, i = 1,2$, *respectively.*

Step 6. Calculate $K = K_o \cap K_l$ *by Definition 8.*

Step 7. Get the optimal solution $\mathbf{x}^*$ *with different* K.

Step 8. Compute the possibility distribution of total return $R(\mathbf{x}^*)$ *with different* K.

In order to illustrate our proposed effective meanings and approaches of the efficient portfolios, we exemplify a real portfolio selection problem in the following section.

IV. Empirical Studies

Example 1 We select five exchange currencies (USD, EUR, AUD, GBP and CHF) from Bank of Tokyo-Mitsubishi. Original data come from every day's closed prices from January 2010 to November 2010. There are 224 interval values in this period (*a, b*), where *a* is the minimum price and *b* is the maximum price in one day. We give some interval values in TABLEI.

TABLEI. Interval values of each exchange currency

	(*a*, *b*)			
USD	(83.4, 84.3)	(83.8, 84.4)	⋯	(83.01, 83.54)
EUR	(108.46,110.01)	(109.98,112.00)	⋯	(111.96,113.65)
AUD	(79.83, 80.82)	(80.52, 81.65)	⋯	(81.03, 82.51)
GBP	(129.54,130.47)	(130.74,131.74)	⋯	(132.69,133.48)
CHF	(83.32, 84.32)	(83.83, 84.44)	⋯	(84.27, 85.12)

First, we calculate the central point $o = \frac{a+b}{2}$ and radius $l = \frac{b-a}{2}$. We give the data in TABELII.

TABLEII. Central point o and radius l of each interval values (a, b)

	(*o*, *l*)			
USD	(83.85, 0.45)	(84.1, 0.3)	⋯	(83.275,0.265)
EUR	(109.235,0.775)	(100.99, 1.01)	⋯	(112.805,0.845)
AUD	(80.325, 0.495)	(81.085,0.565)	⋯	(81.77, 0.74)
GBP	(130.005,0.465)	(131.24, 0.5)	⋯	(133.085,0.395)
CHF	(83.82, 0.5)	(84.135,0.305)	⋯	(84.695, 0.425)

We simulate the values of o and l respectively. We get the probability distributions o and l respectively in exchange currency. We give the result in TABLEIII.

TABLEIII. Parameters of Probability Distribution Functions for Interval Values

	o	l
USD	$\mathrm{W}(29.91, 89.73)$	$\mathrm{W}(3.07, 0.51)$
EUR	$\Gamma(270.87, 0.43)$	$\Gamma(7.38, 0.09)$
AUD	$\Gamma(563.13, 0.14)$	$\Gamma(4.99, 0.11)$
GBP	$\Gamma(601.20, 0.23)$	$\Gamma(7.37, 0.10)$
CHF	$\mathrm{N}(83.95, 2.63^2)$	$\Gamma(8.97, 0.05)$

When we know the distribution function, we use moment method estimator (MME) to estimate our parameter in each distribution function. We can find out the expected values and variances by using those parameters. TABLEIV shows the results.

TABLEIV. Expected Values and Variances for Interval Values

	o_1	o_2	o_3	o_4	o_5
Expected value	88.09	116.47	78.84	138.28	83.95
Variance	13.62	50.08	11.04	31.80	6.92
	l_1	l_2	l_3	l_4	l_5
Expected value	0.46	0.66	0.55	0.74	0.45
Variance	0.03	0.06	0.06	0.07	0.02

Moreover, we give the values of $V_o = [cov(o_i, o_j)]_{5\times5}$ and $V_l = [cov(l_i, l_j)]_{5\times5}$, $\forall\, i, j = 1,2,\dots,5$ are in the following.

$$V_o = \begin{pmatrix} 13.62 & & & & \\ 0.92 & 50.08 & & & \\ 0.04 & -1.15 & 11.04 & & \\ 0.77 & 1.83 & 0.05 & 31.80 & \\ 0.32 & 0.33 & -0.64 & -0.48 & 6.92 \end{pmatrix} \text{ and}$$

$$V_l = \begin{pmatrix} 0.0257 & & & & \\ -0.0004 & 0.0602 & & & \\ -0.0008 & 0.0019 & 0.0625 & & \\ 0.0011 & 0.0029 & 0.0006 & 0.0661 & \\ 0.0001 & -0.0012 & -0.0004 & -0.0020 & 0.0236 \end{pmatrix}.$$

Now, we have all the data we need in our fuzzy portfolio selection model. We rewrite our model with estimated parameters as follows.

$$\left.\begin{array}{c} \max \quad 88.09x_{o_1} + 116.47x_{o_2} + 78.84x_{o_3} + 138.28x_{o_4} + 83.95x_{o_5} \\ \min \quad 13.62{x_{o_1}}^2 + 50.08{x_{o_2}}^2 + 11.04{x_{o_3}}^2 + 31.80{x_{o_4}}^2 + 6.92{x_{o_5}}^2 \\ +2(0.92x_{o_1}x_{o_2} + 0.04x_{o_1}x_{o_3} + 0.77x_{o_1}x_{o_4} + 0.32x_{o_1}x_{o_5} \\ -1.15x_{o_2}x_{o_3} + 1.83x_{o_2}x_{o_4} + 0.33x_{o_2}x_{o_5} \\ +0.05x_{o_3}x_{o_4} - 0.64x_{o_3}x_{o_5} - 0.48x_{o_4}x_{o_5}) \\ \text{s.t.} \quad x_{o_1} + x_{o_2} + x_{o_3} + x_{o_4} + x_{o_5} = 1 \\ x_{o_i} \geq 0 \qquad \forall\, i = 1,2,\dots,5 \end{array}\right\} \quad (12)$$

and

$$\left.\begin{array}{c} \min \quad 0.46x_{l_1} + 0.66x_{l_2} + 0.55x_{l_3} + 0.74x_{l_4} + 0.45x_{l_5} \\ \min \quad 0.03{x_{l_1}}^2 + 0.06{x_{l_2}}^2 + 0.06{x_{l_3}}^2 + 0.07{x_{l_4}}^2 + 0.02{x_{l_5}}^2 \\ +2(-0.0004x_{l_1}x_{l_2} - 0.0008x_{l_1}x_{l_3} + 0.0011x_{l_1}x_{l_4} + 0.0001x_{l_1}x_{l_5} \\ +0.0019x_{l_2}x_{l_3} + 0.0029x_{l_2}x_{l_4} - 0.0012x_{l_2}x_{l_5} \\ +0.0006x_{l_3}x_{l_4} - 0.0004x_{l_3}x_{l_5} - 0.002x_{l_4}x_{l_5}) \\ \text{s.t.} \quad x_{l_1} + x_{l_2} + x_{l_3} + x_{l_4} + x_{l_5} = 1 \\ x_{l_i} \geq 0 \qquad \forall\, i = 1,2,\dots,5 \end{array}\right\} \quad (13)$$

In fact that it is not easy to solve the model (12) and (13). In order to reduce the calculation load, we simplify the minimum goal in (12) and (13) as follows:

We set $G_1 = \min \quad 13.62{x_{o_1}}^2 + 50.08{x_{o_2}}^2 + 11.04{x_{o_3}}^2 + 31.80{x_{o_4}}^2 + 6.92{x_{o_5}}^2 + 2(0.92x_{o_1}x_{o_2} + 0.04x_{o_1}x_{o_3} + 0.77x_{o_1}x_{o_4} + 0.32x_{o_1}x_{o_5} - 1.15x_{o_2}x_{o_3} + 1.83x_{o_2}x_{o_4} + 0.33x_{o_2}x_{o_5} + 0.05x_{o_3}x_{o_4} - 0.64x_{o_3}x_{o_5} - 0.48x_{o_4}x_{o_5})$.

Hence, we have $G_1 \leq (\sqrt{13.62}x_{o_1} + \sqrt{50.08}x_{o_2} + \sqrt{11.04}x_{o_3} + \sqrt{31.80}x_{o_4} + \sqrt{6.92}x_{o_5})^2 \leq {k_1}^2$,

where k_1 ($k_1 \geq 0$) represents the tolerated risk level.

It implies that $3.69x_{o_1} + 7.08x_{o_2} + 3.22x_{o_3} + 5.64x_{o_4} + 2.63x_{o_5} \leq k_1$.

Let $G_2 = \min \quad 0.03{x_{l_1}}^2 + 0.06{x_{l_2}}^2 + 0.06{x_{l_3}}^2 + 0.07{x_{l_4}}^2 + 0.02{x_{l_5}}^2 + 2(-0.0004x_{l_1}x_{l_2} - 0.0008x_{l_1}x_{l_3} + 0.0011x_{l_1}x_{l_4} + 0.0001x_{l_1}x_{l_5} + 0.0019x_{l_2}x_3 + 0.0029x_{l_2}x_{l_4} - 0.0012x_{l_2}x_{l_5} + 0.0006x_{l_3}x_4 - 0.0004x_{l_3}x_{o_5} - 0.002x_{l_4}x_{l_5})$.

Hence, we have $G_2 \leq (\sqrt{0.03}x_{l_1} + \sqrt{0.06}x_{l_2} + \sqrt{0.06}x_{l_3} + \sqrt{0.07}x_{l_4} + \sqrt{0.02}x_{l_5})^2 \leq {k_2}^2$,

where k_2 ($k_2 \geq 0$) represents the tolerated risk level.

It implies that $0.17x_{l_1} + 0.24x_{l_2} + 0.24x_{l_3} + 0.26x_{l_4} + 0.14x_{l_5} \leq k_2$.

Therefore, we rewrite model (12) and (13) in the following.

$$\left.\begin{array}{c} \max \quad 88.09x_{o_1} + 116.47x_{o_2} + 78.84x_{o_3} + 138.28x_{o_4} + 83.95x_{o_5} \\ \text{s.t.} \quad 3.69x_{o_1} + 7.08x_{o_2} + 3.22x_{o_3} + 5.64x_{o_4} + 2.63x_{o_5} \leq k_1 \\ x_{o_1} + x_{o_2} + x_{o_3} + x_{o_4} + x_{o_5} \leq 1 \\ x_{o_i} \geq 0 \qquad \forall\, i = 1,2,\dots,5 \end{array}\right\} \quad (14)$$

and

$$\left.\begin{array}{c} \min \quad 0.46x_{l_1} + 0.66x_{l_2} + 0.55x_{l_3} + 0.74x_{l_4} + 0.45x_{l_5} \\ \text{s.t.} \quad 0.17x_{l_1} + 0.24x_{l_2} + 0.24x_{l_3} + 0.26x_{l_4} + 0.14x_{l_5} \leq k_2 \\ x_{l_1} + x_{l_2} + x_{l_3} + x_{l_4} + x_{l_5} \leq 1 \\ x_{l_i} \geq 0 \qquad \forall\, i = 1,2,\dots,5 \end{array}\right\} \quad (15)$$

We solve the model (14) and (15) by using GP-IGP (Linear and Integer Goal Programming). The result depends on the selection of $k_i, i = 1,2$. TABLEV shows the result of model (14) and TABLEVI shows the result of model (15).

Decision(l)	A	A	A	A	A	A	A

Explain of decision with T-test.

In TABLEV, for example, when $k_1 = 2.5$, we have $\mathrm{x_o}^* = (0,0,0,0,0.95)'$. We calculate the return

$$R = \sum_{i=1}^{n} r_{o_i} x_{o_i} = r_{o_1}x_{o_1} + r_{o_2}x_{o_2} + r_{o_3}x_{o_3} + r_{o_4}x_{o_4} + r_{o_5}x_{o_5} = 0.95 * x_{o_5}.$$

Therefore, we have 224 new data.

We calculate the expected value $\mu_o{}^*$ and standard deviation $S_{o_n}^*$ by Minitab15. The results are $\mu_o{}^* = 79.75$ and $S_{o_n}^* = 2.49$. The hypothesis is $H_0^o: \mu_o = 79.80$, for statistic $T_o = \left|\frac{79.75-79.80}{\frac{2.49}{\sqrt{224}}}\right| = 0.26$. The 95% critical region is (79.42, 80.08).

Since $79.80 \in (79.42, 80.08)$, we accept the hypothesis.

The same method for $k_1 = 3$, we have $\mathrm{x_o}^* = (0,0,0,0.12,0.88)'$. The return

$$R = \sum_{i=1}^{n} r_{o_i} x_{o_i} = r_{o_1}x_{o_1} + r_{o_2}x_{o_2} + r_{o_3}x_{o_3} + r_{o_4}x_{o_4} + r_{o_5}x_{o_5} = 0.12 * x_{o_4} + 0.29 * x_{o_5}.$$

Therefore, we have 224 new data.

We calculate the expected value $\mu_o{}^*$ and standard deviation $S_{o_n}^*$ by Minitab15. The results are $\mu_o{}^* = 90.18$ and $S_{o_n}^* = 2.81$. The hypothesis is $H_0^o: \mu_o = 90.63$, for statistic $T_o = \left|\frac{90.18-90.63}{\frac{2.81}{\sqrt{224}}}\right| = 2.38$. The 95% critical region is (89.81, 90.55).

Since $90.63 \notin (89.81, 90.55)$, we reject the hypothesis.

It is the same way to calculate decision in TABLEVI.

We conclude the result as follows.

In TABLEV, we can see that when $k_1 \geq 3$, we reject the hypothesis. Moreover, we also see that we accept the hypothesis for all k_2 in TABLEVI.

That is we accept the hypothesis when $k_1 = 0.5, 1, 1.5, 2, 2.5.$

and

$$k_2 = 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5, 5.5, 6, 6.5, 7.$$

Hence, the result for $K = k_1 \cap k_2 = 0.5, 1, 1.5, 2, 2.5.$

We give the total expected return in TABLEVII. We get good total expected return when K is small.

TABLEVII. THE EXPECTED RETURN WITH DIFFERENT CONDITIONS K

K	0.5	1	1.5	2	2.5
$\sum_{i=1}^{n} E(o_i)\mathbf{x}_o{}^*$	15.96	31.92	47.88	63.84	79.80
$\sum_{i=1}^{n} E(l_i)\mathbf{x}_l{}^*$	0.09	0.17	0.26	0.34	0.43
Expected Return	(15.97, 16.05)	(31.75, 32.09)	(47.62, 48.11)	(63.50, 64.18)	(79.37, 80.23)

Suppose that we choose $K = k_1 = k_2 = 2.5$, the optimal solution of model (14) is $\mathbf{x}_o{}^* = (0,0,0,0.95)'$ and the optimal solution of model (15) is $\mathbf{x}_l{}^* = (0, 0, 0, 0, 0.95)'$.

Hence, we have our return of fuzzy vector

$$\mathbf{x}^* = [\mathbf{x}_o{}^*, \mathbf{x}_l{}^*]' = \begin{bmatrix} 0, 0, 0, 0, 0.95 \\ 0, 0, 0, 0, 0.95 \end{bmatrix}. \quad (16)$$

Moreover, we get the total expected return

$$\mathrm{E}[\mathrm{R}(\mathbf{x}^*)] = \mathrm{diag}\left(\sum_{\mathrm{i}=1}^{\mathrm{n}} E(o_i)\mathbf{x}_o{}^*, \sum_{\mathrm{i}=1}^{\mathrm{n}} E(l_i)\mathbf{x}_l{}^*\right) = \mathrm{diag}\,(79.80, 0.43). \quad (17)$$

The interval value of the total expected return resulted in (79.37, 80.23).

V. CONCLUSIONS

In this paper, we proposed a method to estimate the probability distribution function with fuzzy data. When we know the probability distribution function with fuzzy data, we can calculate the expected value, variance and covariance by using the estimated parameters of underlying distribution function. Therefore, we can solve the fuzzy portfolio selection model by statistic test. We give an empirical study by using fuzzy portfolio selection model based on statistic test in example 1. We can see that it is more explicit and meaningful to use fuzzy portfolio selection model by statistic test to estimate the maximum return because of considering more information based on vagueness, which comes from original fuzzy data. We have many choices K to decide which expected return is better and have less risk level in our model. Through this method, we also can provide not only one choice of portfolio selection but also two or more for decision makers.

We have further points to improve in the future as follows:

1. In this paper, we just use the most useful probability distribution function in industry to estimate the parameters. We can do more estimation with other probability distribution functions and compare which one gives better results in our fuzzy portfolio selection problem.
2. Moreover, if we can get the triangular fuzzy numbers or trapezoid fuzzy numbers, it will be good for us to examine fuzzy portfolio selection model with statistic test which we proposed is more explicit and easily for decision makers.

***Abstract*—The operation planning in hydrothermal systems with great hydraulic participation, as it is the case of Brazilian system, seeks to determine an operation policy to specify how hydroelectric plants should be operated, in order to use the hydroelectric resources economically and reliably. This paper presents an application of Takagi-Sugeno Fuzzy Inference Systems to obtain an operation policy (PBFIS - Policy Based on Fuzzy Inference Systems) that follows the principles of the optimized operation of reservoirs for electric power generation. PBFIS is obtained through the application of an optimization algorithm for the operation of hydroelectric plants. From this optimization the relationships between the stored energy of the system and the volume of the reservoir of each plant are extracted. These relationships are represented in the consequent parameters of the fuzzy linguistic rules. Thus, PBFIS is used to estimate the operative volume of each hydroelectric plant, based on the value of the energy stored in the system. In order to verify the effectiveness of PBFIS, a computer simulation model of the operation of hydroelectric plants was used so as to compare it with the operation policy in parallel; with the operation policy based on functional approximations; and also with the result obtained through the application of the optimization of individualized plants' operation. With the proposed methodology, we try to demonstrate the viability of PBFIS' obtainment and application, and with the obtained results, we intend to illustrate the effectiveness and the gains which came from it.**

I. Introduction

The operation planning of hydrothermal systems aims to determine an operation policy to specify how thermal and hydraulic subsystem should be operated so that the available resources for electric power generation are used efficiently. The problem of the planning is very complex due to several aspects, such as: the stochasticity of the water inflows and of the electric power market; the hydraulic interconnection of the hydroelectric plants in a cascade; the nonlinear operational characteristics of hydroelectric and thermoelectric plants; the dynamic relationship among the operation decisions taken along the whole horizon; and the transmission constraints of the electric system [1], [2], [3], [4].

In hydrothermal systems with great hydraulic participation, the operation policy seeks to replace the generation of complementary origin (thermo electrical plants, import of energy from other systems and the deficit) by hydroelectric origin generation, whenever possible [5]. Thus, in these hydrothermal systems, the operation planning has to determinate an operation policy for the reservoirs of the generation hydroelectric system as a fundamental point. The operation policy adopted in Brazilian electric power system is the Parallel Policy (PP) [6]. In this operation policy, the reservoirs are operated in parallel, which should maintain the same percent level of their useful volumes. This operation policy has its simplicity as its greatest attraction. However, it doesn't obey the principles of the optimized operation of the reservoirs for electric power generation [7], [8], [9].

To obtain an operation policy that represents the optimized behavior of the reservoirs, initially, the operation of the hydroelectric system is optimized under distinct operative conditions. With this optimization we can get a group of operation points that relate the energy stored in the hydroelectric system with the state of the reservoir of each hydroelectric plant. Figures 1 and 2 exhibit representative points of the optimized operation of some Brazilian power plants.

So that the group of operation points can be used as indicative for an operation policy, the adjustment of functions that represent the behavior of the optimized operation of the reservoirs will be necessary. Several works are related to the obtainment of operation policies, only differentiating in the employed technique for the adjustment of the points obtained relative to the optimized operation. In [10], the authors use third degree polynomial functions to adjust the points obtained with the optimization of the operation in order to obtain the operation policy. In [11], the authors make the adjustment of the points, obtaining polynomial and exponential functions to represent the operational policy whereas in [2], [12], [13], the authors use the method of the least squares in the adjustment of the polynomial, exponential and linear functions. In [14], [15],

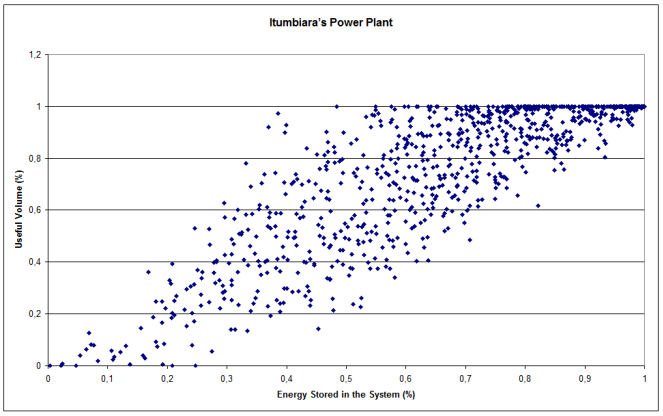

Fig. 2. Representative points of the optimized operation of Itumbiara's power plant.

Artificial Neural Networks (ANNs) are used, more specifically the SONARX model, for the obtainment of an operation policy that follows the principles of the optimized operation.

This paper presents an application of Takagi-Sugeno (TS) Fuzzy Inference Systems [16], responsible for obtaining an operation policy (PBFIS - Policy Based on Fuzzy Inference System) that represents the optimized operation of reservoirs for electric power generation [17]. The parametric functions in the consequents of the TS fuzzy rules and the adjustment easiness starting from a set of input and output data makes the TS fuzzy inference systems be related to the functions approximation task [18]. So as to illustrate the effectiveness of PBFIS, it was evaluated comparatively with the Parallel Policy (PP); with the operation policy based on functional approximations that use polynomial and exponential functions (policy based on polynomial and exponential functions - PBPEF), obtained through the method of the least squares; and also with the results obtained through the optimization of the operation of hydroelectric plants. Hence, we try to demonstrate the viability of the obtainment and application of PBFIS, as well as the energy gain that came from it.

Section 2 presents the problem of the operation planning of hydrothermal systems focusing on the adopted planning horizon, the mathematical formulation, and the operation policy for hydroelectric systems, besides presenting the hydroelectric system used in the case studies of this paper. In the Section 3, some foundations of the Takagi-Sugeno fuzzy inference system are presented, as well as the proposed fuzzy system. Section 4 brings the application of the operation policy for the chosen hydroelectric system, emphasizing the main results of the case studies. Section 5 presents the discussions of the work, followed by Section 6, in which the conclusions and final observations of the work are presented as a whole.

II. OPERATION PLANNING OF HIDROTHERMAL SYSTEMS

A. Hydroelectric System

Figure 3 illustrates the hydroelectric system used in the case studies of this paper. This system is composed of some hydroelectric plants of the Brazilian system. It is pinpointed that the chosen hydroelectric system can be characterized as a complex system, because it contains interlinked plants in parallel and in cascade.

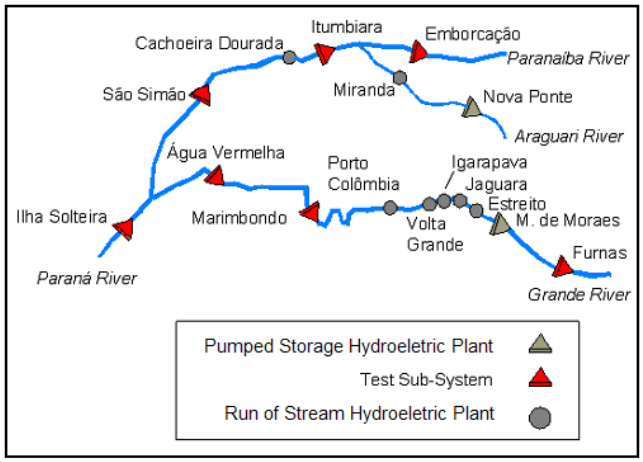

Fig. 3. Hydroelectric system used.

B. Planning Horizon

In this paper, the operation planning was adopted with five-year horizons (monthly discretized), but considering the individualized representation of the hydroelectric plants. The simplification of the composite representation of the system makes the hydroelectric generating system not be used in the most possible efficient way, once the equivalent reservoir of energy doesn't get to represent the individual operative characteristics of the plants. Thus, the individualized representation of each hydroelectric plant is important.

C. Mathematical Formulation

The operation planning of hydrothermal systems, with individualized representation of the hydroelectric plants and with

deterministic water inflows can be formulated according to the following optimization problem:

$$\min \quad \sum_{t=1}^{T} CVP_t \cdot 0,5 \cdot \Phi(D_t - H_t)^2 + V(x_T) \quad (1)$$

$$s.a. \quad E_t = D_t - H_t, \quad (2)$$

$$H_t = \sum_{i=1}^{N} k_i \cdot hl(x_{i,t}^{med}, u_{i,t}) \cdot min[u_{i,t}, q_{i,t}^{max}], \quad (3)$$

$$x_{i,t} = x_{i,t-1} + \\ +(y_{i,t}^{inc} + \sum_{k \in \Omega_i} u_{k,t} - u_{i,t} - x_{i,t}^{evap}) \cdot [\tfrac{\Delta t_t}{10^6}], \quad (4)$$

$$u_{i,t} = q_{i,t} + v_{i,t}, \quad (5)$$

$$x_{i,t}^{min} \leqslant x_{i,t} \leqslant x_{i,t}^{max}, \quad (6)$$

$$u_{i,t}^{min} \leqslant u_{i,t} \leqslant u_{i,t}^{max}, \quad (7)$$

$$q_{i,t}^{min} \leqslant q_{i,t} \leqslant q_{i,t}^{max}, \quad (8)$$

$$x_{i,0} \text{ given}, \quad (9)$$

onde:

- T: number of intervals of the planning horizon;
- N: number of hydroelectric plants;
- CVP: coefficient of present value;
- E_t: total thermal generation [MW];
- H_t: total hydroelectric generation [MW];
- D_t: demand (electric energy market) [MW];
- $x_{i,t}$: volume stored in the reservoir i at the end of the interval t [hm^3]. The values of the initial volumes of the reservoirs are given;
- $x_{i,t}^{med}$: medium volume stored in the reservoir i in the interval t [hm^3];
- $x_{i,t}^{evap}$: volume evaporated in the reservoir i in the interval t t[hm^3];
- $hl_{i,t}$: net water head of the plant i in the interval t [m];
- $y_{i,t}^{inc}$: incremental water inflow to the reservoir of the plant i in the interval t [m^3/s];
- $q_{i,t}$: turbinated flow of the plant i in the interval t [m^3/s];
- $u_{i,t}$: flow release of the plant i in the interval t [m^3/s];
- $v_{i,t}$: spill flow of the plant i during the interval t [m^3/s];
- $x_{i,t}^{max}$, $x_{i,t}^{min}$: maximum and minimum limits of stored volume for the reservoir of the plant *i* at the end of interval *t* [hm^3];
- $u_{i,t}^{max}$, $u_{i,t}^{min}$: maximum and minimum limits of the flow release for the plant *i* in the interval *t* [m^3/s];
- $q_{i,t}^{max}$, $q_{i,t}^{min}$: maximum and minimum limits of turbinated flow for the plant *i* in the interval *t* [m^3/s];
- Δt_t: number of seconds in the interval t [s];
- Ω_i: group of indexes of the plants immediately upstream of plant i.

The objective function is composed of two terms, which represent the operational cost during the horizon planning (Φ) and the future costs associated with the final storage condition from hydroelectric plants to reservoirs (V). As the Brazilian system is a hydrothermal system greatly predominant of hydraulic origin generation, for our purposes, complementary generation system is being used by an equivalent thermoelectric plant that substitutes all non-hydraulic system [19]. Thus, the operational cost is represented by a single cost function of non-hydraulic sources. Future cost is a terminal condition used in the optimization models of the operation to balance the use of water during the planning horizon and its future use [20].

The equality (2) represents the constraints towards the electric power demand in the interval t. The total hydraulic generation of the hydroelectric system is represented by equation (3), given by the sum of the hydraulic production functions of each hydraulic plant. The equation (4) represents the water balance in the reservoir. The output flow of the plant corresponds to the flow released and is equivalent to the sum of the turbinated flow with the spilled flow and it is represented in equation (5). The constraints (6) and (7) represent the storage and the released flow limits of the hydroelectric plants. The limits presented in these inequations vary in time, because these reflect the operational restrictions of the plant and other restrictions associated with the multiple use of water, such as: irrigation, control of floods, navigation, etc. Restriction (8) represents the minimum and maximum limits of turbinated flow, which can be associated with physical restrictions of the plant itself or electric restrictions.

D. Hydroelectric Systems Operation Policy

The operation policies for hydroelectric systems are present in several stages of the operation planning of hydrothermal systems. They are necessary in the aggregation procedure for obtainment of the equivalent reservoir [21], [22], in the simulation of the operation to disaggregate the goals of hydraulic generation of the equivalent reservoir among all the plants [10], and for the evaluation of the performance of the hydroelectric system in several conditions [23], [24]. Additionally, operation policies are also used in the expansion planning of the Brazilian hydrothermal system.

The operation policies for hydroelectric systems try to determine the amount of electric power produced by each one of the plants, through the definition of the storage state of each reservoir. The operation policy can be understood as a group of operation rules, one to each plant (or reservoir) of the system, which defines how these plants will be operated in a coupled way. To implement the coupling in the operation of hydroelectric systems, a global parameter is defined, denominated coupling factor of the operation among the plants, denoted by λ_t. The coupling factor represents the percentage of storage of the system in a certain interval t, and it is calculated (Equation 10) as the proportion between the energy stored in the system (ESS_t) and the maximum energy stored in the system (ESS^{max}), resulting in the values in the interval: $0 \leq \lambda_t \leq 1$.

$$\lambda_t = \frac{ESS_t}{ESS^{max}} \quad (10)$$

With the value of λ, the volume of each reservoir can be determined by the following equation:

$$x_{i,t}(\lambda_t) = x_{i,t}^{min} + f_i(\lambda_t) \cdot (x_{i,t}^{max} - x_{i,t}^{min}) \quad (11)$$

Where:

- $x_{i,t}(\lambda_t)$: operative volume of plant *i* in the interval *t*;
- $f_i(\lambda_t)$: operation rule of the reservoir of plant *i* as function of the parameter λ_t. It expresses the rules of emptying/filling of the reservoir together with the other reservoirs of the hydroelectric system.

III. TAKAGI-SUGENO FUZZY INFERENCE SYSTEMS

The fuzzy inference systems are based on production rules that make use of the linguistic variables [25] to execute a process of decision making. The operation of fuzzy inference systems can be divided in three stages: fuzzification, inference procedures and defuzzification.

In the fuzzy inference systems, usually, crisp (or precise) inputs are considered resulting from observations or measurements. Because of that, it is necessary to make a conversion (fuzzification) of those data for the fuzzy input sets. This way, the fuzzification is a mapping of the domain of the crisp input variable for the fuzzy domain, to attribute linguistic values (vague or qualitative descriptions) defined by membership functions to the entrance variables. The inference procedure is responsible for processing the fuzzy input data together with the production rules, so as to infer the contributions in the fuzzy output of the inference system. A typical production rule of Takagi-Sugeno fuzzy inference model is: if *x* is *F* and *y* is *G*, then, $z = f(x, y)$, where *F* and *G* are fuzzy sets and f is a polynomial function of x and y. The inference procedure in the Takagi-Sugeno model, specifically, consists of obtaining all the individual contributions z_i coming from each one of the fired rules. After this stage, we should combine all of the individual contributions to get the final answer z. Thus, the numeric output is calculated directly by the sum of the outputs pondered by the degree of fired of each rule (μ_i). Therefore, the defuzzification process is unnecessary [26]. This model was proposed as an effort to develop a systematic approach so as to generate fuzzy rules starting from a group of input and output data [27].

The fuzzy inference systems implemented have as input linguistic variable the ESS, defined in the group of linguistic terms (Very Low, Low, Medium, High and Very High)(Figure 4).

In this paper, we specialized for each one of the 7 plants (Figure 3), a Takagi-Sugeno fuzzy inference system. Each TS system is composed of 5 disjunctive inference rules. The syntax of the rules base of the fuzzy systems implemented is represented by the following linguistic conditional declarations:

- Rule 1: If (ESS *é Very Low*), Then $z_1 = f_1(ESS) = a_1 \cdot ESS + b_1$
- Rule 2: If (ESS *é Low*), Then $z_2 = f_2(ESS) = a_2 \cdot ESS + b_2$
- Rule 3: If (ESS *é Medium*), Then $z_3 = f_3(ESS) = a_3 \cdot ESS + b_3$
- Rule 4: If (ESS *é High*), Then $z_4 = f_4(ESS) = a_4 \cdot ESS + b_4$

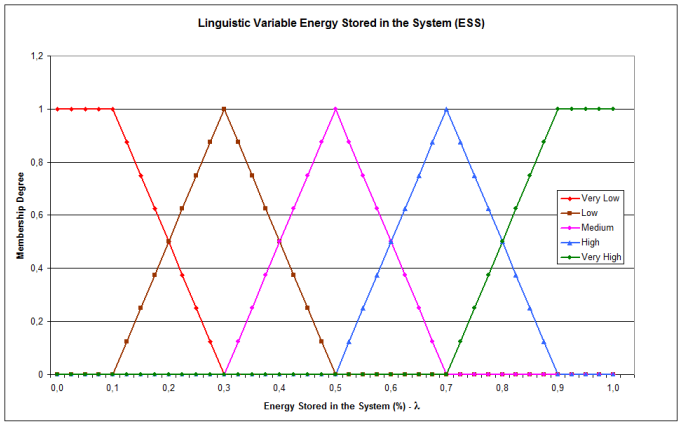

Fig. 4. Input linguistic variable representing the energy stored in the system.

TABLE I
PARAMETERS OF THE CONSEQUENTS OF THE PRODUCTION RULES OF THE FUZZY INFERENCE SYSTEM TO THE PLANT OF EMBORCAÇÃO.

i	ESS	a	b
1	Very Low	$0,5272$	$-0,0188$
2	Low	$0,8928$	$-0,1013$
3	Medium	$1,0796$	$-0,1776$
4	High	$1,2216$	$-0,2690$
5	Very High	$1,4516$	$-0,4533$

- Rule 5: If (ESS *é Very High*), Then $z_5 = f_5(ESS) = a_5 \cdot ESS + b_5$

With the optimization of the hydroelectric system operation, we obtain a set of operation points, which relate the stored energy of the hydroelectric system to the operative volume of each reservoir. For each one of the 5 rules that compose each fuzzy system, linear regression is applied at the points belonging to its activation domain, using the known input/output points, in order to determine the parameters (a_i, b_i) of each one of the $(5 \cdot N)$ polynomial functions relative to the consequent of *N* fuzzy systems (N = 7). Tables I, II and III present the parameters of the consequents of the fuzzy production rules relative to the policy proposed for some reservoirs of the hydroelectric system used.

With the determination of the 70 parameters of the consequents of the linguistic rules (a_i, b_i), the fuzzy system can be put to operation. In the particular matter, the TS fuzzy inference system *i* determines the operation rule of the plant *i* of the hydroelectric system:

$$f_i(\lambda) = \frac{\sum_{j=1}^{5}(z_j \cdot \mu_j)}{\sum_{j=1}^{5}\mu_j};\ i = 1,...,\ N \qquad (12)$$

IV. CASE STUDIES

In this paper, a computer model was used to simulate the operation of hydroelectric systems, so as to allow the performance evaluation of the proposed operation policy (PBFIS). The simulation model used is part of a computer tool that has been developed by the authors for the accomplishment

of studies related to the operation planning of hydrothermal systems. The tool comprehends, besides the simulation model, a model of optimization of the hydrothermal systems operation [28]. The optimization model is used to determine the optimized operation of reservoirs and is inspired in algorithms of optimization designed for the operation planning of hydrothermal systems [29], [30]. It should be stressed that the authors applied a development process (UML Components) [31] based on software components [32] for the construction of the computer models, in order to guide the development of the tool.

The simulation of the operation intends to verify how a hydroelectric system would behave in case it were submitted to certain operation conditions (electric power market, operation policies, operative restrictions, initial volume, etc.). Thus, to make the comparison among the proposed policy (PBFIS), the policy based on polynomial and exponential functions (PBPEF), and the parallel policy (PP); the simulations of the operation are accomplished under the same operation conditions. Therefore, the differences of behavior in the operation of the hydroelectric system will only result from the policies used.

A. Operation Conditions

Five case studies were realized, with the intention of accomplishing a comparison among the three operation policies implemented in the simulation model, under several hydrological conditions. The goal of hydraulic generation (or electric power market) is said to be equal to the hydraulic generation provided by the operation optimization model, for the periods of the report from 1936 to 1941; 1951 to 1956; 1971 to 1976; 2000 to 2005 and with data of LTA (Long Term Average). The natural water inflow corresponds to the flows verified for the same periods of the report. The month of May was adopted (beginning of the dry period for the hydrographic basin of the Brazilian southeastern system) as the beginning month for all case studies. For additional comparisons, the optimization of the hydroelectric system operation was accomplished with water inflows really occurred in the periods, in order to obtain the solution with the perfect knowledge of the water inflows for the whole planning horizon. We emphasize that the solution obtained through the optimization model corresponds to the superior performance limit in the use of the hydroelectric generation resources. We considered in all the case studies that the initial volume stored in the reservoirs were the same as the operative maximum volume.

B. Results

1) Volume Stored in the Reservoirs: Figures 5 and 6 exhibit the trajectories of reservoirs' useful volume of some plants of the hydroelectric system considered for test. A differentiated behavior can be observed for each plant's reservoir, in which the oscillation of the reservoirs' volume is made in function of its positioning in the cascade. In the figures, one can visualize that the more upstream reservoir (Emborcação) presents a smaller storage level during the planning horizon. The plant of Itumbiara, in the intermediate position, presented a medium storage level, while the plants of São Simão downstream, presents lower emptying level (higher storage level).

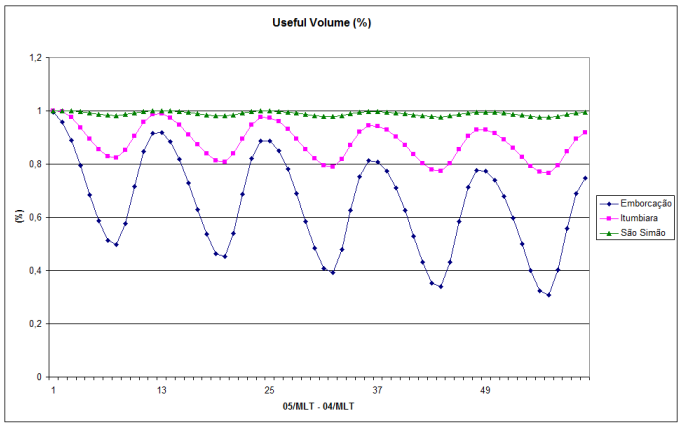

Fig. 5. Trajectories of useful volume in some reservoirs of the hydroelectric system for MLT.

With PBFIS, the downstream plants, whenever possible, remain full, so as to maintain high productivity and, thus, value the water that goes by them. As the energy stored at a plant is valued by the productivity of all downstream plants, the net water head of the plant more downstream, for instance, affects the stored energy of all plants of the cascade. Therefore, the consequent parameters of the fuzzy inference system are adjusted to prioritize higher storage levels in the upstream to the downstream reservoirs in the cascade of plants.

2) Deficit of Energy Stored in the System: Figure 7 illustrates the deficit path of stored energy (in %) in the system for the simulations of the operation accomplished with the three implemented policies, using the LTA. The deficit of energy stored in the system is calculated as the subtraction between the value of the stored energy resulting through the optimized solution, and the values of the stored energy resulting from the

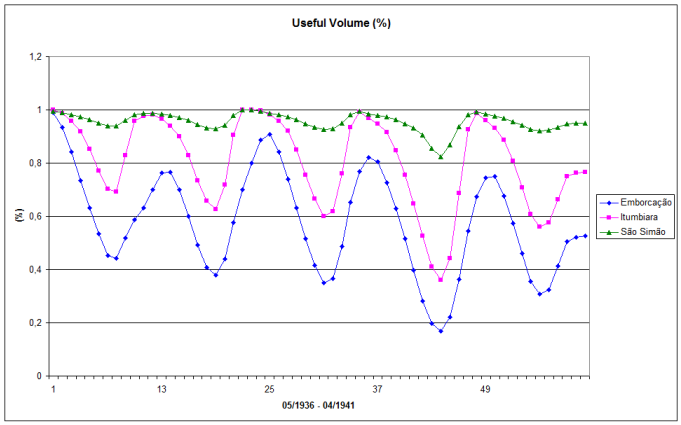

Fig. 6. Trajectories of useful volume in some reservoirs of the hydroelectric system 1936 to 1941.

application of operational policies implemented in the simulation model. A more severe emptying of the group of reservoirs can be noticed when using the parallel policy, followed by a less rigorous emptying when using PBPEF, and an even less accentuated emptying using PB, what implicates a larger efficiency in the use of generation hydroelectric resources, through the proposed policy (PBFIS).

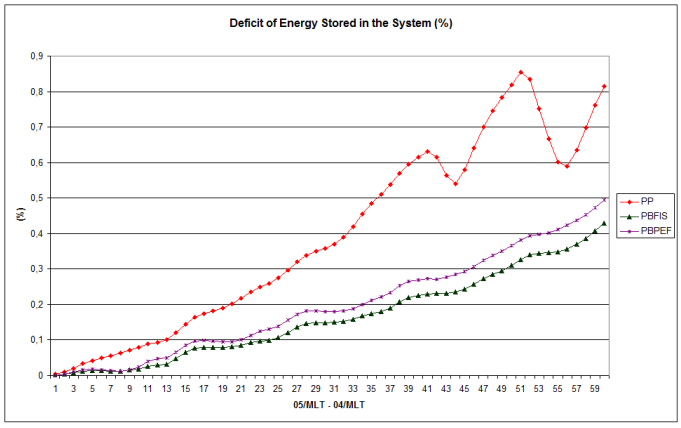

Fig. 7. Trajectories of the deficit of energy stored in the system for MLT.

Table IV allows the reader an additional comparison, in order to verify the efficiency of each operation policy with the optimized solution numerically. Considering the planning horizon involving the years 1936 - 1941, 1951 - 1956, 1971 - 1976, 2000 - 2005 and LTA (05 years of medium flows), we can confirm the greatest efficiency supplied by the proposed policy when compared with the parallel policy, in the use of generation hydroelectric resources. It is noteworthy that when compared with PBPEF, PBFIS only presents more reduced levels of stored energy (or a higher stored energy deficit) in the horizon from 1971 to 1976.

In Figure 8, we can verify the best use of generation hydroelectric benefits, for the proposed policy, where it is noticed that the emptying of the reservoirs is much more

TABLE IV
AVERAGE OF ENERGY STORED IN THE SYSTEM [MW].

Planning Horizon	PP	PBPEF	PBFIS	Optimal Solution
1936-1941	27865.83	29773.74	32299.55	34824.86
1951-1956	24232.82	26817.27	28851.86	38375.47
1971-1976	14329.13	27517.44	26544.69	33470.54
2000-2005	18151.44	21761.86	25847.11	29761.31
LTA	17171.52	25950.09	27437.61	34991.9

intense when the parallel policy and the PBPEF are employed. It may be emphasized that although, during the whole planning horizon, the proposed policy has always presented lower deficit values of energy stored in the system, confirming that this policy needs to use less water to meet the same electric energy market. Additionally, at the end of the planning horizon, we can see that the parallel policy and PBPEF do not get to reach the storage levels obtained by the proposed policy.

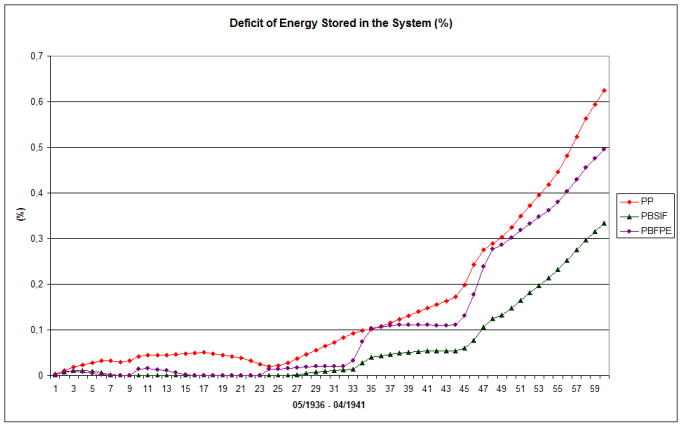

Fig. 8. Trajectories of the deficit of energy stored in the system 1936 to 1941.

Based on the trajectories of deficit of the energy stored in the system, it can be affirmed that, in most case studies accomplished, the simulation of the operation using the proposed policy maximize the hydroelectric benefits of the generation hydrothermal system, as it assists the same market of electric energy, using less water stored in the reservoirs of the plants. Again, at the end of the planning horizon, it is observed that the parallel policy does not get to maintain the close storage levels of the established storage levels for PBFIS and PBPEF. On the contrary, the parallel policy gets to the end of the simulation with more reduced storage levels in the reservoirs, making reliability and the cost of the operation extremely damaged in the continuous operation of the system. Therefore, PBFIS and PBPEF allow the simulation of the hydroelectric system operation to be solid with the continuous operation of the system, since the hydroelectric system does not stop being operated with the end of the planning horizon.

When using the representative operation points of the optimized operation of the reservoirs, the proposed policy (PBFIS) tries to present a differentiated behavior for each reservoir of

plants of hydroelectric system. With the specialization of a fuzzy inference system for each plant, the operation of each one reflects the role that it plays in the hydroelectric system, in agreement with its location in the cascade. Therefore, hydroelectric system is capable of maintaining higher levels of stored energy.

It should be taken into account that the comparisons made with the optimized solution took the optimization with previous knowledge of affluences (optimal absolute), characterizing it as an extremely rigorous pattern. Therefore, the solutions obtained with the simulation model of the operation and the several implemented policies should present a large or smaller degree of sub-optimality.

V. DISCUSSIONS

The proposed operation policy was compared, through some case studies, in the hydroelectric plants of the southeastern Brazilian system, with the policy of parallel operation and with the policy based on functional approximation that uses polynomial and exponential functions. Most results evidenced the efficiency of the proposed policy, taking into account the deficit trajectories and the average of energy stored in the system as parameters. These parameters were obtained by the simulation of the hydroelectric system operation. Regarding the energy stored in the system, the results illustrated that the proposed policy needs less hydraulic resources under the same operation conditions of the parallel policy and PBPEF.

Thus, it is verified that the proposed policy can assure a more reliable and economical supply of the electric power. Economical because the proposed policy needs less hydraulic generation resources than the parallel policy and PBPEF. Reliable because the proposed policy allows the operation of the hydroelectric system with superior storage levels in the reservoirs, reducing the possibility of hydraulic deficits of the hydrothermal generation system. Therefore, the potentiality of the proposed policy can be evidenced in the use of the hydraulic resources turned to electric energy generation.

Additionally, at the end of all planning horizons, it was observed that the parallel policy does not manage to equal the levels of stored energy of the hydroelectric system with the established levels for PBFIS and for PBPEF. Therefore, the proposed policy, besides maximizing the benefits of the generation hydroelectric resources during the planning horizon, still guarantees a larger reliability and a smaller cost of the hydrothermal generation system operation in the continuity of the operation of the hydroelectric system, when arriving at the end of the planning horizon with higher levels of water stored in the reservoirs.

VI. CONCLUSIONS

By the found results, the operation policy based on the Takagi-Sugeno fuzzy inference system establishes a different behavior for the group of reservoirs, so as to maximize the energy stored in the system during the simulation of the hydroelectric system operation. This behavior is obtained through the specific operation for each reservoir, in the agreement with its position in the cascade. With the predominant influence of the quota effect, the plants whose reservoir volume does not have great influence on the energy stored in the hydroelectric system have emptying priority. On the other hand, the plants whose operative volume of the reservoir has great influence on the system's stored energy present filling priority. As the energy stored in a hydroelectric system is valued by the productivity of the downstream plants, the parameter of the fuzzy rule consequents prioritize higher storage levels in the reservoirs from upstream to downstream in the cascade of plants. Thus, the knowledge of the volume oscillations, in the function of the positioning in the cascade, is represented through the fuzzy production rules.

When opting for a fuzzy inference system to determine the operative volume of each hydroelectric plant, we obtained an action/control strategy that can be monitored and interpreted, even from the language viewpoint. It should be emphasized that, as future works, some improvements can still be investigated in relation to parameters of the fuzzy inference system, mainly in the adjustment of the membership functions, the number of rules and the consequents of the rules employing techniques like Artificial Neural Networks of Genetic Algorithms.

VII. THANKS

The authors would like to thank Prof. Dr. Ivan Nunes da Silva of Universidade of São Paulo (Engineering School of São Carlos, Electric Engineering Departament). The authors also thank the financial support of the SEFAZ-PI and FAPESP.

***Abstract*—Some important politico-economic dynamics, in relation to different scenarios involving the finding and exploitation of oil/gas in the exclusive economic zone of Cyprus, have been modeled and examined through the use of suitable fuzzy cognitive maps. In the interrelated dynamics, various important dynamical parameters have been taken into account, reflecting the interests of the republic of Cyprus, as well as the interests of the Greek and Turkish Cypriot communities. In some respects these interests are antagonistic, while in others could be cooperative. The interests of other countries involved in the Cyprus politico-economic problem have also been taken into account. These are primarily Greece, Turkey, United Kingdom, USA, Russia, Israel and the European Union. The main parameters involved in the interrelated dynamics are nationalism, religiousness, knowledge of history, level of educational development, tourism, unemployment, external debt, oil extraction, Anatolian settlers, and the general interests of the countries involved and those of the two communities. The system that has been developed can be used to study the effects of a change in any parameter or a combination of parameters, on the growth and stability of the remaining parameters. Different scenarios on the effects on economies, politics and military involvement have been implemented, observed and appraised.**

Keywords-fuzzy cognitive maps; Cyprus problem; politico-economic modeling.

I. INTRODUCTION

Cyprus is a small island in the Eastern Mediterranean. It has about 900,000 inhabitants. The population consists of approximately 78% Greek-Cypriots, 18% Turkish-Cypriots and the remaining 4% of Armenian, Maronite and Latin-Cypriots. Turkish and Greek Cypriots lived mostly harmoniously for almost five centuries. Since the early 1960s and more intensely after July 1974 when Turkey invaded the island, there have been political problems between the two dominant communities. Turkey occupies about one third of the territory of the Republic of Cyprus, and is systematically changing the social fabric by bringing Anatolian settlers into the island. This creates thrifts and conflicts among the genuine inhabitants.

The dynamics involved for the security and stability of the island, as well as the economic development, are related to the interests of both the Greek-Cypriot and the Turkish-Cypriot communities. Theses dynamics have been influenced largely by the strategic position of the island, being at the Eastern Mediterranean, where many conquerors and civilizations spread their influence (Greek, Roman, Byzantine, Arabs, Francs, Venetians, Crusaders, Ottomans, Turks, and English). The historical roots of the two communities forged them to be both cooperative and antagonistic. Also, the interests of other countries involved in the problem played a significant role in the politico-economic developments. These are primarily Greece, Turkey and the United Kingdom.

The accession in 2004 of Cyprus into the European Union, as well as the recent political – social unrest in the wider Mediterranean neighborhood (Tunisia, Egypt, Libya, Syria and Jordan) has made the involvement of Europe, USA, Russia and Israel to be highly important influential-dynamical factors.

In this work, an attempt to model the dynamics of the problem, using a fuzzy cognitive map-like (FCM) approach has been made. More specifically, the main parameters involved in the interrelated dynamics are:

- The overall interests of the Republic of Cyprus,
- The economic welfare of both communities,

- The risk of conflict between the two major communities,
- The importance of oil/gas exploration,
- The unemployment,
- The level of tourism, and
- The general interests (political, economic, military) of the countries mentioned previously and the interests of the two dominant communities.

A cognitive map is a set of cause-effect relationships that model the interrelationships among specific concepts (also identified as characteristics, factors, parameters, attributes, states, actions, values, goals, trends, events, components, resources etc). By using an appropriate systematic process it is possible to estimate the effect of a change in the state of a specific concept on any other concept (or set of concepts) of the system. The concepts are related through directed graphs. The intensity of the interrelationships among them is not clearly known, and thus, suitable membership functions may be used. Different fuzzy cognitive map paradigms have been proposed [2, 3, 4, 5, 6, 7], and different application areas have been investigated [8, 9, 10, 11, 12, 13]. In most of the applications each concept is related to the other concepts through appropriate degrees of effectiveness (also called sensitivity, weights, causality). Once the parameters have been identified and initialized, the system is allowed to grow through proper simulation. When the system settles, a researcher can observe the effects of a change in the state of one factor on the intensity of change in another.

The work reported here is mainly involved with an effort to apply an FCM variant to the dynamics of the Cyprus problem, aiming at getting some useful insight on the effectiveness and interactivity of the important contributing parameters, primarily the importance of the oil/gas exploration in the future events in Cyprus. Also, it may be used as a study tool for exploring complicated economic-political dynamics through the use of computing simulations.

II. THE FCM SYSTEM

Computationally intelligent systems have largely been inspired by natural or real life systems. A general observation is that dynamical systems in nature as well as political-economical-social systems, in which the parameters are characterized by causal relations, tend to reach quasi-steady states. That is, after interacting with each other, the parameters may reach equilibrium, cyclic behavior, or chaotic oscillation. The parameters of a system change iteratively their values, as a response to the first change(s) that happen in the system. Also, in real systems, an adaptive evolutionary behavior is usually observed, something that is not captured in the classic FCM paradigms.

In the present study, a slightly different approach from the established FCM formalism is adopted.

Consider an FCM system of n interrelated concepts (parameters), which are connected by causal relations, here called sensitivities. The sensitivity relating the changes in the activation of a concept C_j to changes in the activation of a concept C_i is defined by:

$$s_{ij} \equiv \frac{\partial C_j}{\partial C_i} \tag{1}$$

Thus, the total accumulated change in the activation of concept C_j due to changes in concepts C_i is given by:

$$\delta C_j = \sum_{i,i\neq j}^{n} \frac{\partial C_j}{\partial C_i} \delta C_i = \sum_{i,i\neq j}^{n} s_{ij} \delta C_i \tag{2}$$

where,

C is the activation strength of the concept of interest.

s_{ij} is the sensitivity (weight).

It is a measure on how much a change in the current standing of concept C_i affects the changes in the standing of concept C_j.

In discrete time form the above equation becomes:

$$C_j(t+\delta t) = C_j(t) + \delta C_j = C_j(t) + \sum_{i=1}^{n} s_{ij} \left(\delta C_i\right) \tag{3}$$

and in iterative form has been implemented by:

$$C_j(k+1) = C_j(k) + \sum_{i,i\neq j}^{n} s_{ij} \left(C_i(k) - C_i(k-1)\right) \tag{4}$$

where,

k is the iteration counter.

It is pointed here that this approach is different than the approach that is followed by most FCM implementations in two respects:

i) The weights (sensitivities) are defined differently, as previously explained, and

ii) No smoothening activation function, such as the logistic has been used.

The updating is done quasi-statically and interactively until the system evolves to settlement specified by desired boundaries. Any changes in the various concepts affect either directly or indirectly all the other concepts of the system.

III. THE FCM CONCEPTS

For the study presented here, 42 influencing parameters (concepts) have been used. These are shown in Table 1.

It should be mentioned that these factors are difficult to quantify. Also they are not fully agreed by every person involved in the analysis and decision. Some form of fuzzy approximation may be employed, using persons having good knowledge (experts) and extensive experience (politicians). Furthermore, each one of them embodies a general state (and associated trend), as it is commonly employed and understood. For instance by the term "General welfare of the Republic of Cyprus" we mean a state that has characteristics of prosperity, political stability, social development, high quality of life, etc. The initial starting values are also shown in Table 1. These have been estimated by the experts, and given as the average of their suggestions.

Three knowledgeable persons have been asked to suggest the various sensitivities that were used to update the various concepts as per Equation 4. Obviously, there are discrepancies between the values given by each person. This is indicatively

shown in Figure 1, where the values given by three persons are displayed in colours. The green colour shows a non-relationship ($s_{ij} = 0$). The blue numbers are positive sensitivities, and the red negative.

The average of the sensitivities that have been used are as shown in Table 2.

IV. Results and conclusions

The effects of finding and exploring oil and/or gas, on various political, economic and military issues and parameters - based on the average sensitivity values from the three experts (Figure 1) - are shown in Figures 2, 3, 4. In these figures, the horizontal axis shows the initial (starting) values of the concept "IMPORTANCE OF FINDING AND EXPLOITATION OF OIL/GAS", from 0% to 100%, i.e from no natural gas available, to the highest possible. In the vertical axis, the resulting percentage changes in various parameters and factors of interest, which are due to natural gas exploration variations, are shown. These values are obtained after evolution and settling to stable values of the FCM model. The initial values used, other than those of oil/gas, are those displayed in Table 1.

Due to the constraint of having to maintain a reasonably short paper, only three major areas of interest are presented, namely the economic and political effects as well as the military interests. In all the cases examined, the concept C38 (importance of oil/gas exploration) was sequentially initialized to starting values of: 0%, 15%, 30%, 45%, 60%, 75%, and 100%. The exact absolute values are not that important, but rather the relative changes that indicate trends, and can serve as guidance to decision makers, and for better appraisal of the system dynamics.

The various changes and associated trends have been investigated for the following areas of concern:

- Effects on the economic interests of USA, Russia, UK, Israel, Greece, Turkey and Europe.
- Effects on the military interests of USA, UK, Israel, Greece and Turkey.
- Effects on various economic characteristics of the Republic of Cyprus.
- Effects on nationalism of the two communities and the risk of conflict between them.

The FCM model has shown interesting and somewhat expectable trends and effects based on the scenarios studied. However, by closely observing the various trends, some notably interesting observations and conclusions may be made. Specifically, the model predicts that the Turkish Cypriot community and Greek Cypriot community will benefit approximately equally from the prospects of finding and exploiting any natural gas/oil, even though the potential oil/gas fields are located in the south-eastern zone of the Republic, whereas most of the Turkish Cypriot population lives in the north of the island. This of course depends on whether the exploitation is done through peaceful operations. In fact, another relevant observation made, is that any oil/gas exploitation increases the risk of conflict between the two communities. Thus, the situation becomes strongly politically influenced.

As expected the military interests of the countries mentioned, are increasing as the prospects for oil/gas exploitation increase. This increase is also nonlinear, resulting at even more interest, as more natural gas may be exploited (Figure 4). It is also observed that Turkey will show the greatest increase in military interests, followed by Greece.

Also, a very interesting observation can be made concerning the growth of nationalism in the two communities (Figure 3). It is noted that the model predicts a significant increase in the nationalism of the Greek Cypriots, but even higher for the Turkish Cypriot community.

However, it should once again be pointed out that the model is based on what the three experts considered as important parameters, and influencing sensitivities, that may not necessarily agreed by all, and that they may be incomplete and vague. In order to make the model more reliable, one has to get more expert opinions (from politicians, journalists, historians, authoritative analysts etc). Also, results from large scale public opinion research may be incorporated into the system.

Despite that, the proposed FCM model is a highly useful tool for quick explorations, for better understanding of the dynamics involved, for more sound decisions, and for building a basis for more complicated scenarios. However, further explorations are needed to verify the credibility and to fine-tune the various parameters and processes.

***Abstract*—In this paper, integrated a image processing techniques and a fuzzy sliding mode control design for a pneumatic X-Y servo platform system was proposed to realize the picked and placed control of the objects. The key feature of this control scheme is by means of immediately modulated the boundary layer sliding surface and fuzzy function design to improve the steady state error of time response effect. Then, use the image pattern recognition technique to determine the loading and unloading object positions, and drive the Z axis device to active the picking and placing control of the objects to obtain automatic loading-unloading device performance. The validity of the proposed control scheme is verified through practical testing on an experimental pneumatic cylinder X-Y axis servo system device and CCD video camera. In the cases of the step position command input, the test results show that the proposed control scheme and object image pattern recognition technique are capable of reaching the picking and placing precision control of the object.**

Keywords- image processing; fuzzy sliding mode control; pneumatic; pattern recognition; picking and placing control

I. INTRODUCTION

Recently, due to the technological advance, the pneumatic system has been extensively applied in automation fields and automatic production machines. Such as optical electrical industry, medicine industry, packing industry, and foodstuff industry, which production process always needs the pneumatic system convert the compressed air to the mechanical energy power. Owing to the air is easy acquired, low polluted, high-speed activity, and provided a large effective power energy, the pneumatic systems are always adopted in many automation industries. Sometimes, the picked and placed control of the objects for the production process are needed in many automation equipment applications, the pneumatic servo position control is still more considerable. To automatic accurate the picked and placed objects, the image recognized technique are often been addressed. In this paper, the image recognized technique and fuzzy sliding mode controller design are integrated to realize the picked and placed objects control for a pneumatic x-y table system.

However, the pneumatic air is compressible, and the pneumatic system has many nonlinear characteristics, such as the mass flow rate parameters variable and the servo valve dead zone problems [1], there have many challenges in designing a controller for the pneumatic servo control system. To reach a better precision control, there are many nonlinear control strategies have been proposed to deal with the pneumatic servo system, for examples, sliding mode control [1][2], fuzzy control[3], and iterative learning control [4],[5],[6]. Due to its robustness against parameter variations and external disturbance, sliding mode control has been an effective means for controlling nonlinear systems with uncertainties [2]. The traditional sliding mode control always design a boundary layer of the sliding surface to eliminate undesired chattering control input [2]. However, there have some problems to be solved, such as the chattering can be made negligible if the width of the boundary layer is chosen large enough, the guaranteed tracking precision will deteriorate if the available control boundary layer width is limited. For the purpose of obtaining the high tracking accuracy, a thin boundary layer is required. And others, the most commonly used design is the linear sliding surface defined by polynomials with repeat roots [2]. Such sliding surfaces are short of sufficient adjustable free parameters, especially in lower order systems.

In this paper, we designed a switching boundary layer and with adjustable parameters free sliding surface of the sliding mode control scheme [1] for the pneumatic cylinder position servo control system to realize and improve the regulating and tracking control performances. To realize the picking and placing precision control of the objects, the image recognized technique was adopted to identify the pattern position, through the video camera, NI-8252 interface card, and LabVIEW vision and motion builder assistance, the objects pattern center point will be recognized. To accomplish the picked and placed of the objects option, an experimental pneumatic cylinder X-Y axis servo system device is constructed. The proposed

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

controller and the process measuring data were all implement by Pentium IV PC through an NI-6024E interface card with RTW Window target tool box of the Matlab Simulink software designed. Through the test results show that the proposed control scheme is capable of improving the tracking precision of the pneumatic cylinder position control, and for the objects pattern image recognized help, the precision control of picking and placing of the objects with pneumatic system has been come true. The paper is organized as follows: Section 2 a pneumatic cylinder servo system modeling will be constructed, and Section 3 a main control law, fuzzy sliding mode controller design, is also described. Section 4 a pattern image recognized system will be formed with pneumatic servo platform. Experimental results are presented in Section 5, and conclusions are drawn in Section 6.

II. PNEUMATIC CYLINDER SERVO SYSTEM MODELLING

Consider a pneumatic cylinder position servo system which mainly consists of a servo valve and a pneumatic cylinder. Fig.1 shows the structure of pneumatic servo system, the upper portion is a proportional servo valve which actuate the below cylinder with the compressed air flowing into the chamber by the spool displacement X_v of servo valve, hence the pneumatic cylinder can be arrived at any desire position. In general, the response of servo valve is faster than the response of pneumatic cylinder, the orifice area will be proportional to the control input, u, which can be considered as $A_o = K_a K_v u$, where K_a is constant of valve displacement, and K_v is gain constant of valve spool displacement. According to Mocloy & Martin [7],[8] proposed the fluid compressible mass flow rate through the orifice store in chamber can be given by

$$\dot{M}_a = C_{da} C_{ma} A_{oa} P_s \Big/ \sqrt{T_s} \tag{1}$$

$$\dot{M}_b = -C_{db} C_{mb} A_{ob} P_b \Big/ \sqrt{T_b} \tag{2}$$

where, C_{da} and C_{db} are left and right chamber's discharge coefficient respectively, C_{ma} and C_{mb} are left and right chamber's mass flow parameter respectively, A_{oa} and A_{ob} are left and right chamber's orifice area respectively, P_s and P_b are left and right chamber's upstream stagnation pressure respectively, T_s and T_b are left and right chamber's upstream stagnation temperature respectively. However, the mass flow parameters of C_{ma} and C_{mb} have the following calculation:

If $\frac{P_{vc}}{P_o^*} > \left(\frac{2}{\gamma+1}\right)^{\gamma/(\gamma-1)} \approx 0.528$, the C_{ma} and C_{mb} indicate as

$$C_m = \sqrt{\frac{2\gamma}{R(\gamma+1)}\left\{\left(\frac{P_{vc}}{P_o^*}\right)^{2/\gamma} - \left(\frac{P_{vc}}{P_o^*}\right)^{(\gamma+1)/\gamma}\right\}}$$

where, P_{vc} and P_o^* are the orifice static pressure and upstream stagnate pressure respectively, R is the gas parameter, and γ is the ratio of specific heat. If $\frac{P_{vc}}{P_o^*} \le \left(\frac{2}{\gamma+1}\right)^{\gamma/(\gamma-1)} \approx 0.528$, than

$$C_m = \left(\frac{2}{\gamma+1}\right)^{\gamma/(\gamma-1)} \sqrt{\frac{2\gamma}{R(\gamma+1)}} \approx 0.0405 .$$

Fig.2 shows the relationship between of C_m parameter value and $\frac{P_{vc}}{P_o^*}$ value. It can be shown that the C_m parameter is alternated when the orifice gas flow rate decreased. Applying the Law's Conservation of energy [9]

$$\sum \dot{M}_{in} h'_{in} - \sum \dot{M}_{out} h'_{out} + \left\{\frac{dQ}{dt} - \frac{dW}{dt}\right\} = \frac{dE}{dt} \tag{3}$$

where, $\dot{M}_{in}, \dot{M}_{out}$ are mass flow rate of entering the control volume and leaving out the control volume respectively, h'_{in}, h'_{out} are enthalpy of entering the control volume and leaving out the control volume respectively, Q is rate of heat transfer into the chamber, W is kinetic energy for the moving position, E is total of internal energy of the chamber, Eq.(3) can be written as

$$C_p \dot{M}_a T_a - P_a \frac{dV_a}{dt} + \frac{dQ}{dt} = \frac{d}{dt}\left(C_v \rho_a V_a T_a\right) \tag{4}$$

where, C_v is the specific heat value of the air beside constant volume, P_a is the pressure of left chamber, assuming no heat flow in to control volumes, then dQ/dt is small can be ignored, we have

$$\frac{dP_a}{dt} = \frac{\gamma R T_a}{A_a y}\dot{M}_a - \frac{\gamma P_a}{y}\frac{dy}{dt} \tag{5}$$

where, A_a is the cross-sectional area of the left chamber, and y is the displacement of cylinder moving. With the similar procedures to the right chamber of cylinder, we have

$$\frac{dP_b}{dt} = -\frac{\gamma R T_b}{A_b(l-y)}\dot{M}_b + \frac{\gamma P_b}{(l-y)}\frac{dy}{dt} \tag{6}$$

where, l is maximum displacement of pneumatic cylinder, A_b is the cross-sectional area of the right chamber, and P_b is pressure of right chamber. Then the pneumatic cylinder motion equation can be obtained as follows [8],

$$P_a A_a - P_b A_b - b\frac{dy}{dt} - F_f \,\mathbf{sgn}(\dot{y}) - F_L = m\frac{d^2 y}{d^2 t} \tag{7}$$

where, b is damping coefficient, F_f is force due to friction, and F_L is force due to external loading. Substituting (5),(6) into (7) can be obtained as follows

$$\frac{d^3 y}{d^3 t} = \frac{\gamma R}{m}\left[\frac{T_a}{y}\dot{M}_a + \frac{T_b}{1-y}\dot{M}_b\right] - \frac{\gamma}{m}\left[\frac{A_a P_a}{y} - \frac{A_b P_b}{1-y}\right]\frac{dy}{dt} - \frac{b}{m}\frac{d^2 y}{d^2 t} - \frac{\dot{F}_f}{m}\mathbf{sgn}(\dot{y}) - \frac{\dot{F}_L}{m} \tag{8}$$

Then, Substituting (1),(2) into (8),

$$\frac{d^3 y}{d^3 t} = -\frac{\gamma}{m}\left[\frac{A_a P_a}{y} - \frac{A_b P_b}{1-y}\right]\frac{dy}{dt} - \frac{b}{m}\frac{d^2 y}{d^2 t} - \frac{\dot{F}_f}{m}\mathbf{sgn}(\dot{y}) - \frac{\dot{F}_L}{m} + \frac{\gamma R C_d C_m K_a K_v}{m}\left[P_s\sqrt{T_a} - P_b\sqrt{T_b}\right]u \tag{9}$$

where, u is control input, Eq.(9) is a real model of the pneumatic position control system, it's shown that the model is a nonlinear and coefficient variable system. In the Section 3, a multi-variable design sliding surface with switching

boundary later of sliding mode control scheme will be developed to deal with the pneumatic servo system and improving the tracking precision.

III. FUZZY SLIDING MODE CONTROLLER DESIGN

To highlight the main point of the design sliding mode control, we consider the following simple nth-order SISO nonlinear uncertain system [2]:

$$y^{(n)} = f(y, \dot{y}, \ldots, y^{(n-1)}, t) + g(y, \dot{y}, \ldots y^{(n-1)})u \tag{10}$$

where $u, y \in R$, are the input and output, respectively; $f, g: R^n \to R$ are smooth functions. Assume that f is not completely known but can be written as $f = \hat{f} + \Delta f$, where $\hat{f}$ is the nominal part and Δf is the uncertain part which is bounded by a known function F, i.e., $|\Delta f(\mathrm{x}, t)| \le F(\mathrm{x}, t)$, where $\mathrm{x} := [x_1, x_2, \ldots, x_n]^T = \left[y, \dot{y}, \ldots, y^{(n-1)}\right]^T$, and the control gain $g(\mathrm{X})$ is unknown but confined in certain constant range; i.e. $0 < \beta^{\min} \le g(x) \le \beta^{\max}$. where $\beta^{\min}, \beta^{\max}$ are given constants, time-varying or state-dependent functions.

The control object is to find a continuous sliding control u such that the output y of (10) will approximately track a desired signal, y_d, which is assumed to be nth-order continuously differentiable and all of its derivatives are uniformly bounded, i.e., $\lim_{t\to\infty} y(t) = y_d(t)$. Given the tracking error $e(t) := y(t) - y_d(t)$, For any $\lambda_m > 0$, where $m = 1, \ldots, n$, the generalized error as

$$s(t) = \left(\frac{d}{dt} + \lambda_1\right)\left(\frac{d}{dt} + \lambda_2\right)\cdots\left(\frac{d}{dt} + \lambda_m\right)\xi_e(t) \tag{11}$$

where $\xi_e(t) = \int^t e(\tau)d\tau$, the integral of tracking error. Eq. (11) provides a useful transformation so that the original n^{th}-order tracking problem can be transformed into an equivalent 1^{st}-order stabilization problem in s variable. Differentiating s with respect to t and adding the term $\lambda_{n+1}s$ yields

$$\begin{aligned}\dot{s} + \lambda_{n+1}s &= \left(\frac{d}{dt} + \lambda_1\right)\cdots\left(\frac{d}{dt} + \lambda_n\right)\left(\frac{d}{dt} + \lambda_{n+1}\right)\xi_e(t)\\ &= e^{(n)}(t) + c_1 e^{(n-1)}(t) + \cdots + c_{n+1}\xi_e(t)\\ &= f(x) + g(x)u - x_d^{(n)}(t) + c_1 e^{(n-1)}(t) + \cdots + c_{n+1}\xi_e(t)\\ &= \hat{f} + \Delta f + c_1 e^{(n-1)}(t) + \cdots c_{n+1}\xi_e(t) - x_d^{(n)}(t) + g(x)u\end{aligned} \tag{12}$$

where $c_1 = \lambda_1 + \lambda_2 + \cdots + \lambda_{n+1}$, and $c_{n+1} = \lambda_1\lambda_2\cdots\lambda_{n+1}$. Multiplying s in the both sides of Eq.(12), we have

$$\begin{aligned}s\dot{s} &= -\lambda_{n+1}s^2 + [\hat{f} + \Delta f + c_1 e^{(n-1)} + \cdots + c_{n+1}\xi_e - x_d^{(n)} + gu]s\\ &= -\lambda_{n+1}s^2 + [\hat{f} + \Delta f + \hat{w} + gu]s\end{aligned} \tag{13}$$

where $\hat{w} = c_1 e^{(n-1)} + \cdots + c_{n+1}\xi_e - x_d^{(n)}$. The feedback control u for Eq. (13) was designed as

$$u = G(\hat{u} + v) \tag{14}$$

where $G := \frac{1}{\sqrt{\beta^{\min}\beta^{\max}}}$, $\hat{u} = -\hat{f} - \hat{w}$, $v = -Ksat(\frac{s}{\Phi})$. Clearly, $0 < \beta^{-1} \le gG \le \beta$, and $0 < \beta^{-1} \le (gG)^{-1} \le \beta$, where $\beta = \sqrt{\beta^{\max}/\beta^{\min}}$. Whenever $|s| \ge \Phi$, where Φ is the width of the boundary layer, the following result can be obtained

$$s\dot{s} \le -\lambda_{n+1}s^2 - \left(gGK - \left|1 - gG\right|\left|\hat{f} + \hat{w}\right| - \left|\Delta f\right|\right)|s| \tag{15}$$

If we choose K as follows,

$$K \ge \beta(\eta + F) + (\beta - 1)\left|\hat{f} + \hat{w}\right| \tag{16}$$

where $\eta > 0$, then Eq.(15) becomes

$$s\dot{s} \le -\lambda_{n+1}s^2 - \eta|s| \tag{17}$$

Using the Lyapunov function candidate

$$V(s) = \tfrac{1}{2}s^2, \tag{18}$$

it can be shown that, whenever $|s| \ge \Phi$,

$$\dot{V} \le -\lambda_{n+1}s^2 - \eta|s|. \tag{19}$$

This ensures that any trajectory starting from any initial point will reach the boundary layer, $\forall|s| \le \Phi$, in finite time. Consequently, the guaranteed tracking precision will be

$$|e(t)| \le \frac{\Phi}{\lambda_1\lambda_2\cdots\lambda_n} \tag{20}$$

whenever $|s| \le \Phi$.

For smoothness (to reduce chattering) of the control input signal, larger width of the boundary layer is preferred. However, for better tracking accuracy, a boundary layer with smaller width is required [1]. In this paper, the concept of varying width of the boundary layer is proposed, which takes simultaneously the advantages of both the smoothness of the control inputs and the better tracking accuracy. First, let $\Phi = \Phi(|e|)$ and the control input (14) is rewritten as follows

$$v = -Ksat\left(\frac{s}{\Phi(|e|)}\right) \tag{21}$$

We let Φ_1 and Φ_2 are two different boundary layers, $0 < \Phi_2 < \Phi_1$, and ε_1 and ε_2 are two different error, $0 < \varepsilon_2 < \varepsilon_1$. For the relationship of absolute error, $|e|$, and boundary layer Φ are shown in (22)

$$\begin{cases} |e| \ge \varepsilon_1, & \Phi = \Phi_1 \\ \varepsilon_2 \le |e| \le \varepsilon_1, & \Phi = \Phi_a \\ |e| \le \varepsilon_2, & \Phi = \Phi_2 \end{cases} \tag{22}$$

$$\Phi_a = \Phi_2 + \left(\frac{|e| - \varepsilon_2}{\varepsilon_1 - \varepsilon_2} \right) (\Phi_1 - \Phi_2)$$

Therefore, if the initial state is outside the boundary layer, $|s| \ge \Phi_1$, it will be attracted to the boundary layer of sliding surface. Furthermore, if the absolute value of the tracking error is smaller than ε_1, the boundary layer is changed from Φ_1 to Φ_a, and when the absolute value of the tracking error is smaller than ε_2, the boundary layer is fixed at Φ_2, such that the tracking precision and the chattering of the control input signal are improved significantly.

Remark: The widths Φ_1, Φ_2 of boundary layer can be determined, respectively, as follows.

(1). By trial-and-error, the width of the boundary layer Φ is decreased till a visible Chattering of the control input signal occurs and then set $\Phi = \Phi_1$.

(2). A positive constant error ε_1 and ε_2 are used to define the switching threshold of the tracking error such that the width of the boundary is continuously changed from the Φ_1 to the smaller value Φ_2, which is a small enough that the chattering of the control input does not happen and the tracking error precision will be improved.

For $n = 2$ and $\lambda = 1$, the guaranteed tracking error bounds are depicted in Fig. 3, where the real-line region represents the error bound of the proposed sliding mode control with varying boundary layer, while the desh-line region represents that of the conventional sliding mode control with fixed boundary layer. Obviously, the guaranteed steady-state tracking error by using the proposed sliding mode control with switching boundary layer is effectively reduced as shown in Fig. 3.

In section 2, the pneumatic cylinder position system model is a three-order nonlinear system, let

$$f_m(y, \dot{y}, \ddot{y}) = -\frac{\gamma}{m}\left[\frac{A_a P_a}{y} - \frac{A_a P_a}{1-y}\right]\frac{dy}{dt} - \frac{b}{m}\frac{d^2y}{d^2t} - \frac{\dot{F}_f}{m}\mathrm{sgn}(\dot{y}) - \frac{\dot{F}_L}{m} \tag{23}$$

$$g_m(y, \dot{y}, \ddot{y}) = \frac{\gamma R C_d C_m K_a K_v}{m}\left[P_s\sqrt{T_a} - P_b\sqrt{Tb}\right] \tag{24}$$

Then, the system model can be rewritten as follows

$$\overset{(3)}{y} = f(y, \dot{y}, \ddot{y}) + g(y, \dot{y}, \ddot{y})u \,. \tag{25}$$

Let the tracking error be $e(t) = y(t) - y_d(t)$, and $\overset{(3)}{e} = \overset{(3)}{y} - \overset{(3)}{y_d}$, the error equation can be obtained as follows

$$\begin{aligned} \overset{(3)}{e} &= f(\mathbf{y}) + g(\mathbf{y})u - \overset{(3)}{y_d} \\ &= \hat{f}(\mathbf{y}) - \overset{(3)}{y_d} + \Delta f(\mathbf{y}) + g(\mathbf{y})u \end{aligned} \tag{26}$$

Defined the generalized error as

$$\begin{aligned} s &= \left(\frac{d}{dt} + \lambda_1\right)\left(\frac{d}{dt} + \lambda_2\right)\left(\frac{d}{dt} + \lambda_3\right)\int e d\tau \\ &= \dddot{e} + a_1\ddot{e} + a_2\dot{e} + a_3\int e dt \end{aligned} \tag{27}$$

where, $a_1 = (\lambda_1 + \lambda_2 + \lambda_3)$, $a_2 = (\lambda_1\lambda_2 + \lambda_2\lambda_3 + \lambda_1\lambda_3)$, $a_3 = \lambda_1\lambda_2\lambda_3$, we have

$$\begin{aligned} \dot{s} + \lambda_4 s &= \left(\frac{d}{dt} + \lambda_1\right)\left(\frac{d}{dt} + \lambda_2\right)\left(\frac{d}{dt} + \lambda_3\right)\left(\frac{d}{dt} + \lambda_4\right)\int e d\tau \\ &= \overset{(3)}{e} + b_1\ddot{e} + b_2\dot{e} + b_3 e + b_4\int e dt \\ &= \hat{f}(\mathbf{y}) + g(\mathbf{y})u + \Delta f(\mathbf{y}) - \overset{(3)}{y}_d + b_1\ddot{e} + b_2\dot{e} + b_3 e + b_4\int e dt \end{aligned} \tag{28}$$

where, $b_1 = \lambda_1 + \lambda_2 + \lambda_3 + \lambda_4$, $b_2 = \lambda_1\lambda_2 + \lambda_2\lambda_3 + \lambda_3\lambda_4 + \lambda_1\lambda_4 + \lambda_1\lambda_3 + \lambda_2\lambda_4$, $b_3 = \lambda_1\lambda_2\lambda_4 + \lambda_2\lambda_3\lambda_4 + \lambda_1\lambda_3\lambda_4 + \lambda_1\lambda_2\lambda_3$, $b_4 = \lambda_1\lambda_2\lambda_3\lambda_4$,

The feedback control u was designed as

$$u = G(\hat{u} + \hat{v}_f) \tag{29}$$

where, $\hat{u} = -\hat{f}(\mathbf{y}) - \hat{w}$, $\hat{v}_f = -K \cdot fuzzy\left(\frac{s}{\Phi(|e|)}\right)$. In this paper, we change the conventional sliding mode controller's saturation function $v = -Ksat(\frac{s}{\Phi})$ replaced by $\hat{v}_f = -K \cdot fuzzy\left(\frac{s}{\Phi(|e|)}\right)$. Fig. 4 shows the conventional linear saturation function, if it is replaced by the fuzzy function as shown in Fig. 5, it will improve the precision control performance. For the input output membership function are all design by the triangle function as shown as Fig. 6 and Fig. 7. The fuzzy rules of the input output function are proportional relationship as following:

input={NVB, NB, NM, NS, ZE, PS, PM, PB, PVB}

output={NVB, NB, NM, NS, ZE, PS, PM, PB, PVB}

where NVB= Negative Very Big, NB = Negative Big, NM = Negative Medium, NS = Negative Small, ZE = Approximately Zero, PS = Positive Small, PM = Positive Medium, PB = Positive Big, PVB= Positive Very Big.

We choose

$$K \ge \beta(\eta + M) + (\beta - 1)\left|\hat{f} + \hat{w}\right| \tag{30}$$

where, $\eta > 0$, satisfying the inequality:

$$s\dot{s} \le -\lambda_4 s^2 - \eta|s| \tag{31}$$

IV. Image Pattern Recognized System and Pneumatic Servo Platform Constructed

The image pattern recognized system and pneumatic servo platform structure shows as Fig. 8. In the pneumatic platform system above has built a CCD video camera to recognize the objects pattern. The pneumatic servo platform moving control is following the captured image pattern shape center point coordinates by CCD camera with IEEE 1394E transmission line and PCI-8252 interface card to PC. The digital image

signal can be calculated the object pattern center point coordinates by LabVIEW software design program. Then, passing the calculated objects pattern center point coordinates which can be looked as a position command of the pneumatic cylinder to the fuzzy sliding mode controller which design by Matlab Simulink program, and through the NI-6024E AD/DA card with servo valve to drive the cylinder to control the pneumatic cylinder moving position. All of the X-Y axis cylinder position feedback signals are adopted by linear scale resistance. In the end point of the X-Y axis cylinder, there have a vertical Z-axis can be moved up and down, and the end point of vertical Z-axis have sucking disc vacuum device which can be accomplished the objects loading and unloading. So, the picked and placed precision control of the objects for a pneumatic X-Y servo platform by integrating image pattern recognized and fuzzy sliding mode controller design can be achieved. For the image pattern recognized scheme process can be shown in Fig. 9. First, the object pattern image will be captured by CCD video camera. Second, mask the image with threshold method and filter the noise image, then detect the pattern edges of the image. Third, using geometric template matching method recognized the picking object. And, the last step is calculating and sending out the object shape center point coordinate by gravity method.

V. Experimental Results and Discussion

The following parameters of sliding mode controller in practical test as:

$$a_1 = 0.5, a_2 = 50, a_3 = 0.5, b_1 = 0.008, b_2 = 0.11, b_3 = 1.5, \beta = 1.8,$$
$$\eta = 0.05, M = 0, \Phi_1 = 10, \Phi_2 = 0.1, \varepsilon_1 = 0.1, \varepsilon_2 = 0.05, G = 2$$

This paper, using Matlab/Simulink software design the variable boundary layer of fuzzy sliding mode controller, and adopt the LabVIEW software with vision and motion builder to recognize the object pattern image and calculate the object pattern center point coordinate from CCD video camera. Thus the precision control of the picked and placed of the objects for the pneumatic servo platform system can be achieved. In the experimental test, there are four different shape objects, which have triangle, circle, squire, and trapezoid in the pneumatic servo platform shown as in Fig. 10-(1), we can accurately pick the squire shape object and precisely place to the circle object location. The detail process is shown in Fig. 10-(2) to Fig. 10-(5). In Fig. 10-(6) to Fig. 10-(11) shows the trapezoid shape object has been precisely picked and accurately placed it to the triangle shape object location. All of these picked and placed actions are driven by the X-Y axis pneumatic cylinder servo platform and CCD video camera. Fig. 11 shows the X axis pneumatic cylinder position control response, and the tracking error response is shown in Fig. 12. Identically, the Y axis pneumatic cylinder position control response and tracking error response are shown in Fig. 13 and Fig. 14. From the X axis and Y axis tracking error results show that the tracking errors are approximately smaller than ±0.5mm.

VI. Conclusions

In this paper, we propose a variable boundary layer of fuzzy sliding mode controller scheme for the pneumatic cylinder X-Y axis servo platform system to realize precision position control. And apply CCD video camera to capture the object pattern image and recognize its center point coordinate position technique to provide the picked and placed of the objects performance.

***Abstract*—In this study, the digital image processing method in the dynamic measurement system for Stewart platform is investigated. The measured signals of the platform based on the digital image processing method represent as the feedback signal of control system. In the study, the accuracy of control system is reasonable by capturing the image information of platform by using the digital image processing method and getting the detail of platform action directly.**

Keywords-digital image process; Stewart Platform; sensor

I. INTRODUCTION

In recent years, the parallel link manipulators, namely, Stewart platform, have attracted much attention and many studies have been done on the dynamic analysis and/or controller design of the parallel link manipulators. The Stewart platform is a mechanical device with six extensible legs mounted on a level surface in three pairs, crossing over to three mounting points on a top plate. Devices placed on the top plate can be moved in the six degrees of freedom (6 DOF) in which it is possible for a freely-suspended body to move. These are the three linear movements x, y, z (lateral, longitudinal and vertical), and the three rotations pitch, roll, & yaw [1]. Because of its unique capability, the platforms have been employed in many control engineering applications such as simulator shakers, robotic manipulators, etc. [2, 3, 4]

Traditionally, the displacement sensor, namely, linear voltage differential transmitter (LVDT), is used to determine the length of the six extensible legs. The gyro compass are also widely been used to evaluate the dynamic of Stewart platform. In recent year, the Force/torque (F/T) sensors have widely been used in measuring inertia force of Stewart platform [5], monitoring forces of variable directions and intensity [6] and as a component of force feedback controller [7, 8]. In a sensor application, the friction, backlash and other nonlinearities at the passive spherical joints of the Stewart platform will affect the measurements in unpredictable ways.

Digital image processing is the use of computer algorithms to perform image processing on digital images. As a subcategory or field of digital signal processing, digital image processing has many advantages over analog image processing. It allows a much wider range of algorithms to be applied to the input data and can avoid problems such as the build-up of noise and signal distortion during processing.

Many of the techniques of digital image processing, or digital picture processing as it often was called, were developed in the 1960s at the Jet Propulsion Laboratory, Massachusetts Institute of Technology, Bell Laboratories, University of Maryland, and a few other research facilities, with application to satellite imagery, wire-photo standards conversion, medical imaging, videophone, character recognition, and photograph enhancement. The cost of processing was fairly high, however, with the computing equipment of that era. That changed in the 1970s, when digital image processing proliferated as cheaper computers and dedicated hardware became available. Images then could be processed in real time, for some dedicated problems such as television standards conversion. As general-purpose computers became faster, they started to take over the role of dedicated hardware for all but the most specialized and computer-intensive operations.

With the fast computers and signal processors available in the 2000s, digital image processing has become the most common form of image processing and generally, is used because it is not only the most versatile method, but also the cheapest. In this research, the digital camera is used to replace the traditional sensor due to its Advantages by using the image processing method to determine the motion of the platform dynamic.

The remainder of this article is organized as follows: The basic methodologies of the digital image processing which used in this research are discussed in Section 2. In Section 3 shows some experimental results on a realistic Stewart platform by using proposed method. Finally, some conclusions are made in Section 4.

II. MAIN METHODOLOGIES

The charge-coupled device (CCD) is a device for the movement of electrical charge, usually from within the device to an area where the charge can be manipulated, for example conversion into a digital value. Often the device is integrated with an image sensor, such as a photoelectric device to produce

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

the charge that is being read, thus making the CCD a major technology for digital imaging. Although CCDs are not the only technology to allow for light detection, CCDs are widely used in professional, medical, and scientific applications where high-quality image data are required.

The RGB format images capture from the Stewart platform by CCDs are transfer into YUV format. The YUV is a color space typically used as part of a color image pipeline. It encodes a color image or video taking human perception into account, allowing reduced bandwidth for chrominance components, thereby typically enabling transmission errors or compression artifacts to be more efficiently masked by the human perception than using a "direct" RGB-representation. In this research, the algorithms of RGB formatted image transfer into YUV formatted image as follows:

Define

$$R, G, B, Y \in [0, 1].$$

$$U \in [-0.436, 0.436].$$

and

$$V \in [-0.615, 0.615]$$

$$\begin{bmatrix} Y \\ U \\ V \end{bmatrix} = \begin{bmatrix} 0.299 & 0.587 & 0.114 \\ -0.147 & -0.289 & 0.436 \\ 0.615 & -0.515 & -0.100 \end{bmatrix} \begin{bmatrix} R \\ G \\ B \end{bmatrix} \quad (1)$$

The YUV model defines a color space in terms of one luminance (Y) and two chrominance (UV) components. The platform dynamic is determined by the luminance component as the marker position with cyber action system. The coordinate of the platform is shown in Fig 1.

The 6 DOF of the platform are calculated as follows:

Step 1. Find the center O_0 of the platform and calculate the displacement of X, Y, and Z axis.

$$O_0 = \left(\frac{x_2 + x_3}{2}, \frac{y_2 + y_3}{2}, \frac{z_2 + z_3}{2} \right) = (x_i, y_i, z_i) \quad (2)$$

where

$$x_i = \frac{x_2 + x_3}{2},\ y_i = \frac{y_2 + y_3}{2}, \text{ and } z_i = \frac{z_2 + z_3}{2} \quad (3)$$

Step 2. Find the center O_1 of the marker position A to B and the center O_2 of the marker position A to C. Calculate the angles of α, β, and γ, respectively.

$$O_1 = (x_j, y_j, z_j) = \left(\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2}, \frac{z_1 + z_2}{2} \right), \quad (4)$$

$$O_2 = (x_k, y_k, z_k) = \left(\frac{x_1 + x_3}{2}, \frac{y_1 + y_3}{2}, \frac{z_1 + z_3}{2} \right). \quad (5)$$

Such that

$$\gamma = \tan^{-1}\left(\frac{z_i - z_j}{y_i - y_j} \right) = \tan^{-1}\left(\frac{z_3 - z_1}{y_3 - y_1} \right) \quad (6a)$$

$$\beta = \tan^{-1}\left(\frac{z_i - z_k}{x_i - x_k} \right) = \tan^{-1}\left(\frac{z_2 - z_1}{x_2 - x_1} \right) \quad (6b)$$

$$\alpha = \tan^{-1}\left(\frac{x_i - x_j}{y_i - y_j} \right) = \tan^{-1}\left(\frac{x_3 - x_1}{y_3 - y_1} \right) \quad (6c)$$

The marker positions are captured by using three CCDs from fixed X, Y, and Z axis.

III. Experimental Results

The equipment used in the experiment consists of three CCDs form Logic Inc., Taiwan, Borland C++ builder 6, and the software of Microsoft DirectX9.0 SDK, namely GraphEdit. The frame size is 352×288 with 30 frames per second in YUV420 formatted. The pictures captures from three CCDs are synchronizing by GraphEdit and then find the marker positions. The graphical user interface (GUI) is shown as Fig 2.

In Fig 2, the three frame of Stewart platform shown below in the graphical user interface are x axis, y axis, and z axis, respectively. The three white points in the edge of the Stewart platform are marker positions. Those RGB based frames are transfer into YUV formatted by using equation (1) and then the motion of the platform are calculate by using equations (2)-(6). The real time output is shown as Fig 3. In the Fig3, the input signals of the x, y, and z axis are sine wave, respectively. The image processing output signals of the platform and the input commands are almost identical

The non-cyclical movement of the ship will be used as input signal. The sea trial data of the rolling angle from a small yacht and the Stewart platform output are shown as Fig 4 and Fig 5, respectively. The pitching angle of the same yacht and the Stewart platform output are shown as Fig 6 and Fig 7,

respectively. The image processing output signals of the platform and the input commands are almost identical.

IV. CONCLUSION

In this paper, the dynamic measurement system of Stewart platform based on image processing method has been proposed. The traditional sensor of the platform has been replaced by the proposed method and significantly improves the system performance. Based on the experiment results shown as above, the proposed image processing method has the potential to become one of the candidates of the Stewart platform sensor.

The advantage of the proposed method is more cheaply than traditional sensor, i.e., gyro. However, the image processing based sensor could not properly measure the torque on the platform. The disadvantage just mention restricts the possibility which be apply to the platform control system.

Orientation Control of Hovercraft Systems via an SMFLC and Image-Guided Techniques

Chun-Chieh, Wang
Department of Electronic Engineering
Chienkuo Technology University
Changhua City, Taiwan, R.O.C.
jasonccw@ctu.edu.tw

***Abstract*—This paper is concerned with the control of a hovercraft vessel using a sliding mode fuzzy logic control and image-guided techniques. Firstly, we introduce the R/C hovercraft type vessel dynamics. Secondly, the sliding mode fuzzy logic control (SMFLC) is proposed in this paper. A significant feature is that the transient response during the reaching phase has been remarkably improved by the proposed control. Finally, an image-guided technique is presented. To illustrate the effectiveness of the proposed method, we choose the R/C hovercraft vessel as the experimental system. Simulation results showed good responses via the proposed techniques.**

Keywords-R/C hovercraft vessel, Sliding mode fuzzy logic control, Orientation control, Image-guided technique

I. INTRODUCTION

There was extensive research on nonlinear control in connection with the design of autopilots for high-performance aircraft in the early 1950s. In the last few years, the regulation of a ship vessel, by means of two independent thrusters located at the aft, has received sustained attention [1][2][3][4][5]. Nevertheless, position control of an underactuated vehicle is a difficult problem in general. Especially, if the friction is not existent in the environment, an underactuated vehicle often drifts in the direction without actuation. To cite an instance, it is difficult to control positions of such vehicles as a satellite, a hovercraft, and an airship unless sufficient numbers of thruster or torquer are available. Since a large motion leads to inherent nonlinear dynamics, a nonlinear control method is necessary for their position control.

Variable structure control was initiated in Russia by many researchers, like Barbashin [6], Utkin [7], Emelyanov [8]. The control scheme has successfully been applied to many engineering problems including automatic flight control, chemical processes, helicopter stability augmentation systems, electric motors, robots, etc. Variable structure control law is deliberately changed according to some defined rules which depend on the state of the system. The scheme has been mainly considered for continuous-time systems in the form of sliding mode control.

Sliding mode control is known to be very robust against parameter variations and external disturbances and has been widely accepted as an efficient method for tracking control of uncertain nonlinear systems. It has been shown to be able to achieve 'perfect' performance in principle in the presence of parameter uncertainties, bounded external disturbance, etc [9]. However, in order to account for the presence of parameter uncertainties and bounded disturbances, a discontinuous switching function is inevitably incorporated into the control law to achieve so-called sliding condition [10]. Due to imperfect switching in practice it will raise the issue of chattering, which is usually undesirable. To suppress chattering, a continuous approximation of the discontinuous sliding control is usually employed in the literature. Though, the chattering can be made negligible if the width of the boundary layer is chosen large enough, the guaranteed tracking precision will deteriorate if the available control bandwidth is limited. To reach a better compromise between small chattering and good tracking precision in the presence of parameter uncertainties, various compensation strategies have been proposed. For example, integral sliding control [11], [12], [13], sliding control with time-varying boundary layers [5] etc., were presented. Alternatively, applying so-called reaching law approach, Gao et al. [14] proposed sliding controllers such that the trajectories are forced to approach the sliding surface faster when they are far away from the sliding surface. This approach seems to be an efficient method capable of increasing the approaching speed to the sliding surface. However, the behavior of the system dynamics, governed by the transformed first-order equation, can only be predicted through the measurement of the generalized error. Hence the transient response during the reaching phase may not be remarkably improved.

In this work, it is concerned with the control of a hovercraft vessel using an SMFLC and image-guided techniques. The effectiveness of the newly developed control scheme will be demonstrated through the control of the R/C hovercraft vessel. The simulation results validate the superiority and practicality of the proposed method for the orientation control of hovercraft systems.

II. HOVERCRAFT TYPE VESSEL DYNAMICS

We employ an R/C hovercraft (356 mm×212 mm×142 mm) shown in Fig. 1 on a planar ground as the system to be controlled. This model is based on that used in the recent work

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

of Tanaka *et al.* [4]. Fig. 2 shows the hovercraft type vehicle (HTV) model and its coordinate system, where

α : angle of the vehicle
d : distance between the gravity and fans
β : angle between the gravity and fans
m : mass of the vehicle
I : inertia of the vehicle
u_R : force of right side fan
u_L : force of left side fan

Then the HTV dynamics are represented as

$$\begin{aligned} \ddot{x} &= \frac{\cos\alpha}{m} u_1 \\ \ddot{y} &= \frac{\sin\alpha}{m} u_1 \\ \ddot{\alpha} &= \frac{d\sin\beta}{I} u_2 \end{aligned} \tag{1}$$

where $u_1 = u_R + u_L$ and $u_2 = u_R - u_L$. [14]

In this simulation, $\beta = \pi/4$, $m = 0.1$, $I = 0.5$ and $d = 0.1$. Since the control purpose is $\lim_{t\to\infty} y = 0$ and $\lim_{t\to\infty} \alpha = 0$, that is, x is not a controlled variable, the controlled object is described as

$$\begin{aligned} \ddot{y} &= \frac{\sin\alpha}{m} u_1 \\ \ddot{\alpha} &= \frac{d\sin\beta}{I} u_2 \end{aligned} \tag{2}$$

III. FUZZY VARIABLE STRUCTURE CONTROL

Consider a simple n^{th} -order SISO nonlinear system

$$y^{(n)} = f(t, y, ..., y^{(n-1)}) + g(t, y, ..., y^{(n-1)})u \tag{3}$$

Assume that $f = \hat{f} + \Delta f$, where $\hat{f}$ is the known part and Δf is the uncertain part, which includes the internal noise bounded in in $|\Delta f| \le F$. The object is to find a sliding control u such that the output y of (3) will approximately track a desired signal, y_d which is assumed to be n^{th} -order continuously differentiable and all of its derivatives are uniformly bounded. Given the tracking error

$$e(t) = y(t) - y_d(t) \tag{4}$$

Figure 1. Hovercraft type vehicle

For any $q > 0$, define the following transformation

$$s(t) = \left(\frac{d}{dt} + q\right)^{n-1} e(t) \tag{5}$$

Then

$$\dot{s} = \hat{f} + \hat{w} + u \tag{6}$$

where

$$\hat{w} = \sum_{k=1}^{n-1} \binom{n-1}{k-1} e^{(k)} \lambda^{n-k} - y_d^{(n)} \tag{7}$$

An n^{th} -order tracking problem can be transformed into an equivalent 1st-order stabilization problem. It is easy to show that the control law

$$u = \frac{1}{g}\left(\hat{u} + u_f\right) \tag{8}$$

with

$$\begin{cases} \hat{u} = -\hat{f} - \hat{w} \\ u_f = -\Gamma_f sat\left(\dfrac{s}{\Phi}\right) \end{cases} \tag{9}$$

will result in a closed-loop system satisfying the reaching condition:

$$s\dot{s} \le -\eta|s|, \forall |s| \ge \Phi , \tag{10}$$

Provided $\Gamma_f \ge F + \eta$, for some $\eta > 0$. u_f is the output of the FLC. Each fuzzy rule of a FSMC can be expressed as

$$\text{Rule}^i : \text{if } s = LS^i, \text{then } u_f = LU^i.$$

where LS^i is a linguistic value of s in the i-th fuzzy rule.

This controller ensures that starting from any initial state the error trajectory will reach the boundary layer, $|s| \le \Phi$ in finite time.

IV. IMAGE-GUIDED TECHNIQUE [15]

To obtain the relative locations of the landmark and the hovercraft, an image-guided search algorithm is used to find the center of the landmark and the moving vector. These procedures for image processing are shown in Fig. 3.

A. Image Preprocessing

The image preprocessing includes binarization and filtering with the aim of distinguishing the object from the background. To reduce the amount of data, the three-dimensional RGB-image information is transformed into a one-dimensional colour axis. Unfortunately, the regulation of the threshold value usually produces noise.

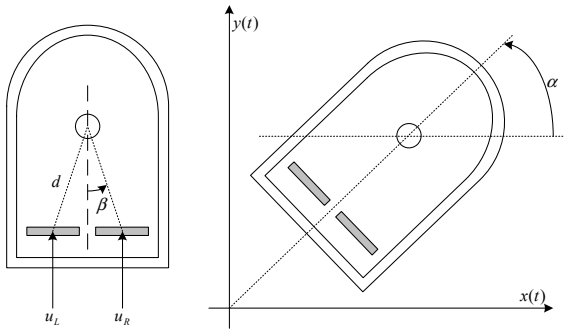

Figure 2. The HTV model and its coordinate system

To improve the image quality, the median and area filters will be used to reduce this noise.

B. Moving-Target Detection

1) Sobel filter

To detect the edge of a binarized picture, a Sobel filter is the most common tool and is very useful. The following two matrices are used as the filter operators:

$$G_x = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix} \tag{11}$$

$$G_y = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & 1 \end{bmatrix}, \tag{12}$$

where G_x and G_y are used for edge detection in the x-direction and the y-direction, respectively. These two 3×3 convolution masks are applied to each pixel. The result of each convolution is treated as a vector representing the edge through the current pixel. If the magnitude of the sum of these two orthogonal vectors is greater than any user-specified threshold, the pixel is marked in black as an edge. Otherwise, the pixel is set to white.

2) Moving-edge detection

To extract the background automatically, a large enough number of successive structures must be available for processing. The procedures for moving-edge detection are shown in Fig. 4. First, three successive structures (I_t , I_{t+1} , I_{t+2})will be taken from CCD, and then the differences $D[I_{t+2} - I_{t+1}]$ and $D[I_{t+1} - I_t]$ can be calculated. The Logical AND operation can be used to evaluate the difference product. Hence, the moving vector of I_{t+1} can be obtained.

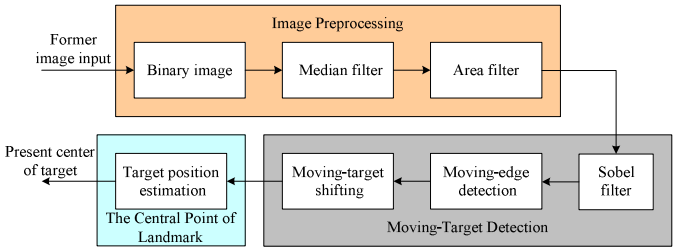

Figure 3. Procedures for image processing

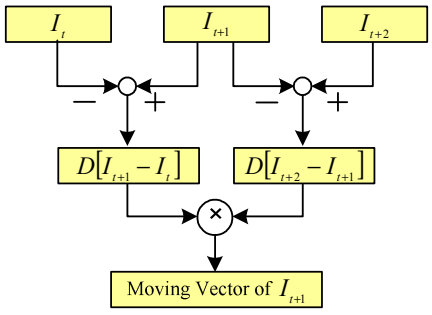

Figure 4. Moving-edge detection

3) Moving-target shifting

As shown in Fig. 5, to overcome image-delay, the moving-target shifting method will be used to get the new landmark *M2*. By comparing $D[I_{t+2} - I_{t+1}]$ with *M1*, the shift values X_d and Z_d can be estimated as follows.

$$\begin{cases} X_d = (C1 - C2) + (A1 - A2) \\ Z_d = (B1 - B2) + (D1 - D2) \end{cases} \tag{13}$$

C. The Central Point of Landmark

In this article, 0 and 1 gray-level images are regarded as the background and the landmark, respectively. If the maximum and minimum values of projection are found on the x-axis and z-axis, respectively, then the center point can be obtained (see Fig. 6).

V. Simulation Results

According to the notations given above, we take $\hat{f}_y = 0$, $\hat{w}_y = \lambda_y \dot{e}_y - \ddot{y}_d$, $\hat{f}_a = 0$, and $\hat{w}_a = \lambda_a \dot{e}_a - \ddot{\alpha}_d$. Initial values are chosen as $(x_0, y_0, \alpha_0) = (1,1,-1.5)$. By setting the parameters as $\Phi_y = 1$, $\lambda_y = 7$, $\Phi_a = 15$, and $\lambda_a = 25$.

The input and output membership functions are shown in Figs. 7 and 8, respectively. The simulation results of [4] are shown in Fig. 9. Figs. 10 and 11 indicate the time responses of the y-axis track and the angle of the vehicle under the proposed control scheme, respectively.

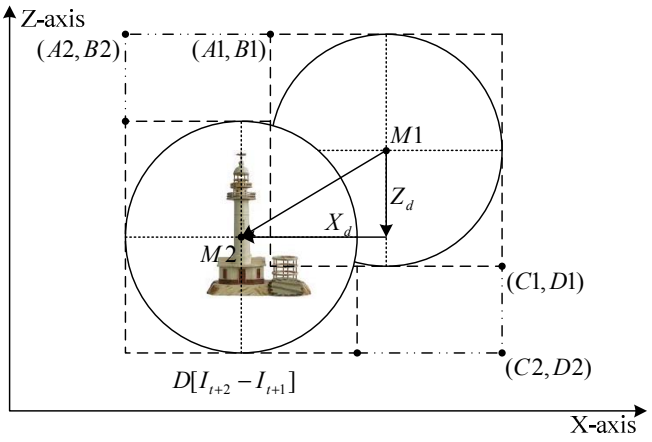

Figure 5. Moving-target shifting

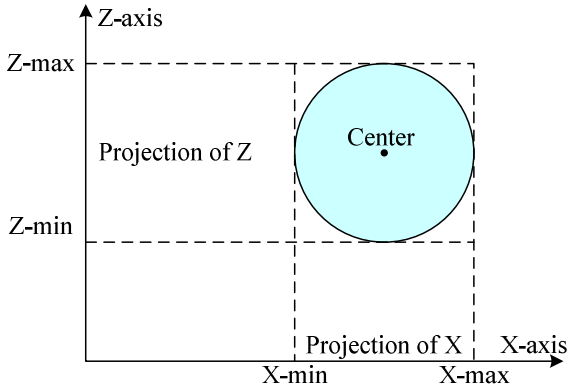

Figure 6. Central point of the landmark

The corresponding control action is shown in Fig. 12 (solid line: force of right side fan; dotted line: force of left side fan). The trajectories are evidently better than those of [3].

VI. CONCLUSION

We have presented an SMFLC scheme and image-guided techniques in this article for a hovercraft vessel. The proposed control scheme has shown to be capable of improving the transient response as well as the steady state response. To illustrate the effectiveness of the proposed method, we choose the R/C hovercraft vessel as the experimental system. The simulation results validate the superiority and practicality of the proposed method for the orientation control of hovercraft systems.

***Abstract*—This study focuses on Gaussian blur estimation for blind image deconvolution (BID) problem. In BID problem, it only uses blurred image and less information of point spread function (PSF) to restore the received the blurred image. Due to restore the received image, the first step is to identify the proper PSF model. The received image does not uniquely define the PSF. Nevertheless these are many applications where the received image have been blurred either by an unknown or a partially know PSF. Therefore, this paper choose Gaussian blur image for further research, which utilized the particle swarm optimization algorithm to search for the unknown PSF. The objective function for searching the parameters of PSF is based on edge detection and image morphology. It can identify the parameters of PSF exactly. Finally, the feasibility and validity of proposed algorithm are demonstrated by several simulations.**

Keywords-Gaussian Blur, Blind Image Deconvolution, Point Sparead Function, Particle Swarm Optimization, Wiener filter, Edge Detector

I. INTRODUCTION

The objective of image restoration is to reconstruct the original scene from a degraded observation which is commonly blurred by a point spread function (PSF). However, the PSF is usually unavailable a prior in many applications, the recovery process becomes a blind image deconvolution (BID) problem. It has also taken a lot attention in many different technical areas, for example photography, medical imaging, astronomical imaging, and so forth.

Referring to the classification [1], BID approaches could be classified into two chief categories according to the stage of blur identifying:

1) A priori blur identification methods: With this approach, the PSF is identified separately from the original image, and later used in combination with one of the classical image restoration algorithms in order to restore the original image. Generally, a parametric blur model may be used.

2) Joint identification methods: With this approach, most of they use an alternating approach to estimate original image and the PSF rather than truly finding the joint solution.

Initially, D. Kundur and D. Hatzinakos proposed the restoration procedure involves recursive filtering of the blurred image to minimize a convex cost function blindly. The feasibility has been confirmed when it is applied on a scene consists of a finite support object against a uniformly black, grey, or white background [2], [3]. After that, different advanced conditions for BID and shortcomings in conventional methods have been addressed and improved respectively. For instance, since the requirement of a hard-decision on whether the blur satisfies a parametric form before their formulations in these algorithms, the precondition inhibits the incorporation of parametric blur knowledge domain into the restoration schemes [4]. The recursive soft-decision approach is therefore proposed by K.H. Yap and el al. Further, they proposed a computational reinforced learning scheme to overcome the drawbacks of conventional methods, for instance, inter-domain dependency and falling into a local solution [5]. C. Vural and el al. thought that conventional methods require either a special parametric PSF form or complex computation; hence, they proposed a non-linear adaptive filtering to minimum dispersion of image. Because this method does not impose constraints on the phase of the blur, its implementation is easy for real applications [6].

Recently, aiming at seek a higher quality of restoration; several evolutionary techniques have been introduced, for example genetic algorithm [7] and evolutionary algorithm [8]. The feasibility and benefits are verified by simulation results in [7], [8]. Most of these algorithms belong to a priori blur identification method because the parameters of blur model are suitably committed to the evolutionary learning. In the preliminary studies, we have utilized particle swarm optimization (PSO) to tackle different issues about BID problem [14], [15]. In [16], we have observed that the edge of a blurred image is thicker than that of an original image. Therefore, following this observation, the edge of a restoration with implied a well estimation for unknown PSF will be presented using PSO in this study. Each particle of PSO presents a probable PSF and evolutes according to the objective function which designed based on edge detection of its restoration.

This paper is organized as follows: Section II introduces the fundamental of blind image deconvolution. Section III is the description of the proposed method. PSO and edge detector used in this work describes first. And then presents

This work was partly supported by Grant NSC 99-2221-E-259-002-MY3, National Science Council, Taiwan, R.O.C.

the objective function and how PSO is used to seek the parameters of PSF. Section IV presents the simulation and results. The conclusion and future works are described in Section V.

II. BLIND IMAGE DECONVOLUTION

The BID problem is an advanced image restoration problem because the received image does not uniquely define the convolved signals. Nevertheless these are many applications where the received images have been blurred either by an unknown or a partially known PSF. Generally speaking, BID must consider three key issues: blur model, PSF estimation, and image restoration. In this section, a brief explanation about blur model and image restoration used in this work is given as following.

A. Blur Model

In many image applications, blurring procedure is modeled by a two-dimensional (2D) linear convolution as following [1]:

$$g(x,y) = f(x,y) * h(x,y) \tag{1}$$

where $g(x, y)$, $f(x, y)$, $h(x, y)$ denote the observed blurred image, original image, and point spread function (PSF), respectively. In (1), $f(x, y)$ and $h(x, y)$ are unavailable information in advance. Therefore, restore the origin image $f(x, y)$ requires the deconvolution of the degraded image $g(x, y)$ from the $h(x, y)$.

The general model of degradation function for Gaussian blurred images is presented as following [9]:

$$h(m,n) = K \exp\left\{-\frac{(m^2+n^2)}{2\sigma^2}\right\} \tag{2}$$

where m and n present the horizontal and vertical space of $h(\cdot)$. K is a normalization constant to ensure the summation of $h(\cdot)$ matrix is one. σ is the standard deviation for the magnitude distribution of $h(\cdot)$.

B. Wiener Filter

The Wiener filter is a image restoration technique for the deconvolution with a priori known PSF. The Wiener filter is usually applied in the frequency domain. Given a blurred image $g(x, y)$, one takes the Discrete Fourier Transform (DFT) to obtain $G(u, v)$. The original image spectrum is estimated by taking the product of $G(u, v)$ with the Wiener filter $W(u, v)$:

$$F(u,v) = G(u,v)W(u,v) \tag{3}$$

The inverse DFT is then used to obtain the original image from its spectrum. The Wiener filter can be stated as follow:

$$W(u,v) = \frac{H^*(u,v)}{|H(u,v)|^2 + \rho} \tag{4}$$

where H(u, v) denote Fourier transform of the PSF. Since the $W(u, v)$ have the possibility to produce the pulse while the $|H(u, v)|^2$ approaches zero. Hence, in (4) adopted ρ to prevent this situation. The ρ value supposes too slightly, is unable to improve the pulse situation effectively; the ρ value supposes too large, will cause $W(u, v)$ to be too small, and will cause the recover image effect variation. After many experiments of the simulation proved that the ρ value about 0.0005 may obtain a good recovered image.

III. PSF IDENTIFICATION

This section will first present the optimization tool for PSF. Next, the difference between an original image and a blurred image is analyzed by edge detection process respectively. The design of objective function is explained as follows. The final subsection presents the procedure of the proposed algorithm.

A. Particle Swarm Optimization

The PSO is a population-based optimization technique that was proposed by Eberhart and Kennedy [10] in 1995. PSO simulates the behavior of bird flocking. The population is referred to as a *swarm*. The particles examine fast convergence to local and/ or global optimal position(s) over a small number of generations. In PSO, each particle represents a potential solution to the optimization task. All particles can find possible solving repeatedly. Each particle moves to a new position according to the new velocity which includes its previous velocity, the past best solution and global best solution. Therefore, when a particle discovers a new probable solution, other particles will move to it for exploring the region with more depth in the process [11].

A swarm in PSO consists of a number of particles. Each particle represents a potential solution to the optimization task. All of the particles iteratively discover the probable solution. Each particle moves to a new position according to the new velocity which includes its previous velocity, and the moving vectors according to the past best solution and global best solution. The best solution is then kept; each particle accelerates in the directions of not only the local best solution but also the global best position. If a particle discovers a new probable solution, other particles will move closer to it in order to explore the region with more depth [11]. In general, there are three attributes, the particles' current position p_i, current velocity v_i and local best position Pb_i, for particles in the search space to present their features. Each particle in the swarm is iteratively updated according to the aforementioned attributes. Assuming that the cost function J is to be minimized so that the particles contain N dimensions, the new velocity of every particle is updated by

$$\begin{aligned} v_i(t+1) = wv_i(t) &+ c_1 \times r_1\left[Pbest_i(t) - p_i(t)\right] \\ &+ c_2 \times r_2\left[Gbest(t) - p_i(t)\right] \end{aligned} \tag{5}$$

For all $i \in 1, \cdots, N$, v_i is the velocity of the i th particle, the w, c_1 and c_2 denote the acceleration coefficients, r_1 and r_2 are elements from two uniform random sequences in the range (0, 1), and t is the number of generations. The new position of a particle is calculated as follow:

$$p_i(t+1) = p_i(t) + v_i(t+1) \tag{6}$$

The past best position of each particle is updated by:

$$Pb_i(t+1)=\begin{cases} P_i(t+1) & \text{,if } f(Pb_i(t))>f(p_i(t+1)) \\ Pb_i(t) & \text{,otherwise} \end{cases} \quad (7)$$

and the best position *Gb* found from all particles in its search dimension during the previous three steps is defined as:

$$Gb(t+1)=\arg\min_{Pb_i} f(Pb_i(t+1)) \quad (8)$$

B. Edge Detector

The edge detector [12] employed in this paper is based on a set of filters obtained from a basis filter d_0 and through successive rotations depicted as Fig. 1. The other filters were obtained by rotating basis filter with bicubic interpolation and by angles multiple of 45^o. Designating by d_θ the filters of the set presented as

$$g_\theta(x)=d_\theta * x \quad (9)$$

The output of the edge detector is given by a combination of those filters' outputs through an L_2 norm

$$f(x)=\sqrt{\sum_{\theta\in\Theta} g_\theta(x)^2} \quad (10)$$

where Θ denote the set of filter orientations under consideration.

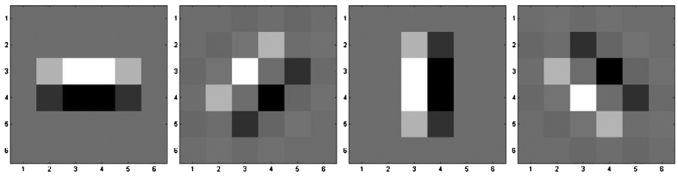

Figure 1. Set of edge detection filters, in the four orientations that were used. The leftmost filter is the basis filter d_0

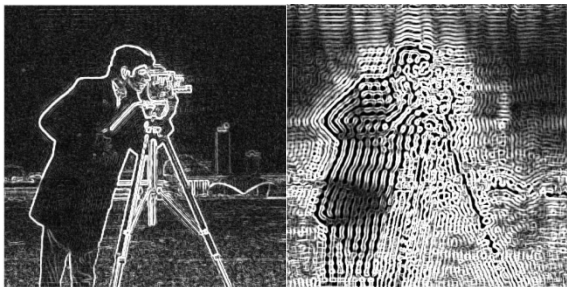
As an example of the detector's operation, Fig. 2 shows the edges that were extracted from the "Cameraman" image by the proposed edge detector.

Figure 2. Edges of "Cameraman" by the proposed edge detector

C. Object Function

In this study, the proposed objective function is based on the results of edge detection for blurred image and recover image respectively. Many observations of image after edge operation are shown as Fig. 3. The observed blurred image presents thick curve of edge as Fig. 3 (a). However, the edge of correct restored image shown as Fig. 3 (b) presents thin curve and the mean brightness of image is bright. Fig. 3 (c) shows the edge of an over-recovered image. Although the edge mean brightness is also bright, it exhibits the existence of the unnecessary ringing phenomenon. Therefore, based on the comparison of difference information of image edge curve, a suitable objective function could be possible defined to distinguish different situations of image.

(a)



(b) (c)

Figure 3. The edge detector of Cameraman image (a) The edge of blurred image (b) The edge of correct restored image (c) The edge of over-recovered image

The main profile of a blurred image could be obtained following below:

$$\hat{g}=f(g)-\frac{1}{n}\sum f(g) \quad (11)$$

where g is blurred image; $f(g)$ is the blurred image after edge detection via (10); n is the total amount of image pixels. The obtained $\hat{g}$ will convert to binary image and its opposition processing. And then, we can obtain the *essential* edge and *non-essential* edge of blurred image as shown in Fig. 4(a) and (b) respectively. With the concept of morphology, the erosion followed by dilation tends to smooth an image, to break narrow joins, and to remove thin protrusions, as shown in Fig.4(c) (d). The value of the blurred image through edge detection filled the *essential* edge and *non-essential* edge as below:

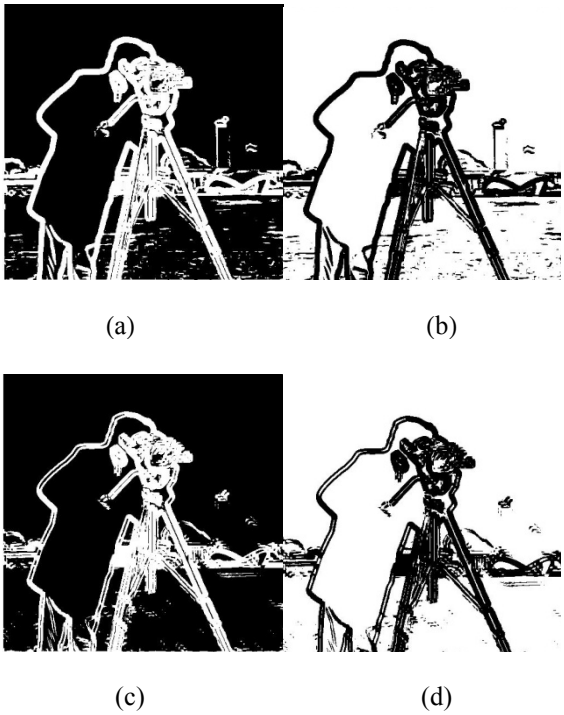
$$\begin{cases} ged = f(g)\times ed \\ gned = f(g)\times ned \end{cases} \quad (12)$$

where *ed* is *essential* edge of blurred image; *ned* is *non-essential* edge of blurred image.

For each stage of the restored image through edge detection, also made the same blurred image with the *essential* edge and *non-essential* edge part information as below:

$$\begin{cases} xed_i = f(x_i)\times ed \\ xned_i = f(x_i)\times ned \end{cases} \quad (13)$$

where $f(x_i)$ denote the edge detection of the i^{th} estimation image.



(a) (b)

(c) (d)

Figure 4. (a) The white place is the essential edge (b) The white place is the non-essential edge. The erosion followed by a dilation of (c) essential edge (d) non essential edge

The relationship between the blurred image and the i^{th} estimation image can be obtained as below:

$$\begin{cases} ered_i = xed_i - ged \\ erned_i = xned_i - gned \end{cases} \quad (14)$$

Then, (*ERed & ERned*) refers to only take information of the edge (*ered & erned*), as follows:

$$\begin{aligned} E\mathrm{Re}d &= \{ered \mid ered \neq 0\} \\ ERned &= \{erned \mid erned \neq 0\} \end{aligned} \quad (15)$$

Through the concept of entropy [13], [14] to calculate the diversity of the edge as following:

$$\begin{cases} Hed = -\sum_{i=1}^{m} P(E\mathrm{Re}d_i)\log P(E\mathrm{Re}d_i) \\ Hned = -\sum_{i=1}^{m} P(ERned_i)\log P(ERned_i) \end{cases} \quad (16)$$

where $P(ERed_i)$ and $P(ERned_i)$ are the distribution probability of the $ERed_i$ and $ERned_i$ respectively. Therefore, the objective function is set as (17), the large objective value shows that the restored image is more clear.

$$J = Hed - Hned \quad (17)$$

D. Framework of the Proposed Algorithm

The framework of the proposed algorithm is shown as Fig. 5, and each step is explained as follows:

a) Receive a blurred image *g* which is convoluted by (1).

b) Initial the particles of PSO randomly.

c) Applying Wiener filter on each particle to restore estimated images by (3) and (4).

d) The values of objective function are calculated on each estimated image.

e) Pb and Gb are selected by (7) and (8).

f) Particles move according to (5) and (6).

g) To check the size of PSF particles average velocity is less than the threshold value (this paper set the threshold value is one) or not. If it isn't done, then redo the step (c) to step (g). Otherwise, the learning is terminated.

Eventually, the optimal PSF could be obtained from final *Gb* which is able to generate the restored image with the best of objective function

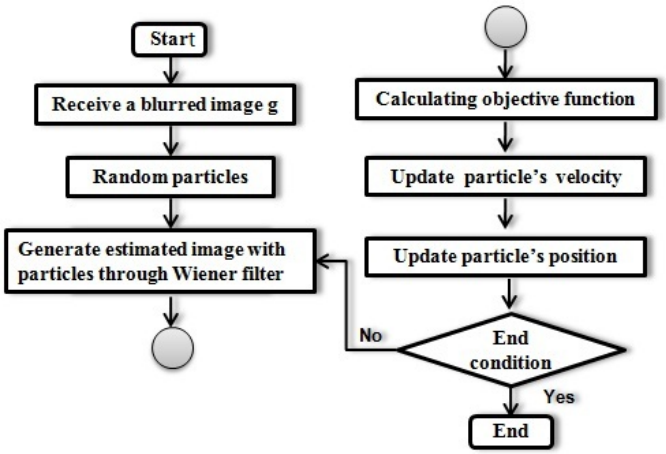


Figure 5. The flowchart of proposed algorithm

IV. EXPERIMENTAL RESULT

For the simulation design, two popular benchmarks, Lena and Cameraman, are the original images which are shown in Fig. 6 (a) and (b) respectively and with the size 512×512. The PSF size is the only knowledge a prior, besides a degraded image.

(a) (b)

Figure 6. The original image (a)Cameraman (b) Lena

The measurement of restoration quality commonly uses the Peak Signal-to-Noise Ratio (PSNR) of the image as below:

TABLE I. ESTIMATION PSF OF RESTORE LENA

Lena									
NO.	PSF of Gaussian blur		Identify of PSF for Gaussian blur				PSNR(db) of blurred image	PSNR(db) of estimation image	
	Size	σ	Size		σ			Avg.	Std.
			Avg.	Std.	Avg.	Std.			
1	5	3	5.3333	1.8257	4.4773	1.4472	77.4935	82.1522	3.3066
2	7	3.5	7.0667	0.2537	4.7291	1.4152	75.6562	80.1690	1.8435
3	9	4	9.9667	1.9384	4.6593	1.4007	74.4668	77.2082	2.9095

TABLE II. ESTIMATION PSF OF RESTORE CAMERAMAN

Cameraman									
NO.	PSF of Gaussian blur		Identify of PSF for Gaussian blur				PSNR(db) of blurred image	PSNR(db) of estimation image	
	Size	σ	Size		σ			Avg.	Std.
			Avg.	Std.	Avg.	Std.			
1	5	3	5.3333	1.8257	4.4346	1.3870	77.3059	83.0344	3.6688
2	7	3.5	7.0667	0.2537	4.5743	1.4676	74.6235	80.3489	2.5050
3	9	4	9.9333	1.7407	4.4366	1.3325	73.0687	76.8471	3.2187

$$PSNR = 10\log_{10}\frac{\sum_{i=1}^{M}\sum_{j=1}^{N}255^2}{\sum_{i=1}^{M}\sum_{j=1}^{N}(f(i,j)-\hat{f}(i,j))^2} \quad (18)$$

where f, $\hat{f}$, M and N denote the original image, restored image, image width and image length respectively. Here three simulations involve different PSF size (5×5, 7×7, and 9×9) and standard deviation (3, 3.5, and 4), the proposed algorithm are implemented for over 30 independent runs. The results are summarized in TABLE I and TABLE II. In each table, the "Avg." means the average PSNR value of estimated image of all runs; and the "Std." presents the standard deviation of PSNR of estimated image of all runs. When the result has smaller Std., it means the algorithm has robust and stability.

From Fig. 7 to Fig. 12, the blurred images and estimated images restored by the proposed algorithm are labeled by (a) and (b) respectively. These figures are contrasted for three different PSF size and standard deviation with two benchmarks. From these figures, it could be observed that the detail of the restorations is quite clear and the estimated results of the restorations approximate to the original image in Fig. 6. Although the proposed method was unable to find the correct standard deviation of PSF, it did not have to the result affects too greatly.

V. .CONCLUSION

To aim the higher quality of blind restoration, this paper presents an algorithm that use PSO to explore the unknown PSF and deploys edge information to design the objective function. Moreover, it associates Wiener filter to restore the estimated image. From simulation results, as general-purposed in parameter definition, high quality restoration is demonstrated.

The proposed algorithm can identify and recover the image only for Gaussian Blind Image, not for real BID problem. The future work, we will study for identifying each kind of blur situation. So that it can identify encounter all the possible with photograph.

***Abstract*—This paper presents a study on merging confidence measures using fuzzy logic. Instead of the previous approaches using the notion of probability, we propose to observe the uncertainty of the recognition hypotheses and the notion of possibility thanks to fuzzy reasoning. Four different confidence measures are developed, coming from different parts of a speech recognizer. Various merging methods are studied to improve the performance of the confidence measures. The methods are evaluated in terms of Confidence Error Rate (CER) and in terms of their Detection Error Tradeoff (DET) curves on a French broadcast news corpus. They are compared to some fuzzy logic aggregation techniques among which the technique based on the Choquet Integral yields to a significant improvement in terms of CER.**

***Keywords*—fuzzy logic, confidence measures, speech recognition, feature aggregation**

I. Introduction

Confidence measures are used in various applications of speech processing [1]. When used with a threshold, a confidence score associated to an hypothesis can lead to the acceptation or rejection of that hypothesis [2]. Confidence measures can also be used to select hypothesis that will increase the amount of training data needed for acoustic models [3]. They can also guide the confirmation strategy in dialog systems [4] and can be used for language identification [5]. In speech recognition, confidence measures give an estimation about the correctness of a given hypothesis. To provide such estimations, many parts of the speech recognition system can be helpful as they can provide an indication about the reliability of the system.

One way to take advantage of the quality of each measure is to find the most performant combination method. Designers often choose between the techniques available and the techniques they know best by simply making an educated guess. A tempting approach is to combine several decision rules, based on various representations and classification schemes, instead of electing only one rule. The expected outcome of an aggregation is a more robust final decision, that will improve the classification ability of a single confidence measure. Well-known operators applying this scheme include the quasi-arithmetic means, the weighted minimum and maximum, and the ordered weighted averaging [6]. Other techniques such as Support Vector Machines (SVM), neural networks and Gaussian Mixture Models (GMM), can also be used to merge scores [7].

However, none of these families of operators can take the possible interactions between the constituents of the aggregation into account. The Choquet integral is then considered because it makes it possible for such interactions to generalize many aggregation operators by choosing specific fuzzy measures such as weighted arithmetic means, ordered weighted averages, order statistics, and median [8], [9], [10]. Fuzzy integrals, and the Choquet integral in particular, have been successfully used as fusion operators in various applications of pattern recognition [11] . The aim of the paper is then to explore how fuzzy integrals and the selection of measures can improve the confidence annotation of recognition hypotheses in speech processing.

In this paper, we will first present the different confidence measures developed for our study. The third section will describe the various aggregation methods which are taken as baselines. In section IV, the two fuzzy logic systems which are used for the experiments are presented. In section V, the corpora used will be detailed along with the evaluation metrics. Some results for each merging method will also be described. Finally, section VI presents how the measures can be selected to improve the results.

II. Confidence measures

Let us consider a set of N recognized words $\{w_1, \ldots, w_N\}$. Each word w can be associated with a confidence measure $m(w)$ defined with the properties:

Property 1:
The measure should be in the usual domain $[0, 1]$ and the measure should be interpretable as the probability that the word w is correct.

Property 2:
As a consequence of the latter property, the correct recognition rate on the emitted words is given by the following approximation:

$$\frac{1}{N}\sum_{i=1}^{N} m(w_i) \approx \text{CWRR} \quad (1)$$

where CWRR is the Correct Word Retained Rate (deletions are not taken into consideration).

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

A. Acoustic measure (AC)

The acoustic measure is based on the comparison of the acoustic likelihood provided by the speech recognition system for a given hypothesis and the one provided by an unconstrained phone loop model defined in [12]:

$$m^*_{ac}(w) = \frac{1}{N_f(w)}[\log P(Y|\lambda_C) - \log P(Y|\lambda_L)] \quad (2)$$

where w is the recognized word with N_f frames, Y is the sequence of acoustic observations, $P(Y|\lambda_C)$ is the acoustic score given by the recognizer model, and $P(Y|\lambda_L)$ is the acoustic score given by an unconstrained phone loop.
This measure is then normalized using a sigmoid-like transformation.

$$m_{ac}(w) = \frac{\exp\left(\frac{m^*_{ac}(w)-\mu}{\sigma}\right) + a}{\exp\left(\frac{m^*_{ac}(w)-\mu}{\sigma}\right) + 1} \quad (3)$$

where μ, σ are the mean and the standard deviation of the initial acoustic measure on a training corpus and $a = 2 * \text{CWRR} - 1$ (for an approximation of the second property defined at the begining of this section).
The value of this measure for a word w will be noted $m_{AC}(w)$.

B. Language Model Back-off Based measure (LMBB)

This measure was previously defined in [12]. It uses the back-off behavior of the language model (LM) to define the confidence score that is associated to a word.
A given word recognized with a given left context is associated with the highest order of n-grams seen in the training corpus concerning this word and this context. For a quadrigram LM, the order can be as high as 4, or it can be 0 if out-of-vocabulary words can be processed.
For example, if the sequence of words 'it is the ninth time' is recognized using a quadrigram model and if the quadrigram [is the ninth time] was observed in the training corpus, 'time' will be associated with the order 4. But if this quadrigram has never been observed, whereas the trigram [the ninth time] has, 'time' will be associated with the order 3, and so on, all the way down to order 1 (or 0 if out-of-vocabulary words can be processed).

It is well known that an error occurring in a word has an impact on the correctness of the words located in the immediate context of this erroneous word. According to this, and assuming that the LM back-off behavior is an acceptable criterion to predict the correctness of a word, our measure considers the LM back-off behavior of the left and right neighbors of a word, in addition to the highest order of n-grams this word is associated with on a training corpus.

So, each recognized word is associated with a triplet corresponding to its class.

In order to reduce the number of classes, each word of a recognized hypothesis is finally associated with a three component label:

1^{st} symbol: -, =, or + when the order of its left neighbor is respectively lower than, equal to, or higher than the order of the considered word,

2^{nd} symbol: the highest order of observed n-grams associated to the given word

3^{rd} symbol: -, =, or + when the order of its right neighbor is respectively lower than, equal to, or higher than the one of the considered word.

By comparing a set of automatic transcriptions with words labeled with these triplets, to a manual transcription of the same set of sentences, the misrecognition rate is computed [1] for each triplet on a training set. This rate is the number of substitutions and insertions divided by the number of recognized words. The misrecognition rate for a given class will later be used as the confidence measure for words labeled with that triplet when processing test data. Indeed, in [12], we showed that there is a correlation between the triplets and the error rate those words are associated with.
The value of this measure for a word w will be noted $m_{LMBB}(w)$.

C. Word posterior probability measure (WP)

Word posterior probabilities can be computed from N-best lists, word-lattices [13] or confusion networks [1], [14]. Roughly, the word posterior probability is the ratio of the *a posteriori* probability of a word and the sum of the *a posteriori* probabilities of all its alternatives. These *a posteriori* probabilities result from a combination of values given by acoustic and language models. Thus, word posteriors can be seen as a summarization of acoustic scores, linguistic scores and the search space topology. In N-best lists, the word posterior probability of a word is approximated with the ratio of the sum of the *a posteriori* probabilities of the occurrences of this word in the N hypotheses in a given position, and the sum of all the *a posteriori* probabilities of occurrences of words in this same position, including occurrences of the given word. In both word lattice and confusion network based approaches, the word posterior probability can be seen as a generalization of the N-best approach, where word-segmentations and search space depth are better considered.

Unfortunately, this measure is affected by pruning heuristics reducing the size of pruned word lattices generated during the recognition process. In practice, the use of this measure can therefore be biased. To overcome this problem, a decision tree can be trained to transform the posterior probabilities into better confidence scores [13].
In this paper, we use a confusion network based approach, directly derived from [15] to compute word posteriors. The value of this measure for a word w will be noted $m_{WP}(w)$.

D. Word posterior probability mapped measure (MAP)

An analysis showed the tendancy of the WP confidence measure to overestimate the probabilities of correct recognition as it was also described in [14]. This is due to the fact that

[1] In this paper, we use 'misrecognition rate' to refer to insertions and substitutions errors only, whereas 'word error rate' refers to the common metric including insertions, substitutions *and deletions*; this distinction is needed when studying recognized words only. The misrecognition rate equals 1-CWRR, the Correct Word Retained Rate previoulsy mentioned.

the lattices used as the basis for the posterior estimation only represent part of the posterior distribution and a significant amount of the probability mass "is missing" as we have explained in the previous section. Therefore, a piecewise linear mapping function is used in order to make this measure more discriminant. The coefficients are computed on a specific training set used for the parameters of the confidence measures and led to a new measure called MAP.
The value of this measure for a word w will be noted $m_{MAP}(w)$.

By aggregating the word posterior probability with other confidence measures which are not affected by the search space size, the performance of the word posterior probability should be improved.

III. Aggregation methods : baselines

We have four measures that come from different parts of the speech recognizer. In order to get the best of each measure, several merging techniques are studied. Various classifiers and aggregation techniques have been computed in order to compare their performance against fuzzy systems.

A. Arithmectic mean

One combination that can be a baseline is a simple arithmetic mean between all the features.

B. Linear least square regression

To take into account the quality of each measure, a simple linear interpolation can be used to fit a predictive model of the word correctness as in the equation:

$$y = \sum_{i=1}^{n} \alpha_i x_i + \alpha_0 \tag{4}$$

The method of the least squares is used to estimate the values of the interpolation parameters on the MTrain data set (see section V-C).
Various combination using the four measures or only three of them are tried.

C. Multi-Layer Perceptron (MLP)

A Multi-Layer Perceptron with two hidden layers is trained with backpropagation. Each measure gets one input node and there is one ouput node.

IV. Fuzzy logic systems

In general, uncertainty in the probability theory is seen in terms of occurrences of known facts. In a speech recognition task, what is known is whether the recognition hypothesis is correct or not. Probability is useful when dealing with serial events that require an enumeration notion of uncertainty but is not very useful when the uncertainty is about the degree of accomplishment of a known situation [16]. Indeed, when applying confidence measures to speech recognition, what we want to know is mainly about the degree of correctness that is associated with the recognition hypotheses. Fuzzy logic systems are therefore relevant for this task because they use the notion of uncertainty from the point of view of "possibility".

Fuzzy logic systems use a set of fuzzy rules to map a number of fuzzy inputs to fuzzy outputs. They allow the classification of fuzzy variables thanks to "if ... then" rules [17].

A. Possibility measures

In [18], the authors express the transformation between probability and possibility by:
Let C be the set composed of $c_1, c_2, ..., c_n$, $p_i = P(c_i)$ be the probability measures of each element of the set C where $p_1 \geq p_2 \geq ... \geq p_n$, and $\pi_i = \Pi(c_i)$ be the possibility measures on the set C, then the optimal solution is :

$$\forall i = 1, n, \pi_i = \sum_{j=i}^{n} p_j \tag{5}$$

This transformation is then used to compute the possibility measures from the scores given by the four experts. Various aggregation techniques can be used to get the final confidence score. In this article, the normalised conjonctive, the disjonctive and the adaptative fusions are computed.

B. Fuzzy Integrals

Let us denote by $X = \{D_1, \ldots, D_n\}$ the set of n decision rules (DR), and $\mathcal{P}$ the power set of X, i.e. the set of all subsets of X.
Definition 1 *A* fuzzy measure *or* capacity, μ, *defined on X is a set function* $\mu : \mathcal{P}(X) \longrightarrow [0, 1]$, *verifying the axioms:*

$$\mu(\emptyset) = 0, \mu(X) = 1 \tag{6}$$

and

$$A \subseteq B \Longrightarrow \mu(A) \leqslant \mu(B) \tag{7}$$

Fuzzy measures generalize additive measures, by replacing the additivity axiom by a weaker one (monotonicity). Fuzzy measures embed particular cases including probability measure, possibility and necessity measures, or belief and plausibility functions.
In our context of decision rule fusion, $\mu(A)$ represents the importance, or the degree of trust in the decision provided by the subset A of DRs. The next step in building a final decision, is to combine the partial confidence degree according to each DR into a global confidence degree, taking those weights into account.

1) The Choquet Integral: The Choquet integral was first introduced in the capacity theory [19], [20].

Definition 2 *Let* μ *be a fuzzy measure on X. The* discrete Choquet *integral of* $\vec{\phi} = [\phi_1, \ldots, \phi_n]^t$ *with respect to* μ, *noted* $\mathcal{C}_\mu(\vec{\phi})$, *is defined by:*

$$\mathcal{C}_\mu(\vec{\phi}) = \sum_{j=1}^{n} \phi_{(j)}[\mu(A_{(j)}) - \mu(A_{(j+1)})] \tag{8}$$

where $(.)$ *is a permutation on the source indexes, such as* $(i) \leq (j) \Rightarrow \phi(i) \leq \phi(j)$*. Also,* $A_{(j)} = \{(j), \ldots, (n)\}$ *represents the* $[j..n]$ *associated criteria in increasing order and* $A_{(n+1)} = \emptyset$*.*

Determining the Fuzzy Measure

There are several methods to determine the most adequate fuzzy measure to be used for a given application and the most straightforward learning approach is based on optimization techniques. The aim is to find the fuzzy measure that best minimizes a criterion on the training set, such has the square error. Considering $(x^k, y^k), k = 1, \ldots, l$, l learning samples where $x^k = [x_1^k, \ldots, x_n^k]^t$ is a n-dimensional vector, and y^k the expected global evaluation of object k, the fuzzy measure can be determined by minimizing [8]:

$$E^2 = \sum_{k=1}^{l} (\mathcal{C}_\mu(x_1^k, \ldots, x_n^k) - y^k)^2 \tag{9}$$

This criterion can be put under a quadratic program form and solved by the Lemke method. Nevertheless the method requires at least $n!/[(n/2)!]^2$ learning samples. When little data is available, matrices may be ill-conditioned, causing a bad behaviour of the algorithm. To cope with the above problems, "heuristic" algorithms were developed.

To our knowledge, the algorithm providing the best approximation was proposed by Grabisch in [11]. It assumes that in the absence of any information, the most reasonable way to aggregate the partial matching degrees is to compute the arithmetic mean on all the inputs. This aggregation using Choquet Integral will be later noted m_{CI}.

The fuzzy measures used in the Choquet Integral method can also be computed thanks to possibility measures (see section IV-A). This aggregation will be later noted m_{CF}.

2) The Sugeno Integral: A Sugeno-type fuzzy inference system has already been proved to be a good classifier [21]. This system was used in [22] with good results on a Spanish speech database. This database was collected via land telephone lines (sampled at 8kHz). On the continous speech database (consisting of 9405 words) the Equal Error Rate went from 22.85 with an MLP down to 22.05 when using a Sugeno-type fuzzy inference system.

For our experiments, the number of input variables corresponds to the four confidence measures and the ouput will be the value of the resulting confidence measure.

Determining the Fuzzy Measure

In this paper, the same kind of Sugeno Integral that was used in [22] is computed, using grid partitioning, and yielded to 16 rules. The generalized bell membership function is used for the fuzzification of the scores given by the speech recognizer. This method of aggregation, using the Sugeno Integral, will later be called m_{SI}.

3) Behavioural Analysis of the Aggregation:

Important Index

The importance index is based on the definition proposed by Shapley in game theory [23]. Its application in the context of fuzzy measures was made by Murofushi and Soneda [24]. It is defined for a fuzzy measure μ and a rule i as:

$$\sigma(\mu, i) = \frac{1}{n} \sum_{t=0}^{n-1} \frac{1}{\binom{n-1}{t}} \sum_{\substack{T \subseteq X \setminus i \\ |T|=t}} [\mu(T \cup i) - \mu(T)] \tag{10}$$

It can be interpreted as an average value of the marginal contribution $\mu(T \cup i) - \mu(T)$ of the decision rule i alone in all combinations.

The measure using the importance index will be noted m_{II}.

Interaction Index

Another useful index in order to apprehend the degree of interaction between decision rules was also introduced by Murofushi and Soneda [24]. The interaction value between the rules i and j, to the presence of elements of the combination $T \subseteq X \setminus ij$ is computed as:

$$(\Delta_{ij}\mu)(T) = \mu(T \cup ij) + \mu(T) - \mu(T \cup i) - \mu(T \cup j) \tag{11}$$

Extending this criteria on every subsets of $T \subseteq X \setminus ij$, an evaluation of the interaction between DRs i and j is :

$$I(\mu, ij) = \sum_{T \subseteq X \setminus ij} \frac{(n-t-2)!t!}{(n-1)!} (\Delta_{ij\mu})(T) \tag{12}$$

This index gives an idea of the complementarity or competitiveness that exist beween measures. A positive interaction between two rules means that the decision rule is discriminative power is increased when used with th second decision rule. Thus, this index will later by used to select measures in order to obtain an aggregation of complementary measures.

V. Experiments

Experiments have been carried out on the ESTER corpus. ESTER is an evaluation campaign of French broadcast news transcription systems which started in 2003 and completed in January 2005 [25]. The recognition system used for those experiments is the LIUM (Laboratoire d'Informatique de l'Université du Maine) system [26]. It is based on the CMU Sphinx 3.3 decoder. Some features were added to the Sphinx decoder, such as acoustic models adaptation using Speaker Adaptative Training (SAT) method or word-lattice rescoring to get a quadrigram language model. More details about the system can be found in [26]. The LIUM system reached the second position of the campaign with an official 23.6% word error rate.

A. Resources

The vocabulary used by the LIUM system contained about 65K words. Acoustic and language models were trained using the official training corpus of the ESTER evaluation campagn. Trigram language model was used during the first two passes processed by the recognizer, while the quadrigram language model was used for the last pass corresponding to a word-lattice rescoring. The word posteriors are computed from these

word-lattices, using acoustic scores from adapted acoustic models and linguistic scores from the 4-gram language model.

B. Training parameters for confidence measures

The parameters that are used to compute the LMBB measure, the AC measure and the MAP measure are estimated from a specific corpus composed of 4h of manually annotated broadcast news from ESTER. This corpus is independent of the training corpus of acoustic and language models and of the training set later refered as MTrain.

C. Corpora used to evaluate the merging techniques

Three corpora are used for the evaluation of the various merging techniques studied in this paper. They come from the official test of the ESTER broadcast news corpus which consists of 10h of continuous speech. Those corpora are noted MTrain, MDev and MTest. MDev is used as a validation set for the MLP and the Sugeno-type fuzzy system. In order to be consistent when defining the test set in an experiment, the choice of the data that are used in this test set (MTest) should be recorded after the data used in the training set. Therefore, MTest is defined by choosing the last 3h30 of the official ESTER test corpus. 3h30 of speech in this database correspond to an approximate amount of 31000 words. It has led to the choice of radio channels that are not contained in MTrain or MDev. As a summary MTrain is composed of 1h of Radio Classique, 1h of France Inter, 1h of France Info and 30 mins of Radio France International (RFI). MDev is composed of 1h of France Culture, 1h of France Info, 1h of France Inter and 30 mins of RFI. MTest is composed of 1h of RFI and 2h30 of Radio Television Marocaine (RTM) and is not a part of MTrain or MDev.

D. Evaluation Metrics

In those experiments, the Confidence Error Rate (CER)[27] is used to assess the relevance of a confidence measure to assess the correctness of a word. The CER is the total number of false accepts and false rejects divided by the total number of hypothesis for a given threshold. It gives an estimation of the classification ability of a confidence measure. The threshold that has led to the minimum CER on MTrain is used when computing the CER on the test set MTest.

Some Detection Error Tradeoff (DET) curves are also shown in order to compare the fuzzy logic techniques used in this article. Those DET curves present the two types of error : the false alarms and the false rejections. In the paper written by Martin [28], the authors show that the DET curve form of presentation is relevant to any detection task where a tradeoff of error types is involved. Thanks to the DET curves, performances of confidence measures in terms of their capabilities to validate correct hypotheses and reject false alarms are evaluated.

E. Single Measures

Table I shows the different measures developed in this paper. The best single measures are the WP measure and the MAP measure which have obtained a CER score of 17.88 on MTest. The mapping technique between the WP measure and the MAP measure preserves the CER score as the piecewise linear transformation does not affect the distribution from the optimal threshold. Those measures alone are relevant to assess the correctness of a word and have a CER which is much lower than the rate of the emitted words that are incorrect (17% on MTrain and 22.3% on MTest). By adding measures that are not affected by pruning heuristics, the aim is then to find the best combination that will lead to a better performance in terms of classification.

TABLE I
RESULTS IN TERMS OF CER FOR THE SINGLE CONFIDENCE MEASURES

Confidence Measure	MTrain (%)	MTest (%)
Incorrect emitted words	17	22.3
WP	14.65	**17.88**
MAP	14.65	**17.88**
AC	16.04	22.18
LMBB	16.05	22.17

F. Results after merging

Several combinations of the four measures were tried. To compare the different techniques, some baselines are computed, which are a simple arithmetic mean, a linear regression between the four single measures, and a MLP.

In order to take advantage of the uncertainty notion from the possibility theory, various fuzzy systems are tried to aggregate the four confidence measures.

Figure 1 illustrates how the Choquet Integral method computes the weights used by the fusion process (section IV). Every path of the lattice leads to a part of the plan where every single measure is associated with a weight p. Depending on which measure is the highest for the current word, it will lead to a different linear interpolation merging the four measures.

For example, let us consider a word w and its four scores coming from each confidence measures. For this word w, we have:

$$m_{WP}(w) < m_{MAP}(w) < m_{AC}(w) < m_{LMBB}(w) \quad (13)$$

The final score $m_{CI}(w)$ that will be associated to that word is:

$$\begin{aligned} & m_{WP}(w) * (p(\{1234\}) - p(\{234\})) \\ +& m_{MAP}(w) * (p(\{234\}) - p(\{34\})) \\ +& m_{AC}(w) * (p(\{34\}) - p(\{4\})) \\ +& m_{LMBB}(w) * p(\{4\}) \end{aligned} \quad (14)$$

Table II summarizes the results of the various combination techniques. The fusions on possibillity measures do not perform well. Every other technique outperforms the arithmetic mean and the linear regression and is more relevant to assess the correctness of a word. As the training corpus is substantial,

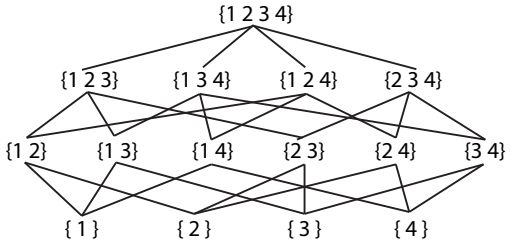

Fig. 1. Lattice for 4 measures. Each path is associated with a weight processed by the Choquet Integral technique on MTrain. {1}, {2}, {3}, {4} corresponds respectively to the weights associated to the WP, MAP, AC and LMBB measure.

TABLE II
RESULTS IN TERMS OF CER FOR THE VARIOUS MERGING TECHNIQUES.

Aggregated Measure	MTrain (%)	MTest (%)
Arithmetic mean	14.18	17.61
MLP	13.87	**17.44**
Linear Regression m_{LR}	13.92	17.55
Normalised conjonctive fusion	16.04	22.16
Disjonctive fusion	16.04	22.15
Adaptative fusion	16.04	22.17
Sugeno Integral m_{SI}	13.72	**17.44**
Choquet Integral with possibility measures	14.72	21.16
Choquet Integral m_{CI}	13.90	**17.49**

the Choquet Integral does not perform better than the Sugeno Integral but they lead to a good performance in terms of CER.

VI. SELECTION OF THE MEASURES

In order to understand the correlation between the different measures and to better aprehend which measure is important in the aggregation and which one is not, their important index and their interaction index can be good indicators. Those indexes are provided by the Choquet lattice and as the Sugeno and Choquet Integrals are very close in terms of the CER score, they will be used with the Choquet Integral to observe the relevance of selecting measures.

The important index is described in section IV-B3. It describes the correlation between the score given by a measure and the correctness of a word. All the important indexes are computed for each confidence measure and are detailed in table III.

TABLE III
IMPORTANCE INDEX OF THE FOUR MEASURES

Confidence measure	Importance Index
WP	0.517512
MAP	1.930417
AC	0.536041
LMBB	1.016030

The first merging technique simply consists in a linear interpolation of the four measures with the importance indexes used as coefficients. The resulting measure is :

$$m_{II}(w) = \frac{0.517512 m_{WP} + 1.930417 m_{MAP} + 0.536041 m_{AC} + 1.01630 m_{LMBB}}{4} \quad (15)$$

The interaction index described in section IV-B3 is also computed on our data. The results are shown in table IV.

TABLE IV
INTERACTION INDEX OF THE FOUR MEASURES

	WP	MAP	AC	LMBB
WP	0.000000	-0.255104	0.041425	-0.776167
MAP	-0.255104	0.000000	-0.418659	-1.405465
AC	0.041425	-0.418659	0.000000	0.102432
LMBB	-0.776167	-1.405465	0.102432	0.000000

The idea to select the measures that will be kept in the aggregation is to look for the measure associated with the weakest important index and for which the interaction index is lower than the average interaction index.

This led to the results shown in table V.

TABLE V
RESULTS IN TERMS OF CER FOR THE AGGREGATION USING SELECTED MEASURES

Aggregated Measure	MTrain (%)	MTest (%)
Choquet Integral (4 measures)	13.90	**17.49**
Linear regression with important indexes m_{II}	13.82	**17.34**
Choquet Integral (3 measures)	13.98	18.22
Choquet Integral (2 measures)	13.91	**17.20**

Those results show the relevance of the use of important indexes. By using them as coefficients in a simple linear regression, the resulting measure outperforms the results of a MLP and of the two fuzzy systems based on the Choquet and the Sugeno integrals.

Selecting the measures that will be used in the aggregation shows a good performance and leads to the best performance in terms of CER when using only two measures with the Choquet Integral.

The DET curve (see figure 2) confirms that, by selecting only two measures for the Choquet Integral, we obtain a relevant aggregation in terms of its ability to reject false alarms. The aggregation of three measures seems to obtain good results for the validation of correct hypotheses.

VII. DISCUSSION AND CONCLUSIONS

This paper presents how fuzzy logic is relevant in measuring the confidence in a speech processing application.

For applications where the interesting aspect of the confidence measure is its classification ability, the CER improvement is important. For example, one might want a confidence measure that is well able to detect incorrect words in order to increase the amount of training data for the acoustic models in an unsupervised way. According to the CER, the fuzzy logic techniques prove to be very efficient and combine the best of the various individual confidence measures involved on each data subset. Compared to a standard MLP, fuzzy integrals and the Choquet Integral in particular can provide a semantic

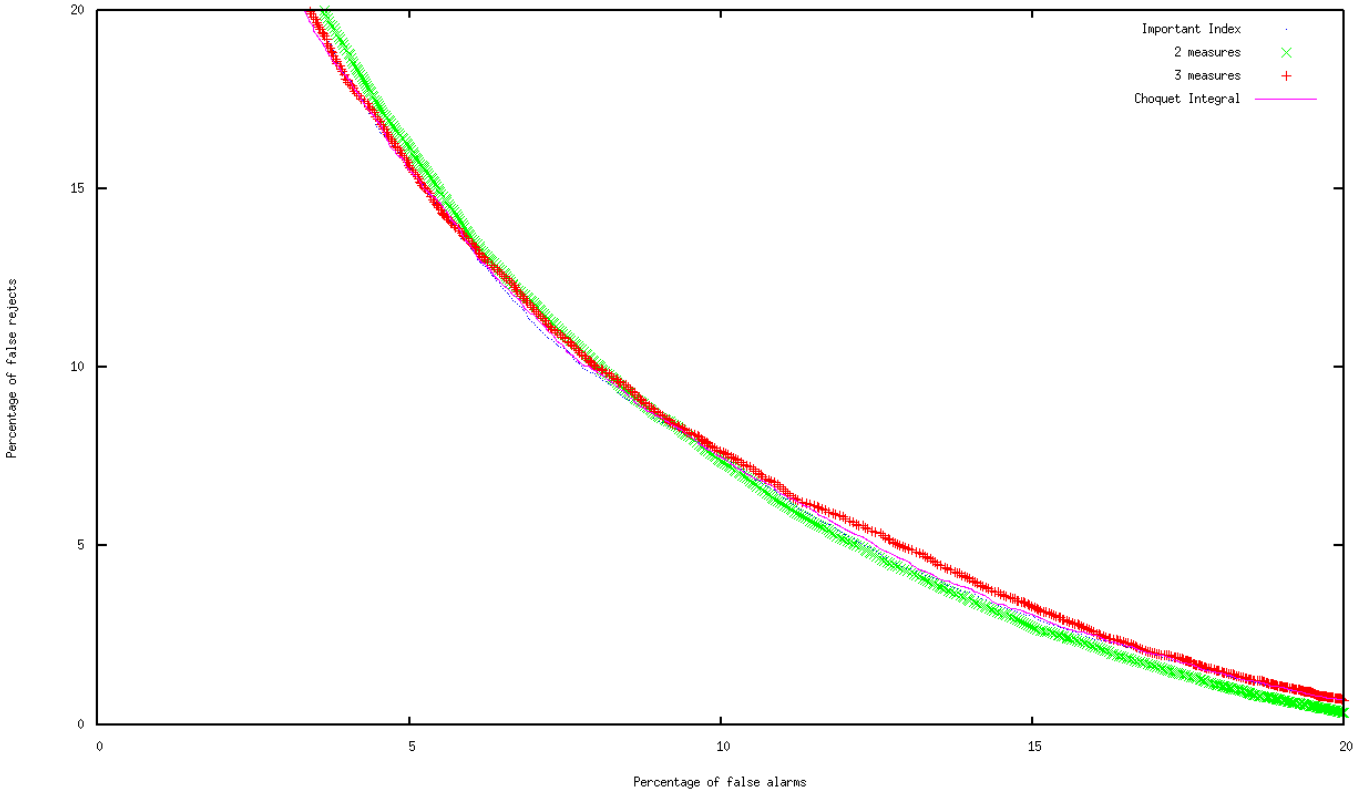

Fig. 2. DET curve for the Choquet Integral with 4, 3 and 2 measures and with the linear regression with important indexes.

interpretation and understanding of the problem. The Choquet integral technique, by selecting only two measures, improves the CER by 4.10% compared to the CER obtained by the best single confidence measure. From DET curves, the selection of the measures has also proven to increase the discriminative ability of confidence measures and to be worthwhile.

In future works, other methods using fuzzy logic will be explored.

***Abstract*—This paper introduces a practical system by combining an Intelligent Fuzzy Controller and vision processing algorithm to obtain an efficient active tracker. Target tracking performance is heavily dependent on a good blend of vision algorithm and control. Because of performance and computational complexity, many visual tracking algorithms cannot be linked with control systems in the real-time tracking. Robustness and speed are the bottlenecks of current visual tracking algorithms. Here, the target's visual model is used along with a kernel-based searching algorithm and a motion detection module to predict the target position. A model update is also incorporated to recognize when the target's appearance is changing due to variations in its position. An Intelligent Fuzzy Controller (IFC) is also synthesized to reach control performance objectives. The IFC used in this tracking system not only helps to track the target accurately in different situations, but also tries to find the target's presence after track loss. Additionally, the parallel processing technique has also been deployed to provide the desired accuracy and speed in real-time tracking. The idea has been implemented in an active camera system to track moving targets.**

Keywords- Intelligent Fuzzy Control, Kernel-Based Object Tracking, Active Tracking, Vision

I. INTRODUCTION

With the rapid enhancement of computational power, object tracking has been an active research area in the computer vision in recent years. It plays an important role in robot tracking, monitoring and surveillance systems, virtual sport, human-computer interfaces [1], vision-based control, smart rooms, military and driver assistance, astronomy and medical science. There are three common approaches that are widely used in object tracking. One is based on Kalman filter or extended the Kalman filter [2]. The Kalman filter assumes that the probability distributions of the states are Gaussian. Another is mean shift [3], [4] which is a robust non-parametric method for climbing density gradients to find the peak of probability model. Third, particle filter as a widely used approach in object tracking is well suited to estimate state of non-linear, non-Gaussian dynamic systems [5], [6]. Tracking under the constraint of low computational complexity presents a challenge in the real time tracking applications.

Recent years have witnessed rapidly growing use of fuzzy control systems in engineering applications. The numerous successful applications of fuzzy control have sparked a flurry of activities in the analysis and design of fuzzy control systems [7]. Stability and robustness are the two major points where the active tracking system presented can benefit from fuzzy controller [8]. Use of different fuzzy rules, depending on situations such as velocity and dimension of target, results in a more efficient controller to track the target. In addition, the tracker can detect the target's presence after track loss by running suitable fuzzy rules. Selecting the appropriate fuzzy rules is a complicated process. Thus, to implement these rules, an intelligent module has been used that runs special fuzzy rules with regard to situations. Therefore, the fuzzy controller is adaptive and the rules change in fuzzy engine intelligently.

In this paper, the target's visual model is used along with a kernel-based searching algorithm and a motion detection module to predict the target position. A model update is also incorporated to recognize when the target's appearance is changing due to variations in its position. An Intelligent Fuzzy Controller (IFC) is also synthesized to reach control performance objectives. In case of target track loss, a search algorithm sweeps the space in the vicinity of last target position to recover the lost target. Additionally, the parallel processing technique has also been deployed to provide the desired accuracy and speed in real-time tracking. The idea has been applied to an active camera system.

II. PROBLEM DEFENITION

The main goal is to track a dynamic target using a camera with two degrees of freedom in pan and tilt directions. This research centers on the tracking of two types of objects. The first type includes objects that are close to the camera such as faces of people. The active camera tracks people's faces regardless of whether they are approaching the camera or moving away from it or turning their heads. This example is expandable to a variety of objects that move around the camera. Sudden and rapid changing of targets aspect and their surroundings is one of the most important properties of them. The environment of target may be cluttered with other objects. Therefore, it is very important that the active camera be able to determine changes and differentiate between objects. The second type includes targets at long distances from the active

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

camera, such as an aircraft. These objects have small aspect in the camera with a small rate of changes. A small unsuitable movement of the active camera causes large tracking errors for distanced objects. Accuracy is therefore crucial.

III. General Operation

Figure 1 shows the schematic of operation of the active camera. Each of pan or tilt angles uses the same operation that is mentioned in figure 1. There are four major modules: The Intelligent Fuzzy Controller (IFC) module makes the appropriate control signal for plant due to errors. The Active Camera module is the sensors, digital camera and motors of the active camera transform the control signal to physical movements in pan and tilt movements. The vision box recognizes the selected dynamic target that must be tracked. In fact, the main goal is to keep the object in the center of the camera. The distance between object and center of the camera is determined as the error, figure 2. The filter box checks the output data coming from the vision box. Filter box uses some rational rules to reject idle data latest In case of target loss, the suitable fuzzy rules runs and an intelligent local search algorithm sweeps the scene in the vicinity of last target position.

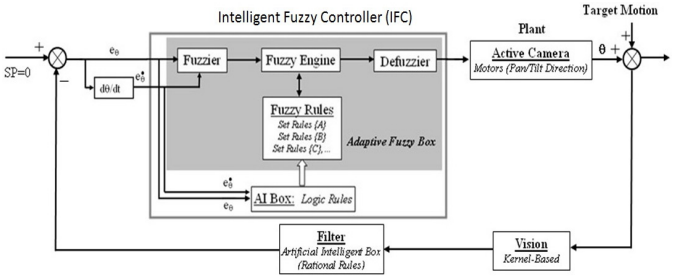

Figure1. The schematic of general operation

IV. Vision Box

As mentioned, vision box recognizes the object and calculates the distance between object and the center of screen camera. This distance transforms to the two angle errors, Δθtilt and Δθpan.

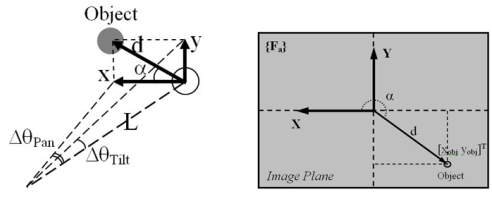

Figure2. $\Delta\theta_{Tilt}$ and $\Delta\theta_{pan}$ are calculated from the distance of the object and the center of screen camera

Δθtilt and Δθpan are calculated from equation (1). In this formula, L is a constant value to normalize Δθtilt and Δθpan.

$$\Delta\theta_{pan} = d\ Sin\alpha / L$$
$$\Delta\theta_{tilt} = d\ Cos\alpha / L \qquad (1)$$

Vision box uses various techniques to recognize and track objects. Following, briefly introduces these techniques.

V. Mean Shift

Recently, the mean shift algorithm was employed for object tracking, measuring the similarity between consecutive frames based on Bhattacharyya coefficient [9]. A major limitation of the mean shift tracker is that it uses one object model to track the target during the entire tracking process. Hence, it fails to track the target as it undergoes severe deformations and rotations. To achieve robust tracking, model updates should be considered. The adaptive Kalman filter can be used to filter the object kernel histogram and obtain the optimal estimate of the object mode [10]. Another problem is also experienced with mean shift tracker. It cannot track objects apart for more than the size of the target model between two consecutive frames. This means that if the camera is unable to capture the target movement between these two frames, it virtually fails to track it. An extension of mean shift algorithm employs spatiograms (instead of histograms) which improves the performance of the mean shift tracker under wild rotations of the target [9]. However, it does not solve the second problem mentioned previously. Thorough global template search for the target is not a practical solution as it burdens the computer in real-time. More importantly, it is not suitable for real time tracking because of the controller stability issues that can result from erratic sampling rates. However, use of spatiogram has one evident advantage over histograms due to the integration of distance information that helps distinguish between different objects of similar color distribution.

Target Representation

To characterize the target, first a feature space is chosen. The reference target model is represented by its pdf (probability density function), q, in the feature space. For instance, the reference model can be chosen to be the color pdf of the target. In the subsequent frame, a target candidate is defined at location y, characterized by the pdf p(y). To satisfy low computation cost imposed by real time processing, discreet densities or m-bin histograms should be used. Thus:

$$\hat{q} = \{\hat{q}_u\}_{u=1\ldots m} \qquad \sum_{u=1}^{m} \hat{q}_u = 1$$
$$\hat{p}(y) = \{\hat{p}_u\}_{u=1\ldots m} \qquad \sum_{u=1}^{m} \hat{p}_u = 1 \qquad (2)$$

Target model

A target is represented by an ellipsoidal region on the image. To eliminate the influence of different target dimensions, all targets are first normalized to unit circle. Let $\{x_i\}_{i=1\cdots n_h}$ be the normalized pixel locations of the target region in the current frame. The probability of feature u in the target model is calculated from:

$$\hat{q}_u = C\sum_{i=1}^{n} k\left(\|x_i\|^2\right)\delta\left[b(x_i) - u\right] \qquad (3)$$

Where b(xi) is the index of the bin at the pixel location Xi and δ is the *Kronecker delta function* and k is an isotropic kernel profile. The presence of such a kernel function assigns more weight to central pixels and reduces the effect of

peripheral pixels. The constant, C, is computed by using the fact that the sum of all probabilities over the *histogram* is one. Figure 3 shows an example of *kernel histogram* construction.

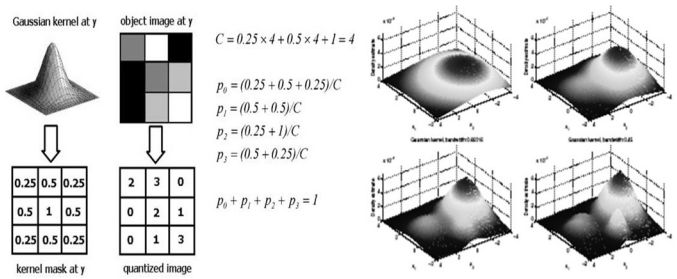

Figure3. Example of kernel histogram construction,
Multi-bandwidth density estimate on 2D artificial Gaussian mixture data.

Target Candidates

Let $\{x_i\}_{i=1\cdots n_h}$ be the normalized pixel locations of target candidate, centered at y in the current frame. The probability of feature u in the target candidate is given by:

$$\hat{P}_u(y) = C_h \sum_{i=1}^{n_h} k\left(\left\|\frac{y - x_i}{h}\right\|^2\right)\delta\left[b(x_i) - u\right] \tag{4}$$

Where h is the bandwidth (number of pixels in the region) of target candidate and C_h can be calculated the same as C_h The similarity function ρ is defined by the *Bhattacharyya coefficient* as:

$$\rho(y) = \sum_{u=1}^{m} \sqrt{\hat{P}_u(y).\hat{q}_u} \tag{5}$$

Target localization

Localization maximizes the similarity function between the two probability density functions. The search for new target location starts at the location y_0 of the target in the previous frame. The Taylor expansion of ρ(y) around ρ(y_0) yields:

$$\rho(y) \approx \frac{1}{2}\sum_{u=1}^{m}\sqrt{\hat{P}_u(\hat{y}_0).\hat{q}_u} + \frac{1}{2}\sum_{u=1}^{m}\hat{P}_u(\hat{y})\sqrt{\frac{\hat{q}_u}{\hat{P}_u(\hat{y}_0)}} \tag{6}$$

Taking the partial derivative of ρ(y) with respect to y and setting it to zero results in the mean shift equation. In this procedure, the kernel is recursively moved from the current location y0 to the new location y_1, therefore:

$$\hat{y}_1 = \frac{\sum_{i=1}^{n_h} x_i.w_i.g\left(\left\|\frac{\hat{y}_0 - x_i}{h}\right\|^2\right)}{\sum_{i=1}^{n_h} w_i.g\left(\left\|\frac{\hat{y}_0 - x_i}{h}\right\|^2\right)} \tag{7}$$

Where,

$$g(x) = -k'(x)$$

Kernels of Epanechnikov profile are typically used, i.e.:

$$k(x) = \begin{cases} \frac{1}{2}c_d^{-1}(d+2)(1-x) & if\ x \le 1 \\ 0 & otherwise \end{cases} \tag{8}$$

Where C_d is the volume of unit d-dimensional sphere and d is the dimension of the state space (2 in this case) [5]. In this case, derivative of the kernel profile, g(x), is constant and equation (7) reduces to:

$$\hat{y}_1 = \frac{\sum_{i=1}^{n_h} x_i.w_i}{\sum_{i=1}^{n_h} w_i} \tag{9}$$

'Hence, the mean shift algorithm calculates the similarity function for the target model and target candidate in subsequent frames and then, estimates the location of the target candidate using (9). This process is repeated until the similarity function goes up and the estimated location of the target changes less than a desirable threshold.

Target model update

Updating the target model during the tracking process is important if this process is to sustain for a long period of time. The generic target model update procedure can take on the following form:

$$q_{t+1} = c \cdot \left(q_t + f\left(\rho\left(q_t, p_t\right), \alpha, \ldots\right) \cdot p_t\right) \tag{10}$$

Where c is an arbitrary constant that is usually one; f is a function of the similarity, ρ, between the current target model and candidate model; α,… are other visually extractable elements such as the perimeter of object in pixel. In (11), f is taken as an exponential function as follows:

$$f = e^{-a[1-\rho(q_t, p_t)]} \tag{11}$$

Where a is the update rate and was taken as 10. In this paper an update function also is used in a similar fashion. The function has the advantage of having the least effect on target model when the similarity function is obtained too low. Hence, even if the target suddenly is buried in scene clutter the updating procedure will have no significant effect on the previous target model and it still holds the visual characteristics of last-seen target.

VI. FILTER

The vision module produces the error value. It is possible that this module produces idle error value, especially when the active camera loses the object or when the environment is very complex and vision module makes mistake in recognizing the object. Some simple logic laws are used in the filter module to check and eliminate the idle error value.

Any target in the real world such as airplane, missile, the human face or anything that the active tracker wants to track, has a continuous movement. It means that targets could not be vanished and appeared in other place immediately. So the big change in error value could not be acceptable and the filter assumes it as an idle error value and eliminates it from the data. In addition, velocity and acceleration of the object are also continuous. The filter part the big error value is replaced with the value that calculates from this formula:

$$\begin{aligned} &if\left(\Delta\theta_{pan}^{t_i} > \alpha_{pan}\right) \Rightarrow \Delta\theta_{pan}^{t_i} = 0.5\left(\Delta\theta_{pan}^{t_{i-1}} + \frac{\Delta\theta_{pan}^{t_{i-2}} + \Delta\theta_{pan}^{t_{i-3}}}{2}\right) \\ &if\left(\Delta\theta_{tilt}^{t_i} > \alpha_{tilt}\right) \Rightarrow \Delta\theta_{tilt}^{t_i} = 0.5\left(\Delta\theta_{tilt}^{t_{i-1}} + \frac{\Delta\theta_{tilt}^{t_{i-2}} + \Delta\theta_{tilt}^{t_{i-3}}}{2}\right) \end{aligned} \tag{12}$$

Where α_{pan} =10o and α_{tilt} =7o. If the active camera couldn't find the target, the search algorithm is operated. In other case, if the vision box loses the target, it produces a null value. This situation happens when the target hides behind other objects. For example, when an airplane goes behind clouds, the vision module can't recognize the position of the target. Thus it produces null value. The logic law that is used here is that the target continues its motion according to its last velocity and acceleration. In this case, filter module estimates the position for the target with the same velocity and acceleration of the target before it disappeared and produces a proximate error value.

$$if\ (\Delta\theta_{pan}^{t_i} > null) \Rightarrow \Delta\theta_{pan}^{t_i} = \Delta\theta_{pan}^{t_{i-1}},\ if\ (\Delta\theta_{tilt}^{t_i} > null) \Rightarrow \Delta\theta_{tilt}^{t_i} = \Delta\theta_{tilt}^{t_{i-1}} \quad (13)$$

Other task of the filter module is to find the lost target. By following human behavior the suitable logic law can be extracted for the active tracker when the tracker loses the target. Actually, when the active tracker loses the target, first it tracks the estimated position proportional to the velocity and acceleration of the target. But if it fails to find the target, the search algorithm is activated. For finding the lost target, first the active camera searches around the target's lost position and it gradually increases the radius of the search area with increasing the rotation pan and tilt angles.

VII. Intelligent Fuzzy Controller

Fuzzy logic is a powerful albeit somehow controversial technique. It permits control without extensive knowledge of the equations of the process and it represents in a very effective way the human reasoning methods [11]. A fuzzy control designer is inevitably faced with two questions: How does one determine the shape of the fuzzy sets, and how many sets are necessary and sufficient? [12] There are some different ways to determine the shape of the fuzzy sets in a controller, based on expert experience and control engineering knowledge, based on the operator's control actions, based on a fuzzy model of the process and based on learning [13].

While non-adaptive fuzzy control has proven its value in some applications, it is sometimes difficult to specify the rule-base for some plants. Additionally, the need could arise to tune the rule-base parameters if the plant changes. This provides the motivation for intelligent fuzzy control, where the focus is on the automatic on-line synthesis and tuning of fuzzy controller parameters [32]. There are several techniques for determining and tuning the fuzzy rules that have some strength and weaknesses which make them suitable for a specific situation. The *Intelligent Fuzzy Controller (IFC)* uses collections of fuzzy rules that each of them is efficient for a specific situation. Fuzzy laws are selected by using intelligent laws in accordance to the situation of the target. Some of these intelligent rules are as follows:

- Distanced targets need high accuracy to be tracked. Every change of the pan and tilt angles at the active camera causes large changes in vision area of the active camera at faraway. Therefore a small unsuitable movement of the active camera causes large tracking errors for faraway targets.
- Because the image of close targets in the camera move quickly and randomly, these targets could be tracked with less accuracy but with higher tracking velocity. High accuracy tracking may result in losing the target.

Three collections of different fuzzy set rules are used in the IAFC:

1. For targets with very slow velocity that are near the camera or faraway targets with slow velocity: if $\Delta\theta_{pan} < 4.5^{deg/sec}$ and if $\Delta\theta_{tilt} < 2.5^{deg/sec}$ the IAFC uses fuzzy set rules that are mentioned at figure 4.
2. For faraway targets with high velocity or near targets with medium velocity, if $4.5 < \Delta\theta_{pan} < 8^{deg/sec}$ and if $2.5 < \Delta\theta_{tilt} < 4.5^{deg/sec}$, the IAFC uses figure 5 fuzzy set laws.
3. For near targets with fast velocity: if $\Delta\dot{\theta}_{pan} > 8^{deg/sec}$ and if $\Delta\theta_{tilt} > 4.5^{deg/sec}$, the IAFC uses figure 6 fuzzy set laws.

Actually the tracker has been run frequently with variety of fuzzy rules. The suitable values and fuzzy laws are selected by considering the results of system operation. Changes in Pan Direction are more than tilt direction because objects generally move horizontally, so the signal controls are stronger for pan direction. For example there is a special collection laws for a target that is near the active camera and has high velocity. For this, accuracy is not very important. The main objective of the active tracker is to avoid losing the target. High accuracy in tracking the target causes losing the target, especially when the direction of target changes instantaneously. But if the velocity of the target is low, active camera can be more accurate in tracking by using other collection of fuzzy laws.

Angle Pan $\alpha=\Delta\theta_{pan}$ Tilt $\beta=\Delta\theta_{tilt}$	Angular Velocity $\dot{\alpha}$ Velocity $\dot{\beta}$	Controller Signal for Pan Direction	Controller Signal for Tilt Direction
Low (-)	Low (-)	High	Medium High
	Zero (·)	Medium High	Medium High

	Very High	Very very Low	Very Low

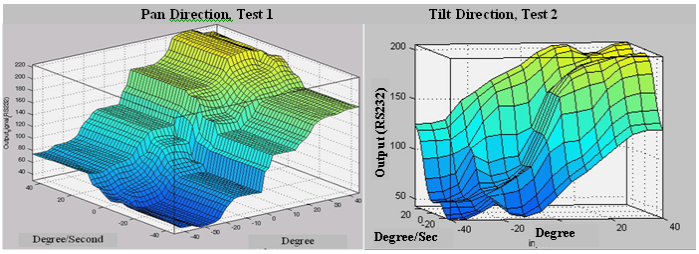

Figure 6. Selected fuzzy rules for near targets with fast velocity. In this case tracking does not need high velocity pan and tilt directions. But it needs to track targets accurately. So, Fuzzy rules produce commands that cause high accurate movement.

Owing to the interconnection of vision and control system, the optimization problem of active tracking is rather nontrivial. For instance, if robustness of tracking algorithm implies more latency, the control system would become unstable. Whereas, high overshoot of the closed loop system will cause the vision processing program to lose sight of the target.

VIII. Implementation And Experimental Results

To achieve an automatic target tracker, motion detection, target tracking and IFC must be combined. To link these two components, computers have been parallelized by the UDP protocol for communications. The vision processor extracts the target's position from the image streams delivered by the camera and packages the data to be sent over the predefined UDP sockets. On the other end, the Matlab ® sits in wait for the UDP packets, calculates the control signals by the fuzzy controller and relays commands to this active camera. The camera could track different objects such as human face or body excellently in both tilt and pan directions. Because of some unknown hardware flaws, sometimes, delays occurred in the tracker. This problem usually is solved because of the robustness of fuzzy controller. Details of active tracker and connections are shown in figure-7.

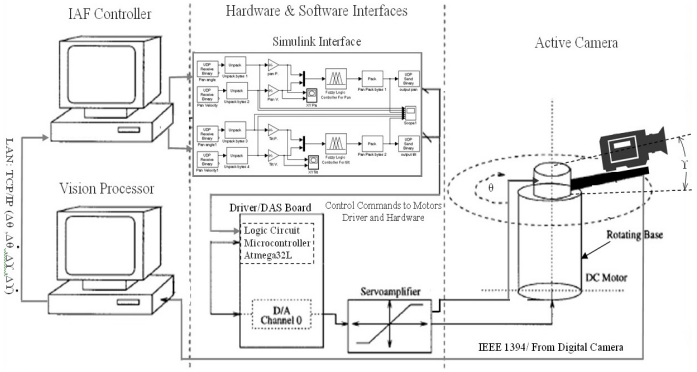

Figure7. The schematic of hardware and software of active camera

To assemble the active tracker, vision processor and fuzzy controller are each implemented on two separate computers. This way allows each portion to usurp full computation power of its own processor.

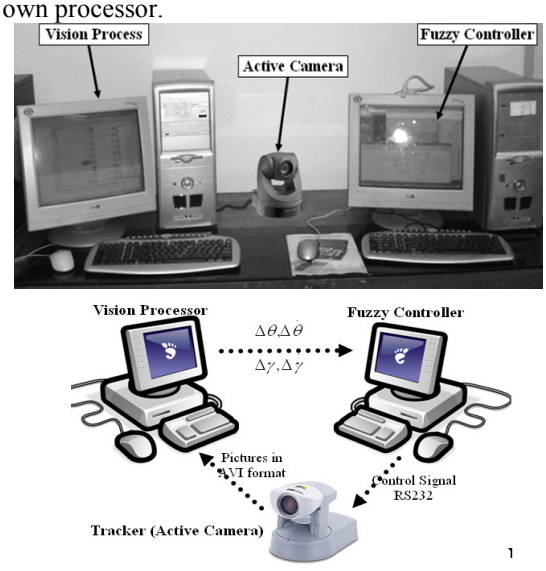

Figure 8. Using the parallel processing, the computational load is divided between two computers and delay times can decrease

Two different experiments are considered to test the fuzzy controller and vision algorithm. In the first experiment, the active camera tracks a black spot on a rotating circular plate which paces back and forth between two limits. The real position of the black spot is:

$$\theta = \tan^{-1}(\frac{r}{l})\sin(\omega t) \quad , \quad \alpha = \tan^{-1}(\frac{r}{l})\cos(\omega t) \qquad (14)$$

Where θ is the pan angle and α is the tilt angle; r refers to the radius of rotation of the black spot and l is distance between the active camera and the circular plate; ω represents the angular velocity of plate and finally t denotes time.

In addition, the normal mean-shift algorithm and a conventional PID controller are developed for comparing by the operation of the IFC and considering of effectiveness of the proposed method precisely. Figure 9, 10 and 11 shows the results in terms of angle of camera and outputs from vision and controller that the active camera has tracked. Figure 9, 10 displays the operation of the normal mean-shift algorithm and a conventional PID controller beyond the IFC algorithm.

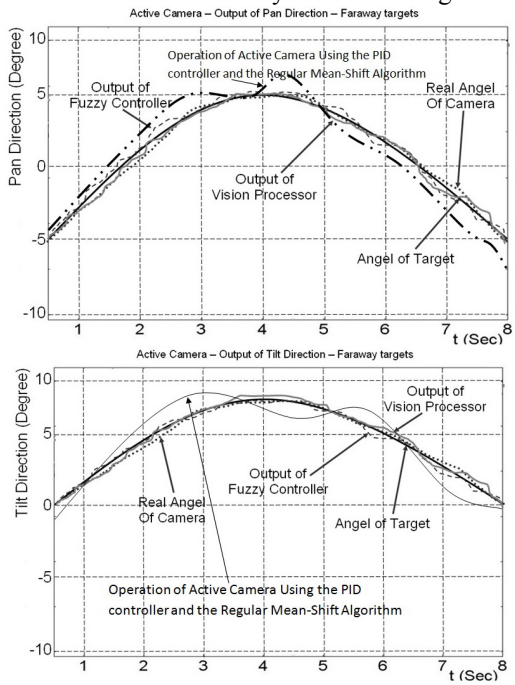

Figure9. Tracking the target with circular path(w=0.4rad/sec). These figures show that the operation of the IFC is better than the operation of the normal mean-shift algorithm and a conventional PID controller

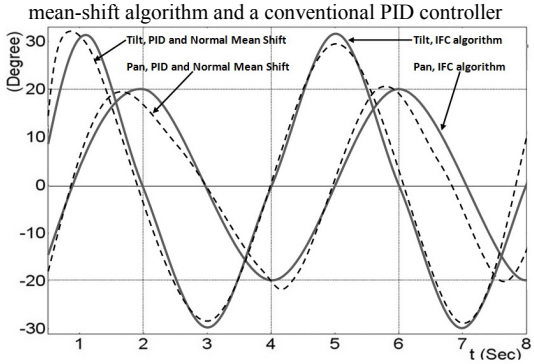

Figure10. Comparison the operation of the IFC and the operation of the normal mean-shift algorithm and a PID controller. The IFC algorithm decreases errors in the active tracker.

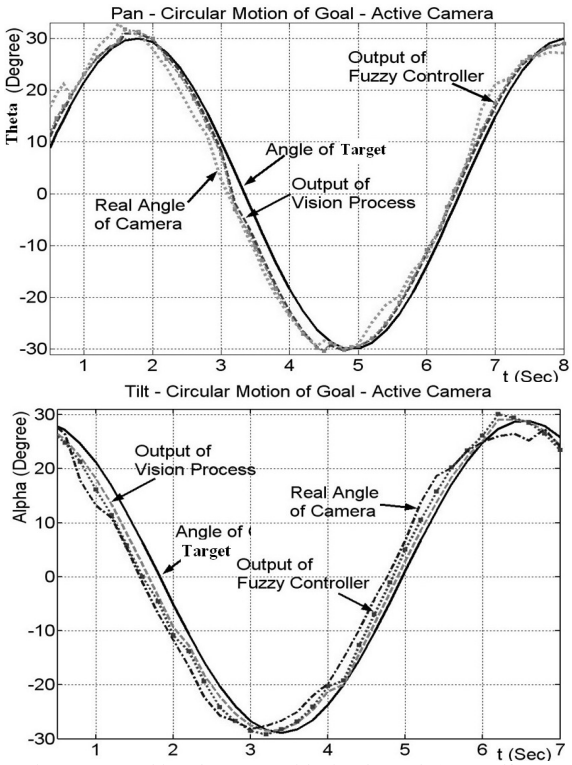

Figure11. Tracking the target with circular path (w=1rad/sec).

In the second experiment, a person with a constant velocity, moves around the camera and camera track his face. Figure 12, 13 shows the results of this experiment in the same way.

Figure13. The pictures show the operation of the vision processor box too

Figure 14 Shows the result of the tracking the faraway targets with high velocity

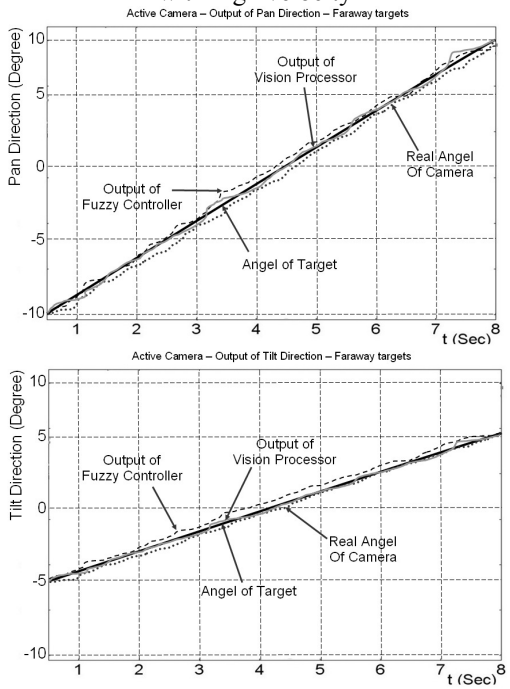

Figure 14. Tracking the faraway targets with high velocity

I. CONCLUSION

A new combination of vision and control have been presented with a new algorithm allowing a robust and accurate detection of moving objects for a small cost in memory consumption and computational complexity that allow us to use ordinary computers and cameras instead of expensive and high performance computers and vision facilities. Although the set faces to delays especially in vision process box and connections (LAN), the IFC usually solves delay problems. In addition, considering the operation of the normal mean-shift algorithm and a conventional PID controller shows that the IFC has better performance. In fact, using the IFC helps the active tracker to miss targets less than the active cameras which use the normal mean-shift algorithm and a conventional PID controller. Undoubtedly, the set can improve by using of more fuzzy rules sets for more different situations and objects.

***Abstract*—In this paper, an interval type 2 (IT2) fuzzy entropy based approach is used to compute optimum thresholds for multistage gray scale image segmentation. By finding the maximum IT2 fuzzy entropy of the gray scale image, the optimum thresholds are computed. A termination criterion for multistage segmentation is also proposed based on the range of computed entropy values of the images. Several experimental results are shown to demonstrate the performance of our proposed algorithm which outperforms type 1 (T1) fuzzy based methods.**

Keywords—Interval type2 (IT2) fuzzy sets, Footprint of uncertainty (FOU), Fuzzy membership function, Ultrafuzziness.

I. INTRODUCTION

Finding the optimal threshold is a critical step in gray scale image segmentation. Gray scale image segmentation is based on the pixel properties of the image and determining the appropriate threshold can be very challenging. In literature there exist several threshold based image segmentation techniques. According to the information exploitation, threshold techniques have been categorized as histogram shape based, clustering based, entropy based, object attribute based and spatial based [1]-[8].

Several fuzzy based methods have also been proposed. Those methods include fuzzy clustering for finding the optimal threshold and maximum entropy gray level computation to distinguish between the foreground and background [4], [9], [10]. Optimal threshold for separation of the background and object exists at the deepest valley of bimodal histogram of the image [11]. However, it is difficult to obtain optimal threshold when distribution of histogram is complex. To cope with this problem, fuzzy entropy was proposed to quantify the vagueness in images [12]. Huang *et al*. introduced a fuzzy approach to the Shannon entropy and concluded that the gray level point where the fuzziness is minimum; is the optimal threshold [13]. Information theoretic approach was used to maximize (minimize) the image information on basis of fuzziness or crispness [14]. This approach is very simple and commonly used for finding the optimal threshold. Rhee *et al*. proposed a numerical method to quickly locate the optimal threshold using fuzzy sets [15].

Type 2 fuzzy sets have been shown to better handle uncertainties than conventional type 1 fuzzy sets [16]. The ability of type 2 fuzzy sets to represent and manage the uncertainty that exists in a fuzzy set allows us to model various uncertainties, which cannot be appropriately managed by type 1 fuzzy sets [17]. Tizhoosh introduced a threshold technique based on type 2 fuzzy sets (i.e., ultrafuzzy sets) [18]. In this paper, we address two problems associated with automatic multilevel image segmentation of gray level images. The first problem is to calculate optimal threshold for segmentation. In doing so, we propose a new segmentation method that incorporates interval type 2 (IT2) fuzzy sets. This is achieved by modeling Gaussian interval type 2 (IT2) fuzzy membership functions using embedded type2 fuzziness [19]. Our goal is to decide whether a pixel belongs to the background or foreground. In this case, measurements of uncertainty can be considered as entropy, index of fuzziness and index of non fuzziness. We obtain the optimal threshold by maximizing the amount of ultrafuzziness. A membership value is then assigned to each pixel depending on its distance from the background and foreground center using some parameterized type 1 fuzzy membership function. Based on the membership values we find the threshold by maximizing the index of ultrafuzziness. The second one is to determine the optimum number of thresholds for an image in the segmentation process. Theoretically, there are as many objects in a gray level image as there are gray levels present in the image, but practically it is very difficult to segment it based on the relevant information present. Furthermore, we propose a termination criterion, which calculates and segments objects based on image entropy information. The concept of this termination criterion is based on segmenting the image in different levels using a tree structure and there is no restriction on the number of objects to be segmented.

The remainder of this paper is organized as follows. Section II contains the brief background of IT2 fuzzy sets and membership function generation used in thresholding. In Section III, our proposed segmentation algorithm and termination criterion are discussed. In Section IV, experimental results and discussion for bimodal and multi stage image segmentation are presented to show the effectiveness of our proposed method. Finally, Section V gives the conclusions.

II. BACKGROUND

A. Interval Type 2 Fuzzy sets (IT2 FS)

When we represent uncertainty for a fuzzy set with an interval type 2 fuzzy set, the primary membership J_x' of a

*Worked at Hanyang University as Research Intern

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

sample x' can be represented as a membership interval with all secondary grades of the primary memberships equaling to one [20]. We define this interval as the footprint of uncertainty (FOU).

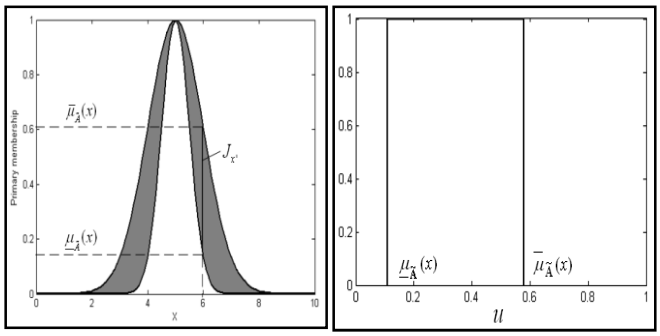
An interval type 2 fuzzy set $\tilde{\mathbf{A}}$ can be represented as

$$\tilde{\mathbf{A}} = \left\{ \left((\mathbf{x}, u), \mu_{\tilde{\mathbf{A}}}(\mathbf{x}, u) \right) \mid \forall \mathbf{x} \in \mathbf{A}, \forall u \in J_{\mathbf{x}} \subseteq [0,1], \mu_{\tilde{\mathbf{A}}}(\mathbf{x}, u) = 1 \right\} \quad (1)$$

Fig. 1 illustrates an example of an interval type 2 fuzzy set where the gray shaded region indicates the FOU. In the figure, the membership value for a 1-dimensional sample x' is represented by the interval between upper ($\overline{\mu}_{\tilde{A}}(x')$) and lower ($\underline{\mu}_{\tilde{A}}(x')$) membership [20]. Therefore, each x' has a primary membership interval as

$$J_{x'} = \left[\underline{\mu}_{\tilde{A}}(x'), \overline{\mu}_{\tilde{A}}(x') \right], \quad (2)$$

and the vertical slice of x' is shown in Fig. 1(b), where the secondary grade for the primary membership of each x' equals one, according to the property of interval type-2 fuzzy sets.



(a) (b)

Fig. 1. Illustration of an interval type-2 fuzzy set: (a) interval type-2 fuzzy set (b) vertical slice on x'.

B. Membership Function Generation

Our main concern of this research is to see whether IT2 fuzzy sets can properly handle uncertainties in comparison to T1 and non fuzzy techniques. Fuzziness depends upon the choice of membership function. Fig. 2 shows examples of membership functions used for measurement of fuzziness in an image. In this paper, we consider Gaussian membership functions (see Fig. 3) and model IT2 membership functions using linguistic hedges (see Fig. 4). Existing methods also used linguistic hedges to create IT2 fuzzy membership functions [21], [22]. The linguistic hedges were obtained by conducting experiments to create the FOU, where the values of linguistic hedges depend on statistical properties of the histogram. It is observed that different membership functions exhibit different segmentation results depending upon the gray level distribution of an image.

Let I denotes an image of size $M \times N$ having L numbers of gray levels and $i(x,y)$ is the gray level of pixel at (x,y) in I. Let $\mu_I(i(x,y))$ denotes the membership value of pixel $i(x,y)$ in image I, then we can define fuzzy image set as

$$I = \{ i(x,y), \mu_I(i(x,y)) \}, \quad (3)$$

where $0 \le \mu_I(i(x,y)) \le 1, \quad x = 0,...,M-1$ and $y = 0,...,N-1$.

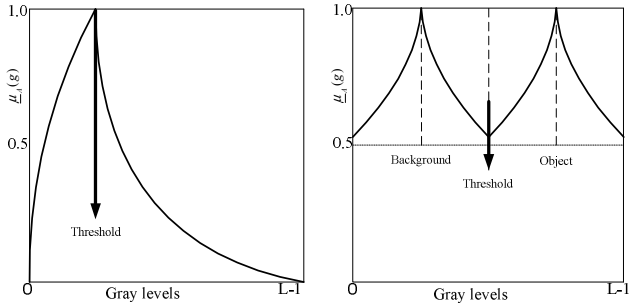
Let $h(g)$ denotes the histogram of an image I. For a given threshold value T, the average levels (center) of the background and object, represented by μ_0 and μ_1, respectively, can be calculated by (4) and (5).

$$\mu_0 = \sum_{g=0}^{T} g\,h(g) \Big/ \sum_{g=0}^{T} h(g) \quad \text{if} \quad i(x,y) \le T \quad (4)$$

and

$$\mu_1 = \sum_{g=T+1}^{L-1} g\,h(g) \Big/ \sum_{g=T+1}^{L-1} h(g) \quad \text{if} \quad i(x,y) > T, \quad (5)$$

The following definitions of fuzziness (entropy) were used to construct type 1 and type 2 fuzzy membership functions [19].



(a) (b)

Fig.2. Two types of membership functions (a) proposed by Tizhoosh .(b) Proposed by Huang .

Definition 1: A general fuzziness measure of a type 1 fuzzy set I, $f(I)$, can be defined as

$$f(I) = k\left(\sum_{i=1}^{N} q(\mu_I(i(x,y)))\right), \quad (6)$$

where k is monotonically increasing function from R^+ to R^+ and q:[0,1]→ R^+ is a function associated with each $i(x,y)$. N is the total number of elements in I. Additionally,

(1) $q(0) = q(1) = 0$;
(2) $q(0.5)$ is a unique maximum of q;
(3) q must be monotonically increasing on [0,0.5] and monotonically decreasing on [0.5,1].

Every pixel in input image should belong to either background or object to some degree of membership depending upon the gray level values.

The type 1 fuzzy membership function $\mu_l(g)$, g is the gray level, is defined as

$$\mu_I(g)=\begin{cases}1.5-\dfrac{1}{1+e^{-\frac{1}{2}\left(\frac{g-\mu_0}{\sigma}\right)^2}} & \text{if } g_{\min}\le g\le T\\ 1.5-\dfrac{1}{1+e^{-\frac{1}{2}\left(\frac{g-\mu_1}{\sigma}\right)^2}} & \text{if } g_{\max}\ge g> T,\\ 0 & \text{otherwise}\end{cases} \tag{7}$$

where $\sigma = |g_{max}-g_{min}|/2\log(1/TOL)$ is the standard deviation and TOL is suitably selected as 0.01. The minimum and maximum occurring non zero gray levels in an image I are denoted as g_{min} and g_{max}, respectively.

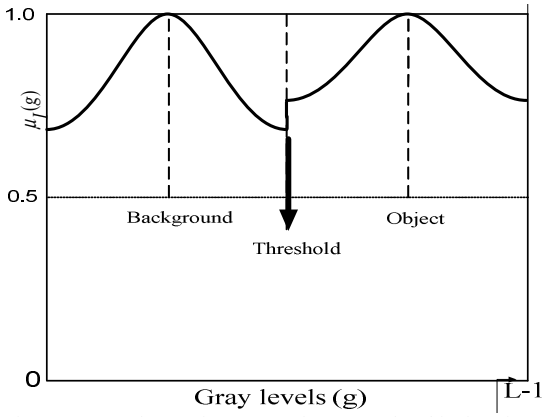


Fig.3. Proposed Gaussian Type 1 fuzzy membership function.

Definition 2: The fuzziness definition of an IT2 fuzzy set $F_{\tilde{A}}$ is the union of the fuzziness of all its embedded type 1 fuzzy sets $\mu_I(g)$, i.e.

$$F_{\tilde{A}} \equiv \bigcup_{\forall \mu_I(g)} f(\mu_i(g)) = [f_l(\tilde{A}), f_r(\tilde{A})], \tag{8}$$

where $f_l(\tilde{A})$ and $f_r(\tilde{A})$ are the minimum and maximum of fuzziness for all $\mu_I(g)$, i.e.

$$f_l(\tilde{A}) = \min_{\forall \mu_I(g)} f(\mu_I(g)) \tag{9}$$

and

$$f_r(\tilde{A}) = \max_{\forall \mu_I(g)} f(\mu_I(g)), \tag{10}$$

Here we provide a simple proof to show that our proposed IT2 MF shown in Fig. 4 follows the above definition. For that we need to show that

$$f_l(\tilde{A}) = \bar{\mu}(g) \tag{11}$$

and

$$f_r(\tilde{A}) = \begin{cases}\underline{\mu}(g); 0.5 \notin [\underline{\mu}(g), \bar{\mu}(g)]\\ 0.5 \text{ otherwise}\end{cases}, \tag{12}$$

Proof: According to definition 1, the fuzziness of a particular gray level g is determined by its deviation from 0.5, the value where it is maximally fuzzy. Membership values that approach 0 or 1 become less fuzzy. The minimum of fuzziness $f_l(\tilde{A})$ is achieved when every value $\mu_I(g)$ is as far away as possible from 0.5 and is satisfied by $\bar{\mu}(g)$ for all gray levels in (11). Similarly, $f_r(\tilde{A})$ is achieved when every $\mu_I(g)$ is as close as possible to 0.5 and is satisfied by $\underline{\mu}(g)$ for all gray levels. When $0.5 \in [\underline{\mu}(g), \bar{\mu}(g)]$, we set $f_r(\tilde{A}) = 0.5$. Therefore, (12) is satisfied.

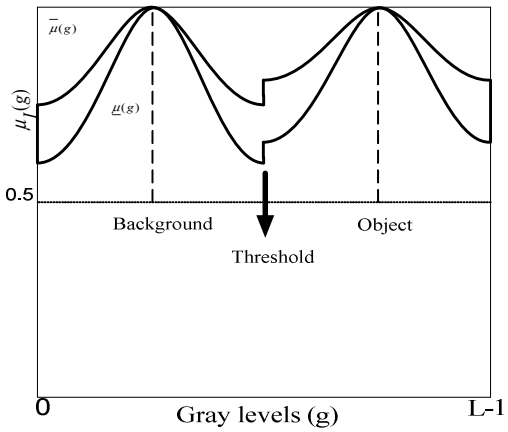

Fig. 4. Modified IT2 modeling of proposed membership function

The upper and lower membership degrees $\bar{\mu}(g)$ and $\underline{\mu}(g)$ can be obtained by linguistic hedges such as deaccentuation and accentuation

$$\bar{\mu}(g) = [\bar{\mu}(g)]^{1/\alpha} \tag{13}$$

And

$$\underline{\mu}(g) = [\underline{\mu}(g)]^{\alpha}, \tag{14}$$

where $\alpha \in (1,2]$[18].

A measure for IT2 ultrafuzziness can be modified for an image as follows

$$\tilde{\gamma}(\tilde{A}) = \frac{1}{MN}\sum_{g=0}^{L-1} h(g)[\bar{\mu}(g) - \underline{\mu}(g)], \tag{15}$$

where h(g) is the histogram of image I [23].

The measure of ultrafuzziness $\tilde{\gamma}(\tilde{A})$ should satisfy following four conditions [24]

(1) *Minimum ultrafuzziness:* $\tilde{\gamma}(\tilde{A}) = 0$ if $\mu_I(g)$ is a type 1 fuzzy set $\forall g \in X\ \bar{\mu}(g) = \underline{\mu}(g)$

(2) *Equal ultrafuzziness:* $\tilde{\gamma}(\tilde{A}) = \tilde{\gamma}(\tilde{\tilde{A}})$

(3) *Reduced ultrafuzziness:* $\tilde{\gamma}(\tilde{A}) \ge \tilde{\gamma}(\tilde{A}')$ if $\tilde{A}'$ is a crisper version of $\tilde{A}$

(4) *Maximum ultrafuzziness:* $\tilde{\gamma}(\tilde{A}) = 1$ if
$\forall g \in X \ \bar{\mu}(g) - \underline{\mu}(g) = 1$

When the ultrafuzziness measure for each gray level is computed, these results in a bell shaped curve [15]. We now need to find the gray level that corresponds to the maximum ultrafuzziness (i.e., optimum gray level g_{opt}).

III. PROPOSED ALGORITHM

Following are the steps involved to describe our proposed multilevel algorithm that includes a termination criterion.

Step 1 *Compute Ultrafuzziness*
Compute IT2 fuzzy entropy of input gray scale image at each gray level using (15) as shown in Fig. 5.

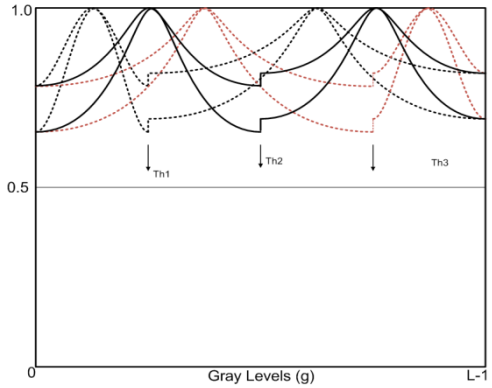

Fig. 5. IT2 MF shifted over gray level histogram range to find maximum fuzziness gray level point. (Shown for proposed Gaussian Membership Function)

Step 2 *Selecting Optimum Threshold*
Compute optimum threshold gray level g_{opt} at which the ultrafuzziness is maximized by selecting the gray level corresponding to the minimum of the computed entropy curve in the interval.

Step 3 *Extensions to Multilevel Thresholding*:
Background and foreground threshold images are obtained based on g_{opt} obtained in Step 2. The foreground may have more than one significant objects and an iterative segmentation approach can be applied to separate foreground into two or more regions by computing another g_{opt} (as in Step 2) in the sections of histogram, obtained after each level of segmentation. For determining the number of times we need to compute threshold for a given image, we use a termination criterion based on the shape of entropy curve.

Step 4 *Termination Criterion*
The termination criterion used in our experiments is obtained from the entropy values computed for a particular section of the histogram during the multilevel threshold procedure. The experiments on the synthetic images show that the thresholded regions of the image have reduced the ultrafuzziness. Since the entropy curve shows the overall ultrafuzziness measure trend for the entire image or sub images, we introduce the termination criterion factor τ as

$$\tau = \frac{\Delta E^{(i)}}{\Psi^{(i)}} \times 255, \qquad (16)$$

where $\Delta E^{(i)}$ denotes the total number of pixels and $\Psi^{(i)} = E_{\max} - E_{\min}$ corresponds to the section of the histogram obtained at the i^{th} level of thresholding.

We start our termination algorithm by segmenting the original image and observing the τ-values for the section of original histogram that is obtained at each level of thresholding. For each level, we compare the current τ-value with the τ-value of the previous level. If we observe saturation in the τ-value in a particular node of a segmenting tree as shown in Fig.6, we stop branching from that particular node. This process is continued until we reach a level where all the possible paths become saturated.

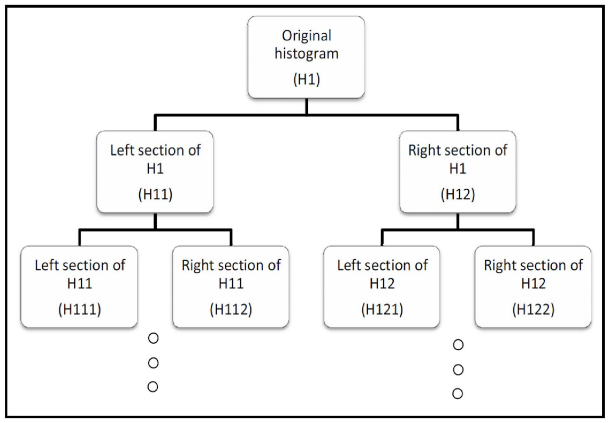

Fig.6. The numbering nomenclature that is used to denote different sections of the image histogram constructed as a tree.

Summary of termination criterion
Let H denotes the histogram of the input image I.
Step 1 Perform the first level segmentation with g_{opt}.
Step 2 Calculate τ as defined in (16) for the first level, based on entropy values.
Step 3 Create right and left histogram sections H_R and H_L about g_{opt} of image histogram H.
Step 4 Calculate τ_r and τ_l , where τ_r and τ_l are τ-values for right and left sections of histogram H.
Step 5 Compare τ_r and τ_l for the i^{th} level segmentation with τ-value of parent histogram H for the $(i-1)^{th}$ threshold.
Step 6 **IF** abs(τ_r-τ)< *TOL* **THEN** Stop thresholding H_R
ELSE Assign H_R as H and return to Step 3
IF abs(τ_l-τ)<*TOL* **THEN** Stop thresholding H_L
ELSE Assign H_R as H and return to Step 3

The above procedure automatically calculates the number of significant objects present in the input image. The tolerance value considered for our experiments is 0.01.

IV. EXPERIMENTAL RESULTS

In this section, experimental results are presented to illustrate the effectiveness of our proposed algorithm. We have

used Gaussian Membership function as our choice of parameterized function as described in Section II.B. The input images used in our experiments are shown in Fig.7.

The results of IT2 fuzzy based segmentation are presented in Fig. 8, 9, and 10. Segmented regions are shown with different gray levels. Performance comparison of type 1 and IT2 approaches have been performed by using ground truth image (mask). In general, to evaluate and compare image segmentation algorithms, masks are visually generated by different subjects as in [18] and [25]. Our masks follow this method and have already been used in [26]. A measure of performance η can be used to compare the results for a particular threshold stage as

$$\eta = 100 \times \frac{|M_1 \cap I_1| + \ldots + |M_n \cap I_n|}{|I_1| + \ldots + |I_n|}, \tag{17}$$

where, I_i and M_i denote the i^{th} class pixels in the original image and mask, respectively, after n multilevel threshold levels.

Fig. 8 shows that the g_{opt} obtained using the IT2 approach gives us better results than the T1 approach. In Table I optimal threshold g_{opt} for type 1 and IT2 fuzzy entropies for some images along with comparison of performances in percentage are listed. Table II shows multilevel threshold results in terms of g_{opt}. The number of threshold levels is determined by the proposed termination criterion. In Table V, the comparison of results obtained by using two different membership functions is shown.

It is to be noted that our proposed algorithm is different from Tizhoosh algorithm in respect to the MF generation method. We have compared our algorithm results with Tizhoosh results and concluded that our proposed MF gives satisfactory results. The second major contribution is automatic selection of number of thresholds based on the information of the IT2 fuzziness of the given image.

Results of Termination Criterion:

Experiments on a synthetic image

Fig.11 shows a synthetically generated image. The entropy curves are also shown along with the segmented images. We conducted experiments on the synthetic image to illustrate our termination criterion, which is based on the normalized range of entropy of the image. The normalization is performed with respect to the number of pixels present in the region of image that corresponds to the subinterval of interest in the histogram.

From Table III, we can observe that the τ-value decreases as the information in the subinterval decreases. We can utilize this information to determine the termination point of the segmentation process with the optimum threshold. We normalize with respect to the number of pixels since it performs better than normalizing with the gray levels. We define the images produced after 3 levels of segmentation in all possible ways, as shown in Fig.11. The experiments performed using synthetic image show that the segmentation steps that should be taken on the basis of above criterion are: 1, 2 and 5 as shown in Table VI.

The results of the termination criterion for the s2 real image are presented in Table IV and we can observe the validity of our termination criterion.

To calculate the efficiency of our multilevel proposed scheme we have calculated the recognition rate based on the masks shown in Fig.12. For this, Gaussian MF and Tizhoosh's MF using linguistic hedges are compared. The results are presented in Table V. The results show that using linguistic hedges from the histograms give desirable results.

V. CONLUSION

We have successfully implemented IT2 fuzzy entropy based image segmentation by incorporating Gaussian membership functions. Our proposed algorithm performs multistage image segmentation successfully by using a termination criterion, which is based on the range of entropy values for a particular image and its thresholded sub-images. The experimental results show that the termination criterion along with Gaussian MF can be effectively used for thresholding of gray scale images with an improved recognition rate. Our future work is focused on a fast and more robust method. Moreover we are currently working on computing the value of linguistic hedges automatically based on the statistical properties of the image histogram.

***Abstract*—A navigation system of a mobile robot in an uncertain environment is one of a popular research area. There are both static and dynamic obstacles in an uncertain environment. If a robot finds a static obstacle, it can select a safe path very easily. However, a dynamic obstacle can move very randomly in the global map. Hence, in this paper, we propose a navigation system in an uncertain environment focusing on dynamic obstacles for a mobile robot. The future position of a dynamic obstacle is modeled using a fuzzy vector. The dangerous region of that obstacle is then computed. Then the free road candidates are computed based on those dangerous regions found. Then the best free road is selected. Finally, the interval type-2 fuzzy logic system is utilized to compute the velocity and angular velocity of a mobile robot. The experiment results show that our navigation system worked in an uncertain environment, i.e., an environment with an obstacle with stable velocity and angular velocity, an environment with an obstacle with random velocity, and an environment with several obstacles with both condition.**

Keywords-interval type-2 fuzzy logic; uncertain environment; fuzzy collision region;collision prediction, obstacle avoidance

I. INTRODUCTION

One of the popular research areas in robot navigation system is to navigate in an unknown or partially unknown dynamic environment. There are both static and dynamic obstacles with uncertainty in position, velocity and angular speed in the dynamic environment. There are several cause of uncertainty, e.g., limitation of the perception system, an incorrect or incomplete data from sensor, and etc. Usually, the navigation algorithm needs to have abilities to avoid collision with obstacles, to fine free road to the goal, and self-localization. A dynamic obstacle position prediction is needed in obstacle avoidance algorithm. To predict future position of a dynamic obstacle, the estimation of the position and velocity of each object are needed.

There are several research works on modeling the motion of the obstacles and dangerous region with uncertainty using a probabilistic distribution [1 – 3]. Then a collision prediction technique is added to improve local path planning algorithm. However, in [1, 3], only linear velocity obstacles are modeled.

In [4, 5], the potential field method is used for obstacle avoidance in robot navigation. The optimal and minimum occupancy path is generated. In [6], the flexible vector field is used for obstacle avoidance. The path found by [6] is shorter than the one from [4]. However, both navigation methods cannot find a good path if there are dynamic obstacles in the scene. In [7], they use radial-basis-function-neural network to predict the movement of the obstacle. However, the movement of the obstacle has to fall into one of the patterns that the system is trained on.

Type-1 fuzzy logic has been used in robotic navigation and control [2, 4, 8 – 11]. Because the system is able to control nonlinear, ill-defined problem and can make a decision under uncertainty environment. Recently, a type-2 fuzzy logic becomes a popular method in controlling a robot [12 – 14] when the fuzzy membership function is hard to define.

This paper presents an autonomous robot navigation algorithm for a mobile robot working in a dynamic environment. In particular, the velocity, angular velocity and position uncertainties of an obstacle are modeled using fuzzy membership functions. Also, the dangerous region computed from future collision region of each obstacle is modeled using a fuzzy vector. After, all dangerous regions are found, the best path is computed. Then the type-2 fuzzy logic system is used to controlled velocity and angular velocity of a robot.

II. INTERVAL TYPE-2 FUZZY LOGIC SYSTEMS

In interval type-2 fuzzy logic system [15], the crisps inputs are mapped into type-2 fuzzy singleton shown in fig. 1. The upper ($\overline{f}$) and lower ($\underline{f}$) membership function is computed. Suppose there are M rules and there are two inputs and one output for each rule. Each rule is in the form of: "If x_1 is F_1 and x_2 is F_2 then y is G" where F_1, F_2 and G are interval type-2 fuzzy sets in linguistic terms of antecedents and consequent, respectively. The minimum t-norm is used to combine the upper and lower membership values of antecedents as shown in Fig. 2 whereas the maximum t-conorm is utilized to aggregate outputs from all rules that are fired. In order to get crisp output, the type reduction and defuzzification is needed.

III. MODEL OF UNCERTAINTY ENVIRONMENT

A. Mobile Robot

In this paper we assume that the robot is a circle with center in (x_R, y_R) when the robot axis is (X_R, Y_R) and Y_R is the orientation of the robot. Whereas the counter clockwise is the positive direction and the angle range of this coordinates is [0, 180]. We assume that the robot can see within the range of *vis*.

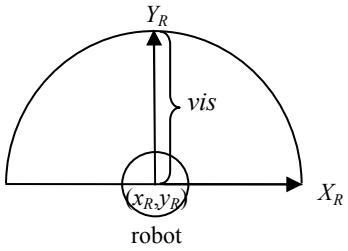

Figure 3. The robot is a circle with centre in (x_R, y_R) and (X_R, Y_R) is Robot axis.

B. Obstacle Modelling

There are both static and dynamic obstacles in an uncertain environment. The mobile robot moves through the environment with its perception setting. In real environment, the position of a static obstacle does not change. We directly use information from the perception system. Hence, the dangerous region in this case is the position of the static obstacle. But dynamic obstacle can change its position with a random move. Therefore, a fuzzy membership function is used to describe the uncertainty in position, velocity, and angular velocity of dynamic obstacles. For simplicity, we assume that the mobile robot can move faster than a dynamic obstacle in this environment. We also assume that the shape of each obstacle is circular. Fig. 4 shows a mobile robot moving in a dynamic environment and a dynamic obstacle *i* is detected by this robot. The dangerous region is the predicted collision region in the future.

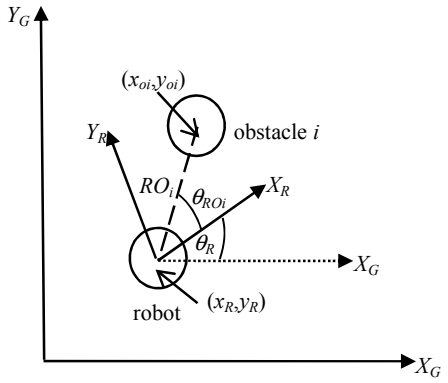

Figure 4. A dynamic obstacle i is detected

To predict a collision region, we need to estimate the position of a dynamic obstacle. Suppose that the current center of the dynamic obstacle *i* is $(xo_i(t_c), yo_i(t_c))$. It is computed based on the global map (X_G, Y_G) at time t_c. The center point can be expressed as:

$$xo_i(t_c) = x_R(t_c) + RO_i \cos(\theta_R(t_c) + \theta_{ROi}(t_c)) \quad (1)$$

$$yo_i(t_c) = y_R(t_c) + RO_i \sin(\theta_R(t_c) + \theta_{ROi}(t_c)) \quad (2)$$

where RO_i denotes the distance between the center of the obstacle *i* and the robot, θ_{ROi} is the relative angle of its center and the robot and $\theta_R(t_c)$ denotes the orientation angle of the robot relative to the global map at time t_c.

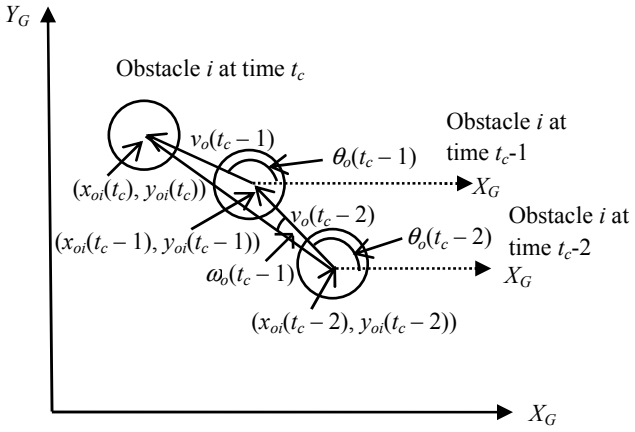

Figure 5. The velocity of obstacle i at time $t_c - 1$ and $t_c - 2$ and angular velocity of obstacle i at time $t_c - 1$

Fig. 5 shows the velocity, angular velocity and angle relative with the global map of a dynamic obstacle *i* at time $t_c - 1$ and $t_c - 2$. If there is an information of the position of a dynamic obstacle at time $t_c - 1$ and t_c, the velocity $v_o(t_c - 1)$ can be calculated. The angular velocity $\omega_o(t_c - 1)$ can be computed if the position of the dynamic obstacle at time $t_c - 2$, $t_c - 1$ and t_c are known.

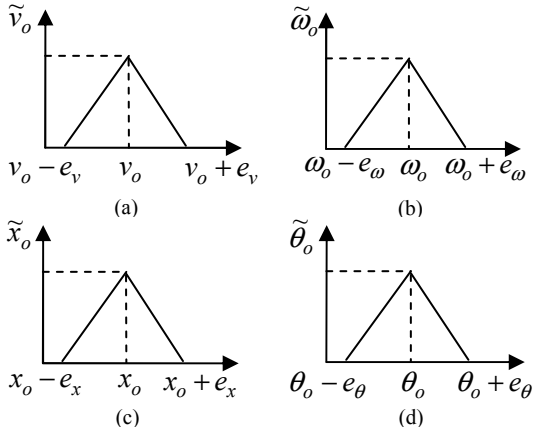

Figure 6. Fuzzy membership function of (a) velocity, (b) angular velocity, (c) position in x or y axis (d) angle relative with global map and

To get the better trend of the direction and magnitude of the velocities, the velocity $v_o(t_c)$ and angular velocity $\omega_o(t_c)$ of dynamic obstacle i are obtained from the calculation of three previous times (t_c-1, t_c-2 and t_c-3), i.e.,

$$v_o(t_c) = \lambda_1 v_o(t_c-1) + \lambda_2 v_o(t_c-2) + \lambda_3 v_o(t_c-3) \quad (3)$$

$$\omega_o(t_c) = \lambda_1 \omega_o(t_c-1) + \lambda_2 \omega_o(t_c-2) + \lambda_3 \omega_o(t_c-3) \quad (4)$$

where λ_1, λ_2 and λ_3 are weight parameters. In the experiment, we set the parameters to 0.5, 0.3 and 0.2 respectively.

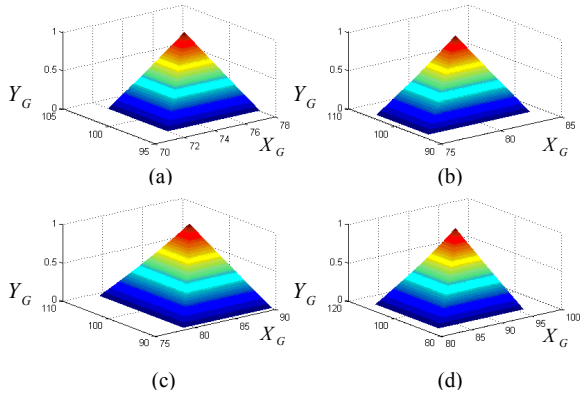

Figure 7. Fuzzy vector ($\tilde{x}_{oi}$, $\tilde{y}_{oi}$) at time (a) t_c+1, (b) t_c+2, (c) t_c+3 and(d) t_c+4

Since there are uncertainty in velocity (v_o) and angular velocity (ω_b) of each dynamic obstacle, we model the uncertainty with triangular fuzzy membership functions for both velocities shown in figures 6(a) and (b). We also model the position and the angle (θ_o) of each dynamic obstacle relative with the global map with triangular fuzzy membership functions shown in figures 6(c) and (d).

The fuzzy sets $\tilde{v}_{oi}, \tilde{\omega}_{oi}$ denote velocity and angular velocity fuzzy sets, whereas $(\tilde{x}_{oi}, \tilde{y}_{oi})$ denotes a position fuzzy vector and $\tilde{\theta}_{oi}$ denotes orientation fuzzy set of dynamic obstacle i. We can computed the position fuzzy vector at time t' by

$$\tilde{x}_{oi}(t') = \tilde{x}_{oi}(t_c) + \left(\tilde{v}_{oi}(t_c)\cos\left(\tilde{\theta}_{oi}(t_c) + \tilde{\omega}_{oi}(t_c)\Delta t\right)\right)\Delta t \quad (5)$$

$$\tilde{y}_{oi}(t') = \tilde{y}_{oi}(t_c) + \left(\tilde{v}_{oi}(t_c)\sin\left(\tilde{\theta}_{oi}(t_c) + \tilde{\omega}_{oi}(t_c)\Delta t\right)\right)\Delta t \quad (6)$$

$$t' = t_c + \Delta t \quad (7)$$

To make the calculation of equations (5) and (6) simple, the lower and upper bound of the support and the core of each fuzzy set is used to compute the lower and upper bound of the support and the core of $\tilde{x}_{oi}$ and $\tilde{y}_{oi}$ in equations (5) and (6). Fig. 7 shows the fuzzy vector ($\tilde{x}_{oi}$, $\tilde{y}_{oi}$) at time t_c + 1 to t_c + 4. Then the dangerous region is computed by extending the support of the fuzzy vector ($\tilde{x}_{oi}$, $\tilde{y}_{oi}$) at time t' with the radius of obstacle i as shown in fig. 8.

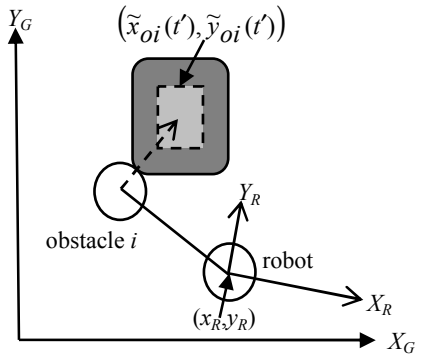

Figure 8. The gray area inside the solid line is the dangerous region whereas the one inside the dashed line is computed from the support of a fuzzy vector ($\tilde{x}_{oi}$, $\tilde{y}_{oi}$).

IV. COLLISION PREDICTION TECHNIQUE

The collision prediction technique is used to predict the dangerous region (a collision region for dynamic obstacles). Since the dangerous region is a fuzzy vector, the predicted collision time is assumed to be a triangular fuzzy set $\tilde{t}_{col}$ with parameter (*Tcola*, *Tcolb*, *Tcolc*) as shown in fig. 9. The lower bound of the support of $\tilde{t}_{col}$ (*Tcola*) is assumed to be the first predicted collision time, whereas the upper bound of the support of that (*Tcolc*) is the last predicted collision time.

The distance between the robot and the obstacle at time $\tilde{t}_{col}$ is

$$\widetilde{disRO}_i(\tilde{t}_{col}) = \sqrt{\left(x_R(\tilde{t}_{col}) - \tilde{x}_{oi}(\tilde{t}_{col})\right)^2 + \left(y_R(\tilde{t}_{col}) - \tilde{y}_{oi}(\tilde{t}_{col})\right)^2} \quad (8)$$

For simplicity, we use the lower bound of the support $(\underline{\tilde{x}}_{oi}, \underline{\tilde{y}}_{oi})$, the core $(\hat{\tilde{x}}_{oi}, \hat{\tilde{y}}_{oi})$ and the upper bound of the support $(\overline{\tilde{x}}_{oi}, \overline{\tilde{y}}_{oi})$ of fuzzy vector ($\tilde{x}_{oi}$, $\tilde{y}_{oi}$) to compute the lower bound ($\underline{\widetilde{disRO}_i}(\tilde{t}_{col})$) and upper bound ($\overline{\widetilde{disRO}_i}(\tilde{t}_{col})$)

of the support and the core ($\widehat{\widetilde{disRO}}_i(\tilde{t}_{col})$) of $\widetilde{disRO}_i(\tilde{t}_{col})$. Hence, the equation (8) will be

$$\widetilde{\widetilde{disRO}}_i(\tilde{t}_{col}) = \sqrt{\left(x_R(\tilde{t}_{col}) - \underline{\tilde{x}}_{oi}(\tilde{t}_{col})\right)^2 + \left(y_R(\tilde{t}_{col}) - \underline{\tilde{y}}_{oi}(\tilde{t}_{col})\right)^2} \quad (9)$$

$$\widehat{\widetilde{disRO}}_i(\tilde{t}_{col}) = \sqrt{\left(x_R(\tilde{t}_{col}) - \hat{\tilde{x}}_{oi}(\tilde{t}_{col})\right)^2 + \left(y_R(\tilde{t}_{col}) - \hat{\tilde{y}}_{oi}(\tilde{t}_{col})\right)^2} \quad (10)$$

$$\underline{\widetilde{disRO}}_i(\tilde{t}_{col}) = \sqrt{\left(x_R(\tilde{t}_{col}) - \overline{\tilde{x}}_{oi}(\tilde{t}_{col})\right)^2 + \left(y_R(\tilde{t}_{col}) - \overline{\tilde{y}}_{oi}(\tilde{t}_{col})\right)^2} \quad (11)$$

Suppose that δ is the shortest distance between the robot and the obstacle. Then, to find $\tilde{t}_{col}$, we can set

$$\widetilde{disRO}_i(\tilde{t}_{col}) = \delta \quad (12)$$

For simplicity, to find *Tcola*, *Tcolb* and *Tcolc* of $\tilde{t}_{col}$, we need to solve equations 13, 14 and 15 respectively with the Leap-frogging Newton's method [16].

$$\left(x_R(\tilde{t}_{col}) - \underline{\tilde{x}}_{oi}(\tilde{t}_{col})\right)^2 + \left(y_R(\tilde{t}_{col}) - \underline{\tilde{y}}_{oi}(\tilde{t}_{col})\right)^2 - \delta^2 = 0 \quad (13)$$

$$\left(x_R(\tilde{t}_{col}) - \hat{\tilde{x}}_{oi}(\tilde{t}_{col})\right)^2 + \left(y_R(\tilde{t}_{col}) - \hat{\tilde{y}}_{oi}(\tilde{t}_{col})\right)^2 - \delta^2 = 0 \quad (14)$$

$$\left(x_R(\tilde{t}_{col}) - \overline{\tilde{x}}_{oi}(\tilde{t}_{col})\right)^2 + \left(y_R(\tilde{t}_{col}) - \overline{\tilde{y}}_{oi}(\tilde{t}_{col})\right)^2 - \delta^2 = 0 \quad (15)$$

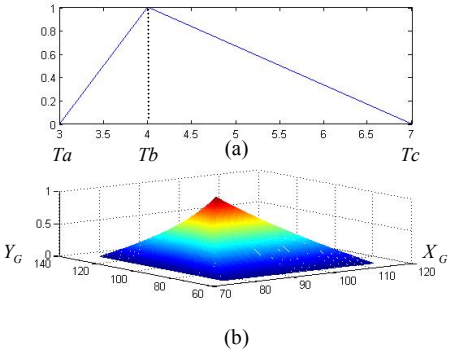

Figure 9. (a) $\widetilde{\Delta t}$ of obstacle *i* (b) the predicted fuzzy vector($\tilde{x}_{oi}$, $\tilde{y}_{oi}$) at time $\tilde{t}_{col}$ of obstacle *i*

Then, we can compute Δt in equation (7). Since $\tilde{t}_{col}$ is a triangular fuzzy set, $\widetilde{\Delta t}$ will be a triangular fuzzy set with parameter (*Ta*, *Tb*, *Tc*) as shown in fig. 9(a). The fuzzy vector ($\widetilde{x}_{oi}$, $\widetilde{y}_{oi}$) at time $\tilde{t}_{col}$ (shown in fig. 9(b)) can be computed from equations (5) and (6). Again, for simplicity, we use the lower bound, the upper bound of the support and the core of the input fuzzy sets to compute the lower bound, the upper bound of the support and the core of $\widetilde{x}_{oi}$ and $\widetilde{y}_{oi}$ in equations (5) and (6).

V. NAVIGATION PLANNING

When all dangerous regions are calculated by collision prediction technique, the robot needs to find the free road that does not intersect with any dangerous regions. In this paper, the finding process is divided into finding the free road candidate (ϕ_{RC}) according to the axis X_R from free sector (all safe regions in global map) and choosing the best free road (ϕ_{RS}) using a costing function.

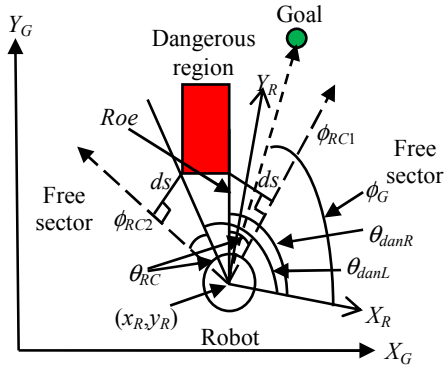

Figure 10. Finding free road candidate when there is 1 obstacle in the path to the goal

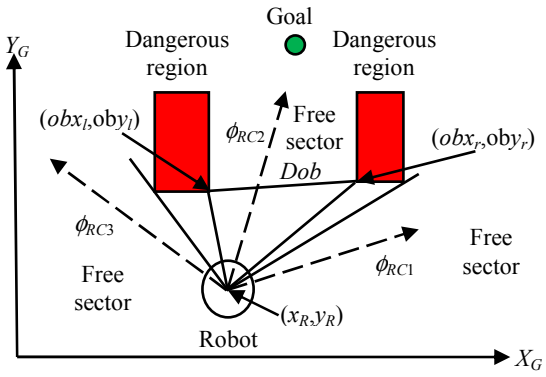

Figure 11. Finding free road candidate when robot moves through a narrow free sector

1) *Finding the free road candidate*

The location of the goal is the important factor in the finding the free road candidate. Hence, this process is as follows

a) If the goal position (ϕ_G) according to the axis X_R is located in the free sector (not in the dangerous region) and there is no collision with any obstacle in between, then $\phi_{RC} = \phi_G$

b) If the goal position (ϕ_G) is not located in the free sector or is inside the free sector and there is a collision with any obstacle in between (shown in fig. 10), then

$$\theta_{RC} = \sin^{-1}\left(\frac{ds}{ROe}\right) \quad (16)$$

where *ds* is the shortest distance between the dangerous region and the choosing path and RO_e is the shortest distance between the dangerous region and the center of the robot. Suppose that

θ_{danR} and θ_{danL} and are the angles from the axis X_R to the right and left boundaries of the dangerous region, respectively. Then we can compute free road candidate on the right (ϕ_{RC1}) and the left (ϕ_{RC2}) free road by

$$\phi_{RC1} = \theta_{danR} - \theta_{RC} \quad (17)$$

$$\phi_{RC2} = \theta_{danL} + \theta_{RC} \quad (18)$$

c) If the path to the goal is in the free sector that is narrow (shown in fig. 11), then we need to compute the movable distance (*Dob*), i.e.,

$$Dob = \sqrt{(obx_l - obx_r)^2 + (oby_l - oby_r)^2} \quad (19)$$

where (obx_l,oby_l) and (obx_r,oby_r) are the left and right boundaries of the left and right dangerous region, respectively. Let the safe width (*Rs*) is bigger than the diameter of the robot, and suppose that *Dob* > *Rs*, then this path is safe. Hence, we can find ϕ_{RC} according to case *a* or *b*.

2) Danger estimation

After the free road candidate ϕ_{RC} is computed and the robot moves following the path ϕ_{RC}, we need to estimate if there is a collision or not. Let $(x_{ro_{near}}, y_{ro_{near}})$ be the center of the nearest dangerous region located in the chosen sector. We can compute $(x_{ro_{near}}, y_{ro_{near}})$ using equations (5) and (6). Let v_R is the velocity of the robot. Then we can compute the position of the robot (x_R, y_R) at time T_{nc} (collision time) using

$$x_R(T_{nc}) = x_R + (v_R \cos(\theta_R + \phi_{RC}))\Delta T_{nc} \quad (20)$$

$$y_R(T_{nc}) = y_R + (v_R \sin(\theta_R + \phi_{RC}))\Delta T_{nc} \quad (21)$$

where ΔT_{nc} is the different time between the current and the collision time. However, T_{nc} is computed using the same method as in section IV. But since we only need this information to estimate the danger in the future of the chosen path, we will use only the core of the nearest dangerous region. Then we can estimate danger (*Dv*) of ϕ_{RC} by

$$Dv(\phi_{RC}) = \begin{cases} 1 & \Delta T_{nc} < T_{safe} \\ \dfrac{T_{ignore} - \Delta T_{nc}}{T_{ignore}} & T_{safe} \le \Delta T_{nc} < T_{ignore} \\ 0 & \Delta T_{nc} \ge T_{ignore} \end{cases} \quad (22)$$

where T_{safe} is the grace period of the stopping time of the robot, T_{ignore} is the threshold of the system.

3) Selection the best free road

The best free road must be the one with the shortest and the safest one. Hence the cost function is

$$COST(\phi_{RC}) = k_1 \cdot \Delta(\phi_{RC}, \phi_G) + k_2(Dv(\phi_{RC})) \quad (23)$$

where $\Delta(\phi_{RC}, \phi_G)$ is the difference between ϕ_{RC} and ϕ_G, k_1 and k_2 are the weight parameters. In the experiment, we set k_1 and k_2 to 0.5 and 1, respectively. Then the best free road ϕ_{RS} is the one that give the lowest $COST(\phi_{RC})$.

VI. DESIGN OF INTERVAL TYPE-2 FUZZY LOGIC

There are several researches on utilizing interval type-2 fuzzy logic as a tool to control mobile robot including the works done by [17 – 19]. Most of those research results show that the intreval type-2 fuzzy logic controller provide better results than type-1 fuzzy logic controller. Hence, in our experiment, we choose to use the interval type-2 fuzzy logic to control our mobile robot.

There are 3 inputs, i.e., D_{angle}, D_v and v_R. D_{angle} is the difference between ϕ_{RS} and Y_R, i.e., $D_{angle} = \Delta(\phi_{RS}, 90)$ as shown in fig.12. There are 2 outputs, i.e., velocity controller parameter (CV_R) and angular velocity controller parameter (CA_R). All of the membership functions utilized in the experiments are manually picked.

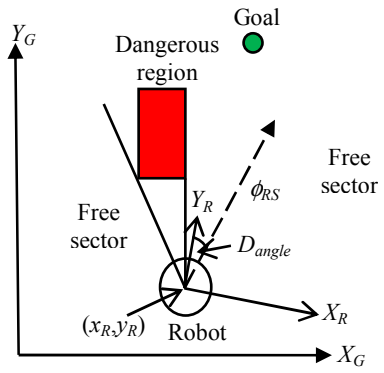

Figure 12. Example of D_{angle}

Figures 13, 14 and 15 show the interval type-2 membership functions of D_{angle}, D_v and v_R. The interval type-2 membership functions of (CV_R) and (CA_R) are shown in figures 16 and 17. The rules used for computing CV_R and CA_R are shown in tables I and II, respectively.

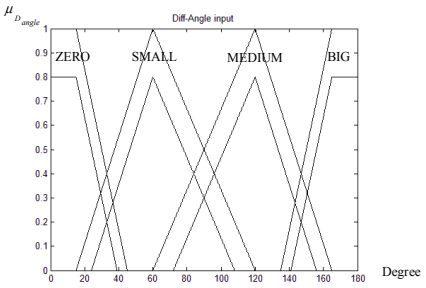

Figure 13. D_{angle} membership functions

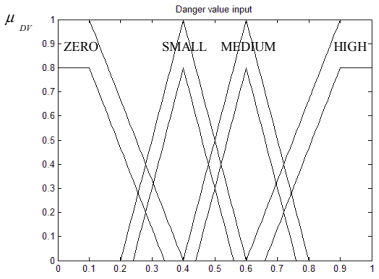

Figure 14. *Dv* membership functions

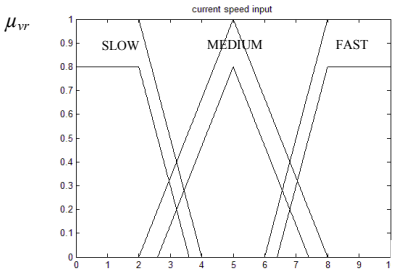

Figure 15. v_R membership functions

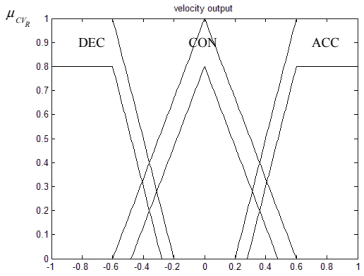

Figure 16. CV_R membership functions

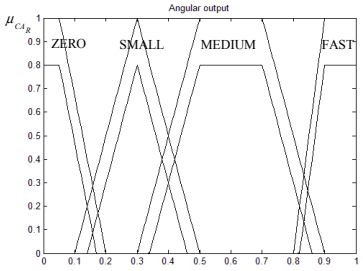

Figure 17. CA_R membership functions

Let ccv_R and cca_R are the defuzzified values of CV_R and CA_R. The velocity and angular velocity of the time $t_c + 1$ is computed by

$$v_R(t_c+1) = v_R(t_c) + ccv_R \cdot \alpha \qquad (24)$$

$$\omega_R(t_c+1) = \begin{cases} cca_R \cdot \omega_{RMAX} & d_{angle} > 0 \\ -cca_R \cdot \omega_{RMAX} & d_{angle} < 0 \end{cases} \qquad (25)$$

where α is the weight parameter and ω_{RMAX} is the maximum angular velocity. Both v_R and ω_R cannot exceed v_{RMAX} and ω_{RMAX}.

TABLE I. FUZZY RULE BASE

VII. SIMULATION RESULTS

In the experiment, we set v_{RMAX} to 10, ω_{RMAX} is set to [-1, 1], and $ccv_R \times \alpha$ is [-5, 5]. The diameters of the robot and each dynamic obstacle are 10, whereas *vis* is set to 75.

A. Unknown dynamic obstacles with stable velocity and angular velocity

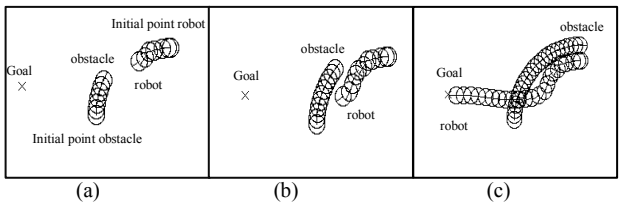

Figure 18. The robot moves to the goal and obstacle moves from bottom to top of the global map (a) both leave from initial, (b) robot decides to avoid obstacle, and (c) robot reaches the goal.

In this scenario, we do not have any information of obstacle. In fig. 18, we set the velocity and angular velocity of the obstacle to 6.3 and – 0.07 radius per time step. Fig. 18(a) shows the robot and obstacle in their starting point and their path. Fig18(b) shows the robot making a decision to avoid the obstacle based on the proposed method. Then the robot moves very fast to the goal once the obstacle is out of sight of the robot (shown in fig. 18(c)).

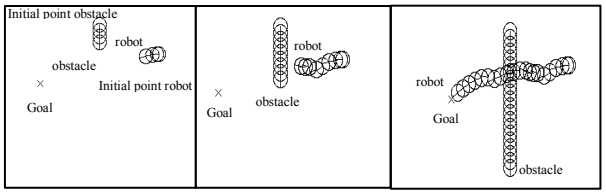

Figure 19. The robot moves to the goal and obstacle moves from top to bottom of the global map (a) both leave from initial, (b) robot decides to avoid obstacle, and (c) robot reaches the goal.

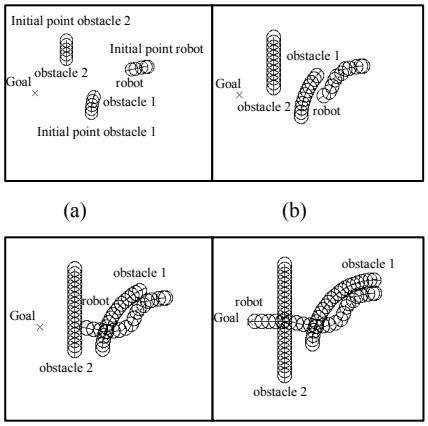

Figure 20. The robot moves to the goal and two obstacles are in the global map (a) robot and obstacles are in the starting point, (b) robot decides to avoid the first obstacle, (c) robot decides to avoid the second obstacle and (d) robot reaches the goal.

Fig. 19 shows the experiment result when the velocity and angular velocity of the obstacle is 7 and 0. Fig. 20 shows the experiment result when there are 2 obstacles with the same setting as in figures 18 and 19.

B. Unknown Dynamic obstacle with unstable velocity and angular velocity

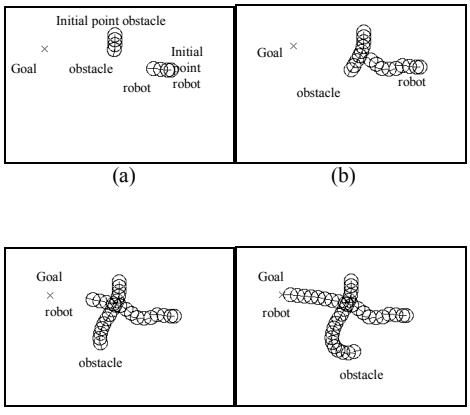

Figure 21. The robot moves to the goal and obstacle moves from top to bottom of the global map (a) robot and obstacles are in the starting point, (b) robot decides to wait for the obstacle to move, (c) the obstacle passes the robot and (d) the robot reaches to goal

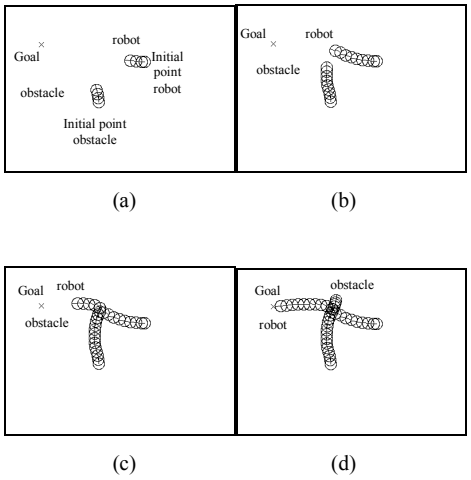

Figure 22. The robot moves to the goal and obstacle moves from bottom to top of the global map (a) robot and obstacles are in the starting point, (b) robot decides to move pass the obstacle, (c) the robot passes the obstacle and (d) the robot reaches to goal

In this experiment, the obstacle moves with random velocity and angular velocity. However, we assume that the robot will move faster than the obstacle. In Fig. 21, the robot decides to wait for the obstacle and then moving towards the goal. Whereas, in Fig. 22, the robot can move pass the obstacle without colliding with the obstacle.

VIII. CONCLUSION

In this work, we propose a navigation system in an uncertain environment (focusing on dynamic obstacle) for a mobile robot. We model the dangerous region for each obstacle by computing it future position fuzzy vector. Then the free road candidates are computed based on those dangerous regions. The best free road is selected based on the shortest and the safest path. Finally the interval type-2 fuzzy logic system is utilized to compute the velocity controller and angular velocity controller of the mobile robot. These parameters are utilized to compute the velocity and angular velocity of the mobile robot. The experiment results show that the mobile robot can find the shortest and safest path in the global map in an uncertain environment, i.e., an environment with an obstacle with stable velocity and angular velocity, an environment with an obstacle with random velocity, and an environment with several obstacles with both condition.

***Abstract*—Interval type-2 fuzzy sets, each of which is characterized by the footprint of uncertainty, are a very useful means to depict the decision information in the process of decision making. In this article, we investigate the decision making problems in which all the information provided by the decision maker is expressed as interval type-2 fuzzy decision matrix where each of the elements is characterized by interval type-2 fuzzy set, and the information about attribute weights is partially known, which may be constructed by various forms. We first utilize the average centroid measure to calculate the average centroid of each attribute value and construct the average centroid matrix of the interval type-2 fuzzy decision matrix. Based on the average centroid matrix and the given attribute weight information, we establish some optimization models to determine the weights of attributes. Furthermore, we develop a procedure to identify the best alternative(s). Finally, we give an illustrative example.**

***Keywords*—Interval type-2 fuzzy sets (IT2 FSs); average centroid matrix; multi-attribute decision making (MADM); incomplete information.**

I. Introduction

Multi-attribute decision making (MADM) problems are widespread in real life decision situations. A MADM problem is to find the most desirable alternative(s) from a set of n feasible alternatives $X = \{x_1, x_2, \ldots, x_n\}$ according to the decision information about attribute weights and attribute values. First of all, the decision maker generally need to determine the importance degrees of a set of m attributes $G = \{g_1, g_2, \ldots, g_m\}$, that is to say, the decision maker need to provide their preference information about attribute weights (for convenience, let the weight vector of attributes be $\omega = (\omega_1, \omega_2, \ldots, \omega_m)^T$, where $\omega_j \geqslant 0, j = 1, 2, \ldots, m$ and $\sum_{j=1}^{m} \omega_j = 1$). In general, the provided attribute weight information may be constructed in the following forms [1], [2], for $i = j$,

1) A weak ranking: $\{\omega_i \geqslant \omega_j\}$;
2) A strict ranking: $\{\omega_i - \omega_j \geqslant \delta_i (> 0)\}$;
3) A ranking with multiples: $\{\omega_i \geqslant \delta_i \omega_j\}, 0 \leqslant \delta_i \leqslant 1$;
4) An interval form: $\{\delta_i \leqslant \omega_i \leqslant \delta_i + \varepsilon_i\}, 0 \leqslant \delta_i < \delta_i + \delta_i \leqslant 1$;
5) A ranking of differences: $\{\omega_i - \omega_j \geqslant \omega_k - \omega_l\}$, for $j \neq k \neq l$.

The estimation of the attribute values plays an important role in MADM. In the process of decision making, the information about attribute values is usually uncertain or fuzzy due to the increasing complexity of the socio-economic environment and the vagueness of inherent subjective nature of human thinking. Many methods have been presented for handling fuzzy MADM problems based on traditional type-1 fuzzy sets (T1 FSs) [3]. Hwang and Yoon [4] presented the technique for order preference by similarity to ideal solution (TOPSIS) method for handling MADM problems. Chen [5] presented a method for handling fuzzy MADM problems based on the similarity measure between T1 FSs. Chen and Hwang [6] presented some methods for handling fuzzy MADM problems. Chen [7] extended the TOPSIS method to present a method to handle group decision-making problems in a fuzzy environment. Chen [8] presented a method to evaluate the rate of aggregative risk in software development using the T1 FS theory in the fuzzy group decision-making environment. Wang and Lin [9] presented a fuzzy multi-criteria group decision-making approach to select configuration items for software development. Li [10] constructed some novel mathematical programming models for fuzzy MADM problems under uncertainty and proposed corresponding solving methods. Wang and Parkan [11] presented a method for handling MADM problems based on the fuzzy preference information of alternatives. Wang and Parkan [12] presented a general MADM approach for integrating subjective preferences and objective information. Yager and Xu [13] presented a continuous ordered weighted geometric operator and its application to decision making. Tsabadze [14] presented a method for fuzzy aggregation based on group expert evaluations. Wang and Chang [15] presented an application of TOPSIS in evaluating initial aircraft training under a fuzzy environment. Wu and Chen [16] presented a maximizing deviation method for group MADM under the linguistic environment. Li [17] developed a compromise ratio methodology for fuzzy multi-attribute group decision making (MAGDM). Hua et al. [18] presented an approach for MADM problems with incomplete information. Fu [19] presented a fuzzy optimization method for multi-criteria decision making. Lin and Wu [20] presented a causal analytical method for group decision-making in the fuzzy environment. Tsai and Wang [21] presented a computing coordination based fuzzy group decision-making method for web service oriented architectures.

Similar to the transition from ordinary sets to T1 FSs [22], when the circumstances are so fuzzy that we have trouble determining the membership grade even as a crisp number

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

in $[0,1]$, we use type-2 fuzzy sets (T2 FSs) [23], [24]. The T2 FSs are now very well established [25] are gaining more and more in popularity [26], [27], [28], [29]. It is known that T2 FSs let us model and minimize the effects of uncertainties in rule-based fuzzy logic systems [22]. The majority of the contributions in the field use interval type-2 fuzzy sets (IT2 FSs) (a particular kind of T2 FSs) which maintain the uncertainty modelling properties of general T2 FSs but reduce the computational efforts that are needed to aggregate them. If we can use IT2 FSs [30] for handling fuzzy decision-making problems, then there is room for more flexibility due to the fact that IT2 FSs provide more flexibility to present uncertainties than traditional T1 FSs. In recent years, some authors have applied the IT2 FS theory to the field of decision making. Wu and Mendel [31], [32] presented a method using the linguistic weighted average and IT2 FSs for handling fuzzy multiple criteria hierarchical group decision-making problems, Wu and Mendel's fuzzy multiple criteria hierarchical group decision making method is to make decisions by means of aggregating the opinions of decision-makers. Wu [33] proposed a novel weighted average as a computing with words engine for MADM, and proposed perceptual reasoning as a computing with words engine for multi-objective decision making. Chen and Lee [34] presented a new method for handling fuzzy multiple criteria hierarchical group decision-making problems based on arithmetic operations and fuzzy preference relations of IT2 FSs. Chen and Lee [35] presented an interval type-2 fuzzy TOPSIS method to handle fuzzy MAGDM problems based on IT2 FSs, and use some examples to illustrate the fuzzy MAGDM process of the proposed method. Chen and Lee [36] presented a new method to handle fuzzy MAGDM problems based on the ranking values and the arithmetic operations of IT2 FSs.

In this paper, we shall focus our attention on the issue of MADM under interval type-2 fuzzy environment where all the information provided by the decision makers is characterized by IT2 FSs and the information about the attribute weights is partially known, which may be constructed by the various forms described above. To do that, the remainder of this paper is organized as follows. In Section II, we give a review of basic concepts and average centroids related to IT2 FSs. Section III presents the considered problem and utilizes the average centroid measure to calculate the average centroid of each attribute value and constructs the average centroid matrix of the interval type-2 fuzzy decision matrix. Based on the average centroid matrix and the given attribute weight information, we establish some optimization models to determine the weights of attributes. Section IV develops an approach to MADM under interval type-2 fuzzy environment, the approach uses the obtained attribute weights and the average centroid matrix of the interval type-2 fuzzy decision matrix to get the overall average centroids of alternatives and the ranking of all the given alternatives. Section V provides a practical example to illustrate the developed approach, and finally, we conclude the paper in Section VI.

II. Preliminaries

Definition 1. [23], [24] A T2 FS $\tilde{A}$ in the universe of discourse X can be represented by a type-2 membership function $\mu_{\tilde{A}}$, shown as follows:

$$\tilde{A} = \{((x,u), \mu_{\tilde{A}}(x,u)) \mid \forall x \in X, \forall u \in J_x \subseteq [0,1]\} \quad (1)$$

where $0 \leqslant \mu_{\tilde{A}}(x,u) \leqslant 1$. The T2 FS $\tilde{A}$ also can be represented as follows:

$$\begin{aligned}\tilde{A} &= \int_{x\in X}\int_{u\in J_x} \mu_{\tilde{A}}(x,u)/(x,u) \\ &= \int_{x\in X}\left[\int_{u\in J_x} \mu_{\tilde{A}}(x,u)/u\right]\Big/x \end{aligned} \quad (2)$$

where x is the primary variable, $J_x \subseteq [0,1]$ is the primary membership of x, u is the secondary variable, and $\int_{u\in J_x} \mu_{\tilde{A}}(x,u)/u$ is the secondary membership function at x. $\int\int$ denotes the union over all admissible x and u. For discrete universes of discourse, $\int$ is replaced by $\sum$.

Definition 2. [30] Let $\tilde{A}$ be a T2 FS in the universe of discourse X represented by the type-2 membership function $\mu_{\tilde{A}}(x,u)$. If all $\mu_{\tilde{A}}(x,u) = 1$, then $\tilde{A}$ is called an IT2 FS. An IT2 FS can be regarded as a special case of a T2 FS, shown as follows:

$$\tilde{A} = \int_{x\in X}\int_{u\in J_x} 1/(x,u) = \int_{x\in X}\left[\int_{u\in J_x} 1/u\right]\Big/x \quad (3)$$

where x is the primary variable, $J_x \subseteq [0,1]$ is the primary membership of x, u is the secondary variable, and $\int_{u\in J_x} 1/u$ is the secondary membership function at x.

Note that (3) means $\tilde{A} : X \to \{[a,b] : 0 \leqslant a \leqslant b \leqslant 1\}$. Uncertainty about $\tilde{A}$ is conveyed by the union of all of the primary memberships, called the footprint of uncertainty of $\tilde{A}$ (FOU($\tilde{A}$)), i.e.,

$$\mathrm{FOU}(\tilde{A}) = \bigcup_{x\in X} J_x \quad (4)$$

In this paper, we present a method to use IT2 FSs for handling fuzzy MADM problems, where the reference points and the heights of the upper and the lower membership functions of IT2 FSs are used to characterize IT2 FSs. A trapezoidal IT2 FS $\tilde{A}$ is shown in Fig. 1. The FOU is shown as the shaded region. It is bounded by an upper membership function (UMF) and a lower membership function (LMF), both of which are T1 FSs.

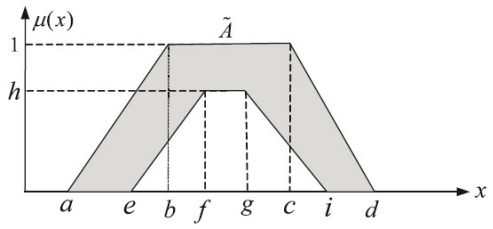

Fig. 1. The nine points to determine a FOU. (a,b,c,d) determines a normal trapezoidal UMF, (e,f,g,i,h) determines a trapezoidal LMF with height h.

Definition 3. [37] The centroid $C(\tilde{A})$ of an IT2 FS $\tilde{A}$ is the union of the centroids of all its embedded T1 FSs A_e, i.e.,

$$C(\tilde{A}) \equiv \bigcup_{\forall A_e} c(A_e) = [c_l(\tilde{A}), c_u(\tilde{A})], \tag{5}$$

where $\bigcup$ is the union operation, and

$$c_l(\tilde{A}) = \min_{\forall A_e} c(A_e) \tag{6}$$

$$c_u(\tilde{A}) = \max_{\forall A_e} c(A_e) \tag{7}$$

$$c(A_e) = \frac{\sum_{i=1}^{N} x_i \mu_{A_e}(x_i)}{\sum_{i=1}^{N} \mu_{A_e}(x_i)} \tag{8}$$

It has been shown [38], [37], [39] that $c_l(\tilde{A})$ and $c_u(\tilde{A})$ can be expressed as

$$c_l(\tilde{A}) = \frac{\sum_{i=1}^{L} x_i \overline{\mu}_{\tilde{A}}(x_i) + \sum_{i=L+1}^{N} x_i \underline{\mu}_{\tilde{A}}(x_i)}{\sum_{i=1}^{L} \overline{\mu}_{\tilde{A}}(x_i) + \sum_{i=L+1}^{N} \underline{\mu}_{\tilde{A}}(x_i)} \tag{9}$$

$$c_u(\tilde{A}) = \frac{\sum_{i=1}^{R} x_i \underline{\mu}_{\tilde{A}}(x_i) + \sum_{i=R+1}^{N} x_i \overline{\mu}_{\tilde{A}}(x_i)}{\sum_{i=1}^{R} \underline{\mu}_{\tilde{A}}(x_i) + \sum_{i=R+1}^{N} \overline{\mu}_{\tilde{A}}(x_i)} \tag{10}$$

Switch points L and R, as well as $c_l(\tilde{A})$ and $c_u(\tilde{A})$ are computed by iterative Karnik-Mendel Algorithms [38], [37], [40].

Centroid-based ranking method: First compute the average centroid for each IT2 FS $\tilde{A}_i$:

$$c(\tilde{A}_i) = \frac{c_l(\tilde{A}_i) + c_u(\tilde{A}_i)}{2}, i = 1, 2, \ldots, N \tag{11}$$

and then sort $c(\tilde{A}_i)$ to obtain the rank of $\tilde{A}_i$.

The ranking method can be viewed as a generalization of Yager's first ranking method for T1 FSs [41] to IT2 FSs.

III. Some models for determining attribute weight

For a MADM problem, let $X = \{x_1, x_2, \ldots, x_n\}$ be a finite set of alternatives and $G = \{g_1, g_2, \ldots, g_m\}$ be a finite set of attributes, and suppose that the decision maker provides the attribute weight information expressed in the forms $1) - 5)$ (see Section I). For convenience, we denote by H the set of the known information about attribute weights given by the decision maker. Let $\tilde{R} = (\tilde{A}_{ij})_{n\times m}$ be an interval type-2 fuzzy decision matrix, where $\tilde{A}_{ij}$ is an IT2 FS, provided by the decision maker for the alternative $x_i \in X$ with respect to the attribute g_j, $1 \leqslant i \leqslant n$, $1 \leqslant j \leqslant m$.

In the situations where the information about attribute weights is completely known, that is, the weight vector $\omega = (\omega_1, \omega_2, \ldots, \omega_m)^T$ of the attributes $g_k (k = 1, 2, \ldots, m)$ can be completely determined in advance, then based on the interval type-2 fuzzy decision matrix $\tilde{R} = (\tilde{A}_{ij})_{n\times m}$, Lee and Chen [36] can utilize the fuzzy ranking method and the arithmetic operations between IT2 FSs to handle fuzzy MADM problems.

However, the information about attribute weights provided by the decision maker is usually incomplete because that the increasing complexity of the socio-economic environment makes it less and less possible for the decision maker to consider all relevant aspects of a problem [1], [2]. How to utilize the interval type-2 fuzzy decision matrix and the known weight information to find the most desirable alternative(s) is an interesting and important issue, which is worth paying attention to.

In the following, we establish some optimization models to determining the weights of attributes.

As interpreted in Section II, the average centroid $c(\tilde{A})$ of an IT FS $\tilde{A}$ can reflect the magnitude of $\tilde{A}$. As a result, we utilize the average centroid function c to define the following concept.

Definition 4. Let $\tilde{R} = (\tilde{A}_{ij})_{n\times m}$ be the interval type-2 fuzzy decision matrix, then the average centroid matrix of $\tilde{R} = (\tilde{A}_{ij})_{n\times m}$ is defined as

$$C = (c_{ij})_{n\times m}$$

where $c_{ij} = c(\tilde{A}_{ij})$ is the average centroid of $\tilde{A}_{ij}$, $1 \leqslant i \leqslant n$, $1 \leqslant j \leqslant m$.

Based on the average centroid matrix, we express the overall average centroid value of each alternative as:

$$c_i(\omega) = \sum_{j=1}^{m} \omega_j c_{ij}, i = 1, 2, \ldots, n. \tag{12}$$

Obviously, the greater the value $c_i(\omega)$, the better the alternative x_i. When we only consider the alternative x_i, then a reasonable vector of attribute weights $\omega = (\omega_1, \omega_2, \ldots, \omega_m)^T$ should be determined so as to maximize $c_i(\omega)$, and thus, we establish the following optimization model:

$$\begin{aligned} (\mathrm{M}-1)\ & max\ c_i(\omega) \\ & s.t.\quad \omega = (\omega_1, \omega_2, \ldots, \omega_m)^T \in H, \\ & \qquad \omega_j \geqslant 0, j = 1, 2, \ldots, m, \sum_{j=1}^{m} \omega_j = 1. \end{aligned}$$

By solving the model $(\mathrm{M}-1)$, we get the optimal solution $\omega^{(i)} = (\omega_1^{(i)}, \omega_2^{(i)}, \ldots, \omega_m^{(i)})^T$ corresponding to the alternative x_i. However, in general, in the process of determining the weight vector $\omega = (\omega_1, \omega_2, \ldots, \omega_m)^T$, we need to consider all the alternatives $x_j (j = 1, 2, \ldots, n)$ as a whole. Thus, we construct a combined weight vector as follows:

$$\begin{aligned} \omega &= w_1\omega^{(1)} + w_2\omega^{(2)} + \cdots + w_n\omega^{(n)} \\ &= \begin{pmatrix} \omega_1^{(1)} & \omega_1^{(2)} & \cdots & \omega_1^{(n)} \\ \omega_2^{(1)} & \omega_2^{(2)} & \cdots & \omega_2^{(n)} \\ \vdots & \vdots & \vdots & \vdots \\ \omega_m^{(1)} & \omega_m^{(2)} & \cdots & \omega_m^{(n)} \end{pmatrix} \begin{pmatrix} w_1 \\ w_2 \\ \vdots \\ w_n \end{pmatrix} \\ &= \Omega w \end{aligned} \tag{13}$$

where

$$\Omega = \begin{pmatrix} \omega_1^{(1)} & \omega_1^{(2)} & \cdots & \omega_1^{(n)} \\ \omega_2^{(1)} & \omega_2^{(2)} & \cdots & \omega_2^{(n)} \\ \vdots & \vdots & \vdots & \vdots \\ \omega_m^{(1)} & \omega_m^{(2)} & \cdots & \omega_m^{(n)} \end{pmatrix}$$

and $w = (w_1, w_2, \ldots, w_n)^T$ is an undetermined nonnegative vector satisfying the condition:

$$ww^T = 1 \tag{14}$$

Let $\bar{c}_i = (c_{i1}, c_{i2}, \ldots, c_{im})(i = 1, 2, \ldots, n)$, then the average centroid matrix C can be expressed as $C = (\bar{c}_1, \bar{c}_2, \ldots, \bar{c}_n)^T$. By (12) and (13), we have

$$c_i(\omega) = \sum_{j=1}^{m} \omega_j c_{ij} = \bar{c}_i \omega = \bar{c}_i \Omega w, i = 1, 2, \ldots, n \tag{15}$$

To determine the combined weight vector $\omega = (\omega_1, \omega_2, \ldots, \omega_m)^T$, we should make all the overall average centroid values $c_i(\omega)(i = 1, 2, \ldots, n)$ as greater as possible, which means to maximize the following vector $c(\omega) = (c_1(\omega), c_2(\omega), \ldots, c_n(\omega))$ under the condition (14). In order to do that, we establish the following multiple objective optimization model:

$$\begin{aligned} (\mathrm{M}-2)\ & max\ c(\omega) = (c_1(\omega), c_2(\omega), \ldots, c_n(\omega)) \\ & s.t.\quad ww^T = 1. \end{aligned}$$

By the equal weighted summation method, the model $(\mathrm{M}-2)$ can be transformed into a single objective optimization model:

$$\begin{aligned} (\mathrm{M}-3)\ & max\ c(\omega)c(\omega)^T \\ & s.t.\quad ww^T = 1. \end{aligned}$$

Let $f(w) = c(\omega)c(\omega)^T$, then by (15), we have

$$f(w) = c(\omega)c(\omega)^T = w^T(C\Omega)^T(C\Omega)w \tag{16}$$

Let $S = (C\Omega)^T(C\Omega)$, then $S^T = (C\Omega)^T(C\Omega) = S$, i.e., S is a real symmetrical matrix. Moreover, $C \geqslant 0$. Therefore, S is a nonnegative definite matrix.

Here, we introduce two useful theorems:

Theorem 1. *[42] Let $B = (b_{ij})_{n\times n}$ be a real symmetrical matrix, i.e.,$B^T = B$, then*

$$\max \frac{x^T B x}{x^T x} = \lambda_{max} \tag{17}$$

where λ_{max} is the largest eigenvalue of B, and x is a nonzero vector.

Theorem 2. *[42] Let $B = (b_{ij})_{n\times n}$ be a real irreducible nonnegative matrix, then*

1) *B has a largest eigenvalue λ_{max}, which is also a unique eigenvalue of B.*
2) *Let $v = (v_1, v_2, \ldots, v_n)^T$ be the eigenvector of λ_{max}, then all $v_j > 0\,(j = 1, 2, \ldots, n)$, i.e., v is a positive eigenvector.*

By Theorems 1 and 2, we know that $f(w)$ has a largest value $\max f(w)$, which is also the largest eigenvalue $\bar{\lambda}_{max}$ of S. $w = (w_1, w_2, \ldots, w_n)^T$ is the eigenvector of $\bar{\lambda}_{max}$, where $\bar{\lambda}_{max}$ is unique, and all $w_i > 0\,(i = 1, 2, \ldots, n)$. After normalizing the eigenvector w, we can utilize (13) to derive the weight vector ω.

IV. An approach to multi-attribute decision making under interval type-2 fuzzy environment

Based on the analysis in Section III, interval type-2 fuzzy MADM with incomplete attribute weight information may be performed via the following steps.

1) Obtain the normalized decision matrix. In general, attributes can be classified into two types: benefit attributes and cost attributes. In other words, the attribute set G can be divided into two subsets: G_1 and G_2, where G_k $(k = 1, 2)$ are the subset of benefit attributes and cost attributes, respectively. Furthermore, $G_1 \cup G_2 = G$ and $G_1 \cap G_2 = \emptyset$, where $\emptyset$ is empty set. Since the m objectives may be measured in different ways, the decision matrix $\tilde{R}$ needs to be normalized besides all the attributes $g_j(j = 1, 2, \ldots, m)$ are of the same type. In this paper we choose the following normalization formula to update the decision matrix $\tilde{R}$:

$$\tilde{A}_{ij} = \begin{cases} \tilde{A}_{ij} & j \in G_1 \\ \tilde{A}_{ij}^c & j \in G_2 \end{cases} \tag{18}$$

   where $\tilde{A}_{ij}^c$ is the complement of $\tilde{A}_{ij}$. Hence, we obtain the normalized decision matrix $\tilde{R} = (\tilde{A}_{ij})_{n\times m}$.
2) Calculate the average centroid matrix $C = (c_{ij})_{n\times m}$ of the normalized decision matrix $\tilde{R} = (\tilde{A}_{ij})_{n\times m}$.
3) Utilize the model $(\mathrm{M}-1)$ to get the optimal weight vectors $\omega^{(i)} = (\omega_1^{(i)}, \omega_2^{(i)}, \ldots, \omega_m^{(i)})^T (i = 1, 2, \ldots, n)$ corresponding to the alternatives $x_i\,(i = 1, 2, \ldots, n)$, and construct the weight matrix Ω.
4) Calculate the normalized eigenvector $w = (w_1, w_2, \ldots, w_n)^T$ of the matrix $(C\Omega)^T(C\Omega)$.
5) Utilize (13) to derive the weight vector $\omega = (\omega_1, \omega_2, \ldots, \omega_m)^T$.
6) Utilize (12) to get the overall average centroid values $c_i(\omega)(i = 1, 2, \ldots, n)$ of the alternatives $x_i\,(i = 1, 2, \ldots, n)$.
7) Rank the alternatives $x_i\,(i = 1, 2, \ldots, n)$ based on the average centroids $c_i(\omega)(i = 1, 2, \ldots, n)$, and then select the most desirable one(s).
8) End.

V. Illustrative example

Table I shows the linguistic terms "Very Low" (VL), "Low" (L), "Medium Low" (ML), "Medium" (M), "Medium High" (MH), "High" (H), "Very High" (VH) and their corresponding IT2 FSs, respectively. In addition, the corresponding average centroids of IT2 FSs are given in Table I (see Reference [43]).

Assume that there are three cars to be evaluated with four attributes "Safety", "Price", "Appearance" and "Performance". Let X be the set of alternatives, where $X = \{x_1, x_2, x_3\}$, and let G be the set of attributes, where $G = \{g_1, g_2, g_3, g_4\}$. Assume that the decision-maker use the linguistic terms shown in Table I to represent the evaluating values of the alternatives with respect to different attributes, respectively, as shown

TABLE I
LINGUISTIC TERMS AND THEIR CORRESPONDING IT2 FSS.

Linguistic terms	IT2 FSs $\left(\tilde{A}\right)$	$c\left(\tilde{A}\right)$
Very Low (VL)	((0, 0, 0.14, 1.97), (0, 0, 0.05, 0.66,1))	0.47
Low (L)	((0, 0, 0.64,2.63), (0, 0, 0.09, 0.99,1))	0.67
Medium Low (ML)	((0.59, 2.00, 3.25, 4.41), (2.29, 2.70, 2.70, 3.21, 0.42))	2.59
Medium (M)	((3.59, 4.75, 5.50, 6.91), (4.86, 5.03, 5.03, 5.14, 0.27))	5.19
Medium High (MH)	((5.38, 7.50, 8.75, 9.81), (7.79, 8.22, 8.22, 8.81, 0.45))	7.9
High (H)	((7.37, 9.41, 10, 10), (8.72, 9.91, 10, 10, 1))	9.3
Very High (VH)	((8.68, 9.91, 10, 10), (9.61, 9.97, 10, 10, 1))	9.69

TABLE II
THE LINGUISTIC TERMS OF IT2 FSS $\tilde{A}$ AND $\tilde{A}^c$.

The linguistic terms of $\tilde{A}$	The linguistic terms of $\tilde{A}^c$
VL	VH
L	H
ML	MH
M	M
MH	ML
H	L
VH	VL

follows:

$$\tilde{R} = \begin{pmatrix} \text{MH} & \text{H} & \text{VH} & \text{VH} \\ \text{H} & \text{MH} & \text{H} & \text{H} \\ \text{VH} & \text{VH} & \text{M} & \text{H} \end{pmatrix}$$

If the information about attribute weights is completely known in advance, here, we suppose that the weight vector $\omega = (0.25, 0.15, 0.25, 0.35)^T$, then we first utilize the average centroid measure [43] and the weighted mean to handle the above problem, which needs the following steps:

1) Considering that the attributes are the benefit attributes except to the attribute "Price" (g_2), then based on the formula (18) and Table II, the decision matrix $\tilde{R}$ can be updated to the following normalized matrix.

$$\tilde{R} = \begin{pmatrix} \text{MH} & \text{L} & \text{VH} & \text{VH} \\ \text{H} & \text{ML} & \text{H} & \text{H} \\ \text{VH} & \text{VL} & \text{M} & \text{H} \end{pmatrix} \tag{19}$$

2) Based on Table I, we can get the average centroid matrix $C = (c_{ij})_{n\times m}$ of the normalized decision matrix $\tilde{R}$ as follows:

$$C = \begin{pmatrix} 7.9 & 0.67 & 9.69 & 9.69 \\ 9.3 & 2.59 & 9.3 & 9.3 \\ 9.69 & 0.47 & 5.19 & 9.3 \end{pmatrix} \tag{20}$$

3) Utilize the weight vector $\omega = (0.25, 0.15, 0.25, 0.35)^T$ and the ith line values $c_{ij}\,(j = 1, 2, 3, 4)$ of the average centroid matrix C to derive the overall average centroids c_i of the alternatives $x_i\,(i = 1, 2, 3)$:
$c_1 = \sum_{j=1}^{4} \omega_j c_{1j} = 7.8895$,
$c_2 = \sum_{j=1}^{4} \omega_j c_{2j} = 8.2835$,
$c_3 = \sum_{j=1}^{4} \omega_j c_{3j} = 7.0455$.
4) Rank the alternatives $x_i\,(i = 1, 2, 3)$ based on the average centroids $c_i\,(i = 1, 2, 3)$: $x_2 \succ x_1 \succ x_3$, and then the most desirable car is x_2.

The decision maker may, however, provide the information about attribute weights with value ranges or order relations as described in Section I because that a decision may be made under time pressure and lack of knowledge, or the decision maker has limited attention and information processing capabilities. For example, the information about attribute weights, given by the decision maker, may be as follows:

$$H = \{0.2 \leqslant \omega_3 \leqslant 0.5,\, \omega_3 - \omega_2 \geqslant \omega_4 - \omega_1,\, \omega_3 - \omega_2 \geqslant 0.1,\, \omega_4 \geqslant \omega_1\}$$

As presented in Section I, many approaches have been developed to dealing with the decision making problems based on IT2 FS theory, however, all of them are not suitable to handle this case, in the following, we will select the best car following the procedure proposed in this paper:

1) Obtain the normalized decision matrix $\tilde{R}$, i.e., (19).
2) Based on Table I, we can get the average centroid matrix $C = (c_{ij})_{n\times m}$ of the normalized decision matrix $\tilde{R}$, i.e., (20).
3) Utilize the model $(\mathrm{M}-1)$ to get the optimal weight vectors $\omega^{(i)} = (\omega_1^{(i)}, \omega_2^{(i)}, \omega_3^{(i)}, \omega_4^{(i)})^T (i = 1, 2, 3)$ corresponding to the alternatives $x^i(\ i = 1, 2, 3)$:
$\omega^{(1)} = (0.05, 0.05, 0.5, 0.4)^T$,
$\omega^{(2)} = (0.225, 0.05, 0.5, 0.225)^T$,
$\omega^{(3)} = (0.2, 0.05, 0.3, 0.45)^T$.
and construct the weight matrix

$$\Omega = \begin{pmatrix} 0.05 & 0.225 & 0.2 \\ 0.05 & 0.05 & 0.05 \\ 0.5 & 0.5 & 0.3 \\ 0.4 & 0.225 & 0.45 \end{pmatrix}$$

then

$$(C\Omega)^T (C\Omega) = \begin{pmatrix} 210.6289 & 208.2285 & 214.1800 \\ 208.2285 & 205.9309 & 211.9237 \\ 214.1800 & 211.9237 & 218.5783 \end{pmatrix}$$

4) Calculate the normalized eigenvector w of the matrix $(C\Omega)^T(C\Omega)$: $w = (0.3325, 0.3289, 0.3386)^T$.
5) Utilize (13) to derive the weight vector ω:

$$\begin{aligned} \omega &= \Omega w \\ &= \begin{pmatrix} 0.05 & 0.225 & 0.2 \\ 0.05 & 0.05 & 0.05 \\ 0.5 & 0.5 & 0.3 \\ 0.4 & 0.225 & 0.45 \end{pmatrix} \begin{pmatrix} 0.3325 \\ 0.3289 \\ 0.3386 \end{pmatrix} \\ &= (0.1583, 0.0500, 0.4323, 0.3594)^T. \end{aligned}$$

6) Utilize (12) to get the overall average centroid values $c_i\,(i = 1, 2, 3)$ of the alternatives $x_i\,(i = 1, 2, 3)$:
$c_1 = \sum_{j=1}^{4} \omega_j c_{1j} = 8.9556$,

$c_2 = \sum_{j=1}^{4} \omega_j c_{2j} = 8.9645$,
$c_3 = \sum_{j=1}^{4} \omega_j c_{3j} = 7.1435$.

7) Rank the alternatives $x_i\,(i = 1, 2, 3)$ based on the average centroids $c_i (i = 1, 2, 3) : x_2 \succ x_1 \succ x_3$, and then the most desirable car is also x_2.

VI. Conclusion

We have investigated the MADM problems under interval type-2 fuzzy environment, and developed an approach to handling the situations where the attribute values are characterized by IT2 FSs, and the information about attribute weights is partially known. We have constructed the average centroid matrix of the interval type-2 fuzzy decision matrix, and established some optimization models to determine the attribute weights. Then we have utilized the obtained attribute weights to get the overall average centroid values of the alternatives, and then find their ranking and select the most desirable one. All these procedures have been illustrated by a decision making problem regarding the selection of cars. In the future, we will apply the developed procedures to some other fields such as medical diagnosis, pattern recognition, machine learning and market prediction, supply chain management, etc.

***Abstract*—In this paper, we describe the main functionality of an initial version of a new fuzzy logic software toolkit based on the R language. The toolkit supports the implementation of several types of fuzzy logic inference systems and we discuss and present several aspects of its capabilities to allow the straightforward implementation of type-1 and interval type-2 fuzzy systems. We include source code examples and visualizations both of type-1 and type-2 fuzzy sets as well as output surface visualizations generated using the R toolkit. Finally, we describe the significant benefits of relying on the R language as a language which is employed across several research disciplines (thus enabling access to fuzzy logic tools to a variety of researchers), outline future developments and most importantly call for contributions, comments and feedback to/on this open-source software development effort.**

Keywords; fuzzy inference software; type-1 fuzzy inference; type-2 fuzzy infererence; open-source software; Matlab; R

I. INTRODUCTION

Since its introduction in 1965 [1], fuzzy logic has become widely popular, both as a specific field of research, as well as a tool for the modeling of and computation with data applied in a myriad of disciplines, from the arts, over medical sciences to industrial control. The vast majority of current applications of fuzzy logic are based on type-1 fuzzy logic.

While the research interest in type-2 fuzzy logic has steadily grown in the last 10 years, the number of applications is still very limited. In particular, the majority of existing applications are mostly confined to applications that are research-led, frequently by members of the fuzzy logic research community, rather than third party applications entirely conceived and implemented for example by practitioners in other fields and industry.

It is a well-known phenomenon in computing that an essential criterion for the adoption of a new method or algorithm, the availability of software implementing said algorithm is essential. Analogously, we believe that for the more widespread adoption and application of non-classical fuzzy logic systems (such as non-stationary, interval type-2 and general type-2 fuzzy systems), the provision of free, widely available, open-source software is essential. As part of this paper, we are introducing an open-source software package based on the R language which is approaching the release of its first version.

This work was partly funded by the RCUK's Horizon Digital Economy Research Hub grant, EP/G065802/1.

R is a free, open-source language and importantly, is already used widely across disciplines (from Computer Science to Social Sciences - such as Political Science). As such, providing freely accessible software to employ non-classical fuzzy systems as part of an R package will allow practitioners and researchers from a wide range of areas to make use of the research developed by the fuzzy logic research community who in turn can incorporate the potentially vast amount of feedback and real-world deployment information into their research.

The paper is intended both to introduce the R fuzzy logic toolbox as well as an invitation to the fuzzy community, particularly the type-2 community, to join with the development effort, give feedback and recommendations.

The paper is structured as follows. Section II provides basic background information on the current availability of packages for the development of non-classical fuzzy logic applications as well as the R language in general. Subsequently, Section III describes the R toolbox and reviews some of the currently available functionality. Section IV provides some sample plots of non-classical fuzzy logic membership functions as well as control surfaces, demonstrating the graphical capabilities of the toolbox. Finally, Section V discusses the current development of the toolbox and describes the planned long-term development.

II. BACKGROUND

The use of toolboxes for implementing type-1 fuzzy systems is widespread owing to the availability of such software to facilitate development. Perhaps the most well known of these is the Fuzzy Logic Toolbox provided for MATLAB® (The Mathworks, Inc.) which allows users to create type-1 fuzzy inference systems using MATLAB® command-line functions or a graphical user interface (GUI) [2].

Currently, there is a lack of toolboxes available for creating other types of fuzzy systems including, in particular, type-2 fuzzy systems. We should note that a several researchers (e.g. J. Mendel) and research groups have opened their source code and made it accessible, however the use of source code still requires in-depth familiarity with the material in question (i.e. non-classical fuzzy logic systems) and thus does not fulfill the same role as toolkits in terms of making the material easily accessible for people from a variety of backgrounds.

Castro et al. have previously demonstrated a toolbox for MATLAB® that provides tools for the development of interval

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

type-2 fuzzy systems [3] which provides a GUI interface similar to that of the MATLAB® Fuzzy Logic Toolbox [2]. While the toolbox allows the implementation of interval type-2 fuzzy systems using MATLAB®, it, being based on the proprietary MATLAB® is restricted in terms of its availability (MATLAB® is subject to license fees) as well as its user base (MATLAB® is predominantly used as part of the physical sciences and engineering). These restrictions as well as the limitation to interval type-2 fuzzy logic limit the adoption potential of the existing MATLAB® based toolbox and currently it is difficult to find examples of its more widespread adoption.

The toolbox introduced as this paper is based on/around the freely available R platform/language. As noted, R offers the advantage of not only being freely available but importantly that it, as a language is accessible to people from a large variety of backgrounds. This in particular should facilitate the experimentation with fuzzy logic and the research and investigation into new problem domains.

Further, the advantage of high-level specialist mathematical languages such as R and MATLAB® is that, in contrast to low-level languages such as C or Java, they provide built-in primitives for representing and manipulating vectors and matrices, which can be used to directly represent and manipulate fuzzy sets. In addition, these languages provide comprehensive built-in graphical capabilities for 2D and 3D plotting, which can be used to visualize fuzzy sets.

R itself is an open-source language and environment for statistical computing and graphics, similar to the S language and environment originally developed at Bell Laboratories (formerly AT&T, now Lucent Technologies) by John Chambers and colleagues. It is a mature, open-source language which is actively maintained by the community. R is similar to MATLAB® in that it is a generic programming environment within which mathematical and statistical techniques are implemented [4]. R is an integrated suite of software facilities for data manipulation, calculation and graphical display, including effective data handling and storage facilities, a suite of operators for calculations on arrays and matrices, a large integrated collection of intermediate tools, graphical facilities for display either on-screen or on hardcopy, and a well-developed, simple and effective programming language which includes conditionals, loops, user-defined recursive functions and input and output facilities. R can be easily extended via packages. (Text adapted from [4]). R is freely downloadable from the main R Project repository [4], and can easily be installed on many platforms including popular versions of Microsoft Windows, Apple Mac OS X and Linux.

In this paper we present a fuzzy logic toolbox for the programming language R that includes tools for creating type-1, non-stationary [5], interval type-2 [6] and zSlices based general type-2 fuzzy systems [7]. At the present stage, the toolbox is in the final stages of development in preparation for the release of its first version. In particular, features such as the general type-2 aspects are being completed, documentation material is being added. This paper aims to encourage the research community to engage and provide feedback and suggestions for the final release. In the following sections, we provide a high level view of some of the features that are currently included.

III. TOOLKIT FEATURES

The R toolkit has several similarities with the MATLAB® toolbox. This is natural as both toolkits/toolboxes implement established fuzzy logic concepts and algorithms. The similarity between both approaches however has the distinct advantage of greatly facilitating the use of either toolkit for authors familiar with the other one.We proceed by illustrating the similarities based on fundamental fuzzy logic concepts between both toolkits in III.A, followed by a basic overview of some of the currently implemented features in terms of type-1 fuzzy logic in III.B and interval type-2 fuzzy logic in III.C.

Non-stationary fuzzy systems and zSlices based general type-2 fuzzy systems' functionality has largely been included in the toolkit but as part of this paper we will focus on the features of "standard" type-1 and interval type-2 fuzzy systems. We are addressing some features of non-classical fuzzy logic systems in Section IV, in particular demonstrating the visualization capabilities of the current toolkit in terms of 3D set visualizations.

A. Similarity between R and MATLAB® toolkits.

As noted, the R toolkit has been designed to maximize the transparency for people who are already familiar with the parameters and specification of fuzzy sets and systems while also making it easy to learn for people who are new to the area. Incidentally, the command line interface employed in the R language results in a high similarity compared to the command line interface operation of the MATLAB® Fuzzy Logic Toolbox. However, while the R language offers many similar functions to MATLAB® and add-on toolboxes (termed 'packages' in R), the language is a development of the S language and not a 'clone' of MATLAB®. Hence, it has detailed syntactic differences from MATLAB®, as summarized in [8].

For example, in MATLAB®, the command:

```
x = [ 1, 2, 3];
```

creates a vector of length 3, while the equivalent in R is:

```
x = c(1, 2, 3) or   x <- c(1, 2, 3)
```

(these two forms of assignment operator are not completely identical, and the latter version is preferred in the R community). Similarly, the MATLAB® command:

```
x = [ 1, 2, 3; 4, 5 6];
```

creates a matrix of 2 rows by 3 columns, while the equivalent in R for this is:

```
x = rbind(c(1,2,3), c(4,5,6))
```

While there are syntactic difference between R and MATLAB®, in terms of the scope of the implementation the current state of the R toolkit is comparable to the MATLAB® Fuzzy Logic Toolbox in terms of type-1 fuzzy logic, however, the R toolkit further addresses more complex types of fuzzy logic such as interval and general type-2 fuzzy logic. For the

majority of the type-1 functionality, one can establish a direct mapping between the functions provided in the R package and those in the MATLAB® Fuzzy Toolbox as is expected because of the underlying fundamental fuzzy logic theory concepts).

The main functions necessary to create and perform fuzzy inference in Mamdani-style are supplied within the package (note that Sugeno / TSK style inference is not currently supported). A wide variety of forms of membership functions are supported similar to those currently provided by MATLAB®. Additionally, currently the common forms of conjunction, disjunction, implication and aggregation operators are supported (including, minimum, maximum, product and probabilistic OR), as well as Mamdani inference and popular forms of defuzzification as further detailed below.

To illustrate the creation of a complete FLC using the R toolkit we have provided a comparison between implementing a completed fuzzy inference system (FIS) in both MATLAB® and using the R toolkit. The example is based on the 'tipper' example provided as part of the MATLAB® Fuzzy Logic Toolbox documentation. The complete source code to set up the example for both MATLAB® and R is provided in Section VI.A and VI.B respectively. Note the expected high similarity between the constructions of a fuzzy inference system in both platforms. Each example also demonstrates the output capabilities, specifically (we use the R notation here):

- *showfis(fis)*
  Produces a summary of the constructed FIS.
- *showrule(fis)*
  Prints the rules of the specific FIS.
- *evalfis(c(1,2), fis)*
  Evaluates the given FIS using the specified input values.
- *evalfis(rbind(c(3,5), c(2,7)), fis)*
  Evaluates the given FIS for the specified set of inputs.
- *gensurf(fis)*
  Produces the control surface (visualisation) for the given FIS.

Overall, the R toolkit is aimed to generally providing at least the same set of features as are offered as part of the MATLAB® Fuzzy Logic Toolbox. As an open-source toolkit, it is hoped that in the medium and long term the overall feature richness and functionality of the toolkit will be increased through open access and contribution. This could potentially also include further components that employ the provided toolkit, such as a Graphical User Interface (GUI) which could further facilitate the implementation of FLCs in particular for users who are not familiar with the implementation of FLCs and/or have no programming background or interest. Further, it is expected that several community-centred "flavours" of the R toolkit will be developed in time (for example for medical applications, applications in economy, etc.).

In the following Sections we describe some of the basic aspects of creating type-1 and interval type-2 fuzzy systems using the toolkit.

B. Type-1 fuzzy logic features.

As part of describing the type-1 functionality we give examples of the basic membership functions currently supported before briefly reviewing the inference and defuzzification operations.

1) Membership Functions.

a) Triangular

Triangular membership functions are created by providing the left, right and center points of the membership function. For example, the source code snippet below produces the membership function depicted in Figure 1.

```
x <- 1:10
y <- trimf(x,c(2,5,8))
```

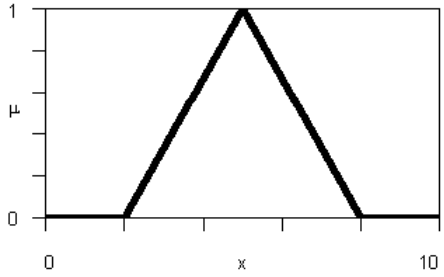

Figure 1 An example of a triangular type-1 membership function produced using the R toolkit.

b) Trapezoidal

For trapezoidal sets, four values describing the left and right slopes of the trapezoid are used to create the membership function. For example, the source code snippet below produces the membership function depicted in Figure 2.

```
x <- 1:10
y <- trapmf(x,c(2,4,6,8))
```

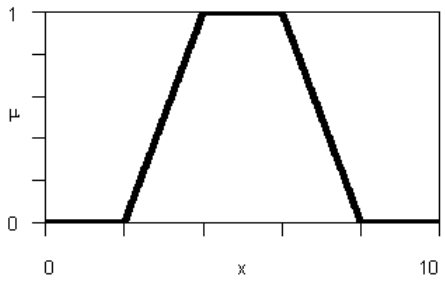

Figure 2 An example of a trapezoidal type-1 membership function produced using the R toolkit.

c) Gaussian

To create a Gaussian membership function the centre of the Gaussian and Sigma (describing the curve) are required. For example, the source code snippet below produces the membership function depicted in Figure 3.

```
x <- 1:10
y <- gaussmf(x,c(2,5))
```

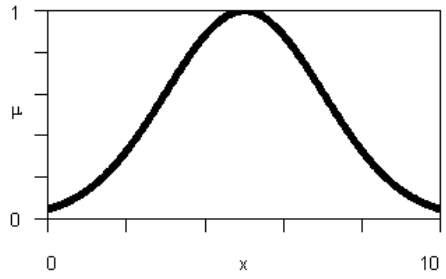

Figure 3 An example of a Gaussian type-1 membership function produced using the R toolkit.

d) Sigmoidal

Sigmoidal membership functions are created using two values representing the centre and width of the slope. For example, the source code snippet below produces the membership function depicted in Figure 4.

x <- 1:10

y <- sigmf(x,c(2,5))

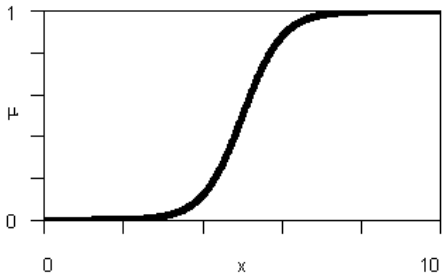

Figure 4 An example of a sigmoidal type-1 membership function produced using the R toolkit.

2) Inference Mechanisms.

The inference mechanisms provided as part of the R toolkit are comparable to those provided by the MATLAB® Fuzzy Logic Toolbox. Specifically, during the rule specification, each rule can be associated with a given weight and the logical connective (AND or OR) can be specified. Considering the 'tipper' example provided in Section VI, we have the example rule specification:

rules= rbind(c(1,1,1,1,2), c(2,0,2,1,1), c(3,2,3,1,2))

The example defines three rules where each rule is described by five parameters (in our example). The parameters are specified analogous to the MATLAB® Fuzzy Logic Toolbox as follows (adopted from [9]) , where *m* is the number of inputs and *n* is the number of outputs:

- The first parameter is the index number for the membership function associated with input 1.
- The second is the index number for the membership function associated with input 2, and so on.
- The next *n* parameters work the same way for the outputs.
- Parameter *m* + *n* + 1 is the weight associated with that rule (typically 1) and parameter *m* + *n* + 2 specifies the connective used (where AND = 1 and OR = 2).

3) Defuzzification Methods.

The following defuzzification methods are currently available as part of the R toolkit:

a) Centroid

This method takes the centre of the area of a membership function on the x-axis.

b) Bisector

Bisector splits the set into two sections of equal area, and takes the vertical that separates the two sections.

c) Mean of maximum

Mean of maximum (MOM) uses the mean value of all discrete x coordinates associated with the maximum membership for the given output set.

d) Smallest of maximum

Smallest of maximum (SOM) uses the smallest value of all discrete x coordinates associated with the maximum membership for the given output set.

e) Largest of maximum

Largest of maximum (LOM) uses the largest value of all discrete x coordinates associated with the maximum membership for the given output set.

Having considered the basic features for type-2 FISs as part of the R toolkit, we proceed to briefly review the currently available interval type-2 features.

C. Interval type-2 fuzzy logic features.

The features available in terms interval type-2 fuzzy systems as part of the R toolkit are briefly summarized below. Specifically, we address the available membership functions in Section III.C.1, followed by the inference capabilities in Section III.C.2 and the type-reduction/defuzzification methods in III.C.3.

1) Membership Functions.

a) Triangular

Type-2 triangular membership functions are created by providing the width of the footprint of uncertainty (FOU), and the left, right and center points of the membership function. For example, the source code snippet below produces the membership function depicted in Figure 5.

x <- 1:10

y <- tri2mf(x,c(1,2,5,8))

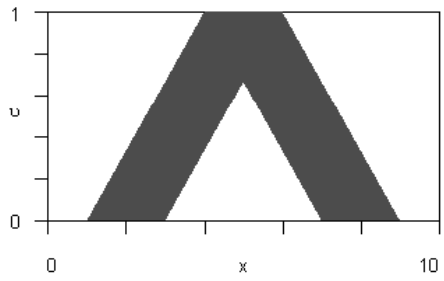

Figure 5 An example of a triangular interval type-2 membership function produced using the R toolkit.

b) Trapezoidal

For type-2 trapezoidal sets, 5 values are required: the width of the FOU, the x coordinate of the leftmost point of the lower membership function, the x coordinate of the rightmost lower membership function, the gradient of the left slope and the gradient of the right slope. For example, the source code snippet below produces the membership function depicted in Figure 5.

x <- 1:10

y <- trapmf2(x, c(1,3,7,1,1))

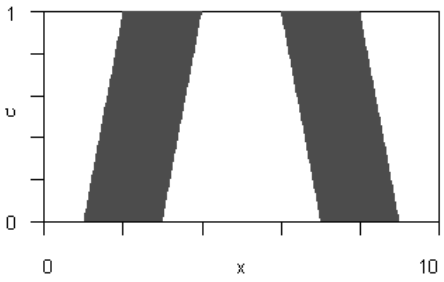

Figure 6 An example of a trapezoidal interval type-2 membership function produced using the R toolkit.

c) Gaussian

To create a Type-2 Gaussian membership function two values of the standard deviation describing the lower and upper membership functions as well as the centre of the Gaussian are required. For example, the source code snippet below produces the membership function depicted in Figure 7.

x <- 1:10

y <- gausst2mf(x,c(1,1.5,5))

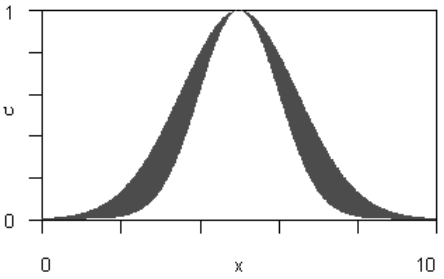

Figure 7 An example of a Gaussian interval type-2 membership function produced using the R toolkit.

2) Inference Mechanisms.

The inference mechanisms are identical to those described in Section III.B.2 for type-1 fuzzy systems but applied to interval type-2 fuzzy sets as described for example in [10].

3) Type-Reduction and Defuzzification.

Type-reduction is currently conducted based on the Karnik-Mendel iterative procedure [11]. The type-reduced set is finally defuzzified by computing the average of its endpoints as in [10].

IV. Sample Visualisations

One of the strengths of R and similar languages is the powerful set of visualization features available. We provide both sample visualizations of linguistic variables (and membership functions) in Section IV.A as well as a comparison of output surface visualizations between the MATLAB and R implementations for the 'tipper' example in Section IV.B.

For all visualizations, the R environment supports a variety of formats for both soft-copy and hard-copy output. The precise details of any implementation depend on the underlying operating system, but in most platforms the production of *jpeg* or *png* graphical formats and *postscript* of Adobe® *pdf* formats is supported.

A. Linguistic Variable and Membership Function Visualisation.

The current R toolkit contains a series of functions for plotting membership functions. Figure 8 and Figure 9 depict examples of visualizing the linguistic variable "Temperature" based on the three linguistic labels *cool*, *warm* and *hot*. The linguistic labels are represented by Gaussian Type-1 and Interval Type-2 membership functions in Figure 8 and Figure 9 respectively.

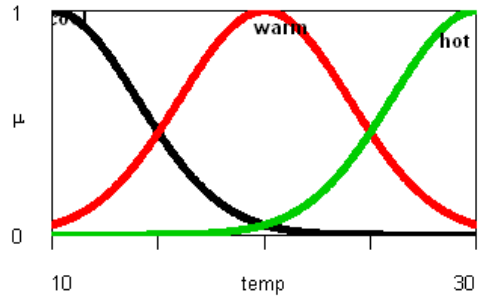

Figure 8 An example of the plotting of multiple type-1 membership functions using the R toolkit.

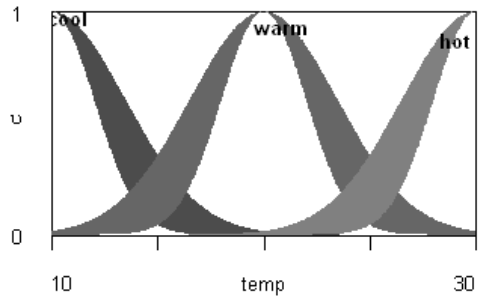

Figure 9 An example of the plotting of multiple interval type-2 membership functions using the R toolkit.

By utilizing the recently released `RGL` library, it is possible to create three dimensional plots of both interval type-2 and general type-2 membership functions. Examples of both are includes as part of Figure 10 and Figure 11 respectively.

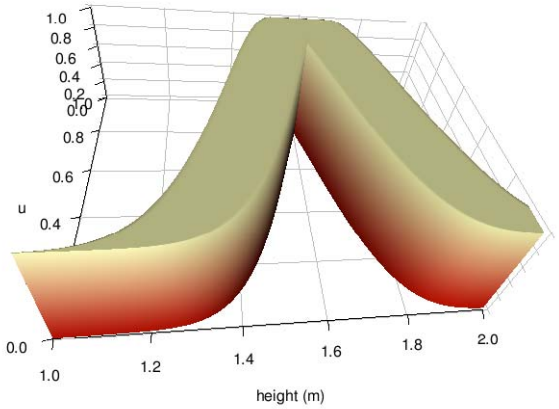

Figure 10 An example of a interval type-2 Gaussian membership function produced using the R toolkit. (shown in 3D)

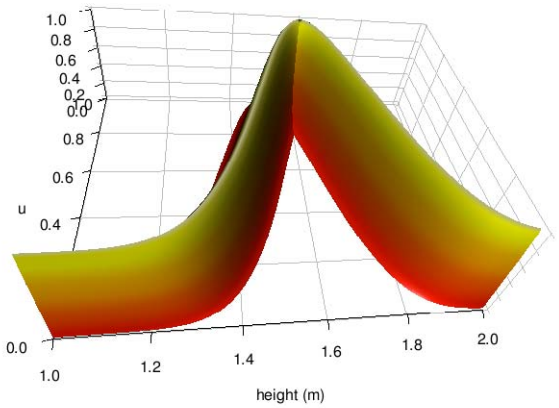

Figure 11 An example of a general type-2 Gaussian membership function produced using the R toolkit.

As well as the visualization of membership functions, the R toolkit also supports the visualization of output surfaces as shown in the following Section.

B. Output Surface Plots

For FIS featuring two input variables and one output variable, the R toolkit supports the generation of a visualization of the output surface using the function `gensurf` (as shown in VI.B).

In order to allow the comparison in terms of visualization between the MATLAB® and R implementations we provide the output surfaces produced for the 'tipper' example (see Appendices) in Figure 12 and Figure 13 respectively.

Note: The control surfaces are shown from a slightly different viewpoint, however the visualization capability of the R toolkit is clearly demonstrated which is the primary aim in this section.

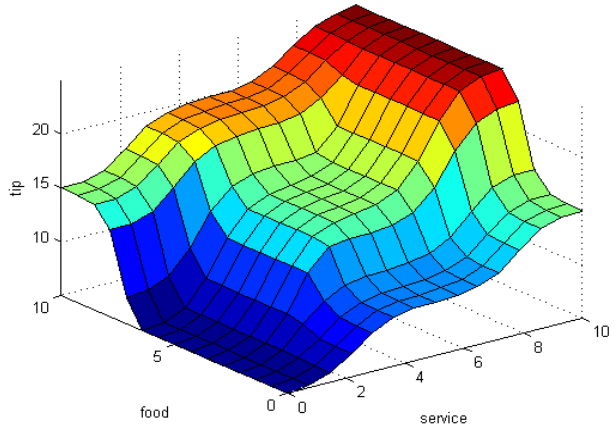

Figure 12 The control surface of the 'tipper' example produced using the MATLAB®.

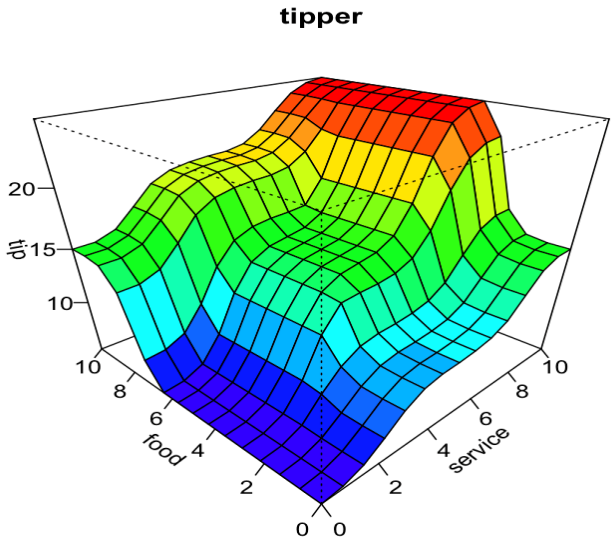

Figure 13 The similar control surface of the 'tipper' example produced using the R toolkit.

V. Conclusions and Future Work

As part of this paper we have given a brief introduction to a Fuzzy Logic toolkit based on the R language. We have provided a brief overview as well as source code samples of the currently available features within the toolkit. Specifically, we have described the functionality in terms of type-1 and interval type-2 fuzzy logic systems and provided examples of the visualization capabilities of the toolkit for type-2 fuzzy systems in general.

The current toolkit already supports other variations of fuzzy systems, including non-stationary fuzzy sets and the basics for zSlices based general type-2 fuzzy systems. We are aiming to complete these and other features and to include appropriate documentation materials before the free release of the toolkit. The open nature of the R language means that the package will be available to be freely expanded by other authors and contributors after its release and additional features such as TSK inference can easily be included.

The purpose of the paper is to get feedback and suggestions from our peers on the current approach, its functionality and applicability, and to gather information on similar efforts that may be underway in order to avoid duplication of work.

R is an ideal choice of language for such a toolbox as it is freely available and used by a wide variety of researchers from a variety of research fields: creating a tool in R will provide a generic infrastructure for a wide range of users and will hopefully lead to an increase in the uptake of fuzzy logic systems (of all flavours).

The result of this work will be an open source toolkit that can be used freely, placing the tools required to create these types of fuzzy system into the hands of all researchers interested in adopting a fuzzy approach.

Acknowledgment

We would like to thank the reviewers for providing a series of helpful and constructive comments and suggestions for the further development of the toolkit.

A Comparison of Non-stationary, Type-2 and Dual Surface Fuzzy Control

Naisan Benatar, Uwe Aickelin and Jonathan M. Garibaldi *Member, IEEE*
School of Computer Science
University of Nottingham
Email: [nxb,uxa,jmg]@cs.nott.ac.uk

***Abstract*—Type-1 fuzzy logic has frequently been used in control systems. However this method is sometimes shown to be too restrictive and unable to adapt in the presence of uncertainty. In this paper we compare type-1 fuzzy control with several other fuzzy approaches under a range of uncertain conditions. Interval type-2 and non-stationary fuzzy controllers are compared, along with 'dual surface' type-2 control, named due to utilising both the lower and upper values produced from standard interval type-2 systems. We tune a type-1 controller, then derive the membership functions and footprints of uncertainty from the type-1 system and evaluate them using a simulated autonomous sailing problem with varying amounts of environmental uncertainty. We show that while these more sophisticated controllers can produce better performance than the type-1 controller, this is not guaranteed and that selection of Footprint of Uncertainty (FOU) size has a large effect on this relative performance.**

Keywords: Interval Type-2 Fuzzy, Robot Boat control, Fuzzy Control, Non-stationary

I. Introduction

Fuzzy controllers use the principles of fuzzy sets and fuzzy logic to automate system controllers. The underpinning technique of fuzzy logic was originally introduced by Zadeh in his seminal paper [1]. In this paper, various types of fuzzy set are used including: type-0 which are identical to crisp sets; type-1 where membership is a continuous real value in $[0, 1]$; and type-2 in which the membership values are themselves type-1 fuzzy sets. The complexity of the sets increases from type-0 to type-2 as the number of dimensions is increased accordingly. Type-1 fuzzy logic has been applied extensively to a range of real-world problems due to the ease with which it can be applied. It has been applied successfully to areas including robotic control, fuzzy decision making and fuzzy classifier systems. However, a number of issues are known to exist in the application of type-1 in problem domains which require decision making in the presence of uncertainty [2]. It is suggested in [3] that such type-1 fuzzy systems have no capacity for modelling uncertainty, which limits their application to more complex real-world problems.

Type-2 fuzzy logic has been proposed as a solution to overcome some of the limitations experienced when using type-1 systems. In contrast to type-1 systems, type-2 systems contain membership functions which in themselves are type-1 fuzzy sets. This adds an extra layer of dimensionality to the system which is postulated to assist in the process of coping with uncertainty in the problem domain. However, this addition of an additional dimension is not without its problems. As a result, additional computational overhead is incurred when implementing type-2 control, which has limited the applicability of type-2 systems to the classical problems solved by type-1 systems, including robotic controllers. This has become less of a problem due to advances in both computational processing power and available memory in computational systems. However, it may still pose a problem when applying type-2 systems to lightweight embedded systems. A more complete overview of interval type-2 fuzzy logic can be found in both [4] and [5].

It has been shown, for example in [6], that type-2 systems can outperform type-1, potentially due to the fact that type-2 fuzzy sets have this 'extra' dimension. There has been some investigation into the reasons underpinning the improved performance of type-2 in comparison with type-1 systems. However, such investigations have been limited in scope. It is also uncertain if improved tuning of type-2 sets or alternative approaches might provide equally good performance without the computational overhead experienced in the application of a full type-2 system.

In conventional type-2 controllers, two control surfaces are obtained, one from the lower bound of interval type-2 defuzzification and one from the upper bound. Due to memory constraints or performance constraints, it is common to implement type-2 fuzzy controllers by calculating the control surface offline, by simply taking the mean of the lower and upper bound value returned by the controller, and then by downloading the resulting surface as a look-up table [7]. In this paper, Birkin and Garibaldi outlined a novel formulation of a controller which maintains the lower and upper control surfaces separately, and then switches dynamically between the surfaces. If the average of the lower and upper control surfaces is used, this novel controller reduces to a 'conventional' interval type-2 controller. Other dynamic combinations are also possible, such that some of the additional information available from an interval type-2 system is maintained in order to be utilised by the controller. This is termed a 'dual-surface' (interval) type-2 controller.

Non-stationary (NS) fuzzy sets, as described in [8] and [9], have been proposed to model variability in human decision making, and may offer a method to alleviate some of the issues raised by the application of type-2 sets. NS fuzzy sets are a relatively new development in the field and are based on the principles of type-1 systems. The 'non-stationary' component refers to variations made to the membership functions defined

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

in a type-1 system. A NS fuzzy set uses perturbations of standard T1 membership functions to produce several slightly different membership function on each iteration through the system. These can then be processed iteratively in the inference system and outputs aggregated, such as by majority vote or mean. NS fuzzy sets have the potential to cope with uncertainty in a problem domain while limiting the additional computational overhead. However, the current extent of comparisons between the different fuzzy controllers is somewhat limited.

It is clear that both theoretical and practical comparisons must be performed in order to understand the differences between the three different fuzzy systems. In this paper we use a simulated autonomous sailing problem (SASP) to examine the practical differences between the different fuzzy control mechanisms. The SASP forms an ideal test-bed for a number of reasons. Firstly, control of an autonomous robot is a challenging problem containing decision making in an uncertain environment. Secondly, this problem involves the interplay between a simulated boat and a dynamic environment, in which data from both the boat and environment are inherently noisy. The amount of uncertainty present in the SASP is an important factor in this application selection. Fuzzy controllers have been researched within the domain of autonomous sailing, especially the application of type-1 controllers, including [10]. In particular, [11] used a type-1 fuzzy system to control an autonomous boat of 1m in length around a predefined course using an attached state machine to handle situations such as tacking (upwind navigation through side to side movement). In this paper it is shown that while the fuzzy controller performed well downwind, it struggled to perform in upwind/tacking scenarios. Fuzzy controllers are not the only method used in the control of autonomous sailing boats. PID controllers [12], and neuro-endocrine approaches [13] have also been successfully applied to navigation problems. Proportional Integral (PI) controllers are also indicated as suitable control mechanisms for autonomous sail boat navigation.

The aim of this paper is to provide a comparison between a number of alternative controllers, including a Proportional-Integral (PI) controller, a type-1 and a conventional interval type-2 controller, when applied to the SASP. We investigate changes in the behaviour of the controllers upon the application of environmental noise, in our case, changes in simulated wind direction. We use a simulator termed 'Tracksail' to perform our experiments (see Section III-A). Performing the experiments in simulation has the distinct advantage that experimental set-ups can be precisely replayed and repeated, allowing for the comprehensive analysis of the different techniques. We examine differences between controllers through the resultant control surfaces and by statistical analysis of the experimental results.

This paper is organised as follows: Section II describes the components of the fuzzy systems that are under test along with a PI controller that was used as a control. Section III outlines the environment and experimental set-up used to make the comparison. This is followed by Section V which presents the results obtained, followed by Section VI which discusses the implications of these results and draws some conclusions. Finally, Section VII outlines some avenues for potential future work.

II. Fuzzy Robot Control

A. Design Decisions

Stelzer's work on fuzzy sailboats [14], [11] is used as a basis for our controller design. Several changes were necessary due to lack of data about our boat model which were used in the paper to determine some of the parameters, such as *rate of turn* and *heeling* of the boat. Error was retained as the difference between current and desired directions in degrees as shown in Equation 1 while an additional input, change in error has been added to the system. This is defined as the change in the error since the previous iteration of the controller as shown in Equation 2.

$$error = Desired\ Direction - Current\ Direction \quad (1)$$

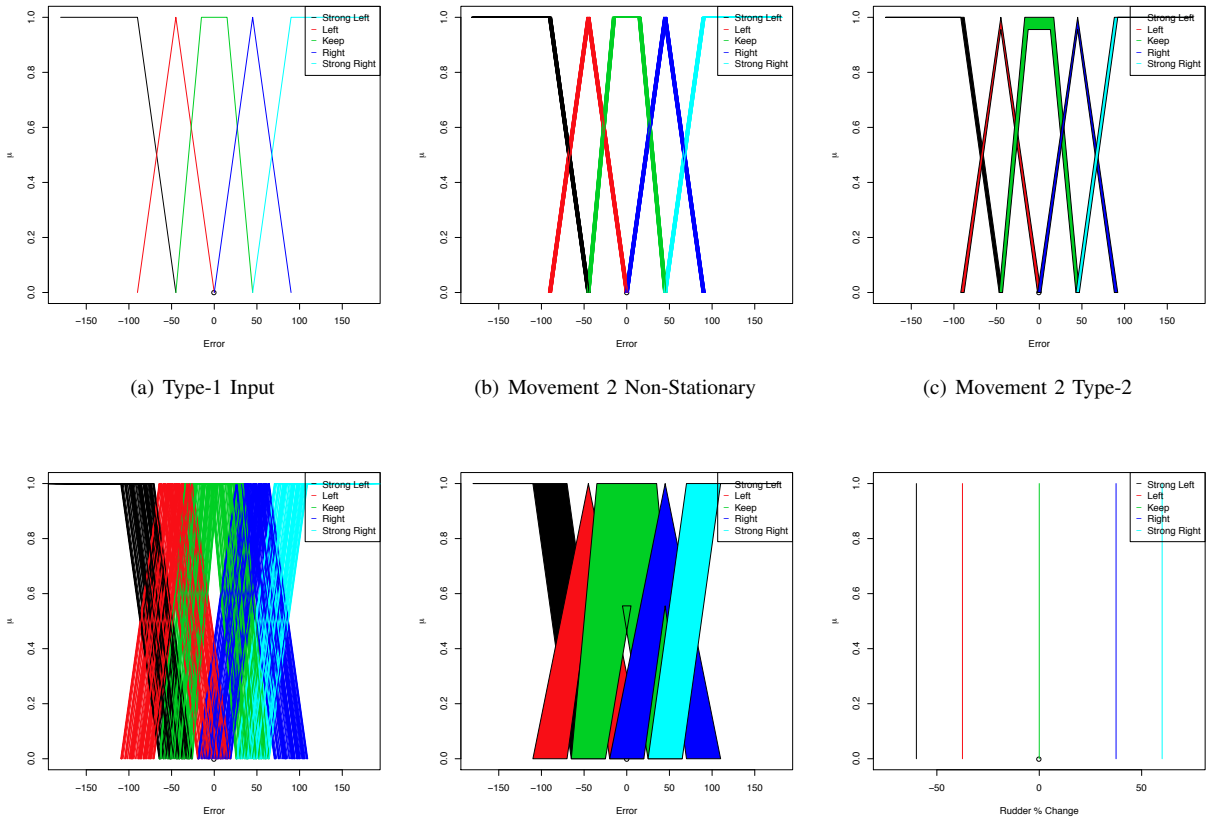
$$\Delta error = Current\ Error - Previous\ Error \quad (2)$$

Each input has five associated fuzzy sets which gives a rule base of 25 rules as shown in Table II-C. The membership functions (MFs) for the terms of the two inputs are shown in Figure 1(a), along with the output of the system which is the percentage change of the rudder of the boat characterised by singleton outputs, shown in Figure 1(f).

Horizontal perturbations of the type-1 membership functions was used to generate our non-stationary controller membership functions. The perturbation function was a horizontal movement defined by a gaussian distribution with a mean of zero. The standard deviation of the distribution was altered several times per batch of experiments to generate several different non-stationary controllers and resulted in input membership functions as shown in Figures 1(b) and 1(d). During execution, each controller would select 30 values from the above distribution to create 30 membership functions which were then processes as a standard type-1 system, the mean of the outputs from each of the 30 systems was taken to give a final output.

Interval type-2 systems in which secondary membership functions are binary instead of continuous can be visualised as a two dimensional area known as the Footprint of Uncertainty (FOU). This makes interval type-2 systems considerably more manageable than the general type-2 variety. We have derived footprints of uncertainty by starting with the simple type-1 and moving a uniform distance along the x-axis in both directions providing a lower and upper bound. This gives FOUs that are very similar in shape to the non-stationary membership functions as shown in Figures 1(c) and 1(e).

A dual surface type-2 controller is implemented to determine if improved results can be achieved through incorporating extra information, such as the upper and lower outputs as outlined in [7]. This employs the algorithm described in Figure 2 for selection of control surfaces and determination of output. This algorithm compares a user chosen metric, in this case the magnitude of the input error with a threshold value.



(a) Type-1 Input (b) Movement 2 Non-Stationary (c) Movement 2 Type-2

(d) Movement 20 Non-stationary (e) Movement 20 Type-2 (f) Type-1 Output Singletons

Fig. 1. Membership functions of Type-1, Type-2 and Non-stationary controllers. Unless stated these are input membership functions

```
error = control_var - set_point
diff = abs(error)
if ( diff < THRESHOLD )
   control_action = (LS + US) / 2
else
   if ( error > 0 )
      control_action = LS
   else
      control_action = US
endif
```

Fig. 2. The dual-surface control algorithm

On this basis, the final output of the system is selected from either the lower, upper or mean value. For this comparison, the original method of using the magnitude of the error in the system is retained. As with other controllers, several different threshold values are used to determine any observable effect on the system and its performance.

B. Tuning & Optimisation

While manual tuning of the original membership functions ([14] and [15]) was performed we did not specifically perform any automatic tuning for two main reasons. Firstly the intention was to ensure generality and this would not be possible were we to use a specific training data set. Secondly it would be difficult to ensure the same ámountóf tuning was performed on each different variety of fuzzy due to the different methods required to tune for example, a type-1 system compared to a type-2, which could potentially lead to unfair comparisons being made.

C. Tacking Behaviours

With respect to the application of our controllers to SASP, additional behaviours need to be defined. One drawback of using SASP for testing these controllers is the limits of the wind — no boat can sail directly into the wind. To solve this problem, higher level control was added which modifies the desired direction input to the controller. Sailing into the wind in practice requires tacking behaviour. The design of the courses for our experiments attempts to minimise this effect by setting courses which should avoid the need to tack. The main-sail on the boat is controlled by a simple set of rules that were previously developed in conjunction with the PI controller and have been shown to provide acceptable performance.

TABLE I
RULE TABLE FOR TYPE-1 CONTROLLER: ROWS SHOW *delta error* FUZZY SETS; COLUMNS SHOW *error* FUZZY SETS; SR: STRONG RIGHT; R: RIGHT; K: KEEP; L: LEFT; SL: STRONG LEFT

	Large Positive	Positive	None	Negative	Large Negative

Left	k	l	r	k	k
Middle	k	l	k	r	k
Right	k	k	l	r	k
Strong Right	l	l	l	sl	sl

III. EXPERIMENTAL SETUP

A. Tracksail

The simulator used for this research, Tracksail has been used previously for development and testing of autonomous sailing robotic systems [16] including the development and tuning of described PI controller. Tracksail is Java based and communicates with controllers by means of a TCP/IP socket allowing any compatible language to be used to control the boat. Each controller is linked into a common framework which provides tacking logic, sensor readings and motor change routines in addition to any other common code required. This ensures consistency between runs with different controllers.

One aim of this work is to investigate changes in the performance of type-2 controllers as the size of the FOU is varied. This is facilitated by the simulator in that it eliminates many categories of uncertainty not directly relevant to this investigation. This includes sensor noise, where the value returned by the sensor does not truly reflect the physical value that it is measuring, for example.

B. Track Configuration

Each experiment batch consists of 30 simulator runs where the tested controller will attempt to guide the boat towards a single way-point which was defined as 550 metres west of its starting point, defined by the simulator as the point (0,0). In the first batch of experiments the wind direction was fixed as 30 degrees across the boat at a fixed velocity of 7 m/s. This means that the wind will not introduce any noise in this experiment. However, we still observed minor differences between runs, potentially attributed to the timing of interacting processes and delays caused by socket processing in the software and operating system.

A series of experiments introduced wind related noise into the system at two distinct levels. Noise was defined as a specified number of wind changes per second and by the size of the arc defined by the *Max* and *Min* wind direction parameters specified in the simulator which are specified in degrees. Experiment two (medium noise) used an arc of 20° and a single wind change every five seconds, while experiment three (high noise) used a 30° arc with a wind change every three seconds.

C. Performance Metrics

Two metrics of performance were collected for all controllers. The first is the total root mean square of the error (RMSE) between the current heading compared with the desired bearing. The second metric is the time taken for the boat to complete the set course which is a straight line distance of 550 'metres'. The correlation between RMSE and time taken is not as trivial as in the case of a wheeled robot as the boat controller must balance deviating from a straight line sufficiently to capture enough wind for forward movement, against the extra time taken to perform this manoeuvre. Higher boat speeds in Tracksail can be reached when the boat is parallel to the wind, with the sail set to 90 degrees. However, if this is performed for the entire duration the boat would not reach its destination. Hence, a balance between speed and keeping on course must be found. This becomes increasingly important as noise is introduced into the wind direction variable.

IV. CONTROLLER SETUP

For reference and control purposes a tuned PI controller is included in the comparison. This controller uses the same input value (error between current and desired bearings) as well as its integral over time instead of the change in error. It uses a P-gain value of 1.7 and an I-gain value of 0.01. These values are derived in previous experiments performed by Suaze and Neal [17].

The running rate for all controllers was fixed at 1Hz. This is chosen to ensure that the more sophisticated controllers can execute a complete control loop. This low running rate may lead to lower performance than optimal as overshoot may occur with slow running controllers. However, as all controllers were subject to the same restrictions, we believe the comparison to be fair.

Five individual values were chosen for the perturbation function of the non-stationary controller, namely 0, 2, 5, 10 and 20 degrees. These values fall within the limits of plausibility for perturbation of the *error* and *delta error* inputs to the system. This provides insight as to where the true optimal value may occur. These measures will also be used to define the FOUs of the interval type-2 systems where the number refers to the width of the FOU at any flat point ($x = c$).

Numerous parameters in the interval type-2 system (and hence the dual surface controller) were fixed to ensure consistency with the type-1 system. Each experiment involves the variation of a single parameter. In the standard type-2 case we defined a parameter `movement` which defines the width of the input FOUs and in the dual surface case we used a variable threshold value with a fixed movement value of 5.

As a validation exercise we ran experiment one (low noise) with type-2, non-stationary and dual surface controllers with the parameters including movement value and threshold (where appropriate) set to zero. This is used to highlight that when upper and lower membership functions are set to be equal, the footprint of uncertainty is reduced down to type-1 sets. This confirmed that the performance is equivalent to that of the standard type-1 system. The small disparity was put down

to operations in the system such as floating point arithmetic which are performed in different orders in the type-2 based and non-stationary systems. We are therefore satisfied that our type-2 and NS implementations are valid and correct when compared with the type-1.

A. Hypothesis

In our experiments we predict that all controllers will show a reduction in performance as the amount of noise introduced into the environment is increased. We anticipate that the performance decrease shown in type-2 systems will be less in magnitude than that of the type-1 controller due to their ability to deal with uncertainty. We also aim elucidate the influence of the size of the FOU on the overall performance of the type-2 controller. In our experiments we ascertain if controllers with larger FOU values will produce improved performances over those with smaller FOUs under higher environmental noise conditions.

V. RESULTS

From Figure 3, it can be observed that as the noise increases (left to right in the subsigures), the courses increase in deviation. This aligns with the hypothesis that increase in environmental noise will result in increasingly non-linear routes.

The results of experiment one (low noise) are shown in Table V, in which it can be observed that the standard type-2 interval controllers have variations in which the RMSE performance is shown to be significantly better than the type-1 and PI controllers. However, there is a peak in the performance increase which occurs at a FOU size of 10 after which performance reduces and drops to lower than that of the PI. A similar pattern is observed in the case of the dual surface controller. However, in this case both RMSE and time taken start off lower

than even the PI but then improves to show the best performance overall. We hypothesise that if the threshold was further increased performance would once again eventually to

TABLE IV

(a) Exp 1 Course Example (Low Noise) (b) Exp 2 Course Example (Medium Noise) (c) Exp 3 Course Example (High Noise)

Fig. 3. Pots of example course taken by PI (green) and Type-2 (blue) at low, medium and high noise levels. Course end point shown as a red circle.

dip below the PI performance level. In this experiment these RMSE improvements do not lead to a significant reduction in time to complete the course compared with the type-1.

Experiment two (medium noise) increases the amount of noise present in the environment with the results shown in Table reftab:Exp2. These clearly show the anticipated drop in performance with the average increase in RMSE being 5.06 and the mean increase in time being 40.2 seconds. A very similar pattern to the previous experiment can be observed in the performance values of the standard type-2 and dual surface results with a peak in performance being observed at a movement level of 10° for the interval type-2 controller, and at a threshold of 50 for the dual-surface controller. Once again it is hypothesised that a threshold greater than that tested would show a drop in performance. Overall, this experiment demonstrates that the type-2 controllers all out-perform the type-1 variety under these noise conditions.

Table V summarises the results of experiment three (high noise). The overall the performance is somewhat lower than for the previous experiment with only one configuration of the dual-surface controller obtaining statistically significant improvements over the type-1 controller, whilst none of the standard interval type-2 or non-stationary approaches achieved this (in the *time taken* metric), though the non-stationary controller did produce two cases in which the RMSE was improved significantly. The mean RMSE increase between experiments one and three were 9.57 with an average time increase of 10.4s.

Two-sided unpaired Mann-Whitney tests are used to determine any statistically significant differences between the type-1 compared against the non-stationary, type-2 and dual-surface controllers. This is performed for both RMSE and *time taken* metrics with a p-value of 0.05 being used to reject the null hypothesis. This test is also performed for the PI and type-1 controllers for all three experiments. The type-1 RMSE proved significantly lower than the PI with low noise (experiment one). For medium and high noise, it was found that the PI is significantly better (lower RMSE) than the type-1 controller. However, in the cases of the total time taken, the type-1 controller was significantly better (lower) than the PI in low and high noise, with the opposite being true for medium noise.

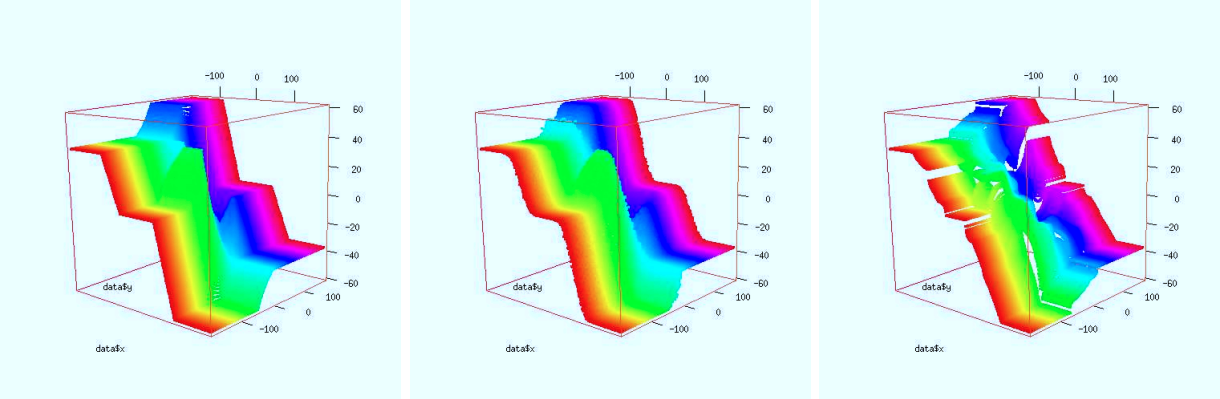
VI. Discussion & Conclusions

Our findings are summarised below, followed by a more detailed analysis and discussion in the following section.

- At low and high noise levels the more sophisticated controllers generally do not show a statically significant improvement when compared to the type-1 controllers. Specific controllers in each category do show this improvement however.
- At medium noise levels type-2, non-stationary and dual-surface controllers generally do exhibit statistically significant improvements on the type-1 method.
- The results difference between PI and type-1 controllers show that type-1 does improve upon the PI for the RMSE metric and improves under lower noise conditions and low and high noise conditions for the time metric.

The fact that the PI controller actually out-performed the type-1 controller in some experiments, however insignificantly, does tend towards the conclusion that some aspects of the type-1 system were not tuned optimally and that further work may be required in this regard. However, any changes required would also affect the other controllers, which have been based on this type-1. For this reason, we do not anticipate that there would be a great deal of alteration in the general ordering of the performance of the various controllers, were this to be done.

Overall, the performance of the pure type-2 controller was somewhat lower than anticipated and it failed to perform significantly better than the type-1 system in some cases, as is especially evident at low and high noise levels. One potential reason that this could be attributed to is the somewhat naïve method by which the FOUs were generated — that is by blurring a type-1 membership function in an equal distance in either direction. However, it has been shown that simple augmentations made to type-2 systems in form of the dual-surface controller can improve the results of this controller



(a) Type-1 Control Surface (b) 20 Non-stationary Control Surface (c) Movement 20 Type-2 Control Surface

Fig. 4. Control Surfaces for Type-1, Type-2 (Movement=20) and Non-stationary (Movement = 20) Controllers at varying noise levels

type somewhat and that if alternative methods for selection between the different outputs were investigated performance could be improved even more.

The results of the non-stationary approach in these experiments shows that in some situations that it can provide equal, or better performance than similar type-2 or dual surface controllers showing that these approaches do offer a viable alternative to type-2 systems as, even though their performance is not always fully comparable, the simplicity to implement in conjunction with the lower computational overhead does give this approach several distinct advantages.

In all of the more sophisticated controllers, the size of the movement (FOU size in type-2 based and horizontal perturbation) had a large effect of the output of the system. In almost all cases there were values selected in which performance decreased markedly. For example, using a value of 20 movement in all three experiments caused the type-2 controller to perform significantly worse than a movement of 10. When the membership functions and FOUs at these levels are observed (Figure 1) it may be suggested that in such cases the degree of overlap would cause considerably more rules to fire than occur at lower movement levels indicating that

would would either have to alter the rule-base to accommodate this or change the shape or spacing of the fuzzy sets so that this was less of a problem. This therefore implies two things. Firstly, the shape of the FOU may well be less important that its overall size or width and, secondly, that the selection of this size must be matched to the size of the uncertainty of the environment in which the controller must perform. To support the experimental work done we have also generated control surfaces for each of the described controllers. Inputs were set between -180° and 180° for both inputs and increased in 1° steps which then map to output percentages between -60% and 60%, resulting in Figure 4 and (zoomed in) Figure 5. It can be seen in the type-1 controller (Figure 4(a)) that the gradient changes are very sharply defined (causing sharp controller changes), which contrasts with both the non-stationary and type-2 controllers that are much smoother, leading to smoother controller transitions. Both varieties show a different type of smoothing with the non-stationary displaying more randomly distributed output points and the type-2 showing a more linear smoothing but both do show the same pattern that as the FOU is increased the smoothness of the transition also appears to increase.

While both of these controllers show this smoothing behaviour, it can also be observed in the type-2 surface that there seem to be artefacts in the form of white lines and areas which are not present on the other surfaces and which seem to increase in size as the footprint of uncertainties are increased. The exact nature and reason behind these artefacts are not yet fully understood but have recently been discussed and reasoned about in [18]. However the existence of these discontinuities highlights the complexity of designing and implementing type-2 fuzzy systems and shows that it is far from a trivial task. Currently available software for implementing type-2 systems is also fairly limited — while some free libraries exist many are implemented in MATLAB which is sometimes unavailable due to cost and licensing issues. There are however a great many type-1 libraries available at no charge and adaptation of one of these to create a non-stationary systems is trivial while adding the necessary code to enable type-2 is significantly harder.

In summary, these experiments show that using type-2 control can certainly give performance that exceeds that of type-1 controllers under certain environmental conditions (medium noise, in our case), whereas this performance gain is not necessarily seen in conditions wither of too low noise or too high noise. While this has long been suspected, we believe this paper provides clear experimental confirmation of this observation. We can also see that with the increase of noise this 'optimal' FOU size will increase with it and that the dual-surface controller gives a computationally inexpensive method for getting even more performance out of a type-2 system, but again careful selection of the threshold value is required to achieve these gains.

VII. Future Work

We have shown that type-2 based systems can certainly be derived from type-1 and produce performance that exceeds type-1 and PI based approaches under certain conditions, described here as a medium noise environment. Further work is required is to formalise these findings and develop a method by which noise levels can be used to generate an estimate of the FOU required for optimal performance to match the given certain conditions. For example in the above case, we would like be able to estimate an effective FOU size based on the size and frequency of the wind changes in the environment. This method could also be applied to non-stationary approaches to observe its behaviour and performance in these scenarios.

***Abstract*—The supplier selection is one of the most important components of production and logistics management for many companies. The supplier selection problem involves different kinds of words in which all of the criteria are weighted using one kind of words and the performance evaluations for all sub-criteria are another kind of words. How to aggregate these words without losing information is a very daunting task using a type-1 fuzzy set (T1 FS) approach. This paper applies a new methodology—Perceptual Computer (Per-C)—to help solve this hierarchical group multi-criteria decision making problem. The Per-C has three components: encoder, computing with words (CWW) engine and decoder. First, the interval approach (IA) is used to obtain interval type-2 fuzzy set (IT2 FS) word models for the words in a pre-specified vocabulary. Second, a linguistic weighted average (LWA) is used to aggregate all the words modeled by IT2 FSs. Finally, a centroid-based ranking method is used to rank the supplier selections, and a similarity measure is used to obtain similarities of the supplier selections. A committee of judges organized with *P* decision makers and *K* experts decides the winning supplier selection as the one with the highest ranking and least similarity to other suppliers.**

***Keywords*-interval type-2 fuzzy set (IT2 FS); perceptual computer (Per-C); supplier selection.**

I. INTRODUCTION

In today's highly competitive environment, outsourcing has become a main stream practice in global business operations [1]; hence, supplier selection is one of the most important components of production and logistics management for many companies. The selection of appropriate suppliers can help companies significantly enhance competitiveness in the market and increase customer satisfaction.

Supplier Selection is a multiple-criteria decision-making (MCDM) problem which is affected by several conflicting factors. Many methods have been proposed and used for supplier evaluation and selection [1-20].

In classical MCDM methods, the ratings and the weights of the criteria are known precisely [3-5]. In fact, human judgments including preferences are often vague, so that a judge can not estimate his preference with an exact numerical value. A more realistic approach may be to use linguistic assessments instead of numerical values to describe the desired value and important weights of criteria.

Because words can mean different things to different people, it is important to use a fuzzy set (FS) model for a word that lets us capture word uncertainty. At present, there are two possible choices, a type-1(T1) FS or an interval type-2(IT2) FS [21-23]. A large number of papers have solved the supplier selection problem using T1 FSs [2,6-20]. That using IT2 FSs as models for words is scientifically correct, whereas using a T1 FS model for a word is scientifically incorrect, follows from the following reasoning [22,24]: (1) A T1 fuzzy set A for a word is well-defined by its MFμ A (x) (x□ X) that is totally certain once all of its parameters are specified; (2) Words mean different things to different people, and so are uncertain; and, therefore, (3) it is contradiction to say that something certain can model something that is uncertain.

Lotfi Zadeh [25-27], the father of Fuzzy Logic, coined the phrase "computing with words" (CWW). He also stated he was interested in developing a computational theory of perceptions—the development of machinery for computing and reasoning with perceptions [28]. Although perceptual computing is a sub-set of CWW, it has a much longer history than CWW. Perceptual Computing used in this paper is associated with the machinery for computing and reasoning with perceptions and data. The architecture for perceptual computing is called a Perceptual Computer (Per-C), and was first used by Mendel [22, 29-30].

This paper is about how the Per-C theory can be applied to the supplier selection problem. The rest of this paper is organized as follows. Section II provides a complete description of the supplier selection problem. Section III introduces a Per-C approach for supplier selections. Section IV gives an example and obtains results using the Per-C approach. Section V draws conclusions.

II. SUPPLIER SELECTION PROBLEM STATEMENT

To achieve a company's purchasing objective, the supplier selection problem may involve n candidate suppliers, each denoted by S_i where $i = 1,\ldots,n$, from which the best supplier is chosen. A committee is organized with $P + K$ judges, where P decision makers are from cross-functional divisions within the company, each denoted by D_p where $p = 1,\ldots,P$, and where K experts are outsiders (i.e., consultants), each denoted by E_k where $k = 1,\ldots,K$. These P decision-makers come up with and decide on a list of M main criteria and l sub-criteria

The work is supported by the National Natural Science Foundation of China (NSFC) under project 70771025.

under each main criterian for supplier selection through brainstorming sessions, and give the weights of all criteria, respectively. The K experts are used to evaluate the performance scores of the sub-criteria for each supplier. The supplier evaluation problem is summarized in Fig. 1. The evaluation criteria of the problem are adopted from [10] on the basis of our literature review. Table I summarizes and defines the abbreviation that are used in Fig. 1.

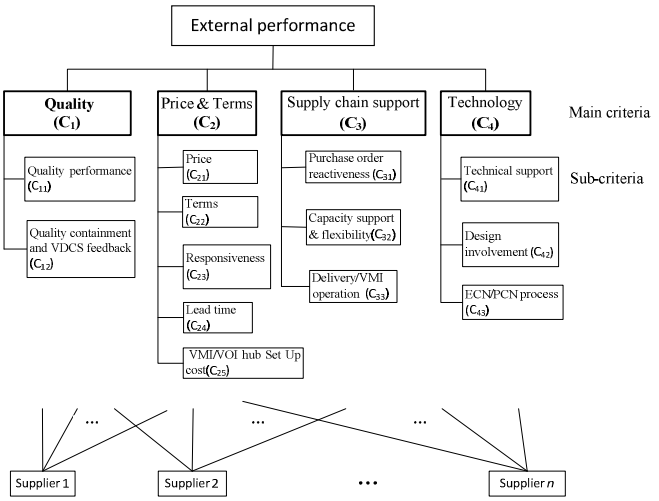

Figure 1. Hierarchical evaluating structure for supplier selections.

It is very clear from this figure that this is a multi-criteria and two-level decision making problem. At the first level each of the n suppliers is evaluated for its performance on four main criteria: Quality (C1), Price & Terms (C2), Supply chain support (C3) and Technology (C4). There are l sub-criteria $(C_{m1}, C_{m2}, \ldots, C_{ms}, \ldots, C_{ml})$ under main criterion m, where $1 \le m \le 4,\ 1 \le s \le l$, and l equals 2, 5, 3 and 3 for C1, C2, C3 and C4, respectively (see Fig. 1). The second level in this hierarchical decision making problem involves a weighted aggregation of the four main criteria for each of n suppliers.

The all sub-criteria are defined using linguistic terms represented by seven words: very poor, poor, medium poor, fair, medium good, good, and very good. The importance weights for all criteria are also defined using linguistic terms represented by seven words: very low, low, medium low, medium, medium high, high, and very high.

This paper provides a new solution method for this group multi-criteria hierarchical supplier selection problem using Perceptual Computing theory and IT2 FSs.

III. PER-C FOR SUPPLIERS EVALUATION

The Per-C has three components: encoder, computing with words (CWW) engine and decoder. It is depicted in Fig. 2. The encoder transforms words into IT2 FSs that activate the CWW engine. The decoder maps the output of the CWW engine into a recommendation and some accompanying data. The CWW engine maps IT2 FSs into IT2 FSs. When perceptual computing is used for the supplier evaluation problem, each of three components must be considered. Table II summarizes and defines the symbols that are used throughout the rest of this paper.

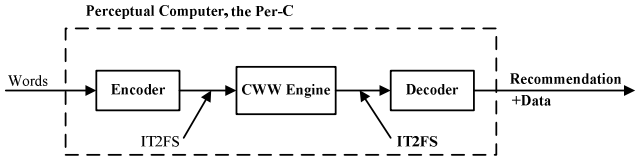

Figure 2. The Per-C that uses IT2 FS models for words [24, 30].

TABLE II. SYMBOLS AND DEFINITIONS

Symbols	Definitions
$\tilde{X}_{ms}^{k}(S_i)$	Assessment of sub-criterion s for major criterion m provided by expert k about S_i (supplier i)
$\tilde{X}_{ms}(S_i)$	Aggregation of $\tilde{X}_{ms}^{k}(S_i)$ across all K experts at S_i
$\tilde{Y}_{m}(S_i)$	Aggregation of $\tilde{X}_{ms}(S_i)$ for major criterion m across all of its sub-criteria, at S_i
$\tilde{Y}(S_i)$	Aggregation of $\tilde{Y}_{m}(S_i)$, at S_i
$\tilde{W}_{m}^{p}$	Linguistic weight assigned by decision maker p to major criterion m
$\tilde{W}_{ms}^{p}$	Linguistic weight assigned by decision maker p to sub-criterion s for major criterion m
$\tilde{W}_{ms}$	Aggregated weight across the P decision makers for sub-criterion s associated with major criterion m
$\tilde{W}_{m}$	Aggregated weight across the P decision makers for major criterion m

A. Encoder

Two codebooks are needed, one for the words that will be used by the experts and another for the weights that will be used by the decision makers. The codebook contains the words and their IT2 FS models.

1) Word FOUs: The interval approach (IA) [31] can be used to model a word using an IT2 FS. It is based on collecting interval end-point data from a group of subjects and does not require any a priori knowledge about FSs; hence, it can be used by anyone. It is a very practical method for mapping subject's data intervals into a footprint of uncertainty (FOU) for a word. The resulting FOUs are either interior, left-shoulder or right-shoulder FOUs (as in Fig. 3), and, it is the data that establishes which FOU models a word.

The IA consists of two parts, a Data Part and a Fuzzy Set (FS) Part. In the Data Part, data intervals (about where a word lies on a pre-specified scale) that have been collected from a group of subjects are pre-processed, after which data statistics are computed for the surviving intervals. In the FS part, FS uncertainty measures are established for a pre-specified triangle T1 MF [always beginning with the assumption that the FOU is an interior FOU, and, if need be, later switching to a shoulder FOU (as in Fig. 3)]. Then the parameters of the

triangle T1 MF are determined using the data statistics, and the derived T1 MFs are aggregated using union leading to an FOU for a word, and finally to a mathematical model for the FOU.

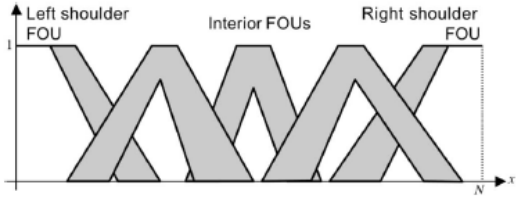

Figure 3. Left-shoulder, right-shoulder and interior FOUs, all of whose LMFs and UMFs are piecewise linear [24,31].

A word that is modeled by an interior FOU has an upper membership function (UMF) that is a trapezoid and a lower membership function(LMF) that is a triangle, but in general neither the trapezoid nor the triangle are symmetrical. A word that is modeled as a left- or right-shoulder FOU has trapezoidal upper and lower MFs; however, the legs of the respective two trapezoids are not necessarily parallel.

2) Word codebook used by experts: This codebook contains the seven words (*very poor, poor, medium poor, fair, medium good, good, very good*) and their FOUs that are used to assess some sub-criteria.

Some sub-criteria have a linguistic negative connotation, and for them, antonyms [32-34] (e. g. , "low" is the antonym of "high") are used instead of the raw words, i. e.

$$\mu_{10-\tilde{A}} = \mu_{\tilde{A}}(10-x) \tag{1}$$

where $10-\tilde{A}$ is the antonym of the IT2 FS $\tilde{A}$. Because an IT2 FS is completely characterized by its LMF ($\underline{A}$) and UMF ($\overline{A}$), each of which is a T1 FS, $\mu_{10-\tilde{A}}(x)$ above is obtained by applying antonyms of T1 FS to $\underline{A}$ and $\overline{A}$. In this paper the following sub-criteria are modeled using antonyms: trade variables, labor cost, inland transportation cost, land cost, law on investment and investment restrictions.

3) Codebook for the weights: This codebook contains the seven words (*very low, low, medium low, medium, medium high, high, very high*) and their FOUs are generated from interval data collected from domain managers and experts.

B. CWW Engine

The Linguistic Weighted Average (LWA) is used for the CWW Engine, because all the weights and ratings are modeled by IT2 FSs.

The *P+K* judges are collected together as a whole committee, so that they can interact and exchange ideas with each other. First, the evaluations of each sub-criterion are aggregated by *K* experts in the committee to get a single evaluation for it; the weights of each criterion assigned by *P* decision makers are aggregated to get a single weight for each of them. Then the aggregated sub-criteria evaluations are aggregated with the aggregated sub-criteria weights to get the four aggregated main criteria evaluations for each supplier. Finally, the aggregated main criteria evaluations are further aggregated with the aggregated weights to get the overall evaluation for each supplier.

Next, we perform four aggregations, as follows (see Table II for the definitions of symbols):

(1) Aggregation of $\widetilde{X}_{ms}^{k}(S_i)$ across the *K* experts at S_i (supplier *i)*:

$$\widetilde{X}_{ms}(S_i) = \frac{\sum_{k=1}^{K} \widetilde{X}_{ms}^{k}(S_i)}{K} \tag{2}$$

(2) Aggregation of linguistic weights $\widetilde{W}_{ms}$ and $\widetilde{W}_{m}$ $(m = 1,2,\ldots,4)$ across the *P* decision makers:

$$\widetilde{W}_{ms} = \frac{\sum_{p=1}^{P} \widetilde{W}_{ms}^{p}}{P} \tag{3}$$

$$\widetilde{W}_{m} = \frac{\sum_{p=1}^{P} \widetilde{W}_{m}^{p}}{P} \tag{4}$$

(3) Aggregation of $\widetilde{Y}_m(S_i)$ $(m = 1,2,3,4)$:

$$\widetilde{Y}_m(S_i) = \frac{\sum_{s=1}^{l} \widetilde{X}_{ms}(S_i)\widetilde{W}_{ms}}{\sum_{s=1}^{l} \widetilde{W}_{ms}} \tag{5}$$

(4) Aggregation of the overall performance $\widetilde{Y}(S_i)$ $(i = 1,2,\ldots,n)$:

$$\widetilde{Y}(S_i) = \frac{\sum_{m=1}^{4} \widetilde{Y}_m(S_i)\widetilde{W}_m}{\sum_{m=1}^{4} \widetilde{W}_m} \tag{6}$$

C. Decoder

The decoder maps the CWW Engine output FOUs into a recommendation. It computes similarity, centroid and rank. The supplier selection with the largest ranking, and with the least similarity to other suppliers will be the best suitable supplier.

1) Similarity computation: Similarity assesses the agreement between FSs. There are six similarity measures for IT2 FSs, but each of them has their drawbacks for CWW, so this paper adopts the similarity measure described in [24, 35], which is an extension of Jaccard similarity measure. In this paper, similarity, $SI[\widetilde{Y}(S_i),\widetilde{Y}(S_j)]$, is computed only for the supplier's overall performances $\widetilde{Y}(S_i)$ (i=1,2…,n), so that a judge can observe how similar the overall performances are. More specifically, $SI[(\widetilde{Y}(S_i),\widetilde{Y}(S_j)]$ is computed, as:

$$SI[\widetilde{Y}(S_i),\widetilde{Y}(S_j)] = \frac{\sum_{i=1}^{N} \min(\overline{\mu}_{\widetilde{Y}(S_i)}(x_i),\overline{\mu}_{\widetilde{Y}(S_j)}(x_i)) + \sum_{i=1}^{N} \min(\underline{\mu}_{\widetilde{Y}(S_i)}(x_i),\underline{\mu}_{\widetilde{Y}(S_j)}(x_i))}{\sum_{i=1}^{N} \max(\overline{\mu}_{\widetilde{Y}(S_i)}(x_i),\overline{\mu}_{\widetilde{Y}(S_j)}(x_i)) + \sum_{i=1}^{N} \max(\underline{\mu}_{\widetilde{Y}(S_i)}(x_i),\underline{\mu}_{\widetilde{Y}(S_j)}(x_i))} \tag{7}$$

where $\overline{\mu}_{\widetilde{Y}(S_i)}(x_i)$, $\underline{\mu}_{\widetilde{Y}(S_i)}(x_i)$ are the MF values on the UMF($\widetilde{Y}(S_i)$) and LMF($\widetilde{Y}(S_i)$), respectively.

2) Centroid computation: The centroid of an IT2 FS provides a measure of the uncertainty of such a fuzzy set [32]. Centroids, $C_{\widetilde{Y}(S_i)}$, are only computed for the supplier's overall performances $\widetilde{Y}(S_i)$ (*i*=1,2…,*n*) and provide a measure of uncertainty for each overall ranking, since all $\widetilde{Y}(S_i)$ have propagated both numerical and linguistic uncertainties through

their computations. $C_{\tilde{Y}(S_i)}$ is the union of the centroids of all of the embedded T1 FSs of $\tilde{Y}(S_i)$; $C_l(S_i)$ and $C_r(S_i)$ are the smallest and largest element of $C_{\tilde{Y}(S_i)}$, and $C_{\tilde{Y}_M(S_i)}$ is the mean of $C_{\tilde{Y}(S_i)}$, i. e.

$$C_{\tilde{Y}(S_i)} = [C_l(S_i), C_r(S_i)] \tag{8}$$

$$C_l(S_i) = \frac{\sum_{i=1}^{L} x_i \overline{\mu}_{\tilde{A}}(x_i) + \sum_{i=L+1}^{N} x_i \underline{\mu}_{\tilde{A}}(x_i)}{\sum_{i=1}^{L} \overline{\mu}_{\tilde{A}}(x_i) + \sum_{i=L+1}^{N} \underline{\mu}_{\tilde{A}}(x_i)} \tag{9}$$

$$C_r(S_i) = \frac{\sum_{i=1}^{R} x_i \underline{\mu}_{\tilde{A}}(x_i) + \sum_{i=R+1}^{N} x_i \overline{\mu}_{\tilde{A}}(x_i)}{\sum_{i=1}^{R} \underline{\mu}_{\tilde{A}}(x_i) + \sum_{i=R+1}^{N} \overline{\mu}_{\tilde{A}}(x_i)} \tag{10}$$

$$C_{\tilde{Y}_M(S_i)} = \frac{C_l(S_i) + C_r(S_i)}{2} \tag{11}$$

In equations (9) and (10), L and R are called "switch points", that are determined by KM Algorithms. Details on KM Algorithms can be found in [21, 24, 37-39].

3) Rank computation: $\tilde{Y}(S_i)$ (i=1,2…,n) in (6) are IT2 FSs; hence, the decoder must rank such IT2 FSs to find the best supplier. According to [24, 35], there are only two ranking methods for IT2 FSs; however both methods have their limitations; hence, this paper uses a simple ranking method based on the centroids of IT2 FSs proposed in [35].

First, the average centroid $C_{\tilde{Y}_M(S_i)}$ is computed for each supplier's overall performance $\tilde{Y}(S_i)$ (i=1,2…,n), using (8)-(11), and then $C_{\tilde{Y}_M(S_i)}$ are sorted to obtain the rank of $\tilde{Y}(S_i)$. Additionally, ranking bands of $\tilde{Y}(S_i)$, $r_{\tilde{Y}(S_i)}$, are computed, i. e. ,

$$r_{\tilde{Y}(S_i)} = C_{\tilde{Y}_M(S_i)} \pm \delta_{\tilde{Y}(S_i)} \tag{12}$$

where $\delta_{\tilde{Y}(S_i)}$ are the half-lengths of each centroid $C_{\tilde{Y}_M(S_i)}$ (n=1,2…,N), i. e.

$$\delta_{\tilde{Y}(S_i)} = \frac{C_r(S_i) - C_l(S_i)}{2} \tag{13}$$

IV. EXAMPLE

In this section, we use an example of a supplier selection decision to demonstrate that the Per-C approach is more appropriate than type-1 fuzzy set (T1 FS) approach. A high technology manufacturing company desires to select a suitable material supplier from three alternative suppliers (S_1, S_2, and S_3) to purchase the key components of new products. Suppose a committee of seven judges, i. e., three decision makers (D_1, D_2 and D_3) and four experts (E_1, E_2, E_3 and E_4), has been formed to determine the best of three suppliers. Table III and Table IV contain the data that will be needed in the example.

Referring to both Table III and Table IV, observe that:

(1) Quality has two sub-criteria, Price & Terms have five sub-criteria, Supply chain support has three sub-criteria, and Technology has three sub-criteria; hence, there are 13 sub-criteria all of which were established ahead of time by three decision makers.

(2) Every major criterion has three weights (in bold-face) all of which were assigned by the three decision makers using words.

TABLE III. CRITERIA WITH THEIR WEIGHTS TABLE [a]

Item	Weighting		
	D_1	D_2	D_3
Criterion1: **Quality (C_1)**	**H**	**VH**	**H**
1. Quality performance (C_{11})	MH	MH	VH
2. Quality containment and VDCS feedback (C_{12})	ML	M	MH

[a] In the 2nd -4thcolumns: VP=Very Poor, P=Poor, MP=Medium Poor, F=Fair, MG=Medium Good, G=Good, VG=Very Good (see Fig. 4).

(3) Every sub-criterion has three weights all of which were assigned by the three decision makers using words.

(4) Every sub-criterion has four performance evaluations, which are shown for all 13 sub-criteria for the three suppliers, and, are words. The word evaluations were obtained from the four experts.

How to aggregate all of these words, although seemingly very difficult, is accomplished by using (2)-(6).

Next, we provide the details for the Encoder, CWW Engine and Decoder and how the outputs from the decoder are used to decide the final winning supplier.

Step 1: *Encoder*

As noted in Section III. A, two codebooks are needed, one for the words that will be used by the experts and the other for the weights used by the decision maker. Two codebooks contain the words and their IT2 FS models.

(1) Codebook used by experts

Seven words were used in this sub-codebook, namely *very poor, poor, medium poor, fair, medium good, good, very good*. FOUs for these words are depicted in Fig. 4. They should be obtained by collecting data from a pool of domain managers and experts and their data intervals should be mapped into word FOUs using the IA whose details can be found in [31,36]. Because this application is being used only to illustrate how a Per-C can be used for supplier evaluation, and we did not have access to domain experts, interval end-point data were not collected for these words. Instead, we adopted the codebook from [31]. Unfortunately, none of the seven words that are actually used in this paper appear in that codebook; so, each word was mapped into a word that was felt to be a synonym for it. The relationships between the terms of the sub-criteria codebook here and that of the codebook in [31] are: v*ery poor=tiny, poor=low amount, medium poor=fair amount, fair=modest amount, medium good=good amount, good=a lot, very good=huge amount.*

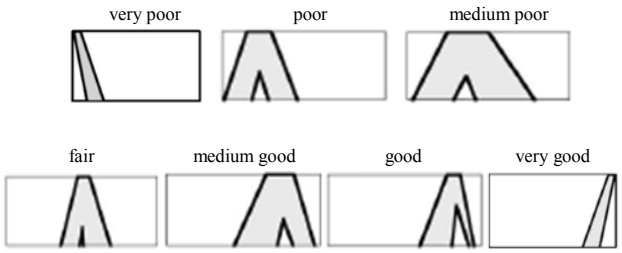

Figure 4. FOUs of the sub-criteria codebook.

For nine sub-criteria with a negative connotation [Quality containment and VDCS feedback (C_{12}), Price (C_{21}), Terms (C_{22}), Responsiveness (C_{23}), Lead time (C_{24}), VMI/VOI hub set up cost (C_{25}), Purchase order reactiveness (C_{31}), Delivery/VMI operation (C_{33}), ECN/PCN process(C_{43})], antonyms were used instead of the raw words, according to (1).

(2) Codebook for the weghts used by the decision makers

The codebook for the weights contains the seven words *very low, low, medium low, medium, medium high, high, very high*, and their FOUs that are depicted in Fig. 5. As above, we adopted each word's synonym from the codebook in [31]. i. e. *very low=very little, low=little, medium low=some, medium=medium, medium high=good amount, high=large, very high=very large*.

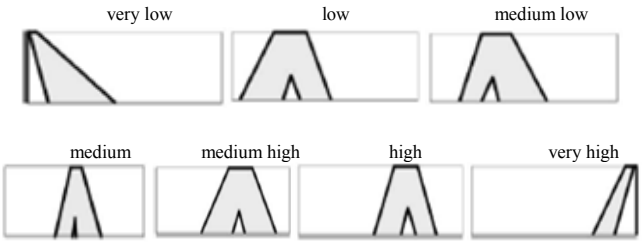

Figure 5. FOUs of the weights codebook.

Step 2: CWW Engine

The linguistic Weighted Average (LWA) was used for the CWW Engine. $\widetilde{X}_{ms}^{k}(S_i)$ (k=1,2,3,4) were aggregated by a LWA to obtain $\widetilde{X}_{ms}(S_i)$ (m=1,2,3,4; i=1,2,3), using (2); $\widetilde{W}_{ms}^{p}$ *and* $\widetilde{W}_{m}^{p}$ (p=1,2,3) were aggregated by LWAs to obtain $\widetilde{W}_{ms}$ *and* $\widetilde{W}_{m}$ (m=1,2,3,4), using (3) and (4), respectively. Each of them can be represented with 9 real numbers.

Each of the four major criteria has a LWA $\widetilde{Y}_m(S_i)$ (m=1,2,3,4; i=1,2,3) computed for it using (5). These four LWAs are then aggregated by another LWA to obtain the overall performance for each supplier, $\widetilde{Y}(S_i)$($i=1,2,3$), using (6).

Step 3: Decoder

The decoder computes the centroid, similarity and rank of the supplier's overall performance $\widetilde{Y}(S_i)(i=1,2,3)$.

(1) Centroid computation

Centroids, $C_{\widetilde{Y}(S_i)}$, and the mean of the centroid, $C_{\widetilde{Y}_M(S_i)}$, were computed for the three supplier's overall performances $\widetilde{Y}(S_i)(i=1,2,3)$ using (8)-(11).

(2) Similarity computation

Similarities, $SI(\widetilde{Y}(S_i),\widetilde{Y}(S_j))$ (i=1,2,3; j=1,2,3), between the three supplier's overall performances $\widetilde{Y}(S_i)$ (i=1,2,3) were computed using (7).

(3) Rank computation

Rankings, $r_{\widetilde{Y}(S_i)}$ (i=1,2,3), of the three suppliers were obtained from (12) and (13).

Step 4: Compute the evaluation results and decide the final winner

This section illustrates the supplier evaluation results for the three suppliers. In all figures, Supplier 1 is represented by the solid curve, Supplier 2 is represented by the dashed curve, and Supplier 3 is represented by the dotted curve. FOUs for Quality, Price & Terms, Supply chain support and Technology are depicted in Fig. 6 (a)-(d), respectively. FOUs for Overall Performance are depicted in Fig. 6 (e). Observe from Fig. 6(e) that not only is FOU ($\widetilde{Y}(S_3)$) visually well to the right of the other two FOUs, but its average centroid (which is on the horizontal axis) is also well to the right of those for Suppliers 1 and 2. FOU ($\widetilde{Y}(S_1)$) is almost the same as FOU ($\widetilde{Y}(S_2)$). So, based on ranking alone, Supplier 3 would be declared the

winner. This happens because Supplier 3 ranks first in Quality and Supply chain suport by a significant amount.

Although Supplier 3 ranks last for Technologe, its FOU is close to those of Suppliers 1 and 2, whereas FOU of Supplier 3 for Price & Terms(C_2) is also very close to those of Suppliers 1 and 2.

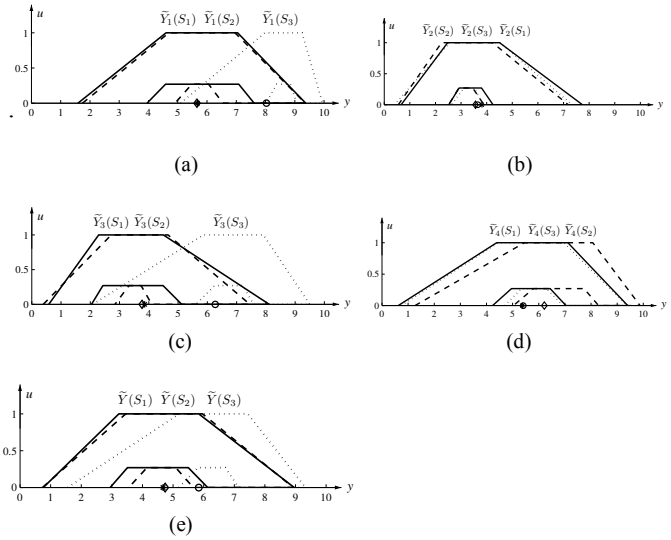

Figure 6. Aggregation results for (a) Criterion 1: Quality; (b) Criterion 2: Price & Terms; (c) Criterion 3: Supply chain support; (d) Criterion 4: Technology; and (e) Overall performances of the three suppliers. The average centroids for Suppliers A, B and C are shown in all figures by and $*, \Diamond$, and $\circ$, respectively.

Table V summarizes the similarities between $\tilde{Y}(S_1), \tilde{Y}(S_2)$ and $\tilde{Y}(S_3)$. Observe that $\tilde{Y}(S_3)$ is not very similar to either $\tilde{Y}(S_1)$ or $\tilde{Y}(S_2)$, and $\tilde{Y}(S_1)$ is very similar to $\tilde{Y}(S_2)$, so choosing Supplier 3 as the winner is further reinforced.

Table VI summarizes the centroids, average centroids, half-lengths and rankings of $\tilde{Y}(S_1), \tilde{Y}(S_2)$ and $\tilde{Y}(S_3)$. Observe that supplier 3 has the largest ranking, while it doesn't have the smallest uncertainty band about that ranking, but the uncertainty band about ranking of it is close to that of the Supplier 1 which has the smallest uncertainty band.

TABLE V. SIMILARITIES OF $\tilde{Y}$ FOR THREE COMPANIES

Supplier	$\tilde{Y}(S_1)$	$\tilde{Y}(S_2)$	$\tilde{Y}(S_3)$
$\tilde{Y}(S_1)$	1.00	0.93	0.56
$\tilde{Y}(S_2)$	0.93	1.00	0.58
$\tilde{Y}(S_3)$	0.56	0.58	1.00

TABLE VI. CENTROIDS, CENTERS OF CENTROID AND RANKING BANDS

Supplier	$\tilde{Y}(S_1)$	$\tilde{Y}(S_2)$	$\tilde{Y}(S_3)$
$C_{\tilde{Y}(S_i)}$	[3.17, 6.17]	[296, 6.52]	[4.25,7.43]
$C_{\tilde{Y}_M(S_i)}$	4.67	4.74	5.84
$r_{\tilde{Y}(S_i)}$	4.67 ± 1.50	4.74 ± 1.78	5.84 ± 1.59

The seven judges ultimately decide supplier 3 is the winner by comparing the three suppliers' overall performances and similarities between them, because supplier 3's overall performance not only has the largest ranking but it also is not similar to the other two suppliers, although the similarity is greater than 0.5 that implies more similar to than less similar to, and one may be less certain about choosing Supplier 3 as the winner.

In summary, the Per-C can consider scenarios with different numbers of judges; hence, one can evaluate the robustness of the final decision.

All the computations were implemented using Matlab software under MS Windows platform. Some basic routines can be found in the personal website of Mendel (http://sipi.usc.edu/~ mendel/software).

V. CONCLUSIONS

In order to enhance competitiveness in the market and increase customer satisfaction, the supplier selection problem for companies is very important. This paper applies a new methodology —Perceptual Computer (Per-C)—to help solve the supplier selection problem. This problem is a hierarchical group multi-criteria decision making problem in which a committee of seven (or more) judges has to decide which of three (or more) suppliers will be chosen. The Per-C has three components: encoder, CWW engine and decoder. During its design the concepts of an antonym and codebooks were needed. Without the LWA it would not have been possible to do what the Per-C has been able to do. The Per-C used the IA to obtain an IT2 FS FOU for a word; it used the LWA to aggregate all the words modeled by IT2 FSs; it used a centroid-based ranking method to rank competing suppliers; and, it also used a Jaccard similarity measure to obtain similarities of the computing suppliers.

***Abstract*—This paper proposes a *type-2 fuzzy functional inference method* which extends fuzzy sets of the antecedent parts to type-2 fuzzy sets. This paper next explains that the type-2 fuzzy functional inference method can be classified to the three models: Model 1 is most common method, and Model 2 is a special case of Model 1. We show that the inference results of both Models 1 and 2 can be easily obtained from the area of fuzzy sets of the consequent parts and center of gravity. Moreover, we state that Model 3 can obtain different results compared with the simplified fuzzy inference method and T–S inference method.**

***Index Terms*—Type-2 fuzzy inference, fuzzy functional inference method, internval type-2 fuzzy sets, fuzzy function, T–S inference method.**

I. Introduction

Since Mamdani [1] applied the concept of fuzzy inference to steam engine experimental device, relevant research and applications have been executed in various fields. Especially, researches on the T–S inference method [2], [3], which is widely used as fuzzy control method and so on, are reported in many papers.

Although the antecedent parts of the T–S inference method are fuzzy sets, the consequent parts are functions. However, it may be completely natural that the consequent parts are also fuzzy. From this reason, Seki and Mizumoto [4], [5] have proposed a *fuzzy functional inference method* in which the consequent parts of the T–S inference method is generalized to fuzzy functions, and shown the equivalence [6]–[15] between the fuzzy functional inference method and the weighted T–S inference method.

On the other hand, Type-2 fuzzy inference model [16]–[19] also has the structure, in which the antecedent parts and consequent parts are fuzzy sets. Type-2 fuzzy inference model has achieved a great success in the various fields.

In this paper, we poropose a *type-2 fuzzy functional inference method* which extends fuzzy sets of the antecedent parts of fuzzy functional inference method to type-2 fuzzy sets. Firstly, we state Model 1 in which the antecedent parts and consequent parts are type-2 fuzzy sets and fuzzy function, respectively. Secondly, we state Model 2 where the antecedent parts and consequent parts are type-1 fuzzy sets and fuzzy function, respectively. And, this paper show that the Model 2 is equivalent to the type-2 TSK fuzzy model, if fuzzy function of consequent parts of Model 2 is limited to a fuzzy function of linear expression. Thirdly, we state Model 3 in which the antecedent parts and/or consequent parts are interval value, respectively. Moreover, we calarify that Model 3 can obtain different results compared with the simplified fuzzy inference method and the T–S inference method.

II. Fuzzy Inference Methods

In this section we review the min–max–gravity method, product–sum–gravity method, T–S inference method, and fuzzy functional inference method.

A. Min–Max–Gravity method

We firstly explain the *min–max–gravity method* as *Mamdani's fuzzy inference method* [1] for the fuzzy inference form (see Fig. 1). The rules of the min–max–gravity method are given as follows:

$$\text{Rule } R_i = \begin{cases} x_1 = A_i^1, x_2 = A_i^2, \ldots, x_n = A_i^n \\ \longrightarrow y = B_i \end{cases} \tag{1}$$

where $x_1, x_2, \ldots, x_n$ are variables of the antecedent part, $A_i^1, A_i^2, \ldots, A_i^n$ fuzzy sets, B_i fuzzy sets of the consequent part, $i = 1, 2, \ldots, M$ and M is the total number of rules.

Each inference result B_i' which is infered from the fact "$x_1^0, x_2^0, \ldots, x_n^0$" and the fuzzy rule "$A_i^1, A_i^2, \ldots, A_i^n \longrightarrow B_i$" is given in the following.

The degree of fitness, h_i, of the fact "$x_1^0, x_2^0, \ldots, x_n^0$" to the antecedent parts "$A_i^1, A_i^2, \ldots, A_i^n$" is given as

$$h_i = \min\{A_i^1(x_1^0), A_i^2(x_2^0), \ldots, A_i^n(x_n^0)\} \tag{2}$$

Thus, the inference result B_i' is given as

$$B_i'(y) \quad = \quad \min\{h_i, B_i(y)\} \tag{3}$$

The final consequence B' of (1) is aggregated from B_1', B_2', $\ldots$, B_M' by using the max. Namely,

$$B'(y) = \max\{B_1'(y), B_2'(y), \ldots, B_M'(y)\} \tag{4}$$

The representative point y_0 for the resulting fuzzy set B' is obtained as the center of gravity of B':

$$y_0 = \frac{\int y \cdot B'(y) dy}{\int B'(y) dy} \tag{5}$$

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

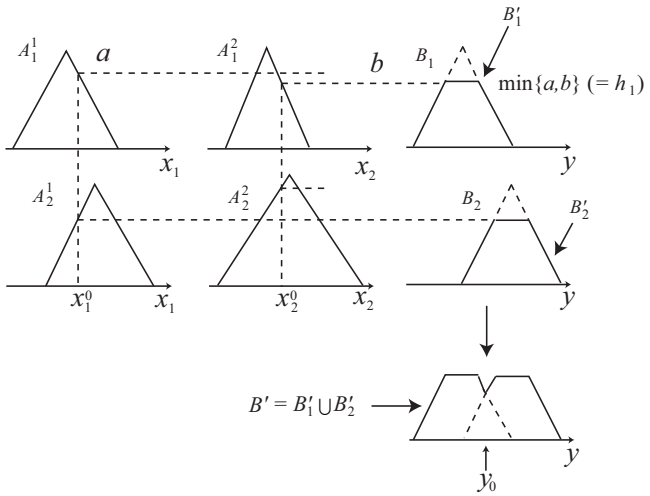

Fig. 1. Min–Max–gravity method.

B. Product–Sum–Gravity method

We secondly explain a fuzzy inference method called *product–sum–gravity method* [20]–[23] for the fuzzy inference form (see Fig. 2). The rules of the product–sum–gravity method are also given as (1).

Each inference result B_i' which is infered from the fact "$x_1^0, x_2^0, \ldots, x_n^0$" and the fuzzy rule "$A_i^1, A_i^2, \ldots, A_i^n \longrightarrow B_i$" is given in the following.

The degree of fitness, h_i, of the fact "$x_1^0, x_2^0, \ldots, x_n^0$" to the antecedent parts "$A_i^1, A_i^2, \ldots, A_i^n$" is given as

$$h_i = A_i^1(x_1^0) \cdot A_i^2(x_2^0) \cdots A_i^n(x_n^0) \tag{6}$$

where $\cdot$ stands for the algebraic product. Thus, the inference result B_i' is given as

$$\begin{aligned} B_i'(y) &= A_i^1(x_1^0) \cdots A_i^n(x_n^0) \cdot B_i(y) \\ &= h_i \cdot B_i(y) \end{aligned} \tag{7}$$

The final consequence B' of (1) is aggregated from $B_1', B_2', \ldots, B_M'$ by using the algebraic sum $(+)$. Namely,

$$B'(y) = B_1'(y) + B_2'(y) + \cdots + B_M'(y) \tag{8}$$

The representative point y_0 for the resulting fuzzy set B' is obtained as the center of gravity of B':

$$y_0 = \frac{\int y \cdot B'(y) dy}{\int B'(y) dy} \tag{9}$$

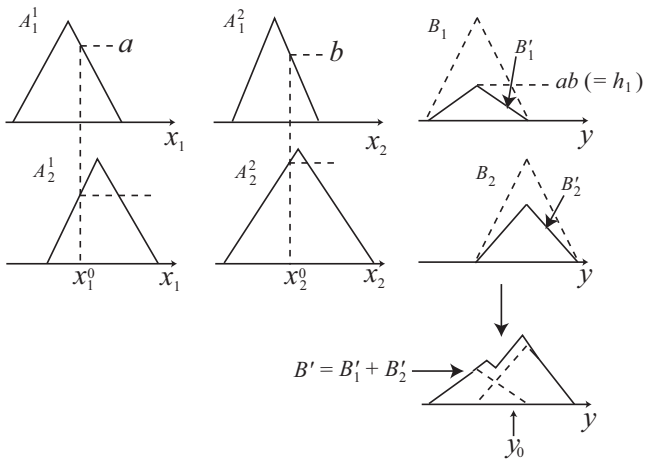

Fig. 2. Product–sum–gravity method.

C. T–S Inference Method

We thirdly explain the *T–S inference method* [2], [3].

Rules in the T–S inference method are constituted as

$$\text{Rule } R_i = \begin{cases} x_1 \text{ is } A_i^1,\ x_2 \text{ is } A_i^2,\ \ldots,\ x_n \text{ is } A_i^n \\ \longrightarrow y = f_i(x_1, x_2, \ldots, x_n) \end{cases} \tag{10}$$

where $x_1, x_2, \ldots, x_n$ are variables of the antecedent part, $A_i^1, A_i^2, \ldots, A_i^n$ fuzzy sets, and $f_i(x_1, x_2, \ldots, x_n)$ functions of the consequent part, $i = 1, 2, \ldots, M$ and M is the total number of fuzzy rules. The inference result y_0 for inputs $x_1^0, x_2^0, \ldots, x_n^0$ is given as

$$y_0 = \frac{\displaystyle\sum_{i=1}^{M} h_i f_i(x_1^0, x_2^0, \ldots, x_n^0)}{\displaystyle\sum_{i=1}^{M} h_i}, \quad h_i = \prod_{j=1}^{n} A_i^j(x_j^0) \tag{11}$$

where h_i is the degree of the ith rule.

The T–S method becomes the simplified fuzzy inference method when function $f_i(x_1, x_2, \ldots, x_n)$ in the consequence part is a constant.

D. Fuzzy Functional Inference Method

Although the antecedent parts of the conventional T–S inference method are fuzzy sets, the consequent parts are function. However, this structure is hard to understand from the different of antecedent parts and consequent parts. Rather, it may be completely natural that the consequent parts are also fuzzy.

In this subsection, we review a *fuzzy functional inference method* [4], [5] in which the consequent parts of the T–S inference method are generalized to fuzzy function. This method can make it easier to understand the structure of rules compared with the ordinary T–S inference method.

The rules in the fuzzy functional inference method are constituted as

$$\text{Rule } R_i = \begin{cases} x_1 \text{ is } A_i^1,\ x_2 \text{ is } A_i^2,\ \ldots,\ x_n \text{ is } A_i^n \\ \longrightarrow y = F_i(x_1, x_2, \ldots, x_n) \end{cases} \tag{12}$$

where $x_1, x_2, \ldots, x_n$ are variables of the antecedent part, $A_i^1, A_i^2, \ldots, A_i^n$ fuzzy sets, and $F_i(x_1, x_2, \ldots, x_n)$ are fuzzy functions.

Since the consequent parts $F_i(x_1, x_2, \ldots, x_n)$ constitutes fuzzy sets, the final output y_0 of the fuzzy functional inference method should be obtained from Mamdani type fuzzy inference method. For example, the inference result y_0 is obtained

as follows when the product–sum–gravity method is used (See Fig. 2).

Given the rules of (12), inputs $x_1^0, x_2^0, \ldots, x_n^0$ and each antecedent part $A_1^i, A_2^i, \ldots, A_n^i$, the degree h_i is obtained as (6), and the inference result $F_i(x_1^0, x_2^0, \ldots, x_n^0)'$ of each fuzzy rule is obtained as

$$F_i(x_1^0, x_2^0, \ldots, x_n^0)'(y) = h_i \cdot F_i(x_1^0, x_2^0, \ldots, x_n^0)(y) \quad (13)$$

where $\cdot$ is the algebraic product.

The final output F' of (12) is obtained by the summation of each inference result $F_i(x_1^0, x_2^0, \ldots, x_n^0)'$ as in (8). Namely,

$$\begin{aligned} F'(y) &= F_1(x_1^0, x_2^0, \ldots, x_n^0)'(y) + \cdots \\ &\quad + F_M(x_1^0, x_2^0, \ldots, x_n^0)'(y) \end{aligned} \quad (14)$$

The representative point y_0 of conclusion F' is obtained as follows:

$$y_0 = \frac{\int y \cdot F'(y) dy}{\int F'(y) dy} \quad (15)$$

III. Type-2 Fuzzy Functional Inference Method

In this section, we poropose a *type-2 fuzzy functional inference method* which extends fuzzy sets of the antecedent parts of fuzzy functional inference method to type-2 fuzzy sets. Rules of the type-2 fuzzy functional inference method are constructed as follows:

$$\text{Rule } R_i = \left\{ \begin{array}{l} x_1 \text{ is } \tilde{A}_i^1,\ x_2 \text{ is } \tilde{A}_i^2,\ \ldots,\ x_n \text{ is } \tilde{A}_i^n \\ \longrightarrow y = F_i(x_1, x_2, \ldots, x_n) \end{array} \right. \quad (16)$$

where $x_1, x_2, \ldots, x_n$ are variables of the antecedent part, $\tilde{A}_i^1, \tilde{A}_i^2, \ldots, \tilde{A}_i^n$ $(i = 1, 2, \ldots, M)$ type-2 fuzzy sets, and $F_i(x_1, x_2, \ldots, x_n)$ are fuzzy functions.

Given input $x_1^0, x_2^0, \ldots, x_n^0$, the degree $H(x_1^0, x_2^0, \ldots, x_n^0)$ is obtained by the extension principle as

$$H_i(x_1^0, x_2^0, \ldots, x_n^0) = \tilde{A}_1^1(x_1^0) * \tilde{A}_2^i(x_2^0) * \cdots * \tilde{A}_n^i(x_n^0) \quad (17)$$

where the operation $*$ is t-norm or average operation [5].

The inference result F' is obtained as follows:

$$F' = S_{i=1}^M H_i(x_1^0, x_2^0, \ldots, x_n^0) * F_i(x_1^0, x_2^0, \ldots, x_n^0) \quad (18)$$

where S is t-conorm, and the operation $*$ is t-norm or average operation, as used in the product–sum–gravity method, min–max–gravity method, and so on. For example, the inference result F' obtained by using the product–sum–gravity method, is given as follows:

$$\begin{aligned} F' &= \sum_{i=1}^M H_i(x_1^0, x_2^0, \ldots, x_n^0) \cdot F_i(x_1^0, x_2^0, \ldots, x_n^0) \\ &= \sum_{i=1}^M F_i'(x_1^0, x_2^0, \ldots, x_n^0) \end{aligned} \quad (19)$$

where $\cdot$ is the algebraic product.

The representative point y_0 of conclusion F' is obtained as follows:

$$y_0 = \frac{\int y \cdot F'(y) dy}{\int F'(y) dy} \quad (20)$$

The representative point y_0 is easily obtained from the area of fuzzy sets of the consequent parts and center of gravity by using the product–sum–gravity method [4], [5].

Note that it is possible to apply the *min–max–gravity method* by replacing algebraic product and algebraic sum with min and max, respectively, in (19).

IV. Property of type-2 fuzzy functional inference method

The type-2 fuzzy functional inference method can be considered as the following three models as well as the type-2 fuzzy logic systems [17].

- Model 1: Antecedent parts are type-2 fuzzy sets, and consequent parts are fuzzy function (see section III).
- Model 2: Antecedent parts are type-1 fuzzy sets, and consequent parts are fuzzy function (see subsection II-D).
- Model 3: Antecedent parts and/or consequent parts are interval value.

In this section, we discuss the property of the type-2 fuzzy functional inference method.

A. Model 1

Model 1 has the structure in which the antecedent parts and consequent parts are type-2 fuzzy sets and fuzzy function, respectively. The inference results of the conventional type-2 inference systems are obtained by using extension principle and type-reduction. However, the inference results of the type-2 fuzzy functional inference method are obtained from each area of (19) and its center of gravity if the additive fuzzy functional inference method [5] is used.

Therefore, we consider the type-2 fuzzy functional inference method in the case of using the product–sum–gravity method. By using the product–sum–gravity method, the inference result F_i' can be obtained as (19).

At first, let the area and the center of gravity of $F_i'(x_1^0, x_2^0, \ldots, x_n^0)$ of (19) be $S_i'(x_1^0, x_2^0, \ldots, x_n^0)$ and $f_i'(x_1^0, x_2^0, \ldots, x_n^0)$, respectively.

We use the following symbol for short:

$$F_i' = F_i'(x_1^0, x_2^0, \ldots, x_n^0) \quad (21)$$

$$f_i' = f_i'(x_1^0, x_2^0, \ldots, x_n^0) \quad (22)$$

$$S_i' = S_i'(x_1^0, x_2^0, \ldots, x_n^0) \quad (23)$$

From [4] and [5], the inference result y_0 of (20) of the type-2 fuzzy functional inference method can be transformed

to

$$
\begin{aligned}
y_0 &= \frac{\int y \cdot F_i'(x)(y)dy}{\int F_i'(x)(y)dy} \\
&= \frac{\int y \cdot \{F_1'(y) + \cdots + F_M'(y)\}dy}{\int \{F_1'(y) + \cdots + F_M'(y)\}dy} \\
&= \frac{\int y \cdot F_1'(y)dy + \cdots + \int y \cdot F_M'(y)dy}{\int F_1'(y)dy + \cdots + \int F_M'(y)dy} \\
&= \frac{S_1' \cdot f_1' + \cdots + S_M' \cdot f_M'}{S_1' + \cdots + S_M'} \qquad (24)
\end{aligned}
$$

From (24), it turns out that the inference reult y_0 of the type-2 fuzzy functional inference method is obtained from the area S_i' and the center of gravity f_i' of each inference result F_i', in case of an additive fuzzy inference method, which uses the addition as in (19) in the aggregation of each inference result.

Remark 1: In (18), the relation of (24) holds as long as the addition is used in the aggregation, even if instead of using algebraic product, min is used to the operation. Because the area, form and center of gravity of F_i' parts only change. □

B. Model 2

Model 2 has the structure in which the antecedent parts and consequent parts are type-1 fuzzy sets and fuzzy function, respectively. The rules of Model 2 are given as (12). The rules of Model 2 is equivalent to that of the type-2 TSK fuzzy system [17], when fuzzy function is limited to fuzzy function of linear expression, i.e., the rules are constructed as follows:

$$
\text{Rule } R_i = \left\{ \begin{array}{l} x_1 \text{ is } A_i^1,\ x_2 \text{ is } A_i^2,\ \ldots,\ x_n \text{ is } A_i^n \\ \longrightarrow y = C_i^0 + C_i^1 x_1 + C_i^2 x_2 + \cdots C_i^n x_n \end{array} \right. \qquad (25)
$$

where $x_1, x_2, \ldots, x_n$ are variables of the antecedent part, and $A_i^1, A_i^2, \ldots, A_i^n$ and $C_i^1, C_i^2, \ldots, C_i^n$ are type-1 fuzzy sets. Therefore, it turns out that Model 2 is extended version of the type-2 TSK fuzzy system.

As well as Model 1, the representative point y_0 of Model 2 is obtained from the area of fuzzy sets of the consequent parts and center of gravity (See [4], [5] for detail).

C. Model 3

Researches on fuzzy inference used interval-valued fuzzy sets are reported in [16]–[19], [24], [25]. Finally, we state a *interval type-2 fuzzy functional inference method* (IT2 fuzzy functional inference method) as Model 3.

Model 3 has the structure in which the antecedent parts and/or consequent parts are interval value.

We shall consider the following simple example (See Fig. 3).

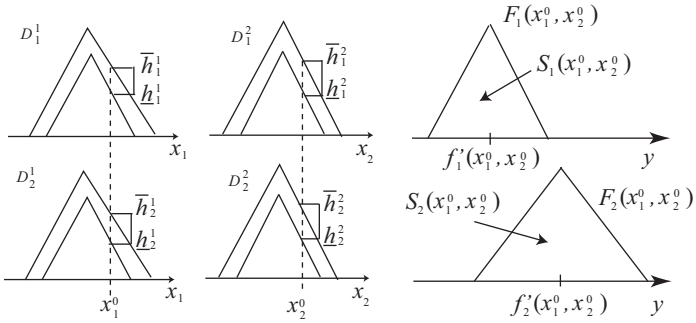

Fig. 3. Type-2 fuzzy functional inference method of Model 3.

$$
\text{Rule } 1: x_1 \text{ is } \tilde{D}_1^1, x_2 = \tilde{D}_1^2 \longrightarrow y = F_1(x_1, x_2) \qquad (26)
$$

$$
\text{Rule } 2: x_1 \text{ is } \tilde{D}_2^1, x_2 = \tilde{D}_2^2 \longrightarrow y = F_2(x_1, x_2) \qquad (27)
$$

where $\tilde{D}_j^i$'s are IT2 fuzzy sets, and $F_i(x_1, x_2)$'s are fuzzy functions.

Given input x_1^0 and x_2^0, the jth degree in the ith input x_i^0 is given as interval value as follows:

$$
\tilde{D}_i^j(x_i^0) = [\underline{h}_i^j, \bar{h}_i^j] \qquad (28)
$$

where $\underline{h}_i^j$ and $\bar{h}_i^j$ represent lower and upper of membership function, respectively.

The inference results of Model 3 are also obtained from the area and center of gravity as (24). That is,

$$
y = \frac{[\underline{h}_1^1\underline{h}_1^2, \bar{h}_1^1\bar{h}_1^2] \cdot S_1 f_1' + [\underline{h}_2^1\underline{h}_2^2, \bar{h}_2^1\bar{h}_2^2] \cdot S_2 f_2'}{[\underline{h}_1^1\underline{h}_1^2, \bar{h}_1^1\bar{h}_1^2] + [\underline{h}_2^1\underline{h}_2^2, \bar{h}_2^1\bar{h}_2^2]} \qquad (29)
$$

where $S_i(= S_i(x_1^0, x_2^0))$ and $f_i'(= f_i'(x_1^0, x_2^0))$ are the area and center of gravity of fuzzy sets of the consequent part, respectively. In the following discussion, we use $y_i = S_i f_i' = S_i(x_1^0, x_2^0) \cdot f_i'(x_1^0, x_2^0)$ $(i = 1, 2)$ for short.

From (17) and (18), we obtain the following inference results.

$$
\begin{aligned}
y &= \frac{[\underline{h}_1^1\underline{h}_1^2, \bar{h}_1^1\bar{h}_1^2] \cdot y_1 + [\underline{h}_2^1\underline{h}_2^2, \bar{h}_2^1\bar{h}_2^2] \cdot y_2}{[\underline{h}_1^1\underline{h}_1^2, \bar{h}_1^1\bar{h}_1^2] + [\underline{h}_2^1\underline{h}_2^2, \bar{h}_2^1\bar{h}_2^2]} \\
&= \frac{[y_1\underline{h}_1^1\underline{h}_1^2 + y_2\underline{h}_2^1\underline{h}_2^2, y_1\bar{h}_1^1\bar{h}_1^2 + y_2\bar{h}_2^1\bar{h}_2^2]}{[\underline{h}_1^1\underline{h}_1^2 + \underline{h}_2^1\underline{h}_2^2, \bar{h}_1^1\bar{h}_1^2 + \bar{h}_2^1\bar{h}_2^2]} \\
&= \left[\frac{y_1\underline{h}_1^1\underline{h}_1^2 + y_2\underline{h}_2^1\underline{h}_2^2}{\bar{h}_1^1\bar{h}_1^2 + \bar{h}_2^1\bar{h}_2^2}, \frac{y_1\bar{h}_1^1\bar{h}_1^2 + y_2\bar{h}_2^1\bar{h}_2^2}{\underline{h}_1^1\underline{h}_1^2 + \underline{h}_2^1\underline{h}_2^2} \right] \qquad (30)
\end{aligned}
$$

where algebraic product and algebraic sum are used as operations.

Note that the following relation holds for interval $X = [a, b]$, $Y = [c, d]$.

$$
X \cdot Y = [\min\{ac, ad, bc, bd\}, \max\{ac, ad, bc, bd\}] \qquad (31)
$$

$$
X/Y = [a, b] \cdot [1/d, 1/c] \qquad (32)
$$

The represetative point y_0 of (30) is given as the average of inference result y, i.e., it is obtained as (33), as shown at the top of the next page.

Since the inference result obtained from the above IT2 fuzzy functinoal inference method, is expressed as a function

$$
\begin{aligned}
y_0 &= \frac{1}{2}\left(\frac{y_1\underline{h}_1^1\underline{h}_1^2+y_2\underline{h}_2^1\underline{h}_2^2}{\bar{h}_1^1\bar{h}_1^2+\bar{h}_2^1\bar{h}_2^2}+\frac{y_1\bar{h}_1^1\bar{h}_1^2+y_2\bar{h}_2^1\bar{h}_2^2}{\underline{h}_1^1\underline{h}_1^2+\underline{h}_2^1\underline{h}_2^2}\right)\\
&= \frac{1}{2}\left(\frac{(y_1\underline{h}_1^1\underline{h}_1^2+y_2\underline{h}_2^1\underline{h}_2^2)(\underline{h}_1^1\underline{h}_1^2+\underline{h}_2^1\underline{h}_2^2)+(y_1\bar{h}_1^1\bar{h}_1^2+y_2\bar{h}_2^1\bar{h}_2^2)(\bar{h}_1^1\bar{h}_1^2+\bar{h}_2^1\bar{h}_2^2)}{(\bar{h}_1^1\bar{h}_1^2+\bar{h}_2^1\bar{h}_2^2)(\underline{h}_1^1\underline{h}_1^2+\underline{h}_2^1\underline{h}_2^2)}\right)\\
&= \frac{1}{2}\left(\frac{y_1(\underline{h}_1^1\underline{h}_1^2)^2+(y_1+y_2)(\underline{h}_1^1\underline{h}_1^2\underline{h}_2^1\underline{h}_2^2)+y_2(\underline{h}_2^1\underline{h}_2^2)^2++y_1(\bar{h}_1^1\bar{h}_1^2)^2+(y_1+y_2)(\bar{h}_1^1\bar{h}_1^2\bar{h}_2^1\bar{h}_2^2)+y_2(\bar{h}_2^1\bar{h}_2^2)^2}{(\bar{h}_1^1\bar{h}_1^2+\bar{h}_2^1\bar{h}_2^2)(\underline{h}_1^1\underline{h}_1^2+\underline{h}_2^1\underline{h}_2^2)}\right)
\end{aligned}
\tag{33}
$$

of the square, it can obtain different results compared with the conventional fuzzy inference methods. This is the reason computation of the inference results of the IT2 fuzzy functional inference method, is inverted by division of the numerator and the denominator in interval as (32).

Remark 2: In (30), the inference results can not be obtained by (32), if $\underline{h}_1^1\underline{h}_1^2+\underline{h}_2^1\underline{h}_2^2$ or $\bar{h}_1^1\bar{h}_1^2+\bar{h}_2^1\bar{h}_2^2$ are 0. □

V. Conclusion

In this paper, we have porposed type-2 fuzzy functional inference method which extends fuzzy sets of the antecedent parts to type-2 fuzzy sets. This paper has explained that the type-2 fuzzy functional inference method can be classified to the three Models. Model 1 is most common method, and Model 2 is a special case of Model 1. We have shown that the inference results of both Models 1 and 2 can be easily obtained from the area of fuzzy sets of the consequent parts and center of gravity. Moreover, we have stated that Model 3 can obtain different results compared with the conventional fuzzy inference methods. However, Model 3 requires cautious use when the firing level becomes 0.

Further studies are required to apply the type-2 fuzzy functional inference methods to real systems.

***Abstract*—This paper discusses the extension of consequent parts of T–S inference model. First, it proposes an extended T–S inference model in which the coefficients of consequent parts of the fuzzy rules are extended from constants to functions. It also shows the property of the proposed model from the point of view of the equivalence and the monotonicity, by using simplified model of the proposed model.**

***Index Terms*—Fuzzy inference, Takagi–Sugeno (T–S) fuzzy inference model, Single Input Connected (SIC) fuzzy inference model, Equivalence, Monotonicity.**

I. Introduction

The fuzzy inference models have powerful capability in nonlinear systems, control, and so on since Zadeh introduced fuzzy sets and Mamdani [1] applied the concept of fuzzy inference to a steam engine experimental device. Especially, researches on the T–S inference model [2], which are widely used as fuzzy control method and so on, are reported in many papers.

The extention of the consequent parts of the T–S model is very difficult. For example, the single input connected fuzzy inference model (SIC model) by Hayashi et al. [4]–[6] can be transformed to the extended simplified fuzzy inference model [3].

From this reason, in this paper, we first propose an extended T–S inference model in which the coefficients of consequent parts of the fuzzy rules are extended from constants to functions, and show that this model can obtain complex inference results.

Second, we consider the extended simplified fuzzy inference model as a simple model of extended T–S inference model. As previously stated, the SIC model can be transformed to the extended simplified fuzzy inference model [3]. However, the extended simplified fuzzy inference model can not be generally transformed to the SIC model, and the equivalence conditions between the extended simplfiied fuzzy inference model and the SIC model were not shown. Therefore, we discuss the equivalence conditions of these models.

Finally, we show the monotonicity [6]–[8] of the extended simplified fuzzy inference model by using the equivalence conditions.

II. Fuzzy Inference Models

In this section we review the T–S inference model [2] and SIC model [4]–[6].

A. T–S Inference Model

Rules in the Takagi–Sugeno (T–S) inference model [2] are constituted as

$$\text{Rule } R_j = \begin{cases} x_1 = A_j^1,\ x_2 = A_j^2,\ \ldots,\ x_n = A_j^n \\ \longrightarrow y = a_0^j + a_1^j x_1 + \cdots + a_n^j x_n \end{cases} \tag{1}$$

where $x_1, x_2, \ldots, x_n$ are variables of the antecedent part, $A_j^1, A_j^2, \ldots, A_j^n$ fuzzy sets, $a_0^j + a_1^j x_1 + \cdots + a_n^j x_n$ functions of consequent part, and a_i^j's are real number. The inference result y^0 for inputs $x_1^0, x_2^0, \ldots, x_n^0$ is given as

$$y^0 = \frac{\sum_{j=1}^{M} h_j (a_0^j + a_1^j x_1^0 + \cdots + a_n^j x_n^0)}{\sum_{j=1}^{M} h_j}, \quad h_j = \prod_{i=1}^{n} A_j^i(x_i^0) \tag{2}$$

where h_j is the degree of the jth rule and M is the total number of the fuzzy rules.

Example 1: We first consider the following T–S rules as a simple example.

$$\begin{array}{l} x_1 = A_1^1, x_2 = A_1^2 \longrightarrow y = 0.45 - 0.2x_1 + 0.35x_2 \\ x_1 = A_1^1, x_2 = A_2^2 \longrightarrow y = -0.1 - 0.2x_1 - 0.1x_2 \\ x_1 = A_1^1, x_2 = A_3^2 \longrightarrow y = 0.05 - 0.2x_1 + 0.25x_2 \\ x_1 = A_2^1, x_2 = A_1^2 \longrightarrow y = 0.4 - 0.3x_1 + 0.35x_2 \\ x_1 = A_2^1, x_2 = A_2^2 \longrightarrow y = -0.15 - 0.3x_1 - 0.1x_2 \\ x_1 = A_2^1, x_2 = A_3^2 \longrightarrow y = -0.3x_1 + 0.25x_2 \\ x_1 = A_3^1, x_2 = A_1^2 \longrightarrow y = 0.25 + 0.1x_1 + 0.35x_2 \\ x_1 = A_3^1, x_2 = A_2^2 \longrightarrow y = -0.3 + 0.1x_1 - 0.1x_2 \\ x_1 = A_3^1, x_2 = A_3^2 \longrightarrow y = -0.15 + 0.1x_1 + 0.25x_2 \end{array} \tag{3}$$

where fuzzy sets, as shown in Fig. 1, are used. From (2), the inference result of (3) is obtained as shown in Fig. 2. □

B. Single Input Connected (SIC) Fuzzy Inference Model

We briefly review the single input connected fuzzy inference model (SIC model) by Hayashi et al. [4]–[6]. The SIC model has n rule modules, and the final inference result is obtained by the weighted average of the degrees of the antecedent part

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

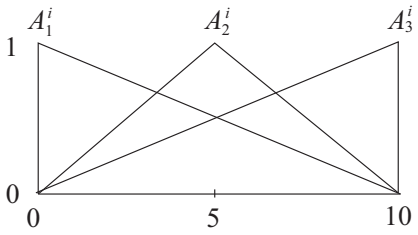

Fig. 1. Fuzzy sets.

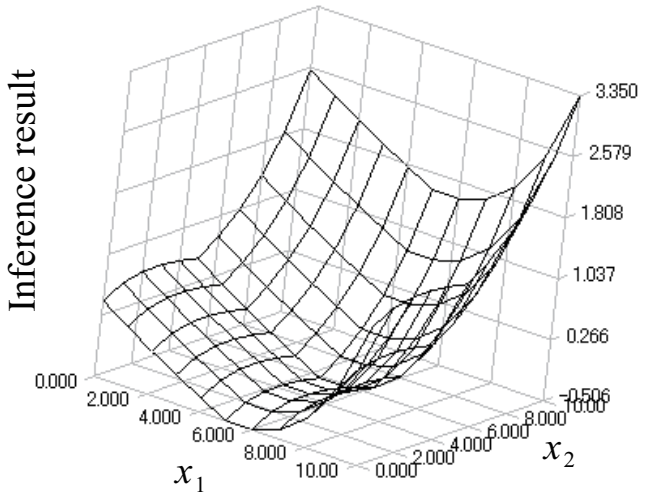

Fig. 2. Inference result by the T–S model of (3).

and consequent part of each rule module. The rule modules of the SIC model are given as

$$\begin{aligned}
&\text{Rules-1} : \{x_1 = A_j^1 \longrightarrow y_1 = y_j^1\}_{j=1}^{m_1} \\
&\qquad\vdots \\
&\text{Rules-}i : \{x_i = A_j^i \longrightarrow y_i = y_j^i\}_{j=1}^{m_i} \\
&\qquad\vdots \\
&\text{Rules-}n : \{x_n = A_j^n \longrightarrow y_n = y_j^n\}_{j=1}^{m_n}
\end{aligned} \tag{4}$$

where Rules-i stands for the ith single input rule module, the ith input item x_i is the sole variable of the antecedent part of the Rules-i, and y_i stands for the variable of its consequent part. A_j^i means the fuzzy set of the jth rule of the Rules-i, y_j^i is real value of consequent part, $i = 1, 2, \ldots, n$, $j = 1, 2, \ldots, m_i$, and m_i is the number of rules in Rules-i.

The degree of the antecedent part in the jth rule of Rules-i is obtained by (5) for input x_i^0.

$$h_j^i = A_j^i(x_i^0) \tag{5}$$

The final inference result y_0 is given as follows by using degrees of antecedent part and consequent part from each rule module.

$$\begin{aligned}
y_0 &= \frac{\sum_{j=1}^{m_1} h_j^1 y_j^1 + \cdots + \sum_{j=1}^{m_n} h_j^n y_j^n}{\sum_{j=1}^{m_1} h_j^1 + \cdots + \sum_{j=1}^{m_n} h_j^n} \\
&= \frac{\sum_{i=1}^{n}\sum_{j=1}^{m_i} h_j^i y_j^i}{\sum_{i=1}^{n}\sum_{j=1}^{m_i} h_j^i}
\end{aligned} \tag{6}$$

III. Extension of Coefficients of Consequent Parts in T–S Inference Model

In this section, we propose an extended T–S inference model in which the coefficients of consequent parts of the fuzzy rules are extended from constants to functions. The rules of proposed model are obtained as follows.

$$\text{Rule } R_j = \left\{ \begin{array}{l} x_1 = A_j^1,\ x_2 = A_j^2,\ \ldots,\ x_n = A_j^n \longrightarrow \\ y = a_0^j(\boldsymbol{x}) + a_1^j(\boldsymbol{x})x_1 + \cdots + a_n^j(\boldsymbol{x})x_n \end{array} \right. \tag{7}$$

where $x_1, x_2, \ldots, x_n$ are variables of the antecedent part, $A_j^1, A_j^2, \ldots, A_j^n$ fuzzy sets, and $a_i^j(\boldsymbol{x})$'s are functions of coefficients of consequent part, where $a_i^j(\boldsymbol{x})$ is accorded a considerable degree. The inference result y^0 for inputs $x_1^0, x_2^0, \ldots, x_n^0$ is given as

$$y^0 = \frac{\sum_{j=1}^{M} h_j(a_0^j(\boldsymbol{x}) + a_1^j(\boldsymbol{x})x_1^0 + \cdots + a_n^j(\boldsymbol{x})x_n^0)}{\sum_{j=1}^{M} h_j} \tag{8}$$

where h_j is obtained in the same way as the conventional T–S inference model.

Example 2: We consider the rules of (9) of an extended T–S inference model, as a simple extension of (3), which is shown at the bottom of the next page, where fuzzy sets of Fig. 1 are used. From (8), the inference result of (9) is obtained as shown in Fig. 3. From the result, we can find out that the above extended T–S model can obtain complex inference results. □

IV. Property of extended T–S Inference Model by Using Equivalence

Generally speaking, decision of the coefficient functions of the proposed T–S model is very difficult. Therefore, in this section, we discuss the extended simplified fuzzy inference model which reduce a part of the functions of the consequent parts to real number, as a simple version of extended T–S model.

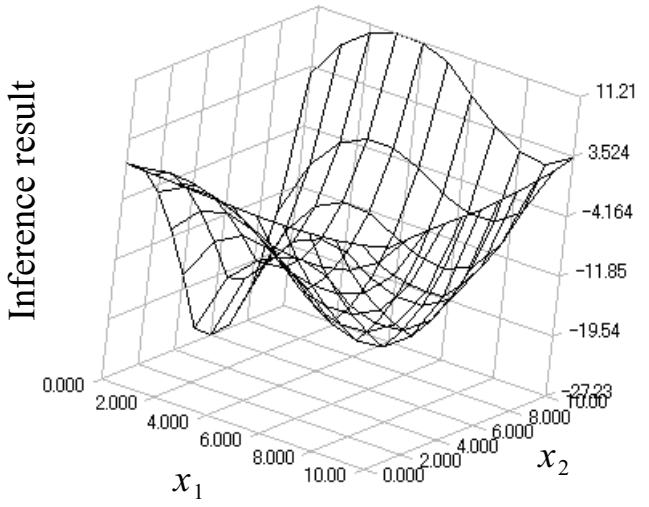

Fig. 3. Inference result by the extended T–S model of (9).

A. Equivalence

Reference [3] has shown that the SIC model can be transformed to the simplified fuzzy inference model which extends the coefficients of consequent parts to a compatibility function, but not vice versa. Therefore, we first show that the extended simplified fuzzy inference model can be transformed to the SIC model under a condition.

In order to distinguish subscript j of Rules-i in (4), j_i is used, and thus (4) is rewritten as

$$\text{Rules-}i : \{x_i = A^i_{j_i} \longrightarrow y_i = y^i_{j_i}\}_{j_i=1}^{m_i} \tag{10}$$

We can obtain the following rules of the extended simplified fuzzy inference model which corresponds to (10) of the rules of the SIC model [3]:

$$\begin{aligned} &x_1 = A^1_{j_1}, x_2 = A^2_{j_2}, \ldots, x_n = A^n_{j_n} \\ \longrightarrow y = &\frac{\sum_{j_i=1}^{m_1} h^1_{j_i}}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h^i_{j_i}} \cdot y^1_{j_1} + \cdots + \frac{\sum_{j_i=1}^{m_n} h^n_{j_i}}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h^i_{j_i}} \cdot y^n_{j_n} \end{aligned} \tag{11}$$

where $j_i = 1, 2, \ldots, m_i$.

Now, we consider the rules of the extended simplified fuzzy inference model as follows.

$$x_1 = A^1_1, x_2 = A^2_1 \longrightarrow y = f_1(x_1, x_2) = a \tag{12}$$
$$x_1 = A^1_1, x_2 = A^2_2 \longrightarrow y = f_2(x_1, x_2) = b \tag{13}$$
$$x_1 = A^1_2, x_2 = A^2_1 \longrightarrow y = f_3(x_1, x_2) = c \tag{14}$$
$$x_1 = A^1_2, x_2 = A^2_2 \longrightarrow y = f_4(x_1, x_2) = d \tag{15}$$

Suppose that the rules of the SIC model corresponding to (12)–(15) are given as

$$\begin{aligned} \text{Rules-1} &= \begin{cases} x_1 = A^1_1 \longrightarrow y_1 = y^1_1 \\ x_1 = A^1_2 \longrightarrow y_1 = y^1_2 \end{cases} \\ \text{Rules-2} &= \begin{cases} x_2 = A^2_1 \longrightarrow y_2 = y^2_1 \\ x_2 = A^2_2 \longrightarrow y_2 = y^2_2 \end{cases} \end{aligned} \tag{16}$$

Then, according to (10) and (11), (17)–(20), which are shown at the bottom of the next page, can be deduced from (16). From the correspondence of (12)–(15) and (17)–(20), we have the following relations:

$$\frac{\sum_{j_i=1}^{m_1} h^1_{j_i}}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h^i_{j_i}} \cdot y^1_1 + \frac{\sum_{j_i=1}^{m_n} h^2_{j_i}}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h^i_{j_i}} \cdot y^2_1 = a \tag{21}$$

$$\frac{\sum_{j_i=1}^{m_1} h^1_{j_i}}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h^i_{j_i}} \cdot y^1_1 + \frac{\sum_{j_i=1}^{m_n} h^2_{j_i}}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h^i_{j_i}} \cdot y^2_2 = b \tag{22}$$

$$\frac{\sum_{j_i=1}^{m_1} h^1_{j_i}}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h^i_{j_i}} \cdot y^1_2 + \frac{\sum_{j_i=1}^{m_n} h^2_{j_i}}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h^i_{j_i}} \cdot y^2_1 = c \tag{23}$$

$$\frac{\sum_{j_i=1}^{m_1} h^1_{j_i}}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h^i_{j_i}} \cdot y^1_2 + \frac{\sum_{j_i=1}^{m_n} h^2_{j_i}}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h^i_{j_i}} \cdot y^2_2 = d \tag{24}$$

$$\begin{aligned}
&x_1 = A^1_1, x_2 = A^2_1 \longrightarrow y = 0.45 - 0.2x_1 + 0.35x_2 \\
&x_1 = A^1_1, x_2 = A^2_2 \longrightarrow y = -0.1(-0.2x_1 + 5)x_1 - (0.1x_2 - 10)x_2 \\
&x_1 = A^1_1, x_2 = A^2_3 \longrightarrow y = 0.05 - 0.2x_1 + 0.25x_2 \\
&x_1 = A^1_2, x_2 = A^2_1 \longrightarrow y = 0.4 - 0.3x_1 + 0.35x_2 \\
&x_1 = A^1_2, x_2 = A^2_2 \longrightarrow y = -0.15 - (0.3x_1 - 10)x_1 - 0.1x_2 \\
&x_1 = A^1_2, x_2 = A^2_3 \longrightarrow y = (-0.3x_1 - 2)x_1 + (0.25x_2 + 1)x_2 \\
&x_1 = A^1_3, x_2 = A^2_1 \longrightarrow y = 0.25 + 0.1x_1 + 0.35x_2 \\
&x_1 = A^1_3, x_2 = A^2_2 \longrightarrow y = -0.3 + 0.1x_1 - 0.1x_2 \\
&x_1 = A^1_3, x_2 = A^2_3 \longrightarrow y = -0.15 + 0.1x_1 + 0.25x_2
\end{aligned} \tag{9}$$

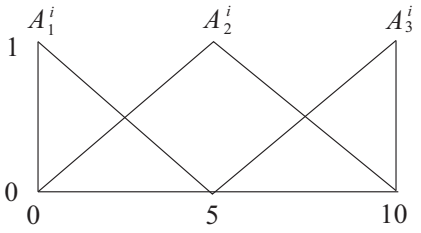

Fig. 4. Fuzzy sets with fuzzy partition.

From (21)–(24), the relation (25) is obtained

$$a + d = b + c \tag{25}$$

Under the conditions of (25), the rules of the SIC model of (16) can be obtained if $\frac{\sum_{j_i=1}^{m_1} h_{j_i}^1}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h_{j_i}^i}$, $\frac{\sum_{j_i=1}^{m_1} h_{j_i}^2}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h_{j_i}^i}$, y_1^1, y_2^1, y_1^2, and y_2^2 of (21)–(24) are fixed.

Example 3: We consider an example of the rules of the SIC model used in [3] as follows:

$$\text{Rules-1} = \begin{cases} x_1 = A_1^1 \longrightarrow y_1 = 1 \\ x_1 = A_2^1 \longrightarrow y_1 = 2 \\ x_1 = A_3^1 \longrightarrow y_1 = 1 \end{cases}$$

$$\text{Rules-2} = \begin{cases} x_2 = A_1^2 \longrightarrow y_2 = 1 \\ x_2 = A_2^2 \longrightarrow y_2 = 3 \\ x_2 = A_3^2 \longrightarrow y_2 = 5 \end{cases} \tag{26}$$

where fuzzy sets A_1^i, A_2^i, A_3^i $(i = 1, 2)$ in Fig. 4 are used. The inference results of (26) by the SIC model are obtained as shown in Fig. 5.

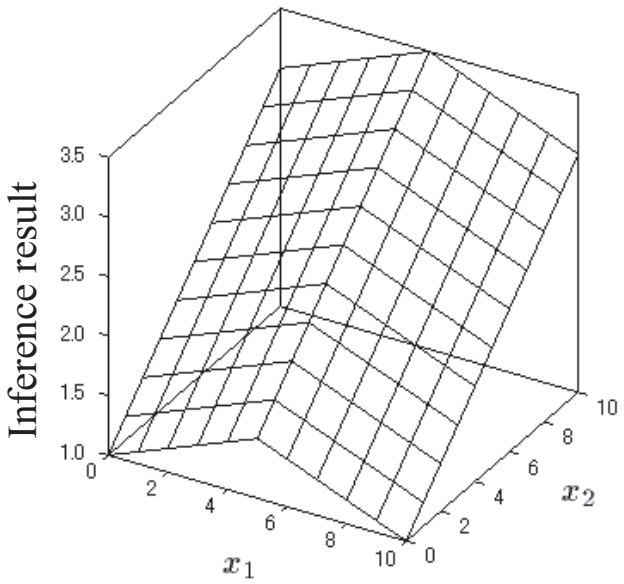

Fig. 5. Inference result by the SIC model of (26).

On the other hand, based on the above discussion, we obtain the rules of the extended simplified fuzzy inference model as (27), as shown at the bottom of the next page.

Note that $y_1^1 = 1, y_2^1 = 2, y_3^1 = 1$, and $y_1^2 = 1, y_2^2 = 3, y_3^2 = 5$ from (26), and the functional coefficients are as follows because fuzzy sets of antecedent parts constitute fuzzy

$$x_1 = A_1^1, x_2 = A_1^2 \longrightarrow y = \frac{\sum_{j_i=1}^{m_1} h_{j_i}^1}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h_{j_i}^i} \cdot y_1^1 + \frac{\sum_{j_i=1}^{m_n} h_{j_i}^2}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h_{j_i}^i} \cdot y_1^2 = a \tag{17}$$

$$x_1 = A_1^1, x_2 = A_2^2 \longrightarrow y = \frac{\sum_{j_i=1}^{m_1} h_{j_i}^1}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h_{j_i}^i} \cdot y_1^1 + \frac{\sum_{j_i=1}^{m_n} h_{j_i}^2}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h_{j_i}^i} \cdot y_2^2 = b \tag{18}$$

$$x_1 = A_2^1, x_2 = A_1^2 \longrightarrow y = \frac{\sum_{j_i=1}^{m_1} h_{j_i}^1}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h_{j_i}^i} \cdot y_2^1 + \frac{\sum_{j_i=1}^{m_n} h_{j_i}^2}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h_{j_i}^i} \cdot y_1^2 = c \tag{19}$$

$$x_1 = A_2^1, x_2 = A_2^2 \longrightarrow y = \frac{\sum_{j_i=1}^{m_1} h_{j_i}^1}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h_{j_i}^i} \cdot y_2^1 + \frac{\sum_{j_i=1}^{m_n} h_{j_i}^2}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h_{j_i}^i} \cdot y_2^2 = d \tag{20}$$

TABLE I
RULES OF EXTENDED SIMPLIFIED FUZZY INFERENCE MODEL IN TABLE FORM

		x_2			
		A_1^2	A_2^2	$\cdots$	A_n^2
x_1	A_1^1	$f(x_1,x_2)_{(1,1)}$	$f(x_1,x_2)_{(1,2)}$	$\cdots$	$f(x_1,x_2)_{(1,n)}$
	A_2^1	$f(x_1,x_2)_{(2,1)}$	$f(x_1,x_2)_{(2,2)}$	$\cdots$	$f(x_1,x_2)_{(2,n)}$
	$\vdots$	$\vdots$	$\vdots$		$\vdots$
	A_m^1	$f(x_1,x_2)_{(m,1)}$	$f(x_1,x_2)_{(m,2)}$	$\cdots$	$f(x_1,x_2)_{(m,n)}$

partition.

$$\frac{\sum_{j_i=1}^{m_1} h_{j_i}^i}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h_{j_i}^i} = \frac{1}{2} \tag{28}$$

From (27), the extended simplified fuzzy inference model can obtain the same result of the SIC model as shown in Fig. 5.

In the case of (27), considering the elicitation process of (25), the equivalence conditions between the extended simplified fuzzy inference model and SIC model are obtained as follows:

$$f_1(x_1,x_2) + f_5(x_1,x_2) = f_2(x_1,x_2) + f_4(x_1,x_2) \tag{29}$$
$$f_2(x_1,x_2) + f_6(x_1,x_2) = f_3(x_1,x_2) + f_5(x_1,x_2) \tag{30}$$
$$f_4(x_1,x_2) + f_8(x_1,x_2) = f_5(x_1,x_2) + f_7(x_1,x_2) \tag{31}$$
$$f_5(x_1,x_2) + f_9(x_1,x_2) = f_6(x_1,x_2) + f_8(x_1,x_2) \tag{32}$$

□

(25) and (29)–(32) show that two diagonal sums of rules in table form should be equal.

Therefore, as the generalization of the above results, we have the following Theorem regarding the equivalence between the extended simplified fuzzy inference model and the SIC model.

Theorem 1: In the extended simplified fuzzy inference model, when the rules of the extended simplified fuzzy inference model are given in table form, as shown in Table I, and the following conditions are satisfied, the inference result is equal to that of the SIC model.

$$\begin{aligned} &f(x_1,x_2)_{(i,j)} + f(x_1,x_2)_{(i+1,j+1)} \\ &= f(x_1,x_2)_{(i+1,j)} + f(x_1,x_2)_{(i,j+1)} \end{aligned} \tag{33}$$

B. Monotonicity

It is important that inference results have the property of monotonicity; this is necessary when fuzzy inference is applied to evaluation problems, engineering problems, etc. However, deriving the monotonic conditions of the fuzzy inference model is very difficult [7], [8]. In this subsection, we show the monotonicity of extended simplified fuzzy inferece model by using equivalence conditions as shown in previous subsestion.

We have the following Theorem regarding the monotonicity of the extended simplified fuzzy inference model.

Theorem 2: For the extended simplified fuzzy inference model, the inference results monotonically increase, if the antecedent parts and consequent parts of each input item are monotonically increasing, and the fuzzy sets constitute fuzzy partitions, when the condition (33) is satisfied. □

proof: Inference result y^0 of the extended simplified fuzzy inference model becomes as follows from (11):

$$y^0 = \frac{\sum_{j=1}^{M}\left\{h_j\left(\frac{y_{j_1}^1\sum_{j_i=1}^{m_1} h_{j_i}^1}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h_{j_i}^1} + \cdots + \frac{y_{j_n}^n\sum_{j_i=1}^{m_n} h_{j_i}^n}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h_{j_i}^n}\right)\right\}}{\sum_{j=1}^{M} h_j} \tag{34}$$

$$\begin{aligned}
x_1 = A_1^1, x_2 = A_1^2 &\longrightarrow y = f_1(x_1,x_2) = 0.5\cdot y_1^1 + 0.5\cdot y_1^2 = 1 \\
x_1 = A_1^1, x_2 = A_2^2 &\longrightarrow y = f_2(x_1,x_2) = 0.5\cdot y_1^1 + 0.5\cdot y_2^2 = 2 \\
x_1 = A_1^1, x_2 = A_3^2 &\longrightarrow y = f_3(x_1,x_2) = 0.5\cdot y_1^1 + 0.5\cdot y_3^2 = 3 \\
x_1 = A_2^1, x_2 = A_1^2 &\longrightarrow y = f_4(x_1,x_2) = 0.5\cdot y_2^1 + 0.5\cdot y_1^2 = 1.5 \\
x_1 = A_2^1, x_2 = A_2^2 &\longrightarrow y = f_5(x_1,x_2) = 0.5\cdot y_2^1 + 0.5\cdot y_2^2 = 2.5 \\
x_1 = A_2^1, x_2 = A_3^2 &\longrightarrow y = f_6(x_1,x_2) = 0.5\cdot y_2^1 + 0.5\cdot y_3^2 = 3.5 \\
x_1 = A_3^1, x_2 = A_1^2 &\longrightarrow y = f_7(x_1,x_2) = 0.5\cdot y_3^1 + 0.5\cdot y_1^2 = 1 \\
x_1 = A_3^1, x_2 = A_2^2 &\longrightarrow y = f_8(x_1,x_2) = 0.5\cdot y_3^1 + 0.5\cdot y_2^2 = 2 \\
x_1 = A_3^1, x_2 = A_3^2 &\longrightarrow y = f_9(x_1,x_2) = 0.5\cdot y_3^1 + 0.5\cdot y_3^2 = 3
\end{aligned} \tag{27}$$

From Reference [3] and the equivalence condition, as shown in this paper, we can transform the inference results of extended simplified fuzzy inference model from (34) into

$$
\begin{aligned}
y^0 &= \frac{\sum_{j_i=1}^{m_1} h_{j_i}^1}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h_{j_i}^i} \cdot \frac{\sum_{j_1=1}^{m_1} h_{j_1}^1 y_{j_1}^1}{\sum_{j_1=1}^{m_1} h_{j_1}^1} + \cdots \\
&\quad + \frac{\sum_{j_n=1}^{m_n} h_{j_n}^n}{\sum_{i=1}^{n}\sum_{j_i=1}^{m_i} h_{j_i}^i} \cdot \frac{\sum_{j_n=1}^{m_n} h_{j_n}^n y_{j_n}^n}{\sum_{j_n=1}^{m_n} h_{j_n}^n} \\
&= \frac{\sum_{i=1}^{n}\sum_{j=1}^{m_i} h_j^i y_j^i}{\sum_{i=1}^{n}\sum_{j=1}^{m_i} h_j^i} \qquad (35)
\end{aligned}
$$

(Confer [3] for detail of proof). (35) is equal to the inference results of the SIC model of (6). Reference [6] has shown that the monotonicity of SIC model is satisfied, if the antecedent parts and consequent parts of each input item are monotonically increasing, and the fuzzy sets constitute fuzzy partitions. Therefore, Theorem 2 holds. □

Note that the monotonicity of the extended T–S inference model can be also argued as well as the extended simplified fuzzy inference model, if the consequent functions are positive value and monotonically increasing, the antecedent parts are monotonically increasing, and the fuzzy sets constitute fuzzy partitions.

V. Conclusion

In this paper, we proposed an extended T–S inference model in which the coefficients of consequent parts of the fuzzy rules are extended from constants to functions.

To decide the coefficient functions of the model is generally vry difficult. However, we showed an example of the coefficient functions and its property, by using simplified model of this model.

We have also shown the equivalence conditions between the extended simplified fuzzy inference model and the SIC model. Since the SIC model is applied to PID control, etc., and good results are obtained, the proposed model will be also useful. Moreover, we clarified to obtain the monotonicity condition of this model easily, by using the above equivalence conditions.

Since the number of the parameters of the general proposed model, as shown in (7), is large compared with the conventional T–S inference model, it may obtain good results in various fields. However, how to select and optimization of its parameters should be investigated.

Further studies are required to find out other applicative coefficient functions, and to apply this model to real systems.

***Abstract*—In this paper, two issues relating to modeling of a monotonicity-preserving Fuzzy Inference System (FIS) are examined. The first is on designing or tuning of Gaussian Membership Functions (MFs) for a monotonic FIS. Designing Gaussian MFs for an FIS is difficult because of its spreading and curvature characteristics. In this study, the *sufficient conditions* are exploited, and the procedure of designing Gaussian MFs is formulated as a constrained optimization problem. The second issue is on the testing procedure for a monotonic FIS. As such, a testing procedure for a monotonic FIS model is proposed. Applicability of the proposed approach is demonstrated with a real world industrial application, i.e., Failure Mode and Effect Analysis. The results obtained are analysis and discussed. The outcomes show that the proposed approach is useful in designing a monotonicity-preserving FIS model.**

Keywords-Fuzzy Inference System, monotonicity property, Gaussian membership functions, sufficient conditions, monotonicity testing

I. INTRODUCTION

Many real-world systems abide the monotonicity property between the input(s) and output(s) of a system. Consider an Fuzzy Inference System (FIS), $y = f(x_1, x_2, \dots, x_i, \dots, x_n)$, that fulfils the condition of monotonicity between its output, y, with respect to its input, x_i. The output monotonically increases or decreases as the input increases, i.e., $f(x_1, x_2, \dots, x_i^1, \dots, x_n) \leq f(x_1, x_2, \dots, x_i^2, \dots, x_n)$ or $f(x_1, x_2, \dots, x_i^1, \dots, x_n) \geq f(x_1, x_2, \dots, x_i^2, \dots, x_n)$, respectively, for $x_i^1 < x_i^2$. The monotonicity property is an additional qualitative information/ knowledge that can be exploited to obtain an interpretable and optimized FIS model [1]. The importance of this line of study has been highlighted in a number of recent publications [1-8]. But, there are only a few articles that address the problem of designing a monotonicity-preserving FIS model [2]. A useful foundation of the study is the *sufficient conditions*, which comprise a set of mathematical conditions derived with the assumption that $dy/dx_i \geq 0$ or $dy/dx_i \leq 0$, for the monotonic increasing or decreasing condition, respectively, via *partial differentiation* and the *quotient rule* [3].

This paper attempts to address two issues related to modeling of a monotonicity-preserving FIS model. A common issue in FIS modeling is how fuzzy Membership Functions (MFs) are designed and tuned. One of the difficulties of designing Gaussian MFs is because of their spreading and curvature characteristics [4]. Although the *sufficient conditions* have been adopted as the condition for designing MFs [2, 5-7], it is not clear how a good MF design should be. In [9], the use of computing with words in risk assessment has been reviewed, and it has been highlighted that designing MFs is a crucial problem. Thus, in this paper, the *sufficient conditions* are further extended, and applied to designing Gaussian MFs. As the design of Gaussian MFs is formulated as a constrained optimization problem, the extended *sufficient conditions* are used as the hard constraint for optimization. An objective function is also used to compare a set of candidates (Gaussian MFs) with other available information. In addition, a Genetic Algorithm (GA) is deployed to provide a solution for the optimization problem.

The second issue is how the monotonicity property of an FIS model can be measured or evaluated. From the literature, a monotonicity measure of data in neural network modeling was introduced by Daniels and Velikova [10]. However, the monotonicity measure in FIS modeling receives little attention. Thus, a method to measure the degree of fulfillment of the monotonicity property of an FIS model is proposed. The monotonicity measure is important because the exact condition(s) for an FIS to satisfy the monotonicity property is unknown, and the mathematical proof of monotonicity is difficult [8]. There is a possibility for an FIS to be monotonic even when the *sufficient conditions* are not fulfilled. Hence, the proposed monotonicity measure is useful to give an indication whether the designed FIS model is monotonic in practice. The effectiveness of our proposed techniques is demonstrated using a real industrial application, i.e., Failure Mode and Effect Analysis (FMEA) with an FIS-based Risk Priority Number (RPN) [11-12] model. This is a typical example for FIS-based risk assessment models [9] that require the monotonicity property [11].

This paper is organized as follows. In section II, a review on Gaussian MFs, FIS models, and the *sufficient conditions* are presented. In section III, the proposed technique for optimizing Gaussian fuzzy MFs is explained. In section IV, the proposed technique to measure the monotonicity property is described.

In section V, experimental results are presented and discussed. Finally, concluding remarks are given in section VI.

II. Background of Gaussian Fuzzy Sets, Fuzzy Inference Systems, and the Sufficient Conditions

A. Gaussian Fuzzy Sets

A Gaussian MF (see Fig. 1) can be represented as

$$\mu_G(x; c, \sigma) = e^{-[x-c]^2/2\sigma^2} \quad (1)$$

where c is the center of the fuzzy set, and σ parameterizes the width of the fuzzy set. The α-cut of a fuzzy set is a crisp set that contains all the elements of the universe set X that have a membership grade equals to or greater than α, where $1 \geq \alpha > 0$ (Note that a Gaussian MF is a non-zero MF). Based on the α -cut of a fuzzy set, the width of the fuzzy set, W_α, is determined. From Fig. 1, W_α is ac or cb, which can be determined by (2).

$$W_\alpha = ac = cb = \sqrt[2]{(-\ln \alpha)(2\sigma^2)} \quad (2)$$

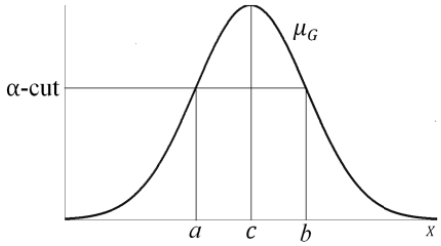

Figure 1. A Gaussian membership function

B. Fuzzy Inference Systems

The fuzzy production rules for an n-input FIS model, where $n > 0$, can be represented as follows.

$R^{j_1,j_2,\ldots,j_n}$:

$If\ (x_1 is\ A_1^{j_1}) AND\ (x_2 is\ A_2^{j_2}) \ldots AND (x_n is\ A_n^{j_n}),$
$THEN (y\ is\ B^{j_1,j_2,\ldots,j_n}) \qquad 1 \leq j_i \leq M_i.$

The AND operator in the rule antecedent part is the product function. For the x_i domain, its MFs are $\mu_i^1(x_i)$, $\mu_i^2(x_i)$, …, and $\mu_i^{n_i}(x_i)$. The upper and lower limits for the universe of discourse of x_i are $\overline{x_i}$ and $\underline{x_i}$, respectively. The output is obtained by using the weighted average of a representative value, $b^{j_1,j_2,\ldots,j_n}$ with respect to its compatibility grade, as in (3).

$$y = \frac{\sum_{j_n=1}^{j_n=M_n} \ldots \sum_{j_2=1}^{j_2=M_2} \sum_{j_1=1}^{j_1=M_1} \left(\mu_1^{j_1}(x_1) \times \mu_2^{j_2}(x_2) \times \ldots \times \mu_n^{j_n}(x_n) \times b^{j_1,j_2,\ldots,j_n}\right)}{\sum_{j_n=1}^{j_n=M_n} \ldots \sum_{j_2=1}^{j_2=M_2} \sum_{j_1=1}^{j_1=M_1} \left(\mu_1^{j_1}(x_1) \times \mu_2^{j_2}(x_2) \times \ldots \times \mu_n^{j_n}(x_n)\right)} \quad (3)$$

where $b^{j_1,j_2,\ldots,j_n}$ is the representative value of $B^{j_1,j_2,\ldots,j_n}$, i.e., $b^{j_1,j_2,\ldots,j_n} = Rep\,(B^{j_1,j_2,\ldots,j_n})$. This value represents the overall location of the MF. It can be obtained via defuzzification, or be represented by the point whereby the membership value is 1.

C. Sufficient Conditions

The first derivative of an FIS model, as in (3), returns a weighted addition series. The *sufficient conditions* assume that all the components in the weighted addition series are always *greater than or equal to* zero, or *less than* or *equal to* zero. Two conditions can be derived [3], as follows.

Condition 1. At the rule antecedent part, $(d\mu_i^p(x)/dx)/\mu_i^p(x) \geq (d\mu_i^q(x)/dx)/\mu_i^q(x)$, where $p > q$. Note that $(d\mu(x)/dx)/\mu(x)$ is the ratio between the rate of change in the membership degree and the membership degree itself. The derivative of a Gaussian MF with respect to x is $G'(x) = -((x-c)/\sigma^2)G(x)$. Note that $(d\mu(x)/dx)/\mu(x)$ for a Gaussian MF, i.e., $(G'(x)/G(x))$, returns a linear function, i.e. $E(x) = G'(x)/G(x) = -(1/\sigma^2)x + (c/\sigma^2)$.

Condition 2. At the rule consequent part, $b^{j_1,j_2,\ldots j_i=p,\ldots,j_n} - b^{j_1,j_2,\ldots j_i=q,\ldots,j_n} \geq 0$ or $b^{j_1,j_2,\ldots j_i=p,\ldots,j_n} - b^{j_1,j_2,\ldots j_i=q,\ldots,j_n} \leq 0$ for $dy/dx_i \geq 0$ or $dy/dx_i \leq 0$, respectively. This condition suggests that a monotonic rule base is required.

III. Optimization of Fuzzy Membership Functions

A. Extension for ***Condition 1***

Conditions 1 and **2** can be included as part of the FIS modeling process [2, 5-7]. **Condition 1** is an inequality that can be used to check the validity of Gaussian MF design i.e., a fuzzy partition. **Condition 2** can be used to check the validity of the rules in a monotonic FIS model. In this paper, the focus is on **Condition 1**.

In this work, $\left(d\mu_i^p(x)/dx\right)/\mu_i^p(x))$ is viewed as a projection of the Gaussian MFs, which allows the MFs to be visualized. As an example, two Gaussian MFs, $G_1 = e^{-[x-c_1]^2/2\sigma_1{}^2}$ and $G_2 = e^{-[x-c_2]^2/2\sigma_2{}^2}$, where $c_1 < c_2$, are considered. Their $G'(x)/G(x)$ ratios are $E_1(x) = -(1/\sigma_1{}^2)x + (c_1/\sigma_1{}^2)$ and $E_2(x) = -(1/\sigma_2{}^2)x + (c_2/\sigma_2{}^2)$, respectively. To satisfy **Condition 1,** $E_1(x) \leq E_2(x)$ is required for the defined universe of discourse. Hence, (4) and (5) are required.

$$E_1\left(\underline{x_i}\right) \leq E_2\left(\underline{x_i}\right) \quad (4)$$

$$E_1(\overline{x_i}) \leq E_2(\overline{x_i}) \quad (5)$$

B. Optimization of Gaussian Membership Functions

In this paper, the proposed extension for **Condition 1** (from section III(*A*)) is further exploited to be part of a Gaussian MF design process. It acts as the constraint for an optimization problem. For an input domain, x_i with n_i Gaussian MFs, the Gaussian MFs are parameterized by c_1, c_2, …, c_{n_i} and σ_1, σ_2, …σ_{n_i}. The design of the Gaussian MFs is formulated as a constrained optimization problem, as follows.

An objective function, $f(c_1, c_2, \ldots, c_{n_i}, \sigma_1, \sigma_2, \ldots, \sigma_{n_i})$, is optimized subjected to constraints as follow.

$\#\ 1.\ E_q\left(\underline{x_i}: c_q, \sigma_q\right) \le E_{q+1}\left(\underline{x_i}: c_{q+1}, \sigma_{q+1}\right)$ for $q = 1,2, \dots n_{i-1}$

$\#2.\ E_q\left(\overline{x_i}: c_q, \sigma_q\right) \le E_{q+1}\left(\overline{x_i}: c_{q+1}, \sigma_{q+1}\right)$ for $q = 1,2, \dots n_{i-1}$

Constraints #1 and #2 are the conditions of feasible Gaussian MFs design for a monotonic FIS model. The search process can be achieved by various optimization techniques, e.g., a non-linear programming technique, GA, particle swarm optimization, or harmonic search.

C. A Case Study on Failure Mode and Effect Analysis

Failure Mode and Effect Analysis (FMEA) is a popular problem prevention methodology that can be interfaced with many engineering and reliability models [11]. FMEA uses a Risk Priority Number (RPN) model to evaluate the risk associated with each failure mode [11]. The RPN model considers three risk factors, i.e., severity (S), occurrence (O), and detect (D), and produces an RPN score ($RPN = g_{RPN}(S, O, D)$) [11]. The three input factors are estimated by the domain experts in accordance with the scale from "1" to "10" based on a set of commonly agreed evaluation criteria, which are presented with the scale tables [11].

In this paper, the focus is on designing an FIS-based RPN model [11-12] that satisfies the monotonicity property. The FIS-based RPN model considered S, O, and D as the inputs and the RPN as the output. The Gaussian MFs of S, O, and D are generated from the respective scale tables. As an example, Table 1 shows the scale table of S, which is used in a semiconductor manufacturing plant. There are 5 linguistic terms; each is represented by a Gaussian MF. The relationship between S, O, and D and the RPN are expressed with a set of fuzzy If-Then rules.

Table 1. The scale table for Severity

Rank	Linguistic Terms	Criteria	Lower Limit	Mid-point	Upper Limit
10	Very High (Liability)	Failure will affect safety or compliance to law.	9.5	10	-
9~8	High (Reliability / reputation)	Customer impact. Major reliability excursions.	7.5	8.5	9.5
7~6	Moderate (Quality / Convenience)	Impacts customer yield. Wrong package/par/marking.	5.5	6.5	7.5
5~2	Low (Special Handling)	Yield hit, Cosmetic.	1.5	3.5	5.5
1	None (Unnoticed)	Unnoticed.	-	1	1.5

In our previous work [5-6, 11], it has been demonstrated that an effective FIS-based RPN model should satisfy the monotonicity property. This is because the input attributes (i.e., the S, O, and D ratings) are defined in such a way that the higher the rating, the more critical the situation is. The output (i.e., the RPN score) is a measure of the failure risk. The monotonicity property is important to allow a valid comparison among all failure modes to be made.

D. Gaussian MFs Design

A qualitative scale table usually consists of several partitions, each with some criteria. Each partition can have different width, and it can be represented using three points, i.e., the lower limit, the mid-point, and the upper limit. The width of the n partition, $W^n_{partition}$, is defined as follows:

$$W^n_{partition} = upperlimit^n - midpoint^n = midpoint^n - lowerlimit^n \quad (6)$$

As an example, the scale table of S (Table 1) consists of five partitions, i.e., 1, 2-5, 6-7, 8-9, and 10. The lower limit, the mid-point, and the upper limit for the second partition ($n = 2$), i.e., 2-5, are 1.5, 3.5, and 5.5, respectively, while $W^2_{partition}$ is 2.

In this paper, we attempt to search for a set of Gaussian MFs with their widths nearest to the widths of the partitions in the scale table. The width of a Gaussian MFs can be defined using (2) with $\alpha = 0.5$ [13-14]. The issue is on how to formulate a useful objective function. In this paper, the investigation is focused on formulating an objective function, as in (7). It is a measure of total similarity of the generated MFs corresponding to the partitions of scale table. We further assume that $c_1, c_2, \dots, c_{n_i}$ are mid-points for these partitions which need not to be optimized.

$$f\left(c_1, c_2, \dots, c_{n_i}, \sigma_1, \sigma_2, \dots, \sigma_{n_i}\right) = f\left(\sigma_1, \sigma_2, \dots, \sigma_{n_i}\right) = \sqrt[2]{\sum_{n=1}^{n=n_i}\left(W^n_{partition} - W^n_{\alpha}\right)^2} \quad (7)$$

E. Genetic Algorithm

The problem formulated can be solved using a GA, a population-based stochastic optimization technique. Each potential solution set, in the form of $\left(\sigma_1, \sigma_2, \dots, \sigma_{n_i}\right)$, is represented as an individual. The GA is used to search for the solution set with the best fitness value.

Figure 2 shows the general procedure of the GA. The hard constraints, i.e., constraints #1 and #2, are considered as penalties of the GA objective function to be minimized, as in (8). We attempt to minimize (7), which is part of the GA objective function.

$$GA\ Objective\ function = W_{penalty} \times \left(\begin{cases} 0\ if\ constraints\ \#1 \text{ and } \#2\ fulfilled \\ 1\ if\ constraints\ \#1 \text{ and } \#2\ not\ fulfilled \end{cases}\right) + f\left(\sigma_1, \sigma_2, \dots, \sigma_{n_i}\right) \quad (8)$$

```
%Note: Initialize variable
    Initial population (each individual is σ1, σ2, ..., σni)
    While stopping criteria is not triggered
    {
    Evaluate each individual with (8)
    Record the best individual sets
    Crossover
    Mutation
    Evaluate the stopping criteria
    }
```

Figure 2. Pseudo-code of the proposed GA-based MFs optimization model

IV. A MEASURE FOR THE MONOTONICITY PROPERTY

From the literature, the measure of the degree of monotonicity for a data set, D is defined by (9) [10]. The aim is to represent the monotonic relationship using a numerical value from 0 to 1. A value close to 1 indicates an increasing monotonic relationship among data. A value near to 0 indicates a decreasing monotonic relationship among data. A value near to 0.5 indicates no monotonic relationship among data.

$$Degree\ of\ monotonicity = \frac{\#\ Monotone\ pairs(D)}{\#Comparable\ pairs\ (D)} \tag{9}$$

In this paper, fulfillment of the monotonicity property of an FIS model is measured by comparing the output pairs of an FIS model. Instead of indicate the monotonic increasing or decreasing relationship of a data set as in [10], an index that indicates whether an FIS model observes the monotonicity property is proposed. The procedure is as follows.

Let $y = f(\bar{x})$ be represented by an n-dimension matrix y_{x_k}. y_{x_k} is the output of $f(x_k)$, correspond to a input(s) vector, x_k=[x_1, $x_2, \dots, x_n$], $k = 1,2, \dots n$. The test procedure test is as follows.

(A) Determine the upper and lower limits of the universe of discourse for input(s), i.e., x_k, and denote them as $\bar{x}_k$ and $\underline{x_k}$, respectively.

(B) Divide x_k into n_k^t divisions. The grid size of x_k, $gs_k = \left(\bar{x}_k - \underline{x_k}\right)/n_k^t$. $y_{x_1,x_2,\dots,x_n}$ is denoted as a $n_1^t \times n_2^t \times \dots \times n_n^t$ matrix.

(C) Compare $y_{x_{k=1,2,3\dots n,k\neq i},\underline{x_i}+gs_i\times m_i}$ and $y_{x_{k=1,2,3\dots n,k\neq i},\underline{x_i}+(gs_i+1)\times m_i}$, $m_i = 0,1,2,\dots,n_i^t - 1$, with a function denoted as $monotone\left(y_{x_{k=1,2,3\dots n,k\neq i},\underline{x_i}+gs_i\times m_i}\right)$. Equation (10) or (11) is adopted for a monotonic increasing or decreasing relationship, respectively.

$$monotone\left(y_{x_{k=1,2,3\dots n,k\neq i},\underline{x_i}+gs_i\times m_i}\right) = \begin{cases} 1 & if\ y_{x_{k=1,2,3\dots n,k\neq i},\underline{x_i}+gs_i\times m_i} \leq y_{x_{k=1,2,3\dots n,k\neq i},\underline{x_i}+(gs_i+1)\times m_i} \\ 0 & if\ y_{x_{k=1,2,3\dots n,k\neq i},\underline{x_i}+gs_i\times m_i} > y_{x_{k=1,2,3\dots n,k\neq i},\underline{x_i}+(gs_i+1)\times m_i} \end{cases} \tag{10}$$

$$monotone\left(y_{x_{k=1,2,3\dots n,k\neq i},\underline{x_i}+gs_i\times m_i}\right) = \begin{cases} 1 & if\ y_{x_{k=1,2,3\dots n,k\neq i},\underline{x_i}+gs_i\times m_i} \geq y_{x_{k=1,2,3\dots n,k\neq i},\underline{x_i}+(gs_i+1)\times m_i} \\ 0 & if\ y_{x_{k=1,2,3\dots n,k\neq i},\underline{x_i}+gs_i\times m_i} < y_{x_{k=1,2,3\dots n,k\neq i},\underline{x_i}+(gs_i+1)\times m_i} \end{cases} \tag{11}$$

(D) Obtain the $Monotone\ index$ between y and x_i for an FIS model using (12).

$$Monotone\ index = \frac{\sum_{m_n=1}^{m_n=n_n^t} \dots \sum_{m_1=1}^{m_1=n_1^t} \sum_{m_i=1}^{m_i=n_i^t-1} \left(monotone\left(y_{x_{k=1,2,3\dots n,k\neq i},\underline{x_i}+gs_i\times m_i}\right)\right)}{\sum_{m_n=1}^{m_n=n_n^t} \dots \sum_{m_1=1}^{m_1=n_1^t} \sum_{m_i=1}^{m_i=n_i^t-1} (1)} \tag{12}$$

In short, first, all possible comparable sets of y and x_i are generated. The number of the monotonic pairs is counted. The degree of monotonicity is obtained with (12). As an example, the monotonicity property between S and the RPN for an FIS-based RPN can be measured as follows.

Comparable points in the form of [S,O,D] are generated. Examples of comparable points are [1,1,1] and [2,1,1], [2,1,1] and [3,1,1],…, [9,1,1] and [10, 1,1], …, [1,1,2] and [2,1,2,], …and finally [9, 10, 10] and [10, 10, 10]. The RPN scores for [1,1,1] ($g_{RPN}(1,1,1)$) and [2,1,1] ($g_{RPN}(2,1,1)$) are compared, and their fulfillment of monotonicity ($g_{RPN}(1,1,1) \leq g_{RPN}(2,1,1)$) are checked. The same goes to other comparable points. In this study, a total of 900 comparable points are generated between S and the RPN. The same procedure can be applied to O and the RPN, as well as D and the RPN. In total, there are 2700 (3×900) comparable points that have been generated for evaluation of the monotonicity property in the study.

V. EXPERIMENTAL RESULT AND DISCUSSIONS

Figure 3 depicts the objective function versus the number of generations of the GA. Figure 4 depicts the optimized Gaussian MFs of S using the best individual after 300 iterations. Figure 5 depicts the projection of the Gaussian MFs using **Condition 1**. From the results, it is obvious that the proposed techniques can be used to automatically generate a set of optimized Gaussian MFs, which are able to fulfill **Condition 1.** From Figure 4, it can be observed that the width of each Gaussian MF is close to the scale table of S.

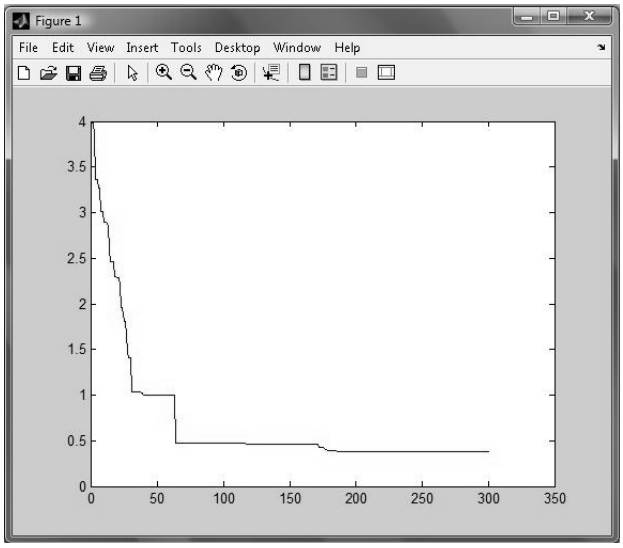

Figure 3 Objective function versus the number of generations of the GA-based MFs design procedure

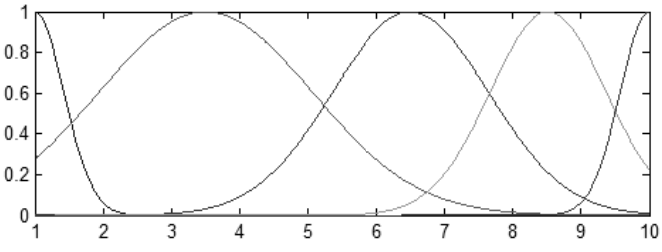

Figure 4 Projection of the MFs for Severity

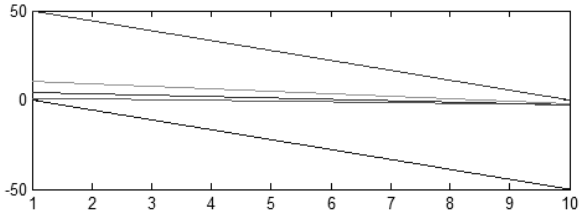

Figure 5 Optimized MFs for Severity.

Table 2 shows the scale table of D of the FIS-based RPN model. There are 6 linguistic terms, each is represented by a Gaussian MF.

Table 2 The scale table for Detect

Rank	Linguistic Terms	Criteria	Lower Limit	Mid-point	Upper Limit
10	Extremely Low	No Control available.	9.5	10	-
9	Very Low	Controls probably will not Detect	8.5	9	9.5
8~7	Low	Controls may not Detect excursion until reach next functional area.	6.5	7.5	8.5
6~5	Moderate	Controls are able to Detect within the same functional area	4.5	5.5	6.5
4~3	High	Controls are able to Detect within the same machine/module.	2.5	3.5	4.5
2~1	Very High	Controls will Detect excursions before next lot is produced. Prevent excursion from occurring	-	1	2.5

Figure 6 depicts the optimized Gaussian MFs for scale table D using the best individual after 300 iterations. From Figure 6, it can be seen that the width of each of Gaussian MF is close to the scale table of D. Figure 7 depicts the projection of the MFs using **Condition 1.**

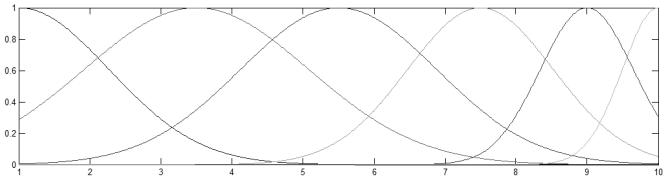

Figure 6 Projection of the MFs for Detect.

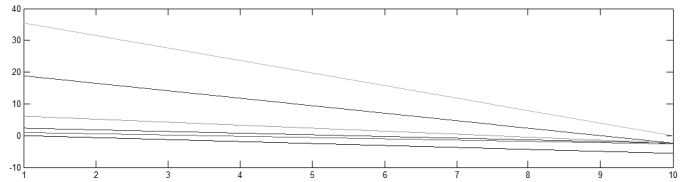

Figure 7 Optimized MFs for Detect.

In order to validate the Gaussian MFs designed using the proposed techniques, a data set collected from a real semiconductor manufacturing process, i.e., the test handler process, is used for experimentation. Figures 8 and 9 depict the surface plots of the RPN versus S and O, while D is kept at 10 and 1, respectively. Note that monotonic surface plots are obtained.

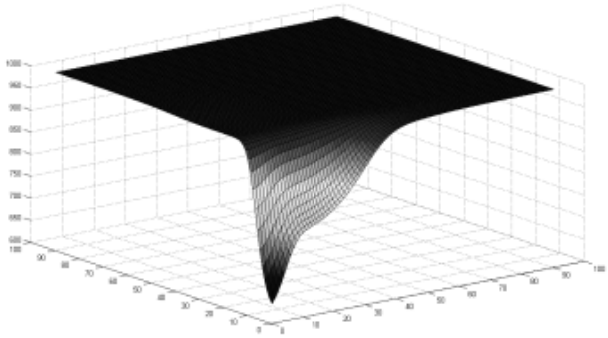

Figure 8 RPN versus S and O for the test handler process, while D=10

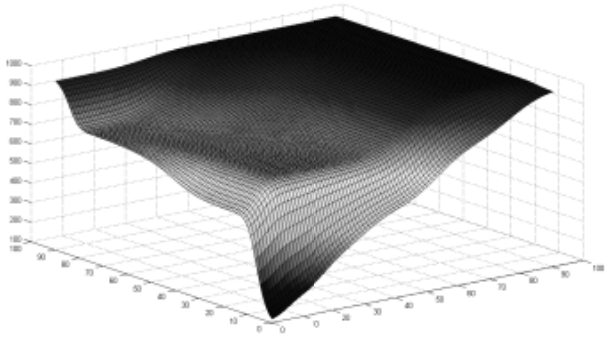

Figure 9 RPN versus S and O for the test handler process, while D=1

However, it is not straightforward to evaluate the monotonicity relationship between the RPN and S, O, and D. The surface plot may not be an effective method in this regard. As such, we propose to test the monotonic relationship using procedure in section IV. Here, comparable points are generated, and the *degree of monotonicity* is obtained. The results are summarized in Table 3. As can be seen, the *degree of monotonicity* is 1. This vindicates the monotonic increasing relationships between the RPN and S, O, and D. In another words, the monotonicity property is guaranteed.

Table 3 The scale table for Severity

Data set	#Comparable pairs	#Monotone pairs	Degree of monotonicity
Test handler	2700	2700	1

VI. SUMMARY

In this paper, the monotonicity property of an FIS model has been investigated, and a novel technique for designing

Gaussian MFs for a monotonic FIS model has been proposed. The technique shows how a set of Gaussian MFs can be generated from a qualitative scale table. The proposed technique is useful, as it allows the Gaussian MFs design procedure for a monotonic FIS model to be automated. The proposed method can be applied to various FIS modeling problems that involve a qualitative scale table, e.g., assessment and decision problems, as well as education assessment problem [7].

On the other hand, the use of a monotonicity measure in FIS modeling has been proposed in this paper. The usefulness of the proposed techniques has been demonstrated with a real industrial case study, i.e., an FIS-based RPN model for FMEA. Promising results have been obtained.

For further work, the use of other α values can be examined. Besides, other techniques such as nonlinear programming, particle swam optimization, and harmony search can be adopted for optimization purposes. Applicability of the monotonic FIS models to other domains, e.g. education assessment, can be investigated too.

ACKNOWLEDGMENT

The financial support provided by a Fundamental Research grant (No. FRGS/02(10)/752/2010(38)) and USM RU Grant (No. 814089) for this work is highly appreciated.

***Abstract*—Triangulated irregular network (TIN) has been used for representing general type-2 fuzzy sets and gained some results of reducing computational complexity. In general, TIN-based algorithms are still complex and difficulty to deploy in applications. So, an approach based on refinement constraint TIN (CTIN) for representing general type-2 fuzzy set is proposed. The paper deals with the use CTIN in general type-2 fuzzy logic systems (GT2FLS). Operations are developed for general type-2 fuzzy sets. A T2FLS is designed and implemented in comparing previous approaches under an application of robot navigation.**

***Index Terms*—Type-2 Fuzzy Sets, Type-2 Fuzzy Logic Systems, Type-2 Fuzzy Inference, Geometric Representation**

I. Introduction

Type-2 fuzzy logic systems has widely been used in many applications. Almost applications are limited by computational complexity of general T2FLS. Recently, these are many researches arising from reduction the complexity of these systems that depend on representation of type-2 fuzzy sets. There are many approaches to representation of type-2 fuzzy sets. The point-based representation [5], [6], [7], [8] has proposed with operations and computation of type-2 fuzzy sets and systems. Mendel et al [9], [10] proposed the representation based on embedded fuzzy sets, vertical slices. Starczewski [17] introduced a method for complexity reduction of operations on triangular type-2 fuzzy sets. For the this purpose, Coupland et al [2] proposed geometric method for representation type-1 and interval type-2 fuzzy sets, new algorithms for various operations on type-1 and type-2 fuzzy sets and for defuzzification. Coupland et al [3], [4] presented new techniques using upper and lower surfaces for performing logical operations on type-2 fuzzy sets with considering computational speed and accuracy. In [14], [15], authors proposed an approach to TIN-based geometric representation of type-2 fuzzy sets with or without using upper and lower surfaces. Hagras et al [20], [21], [22] proposed an approach to representation of type-2 fuzzy sets using zSlices that be able to gap interval type-2 fuzzy sets and general type-2 fuzzy sets. A similar approach to representation of type-2 fuzzy sets was proposed by Mendel et al [11], [12] based on α - plane representation.

The paper introduces an approach to representation of general type-2 fuzzy sets, called ϵ_u-approximation. A constrained TIN representing T2FS is triangulated from set of points set that satisfy ϵ_u-approximate criterion. This representation is the basis for designing algorithms of general type-2 fuzzy logic systems. This approach is considered under two respects: computational speed and accuracy. An computational process of general type-2 FLSs (GT2FLS) involving fuzzification, inference process, aggregation and defuzzification are proposed in comparing with previous methods. Computation for GT2FLS is able to deploy in real time applications. Because geometric algorithms are only computed at vertices of TIN based on operations of interval type-2 fuzzy sets. Experimental results are shown in comparisons on speed and accuracy with other approaches. The paper also discusses the feasibility of proposed algorithms by implementing RCTIN-based type-2 fuzzy logic systems under avoidance behavior of robot navigation with reported runtime tables.

The paper is organized as follows: II presents an overview on type-2 fuzzy sets and inference, ϵ-approximation representation of type-2 fuzzy sets; III introduces ϵ_u-approximate representation and applications to operations involving meet and join under minimum, negation; IV presents a general T2FLS involving sub-processes such as fuzzification, inference process, aggregation and defuzzification. V introduces implementation and discussion of the feasibility under the experimentation of robot navigation; V is conclusion and future works.

II. Geometric Representation for General Type-2 Fuzzy Sets

A. Type-2 Fuzzy Sets

A type-2 fuzzy set in X is denoted $\tilde{A}$, and its membership grade of $x \in X$ is $\mu_{\tilde{A}}(x,u), u \in J_x \subseteq [0,1]$, which is a type-1 fuzzy set in [0, 1]. The elements of domain of $\mu_{\tilde{A}}(x,u)$ are called primary memberships of x in $\tilde{A}$ and memberships of primary memberships in $\mu_{\tilde{A}}(x,u)$ are called secondary memberships of x in $\tilde{A}$.

Definition 2.1: A $type-2\ fuzzy\ set$, denoted $\tilde{A}$, is characterized by a type-2 membership function $\mu_{\tilde{A}}(x,u)$ where $x \in X$ and $u \in J_x \subseteq [0,1]$, i.e.,

$$\tilde{A} = \{((x,u), \mu_{\tilde{A}}(x,u)) | \forall x \in X, \forall u \in J_x \subseteq [0,1]\} \quad (1)$$

or

$$\tilde{A} = \int_{x \in X} \int_{u \in J_x} \mu_{\tilde{A}}(x,u))/(x,u), J_x \subseteq [0,1] \quad (2)$$

in which $0 \leq \mu_{\tilde{A}}(x,u) \leq 1$.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

At each value of x, say $x = x'$, the 2-D plane whose axes are u and $\mu_{\tilde{A}}(x', u)$ is called a $vertical\ slice$ of $\mu_{\tilde{A}}(x, u)$. A *secondary membership function* is a vertical slice of $\mu_{\tilde{A}}(x, u)$. It is $\mu_{\tilde{A}}(x = x', u)$ for $x \in X$ and $\forall u \in J_{x'} \subseteq [0, 1]$, i.e.

$$\mu_{\tilde{A}}(x = x', u) \equiv \mu_{\tilde{A}}(x') = \int_{u \in J_{x'}} f_{x'}(u)/u, J_{x'} \subseteq [0, 1] \quad (3)$$

in which $0 \leq f_{x'}(u) \leq 1$.

In manner of embedded fuzzy sets, a type-2 fuzzy sets [9] is union of its type-2 embedded sets, i.e

$$\tilde{A} = \sum_{j=1}^{n} \tilde{A}_e^j \quad (4)$$

where $n \equiv \prod_{i=1}^{N} M_i$ and $\tilde{A}_e^j$ denoted the j^{th} type-2 embedded set of $\tilde{A}$, i.e.,

$$\tilde{A}_e^j \equiv \{\left(u_i^j, f_{x_i}(u_i^j)\right), i = 1, 2, ..., N\} \quad (5)$$

where $u_i^j \in \{u_{ik}, k = 1, ..., M_i\}$.

Let $\tilde{A}, \tilde{B}$ be type-2 fuzzy sets whose secondary membership grades are $f_x(u), g_x(w)$, respectively. Theoretic operations of type-2 fuzzy sets such as union, intersection and complement are described [6] as follows:

$$\mu_{\tilde{A} \cup \tilde{B}}(x) = \mu_{\tilde{A}}(x) \sqcup \mu_{\tilde{B}}(x) = \int_u \int_v (f_x(u) \star g_x(w))/(u \vee w) \quad (6)$$

$$\mu_{\tilde{A} \cap \tilde{B}}(x) = \mu_{\tilde{A}}(x) \sqcap \mu_{\tilde{B}}(x) = \int_u \int_v (f_x(u) \star g_x(w))/(u \star w) \quad (7)$$

$$\mu_{\tilde{A}}(x) = \mu_{\neg \tilde{A}}(x) = \int_u (f_x(u))/(1 - u) \quad (8)$$

where $\vee$, $\star$ are t-cornorm, t-norm, respectively. Type-2 fuzzy sets are called an interval type-2 fuzzy sets if the secondary membership function $f_{x'}(u) = 1\ \forall u \in J_x$.

B. Delaunay Triangulation

A *topographic surface* σ is the image of a real bivariate function f defined over a domain D in the Euclidean plane, as

$$\sigma = \left\{(x, u, f(x, u))\middle|(x, u) \in D\right\} \quad (9)$$

A polyhedral model is the image of a piecewise-line function f described on a partition of D into polygonal regions $\{T_1, ..., T_k\}$ and the image of f over each region $T_i (i = 1, ..., k)$ is a planar patch. If all of T_is $(i = 1, .., k)$ are triangles then the polyhedral model is called a $Triangulated\ Irregular\ Network$ (TIN). Hence, σ may be represented approximately by a TIN, as

$$\sigma \tilde{=} \sum_{i=1}^{k} \left\{(x, u, f_i(x, u))\middle|(x, u) \in T_i\right\}, \bigcup_{i=1}^{k} T_i \equiv D \quad (10)$$

where f_is $(i = 1, ..., k)$ are planar equations.

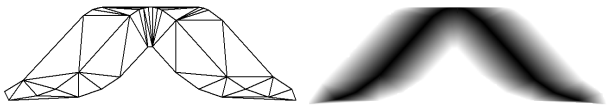

Fig. 1. Example of representation of a type-2 Gaussian fuzzy sets

The $Delaunay\ triangulation$ of a set V of points in IR^2 is a subdivision of the convex hull of V into triangles having their vertices at points of V, and such that triangles are as much aquiangular as possible. More formally, a triangulation τ of V is a Delaunay triangulation if and only if, for any triangle t of τ, the circumcircle of t does not contain any point of V in its interior. This property is called the $empty\ circle\ property$ of the Delaunay triangulation.

C. Geometric Representation of Type-2 Fuzzy Sets

In [15], geometric representation of type-2 fuzzy sets is presented as an approach based on TIN. Concept of ε-approximation set is used to approximately discretize the membership grades of type-2 fuzzy sets into triangular patches. ϵ-approximation is defined as follows:

Definition 2.2: A type-2 fuzzy set is called ϵ-approximation set, denoted $\tilde{A}^*$, of $\tilde{A}$ in continuous domain D if

$$\|\mu_{\tilde{A}}(x, u) - \mu_{\tilde{A}^*}(x, u)\| \leq \varepsilon, (x, u) \in D \quad (11)$$

The theorem on representation of a type-2 fuzzy set referenced as *Approximation Theorem* is presented as follows:

Theorem 2.1 (Approximation Theorem): Let $\tilde{A}$ be type-2 fuzzy set with membership grade $\mu_{\tilde{A}}(x, u)$ in continuous domain D. There exists a type-2 fuzzy set with membership grade is a TIN $T_{\tilde{A}}$, denoted $\tilde{A_T}$, so that $\tilde{A_T}$ is ϵ-approximation set of $\tilde{A}$, i.e,

$$\|\mu_{\tilde{A}}(x, u) - \mu_{\tilde{A_T}}(x, u)\| < \epsilon, \ \ \forall (x, u) \in D. \quad (12)$$

Fig. 1 is the TIN consisting of 36 vertices and 48 faces that represents approximately of Gaussian type-2 fuzzy sets with $\epsilon = 0.1$. The primary membership function is a Gaussian with fixed deviation and mean $m_k \in [m_1, m_2]$ and the secondary membership function is a triangular membership function that its apex is at the Gaussian function with mean $(m_1 + m_2)/2$. At the point (x, u) that its color is darker, the value of $\mu_{\tilde{A}}(x, u)$ is closer 1.0, otherwise $\mu_{\tilde{A}}(x, u)$ is closer 0.0.

III. Refinement CTIN Based Type-2 Fuzzy Sets

TIN-based representation of type-2 FS gives nice results, but computational complexity is still large. To gain more effective computational method, refinement constrain triangulated irregular network (CTIN) is proposed to represent a general T2FS. This section introduces the approach to representation using refinement CTIN and applications to operations of T2FS.

A. Representation of T2FSs Using Refinement CTIN

TIN is formed from set of points in the 3-dimensional space with satisfying Delaunay criterion, called Delaunay triangulation. CTIN is TIN satisfying Delaunay criterion with each input segment appears as an edge of triangulation. Input of CTIN is a planar straight line graph (PSLG). A PSLG is a set of vertices and segments that satisfies two constraints. First, for each segment contained in a PSLG, the PSLG must also contain the two vertices that serve as endpoints for that segment. Second, segments are permitted to intersect only at their endpoints. Fig. (2) depicts an example of PSLG with 13 vertices and 9 segments.

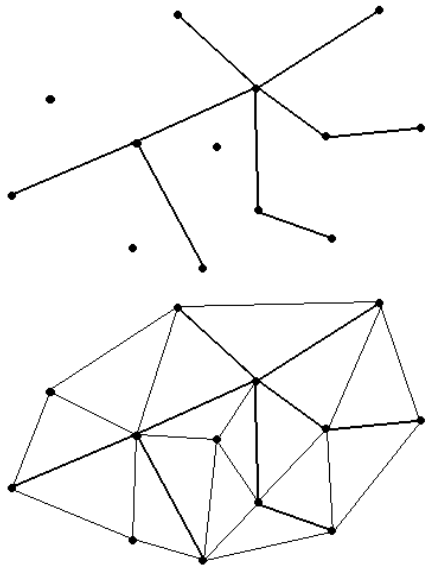

Fig. 2. An example of PSLG and its CTIN

To represent a type-2 fuzzy set using CTIN, a PSLG is approximately retrieved from type-2 fuzzy set $\tilde{A}$. The following is some definitions of ε_u criterion that points out how to retrieve a PSLG.

Definition 3.1 (ε_u approximation): On α-cut plane at z level of the type-2 fuzzy set $\tilde{A}$, the point $P'_{(x,u')} \in \alpha$ is called a ε_u-approximate point of $P_{(x,u)} \in \alpha$ if $\|u - u'\| < \varepsilon$.

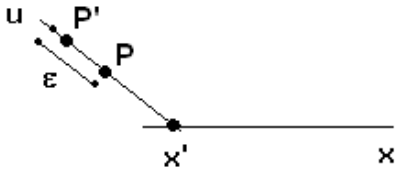

Fig. 3. The P' point is ε_u-approximate point of P.

Let type-2 fuzzy set $\tilde{A}$ and $n+1$ α-planes at levels $\{z_i = \frac{i}{n}, i = 0, 1, ..., n\}$. A contour at the level z_i of $\tilde{A}$, denoted $\tilde{Z}_i$, is a poly-line that involves its vertices on α-plane z_i. A contour $\tilde{Z}_i, (i = 0, 1, ..., n)$ is called ε_u-approximate contour of type-2 fuzzy set $\tilde{A}$ if each point $P'_{(x,u')} \in \tilde{Z}_i$ is also ε_u-approximate point of $P_{(x,u)} \in \tilde{A}$ at the level z_i. Thence, an ε_u-approximate type-2 fuzzy set is described as follows:

Definition 3.2 (ε_u-approximate T2FS): A type-2 fuzzy set $\tilde{A}'$ is called ε_u-approximate type-2 fuzzy set at n levels of $\tilde{A}$ if $n+1$ its contours $(Z_0, Z_1, ..., Z_n)$ are ε_u-approximate contour of $\tilde{A}$.

At each level k of $\tilde{A}$, contour Z_k is an interval type-2 fuzzy set, thus upper (lower) contour, denoted UC_k (LC_k), is upper (lower) bound segments of the contour. In case of $k = 0$, UC_0 (LC_0) is upper (lower) membership function (UMF/LMF) of interval type-2 fuzzy set that is an overlap of the FOU of $\tilde{A}$.

Definition 3.3: (Refinement CTIN) A TIN representing $\tilde{A}$ is called *refinement CTIN* of $\tilde{A}$ at K levels, denoted $T_{\tilde{A}}$, if $T_{\tilde{A}}$ is generated from PSLG involving set of vertices V and set of segments L, in which $\forall v \in V$ be ε_u-approximate points and L is set of segments extracted from K ε_u-approximate contours of $\tilde{A}$.

Hence, a general type-2 fuzzy set is able to be represented by a refinement CTIN as the following theorem.

Theorem 3.1: Let $\tilde{A}$ be a type-2 fuzzy set with continuous membership grade $\mu_{\tilde{A}}(x)$ in continuous domain D and enough small ε_u. These exists *refinement* CTIN that represents $\tilde{A}$ with ε_u-approximation at K levels.

Proof:

Call $T_{\tilde{A}}$ is refinement CTIN that is generated from a PSLG with set of vertices V and set of segments L extracted from $\tilde{A}$ at K levels. Suppose that exists a point $P_{(x_p,u_p,z_p)}$ on $T_{\tilde{A}}$ not to satisfy ε_u-approximate criteria. Thus P is belong to one of α-planes $Z_0, Z_1, ..., Z_{K-1}$. $T_{\tilde{A}}$ is refinement CTIN then P is inside the edge (for example v_iv_j) of $T_{\tilde{A}}$. Denote $P_0(x_{P_0}, u_{P_0}, z_{P_0})$ be the point on the edge v_iv_j that distance to respective point of $\tilde{A}$ in u-axis is maximum, i.e.

$$\{\| u_{P_0} - u \|\} \rightarrow max, z_{P_0} = \mu_{\tilde{A}}(x_{P_0}, u) \qquad (13)$$

Note that P_0 is able to coincide with P. Call t_k, t_l are two adjacent triangles of v_iv_j. The edge v_iv_j is split into two sub-edge v_iP_0 and P_0v_j, so t_k, t_l are divided into four sub-triangle. According to supposition, $\mu_{\tilde{A}}(x)$ is continuous in domain D then distance from the respective point P' of P in new edge v_iP_0 or P_0v_j of $T_{\tilde{A}}$ to respective point on $\tilde{A}$ is closer than P, i.e.

$$\| u_{P'} - u \| < \| u_P - u \|, z_P = z_P = \mu_{\tilde{A}}(x_P, u) \qquad (14)$$

If these still exists a point P inside edges v_iP_0 or P_0v_j that not to satisfy ε_u-approximation then the edge is split into sub-edges as above way. The end of each splitting step, the P is closely moved to respective point of $\tilde{A}$. Because of the continuousness of $\mu_{\tilde{A}}(x)$, these no exists any point inside sub-edge that not to satisfy ε_u-approximation after the limited incremental splitting steps. ■

Example: Let $\tilde{A}$ be Gaussian type-2 fuzzy set with $I = 5$ levels, i.e. $z_i = i/I, i = 0, 1, .., I$. Upper (lower) membership

functions at each level are described as follows:

$$f_U^i(x) = (0.9 + \frac{0.1(I-i)}{I})e^{(-\frac{x^2}{2(\sigma_1 - i*(\sigma_1-\sigma_2)/(2I))^2})}$$
$$f_L^i(x) = (0.9 - \frac{0.1(I-i)}{I})e^{(-\frac{x^2}{2(\sigma_2 + i*(\sigma_1-\sigma_2)/(2I))^2})} \quad (15)$$

Fig. 4 is to describe CTIN based type-2 fuzzy set that represent $\tilde{A}$ as the formula (15).

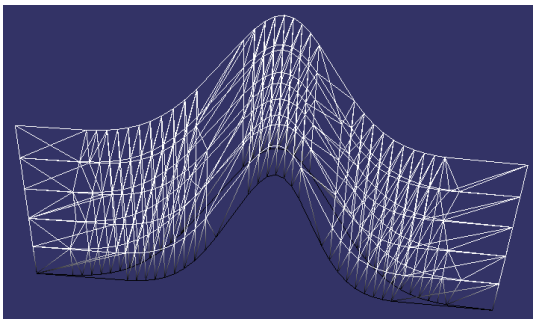

Fig. 4. Example of ε_u approximate representation of $\tilde{A}$

B. Operations

Theoretic operations of type-2 fuzzy sets are described as formulations (6)-(8). Arcording to [6], operations of n type-2 fuzzy sets are computed using max t-conorm and min t-norm as follows:

Join operation:

$$\mu_{\sqcup_{i=1}^n F_i}(\theta) = \begin{cases} \wedge_{i=1}^n \mu_{F_i}(\theta) & \theta < \upsilon_1 \\ \wedge_{i=k+1}^n \mu_{F_i}(\theta) & \upsilon_k \le \theta < \upsilon_{k+1}, 1 \le k < n \\ \vee_{i=1}^n \mu_{F_i}(\theta) & \theta > \upsilon_n \end{cases} \quad (16)$$

Meet operation:

$$\mu_{\sqcap_{i=1}^n F_i}(\theta) = \begin{cases} \vee_{i=1}^n \mu_{F_i}(\theta) & \theta < \upsilon_1 \\ \wedge_{i=1}^k \mu_{F_i}(\theta) & \upsilon_k \le \theta < \upsilon_{k+1}, 1 \le k < n \\ \wedge_{i=1}^n \mu_{F_i}(\theta) & \theta \ge \upsilon_n \end{cases} \quad (17)$$

in which $\wedge$ is a t-norm and $\vee$ is a t-conorm, υ_i is a value such that $\mu_{F_i}(\upsilon_i)$ is at the apex of $\mu_{F_i}(x)$, $i = 1, ..., n$.

Suppose that $\tilde{A}_i (i = 1, ..., n)$ are ε_u type-2 fuzzy sets based on refinement CTIN with L levels. Call V_i is vertices of $\tilde{A}_i$ and $V = \cup_{i=1}^n V_i$. Join (meet) operations of n type-2 fuzzy sets $\tilde{A}_i$ using max t-conorm and min t-norm are described as the following theorem.

Theorem 3.2: Let $\tilde{A}_i (i = 1, .., n)$ be ε_u type-2 fuzzy sets based on refinement CTIN with L levels. Call I_k is set of intersection points between k^{th}-level contours of $\tilde{A}_i$. Join (meet) operation of $\tilde{A}_i$, called $\tilde{B}$, is computed according to the formula (16) ((17) for meet operation) at $v \in V \cup (\cup_{k=0}^K I_k)$. B is ε_u type-2 fuzzy sets based on refinement CTIN with L levels.

The following is the algorithm for computing join, meet operations using max t-conorm, min t-norm of n refinement CTIN-based type-2 fuzzy sets.

Algorithm 3.1 (Join/Meet Operations): .
Input: n RCTIN-based type-2 fuzzy sets $\tilde{A}_i$, $(i = 1, ..., n)$.
Output: $\tilde{B} = \sqcup_{i=1}^n \tilde{A}_i$ ($\tilde{B} = \sqcap_{i=1}^n \tilde{A}_i$ for meet operation).

1) For each level $k = \overline{0, L}$.
   a) Compute I_k set of intersection points of k^{th} contours of $\tilde{A}_i$.
   b) For each $v \in I_k$
      If $v \notin \tilde{A}_i$ then insert v into the $\tilde{A}_i$'s TIN.
2) For each level $k = \overline{0, L}$.
   For each vertex $v \in V$ belong to k^{th} contour
   a) Compute vertex $v' \in \tilde{B}$ of join (meet) operation according to (16) or (17).
   b) If v' is not a vertex of $\tilde{A}_i$s then reject v'.
   c) Otherwise add v' into $V_{\tilde{B}}^k$, i.e. set of vertices at k^{th} level of $\tilde{B}$.
3) Triangulate set of vertices $V_{\tilde{B}} = \cup_{k=0}^L V_{\tilde{B}}^k$ with PSLG (segments in $V_{\tilde{B}}^k$).

Example: Let $\tilde{A}_1, \tilde{A}_2$ be two RCTIN-based fuzzy sets described as the formula (15) with $m_1 = 1.0, m_2 = 1.5, \sigma_{11} = 0.4, \sigma_{12} = 0.3, \sigma_{21} = 0.5, \sigma_{22} = 0.3$. Fig. (5) show results of join/meet operations.

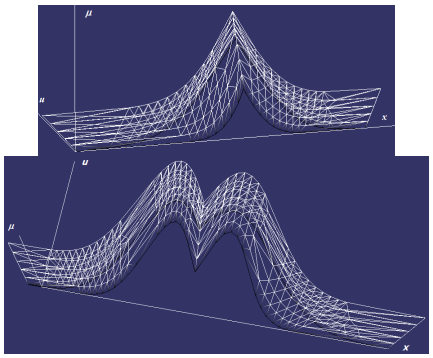

Fig. 5. Example of join/meet operations.

IV. Refinement CTIN Based Type-2 Fuzzy Logic Systems

A. Rule base and fuzzifier

Fig. 6 shows the structure of a RCTIN-based type-2 FLS. The difference from general type-2 FLS contains only geometric defuzzification in the output processing block.

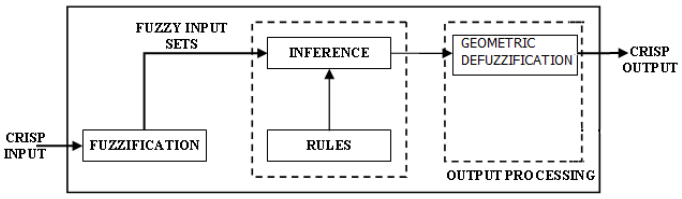

Fig. 6. The structure of RCTIN based type-2 fuzzy logic systems

The singleton fuzzifier maps the crisp input into a RCTIN-based type-2 fuzzy set. We consider only singleton fuzzification, for which the input fuzzy set has only a single point of

nonzero membership. The "IF-THEN" rules has the form, for l^{th} rule, as follows:

R^l : IF x_1 is $\tilde{F}_1^l$ and x_2 is $\tilde{F}_2^l$ and ... and x_p is $\tilde{F}_p^l$ THEN y is $\tilde{G}^l$

where: x_is are inputs; $\tilde{F}_i^l$s are antecedent sets (i=1, 2, ..., p); $\tilde{G}^l$ is the output.

Example: Consider the RCTIN-based type-2 fuzzy set that described as the formula (15). Using singleton fuzzifier at $x = 0.8$, output of the fuzzifier is a RCTIN-based type-2 fuzzy set as the Fig. 7.

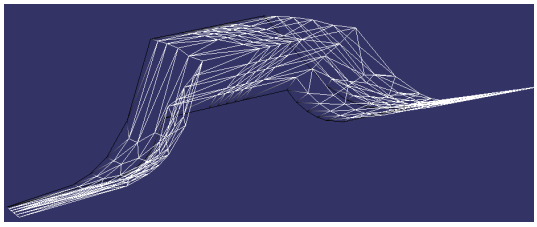

Fig. 7. Example on output of fuzzifier

B. Inference Engine

Inference engine combines rules and gives a mapping from input type-2 fuzzy sets to output type-2 fuzzy sets. Multiple antecedents in rules are connected by the meet operation. The membership grades in the input sets are combined with those in the output sets using the $sup-star$ composition. To do this one needs to find meets and joins of type-2 sets, as well as compositions of type-2 relations. Note that mentioned type-2 fuzzy sets are RCTIN-based type-2 fuzzy sets.

The output of the inference engine is a RCTIN-based type-2 fuzzy set. We do defuzzification by finding its geometric centroid, that is described more detail in the next section.

The following is the inference processing of RCTIN-based type-2 FLS:

Consider a RCTIN-based type-2 FLS having p inputs, $x_1 \in X_1, x_2 \in X_2, ..., x_p \in X_p$, and one output $y \in Y$. Suppose that it has M rules where the l^{th} rule has the form

$$R^l \text{ : IF } x_1 \text{ is } \tilde{F}_1^l \text{ AND ... AND } x_p \text{ is } \tilde{F}_p^l \text{ THEN } y \text{ is } \tilde{G}^l. \tag{18}$$

This rule represents a RCTIN-based type-2 fuzzy relation between the input space $X_1 \times X_2 \times ... \times X_p$ and the output space Y of the FLS. The membership function of this type-2 relation is denoted as $\mu_{\tilde{F}_1^l \times ... \times \tilde{F}_p^l \to \tilde{G}^l}(x, y)$, where $\tilde{F}_1^l \times ... \times \tilde{F}_p^l$ denotes the Cartesian product of $\tilde{F}_1^l$, ..., $\tilde{F}_p^l$, and $x = \{x_1, x_2, ..., x_p\}$.

When an input $\mathbf{x}'$ is applied, the composition of the fuzzy set $\tilde{X}'$ to which $\mathbf{x}''$ belongs and the rule R^l is found by using the extended sup-star composition

$$\mu_{\tilde{X}' \circ \tilde{F}_1^l \times ... \times \tilde{F}_p^l \to \tilde{G}^l}(y) = \sqcap_{x \in \tilde{X}'} [\mu_{\tilde{X}'}(x) \sqcap \mu_{\tilde{F}_1^l \times ... \times \tilde{F}_p^l \to \tilde{G}^l}(x, y)] \tag{19}$$

We denote $\tilde{X}' \circ \tilde{F}_1^l \times ... \times \tilde{F}_p^l \to \tilde{G}^l$ as $\tilde{B}^l$, the output set corresponding to the l^{th} rule. We use singleton fuzzification and the product or minimum implication, inference process of rule l^{th} is described as follows:

Fig. 8. Centroid computations of $\tilde{A}$ by partitioning the space of uncertainty

$$\begin{aligned} \mu_{\tilde{B}^l}(y) &= \mu_{\tilde{F}_1^l}(x_1) \sqcap \mu_{\tilde{F}_2^l}(x_2) \sqcap ... \sqcap \mu_{\tilde{F}_p^l}(x_p) \sqcap \mu_{\tilde{G}^l}(y) \\ &= \mu_{\tilde{G}^l}(y) \sqcap [\sqcap_{i=1}^p \mu_{\tilde{F}_i^l}(x_i)] \end{aligned} \tag{20}$$

The output sets of rules are combined in a type-2 fuzzy set by using $join$ operation, i.e.

$$\mu_{B'}(y) = \sqcup_{i=1}^K \mu_{\tilde{B}^i}(y) \tag{21}$$

in which K is number of fired rules and $\mu_{\tilde{B}^i}(y)$ is output of i^{th} fired rule.

Consider a vertex v of the TIN that represents output RCTIN-based type-2 fuzzy set of l^{th} rule. Suppose that v belongs to Z_k contour. After inference process, abscissa x, z of v are no change, abscissa u of v is computed as follows:

If $u_v = max_u\{\mu_{\tilde{G}}(x_v, u)\}$ then

$$u'_v = u_v \star [max_y\{Z^k_{\tilde{F}_1}(x_1)\} \star ... \star max_y\{Z^k_{\tilde{F}_1}(x_1)\}] \tag{22}$$

If $u_v = min_u\{\mu_{\tilde{G}}(x_v, u)\}$ then

$$u'_v = u_v \star [min_y\{Z^k_{\tilde{F}_1}(x_1)\} \star ... \star min_y\{Z^k_{\tilde{F}_1}(x_1)\}] \tag{23}$$

The algorithm for inference engine is described as follows:

Algorithm 4.1 (Inference engine): .

Input: $n+1$ RCTIN-based type-2 fuzzy sets $\tilde{A}_i, \tilde{G}$, ($i = 1, ..., n$).

Output: RCTIN-based type-2 fuzzy set $\tilde{G}$ is output of inference process.

1) For each contour $Z_k, k = \overline{0, L}$.
   a) For each vertex v is on the Z_k
   b) if v belongs to upper surface, i.e $u_v = max_u\{\mu_{\tilde{G}}(x_v, u)\}$
      computing u'_v as the formula (22).
   c) otherwise
      computing u'_v as the formula (23).

C. Defuzzification

Defuzzification is the most complex process of theoretic type-2 fuzzy logic systems. This section is described a defuzzification based on finding center of gravity of the space of uncertainty.

Let V_i with center of gravity $cog_i = (x_{ci}, y_{ci}, z_{ci})$ and mass m_i $(i = 1, \ldots, P)$ are objects in three-dimensions space. The gravity center of the system of massive objects is computed as follows:

$$\mathbf{c} = \frac{\sum_{i=1}^P \mathbf{cog}_i * m_i}{\sum_{i=1}^P m_i} \tag{24}$$

If mass density of objects is equilateral then equation (24) is rewritten as follows:

$$\mathbf{c} = \frac{\sum_{i=1}^P \mathbf{cog}_i * V_i * md}{\sum_{i=1}^P V_i * md} = \frac{\sum_{i=1}^P \mathbf{cog}_i * V_i}{\sum_{i=1}^P V_i} \tag{25}$$

where V_is are volumes of massive objects and dm is their mass density.

Let $\tilde{A}$ be RCTIN-based type-2 fuzzy set that contains N vertices $v_k (k = 1, \ldots, N)$ and M faces $f_k (k = 1, \ldots, M)$. In order to compute the center of gravity of the uncertainty space of $\tilde{A}$, $T_{\tilde{A}}$ is divided into 3-dimensional patches based on triangles of TIN. For each triangle, we make a triangular prism in which its vertices are the three vertices of the triangle and the three points of these vertices are projected on 2-dimensional plane (x, u). Next, triangular prisms are also divided into three tetrahedrons. Hence, the TIN of $\tilde{A}$ is divided into $3M$ tetrahedrons. Let t_k with center of gravity $c_k = (x_k, u_k, y_k)$ and volume V_k is the k^{th} tetrahedrons $(k = 1, \ldots, 3M)$. Because mass density of tetrahedrons is equilateral, the center of gravity of system of tetrahedrons is computed by using 25 as follows:

$$\mathbf{c} = \frac{\sum_{i=1}^{3M} \mathbf{c}_i * V_i}{\sum_{i=1}^{3M} V_i} \tag{26}$$

For a tetrahedron with vertices $\mathbf{v}_1 = (v_{11}, v_{12}, v_{13})$, $\mathbf{v}_2 = (v_{21}, v_{22}, v_{23})$, $\mathbf{v}_3 = (v_{31}, v_{32}, v_{33})$, and $\mathbf{v}_4 = (v_{41}, v_{42}, v_{43})$, the volume is computed using a dot product (.) and a cross product ($\times$), yielding

$$\mathbf{V} = \frac{|(\mathbf{v}_1 - \mathbf{v}_4).((\mathbf{v}_2 - \mathbf{v}_4) \times (\mathbf{v}_3 - \mathbf{v}_4))|}{6} \tag{27}$$

Algorithm 4.2 (Defuzzification): .
Input: $T_{\tilde{A}}$ is a T2FS.
Output: $fDefuzz$ is output value.
For each triangle t_k of $T_{\tilde{A}}$

1) Make triangular prism with with six vertices: v_1, v_2, v_3, $v_{1'}, v_{2'}, v_{3'}$ in which abscissa y of $v_{1'}, v_{2'}, v_{3'}$ is zero.
2) Divide the triangular prism into three tetrahedrons in which their vertices are $(v_{1'}, v_1, v_2, v_3)$, $(v_{1'}, v_2, v_{2'}, v_3)$ and $(v_{1'}, v_3, v_{2'}, v_{3'})$.
3) Compute centroid of each tetrahedron.
4) Compute volume of each tetrahedron as equation (27).
5) Compute centroid of the space of uncertainty of $\tilde{A}$ as equation (26).
6) Abscissa $fDefuzz = x$ of the centroid is the output of type-reduction and defuzzification.

V. Experimental Results

A. Comparisons

Algorithms are experimented to get comparisons in runtime and accuracy between the proposed method and previous methods. On runtime, the proposed representation is compared with TIN-based representation [15]. All of algorithms are implemented on Laptop HP DV9500 Core 2 Duo T7500 RAM 2GB with statistics summarised in the following table.

TABLE I
Sum of cumulative time of 100 replications (in seconds)

	Meet	Join	Negation	Inference
TIN-based representation	2.278	2.293	0.003	1.880
The proposed method	0.0118	0.0205	0.000015	0.0128

On the manner of accuracy, the proposed method (RCTIN) is compared with zSlice-based representation [18], [19]. I is number of slices/contours of a zSlice type-2 fuzzy sets or RCTIN type-2 fuzzy sets. Results on accuracy, summarised in the table II, show that RCTIN type-2 fuzzy sets accurately represent the original type-2 fuzzy sets in case primary and secondary membership grades is piece-wise linear functions.

TABLE II
Comparison on errors in representation

I	3	5	10	50	100
zSlice (triangle)	0.0251	0.0156	0.0075	0.0015	0.00075
RCTIN (triangle)	0.0	0.0	0.0	0.0	0.0
zSlice (Gaussian)	0.0623	0.0374	0.0187	0.00374	0.00187
RCTIN (Gaussian)	0.0039	0.0023	0.0012	0.00023	0.00012

B. Problems

We implement RCTIN-based type-2 fuzzy logic systems with collision avoidance behavior of robot navigation. The fuzzy logic systems have two inputs: the extended fuzzy directional relation [23] and range to obstacle, the output is angle of deviation (AoD). The behavior is experimented in comparisons between type-1 FLS and RCTIN-based general type-2 FLS. The fuzzy rule has the form as following:

IF FDR is $\tilde{A}_i$ AND Range is $\tilde{B}_i$ THEN AoD is $\tilde{C}_i$
where $\tilde{A}_i$, $\tilde{B}_i$, $\tilde{C}_i$ are type-2 fuzzy sets of antecedent and consequent, respectively.

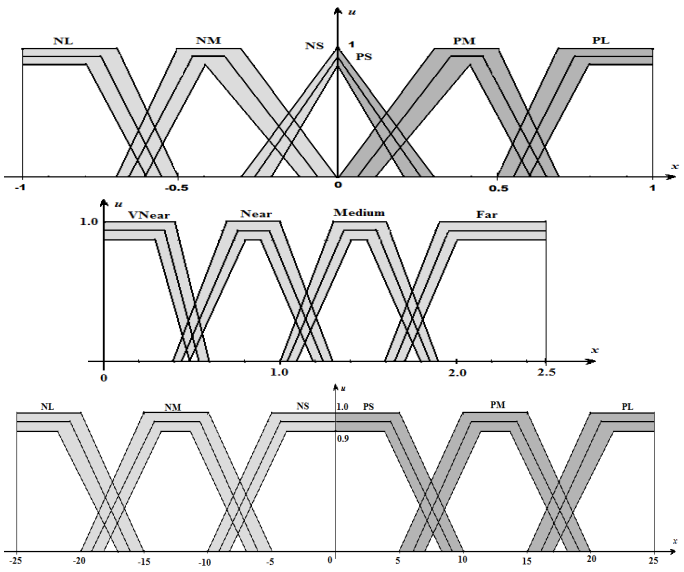

Fig. 9. Membership grades of CA behavior.

The fuzzy directional relation has six linguistic values (NLarge, NMedium, NSmall, PSmall, PMedium and PLarge). The range from robot to obstacle is divided in three subsets: VNear, Near, Medium and Far. The output of fuzzy if-then is a linguistic variable representing for angle of deviation, has six linguistic variables the same the fuzzy directional relation with the different membership functions. Linguistic values are

general type-2 fuzzy subsets that membership functions are described in Fig. 9. Membership grades are general type-2 fuzzy sets with vertical slide is triangular in which $z = 0$ for all points on upper/lower MF and $z = 1$ for all points on middle MF. For type-1 behavior, linguistic variables of inputs and output are the same type-2 behavior and their membership functions are upper MF of type-2 membership functions. RCTIN-based type-2 fuzzy subsets are triangulated at 5 levels. The rule-base is described in the table III.

TABLE III
THE RULE BASE OF COLLISION AVOIDANCE BEHAVIOR

FDR	Range	AoD	FDR	Range	AoD
NS	VN	PL	PS	VN	NL
NS	N	PL	PS	N	NL
NS	M	PM	PS	M	NM
NS	F	PS	PS	F	NS
NM	VN	PM	PM	VN	NM
NM	N	PM	PM	N	NM
NM	M	PM	PM	M	NM
NM	F	PS	PM	F	NS
NL	VN	PM	PL	VN	NM
NL	N	PM	PL	N	NM
NL	M	PS	PL	M	NS
NL	F	PS	PL	F	NS

RCTIN-based type-2 FLS is tested on whole of input spaces that is discretized with step of 0.1 in which $FDR \in [-1, 1]$ and $Range \in [0.5, 2.5]$. Fig. 10 shows inference surface of avoidance behavior based on RCTIN Type-2 FLS. Results is summarized as follows:

TABLE IV
EXPERIMENTAL RESULTS OF AVOIDANCE BEHAVIOR

	Type-1 FLS	RCTIN Type-2 FLS
Number of discretized points	441	441
Run-time (in milliseconds) for all of discretized input space	92	524
Minimum AoD	-21.111	-20.54
25%-tile AoD	-4.405	-4.676
Median AoD	-3.889	0
75%-tile AoD	4.222	5.591
Maximum AoD	18.359	18.058
Mean AoD	-0.7178	-0.3172

VI. CONCLUSION

An approach to RCTIN-based representation of generalized type-2 fuzzy sets is presented with implementations of avoidance behavior. The basis for this approach is ε_u representation of type-2 membership grades. Geometric operations involving join under minimum, meet under minimum, negation, inference and defuzzification are developed base on this representation. Geometric computation of RCTIN-based general type-2 fuzzy logic system are implemented under avoidance behavior of robot navigation. Results in comparisons with previous approach show that the proposed approach considerably reduce computational complexity.

The next goal is to implement the general type-2 FLS in applications under other hardware such as FGPA or embedded systems. And other approach is to use RCTIN for intelligent systems such as ANFIS or TSK fuzzy logic systems.

On a Strengthening Connective for Flexible Database Querying

Patrick Bosc, *Member*, *IEEE*, and Olivier Pivert

***Abstract*—In most of query languages, conjunctive and disjunctive combinations of conditions remain the usual way for aggregation. Fuzzy query languages also offer trade-off operators, such as means in order to compensate between elementary conditions. In this paper, we investigate a new type of condition basically founded on the interaction between two predicates, thus enriching the panoply of tools the user is provided with and enhancing the power of query languages.**

***Index Terms*—Databases, fuzzy queries, fuzzy connectives.**

I. Introduction

Query languages based on fuzzy sets include a wide range of connectives, among which conjunction/disjunction and their weighted version, mean operators and quantified statements such as "most of $P_1, \ldots, P_n$" where P_i is a fuzzy condition. So doing, preferences are introduced at a double level: i) atomic fuzzy predicates which allow for stating that some values are preferred to others, and ii) connectors which permit to specify that some terms are more important than others or can be compensated by others.

Here, we would like to focus on an operator that has a counterpart in natural language, for which an interpretation is proposed in the context of information selection/retrieval in a database querying process. More precisely, it connects two predicates P_1 (or X *is* A) and P_2 (or Y *is* B) and it writes as follows: "P_1 *all the more as* P_2". A typical example of such a condition is: "find second hand cars that are all the cheaper as their mileage is high". The idea is to express a reinforcement of P_1 as P_2 is more and more satisfied. This obviously defines a new type of condition based on a sophisticated interaction between the two predicates involved, which are not interchangeable. One originality lies in the fact that the connector "all the more as" is by nature non commutative as are the connectors "and possibly" [1] or "then" [2] proposed earlier by other authors. Let us notice that "P_1 *all the more as* P_2" does not make sense in the Boolean context where there is no graduality in the satisfaction of a Boolean predicate, whereas this notion is at the heart of the interpretation of this type of new condition.

We consider an interpretation according to which "P_1 *all the more as* P_2" basically depends on P_1 and is not a matter of "joint" satisfaction of the predicates P_1 and P_2 as it is the case when an implication-based approach is taken. Indeed, if the gradual rule [3] "$P_2 \Rightarrow_{R-i} P_1$" is used ($\Rightarrow_{R-i}$ denoting an R-implication [4]), the truth value obtained may be high although P_1 is weakly satisfied (it suffices that the level of satisfaction of P_1 attains that of P_2 to get full satisfaction). We rather start with the idea that if the grade of satisfaction for P_1 is low, the grade of satisfaction of "P_1 *all the more as* P_2" must also be low. Our approach to interpreting the condition "P_1 *all the more as* P_2" consists in strengthening P_1 more and more as P_2 is more and more satisfied. We consider that "P_1 *all the more as* P_2" reduces to P_1 when P_2 is false and becomes "*very* P_1" when P_2 is true.

We situate our proposal as an enrichment of the SQLf query language [5]. As a consequence, the new condition is associated with a single truth value taken in the unit interval, which makes it possible to compose it with usual predicates (atomic or not).

The rest of the paper is structured as follows. Some basic notions about fuzzy predicates and queries are first recalled in Section 2. Then, different ways for strengthening a predicate are presented in Section 3. Section 4 is devoted to a detailed study of the new type of predicate "P_1 *all the more as* P_2". In Section 5, an inclusion operator derived from *all the more as* is suggested as well as its use in some advanced SQLf queries. The conclusion summarizes the contributions of the paper and draws some lines for future works.

II. Reminders on fuzzy predicates and queries

Regular sets allow for the definition of Boolean predicates. In an analogous way, gradual predicates (or conditions) can be associated with fuzzy sets [6] aimed at describing classes of objects with vague boundaries. Often, elementary fuzzy predicates correspond to adjectives of the natural language, such as *young*, *tall*, *cheap* or *well-paid*. A fuzzy predicate P can be modeled as a function μ_P (usually of triangular or trapezoidal shape) from one (or several) domain(s) X to the unit interval [0, 1]. The degree $\mu_P(x)$ represents the extent to which element x satisfies the vague predicate P (or equivalently the extent to which x belongs to the fuzzy set of objects which match the fuzzy concept P). An elementary fuzzy predicate can also compare two attributes using a gradual comparison operator such as *more or less equal*.

It is possible to alter the meaning of a given predicate using a modifier which is generally associated with an adverb (e.g., *very*, *more or less*, *relatively*). For instance, *very cheap* is more

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

restrictive than *cheap* and *fairly high* is less demanding than *high*. The meaning of the predicate *mod* P (where *mod* is a modifier) may be defined in a compositional way and different approaches have been advocated, among which: $\mu_{modP}(x) = (\mu_P(x))^n$ (see [7]]).

Atomic and modified predicates can be involved in compound predicates which go far beyond those used in regular queries. Conjunction (resp. disjunction) is interpreted by means of a triangular norm $\top$ (resp. co-norm $\perp$), for instance the minimum (resp. the maximum). As to negation, it is interpreted as: $\forall x, \mu_{\neg P}(x) = 1 - \mu_P(x)$. Weighted conjunction and disjunction as well as weighted means or OWA can be used to assign a different importance to each of the predicates (see [8], [4] for more details).

The operations from the relational algebra can be straightforwardly extended to fuzzy relations by considering fuzzy relations as fuzzy sets on the one hand and by introducing fuzzy predicates in the appropriate operations on the other hand. Indeed, a fuzzy relation is designed as a fuzzy subset of a Cartesian product of domains. Thus, any such fuzzy relation r can be seen as made of weighted tuples, denoted by μ/t, where μ expresses the extent to which tuple t belongs to the relation, i.e., is compatible with the concept conveyed by r. As an illustration, we give the definition of the fuzzy selection hereafter, where "cond" denotes a fuzzy predicate built according to what was said above:

$$\mu_{sel(r,cond)}(t) = \top(\mu_r(t), \mu_{cond}(t)).$$

The language called SQLf described in [5] extends SQL so as to support fuzzy queries and it serves as a background in the rest of the paper.

III. Strengthening Operators

A. Introduction

As mentioned previously, the basis for interpreting the condition "P_1 *all the more as* P_2" is to strengthen predicate P_1 depending on the satisfaction of predicate P_2. In particular, when P_2 is true (degree equal to 1), the final satisfaction will be that of *very* P_1. So, we will look at various ways to move from P to *very* P along with their compliance with the following three common sense properties:

S1: $\forall(x,\ y),\ \mu_P(x) \geq \mu_P(y) \Rightarrow \mu_{very\ P}(x) \geq \mu_{very\ P}(y)$,
S2: *core*(*very* P) $\subseteq$ *core*(P),
S3: $\forall x,\ ((\mu_P(x) \in]0,\ 1[\Rightarrow \mu_{veryP}(x) < \mu_P(x)) \wedge$
$(\mu_P(x) \in \{0,\ 1\} \Rightarrow \mu_{very\ P}(x) \leq \mu_P(x)))$.

In other words, property S1 states that the strengthening operator *very* does not change the ordering of elements, property S2 tells that *very* P is at least as demanding as P for the elements that are completely in agreement with predicate P, and property S3 imposes that for any element which somewhat (except fully) satisfies predicate P, predicate *very* P is strictly less satisfied (there is a true strengthening).

B. Different strengthening approaches

1) Use of a triangular norm: A well known way for reinforcing a predicate P is to define:

$$\mu_{very\ P}(x) = \mu_{\top^n(P)}(x)$$

where $\top$ stands for a non idempotent triangular norm. For instance, with the product and Łukasiewicz' norm, one gets respectively:

$$\mu_{very\ P}(x) = \mu_{P^n}(x) = (\mu_P(x))^n$$
$$\mu_{very\ P}(x) = \mu_{P^n}(x) = max(n \cdot \mu_P(x) - n + 1,\ 0).$$

In such a framework, the interpretation of the statement "X *is* A *all the more as* Y *is* B" applying to an element t, denoted by $atma(A,\ B)(t)$, will be such that:

$$atma(A,\ B)(t) = f_1(A,\ B,\ n,\ t) = \mu_{A^n}(t) \text{ if } \mu_B(t) = 1$$

with n a given powering coefficient.

The satisfaction of properties S1-S3 by this strengthening method is now examined:

S1: if $\mu_P(x) \geq \mu_P(y)$ then $\mu_{P^n}(x) \geq \mu_{P^n}(y)$ due to the monotonicity of norms with respect to both arguments, then $\mu_{very\ P}(x) \geq \mu_{very\ P}(y)$
S2: if $\mu_P(x) = 1$ then $\mu_{P^n}(x) = \top(1,\ \ldots,\ 1) = 1$ due to the fact that 1 is a neutral element of any norm, and we have $core(P) = core(very\ P)$,
S3: when $\mu_P(x) = 0, \mu_{\top^n(P)}(x) = \mu_P(x) = 0$; when $\mu_P(x) = 1, \mu_{\top^n(P)}(x) = \mu_P(x) = 1$; when $\mu_P(x) \in]0,\ 1[$, the strict inferiority of $\mu_{\top^n(P)}(x)$ with respect to $\mu_P(x)$ is not necessarily satisfied by a triangular norm $\top$, except if $\top$ is Archimedean; in such a case, by definition it is ensured that $\top(y,\ y) < y$ for any $y \in]0,\ 1[$ (see [4]). Then, we have: $\top(y,\ \ldots,\ y) = \top^n(y) < y$ and $\mu_{very\ P}(x) = \mu_{\top^n(P)}(x) < \mu_P(x)$ when $\mu_P \in]0, 1[$.

So, we can conclude that if an Archimedean norm ($\top$) is used (for instance the product), the strengthening mechanism defined as $\mu_{very\ P}(x) = \mu_{\top^n(P)}(x)$ complies with all three desired properties.

2) Translation: A second approach to reinforcing a predicate is to translate its membership function. If P is an increasing (resp. a decreasing) predicate, the translation is to the right (resp. left). In the more general case of a predicate P with a trapezoidal membership function, two translations take place, to the right for its increasing part and to the left for its decreasing part. For an increasing predicate P (situation considered later on), one has the following formula:

$$\mu_{very\ P}(x) = \mu_P(x - \tau)$$

where τ is a positive value (shift). Then, the interpretation of the statement "X *is* A *all the more as* Y *is* B" applying to an element t will be such that:

$$atma(A,\ B)(t) = f_2(A,\ B,\ \tau,\ t) = \mu_A(t - \tau) \text{ if } \mu_B(t) = 1$$

with τ a given magnitude of the translation.

Such a mechanism satisfies properties S1-S3 due to the monotonicity of P and the very nature of a translation.

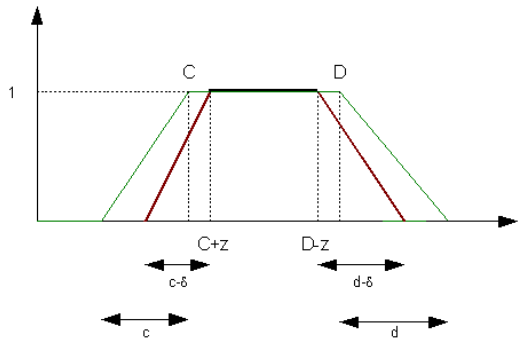

Fig. 1. Principle of the erosion operation

3) Erosion: The last strengthening technique considered here to build *very* P from P is called erosion [9] and it relies on the idea of a semantic proximity between the initial and the modified (reinforced) predicates. It makes use of a proximity relation E between two (numeric) values x and y which is reflexive and symmetric, and the quantity $\mu_E(x, y)$ can be viewed as a degree of approximate equality of x and y. This quantity can be defined as:

$$\mu_E(x,\ y) = \mu_Z(x - y)$$

which depends only on the difference between x and y. The parameter Z, called a tolerance indicator, is a fuzzy subset of the real line centered in 0 which has a trapezoidal membership function whose core is $[-z,\ z]$ and whose support is $[-z - \delta,\ z + \delta]$, denoted by $(-z,\ z,\ -\delta,\ \delta)$. So doing, the degree produced by $\mu_Z(x - y)$ evaluates the extent to which $(x - y)$ is close to 0 (according to Z). In other words, z is the maximal difference for which x and y are considered completely "approximately equal" and $z + \delta$ is the difference over which x and y are "not at all approximately equal". Using this proximity relation E parameterized by Z, a fuzzy set (or a predicate) P may be eroded into *very* P as follows:

$$\mu_{very P}(x) = \mu_{P \ominus Z}(x)$$

where $\ominus$ denotes Minkowski's difference defined as [10]:

$$\mu_{F \ominus Z}(r) = inf_s(\mu_Z(r - s) \rightarrow_{Gd} \mu_F(s)),$$

where $\rightarrow_{Gd}$ is the so-called Gödel implication ($p \rightarrow_{Gd} q) = 1$ if $p \leq q$, q otherwise). Then, the interpretation of the statement "X is A all the more as Y is B" applying to an element t will be such that:

$$atma(A,\ B)(t) = f_3(A,\ B,\ Z,\ t) = \mu_{A \ominus Z}(t) \text{ if } \mu_B(t) = 1$$

with Z a given tolerance indicator for the erosion.

Fig. (1) illustrates the behavior of the erosion operator acting on a fuzzy predicate P whose trapezoidal membership function is $(C,\ D,\ c,\ d)$. Of course, one must have $z \leq \frac{D-C}{2}$, $\delta \leq c$ and $\delta \leq d$. If z (resp. δ) equals 0, the core (resp. support) of the initial predicate remains unchanged. Such a strengthening operator satisfies Properties S1-S3 due to the nature of the erosion operator which corresponds to a difference in terms of membership functions (cf. Fig. (1)). Let us notice that erosion may modify the core and/or the support of the initial predicate, while translation does reduce both and the composition using any triangular norm leads to a reinforced predicate (*very P*) with the same core and support as the initial one (*P*).

IV. The connector "all the more as"

A. Axioms for this connector

We now review a bunch of axioms that can serve as a reasonable basis for defining the predicate "X *is* A *all the more as* Y *is* B". The following properties will act as a mandatory requirement for any definition of the connector "all the more as":

A1: decreasing monotonicity in the second argument, i.e.:

$$\mu_B(t.Y) > \mu_B(t'.Y) \wedge \mu_A(t.X) = \mu_A(t'.X) \Rightarrow atma(A,\ B)(t) \leq atma(A,\ B)(t'),$$

A2: increasing monotonicity in the first argument, i.e.:

$$\mu_A(t.X) > \mu_A(t.X) \wedge \mu_B(t.Y) = \mu_B(t'.Y) \Rightarrow atma(A,\ B)(t) \geq atma(A,\ B)(t'),$$

A3: when X is not at all A, "Y *is* B" has no effect, i.e.:

$$\mu_A(t.X) = 0 \Rightarrow \forall \mu_B(t.Y),\ atma(A,\ B)(t) = 0,$$

A4: when Y is not at all B, the value of "X *is* A *all the more as* Y *is* B" is that of "X *is* A", i.e.:

$$\mu_B(t.Y) = 0 \Rightarrow \forall \mu_A(t.X),\ atma(A,\ B)(t) = \mu_A(t.X),$$

A5: when "Y *is* B" is somewhat satisfied, the value of the statement "X *is* A *all the more as* Y *is* B" must result in an effective strengthening of "X *is* A" (except for the extreme truth values 0 and 1), i.e.:

$$(\mu_A(t.X) \in]0, 1[\ \wedge\ \mu_B(t.Y) > 0) \Rightarrow atma(A,\ B)(t) < \mu_A(t.X).$$

B. A plausible definition

As mentioned before, the interpretation of the statement "X *is* A *all the more as* Y *is* B" will have two extreme points: $\mu_A(t.X)$ when $\mu_B(t.X)$ is false and $\mu_{very A}(t.X)$ when $\mu_B(t.X)$ is completely satisfied. We suggest a linear transition between these two states, which has the advantage of being general for the three families of strengthening operators evoked before. This choice leads to the following definition of the connector "all the more as":

$$atma(A,\ B)(t) = (\mu_{very\ A}(t.X) - \mu_A(t.X)) \cdot \mu_B(t.Y) + \mu_A(t.X). \quad (1)$$

Let us remark that, in the particular case of the use of the norm product (strengthening of type 1), it could also be possible to have the following definition:

$$atma(A,\ B)(t) = (\mu_A(t.X))^{((n-1)\cdot\mu_B(t.Y)+1)} = (\mu_A(t.X))^{\mu_B(t.Y)+1} \text{ for } n = 2.$$

Example 1. Let us consider the relation *secondhandcars*(#*c*, *brand*, *name*, *year*, *price*, *mileage*, *horsepower*) with the tuples:

$t_1 = \langle$13, Ford, Focus, 2005, 6000, 40000, 75$\rangle$,
$t_2 = \langle$264, Renault, Clio, 2002, 4000, 130000, 75$\rangle$,
$t_3 = \langle$59, Toyota, Prius, 2006, 15000, 90000, 115$\rangle$,
$t_4 = \langle$508, Peugeot, 307, 2004, 5500, 100000, 110$\rangle$,
$t_5 = \langle$4, Ford, Mondeo, 2005, 6000, 125000, 110$\rangle$,
$t_6 = \langle$78, Renault, Megane, 2006, 7000, 110000, 110$\rangle$,
$t_7 = \langle$112, Nissan, Primera, 2008, 16000, 30000, 130$\rangle$

and the query looking for cars whose horsepower is less than 120 and whose price is all the cheaper as their mileage is high. The predicates "cheap" and "high" are assumed to be defined as follows:

$$\mu_{cheap}(p) = \begin{cases} 1 \text{ if } p \leq 5,000, \\ 0 \text{ if } p \geq 7,500, \\ \text{linear in-between,} \end{cases}$$

$$\mu_{high}(m) = \begin{cases} 0 \text{ if } m \leq 80,000, \\ 1 \text{ if } m \geq 120,000, \\ \text{linear in-between.} \end{cases}$$

Clearly, the seventh car does not qualify for the query since its horsepower exceeds the limit imposed by the user. With the first type of strengthening, the grades obtained by the first six cars are:

0.6/t_1, 1/t_2, 0/t_3, 0.72/t_4, 0.36/t_5, 0.08/t_6 with the product and n = 2,
0.6/t_1, 1/t_2, 0/t_3, 0.7/t_4, 0.2/t_5, 0.05/t_6 with Łukasiewicz' norm and n = 2,
0.6/t_1, 1/t_2, 0/t_3, 0.656/t_4, 0.216/t_5, 0.056/t_6 with the product and n = 3,
0.6/t_1, 1/t_2, 0/t_3, 0.6/t_4, 0/t_5, 0.05/t_6 with Łukasiewicz' norm and n = 3.

If a translation (to the left since the predicate is decreasing) is used to define *very cheap*, the grades are:

0.6/t_1, 1/t_2, 0/t_3, 0.6/t_4, 0.2/t_5, 0.05/t_6 with τ = 100,
0.6/t_1, 0.6/t_2, 0/t_3, 0.4/t_4, 0/t_5, 0.05/t_6 with τ = 200.

Last, with an erosion to reinforce *cheap*, the grades obtained are:

0.6/t_1, 1/t_2, 0/t_3, 0.73/t_4, 0.33/t_5, 0.05/t_6 with Z = (0, 0, 0, 100),
3 0.6/t_1, 1/t_2, 0/t_3, 0.68/t_4, 0.42/t_5, 0.05/t_6 with Z = (0, 100, 0, 0).

As can be seen, the results may significantly depend on the type of strengtening used as well as of the parameters chosen for a given type. $\diamond$

C. Compliance with the axioms

In this subsection, we show that, if the strengthening mechanism used to reinforce "X is A" complies with Properties S1-S3 (see Section III) in expression (1), Axioms A1-A5 are satisfied.

A1: Let us take two tuples t and t' such that: i) $\mu_A(t.X) = \mu_A(t'.X)$ and ii) $\mu_B(t.Y) > \mu_B(t'.Y)$. We have:

$$\begin{aligned} &atma(A,\ B)(t) - atma(A,\ B)(t') \\ &= (\mu_{very\ A}(t.X) - \mu_A(t.X)) \cdot \mu_B(t.Y) + \mu_A(t.X) - \\ &\quad (\mu_{very\ A}(t'.X) - \mu_A(t'.X)) \cdot \mu_B(t'.Y) - \mu_A(t'.X) \\ &= (\mu_{very\ A}(t.X) - \mu_A(t.X)) \cdot (\mu_B(t.Y) - \mu_B(t'.Y)). \end{aligned}$$

The first term is negative or equal to 0 due to the validity of Property S3 and the second one is positive according to the hypotheses stated above. So, we have:

$atma(A,\ B)(t) - atma(A,\ B)(t') \leq 0$, i.e.:
$atma(A,\ B)(t) \leq atma(A,\ B)(t')$

and Property A1 holds.

A2: Let us take two tuples t and t' such that: i) $\mu_A(t.X) > \mu_A(t'.X)$ and ii) $\mu_B(t.Y) = \mu_B(t'.Y)$. We have:

$$\begin{aligned} &atma(A,\ B)(t) - atma(A,\ B)(t') \\ &= (\mu_{very\ A}(t.X) - \mu_A(t.X)) \cdot \mu_B(t.Y) + \mu_A(t.X) - \\ &\quad (\mu_{very\ A}(t'.X) - \mu_A(t'.X)) \cdot \mu_B(t'.Y) - \mu_A(t'.X) \\ &= (\mu_{very\ A}(t.X) - \mu_{very\ A}(t'.X)) \cdot \mu_B(t.Y) + \\ &\quad (\mu_A(t.X) - \mu_A(t'.X)) \cdot (1 - \mu_B(t.Y)). \end{aligned}$$

From Axiom S1, we have:

$$\begin{aligned} \mu_A(t.X) > &\mu_A(t'.X)) \Rightarrow \\ &\mu_{very\ A}(t.X) \geq \mu_{veryA}(t'.X) \end{aligned}$$

and the first term of the sum is positive or equal to 0. The first term of the product is positive according to the hypotheses made above and the second term is positive or equal to 0. It follows that the previous expression yields a result that is positive or equal to 0, so:

$atma(A,\ B)(t) - atma(A, B)(t') \geq 0$, i.e.:
$atma(A,\ B)(t) \geq atma(A, B)(t')$

and Property A2 holds.

A3: Let us consider a tuple t such that $\mu_A(t.X) = 0$. Due to the validity of S3, one has $\mu_{very\ A}(t.X) = 0$. Then:

$$\begin{aligned} &atma(A,\ B)(t) = \\ &\quad (\mu_{very\ A}(t.X) - \mu_A(t.X)) \cdot \mu_B(t.Y) + \mu_A(t) = 0. \end{aligned}$$

A4: Let us now take a tuple t such that $\mu_B(t.Y) = 0$. We have:

$$\begin{aligned} &atma(A,\ B)(t) \\ &\quad = (\mu_{very\ A}(t.X) - \mu_A(t.X)) \cdot \mu_B(t.Y) + \mu_A(t) \\ &\quad = \mu_A(t). \end{aligned}$$

A5: Let us consider a tuple t such that: i) $\mu_A(t.X) \in]0, 1[$ and ii) $\mu_B(t.Y) > 0$. We have:

$$\begin{aligned} &atma(A,\ B)(t) = \\ &\quad (\mu_{very\ A}(t.X) - \mu_A(t.X)) \cdot \mu_B(t.Y) + \mu_A(t) \end{aligned}$$

where $(\mu_{very\ A}(t.X) - \mu_A(t.X))$ is strictly negative, then $(\mu_{very\ A}(t.X) - \mu_A(t.X)) \cdot \mu_B(t.Y)$ as well. Consequently $atma(A, B)(t) < \mu_A(t.X)$ and Axiom A5 holds.

Finally, it turns out that the strengthening approaches previously proposed (composition with an Archimedean norm, translation, erosion) are convenient for the interpretation of the statement "*X is A all the more as Y is B*". When applied to a tuple t of a relation r, the preceding predicate is defined as follows:

- with an Archimedean norm $\top$:
$$atma(A,\ B)(t) = f_1(A,\ B,\ n,\ t)$$
$$= (\mu_{\top^n(A)}(t.X) - \mu_A(t.X)) \cdot \mu_B(t.Y) + \mu_A(t.X),$$
- with a translation of magnitude $\tau > 0$ to the right applying to an increasing initial predicate A:
$$atma(A,\ B)(t) = f_2(A,\ B,\ \tau,\ t)$$
$$= (\mu_A(t.X - \tau) - \mu_A(t.X)) \cdot \mu_B(t.Y) + \mu_A(t.X),$$
- with the erosion operator associated with indicator $Z = (-z,\ z,\ -\delta,\ \delta)$:
$$atma(A,\ B)(t) = f_3(A,\ B,\ Z,\ t)$$
$$= (\mu_{A \ominus Z}(t.X) - \mu_A(t.X)) \cdot \mu_B(t.Y) + \mu_A(t.X).$$

D. The connector "all the less as"

By analogy with the operator "all the more as", one may think of a predicate "*X is A all the less as Y is B*". In such a case, one will not reinforce but weaken condition A (from "A" to "more or less A"). The interpretation is based on the fact that one is all the less demanding on the fact that X is A as the condition "*Y is B*" is more and more satisfied, similarly to the interpretation of "*X is A all the more as Y is B*" where one is all the more demanding on the fact that X is A as the condition "*Y is B*" is more and more satisfied. The generic formulation of the degree of satisfaction of the condition "*X is A all the less as Y is B*" is then given by:

$$atla(A,\ B)(t) =$$
$$(\mu_{more\ or\ less A}(t.X) - \mu_A(t.X)) \cdot \mu_B(t.Y) + \mu_A(t.X).$$

By analogy with the strengthening case, this expression will have three instantiations, namely:

- with an Archimedean co-norm $\perp$:
$$atla(A,\ B)(t) = f'_1(A,\ B,\ n,\ t)$$
$$= (\mu_{\perp^n(A)}(t.X) - \mu_A(t.X)) \cdot \mu_B(t.Y) + \mu_A(t.X),$$
- with a translation of magnitude $\tau > 0$ to the left applying to an increasing initial predicate A:
$$atla(A,\ B)(t) = f'_2(A,\ B,\ \tau,\ t)$$
$$= (\mu_A(t.X + \tau) - \mu_A(t.X)) \cdot \mu_B(t.Y) + \mu_A(t.X),$$
- with the dilation operator associated with indicator $Z = (-z,\ z,\ -\delta,\ \delta)$:
$$atla(A,\ B)(t) = f'_3(A,\ B,\ Z,\ t)$$
$$= (\mu_{A \oplus Z}(t.X) - \mu_A(t.X)) \cdot \mu_B(t.Y) + \mu_A(t.X),$$
where $\oplus$ denotes the addition of fuzzy numbers.

Example 2. Let us consider the relation *secondhandcars* introduced in Example 1 with the following extension:

$t_8 = \langle 19,$ Ford, Focus, 2005, 6000, 80000, $75\rangle$,
$t_9 = \langle 21,$ Renault, Clio, 2002, 6000, 60000, $75\rangle$,
$t_{10} = \langle 132,$ Citroen, C1, 2006, 4000, 50000, $60\rangle$,
$t_{11} = \langle 75,$ Peugeot, 307, 2004, 7500, 50000, $90\rangle$,
$t_{12} = \langle 57,$ Opel, Astra, 2008, 10000, 55000, $115\rangle$

and the query looking for cars whose horsepower is more than 55 and whose price is all the less cheap as their mileage is low. The predicate *cheap* is defined as in Example 1, and *low* as follows:

$$\mu_{low}(m) = \begin{cases} 1 \text{ if } m \leq 50,000, \\ 1 \text{ if } m \geq 70,000, \\ \text{linear in-between.} \end{cases}$$

If we assume that the weakening is done using a translation (to the right in this case) whose magnitude is $\tau = 100$, we have to compute for each tuple t:

$$(\mu_{more\ or\ less\ cheap}(t.price - \tau) -$$
$$\mu_{cheap}(t.price)) \cdot \mu_{low}(t.mileage) + \mu_{cheap}(t.price)$$

which leads to:

0.6/t_8 since $\mu_{low}(80000) = 0, \mu_{cheap}(6000) = 0.6,$
$\mu_{more\ or\ less\ cheap}(6000) = 1,$
0.8/t_9 since $\mu_{low}(60000) = 0.5, \mu_{cheap}(6000) = 0.6,$
$\mu_{more\ or\ less\ cheap}(6000) = 1,$
1/t_{10} since $\mu_{low}(50000) = 1, \mu_{cheap}(4000) = 1,$
$\mu_{more\ or\ less\ cheap}(4000) = 1,$
0.4/t_{11} since $\mu_{low}(50000) = 1, \mu_{cheap}(7500) = 0,$
$\mu_{more\ or\ less\ cheap}(7500) = 0.4,$
0/t_{12} since $\mu_{low}(55000) = 0.75, \mu_{cheap}(10000) = 0,$
$\mu_{more\ or\ less\ cheap}(10000) = 0.$

By the way, it is worth noticing that the approach chosen for the interpretation of "price *is* cheap *all the less as* mileage *is* low" is not equivalent to "price *is all the cheaper as* mileage *is not* low", which is not quite surprizing. For tuple t_9, this second interpretation would lead to the grade 0.4 ($(0.2 - 0.6) * 0.5 + 0.6$) instead of 0.8.$\diamond$

V. A derived implication and its application to database querying

A. Deriving an implication from "all the more as"

Let us come back to the expression of the predicate "*X is A all the more as Y is B*" and the reinforcement of predicate A using an Archimedean norm $\top$:

$$atma(A,\ B)(t) = f_1(A,\ B,\ n,\ t)$$
$$= (\mu_{\top^n(A)}(t.X) - \mu_A(t.X)) \cdot \mu_B(t.Y) + \mu_A(t.X).$$

One may observe that this formula rewrites:

$$(\top^n(q) - q) \cdot p + q$$

letting $p = \mu_B(t.Y), q = \mu_A(t.X)$. This latter formula may be calculated for any two quantities p and q of the unit interval.

Let us now define:

$$I_{(\top,\, n)}(p,\, q) = \begin{cases} 1 \text{ if } p = 0, \\ (\top^n(q) - q) \cdot p + q \text{ otherwise,} \end{cases}$$

where $\top$ denotes a non idempotent norm. Operator $I_{(\top,\, n)}$ complies with the following four properties:

- $\forall q,\, p_1 < p_2 \Rightarrow I_{(\top,\, n)}(p_1,\, q) \geq I_{(\top,\, n)}(p_2,\, q)$ since the term $(\top^n(q) - q)$ is negative,
- $\forall p,\, q_1 < q_2 \Rightarrow I_{(\top,\, n)}(p,\, q_1) \leq I_{(\top,\, n)}(p,\, q_2)$ since $I_{(\top,\, n)}(p,\, q_2) - I_{(\top,\, n)}(p,\, q_1) = (q_2 - q_1) \cdot (1 - p)) + (\top^n(q_2) - \top^n(q_1)) \cdot p$, where $(q_2 - q_1) > 0$ and $(\top^n(q_2) - \top^n(q_1)) \geq 0$ from Axiom S1,
- $\forall q,\, I_{(\top,\, n)}(0,\, q) = 1$ — by definition
- $\forall p,\, I_{(\top,\, n)}(p,\, 1) = 1$ since $I_{(\top,\, n)}(p,\, 1) = (\top^n(1) - 1) \cdot p + 1 = 1$.

So, this operator satisfies four of the most cited (see e.g., [4]) properties of fuzzy implications. The fact that $(1 \Rightarrow_f q = q)$ does not hold, but instead $(1 \Rightarrow_f q = \top^n(q))$ (for instance q^n with the product), may be considered acceptable in view of a "reinforcement-based implication", which could be seen as a new type of fuzzy implication, in addition to R-implications and S-implications in particular (see [3]).

B. Application to inclusion queries

We now tackle queries calling on an inclusion. For instance, consider the fuzzy relation *Profile* whose schema is (*emp, skill*) describing the skills possessed by the employees of a company along with a given level (between 0 and 1). The query looking for the employees whose set of skills is included in that associated with John writes:

select *emp* **from** *Profile* **where** emp $\neq$ "John"
group by *emp* **having set**(*skill*) **included-in**
(**select** *skill* **from** *Profile* **where** *emp* = "John")

in an SQL-like language (e.g., SQLf) equipped with a gradual operator (*included-in*) aimed at assessing the extent to which a fuzzy set is included in another. Usually, the interpretation of the inclusion operator is founded on an implication:

$$E \subseteq F \Leftrightarrow \forall x \in X,\, x \in E \Rightarrow x \in F$$

which, for the query above, should be extended with a fuzzy implication (denoted by $\rightarrow_f$) as:

$$deg(E \subseteq F) = min_{x \in X}\, \mu_E(x) \rightarrow_f \mu_F(x).$$

Different semantics of the inclusion are obtained depending on the family of fuzzy implication taken. An R-implication naturally extends the usual implication in the sense that if E is included in F according to Zadeh ($\forall x \in X,\, \mu_E(x) \leq \mu_F(x)$) the maximal degree (1) is returned, while an S-implication leads to a more demanding type of inclusion where full satisfaction is reached when the support of E is included in the core of F. Of course, the use of $I_{(\top,\, n)}$ gives birth to a third kind of semantics, more demanding than S-implications, for which 1 is obtained only when q = 1. Here, an element x of X must be in F all the more as it is in E according to the behavior of the connective *all the more as* at the heart of implication $I_{(\top,\, n)}$.

Example 3. With the following extension of relation *Profile*:

1/⟨John, A⟩, 0.7/⟨John, B⟩, 0.3/⟨John, C⟩,
0.6/⟨Peter, A⟩, 1/⟨Peter, B⟩, 0.1/⟨Peter, D⟩,
0.1/⟨Mary, A⟩, 0.2/⟨Mary, B⟩, 0.4/⟨Mary, C⟩,
0.9/⟨Jebediah, A⟩, 1/⟨Jebediah, C⟩

the results of the previous query are:

- with Gödel implication ($p \rightarrow_{Gd} q = 1$ if $p \leq q$, q otherwise): {0.3/Mary, 0.3/Jebediah}
- with Kleene-Dienes implication ($p \rightarrow_{KD} q = max(1 - p,\, q)$): {0.7/Peter, 0.6/Mary, 0.3/Jebediah} ,
- with $I_{(\top,\, n)}$ using $\top(x,\, y) = x.y$ and $n = 2$: {0.216/Mary, 0.09/Jebediah}. ⋄

VI. Conclusion

In this paper, we have proposed a new connective that gives birth to a new semantics for the aggregation of two predicates. The new predicate obtained writes "*X is A all the more as Y is B*" and the idea is to use a predicate B to reinforce predicate A into *very* A. The strengthening operates in a linear way, i.e., A applies when B is false and when B is true the result is μ_{veryA}. Strengthening A using a composition via an Archimedean norm, a translation or an erosion operation turns out to be appropriate to guarantee that reasonable properties hold for the new predicate "*X is A all the more as Y is B*". Such a predicate can be used in selection operations, but it may also serve as a basis for defining an implication operator. So, we are provided with a means to define a new type of inclusion conveying the notion of reinforcement. This work opens several perspectives, especially that of implementing the new selection and inclusion operator in the SQLf language.

***Abstract*—This paper studies the behavior of a multiobjective Genetic Algorithm for jointly performing a feature selection and granularity learning for Fuzzy Rule-Based Classification Systems in the scenario of imbalanced data-sets. We refer to imbalanced data-sets when the class distribution is not uniform, a situation that it is present in many real application areas.**

We consider two different measures, one for the precision of the model and other for its complexity as the two objectives to optimize. In one previous approach, we aggregate these two measures in a single-objective Genetic Algorithm, and thus, a multiobjective approach of that Genetic Algorithm would yield a set of models with different trade-off between high accuracy and low complexity rather than a unique model, provided by the single-objective Genetic Algorithm. The experimental analysis, carried out over a wide range of imbalanced data-sets, shows that our approach is able to obtain a set of models with good trade-off between the two objectives considered but it is an open problem how to select the solution with best prediction ability from the whole set of solutions obtained.

***Index Terms*—Fuzzy Rule-Based Classification Systems, imbalanced data-sets, Multiobjective Genetic Algorithms, feature selection, granularity level.**

I. Introduction

Fuzzy Rule Based Classification Systems (FRBCSs) are considered a very useful tool in the framework of computational intelligence, since they provide a very interpretable model for the end user [1]. An FRBCS presents two main components: the Inference System and the Knowledge Base (KB). The KB is composed of the Rule Base (RB) constituted by the collection of fuzzy rules, and of the Data Base (DB), containing the membership functions of the fuzzy partitions associated to the linguistic variables. The composition of the KB of an FRBCS directly depends on the problem being solved. If there is no expert information about the problem under solving, an automatic learning process must be used to derive the KB from examples.

The problem of imbalanced data-sets [2] for binary classification occurs when the number of instances for each class are very different between them, which can lead to a good classification of the majority class and a poor accuracy on the minority examples. Furthermore, the less representative class is usually the one which has more interest from the point of view of the learning task [3]. We must stress the importance of imbalanced data-sets, since such type of data appears in most of the real domains of classification such as medical diagnosis, finances, bioinformatics, image recognition and so on. The good behavior of FRBCS when dealing with imbalanced data-sets has been recently analyzed in [4].

Unfortunately, the use of FRBCSs in problems that presents a high number of features can originate RBs with a large number of rules, thus presenting a low degree of interpretability and a possible overfitting (the error over the training data-set is very low but the FRBCS present a significative decrease on the prediction ability). This problem can be addressed from a feature selection process that reduces the number of features used by the FRBCS.

On the other hand, the number of labels per linguistic variable (granularity) is an information that has not been considered to be relevant for the majority of FRBCS learning methods. The usual way to proceed involves choosing a number of linguistic terms for each linguistic variable, which is normally the same for all of them (the most used values are the odd numbers between 3 and 7). This operation mode to choose the granularity level is not always appropriate since it has a significant influence on the FRBCS performance. The fuzzy partition granularity of a linguistic variable can be viewed as a sort of context information with a major influence in the FRBCS behavior. Considering a specific label set for a variable, some labels can result irrelevant, that is, they can contribute nothing and even can cause confusion. In other cases, it would be necessary to add new labels to appropriately differentiate the values of the variable. The high influence of granularity in fuzzy modeling has analyzed in [5] and some approaches for automatic learning of the KB in fuzzy modeling and fuzzy classification include the granularity learning [6], [7]. In a previous work [8], we analyze the influence of granularity learning in the performance of FRBCSs for imbalanced data-sets, and the results obtained show that a significant improvement in the classification ability is possible just by learning an adequate number of labels per variable although the complexity of the model was lightly increased.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

In [9], we proposed a Genetic Algorithm (GA) for jointly perform a feature selection and a granularity learning, considering a classical FRBCS learning method to derive the RB, the Chi et al.'s approach [10]. The main objective of that method was to obtain FRBCS for imbalanced data-sets with high prediction ability joint with a significative reduction of the model complexity in order to increase the FRBCS interpretability. To achieve that purpose, we considered two measures, one for the model accuracy and the other for the model complexity. We aggregated this two measures as the final fitness value of a standard generational GA (single objective). Therefore, the obtained models will have priority on high accuracy or low complexity depending on the relative weights of each measure in the final fitness function. As we were interested in the model with best prediction ability (highest value for the accuracy measure over the test data set), we tested various possibilities for these weighting factors, but the more adequate values are strongly dependent on the data-set considered. The results of that proposal were very promising but there were two drawbacks:

- Selecting the weighting factors. We proposed concrete values that obtained the best average in prediction ability of all the executions tested, but each data-set has its own optimal values.
- The GA provide only one solution. In some cases, designers are more interested in FRBCS with very low complexity rather than the highest prediction ability and it is necessary several executions of the GA with different weighting factors for obtaining the FRBCS desired.

It seems logical that these drawbacks can be avoided considering the two values of the fitness function as separate objectives in a Multiobjective Genetic Algorithm (MGA), that generate a set of FRBCSs with different trade-off between models with high accuracy (and normally, high complexity) and models with low complexity (and normally, low accuracy). The advantages of this approach are the elimination of parameters (weighting factors) and the extended set of different solutions obtained in one simple run.

In this paper we study the behavior of a multiobjective version of the GA presented in [9], using the well known Non dominated Sorting Genetic Algorithm (NSGA-II) [11]. In the analysis of results we will study the set of solutions obtained, with special regard to the relationship between the accuracy measure for the training data set and the accuracy measure for the test data set, in order to analyze the possible overfitting. This study can help us to deal with a new problem that appears with this multiobjective approach, the difficulty of determining the prediction ability (accuracy measure for the test data set) from the whole set of solutions obtained, as we will comment in the comparison of this approach with other methods that provide only one solution. There are some recent proposals that use a multiobjective GA for designing Fuzzy systems in classification and regression [12], [13], [14], [15], but these approaches only analyzes the prediction ability in one or a few solutions of the whole set of solutions provided.

We have selected a large collection of imbalanced data-sets from KEEL data-set repository[1] [16] for developing our experimental analysis. In order to deal with the problem of imbalanced data-sets we will make use of a preprocessing technique, the "Synthetic Minority Over-sampling Technique" (SMOTE) [17], to balance the distribution of training examples in both classes.

This paper is organized as follows. First, Section II and Section III introduce, respectively, the preliminary concepts of FRBCSs and imbalanced data-sets used in this paper. Next, in Section IV we will expose our proposal, a MGA for feature selection and granularity learning. Section V describes the experimental study and finally, in Section VI, some conclusions will be pointed out.

II. Fuzzy Rule Based Classification Systems

Any classification problem consists of m training patterns $x_p = (x_{p1}, \ldots, x_{pn})$, $p = 1, 2, \ldots, m$ from M classes where x_{pi} is the ith attribute value ($i = 1, 2, \ldots, n$) of the p-th training pattern.

In this work we use fuzzy rules of the following form for our FRBCSs:

$$\text{Rule } R_j: \text{ If } x_1 \text{ is } A_{j1} \text{ and } \ldots \text{ and } x_n \text{ is } A_{jn} \text{ then Class = } C_j \text{ with } RW_j \quad (1)$$

where R_j is the label of the jth rule, $x = (x_1, \ldots, x_n)$ is an n-dimensional pattern vector, A_{ji} is an antecedent fuzzy set, C_j is a class label, and RW_j is the rule weight [18]. We use triangular MFs as antecedent fuzzy sets.

In order to build the RB, we have chosen a classical and simple FRBCS, following the same scheme as our previous works [4], [19], [8], [9]: the Chi *et al.*'s rule generation method [10]. This FRBCS design method is an extension of the well-known Wang and Mendel method [20] to classification problems.

III. Basic concepts on imbalanced data-sets

Learning from imbalanced data is an important topic that has recently appeared in the Machine Learning community [2]. We refer to imbalanced data when the class distribution is not uniform. In this situation, the number of examples that represents one of the classes of the data-set (usually the concept of interest) is much lower than that of the other classes.

Standard classifier algorithms have a bias towards the majority class, since the rules that predicts the higher number of examples are positively weighted during the learning process in favor of the accuracy metric. Consequently, the instances that belongs to the minority class are misclassified more often than those belonging to the majority class [21].

We will use the imbalance ratio (IR) [22] as a threshold to categorize the different imbalanced scenarios, which is defined as the ratio of the number of instances of the majority class and the minority class. We consider that a data-set presents a high degree of imbalance when its IR is higher than 9 (less than 10% of positive instances).

[1] http://www.keel.es/dataset.php

In a previous work on this topic [4], we analysed the cooperation of some preprocessing methods with FRBCSs, showing a good behavior for the oversampling methods, specially in the case of the SMOTE methodology [17]. We will employ in this contribution the same SMOTE algorithm in order to deal with imbalanced data-sets. In short, its main idea is to form new minority class examples by interpolating between several minority class examples that lie together. Thus, the overfitting problem is avoided and causes the decision boundaries for the minority class to spread further into the majority class space.

Most of proposals for automatic learning of classifiers use some kind of accuracy measure like the classification percentage over the example set. However, these measures can lead to erroneous conclusions working with imbalanced data-sets since it doesn't take into account the proportion of examples for each class. So, in this work we use the Area Under the Curve (AUC) metric [23], which can be defined as

$$AUC = \frac{1 + TP_{rate} - FP_{rate}}{2} \tag{2}$$

where TP_{rate} is the percentage of positive cases correctly classified as belonging to the positive class and FP_{rate} is the percentage of negative cases misclassified as belonging to the positive class.

IV. Multiobjective Genetic Algorithm for Feature Selection and Granularity Learning

The proposed method is a multiobjective approach of a genetic process for the DB learning that allows us to select a set of variables (feature selection) and learn an adequate number of labels for each selected variable (granularity learning), that was proposed in [9]. The possible values considered for the granularity are taken from the set $\{2, \ldots, 7\}$. Once the granularity for each selected feature is determined, the DB is built. Uniform partitions with triangular membership functions are considered due to its simplicity. Next, we use a quick method that derives the fuzzy classification rules and then the whole KB is obtained. We must recall from a previous section that the RB learning algorithm used in this work is the method proposed in [10], that we have called the Chi et al.'s rule generation method.

We denote our proposal as MGA-FS-GL (Multiobjective GA for Feature Selection and Granularity Learning). The main purpose of MGA-FS-GL is to obtain a set of FRBCSs with different trade-off between good accuracy and reduced complexity taking the feature selection and granularity learning as a base. We have used the well known Non dominated Sorting Genetic Algorithm (NSGA-II [11]) as MGA scheme. Next, we describe the main components of MGA-FS-GL.

A. Encoding the DB

For a classification problem with *N* variables, each chromosome will be composed of two parts to encode the relevant variables and the number of linguistic terms for variable (i.e. the granularity):

- Relevant variables (C_V): the selected features are stored in a binary coded array of length N. In this array, an 1 indicates that the correspondent variable is selected for the FRBCS.
- Granularity level (C_G): the number of labels per variable is stored in an integer array of length *N*. The possible values are taken from the set $\{2, \ldots, 7\}$.

If v_i is the bit that represents whether the variable i is selected and g_i is the granularity of variable i, a representation of the chromosome is shown next:

$$C_V = (v_1, v_2, \ldots, v_N) \quad C_G = (g_1, g_2, \ldots, g_N) \quad C = C_V C_G$$

It would be possible to merge both parts considering only an integer array, for example, including the value 1 as a placeholder for not using the variable. We use the two parts coding scheme to assign the same importance to both parts and to make easy the possibility of removing features as the mutation on the first part of the chromosome changes a selected variable for a non selected variable.

B. Initial Gene Pool

The initial population is composed of six groups with a different number of selected variables. Let g be the cardinality of the significant term set for the C_V part, in our case $g = 6$, corresponding to the six possibilities for the number of labels $(2 \ldots 7)$. The generation of the initial population is described below:

- In the first group all the chromosomes have all the features selected that is, $C_V = (1, 1, 1, \ldots, 1)$. It is composed of $g+10$ chromosomes. The first g individuals have the same granularity in all its variables. For each granularity level, one individual is created. In the second 10 chromosomes the granularity level is randomly selected.
- The next four groups have the same structure than the first group but each one of them with a different percentage of randomly selected variables (75%, 50%, 25% and 10%). So, each group has $g+10$ chromosomes (16 in our case).
- The last group is composed for the remaining chromosomes, and all of their components are randomly selected.

The minimum number of individuals is the sum of the chromosomes of the five first groups: $(g + 10) \times 5$ (80 for our proposal). We try to cover a wide zone of the search space with this population.

C. Evaluating the chromosome

There are three steps that must be done to evaluate each chromosome:

- Generate the DB using the information contained in the chromosome. For all the selected variables ($v_i = 1$), a uniform fuzzy partition with triangular membership functions is built considering the number of labels of that variable (g_i).
- Generate the RB by running the the Chi et al.'s method.
- Calculate the two measure values of the resultant FRBCS:
  - Accuracy measure: AUC metric over the training data-set (AUC_{Tr}).
  - Complexity measure: the sum of the granularity levels of all the selected variables (denoted by Ng

in the following). By using this values as complexity measure, as an example, the following situations are considered equivalent:

- Selection of 6 features of granularity 2
- Selection of 4 features of granularity 3
- Selection of 3 features of granularity 4
- Selection of 2 features of granularity 6

Finally, MGA-FS-GL considers two objectives to be minimized:

- $1 - AUC_{Tr}$ (as accuracy objective)
- Ng/N (as complexity objective)

D. Genetic operators

1) Crossover: The crossover works in the two parts of the chromosome at the same time. Therefore, an standard crossover operator is applied over C_V and C_G. This operator performs as follows: a crossover point p is randomly generated and the two parents are crossed at the p-th variable (the possible values for p are $\{2, \ldots, N\}$). The crossover is developed this way in the two chromosome parts, C_V and C_G, thereby producing two meaningful descendants.

2) Mutation: . Two different operators are used, each one of them acting on different chromosome parts. A brief description of them is given below:

- *Mutation on* C_V: As this part of the chromosome is binary coded, a simple binary mutation is developed, flipping the value of the gene.
- *Mutation on* C_G: The mutation operator selected for C_G performs a slight change in the selected variable. Once a granularity level is randomly selected to be muted, a local modification is developed by changing the number of labels of the variable to the immediately upper or lower value (the decision is made at random). When the value to be changed is the lowest (2) or highest one (7), the only possible change is developed.

V. Experimental study

We will study the performance of MGA-FS-GL employing a large collection of imbalanced data-sets with different imbalance ratio (IR). We divide the data-sets in two main groups:

- Data-sets with high imbalance :$IR > 9$
- Data-sets with low imbalance :$IR < 9$

Specifically, we have considered forty-four data-sets with different IR (twenty-two of each group) from KEEL data-set repository [16], which are publicly available on the corresponding web-page (http://www.keel.es/dataset.php), including general information about them. Table I show these data-sets, where we denote the number of examples (#Ex.), number of attributes (#Atts.), class name of each class (minority and majority), class attribute distribution and IR. This table is in ascendant order according to the IR. For the sake of obtaining binary imbalanced problems, the positive and negative classes are defined as the joint of one or more classes, which are specified in column *Class* of Table I separated by a semicolon. In order to reduce the effect of imbalance, we will employ the SMOTE preprocessing method [17] for all our experiments, considering only the 1-nearest neighbor to generate the synthetic samples, and balancing both classes to the 50% distribution.

To develop the different experiments we consider a *5-folder cross-validation model*, i.e., 5 random partitions of data with a 20%, and the combination of 4 of them (80%) as training and the remaining one as test. For each data-set we consider the average results of the five partitions. The data partitions used in this paper can be found in KEEL-dataset repository [41].

The configuration for the FRBCS is presented in Table II being "Conjuction operator" the operator used to compute the compatibility degree of the example with the antecedent of the rule and the operator used to compute the compatibility degree and the rule weight. This parameter selection has been carried out according to the results achieved by the Chi et al.'s method in our former studies on imbalanced data-sets [4]:

TABLE II
Configuration for the FRBCS

Conjunction operator:	Product T-norm
Rule Weight:	Penalized Certainty Factor [18]
Fuzzy Reasoning Method:	Winning Rule

The specific parameters setting for the GA of MGA-FS-GL is listed below, being N the number of variables:

- Number of evaluations: $1000 \cdot N$
- Population Size: 100 individuals
- Crossover Probability P_c : 1.0
- Mutation Probability P_m : 0.2

The final result of MGA-FS-GL is a set of non dominated solutions i.e., none of them is better than another in the two objectives. This set is called the *Pareto front*. The usual way to analyze the results of a classification model in machine learning involves a comparison among the obtained model and the models obtained for other learning methods used in the specialized literature, including an statistical analysis of various measures being the prediction ability (in our case, the AUC_{Tst}) the main one. So, only one solution for each data-set is used in the comparison. In the case of a cross-validation scheme, it is used the mean of the unique solution obtained for each combination of training set/test set.

Therefore, it is difficult to show, in the previous way, the results of MGA-FS-GL because there are not five solutions for each data-set but five sets of non dominated solutions and the cardinality of that sets (Pareto fronts) is usually different. Thus, it is not possible to establish a comparison among the five sets of FRBCSs obtained for each data-set due to the different number of non dominated solutions and it is not possible to compare one solution (obtained for the reference models) opposite to a set of solutions. A possible way to deal with this problem was proposed in [12], where three different non dominated solutions were selected from the whole Pareto fronts and then, these models can be used as individual solutions for comparison with classical methods:

- The best solution for the accuracy objective (greatest value in AUC_{Tr}), named best accuracy (BA)

TABLE I
SUMMARY DESCRIPTION FOR IMBALANCED DATA-SETS

Data-set	#Ex.	#Atts.	Class (min., maj.)	%Class(min.; maj.)	IR
Data-sets with Low Imbalance (IR 1.5 to 9)

- The solution with the worst value for the accuracy objective (lowest value in AUC_{Tr}). So, the one with the less value for the complexity objective, named best interpretability (BI)
- The solution with the intermediate value for both objectives, named intermediate (I)

Therefore, these chosen solutions can be considered a brief sample of the whole set of solutions with different trade-off between accuracy and interpretability. Table III present the detailed results for these three selected solutions, showing the expected trend in the prediction ability: the most accurate solutions present certain overfitting. The intermediate solutions have a better behavior, since they present a good prediction ability (AUC_{Tst} lightly worse than the previous) and better interpretability (less number of rules) than the previous. The solutions with best interpretability have a very poor prediction ability since they are models with very few number of rules (normally, with only one feature selected).

One way to obtain more accurate solutions with good interpretability is to choose the FRBCS with at least two variables selected, and with the lowest value for the complexity measure. In fact, it would be easy to change MGA-FS-GL to ignore the models with only one selected feature, reducing the search space. However, we think that it is interesting to obtain these models as they provide information on what is the most relevant variable and, in some data-sets, the solution with best interpretability present a good prediction ability (*Yeast6, Yeast2vs4*) and the best prediction ability in one case (*Yeast05679vs4*).

Now, We will compare these solutions of MGA-FS-GL with the models obtained for the following methods:

- The method proposed in [9] (denoted GA-FS-GL). The single objective GA version of MGA-FS-GL where the fitness function is the weighted aggregation of the two objective values.

- The original Chi et al.'s method [10], where a previous definition for the DB is needed, normally by the use of uniform fuzzy partitions with the same number of labels in all the variables. Therefore, it is necessary to choose a number of labels, being the usual values employed for any standard FRBCS approach in the specialized literature 3, 5 and 7 labels per variable. According to this fact, we include these three possibilities in the experimental study. In the latter, we will refer these methods as G3-Chi, G5-Chi, G7-Chi, respectively.
- The method proposed in [8] (denoted GA-GL), that uses a single objective GA (similar to the used in GA-FS-GL) only for granularity learning.
- C4.5 [24], a method of reference in the field of classification with imbalanced data-sets [25], [22].

All the previous methods have all the variables selected except GA-FS-GL, that includes a feature selection in the same way as MGA-FS-GL. The FRBCS approaches (GA-FS-GL, GA-GL, G3-Chi, G5-Chi and G7-Chi) have the same configuration as MGA-FS-GL (Table II)

Table IV shows the mean of the AUC and the number of rules (NR) for the different groups of data-sets (Low imbalance, High Imbalance and all of them). There are three lines for MGA-FS-GL, corresponding with the three solutions selected: best accuracy (BA), intermediate (I) and best interpretability (BI).

As can be observed in Table IV for all the data-sets, the single objective version of the genetic learning process described (GA-FS-GL) presents the best results. Its prediction ability is better than the other methods except for GA-GL. A GA designed only for granularity learning (GA-GL) obtains the best results in prediction ability but with a high increase of the number of rules (less interpretability). Regarding to the complexity of the models (lower NR), GA-FS-GL presents

TABLE IV
AVERAGE TABLE OF RESULTS IN AUC_{Tr}, AUC_{Tst} AND NUMBER OF RULES (NR) FOR THE DIFFERENT DEGREES OF IMBALANCE

Algorithm	Low Imbalance			High Imbalance			All Data-sets		
	AUC_{Tr}	AUC_{Tst}	NR	AUC_{Tr}	AUC_{Tst}	NR	AUC_{Tr}	AUC_{Tst}	NR
G3-Chi	86.03	82.14	124.70	85.09	80.52	68.67	85.56	81.33	96.69

G7-Chi	93.95	74.40	387.18	93.66	74.90	272.02	93.81	74.65	329.60
GA-GL	92.03	84.20	177.41	91.33	81.98	82.36	91.68	83.09	129.89
GA-FS+GL	85.77	83.53	26.98	85.33	80.91	12.79	85.55	82.22	19.89
C4.5	95.00	86.09	26.05	95.93	78.25	22.45	95.46	82.17	24.25
MGA-FS+GL(BA)	93.45	80.03	318.26	92.40	78.91	191.83	92.93	79.47	255.05
MGA-FS+GL(I)	83.31	80.19	138.46	80.70	76.91	51.22	82.00	78.55	94.84
MGA-FS+GL(BI)	59.05	58.54	2.46	55.04	54.79	2.56	57.05	56.66	2.51

the lesser number of rules, except for the solution with best interpretability of MGA-FS-GL, that presents the worse value for the prediction ability. The improvement of GA-FS-GL in the number of rules is even better in the group of data-sets with high imbalance, demonstrating its suitability to the framework of imbalanced data-sets.

Anyway, None of the three selected solutions of MGA-FS-GL obtain better results on AUC_{Tst} than the obtained with GA-FS-GL (considering the weighting factors proposed in [9]). However, MGA-FS-GL provide models with very good prediction ability in each Pareto front. If we chose the solutions with best AUC_{Tst} for each set of non dominated solutions, the global mean of the AUC_{Tst} for all the data-sets would be 86.32, significantly higher than those obtained with GA-FS-GL and the other methods used for comparison. Hence, MGA-FS-GL performs very well, but the unsolved problem is to find these solutions with the best prediction ability as they occupy different positions along the Pareto front of each data-set. This situation is represented in Figure 1 where the Pareto fronts obtained for MGA-FS-GL in the first partition of four problems are showed (including also the AUC_{Tst} of each non dominated solution). There are different "types" of behavior among the data-sets regarding to the values of AUC_{Tst}:

- In some cases, the values of AUC_{Tst} follow the same trend as AUC_{Tr} (Vowel0). In such data-sets, the trade-off between accuracy and interpretability is also fulfilled for the AUC_{Tst} and the final user can choose the most suitable FRBCS (depending on his preferences) assuming that AUC_{Tr} is similar to the prediction ability in all models. Unfortunately, this situation occurs only in a few data-sets.
- Many data-sets present overfitting, the AUC_{Tst} is then increased from the FRBCS with best AUC_{Tr} to an optimal value from which descends again. This point corresponds to a particular combination of weights in GA-FS-GL, which is specific for each data-set. Therefore, finding this value is a difficult problem to solve. In some cases there are a great overfitting in the solutions with best AUC_{Tr} (Wisconsin) while in other cases the overfitting is lesser and there is a smooth decrease of the AUC_{Tst} from the optimal value (Ecoli3).
- Finally, in other cases, the AUC_{Tst} follows a chaotic behavior (Glass4). So, the data fracture between the training set and the test set is very high and it is impossible to determine the solution with best prediction ability.

As most of the data-sets belong to one of the last two "types", we recommend using GA-FS-GL when the main purpose is to obtain only one model with high prediction ability (and not much complexity), unless there are some evidence to establish that the problem belongs to the first category of the previously described. MGA-FS-GL is particulary useful when many solutions with different trade-off between accuracy and interpretability is required, but it is very difficult to find the solution with best prediction ability, as that measure can not be used in the learning process. Moreover, it is difficult to know the behavior of the accuracy measure in the test data set (compared with the known behavior in training data set), that it would be valuable for selecting the most adequate solution if we were interested, for example, in a solution with a minimum degree of interpretability.

VI. CONCLUSIONS

This contribution analyzes the behavior of a multiobjective version of a previously proposed Genetic Algorithm to design FRBCS for imbalanced data-sets. The genetic learning process is used for feature selection and granularity learning, which is combined with an efficient fuzzy classification rule generation method to obtain the complete KB of the FRBCS.

The proposed approach obtains a set of FRBCSs with different trade-off between accuracy and interpretability in which to find the model with the best prediction ability generally is non evident.

***Abstract*—Fuzzy decision trees are widely employed to face classification problems since they combine the high interpretability given by the decision tree and the capability of management of the uncertainty inherent to fuzzy logic.**

However, the success of fuzzy systems in general depends, to a large degree, on the choice of the membership functions. For this reason, we propose to model the linguistic labels by means of Interval-Valued Fuzzy Sets to take into account the ignorance related to their definition. On the other hand, we define an evolutionary method to tune the shape of the Interval-Valued Fuzzy Sets looking for the best ignorance degree that each Interval-Valued Fuzzy Set represents.

In this contribution, we will make use of the fuzzy ID3 algorithm as a base technique from which to apply our methodology. The experimental study shows how our methodology enhances the performance of the base fuzzy decision tree. Furthermore, we compare our approach with respect to four state-of-the-art fuzzy decision trees and C4.5 as a representative algorithm for crisp decision trees. The goodness of our proposal is tested on a large collection of data-sets and it is supported by an exhaustive statistical analysis.

***Keywords*—Linguistic Fuzzy Rule-Based Classification Systems, Interval-Valued Fuzzy Sets, Ignorance functions, Tuning, Fuzzy Decision Tree, Classification.**

I. Introduction

Classification problem is one of the most studied problems in machine learning and data mining [1]. In order to face this task, a classifier needs to be induced by means of a learning algorithm. The classifier is a model encoding a set of criteria that allows a data instance to be assigned to a particular class depending on the value of certain variables. Different kinds of models, such as fuzzy rule-based classification systems or Fuzzy Decision Trees (FDTs), can be used to represent classifiers.

Specifically, FDTs are a suitable solution to face classification problems due to the good synergy between the handling of the uncertainty provided by fuzzy logic [2] and the good interpretability given by decision trees [3]. Among the large number of techniques proposed in the specialized literature for designing FDTs [4], [5], the fuzzy ID3 algorithm [6] is widely employed since it is a popular and efficient method to construct a FDT [7].

In fuzzy systems, like FDTs, the definition of the membership functions used to represent the linguistic labels is truly significant. When defining the fuzzy partitions, either through expert knowledge or homogeneously over the input space, it is possible to have an ignorance degree (lack of information) which makes their definition difficult. The theory of Interval-Valued Fuzzy Sets (IVFSs) [8] has proved to be a suitable tool to model this ignorance [9]. Specifically, we have shown that the use of IVFSs is useful to improve the performance of fuzzy rule-based classification systems [10].

In this contribution, we propose to model the linguistic labels of the classifier by means of IVFSs. To do so, we use a new parametrized construction method of IVFSs that starts from the fuzzy sets composing the knowledge base of the system. The length of each IVFS is proportional to the degree of ignorance related to the definition of the corresponding membership function, which is measured using weak ignorance functions. We must point out that we introduce the IVFSs after the induction process and we study their influence in the fuzzy reasoning mechanism, which has to be modified to take into account this modeling of the linguistic labels. As a result, a good management of the uncertainty is provided for the system while its interpretability is maintained.

Additionally, we propose the definition of an evolutionary methodology that allows to compute the optimal ignorance degree that each IVFS represents. To do so, we modify the parameters used in the IVFSs construction method to weight the degree of ignorance and consequently, we tune the length of the IVFSs. In this manner, the membership functions will be fine-tuned leading to an improvement of the performance of the system in a general framework.

The aim of our study is to show the goodness of our proposed methodology using the fuzzy ID3 algorithm as the base technique. To do so, we will compare our approach with respect to both the base FDT and with four state-of-the-art FDTs, namely the simple pattern tree [11], a look-ahead approach [12], the FDT proposed by Janikow in [13] and a method which fuzzifies the Gini index [14]. Furthermore, we will also compare our methodology with C4.5 [15]

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

as a reference algorithm of crisp decision trees. In order to obtain well-founded conclusions, we have considered 20 numerical data-sets from the KEEL data-set repository [16] (http://www.keel.es/dataset.php). The measure of performance is based on accuracy rate and the study is supported by the proper statistical analysis, as suggested in the literature [17], [18], [19].

The work is arranged as follows: Section II provides some preliminary concepts of IVFSs and also describes the generation of IVFSs employing weak ignorance functions. The induction process of the fuzzy ID3 algorithm together with the modifications carried out in the reasoning mechanism, due to the use of IVFSs, are shown in Section III. In Section IV we describe in detail our methodology to tune the membership functions by means of GAs and the evolutionary method is also explained. Then, the experimental study is presented in Section V and we finish the work with some concluding remarks in Section VI.

II. Linguistic Labels Modeled by means of Interval-Valued Fuzzy Sets

In this work we propose to model the linguistic labels by means of IVFSs in order to take into account the ignorance related to the definition of the membership functions.

In this section, we remind some theoretical concepts which are necessary to understand the remainder of this contribution. Then, we define the construction method of IVFSs starting from given fuzzy sets in which we employ weak ignorance functions to measure the ignorance associated with the definition of the membership functions. Finally, we present our new methodology to model the linguistic labels by means of IVFSs.

A. Preliminaries

Let us denote by $L([0,1])$ the set of all closed subintervals in $[0,1]$, that is,

$$L([0,1]) = \{\mathbf{x} = [\underline{x}, \overline{x}] | (\underline{x}, \overline{x}) \in [0,1]^2 \text{ and } \underline{x} \leq \overline{x}\}.$$

We also denote $0_L = [0,0]$ and $1_L = [1,1]$.

Definition 1: An interval-valued fuzzy set (IVFS) [20], [21] (or interval type 2 fuzzy set) A on the universe $U \neq \emptyset$ is a mapping $A : U \to L([0,1])$, such that

$$A(u_i) = [\underline{A}(u_i), \overline{A}(u_i)] \in L([0,1]), \text{ for all } u_i \in U.$$

We denote by $\mathcal{FS}(U)$ the set of all fuzzy sets on U and by $\mathcal{IVFS}(U)$ the set of all IVFSs on U. We also denote by W the length of the interval under consideration, that is

$$W(A(u_i)) = \overline{A}(u_i) - \underline{A}(u_i).$$

To order the IVFSs we use the order relation defined by Xu and Yager [22]. Using this relationship on $L([0,1])$ is easy to see that the smallest element of $L([0,1])$ is 0_L and the largest is 1_L.

We will now recall the extension of t-norms and t-conorms in $[0,1]$ (see [23]) to IVFSs [20], [24].

Definition 2: A function $\mathbf{T} : (L([0,1]))^2 \to L([0,1])$ is said to be an *interval-valued t-norm* (IV t-norm) if it is commutative, associative, increasing in both arguments (with respect to the order $\mathbf{x} \leq_L \mathbf{y}$ if and only $\underline{x} \leq \underline{y}$ and $\overline{x} \leq \overline{y}$), and has the neutral element 1_L. In the same way, a function $\mathbf{S} : (L([0,1]))^2 \to L([0,1])$ is said to be an *interval-valued t-conorm* (IV t-conorm) if it is commutative, associative, increasing, and has the neutral element 0_L.

Definition 3: a) An IV t-norm is said to be *t-representable* if there are two t-norms T_a and T_b in $[0,1]$ so that $\mathbf{T}(\mathbf{x},\mathbf{y}) = [T_a(\underline{x},\underline{y}), T_b(\overline{x},\overline{y})]$ for all **x, y** $\in L([0,1])$.
b) An IV t-conorm is said to be *s-representable* if there are two t-conorms S_a and S_b in $[0,1]$ so that $\mathbf{S}(\mathbf{x},\mathbf{y}) = [S_a(\underline{x},\underline{y}), S_b(\overline{x},\overline{y})]$ for all **x, y** $\in L([0,1])$.

We will use $\mathbf{T}_{T_a,T_b}$ to denote the t-representable IV t-norm that can be represented by T_a and T_b as defined above. Similarly, a specific s-representable IV t-conorm will be denoted $\mathbf{S}_{S_a,S_b}$.

In this work we only use t-representable IV t-norms and s-representable IV t-conorms.

Let $[\underline{x}, \overline{x}]$, $[\underline{y}, \overline{y}]$ be two intervals in $\mathbb{R}$ so that $\underline{x} \leq \underline{y}$ and $\overline{x} \leq \overline{y}$, the rules of interval arithmetic employed in this contribution are as follows:

- Addition: $[\underline{x}, \overline{x}] + [\underline{y}, \overline{y}] = [\underline{x} + \underline{y}, \overline{x} + \overline{y}]$.
- Subtraction: $[\underline{x}, \overline{x}] - [\underline{y}, \overline{y}] = [\underline{x} - \overline{y}, \overline{x} - \underline{y}]$.
- Multiplication: $[\underline{x}, \overline{x}] * [\underline{y}, \overline{y}] = [\underline{x} * \underline{y}, \overline{x} * \overline{y}]$.
- Division: $[\underline{x}, \overline{x}]/[\underline{y}, \overline{y}] = [\underline{x}/\overline{y}, \overline{x}/\underline{y}]$ assuming $0 < \underline{y}$.

We defined a weak ignorance function from the concept of ignorance function given in [9] as follows:

Definition 4: A weak ignorance function [25] is a mapping

$$g : [0,1] \to [0,1]$$

that satisfies:

(g1) $g(x) = g(1-x)$ for all $x \in [0,1]$;
(g2) $g(x) = 0$ if and only if $x = 0$ or $x = 1$;
(g3) $g(0.5) = 1$.

Example 1: $g(x) = 2 \cdot \min(x, 1-x)$ is a weak ignorance function.

B. Construction of Interval-Valued Fuzzy Sets of Fixed Length From a Fuzzy Set

Our aim in this section is to construct an IVFS starting from any given fuzzy set. To do so, we define a function G parametrized by δ and γ, which satisfy a determined set of properties. These properties allow to obtain intervals in such a way that their length is proportional to the ignorance degree and the initial membership degree is within the interval.

Proposition 1: Let $\delta, \gamma \in [0,1]$ with $\delta \geq \gamma \geq \delta \cdot x$. The function

$$\begin{aligned} &G : [0,1]^4 \to L([0,1]) \text{ given by} \\ &G(x,y,\delta,\gamma) = [x \cdot (1 - \delta \cdot y), x \cdot (1 - \delta \cdot y) + \gamma \cdot y)] \end{aligned} \tag{1}$$

satisfies the following properties:

1) $x \in G(x,y,\delta,\gamma)$;
2) $W(G(x,y,\delta,\gamma)) = \gamma \cdot y$;

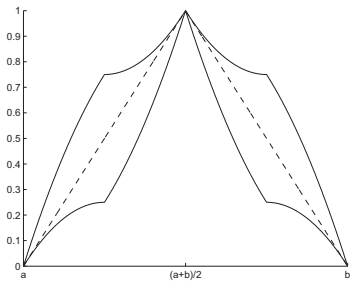

Fig. 1: Initial constructed IVFS.

3) If $x = 0$, then $G(0, y, \delta, \gamma) = [0, \gamma \cdot y]$;
4) If $y = 0$, then $G(x, 0, \delta, \gamma) = [x, x]$;
5) If $\delta = \gamma$, then:

$$\underline{G}(x, y, \delta, \delta) + \overline{G}(1 - x, y, \delta, \delta) = 1$$
$$\overline{G}(x, y, \delta, \delta) + \underline{G}(1 - x, y, \delta, \delta) = 1.$$

According to the previous proposition, we define Theorem 1 as the new construction of IVFSs.

Theorem 1: Let $A \in \mathcal{FS}(U)$. If for each $u_i \in U$ we take $g(A(u_i))$, $\delta(u_i)$, $\gamma(u_i) \in [0, 1]$, then the set

$$\begin{aligned} &A_{IV} = \{(u_i, A_{IV}(u_i)) | u_i \in U\} \text{ where} \\ &A_{IV}(u_i) = G(A(u_i), g(A(u_i)), \delta(u_i), \gamma(u_i)) \end{aligned} \tag{2}$$

is an IVFS on U.

C. Modeling Linguistic Labels by means of Interval-Valued Fuzzy Sets

In this section, we describe our methodology to generate linguistic labels modeled by means of IVFSs starting from given fuzzy sets.

We use the initial fuzzy sets (dashed line in Fig. 1 whose expression is shown in Eq. (3)) as the base to construct the IVFSs (solid line in Fig. 1) by means of Theorem 1. In the initial construction of the IVFSs, we consider the middle degree of ignorance. Therefore, we initialize $\delta(u_i) = \gamma(u_i) = 0.5$ for all $u_i \in U$ since, according to Theorem 1, the minimum value of both parameters is 0 and the maximum is 1.

$$\mu_A(u_i) = \begin{cases} 0, & \text{if } u_i \leq a, \\ \frac{2}{b-a}(u_i - a), & \text{if } a \leq u_i \leq \frac{a+b}{2} \text{ and } b \neq a, \\ \frac{2}{a-b}(u_i - b), & \text{if } \frac{a+b}{2} \leq u_i \leq b \text{ and } b \neq a, \\ 0, & \text{if } b \leq u_i, \end{cases} \tag{3}$$

III. Fuzzy ID3 with Interval-valued Fuzzy Sets

In this section, we describe the induction process of the fuzzy ID3 algorithm and then we introduce our methodology, that is, the construction of the IVFSs and the modifications carried out both in the computation of the relative frequencies and in the reasoning mechanism.

A. Fuzzy ID3 Induction

Let the universe of objects be described by n attributes $A = A^{(1)}, ..., A^{(n)}$. An attribute $A^{(k)}$ takes m_k values of fuzzy subsets $A_1^{(k)}, A_2^{(k)}, ..., A_{m_k}^{(k)}$. There are a total of N training instances. Based on the attributes, an object is classified into *m* classes $C_1, C_2, ..., C_m$. We use the symbol M(·) to denote the cardinality of a given fuzzy set. The key to the fuzzy ID3 algorithm is to select the expanded attribute, which can be performed in the following steps [7]:

(1) For each attribute value (fuzzy subset) $A_i^{(k)}, (i = 1, 2, ..., m_k)$, to compute its relative frequencies with respect to class $C_j, (j = 1, 2, ..., m)$:

$$p_i^{(k)}(j) = \frac{M(A_i^{(k)} \cap C_j)}{M(A_i^{(k)})} \tag{4}$$

(2) For each attribute value (fuzzy subset) $A_i^{(k)}, (i = 1, 2, ..., m_k)$, to compute its fuzzy classification entropy:

$$Entr_i^{(k)} = \sum_{j=1}^{m} -p_i^{(k)}(j) log(p_i^{(k)}(j)), \tag{5}$$

(3) To compute the average fuzzy classification entropy of the *k*th attribute:

$$E_k = \sum_{i=1}^{m_k} \frac{M(A_i^{(k)})}{\sum_{j=1}^{m_k} M(A_j^{(k)})} Entr_i^{(k)}. \tag{6}$$

(4) Select such an integer k_0, that

$$E_{k_0} = \arg \min_{1 \leq k \leq n} (E_k) \tag{7}$$

With a given evidence significance level α, a truth level threshold β and being A the set of attributes of the problem, the induction process consists of the following steps [6]:

(1) Execute the α-cut of the set of fuzzified examples with the evidence significant level.
(2) Measure the average fuzzy classification entropy associated with each attribute and select the attribute with the smallest average fuzzy classification entropy as the root decision node.
(3) Delete all empty branches of the decision node. For each nonempty branch of the decision node, compute the relative frequencies of all objects within the branch into each class. If the relative frequency of one class is above the given threshold β, terminate the branch as a leaf. Otherwise, do further research if an additional attribute will further partition the branch (i.e. generate more than one nonempty branch). If yes, select the attribute with the smallest average fuzzy classification entropy as a new decision node from the branch. If not, terminate this branch as a leaf. At the leaf, each class will has its relative frequency.
(4) Repeat step 3 for all newly generated decision nodes until no further growth is possible (i.e. all the attributes have been used), the decision tree then is complete.

B. Fuzzy ID3 with Interval-Valued Fuzzy Sets: A New Fuzzy Reasoning Method

The fuzzy sets composing the data base of the FDT, generated by the algorithm previously described, are created homogeneously over the input space. These fuzzy sets are employed as the starting point to construct the IVFSs using the construction method presented in Section II-C.

The modeling of the linguistic labels by means of IVFSs implies two main modifications. The relative frequencies of the classes in each leaf must be elements of $L([0,1])$. To do so, we compute the relative frequencies (Eq. (4)) associated with the lower and the upper bounds respectively. On the other hand, the reasoning mechanism, used to classify novel examples, is adapted as follows:

In a FDT, a path is the connection from the root node to each leaf. Suppose that the FDT contains *l* leaves, consequently *l* paths ($Path^i, i = 1, 2, ..., l$). For each leaf, the path *i* has N_i nodes ($Path^i_1$, $Path^i_2$, ...,$Path^i_{N_i}$). Let *e* be an example to be classified in one of the *m* classes. We must recall that each node is modeled by means of an IVFS, therefore, $Path^i_k(e_k) = [\underline{Path^i_k}(e_k), \overline{Path^i_k}(e_k)] \in L([0,1])$ with $k = 1, ..., N_i$. The *interval-valued fuzzy reasoning mechanism* follows the following 4 key steps:

- To compute the matching degree between each path and the new example. We apply a t-representable IV t-norm as the conjunction among the nodes in each path.

$$M_i = \mathbf{T}_{T_a,T_b}([\underline{Path^i_1}(e_1), \overline{Path^i_1}(e_1)], ...,$$

$$[\underline{Path^i_{N_i}}(e_{N_i}), \overline{Path^i_{N_i}}(e_{N_i})]) =$$

$$[T_a(\underline{Path^i_1}(e_1), ..., \underline{Path^i_{N_i}}(e_{N_i})),$$

$$T_b(\overline{Path^i_1}(e_1), ..., \overline{Path^i_{N_i}}(e_{N_i}))], i = 1, 2, ..., l$$

- To compute the certainty of each class in each leaf. We apply a t-representable IV t-norm to weight the matching degree of the example along the paths with the relative frequencies of the leaves.

$$Cert^i_j = \mathbf{T}_{T_c,T_d}([\underline{M_i}, \overline{M_i}], [\underline{p_i}(j), \overline{p_i}(j)]) =$$

$$[T_c(\underline{M_i}, \underline{p_i}(j)), T_d(\overline{M_i}, \overline{p_i}(j))], j = 1, ..., m, i = 1, ..., l$$

- To compute the total certainty of each class. We employ the interval addition to aggregate certainties of the same class in all the paths.

$$Total_Certainty_j = \sum_{i=1}^{l} [\underline{Cert^i_j}, \overline{Cert^i_j}], j = 1, ..., m$$

- Classify the example in the class which maximizes the total certainty following the relationship presented below.

For any interval $[\underline{x}, \overline{x}]$, $[\underline{y}, \overline{y}]$ on $\mathbb{R}$, we use the following relationship based on the score and accuracy functions given in [22] (see Subsection II-A): let $s([\underline{x}, \overline{x}]) = \underline{x} + \overline{x}$ and $s([\underline{y}, \overline{y}]) = \underline{y} + \overline{y}$ be the scores of $[\underline{x}, \overline{x}]$ and $[\underline{y}, \overline{y}]$ respectively. Let $h([\underline{x}, \overline{x}]) = \overline{x} - \underline{x}$ and $h([\underline{y}, \overline{y}]) = \overline{y} - \underline{y}$ be the accuracy degrees of $[\underline{x}, \overline{x}]$ and $[\underline{y}, \overline{y}]$ respectively. Then

- If $s([\underline{x}, \overline{x}]) < s([\underline{y}, \overline{y}])$, then $[\underline{x}, \overline{x}] < [\underline{y}, \overline{y}]$;
- If $s([\underline{x}, \overline{x}]) = s([\underline{y}, \overline{y}])$, then
  a) If $h([\underline{x}, \overline{x}]) = h([\underline{y}, \overline{y}])$, then $[\underline{x}, \overline{x}] = [\underline{y}, \overline{y}]$;
  b) if $h([\underline{x}, \overline{x}]) < h([\underline{y}, \overline{y}])$, then $[\underline{x}, \overline{x}] < [\underline{y}, \overline{y}]$.

IV. Genetic Tuning of the Linguistic Labels

Membership functions, which are usually obtained by normalization process or defined by experts, remains fixed during the induction process. Consequently, they could not be perfectly adapted to the context of each problem. To solve this problem, it can be appropriate to carry out a post-processing tuning step in which membership functions are tuned leading to a better adaptation of the system to the specific problem we are dealing with.

The optimization post-processing step is often performed by means of a GA. The hybridization between fuzzy logic and GAs leads to Genetic Fuzzy Systems (GFSs) [26], which are basically fuzzy systems augmented by learning processes based on evolutionary computation. GFS approaches are usually divided into two processes, tuning and learning. Specifically, the genetic tuning process consists of automatically selecting the best system parameters for improving the performance of the initial model without modifying the rule base.

In the remainder of this section we will first introduce the tuning approach of the linguistic labels and then we will describe in detail the evolutionary model for tuning the membership functions.

A. Ignorance Weighting Factor Tuning

The initial set-up of the linguistic labels, which are modeled by IVFSs, could not be well-suited for the specific problem we are dealing with. Therefore, it seems necessary to tune the shape of each IVFS, which is determined by the parameters employed in the IVFSs construction method (Section II-B).

As we have introduced in Subsection II-C, we consider the middle degree of ignorance for the initial construction of all the IVFSs ($\delta = \gamma = 0.5$). However, the ignorance degree can vary depending on the linguistic label, since the amount of available information to define each fuzzy term may not be the same.

Therefore, we propose the application of a genetic tuning step in which we adapt the parameters δ and γ (see Theorem 1), keeping the restriction $\delta \geq \gamma \geq \delta \cdot x$. Consequently, the amount of ignorance that each IVFS represents will vary depending on how the membership function suits the problem.

Fig. 2 depicts the behaviour of the proposed tuning approach. The original IVFS is shown in light gray whereas its final shape (afterwards the genetic tuning) is depicted in dark gray. We observe that the shape of the final IVFS is thinner than that of the initial IVFS.

B. Evolutionary Model

In order to apply the genetic tuning, we will consider the use of CHC algorithm [27]. This algorithm is a classical evolutionary model which presents a good trade-off between

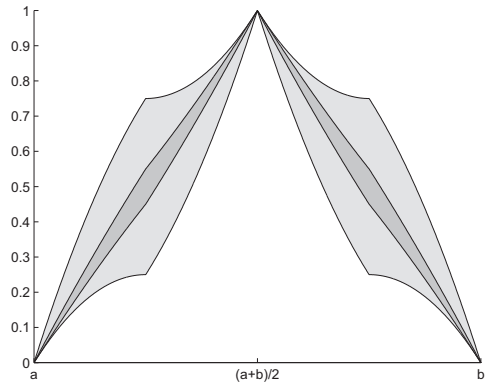

Fig. 2: Ignorance weighting factor genetic tuning. The final values of the parameters are: $\delta = 0.1$, $\gamma = 0.1$.

diversity and convergence, being a good choice in complex problems. The components needed to design this process are explained below:

1) *Coding Scheme:* A real coding is considered. Let us consider the following number of labels per variable: $(m^1, m^2, ..., m^n)$, with n being the number of variables. δ and $\gamma \in [0, 1]$ represent the genes used to encode the parameters which weight the degree of ignorance. Then, the representation of the chromosome is as follows:

$$C_{ET} = (\delta_{11}, \gamma_{11}, ..., \delta_{1m^1}, \gamma_{1m^1}, \delta_{21}, \gamma_{21}, ..., \delta_{2m^2}, \gamma_{2m^2}, ..., \delta_{n1}, \gamma_{n1}, ..., \delta_{nm^n}, \gamma_{nm^n})$$

Therefore, the chromosome length is equal to two times the number of variables times the number of linguistic labels.
2) *Chromosome Evaluation:* The fitness function is the classification accuracy.
3) *Initial Gene Pool:* The initial pool is obtained initializing three individuals having all of the genes with values of 0, 0.5 and 1, corresponding with the situations of minimum, middle and maximum degree of ignorance respectively. The remaining individuals will have initialized all the genes randomly in their respective domains.
4) *Crossover Operator:* We consider the Parent Centric BLX (PCBLX) operator, which is based on the BLX-α. We consider the incest prevention mechanism, checking and modifying an initial threshold, in order to apply the PCBLX operator.
5) *Restarting approach:* When the threshold value is lower than zero, all the chromosomes are regenerated at random in their respective domains. Furthermore, the best global solution found is included in the population to increase the convergence of the algorithm as in the elitist scheme.

V. Experimental Study

This study is oriented towards analysing the goodness of our evolutionary tuning method applied to the FDT generated by the fuzzy ID3 algorithm. To do so, we develop an experimental analysis in which we compare our methodology with respect to several state-of-the-art FDTs and also with C4.5.

In this section, we present the experimental set-up in first place. Next, we briefly describe the FDTs for the comparison together with the parameters employed in the study. Then we introduce the statistical tests used and finally, we present the results together with the corresponding analysis.

A. Experimental Set-Up

We have selected a wide benchmark of 20 numerical data-sets selected from the KEEL data-set repository [16], which are publicly available on the corresponding web page [1] including general information about them, partitions for the validation of the experimental results and so on. Table I summarizes the properties of the selected data-sets, showing for each data-set the number of examples (#Ex.), the number of attributes (#Atts.) and the number of classes (#Class.). We must point out that the *magic, page-blocks, ring* and *shuttle* data-sets have been stratified sampled at 10% in order to reduce their size for training. In the case of missing values, (*cleveland* and *wisconsin*), those instances have been removed from the data-set.

TABLE I: Summary Description for the employed data-sets.

A *5-folder cross-validation model* was considered in order to carry out the different experiments. That is, we split the data-set into 5 random partitions of data, each one with 20% of the patterns, and we employ a combination of 4 of them (80%) to train the system and the remaining one to test it. Furthermore, the process was repeated 3 times using a different seed to obtain a sample of 15 results, which have been averaged for each data-set.

[1] http://www.keel.es/dataset.php

B. Fuzzy Decision Trees for Comparison and Parameters Set-Up

In this work, we have considered four FDTs in order to compare our methodology with respect to different approaches of the literature. Next, we briefly describe each FDT together with their specific configuration values:

- The first approach fuzzifies the Gini index [14]. This method uses the SLIQ decision tree as the base algorithm, which uses the Gini index as the split measure, and fuzzifies its decision boundaries during the tree induction. The configuration is as follows:
  - Number of labels per variable: 3 labels.
  - Threshold = 0.85.
  - Maximum number of patterns in a leaf: 5% of the number of patterns.
  - Maximum depth: number of attributes.
- The second approach is the look-ahead method [12]. This method attempts to establish a decision node by analyzing both a split measure and the classifiability of instances that are split along branches of the node. The specific values of its configuration are:
  - Number of labels per variable: 3 labels.
  - Split measure: Information Gain.
  - Number of neighbours: 3.
  - Weighting factor: 1.
- The third proposal is the FDT proposed by Janikow in [13]. This is a classical FDT widely employed in the specialized literature whose configuration is as follows:
  - Number of labels per variable: 3 labels.
  - Conjunction operator: product T-norm.
- Finally, we have selected the simple pattern tree algorithm [11]. This approach, instead of constructing one tree, whose leaves have a probability distribution expressing the membership of each class, constructs one tree per class using aggregation and similarity functions. We have chosen the following configuration:
  - Aggregation functions: min and max operators.
  - Similarity function: the similarity related with the root mean square error.
  - Number of labels per variable: 3 labels.

The specific configuration for the fuzzy ID3 algorithm with and without IVFSs (presented in Table II) and the ones of the selected FDTs in this work, have been selected experimentally since they provide the best performance for each method. Regarding the genetic tuning process presented in Section IV, it employs populations composed by 50 individuals, 30 bits per gen in order to perform the *gray* codification and the number of evaluations is 5.000 times the number of attributes.

C. Statistical Tests for Performance Comparison

In this work, we use some hypothesis validation techniques in order to give a statistical support to the result analysis. We will use a non parametric test, because the initial conditions that guarantee the reliability of the parametric tests cannot be fulfilled [17], [18]. We employ the Wilcoxon rank test [28] as non parametric statistical procedure to make comparisons between two algorithms; we use the Friedman aligned ranks test [29] to detect statistical differences among a group of results and the Holm post-hoc test [30] to find the algorithms that reject the equality hypothesis with respect to a selected control method.

These tests are suggested in the studies presented in [17], [18], [19], where its shown that their use in the field of machine learning is highly recommended. A complete description of the test and software for its use can be found on the website: http://sci2s.ugr.es/sicidm/.

TABLE II: Parameter specification for the FDTs.

Fuzzy ID3

D. Analysis of the Behaviour of the Evolutionary Tuning Method.

Table III shows the classification accuracy provided by our methodology and the different approaches considered in this work, specifically:

- F-ID3_IVFS_ET: the fuzzy ID3 algorithm with IVFSs and the evolutionary tuning method.
- F-ID3: the standard fuzzy ID3 algorithm.
- SPT: the simple pattern tree algorithm.
- LA: the look-ahead approach with the information gain heuristic.
- Fgini: the approach in which authors fuzzify the Gini index.
- Janikow: the classical FDT.
- C4.5: the well known decision tree.

Results are grouped in pairs for training and test, where the best global result for each data-set is stressed in **bold-face**.

From the results of Table III, it can be observed that our methodology enhances the performance of the fuzzy ID3 algorithm in most of the data-sets. Furthermore, the goodness of our evolutionary tuning model is shown since it increases the initial performance of the fuzzy ID3 algorithm in such a way that the results obtained by the remaining FDTs are clearly outperformed, as it achieves the best global performance and provides the best performance in 11 of the 17 data sets. This situation is confirmed in Fig. 3, where the rankings of the different approaches are presented, showing that the best ranking is provided by our evolutionary tuning method.

In order to detect significant differences among the results of the different approaches, we carry out the Friedman aligned rank test. This test obtains a p-value near to zero (0.004),

which implies that there are significant differences between the results. For this reason, we can apply a post-hoc test to compare our methodology against the remaining FDTs. Specifically, a Holm test is applied, which is presented in Table IV. The statistical analysis reflects that all of the FDTs considered in this study are outperformed by our approach.

TABLE IV: Holm test to compare the evolutionary tuning method with all the FDTs. The evolutionary tuning model is used as the control method.

i	Algorithm	z	p	α/i	Hypothesis ($\alpha = 0.05$)
5	SPT	4.74	2.15E-6	0.01	Rejected for F-ID3_IVFS_ET
4	Fgini	4.10	4.05E-5	0.0125	Rejected for F-ID3_IVFS_ET
3	F-ID3	3.07	0.002	0.017	Rejected for F-ID3_IVFS_ET
2	LA	2.76	0.006	0.025	Rejected for F-ID3_IVFS_ET
1	Janikow	2.37	0.018	0.05	Rejected for F-ID3_IVFS_ET

Regarding C4.5, the results presented in Table III also show that our evolutionary tuning approach achieves a significant global improvement. A Wilcoxon test (Table V) will help us to make a pairwise comparison between both approaches. We can observe that the null hypothesis of equivalence is rejected in favour of the evolutionary tuning method with a high level of confidence.

TABLE V: Wilcoxon Test to compare the C4.5 algorithm (R^+) against the evolutionary tuning method (R^-).

Comparison	R^+	R^-	Hypothesis ($\alpha = 0.05$)	p-value
C4.5 vs. F-ID3_IVFS_ET	44	166	Rejected for F-ID3_IVFS_ET	0.023

VI. Conclusion

In this work we have proposed a methodology to improve the performance of FDTs by means of IVFSs and a post-processing genetic tuning step. To do so, we have modeled the linguistic labels by means of IVFSs to take into account the ignorance related to the definition of the membership functions. The degree of ignorance is weighted by two parameters and, in this manner, the shapes of the IVFSs are determined. This parametrization allows us to analyse the most appropriate set-up of the IVFSs partitions by means of a post-processing genetic tuning step. In this manner, we compute the best ignorance degree that each IVFS represents.

The experimental study has shown the quality of our approach since, applied to the FDT generated by the fuzzy ID3 algorithm, allows to outperform both the results of the base FDT and the ones of several state-of-the-art FDTs. We must highlight that our proposed approach also enhances the results of a reference algorithm in data mining like C4.5. The results obtained with this methodology allow us to determine, with the corresponding statistical support, that the proposed synergy is very useful to solve classification tasks.

***Abstract*—Traditionally, fuzzy rule based models work with a fixed set of features to describe a particular problem. Our proposal is to use feature construction by means of functions in order to obtain new variables that allow us to get more information about the problem. In particular, we propose the use of previously defined functions over the input variables in the antecedent of the rules. This let us to know if a combination of variables is able to provide us with more information than each one of them separately. In addition, we use a structure that helps us to manage and also restrict the number of functions under consideration by the learning algorithm. We also present a new model of rule in order to represent this kind of knowledge by extending a basic learning fuzzy rule-based model. Finally, we show the experimental study associated with this work.**

***Keywords*—Genetic Fuzzy Systems, Feature Construction, Iterative Learning Approach, Classification.**

I. Introduction

One of the most important areas in the development of applications based on fuzzy logic has been and is the design of fuzzy rule-based systems. In the literature different types of fuzzy rules have been used for different applications. The most common ones are the linguistic rule [1] and the TSK rule [2]. The first one presents a traditional model of rule whose antecedent and consequent is composed of linguistic variables. The second one proposed a model based on rules whose antecedent is composed of linguistic variables and the consequent is represented by a function of the input variables, frequently a linear function. A very well known extension of the linguistic rule is the DNF rule in which each input variable takes as a value a set of linguistic terms whose members are joined by a disjunctive operator, whilst the output variable remains an usual linguistic variable with a single value associated. Another types of extensions of fuzzy rules have been proposed, such as rules with weights, rules with double consequent, relational rules, etc. Each one of these different types of rules have been proposed with the idea of improving the system accuracy or to improve the system interpretability or both of them.

Traditionally, in fuzzy rule-based systems the number of variables in the antecedent is fixed, so now we want to explore the way to include new variables in the antecedent that result as a combination of the existing ones in order to improve the system description. That means that we need to apply feature construction techniques.

Many papers have been written regarding feature construction. In [3] a method is proposed in order to reduce the set of features by means of arithmetics expression trees that work only with numerical attributes. They focused the importance of making a feature selection before doing the feature construction. This is because the construction of new variables is more efficient after reducing the initial searching space. In other works as [4] feature construction is used in order to create new attributes that will be the input data for another algorithm. The process of obtaining the new features is optimized by means of genetic algorithms. On the other hand, as shown in [5], feature construction is proposed for searching effective features sets that improves the quality of recognition methods. This is obtained using the composition of fuzzy relations.

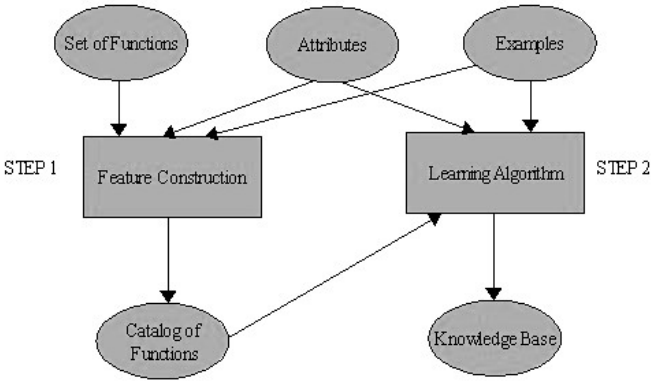

Fig. 1. Rule extraction process

In general, our proposal consists of incorporating new attributes in the learning process for obtaining an improved knowledge of the problem. In concrete, we can describe our proposal as a process with two steps: the first one is oriented to construct new attributes from the combination of the initial attributes by a set of predetermined functions. An information measurement is defined for evaluating the relevance of each new attribute. This step finishes returned the set of the best attributes that we call *catalog*. The second step takes the catalog and the training example set for obtaining a knowledge base that solves the learning problem. Figure 1 shows a graphical representation of the mentioned steps as far as the tasks taken into account in each one of them.

Next section shows a brief introduction about the rule

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

model we propose. Section III explains the feature construction step showing a pseudo code with the algorithm used to obtain the most relevant features and the inference process. The fourth section describes the most relevant details of the learning algorithm NSLV, and the necessary changes done in order to extract fuzzy rules with functions in the antecedent. Section V shows the experimental results obtained as well as the study related to these results. Finally, last section is devoted for conclusions and future work related to this study.

II. Fuzzy Rules with Functions in the Antecedent

In this section we introduce the use of a new model of rule that can include functions as a component of the antecedent. First of all we will remind the linguistic fuzzy model of rules.

Linguistic rules present the following structure:

IF X_1 is A_1 and X_2 is A_2 and $\ldots$ and X_n is A_n

THEN Y is B

where $X_1, X_2, \ldots, X_n$ are the antecedent variables defined on the universes $U_1, U_2, \ldots, U_n$, and Y is the consequent variable defined on the universe V. $A_1, A_2, \ldots, A_n$ and B are fuzzy subsets defined on the respective universes.

We want to improve the capacity of knowledge representation of fuzzy models allowing that a function can be included as part of the description of a rule. To extend the rule model is easy since that a function can be considered like other variable. So, let's consider the following rule:

IF X_1 is A_1 and $SUM\{X_1, X_2\}$ is A_3

THEN Y is B

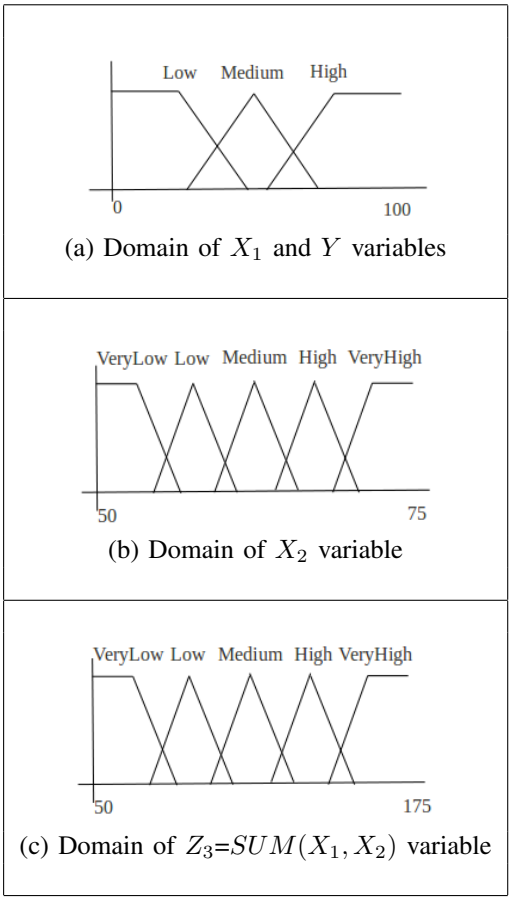
where $SUM(X_1, X_2)$ would be defined as $X_1 + X_2$ and A_3 is a fuzzy value that belongs to the function's domain.

We can interpret that $Z = SUM(X_1, X_2)$, being Z a linguistic variable defined on a fuzzy domain where A_3 is a fuzzy label that is member of that domain. Therefore, to work with functions in the antecedent of the rule does not modify the traditional inference process of the linguistic rules.

Let's suppose the following variables X_i, X_j, are defined in a fuzzy bounded domain $U_i = [inf_i, sup_i]$ and $U_j = [inf_j, sup_j]$ respectively. The range for the resultant variable Z, that represent the function $f(X_i, X_j)$, will depend on the operation selected in each case, but in general, it could be defined as $[min_{x_i \in U_i, x_j \in U_j} f(x_i, x_j), max_{x_i \in U_i, x_j \in U_j} f(x_i, x_j)]]$. For this range, we consider a fixed number of uniformly distributed linguistic labels in order to define the domain of the new variable (in this work, this value is fixed to five).

Below we show an example of the reasoning to obtain the domain for a new variable obtained by applying a function over two input variables.

Given variables X_1 and X_2, with the fuzzy domain shown in Fig. 2(a) and Fig. 2(b) respectively, we can define the domain of the resultant variable $Z_3 = SUM(X_1, X_2)$ as is shown in Fig. 2c.



(a) Domain of X_1 and Y variables

(b) Domain of X_2 variable

(c) Domain of Z_3=$SUM(X_1, X_2)$ variable

Fig. 2. Domains associated to the variables of the example

Now we can show an example of the particular type of rules we are using:

IF X_1 is Low and $SUM\{X_1, X_2\}$ is $Medium$

THEN Y is $Medium$

where Y is the consequent variable that takes values on the same fuzzy domain as X_1 (Fig. 2(a)).

III. Step 1: Feature Construction

The first step of the learning process tries to find a set of new attributes that allow us to acquire more information about the problem. As it is shown in Figure 1, the input of this step consists in the initial variables set (V), the training example set (E) and a set of predetermined functions (F). The new variables are constructed applying the functions over some of the input variables. Although the general model could work with any kind of functions, from now on we will only work with binary functions, that is, functions over two variables. The relevance of each new attribute is evaluated using an information measure on the examples from the training set. The following code describes the process:

- FOREACH **f** in **F**
  - FOREACH subset **S** of **V**
    - $info(f(S), E)$ is a measure of the relevance of the f function with S variables, calculated on the training set.
    - IF $(info(f(S), E)) > k$, being k a threshold that establishes the minimum value for a function to be selected.
      - $f(S)$ is added to the final set of new attributes.
- RETURN the set of new attributes.

We take F as a set of previously defined (by an expert) functions. For each one of these functions we consider a subset of the input variables set. In order to know the relevance degree of the function over the set of examples we use an information measure. This measure is detailed below [6], [7]:

$$\rho(X,Y) = \frac{I(X,Y)}{H(X,Y)} \tag{1}$$

where

$$I(X,Y) = \sum_x \sum_y -p(x,y)\ log_2(\frac{p(x)p(y)}{p(x,y)}) \tag{2}$$

and H(X,Y) is the Shannon entropy over two variables, defined as

$$H(X,Y) = \sum_x \sum_y -p(x,y)\ log_2\ p(x,y). \tag{3}$$

The ρ measure estimates the dependence between two generic variables X and Y in the following way: values of $\rho(X,Y)$ close to zero determine a high degree of independence of both variables, whereas values close to one demonstrate a high degree of functional dependency between them. This is the expression we calculate:

$$\rho(Z_k,Y) = \frac{I(Z_k,Y)}{H(Z_k,Y)} \tag{4}$$

where $Z_k = f_k(X_i, X_j)$ is the particular function to be evaluated and Y is the classification measure. In these expressions, Z_k is a new variable.

Once we have this information measure we compare it with a threshold (k) that establishes the minimum value for a function to be selected. The comparison method is explained as follows. We consider the value M_I as the maximum information given by any possible initial variable and it is defined by:

$$M_I = max_p(\rho(X_p,Y)), \forall p \in \{1..n\} \tag{5}$$

being **n** the number of initial variables and **Y** the classification variable. Then, the comparison expression would be:

$$\rho(Z_k,Y) > \alpha * M_I \tag{6}$$

being $\alpha \in [0,1]$ and $k = \alpha * M_I$ the threshold. For the experimental study we considered $\alpha = 0.9$.

So, if the function's information measure exceeds the established threshold, this new variable is added to the final set of new attributes. Finally, this set of new attributes is returned at the end of the process.

The output of the previous algorithm is used to define a new structure that we will call catalog of functions (CF). In a formal way it is an index set where each entry is a relevant function to be consider by the learning algorithm. For a given *i*, *j*, *r*, we define a catalog entry as a three-position vector where the first and the second values make reference to the variables involved in the function (that is, the index of the variables in the chromosome) and the last one is the function applied to these variables. An illustrative example for the previous given values would be $f_r(X_i, X_j)$. By this way, we will be able to associate to this function an integer representing the index of the function in the catalog. This integer can be described by means of the expression $\beta(i,j,k)$ because it is ordered in the catalog. Now we can define the new proposed model of fuzzy rules as follows:

IF X_1 is $A_1 \wedge \ldots \wedge X_n$ is $A_n \wedge \{\wedge_{(i,j,k)\in H} f_k(X_i, X_j)$ is $E_k\}$

THEN Y is B

where A_i are the antecedent values, B is the consequent value and $H \subseteq CF$ is an index subset defining the specific function participating in the rule. We also define $Z_{\beta(i,j,k)} = f_k(X_i, X_j)$, as a new variable resulting of applying the function f_k over the variables (X_i, X_j). On the other hand, $E_1, \ldots, E_k$ are fuzzy values for $Z_1, \ldots, Z_k$.

As we have been managing an extended version of this kind of rules (**DNF rules**), we are able to assign a set of values from its domains to each antecedent variable, so now the new rule definition is

IF X_1 is $\tilde{A_1} \wedge \ldots \wedge X_n$ is $\tilde{A_n} \wedge \{\wedge_{(i,j,k)\in H} f_k(X_i, X_j)$ is $\tilde{E_k}\}$

THEN Y is B

with $\tilde{A_i}$ being a set of fuzzy values on universe U and $\tilde{E_i}$ a set of fuzzy values defined on a fuzzy domain. From now on, we will refer to this kind of rules as Fuzzy Functional Rules (**FFR**). It is important to mention that the new variables Z_i will have their own domain depending on the domains of the variables involved in the function. That is, it only has sense to apply the functions to compatible variables (taking into account the units).

Our model includes a weight for each rule. This weight, a value in [0, 1], is interpreted as a measure of its prediction capability. In the inference process, the weight of each rule modifies the adaptation to the example with the antecedent of the rule by means of a product operation. The winner rule is the one that obtains the highest value in this adaptation process.

IV. Step 2: Learning Algorithm

Our goal is to design a learning algorithm capable to obtain a knowledge base that better represents our problem. We think that the inclusion of functions in the antecedent of the rules can increase the amount of information about the set of examples we are working with. In order to do that we will take as a base algorithm the learning algorithm of fuzzy rules NSLV. Now we are going to describe the behavior of NSLV as well as the extension of this algorithm that is able to include new features, NSLV-F.

A. The learning algorithm NSLV

NSLV[8] is a genetic fuzzy rule learning algorithm that use a sequential covering strategy [9]. This strategy reduces the problem of learning a disjunctive set of rules to a sequence of simpler problems, each requiring that a single conjunctive rule be learned.

SEQUENTIAL-COVERING(T,A,E,D)

- Learned-rules ← {}
- Rule ← LEARN-ONE-RULE(T,A,E)
- while PERFORMANCE(Rule,E) $>$ D, do
  - Learned-rules ← Learned-rules + Rule
  - E ← E-examples correctly classified by Rule
  - Rule ← LEARN-ONE-RULE(T,A,E)
- Learned-rules ← sort Learned-rules accord to PERFORMANCE over E
- return Learned-rules

where T is the target attribute, A is the attribute set, E is the set of examples and D is a threshold.

The sequential covering algorithm reduces the problem of learning a disjunctive set of rules to a sequence of simpler problems, each requiring that a single conjunctive rule be learned.

NSLV uses a genetic algorithm (GA) to implement the **LEARN-ONE-RULE** procedure. The input of this **GA** is a target attribute, representing the consequent variable, the complete set of antecedent variables and the set of examples, and the output is a single rule that covers at least some of the examples. The criteria for selecting the best rule in NSLV is based on obtaining a single rule that covers many of the positive examples and few of the negative examples. The idea is formulated through the consistency and completeness conditions for a rule [10]. The final criterium is the product of a consistency measure by the a completeness measure.

Therefore, each individual of the population represents a complete rule. NSLV uses a DNF model of rule and therefore each variable takes as value a set of linguistic terms whose members are joined by a disjunctive operator. The genetic algorithm represents each DNF rule by three different elements or levels (Fig. 3):

- *The variable level*. This level contains a gene for each predictive variable involved in the problem. Each gene represents a real value that it is interpreted as the relevance degree of a predictive variable on the rule. Furthermore, a special gene is added in this level that it is interpreted as activation threshold, that is, the variables which associated genes have values less than the threshold are not considered in the antecedent of the rule. Therefore, the use of this level allow us to develop an embedded feature selection process [11].
  Two genetic operators are used in this level, two points crossover and real uniform mutation. The generation of this level in the initial population is based on information measure obtained from the training set. This measure permits to establish an initial relevance degree of each variable in the problem. The obtained values are used for all individual of population on this level. The activation threshold is randomly generated between the maximun and mininum value of the initial relevance degree obtained. A more detailed description can be found in [12].
- *The value level*. It is composed of the sequence of assignments to the predictive variables, where each assignment variable/value is represented by a binary string. The complete level is composed by concatenation of the binary strings representing the assignments variable/values for all input variables. The assignment of a certain variable will appear in the description of the rule if the value of its associated gene in the variable level permits to be considered to the variable relevant for this rule.
  We use a binary representation and two genetic operators on this level, two points crossover and binary uniform mutation. The generation of this level in the initial population is the following: known the consequent value (generated previously in the consequent level), an example of this class is selected. The more specific antecedent for this example is obtained and it is used for coding the individual. This process is repeated for all individuals of the population.
- *The consequent level*. It codes the value of the classification variable of the rule. This level is composed by one gene that is represented by a integer value.
  The integer uniform mutation is the unique genetic operator considered on this level and in the initial population this level is randomly generated.

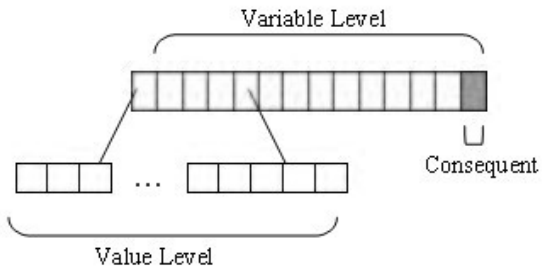


Fig. 3. A rule representation in NSLV

NSLV uses a steady state genetic algorithm. In this case, the selection process is the following: two individuals of the

population are selected, the crossover operators on levels are applied between them obtaining two new individuals. The mutation operators are used for modifying the new individuals. They are evaluated and interchanged by the two worst individuals of the population. Therefore, in each generation of the genetic process only two new individuals are generated and evaluated.

B. NSLV-F: A genetic learning algorithm of fuzzy functional rules

In the current section we explain the changes made in the latest version of NSLV in order to be able to learn FFR. Basically we need to modify the learning algorithm code so it is possible to learn this new type of rules. Thus, the first change takes place in one's own representation of each rule. In this way, we have created a new substructure called function level that encodes the active functions that appear in the rule.

The function level. This level represents from the total set of functions, those that are part of the antecedent of the rule. The individual keeps the same number of levels that the older version apart from this new one. The maximum number of functions that can be included in a single rule is defined by a parameter. In the experiments we have considered up to 10 functions in each rule. This function level use an integer coding where 0 indicates no function considered and any other positive value will refer to the index of the function in the catalog (Fig. 4).

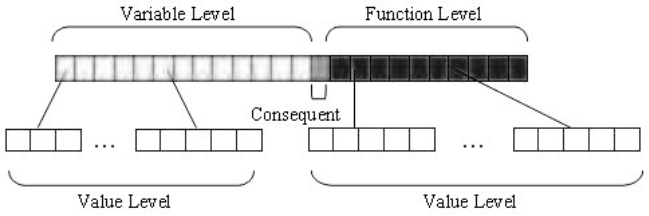

Fig. 4. A rule representation in NSLV-F

Paying attention to genetic operators, we keep the same operators for variables, antecedent values and consequent values used in NSLV. As the function level uses an integer codification, we use two points crossover and a mutation operators for integer coding. The mutation operation defined for this level has associated a probability. This probability establishes if one value of the structure is modified (in the experimental study this value has been set to **0,2**). When the previous fact occurs, a position of the level is randomly selected. If that position has zero value a new random value is generated for selecting a new function of the Catalog. If the position has a different value from zero, then zero value is assigned to that position.

As now we have a new value level associated to the function level which uses a binary coding, we also define the same two genetic operators that were defined for the value level associated to the variable level. That is, two points crossover and binary uniform mutation.

In the initial population all individuals start having the genes of their function level with zero value. That means that at the beginning of the genetic process no functions are considered in the chromosome.

V. Experimental Study

In this section we compare the behavior of the new learning algorithm with respect to the base algorithm NSLV. We also compare it with other classical fuzzy rule learning algorithms. The experimental study was performed on 9 databases of the UCI Repository of Machine Learning Databases and Domain Theories [13] and also on Tao database [14].

TABLE I describes the previously mentioned databases, where each row represents the number of examples (#E), variables (#V), continuous variables (#C), nominal variables (#N), classes (#Cl) and missing values (M).

TABLE I
Database used in the experimental study.

Database	#E	#V	#C	#N	#Cl	M

We have considered in all databases five uniformly distributed linguistic labels to define the domain of the continuous variables. In both algorithms, we use the missing values treatment described in [15]. The results have been obtained by ten-fold cross validation, using the same partition for all algorithms. Parameter ***m*** determines the minimum number of individuals in the population that must be in a class. In all experiments, this value was fixed to $\frac{|pop|}{|cl|+1}$, where $|pop|$ is the size of the population and $|cl|$ is the number of classes. The size of the population was fixed to 100.

First of all we are going make a brief description of the functions considered by the algorithm in the experimental study.

A. Functions

In this empirical part we have taken into account only three possible functions:

- SUM (X_i,X_j), defined as X_i + X_j
- PRODUCT (X_i,X_j) defined as X_i * X_j
- SUBT_ABS (X_i,X_j) defined as $|X_i - X_j|$.

The adding and subtract functions will not be considered with variables with non compatible units. It would not have sense to consider the $SUM(X_1, X_2)$ where X_1 and X_2 measure time and weight respectively. It is important to remark that the domain of the new variables generated will

B. Comparing NSLV with NSLV-F

We have focused our study in the following indicators: accuracy on training set (Training), accuracy on test set (Test) and number of rules (Rules).

Training and Test figure the accuracy of the learned model. On the other hand, Rules define the size and the interpretabilitiy of the knowledge base.

To perform the comparison was used Bonferroni-Dunn test [16]. It establishes that two classifiers have differences if they differ in at least one critical distance. This distance depends on the number of databases, the number of learning algorithms to compare and a critical value q_α, with error α. In that case we took 0.05, $q_\alpha = 1.960$. Finally, for 10 databases and two classifiers, the critical distance (CD) is **0,619**.

The results are shown in TABLE II, TABLE III and TABLE IV. The first column indicates databases evaluated. The second and the third columns represent the results for NSLV and NSLV-F algorithms respectively. First row shows indicators evaluated and the last one contains the value estimated for Bonferroni-Dunn test.

As we can see, there are significant differences in test (TABLE III). This means that NSLV-F improves the accuracy with respect to NSLV. Another important fact is that the results obtained for Training (TABLE II) and Rules (TABLE IV) have no significant differences, so the number of learned rules are approximately the same and they cover almost the same number of examples. Anyway, the improvement obtained in the Test results could be due to the greater ability to generalize of NSLV-F. The inclusion of new variables created by input variables combinations (by means of functions), allow us to obtain more general rules that increase the prediction capacity of the model.

TABLE V shows a rule set obtained by NSLV-F from Tao database. This database is a synthetic problem composed by two real predictive variables, $var0$ and $var1$, and two classes, $C0$, $C1$. We can see that the knowledge base is composed by three rules and it only uses $var0$ and a combination of both initial variables SUM($var0$, $var1$). The point is that the variable $var1$ does not appear alone in any rule. So that, we would be able to conclude that, in this particular case, the new variable SUM($var0$, $var1$) makes possible to obtain more general rules or even gives more information that the variable $var1$ on its own. So we find one of the main reasons why this new model is proposed.

C. Comparing NSLV-F with other fuzzy rule learning algorithms on accuracy

In this section we compare NSLV-F with other well-known fuzzy rule learning algorithms. We have used KEEL platform [17] and for all algorithms we have used the recommendation settings by KEEL. The fuzzy algorithms are the following:

- Fuzzy Ishibuchi99 [18]: Its genetic algorithm handles each fuzzy rule as an individual, and a fitness value is assigned to each rule. It uses linguistic values with

Rank	3.6	3.9	4.25	4.1	2.95	2.2

fixed membership functions as antecedent fuzzy sets, so a linguistic interpretation of each fuzzy rule is easily obtained.

- Fuzzy GAP [19]: It classifies an instance as a result of a quadratic combination of its features. The weights of such combination are fitted as a quadratic discriminant. An instance is classified with the class that has the better value for the quadratic combination of its features.
- Fuzzy SAP [19]: A Simulated Annealing algorithm is used to learn a fuzzy classifier. For each hypothesis, the number of labels and number of rules must be given. In same way, as it is possible to manage any combination of conjunction and/or disjunctions in the antecedent part of a fuzzy rule, a maximum deep tree size must be given too. Those parameters are, in conjunction with Simulated Annealing typical parameters, of capital importance in the evolution of this method.
- Fuzzy GP [20]: Combining genetic programming operators with Simulated Annealing Search to evolve fuzzy rule based classifiers.
- Fuzzy Chi-RW: This algorithm takes as base algorithm the Chi et al. [21] but adding weights to rules. The algorithm is an adapted version of Wang-Mendel algorithm[22] for classification problems.

In TABLE VI appears the result of comparison with the fuzzy methods mentioned before. In this case, for 10 databases and 6 classifiers, the critical distance is **1.05**. Bonferroni test reveals that there are significant differences in test parameter and that NSLV-F has the best result, being significantly better than GP, Chi and Ishibushi. There are not significant differences with the rest of the algorithms.

VI. CONCLUSIONS AND FUTURE WORK

In this work we have presented a learning algorithm that introduces the concept of feature construction by using functions as a way of creating new attributes. The basic idea is to consider not only the knowledge given by the input variables but also the knowledge that can be extracted from the combination of these input variables. In order to do that we combine the variables by using some previously defined functions. These functions will be managed by means of a structure that will also contain the most promising ones taking into account an information measure. A new model of rule has been also proposed in order to represent this kind of knowledge. In addition, we took as basic algorithm a learning fuzzy rule-based one and we extended it to obtain this new model. Finally, the experimental results show that our proposal gives us the possibility of finding more general rules and also increases the prediction capability of the model. Our purpose is to go on improving the current model in order to consider more functions in the future that could give us better results. Anyway, this is an initial approximation and it will be necessary to go on searching for other functions that allow us to improve the accuracy and efficiency of the process.

***Abstract*—When the Adaboost algorithm is used for extracting fuzzy rules from data, each rule is regarded as a weak learner, and knowledge bases as assimilated to ensembles. In this paper we propose an extension of this framework for obtaining fuzzy rule-based classifiers from imprecise data. In the new approach, the mentioned search of the best rule at each iteration is carried out by a genetic algorithm with a fuzzy fitness function. The instances will be assigned fuzzy weights, however each fuzzy rule will be associated to a crisp number of votes.**

***Index Terms*—Genetic Fuzzy Systems, Low Quality Data, Boosting**

I. Introduction

Boosting algorithms combine different classifiers for obtaining an ensemble that performs better than any of its components [1]. These algorithms repeatedly invoke a learning algorithm to successively generate a committee of simple, inaccurate classifiers. Each time a new simple classifier is added to this ensemble, the examples in the training set are re-weighted so that future classifiers will focus on the most difficult examples, and a voting strength is assigned to the classifier. The number of votes a classifier is given depends on the confidence in its classification accuracy, as measured on the training set.

Fuzzy Rule Based Classification Systems (FRBCS) can also be regarded as ensembles, where each fuzzy rule is matched to one of the mentioned simple classifiers. When an appropriate reasoning scheme is used, it has been shown that the mechanism used for obtaining the output of a FRBCS, given an input value, can be assimilated to a voting process [2], and the voting strength of each simple classifier is the product of the compatibility between the antecedent of the corresponding fuzzy rule and the degree of certainty of its consequent. This interpretation has been used before, and the Adaboost algorithm has been applied to the learning of fuzzy rules from data [3][4][5], in combination with a Genetic Algorithm (GA). The resulting learning algorithm is a Genetic Fuzzy System (GFS) that shares certain properties with Iterative Rule Learning approaches [6]. Furthermore, after the work of Friedman [7], this process has been regarded as a forward stepwise estimation of the statistical parameters defining a logit transform of a Generalized Additive Model, giving rise to the LogitBoost algorithm [7] and its genetic extension for learning FRBCS from data [8]. The use of boosting techniques for learning fuzzy rules from data is therefore a well known technique, whose main virtues are a fast learning and accurate results, but this use is not free from problems. The first drawback of the employment of Adaboost for learning FRBCS is in the use of a voting-based inference, that makes the linguistic interpretation of the Knowledge Base (KB) harder. This problem was addressed in [9], where a new algorithm was proposed for which the degrees of confidence in the consequents of the rules were iteratively adjusted until the results produced by a "winner-takes-all" type of inference were similar to that of voting. Nevertheless, there are other difficulties that are still open. A second issue with the application of Adaboost to the learning of fuzzy rules lies in the requirements imposed to the data, that must be precisely perceived: being based in Generalized Additive Models, Adaboost or Logitboost can cope with random uncertainty, but they are not able to process data when a combination of epistemic and random uncertainties is present [10]. Because of these reasons, this paper contains a new proposal for applying the Adaboost algorithm for learning FRBCS from low quality data [11], including both problems with imprecisely perceived features and problems with a partial lack of knowledge about the class labels attributed to some instances.

The organization of this work is as follows: the following section, briefly introduces the Adaboost algorithm, describes the type of fuzzy classifiers that are boosted and recall a method for boosting descriptive fuzzy rule bases [12]. In Section 3, we propose an extension of this algorithm for interval and fuzzy data. In Section 4 some properties of the proposed algorithms are evaluated on a number of data sets and compared to that of other GFS for low quality data. In Section 5 some concluding remarks and future works are discussed.

II. Adaboost and fuzzy rule based classifiers

At this point we introduce the basic notation employed throughout the paper. Let $\mathbf{X}$ be the feature space, and let $\mathbf{x}$ be a feature vector $\mathbf{x} = (x_1, \ldots, x_n) \in \mathbf{X}$. Let p be the number of classes. The training set is a sample of m classified examples

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

$(\mathbf{x}_i, y_i)$, where $\mathbf{x}_i \in \mathbf{X}$, $1 \leq y_i \leq p$, $1 \leq i \leq m$.

The KB of the FRBCS comprises N rules. The antecedents of the rules are logical combinations of fuzzy logic asserts, whose degrees of truth are modeled by N fuzzy subsets $A^j \in \mathcal{F}(\mathbf{X})$, forming a fuzzy partition $\mathcal{A} = \{A^j\}_{j=1\ldots N}$ of the feature space. A fuzzy rule based classifier is therefore defined by means of a fuzzy relationship defined on $\mathcal{A} \times \{1, \ldots, p\}$. Values of this relationship describe the degrees of compatibility among the fuzzy subsets of the feature space collected in $\mathcal{A}$, and each of the classes. In other words, for every antecedent A^j there are p numbers between 0 and 1 that represent the confidence in the assertion "All elements in the fuzzy set A^j belong to class number k". Values close to 1 indicate "high confidence," and values close to 0 denote "absence of knowledge about the assertion."

In this paper, we will translate the former fuzzy relationship into linguistic statements by combining p terms

$$\text{compatibility}(A^j, c_k) = s_k \quad k = 1, \ldots p,$$

into a single sentence, as follows:

$$\text{if } \mathbf{x} \text{ is } A^j \text{ then truth}(c_1) = s_1^j \text{ and } \cdots \text{ and truth}(c_p) = s_p^j.$$

The antecedents A^j are decomposed in a Cartesian product of fuzzy sets defined over each feature, $A^j = A_1^j \times A_2^j \times \ldots \times A_n^j$, thus the rules are

$$\begin{gathered}\text{if } x_1 \text{ is } A_1^j \text{ and } \ldots \text{ and } x_n \text{ is } A_n^j \\ \text{then truth}(c_1) = s_1^j \text{ and } \cdots \text{ and truth}(c_p) = s_p^j.\end{gathered}$$

An instance $\mathbf{x}$ is assigned to the class

$$\arg\max_{k=1,\ldots,p} \bigvee_{j=1}^{N} A^j(\mathbf{x}) \wedge s_k^j \tag{1}$$

where "$\wedge$" is the product and "$\vee$" is the arithmetic sum, so called "maximum voting scheme" [13].

A. The Adaboost algorithm

Let us define a set $\{g^1, g^2, \ldots, g^N\}$ of simple, but possibly unreliable binary classifiers. Boosting consists in combining these low quality classifiers (so called "weak hypotheses" in the boosting literature) with a voting scheme to generate an overall classifier that performs better than any of its individual constituents alone. It has been shown that a fuzzy rule can be regarded as a particular case of a weak hypothesis, and a fuzzy rule base can be interpreted as a weighted combination of weak hypotheses.

Weak hypotheses take feature values as input and produce both a class number as well as a degree of confidence in the given classification. In two-classes problems, these two outputs are encoded by a single real number, $g^j(\mathbf{x}) \in \mathbf{R}$, whose sign is interpreted as the label of $\mathbf{x}$ and whose absolute value is interpreted as the confidence in the classification. The higher this value the more confidence is given to the classification. AdaBoost is intended to produce a linear threshold of all hypotheses:

$$\text{sign}\left(\sum_{j=1}^{N} \alpha^j g^j(\mathbf{x})\right). \tag{2}$$

Observe that Adaboost can operate with any learning algorithm that generates a confidence rated classifier on a given weighted data set. There are different algorithms for assigning the number of votes to a weak hypothesis, and for adjusting the weights of the examples. For example, in confidence-rated Adaboost [15] the number of votes of the weak hypothesis g^h is given by the value α^h that minimizes the following function:

$$Z(\alpha) = \sum_{i=1}^{m} w_i \exp(-\alpha y_i g^h(\mathbf{x}_i)) \tag{3}$$

and the weights w_i of the examples are updated according to

$$w_i \leftarrow w_i \exp(-\alpha^h y_i g^h(\mathbf{x}_i))/v \tag{4}$$

where v is a normalization factor such that $\sum w_i = 1$. There are analytical approximations and heuristics that may replace this formula in specific problems.

B. Boosting fuzzy rules in binary problems

For the sake of simplicity, we restrict the discussion for the time being to two-classes problems $y_i \in \{-1, 1\}$. The space of weak hypotheses is, in this case, the product space of the fuzzy partition and the class labels, $\mathcal{A} \times \{-1, 1\}$. Given the results in the preceding subsection, the fitness of a fuzzy rule is

$$\text{fitness}(\text{ if } \mathbf{x} \text{ is } A^j \text{ then } c^j) = \sum_i w_i \exp(-y_i c^j A^j(\mathbf{x}_i)) \tag{5}$$

and the number of votes of this rule is the value of α minimizing the following expression [14]:

$$Z(\alpha) = \sum_i w_i \exp(-\alpha y_i A^j(\mathbf{x}_i)). \tag{6}$$

$Z(\alpha)$ is convex except for the case in which the rule antecedent does not cover any negative examples; for avoiding this and other numerical instabilities, a term that penalizes large values of α is added

$$Z(\alpha) = \sum_i w_i \exp(-\alpha y_i A^j(\mathbf{x}_i)) + \sum_{i:A^j(\mathbf{x}_i)=0} w_i \exp(|\alpha\epsilon|) \tag{7}$$

where ϵ is determined by hand.

The weights w_i of all the instances are recalculated each time a new weak learner is added to the ensemble. The weights of correctly classified instances are lowered, and these of misclassified examples are increased, using the expression that follows:

$$w_i \leftarrow \frac{w_i \exp(-\alpha^j y_i A^j(\mathbf{x}_i))}{\sum_i w_i \exp(-\alpha^j y_i A^j(\mathbf{x}_i))} \tag{8}$$

Notice, that an instance is never completely removed unless $\alpha^j \to \infty$, which is prevented by the penalty term in eq. (7).

C. Boosting fuzzy rules in multiclass problems

We have mentioned that the space of weak hypothesis in two-classes problems is $\mathcal{A} \times \{c_1, c_2\}$. That is to say, the j-th iteration of the learning algorithm searches for a pair (A^j, c^j), which are parameters of the rule

$$\text{if } \mathbf{x} \text{ is } A^j \text{ then } c^j, \tag{9}$$

for which the fitness value is maximum. This value was defined in Eq. (5), which we rewrite here as follows:

$$\begin{aligned}\text{fitness}(\text{if } \mathbf{x} \text{ is } A^j \text{ then } c^j) = \\ \sum_{i:y_i=c^j} w_i \exp(A^j(\mathbf{x}_i)) \\ +\sum_{i:y_i\neq c^j} w_i \exp(-A^j(\mathbf{x}_i)).\end{aligned} \tag{10}$$

Once the pair (A^j, c^j) maximizing this fitness function is found, the rule is assigned a number of votes s^j (see Eq. (6)), thus its final linguistic writing is:

$$\text{if } \mathbf{x} \text{ is } A^j \text{ then truth}(c^j) = s^j. \tag{11}$$

For extending this scheme to multiclass problems [3] the initial problem is transformed into p binary problems, where the instances of the k-th binary problem are re-labelled:

$$y_i^{(p)} = \begin{cases} 1 & y_i = p \\ -1 & y_i \neq p. \end{cases} \tag{12}$$

The solution of the k-th problem comprises fuzzy rules with this form:

$$\begin{aligned}&\text{if } x_1 \text{ is } A_1^j \text{ and } \ldots \text{ and } x_n \text{ is } A_n^j \\ &\text{then tr(class} = c_k) = s_1^{jk} \text{ and tr(class} \neq c_k) = s_{-1}^{jk}.\end{aligned} \tag{13}$$

These rules can be replaced by their equivalent p-classes consequents, by substituting the "class $\neq c_k$" label with the corresponding set of class labels of the multi-class problem, i.e.

$$\begin{aligned}&\text{if } x_1 \text{ is } A_1^j \text{ and } \ldots \text{ and } x_n \text{ is } A_n^j \text{ then} \\ &\text{tr}(c_1, \ldots, c_k, \ldots, c_p) = (s_{-1}^{jk}, \ldots, s_{-1}^{jk}, s_1^{jk}, s_{-1}^{jk}, \ldots, s_{-1}^{jk}).\end{aligned} \tag{14}$$

III. An extension of the Adaboost algorithm to learn fuzzy rule based classifiers from low quality data

We will represent the epistemic uncertainty in the data by means a nested set of confidence intervals, that provide us with the same information about the unknown value as a possibility distribution for which the α-cuts of its associated fuzzy membership function are confidence intervals with level $1-\alpha$, as explained in [11]. Representing the imprecision by means of sets of possible values implies that the output of the FRBCS might not be completely determined and generally speaking, it will be a fuzzy subset of the class labels. From the foregoing it can be deduced that the fitness of a rule should also be a set, however extending Eq. 5 is not trivial. Different decisions can be taken that influence the accuracy of the method and also its computational cost.

Let us use an illustrative example for introducing the problems that arise when we regard the computation of the output of an FRBCS for imprecise data as a voting-based committee. Suppose that we are given the KB that follows:

if $x < 1.5$ then truth(class is A)= 0.4 and truth(class is B)= 0.8
if $x \in [1, 2]$ then truth(class is A)= 0.8 and truth(class is B)= 0.1
if $x > 2$ then truth(class is A)= 0.2 and truth(class is B)= 0.6

and the input is

$x \in [1.2, 1.8]$.

If we determine first the set of compatibilities of each rule with the imprecise example and then add the sets of votes, the situation is as follows:

Rule	Votes for class 'A'	Votes for class 'B'
Rule # 1:	{0,0.4}	{0,0.8}
Rule # 2:	0.8	0.1
Rule # 3:	0	0
Total	{0.8, 1.2}	{0.1, 0.9}

In words, the output of the classifier is the set of classes {A,B}, because we cannot state that any element of {0.8, 1.2} is higher than any element of {0.1, 0.9} neither the opposite. However, this course of reasoning will not always produce the most specific answer. Observe that, if the actual value of x is between 1.2 and 1.5, rules 1 and 2 are true, thus the number of votes of classes 'A' and 'B' are 1.2 and 0.9. If the value of x is between 1.5 and 1.8, the number of votes are 0.8 and 0.1. In either case, the object should have been assigned the class 'A'.

With this example we have shown that regarding a KB as an ensemble is not immediate when the data are imprecise: the most specific output of the classifier, when the input is a crisp set, is the set of classes

$$\text{class}(\overline{X}) = \{\arg \max_{k=1\ldots p} \sum_{j=1}^{N} A^j(x) s_k^j \mid x \in \overline{X}\}. \tag{15}$$

However, if we regard the KB as an ensemble of weak classifiers, where each one of them is assigned a set-valued, number of votes, the output is the set

$$\text{bclass}(\overline{X}) = \operatorname*{notdom}_{k=1\ldots p} \left\{ \bigoplus_{j=1}^{N} s_k^j \odot \{A^j(x) \mid x \in \overline{X}\} \right\} \tag{16}$$

where the operator "notdom" means

$$\operatorname*{notdom}_{k=1\ldots p}\{V_k\} = \{q \mid V_q \preceq V_r, r = 1, \ldots, p\} \tag{17}$$

and the precedence between set-valued votes is

$$A \prec B \iff a < b \text{ for all } a \in A, b \in B \tag{18}$$

$$A \parallel B = \neg((A \prec B) \vee (B \prec A)) \tag{19}$$

$$A \preceq B = (A \prec B) \vee (A \parallel B). \tag{20}$$

Observe that

$$\text{class}(\overline{X}) \subseteq \text{bclass}(\overline{X}) \tag{21}$$

but the equality does not hold, in general.

If the data is fuzzy, the situation is similar. The most specific output of the classifier is the fuzzy set whose membership function is as follows:

$$\begin{aligned}\text{class}(\widetilde{X})(t) = \quad &\max\{\alpha \mid \\ &t = \arg\max_{k=1\ldots p} \textstyle\sum_{j=1}^{N} A^j(x) s_k^j \\ &\text{and } \widetilde{X}(x) \geq \alpha\}.\end{aligned} \tag{22}$$

In case we regard the KB as an ensemble of weak classifiers, where each one of them is assigned a fuzzy number of votes, the output is in turn the fuzzy set

$$\text{bclass}(\widetilde{X})(t) = \max\{\alpha \mid t \in \text{bclass}([\widetilde{X}]_\alpha)\}. \tag{23}$$

Summarizing, when the data is imprecise, the most voted option of the ensemble is not known but our information about it is a normal fuzzy set. If the KB is furthermore regarded as an ensemble, thus the number of votes of each rule are independently computed, the fuzzy set describing the result of the classification is a superset of the result given by Eq. (22). This loss of specificity in the view of a KB as an ensemble has to be taken into account in the definition of the fitness function.

A. Fitness of a rule with interval or fuzzy data

We propose to generalize the fitness function in Eq. (10) to interval-valued data with the set-valued function that follows, which is based on the bounds given in Eq. (16):

$$\begin{aligned}&\overline{\text{fitness}}_{\{(\overline{\mathbf{x}}_i,\overline{y}_i)\}}(\text{if } \mathbf{x} \text{ is } A^j \text{ then } c^j) = \\ &\quad \oplus_{i:\overline{y}_i=c^j} \overline{w}_i \odot \{\exp(A^j(x)) \mid x \in \overline{\mathbf{x}}_i\} \oplus \\ &\quad \oplus_{i:\overline{y}_i\cap c^j=\emptyset} \overline{w}_i \odot \{\exp(-A^j(x)) \mid x \in \overline{\mathbf{x}}_i\} \oplus \\ &\oplus_{i:\overline{y}_i\neq c^j,\, \overline{y}_i\cap \overline{c}^j\neq\emptyset} \overline{w}_i \odot \{\exp(\{A^j(x), -A^j(x)\}) \mid x \in \overline{\mathbf{x}}_i\}\end{aligned} \tag{24}$$

Observe that we allow the use of set valued weights $\overline{w}_i$. In turn, applying the extension principle, the same function can be extended to fuzzy data. The membership function of the fuzzy fitness of a rule is

$$\begin{aligned}&\widetilde{\text{fitness}}_{\{(\widetilde{\mathbf{x}}_i,\widetilde{y}_i)\}}(\text{if } \mathbf{x} \text{ is } A^j \text{ then } c^j)(t) = \\ &\max\{\alpha \mid t \in \overline{\text{fitness}}_{\{([\widetilde{\mathbf{x}}_i]_\alpha,[\widetilde{y}_i]_\alpha)\}}(\text{if } \mathbf{x} \text{ is } A^j \text{ then } c^j)\},\end{aligned} \tag{25}$$

where t is a real number.

B. Issues with the fitness of a rule in multiclass problems

When extending the procedure seen in Section II-C for solving multi-class problems, the intermediate binary sets of data might contain unlabeled instances. Let us explain this with an illustrative example.

Consider the imprecise dataset that follows, comprising three crisp examples with set-valued labels. It is remarked that, in this context, an instance labelled "$\{c_1, c_2\}$" means that we are sure that the true class of the object is not c_3, but this knowledge cannot be further precised:

$(x_1, y_1) = (1, \{c_1, c_2\})$
$(x_2, y_3) = (2, \{c_1, c_3\})$
$(x_3, y_3) = (3, \{c_2, c_3\})$.

Following the procedure described in Section II-C, this dataset will be decomposed in three binary problems. Let us generalize that procedure to imprecise instances by using the most specific set of labels that is compatible with the data, as follows:

Problem # 1
$(1, \{1, -1\})$
$(2, \{1, -1\})$
$(3, -1)$

Problem # 2
$(1, \{1, -1\})$
$(2, -1)$
$(3, \{1, -1\})$

Problem # 3
$(1, -1)$
$(2, \{1, -1\})$
$(3, \{1, -1\})$

Each one of these three datasets has two elements whose classes are $\{-1, 1\}$ and therefore the fitness does not depend on how they are labelled: for instance, for Problem # 1, no matter which rule between

$$\text{if x=1 then t(class = 1)=}s_1^{1,1}$$

and

$$\text{if x=1 then t(class} \neq \text{ 1)=}s_{-1}^{1,1}$$

is chosen, the same fitness is obtained (see Eq. 24).

In this case, a learning algorithm which is only guided by the optimization of the fitness function can produce any KBs formed by selecting one rule from each line that follows. We have grayed out the rules that do not appear in an arbitrary selection, whose merging will be studied later.

Problem # 1
if x=1 then t(class = 1)=$s_1^{1,1}$ $\approx$ if x=1 then t(class $\neq$ 1)=$s_{-1}^{1,1}$
if x=2 then t(class = 1)=$s_1^{2,1}$ $\approx$ if x=2 then t(class $\neq$ 1)=$s_{-1}^{2,1}$
if x=3 then t(class $\neq$ 1)=$s_{-1}^{3,1}$

Problem # 2
if x=1 then t(class = 2)=$s_1^{1,2}$ $\approx$ if x=1 then t(class $\neq$ 2)=$s_{-1}^{1,2}$
if x=2 then t(class $\neq$ 2)=$s_{-1}^{2,2}$
if x=3 then t(class = 2)=$s_1^{3,2}$ $\approx$ if x=3 then t(class $\neq$ 2)=$s_{-1}^{3,2}$

Problem # 3
if x=1 then t(class $\neq$ 3)=$s_{-1}^{1,3}$
if x=2 then t(class = 3)=$s_1^{2,3}$ $\approx$ if x=2 then t(class $\neq$ 3)=$s_{-1}^{2,3}$
if x=3 then t(class = 3)=$s_1^{3,3}$ $\approx$ if x=3 then t(class $\neq$ 3)=$s_{-1}^{3,3}$

The merging of the selected rules is

if x=1 then t(1,2,3)=($s_1^{1,1}$+$s_{-1}^{1,3}$,$s_1^{1,2}$+$s_{-1}^{1,3}$,0)
if x=2 then t(1,2,3)=($s_1^{2,1}$+$s_{-1}^{2,2}$,0,$s_{-1}^{2,2}$+$s_1^{2,3}$)
if x=3 then t(1,2,3)=($s_{-1}^{3,3}$,$s_{-1}^{3,1}$+$s_1^{3,2}$+$s_{-1}^{3,3}$,$s_{-1}^{3,1}$).

Observe that the result of this arbitrary selection has assigned a non-null degree confidence to the class c_1 in the third rule, which obviously is not the best possible KB for this problem. We realize that there are other selections that achieve the objective, but our point is showing that there is a chance that the committee does not contain the proper rules unless the unlabeled instances in the intermediate problems are removed, as follows:

Problem # 1
if x=3 then t(class $\neq$ 1)=$s_{-1}^{3,1}$

Problem # 2
if x=2 then t(class $\neq$ 2)=$s_{-1}^{2,2}$

Problem # 3
if x=1 then t(class $\neq$ 3)=$s_{-1}^{1,3}$

whose merging is:

if x=1 then t(1,2,3)=($s_{-1}^{1,3}$,$s_{-1}^{1,3}$,0)
if x=2 then t(1,2,3)=($s_{-1}^{2,2}$,0,$s_{-1}^{2,2}$)
if x=3 then t(1,2,3)=(0,$s_{-1}^{3,1}$,$s_{-1}^{3,1}$).

Notwithstanding, if the unlabeled instances are removed then additional problems with the decomposition in binary problems will appear. Since the pruned individual problems do not longer contain information about where the removed instances were located, it may happen that the corresponding areas of the feature space are covered at the same time by different rules that negatively interact between themselves. This problem also happens with Iterative Rule Learning (IRL) algorithms [12], where it is solved by a simplification stage that it is not a part of the boosting algorithm. Therefore, we have decided to simplify the search and not to generate the intermediate datasets when working with multiclass problems, and propose instead to define the fitness of a rule with multiple consequents as a vector of values, and to define a lexicographic ordering between them. The fitness function we propose is as follows:

$$\begin{aligned}
&\overline{\text{fitness}}_{\{(\overline{\mathbf{x}}_i,\overline{y}_i)\}}(\text{if } \mathbf{x} \text{ is } A^j \text{ then } (c_1,\ldots,c_p)) = \\
&\Big(\textstyle\bigoplus_{\overline{y_i}=c_1} \overline{w}_i \odot \exp(\{A^j(x) \mid x \in \overline{\mathbf{x}}_i\}) \oplus \\
&\textstyle\bigoplus_{c_1 \in \overline{y}_i, c_1 \neq \overline{y}_i} \overline{w}_i \odot \\
&\qquad \exp(\{-A^j(x), A^j(x) \mid x \in \overline{\mathbf{x}}_i\}) \oplus \\
&\textstyle\bigoplus_{c_1 \notin \overline{y}_i} \overline{w}_i \odot \exp(\{-A^j(x) \mid x \in \overline{\mathbf{x}}_i\}), \\
&\quad \vdots \\
&\textstyle\bigoplus_{\overline{y_i}=c_p} \overline{w}_i \odot \exp(\{A^j(x) \mid x \in \overline{\mathbf{x}}_i\}) \oplus \\
&\textstyle\bigoplus_{c_p \in \overline{y}_i, c_p \neq \overline{y}_i} \overline{w}_i \odot \\
&\qquad \exp(\{-A^j(x), A^j(x) \mid x \in \overline{\mathbf{x}}_i\}) \oplus \\
&\textstyle\bigoplus_{c_p \notin \overline{y}_i} \overline{w}_i \odot \exp(\{-A^j(x) \mid x \in \overline{\mathbf{x}}_i\})\Big).
\end{aligned} \tag{26}$$

In turn, the lexicographic precedence between two crisp fitness vectors $A = (a_1, \ldots, a_p)$ and $B = (b_1, \ldots, b_p)$ is as follows: let us first define two permutations of the set $\{1, \ldots, p\}$, denoted $(k_1^a, \ldots, k_p^a)$ and $(k_1^b, \ldots, k_p^b)$, such that $a_{k_1^a} \geq \ldots \geq a_{k_p^a}$ and $b_{k_1^b} \geq \ldots \geq b_{k_p^b}$. Then,

$$\begin{aligned}
&A \prec B \iff \exists m \in \{1,\ldots,p\} \mid \\
&\quad (a_{k_q^a} = b_{k_q^b})\ \forall q \in \{1,\ldots,m-1\} \wedge (a_{k_m^a} > b_{k_m^b}).
\end{aligned} \tag{27}$$

The extension of both the fitness function and the lexicographic ordering to fuzzy values results from applying the extension principle and from replacing the comparisons between real numbers with a suitable fuzzy ranking. The expression of the fitness function, in the general case, is as follows:

$$\begin{aligned}
&\widetilde{\text{fitness}}_{\{(\widetilde{\mathbf{x}}_i,\widetilde{y}_i)\}}(\text{if } \mathbf{x} \text{ is } A^j \text{ then } (c_1,\ldots,c_p))(t) = \\
&\quad \overline{\max}\{\alpha \mid t \in \\
&\quad \overline{\text{fitness}}_{\{([\widetilde{\mathbf{x}}_i]_\alpha,[\widetilde{y}_i]_\alpha)\}}(\text{if } \mathbf{x} \text{ is } A^j \text{ then } (c_1,\ldots,c_p))\},
\end{aligned} \tag{28}$$

where t denotes a p-dimensional vector of real values.

C. Assignment of weights to the consequent part

The extension of Eq. (7) to set-valued data and multiclass problems consists in assigning to the k-th class in the consequent of the rule a confidence equal to the value of α_k minimizing the set-valued function Z^k defined as follows:

$$\begin{aligned}
&\overline{Z}^k_{\{(\overline{\mathbf{x}}_i,\overline{y}_i)\}}(\alpha) = \\
&\quad \{ \textstyle\oplus_{i:c_k=\overline{y}_i} \overline{w}_i \odot \exp(-\alpha A^j(x)) \oplus \\
&\quad \textstyle\oplus_{i:c_k\notin\overline{y}_i} \overline{w}_i \odot \exp(\alpha A^j(x)) \oplus \\
&\quad \textstyle\oplus_{i:c_k\neq\overline{y}_i,\, c_k\in\overline{y}_i} \overline{w}_i \odot \exp(\{-\alpha A^j(x), \alpha A^j(x)\}) \\
&\quad \mid x \in \overline{\mathbf{x}}_i\}.
\end{aligned} \tag{29}$$

A numerical stabilization term

$$\bigoplus_{i:A^j(x)=0\ \forall x\in\overline{\mathbf{x}}_i} \overline{w}_i \exp(|\alpha\epsilon|) \tag{30}$$

with a suitable value of ϵ can also be added, if needed.

The extension of Eq. (29) to fuzzy data is as follows:

$$\widetilde{Z}^k_{\{(\widetilde{\mathbf{x}}_i,\widetilde{y}_i)\}}(\gamma)(t) = \max\{\alpha \mid t \in \overline{Z}^k_{\{([\widetilde{\mathbf{x}}_i]_\alpha,[\widetilde{y}_i]_\alpha)\}}(\gamma)\}. \tag{31}$$

In both the set-valued and fuzzy cases, the values of α_k can be found with a greedy algorithm that uses a precedence operator between fuzzy sets. However, this optimization is not as efficient as the Brent search used in the crisp version of the algorithm. Since the optimization must be launched each time a fitness value is computed, in this paper we have decided to approximate the value of α_k by the center of the set

$$\overline{\alpha}_k = \log(1 - E_k) - \log(E_k) \tag{32}$$

where E_k is a normalized weighted sum of the compatibilities of the antecedent of the j-th rule with the elements of the dataset whose class does not match the k-th term in the consequent:

$$\begin{aligned}
E_k = K \odot \Big(&\textstyle\bigoplus_{\{i:c_k\notin\overline{y}_i\}} \overline{w}_i \odot \{A^j(x) \mid x \in \overline{\mathbf{x}}_i\} \oplus \\
&\bigoplus_{\{i:c_k\neq\overline{y}_i \wedge c_k\in\overline{y}_i\}} \overline{w}_i \odot \{\{0, A^j(x)\} \mid x \in \overline{\mathbf{x}}_i\}\Big)
\end{aligned} \tag{33}$$

The normalization factor K is the inverse of the upper bound of the normalized weighted sum of the compatibilities of the antecedent of the j-th rule with all the elements of the dataset:

$$K = (\sum_i \max\{\overline{w}_i\} \cdot \max\{A^j(x) \mid x \in \overline{\mathbf{x}}_i\})^{-1}. \tag{34}$$

D. Assignment of weights to the examples

After the j-th rule is added, the weights of the instances are recomputed as follows:

$$\overline{w}'_i = \bigcup_{x\in\overline{\mathbf{x}}_i} w'_i(x) \tag{35}$$

where $w'_i(x) =$

$$K' \odot \overline{w}_i \odot \begin{cases} c_k = \overline{y}_i & \exp(-\alpha_k A^j(x)) \\ c_k \notin \overline{y}_i & \exp(\alpha_k A^j(x)) \\ \text{else} & \exp(\alpha_k A^j(x) \odot \{-1, 1\}) \end{cases} \tag{36}$$

and K' is a crisp normalization factor such that $\max \oplus_i \overline{w}'_i = 1$.

E. Some details of the genetic algorithm

Adaboost depends on a procedure that fits a weak learner to the weighted training set. If the vector-valued fitness we have proposed in this paper is to be used, learning a weak classifier reduces to finding the antecedent A^j that optimizes the fitness function explained in section III-B, with respect to the lexicographic ordering defined in the same section. Since all possible values of the fitness can be compared between themselves, implementing this criterion amounts to redefining the meaning of the operator "less than" ($<$) in an ordinary GA; there is no need to use multicriteria techniques [16], thus we have used instead a standard generational scheme with a tournament-based selection.

Details of this algorithm can be found in [3]. Let us recall for the convenience of the reader the only part in this GA besides the fitness function (whose explanation has occupied most of this paper) which departs from a standard implementation: the coding of the fuzzy memberships.

Descriptive fuzzy rules are coded by an integer, which is the index j of the antecedent A^j in $\mathcal{A}$. This integer is encoded in turn, by a sequence of n numbers that refer to labels of the linguistic terms in the underlying fuzzy partitions. In addition to linguistic labels describing subsets of the domain of each variable, such as "LOW" and "HIGH", each linguistic variable includes a wild card label "ANY VALUE", with a membership degree of 1 across the entire universe of discourse.

The linguistic expression of a fuzzy rule that contains a wild card can be simplified, as illustrated by the following example: assume a classification problem with two features (weight,height), where height=$\{$low,high$\}$ and weight=$\{$light, heavy$\}$. The two linguistic variables are extended with a wild card term such that height=$\{$low, high, anyvalue$\}$ and weight=$\{$light, heavy, anyvalue$\}$. If the rule antecedent is described by "anyvalue$\times$heavy", the linguistic expression

if height is anyvalue and weight is heavy then t(1,2)=(0.4,0.8)

is simplified to

if weight is heavy then t(1,2)=(0.4,0.8).

This property of the genetic representation allows it to code general rules that only refer to a subset of all possible features, thus enabling the boosting algorithm to take advantage of feature selection.

The last rule is coded by the sequence (3,2), as "anyvalue" is the third linguistic term in the first linguistic variable, and "heavy" is the second term in the second linguistic variable. Observe that the class labels in the rule consequent are not part of the genetic codification, neither the confidences degrees in the consequents are.

IV. Numerical results

In this section we include the first results of the implementation of Adaboost for learning fuzzy rules from low quality data, applied to the imprecise datasets "Diagnosis of the Dyslexic" [17] and "Athletics at Oviedo University" [18]. We include first a brief description of these datasets and then we discuss the compared results of the application of the new method to these problems.

A. Description of the datasets and experimental settings

The datasets "Diagnosis of the Dyslexic" and "Athletics at the Oviedo University", have been introduced in [19] and [20], respectively, and are available in the data set repository of keel-dataset (http://www.keel.es/datasets.php) [21], [22]. The names, the number of examples (Ex.), number of attributes (Atts.), the classes (Classes) and the fraction of patterns of each class (%Classes) for each dataset are displayed in Table I. Observe that the proportions of the different patterns are intervals, because the class labels of some instances are imprecise.

TABLE I
SUMMARY DESCRIPTIONS OF DATASETS WITH META-INFORMATION.

Dataset	Ex.	Atts.	Classes	%Classes
B200mlI	19	4	2	([0.47,0.73],[0.26,0.52])
B200mlP	19	5	2	([0.47,0.73],[0.26,0.52])
Long	25	4	2	([36,64],[36,64])
BLong	25	4	2	([36,64],[36,64])
100mlI	52	4	2	([0.44,0.63],[0.36,0.55])
100mlP	52	4	2	([0.44,0.63],[0.36,0.55])
B100mlI	52	4	2	([0.44,0.63],[0.36,0.55])
B100mlP	52	4	2	([0.44,0.63],[0.36,0.55])
Dyslexic-12-12	65	12	3	([0.32,0.43],[0.32,0.52], [0.12,0.30])
Dyslexic-11-01	65	11	3	([0.43,0.53],[0.23,0.35], [0.12,0.30])
Dyslexic-11-12	65	11	3	([0.32,0.43],[0.32,0.52], [0.12,0.30])

All the experiments have been run with a population size of 100, probabilities of crossover and mutation of 0.9 and 0.1, respectively, and limited to 150 generations. The fuzzy partitions of the labels are uniform and their size is 5. All the imprecise experiments were repeated 100 times with bootstrapped resamples of the training set. Each partition of test contains 1000 tests.

B. Differences in accuracy

The compared accuracies between the proposed algorithm (Boosting_LQD) and other GFS capable of extracting rules from low quality data (GFS [23] and MR_GFS [24]) data are shown in Table II. The results are expressed by means of intervals, that are our best bounds about the mean values of the test error. These intervals are defined by the expression

$$\overline{\text{error}} = \left\{ \frac{1}{m} \sum_{i=1}^{m} e_i \mid e_i \in \overline{e}_i \right\} \tag{37}$$

where

$$\overline{e}_i = \begin{cases} 0 & \text{bclass}(\overline{x}_i) = \overline{y}_i \text{ and } \#(\overline{y}_i) = 1, \\ 1 & \text{bclass}(\overline{x}_i) \cap \overline{y}_i = \emptyset, \\ \{0,1\} & \text{else.} \end{cases} \tag{38}$$

The method "Boosting_LQD" shows a better performance than the remaining classifiers, in both binary problems (Athletics datasets) and multiclass (Dyslexic datasets). Observe that MR_GFS could not be applied to the multiclass datasets in this paper because a suitable matrix of costs was not given for

TABLE II
BEHAVIOUR OF "GFS", "MR_GFS" AND "BOOSTING_LQD" IN SEVERAL DATASETS OF ATHLETICS AND DYSLEXIA.

Dataset	GFS	MR_GFS	Boosting_LQD
100mlI	[0.176,0.378]	[0.178,0.380]	[0.170,0.376]
100mlP	[0.176,0.360]	[0.188,0.367]	[0.180,0.358]
Long	[0.321,0.590]	[0.288,0.557]	[0.231,0.499]
BLong	[0.326,0.625]	[0.286,0.586]	[0.219,0.519]
B100mlI	[0.172,0.369]	[0.188,0.385]	[0.158,0.356]
B100mlP	[0.160,0.349]	[0.161,0.350]	[0.161,0.350]
B200mlI	[0.232,0.473]	[0.178,0.418]	[0.171,0.415]
B200mlP	[0.262,0.480]	[0.215,0.433]	[0.188,0.406]
Athletics mean	[0.228,0.453]	[0.210,0.434]	[0.184,0.409]
Dyslexic-12-12	[0.386,0.557]	N/A	[0.376,0.530]
Dyslexic-11-01	[0.445,0.573]	N/A	[0.447,0.567]
Dyslexic-11-12	[0.528,0.690]	N/A	[0.458,0.595]
Dyslexic mean	[0.453,0.606]	N/A	[0.427,0.564]
Global mean	[0.340,0.529]	N/A	[0.305,0.486]

these datasets. The good behavior of the algorithm in the binary problems "Long", "BLong", "B200mlI" and "B200mlP" was remarkable, as shown in the graphs of the dispersion of the results of the 100 bootstrap tests, that have been plotted in Figures 1 to 3. In these Figures, the horizontal coordinate measures the fraction of errors of the boosting algorithm, and the vertical coordinate measures the same parameter in the counterpart algorithm. Each filled circle represents a case where the boosting algorithm was the best choice, and the squares mean the opposite result. A blank circle or square means a tie (or a difference with is not significant) between both algorithms. Those figures where there is a high density of filled circles in the upper left part signal cases where the dispersion of the results is compatible with a statistically significant improvement of the bound, and those cases where the cloud is near the diagonal or in the lower, right part display situations where the differences, if exist, are not significant.

In multiclass problems there is a substantial improvement in the datasets "Dyslexic-11-12" (Figure 4) and "Dyslexic-12-12" and a slight improvement in "Dyslexic-11-01" (Figure 5). By comparing the results obtained by the boosting algorithm in "Dyslexic-12-12" and "Dyslexic-11-12" we detect that the removal of the imprecision in the input values (dataset "Dyslexic-11-12") indeed lowers the performance of the algorithm, supporting a result already found in [17]. Moreover, the boosting algorithm show us that the imprecise outputs of that dataset are significant for determining the weights of the instances and the confidences in the consequents.

V. CONCLUDING REMARKS

In this paper we have proposed a new extension of the Adaboost algorithm for learning fuzzy rule based classifiers from interval-valued or fuzzy data. Fuzzy rules were regarded as weak learners and knowledge bases as ensembles. The number of votes of a weak learner was identified with the degree of confidence of its corresponding consequent. Both the objective function of the Adaboost algorithm and the weights of the instances were assigned interval or fuzzy values, however the number of votes each weak learning is assigned

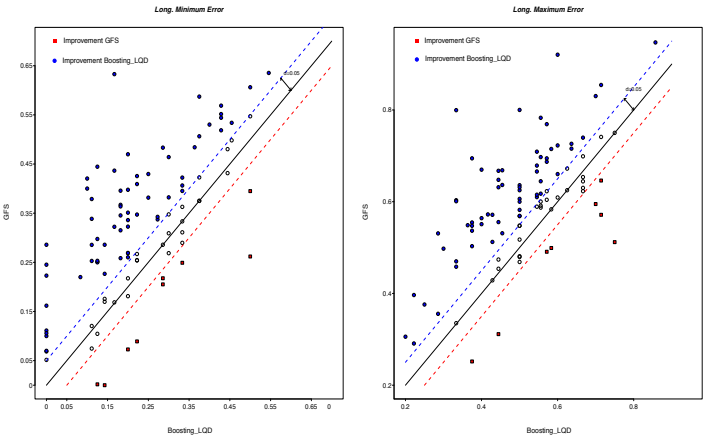

Fig. 1. Behaviour of "GFS" and "Boosting_LQD" respect to the dataset Long. **Left figure:** Lower bounds. **Right figure:** Upper bounds.

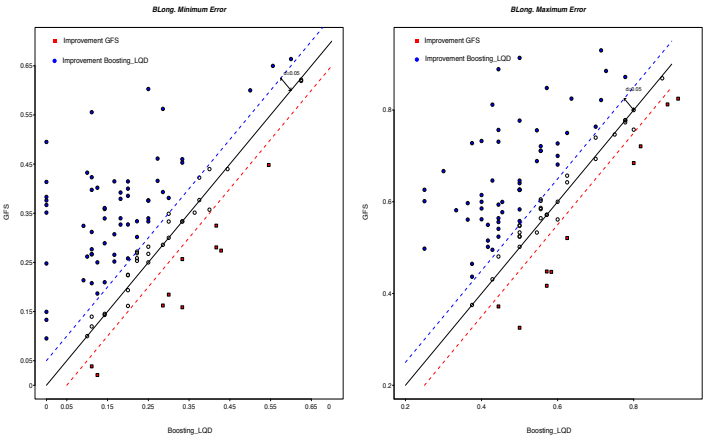

Fig. 2. Behaviour of "GFS" and "Boosting_LQD" respect to the dataset BLong. **Left figure:** Lower bounds. **Right figure:** Upper bounds.

has been designed to be a crisp number thus the classifier does not introduce uncertainty of its own.

The results of the new algorithm have been compared to that of previous genetic algorithms for low quality data. The results prove that this technique is fast, its accuracy is competitive and the number of rules in the knowledge base is not higher than that of the alternatives. On the other hand, it uses a voting-based inference, whose linguistic quality is not the best, and the performance gain is not highly relevant for multiclass problems.

***Abstract*—Fuzzy modeling is one of the most known and used techniques in different areas to emulate the behavior of systems and processes. In most cases, as in data-driven fuzzy modeling, these fuzzy models reach a high performance from the point of view of accuracy, but from other points of view, such as complexity or interpretability, the models can present a poor performance.**

Several approaches are found in the specialized literature to reduce the complexity and improve the interpretability of the fuzzy models. Here, a post-processing approach is taken into account via the definition of the rules selection criterion that aims to choose the most relevant rules according to the well-known accuracy-interpretability trade-off. This criterion is based on Orthogonal Transformations, here the QRP transformation is taking into consideration, and its parameters are tuned genetically. The main objective is to check the true significance, drawbacks and advantages the firing matrix of the rules, that is the foundation of the most usual approaches based on orthogonal transformations for the complexity reduction of the fuzzy models.

A neuro-fuzzy system, FasArt (Fuzzy Adaptive System ART based), and several case studies, data sets from the KEEL Project Repository, are used to tune and check this approach. This neuro-fuzzy system generates Mamdani fuzzy rule based systems (FRBSs), each with its own particularities and complexities from the point of view of fuzzy sets and rule generation. NSGA-II is the MOEA tool used to tune the criterion parameters based on accuracy-interpretability ideas.

***Index Terms*—Fuzzy Systems, Interpretability, Accuracy, Rule Selection, Orthogonal Transformations, Genetic Algorithm**

I. Introduction

Fuzzy modeling is one the most known approaches for a wide range of problems. Data-driven rule based fuzzy models have been used in several and very different scientific and technical areas [1], [2], [3], [4], [5].

In general, the fuzzy models taken into consideration in real world applications have been data-driven and rule based fuzzy models due to their advantages: easy use and performance. This performance has usually been evaluated on the basis of the accuracy of the models, thus minimizing the error between the real output an the estimated output generated by the fuzzy models. But other aspects have not been taken into consideration: complexity, interpretability, etc. Some of them are base principles of fuzzy logic but these fuzzy models used them as simple mathematical tools, losing their original fuzzy meaning.

Complexity is a very usual index or measure, and it is a problem in data-driven rule based fuzzy models, so the reduction of this complexity permits important aspects of the fuzzy models to be improved, gaining a better performance for these models. The question is the way in which this complexity reduction must be carried out [6], [7], [8], [9], [10], [11].

Here, the complexity reduction is carried out based on Orthogonal Transformations and accuracy-interpretability trade-off, as this approach has traditionally been focused in most works [12]. The goal of this work is a postprocessing approach to simplify a rule-based fuzzy model based on a simple $Criterion\ of\ selection$ that is tuned by a genetic approach, and, in this way, checks the possibilities and drawbacks of this type of approach.

The paper is organized as follows: first, in Section II, a brief description of alternative points of view about fuzzy modeling, interpretability and accuracy are given. Also in this section, a brief description of orthogonal transformation and, specially, QR decomposition with column pivoting - QRP, are given, and finally, several complexity and interpretability measures are proposed. In Section III, a $Criterion$ to select the best rules is described. In Section IV the methodology used in this work is described. Some experimental studies are carried out and the main results obtained are discussed in Section V. Finally, in Section VI, the most interesting conclusions obtained from this work are set out.

II. Fuzzy Modeling: Accuracy vs.Interpretability

Initially, two well known modeling approaches to generate fuzzy rules are described in the technical and scientific literature [13], [14], [15]:

1) *Precise Fuzzy Modeling*, whose main goal is to obtain as much accuracy as possible. In general, the models generated have a good accuracy but a low level of interpretability. This modeling is popular with data-driven knowledge but expert knowledge is also considered.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

2) *Linguistic Fuzzy Modeling*, these models have a good level of interpretability but poor accuracy. Here, knowledge from experts and from data guide the modeling process.

Both approaches have their own drawbacks and advantages, but there are several ways to deal with the generation of fuzzy systems whose performance includes an adequate accuracy-interpretability trade-off:

- Algorithms take into account the idea of accuracy-interpretability during the generation of the fuzzy system. i.e genetic fuzzy systems [14], [16].
- Orthogonal transformations where the interpretability is improved by complexity reduction rules [12], [17], [18], [19].

The orthogonal transformations, used traditionally, permit relevant simplifications, but the loss of accuracy is also very high. In most of the usual works about this topic and approach, the accuracy-interpretability is not truly involved, and, in addition, the experimental work is not sufficient to reach relevant conclusions.

These orthogonal transformations are used for rule selection/reduction in fuzzy modeling in two approaches [12]: the range-revealing approach (Singular Value Decomposition (SVD) or QRP) and those that evaluate the individual contributions of the rules (Orthogonal Least Squares (OLS)).

In this work, range-revealing methods are used, so the fuzzy model can be written as a linear regression problem [19]:

$$y = P * \theta + e \tag{1}$$

SVD is used to determine the effective rank of the rule firing matrix (P). This can be expressed as:

$$p_i(x) = \frac{\prod_{j=1}^{N} A_{ij}(x_j)}{\sum_{k=1}^{M} \prod_{j=1}^{N} A_{kj}(x_j)} \tag{2}$$

where $x = [x_1, .., x_N]^T$ is the input vector, $A_{i1}, ...A_{iN}$ are fuzzy sets defined in the antecedent space and M is the number of rules of the fuzzy model. The most important rules are those whose singular values are higher.

The QRP approach can produce a rule ordering without an rank estimation. Here, QRP is directly applied to P, obtaining a permutation matrix [20]: The QR decomposition of P is given by $P * \Pi = Q * R$, where $\Pi \in \Re^{M*M}$ is a permutation matrix, $Q \in \Re^{N*M}$ has orthogonal columns and $R \in \Re^{M*M}$ is upper triangular, such that

$$R = \begin{bmatrix} R_{11} & R_{12} \\ 0 & R_{kk} \end{bmatrix} \tag{3}$$

The diagonal values of *R* are called $R-values$ $(|R(kk)|)$ [17], which track the singular values $\sigma(P)$, so the most active and least redundant rules are those whose R-values are higher [19] in the original fuzzy rule space.

III. Rule Selection Based on QRP Transformations and Genetic Algorithm: a $Criterion$

The objective of this work is to try to check the orthogonal transformations, in this case QRP. To reach this goal, a simple $Criterion$ is defined in order to address the post-processing rule selection based on the relevance of each rule, then some conclusions about orthogonal transformations can be reached. In this case QRP and its R-values, in decreasing order, have been considered for this approach.

The main problem in the use of orthogonal transformations for rule ordering and selection is the selection $Criterion$. The goal of this work is to select rules automatically based on the percentage of R-values associated with the selected rules. This selection must be guided by a good trade-off between accuracy and interpretability.

A. Rule Selection: a $Criterion$

In order to address the post-processing rule selection, with the aim of reducing the complexity of the fuzzy model while preserving most of its accuracy, the next $Criterion$ has been proposed:

Given a fuzzy rule model whose complexity is to be reduced by rule selection, the rules to be taken into consideration in the new fuzzy model are those rules associated to R-values whose aggregation is greater than a threshold value, β. In this way, most of the behavior (and variability) of the rules is theoretically preserved:

Given a set of n fuzzy rules, each one associated with an R-value, and given R_{norm_i} the normalized R-value of the rule i, such that

$$R_{norm_i} = \frac{R - values_{Rule_i}}{\sum_{j=1}^{j=n} R - values_{Rule_j}}$$

then

$$Rule_1, .., Rule_k \in ReducedModel$$

if

$$\sum_{i=1}^{i=k} R_{norm_i} \geq \beta, \quad k \leq n$$

where

$$\beta = \textit{Percentage of information (rules)}$$

B. Accuracy and Interpretability Measures

The accuracy and interpretability measures considered in this work are defined in [21]. The $accuracy$ of the model is measured through its Mean Squared Error (MSE) (Eq. 4):

$$MSE = \frac{1}{N} \sum_{i=1}^{N} (Y_i - Y_i')^2 \tag{4}$$

The $interpretability$ measure is a set of simple indexes based on similarity and complexity. In both cases, a lower value has a positive influence on reducing the complexity

and improving the interpretability of the fuzzy models. These indexes are:

- *Compactness* or *Number of rules*.
- *Similarity* amongst rules.
- *Redundancy* of the fuzzy rule set.
- *Incoherency* of rules.
- *Completeness* or *No-Coverage*.

¿From these indexes, the function to measure the interpretability is (Eq. 5)

$$\begin{aligned} Inter_C = ArithmeticMean(\\ \lambda_{nr} * RuleNumber_{nor}, \lambda_s * Similarity_{nor}, \\ \lambda_r * Redundancy_{nor}, \lambda_i * Incoherency_{nor}, \\ \lambda_{nc} * NoCoverage_{nor}) \\ \lambda_j \in (0,1) \end{aligned} \quad (5)$$

Here, λ_j = 1 because it gives equal weight to all indexes, and the normalization is (Eq. 6):

$$Index_{nor} = \frac{Index_{Current} - Index_{Original}}{Index_{Current}} \quad (6)$$

C. Genetic Algorithm and Neuro-Fuzzy Systems

A genetic algorithm and a neuro-fuzzy system are used in this work to check and analyze the proposal.

The well-known multi-objective evolutionary algorithm NSGA-II [22] is taken into account in this work. Two fitness functions from MSE and $Inter_C$ are used to reach a fuzzy model with a good accuracy-interpretability trade-off. A third fitness is used to penalize smaller R-values corresponding to less active and more redundant rules, such that,

$$Penalty_{R-values} = \sqrt[n]{\prod_{i=1}^{n} 1 - R_{norm_i}} \quad (7)$$

and a restriction is imposed to ensure an adequate percentage of information (rules).

Neuro-Fuzzy systems are very popular approaches to generate fuzzy rule based systems, taking advantage of the learning capacity of Artificial Neural Networks (ANN) and the explanatory capacity of Fuzzy Logic. In this work, the neuro-fuzzy system FasArt [23], [24] has been used, which is a neuro fuzzy system based on the Adaptive Resonance Theory (ART). FasArt introduces an equivalence between the activation function of each FasArt neuron and a membership function. In this way, FasArt is equivalent to a Mamdani fuzzy rule-based system with: Fuzzification by single point, Inference by product, and Defuzzification by average of fuzzy set centers. A full description of this model can be found in [23] and [24].

IV. Tuning the $Criterion$: Methodology

The methodology of this work is focused on tuning the *Criterion of selection* proposed in III-A and its parameter (β). To reach this goal, the methodology used is made up of four general steps:

1) *Initial model generation.*
   For each data set to be considered, two cases of fuzzy models are generated by FasArt: compact and complex.
2) *Tuning of the $Criterion$, β parameter, by MOEA for each fuzzy model*
   This is based on the accuracy-interpretability trade-off and the R-values associated of the fuzzy rules.
   The β parameter is tuned for each fuzzy model data set, in three representative points of the Pareto Front ([6]):
   - The most interpretable model: Best $Inter_C$ (BI).
   - The most accurate model: Best Acc (BA).
   - The balanced interpretability-accuracy model: Balanced $Inter_C - Acc$ (BIA).

   Here, the multi-objetive genetic algorithm uses the three fitness functions of Eq. 8 and the restriction of Eq. 9:

$$\begin{aligned} max(Accuracy) = min(MSE) \\ max(Interpretability) = min(Inter_C) \\ max(Penalty) = max(Penalty_{R-values}) \end{aligned} \quad (8)$$

$$\beta \in [60\% - 85\%] \quad (9)$$

   The fitness functions involve the accuracy-interpretability trade-off and penalize smaller R-values, which correspond to less active and more redundant rules. The restriction is imposed to preserve an adequate percentage of information (rules). In this work, a first run of the MOEA with the two first functions was carried out in order to estimate the restriction range of Eq. 9.
3) *Generalization of $Criterion$: Generation of the β parameter from $\beta_i's$.*
   Taking into consideration the particular tuning obtained for each fuzzy model, a general range of β is carried out for cross-validation:

```
for Criterion = 1 do
  for Model = Compact:Complex do
    for Accur-Interpret Point=BI:BA:BIA do
      for N datasets do
        All possible combinations of 2/3 of data set, each one with its β (β'_i s), are done: β's training.
        For each combination, the mean and median are done, obtaining new β's (2*num-combination).
        MSE and Inter_C are calculated with these new β's, for 2/3 and the remaining 1/3: β's test.
        The mean of MSE and Inter_C are done.
        The best accuracy (min(MSE)) and the best interpretability (min(Inter_C)) are selected and each one has a β associated obtaining two c.
        The final β is obtained to find the mean/median of these two β's. This midpoint gives a good accuracy-interpretability trade-off .
      end for
    end for
  end for
end for
```

    end for
  end for
  Analysis of results
end for
```

V. EXPERIMENTS: RESULTS AND ANALYSIS

The proposal described in previous sections is checked using nine data sets from the KEEL project [1] (Table I) [25], [26].

In accordance with the methodology described in section IV:

1) Two types of base fuzzy models are generated by FasArt for each data set: Model1-Compact and Model2-Complex.
2) MOEA has been run using several options and the best results (based on best MSE and $Inter_C$) have been obtained combining the three fitness functions formulated in Eq. 8 with the restriction of Eq. 9.
   In this work, all the *genetic operators* are used in their default options:
   - Tournament without replacement for selection. Tournament size $= 2$.
   - Simulated binary for crossover. Crossover probability $= 0.9$.
   - Polynomial for mutation. Mutation probability $= 0.1$.

   From here, the β's obtained for MOEA for each data set are shown in Table II.
   These β's of Table II are used to tune a general β by cross validation, as described in point 3 of section IV, then the best accuracy and interpretability are obtained for the β's shown in Table III.
   The final value of β, so the final tuning of the $Criterion$, is obtained by taking the mean/median of these two β's in order to obtain a compromise between the best accuracy point and the best interpretability point. The final β's are shown in Table IV.
3) MSE and $Inter_C$ are calculated for nine data sets, selecting the percentage of R-values corresponding to the final β's (Table IV).

To see the results obtained for MSE and $Inter_C$ with their indexes of accuracy and interpretability, each study case is done with the new β's and the results are shown in the following subsections.

A. Performance of the Fuzzy Models

Table V summarizes the main performance aspects of the base fuzzy models generated. The indexes shown in the tables are the squared error for training (MSE_{tra}) and the test (MSE_{tst}), the rule number (RN), the similarity (S), the redundancy (R), the incoherency (I) and the percentage of completeness (C).

The performance of these base fuzzy models are matched with Wang & Mendel Models in [6]. In general, the complex models show a higher accuracy, while the compact models have a similar performance in some cases, and in others are a little more accurate or a little worse (see Table VI). The highlighted values mean that the performance (NR/MSE) in the FasArt models is greater than in Wang & Mendel.

Thus, these fuzzy models can be simplified in order to reach better and less complex fuzzy models using a more adequate accuracy-interpretability trade-off based on this proposal.

B. Reducing the complexity of the Fuzzy Models: Results and Analysis

The analysis of the results is organized according to the compact base fuzzy models and the complex base fuzzy models. In both cases, the values of MSE and $Inter_C$ with their indexes are presented.

1) Compact Models: Table VII shows the averaged results obtained by the characteristic models considered in this work over 5 runs for each case study considered. Specifically, the table shows the mean squared error for the test, MSE_{tst}, and the mean of the proposed index $Inter_C$, for each one of the three characteristic models taken into account: BI, BIA and BA. The first line shows the initial/original model (I) and the second line shows the improved model performance (F).

Tables VIII, IX and X show the mean values of some individual indexes for the final β's: the mean squared error for training (MSE_{tra}) and testing (MSE_{tst}), the mean rule number (RN), the mean similarity (S), the mean redundancy (R), the mean incoherency (I) and the mean percentage of completeness ($C\%$).

These tables show that the interpretability is always improved, while the accuracy is only improved sometimes. This is because the selection of rules with orthogonal transformations is done by removing the rules whose R-values are smaller, but

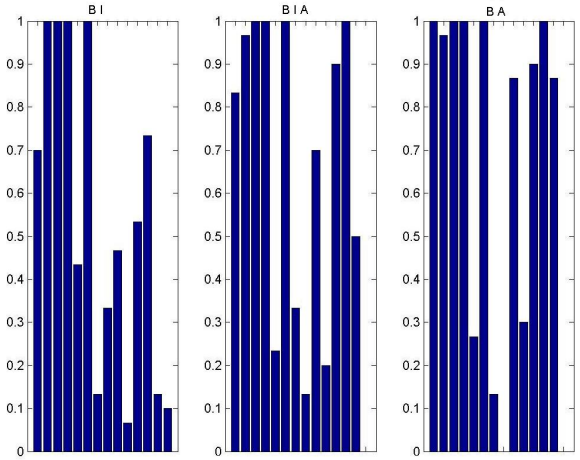

Fig. 1. Selected Rules for MOEA in PLA1

these R-values provide accuracy to the system, as can be seen in Figure 1.

This table shows the rules selected by MOEA in the case of a data set (in this example PLA1 with 14 rules) for the three points (BI, BA and BIA). In the x-axis are the rules from highest to lowest importance (from left to right), as the R-values, and the vertical axis is the percentage of times that MOEA selects each rule. Thus, 0.5 means that a rule has been selected for 50% of the time.

Figures 2, 3 and 4 show similar selections for Model1 with other data sets. In all cases, it can be seen that the rules associated to small R-values are selected, even in the best Acc point.

2) Complex Models: Table XI shows the averaged results obtained by the characteristic models considered in this work over 5 runs for each case study considered. As compact models, the table shows the mean squared error for the test, MSE_{tst}, and the mean of the proposed index $Inter_C$, for each one of the three points: BI, BIA and BA.

The first line shows the initial/original model (I) and the second line shows the improved model performance (F) for

these three characteristic models.

Tables XII, XIII, XIV show the mean and individual values for some indexes considered for the final β's: the mean squared error for training (MSE_{tra}) and testing (MSE_{tst}), the mean rule number (RN), the mean similarity (S), the mean redundancy (R), the mean incoherency (I) and the mean percentage of completeness (C%).

These tables show that the interpretability is always improved, while the accuracy is only improved for one data set and for the best Acc point. This is normal because complex models have an original high precision.

However, the accuracy is also reduced by the rule selection, and this is connected with orthogonal transformations: the firing matrix used to obtain the R-values only takes into account the antecedents of the rules. Thus, there are important rules for the accuracy of the system which are removed. These rules can correspond to small R-values and Figures 1, 2, 3 and 4 show these drawbacks: rules with small R-values are selected by the MOEA to provide accuracy and to obtain a good interpretability-accuracy trade-off.

3) Global Analysis: In general, the results show the advantages and some of the drawbacks obtained when orthogonal transformation are applied to the firing matrix of the fuzzy rule based model: a high reduction of the complexity, so the levels of interpretability under fuzzy criteria are increased (see Tables VII and XI).

However, on the other hand, the model accuracy is decreased in most of the cases. This reduction of the accuracy can be highly relevant due to the hard simplification achieved by orthogonal transformations. This happens, even taking into consideration the most relevant rules based on their $R{-}values$. The cause for this is: some of the rules removed correspond to the smaller R-values, or those near to zero, and these R-values correspond to non active and redundant rules. Redundant rules, however, can significantly contribute to the output system.

This can be shown by looking at the selection of rules that MOEA carries out according to the restrictions commented in point 2 of section IV: although smaller R-values are penalized, the algorithm continues to select some of the small R-values, to provide the system with accuracy (see Figures 1 to 4).

VI. CONCLUSIONS

This work deals with the complexity reduction of fuzzy models via Orthogonal Transformations, QRP: The goal is to check the limitations of the traditional application of this type of transformation to the firing matrix of a fuzzy model. In

order to check this, a $Criterion$ for fuzzy rule selection has been defined based on R-values, and its parameter has been tuned by a MOEA. This tuning has been carried out taking into consideration the accuracy-interpretability trade-off.

In all cases, interpretability has been improved considerably. The number of rules is always reduced, to 70% in some cases, and the rest of the indexes defined to measure the interpretability are also reduced in most cases.

However, in most cases, there is a loss of accuracy. This is due to the fact that orthogonal transformations for rule reduction are usually based on a firing matrix (P) involving the rule antecedent [19], [12]. The rules associated with the smaller R-values are removed because they are considered not relevant, but these rules usually provide a better accuracy.

In this work, the R-values for rule selection are obtained from the firing matrix (P). The results show that this matrix is not sufficient for this selection of rules because the rules associated with the small R-values are removed, and some of these rules can be important to obtain a good accuracy.

Future work is focused on a more realistic *"firing matrix"*, or index-values for rule selection, considering other elements of the fuzzy models such as the inference mechanism or consequents.

***Abstract*—This paper proposes a novel Hierarchical Genetic Fuzzy Rule-Based Classification System (HGFRBCS), targeted at effectively handling high-dimensional classification tasks. A hierarchical fuzzy rule base comprises rules with linguistic terms from a multi-granular fuzzy sets database, whereby lower levels define thicker granularities of the input space fuzzy partition. The proposed system is developed through sequential repeating steps: in each step a fuzzy rule base is created using a given granularity. Subsequently, the best performing rules are inserted in the hierarchical rule base and the process is repeated again, considering a thicker granularity. The whole process is coordinated by a boosting scheme, which localizes new rules in uncovered regions of the feature space. Comparative results for various real-world high-dimensional classification problems indicate the effectiveness of the proposed methodology.**

Fuzzy rule-based classification system (FRBCS); hierachical fuzzy partitions; genetic fuzzy systems

I. INTRODUCTION

The interpretational properties of Genetic Fuzzy Rule-Based Classification Systems (GFRBCSs) [1] have rendered them useful tools in the field of data mining over the past two decades [2]. In particular, linguistic FRBCSs [3]–[4] have the most intuitive representation, comprising rules with linguistic terms from a common fuzzy sets database. Their main drawback is a possible loss in accuracy when dealing with complex classification tasks, resulting from the inflexibility introduced by the discretization of the input space into a fixed number of fuzzy sets with predefined membership functions.

In order to increase classification accuracy, a hierarchical framework for building FRBCSs has been recently proposed [5]–[6]. This approach applies a two-level methodology. In the first level, a fuzzy rule base is created with an initial fuzzy set database. Poorly performing rules are removed from the rule base and replaced by rules defined in a thicker fuzzy partition granularity. In the second level, a genetic rule selection procedure is performed, which selects the best cooperating rules from the hierarchical rule base (HRB). However, the rule extraction algorithm (REA) considered in this approach results in the generation of a high number of fuzzy rules, as the results in [6] indicate. Another drawback of the approach is that it does not consider any feature reduction procedure, resulting in fuzzy rules with a complex linguistic structure when dealing with high-dimensional classification problems.

Another HGFRBCS has been previously proposed in [7], whose HRB structure resembles the philosophy followed by the herein proposed system. In this approach, an initial pool of candidate fuzzy rules is considered, defined in fuzzy partitions with different granularities. Subsequently, a genetic rule selection procedure selects the best cooperating rules, in order to form the final HRB. The main drawback of this approach lies in the creation of the initial pool of fuzzy rules, which is performed by considering the complete rule base for each fuzzy partition granularity, rendering the procedure ineffective in high-dimensional problems.

In this paper we propose a HGFRBCS which aims at producing compact yet high-performing HRBs in high-dimensional classification tasks. The basic idea is to repeatedly invoke a rule base extraction algorithm (RBEA), each time considering a fuzzy partition of thicker granularity. Fuzzy rules that increase the HRB's performance are maintained, whereas the rest are disregarded. In order for new rules to be created in uncovered regions of the feature space, we consider a boosting scheme that penalizes previously well covered patterns, so that new valuable rules will be localized in uncovered or mixed regions of the feature space. As the basic RBEA we consider a GFRBCS from a previous contribution of ours [8], which has been proven to generate compact rule bases, with low computational requirements.

The rest of the paper is organized as follows. Section II summarizes some of the basic concepts that will be used throughout the paper. In Section III we provide a brief description of the basic RBEA. Section IV details the framework for building the hierarchical fuzzy rule base. Experimental results for a number of high-dimensional classification problems are reported in Section V and the paper concludes in Section VI with some final remarks.

II. PRELIMINARIES

This section introduces the notation that will be used in the rest of the paper, along with a description of the proposed system's fuzzy inference mechanism implementation and the boosting algorithm considered.

A. Fuzzy Reasoning

We consider a classification problem defined in an N-dimensional feature space $\boldsymbol{x} = [x_1, \ldots, x_N] \in \Re^N$ and an M-dimensional class space $\boldsymbol{C} = \{C_1, \ldots, C_M\}$ and a set of Q labeled patterns $E = \{(\boldsymbol{x}^p, c^p),\ p = 1, \ldots, Q\}$. The proposed FRBCS comprises a number of linguistic DNF fuzzy rules, having the form:

$$R_k\text{: IF } x_1 \text{ is } A_1^k \text{ and} \cdots x_N \text{ is } A_N^k \text{ THEN } y \text{ is } C^k \text{ with } r^k, \quad (1)$$

where each input variable x_i takes as a value a set of linguistic terms $A_i^k = \{L_i^1 \text{ or } \cdots \text{ or } L_i^{\ell_k}\}$ joined by a disjunctive operator, whereas the output variable (y) is one of the class labels $C^k \in \boldsymbol{C}$. We will also consider that some input variables in each rule may be absent, which, in fuzzy terms, has the meaning of a "don't care" fuzzy set (a fuzzy set with a unity membership grade for its entire universe of discourse). For the sake of simplicity, in the rest of the paper we will refer to an input variable (feature) x_i as *active* when the fuzzy clause "x_i is A_i^k" is present in the rule and as *inactive* in the opposite case. Moreover, each fuzzy rule includes a certainty degree $r^k \in [0,1]$ which represents the confidence of the classification in the class label of the consequent (C^k). This certainty degree is calculated in our proposal through

$$r^k = \sum_{p|c^p = C^k} \mu^k(\boldsymbol{x}^p) \Big/ \sum_{p=1}^{Q} \mu^k(\boldsymbol{x}^p), \quad (2)$$

where $\mu^k(\boldsymbol{x}^p)$ is the degree of compatibility between an example and the antecedent part of a fuzzy rule (also known as matching degree). This matching degree is calculated as follows:

$$\mu^k(\boldsymbol{x}^p) = \bigwedge_{i=1}^{N} \left\{ \bigvee_{q=1}^{\ell_k} \mu_{L_i^q}(x_i^p) \right\}, \quad (3)$$

where $\mu_{L_i^q}(x_i^p)$ is the membership grade of each linguistic term participating in the formulation of ith variable's fuzzy value, and $\wedge$ and $\vee$ denote the AND and OR operators, respectively. The AND operator is implemented conventionally through the minimum operator, whereas the OR operator is implemented through the bounded sum, defined for two membership values a and b as:

$$\text{bs}(a,b) = \min(1, a+b) \quad (4)$$

With this choice, the composite fuzzy set is mathematically equivalent to a trapezoidal fuzzy set, having a far more reasonable interpretation than the one provided by the usually selected maximum operator, which results in taking the envelop of neighboring membership functions.

Since the proposed system implements a HRB, the linguistic terms A_i^k in each rule are defined in a fuzzy partition of a certain granularity. Hence, a hierarchical database (HDB) of fuzzy sets is defined, comprising S hierarchy levels with respective granularities $G(t)$, $t = 1, \ldots, S$. All linguistic terms participating in one rule are restricted to belong to the same hierarchy level.

Finally, we use the so-called maximum voting scheme in order to classify a given feature vector $\boldsymbol{x}^p$, defined as:

$$C_{\max} = \arg\max_{j=1,\ldots,M} \sum_{R^k | C^k = j} \mu^k(\boldsymbol{x}^p) \cdot r^k \quad (5)$$

B. Boosting Scheme

As mentioned in the introduction, the proposed system iteratively calls a RBEA, considering each time a fuzzy partition of thicker granularity. In order to localize new rules in uncovered regions of the feature space, we need a mechanism which will penalize previously covered examples. Such a framework can be provided by the so-called boosting algorithms. AdaBoost [9] is the most well-known boosting algorithm and its main idea is to combine a set of low quality classifiers (called weak hypotheses in the boosting literature) with a voting scheme, in order to generate an overall classifier that performs better than any of its constituents alone. In the context of FRBCSs, each fuzzy rule can be regarded as a simple but partial (in terms of overall classification performance) classifier. Assuming a training patterns set $E_{\text{trn}} = \{e^p = (\boldsymbol{x}^p, c^p),\ p = 1, \ldots, Q\}$, the AdaBoost algorithm assigns a weight w^p to each one of the Q training patterns, all initialized with a unity value $w^p = 1$. Each time a new rule R^k is inserted in the HRB, AdaBoost computes the error $E(R^k)$ of the rule, taking into consideration the examples' previous weights and their matching degrees:

$$E(R^k) = \frac{\sum_{p|c^p = C^k} w^p \mu^k(\boldsymbol{x}^p)}{\sum_{p=1}^{Q} w^p \mu^k(\boldsymbol{x}^p)}. \quad (6)$$

Incorrectly classified patterns retain their former weights, whereas the weights of correctly classified patterns are reduced by a factor $\beta^k(\boldsymbol{x}^p)$:

$$w^p \leftarrow \begin{cases} w^p, & \text{if } C^k \neq c^p \\ w^p \cdot \beta^k(\boldsymbol{x}^p), & \text{if } C^k = c^p. \end{cases} \quad (7)$$

The factor

$$\beta^k(\boldsymbol{x}^p) = \left(\frac{E(R^k)}{1 - E(R^k)} \right)^{\mu^k(\boldsymbol{x}^p)} \quad (8)$$

depends on the current rule's error and its matching degree with the pth pattern. Effectively, examples that are classified correctly and match the rule antecedent are down-weighted, whereas misclassified or uncovered examples maintain their original weights.

We should note that there is an important difference between fuzzy rules and the notion of the weak hypothesis in the boosting literature. The weak hypothesis is assumed to be a low performing classifier that, however, covers the whole feature space. On the contrary, a fuzzy rule is a local model, covering only a specific subspace of the feature space.

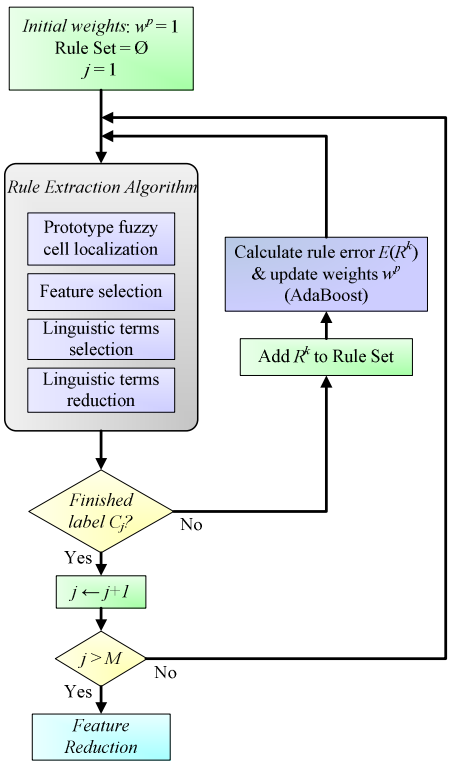

Figure 1. Outline of FaIRLiC's learning algorithm.

Therefore, under the AdaBoost philosophy, classifiers that are created at later stages handle mostly uncovered regions of the feature space, but are allowed to also (correctly) classify previously down-weighted patterns. In FRBCSs this is generally an undesirable behavior, since superfluous fuzzy rules with high overlapping may be produced. To that extent, special provision must be made to avoid such phenomena when applying the AdaBoost algorithm in the derivation of GFRBCSs.

III. Rule Base Extraction Algorithm

In a previous work [8], we introduced the so-called Fast Iterative Rule-Based Linguistic Classifier (FaIRLiC), a GFRBCS designed under the Iterative Rule Learning (IRL) approach [1]. This system is characterized by the compact rule base structure it produces, the overall good classification accuracy attained and the relatively low time requirements of its learning algorithm. Due to these attributes it has been selected here as the basic RBEA of the proposed system. In the rest of this section, we provide a brief description of FaIRLiC. A more comprehensive description can be found in the aforementioned reference.

An outline of FaIRLiC's learning algorithm is depicted in Fig. 1. FaIRLiC constructs a FRBCS comprising DNF rules in the form of (1), with a fuzzy partition of a certain granularity, selected by the designer. Following the IRL approach, the system is constructed through repeated invocation to a rule extraction algorithm, each time returning the best fuzzy rule found under the current distribution of the training examples. This distribution is controlled by the AdaBoost algorithm presented in Section II.B. Hence, each time a new rule is added to the final rule base, the weights of correctly covered examples are down-weighted and subsequent invocation to the algorithm concentrate on uncovered patterns.

The rule extraction algorithm is performed in four successive steps: a) prototype fuzzy cell localization, b) feature selection, c) linguistic terms selection and d) linguistic terms reduction. The first step initializes the algorithm by selecting the most promising single linguistic term for each input variable. Given these terms, the second step performs a genetic feature selection procedure. After having selected the relevant features of the rule, a genetic algorithm (GA) in the third step identifies the DNF-type linguistic terms that will be included in its antecedent part, for each active feature. The final step is a simple deterministic one, which corrects the fuzzy rule from extending to empty subspaces of the feature space. Specifically, for each active input variable we remove one fuzzy term at a time (if there are more than two) and accept that change if the classification performance does not decrease. The inner fuzzy sets of a contiguous block of linguistic terms are never removed, in order to avoid the creation of intermittent composite fuzzy sets.

Throughout FaIRLiC's rule extraction algorithm we evaluate extensively a feature selection oriented metric, the so-called Feature Partition Vector (FPV). The FPV quantifies the degree to which each feature can correctly classify each one of the training examples, independently from other features. This metric is used in order to localize the initial linguistic terms (first step) in the most informative region of the equivalent input variable, as well as for the initialization of the population and the application of special genetic operators in the second step. Moreover, a modified coverage fitness function is considered for the GAs in the second and third steps, which explicitly discourages new rules to cover previously well-covered examples.

Similarly to the SLAVE algorithm [10], we learn one class label at a time, with no particular order being assumed. When no more useful rules can be produced for the class under consideration, the algorithm proceeds to the next class label. Two conditions are considered to judge if the algorithm should proceed to the next class label:

- The new rule's fitness value is zero (in either the feature selection or the linguistic terms selection steps), which signifies the inability of the rule extraction algorithm to find a new useful rule.
- The classification performance of the rule base obtained so far does not increase more than a pre-specified threshold on a validation set of examples. Accordingly, our initial set of labeled patterns is split into three disjoint sets: the training, the validation, and the testing ones.

As a final step, we perform a deterministic feature reduction step, which is similar to the linguistic terms reduction one. Specifically, for each rule we inactivate one input variable at a time and observe the performance of the system in the training and validation sets. If these performances do not degrade and the rule's consequent does not change, we accept

Initialization: $w^p = 1$; $a^{NPR} = a_{\text{init}}^{NPR}$; HRB = Ø

the chance. Moreover, since removing a feature results in a generalization of the rule, we also assure that the overlapping between rules describing the same class label does not increase.

IV. Iterative Hierarchical Framework

Here we introduce the Hierarchical Rule-Based Linguistic Classifier (HiRLiC), which is a framework for building HGFRBCSs. As mentioned in the introduction, HiRLiC repeatedly calls a RBEA (the FaIRLiC algorithm), each time considering a fuzzy partition of thicker granularity. Since FaIRLiC considers DNF-type rules in the form of (1), one might suggest to select a very fine granularity of the input space and then request FaIRLiC to implicitly identify the required granularity for each rule, by selecting the appropriate linguistic terms to be joined by the OR disjunctive operator. However, in an N-dimensional classification problem with each input variable being partitioned into ℓ fuzzy sets, plus the "don't care" (inactive feature) fuzzy set, the search space for simple linguistic rules is $(\ell+1)^N$. The actual search space is much larger if we consider the DNF type of the fuzzy rules. As the dimensionality of the feature space increases, the search space of the problem increases exponentially, thus degrading the effectiveness of FaIRLiC's GA-driven learning algorithm.

To overcome the aforementioned problem, HiRLiC decomposes the problem into smaller, easier to tackle sub-problems. Through AdaBoost, the algorithm initially concentrates in uncovered regions of the feature space, allowing the mixed areas in the borders of neighboring classes to be handled in a later stage, when a finer partition will be available and most of the easily discriminated patterns will have been practically removed (their weight values will be close to zero). When seen under this scope, HiRLiC employs a higher-level IRL methodology: just as FaIRLiC repeatedly calls a rule extraction algorithm and uses the (local) AdaBoost weights to localize new rules in uncovered regions of the feature space, so does HiRLiC iteratively invoke a RBEA in different hierarchy levels, using the (global) AdaBoost weights as the control mechanism. To that extent, HiRLiC is able to effectively handle the large search space, thus increasing its base weak learner's, that is FaIRLiC's, classification accuracy.

TABLE I. Summary Description of the Datatsets

An outline of the HiRLiC learning methodology is given in Fig. 2. Initially we consider and empty HRB and the AdaBoost algorithm assigns unity weights to the training patterns. The designer selects the number S of the hierarchy levels to be considered, along with the respective granularities of the fuzzy partitions $G(t)$, $t = 1,\ldots,S$. For each hierarchy level t, the FaIRLiC algorithm is executed, producing fuzzy rules defined in a fuzzy partition with $G(t)$ granularity, as shown in Fig. 1. The only difference is that instead of initializing FaIRLiC's AdaBoost weights with unity values (top box in Fig. 1) we provide a copy HiRLiC's (global) current weight values.

Obviously, the most crucial point is the selection of the rules to be inserted in the HRB and the ones that will be rejected. We cannot rely solely on the classification accuracy of the HRB, since rules describing currently unhandled class labels will always increase its classification accuracy. In particular, we want to (at least initially) promote confident rules, that is, rules covering a high number of positive examples and a low number of negative ones. Therefore, we propose the use of the negative to positive examples ratio (*NPR*), which is simply defined as the ratio of the fuzzy number of positive examples n^+ to the fuzzy number of negative ones n^-. For the kth fuzzy rule, describing the C^k class label, these numbers are defined, respectively, as:

$$n^+ = \sum_{p|c^p=C^k} \mu^k(\boldsymbol{x}^p), \tag{9}$$

$$n^- = \sum_{p|c^p\neq C^k} \mu^k(\boldsymbol{x}^p). \tag{10}$$

If the *NPR* of a rule is lower than a threshold value a^{NPR}, then this rule is considered to be a *promising* one and it is inserted into the respective rule set of promising rules $R_{pr}(t)$. Generally, we should be stricter in the initial steps, where coarse granularities are considered, and relax this restriction as the algorithm proceeds to lower levels of the hierarchy. To achieve this, the designer chooses an initial threshold value $a_{\text{init}}^{NPR} < 1$ and this threshold increases linearly for subsequent hierarchy levels, achieving a unity value in the last (S) level. Hence, the threshold value at level t is expressed as:

$$a_t^{NPR} = a_{\text{init}}^{NPR} + (1 - a_{\text{init}}^{NPR})\frac{t-1}{S-1}. \tag{11}$$

After creating the rule set $R_{pr}(t)$, we insert each one of the rules into the HRB (one at a time), in the order of their creation. If the classification performance of the HRB on the validation set of examples increases with the insertion of a rule, then this rule is accepted and HiRLiC's AdaBoost weights are updated (see Fig. 2), according to (6)–(8). Otherwise the rule is rejected. Through this procedure, only rules that cooperate well with the previous HRB are inserted into the final model.

Note that all available S hierarchy levels are evaluated. Nevertheless, it is acceptable that no rules with a certain granularity $G(t)$ will be inserted in the final model. Hence, the final system utilizes only the necessary levels of the hierarchical fuzzy sets database. We should also remark, that easily discriminated classes with broad coverage will be generally handled first, which in general will result in faster execution of the FaIRLiC algorithm in later steps.

Finally, before exporting the final HRB, we perform two deterministic rule base refinement procedures, namely, rule reduction and feature reduction, as shown in Fig. 2. The features reduction algorithm is the same as the one performed at the end of FaIRLiC's algorithm (see Section III), whereas rule reduction is a similar procedure which removes one rule at a time and accepts the change if both the training and validation performance rates do not degrade. Arguably, the objectives pursued by these procedures have already been achieved in previous steps to a large extent. Indeed, for the datasets considered in our experimental setup, the average decrease in the numbers of rules and features per rule was 9.74 % and 5.07 %, respectively. Nevertheless, their application is advocated by their practically negligent computational requirements.

V. EXPERIMENTAL STUDY

In order to analyze the performance of the proposed methodology we considered 12 real-world experiments with a medium to high number of features. Table I summarizes the most important characteristics of these datasets. The first 7 datasets are from the UCI repository [11], whereas the Texture dataset is from the ELENA project [12]. The last four are remote sensing classification tasks from satellite imagery. In particular, a multispectral IKONOS image was acquired from an area surrounding Lake Koronia in northern Greece. Advanced higher order spectral and spatial features were subsequently derived from the initial four bands of the image, resulting in a total of 53 features. In order to conduct additional studies from the quality of the ecosystem point of view, the area was carefully segmented into two zones: the agricultural (KorAgro) and the wetland (KorWet) ones. For the sake of completeness, the whole (original) dataset is also considered (KorWhole) here. A detailed description of these datasets can be found in [13]–[14]. Finally, the Thasos dataset was obtained from a hyperspectral Hyperion image (level 1 radiometric product), covering a part of Thasos, Greece's most northerly island [15]. It comprises a total of 198 features in the visible near infrared (VNIR) (400–1000 nm) and shortwave infrared (900–2500 nm) range of the electromagnetic spectrum.

To develop the different experiments we consider a 5-fold cross-validation model, that is, 5 random partitions with 20 % of the data and the combination of 4 of them (80 %) as training and the remaining 20 % as testing. Due to the computational requirements of FaIRLiC and HiRLiC, the training partitions were further split into two equal parts, resulting in the final training and validation partitions. Moreover, we performed six independent runs on each partition, using different random seeds, since GAs are stochastic processes. In each case, the average results over these 30 runs are given.

The parameters used for FaIRLiC are the same as the ones proposed in [8], either when running it independently or as a part of HiRLiC's learning algorithm. When FaIRLiC is tested as a standalone classifier, we use 9 fuzzy sets per input variable, as a reasonable number of fuzzy sets used in many GFRBCSs of the respective literature. In applying HiRLiC, we consider $S = 7$ hierarchy levels with odd granularities from 3 to 15, that is, $\boldsymbol{G} = \{3, 5, 7, 9, 11, 13, 15\}$. The initial *NPR* threshold for HiRLiC was set to $a_{\text{init}}^{NPR} = 0.2$, so that at the first iteration (3 fuzzy sets per input variable) a rule is inserted into the promising rule set only if its negative examples are fewer than 20 % of its positive ones. The two systems were coded in C++ and all experiments were conducted on an Intel Core 2 Quad Q9650 at 3.0 GHz.

P (%) = Testing performance (%); # R = number of rules; GU = number of features globally used; # F/R = average number of features per rule.

We will first compare the average results obtained by FaIRLiC and HiRLiC, which are shown in Tables II and III, respectively. These tables include – for each dataset – the testing classification accuracy, the number of rules, the average number of globally used features, the number of features per rule, and the runtime of each algorithm in seconds. The term globally used features is used to express the number of features being evaluated by the whole rule base, that is, the features that appear at least once in any rule of the system. Table III also includes the average hierarchy depth of HiRLiC, meaning the average number of hierarchy levels that are actually being utilized by at least one rule of the rule base. The last row of each table reports the respective average values for all datasets considered.

From the performance point of view, HiRLiC outperforms FaIRLiC in all datasets, with the additional performance gain ranging from 2.12 % (Sonar) to 10.39 % (Libras). In most cases, HiRLiC's classification performance is more than 3 % higher that FaIRLiC's ones. This fact proves the fulfillment of our primary objective, which was to increase the classification ability of the base classifier. From the model simplicity point of view, the number of features per rule have marginally increased, while the rule base size increased, subsequently resulting in a higher number of globally used features. However, observing the feature and class space dimensionality of each dataset, we can argue that the obtained HRBs are generally compact, retaining their former interpretability properties to a considerable degree. Obviously, the time requirements of HiRLiC's learning algorithm is multiple of FaIRLiC's ones, since the former repeatedly invokes the latter. Nevertheless, FaIRLiC's learning is fast enough to maintain the HiRLiC's execution times to an acceptable level, especially if we take under consideration the high number of training patterns for most of the datasets.

To validate HiRLiC's performance, we compared it against three other GFRBCSs of the literature, namely, the SGERD [16], Ishibuchi's GCCL [17] and 2SLAVE-2 [10] systems, tested using the Keel software package [18]. The number of fuzzy sets per input variable for 2SLAVE-2 was set to 9, as we have done with FaIRLiC. For Ishibuchi's GCCL we tested granularities from 3 to 9 (the maximum allowed in the Keel software) fuzzy sets per input variable and we finally chose a granularity value of 5, as it achieved the highest classification accuracy in the vast majority of the considered datasets. The rest of the parameters for these three systems were set to the respective values proposed by the authors.

In Table IV we present a comparison of HiRLiC with the three aforementioned GFRBCSs. The results for Ishibuchi's GCCL in the Thasos dataset are missing because the method was unable to produce any useful rules (zero number of rules was obtained) for this dataset. Performance-wise, HiRLiC was found to clearly outperform SGERD and Ishibuchi's GCCL, as well as 2SLAVE-2 in most cases, although the difference with the latter is smaller. However, 2SLAVE-2 resulted in significantly more complex rule bases, with a higher number of features per rules and number of rules than HiRLiC. Ishibuchi's GCCL resulted in fuzzy rule bases with high number of rules, whereas the structure of SGERD is overall approximately equivalent to FaIRLiC's one (see Table II), although the former attained lower classification accuracies in most datasets. From this comparative analysis, we can conclude that HiRLiC results in high performing rule-based classifiers, maintaining a reasonably compact rule base structure at the same time.

VI. CONCLUSION

This paper presented a novel framework for developing hierarchical GFRBCSs, targeting at increasing the classification accuracy of the obtained model. HiRLiC is constructed through an iterative process, by repeated invocations to a basic RBEA, each time considering a fuzzy partition of thicker granularity. A boosting algorithm is responsible for focusing the algorithm towards the uncovered or highly mixed regions of the feature space. The rules provided by the RBEA are evaluated by the HRB and are included in the final model only if they are confident and increase the system's performance. Extensive experimental analysis on various real-world high-dimensional classification tasks has proved the proposed methodology's ability to increase the classification accuracy of the system, maintaining at the same time a reasonably compact structure.

***Abstract*—In the framework of multi-objective evolutionary fuzzy systems (MOEFSs), the search space grows as the number of features of the dataset increases, leading to a slow and possibly difficult convergence of the evolutionary algorithm. Furthermore, mainly due to the fitness evaluation, datasets with a large number of instances require very high computational costs. In this paper, we propose a co-evolutionary approach to generate sets of Mamdani fuzzy rule-based systems (MFRBSs) with different trade-offs between accuracy and interpretability. We aim to deal with high dimensional and large datasets and to learn together the rule base (RB) and the membership function parameters. To reduce the search space, we perform the multi-objective evolutionary learning of the RB by selecting reduced sets of rules and conditions from a previously generated RB. Further, to lessen the computational costs, during the multi-objective evolutionary learning process, periodically, a single-objective genetic algorithm evolves a population of reduced training sets. We show the preliminary results obtained by applying our approach to two real world high dimensional and large regression datasets.**

Keywords: multi-objective evolutionary fuzzy systems; high dimensional datasets; large datasets; regression problems

I. INTRODUCTION

Two main approaches can be exploited to design fuzzy rule-based systems (FRBSs): i) to elicit the knowledge from a human expert and ii) to extract this knowledge from available information (typically, input-output samples). In complex application domains, with a large quantity of information sources, the first approach is difficultly applicable. Thus, the second approach is often the unique alternative.

Several techniques have been proposed in the literature to generate FRBSs from available data [1]-[3]. Among these techniques, multi-objective evolutionary fuzzy systems (MOEFSs) have been successfully used in the last years to generate sets of FRBSs with different trade-offs between accuracy and interpretability [4][5]. MOEFSs exploit multi-objective evolutionary algorithms (MOEAs) to perform the learning [6][7] or the selection [8] of rules, and the tuning of the data base (DB) [9], with a prefixed DB and rule base (RB), respectively. Further, the most recent works describe approaches to concurrently learn [10]-[13] or select [14]-[16] rules together with some elements of the DB, such as the membership function (MF) parameters and the granularities.

In real word applications, we often have to manage high-dimensional and large datasets. Let us consider, for instance, some applications such as environmental monitoring, traffic control or weather forecasting. Here, a large amount of sensors is typically used, thus generating data characterized by a large number of features. Further, if the sampling frequency is high, the resulting datasets comprise a very large amount of instances.

Dealing with high dimensional and large datasets is a challenge topic in the context of MOEFSs [4]. A high number of dimensions increases the search space, especially in rule learning approaches, thus affecting the performance of the evolutionary algorithm in terms of convergence and solution quality. A large number of instances, as mentioned in [4] and confirmed by the experimental results discussed in several papers [10]-[12], makes the computation of the fitness very time-consuming, thus hindering the full exploitation of the evolutionary process by obliging to limit the number of iterations.

Four main approaches have been followed to reduce these drawbacks in MOEFSs: i) to use data reduction techniques, such as feature selection [17][18] and instance selection [19][20], ii) to exploit parallel evolutionary algorithms [19][21], iii) to use some fitness approximation approaches [22], and iv) to exploit ad-hoc modified MOEAs [23][24].

In this contribution, we introduce a novel approach to generate sets of Mamdani FRBSs (MFRBSs) with different trade-offs between accuracy and RB complexity from high dimensional and large datasets. We aim to concurrently learn the RBs and the parameters of MFs in the same multi-objective evolutionary process.

To reduce the search space in the generation of the rules, we exploit the RB generation method recently introduced by us in [24]: RBs are determined by selecting a reduced number of rules and conditions during the evolutionary process from a previously generated RB. In [24], we used the Wang and

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Mendel algorithm [1] and denoted the approach as two-level rule selection (2LRS): at the first level we select the rules and at the second level we select the conditions. In contrast with the RB learning process exploited in our previous works [7][10]-[12], the 2LRS approach allows considerably reducing the search space, especially when the number of features is high, though preserving some good characteristics of a learning approach (actually, once determined the rule at the first level, at the second level the selection of conditions appears more similar to a learning than a selection process). We experimentally verified that the new approach allows the specific MOEA used in the experiments, namely (2+2)M-PAES, to rapidly converge to a set of solutions with trade-offs between accuracy and complexity comparable to the ones computed by the RB learning process of our previous works. In particular, we experimentally verified that the (2+2)M-PAES with the 2LRS approach achieves after 50000 evaluations Pareto front approximations comparable to the ones achieved by the (2+2)M-PAES with the rule learning after 300000 evaluations.

Further, to deal with large datasets, we integrate the 2LRS in our co-evolutionary model proposed in [20]. Here, during the execution of the MOEA, periodically, a single-objective genetic algorithm (SOGA) evolves a population of reduced training sets (RTSs).

We have aim to verify whether the co-evolutionary approach allows generating a set of MFRBSs that are statistically equivalent to those generated using the overall training set (OTS). In order to prove the positive behaviour of the new co-evolutionary approach, we show some preliminary results on two real world high dimensional and large datasets.

The paper is organized as follows: Section II briefly describes the MFRBSs and introduces some notation. In Section III, we describe the co-evolutionary approach aimed at concurrently selecting training instances and performing multi-objective evolutionary learning of MFRBSs. Finally, Section IV shows the experimental results and Section V draws some final conclusions.

II. MAMDANI FUZZY SYSTEMS

Let $\mathbf{X} = \{X_1, ..., X_f, ..., X_F\}$ be the set of input variables and X_{F+1} be the output variable. Let U_f, with $f = 1, ..., F+1$, be the universe of the f^{th} variable. Let $P_f = \left\{A_{f,1}, ..., A_{f,T_f}\right\}$ be a strong fuzzy partition of T_f fuzzy sets on variable X_f. An MFRBS is composed of M rules expressed as:

$$R_m: \quad \textbf{IF } X_1 \textbf{ is } A_{1,j_{m,1}} \textbf{ AND } \ldots \textbf{ AND } X_F \textbf{ is } A_{F,j_{m,F}} \quad \textbf{THEN } X_{F+1} \textbf{ is } A_{F+1,j_{m,F+1}} \ (m = 1, ..., M) \tag{1}$$

The RB of an MFRBS can be completely described by a matrix $J \in \mathbb{N}^{M \times (F+1)}$, where the generic element $j_{m,f}$, with $m \in \{1, ..., M\}$ and $f \in \{1, ..., F+1\}$, indicates that fuzzy set $A_{f,j_{m,f}}$ has been selected for variable X_f in rule R_m. We use the product and the centre of gravity method as AND logical operator and defuzzification method, respectively.

We adopt triangular fuzzy sets $A_{f,j}$ defined by the tuple $(a_{f,j}, b_{f,j}, c_{f,j})$, where $a_{f,j}$ and $c_{f,j}$ correspond to the left and right extremes of the support of $A_{f,j}$, and $b_{f,j}$ to the core. Since we use strong fuzzy partitions, we assume that $a_{f,1} = b_{f,1}$, $b_{f,T_f} = c_{f,T_f}$, and for $j = 2, \ldots, T_f - 1$, $b_{f,j} = c_{f,j-1}$ and $b_{f,j} = a_{f,j+1}$.

To take the "don't care" condition into account, a new fuzzy set $A_{f,0}$ $(f = 1, ..., F)$ is added to all the F input partitions P_f. This fuzzy set is characterized by an MF equal to 1 on the overall universe. The terms $A_{f,0}$ allow generating rules which contain only a subset of the input variables.

Given a set of N input observations $\mathbf{x}_n = [x_{n,1}, ..., x_{n,F}]$, with $x_{n,f} \in \Re$, and the set of the corresponding outputs $x_{n,F+1} \in \Re$, $n = 1, ..., N$, we aim to generate a set of MFRBSs with different trade-offs between accuracy and interpretability. As regards MFRBS interpretability, several definitions can be found in the literature [25][26]. In particular, MFRBS interpretability can be analyzed in terms of RB complexity and DB integrity. In this work, the DB integrity is ensured by using strong fuzzy partitions with a low level of granularity. Thus, for the sake of simplicity, we measure the interpretability in terms of only RB complexity.

III. THE PROPOSED APPROACH

In this work, we exploit both the effectiveness of the 2LRS in managing high dimensional datasets and the efficacy of the evolutionary training set selection (TSS) in reducing the computational complexity when dealing with large datasets. To this aim, we follow the same approach that we have described in [20], in which a co-evolutionary algorithm has been proposed to perform both the TSS and the multi-objective evolutionary RB learning. Unlike in [20], however, we adopt the 2LRS in place of the RB learning.

A. The Co-Evolutionary Algorithm

Fig. 1 shows the execution flow of the co-evolutionary algorithm by using the UML activity diagram notation. In the activity diagram, rectangles represent data objects, rounded rectangles represent activities and diamonds are used as decision and merge points. The algorithm handles two populations: the KB population, aimed at performing the 2LRS and the MF parameter learning, and the reduced training set (RTS) population, aimed at performing the TSS.

First of all, we apply the WM algorithm to the OTS to generate the set of candidate rules. We assume that the linguistic variables are uniformly partitioned with T_f fuzzy sets. Then, TSS is fulfilled by means of an SOGA while the 2LRS and the MF parameter learning are carried out by applying the (2+2)M-PAES algorithm.

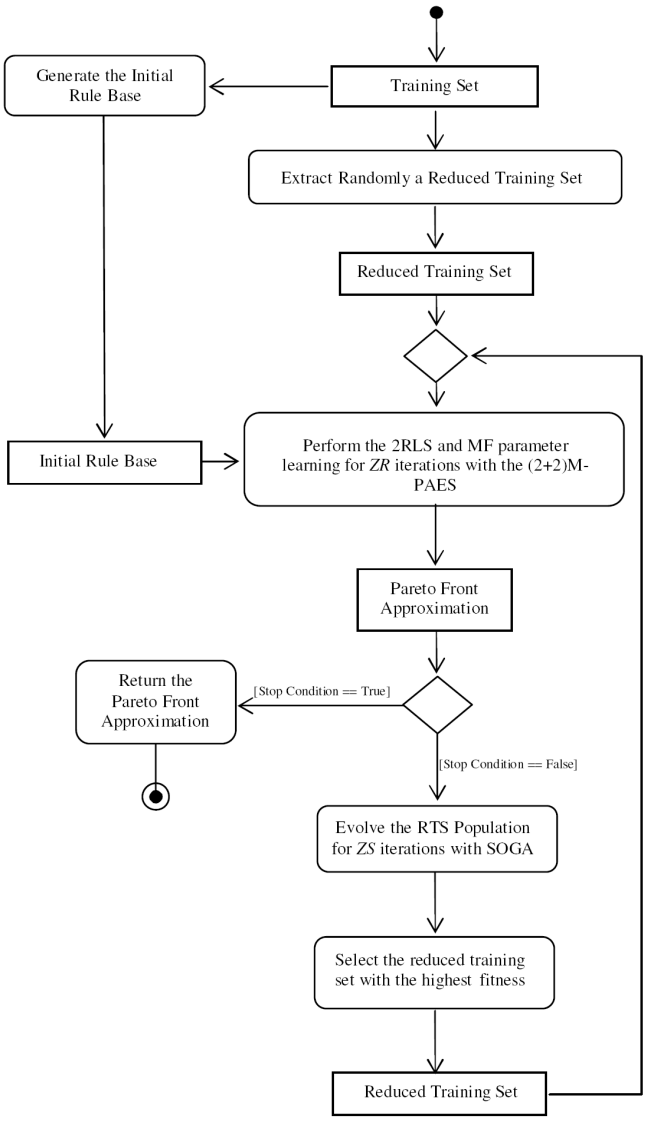

Figure 1. Activity diagram of the co-evolutionary apprach

The SOGA and (2+2)M-PAES are cyclically executed one after the other. The RTS population evolves for a fixed number *ZS* of fitness evaluations in order to search for an RTS which is a good representative of the OTS. Thus, the RTS is used in the (2+2)M-PAES to perform the multi-objective 2LRS and MF parameters learning with different trade-offs between accuracy and RB complexity. (2+2)M-PAES is executed for a fixed number *ZR* of RB fitness evaluations. The resulting approximated Pareto front (set of non-dominated MFRBSs with different accuracy-complexity tradeoffs) is used in the execution of the SOGA to calculate the fitness function.

At the end of its execution, our algorithm returns a set of non-dominated MFRBSs in the complexity-accuracy plane. Even though several stop conditions can be considered, we terminate the execution of our algorithm when a prefixed number of KB fitness evaluations have been performed. In this way, we are able to carry out comparisons with different techniques using the same number of KB fitness evaluations.

In the following, we introduce and discuss the 2LRS and the MF parameters learning, including their coding and the mating operators. Finally, we introduce the MOEA exploited in the evolutionary process.

B. The Multi-objective Evolutionary Two-Level Rule Selecion and MF Learning

The 2LRS and the MF parameters learning are carried out by (2+2)M-PAES, which determines an approximation of the optimal Pareto front by concurrently minimizing the MSE and the RB complexity.

The MSE is calculated as:

$$MSE = \frac{1}{2 \cdot |E|} \sum_{l=1}^{|E|} \left(F(x^l) - y^l \right)^2$$

where $|E|$ is the size of the dataset, $F(x^l)$ is the output obtained from the MFRBS when the *l-th* input pattern is considered, and y^l is the desired output. RB complexity is measured as sum of the conditions which compose the antecedents of the rules included in the RB. Thus, low values of complexity correspond to RB characterized by a low number of rules and a low number of input variables really used in each rule.

We indicate with J_{WM} and M_{WM} the RB generated by applying the WM algorithm to the OTS and the number of rules of this RB, respectively. We recall that the antecedent of each candidate rule has one condition for each linguistic variable, since the WM algorithm performs no selection of the conditions. Further, especially when dealing with large and high dimensional datasets, the WM algorithm could generate RBs composed by a huge number of rules. For this reason, in order to generate compact and interpretable RBs, we fix the maximum number M_{MAX} of rules which can compose the RB. Further, the minimum number of rules that must be present in the RB is fixed by the user-defined parameter M_{MIN}.

We exploit a chromosome C^{KB} composed of two parts (C_1^{KB}, C_2^{KB}), which define the RB and the positions of the centroids of each fuzzy set in each linguistic variable, respectively. The C_1^{KB} part of the chromosome is a vector of M_{MAX} pairs $\mathbf{p}_m = (k_m, \mathbf{v}_m)$, where $k_m \in [0,...,M_{WM}]$ identifies the index of the rule in J_{WM} selected for the current RB and $\mathbf{v}_m = [v_{m,1},...,v_{m,F}]$ is a binary vector which indicates, for each condition in the rule, if the condition is present or corresponds to a don't care. In particular, if $k_m = 0$, the m^{th} rule is not included in the RB. In this way we manage to generate RBs with a lower number of rules than M_{MAX}. Further, if $v_{m,f} = 0$, the f^{th} condition of the m^{th} rule is replaced by a don't care condition; otherwise it remains unchanged.

As regards C_2^{KB}, since we adopt strong fuzzy partitions with, for $j = 2, \ldots, T_f - 1$, $b_{f,j} = c_{f,j-1}$ and $b_{f,j} = a_{f,j+1}$, in order to define each fuzzy set of the partition it is sufficient to fix the positions of the cores $b_{f,j}$ along the universe U_f of the f^{th} variable (we normalize each variable in [0,1]). Since $b_{f,1}$ and b_{f,T_f} coincide with the extremes of the universe, the partition of each linguistic variable X_f is completely defined by $T_f - 2$ parameters. Finally, C_2^{KB} consists of $F+1$ vectors of $T_f - 2$ real numbers: the f^{th} vector contains the $\left[b_{f,2},...,b_{f,T_f-1}\right]$ cores which define the positions of the MFs for the linguistic variable X_f.

To ensure a good integrity level of the MFs, in terms of order, coverage and distinguishability, $\forall j \in [2, T_f - 1]$, we force $b_{f,j}$ to vary in the definition interval $\left[b_{f,j} - \frac{b_{f,j} - b_{f,j-1}}{2}, b_{f,j} + \frac{b_{f,j+1} - b_{f,j}}{2}\right]$.

The evolutionary process is performed by means of the (2+2)M-PAES proposed in [7], where both crossover and mutation operators are independently applied to each part of the chromosome. In particular we apply the one-point crossover to the C_1^{KB} part and the BLX-α crossover, with α = 0.5, to the C_2^{KB} part.

Let s_1 and s_2 be two selected parent chromosomes. The common gene for the one point crossover is chosen by extracting randomly a number in $[1, \rho_{MAX} - 1]$, where ρ_{MAX} is the maximum number of rules in s_1 and s_2. The crossover point is always chosen between two rules and not within a rule. When we apply the one-point crossover to the RB part, we can generate an RB with one or more pairs of equal rules. In this case, we simply eliminate one of the rules from each pair setting the correspondent k_m to zero. This allows us to reduce the total number of rules.

As regards the mutation, for the C_1^{KB} part we have defined three operators. The first step of each operator is to randomly select a pair $\mathbf{p}_m$, i.e. a rule, in the chromosome. The first operator replaces the value of k_m in the selected pair with an integer value randomly generated in $[1,...,M_{WM}]$. The second operator removes a rule from the RB by setting k_m of the selected pair to zero. Finally, the third operator modifies the antecedent $\mathbf{v}_m$ of the selected rule by complementing each gene $v_{m,f}$ with a probability equal to P_{cond} ($P_{cond} = 2/F$ in the experiments). After applying the three mutation operators, we remove the duplicate rules in the RB.

The mutation operator applied to C_2^{KB}, first, randomly chooses a variable X_f, $f \in [1, F+1]$, and a fuzzy set $j \in [2, T_f - 1]$ and then replaces the value of $b_{f,j}$ with a value randomly chosen within the definition interval of $b_{f,j}$.

The crossover operators are independently applied to C_1^{KB} and C_2^{KB} with probabilities P_{c1}^{KB} and P_{c2}^{KB}, respectively. As regards mutation, the first, second and third operators are applied to C_1^{KB} with probabilities P_{add}^{KB}, 0.1- P_{add}^{KB}, and P_{mod}^{KB}, respectively. Finally, the mutation operator is applied to C_2^{KB} with probability P_{m2}^{KB}.

C. The Single-objective Training Set Selection

We split the OTS into *B* disjoint blocks: each block contains *I=N/B* instances randomly extracted from the OTS. Each RTS consists of *K* blocks. Thus, in the SOGA we exploit a chromosome C^{TS} which codifies the *K* blocks included in the RTS: each gene is an integer which varies from 1 to *B* and represents the index of the block selected to be included in the RTS.

The aim of the evolutionary process is to find the *K* blocks which are the best representatives of the OTS. We measure the degree *DR* of representativeness as follows. First, for each solution C_i^{KB} ($i = 1,..., N^{KB}$, where N^{KB} is the number of solutions contained into the (2+2)M-PAES archive), we compute the MSE/2 by using the OTS and the RTSs codified in all chromosomes C_j^{TS} ($j = 1,..., N^{TS}$, where N^{TS} is the number of individuals in the SOGA population). We refer to these MSEs as $MSE_i / 2$ and $MSE_{i,j} / 2$, respectively. Then, we compute:

$$DR_j = \frac{1}{N^{KB}} \sum_{i=1}^{N^{KB}} \frac{|\, MSE_i / 2 - MSE_{i,j} / 2 \,|}{\max\left(MSE_i / 2, MSE_{i,j} / 2\right)}. \quad (2)$$

The lower the value of DR_j, the more the RTS encoded in C_j^{TS} achieves performance similar to the OTS.

In order to perform the optimization of the TSS population, we exploit a classical SOGA. We start with a randomly generated initial population P_0. At each iteration *t*, the fitness function DR_j of each individual *j* is evaluated and individuals are selected for reproduction by using the roulette wheel selection. To generate the offspring population Q_t of N^{TS} individuals both one-point crossover and mutation are used. The mutation operator, when selected, randomly chooses a gene in [1, *K*] and changes the value of the gene with an integer randomly chosen in the interval [1, *B*].

The one-point crossover could generate descendants with one or more pairs of genes which have the same value. This corresponds to have duplicate blocks in the *K* blocks which compose the RTS. If this occurs, we change randomly the value of one of the equal genes so as to eliminate duplicate blocks. In the experiments, we executed the one-point

crossover and the mutation operators with probabilities P_c^{TS} and P_m^{TS}, respectively.

The new population P_{t+1} coincides with Q_t except for the worst 5% individuals which are replaced with the best 5% individuals of P_t (in practice, we use an elitist strategy where the worst individuals of the offspring population are replaced with the best individuals of the parent population with a percentage of 5%).

IV. Experimental Results

The method has been tested on two regression problems (available at http://sci2s.ugr.es/keel/category.php?cat=reg#sub2), namely Elevators and Ailerons. As shown in Table I, the datasets are characterized by a high number of both input variables and input/output patterns.

We compare the results obtained by the proposed co-evolutionary approach (denoted as PAES-SOGA(10%)), which uses the 10% of the OTS, with the ones obtained by executing the (2+2)M-PAES with the 2LRS on the OTS (denoted as PAES). We performed a five-fold cross validation and executed each fold six trials with different seeds (thirty trials in total).

Table II shows the values used for the parameters of PAES and of PAES-SOGA(10%) in the experiments. These parameters have been obtained after a long experimentation. In particular, the choice of the probability values derives from an accurate analysis carried out to balance exploitation and exploration during the evolutionary process.

As stopping condition, we use the maximum number of evaluations. This number of evaluations is fixed to 50000 for both the algorithms. In the case of PAES-SOGA(10%) we consider as total number of evaluations the ones performed on the RTS.

Since the generation of the RBs is based on the selection of rules and conditions from the initial RB computed by the WM algorithm, in Table III we show the mean values $\overline{MSE_{TR}/2}$ and $\overline{MSE_{TS}/2}$, and the standard deviations σ_{TR} and σ_{TS} of the MSE/2 computed on the training and test sets, respectively, and the mean number $\overline{R}$ and the standard deviation σ_R of the rules of the MFRBSs generated by the WM algorithm.

In order to analyze the effectiveness of the evolutionary process when the RTSs are used in place of the OTSs, we adopt the hypervolume indicator, computed by using the MSE/2 calculated on the OTS for both PAES and PAES-SOGA(10%). Thus, for the PAES-SOGA(10%), we re-compute the MSE/2 of the solutions contained in the final archive by using the OTS in place of the RTS. The new values of MSE/2 might make some solution dominated by other solutions in the archive. Thus, before computing the indicator, we select the non-dominated solutions so as to generate again a Pareto front approximation.

TABLE I. Datasets Used in the Experiments

Dataset name	Number of patterns	Number of input variables
Elevators (ELV)	16599	18
Ailerons (AIL)	13750	40

TABLE II. Values of the Parameters Used in the Experiments

Parameter		Value
AS	(2+2)M-PAES archive size	64
N^{TS}	SOGA population size	32
ZS	Number of evaluations in the SOGA for each cycle	64
ZR	Number of evaluations in the (2+2)M-PAES block	640
T_f	Number of fuzzy sets in each variable X_f, f	3
M_{MIN}	Minimum number of rules	5
M_{MAX}	Maximum number of rules	30
P_{c1}^{KB}	Probability of applying the crossover operator to C_1^{KB}	0.2
P_{c2}^{KB}	Probability of applying the crossover operator to C_2^{KB}	0.5
P_{m1}^{KB}	Probability of applying the mutation to C_1^{KB}	0.1
P_{add}^{KB}	Probability of applying the first mutation operator to C_1^{KB}	0.07
P_{mod}^{KB}	Probability of applying the third mutation operator to C_1^{KB}	0.7
P_{m2}^{KB}	Probability of applying the mutation operator to C_2^{KB}	0.2
P_c^{TS}	Probability of applying the crossover operator to C^{TS}	0.1
P_m^{TS}	Probability of applying the mutation operator to C^{TS}	0.01
I	Number of instances in a block	5

TABLE III. Average Results Achieved by the WM Algorithm

	$\overline{MSE_{TR}/2}$ (σ_{TR})	$\overline{MSE_{TS}/2}$ (σ_{TS})	$\overline{R}$ (σ_R)
ELV	1.584E-5 (0.024E-5)	1.596E-5 (0.076E-5)	537.7 (11.9)
AIL	3.19E-8 (0.19E-8)	3.26E-8 (0.23E-8)	1116.8 (51.3)

The hypervolume indicator, whose features and properties have been discussed in detail in [27], measures the hypervolume of the portion of the objective space that is weakly dominated by a Pareto front approximation. The computations of the hypervolume were performed using the performance assessment package provided in the PISA toolkit [28]. In this package, the value of the indicator is normalized in [0,1] and lower values are associated with better performances.

The analysis of the box plots, shown in Figs. 2 and 3, suggests that in both datasets the hypervolumes of the Pareto front approximations generated by the PAES-SOGA(10%) and PAES are quite similar. This is also confirmed by the results of the Wilcoxon signed-rank test [28] executed with significance level α = 0.05. Indeed, the two distributions of the hypervolumes associated with the two algorithms result to be statistically equivalent. This means that the evolutionary process, in terms of both exploration and exploitation, is not affected by using the RTSs rather than the OTS.

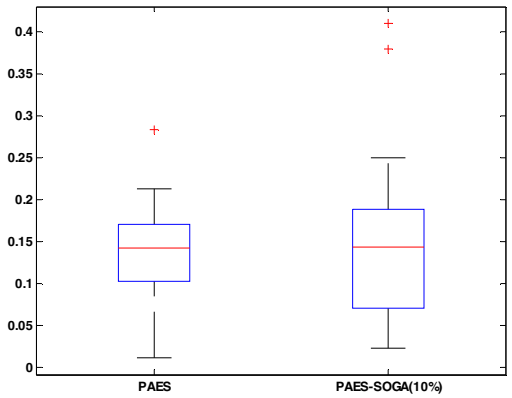

Figure 2. Box plots of the hypervolume indicators for the ELV dataset

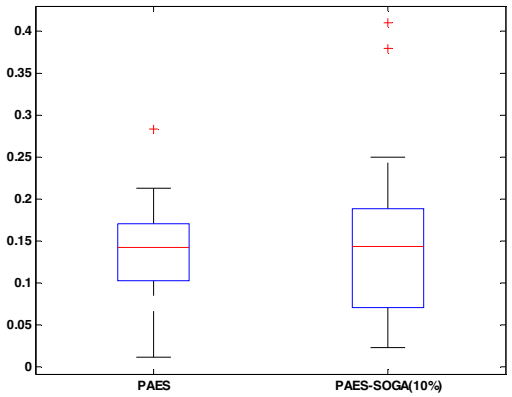

Figure 3. Box plots of the hypervolume indicators for the AIL dataset

To evaluate the MFRBSs generated by PAES and PAES-SOGA(10%) in terms of accuracy and complexity, we applied the procedure introduced in [10]. This procedure analyzes the mean and standard deviation of three representative points of the approximated Pareto front on the plane complexity-MSE/2, namely the first (the most accurate and complex), the median and the last (the least accurate and complex). This three points are referred as FIRST, MEDIAN and LAST, respectively. From an operative point of view, for each of the thirty trails, first we order the solutions of the approximated Pareto front for increasing MSE/2 values, then, we calculate the average values and the corresponding standard deviations over the thirty trials, of the MSE/2 and complexity values related to the three points for both the training and test sets.

In Figures 4 and 5, we plot the average values of the three points for ELV and AIL datasets, respectively, both on the training and test sets. We observe that there do not exist substantial differences between the training and test sets. This highlights that both the algorithms do not suffer from the overfitting problem. This result is particularly significant for PAES-SOGA(10%) which uses an RTS for most of the evolutionary optimization process. Further, though the solutions generated by PAES-SOGA(10%) are characterized by approximately the same MSE/2 as the ones generated by PAES, they result to be generally less complex.

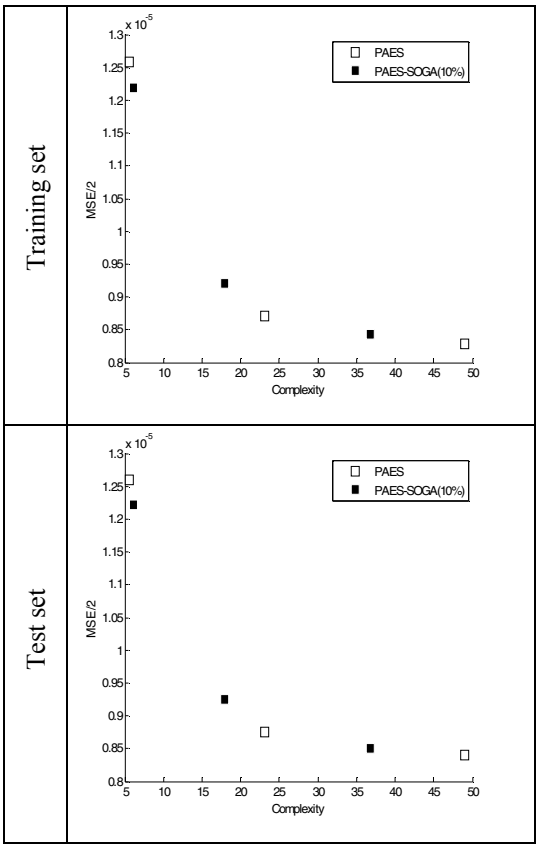

Figure 4. Average values of the FIRST, MEDIAN and LAST solutions for the ELV dataset

Tables IV and V show the mean values and the standard deviations of the MSE/2 on both the training ($\overline{\text{MSE}_{\text{TR}}/2}$ and σ_{TR}) and test ($\overline{\text{MSE}_{\text{TS}}/2}$ and σ_{TS}) sets, the average complexity ($\overline{\text{COMP}}$ and σ_{COMP}), the average number of rules ($\overline{\text{RULES}}$ and σ_{RULES}) and the average number of input variables used in the final KBs ($\overline{\text{VARS}}$ and σ_{VARS}). A careful analysis of these tables confirms the great similarity of the two Pareto front approximations generated by PAES and PAES-SOGA(10%).

In order to assess if there exist statistical differences among the MSE/2 corresponding to the FIRST, MEDIAN and LAST solutions generated by the PAES-SOGA(10%) and PAES, we applied the Wilcoxon signed-rank test with 95% confidence (columns **W-t$_{\text{TR}}$** and **W-t$_{\text{TS}}$**).

The interpretation of the **W-t$_{\text{TR}}$** and **W-t$_{\text{TS}}$** columns are as follows:

* represents the best result (the most accurate);

\+ means that the best result has better performance than that of the corresponding row;

= means that the best result has performance comparable to that of the corresponding row.

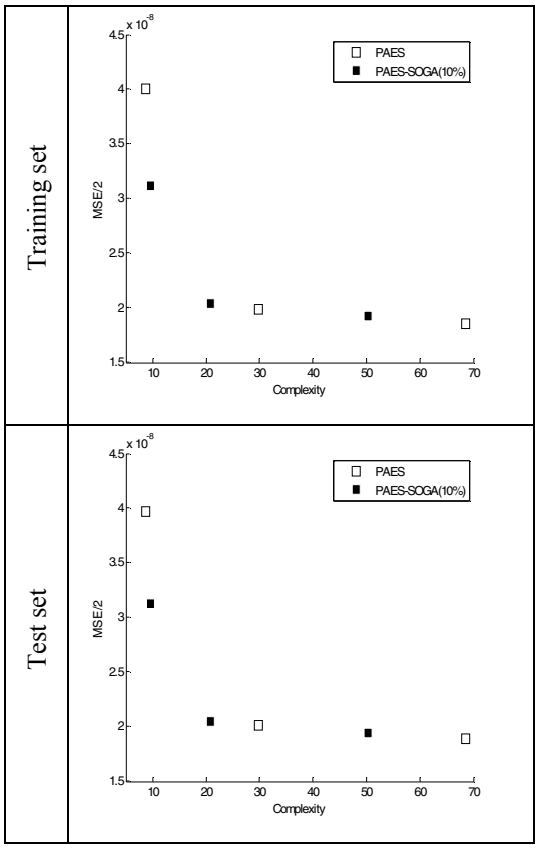

Figure 5. Average values of the FIRST, MEDIAN and LAST solutions for the AIL dataset

The results of the test confirm that choosing a specific solution in a Pareto front approximation generated by PAES is not different from choosing a corresponding solution in a Pareto front approximation obtained by the PAES-SOGA(10%), at least in terms of MSE/2. Also, typically, the solutions generated by the PAES-SOGA(10%) are characterized by a lower complexity.

TABLE IV. AVERAGE RESULTS ACHIEVED BY THE DIFFERENT MOEAS IN CORRESPONDENCE TO THE FIRST, MEDIAN AND LAST SOLUTIONS FOR THE ELV DATASET

		$\overline{MSE_{TR}/2}$ (σ_{TR})	W-t_{TR}	$\overline{MSE_{TS}/2}$ (σ_{TS})	W-t_{TR}	$Comp$ (σ_{Comp})	R (σ_R)
FIRST	PAES-SOGA(10%)	0.843E-5 (0.040E-5)	=	0.856E-5 (0.053E-5)	=	41.5 (14.9)	10.9 (2.5)
	PAES	0.824E-5 (0.049E-5)	*	0.846E-5 (0.053E-5)	*	48.1 (13.1)	11.4 (2.3)
MEDIAN	PAES-SOGA(10%)	0.899E-5 (0.087E-5)	=	0.915E-5 (0.090E-5)	=	20.5 (6.2)	9.0 (2.0)
	PAES	0.867E-5 (0.045E-5)	*	0.882E-5 (0.051E-5)	*	23.1 (5.4)	9.4 (1.8)
LAST	PAES-SOGA(10%)	1.233E-5 (0.110E-5)	=	1.253E-5 (0.121E-5)	=	5.3 (1.4)	5.0 (0.0)
	PAES	1.231E-5 (0.171E-5)	*	1.250E-5 (0.155E-5)	*	5.9 (3.9)	5.0 (0.0)

Finally, by analyzing the execution times of the two algorithms, we realized that using an RTS that contains the 10% of the overall training set allows us to save on average the 86% of the execution time.

TABLE V. AVERAGE RESULTS ACHIEVED BY THE DIFFERENT MOEAS IN CORRESPONDENCE TO THE FIRST, MEDIAN AND LAST SOLUTIONS FOR THE AIL DATASET

		$\overline{MSE_{TR}/2}$ (σ_{TR})	W-t_{TR}	$\overline{MSE_{TS}/2}$ (σ_{TS})	W-t_{TR}	$Comp$ (σ_{Comp})	R (σ_R)
FIRST	PAES-SOGA(10%)	1.92E-8 (0.10E-8)	=	1.94E-8 (0.11E-8)	=	50.3 (31.7)	7.9 (1.75)
	PAES	1.85E-8 (0.09E-8)	*	1.89E-8 (0.11E-8)	*	68.5 (49.5)	9.2 (2.4)
MEDIAN	PAES-SOGA(10%)	2.04E-8 (0.15E-8)	=	2.05E-8 (0.18E-8)	=	20.7 (13.8)	6.2 (0.9)
	PAES	1.99E-8 (0.18E-8)	*	2.02E-8 (0.19E-8)	*	29.7 (19.2)	6.9 (1.0)
LAST	PAES-SOGA(10%)	3.12E-8 (0.77)	*	3.13E-8 (0.82E-8)	*	9.6 (11.7)	5.0 (0.1)
	PAES	4.00E-8 (2.57E-8)	=	3.97E-8 (2.46E-8)	=	8.7 (9.8)	5.0 (0.0)

V. CONCLUSION

In this paper, we have proposed a novel approach to deal with high dimensional and large datasets in the framework of multi-objective evolutionary learning of Mamdani Fuzzy Rule-based Systems (MFRBSs) with different trade-offs between accuracy and interpretability.

The proposed algorithm is based on a co-evolutionary approach which allows us to concurrently perform an evolutionary training set selection (TSS) and a multi-objective evolutionary learning of the rule base (RB) and of the membership functions parameters. The RB is built by selecting first a reduced number of rules from a previously generated rule base, and then a reduced number of conditions for each selected rule. In this way, we are able to improve the convergence ability of the learning process in terms of speed and quality of the generated solutions. Furthermore, the evolutionary TSS allows us to save considerable execution time.

We experimented our method (PAES-SOGA) on two real world regression problems, characterized by a high number of both input variables and input/output patterns. The obtained results have been compared with the ones obtained by the same learning method applied using the overall dataset (PAES). By using statistical tests, we have shown that the Pareto front approximations are statistically equivalent in terms of the hypervolume indicator and three representative points. Furthermore, though the PAES-SOGA uses a reduced training set, the algorithm does not suffer from overfitting. Finally, we have observed that, the use of a training set containing the 10% of the overall training set allows us on average to save the 86% of the execution time needed when the overall training set is used.

***Abstract*—We investigate a generalized control problem via the Circle criterion borrowed from system theory; the generalized controller can be cast into existing canonical controllers depending on parameterizations. We first show a fuzzy version of the Circle criterion and then provide a synthesis result based on the Circle criterion, establishing closed-loop stabilizability for state-feedback controllers. In this paper, we show how to incorporating the membership information by approximating the cone of copositive matrices via SOS that is solvable by SOSTOOLS. Finally the validity and applicability of the approach are illuminated by examples.**

***Index Terms*—Stabilizing controllers; Circle criterion; TS fuzzy models; Linear matrix inequality (LMI); Sum of Squares (SOS); Exact solutions**

I. Introduction

OVER the decades, a large number of important results on stabilization have been derived for TS fuzzy models, which rely on the existence of a common P matrix to a quadratic Lyapunov function [1]. In a broader view, a fuzzy system may have nonlinear functions (such as parameter uncertainties, saturating inputs) involved in the model. How to tackle such problem becomes the focus of this paper. Motivated by the above mentioned nonlinearity involved in a fuzzy model and the literature on system theory [2], [3], [4], [5], [6] and references therein, we investigate a unified approach to synthesize stabilizing controllers for nonlinear fuzzy systems via system criteria. The multivariate circle criterion has been used to graphically analyze the robust stability of a fuzzy feedback linearization regulator [7]. Furthermore the circle criterion and the related Popov criterion have suggested ways to study the stability of Mamdani-type fuzzy control systems with a linear plant [8], [9], [10], [11]. While most existing papers use Mamdani-type fuzzy systems, when applying the circle criterion via graphical analysis, is for stability test, we focus on T-S fuzzy control models. Equipped with the system criteria in order to profit from the advantage of convex optimization, we propose a generalized controller, which unifies all existing controllers, for T-S fuzzy control systems, aiming at synthesizing stabilizing controllers such that the corresponding closed-loop fuzzy system is asymptotically stable. Although various control laws have been studied in the fuzzy literature, there exist no reports showing, via the generalized controller, the subtle relations among all stabilizing control laws.

This work was supported in part by the National Science Council of the ROC under grant NSC-98-2221-E-008-110.

Genetically, stability/stabilization of a fuzzy control problem is a copositive problem since checking positivity of the fuzzy matrix-valued polynomial in μ ($-\sum_i \sum_j \mu_i \mu_j M_{ij} > 0$) involves copositive matrices $-M_{ij}$, known to be NP-hardness. To avoid the NP-hardness, a solution to this problem was proposed by Parrilo [12] who showed that one can approximate the copositive cone to a given accuracy by a sufficiently large set of LMIs (therefore, only sufficient condition is shown.) Following the developments [13], [14], [15], [16], [17], we, via SOS, investigate copositive relaxation searching for existence of an SOS decomposition assuring exactness of solution to fuzzy PD-LMIs. Under this relaxation, the search for a bounded degree d, indicating exactness, can be efficiently performed and cast as an SOS program, establishing the use of SOS decomposition to solve the LMI formulations.

The organization of this paper is as follows. Section II rederives a fuzzy version of the Circle theorems expressed in an LMI formulation. In section III, a state feedback controller falling out of the general setting is addressed. The mechanism involved demonstrates that a unified treatment aiming at solving the absolute stability problems is addressed. An illustrative example is considered in Section V and concluding remarks are made in Section VI.

Notations: The symbol $\star$ is used for the transposed elements in a symmetric matrix, and $M < 0$ means a negative-definite symmetric matrix M. The notations Y_μ and $Y_{\mu\mu}$ stand for $\sum_{i=1}^r \mu_i Y_i$ and $\sum_{i=1}^r \sum_{j=1}^r \mu_i \mu_j Y_{ij}$, where $\mu_i \geq 0$ and $\sum_{i=1}^r \mu_i = 1$. The indices $i, j = 1, 2, \cdots, r$ (number of fuzzy rules) are used throughout this paper. ! denotes factorial for combinatoric expression. Let $\mathcal{K}(h)$, where h is the degree of a polynomial in μ, be the set of r-tuple defined below:

$$\mathcal{K}(h) = \{(k_1\ k_2\ \cdots\ k_r) : k_1 + k_2 + \cdots + k_r = h,$$

$$\forall k_i \in I^+(non - negative\ integers), i = 1, 2, \cdots, r\}.$$

Since the number of rules in the fuzzy rule base is r, the number of elements in $\mathcal{K}(h)$ is given by $J(h) = (r + h - 1)!/(h!(r-1)!)$. To ease the presentation, we adopt the short

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

hand notations displayed below:

$$\begin{aligned} k &= k_1 k_2 \cdots k_r \\ \mu^k &= \mu_1^{k_1}\mu_2^{k_2}\cdots\mu_r^{k_r} \\ \pi(k) &= (k_1!)(k_2!)\cdots(k_r!). \end{aligned}$$

$$\mathcal{C}_{ii}^k(h) = \frac{(h!)k_i(k_i-1)}{\pi(k)},\ \mathcal{C}_{ij}^k(h) = \frac{(h!)k_ik_j}{\pi(k)}.$$

II. The Circle Criterion

We first state the Circle criterion and then study the synthesis of a state feedback controller. To facilitate the presentation, we assume that the readers are familiar with the basic fuzzy setup consisting of r fuzzy rules whose consequent parts are characterized by local Takagi-Sugeno type linear models. Then by using a standard fuzzy inference method – singleton fuzzifier, product fuzzy inference and weighted average defuzzifier, the inferred fuzzy model of interest, after normalization, is described by the following nominal (closed-loop) fuzzy system

$$\left[\begin{array}{c} \dot{x} \\ z \end{array}\right] = \left[\begin{array}{cc} \mathcal{A}_\mu & -\mathcal{B}_\mu \\ \mathcal{C}_\mu & -\mathcal{D}_\mu \end{array}\right]\left[\begin{array}{c} x \\ \phi(z,\cdot) \end{array}\right] \tag{1}$$

where $x \in R^n$, $\phi(z,\cdot) \in R^m$, $z \in R^m$ and $\mu_i \geq 0$ are the state vector, time-varying nonlinearity, controlled output, and grade of membership, respectively. The "$\cdot$" in the function $\phi(z,\cdot)$ means either the continuous-time t or the discrete-time k. $\mathcal{A}_i$, $\mathcal{B}_i$, $\mathcal{C}_i$, and $\mathcal{D}_i$ are real constant matrices of appropriate dimensions. It is noted that the negative signs in front of $\mathcal{B}_\mu$ and $\mathcal{D}_\mu$ are due to the negative feedback connection in system theory. Although the signs can be absorbed into the matrices, we keep the negative signs to signal the trait of absolute stability. We assume $(\mathcal{A}_i, \mathcal{B}_i)$ is completely controllable and $(\mathcal{A}_i, \mathcal{C}_i)$ is completely observable. To understand the Circle criterion

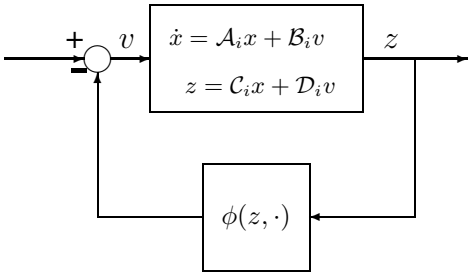

Fig. 1. Fuzzy local subsystem with nonlinear feedback connection.

borrowed from absolute stability, we need to introduce the nonlinear structure of the feedback connection ϕ depicted in Figure 1. The following definition is useful to this aim.

Definition 1 (Nonlinear Connection): Let $K_{\min} = diag(\alpha_1,\cdots,\alpha_m)$ and $K_{\max} = diag(\beta_1,\cdots,\beta_m)$ be two given diagonal matrices, the nonlinearity is characterized by the following sector bounded set $\Phi_c = \{\phi(z,\cdot) : R^m \times R^+ \rightarrow R^m$ such that $(\phi - K_{\min}z)'(\phi - K_{\max}z) \leq 0.\}$, where R^+ denotes positive real numbers for the continuous-time space over $[0.\infty)$.

The function $\phi(z,\cdot)$ defined above represents a memoryless, possibly time-varying nonlinearity. It is assumed that $\phi(z,\cdot)$ satisfies the Lipschitz condition $||\phi(z_1,\cdot)-\phi(z_2,\cdot)|| \leq L||z_1 - z_2||$ for all $(z_1,\cdot)$ and $(z_2,\cdot) \in R^m \times R^+$, where the positive constant L is called the Lipschitz constant. Moreover, it is sectorly bounded as defined in Definition 1.

Remarks:

1) For the scalar case $m = 1$, the sector condition characterizing Φ_c is equivalent to the more familiar SISO condition $\alpha_1 z \leq \phi \leq \beta_1 z$.
2) In this paper we interpret the nonlinear connection ϕ as a nonlinear term in local submodels representing unmodel dynamics. However, if ϕ were energy bounded external disturbance ($w \in L_2$), the setting (1) would be a typical H_∞ problem.

Given the definition, we establish the following theorem for the continuous-time systems.

Theorem 1 (Continuous Circle): The nominal system (1) is asymptotically stable if there exists a $\mathcal{P} > 0$ satisfying

$$M_i = \left[\begin{array}{ccc} \mathcal{A}_i'\mathcal{P} + \mathcal{P}\mathcal{A}_i & -\mathcal{P}\mathcal{B}_i + \mathcal{C}_i\bar{K}' & \mathcal{C}_i' \\ -\mathcal{B}_i'\mathcal{P} + \bar{K}\mathcal{C}_i & -I - (\bar{K}\mathcal{D}_i + \star) & -\mathcal{D}_i' \\ \mathcal{C}_i & -\mathcal{D}_i & 2K_1 \end{array}\right] < 0 \tag{2}$$

where $K_1 = (K_{\min}'K_{\max} + \star)^{-1} < 0$ and $\bar{K} = (K_{\min} + K_{\max})/2$.

Proof: Using a quadratic Lyapunov function $V(t) = x'\mathcal{P}x$ to show that the system (1) is asymptotically stable, we derive a stability condition for the following inequality

$$\dot{V} - (\phi - K_{\min}z)'(\phi - K_{\max}z) < 0. \tag{3}$$

We know in passing that the second term in (3) is negative by Definition 1. That is to say satisfaction of (3) implies

$$\dot{V} < (\phi - K_{\min}z)'(\phi - K_{\max}z) \leq 0$$

and the underlying systems is stable absolutely. The problem under study is referred to as the absolute stability problem, also known as the Luré problem. To continue the stability proof, it is straightforward to verify the following identity

$$\begin{aligned} & \dot{V} - (\phi - K_{\min}z)'(\phi - K_{\max}z) \\ = \ & x'(\mathcal{A}_\mu'\mathcal{P} + \mathcal{P}\mathcal{A}_\mu)x - \phi'\mathcal{B}_\mu'\mathcal{P}x - x'\mathcal{P}\mathcal{B}_\mu\phi \\ - \ & \phi'\phi + \phi' K_{\max}\mathcal{C}_\mu x \\ + \ & x'\mathcal{C}_\mu' K_{\min}'\phi - \phi' K_{\max}\mathcal{D}_\mu\phi \\ - \ & \phi'\mathcal{D}_\mu' K_{\min}'\phi - x'\mathcal{C}_\mu' K_{\min}' K_{\max}\mathcal{C}_\mu x \\ - \ & \phi'\mathcal{D}_\mu' K_{\min}' K_{\max}\mathcal{D}_\mu\phi \\ + \ & \phi'\mathcal{D}_\mu' K_{\min}' K_{\max}\mathcal{C}_\mu x + x'\mathcal{C}_\mu' K_{\min}' K_{\max}\mathcal{D}_\mu\phi \\ = \ & \left[\begin{array}{c} x \\ \phi \end{array}\right]' M_\mu \left[\begin{array}{c} x \\ \phi \end{array}\right] \end{aligned}$$

where the matrix M_μ is defined below

$$\begin{aligned} M_\mu = & \left[\begin{array}{cc} \mathcal{A}_\mu'\mathcal{P} + \mathcal{P}\mathcal{A}_\mu & -\mathcal{P}\mathcal{B}_\mu + \mathcal{C}_\mu\bar{K}' \\ -\mathcal{B}_\mu'\mathcal{P} + \bar{K}\mathcal{C}_\mu & -I - (\bar{K}\mathcal{D}_\mu + \star) \end{array}\right] \\ & - \left[\begin{array}{c} \mathcal{C}_\mu' \\ -\mathcal{D}_\mu' \end{array}\right] \frac{(K_{\min}'K_{\max} + \star)}{2} \left[\begin{array}{cc} \mathcal{C}_\mu & -\mathcal{D}_\mu \end{array}\right]. \end{aligned} \tag{4}$$

A sufficient condition ensuring (3) is $M_\mu < 0$. To recast $M_\mu < 0$ into a feasibility problem solvable by convex algorithms, performing the Schur complement on $M_\mu < 0$ and factoring out $\sum_{i=1}^{r} \mu_i$ yields the sufficient condition LMI (2). ■

III. Generalized Stabilizing Controllers

Having established the working theorems, we are ready to consider stabilization problems concerning absolute stability. To begin, setting up a T-S fuzzy model

$$\begin{bmatrix} \dot{x} \\ z \\ y \end{bmatrix} = \begin{bmatrix} A_\mu & -B_{1\mu} & B_{2\mu} \\ C_{1\mu} & -D_{11\mu} & D_{12\mu} \\ C_{2\mu} & -D_{21\mu} & 0 \end{bmatrix} \begin{bmatrix} x(\cdot) \\ \phi(z,\cdot) \\ u(\cdot) \end{bmatrix} \tag{5}$$

where $y \in R^q$ is the measured output, u is the control input, and all other variables are as in (1). A measured output variable y is a system variable that can be measured or through which the system influences its environment while a controlled output z is a system variable that can be controlled by some control scheme but not necessarily measurable.

To stabilize the T-S fuzzy model, we consider a generalized controller inspired by [5]

$$\begin{bmatrix} \dot{\hat{x}} \\ u \end{bmatrix} = \begin{bmatrix} F_{\mu\mu} & G_\mu & S_\mu \\ N_\mu & J & 0 \end{bmatrix} \begin{bmatrix} \hat{x} \\ y \\ u \end{bmatrix} \tag{6}$$

where F_{ij}, G_i, S_i, N_i and J are generalized parameters of appropriate dimensions. The generalized controller above has a nice merit encompassing the dynamic output feedback controller, the observed-state feedback controller and the state feedback controller.

To describe a state feedback controller, simply neglect the dynamic part of (6) by setting $F_{\mu\mu} = 0$, $G_\mu = 0$, $S_\mu = 0$, $J = 0$, and letting $\hat{x} = x$. Such control depends only on the fuzzy blending of the state x, known as a static (memoryless) state feedback (fuzzy) control or a PDC controller in fuzzy community.

Substituting the controller (6) into the open loop system (5), we have the closed-loop system displayed below.

$$\begin{bmatrix} \dot{\overline{x}} \\ z \end{bmatrix} = \begin{bmatrix} \mathcal{A}_{\mu\mu} & -\mathcal{B}_{\mu\mu} \\ \mathcal{C}_{\mu\mu} & -\mathcal{D}_{\mu\mu} \end{bmatrix} \begin{bmatrix} \overline{x} \\ \phi(z,\cdot) \end{bmatrix} \tag{7}$$

where

$$\bar{x} = \begin{bmatrix} x \\ \hat{x} \end{bmatrix}$$

$$\mathcal{A}_{\mu\mu} = \sum_{i=1}^{r}\sum_{j=1}^{r} \mu_i\mu_j \begin{bmatrix} A_i + B_{2i}JC_{2j} & B_{2i}N_j \\ G_iC_{2j} + S_iJC_{2j} & F_{ij} + S_iN_j \end{bmatrix}$$

$$\mathcal{B}_{\mu\mu} = \sum_{i=1}^{r}\sum_{j=1}^{r} \mu_i\mu_j \begin{bmatrix} B_{1i} + B_{2i}JD_{21j} \\ G_iD_{21j} + S_iJD_{21j} \end{bmatrix}$$

$$\mathcal{C}_{\mu\mu} = \sum_{i=1}^{r}\sum_{j=1}^{r} \mu_i\mu_j \begin{bmatrix} C_{1i} + D_{12i}JC_{2j} & D_{12i}N_j \end{bmatrix}$$

$$\mathcal{D}_{\mu\mu} = \sum_{i=1}^{r}\sum_{j=1}^{r} \mu_i\mu_j (D_{11i} + D_{12i}JD_{21j}).$$

Having established the closed-loop system (7) with the generalized controller (6) embedded, our investigation is performed on the basis of this setting and then derive the corresponding results for stabilization analysis and controller synthesis.

A. State Feedback Synthesis - LMI

A corollary characterizing state feedback controller synthesis fall out immediately by simplifying the generalized controller (6) to a state feedback controller $u = \sum_{i=1}^{r} \mu_i N_i x = N_\mu x$.

Corollary 1 (State Feedback Ctr, LMI): The closed-loop system (7) is asymptotically stable for all $\phi(z,\cdot) \in \Phi_c$ if, given $K_{\min}$ and $K_{\max}$, there exists a feasible solution $(Q > 0, \mathbf{N}_j)$ satisfying (8) where $K_1 = (K'_{\min}K_{\max} + \star)^{-1} < 0$, $\bar{K} = (K_{\min} + K_{\max})/2$, and $\mathbf{N}_j = N_jQ$.

Proof: The proof is straightforward, given Theorem 1. ■

Noting that the PD-LMIs (4) is a matrix-valued polynomial of degree 1 (a.k.a. affine) in μ, and $\sum_{i,j=1}^{r} \mu_i\mu_j M_{ij}$, where M_{ij}, at the top of next page, is defined in (8), is of degree 2 (a.k.a. quadratic) in μ.

IV. Sum of Squares

Applying Lyapunov-based quadratic stability to the aforementioned fuzzy control system (7), Corollary 1 is shown to bear the following form

$$M_{\mu\mu} < 0 \tag{9}$$

By applying matrix-valued Pólya's Theorem [18], [19], [20], (9) leads to

$$(\sum_{i=1}^{r} \mu_i)^d M_{\mu\mu} < 0 \tag{10}$$

The PD-LMIs (10) comprise of infinitely many LMIs, thus being a feasibility problem of infinite dimensions. We need to obtain a set of convex finite-dimensional LMI conditions associated to PD-LMIs (10) so that the relaxation becomes a finite-dimensional problem. The proposed methodology is formally stated below.

Theorem 2 (Exact Solutions for QS): Given $K_{\min}$ and $K_{\max}$. The closed-loop T-S fuzzy control system (7) is quadratically stabilizable by a state feedback PDC control (6) if and only if there exist matrices $\mathbf{N}_j$, $j = 1, 2, \ldots, r$; $Q = Q' > 0$ and a sufficient large $d > 0$ such that

$$\sum_{k \in \mathcal{K}(d+2)} H^k \mu^k < 0 \tag{11}$$

where

$$H^k = \sum_{i=1}^{r} C_{ii}^k(d) M_{ii} + \sum_{i=1}^{r-1}\sum_{j=i+1}^{r} C_{ij}^k(d)(M_{ij} + M_{ji})$$

and M_{ij} is defined in (8).

Proof: See Theorem 1 in [21] and Lemma 1 in [15]. ■

For Theorem 2, the challenge lies on how the above conditions can be verified. To this end, we seek help from SOS. The details are documented in [13] whilst the corresponding

$$M_{ij} = \begin{bmatrix} A_iQ + B_{2i}\mathbf{N}_j + \star & \star & \star \\ -B_{1i}' + \bar{K}(C_{1i}Q + D_{12i}\mathbf{N}_j) & -I - (\bar{K}D_{11i} + \star) & \star \\ (C_{1i}Q + D_{12i}\mathbf{N}_j) & -D_{11i} & 2K_1 \end{bmatrix} < 0 \tag{8}$$

LMI details are documented in [14]. We emphasize that the homogeneous polymomially parameter-dependent (HPPD) function (11) takes the membership μ into accounts, yielding less conservative results.

A. State Feedback Synthesis - SOS

Therefore, by deliberately working on polynomials consisting of basis monomials, the negated condition in Theorem 2 can be relaxed to the existence of SOS decomposition. Under this relaxation, the search for a bounded degree $2d+4$ can be efficiently solved. The SOS program is therefore formally stated below.

Corollary 2 (State Feedback Ctr, SOS): Given $K_{\min}$ and $K_{\max}$. There exist a matrix $Q = Q' > 0$ and a PDC controller (6) solving (9) if and only if for each $k \in \mathcal{K}(d+2)$ and a sufficiently large $d > 0$ there exist matrices $\mathbf{N}_j$, $j = 1, 2, \ldots, r$, $Q = Q' > 0$ such that

$$-v_1' \left(\sum_{k \in \mathcal{K}(d+2)} (H^k + \phi_1 I) x^{2k} \right) v_1 \text{ is SOS}$$
$$v_2' \left((Q - \phi_2 I) x^{2k} \right) v_2 \text{ is SOS}$$

ϕ_1 and ϕ_2 are sufficiently small positive constants and v_1, v_2 are vectors independent of x.

Proof: The proof is readily obtained from Theorem 2 and the copositive statement following Theorem 2. ■

V. An Example

A. Inverted pendulum on a cart

Consider the problem of balancing and swinging up of an inverted pendulum on a cart [6]. The system is approximated by the following two-rule model:

$$\text{IF } x_1 \text{ is about } 0 \text{ THEN } \dot{x} = A_1 x + B_1 v$$
$$\text{IF } x_1 \text{ is about } \pm\frac{\pi}{2} \text{ THEN } \dot{x} = A_2 x + B_2 v$$

where

$$A_1 = \begin{bmatrix} 0 & 1 \\ \frac{g}{\frac{4l}{3} - aml} & 0 \end{bmatrix}, B_1 = \begin{bmatrix} 0 \\ \frac{-\mu a}{\frac{4l}{3} - aml + b_1} \end{bmatrix}$$
$$A_2 = \begin{bmatrix} 0 & 1 \\ \frac{2g}{\pi(\frac{4l}{3} - aml\beta^2)} & 0 \end{bmatrix}, B_2 = \begin{bmatrix} 0 \\ \frac{-\mu a\beta}{\frac{4l}{3} - aml\beta^2 + b_2} \end{bmatrix}$$

and $\beta = \cos(88^\circ)$. Membership functions for Rule 1 and Rule 2 are given as follows:

$$p_1 = \cos(x_1), \;\; p_2 = 1 - p_1.$$

The control objective is to balance the inverted pendulum for the approximation range $x_1 \in [-\pi/2, \pi/2]$. The saturation function ϕ is given by

$$\phi = \begin{cases} u & if \; |u| \le 0.1 \\ 0.1 + 0.5(u - 0.1) & if \; u > 0.1 \\ -0.1 - 0.5(-u - 0.1) & if \; u < -0.1 \end{cases}$$

To demonstrate the superiority of SOS technique as opposed to LMI method, a comparison study for feasibility is conducted. Two varying parameters b_1 and b_2 are inserted into input matrices for feasibility test and the results are obtained for $d = 0$ and shown in Figures 2-3 respectively. It is crystal clear that SOS method can explore more solution space than LMI scheme.

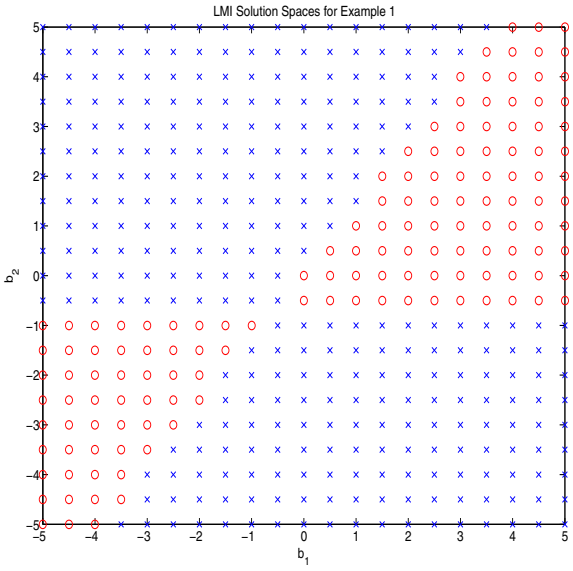

Fig. 2. LMI feasibility test

VI. Conclusion

A feedback stabilization problems involving absolute stability is presented. The Circle criterion borrowed from absolute stability is applied to derive LMI and SOS test conditions. Both results are shown, validating that the feasibility via SOS is much less conservative than that of LMIs scheme. A protruding feature of the SOS approach is that NO slack variables are involved and the membership functions are considered.

***Abstract*—A novel approach to control of general nonlinear system based on T-S fuzzy model is presented in this paper. Firstly, it is shown that a general nonlinear system can be approximated by a generalized T-S fuzzy model to arbitrary degree of accuracy on any compact set. And the basic idea of the proposed approach is to stabilize the general nonlinear system by solving a robust stabilization problem of the developed T-S fuzzy system with the approximation errors as the uncertainty term. Then using a piecewise Lyapunov function, robust semi-global stabilization and generalized $\mathscr{H}_2$ control of the general nonlinear system are formulated in the form of linear matrix inequalities. Finally, an example is provided to demonstrate the effectiveness of the proposed approaches.**

***Index Terms*—Approximation, General nonlinear systems, Piecewise Lyapunov functions, T-S fuzzy model, Robust Control.**

I. Introduction

Takagi and Sugeno (T-S) type fuzzy models [1] have been widely studied recently and proved to be one of the most powerful approaches to nonlinear control [2]-[5]. This model describes a nonlinear system by a group of fuzzy IF-THEN rules in the form of local linear or affine models which are smoothly connected by fuzzy membership functions. And this structure provides a basis for systematic stability analysis and controller design of T-S fuzzy control systems in view of powerful conventional control theory.

In the past decades, a large volume of works on theoretical results of stability analysis and controller synthesis of T-S fuzzy systems have been published. Readers can refer to the survey paper [6] and the references therein for details. By using the direct Lyapunov method, it is shown that stability analysis and controller design of T-S fuzzy systems can be facilitated by searching for a common quadratic Lyapunov function [7]. In order to reduce the conservatism of common quadratic Lyapunov function based approaches, some results based on piecewise quadratic and fuzzy Lyapunov functions have been proposed [8]-[16].

T-S fuzzy models have been shown to be universal function approximators in the sense that they are able to approximate any smooth nonlinear functions to arbitrary degree of accuracy in any convex compact region [17]-[19]. However, it is shown in [19] that the *commonly used* linear or affine T-S fuzzy models, where the control variables are not included in the premise variables are only able to approximate *affine nonlinear systems* to any degree of accuracy on any compact set. This implies that only the stabilization problem of *affine nonlinear systems* can be solved based on the *commonly used* T-S fuzzy models. In other words, to deal with more general nonlinear systems, a more general T-S fuzzy dynamic model should be employed.

Recently, some results on control design of more general nonlinear systems based on modified T-S fuzzy models have appeared in literature [20]-[22]. To describe conventional general nonlinear system approximately, the authors in [21] analyzed T-S fuzzy model with state variables and control variables contained in the conditional part of fuzzy rules, with each local model describes the dynamics of one state variable or control variable. The authors in [22] also analyzed the case that the control vector is a part of premise variables. However, only Mamdani-type fuzzy models were considered. Thus many fuzzy rules need to be used in these methods to describe global nonlinear systems and the construction of controllers is also very complex.

In this paper, we investigate the controller synthesis of general nonlinear systems based on a class of generalized T-S

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

fuzzy models, which are proved to be universal approximators. It is shown that the stabilization problem of a general nonlinear system can be solved as robust stabilization problems of a generalized T-S fuzzy system with the approximation errors as the uncertainty term. It is also noted that with the control variables included in the conditional part of fuzzy rules, the two mainly used control schemes, say, the normally parallel distributed compensation and the local compensation [2], [6], [8], can not be applied due to the logic conflicts between antecedences and consequences. Thus a dynamic state feedback controller is employed instead. Based on a piecewise Lyapunov function, it is shown that the robust semi-global stabilization and generalized $\mathscr{H}_2$ controller design results can be obtained based on the feasible solutions of a set of linear matrix inequalities that are numerically efficient with commercially available software.

The rest of this paper is structured as follows. The section II is devoted to the description of the generalized T-S fuzzy models and the proof of its universal approximation property. In section III and IV, the robust semi-global stabilization and generalized $\mathscr{H}_2$ control design results of the nonlinear system will be presented respectively. Simulation results will be provided in section V to demonstrate the effectiveness of the proposed approaches. Conclusions will be given in section VI.

Notations. The notations used in this paper are fairly standard. The notation $\star$ is used to indicate the terms that can be induced by symmetry. For example, $\begin{bmatrix} A & B^T \\ B & C \end{bmatrix} = \begin{bmatrix} A & \star \\ B & C \end{bmatrix}$. "$T$" represents vector or matrix transpose. $\mathbf{I}_n$ and $\mathbf{0}_{m\times n}$ are used to denote the $n \times n$ identity matrix and the $m \times n$ zero matrix, respectively. The subscripts n and $m \times n$ are omitted when the size is not relevant or can be determined from the context. The notation $l_2[0, N]$ will be used for discrete-time vector-valued functions, i.e., $z_d : [0, N] \to \Re^k \in l_2[0, N]$ if $\sum_{t=1}^{N} z_d^T(t)z_d(t) < \infty$. The l_2- norm is defined as $||z_d(t)||_2 = \sqrt{\sum_{t=1}^{N} z_d^T(t)z_d(t)}$ and the $l_\infty-$ norm is defined as $||z_d(t)||_\infty = \sqrt{\sup_t\{z_d^T(t)z_d(t)\}}$.

II. Generalized T-S Fuzzy Model and Universal Function Approximation

Let us consider a general nonlinear system described by the following equation,

$$x(t + 1) = G(x(t), u(t)), \tag{1}$$

where $x(t) = [x_1(t), ..., x_n(t)]^T \in X = \prod_{i=1}^{n} X_i \subset \Re^n$ with $x_0 = [0, ..., 0]^T \in X$ and $u(t) = [u_1(t), ..., u_m(t)]^T \in U = \prod_{j=1}^{m} U_j \subset \Re^m$ with $u_0 = [0, ..., 0]^T \in U$. Throughout the paper, it is always assumed that the origin is the equilibrium of the system, that is, $G(0, 0) = 0$, and $G(x, u)$ is a continuously differentiable function on $X \times U$. Further it is assumed that $X \times U = \prod_{i=1}^{n}[\underline{x}_i, \bar{x}_i] \times \prod_{j=1}^{m}[\underline{u}_j, \bar{u}_j]$ is a compact set on $\Re^n \times \Re^m$.

Our objective is to develop an approach to control of such general nonlinear systems via a way of Takagi-Sugeno (T-S) fuzzy modelling. For this purpose, we consider to approximate the nonlinear systems by the following class of generalized T-S fuzzy models at first,

Plant rule $\mathcal{R}^l$:

IF $x_1(t)$ is μ_1^l AND ... AND $x_n(t)$ is μ_n^l ; $u_1(t)$ is ν_1^l AND ... AND $u_m(t)$ is ν_m^l

$$\textbf{THEN} \quad x(t+1) = A_l x(t) + B_l u(t); l \in \mathscr{L} := \{1, ...r\} \tag{2}$$

where $\mathcal{R}^l$ denotes the lth rule, r the total number of rules, μ_i^l and ν_j^l the fuzzy sets, $x(t) \in \Re^n$ the state vector, $u(t) \in \Re^m$ the input vector, and $[A_l, B_l]$ the matrices of the lth local model.

Under the center-average defuzzifier, product inference and singleton fuzzifier, the T-S fuzzy system in (2) can be expressed as follows,

$$x(t + 1) = F(x(t), u(t)), \tag{3}$$

with

$$\begin{cases} F(x, u) = \sum_{l=1}^{r} \mu_l(x, u)[A_l x(t) + B_l u(t)], \\ \mu_l(x, u) = \frac{\prod_{i=1}^{n} \mu_i^l(x_i) \prod_{j=1}^{m} \nu_j^l(u_j)}{\sum_{l=1}^{r} \prod_{i=1}^{n} \mu_i^l(x_i) \prod_{j=1}^{m} \nu_j^l(u_j)}, \end{cases} \tag{4}$$

where $\mu_l(x, u)$ are so-called normalized fuzzy membership functions satisfying $\mu_l(x, u) \geq 0$ and $\sum_{l=1}^{r} \mu_l(x, u) = 1$ [8].

Remark 2.1. In the commonly used T-S fuzzy model, which is referred as "the standard T-S fuzzy model" in [19], the control variable u is not included in the conditional part of the rule. It has been shown in [19] that the commonly used T-S fuzzy model, where the control variable u is not included in the premise part of the rule, are only able to approximate affine nonlinear systems. Thus, to represent the more general nonlinear systems given in (1), a more general T-S fuzzy model, such as those given in (2) or (3) is needed. These models are referred to be the generalized T-S fuzzy model in this paper.

Before giving the main results of this section, we first introduce a lemma.

Lemma 2.1. [19] If vector value function $f(z) = [f_1(z_1, ..., z_N), ..., f_n(z_1, ..., z_N)]^T$ is continuously differentiable on $Z = \prod_{i=1}^{N}[\alpha_i, \beta_i]$ with $0 \in Z$ and $f(0) = 0$, then for $i = 1, ..., N$ the vector value function

$$G_i(z) = g_i(z_i, ..., z_N) = \begin{cases} \frac{f(0,...,z_i,z_{i+1},...,z_N) - f(0,...,0,z_{i+1},...,z_N)}{z_i}, & z_i \neq 0 \\ \frac{\partial f(0,...,0,z_{i+1},...,z_N)}{\partial z_i}, & z_i = 0 \end{cases} \tag{5}$$

is continuous on Z and

$$f(z) = \sum_{i=1}^{N} G_i(z)z_i = \sum_{i=1}^{N} g_i(z_i, ..., z_N)z_i. \tag{6}$$

Then one has the following result.

Theorem 2.1. Let a general nonlinear system be given in (1) where $G(x, u)$ on the compact set $X \times U$ is continuously

differentiable with $G(0,0) = 0$. Then, for any $\epsilon_1 > 0$ and $\epsilon_2 > 0$, there exists a T-S fuzzy model $F(x,u) = \sum_{l=1}^{r} \mu_l(x,u)[A_l x(t) + B_l u(t)]$ given in (3) such that, for any $(x,u) \in X \times U$

$$G(x,u) = F(x,u) + E(x,u), \tag{7}$$

and

$$\|E(x,u)\| \leq \epsilon_1 \|x\| \ + \epsilon_2 \|u\|. \tag{8}$$

Proof. See [23].

Remark 2.2. Noticing that $X \times U = \prod_{i=1}^{n}[\underline{x}_i, \bar{x}_i] \times \prod_{j=1}^{m}[\underline{u}_j, \bar{u}_j]$ are bounded, the norm bound of approximation error $\Delta E(x,u)$ will be as small as needed by choosing $\epsilon_1 > 0$ and $\epsilon_2 > 0$ accordingly. In other words, the fuzzy control system given in (3) can approximate the general nonlinear system (1) to any degree of accuracy.

Remark 2.3. It is noted the decomposition procedure in proof of Theorem 2.1 can be conducted both in continuous-time case and discrete-time case. Thus one can conclude that any given continuous-time general nonlinear systems satisfying the described conditions in Theorem 2.1 can also be approximated by a continuous-time generalized T-S fuzzy model to any degree of accuracy.

Remark 2.4. Based on Theorem 2.1, one can easily conclude that the stabilization of a general nonlinear system given in (1) can be solved as a robust stabilization problem of its corresponding T-S fuzzy model with the approximation errors as the uncertainty term.

III. Robust Controller Design for Nonlinear Systems

It has been shown in the previous section that a general nonlinear system described by (1) can be exactly expressed in a compact set by a T-S fuzzy model with some uncertainties as follows,

$$\begin{aligned} x(t+1) = F(x(t),u(t)) + \Delta A(x(t),u(t))x(t) \\ + \Delta B(x(t),u(t))u(t), \end{aligned} \tag{9}$$

where $F(x(t),u(t))$ is described by (4) and

$$\|\Delta A(x(t),u(t))\| \leq \epsilon_1 \quad \text{and} \quad \|\Delta B(x(t),u(t))\| \leq \epsilon_2.$$

In this section, we will develop a robust control design approach to the general nonlinear systems (1) via the way of T-S fuzzy modeling in terms of system (9) based on a piecewise Lyapunov function.

In order to facilitate the piecewise controller design, we partition the premise variable space S into crisp regions and fuzzy regions [3]. Denote those regions from the premise variable space partition as $\{S_i\}_{i \in \mathscr{I}}$ with $\mathscr{I}$ as the set of region indices.

Define $\mathscr{K}(i)$ the indices of fired rules in each region S_i, $i \in \mathscr{I}$, then the crisp regions and fuzzy regions can be defined respectively by

$$S_i := \Big\{(x(t),u(t)) | \mu_k(x(t),u(t)) = 1, k \in \mathscr{K}(i)\Big\}, \tag{10}$$

and

$$S_i := \Big\{(x(t),u(t)) | 0 \leq \mu_k(x(t),u(t)) < 1, k \in \mathscr{K}(i)\Big\}. \tag{11}$$

Based on such a partition method, the global fuzzy model (9) in each region can be rewritten by a blending of $k \in \mathscr{K}(i)$ subsystems,

$$\begin{aligned} x(t+1) = \sum_{k \in \mathscr{K}(i)} \mu_k(x,u)\Big\{(A_k + \Delta A(x,u))x(t) \\ + (B_k + \Delta B(x,u))u(t)\Big\}. \end{aligned} \tag{12}$$

In order to stabilize the nonlinear system in (12), we employ the following piecewise dynamic state feedback controller,

$$u(t+1) = F_i x(t) + G_i u(t), (x,u) \in S_i, i \in \mathscr{I}. \tag{13}$$

Then the closed-loop control system can be described by

$$\bar{x}(t+1) = \left\{ \sum_{k \in \mathscr{K}(i)} \mu_k(\bar{x}(t)) \mathcal{A}_{ki} + R \Delta E \right\} \bar{x}(t), \bar{x}(t) \in S_i, \tag{14}$$

where $\mathcal{A}_{ki} = \bar{A}_k + \bar{B}_k \bar{K}_i$ and

$$\begin{cases} \bar{x}(t) = \begin{bmatrix} x(t) \\ u(t) \end{bmatrix}, \bar{A}_k = \begin{bmatrix} A_k & B_k \\ \mathbf{0}_{m\times n} & \mathbf{0}_{m\times m} \end{bmatrix}, \\ \bar{B}_k = \begin{bmatrix} \mathbf{0}_{n\times m} \\ \mathbf{I}_m \end{bmatrix}, R = \begin{bmatrix} \mathbf{I}_n \\ \mathbf{0}_{m\times n} \end{bmatrix}, \\ \Delta E = \begin{bmatrix} \Delta_A & \Delta_B \end{bmatrix}, \bar{K}_i = \begin{bmatrix} F_i & G_i \end{bmatrix}. \end{cases}$$

In addition, we define a new set that represents all possible state transitions among regions of the closed-loop T-S fuzzy system in (14) as follows,

$$\Omega := \{(i,j) | \bar{x}(t) \in S_i, \bar{x}(t+1) \in S_j, i,j \in \mathscr{I}\}. \tag{15}$$

For a piecewise Lyapunov function candidate we consider functions of the following form:

$$V(\bar{x}(t)) = \bar{x}(t)^T P_i \bar{x}(t), \bar{x}(t) \in S_i, i \in \mathscr{I}. \tag{16}$$

Suppose the upper bound of the uncertainty ΔE is given by

$$\Delta E^T \Delta E = \begin{bmatrix} \Delta_A^T \\ \Delta_B^T \end{bmatrix} \begin{bmatrix} \Delta_A & \Delta_B \end{bmatrix} \leq \bar{\epsilon}^2 \mathbf{I}_{(m+n)}. \tag{17}$$

Then we have the following stabilization results of nonlinear system (1).

Theorem 3.1. The nonlinear system (1) can be semi-globally asymptotically stabilized by the fuzzy controller in (13), if there exist a set of positive-definite matrices $X_i, i \in \mathscr{I}$, a set of positive constants $\varepsilon_i, i \in \mathscr{I}$ and a set of matrices $Q_i, i \in \mathscr{I}$, such that the following LMIs are satisfied,

$$\begin{aligned} \begin{bmatrix} X_i & \star & \star & \star \\ A_k X_i + B_k Q_i & X_j & \star & \star \\ \bar{\epsilon} X_i & \mathbf{0} & \varepsilon_i \mathbf{I} & \star \\ \mathbf{0} & \varepsilon_i R^T & \mathbf{0} & \varepsilon_i \mathbf{I} \end{bmatrix} > 0, \\ k \in \mathscr{K}(i), (i,j) \in \Omega. \end{aligned} \tag{18}$$

Moreover, the controller gains are given by

$$\bar{K}_i = Q_i X_i^{-1}, i \in \mathscr{I}. \tag{19}$$

Proof. See [23].

IV. Robust Generalized $\mathscr{H}_2$ Controller Design For Nonlinear Systems

In this section, we will address the generalized $\mathscr{H}_2$ controller synthesis problem [11] for a general nonlinear system with disturbances, which is described by

$$x(t+1) = G(x(t), u(t)) + H(x(t), u(t))w(t), \tag{20}$$

where $w(t) \in \Re^p$ is the external disturbance and other variables are the same as those defined in (1).

Based on the approximation results presented in section II, the nonlinear system (20) can be exactly expressed in a compact set by the following T-S fuzzy model with some uncertainties,

Plant rule $\mathcal{R}^l$: IF $x_1(t)$ is μ_1^l AND ... AND $x_n(t)$ is μ_n^l ; $u_1(t)$ is ν_1^l AND ... AND $u_m(t)$ is ν_m^l **THEN**

$$\begin{cases} x(t+1) = (A_l + \Delta A)x(t) + (B_l + \Delta B)u(t) \\ \qquad\qquad + (H_l + \Delta H)w(t), \\ z(t) = C_l x(t) + D_l u(t), l \in \mathscr{L} := \{1, 2, ...r\}. \end{cases} \tag{21}$$

Then using the same controller described in (13), the same premise variable space partition method as in section III, and adopting the same definitions of symbols as in (15), the closed-loop control system consisting of (20) or (21) and (13) can be described by the following equations,

$$\begin{cases} \bar{x}(t+1) = \mathcal{A}_{ic}\bar{x}(t) + \mathcal{H}_{ic}w(t), \\ z(t) = \mathcal{C}_{ic}\bar{x}(t), \quad \bar{x}(t) \in S_i \end{cases} \tag{22}$$

where

$$\begin{cases} \mathcal{A}_{ic} = \sum\limits_{k \in \mathscr{K}(i)} \mu_k(\bar{x})\mathcal{A}_{ki}^c = \sum\limits_{k \in \mathscr{K}(i)} \mu_k(\bar{x})(\mathcal{A}_{ki} + R\Delta E), \\ \mathcal{H}_{ic} = \sum\limits_{k \in \mathscr{K}(i)} \mu_k(\bar{x})\mathcal{H}_k^c = \sum\limits_{k \in \mathscr{K}(i)} \mu_k(\bar{x})R(H_k + \Delta H), \\ \mathcal{C}_{ic} = \sum\limits_{k \in \mathscr{K}(i)} \mu_k(\bar{x})\bar{C}_k = \sum\limits_{k \in \mathscr{K}(i)} \mu_k(\bar{x})[C_k \quad D_k]. \end{cases}$$

Similar to the case of stabilization discussed in Section III, the global results on generalized $\mathscr{H}_2$ control of the model (21) would imply the semi-global results on generalized $\mathscr{H}_2$ control of the system (20) due to the restriction of a compact set for the description of (20) via (21).

We at first introduce the following definition of the generalized $\mathscr{H}_2$ control.

Definition 4.1. [12] Let a constant $\gamma > 0$ be given. The closed-loop control system (22) is said to be asymptotically stable with generalized $\mathscr{H}_2$ performance γ if both of the following conditions are satisfied,

1) The disturbance-free system is globally asymptotically stable,

2) The generalized $\mathscr{H}_2$ norm of the system, which is defined as

$$\mathscr{H}_2 := \sup_{N \in \{1,2,...\}} \Big\{ \|z_N\| : x_0 = 0, \sum_{k=0}^{N-1} (\omega_k^T(t)\omega_k(t)) \le 1 \Big\},$$

is less than γ.

Before present the generalized $\mathscr{H}_2$ controller design results, we first introduce two lemmas,

Lemma 4.1.[12] The discrete-time fuzzy system (22) is stable with generalized $\mathscr{H}_2$ performance, if there exist a set of positive-definite matrices $P_i, i \in \mathscr{I}$ such that the following matrix inequalities are satisfied,

$$\begin{cases} P_i - \dfrac{1}{\gamma^2}\bar{C}_k^T\bar{C}_k > 0, i \in \mathscr{I}, & \text{(23a)} \\ (\mathcal{A}_{ki}^c)^T P_j \mathcal{H}_k^c (\mathcal{H}_k^c P_j \mathcal{H}_k^c - \mathbf{I})^{-1} (\mathcal{H}_k^c)^T P_j \mathcal{A}_{ki}^c \\ +(\mathcal{A}_{ki}^c)^T P_j \mathcal{A}_{ki}^c - P_i < 0. & \text{(23b)} \end{cases}$$

Lemma 4.2. [24] Given matrices $\Delta E(\mu)$ satisfying

$$\begin{cases} \Delta E^T(\mu)\Delta E(\mu) \le \bar{\epsilon}^2\mathbf{I} & \forall \mu \in M, \quad \text{(24a)} \\ \Delta E^T(\mu^*)\Delta E(\mu^*) = \bar{\epsilon}^2\mathbf{I} & \mu^* \in M, \quad \text{(24b)} \end{cases}$$

there exists a set of positive-definite symmetric matrix $P_i, i \in \mathscr{I}$ such that,

$$\begin{aligned} &(A + R\Delta E)^T P_j H(\mathbf{I} - H^T P_j H)^{-1} H^T P_j (A + R\Delta E) \\ &+ (A + R\Delta E)^T P_j (A + R\Delta E) - P_i < 0, \end{aligned} \tag{25}$$

if and only if there exists a set of positive constants $\varepsilon_i, i \in \mathscr{I}$ such that the following conditions hold,

$$\begin{cases} \bar{P}_j = P_j^{-1} - HH^T - \varepsilon_i RR^T > 0, & \text{(26a)} \\ A^T \bar{P}_j^{-1} A - P_i + \dfrac{1}{\varepsilon_i}\bar{\epsilon}^2\mathbf{I} < 0. & \text{(26b)} \end{cases}$$

Suppose the upper bound of uncertainty ΔH is given by

$$\Delta H \Delta H^T \le \bar{\epsilon}_h^2 \mathbf{I}_n. \tag{27}$$

then based on Lemmas 4.1, 4.2 and the upper bounds defined in (17) , one has the following result.

Theorem 4.1. Given a constant $\gamma > 0$, the nonlinear system (20) can be semi-globally asymptotically stabilized with generalized $\mathscr{H}_2$ performance γ via the controller in (13) , if there exist a set of positive definite matrices $X_i, i \in \mathscr{I}$, a set of matrices $Q_i, i \in \mathscr{I}$ and a set of positive constants $\varepsilon_i, i \in \mathscr{I}$ such that the following LMIs are satisfied,

$$\begin{bmatrix} X_i & \star \\ \bar{C}_k X_i & \gamma^2\mathbf{I} \end{bmatrix} > 0, \tag{28}$$

$$\begin{bmatrix} X_i & \star & \star \\ \bar{\epsilon}X_i & \varepsilon_i\mathbf{I}_n & \star \\ \bar{A}_k X_i + \bar{B}_k Q_i & \mathbf{0} & \Upsilon_{kij} \end{bmatrix} > 0, \quad k \in \mathscr{K}(i), (i,j) \in \Omega, \tag{29}$$

where $\Upsilon_{kij} = X_j - R(2(H_k H_k^T + \bar{\epsilon}_h^2\mathbf{I}_n) - \varepsilon_i\mathbf{I}_n)R^T$.

Moreover, the controller gains can be determined by

$$\bar{K}_i = Q_i X_i^{-1}, i \in \mathscr{I}. \tag{30}$$

Proof. The proof is omitted here.

It follows from Theorem 4.1 that the minimum generalized $\mathscr{H}_2$ performance index γ can be obtained by the following convex optimization algorithm [25].

Algorithm 4.1: $\min_{X_i,Q_i,\varepsilon_i} \gamma^2$, subject to LMIs (28) and (29).

V. Simulation Studies

Control of the inverted pendulum is one of the benchmark examples to demonstrate novel nonlinear control approaches. It is also noted that actuator models in the inverted pendulum are often given by the hyperbolic tangent functions of control input u. To show the performance of the above controller design results, we consider the balancing problem of an inverted pendulum on a cart. The equation of motion for the pendulum are

$$\begin{aligned}\dot{x}_1 &= x_2\\ \dot{x}_2 &= \frac{g\sin(x_1) - aml x_2^2 \sin(2x_1)/2 - a\cos(x_1)v}{4l/3 - aml\cos^2(x_1)} + w\\ v &= (\arctan(u) + 0.15u) * 10^3\end{aligned}$$

where x_1 denotes the angle of pendulum from the vertical, and x_2 is the angular velocity. $g = 9.8m/s^2$ is the gravity constant, m is the mass of pendulum, M is the mass of the cart, $2l$ is the length of the pendulum and w is the disturbance. Note the input force is given by $\arctan(u) + 0.15u$ with an amplifier 1000 connected. In this simulation, we choose $m = 2.0$kg, $M = 8.0$kg, $2l = 1.0$m.

We linearize the plant around the following operating points, $(x;u) = (0;0;0)$, $(0;0;\pm 3)$, $(\pm 88^\circ;0;0)$, and $(\pm 88^\circ;0;\pm 3)$ respectively, and consider the approximation errors between the linearized local model and the original nonlinear models as norm-bounded uncertainties. By the standard discretization procedure [14] with sampling time $T = 0.01$s, we can obtain the following uncertain discrete-time dynamic T-S fuzzy model,

Plant rule $\mathcal{R}^l$: IF $|x_1|$ is μ^l And $|u|$ is ν^l **THEN**

$$\begin{cases} x(t+1) = (A_l + \Delta A)x(t) + (B_l + \Delta B)u(t), \\ \qquad\qquad + (H_l + \Delta H)w(t) \\ z(t) = C_l x(t) + D_l u(t), l \in \mathscr{L} := \{1,2,3,4\}. \end{cases}$$

where

$$\begin{aligned} A_1 = A_2 &= \begin{bmatrix} 1 & 0.01 \\ 0.1729 & 1 \end{bmatrix},\\ A_3 = A_4 &= \begin{bmatrix} 1 & 0.01 \\ 0.0036 & 1 \end{bmatrix},\\ B_1 = \begin{bmatrix} 0 \\ -2.03 \end{bmatrix}, B_2 &= \begin{bmatrix} 0 \\ -1.38 \end{bmatrix},\\ B_3 = \begin{bmatrix} 0 \\ -0.060 \end{bmatrix}, B_4 &= \begin{bmatrix} 0 \\ -0.041 \end{bmatrix},\\ C_1 = C_2 = C_3 = C_4 &= \begin{bmatrix} 0.5 & 1 \end{bmatrix},\\ H_1 = H_2 = H_3 = H_4 &= \begin{bmatrix} 0 \\ 0.01 \end{bmatrix},\\ D_1 = 0.05, D_2 = D_3 = D_4 &= 0.01. \end{aligned}$$

Suppose the upper bounds of uncertainties ΔA and ΔB are given by (17) with $\bar{\epsilon} = 0.005$. It is noted that the uncertainty $\Delta H = 0$.

By using the space partition method given in section III, the premise variable space is partitioned into six regions. The membership functions and the corresponding local regions are shown in Fig. 1.

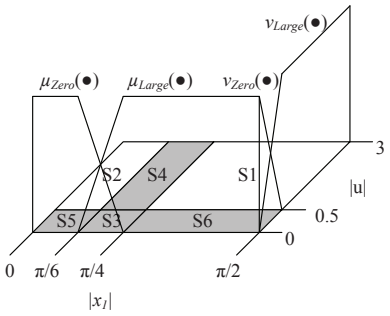

Fig. 1. MFs and the partitioned regions

By applying Algorithm 4.1, the minimum $\mathscr{H}_2$ performance $\gamma_{\min} = 0.0572$ is obtained and the corresponding controller gains are given by

$$\begin{aligned} \bar{K}_1 &= \begin{bmatrix} 0.5660 & 0.4997 & -0.0202 \end{bmatrix},\\ \bar{K}_2 &= \begin{bmatrix} 0.6613 & 0.5111 & -0.6974 \end{bmatrix},\\ \bar{K}_3 &= \begin{bmatrix} 1.1039 & 0.9744 & -1.0127 \end{bmatrix},\\ \bar{K}_4 &= \begin{bmatrix} 0.8436 & 0.7292 & -0.5135 \end{bmatrix},\\ \bar{K}_5 &= \begin{bmatrix} 0.7935 & 0.6286 & -1.0604 \end{bmatrix},\\ \bar{K}_6 &= \begin{bmatrix} 0.5673 & 0.5019 & -0.0245 \end{bmatrix}. \end{aligned}$$

To illustrate the performance of the approaches proposed in this paper, we first show the state trajectories and control input of the closed-loop system under initial condition $x(0) = (89^\circ, 0)$ in Fig. 2. It can be found that the two states converge to zero when the external disturbance $w(t) = 0$. Next we illustrate the disturbance attenuation performance. Assume zero initial conditions, Fig. 3 shows the response of the ratio $\frac{\max|z(1:\kappa)|}{\sqrt{\sum_{i=0}^{\kappa} w^T(i)w(i)}}$ of the closed-loop control system. The disturbance is $w(t) = e^{-0.02t}\sin(\pi t)$. It shows that the performance is satisfactory and the ratio $\frac{\max|z(1:\kappa)|}{\sqrt{\sum_{i=0}^{\kappa} w^T(i)w(i)}}$ is less than 0.01, which is less than the minimum disturbance attenuation level $\gamma_{\min} = 0.0572$.

A number of simulations have been conducted and it is found that the pendulum can be balanced from $x_1 \in [-89^\circ, 89^\circ]$ with guaranteed performance. Note that the control input is also bounded.

VI. Conclusions

A class of generalized T-S fuzzy models have been proposed and shown to be universal approximators to general nonlinear

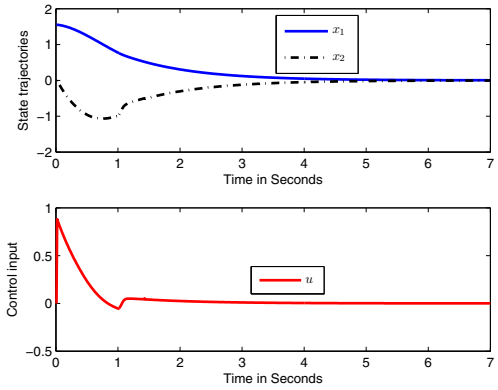

Fig. 2. State trajectories and control input

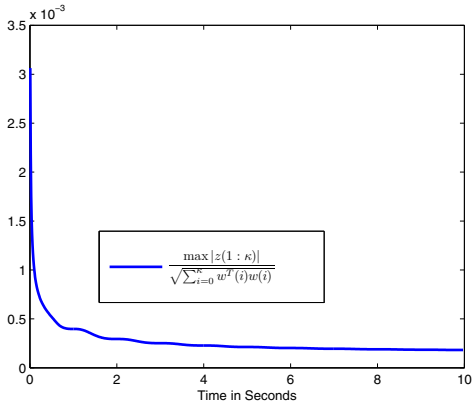

Fig. 3. Response of the ratio $\frac{\max|z(1:\kappa)|}{\sqrt{\sum_{i=0}^{\kappa} w^T(i)w(i)}}$

systems. Based on this kind of T-S fuzzy models and piecewise quadratic Lyapunov functions, approaches to stabilization and generalized $\mathscr{H}_2$ control of those general nonlinear systems have been developed. It is shown that the general nonlinear systems can be semi-globally stabilized with/without generalized $\mathscr{H}_2$ performance by solving a set of linear matrix inequalities. An example is presented to demonstrate the effectiveness of the proposed approaches. It is believed that the approaches proposed in this paper provide a new avenue to solve much more difficult control problem for general nonlinear systems.

***Abstract*—This paper presents a polynomial fuzzy observer design for a wider class of polynomial fuzzy systems via a sum of squares (SOS, for brevity) approach. The proposed SOS-based framework provides a number of innovations and improvements over the existing LMI-based approaches to Takagi-Sugeno (T-S) fuzzy controller and observer designs. First, we briefly summarize previous results for a class of polynomial fuzzy systems that is more general representation of the well-known T-S fuzzy system. Next, we propose a polynomial fuzzy observer to estimate states in a wider class of polynomial fuzzy systems and derive SOS conditions to design polynomial fuzzy controllers and observers. A remarkable feature of the SOS design conditions is that they realize the so-called separation principle, that is, that a polynomial fuzzy controller and observer for this class can be separately designed without lack of guaranteeing the stability of the overall control system in addition to converging state estimation error (via the observer) to zero. The design conditions in the proposed approach can be represented in terms of SOS and are symbolically and numerically solved via the recent developed SOSTOOLS and a semidefinite program (SDP) solver, respectively. To illustrate the validity and applicability of the proposed approach, a design example is provided. The example demonstrates advantages of the SOS-based approach for the existing LMI approaches to T-S fuzzy observer designs.**

Keywords: polynomial fuzzy controller, polynomial fuzzy observer, polynomial fuzzy system, sum of squares

I. Introduction

The Takagi-Sugeno (T-S) fuzzy model-based control methodology [1], [2] has received a great deal of attention after LMI-based designs have been discussed in [3]-[4]. The fuzzy model-based control methodology provides a natural, simple and effective design approach to complement other nonlinear control techniques (e.g., [5]) that require special and rather involved knowledge.

Recently, the authors have first presented a sum of squares (SOS, for brevity) approach [6]-[11] to polynomial fuzzy control system designs. This is a completely different approach from the existing LMI approaches [2], [12]-[24]. Our SOS approach [6]-[11] provided more extensive results for the existing LMI approaches to T-S fuzzy model and control. However, to the best of our knowledge, there existed no literature on SOS-based observer designs for polynomial fuzzy systems before our previous result has been given in [25].

This paper presents SOS-based observer designs for a wider class than the class of the polynomial fuzzy systems discussed in [25]. The proposed SOS-based framework for polynomial fuzzy systems provides a number of innovations and improvements over the existing LMI approaches to T-S fuzzy observer-based control, e.g., [2], [12], [13]. First, it is known that nonlinear systems with polynomial terms can not be generally converted to globally exact T-S fuzzy models. Only local or semi-global T-S fuzzy models can be constructed for such nonlinear systems [2]. Thus, resulting control design conditions guarantee global stabilization and global state-estimation convergence only for local or semi-global models, but not always guarantee global stabilization and global state-estimation convergence for original nonlinear systems. On the other hand, it is possible to convert even nonlinear systems with polynomial terms to globally exact polynomial fuzzy models. Hence all the conditions derived here guarantee global stabilization and global state-estimation convergence for original nonlinear systems that are perfectly equivalent to polynomial fuzzy models. Secondly, even if local or semi-global T-S fuzzy models are permitted to use in practical sense, variables in polynomial terms appear in premise (part) variables of T-S fuzzy models. In polynomial fuzzy models, variables in polynomial terms do not appear in their premise parts and remain in system polynomial matrices $\boldsymbol{A}_i$ and $\boldsymbol{B}_i$ in consequence parts of polynomial fuzzy models. The difference is quite large from fuzzy observer design points of view. In general, fuzzy observer designs are not permitted to have premise variables depending on the states to be estimated. Therefore, T-S fuzzy observer designs can not be generally applied to nonlinear systems with polynomial terms. Conversely, the polynomial fuzzy observer designs proposed in this paper can be applied to even such systems. We will see these facts in the design examples later.

This paper presents an SOS-based observer design for a wider class of polynomial fuzzy systems. First, we present the previous results in [25], i.e., an observer-based design for the polynomial fuzzy systems with the polynomial matrices $\boldsymbol{A}_i$ and $\boldsymbol{B}_i$ being independent of the states $\boldsymbol{x}$ to be estimated (shortly name it as Class I). Secondly, in this paper, we newly provide an observer-based design for a wider class of polynomial fuzzy systems with the polynomial matrices

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

$\boldsymbol{A}_i$ that are permitted to be dependent of the states $\boldsymbol{x}$ to be estimated (shortly name it as Class II). It should be emphasized that the design conditions derived in this paper realize the so-called separation design even for the wider class. All the design conditions discussed here are represented in terms of SOS.

It is well known that stability conditions for the T-S fuzzy system reduce to LMIs, e.g., [2]. Hence, the stability conditions can be solved numerically and efficiently by interior point algorithms, e.g., by LMI solvers. On the other hand, some kinds of control design conditions [6]-[11] for polynomial fuzzy systems reduce to SOS problems. Clearly, it is difficult to directly slove the problems by LMI solvers and the problems can be solved via the SOSTOOLS [26] and an SDP solver. Thus, SOS can be regarded as an extensive representation of LMIs. The computational method used in this paper relies on the SOS decomposition of multivariate polynomials. A multivariate polynomial $f(\boldsymbol{x}(t))$ (where $\boldsymbol{x}(t) \in R^n$) is an SOS if there exist polynomials $f_1(\boldsymbol{x}(t))$, $\cdots$, $f_k(\boldsymbol{x}(t))$ such that $f(\boldsymbol{x}(t)) = \sum_{i=1}^{k} f_i^2(\boldsymbol{x}(t))$. It is clear that $f(\boldsymbol{x}(t))$ being an SOS naturally implies $f(\boldsymbol{x}(t)) \geq 0$ for all $\boldsymbol{x}(t) \in R^n$. For more details of SOS, see [26].

The rest of the paper is organized as follows. Section II recalls a polynomial fuzzy system defined in [6]-[11] and previsou result [25]. Section III discusses an SOS-based polynomial fuzzy controller and observer design for Class II. In addition, Section IV entails a design example to demonstrate the viability of our SOS design approach.

In this paper, to save the space, we employ the following short notations with respect to matrix representation.

$\mathcal{L}\{\boldsymbol{M}\} = \boldsymbol{M}^T + \boldsymbol{M}$,

$\boldsymbol{E}_1 = diag[\epsilon_{11}\ \epsilon_{12}\ \cdots\ \epsilon_{1s}]$,

$\boldsymbol{E}_{2i}(\boldsymbol{x}) = diag[\epsilon_{2i1}(\boldsymbol{x})\ \epsilon_{2i2}(\boldsymbol{x})\ \cdots\ \epsilon_{2is}(\boldsymbol{x})]$,

where $\boldsymbol{M}$ is an arbitrary square matrix. ϵ_{1k} $(k = 1, 2, \cdots, s)$ are positive values and $\epsilon_{2ik}(\boldsymbol{x})$ $(i = 1, 2, \cdots, r,\ k = 1, 2, \cdots, s)$ are nonnegative polynomials such that $\epsilon_{2ik}(\boldsymbol{x}) > 0$ for $\boldsymbol{x} \neq \boldsymbol{0}$. ϵ_{1k} and $\epsilon_{2ik}(\boldsymbol{x})$ ($\boldsymbol{E}_1$ and $\boldsymbol{E}_{2i}(\boldsymbol{x})$) will be used as slack variables (matrices) to keep positivity of SOS conditions derived in this paper. s is the matrix size of $\boldsymbol{E}_1$ and $\boldsymbol{E}_{2i}(\boldsymbol{x})$ that are assumed to have appropriate dimensions. r is the number of fuzzy model rules.

II. Previous Results

A. Polynomial fuzzy model

This subsection II-A recalls a polynomial fuzzy system defined in [6]-[11]. Consider the following nonlinear system:

$$\dot{\boldsymbol{x}}(t) = f(\boldsymbol{x}(t), \boldsymbol{u}(t)), \tag{1}$$

where f is a smooth nonlinear function such that $f(\boldsymbol{0}, \boldsymbol{0}) = \boldsymbol{0}$. $\boldsymbol{x}(t) = [x_1(t)\ x_2(t)\ \cdots\ x_n(t)]^T$ is the state vector and $\boldsymbol{u}(t) = [u_1(t)\ u_2(t)\ \cdots\ u_m(t)]^T$ is the input vector. In [6] and [9], we proposed a new type of fuzzy model with polynomial model consequence, i.e., fuzzy model whose consequent parts are represented by polynomials. Using the sector nonlinearity concept [2], we exactly represent (1) with the following polynomial fuzzy model (2). The main difference between the T-S fuzzy model [27] and the polynomial fuzzy model is consequent part representation. The fuzzy model (2) has a polynomial model consequence.

Model Rule i:

$$\begin{aligned} &If\ z_1(t)\ is\ M_{i1}\ and \cdots\ and\ \ z_p(t)\ is\ M_{ip} \\ &then\ \dot{\boldsymbol{x}}(t) = \boldsymbol{A}_i(\boldsymbol{x}(t))\boldsymbol{x}(t) + \boldsymbol{B}_i(\boldsymbol{x}(t))\boldsymbol{u}(t), \end{aligned} \tag{2}$$

where $i = 1, 2, \cdots, r$. r denotes the number of $Model\ Rules$. $z_j(t)$ $(j = 1, 2, \cdots, p)$ is the premise variable. Note that $z_j(t)$ is assumed to be independent of the states $\boldsymbol{x}$ to be estimated. In other words, each $z_j(t)$ is a measurable time-varying quantity that may be measurable external variables, outputs and/or time. The membership function associated with the ith $Model\ Rule$ and the jth premise variable component is denoted by M_{ij}. $\boldsymbol{A}_i(\boldsymbol{x}(t)) \in \boldsymbol{R}^{n \times n}$ and $\boldsymbol{B}_i(\boldsymbol{x}(t)) \in \boldsymbol{R}^{n \times m}$ are polynomial matrices in $\boldsymbol{x}(t)$. Therefore, $\boldsymbol{A}_i(\boldsymbol{x}(t))\boldsymbol{x}(t) + \boldsymbol{B}_i(\boldsymbol{x}(t))\boldsymbol{u}(t)$ is a polynomial vector. Thus, the polynomial fuzzy model (2) has a polynomial in each consequent part.

The defuzzification process of the model (2) can be represented as

$$\dot{\boldsymbol{x}}(t) = \sum_{i=1}^{r} h_i(\boldsymbol{z}(t))\{\boldsymbol{A}_i(\boldsymbol{x}(t))\boldsymbol{x}(t) + \boldsymbol{B}_i(\boldsymbol{x}(t))\boldsymbol{u}(t)\}, \tag{3}$$

where

$$h_i(\boldsymbol{z}(t)) = \frac{\prod_{j=1}^{p} M_{ij}(z_j(t))}{\sum_{k=1}^{r} \prod_{j=1}^{p} M_{kj}(z_j(t))}.$$

It should be noted from the properties of membership functions that $h_i(\boldsymbol{z}(t)) \geq 0$ for all i and $\sum_{i=1}^{r} h_i(\boldsymbol{z}(t)) = 1$. Thus, the overall fuzzy model is achieved by fuzzy blending of the polynomial system models.

It is in general difficult to separately design a polynomial controller and a polynomial observer for (3) since $\boldsymbol{A}_i(\boldsymbol{x}(t))$ and $\boldsymbol{B}_i(\boldsymbol{x}(t))$ are dependent of the states $\boldsymbol{x}(t)$ to be estimated. Hence, as a first step, we introduce the following representation of polynomial fuzzy systems.

$$\dot{\boldsymbol{x}}(t) = \sum_{i=1}^{r} h_i(\boldsymbol{z}(t))\{\boldsymbol{A}_i(\boldsymbol{\rho}_A(t))\boldsymbol{x}(t) + \boldsymbol{B}_i(\boldsymbol{\rho}_B(t))\boldsymbol{u}(t)\}, \tag{4}$$

where (4) reduces to (3) when $\boldsymbol{\rho}_A(t) = \boldsymbol{\rho}_B(t) = \boldsymbol{x}(t)$. In general, we can consider three types of polynomial observer-based control according to three classes of polynomial fuzzy systems:

Class I: $\boldsymbol{\rho}_A(t) = \boldsymbol{\zeta}(t)$ and $\boldsymbol{\rho}_B(t) = \boldsymbol{\zeta}(t)$.

Class II: $\boldsymbol{\rho}_A(t) = \boldsymbol{x}(t)$ and $\boldsymbol{\rho}_B(t) = \boldsymbol{\zeta}(t)$.

Class III: $\boldsymbol{\rho}_A(t) = \boldsymbol{\rho}_B(t) = \boldsymbol{x}(t)$.

$\boldsymbol{\zeta}(t)$ is a measurable time-varying vector that may be measurable external variables, outputs and/or time. In other words, $\boldsymbol{\zeta}(t)$ is assumed to be independent of the states $\boldsymbol{x}(t)$ to be estimated. As we can see, Class III is the most complicated class. We have already presented a polynomial fuzzy observer design for Class I in [25]. This paper focuses on a polynomial fuzzy observer design for a wider class, i.e., for Class II. A polynomial fuzzy observer-based design for Class III will be presented in [28].

From now, to lighten the notation, we will drop the notation with respect to time t. For instance, we will employ $\boldsymbol{x}$ and $\hat{\boldsymbol{x}}$ instead of $\boldsymbol{x}(t)$ and $\hat{\boldsymbol{x}}(t)$, respectively, where $\hat{\boldsymbol{x}}(t)$ denotes the state estimated by a polynomial fuzzy observer as will be discussed later. Thus, we drop the notation with respect to time t, but it should be kept in mind that $\boldsymbol{x}$ and $\hat{\boldsymbol{x}}$ means $\boldsymbol{x}(t)$ and $\hat{\boldsymbol{x}}(t)$, respectively.

Next, we define the outputs for the polynomial fuzzy model as

$$\boldsymbol{y} = \sum_{i=1}^{r} h_i(\boldsymbol{z}) \boldsymbol{C}_i \boldsymbol{x}, \tag{5}$$

where $\boldsymbol{y} \in \mathbb{R}^q$ is the output.

B. Previous Result (Class I Observer Design [25])

This subsection presents the previous result discussed in [25].

Consider the following polynomial fuzzy system. The system matrices $\boldsymbol{A}_i$ and $\boldsymbol{B}_i$ depend on the vector $\boldsymbol{\zeta}$,

$$\begin{cases} \dot{\boldsymbol{x}} = \sum_{i=1}^{r} h_i(\boldsymbol{z}) \{ \boldsymbol{A}_i(\boldsymbol{\zeta}) \boldsymbol{x} + \boldsymbol{B}_i(\boldsymbol{\zeta}) \boldsymbol{u} \} \\ \boldsymbol{y} = \sum_{i=1}^{r} h_i(\boldsymbol{z}) \boldsymbol{C}_i \boldsymbol{x}, \end{cases} \tag{6}$$

where $\boldsymbol{y} \in \mathbb{R}^q$ denotes the output.

We design a polynomial fuzzy observer to estimate the states of (6).

$$\begin{cases} \dot{\hat{\boldsymbol{x}}} &= \sum_{i=1}^{r} h_i(\boldsymbol{z}) \{ \boldsymbol{A}_i(\boldsymbol{\zeta}) \hat{\boldsymbol{x}} + \boldsymbol{B}_i(\boldsymbol{\zeta}) \boldsymbol{u} \\ & \qquad + \boldsymbol{L}_i(\boldsymbol{\zeta}) (\boldsymbol{y} - \hat{\boldsymbol{y}}) \} \\ \hat{\boldsymbol{y}} &= \sum_{i=1}^{r} h_i(\boldsymbol{z}) \boldsymbol{C}_i \hat{\boldsymbol{x}}, \end{cases} \tag{7}$$

where $\hat{\boldsymbol{x}} \in \mathbb{R}^n$ is the sate vector estimated by the fuzzy observer and $\hat{\boldsymbol{y}} \in \mathbb{R}^q$ is estimated output calculated from $\hat{\boldsymbol{y}} = \sum_{i=1}^{r} h_i(\boldsymbol{z}) \boldsymbol{C}_i \hat{\boldsymbol{x}}$.

To stabilize the system (6) and (7), we design a polynomial fuzzy controller with the state-feedback estimated by the polynomial fuzzy observer.

$$\boldsymbol{u} = -\sum_{i=1}^{r} h_i(\boldsymbol{z}) \boldsymbol{F}_i(\boldsymbol{\zeta}) \hat{\boldsymbol{x}} \tag{8}$$

Theorem 1 provides SOS conditions to separately design the polynomial fuzzy controller (8) and the polynomial fuzzy observer (7).

Theorem 1. *[25] If there exist positive definite matrices $\boldsymbol{X}_1 \in \mathbb{R}^{n \times n}$, $\boldsymbol{X}_2 \in \mathbb{R}^{n \times n}$ and polynomial matrices $\boldsymbol{M}_i(\boldsymbol{\zeta}) \in \mathbb{R}^{p \times n}$, $\boldsymbol{N}_i(\boldsymbol{\zeta}) \in \mathbb{R}^{n \times q}$ such that (9)∼(14) are satisfied, the polynomial fuzzy controller (8) stabilizes the system (6) and the estimation error via the polynomial observer (7) tends to zero.*

$$\boldsymbol{v}_1^T (\boldsymbol{X}_1 - \boldsymbol{E}_1) \boldsymbol{v}_1 \quad is \quad SOS \tag{9}$$

$$\boldsymbol{v}_2^T (\boldsymbol{X}_2 - \boldsymbol{E}_2) \boldsymbol{v}_2 \quad is \quad SOS \tag{10}$$

$$-\boldsymbol{v}_3^T \Big(\mathcal{L}\{ \boldsymbol{A}_i(\boldsymbol{\zeta}) \boldsymbol{X}_1 - \boldsymbol{B}_i(\boldsymbol{\zeta}) \boldsymbol{M}_i(\boldsymbol{\zeta}) \} + \boldsymbol{E}_{3i}(\boldsymbol{\zeta}) \Big) \boldsymbol{v}_3 \quad is \quad SOS \tag{11}$$

$$-\boldsymbol{v}_4^T \Big(\mathcal{L}\{ \boldsymbol{X}_2 \boldsymbol{A}_i(\boldsymbol{\zeta}) - \boldsymbol{N}_i(\boldsymbol{\zeta}) \boldsymbol{C}_i \} + \boldsymbol{E}_{4i}(\boldsymbol{\zeta}) \Big) \boldsymbol{v}_4 \quad is \quad SOS \tag{12}$$

$$-\boldsymbol{v}_5^T \Big(\mathcal{L}\{ \boldsymbol{A}_i(\boldsymbol{\zeta}) \boldsymbol{X}_1 - \boldsymbol{B}_i(\boldsymbol{\zeta}) \boldsymbol{M}_j(\boldsymbol{\zeta}) \} + \mathcal{L}\{ \boldsymbol{A}_j(\boldsymbol{\zeta}) \boldsymbol{X}_1 - \boldsymbol{B}_j(\boldsymbol{\zeta}) \boldsymbol{M}_i(\boldsymbol{\zeta}) \} \Big) \boldsymbol{v}_5 \quad is \quad SOS \tag{13}$$

$$-\boldsymbol{v}_6^T \Big(\mathcal{L}\{ \boldsymbol{X}_2 \boldsymbol{A}_i(\boldsymbol{\zeta}) - \boldsymbol{N}_i(\boldsymbol{\zeta}) \boldsymbol{C}_j \} + \mathcal{L}\{ \boldsymbol{X}_2 \boldsymbol{A}_j(\boldsymbol{\zeta}) - \boldsymbol{N}_j(\boldsymbol{\zeta}) \boldsymbol{C}_i \} \Big) \boldsymbol{v}_6 \quad is \quad SOS \tag{14}$$

where $\boldsymbol{v}_1$, $\boldsymbol{v}_2$, $\boldsymbol{v}_3$, $\boldsymbol{v}_4$ $\boldsymbol{v}_5$ and $\boldsymbol{v}_6 \in \mathbb{R}^n$ denote vectors that are independent of $\boldsymbol{x}$, $\hat{\boldsymbol{x}}$ and $\boldsymbol{\zeta}$. From the solutions $\boldsymbol{X}_1$ and $\boldsymbol{M}_i(\boldsymbol{\zeta})$, we obtain polynomial feedback gains $\boldsymbol{F}_i(\boldsymbol{\zeta})$ as $\boldsymbol{F}_i(\boldsymbol{\zeta}) = \boldsymbol{M}_i(\boldsymbol{\zeta}) \boldsymbol{X}_1^{-1}$. From the solutions $\boldsymbol{X}_2$ and $\boldsymbol{N}_i(\boldsymbol{\zeta})$, we obtain polynomial observer gains $\boldsymbol{L}_i(\boldsymbol{\zeta})$ as $\boldsymbol{L}_i(\boldsymbol{\zeta}) = \boldsymbol{X}_2^{-1} \boldsymbol{N}_i(\boldsymbol{\zeta})$ as well.

Remark 1. *The conditions (9), (11) and (13) are for SOS conditions of polynomial fuzzy controller design. The conditions (10), (12) and (14) are for SOS conditions of polynomial fuzzy observer design. Thus, Theorem 1 provides SOS design conditions to separately design polynomial fuzzy controllers and observers.*

Remark 2. *If $\boldsymbol{A}_i(\boldsymbol{\zeta})$, $\boldsymbol{B}_i(\boldsymbol{\zeta})$, $\boldsymbol{L}_i(\boldsymbol{\zeta})$ and $\boldsymbol{F}_i(\boldsymbol{\zeta})$ reduce to constant matrices in (6), (7) and (8), they reduce to the ordinary T-S fuzzy model, the T-S fuzzy controller and observer, respectively. In addition, Theorem 1 reduces to the existing LMI design conditions, e.g., [13], for the T-S fuzzy controller and observer. Hence, Theorem 1 provides more general results.*

Remark 3. *Currently, sum of squares programs (SOSPs) are solved by reformulating them as semidefinite programs (SDPs). SOSTOOLS automates the conversion from SOSP to SDP and the SDP can be solved by a SDP solver [26]. At present, SOSTOOLS uses other free MATLAB add-ons such as SeDuMi [29] or SDPT3 [30] as the SDP solver. In this paper, we numerically find $\boldsymbol{X}_1$, $\boldsymbol{X}_2$, $\boldsymbol{M}_i(\boldsymbol{\zeta})$ and $\boldsymbol{N}_i(\boldsymbol{\zeta})$ satisfying the SOS conditions in Theorem 1 via SeDuMi in addition to SOSTOOLS. For more details of how to solve the SDPs using SeDuMi, see [26] and [29].*

Remark 4. *To obtain more reliable solutions for SOS conditions, we perform the following double checking throughout this paper. We first carefully check whether the command 'sossolve' find a solution without any error messages, i.e., pinf=0, dinf=0 and numerr=0, or not. If any error messages exist, we judge 'infeasible'. After getting the feasible solutions using the command 'sossolve', the 'findsos' command is employed to check the feasibility of SOS conditions by substituting solutions into SOS conditions. We also carefully check whether the command 'findsos' provides a feasibility solution or not. If the command 'findsos' returns an infeasible result, we also judge 'infeasible'. This double checking is important to have reliable solutions in the use of SOSTOOLS [26] and SeDuMi [29].*

Remark 5. *The conditions $\epsilon_{1k} > 0$, $\epsilon_{2k} > 0$, $\epsilon_{3ik}(\boldsymbol{\zeta}) > 0$ and $\epsilon_{4ik}(\boldsymbol{\zeta}) > 0$ for $\boldsymbol{\zeta} \neq 0$ can be accommodated by sum of squares optimization in a similar way as in [31].*

III. Polynomial Controller and Observer Design for Class II

In Section II-B, we discussed an observer design for the polynomial fuzzy system (6) with $\boldsymbol{A}_i(\zeta)$ and $\boldsymbol{B}_i(\zeta)$ matrices. This section presents a more complicated class, i.e., $\boldsymbol{A}_i$ depends on the state $\boldsymbol{x}$ instead of the vector $\boldsymbol{\zeta}$. Although the separation design for Class II is difficult, we derive SOS conditions to achieve it in this section. The reason will be mentioned in Remark 6.

Consider the following polynomial fuzzy system.

$$\begin{cases} \dot{\boldsymbol{x}} = \sum_{i=1}^{r} h_i(\boldsymbol{z})\{\boldsymbol{A}_i(\boldsymbol{x})\boldsymbol{x} + \boldsymbol{B}_i(\boldsymbol{\zeta})\boldsymbol{u}\} \\ \boldsymbol{y} = \sum_{i=1}^{r} h_i(\boldsymbol{z})\boldsymbol{C}_i\boldsymbol{x} \end{cases} \tag{15}$$

We design a polynomial fuzzy observer to estimate the states of (15).

$$\begin{cases} \dot{\hat{\boldsymbol{x}}} = \sum_{i=1}^{r} h_i(\boldsymbol{z})\{\boldsymbol{A}_i(\hat{\boldsymbol{x}})\hat{\boldsymbol{x}} + \boldsymbol{B}_i(\boldsymbol{\zeta})\boldsymbol{u} \\ \qquad\qquad +\boldsymbol{L}_i(\hat{\boldsymbol{x}})(\boldsymbol{y} - \hat{\boldsymbol{y}})\} \\ \hat{\boldsymbol{y}} = \sum_{i=1}^{r} h_i(\boldsymbol{z})\boldsymbol{C}_i\hat{\boldsymbol{x}} \end{cases} \tag{16}$$

To stabilize the system, we design a polynomial fuzzy controller with the state-feedback estimated by the polynomial observer.

$$\boldsymbol{u} = -\sum_{i=1}^{r} h_i(\boldsymbol{z})\boldsymbol{F}_i(\hat{\boldsymbol{x}})\hat{\boldsymbol{x}} \tag{17}$$

The difference between (17) and (8) is that (17) has the polynomial feedback gains in $\hat{\boldsymbol{x}}$ instead of those in $\boldsymbol{\zeta}$ in (8) Theorem 2 provides SOS conditions to separately design the polynomial fuzzy controller (17) and the polynomial fuzzy observer (16).

Theorem 2. *If there exist positive definite matrices $\boldsymbol{X}_1 \in \mathbb{R}^{n\times n}$, $\boldsymbol{X}_2 \in \mathbb{R}^{n\times n}$ and polynomial matrices $\boldsymbol{M}_i(\hat{\boldsymbol{x}}) \in \mathbb{R}^{p\times n}$, $\boldsymbol{N}_i(\hat{\boldsymbol{x}}) \in \mathbb{R}^{n\times q}$ satisfying (18)∼(23), the polynomial fuzzy controller (17) stabilizes the system (15) and the estimation error via the polynomial fuzzy observer (16) tends to zero.*

$$\boldsymbol{v}_1^T(\boldsymbol{X}_1 - \boldsymbol{E}_1)\boldsymbol{v}_1 \quad is \quad SOS \tag{18}$$

$$\boldsymbol{v}_2^T(\boldsymbol{X}_2 - \boldsymbol{E}_2)\boldsymbol{v}_2 \quad is \quad SOS \tag{19}$$

$$-\boldsymbol{v}_3^T\Big(\mathcal{L}\{\boldsymbol{A}_i(\hat{\boldsymbol{x}})\boldsymbol{X}_1 - \boldsymbol{B}_i(\boldsymbol{\zeta})\boldsymbol{M}_i(\hat{\boldsymbol{x}})\} + \boldsymbol{E}_{3i}(\boldsymbol{\zeta},\hat{\boldsymbol{x}})\Big)\boldsymbol{v}_3 \quad is \quad SOS \tag{20}$$

$$-\boldsymbol{v}_4^T\Big(\mathcal{L}\{\boldsymbol{X}_2\bar{\boldsymbol{A}}_i(\boldsymbol{x},\hat{\boldsymbol{x}}) - \boldsymbol{N}_i(\hat{\boldsymbol{x}})\boldsymbol{C}_i\} + \boldsymbol{E}_{4i}(\boldsymbol{x},\hat{\boldsymbol{x}})\Big)\boldsymbol{v}_4 \quad is \quad SOS \tag{21}$$

$$-\boldsymbol{v}_5^T\Big(\mathcal{L}\{\boldsymbol{A}_i(\hat{\boldsymbol{x}})\boldsymbol{X}_1 - \boldsymbol{B}_i(\boldsymbol{\zeta})\boldsymbol{M}_j(\hat{\boldsymbol{x}})\} + \mathcal{L}\{\boldsymbol{A}_j(\hat{\boldsymbol{x}})\boldsymbol{X}_1 - \boldsymbol{B}_j(\boldsymbol{\zeta})\boldsymbol{M}_i(\hat{\boldsymbol{x}})\}\Big)\boldsymbol{v}_5 \quad is \quad SOS \quad i < j \le r \tag{22}$$

$$-\boldsymbol{v}_6^T\Big(\mathcal{L}\{\boldsymbol{X}_2\bar{\boldsymbol{A}}_i(\boldsymbol{x},\hat{\boldsymbol{x}}) - \boldsymbol{N}_i(\hat{\boldsymbol{x}})\boldsymbol{C}_j\} + \mathcal{L}\{\boldsymbol{X}_2\bar{\boldsymbol{A}}_j(\boldsymbol{x},\hat{\boldsymbol{x}}) - \boldsymbol{N}_j(\hat{\boldsymbol{x}})\boldsymbol{C}_i\}\Big)\boldsymbol{v}_6 \quad is \quad SOS \quad i < j \le r \tag{23}$$

where $\bar{\boldsymbol{A}}_i(\boldsymbol{x},\hat{\boldsymbol{x}})\boldsymbol{e} = \boldsymbol{A}_i(\boldsymbol{x})\boldsymbol{x} - \boldsymbol{A}_i(\hat{\boldsymbol{x}})\hat{\boldsymbol{x}}$. $\boldsymbol{v}_1$, $\boldsymbol{v}_2$, $\boldsymbol{v}_3$, $\boldsymbol{v}_4$, $\boldsymbol{v}_5$, $\boldsymbol{v}_6$ $\in \mathbb{R}^n$ denote vectors that are independent of $\boldsymbol{x}$, $\hat{\boldsymbol{x}}$ and $\boldsymbol{\zeta}$. From the solutions $\boldsymbol{X}_1$ and $\boldsymbol{M}_i(\hat{\boldsymbol{x}})$, we obtain polynomial feedback gains $\boldsymbol{F}_i(\hat{\boldsymbol{x}})$ as $\boldsymbol{F}_i(\hat{\boldsymbol{x}}) = \boldsymbol{M}_i(\hat{\boldsymbol{x}})\boldsymbol{X}_1^{-1}$. From the solutions $\boldsymbol{X}_2$ and $\boldsymbol{N}_i(\hat{\boldsymbol{x}})$, we obtain polynomial observer gains $\boldsymbol{L}_i(\hat{\boldsymbol{x}})$ as $\boldsymbol{L}_i(\hat{\boldsymbol{x}}) = \boldsymbol{X}_2^{-1}\boldsymbol{N}_i(\hat{\boldsymbol{x}})$ as well.

Proof: Consider the estimation error, $\boldsymbol{e} = \boldsymbol{x} - \hat{\boldsymbol{x}}$, by the observer. Then, the error system with respect to $\boldsymbol{e}$ can be represented as

$$\begin{aligned} \dot{\boldsymbol{e}} &= \sum_{i=1}^{r}\sum_{j=1}^{r} h_i(\boldsymbol{z})h_j(\boldsymbol{z})\{\boldsymbol{A}_i(\boldsymbol{x})\boldsymbol{x} - \boldsymbol{A}_i(\hat{\boldsymbol{x}})\hat{\boldsymbol{x}} - \boldsymbol{L}_i(\hat{\boldsymbol{x}})\boldsymbol{C}_j\boldsymbol{e}\} \\ &= \sum_{i=1}^{r}\sum_{j=1}^{r} h_i(\boldsymbol{z})h_j(\boldsymbol{z})\{\bar{\boldsymbol{A}}_i(\boldsymbol{x},\hat{\boldsymbol{x}}) - \boldsymbol{L}_i(\hat{\boldsymbol{x}})\boldsymbol{C}_j\}\boldsymbol{e}, \end{aligned}$$

where $\bar{\boldsymbol{A}}(\boldsymbol{x},\hat{\boldsymbol{x}})\boldsymbol{e} = \boldsymbol{A}(\boldsymbol{x})\boldsymbol{x} - \boldsymbol{A}(\hat{\boldsymbol{x}})\hat{\boldsymbol{x}}$. The augmented system with the augmented vector $\boldsymbol{x}_v = \begin{bmatrix}\hat{\boldsymbol{x}}^T & \boldsymbol{e}^T\end{bmatrix}^T$ is given as

$$\begin{aligned} \dot{\boldsymbol{x}}_v &= \sum_{i=1}^{r}\sum_{j=1}^{r} h_i(\boldsymbol{z})h_j(\boldsymbol{z}) \\ &\quad\times \begin{bmatrix} \boldsymbol{A}_i(\hat{\boldsymbol{x}}) - \boldsymbol{B}_i(\boldsymbol{\zeta})\boldsymbol{F}_j(\hat{\boldsymbol{x}}) & \boldsymbol{L}_i(\hat{\boldsymbol{x}})\boldsymbol{C}_j \\ \boldsymbol{0} & \bar{\boldsymbol{A}}_i(\boldsymbol{x},\hat{\boldsymbol{x}}) - \boldsymbol{L}_i(\hat{\boldsymbol{x}})\boldsymbol{C}_j \end{bmatrix}\boldsymbol{x}_v \\ &= \sum_{i=1}^{r} h_i^2(\boldsymbol{z})\boldsymbol{G}_{ii}(\boldsymbol{x},\boldsymbol{\zeta},\hat{\boldsymbol{x}})\boldsymbol{x}_v \\ &\quad + \sum_{i=1}^{r}\sum_{i<j}^{r} h_i(\boldsymbol{z})h_j(\boldsymbol{z})\left(\boldsymbol{G}_{ij}(\boldsymbol{x},\boldsymbol{\zeta},\hat{\boldsymbol{x}}) + \boldsymbol{G}_{ji}(\boldsymbol{x},\boldsymbol{\zeta},\hat{\boldsymbol{x}})\right)\boldsymbol{x}_v \end{aligned} \tag{24}$$

where

$$\boldsymbol{G}_{ij}(\boldsymbol{x},\boldsymbol{\zeta},\hat{\boldsymbol{x}}) = \begin{bmatrix} \boldsymbol{G}_{11_{ij}}(\boldsymbol{\zeta},\hat{\boldsymbol{x}}) & \boldsymbol{G}_{12_{ij}}(\hat{\boldsymbol{x}}) \\ \boldsymbol{0} & \boldsymbol{G}_{22_{ij}}(\boldsymbol{x},\hat{\boldsymbol{x}}) \end{bmatrix},$$
$$\boldsymbol{G}_{11_{ij}}(\boldsymbol{\zeta},\hat{\boldsymbol{x}}) = \boldsymbol{A}_i(\hat{\boldsymbol{x}}) - \boldsymbol{B}_i(\boldsymbol{\zeta})\boldsymbol{F}_j(\hat{\boldsymbol{x}}),$$
$$\boldsymbol{G}_{12_{ij}}(\hat{\boldsymbol{x}}) = \boldsymbol{L}_i(\hat{\boldsymbol{x}})\boldsymbol{C}_j,$$
$$\boldsymbol{G}_{22_{ij}}(\boldsymbol{x},\hat{\boldsymbol{x}}) = \bar{\boldsymbol{A}}_i(\boldsymbol{x},\hat{\boldsymbol{x}}) - \boldsymbol{L}_i(\hat{\boldsymbol{x}})\boldsymbol{C}_j.$$

Now, consider a candidate of Lyapunov function.

$$V(\boldsymbol{x}_v) = \boldsymbol{x}_v^T \tilde{\boldsymbol{X}} \boldsymbol{x}_v, \tag{25}$$

where

$$\tilde{\boldsymbol{X}} = \begin{bmatrix} \alpha \boldsymbol{X}_1^{-1} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{X}_2 \end{bmatrix}, \tag{26}$$

α is a positive value, $\boldsymbol{X}_1^{-1} \in \mathbb{R}^{n\times n}$ and $\boldsymbol{X}_2 \in \mathbb{R}^{n\times n}$ are positive definite matrices. Note that $V(\boldsymbol{x}_v) > 0$ at $\boldsymbol{x}_v \neq \boldsymbol{0}$. It is clear from Lyapunov theory that the overall control system (24) is stable if it is proved that $\dot{V}(\boldsymbol{x}_v) < 0$ at $\boldsymbol{x}_v \neq \boldsymbol{0}$.

The time derivative of $V(\boldsymbol{x}_v)$ along the trajectory of the system is obtained as

$$\begin{aligned}\dot{V}(\boldsymbol{x}_v) =& \sum_{i=1}^{r}\sum_{j=1}^{r} h_i(\boldsymbol{z})h_j(\boldsymbol{z})\boldsymbol{x}_v^T \mathcal{L}\{\tilde{\boldsymbol{X}}\boldsymbol{G}_{ij}(\boldsymbol{x},\boldsymbol{\zeta},\hat{\boldsymbol{x}})\}\boldsymbol{x}_v \\ =& \sum_{i=1}^{r} h_i^2(\boldsymbol{z})\boldsymbol{x}_v^T \mathcal{L}\{\tilde{\boldsymbol{X}}\boldsymbol{G}_{ii}(\boldsymbol{x},\boldsymbol{\zeta},\hat{\boldsymbol{x}})\}\boldsymbol{x}_v \\ &+ \sum_{i=1}^{r}\sum_{i<j}^{r} h_i(\boldsymbol{z})h_j(\boldsymbol{z})\times \\ &\boldsymbol{x}_v^T \mathcal{L}\{\tilde{\boldsymbol{X}}\left(\boldsymbol{G}_{ij}(\boldsymbol{x},\boldsymbol{\zeta},\hat{\boldsymbol{x}}) + \boldsymbol{G}_{ji}(\boldsymbol{x},\boldsymbol{\zeta},\hat{\boldsymbol{x}})\right)\}\boldsymbol{x}_v.\end{aligned}$$

If the following conditions are satisfied, $\dot{V}(\boldsymbol{x}_v) < 0$ at $\boldsymbol{x}_v \neq \boldsymbol{0}$.

$$\mathcal{L}\{\tilde{\boldsymbol{X}}\boldsymbol{G}_{ii}(\boldsymbol{x},\boldsymbol{\zeta},\hat{\boldsymbol{x}})\} < \boldsymbol{0} \tag{27}$$
$$\mathcal{L}\{\tilde{\boldsymbol{X}}\left(\boldsymbol{G}_{ij}(\boldsymbol{x},\boldsymbol{\zeta},\hat{\boldsymbol{x}}) + \boldsymbol{G}_{ji}(\boldsymbol{x},\boldsymbol{\zeta},\hat{\boldsymbol{x}})\right)\} \leq \boldsymbol{0} \quad i < j \leq r \tag{28}$$

As well as in the proof of Theorem 1, (27) can be separately rewritten as

$$\mathcal{L}\{\boldsymbol{X}_1^{-1}(\boldsymbol{A}_i(\hat{\boldsymbol{x}}) - \boldsymbol{B}_i(\boldsymbol{\zeta})\boldsymbol{F}_i(\hat{\boldsymbol{x}}))\} < \boldsymbol{0}, \tag{29}$$
$$\mathcal{L}\{\boldsymbol{X}_2(\bar{\boldsymbol{A}}_i(\boldsymbol{x},\hat{\boldsymbol{x}}) - \boldsymbol{L}_i(\hat{\boldsymbol{x}})\boldsymbol{C}_i)\} < \boldsymbol{0}. \tag{30}$$

Multiplying both side of (29) by $\boldsymbol{X}_1$ and defining a new variable $\boldsymbol{M}_i(\hat{\boldsymbol{x}}) = \boldsymbol{F}_i(\hat{\boldsymbol{x}})\boldsymbol{X}_1$, we obtain the following conditions.

$$\mathcal{L}\{\boldsymbol{A}_i(\hat{\boldsymbol{x}})\boldsymbol{X}_1 - \boldsymbol{B}_i(\boldsymbol{\zeta})\boldsymbol{M}_i(\hat{\boldsymbol{x}})\} < \boldsymbol{0} \tag{31}$$

Defining another new variable $\boldsymbol{N}_i(\hat{\boldsymbol{x}}) = \boldsymbol{X}_2\boldsymbol{L}_i(\hat{\boldsymbol{x}})$, the inequality (30) can be described as

$$\mathcal{L}\{\boldsymbol{X}_2\bar{\boldsymbol{A}}_i(\boldsymbol{x},\hat{\boldsymbol{x}}) - \boldsymbol{N}_i(\hat{\boldsymbol{x}})\boldsymbol{C}_i\} < \boldsymbol{0}. \tag{32}$$

In the same way as above, (28) can be also represented as

$$\begin{aligned}&\mathcal{L}\{\boldsymbol{A}_i(\hat{\boldsymbol{x}})\boldsymbol{X}_1 - \boldsymbol{B}_i(\boldsymbol{\zeta})\boldsymbol{M}_j(\hat{\boldsymbol{x}})\} \\ &+ \mathcal{L}\{\boldsymbol{A}_j(\hat{\boldsymbol{x}})\boldsymbol{X}_1 - \boldsymbol{B}_j(\boldsymbol{\zeta})\boldsymbol{M}_i(\hat{\boldsymbol{x}})\} \leq \boldsymbol{0},\end{aligned} \tag{33}$$

$$\begin{aligned}&\mathcal{L}\{\boldsymbol{X}_2\bar{\boldsymbol{A}}_i(\boldsymbol{x},\hat{\boldsymbol{x}}) - \boldsymbol{N}_i(\hat{\boldsymbol{x}})\boldsymbol{C}_j\} \\ &+ \mathcal{L}\{\boldsymbol{X}_2\bar{\boldsymbol{A}}_j(\boldsymbol{x},\hat{\boldsymbol{x}}) - \boldsymbol{N}_j(\hat{\boldsymbol{x}})\boldsymbol{C}_i\} \leq \boldsymbol{0}\end{aligned} \tag{34}$$

for $i < j \leq r$. It is clear from the inequality conditions (31)-(34) that $\dot{V}(\boldsymbol{x}_v) < 0$ at $\boldsymbol{x}_v \neq \boldsymbol{0}$ if the SOS conditions (18)$\sim$(23) hold.

■

Remark 6. *As we can see, Theorems 1 and 2 show that the so-called separation principle is realized, i.e., that the fuzzy polynomial controller and observer can be separately designed without lack of guaranteeing the stability of the overall control system in addition to converging state estimation error (via the observer) to zero. This is a very important point in our fuzzy polynomial controller and observer design. In particular, in Theorem 2, a key feature of realizing the separation design is that, by introducing the transformation $\bar{\boldsymbol{A}}(\boldsymbol{x},\hat{\boldsymbol{x}})\boldsymbol{e} = \boldsymbol{A}(\boldsymbol{x})\boldsymbol{x} - \boldsymbol{A}(\hat{\boldsymbol{x}})\hat{\boldsymbol{x}}$, the (2,1) element in $\boldsymbol{G}_{ij}(\boldsymbol{x},\boldsymbol{\zeta},\hat{\boldsymbol{x}})$ becomes zero element (matrix). This transformation idea leads to the successful separation design.*

IV. Design Example

Consider the following nonlinear system, where x_1 is measurable and $y = x_1$.

$$\begin{cases} \dot{x}_1 = \sin x_1 - 0.3x_2 + (x_1^2 + 1)u \\ \dot{x}_2 = -1.5x_1 - 2x_2 - x_2^3 \end{cases} \tag{35}$$

Fig. 1 shows system behaviors without inputs. It can be seen from Fig. 1 that the system is unstable.

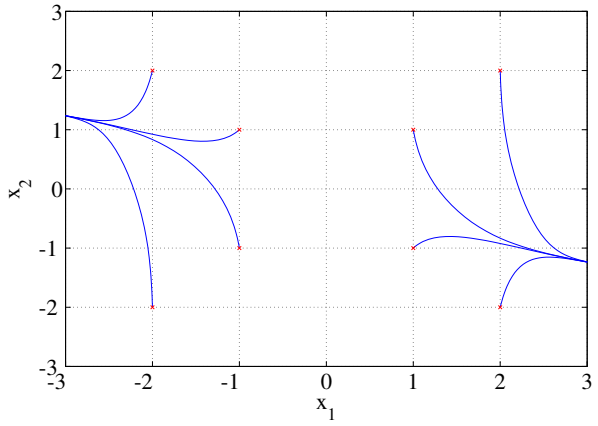

Fig. 1. System behaviors without inputs.

This system has polynomial terms $(x_1^2 + 1)u$ and x_2^3. To obtain a T-S fuzzy model, we need to assume the ranges of x_1 and x_2. Thus, the T-S fuzzy model is a local model. This means that the T-S fuzzy model stabilization and state-estimation convergence are not guaranteed for outside the ranges. The polynomial fuzzy model constructed in this example can exactly and globally represent the dynamics of the original system. Even if a local or semi-global T-S fuzzy model is permitted to use in practical sense, the premise variable vector $\boldsymbol{z}$ contain x_2 to be estimated. Hence, the previous LMI conditions mentioned above can not be applied to the nonlinear system. On the other hand, the premise variable vector $\boldsymbol{z}$ in

polynomial fuzzy model does not contain x_2 and x_2 appears in polynomial system matrices $\boldsymbol{A}_i$ in consequent parts of polynomial fuzzy models. Since the Class II design permits to have unmeasurable states in $\boldsymbol{A}_i$ matrices, it is possible to design a polynomial fuzzy observer in this example.

The dynamics of the nonlinear system can be exactly represented as the polynomial fuzzy system (15), where $r = 2$, $\boldsymbol{z} = \boldsymbol{\zeta} = y$,

$$
\begin{aligned}
&\boldsymbol{A}_1(\boldsymbol{x}) = \begin{bmatrix} 1 & -0.3 \\ -1.5 & -2 - x_2^2 \end{bmatrix}, \\
&\boldsymbol{A}_2(\boldsymbol{x}) = \begin{bmatrix} -0.2172 & -0.3 \\ -1.5 & -2 - x_2^2 \end{bmatrix}, \\
&\boldsymbol{B}_1(\boldsymbol{\zeta}) = \boldsymbol{B}_2(\boldsymbol{\zeta}) = \begin{bmatrix} y^2 + 1 \\ 0 \end{bmatrix}, \\
&\boldsymbol{C}_1 = \boldsymbol{C}_2 = \begin{bmatrix} 1 & 0 \end{bmatrix}, \\
&h_1(\boldsymbol{z}) = \frac{\sin y + 0.2172y}{1.2172y}, \\
&h_2(\boldsymbol{z}) = \frac{y - \sin y}{1.2172y}.
\end{aligned}
$$

In this example, note that

$$
\begin{aligned}
\bar{\boldsymbol{A}}_1(\boldsymbol{x}, \hat{\boldsymbol{x}})\boldsymbol{e} &= \boldsymbol{A}_1(\boldsymbol{x})\boldsymbol{x} - \boldsymbol{A}_1(\hat{\boldsymbol{x}})\hat{\boldsymbol{x}} \\
&= \begin{bmatrix} 1 & -0.3 \\ -1.5 & -2 - x_2^2 - x_2\hat{x}_2 - \hat{x}_2^2 \end{bmatrix} \begin{bmatrix} e_1 \\ e_2 \end{bmatrix},
\end{aligned}
$$

$$
\begin{aligned}
\bar{\boldsymbol{A}}_2(\boldsymbol{x}, \hat{\boldsymbol{x}})\boldsymbol{e} &= \boldsymbol{A}_2(\boldsymbol{x})\boldsymbol{x} - \boldsymbol{A}_2(\hat{\boldsymbol{x}})\hat{\boldsymbol{x}} \\
&= \begin{bmatrix} -0.2172 & -0.3 \\ -1.5 & -2 - x_2^2 - x_2\hat{x}_2 - \hat{x}_2^2 \end{bmatrix} \begin{bmatrix} e_1 \\ e_2 \end{bmatrix}.
\end{aligned}
$$

By solving the SOS conditions in Theorem 2, we have $\boldsymbol{X}_i$ $\boldsymbol{M}_i(\hat{\boldsymbol{x}})$ and $\boldsymbol{N}_i(\hat{\boldsymbol{x}})$, where the orders of $\boldsymbol{M}_i(\hat{\boldsymbol{x}})$ and $\boldsymbol{N}_i(\hat{\boldsymbol{x}})$ are two.

$$
\begin{aligned}
&\boldsymbol{X}_1 = \begin{bmatrix} 0.41696 & 0.34597e^{-6} \\ 0.34597e^{-6} & 0.50738 \end{bmatrix} \\
&\boldsymbol{X}_2 = \begin{bmatrix} 0.95521 & 0.11778e^{-5} \\ 0.11778e^{-5} & 0.61866 \end{bmatrix} \\
&\boldsymbol{M}_1(\boldsymbol{\zeta}) = \begin{bmatrix} 0.90492 \\ 0.25275e^{-5} - 0.19247e^{-11}\hat{x}_2^2 \end{bmatrix} \\
&\boldsymbol{M}_2(\boldsymbol{\zeta}) = \begin{bmatrix} 0.57747 \\ 0.22252e^{-5} - 0.19251e^{-11}\hat{x}_2^2 \end{bmatrix} \\
&\boldsymbol{N}_1(\boldsymbol{\zeta}) = \begin{bmatrix} 1.6776 \\ -0.90461 - 0.32618e^{-5}\hat{x}_2^2 \end{bmatrix} \\
&\boldsymbol{N}_2(\boldsymbol{\zeta}) = \begin{bmatrix} 0.61447 \\ -0.87404 - 0.32619e^{-5}\hat{x}_2^2 \end{bmatrix}
\end{aligned}
$$

From the solutions $\boldsymbol{X}_i$ $\boldsymbol{M}_i(\hat{\boldsymbol{x}})$ and $\boldsymbol{N}_i(\hat{\boldsymbol{x}})$, we obtain the following polynomial feedback and observer gains,

$$
\begin{aligned}
&\boldsymbol{F}_1(\hat{\boldsymbol{x}}) = \begin{bmatrix} 2.17028 + 0.31476e^{-17}\hat{x}_2^2 \\ 0.35016e^{-5} - 0.37934e^{-11}\hat{x}_2^2 \end{bmatrix} \\
&\boldsymbol{F}_2(\hat{\boldsymbol{x}}) = \begin{bmatrix} 1.38495 + 0.31482e^{-17}\hat{x}_2^2 \\ 0.34413e^{-5} - 0.37942e^{-11}\hat{x}_2^2 \end{bmatrix} \\
&\boldsymbol{L}_1(\boldsymbol{y}, \hat{\boldsymbol{x}}) = \begin{bmatrix} 1.75626 + 0.650097e^{-11}\hat{x}_2^2 \\ -1.46221 - 0.52724e^{-5}\hat{x}_2^2 \end{bmatrix} \\
&\boldsymbol{L}_2(\boldsymbol{y}, \hat{\boldsymbol{x}}) = \begin{bmatrix} 0.64328 + 0.65012e^{-11}\hat{x}_2^2 \\ -1.41280 - 0.52725e^{-5}\hat{x}_2^2 \end{bmatrix}
\end{aligned}
$$

Fig. 2 shows the control and estimation result by the designed polynomial fuzzy controller and observer, where the initial states are $\boldsymbol{x}(0) = [1\ \ 1]$ and $\hat{\boldsymbol{x}}(0) = [0\ \ 0]$. Fig. 3 shows control trajectories for same initial states as in Fig. 1. It can be seen from the figures that the designed controller stabilizes the nonlinear system and the estimation error via the polynomial fuzzy observer tends to zero.

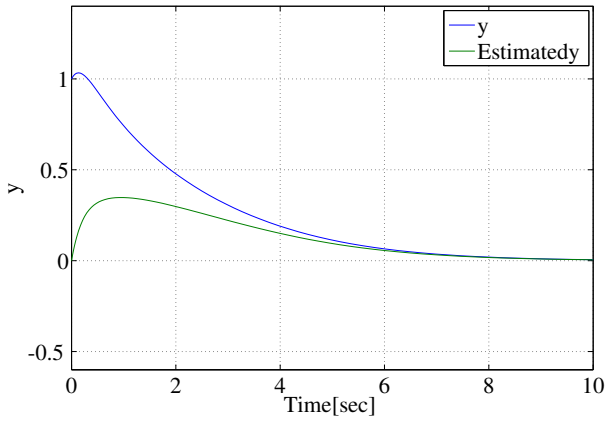

Fig. 2. Control and estimation result.

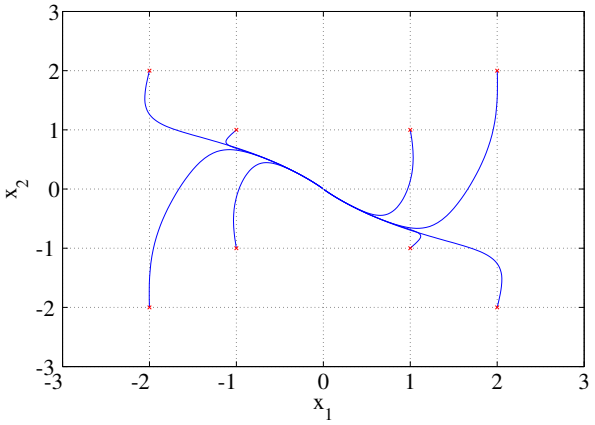

Fig. 3. Control trajectories for same initial states as in Fig. 1.

Remark 7. *Since $\boldsymbol{A}_1(\boldsymbol{x})$ and $\boldsymbol{A}_2(\boldsymbol{x})$ have unmeasurable x_2 in this design example, the Class I SOS-based observer design (Theorem 1) can not be applied to this design example. The previous LMI conditions mentioned above can not be also applied to the nonlinear system. On the other hand, since the Class II design (Theorem 2) permits to have unmeasurable states in $\boldsymbol{A}_i$ matrices, it is possible to design a polynomial fuzzy observer in this example.*

V. Conclusions

This paper has presented a sum of squares (SOS) approach to polynomial fuzzy controllers and observers for a wider class of polynomial fuzzy systems. To illustrate the validity and applicability of the proposed approach, a design example has been provided. The example has demonstrated advantages of the SOS-based approaches for the existing LMI approaches to T-S fuzzy observer designs.

Our next subjects are to derive SOS observer design conditions even for Class III [28] and to apply our observer designs to helicopter control [11].

***Abstract*—This study introduces H_∞ decentralized static output feedback fuzzy control design for nonlinear interconnected systems via T-S fuzzy models. In general, due to the interactions among subsystems, it is difficult to design an H_∞ decentralized output feedback controller for nonlinear interconnected systems. A singular value decomposition (SVD) method is proposed in this study to solve the H_∞ decentralized static output feedback fuzzy control problem. By the proposed SVD method, the problem of H_∞ decentralized static output feedback fuzzy control design for nonlinear interconnected systems is characterized in terms of solving an eigenvalue problem (EVP). This EVP can be easily solved by using a LMI-based optimization method. Finally, simulation example is given to illustrate the design procedure and robust performance of the proposed methods.**

I. INTRODUCTION

Due to the physical configuration and high dimensionality of interconnected systems, a centralized control is neither economically feasible nor even necessary. Therefore, a decentralized control scheme is preferred in control design of the large-scale interconnected systems. In other words, the decentralized control scheme attempts to avoid difficulties in complexity of system design. In the past three decades, there are many applications of linear decentralized methodologies to spacecraft dynamics, power systems, industrial processes, transportation networks and others [1], [15]. On the other hand, there are few studies concerning with the stabilization control design for the interconnected nonlinear systems because of the complexity among them [24], [13], [14]. Due to the effects of nonlinear interconnection among subsystems, there is still no efficient way to deal with the decentralized control problem of nonlinear interconnected systems, especially for the output feedback control case.

In the past few years, there has been rapidly growing interest in decentralized fuzzy control for the nonlinear interconnected systems using T-S fuzzy model. However, most of them are state feedback cases [10], [9], [21], [22]. On the other hand, there are few studies concerned with the systematic synthesis of output feedback control design for nonlinear interconnected systems using the T-S fuzzy models [18], [19]. The output feedback control design for nonlinear systems using the T-S fuzzy models is more general and complex than the state feedback one. When dealing with output feedback control design, either a dynamic output feedback (fuzzy observer-based) case or a static output feedback case is considered. For the dynamic output feedback case, a fuzzy observer is also involved as well as the fuzzy controller [20], [8]. In other words, for the fuzzy observer-based output feedback control design, a fuzzy observer should also be involved to estimate the system states using the output information and a fuzzy controller is constructed using the estimated states. For the static output feedback case [12], [3], [4], [5], [11], [6], [23], the fuzzy controller depends on the system outputs only without the complex structures of the fuzzy observer. In general, the control design of static output feedback is more straightforward but less flexible than that of dynamic output feedback and the structure of static output feedback controller is much simpler than that of dynamic output feedback controller. This study introduces H_∞ decentralized static output feedback fuzzy control design for nonlinear interconnected systems via T-S fuzzy models. A SVD method is proposed in this study to solve the H_∞ decentralized static output feedback fuzzy control design for nonlinear interconnected systems, which can be characterized in terms of solving an EVP for each subsystem. The EVP can be easily solved by using a genetic algorithm and a LMI-based optimization method. The SVD approach provides different aspect from the linear transformation approach [12], [11] and moreover the proposed SVD method is very simple and easy to follow.

The main contributions of this paper are stated as follows: (1) The H_∞ output feedback control problem for nonlinear interconnected systems is studied via a decentralized static output feedback fuzzy controller. (2) A SVD method is proposed to solve H_∞ decentralized static output feedback fuzzy control problem which can be characterized in terms of solving an EVP for each subsystem. By the proposed SVD method, the decentralized static fuzzy control gains for each subsystem can be obtained efficiently.

The paper is organized as follows. The system description is presented in Section II. In section III, the H_∞ decentralized static feedback fuzzy control design for the nonlinear inter-

connected systems is introduced. In Section IV, simulation example is provided to demonstrate the design procedures. Finally, concluding remarks are made in Section V. In what follows, $M_{[m\times n]}$ denotes a $m\times n$ matrix and $I_{[n\times n]}$ and $0_{[m\times n]}$ denote a $n \times n$ identity matrix and a $m \times n$ zero matrix, respectively. If dimensions of matrices are not particularly defined, they are of appropriate and clear dimensions.

II. SYSTEM DESCRIPTION

A T-S fuzzy dynamic model [16] has been proposed to represent locally linear input/output relations for nonlinear systems. This fuzzy dynamic model is described by fuzzy If-Then rules and will be employed here to deal with the control design problem of a nonlinear interconnected system S which is composed of N subsystems S_i $(i = 1, ..., N)$. The k^{th} rule of the fuzzy model of subsystem S_i is proposed as the following form [10], [9], [21], [22], [18], [19]:

Plant Rule k :

$$\begin{array}{ll} \textbf{If} & z_{i1}(t) \text{ is } F_{i1}^k \ldots \text{and } z_{iq_i}(t) \text{ is } F_{iq_i}^k \\ & \dot{x}_i(t) = A_{ik}x_i(t) + B_{1ik}u_i(t) \\ \textbf{Then} & \quad + \sum_{j=1, j\neq i}^{N} [A_{ijk}x_j(t)] + B_{2ik}w_i(t) \\ & y_i(t) = C_i x_i(t) \text{ for } k = 1, \ldots, L_i \end{array} \tag{1}$$

where $x_i(t) = [\ x_{i1}(t),\ \cdots,\ x_{in_i}(t)\ ]^T \in R^{n_i}$ denotes the vector of state, $u_i(t) = [\ u_{i1}(t),\ \cdots,\ u_{im_i}(t)\ ]^T \in R^{m_i}$ denotes the vector of control input, $w_i(t)$ denotes the vector of the external disturbance, $y_i(t) = [\ y_{i1}(t),\ \cdots,\ y_{ip_i}(t)\ ]^T \in R^{p_i}$ denotes the vector of output, $F_{i1}^k, ..., F_{iq_i}^k$ are the fuzzy sets, L_i is the number of If-Then rules of the subsystem S_i, the matrices A_{ik}, B_{1ik}, A_{ijk}, B_{2ik}, and C_i are of appropriate dimensions, and $z_{i1}(t), \ldots, z_{iq_i}(t)$ are the premise variables.

Remark 1: For different subsystem, the number of rules may be different. In other words, L_i can be different for different subsystem. ■

Remark 2: Since in this study the static output feedback control is considered, the premise variables $z_{i1}(t), \ldots, z_{iq_i}(t) \in y_i(t)$ with $q_i \leq p_i$ for subsystem S_i are assumed. ■

Remark 3: In this study, $C_i \in R^{p_i\times n_i}$ $(i = 1, ..., N)$ with full row rank are assumed, i.e., $rank(C_i) = p_i$. Hence, a singular value decomposition (SVD) of the output matrix C_i for the subsystem S_i can be defined as

$$C_i = U_i S_i V_i^T = U_i S_i V_i^{-1} \tag{2}$$

where

$$\begin{array}{rcl} U_i & \in & R^{p_i\times p_i} \\ S_i & = & [\ \Sigma_{i[p_i\times p_i]} \quad 0_{[p_i\times(n_i-p_i)]}\ ] \in R^{p_i\times n_i} \\ V_i & \in & R^{n_i\times n_i} \end{array}$$

and

$$\Sigma_i = diag\{\ \bar{\sigma}_{i1},\ \ \bar{\sigma}_{i2},\ \ \cdots,\ \ \bar{\sigma}_{ip_i}\ \} \in R^{p_i\times p_i}$$

with singular values $\bar{\sigma}_{i1} \geq \bar{\sigma}_{i2} \geq \cdots \geq \bar{\sigma}_{ip_i} > 0$. Note that, since U_i and V_i are orthogonal matrices, $U_i^T = U_i^{-1}$, $V_i^T = V_i^{-1}$, and then $V_i^T V_i = V_i V_i^T = V_i^{-1} V_i = V_i V_i^{-1} = I_{[n_i\times n_i]}$. ■

The overall fuzzy model of subsystem S_i can be rearranged as the following form:

$$\begin{array}{rcl} \dot{x}_i(t) & = & \sum_{k=1}^{L_i} h_k(z_i(t))\{A_{ik}x_i(t) + B_{1ik}u_i(t) \\ & & + \sum_{j=1, j\neq i}^{N} [A_{ijk}x_j(t)] + B_{2ik}w_i(t)\} \\ y_i(t) & = & \sum_{k=1}^{L_i} h_k(z_i(t))[C_i x_i(t)] \end{array} \tag{3}$$

where $\mu_k(z_i(t)) = \prod_{q=1}^{q_i} F_{iq}^k(z_{iq}(t))$, $h_k(z_i(t)) = \frac{\mu_k(z_i(t))}{\sum_{k=1}^{L}\mu_k(z_i(t))}$, $z_i(t) = [z_{i1}(t), \ldots, z_{iq_i}(t)]$, and $F_{iq}^k(z_{iq}(t))$ is the grade of membership of $z_{iq}(t)$ in F_{iq}^k $(q = 1, ..., q_i)$. It is assumed that $\mu_k(z_i(t)) \geq 0$ and $\sum_{k=1}^{L} \mu_k(z_i(t)) > 0$ for $k = 1, 2, \ldots, L_i$ for all t. Therefore, we get $h_k(z_i(t)) \geq 0$ for $k = 1, 2, \ldots, L_i$ and $\sum_{k=1}^{L_i} h_k(z_i(t)) = 1$.

The aim of this study is to propose a decentralized static output feedback fuzzy controller for nonlinear interconnected systems. Suppose the following decentralized static output feedback fuzzy controller is proposed to deal with the nonlinear interconnected subsystem S_i :

Control Rule s :

$$\begin{array}{ll} \textbf{If} & z_{i1}(t) \text{ is } F_{i1}^s \ldots \text{and } z_{iq_i}(t) \text{ is } F_{iq_i}^s \\ \textbf{Then} & u_i(t) = K_{is}y_i(t) \end{array} \tag{4}$$

for $s = 1, 2, \ldots, L_i$. The overall decentralized static output feedback fuzzy controller for the i^{th} subsystem is represented as follows:

$$\begin{array}{rcl} u_i(t) & = & \sum_{s=1}^{L_i} h_s(z_i(t))K_{is}y_i(t) \\ & = & \sum_{s=1}^{L_i} h_s(z_i(t))[K_{is}C_i x_i(t)] \end{array} \tag{5}$$

where K_{is} is the static fuzzy control gain for the s^{th} control rule and the i^{th} interconnected subsystem S_i.

After some manipulation, the i^{th} subsystem can be expressed as the following compact form:

$$\begin{array}{rcl} \dot{x}_i(t) & = & \sum_{j=1, j\neq i}^{N} \sum_{k=1}^{L_i} h_k(z_i(t)) \sum_{s=1}^{L_i} h_s(z_i(t))[\bar{A}_{iks}x_i(t) \\ & & + A_{ijk}x_j(t) + B_{2ik}w_i(t)] \end{array} \tag{6}$$

where

$$\begin{array}{rcl} \bar{A}_{iks} & = & A_{ik} + B_{1ik}K_{is}C_i \\ & = & A_{ik} + B_{1ik}K_{is}U_i S_i V_i^{-1}. \end{array}$$

III. H_∞ DECENTRALIZED STATIC OUTPUT FEEDBACK FUZZY CONTROL SYNTHESIS FOR NONLINEAR INTERCONNECTED SYSTEMS

The purpose of this study is to determine a decentralized static output feedback fuzzy controller in (5) for the system in (6) with the guaranteed H_∞ performance for all $w_i(t) \in L_2$. Let us consider the H_∞ performance for subsystem S_i as follows [18], [19], [12], [5], [11], [23]

$$\frac{\int_0^{t_f} x_i^T(t)\Psi_i x_i(t)dt}{\int_0^{t_f} w_i^T(t)w_i(t)dt} \le \rho_i^2 \tag{7}$$

or

$$\int_0^{t_f} x_i^T(t)\Psi_i x_i(t)dt \le \rho_i^2 \int_0^{t_f} w_i^T(t)w_i(t)dt \tag{8}$$

where Ψ_i is symmetric positive definite weighting matrix, t_f is terminal time of control, ρ_i is a prescribed attenuation level for the subsystem S_i. The physical meaning of (7) or (8) is that the effect of any $w_i(t) \in L_2$ on state $x_i(t)$ must be attenuated below a desired level ρ_i^2 from the viewpoint of energy, no matter what $w_i(t)$ is, i.e., the L_2 gain from $w_i(t)$ to $x_i(t)$ must be less than or equal to a prescribed value ρ_i^2. The H_∞ performance with a prescribed attenuation level is useful for a robust stabilization design without knowledge of $w_i(t)$. Thereafter, the attenuation level ρ_i^2 for each subsystem can also be minimized so that the H_∞ performance in (8) is reduced as small as possible.

Hence, if initial conditions are also considered, the H_∞ performance for subsystem S_i in (8) can be modified as follows

$$\begin{aligned} &\int_0^{t_f} x_i^T(t)\Psi_i x_i(t)dt \\ \le\ & x_i^T(0)\tilde{P}_i x_i(0) + \rho_i^2 \int_0^{t_f} w_i^T(t)w_i(t)dt \end{aligned} \tag{9}$$

where $\tilde{P}_i = (V_i^{-1})^T \bar{P}_i (V_i^{-1})$ is a symmetric positive definite weighting matrix.

For simplicity, the notation $\begin{bmatrix} M_{11} & * \\ M_{21} & M_{22} \end{bmatrix} \triangleq \begin{bmatrix} M_{11} & M_{21}^T \\ M_{21} & M_{22} \end{bmatrix}$ is adopted throughout this paper. Then, we get the following main result for the H_∞ decentralized static output feedback fuzzy control.

Theorem 1: In the nonlinear interconnected systems (6), if there exist symmetric positive matrices Q_i with

$$Q_i = \begin{bmatrix} Q_{i1[p_i \times p_i]} & 0 \\ 0 & Q_{i2[(n_i-p_i)\times(n_i-p_i)]} \end{bmatrix} \in R^{n_i \times n_i}$$

and matrices $\bar{Y}_{is}$ with

$$\bar{Y}_{is} = \begin{bmatrix} Y_{is[m_i \times p_i]} & 0_{[m_i \times (n_i-p_i]} \end{bmatrix} \in R^{m_i \times n_i}$$

such that the following LMIs

$$\begin{bmatrix} \{\bar{M}_1 + \bar{M}_1^T\} & * & * & * \\ \bar{A}_{ijk}^T & 0 & * & * \\ \bar{B}_{2ik}^T & 0 & -\rho_i^2 I & * \\ Q_i & 0 & 0 & -\Psi_{vi}^{-1} \end{bmatrix} \le 0 \tag{10}$$

hold for $i, j = 1, 2, ..., N$ $(j \ne i)$ and $k \le s = 1, 2, ..., L_i$ s.t. $h_k(\cdot) \cap h_s(\cdot) \ne \emptyset$, where

$$\begin{aligned} \bar{M}_1 &= \frac{(\bar{A}_{ik}Q_i + \bar{B}_{1ik}\bar{Y}_{is}) + (\bar{A}_{is}Q_i + \bar{B}_{1is}\bar{Y}_{ik})}{2} \\ \bar{A}_{ik} &= V_i^{-1}A_{ik}V_i \\ \bar{B}_{1ik} &= V_i^{-1}B_{1ik} \\ \bar{A}_{ijk} &= V_i^{-1}A_{ijk} \\ \bar{B}_{2ik} &= V_i^{-1}B_{2ik} \\ \Psi_{vi} &= V_i^T\Psi_i V_i = V_i^{-1}\Psi_i V_i, \end{aligned}$$

then (i) the H_∞ control performance in (9) is guaranteed for a prescribed ρ_i^2 in the case of $w_i(t) \ne 0$ and (ii) the interconnected systems S is stable in the sense of Lyapunov in the case of $w_i(t) = 0$. Moreover, the static fuzzy control gains can be obtained as

$$K_{is} = Y_{is}Q_{i1}^{-1}\Sigma_i^{-1}U_i^{-1}.$$

Proof: From (9), we obtain

$$\begin{aligned} &\int_0^{t_f} x_i^T(t)\Psi_i x_i(t)dt \\ =\ & \int_0^{t_f} \{x_i^T(t)\Psi_i x_i(t) + \frac{d}{dt}[x_i^T\tilde{P}_i x_i]\}dt \\ & + x_i^T(0)\tilde{P}_i x_i(0) - x_i^T(t_f)\tilde{P}_i x_i(t_f) \\ \le\ & x_i^T(0)\tilde{P}_i x_i(0) \\ & + \int_0^{t_f} \{x_i^T(t)\Psi_i x_i(t) + \frac{d}{dt}[x_i^T\tilde{P}_i x_i]\}dt \\ =\ & x_i^T(0)\tilde{P}_i x_i(0) \\ & + \sum_{j=1, j\ne i}^{N} \sum_{k=1}^{L_i} h_k^2(z_i(t)) \int_0^{t_f} \{x_i^T(t)\Psi_i x_i(t) \\ & + \eta^T \begin{bmatrix} \{\Psi_i & * & * \\ +\tilde{P}_i(\frac{\bar{A}_{ikk}+\bar{A}_{ikk}}{2}) & & \\ +(\frac{\bar{A}_{ikk}+\bar{A}_{ikk}}{2})^T\tilde{P}_i\} & & \\ A_{ijk}^T\tilde{P}_i & 0 & * \\ B_{2ik}^T\tilde{P}_i & 0 & -\rho_i^2 I \end{bmatrix} \eta \\ & \}dt + 2 \sum_{j=1, j\ne i}^{N} \sum_{k=1}^{L_i} h_k(z_i(t)) \sum_{k<s}^{L_i} h_s(z_i(t)) \\ & \times \int_0^{t_f} \{x_i^T(t)\Psi_i x_i(t) \\ & + \eta^T \begin{bmatrix} \{\Psi_i & * & * \\ +\tilde{P}_i(\frac{\bar{A}_{iks}+\bar{A}_{isk}}{2}) & & \\ +(\frac{\bar{A}_{iks}+\bar{A}_{isk}}{2})^T\tilde{P}_i\} & & \\ A_{ijk}^T\tilde{P}_i & -I & * \\ B_{2ik}^T\tilde{P}_i & 0 & -\rho_i^2 I \end{bmatrix} \eta \\ & \}dt + \rho_i^2 \int_0^{t_f} w_i^T(t)w_i(t)dt \end{aligned} \tag{11}$$

where $\eta^T = \left[\begin{array}{ccc} x_i^T(t), & x_j^T(t), & w_i^T(t) \end{array} \right]$. From (11), if

$$\left[\begin{array}{cc} \{\Psi_i + (V_i^{-1})^T \bar{P}_i (V_i^{-1})(\frac{\bar{A}_{iks}+\bar{A}_{isk}}{2}) & * \quad * \\ +(\frac{\bar{A}_{iks}+\bar{A}_{isk}}{2})^T (V_i^{-1})^T \bar{P}_i (V_i^{-1})\} & \\ A_{ijk}^T (V_i^{-1})^T \bar{P}_i (V_i^{-1}) & 0 \quad * \\ B_{2ik}^T (V_i^{-1})^T \bar{P}_i (V_i^{-1}) & 0 \quad -\rho_i^2 I \end{array} \right] \leq 0 \tag{12}$$

for $i, j = 1, 2, ..., N$ $(j \neq i)$ and $k \leq s = 1, 2, ..., L_i$, then we obtain

$$\begin{aligned} & \int_0^{t_f} x_i^T(t) \Psi_i x_i(t) dt \\ \leq \quad & x_i^T(0) \tilde{P}_i x_i(0) + \rho_i^2 \int_0^{t_f} w_i^T(t) w_i(t) dt. \end{aligned} \tag{13}$$

By pre-multiplying $\left[\begin{array}{ccc} V_i & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{array} \right]^T$ and post-multiplying $\left[\begin{array}{ccc} V_i & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{array} \right]$ to (12), we obtain

$$\left[\begin{array}{cc} \{V_i^T \Psi_i V_i & \\ +\bar{P}_i (V_i^{-1})(\frac{\bar{A}_{iks}+\bar{A}_{isk}}{2}) V_i & * \quad * \\ +V_i^T (\frac{\bar{A}_{iks}+\bar{A}_{isk}}{2})^T (V_i^{-1})^T \bar{P}_i\} & \\ A_{ijk}^T (V_i^{-1})^T \bar{P}_i & 0 \quad * \\ B_{2ik}^T (V_i^{-1})^T \bar{P}_i & 0 \quad -\rho_i^2 I \end{array} \right] \leq 0. \tag{14}$$

By the following definitions,

$$\begin{aligned} \bar{A}_{ik} &= V_i^{-1} A_{ik} V_i \\ \bar{B}_{1ik} &= V_i^{-1} B_{1ik} \\ \bar{A}_{ijk} &= V_i^{-1} A_{ijk} \\ \bar{B}_{2ik} &= V_i^{-1} B_{2ik} \\ \Psi_{vi} &= V_i^T(\Psi_i) V_i = V_i^{-1}(\Psi_i) V_i, \end{aligned}$$

(14) can be expressed as the following compact form

$$\left[\begin{array}{ccc} \Psi_{vi} + \bar{P}_i \bar{M}_2 + \bar{M}_2^T \bar{P}_i & * & * \\ \bar{A}_{ijk}^T \bar{P}_i & 0 & * \\ \bar{B}_{2ik}^T \bar{P}_i & 0 & -\rho_i^2 I \end{array} \right] \leq 0. \tag{15}$$

where $\bar{M}_2 = (\frac{(\bar{A}_{ik}+\bar{B}_{1ik}K_{is}U_iS_i)+(\bar{A}_{is}+\bar{B}_{1is}K_{ik}U_iS_i)}{2})$.

By pre-multiplying $\left[\begin{array}{ccc} Q_i & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{array} \right]$ and post-multiplying $\left[\begin{array}{ccc} Q_i & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{array} \right]$ to (15), we obtain

$$\left[\begin{array}{ccc} \{Q_i \Psi_{vi} Q_i + \bar{M}_3 + \bar{M}_3^T\} & * & * \\ \bar{A}_{ijk}^T & 0 & * \\ \bar{B}_{2ik}^T & 0 & -\rho_i^2 I \end{array} \right] \leq 0 \tag{16}$$

where
$\bar{M}_3 = (\frac{(\bar{A}_{ik}Q_i+\bar{B}_{1ik}K_{is}U_iS_iQ_i)+(\bar{A}_{is}Q_i+\bar{B}_{1is}K_{ik}U_iS_iQ_i)}{2})$ and

$$Q_i = \bar{P}_i^{-1} = Q_i^T > 0.$$

Note that, by the Schur complements [2], (16) is equivalent to

$$\left[\begin{array}{cccc} \{\bar{M}_3 + \bar{M}_3^T\} & * & * & * \\ \bar{A}_{ijk}^T & 0 & * & * \\ \bar{B}_{2ik}^T & 0 & -\rho_i^2 I & * \\ Q_i & 0 & 0 & -\Psi_{vi}^{-1} \end{array} \right] \leq 0. \tag{17}$$

For the simplicity of design, let

$$Q_i = \left[\begin{array}{cc} Q_{i1} & 0 \\ 0 & Q_{i2} \end{array} \right] \tag{18}$$

and then

$$\begin{aligned} & \bar{B}_{1ik} K_{is} U_i S_i Q_i \\ = \quad & \bar{B}_{1ik} K_{is} U_i \left[\begin{array}{cc} \Sigma_i & 0 \end{array} \right] \left[\begin{array}{cc} Q_{i1} & 0 \\ 0 & Q_{i2} \end{array} \right] \\ = \quad & \bar{B}_{1ik} \left[\begin{array}{cc} K_{is} U_i \Sigma_i Q_{i1} & 0 \end{array} \right] \\ = \quad & \bar{B}_{1ik} \left[\begin{array}{cc} Y_{is} & 0 \end{array} \right] = \bar{B}_{1ik} \bar{Y}_{is} \end{aligned} \tag{19}$$

where

$$\begin{aligned} Y_{is} &= K_{is} U_i \Sigma_i Q_{i1} \\ \bar{Y}_{is} &= \left[\begin{array}{cc} Y_{is} & 0 \end{array} \right]. \end{aligned}$$

By substituting (18) and (19) into (17), we obtain the following LMIs

$$\left[\begin{array}{cccc} \{\bar{M}_1 + \bar{M}_1^T\} & * & * & * \\ \bar{A}_{ijk}^T & 0 & * & * \\ \bar{B}_{2ik}^T & 0 & -\rho_i^2 I & * \\ Q_i & 0 & 0 & -\Psi_{vi}^{-1} \end{array} \right] \leq 0. \tag{20}$$

where $\bar{M}_1 = \frac{(\bar{A}_{ik}Q_i+\bar{B}_{1ik}\bar{Y}_{is})+(\bar{A}_{is}Q_i+\bar{B}_{1is}\bar{Y}_{ik})}{2}$.

If we can solve $Q_i = diag\{ \begin{array}{cc} Q_{i1}, & Q_{i2} \end{array} \}$ and $\bar{Y}_{is} = \left[\begin{array}{cc} Y_{is} & 0 \end{array} \right]$ from the above LMIs, the decentralized static fuzzy control gains can be obtained as

$$K_{is} = Y_{is} Q_{i1}^{-1} \Sigma_i^{-1} U_i^{-1}. \tag{21}$$

Therefore, the H_∞ control performance is achieved with a prescribed ρ_i^2 in the case of $w_i(t) \neq 0$. In the case of $w_i(t) = 0$, let us define a Lyapunov function for the subsystem S_i in (6) as

$$LF_i(t) = x_i^T(t) \tilde{P}_i x_i(t)$$

where $\tilde{P}_i = (V_i^{-1})^T \bar{P}_i (V_i^{-1})$ is a symmetric positive definite weighting matrix. Thus, the Lyapunov function for the overall interconnected system S can be defined as

$$LF(t) = \sum_{i=1}^{N} LF_i(t) = \sum_{i=1}^{N} \{x_i^T(t) \tilde{P}_i x_i(t)\}.$$

The time derivative of the Lyapunov function $LF(t)$ is

$$\begin{aligned}
&\frac{d}{dt}(LF(t)) \\
=\ & \sum_{i=1}^{N}\sum_{j=1,j\neq i}^{N}\sum_{k=1}^{L_i} h_k(z_i(t))\sum_{s=1}^{L_i} h_s(z_i(t)) \\
&\times\{[\bar{A}_{iks}x_i(t)+A_{ijk}x_j(t)]^T\tilde{P}_i x_i(t) \\
&+x_i^T(t)\tilde{P}_i[\bar{A}_{iks}x_i(t)+A_{ijk}x_j(t)]\} \\
=\ & \sum_{i=1}^{N}\sum_{j=1,j\neq i}^{N}\sum_{k=1}^{L} h_k(z_i(t))\sum_{s=1}^{L} h_s(z_i(t)) \\
&\times\{\bar{\eta}^T\begin{bmatrix}\tilde{P}_i\bar{A}_{iks}+\bar{A}_{iks}^T\tilde{P}_i & * \\ A_{ijk}^T\tilde{P}_i & 0\end{bmatrix}\bar{\eta}\} \\
=\ & \sum_{i=1}^{N}\sum_{j=1,j\neq i}^{N}\sum_{k=1}^{L_i} h_k^2(z_i(t)) \\
&\times\{\bar{\eta}^T\begin{bmatrix}\{\tilde{P}_i(\frac{\bar{A}_{ikk}+\bar{A}_{ikk}}{2}) & * \\ +(\frac{\bar{A}_{ikk}+\bar{A}_{ikk}}{2})^T\tilde{P}_i\} & \\ A_{ijk}^T\tilde{P}_i & 0\end{bmatrix}\bar{\eta}\} \\
&+2\sum_{i=1}^{N}\sum_{j=1,j\neq i}^{N}\sum_{k=1}^{L_i} h_k(z_i(t))\sum_{k<s}^{L_i} h_s(z_i(t)) \\
&\times\{\bar{\eta}^T\begin{bmatrix}\{\tilde{P}_i(\frac{\bar{A}_{iks}+\bar{A}_{isk}}{2}) & * \\ +(\frac{\bar{A}_{iks}+\bar{A}_{isk}}{2})^T\tilde{P}_i\} & \\ A_{ijk}^T\tilde{P}_i & 0\end{bmatrix}\bar{\eta}\} \qquad (22)
\end{aligned}$$

where $\bar{\eta}^T = [\ x_i^T(t),\quad x_j^T(t)\ ]$. From (22), if

$$\begin{bmatrix}\tilde{P}_i(\frac{\bar{A}_{iks}+\bar{A}_{isk}}{2})+(\frac{\bar{A}_{iks}+\bar{A}_{isk}}{2})^T\tilde{P}_i & * \\ A_{ijk}^T\tilde{P}_i & 0\end{bmatrix}\le 0 \qquad (23)$$

for $i,j=1,2,...,N$ $(j\neq i)$ and $k\le s=1,...,L_i$, then $\frac{d}{dt}(LF(t))\le 0$. It is easy to show that (12), which is equivalent to (10) if Q_i in (18) is specified, implies (23) and then the interconnected system S is stable in the sense of Lyapunov, if the LMIs in (10) hold. This completes the proof. ■

As mentioned, to obtain better robust performance, the attenuation level ρ_i^2 for each subsystem can be minimized so that the H_∞ performance in (9) is reduced as small as possible. Therefore, the H_∞ static output feedback fuzzy control problem for the nonlinear interconnected systems can be formulated as the following minimization problem which is also called eigenvalue problem (EVP).

$$\begin{array}{ll}\min & \sum_{i=1}^{N}\rho_i^2 \\ \text{subject to} & Q_i=Q_i^T>0,\ \bar{Y}_{is},\ \text{and (10).}\end{array} \qquad (24)$$

Remark 4: By the above formulation in (24), the attenuation level ρ_i^2 for each subsystem may not be the minimum but the sum of the attenuation level ρ_i^2, i.e., $\sum_{i=1}^{N}\rho_i^2$, is minimal, which means the formulation in (24) finds the attenuation level ρ_i^2 as small as possible for each subsystem by minimizing $\sum_{i=1}^{N}\rho_i^2$ with equal weighting for each subsystem. For the simplicity of design, one may assume $\rho_1=\rho_2=\cdots=\rho_N=\rho$. In such a case, the EVP in (24) can be simplified as follows:

$$\begin{array}{ll}\min & \rho^2 \\ \text{subject to} & Q_i=Q_i^T>0,\ \bar{Y}_{is},\ \text{and (10).}\end{array} \qquad (25)$$

■

According to the analysis above, the H_∞ decentralized static output feedback fuzzy control design is summarized as follows:

Design Procedure:

Step 1: Construct the fuzzy plant rules in (1).

Step 2: Perform the SVD for the output matrices $C_i = U_iS_iV_i^T = U_i[\ \Sigma_i\quad 0\ ]V_i^T$ $(i=1,...,N)$ in (2).

Step 3: Solve the EVP in (24) and then obtain the corresponding minimal attenuation level ρ_i^2 and the corresponding $Q_i = diag\{\ Q_{i1},\quad Q_{i2}\ \}$ and $\bar{Y}_{is} = [\ Y_{is}\quad 0\ ]$ (thus decentralized static fuzzy control gains $K_{is}=Y_{is}Q_{i1}^{-1}\Sigma_i^{-1}U_i^{-1}$ can also be obtained), simultaneously.

Step 4: Construct the H_∞ decentralized static output feedback fuzzy controller in (5).

IV. SIMULATION EXAMPLE

In this section, the stabilization problem of two interconnected systems S_1 and S_2 using the proposed decentralized static output feedback fuzzy control scheme is considered. For the subsystem S_1, a modified Lorenz's equation with input, outputs, and interconnected terms from subsystem S_2 is given by

$$S_1:\ \begin{cases}\dot{x}_{11}=-10x_{11}+10x_{12}+0.1x_{22} \\ \qquad +u_1(t)+0.1w_{11} \\ \dot{x}_{12}=28x_{11}-x_{12}-x_{11}x_{13} \\ \qquad -0.3x_{21}+0.1w_{12} \\ \dot{x}_{13}=x_{11}x_{12}-8/3x_{13}+0.05x_{21} \\ \qquad -0.01x_{22}+0.1w_{13} \\ y_{11}=x_{11} \\ y_{12}=5x_{12}+2x_{13}\end{cases} \qquad (26)$$

where external disturbance

$$\begin{aligned}&w_1(t)=[\ w_{11},\quad w_{12},\quad w_{13}\ ]^T \\ &=[\ 50\sin(10t)e^{-0.5t},\quad 50\cos(10t)e^{-t}, \\ &50[\sin(10t)+\cos(10t)]e^{-0.2t}]^T\in L_2.\end{aligned}$$

For this subsystem S_1, the modified Lorenz's equation can be exactly represented by the following two-rule fuzzy model under $x_{11}\ (=y_{11})\in[\ -\kappa_1,\quad \kappa_1\ ]$ [17].

Rule 1 : IF y_{11} is F_{11}^1

THEN $\dot{x}_1(t) = A_{11}x_1(t)+A_{121}x_2(t)+B_{111}u_1(t)+B_{211}w_1(t)$, and $y_1(t)=C_1x_1(t)$,

Rule 2 : IF y_{11} is F_{11}^2

THEN $\dot{x}_1(t) = A_{12}x_1(t)+A_{122}x_2(t)+B_{112}u_1(t)+B_{212}w_1(t)$, and $y_1(t)=C_1x_1(t)$,

where $x_1(t) = [\ x_{11},\ x_{12},\ x_{13}\ ]^T$, $y_1(t) = [\ y_{11},\ y_{12}\ ]^T$,

$$\begin{aligned} A_{11} &= \begin{bmatrix} -10 & 10 & 0 \\ 28 & -1 & -\kappa_1 \\ 0 & \kappa_1 & -8/3 \end{bmatrix}, \\ A_{12} &= \begin{bmatrix} -10 & 10 & 0 \\ 28 & -1 & \kappa_1 \\ 0 & -\kappa_1 & -8/3 \end{bmatrix}, \\ C_1 &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 5 & 2 \end{bmatrix}, \\ A_{12k} &= \begin{bmatrix} 0 & 0.1 \\ -0.3 & 0 \\ 0.05 & -0.01 \end{bmatrix}, \\ B_{11k} &= [\ 1 \quad 0 \quad 0\ ]^T, \\ \text{and } B_{21k} &= 0.1 I_{[3\times 3]}\ (k = 1, 2) \end{aligned}$$

where $F_{11}^1 = \frac{1}{2}(1 + \frac{y_{11}}{\kappa_1}) = h_1(y_{11})$, $F_{11}^2 = \frac{1}{2}(1 - \frac{y_{11}}{\kappa_1}) = h_2(y_{11})$, and $\kappa_1 = 30$.

For the subsystem S_2, a modified Duffing forced-oscillation model with input, output, and interconnected terms from subsystem S_1 is given by

$$S_2 : \begin{cases} \dot{x}_{21} = x_{22} + 0.05x_{11} - 0.01x_{12} \\ \qquad +6\cos(t) + 0.5u_2^*(t)) + 0.5w_{21} \\ \dot{x}_{22} = -x_{21}^3 - 0.1x_{22} - 0.01x_{12} + 0.04x_{13} \\ \qquad +12\cos(t) + u_2^*(t) + 0.03w_{22} \\ y_{21} = 10x_{21} \end{cases} \tag{27}$$

where external disturbance $w_2(t) = [\ w_{21},\ w_{22}\ ]^T = [\ N_1 e^{-0.5t},\ N_2 e^{-t}\ ]^T \in L_2$, where $N_1 = 200 sign[\sin(10t)]$ and $N_2 = 200 sign[\cos(10t)]$ are assumed to be periodic square wave with period $\frac{2\pi}{10}$ and magnitude ± 200. For this subsystem S_2, the modified Duffing forced-oscillation model can be exactly represented by the following two-rule fuzzy model under $x_{21}\ (= 0.1y_{21}) \in [\ -\kappa_2,\ \kappa_2\ ]$ [17].

Rule 1 : IF $0.1y_{21}$ is F_{21}^1

THEN $\dot{x}_2(t) = A_{21}x_2(t) + A_{211}x_1(t) + B_{121}u_2(t) + B_{221}w_2(t)$, and $y_2(t) = C_2x_2(t)$,

Rule 2 : IF $0.1y_{21}$ is F_{21}^2

THEN $\dot{x}_2(t) = A_{22}x_2(t) + A_{212}x_1(t) + B_{122}u_2(t) + B_{222}w_2(t)$, and $y_2(t) = C_2x_2(t)$,

where $x_2(t) = [\ x_{21},\ x_{22}\ ]^T$, $y_2(t) = y_{21}$, $u_2(t) = 12\cos(t) + u_2^*(t)$,

$$\begin{aligned} A_{21} &= \begin{bmatrix} 0 & 1 \\ 0 & -0.1 \end{bmatrix}, \\ A_{22} &= \begin{bmatrix} 0 & 1 \\ -\kappa_2^2 & -0.1 \end{bmatrix}, \\ C_2 &= [\ 10 \quad 0\ ], \\ A_{21k} &= \begin{bmatrix} 0.05 & -0.01 & 0 \\ 0 & -0.01 & 0.04 \end{bmatrix}, \\ B_{12k} &= [\ 0.5 \quad 1\ ]^T, \\ \text{and } B_{22k} &= \begin{bmatrix} 0.05 & 0 \\ 0 & 0.03 \end{bmatrix}\ (k = 1, 2) \end{aligned}$$

where $F_{21}^1 = (1 - \frac{(0.1y_{21})^2}{\kappa_2^2}) = h_1(y_{21})$, $F_{21}^2 = \frac{(0.1y_{21})^2}{\kappa_2^2} = h_2(y_{21})$, and $\kappa_2 = 50$.

Remark 5: For the simplicity of design, we can assume $\rho_1 = \rho_2 = \rho$ for these two subsystems in this example. ■

There is no efficient algorithm in Matlab [7] to solve the nonstrict LMIs in (10), therefore one may replace the diagonal zero entry in (10) by a negative value to solve the nonstrict LMIs problem in (24). Consequently, the solutions of the nonstrict LMIs in (10) can be obtained correspondingly by solving the following strict LMIs if ε^2 is small enough, for example $\varepsilon^2 \le 10^{-8}$.

$$\begin{bmatrix} \bar{M}_1 & * & * & * \\ \bar{A}_{ijk}^T & -\varepsilon^2 I & * & * \\ \bar{B}_{2ik}^T & 0 & -\rho_i^2 I & * \\ Q_i & 0 & 0 & -\Psi_{vi}^{-1} \end{bmatrix} < 0 \tag{28}$$

To obtain feasible solutions for the strict LMIs in (28), the weighting matrices Ψ_1 and Ψ_2 should be small enough. In this example, $\varepsilon^2 = 10^{-8}$ and the weighting matrices are chosen as follows

$$\Psi_1 = 5 \times 10^{-8} I_{[3\times 3]},\ \Psi_2 = 5 \times 10^{-8} I_{[2\times 2]}.$$

Then, following the **Design Procedure** in the above section, the SVD of C_1 and C_2 is given as follows:

$$\begin{aligned} C_1 &= \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} 5.3852 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix} \\ &\quad \times \begin{bmatrix} 0 & 1 & 0 \\ 0.9285 & 0 & -0.3714 \\ 0.3714 & 0 & 0.9285 \end{bmatrix}^T, \\ C_2 &= [1] [\ 10 \quad 0\ ] \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}^T. \end{aligned}$$

Solving the EVP in (25), one can obtain the corresponding minimal attenuation level $\rho_{\min}^2 = 3 \times 10^{-8}$ and

$$\begin{aligned} Q_1 &= diag\{\ Q_{11},\ Q_{12}\ \} \\ &= 10^7 \times \begin{bmatrix} 3.6452 & -0.6262 & 0 \\ -0.6262 & 0.4863 & 0 \\ 0 & 0 & 3.519 \end{bmatrix} \\ Q_2 &= diag\{\ Q_{21},\ Q_{22}\ \} \\ &= 10^6 \times \begin{bmatrix} 0.0003 & 0 \\ 0 & 1.9996 \end{bmatrix} \\ \bar{Y}_{11} &= 10^8 \times [\ -2.3573 \quad -7.0707 \quad 0\ ] \\ \bar{Y}_{12} &= 10^8 \times [\ -2.7502 \quad -3.8084 \quad 0\ ] \\ \bar{Y}_{21} &= [\ -2.0096 \times 10^6 \quad 0\ ] \\ \bar{Y}_{22} &= [\ -1.3050 \times 10^6 \quad 0\ ]. \end{aligned}$$

The decentralized static output feedback fuzzy control gains can be found as follows

$$\begin{aligned} K_{11} &= [\ -197.3995 \quad -7.4974\ ], \\ K_{12} &= [\ -113.0383 \quad -5.0066\ ], \\ K_{21} &= -713.0568,\ K_{22} = -463.0563. \end{aligned}$$

Therefore, the proposed decentralized static output feedback fuzzy controller is constructed as

$$u_i(t) = \sum_{s=1}^{2} h_s(y_{s1}) K_{is} y_i(t), \ \ (i = 1, 2).$$

Ignoring the effect of initial conditions, the H_∞ performance in this example can be written as follows

$$5 \times 10^{-8} \int_0^{t_f} x_i^T(t) x_i(t) dt \leq 3 \times 10^{-8} \int_0^{t_f} w_i^T(t) w_i(t) dt$$

which is equivalent to

$$\frac{\int_0^{t_f} x_i^T(t) x_i(t) dt}{\int_0^{t_f} w_i^T(t) w_i(t) dt} \leq 0.6$$

The following table shows the results for the different choice of ε^2 and Ψ_i, respectively.

ε^2	Ψ_i	$\rho^2_{\min}$
10^{-8}	5×10^{-8}	3×10^{-8}
10^{-9}	5×10^{-9}	3×10^{-9}
$10^{-9.5}$	$5 \times 10^{-9.5}$	9.571×10^{-10}

Remark 6: In the above example, if $\varepsilon^2 < 10^{-9.5}$, no feasible solution can be found. ■

Figs. 1-4 present the simulation results with initial conditions $(\ x_{11}(0),\ \ x_{12}(0),\ \ x_{13}(0)\ ) = (\ 5,\ \ 10,\ \ -5\ )$ and $(\ x_{21}(0),\ \ x_{22}(0)\ ) = (\ 4.5,\ \ -5\ )$. The trajectories of state variables $x_{11}(t)$, $x_{12}(t)$, and $x_{13}(t)$ are shown in Fig. 1 while the trajectories of state variables $x_{21}(t)$ and $x_{22}(t)$ are shown in Fig. 2. The control inputs $u_1(t)$ and $u_2^*(t) = u_2(t) - 12\cos(t)$ are applied at $t = 2\ (sec)$ and shown in Fig. 3 and Fig. 4, respectively. From Fig. 1 and Fig. 2, one observes that the states are very oscillating before $t < 2\ (sec)$ but all states are stabilized rapidly after the control inputs are applied. From the simulation results, the proposed H_∞ decentralized static output feedback fuzzy control scheme can solve the output feedback control problem for nonlinear interconnected systems effectively and systematically with the aid of LMI-based optimization method.

V. CONCLUSIONS

In this study, H_∞ decentralized static output feedback fuzzy control design for nonlinear interconnected systems is considered via T-S fuzzy models. Furthermore, the stability of the nonlinear interconnected systems is also guaranteed by the proposed decentralized static output feedback control scheme. A SVD method is proposed to solve the H_∞ static output feedback stabilization problem for the nonlinear interconnected systems, which can be characterized in terms of an EVP for each subsystem. By the proposed SVD method, the H_∞ decentralized static fuzzy control gains can be obtained efficiently. The proposed decentralized static output feedback fuzzy control scheme is very simple without complex control algorithms. Therefore, it is suitable for practical applications. Simulation example is given to illustrate the design procedure and robust performance of the proposed method.

***Abstract*—An approach to adaptive fuzzy sliding-mode control (SMC) for a class of nonlinear dynamical systems with lumped parameter uncertainties accompanied with control input is proposed and analyzed. The approach guarantees that the system state will be uniformly ultimately bounded. Also, discussion on how to alleviate the conservativeness of the approach is provided. Finally, computer simulations illustrate the effectiveness of the control approach proposed in this paper.**

Keywords - adaptive fuzzy control; T-S fuzzy model; sliding-mode control; Uncertainties

I. Introduction

In recent years, there have been significant advances in the study of the stability analysis and controller synthesis for the so-called Takagi-Sugeno (T-S) fuzzy systems, which have been used to represent certain complex nonlinear systems. The overall model of the system is obtained by the fuzzy blending of these local models. The control design is carried out based on the fuzzy model by the so-called parallel distributed compensation (PDC) scheme [1]. For each local linear model, a linear feedback control is designed. The resulting overall controller is again a fuzzy blending of the individual linear controllers. Originally, Tanaka and his colleagues have provided certain conditions that are sufficient for the stability of the T-S fuzzy systems in the sense of Lyapunove [2]. The feedback control gain in each PDC control rule is obtained by solving certain linear matrix inequalities (LMIs).

Although a nonlinear system can be handled by a PDC controller based on the T-S fuzzy model, the control performance depends on the precision of the T-S fuzzy model. That is, if the model uncertainties between the system to be controlled and the T-S fuzzy model are significantly large, then the control performance is no longer to be as good as we expected. To compensate for the uncertainties and/or disturbances, several system design and analysis approaches have be proposed. Among the existing robust control approaches, fuzzy sliding-mode control (SMC) has been recognized as an effective robust control approach for uncertain systems. SMC is a particular type of variable structure control. Variable structure control systems are designed to derive and then constrain the system state to lie within a neighborhood of the sliding surface. There are many advantages to this approach [8]. In particular, the closed-loop response becomes totally insensitive to a particular class of uncertainties. This invariance property clearly makes the methodology an appropriate candidate for robust control. In addition, the ability to specify performance directly make SMC attractive from the design perspective. The result of Zheng *et al.* [3] is an elaborate example to illustrate that the SMC theory can be successfully applied to robust stabilization of uncertain nonlinear system with T-S fuzzy model, where uncertainties include parameter perturbation and external disturbances for which their upper-bounds are available. The ordinary T-S fuzzy model has been further extended to time-delay systems with uncertainties based on the SCM theory [4], [5]. More recently, by introducing some coordinate transformations to design a reduced-order sliding-mode dynamics, some excellent results on fuzzy sliding-mode control for nonlinear systems with uncertainties, particularly a lumped uncertainties accompanied with control input were reported [6], [7]. However, it should be pointed out that there are some limitations to the existing results. The main drawback comes to the assumption that requires the same control matrix, *i.e.,* $B_1 = B_2 = \cdots = B_r$ in the T-S fuzzy model with r rules; however, in practical applications that are a lot of cases where the control matrices are different in the T-S fuzzy model. Second, though all results showed the system state would be uniformly ultimately bounded when using some adaptive laws to deal with unknown parameters in the T-S fuzzy model, the boundedness was not mentioned further, which implies that such results are conservative.

Motivated by the aforementioned observations, in this paper we propose an adaptive SMC approach based on the T-S fuzzy model with uncertainties, trying to remove some strict assumptions on the system and alleviate the conservatism of the control results. Also, computer simulations are provided to illustrate the effectiveness of the proposed control approach.

II. Problem Description

It is now well known that T-S fuzzy models can provide an effective representation of complex nonlinear systems. Therefore, in this study, the nonlinear system under consideration is represented by T-S fuzzy models. Consider the following T-S fuzzy model:

Plant Rule i :
IF $\theta_1(t)$ is M_1^i and $\cdots$ and $\theta_p(t)$ is M_p^i,
THEN $\dot{x}(t) = A_i x(t) + B_i(x(t))\left(u(t) + \mathcal{U}_i(x(t))\right),$

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

where $\theta_j^i (i = 1, 2, \cdots, r, j = 1, 2, \cdots, p)$ are variables in the antecedent; M_j^i, fuzzy sets with membership functions $\mu_{M_j^i}(\theta_j)$; $x(t) \in R^n$, system state; $u(t) \in R^m$, control input; $A_i \in R^{n\times n}$ and $B_i(x(t)) \in R^{n\times m}$, system and input matrices; $\mathcal{U}_i(x(t)) \in R^m$, lumped uncertainties including external disturbance. In this paper, we suppose that rank$(B) = m < n$. The overall fuzzy model is of the following form accordingly:

$$\dot{x}(t) = \sum_{i=1}^{r} \alpha_i(t)\big\{A_i x(t) + B_i(x(t))\left(u(t) + \mathcal{U}_i(x(t))\right)\big\}, \quad (1)$$

where

$$\alpha_i(t) = \frac{w_i(t)}{\sum_{i=1}^r w_i(t)} \geq 0, \quad \sum_{i=1}^r \alpha_i(t) = 1,$$
$$w_i(t) = \prod_{j=1}^p \mu_j^i(\theta_j(t)).$$

For the T-S fuzzy model above, we make the following assumptions.

A1: $B_i(x(t)) = B \cdot G_i(x(t))$, where $B \in R^{n\times m}$, rank$(B) = m < n$, $G_i(x(t)) \in R^{m\times m}$ is a known matrix function such that det $G_i(x(t)) \neq 0$, and of known sign; without loss of generality this sign can be taken as positive. Also, any (A_i, B) is a controllable pair.

A2: The lumped uncertainties $\mathcal{U}_i(x(t))$ are assumed to satisfy the following conditions:

$$||\mathcal{U}_i(x(t))|| \leq c_i^* + k_i^*||x(t)||, \quad (2)$$

where c_i^*, k_i^* are unknown positive constants, $||\cdot||$ denotes the Euclidean norm of a vector or a matrix.

It is noted that the T-S fuzzy model considered in this paper is significantly different from the models in this scope (see [6]-[7], for example), in which they took $B_i(x(t)) = B$ for $i = 1, 2, \cdots, r$. This implies that there is the same gain for control input $u(t)$ in each local model. Consequently, the overall fuzzy model (1) becomes

$$\dot{x}(t) = \sum_{i=1}^{r} \alpha_i(t)\big\{A_i x(t) + B\mathcal{U}_i(x(t)\big\} + Bu(t). \quad (3)$$

Although (3) has the benefit that the corresponding controllers are easier to be designed, apparently, its applications are severely restricted. Therefore, one of challenges in this paper is to design an adaptive fuzzy controller based on the T-S fuzzy model (1) towards more flexibility.

From here, unless confusion arises arguments such as t will be omitted just for notational convenience.

Letting $T_r \in R^{n\times n}$ be an orthogonal matrix such that

$$T_r A_i T_r^T = \begin{bmatrix} A_{11i} & A_{12i} \\ A_{21i} & A_{22i} \end{bmatrix} \triangleq \bar{A}_i, \quad T_r B = \begin{bmatrix} 0 \\ B_2 \end{bmatrix}, \quad (4)$$

where $A_{11i} \in R^{(n-m)\times(n-m)}$, $A_{12i} \in R^{(n-m)\times m}$, $A_{21i} \in R^{m\times(n-m)}$, $A_{22i} \in R^{(n-m)\times m}$, $B_2 \in R^{m\times m}$, and $z = T_r x$, then by pre-multiplying T_r on the both sides of (1), one obtains the following regular form.

$$\begin{aligned} \dot{z} &= \sum_{i=1}^{r} \alpha_i \left(\bar{A}_i z + \begin{bmatrix} 0 \\ B_2 \end{bmatrix} G_i\left(u + \mathcal{U}_i\right)\right) \\ &= \begin{bmatrix} \bar{A}_{11} & \bar{A}_{12} \\ \bar{A}_{21} & \bar{A}_{22} \end{bmatrix} z + \begin{bmatrix} 0 \\ B_2 \end{bmatrix} \sum_{i=1}^{r} \alpha_i G_i\left(u + \mathcal{U}_i\right), \quad (5) \end{aligned}$$

where

$$\bar{A}_{11} = \textstyle\sum_{i=1}^r \alpha_i A_{11i}, \quad \bar{A}_{12} = \sum_{i=1}^r \alpha_i A_{12i}, \quad (6)$$
$$\bar{A}_{21} = \textstyle\sum_{i=1}^r \alpha_i A_{21i}, \quad \bar{A}_{22} = \sum_{i=1}^r \alpha_i A_{22i}, \quad (7)$$

and $\mathcal{U}_i$ is a function with respect to $T_r^{-1} z$ at this point in time. Letting $z = [z_1^T \ z_2^T]^T$, where $z_1 \in R^{n-m}, z_2 \in R^m$, (5) can be transformed into

$$\dot{z}_1 = \bar{A}_{11} z_1 + \bar{A}_{12} z_2, \quad (8)$$

$$\dot{z}_2 = \bar{A}_{21} z_1 + \bar{A}_{22} z_2 + B_2 \sum_{i=1}^{r} \alpha_i G_i\left(u + \mathcal{U}_i\right). \quad (9)$$

This transformation can be accomplished for any given controllable pair (A_i, B), where B is full rank using some MATLAB commands [8].

III. Control System Design

SMC system design can be decoupled into two independent tasks. The first one is the selection of an appropriate sliding surface, which should have the property that the desired performance can be achieved while the system state remains on the sliding surface. Another task is to design a control law in order to force the system state to reach the sliding surface in spite of uncertainties in the system.

A. Sliding Surface Design

The corresponding sliding surface is chosen as follows.

$$s(t) = \bar{C} z(t) = 0 \quad (10)$$

where $\bar{C} \triangleq [-C_1 \ C_2]$ with $C_1 \in R^{m\times(n-m)}$, $C_2 = C_2^T \in R^{m\times m}$, which is positive-definite, are parameters to be designed. It follows from (10) that $z_2 = C_2^{-1} C_1 z_1$, and from (8) that

$$\dot{z}_1 = \left(\bar{A}_{11} + \bar{A}_{12} C_2^{-1} C_1\right) z_1, \quad (11)$$

which is a reduced-order $(n - m)$ sliding mode dynamics. Thus, the result of designing sliding surface can be provided as follows.

Theorem 1: Consider system (11). If there exists matrices $Q = Q^T \in R^{(n-m)\times(n-m)}$, $C_2 = C_2^T \in R^{m\times m}$, which are positive-definite, $M \in R^{m\times(n-m)}$, such that the following LMIs satisfied:

$$\begin{bmatrix} A_{11i}Q + QA_{11i}^T & M^T & A_{12i} \\ M & -C_2 & 0 \\ A_{12i}^T & 0 & -C_2 \end{bmatrix} < 0, \quad i = 1, 2, \cdots r. \quad (12)$$

then the sliding surface (10) with

$$C_1 = MQ^{-1} \quad (13)$$

will guarantee that the sliding motion in (11) is asymptotically stable.

Proof: Let us define a Lyapunov function candidate as

$$V(t) = z_1(t)^T Q^{-1} z_1(t). \tag{14}$$

Then, taking the time derivative along the state trajectory of system (11), one obtains

$$\begin{aligned}\dot{V}(t) &= z_1^T \Big(\bar{A}_{11}^T Q^{-1} + \left(C_2^{-1} C_1\right)^T \bar{A}_{12}^T Q^{-1} \\ &\quad + Q^{-1} \bar{A}_{11} + Q^{-1} \bar{A}_{12} C_2^{-1} C_1 \Big) z_1. \end{aligned} \tag{15}$$

Obviously, it follows from (15) that the sliding motion (11) is asymptotically stable, if

$$\begin{aligned}&\bar{A}_{11}^T Q^{-1} + C_1^T C_2^{-1} \bar{A}_{12}^T Q^{-1} \\ &+ Q^{-1} \bar{A}_{11} + Q^{-1} \bar{A}_{12} C_2^{-1} C_1 < 0. \end{aligned} \tag{16}$$

By pre- and post-multiplying (16) by Q, it follows that

$$Q \bar{A}_{11}^T + M^T C_2^{-1} \bar{A}_{12}^T + \bar{A}_{11} Q + \bar{A}_{12} C_2^{-1} M < 0, \tag{17}$$

where the fact that $M = C_1 Q$ is used. Due to the facts that $C_2^{-1} > 0$ and

$$\left(M - A_{12}^T\right)^T C_2^{-1} \left(M - A_{12}^T\right) \geq 0,$$

which leads to

$$M^T C_2^{-1} \bar{A}_{12}^T + \bar{A}_{12} C_2^{-1} M \leq M^T C_2^{-1} M + \bar{A}_{12} C_2^{-1} \bar{A}_{12}^T,$$

therefore, the condition for the sliding motion being asymptotical stable (17) can be replaced by the following inequality.

$$Q \bar{A}_{11}^T + \bar{A}_{11} Q + M^T C_2^{-1} M + \bar{A}_{12} C_2^{-1} \bar{A}_{12}^T < 0. \tag{18}$$

By applying the Schur complement formula to (18) and using (6), (7), it leads to LMIs (12). After all, we can conclude that the $(n-m)$ reduced-order sliding mode dynamics (11) is asymptotically stable. This completes the proof. □

Although LMIs (12) can guarantee that the sliding motion (11) is asymptotically stable, *i.e.,*

$$\bar{A}_{11} + \bar{A}_{12} C_2^{-1} C_1 < 0, \tag{19}$$

it is not taken into account how to make the state converge to 0, which is the equilibrium point in this paper, as fast as possible.

In what follows, let us consider the matter. From (11) we have

$$z_2(t) = \exp\left(A_{11} + \bar{A}_{12} C_2^{-1} C_1\right) z_2(0),$$

implying that we should find the minimum value of $A_{11} + \bar{A}_{12} C_2^{-1} C_1$ so that z_2 shrinks to 0 most rapidly. Substituting (13) into (19), it follows that

$$\bar{A}_{11} Q + \bar{A}_{12} C_2^{-1} M < 0, \tag{20}$$

which implies that the minimum values of the left side of inequality (17), then LMIs (12) lead to the minimum one of $\bar{A}_{11} + \bar{A}_{12} C_2^{-1} C_1$.

Let $R_i = R_i^T > 0$ be any given matrices, then, the minimum values of the left sides of LMIs (12) can be found by solving the following LMIs, searching the minimum value of γ.

$$\begin{aligned}&\begin{bmatrix} A_{11i} Q + Q A_{11i}^T & M^T & A_{12i} \\ M & -C_2 & 0 \\ A_{12i}^T & 0 & -C_2 \end{bmatrix} < \gamma R_i, \\ &\qquad\qquad\qquad\qquad i = 1, 2, \cdots r. \end{aligned} \tag{21}$$

Since R_i are fixed, the left sides in (21) become smaller in order to get a smaller γ. Eventually, the minimum values of the left sides can be achieved. Summarizing above, we obtain the following corollary.

Corollary 1: Consider system (11). If there exists matrices $Q = Q^T \in R^{(n-m)\times(n-m)}$, which is positive-definite, $M \in R^{m\times(n-m)}$, $C_2 = C_2^T \in R^{m\times m}$, such that the following LMIs satisfied:

$$\begin{aligned}&\min \gamma \ \texttt{subject to} \\ &\begin{cases} \texttt{LMIs } (12) \\ \texttt{LMIs } (21) \end{cases} \end{aligned} \tag{22}$$

where $R_i = R_i^T > 0$ are some given matrices with appropriate dimensions, then the sliding surface (10) with (13) will guarantee that the sliding motion in (11) is asymptotically stable with the maximum convergence rate.

LMIs (22) can be solved by using existing software packages such as `mincx` solver in the LMI Control Toolbox with MATLAB.

Regarding the LMIs in Theorem 1, we give the following remark.

Remark 1: Since $M^T C_2^{-1} M + \bar{A}_{12} C_2^{-1} \bar{A}_{12}^T > 0$, the condition for the sliding motion being asymptotical stable (17), also, can be transferred into

$$Q \bar{A}_{11}^T + \bar{A}_{11} Q + \left(M + \bar{A}_{12}^T\right)^T C_2^{-1} \left(M + \bar{A}_{12}^T\right) < 0,$$

which leads to the following LMIs by using the Schur complement formula.

$$\begin{bmatrix} A_{11i} Q + Q A_{11i}^T & M^T + A_{12i} \\ M + A_{12i}^T & -C_2 \end{bmatrix} < 0. \tag{23}$$

That is, LMIs (23) may be another solutions if LMIs (12) are infeasible, though it is difficult to say which of LMIs (12) and (23) is more feasible.

Remark 2: In case neither LMIs (12) nor (23) is feasible, it is not longer to take C_2 as a matrix variable in the LMIs, *i.e.*, we have to provide a prescribed matrix, for example an identity matrix, so that (17) turns out to be an LMI. In this case, therefore, either LMIs (12) or (23) are replaced by

$$\begin{aligned}&A_{11i} Q + Q A_{11i}^T + M^T C_2^{-1} A_{12i}^T + A_{12i} C_2^{-1} M < 0, \\ &\qquad\qquad i = 1, 2, \cdots r. \end{aligned} \tag{24}$$

B. Control Law

After designing the sliding surface so that the reduced-order sliding mode dynamics has the desired response, the next step of the SMC design procedure is to design a switching feedback control law such that the reachability of the specified sliding surface (10) is ensured.

Theorem 2: Consider the T-S fuzzy model (1) subject to the assumptions A1 and A2 provided in section II. Let us suppose that the LMIs (12), which are associated with the T-S fuzzy model by (4), are feasible and that the sliding surface is given by (10), where C_1 is given by (13) and C_2 is a solution of the LMIs. Then, the all signals involved in the closed-loop system (1) with the following control law are uniformly ultimately bounded.

$$\begin{aligned} u(t) &= -\sum_{i=1}^{r} \alpha_i \left\{ (C_2B_2)^{-1} \psi_i(t) \bar{C}\bar{A}_i z(t) + \phi_i(t) \right\} \\ &\quad - \frac{(C_2B_2)^{-1}}{\lambda_{\min}} \mu \ s(t), \end{aligned} \tag{25}$$

where $\mu > 0$, $\lambda_{\min} = \min\{\lambda(G_1), \lambda(G_2), \cdots, \lambda(G_r)\}$,

$$\psi_i(t) = \begin{cases} \frac{1}{\lambda_{\min}}, & s(t)^T \bar{C}\bar{A}_i z(t) \geq 0; \\ \frac{1}{\lambda_{\max}}, & \text{otherwise}, \end{cases} \tag{26}$$

$$\phi_i(t) = \begin{cases} \frac{\mathrm{sgn}(B_2^T C_2^T s(t))}{\lambda_{\min}} \hat{\rho}_i(t) ||G_i||, & \hat{\rho}_i(t) \geq 0; \\ \frac{\mathrm{sgn}(B_2^T C_2^T s(t))}{\lambda_{\max}} \hat{\rho}_i(t) ||G_i||, & \text{otherwise}, \end{cases} \tag{27}$$

$$\hat{\rho}_i(t) = \hat{c}_i(t) + \hat{k}_i(t) ||z(t)||, \tag{28}$$

$\lambda_{\max} = \max\{\lambda(G_1), \lambda(G_2), \cdots, \lambda(G_r)\}$, and adaptive laws are

$$\dot{\hat{c}}_i(t) = \alpha_i \gamma_{1i} \left(-\epsilon_1 \hat{c}_i(t) + ||G_i|| ||B_2^T C_2^T s(t)|| \right), \tag{29}$$

$$\dot{\hat{k}}_i(t) = \alpha_i \gamma_{2i} \left(-\epsilon_2 \hat{k}_i(t) + ||G_i|| ||B_2^T C_2^T s(t)|| ||z(t)|| \right), \tag{30}$$

where $\gamma_{1i}, \gamma_{2i}, \epsilon_1$, and ϵ_2 are positive design parameters.

Proof: From (5) and (10), we have

$$\dot{s} = \sum_{i=1}^{r} \alpha_i \left(\bar{C}\bar{A}_i z + C_2B_2G_i \left(u + \mathcal{U}_i \right) \right). \tag{31}$$

Let us define a Lyapunov function candidate as follows.

$$V(t) = \frac{1}{2} s(t)^T s(t) + \frac{1}{2} \sum_{i=1}^{r} \left\{ \gamma_{1i}^{-1} \tilde{c}_i^2(t) + \gamma_{2i}^{-1} \tilde{k}_i^2(t) \right\}, \tag{32}$$

where $\tilde{c}_i(t) = c_i^* - \hat{c}_i(t), \tilde{k}_i(t) = k_i^* - \hat{k}_i(t)$.
Using (31), the time derivative of V on any trajectory of the closed-loop system is
