$$\mu_{\tilde{B}^l}(y) = \mu_{\tilde{G}^l}(y) \sqcap \left[\sqcap_{i=1}^n \mu_{\tilde{F}_i^l}(x_i') \right]. \tag{3}$$

where the firing set $\sqcap_{i=1}^n \mu_{\tilde{F}_i^l}(x_i') \equiv F^l(\boldsymbol{x}')$ is an interval type-1 set, i.e.,

$$F^l(\boldsymbol{x}') = \left[\underline{f}^l(\boldsymbol{x}'), \overline{f}^l(\boldsymbol{x}') \right] \tag{4}$$

$$\underline{f}^l(\boldsymbol{x}') = \underline{\mu}_{\tilde{F}_1^l}(x_1') \bigstar \cdots \bigstar \underline{\mu}_{\tilde{F}_1^n}(x_n') \tag{5}$$

$$\overline{f}^l(\boldsymbol{x}') = \overline{\mu}_{\tilde{F}_1^l}(x_1') \bigstar \cdots \bigstar \overline{\mu}_{\tilde{F}_1^n}(x_n'). \tag{6}$$

Here $\underline{\mu}_{\tilde{F}_i^l}(x_i')$ is the lower membership grade of $\tilde{F}_i^l$, whereas $\overline{\mu}_{\tilde{F}_i^l}(x_i')$ is the upper membership grade of $\tilde{F}_i^l$, symbol $\bigstar$ denotes the t-norm, which corresponds to the conjunction "and" in (2). The fired output consequent set, $\mu_{\tilde{B}^l}(y)$, for the l th rule is the IT2 fuzzy set

$$\mu_{\tilde{B}^l}(y) = \int_{b^l \in \left[\underline{f}^l \bigstar \underline{\mu}_{\tilde{G}^l}(y), \overline{f}^l \bigstar \overline{\mu}_{\tilde{G}^l}(y) \right]} 1/b^l \tag{7}$$

where $\underline{\mu}_{\tilde{G}^l}$ and $\overline{\mu}_{\tilde{G}^l}$ are the lower and upper membership grades of consequent IT2 fuzzy set, $\tilde{G}^l$.

4) Type-Reduction and Defuzzification: The outputs of the inference engine are IT2 fuzzy sets which need to be type-reduced and then defuzzified to produce a crisp output. Assume maximum t-conorm, product t-norm, product implication, and center of sets type reduction are used. Then in the type-reduction, the type-reduced set is an interval type-1 fuzzy set $[y_l', y_r']$. The outputs y_l' and y_r' can be computed using the Karnik-Mendel iterative procedure. In this procedure, assume singleton consequent sets are used, the consequent parameters are reordered in ascending order. Let $\mathbf{y} = (y^1, \ldots, y^M)^{\mathrm{T}}$ denote the original rule-ordered consequent values, and let $\hat{\mathbf{y}} = (\hat{y}^1, \ldots, \hat{y}^M)^{\mathrm{T}}$ denote the reordered sequences, where $\hat{y}^1 \leq \hat{y}^2 \leq \ldots \leq \hat{y}^M$. The relationship between $\mathbf{y}$ and $\hat{\mathbf{y}}$ is

$$\hat{\mathbf{y}} = \mathbf{Q}\mathbf{y} \tag{8}$$

where $\mathbf{Q}$ is $M \times M$ permutation matrix with elementary vectors as columns, and these vectors are arranged to move elements in $\mathbf{y}$ to new locations in ascending order in the transformed vector $\hat{\mathbf{y}}$. The original rule firing strength orders $\underline{\mathbf{f}} = (\underline{f}^1, \underline{f}^2, \ldots, \underline{f}^M)^{\mathrm{T}}$ and $\overline{\mathbf{f}} = (\overline{f}^1, \overline{f}^2, \ldots, \overline{f}^M)^{\mathrm{T}}$ are reordered accordingly. And the new orders for $\underline{\mathbf{f}}$ and $\overline{\mathbf{f}}$ are $\mathbf{Q}\underline{\mathbf{f}}$ and $\mathbf{Q}\overline{\mathbf{f}}$ respectively. According to [23], [24], the output y_l' can be computed as

$$\begin{aligned} y_l' =& \frac{\sum_{i=1}^{L} (\mathbf{Q}\overline{\mathbf{f}})_i \hat{y}^i + \sum_{i=L+1}^{M} (\mathbf{Q}\underline{\mathbf{f}})_i \hat{y}^i}{\sum_{i=1}^{L} (\mathbf{Q}\overline{\mathbf{f}})_i + \sum_{i=L+1}^{M} (\mathbf{Q}\underline{\mathbf{f}})_i} \\ =& \frac{\overline{\mathbf{f}}^{\mathrm{T}} \mathbf{Q}^{\mathrm{T}} \mathbf{E}_1^{\mathrm{T}} \mathbf{E}_1 \mathbf{Q}\mathbf{y} + \underline{\mathbf{f}}^{\mathrm{T}} \mathbf{Q}^{\mathrm{T}} \mathbf{E}_2^{\mathrm{T}} \mathbf{E}_2 \mathbf{Q}\mathbf{y}}{\mathbf{p}_l^{\mathrm{T}} \mathbf{Q}\overline{\mathbf{f}} + \mathbf{g}_l^{\mathrm{T}} \mathbf{Q}\underline{\mathbf{f}}} \end{aligned} \tag{9}$$

where L and R denote the left and right crossover points respectively,

$$\begin{aligned} \mathbf{p}_l &= (\underbrace{1, 1, \ldots, 1}_{L}, 0, \ldots, 0)^{\mathrm{T}} \in R^{M \times 1} \\ \mathbf{g}_l &= (0, \ldots, 0, \underbrace{1, 1, \ldots, 1}_{M-L})^{\mathrm{T}} \in R^{M \times 1} \\ \mathbf{E}_1 &= (\mathbf{e}_1, \mathbf{e}_2, \ldots, \mathbf{e}_L, \mathbf{0}, \ldots, \mathbf{0})^{\mathrm{T}} \in R^{L \times M} \\ \mathbf{E}_2 &= (\mathbf{0}, \ldots, \mathbf{0}, \boldsymbol{\varepsilon}_1, \boldsymbol{\varepsilon}_2, \ldots, \boldsymbol{\varepsilon}_{M-L})^{\mathrm{T}} \in R^{(M-L) \times M} \end{aligned}$$

and where $\mathbf{e}_i \in R^L$ and $\boldsymbol{\varepsilon}_i \in R^{M-L}$ are elementary vectors. Similarly, the output y'_r can be expressed as

$$\begin{aligned} y'_r =& \frac{\sum_{i=1}^{R}(\mathbf{Q}\underline{\mathbf{f}})_i \hat{y}^i + \sum_{i=R+1}^{M}(\mathbf{Q}\overline{\mathbf{f}})_i \hat{y}^i}{\sum_{i=1}^{R}(\mathbf{Q}\underline{\mathbf{f}})_i + \sum_{i=R+1}^{M}(\mathbf{Q}\overline{\mathbf{f}})_i} \\ =& \frac{\underline{\mathbf{f}}^{\mathrm{T}}\mathbf{Q}^{\mathrm{T}}\mathbf{E}_3^{\mathrm{T}}\mathbf{E}_3\mathbf{Q}\mathbf{y} + \overline{\mathbf{f}}^{\mathrm{T}}\mathbf{Q}^{\mathrm{T}}\mathbf{E}_4^{\mathrm{T}}\mathbf{E}_4\mathbf{Q}\mathbf{y}}{\mathbf{p}_r^{\mathrm{T}}\mathbf{Q}\underline{\mathbf{f}} + \mathbf{g}_r^{\mathrm{T}}\mathbf{Q}\overline{\mathbf{f}}} \end{aligned} \tag{10}$$

where

$$\begin{aligned} \mathbf{p}_r &= (\underbrace{1,1,\ldots,1}_{R},0,\ldots,0)^{\mathrm{T}} \in R^{M\times 1} \\ \mathbf{g}_r &= (0,\ldots,0,\underbrace{1,1,\ldots,1}_{M-R})^{\mathrm{T}} \in R^{M\times 1} \\ \mathbf{E}_3 &= (\mathbf{e}_1,\mathbf{e}_2,\ldots,\mathbf{e}_R,\mathbf{0},\ldots,\mathbf{0})^{\mathrm{T}} \in R^{R\times M} \\ \mathbf{E}_4 &= (\mathbf{0},\ldots,\mathbf{0},\boldsymbol{\varepsilon}_1,\boldsymbol{\varepsilon}_2,\ldots,\boldsymbol{\varepsilon}_{M-R})^{\mathrm{T}} \in R^{(M-R)\times M} \end{aligned}$$

and where $\mathbf{e}_i \in R^R$ and $\boldsymbol{\varepsilon}_i \in R^{M-R}$ are elementary vectors. Finally, by computing the average of y'_l and y'_r, the interval set is defuzzified to generate the system output as

$$y' = \frac{y'_l + y'_r}{2}. \tag{11}$$

View $\boldsymbol{\theta} = \mathbf{y} = (y^1,\ldots,y^M)^{\mathrm{T}}$ as adjustable parameters, then (11) can be written as

$$y' = \boldsymbol{\phi}^{\mathrm{T}}\boldsymbol{\theta} \tag{12}$$

where

$$\begin{aligned} \boldsymbol{\phi}^{\mathrm{T}} =& \frac{\overline{\mathbf{f}}^{\mathrm{T}}\mathbf{Q}^{\mathrm{T}}\mathbf{E}_1^{\mathrm{T}}\mathbf{E}_1\mathbf{Q} + \underline{\mathbf{f}}^{\mathrm{T}}\mathbf{Q}^{\mathrm{T}}\mathbf{E}_2^{\mathrm{T}}\mathbf{E}_2\mathbf{Q}}{2(\mathbf{p}_l^{\mathrm{T}}\mathbf{Q}\overline{\mathbf{f}} + \mathbf{g}_l^{\mathrm{T}}\mathbf{Q}\underline{\mathbf{f}})} \\ &+ \frac{\underline{\mathbf{f}}^{\mathrm{T}}\mathbf{Q}^{\mathrm{T}}\mathbf{E}_3^{\mathrm{T}}\mathbf{E}_3\mathbf{Q} + \overline{\mathbf{f}}^{\mathrm{T}}\mathbf{Q}^{\mathrm{T}}\mathbf{E}_4^{\mathrm{T}}\mathbf{E}_4\mathbf{Q}}{2(\mathbf{p}_r^{\mathrm{T}}\mathbf{Q}\underline{\mathbf{f}} + \mathbf{g}_r^{\mathrm{T}}\mathbf{Q}\overline{\mathbf{f}})} \end{aligned} \tag{13}$$

is a regressive vector. Now as shown in (12), the singleton IT2 FLS is expressed as linear in the parameters.

III. Modeling of Marine Vessels

The model of positioned vessels may be divided into two groups [25], namely process plant model and control plant model. The process plant model is used for numerical analysis of the performance and stability of the closed-loop system by simulating the real plant dynamics as closely as possible. It includes process disturbance, sensor outputs and control inputs. The control plant model, which is used for controller design and theoretical stability analysis (e.g., in the sense of Lyapunov), is a simplified form of the process plant model.

A. Process Plant Model

1) Kinematics: In DP, the motions and state variables of the system are conventionally defined and measured with respect to two reference frames as shown in Fig. 2, namely earth-fixed frame and body-fixed frame. The earth-fixed frame, denoted as $\mathrm{X_E Y_E Z_E}$, is used for global guidance and navigation. The body-fixed frame, denoted as XYZ, is fixed to the vessel with its origin located at the vessel's center of gravity. Let

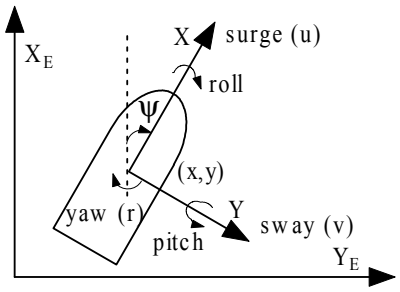

Fig. 2. 2D Earth-fixed and body-fixed reference frames.

$\boldsymbol{\eta}' = [x, y, z, \phi, \theta, \psi]^{\mathrm{T}}$ be the vector denoting the position and orientation of the vessel relative to an earth-fixed frame, and let $\boldsymbol{\nu}' = [u, v, w, p, q, r]^{\mathrm{T}}$ represent the translation and rotation velocities of the vessel decomposed in a body-fixed frame. These six modes are referred to as the surge, sway, heave, roll, pitch, yaw modes of a vessel. Then, the transformation between the earth-fixed and body-fixed velocity vectors is

$$\dot{\boldsymbol{\eta}}' = \mathbf{J}'(\boldsymbol{\eta}')\boldsymbol{\nu}'. \tag{14}$$

where $\mathbf{J}'(\boldsymbol{\eta}')$ is a state dependent transformation matrix, whose definition can be found in [3].

2) Dynamics: The six degrees of freedom (DOF) model formulation is based on [6], [7]. The equation of motion, which is in body-fixed frame, for the nonlinear low frequency model of a floating vessel traveling in low speed is given by

$$\mathbf{M}'\dot{\boldsymbol{\nu}}' + \bar{\mathbf{B}}'\boldsymbol{\nu}'_r + \mathbf{G}'\boldsymbol{\eta}' + \boldsymbol{\mu}' = \boldsymbol{\tau}' + \boldsymbol{\tau}'_{\text{CFD}} + \boldsymbol{\tau}'_{\text{wave}} \tag{15}$$

where $\mathbf{M}' = \mathbf{M}'_{RB} + \bar{\mathbf{A}}' \in R^{6\times 6}$ is the sum of the system inertia matrix and added mass matrix, $\bar{\mathbf{B}}' \in R^{6\times 6}$ is the potential damping matrix, $\mathbf{G}' \in R^{6\times 6}$ is the restoring matrix, $\boldsymbol{\mu}' \in R^6$ is computed using a state space model to represent the fluid memory effect,

$$\dot{\boldsymbol{\chi}} = \mathbf{A}_r\boldsymbol{\chi} + \mathbf{B}_r\boldsymbol{\nu}'_r \tag{16}$$

$$\boldsymbol{\mu}' = \mathbf{C}_r\boldsymbol{\chi} + \mathbf{D}_r\boldsymbol{\nu}'_r \tag{17}$$

and where $(\mathbf{A}_r, \mathbf{B}_r, \mathbf{C}_r, \mathbf{D}_r)$ are constant matrices of appropriate dimensions. $\boldsymbol{\tau}' \in R^6$ is control force vector produced by thruster system, $\boldsymbol{\tau}'_{\text{CFD}} \in R^6$ is cross-flow drag and surge resistance vector, $\boldsymbol{\tau}'_{\text{wave}} \in R^6$ is wave load vector, which is computed according to Response Amplitude Operator tables, and $\boldsymbol{\nu}'_r = \boldsymbol{\nu}' - \boldsymbol{\nu}'_c \in R^6$ is the relative velocity vector between vessel velocity vector $\boldsymbol{\nu}'$ and sea current velocity vector $\boldsymbol{\nu}'_c$. All the detailed definition and computation of the above matrices and vectors can be found in [3], [6] and references therein.

B. Control Plant Model

To facilitate the controller design and analytical stability analysis, the process plant model presented in previous subsection is simplified based on the following assumptions.

Assumption 1: The motions along heave, roll, and pitch directions are ignored. In fact, this is an appropriate assumption since a conventional ship is metacentric stable which implies that there exist restoring force and moments along those

directions. As a result of this assumption, the dimension of the restoring matrix $\mathbf{G}' \in R^{6\times 6}$ in (15) is reduced to yield $\mathbf{G} \in R^{3\times 3} = \mathbf{0}$.

Assumption 2: The state variables, i.e. displacements and velocities along surge, sway, and yaw directions, are measured by on-board devices such as GPS, gyro system, and accelerometers. This is a acceptable assumption due to the development of integration system of inertial sensors and satellite navigation system.

Assumption 3: The effect of sea current is ignored. This assumption is for the convenience of theoretical analysis.

Assumption 4: The various kinds of time-varying hydrodynamic disturbances, i.e. $\boldsymbol{\mu}'$, $\boldsymbol{\tau}'_{\text{CFD}}$, and $\boldsymbol{\tau}'_{\text{wave}}$ in (15), could be estimated by singleton IT2 FLSs in the form of

$$\begin{aligned} \boldsymbol{\tau}'_d &= -\Phi'(\boldsymbol{\nu}')\Theta' \\ &= \boldsymbol{\tau}'_{\text{CFD}} + \boldsymbol{\tau}'_{\text{wave}} - \boldsymbol{\mu}' \end{aligned} \tag{18}$$

where

$$\Theta' = (\boldsymbol{\theta}_1'^{\mathrm{T}}, \boldsymbol{\theta}_2'^{\mathrm{T}}, \ldots, \boldsymbol{\theta}_6'^{\mathrm{T}})^{\mathrm{T}} \in R^{6M\times 1} \tag{19}$$

is a weighting vector and

$$\Phi'(\boldsymbol{\nu}') = \text{diag}[\boldsymbol{\phi}_1'^{\mathrm{T}}, \boldsymbol{\phi}_2'^{\mathrm{T}}, \ldots, \boldsymbol{\phi}_6'^{\mathrm{T}}] \in R^{6\times 6M} \tag{20}$$

is a regressive matrix, M is the number of rules for each sub-FLS. So far, this assumption is not well established, since there is still a lack of rigorous proof that singleton IT2 FLS is universal approximator, but the assumption will be checked by subsequent simulations. The situation is different for type-1 case, as there has been a lot of works showing that type-1 FLS is universal approximator [11]–[14].

Application of Assumptions 1-4 to (14) and (15) yields the following control plant model for DP.

$$\dot{\boldsymbol{\eta}} = \mathbf{J}(\boldsymbol{\eta})\boldsymbol{\nu} \tag{21}$$

$$\mathbf{M}\dot{\boldsymbol{\nu}} + \bar{\mathbf{B}}\boldsymbol{\nu} = \boldsymbol{\tau} - \Phi(\boldsymbol{\nu})\Theta \tag{22}$$

where $\boldsymbol{\eta} = [x, y, \psi]^{\mathrm{T}}$ and $\boldsymbol{\nu} = [u, v, r]^{\mathrm{T}}$ are the vectors representing displacement and velocity along surge, sway, and yaw, $\mathbf{J}(\boldsymbol{\eta}) \in R^{3\times 3}$ is the rotation matrix, note that $\mathbf{J}\mathbf{J}^{\mathrm{T}} = \mathbf{I}$ ($\mathbf{I}$ is the identity matrix), $\mathbf{M} \in R^{3\times 3}$ is the system inertia matrix including added mass, $\bar{\mathbf{B}} \in R^{3\times 3}$ is the potential damping matrix,

$$\Theta = (\boldsymbol{\theta}_1^{\mathrm{T}}, \boldsymbol{\theta}_2^{\mathrm{T}}, \boldsymbol{\theta}_3^{\mathrm{T}})^{\mathrm{T}} \in R^{3M\times 1} \tag{23}$$

is the weighting vector and

$$\Phi(\boldsymbol{\nu}) = \text{diag}[\boldsymbol{\phi}_1^{\mathrm{T}}(\boldsymbol{\nu}), \boldsymbol{\phi}_2^{\mathrm{T}}(\boldsymbol{\nu}), \boldsymbol{\phi}_3^{\mathrm{T}}(\boldsymbol{\nu})] \in R^{3\times 3M} \tag{24}$$

is the regressive matrix. Thus, here three sub-FLSs are used to estimate the hydrodynamic disturbances.

IV. Adaptive Fuzzy Logic Controller Design

The control objective for DP is to position and orientate the vessel to a fixed placement via attached thruster system, which actually is a regulation problem. In this section, an indirect adaptive fuzzy logic controller for DP is proposed, the regulation error is proved to globally asymptotically converge to zero. Rigorous analysis shows the resultant closed-loop system is passive.

A. Control and Adaptive Law

The proposed control and adaptive law for plant (21), (22) are as follows.

$$\boldsymbol{\tau} = -\lambda_1\boldsymbol{\nu} - \lambda_2\mathbf{J}^{\mathrm{T}}(\boldsymbol{\eta})\boldsymbol{e} + \Phi(\boldsymbol{\nu})\hat{\Theta} \tag{25}$$

$$\dot{\hat{\Theta}} = \lambda_3\Phi^{\mathrm{T}}(\boldsymbol{\nu})(\lambda_4\boldsymbol{\nu} + \frac{2\mathbf{J}^{\mathrm{T}}(\boldsymbol{\eta})\boldsymbol{e}}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}}) \tag{26}$$

where $\boldsymbol{e} = \boldsymbol{\eta} - \boldsymbol{\eta}_d \in R^3$ is the control error vector between vessel displacement vector $\boldsymbol{\eta}$ and the desired vessel placement vector $\boldsymbol{\eta}_d$, $\tilde{\Theta} = \Theta - \hat{\Theta} \in R^{3M}$ is the error vector between true Θ in (22) and adapted $\hat{\Theta}$, and λ_i $(i = 1, \ldots, 4)$ are positive constant.

Application of control and adaptive law (25), (26) to the plant (21), (22) yields the resultant closed-loop system

$$\mathbf{M}\dot{\boldsymbol{\nu}} + \bar{\mathbf{B}}\boldsymbol{\nu} = -\lambda_1\boldsymbol{\nu} - \lambda_2\mathbf{J}^{\mathrm{T}}(\boldsymbol{\eta})\boldsymbol{e} - \Phi(\boldsymbol{\nu})\tilde{\Theta} \tag{27}$$

$$\dot{\tilde{\Theta}} = \lambda_3\Phi^{\mathrm{T}}(\boldsymbol{\nu})(\lambda_4\boldsymbol{\nu} + \frac{2\mathbf{J}^{\mathrm{T}}(\boldsymbol{\eta})\boldsymbol{e}}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}}) \tag{28}$$

$$\dot{\boldsymbol{e}} = \dot{\boldsymbol{\eta}} = \mathbf{J}(\boldsymbol{\eta})\boldsymbol{\nu}. \tag{29}$$

B. Stability Analysis

Theorem 1: The states $(\boldsymbol{e}, \boldsymbol{\nu})$ of the closed-loop system (27)-(29) globally asymptotically converge to $(\mathbf{0}, \mathbf{0})$ if

$$\lambda_4 > \max\{\frac{2\lambda_M}{\sqrt{\lambda_2\lambda_m}}, \frac{(\lambda_d + 2\lambda_1)^2 + 16\lambda_2\lambda_M}{4\lambda_2\lambda_d + 8\lambda_1\lambda_2}\}, \tag{30}$$

where λ_m and λ_M are the minimum and maximum eigenvalue of matrix $\mathbf{M}$ respectively, and λ_d is the minimum eigenvalue of matrix $\bar{\mathbf{B}} + \bar{\mathbf{B}}^{\mathrm{T}}$.

Proof: Consider the following Lyapunov function candidate.

$$V = \frac{\lambda_2\lambda_4}{2}\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e} + \frac{\lambda_4}{2}\boldsymbol{\nu}^{\mathrm{T}}\mathbf{M}\boldsymbol{\nu} + \frac{2\boldsymbol{\nu}^{\mathrm{T}}\mathbf{M}\mathbf{J}^{\mathrm{T}}\boldsymbol{e}}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}} + \frac{1}{2\lambda_3}\tilde{\Theta}^{\mathrm{T}}\tilde{\Theta} \tag{31}$$

To make sure the Lyapunov function candidate V positive definite, due to the fact $\|\mathbf{J}\| = 1$ and $\lambda_m\mathbf{I} \le \mathbf{M} \le \lambda_M\mathbf{I}$, we have

$$\begin{aligned} V_1 =& \frac{\lambda_2\lambda_4}{2}\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e} + \frac{\lambda_4}{2}\boldsymbol{\nu}^{\mathrm{T}}\mathbf{M}\boldsymbol{\nu} + \frac{2\boldsymbol{\nu}^{\mathrm{T}}\mathbf{M}\mathbf{J}^{\mathrm{T}}\boldsymbol{e}}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}} \\ \ge& \frac{\lambda_2\lambda_4}{2}\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e} + \frac{\lambda_4\lambda_m}{2}\boldsymbol{\nu}^{\mathrm{T}}\boldsymbol{\nu} - \frac{2\lambda_M}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}}\boldsymbol{\nu}^{\mathrm{T}}\boldsymbol{e}, \end{aligned}$$

If $4\lambda_M^2 - \lambda_4^2\lambda_2\lambda_m < 0$ i.e., $\lambda_4 > 2\lambda_M/\sqrt{\lambda_2\lambda_m}$, then V_1 is positive definite, additionally,

$$V_2 = \frac{1}{2\lambda_3}\tilde{\Theta}^{\mathrm{T}}\tilde{\Theta}$$

is positive definite, thus $V = V_1 + V_2$ is positive definite.

Differentiation of V along the trajectory of the closed-loop system (27)-(29) yields

$$\begin{aligned} \dot{V} =& -\lambda_4\boldsymbol{\nu}^{\mathrm{T}}\bar{\mathbf{B}}\boldsymbol{\nu} - \lambda_1\lambda_4\boldsymbol{\nu}^{\mathrm{T}}\boldsymbol{\nu} + \frac{2\boldsymbol{\nu}^{\mathrm{T}}\mathbf{M}\boldsymbol{\nu}}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}} - \frac{2\mathbf{e}^{\mathrm{T}}\mathbf{J}\bar{\mathbf{B}}\boldsymbol{\nu}}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}} \\ & - \frac{2\lambda_1\mathbf{e}^{\mathrm{T}}\mathbf{J}\boldsymbol{\nu}}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}} - \frac{2\lambda_2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}} - \frac{8\boldsymbol{e}^{\mathrm{T}}\boldsymbol{\nu}\boldsymbol{\nu}^{\mathrm{T}}\mathbf{M}\boldsymbol{e}}{(1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e})^2}. \end{aligned}$$

Applying $\lambda_d\mathbf{I} \le \bar{\mathbf{B}} + \bar{\mathbf{B}}^{\mathrm{T}}$, we have

$$\dot{V} \le -(\frac{\lambda_4\lambda_d}{2} + \lambda_1\lambda_4 - 2\lambda_M)\boldsymbol{\nu}^{\mathrm{T}}\boldsymbol{\nu} - (\lambda_d + 2\lambda_1)\boldsymbol{e}^{\mathrm{T}}\boldsymbol{\nu} - 2\lambda_2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e},$$

If $(\lambda_d + 2\lambda_1)^2 - 8\lambda_2((\lambda_4\lambda_d)/2 + \lambda_1\lambda_4 - 2\lambda_M) < 0$ i.e.,

$$\lambda_4 > \frac{(\lambda_d + 2\lambda_1)^2 + 16\lambda_2\lambda_M}{4\lambda_2\lambda_d + 8\lambda_1\lambda_2}$$

then $\dot{V} \leq 0$, which means the derivative of the Lyapunov function candidate is semi-negative definite. Moreover, the largest invariant set contained in the set $\dot{V} \equiv 0$ is contained in the set $(\boldsymbol{e}, \boldsymbol{\nu}) = (\mathbf{0}, \mathbf{0})$.

Now, according to Krasovskii-La Salle Theorem, we may conclude the point $(\boldsymbol{e}, \boldsymbol{\nu})$ globally asymptotically converges to $(\mathbf{0}, \mathbf{0})$, and $\dot{\tilde{\Theta}} = 0$, which means $\hat{\Theta}$ is bounded, if

$$\lambda_4 > \max\{\frac{2\lambda_M}{\sqrt{\lambda_2\lambda_m}}, \frac{(\lambda_d + 2\lambda_1)^2 + 16\lambda_2\lambda_M}{4\lambda_2\lambda_d + 8\lambda_1\lambda_2}\}.$$

■

Remark 1: For plant (21), (22), an intuitive adaptive law may be

$$\dot{\tilde{\Theta}} = \lambda_5 \Phi^{\mathrm{T}}(\boldsymbol{\nu})\boldsymbol{\nu}, \tag{32}$$

but rigorous analysis indicates that the regulation error using such adaptive law cannot be asymptotically convergence.

Remark 2: Here, the theorem is developed for the case where the gains λ_i $(i = 1, \ldots, 4)$ are scalar, the case where the gains are matrices can be easily extended to in a similar approach.

C. Passivity Interpretation

Passivity theory gives a framework for the design and analysis of control systems using an input-output description according to energy-related considerations. And the input-output description further allows for a modular approach to control systems design and analysis [26]. As illustrated in Fig. 3, the closed-loop system (27)-(29) can be interpreted as the negative feedback interconnection of two subsystems with respective inputs u_1, u_2 and outputs y_1 and y_2, with $y_1 = u_2$ and $y_2 = -u_1$, and the two subsystems as follows.

Subsystem 1:

$$\begin{cases} \mathbf{M}\dot{\boldsymbol{\nu}} + \bar{\mathbf{B}}\boldsymbol{\nu} = -\lambda_1\boldsymbol{\nu} - \lambda_2\mathbf{J}^{\mathrm{T}}(\boldsymbol{\eta})\boldsymbol{e} + u_1 \\ y_1 = \lambda_4\boldsymbol{\nu} + \frac{2\mathbf{J}^{\mathrm{T}}(\boldsymbol{\eta})\boldsymbol{e}}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}} \end{cases} \tag{33}$$

Subsystem 2:

$$\begin{cases} \dot{\tilde{\Theta}} = \lambda_3 \Phi^{\mathrm{T}}(\boldsymbol{\nu}) u_2 \\ y_2 = \Phi(\boldsymbol{\nu})\tilde{\Theta} \end{cases} \tag{34}$$

Theorem 2: The closed-loop system (27)-(29) is passive if (30) is satisfied.

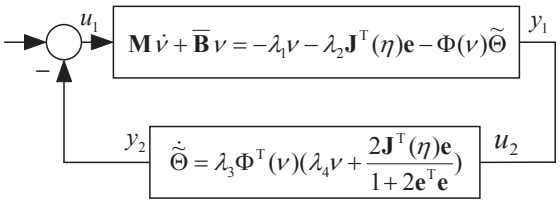

Fig. 3. Closed-loop equivalent representation.

Proof: For subsystem 1, its supply rate is

$$\begin{aligned} &\int_0^t u_1^{\mathrm{T}} y_1 ds \\ &= \int_0^t (\lambda_4\boldsymbol{\nu} + \frac{2\mathbf{J}^{\mathrm{T}}\boldsymbol{e}}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}})^{\mathrm{T}}(\mathbf{M}\dot{\boldsymbol{\nu}} + \bar{\mathbf{B}}\boldsymbol{\nu} + \lambda_1\boldsymbol{\nu} + \lambda_2\mathbf{J}^{\mathrm{T}}\boldsymbol{e})ds \\ &= \int_0^t [\lambda_2\lambda_4\boldsymbol{\nu}^{\mathrm{T}}\mathbf{J}^{\mathrm{T}}\boldsymbol{e} + \frac{d}{ds}(\frac{\lambda_4}{2}\boldsymbol{\nu}^{\mathrm{T}}\mathbf{M}\boldsymbol{\nu} + \frac{2\boldsymbol{\nu}^{\mathrm{T}}\mathbf{M}\mathbf{J}^{\mathrm{T}}\boldsymbol{e}}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}})]ds \\ &+ \int_0^t [\lambda_4\boldsymbol{\nu}^{\mathrm{T}}\bar{\mathbf{B}}\boldsymbol{\nu} + \lambda_1\lambda_4\boldsymbol{\nu}^{\mathrm{T}}\boldsymbol{\nu} - \frac{2\boldsymbol{\nu}^{\mathrm{T}}\mathbf{M}\boldsymbol{\nu}}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}} + \frac{2\mathbf{e}^{\mathrm{T}}\mathbf{J}\bar{\mathbf{B}}\boldsymbol{\nu}}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}} \\ &+ \frac{2\lambda_1\mathbf{e}^{\mathrm{T}}\mathbf{J}\boldsymbol{\nu}}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}} + \frac{2\lambda_2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}}{1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e}} + \frac{8\boldsymbol{e}^{\mathrm{T}}\boldsymbol{\nu}\boldsymbol{\nu}^{\mathrm{T}}\mathbf{M}\boldsymbol{e}}{(1+2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e})^2}]ds, \end{aligned}$$

if (30) is satisfied,

$$\int_0^t u_1^{\mathrm{T}} y_1 ds \geq V_1(t) - V_1(0),$$

which means the subsystem 1 is passive with supply rate $\int_0^t u_1^{\mathrm{T}} y_1 ds$ and storage function V_1, which has been defined during the proof for Theorem 1.

For subsystem 2 its supply rate is

$$\begin{aligned} \int_0^t u_2^{\mathrm{T}} y_2 ds &= \int_0^t \tilde{\Theta}^{\mathrm{T}}\Phi^{\mathrm{T}}(\boldsymbol{\nu}) u_2 ds \\ &= \int_0^t \tilde{\Theta}^{\mathrm{T}} \frac{1}{\lambda_3}\dot{\tilde{\Theta}} ds \\ &\geq V_2(t) - V_2(0) \end{aligned}$$

which means the subsystem 2 is passive with supply rate $\int_0^t u_2^{\mathrm{T}} y_2 ds$ and storage function V_2.

According to the fact that the negative feedback interconnection of two passive systems is passive, the closed-loop system (27)-(29) is passive. ■

V. Simulation Studies

The simulation studies are performed on the platform of Marine System Simulator developed in Norwegian University of Science and Technology [27]. The S-175 container ship is used as case study. The subsequent simulation results are obtained for following seas with the International Towing Tank Conference (ITTC) wave spectrum using significant wave height $H_s = 5$ m and peak frequency $\omega_0 = 0.56$ rad/s. The significant wave height H_s is used to classify the type of sea, $H_s = 5$ m corresponds to very rough sea with large waves. Even though ignored during Lyapunov analysis, the sea current is set with speed $V_c = 2$ m/s and direction $\beta_c = 30^\circ$

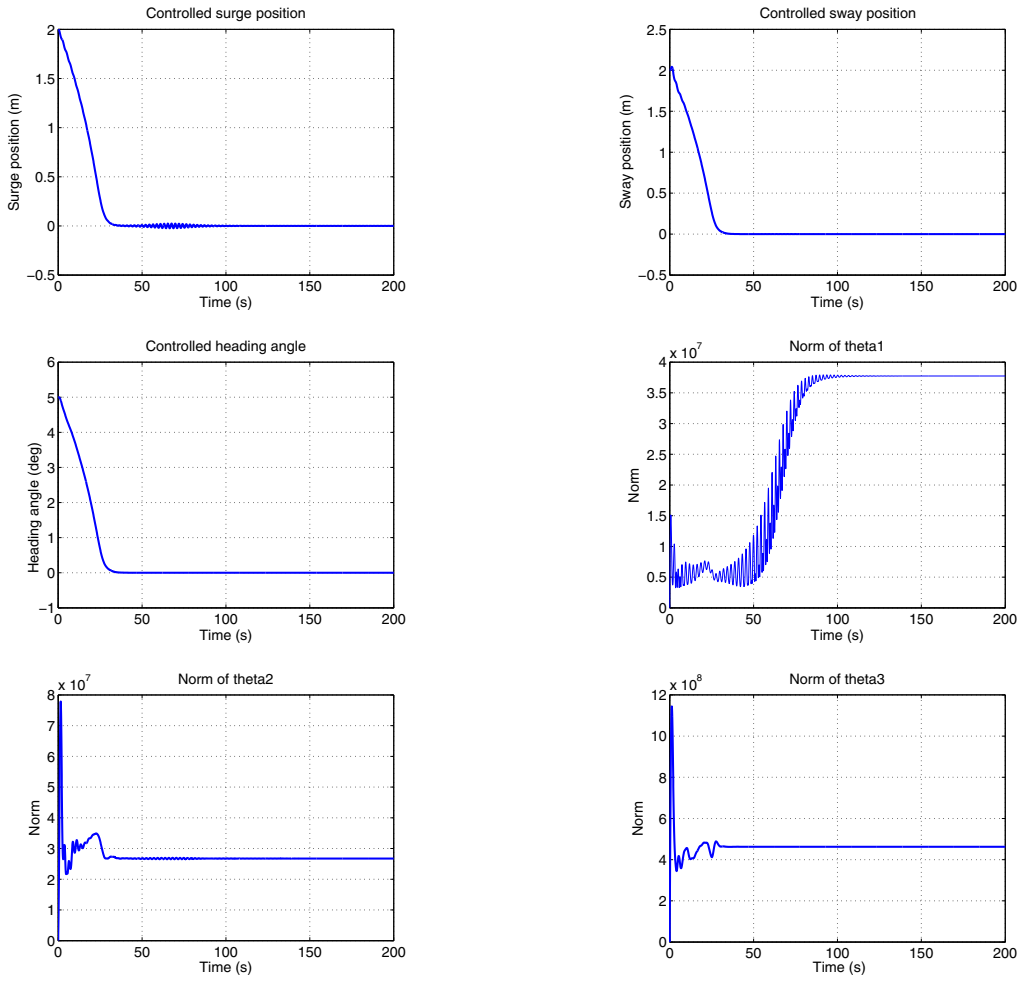

Fig. 4. Plots 1-3 show the controlled position and heading angle of the vessel. Plots 4-6 show the norms of the adapted weighting vectors.

in the following simulations. The control objective is set to regulate the vessel to state $[\boldsymbol{\eta}_d^{\mathrm{T}}, \boldsymbol{\nu}_d^{\mathrm{T}}] = [\mathbf{0}, \mathbf{0}]$ from initial state $[\boldsymbol{\eta}_0^{\mathrm{T}}, \boldsymbol{\nu}_0^{\mathrm{T}}] = [2, 2, 5^\circ, 0, 0, 0]$.

A. Closed-loop Performance

Although the controller (25), (26) is designed based on the control plant model (21), (22), it is tested with the process plant model (14), (15). As indicated in (12), (23), and (24), three singleton IT2 sub-FLSs are used to approximate the complex hydrodynamic disturbances. In each sub-system, each of the input domain is partitioned by three fuzzy membership functions labeled as **N**, **Z**, and **P**, thus there are 27 rules and 27 adjustable consequent parameters accordingly. The primary membership functions of the antecedent IT2 fuzzy sets are chosen to be Gaussian function with uncertain standard deviation, i.e.,

$$\mu_{\tilde{F}_i^j}(x_j) = \exp[-\frac{1}{2}(\frac{x_j - m_i}{\sigma})^2] \quad \sigma \in [\underline{\sigma}, \overline{\sigma}] \qquad (35)$$

where $i = 1, 2, 3$ is the index of three fuzzy membership functions for jth input and $j = 1, 2, 3$ is the index of three inputs. The inputs to each sub-system is scaled properly so that the means for the Gaussian functions are fixed at $m_1 = -1$, $m_2 = 0$, and $m_3 = 1$ for each input, and the standard deviation for all of the lower membership function is fixed at $\underline{\sigma} = 0.6$, whereas the one for all of the upper membership function is $\overline{\sigma} = 0.8$. Set $\lambda_1 = 4.3 \times 10^6$, $\lambda_2 = 4.3 \times 10^5$, $\lambda_3 = 5 \times 10^8$, and $\lambda_4 = 5$ in (25) and (26). The controlled position and heading angle of the vessel are shown in plot 1-3 of Fig. 4, from which it can be observed that the closed-loop system is stable, the control performance is satisfactory despite the time-varying hydrodynamic disturbances, and the sub-FLSs efficiently approximate the complex disturbances although universal approximation property for IT2 FLS has not been established yet. Plot 4-6 of Fig. 4 show the norms of the adapted weighting vectors $\|\hat{\boldsymbol{\theta}}_i\|$ $(i = 1, 2, 3)$, they verify the boundedness of $\hat{\boldsymbol{\Theta}}$. Note that the norm of weighting vector $\hat{\boldsymbol{\theta}}_1$ shows fluctuation during the simulation, it is because the disturbances along the surge direction fluctuate heavily at the start of the simulation.

B. Comparison with a PD Controller

Comparative study between the designed controller and a linear proportional derivative (PD) controller is presented. The

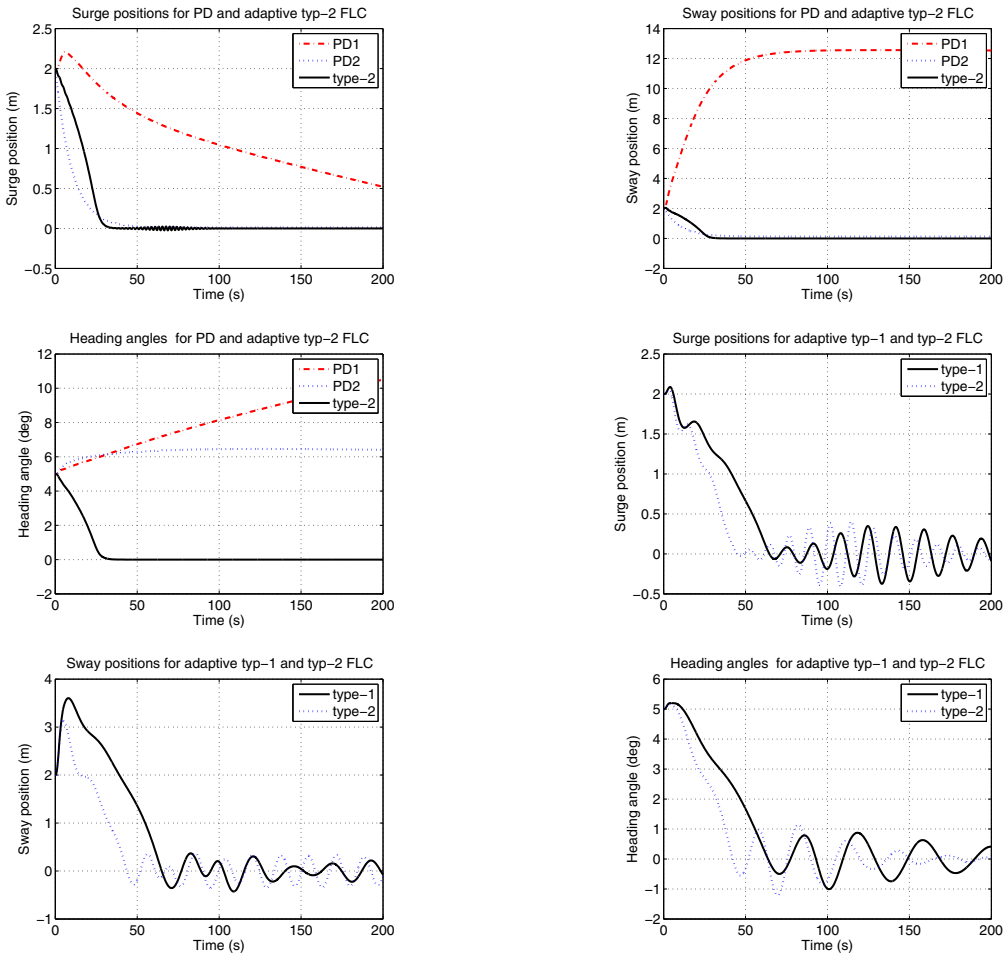

Fig. 5. Plots 1-3 show the positions and heading angles of the vessel for two PD controllers and the adaptive type-2 FLC. Plots 4-6 show the positions and heading angles of the vessel for the adaptive type-1 and type-2 FLC.

PD controller is in the form of

$$\boldsymbol{\tau} = -\lambda_5 \boldsymbol{\nu} - \lambda_6 \mathbf{J}^{\mathrm{T}}(\boldsymbol{\eta}) \boldsymbol{e}. \tag{36}$$

Two sets of control gains are implemented for the PD controller, $\lambda_5^1 = 4.3 \times 10^6$, $\lambda_6^1 = 4.3 \times 10^5$ and $\lambda_5^2 = 4.3 \times 10^8$, $\lambda_6^2 = 4.3 \times 10^7$, meanwhile the parameter settings for the adaptive type-2 FLC are kept same as the one in previous subsection. The results are shown in plot 1-3 of Fig. 5, from which it can be seen that with same proportion and derivative gains, the designed controller achieves satisfactory performance, whereas the PD controller is unstable. With its proportion and derivative gains increasing, the PD controller can be stable, but still with large steady state error due to disturbances. Besides, large control gains are not recommended in practice as they reduce robustness and cause large overshoots. Hence, the designed controller performs much better than the PD controller and has better disturbance rejection property.

C. Comparison with an Adaptive Type-1 FLC

Replace the components in (24) and correspondingly in (25) and (26) with fuzzy basis function vector [10], [11],

$$\boldsymbol{\phi}^{\mathrm{T}} = (\phi^1(\mathbf{x}), \ldots, \phi^M(\mathbf{x})) \tag{37}$$

where fuzzy basis function is defined as

$$\phi^l(\mathbf{x}) = \frac{\Pi_{i=1}^n \mu_{F_i^l}(x_i)}{\Sigma_{l=1}^M (\Pi_{i=1}^n \mu_{F_i^l}(x_i))}, \tag{38}$$

the controller (25), (26) becomes an adaptive type-1 FLC. In this subsection, the adaptive type-2 FLC is compared with such an adaptive type-1 FLC. For each sub-system in the adaptive type-2 FLC, the parameter settings are kept identical as the one in previous subsection, whereas for each sub-system in type-1 case, each of the input domain is partitioned by five fuzzy membership functions labeled as **NL**, **NS**, **Z**, **PS**, and **PL**, thus there are 125 rules and 125 adjustable consequent parameters accordingly in contrast to 27 rules and parameters for type-2 case. The membership functions of the antecedent sets for each input are chosen as Gaussian functions, i.e.,

$$\mu_{F_i^j}(x_j) = \exp[-\frac{1}{2}(\frac{x_j - m_i}{\sigma})^2]. \tag{39}$$

where $i = 1, \ldots, 5$ is the index of five fuzzy membership functions for jth input and $j = 1, 2, 3$ is the index of three inputs. While the means are set as $(m_1, \ldots, m_5) =$

$(-1, -0.5, 0, 0.5, 1)$, the standard deviations for all the Gaussian functions are fixed at $\sigma = 0.4$. Set $\lambda_1 = 4.3 \times 10^6$, $\lambda_2 = 4.3 \times 10^5$, $\lambda_3 = 1.5 \times 10^7$, and $\lambda_4 = 5$ in (25) and (26) for both adaptive type-1 and type-2 FLCs, the resultant positions and heading angles of the vessel are shown in plot 4-6 of Fig. 5, from which it can be observed that the rising and settling time for adaptive type-2 FLC is shorter than that for type-1 case, even though type-1 case uses more rules. To quantify the performance differences between adaptive type-1 and type-2 FLCs, the integral of time-weighted absolute errors (ITAE) for both cases in the following form are calculated.

$$P_x = \int_0^T t|x|dt \tag{40}$$

$$P_y = \int_0^T t|y|dt \tag{41}$$

$$P_\psi = \int_0^T t|\psi|dt \tag{42}$$

where T is the total simulation time. The results are shown in Table I, and the ITAE for the type-2 case are smaller than those for type-1 case along all the three degrees of freedom. Regarding the computational burden, type-reduction for type-2 case does take some time, but the time is very little as only a few rules are fired simultaneously and it has been proved Karnik-Mendel algorithm is super-exponentially convergent [28]. In addition, the real-time application of the type-2 FLS has been reported [29]. Thus, type-reduction should not be an issue that causes any stability problem. In a word, it seems that the type-2 FLS has better approximation property with less rules than its type-1 counterpart, and rigorous theoretical examination is needed.

TABLE I
ITAE FOR ADAPTIVE TYPE-1 AND TYPE-2 FLCS

ITAE	P_x	P_y	P_ψ
Type-1	4604	5960	210
Type-2	3252	4951	121

VI. CONCLUSIONS

In this paper, an indirect adaptive type-2 FLC has been designed for DP vessels with attached thrusters in the presence of complex hydrodynamic disturbances. It has been proved that the regulation error under the proposed control globally asymptotically converges to zero and the closed-loop system under the proposed control is passive. Simulation results have demonstrated that the adaptive type-2 FLC is effective and robust. When compared against a PD controller, the proposed controller has better control performance and disturbance rejection property. Comparison with its type-1 counterpart suggests type-2 FLS has better approximation property, but rigorous theoretical examination is necessary.

Abstract— **This paper proposes a new type fuzzy neural systems, denotes IT2RFNS-A (interval type-2 recurrent fuzzy neural system with asymmetric membership function), for nonlinear systems control. To enhance the performance and approximation ability, the TSK-type consequent part is adopted for IT2RFNS-A. The gradient information of the IT2RFNS-A is not easy to obtain due to the asymmetric membership functions and interval valued sets. The corresponding stable learning is derived by simultaneous perturbation stochastic approximation (SPSA) algorithm which guarantees the convergence and stability of the closed-loop systems. Simulation and comparison on the control of Chua's chaotic circuit is done to show the feasibility and effectiveness of proposed method.**

Keywords- Nonlinear systems, fuzzy neural system, type-2 fuzzy system, Lyapunov theorem, SPSA algorithm

I. INTRODUCTION

In past few decades, the fuzzy neural network (FNN) which provides the advantages of both neural network and fuzzy system is successfully applied to nonlinear system identification and control [1-4]. In the FNN, the symmetric and fixed membership functions are commonly adopted to simplify the design procedure. However, a large number of fuzzy rules should be used to achieve the specified performance [5, 6]. Thus, an asymmetric fuzzy membership function (AFMF) has been proposed to solve this problem. The AFMF is discussed and analyzed that it can effectively improve the accuracy and achieve the specific performance with fewer fuzzy rules [7, 8].

Recently, the type-2 fuzzy sets (T2 FSs) are gaining more and more in popularity [9, 10]. The T2 FSs are described by membership functions (MFs) that are characterized by more parameters than the type-1 fuzzy sets (T1 FSs). Hence, the T2 FSs provide us with more design degree of freedom. Nevertheless, due to the computational complexity of using the T2 FS, most people only use interval type-2 fuzzy sets (IT2 FSs) [10]. The computations associated with IT2 FSs are very manageable which makes it quite practical [11]. Many results has been shown that the interval type-2 fuzzy logic system (IT2 FLS) can successfully apply to cope with the control problems and perform well [12-17]. In our previous research [18-21], we proposed a type-2 fuzzy neural network with asymmetric membership function (T2FNN-A) which combines the IT2 FLS with neural network. Then, in order to improve the efficiency of the T2FNN-A, we proposed an interval type-2 fuzzy neural system with asymmetric membership function (IT2FNS-A) which utilizes several enhanced techniques such as Takagi-Sugeno-Kang fuzzy logic system (TSK FLS) and embedded type-reduction network layer [22]. These modifications not only improve the approximation accuracy of the T2FNN-A, but also achieve the specific performance with fewer fuzzy rules. However, a major drawback of the IT2FNS-A is that its application domain is limited to static problem due to its feedforward network structure. Using IT2FNS-A to process dynamic problems is inefficient. Thus, in this paper, we propose an interval type-2 recurrent fuzzy neural system with asymmetric membership functions (IT2RFNS-A) which provides the memory elements and extends the basic ability of the IT2FNS-A to include the dynamic problems. In addition, since the feedback layer captures the dynamic response of the system, the approximation accuracy of the network is improved.

In training of the neural network, the back-propagation (BP) algorithm is widely used. There is, however, a critical problem where the differential information of the system is very difficult to obtain because there are too many adjustable parameters in the IT2RFNS-A. Herein, we adopt the simultaneous perturbation stochastic approximation (SPSA) algorithm which is proposed by Spall [23-25]. This algorithm is based on the approximation to gradient formed from the measurements of the objective function. Hence, a great deal of computational effort is saved. Nevertheless, there still remains a problem. Because of the stochastic characteristic of SPSA algorithm, we cannot guarantee that every search step length is appropriate which may lead to the invalid search. To overcome this situation, we employ the Lyapunov stability analysis to derive the optimal learning step length for guaranteeing the stability of the closed-loop system. In addition, the efficient training is also ensured.

The remainder of this paper is organized as follows. In Section II, we cover the prerequisite material to be used in the study. Section III illustrates the proposed IT2RFNS-A. The

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

simulation results on chaotic system control of the Chua's chaotic circuit are shown in Section IV. Finally, the conclusion is given in Section V.

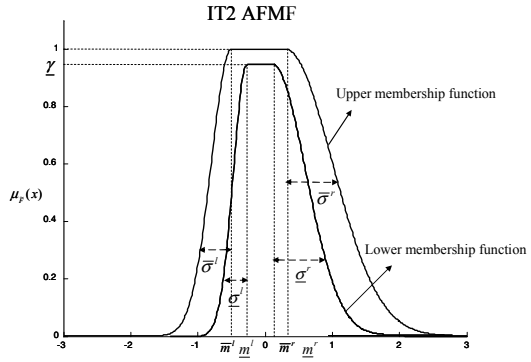

Figure 1. Construction of interval type-2 asymmetric fuzzy membership function.

II. PRELIMINARIES

A. Interval Type-2 Asymmetric Fuzzy Membership Function

Several literatures indicate that using AFMFs can improve the approximation accuracy and for effectively reducing the number of fuzzy rules [5-8]. It also provides better performance than traditional fuzzy systems on application of function approximation, modeling, and control. The learning capability and flexibility can be upgraded [5-8]. Here, we introduce the IT2 AFMFs. According to previous results [8], Gaussian functions are used to construct IT2 AFMFs, as shown in Fig. 1. Each IT2 AFMF is constructed by parts of four Gaussian functions. The upper and lower membership functions (MFs) are constructed by using two Gaussian MFs and one segment. The superscripts "l" and "r" denote the left and right curves of MF. The parameters of the lower and upper MFs are denoted by "$\underline{\ }$" and "$\overline{\ }$", respectively. Accordingly, the upper AFMF is constructed as:

$$\overline{\mu}_{\tilde{F}}(x)=\begin{cases} e^{-\frac{1}{2}\left(\frac{x-\overline{m}^{l}}{\overline{\sigma}^{l}}\right)^{2}}, \text{for } x\le \overline{m}^{l} \\ 1 \qquad\quad , \text{for } \overline{m}^{l}<x<\overline{m}^{r} \\ e^{-\frac{1}{2}\left(\frac{x-\overline{m}^{r}}{\overline{\sigma}^{r}}\right)^{2}}, \text{for } \overline{m}^{r}\le x \end{cases} \tag{1}$$

where $\overline{m}^{l}$ and $\overline{m}^{r}$ denote the means of two Gaussian MFs satisfying $\overline{m}^{l}\le\overline{m}^{r}$, and $\overline{\sigma}^{l}$ and $\overline{\sigma}^{r}$ denote the deviations (width) of two Gaussian MFs. Similarly, the lower AFMF is

$$\underline{\mu}_{\tilde{F}}(x)=\begin{cases} \lambda\cdot e^{-\frac{1}{2}\left(\frac{x-\underline{m}^{l}}{\underline{\sigma}^{l}}\right)^{2}}, \text{for } x\le \underline{m}^{l} \\ \lambda \qquad\quad , \text{for } \underline{m}^{l}<x<\underline{m}^{r} \\ \lambda\cdot e^{-\frac{1}{2}\left(\frac{x-\underline{m}^{r}}{\underline{\sigma}^{r}}\right)^{2}}, \text{for } \underline{m}^{r}\le x \end{cases} \tag{2}$$

where $\underline{m}^{l}\le\underline{m}^{r}$. To avoid a small activation value, λ is chosen to be $0.5\le\lambda\le1$. Thus, the following restrictions should be added to avoid unreasonable MFs:

$$\overline{m}^{l}\le\underline{m}^{l}\le\underline{m}^{r}\le\overline{m}^{r},\ \underline{\sigma}^{l}\le\overline{\sigma}^{l},\ \underline{\sigma}^{r}\le\overline{\sigma}^{r},\quad 0.5\le\lambda\le1. \tag{3}$$

B. Simultaneous Perturbation Stochastic Approximation Algorithm

This section introduces the SPSA algorithm briefly. The detail description can be found in literature [25]. Consider a problem of finding the minimum of objective function $f(W)$. The SPSA algorithm computes the parameter W at next iteration as

$$W(k+1)=W(k)-a_k g(W(k)) \tag{4}$$

where $g(.)$ is estimated gradient result for objective function $f(.)$, i.e., $\frac{\partial f(W)}{\partial W}\approx g(W)$. a_k is the learning step length which is decreased over iterations with $a_k=a/(k+A)^{\alpha}$, where a, A, and α are positive configuration coefficients [25]. The SPSA approach estimates the gradient $g(.)$ using following method. Assume that the dimension of parameter W is p. Let $\Delta_k=[\Delta_{k1}\ \Delta_{k2}\ \ldots\ \Delta_{kp}]$ be a p-dimensional vector whose element is mutually independent zero-mean random variable. Then, the estimation of the gradient at kth iteration can be computed by SPSA algorithm

$$g(W(k))=\frac{f(W(k)+c_k\Delta_k)-f(W(k))}{c_k}\left[\Delta_{k1}^{-1}\ \Delta_{k2}^{-1}\ \ldots\ \Delta_{kp}^{-1}\right]^{T} \tag{5}$$

$c_k=c/(k+1)^{\gamma}$ is gain sequence, where c and γ are nonnegative configuration coefficients. Obviously, all the elements of the parameter W are perturbed simultaneously, and only two measurement of the objective function are needed to estimate the gradient. In addition, Δ_k is usually obtained using Bernoulli ±1 distribution with equal probability for each value.

In general, the gradient information of neural fuzzy system is not easy to obtain due to the asymmetric membership functions and interval valued sets. Herein, we adopt the SPSA algorithm to derive the stable learning rule which guarantees the convergence and stability of the closed-loop systems.

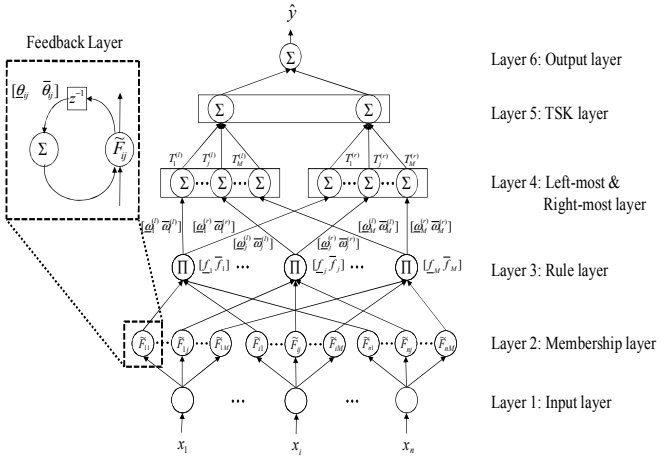

Figure 2. Diagram of the proposed interval type-2 recurrent fuzzy neural system with asymmetric membership functions.

III. Interval Type-2 Recurrent Fuzzy Neural System with Asymmetric Membership Function

A. Fuzzy Reasoning of IT2RFNS-A

The proposed IT2RFNS-A realizes the fuzzy inference into the IT2RFNS-A systems. Assume that an IT2RFNS-A system has M rules and n inputs, the jth rule can be expressed as

$$\begin{aligned} R^j &: \text{IF } z_{1j} \text{ is } \widetilde{F}_{1j} \text{ and } ... \text{ and } z_{nj} \text{ is } \widetilde{F}_{nj}, \\ &\text{THEN } Y_j = C_{j0} + C_{j1}x_1 + C_{j2}x_j + ... + C_{jn}x_n \end{aligned} \tag{6}$$

where z_{ij} is input linguistic variable of the jth rule, $\widetilde{F}_{ij}$ is interval type-2 antecedent fuzzy set, C_{ji} is type-1 consequent fuzzy set, x_i is the network input, and Y_j is the output of the jth rule and is also a type-1 fuzzy set (because it is the linear combination of type-1 fuzzy sets). Note that the input linguistic variable z_{ij} has the system input term and the past information which is introduced in Section III.B. Due to the IT2 FSs are used for the antecedent part and the interval type-1 fuzzy sets are used for the consequent part of the type-2 TSK rule, $\mu_{\widetilde{F}_{ij}}$ and C_{ji} are interval sets, i.e.,

$$\mu_{\widetilde{F}_{ij}}(z_{ij}) = \left[\underline{\mu}_{\widetilde{F}_{ij}}(z_{ij}) \quad \overline{\mu}_{\widetilde{F}_{ij}}(z_{ij}) \right] \tag{7}$$

$$C_{ji} = [c_{ji} - s_{ji} \quad c_{ji} + s_{ji}] \tag{8}$$

where c_{ji} denotes the center (mean) of C_{ji}, and s_{ji} denotes the spread of C_{ji}. Therefore, using the product t-norm, the firing strength associated with the jth rule is

$$F_j(\mathbf{z}) = [\underline{f}_j(\mathbf{z}) \quad \overline{f}_j(\mathbf{z})] \tag{9}$$

where

$$\underline{f}_j(\mathbf{z}) = \underline{\mu}_{\widetilde{F}_{1j}}(z_{1j}) * \cdots * \underline{\mu}_{\widetilde{F}_{nj}}(z_{nj}) \tag{10}$$

and

$$\overline{f}_j(\mathbf{z}) = \overline{\mu}_{\widetilde{F}_{1j}}(z_{1j}) * \cdots * \overline{\mu}_{\widetilde{F}_{nj}}(z_{nj}) . \tag{11}$$

The consequent of rule R^j, Y_j is also an interval set, i.e., $Y_j = [y_j^l \quad y_j^r]$, where

$$y_j^l = (c_{j0} + \sum_{i=1}^{n} c_{ji}x_{ij}) - (s_{j0} + \sum_{i=1}^{n} s_{ji}|x_{ij}|) \tag{12}$$

and

$$y_j^r = (c_{j0} + \sum_{i=1}^{n} c_{ji}x_{ij}) + (s_{j0} + \sum_{i=1}^{n} s_{ji}|x_{ij}|) . \tag{13}$$

By applying the Extension principle [26], the output of the FLS is

$$\begin{aligned} Y_{TSK}(\mathbf{z}) &= [y^l \quad y^r] \\ &= \int_{y_1 \in [y_1^l \ y_1^r]} \cdots \int_{y_M \in [y_M^l \ y_M^r]} \int_{f_1 \in [\underline{f}_1 \ \overline{f}_1]} \cdots \int_{f_M \in [\underline{f}_M \ \overline{f}_M]} 1 \Big/ \frac{\sum_{j=1}^{M} f_j y_j}{\sum_{j=1}^{M} f_j} \end{aligned} \tag{14}$$

where $\underline{f}_j$, $\overline{f}_j$, y_j^l, and y_j^r are computed using (10)-(13). To compute $Y_{TSK}(\mathbf{z})$, we need to compute its two end-points y^l and y^r by type-reduction operation [26]. Finally, we defuzzify it using the average of y^l and y^r. Hence, the defuzzified output of IT2RFNS-A is

$$y(\mathbf{z}) = \frac{y^l + y^r}{2} . \tag{15}$$

B. Network Structure of IT2RFNS-A

The IT2RFNS-A consists of six feed-forward layers and a feedback one. Layer 1 accepts input variables. Layer 2 is used to calculate the interval type-2 AFMF grade. Feedback layer which is embedded in Layer 2 is used to store the past information. Layer 3 forms the fuzzy rule base. Layer 4 is used for type-reduction. The TSK consequent part is implemented into Layer 5. Layer 6 is the output layer.

Next, we would indicate the signal propagation and the operation functions of the node in each layer. For convenience, the multi-input-single-output (MISO) case is considered here. The schematic diagram of the proposed IT2RFNS-A is shown in Fig. 2. In the following description, $O_i^{(l)}$ denotes the ith output node in layer l.

Layer 1: Input Layer

For the ith node of layer 1, the net input and the net output are represented as:

$$O_i^{(1)} = x_i . \tag{16}$$

The x_i represents the ith input to the ith node of layer 1. The nodes in this layer only transmit input values to the next layer directly.

Layer 2: Membership Layer

In this layer, each node performs the interval type-2 asymmetric fuzzy membership function, i.e.,

$$\begin{aligned} O_{ij}^{(2)} &= \mu_{\widetilde{F}_{ij}}(O_i^{(1)} + O_i^{(f)}) \\ &= [\underline{O}_{ij}^{(2)} \quad \overline{O}_{ij}^{(2)}]^T \\ &= [\underline{\mu}_{\widetilde{F}_{ij}}(O_i^{(1)} + O_i^{(f)}) \quad \overline{\mu}_{\widetilde{F}_{ij}}(O_i^{(1)} + O_i^{(f)})]^T \end{aligned} \tag{17}$$

where subscript $_{ij}$ indicates the jth term of the ith input $O_i^{(1)}$, $\mu_{\widetilde{F}_{ij}}$ is an IT2 AFMF as shown in Fig. 1. Note that the output of layer 2 and the feedback weight are interval values. According to the results of [27], the type-reduction can be integrated into the network, $O_i^{(f)}$ is the output of feedback layer

$$O_i^{(f)}(k) = \frac{\underline{O}_{ij}^{(2)}(k-1) \cdot \underline{\theta}_{ij} + \overline{O}_{ij}^{(2)}(k-1) \cdot \overline{\theta}_{ij}}{\underline{\theta}_{ij} + \overline{\theta}_{ij}} \tag{18}$$

where $\underline{\theta}_{ij}$ and $\overline{\theta}_{ij}$ denote the link weight of the feedback unit. Clearly, the input of this layer contains the memory terms $\underline{O}_{ij}^{(2)}(k-1)$ and $\overline{O}_{ij}^{(2)}(k-1)$ which store the past information of the network.

Layer 3: Rule Layer

This layer is used for computing firing strength of the rule. From (9)-(11), we obtain

$$\underline{f}_j = \underline{\mu}_{\widetilde{F}_{1j}}(O_1^{(1)} + O_1^{(f)}) * \cdots * \underline{\mu}_{\widetilde{F}_{nj}}(O_n^{(1)} + O_n^{(f)}) \tag{19}$$

$$\overline{f}_j = \overline{\mu}_{\tilde{F}_{1j}}(O_1^{(1)} + O_1^{(f)}) * \cdots * \overline{\mu}_{\tilde{F}_{nj}}(O_n^{(1)} + O_n^{(f)}) \quad (20)$$

where $\underline{\mu}_{\tilde{F}_{ij}}(\cdot)$ and $\overline{\mu}_{\tilde{F}_{ij}}(\cdot)$ are the lower and upper membership grades of $\mu_{\tilde{F}}(\cdot)$. Therefore, for the jth rule, the operation function of the node in this layer is

$$O_j^{(3)} = \left[\underline{O}_j^{(3)} \quad \overline{O}_j^{(3)}\right]^T = \left[\prod_{i=1}^{n} \underline{O}_{ij}^{(2)} \quad \prod_{i=1}^{n} \overline{O}_{ij}^{(2)}\right]^T \quad (21)$$

Layer 4: Left-most & Right-most layer

According to [27], the type-reduction can be integrated into the network layer by calculating their left-most and right-most value. That is, the complicated type-reduction method such as KM algorithm can be reduced as

$$O_j^{(4)} = \left[O_{jl}^{(4)} \; O_{jr}^{(4)}\right]^T = \left[\frac{\overline{\omega}_j^l \overline{O}_j^{(3)} + \underline{\omega}_j^l \underline{O}_j^{(3)}}{\overline{\omega}_j^l + \underline{\omega}_j^l} \quad \frac{\overline{\omega}_j^r \overline{O}_j^{(3)} + \underline{\omega}_j^r \underline{O}_j^{(3)}}{\overline{\omega}_j^r + \underline{\omega}_j^r}\right]^T \quad (22)$$

where the link weights are $\underline{\omega}^l = [\underline{\omega}_1^l \cdots \underline{\omega}_M^l]^T$, $\overline{\omega}^l = [\overline{\omega}_1^l \cdots \overline{\omega}_M^l]^T$, $\underline{\omega}^r = [\underline{\omega}_1^r \cdots \underline{\omega}_M^r]^T$, and $\overline{\omega}^r = [\overline{\omega}_1^r \cdots \overline{\omega}_M^r]^T$. Note that $\underline{\omega}_j^l < \overline{\omega}_j^l$ and $\underline{\omega}_j^r < \overline{\omega}_j^r$.

Layer 5: TSK Layer

From (12) and (13), we can obtain

$$\begin{aligned} T_j &= \left[T_j^l \; T_j^r\right]^T \\ &= \left[\left(c_{j0} + \sum_{i=1}^{n} c_{ji} x_i\right) - \left(s_{j0} + \sum_{i=1}^{n} s_{ji} |x_i|\right)\right. \\ &\quad \left.\left(c_{j0} + \sum_{i=1}^{n} c_{ji} x_i\right) + \left(s_{j0} + \sum_{i=1}^{n} s_{ji} |x_i|\right)\right]^T. \end{aligned} \quad (23)$$

Then, the output of this layer is

$$O^{(5)} = \left[O_l^{(5)} \; O_r^{(5)}\right]^T = \left[\frac{\sum_{j=1}^{M} O_{jl}^{(4)} T_j^l}{\sum_{j=1}^{M} O_{jl}^{(4)}} \quad \frac{\sum_{j=1}^{M} O_{jr}^{(4)} T_j^r}{\sum_{j=1}^{M} O_{jr}^{(4)}}\right]^T. \quad (24)$$

Layer 6: Output Layer

Layer 6 is the output layer which is used to implement the defuzzification operation. Each node is the actual output that will be pumped out this system. From (15), the crisp output is

$$O^{(6)} = \frac{O_l^{(5)} + O_r^{(5)}}{2}. \quad (25)$$

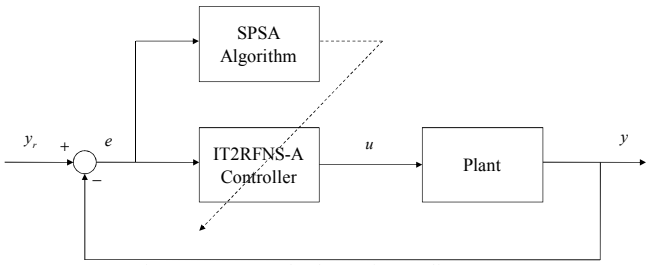

Figure 3. Control scheme for nonlinear system.

C. Training of IT2RFNS-A by A Stable SPSA Algorithm

Consider the nonlinear control problem, our goal is to generate a proper control signal $u(k)$ such that the system output $y(k)$ follows the desired trajectory $y_r(k)$, where k is the time index of discrete-time case. The IT2RFNS-A with the stable SPSA algorithm plays the role of controller for nonlinear plant, the adaptive control scheme is shown in Fig. 3. For convenience, we consider the single-output case and the tracking error is defined as

$$e(k) = y_r(k) - y(k). \quad (26)$$

Then, we define the objective function (error cost function) as

$$E(k) = \frac{1}{2} e^2(k) = \frac{1}{2}\left(y_r(k) - y(k)\right)^2. \quad (27)$$

Our goal is to generate the control signal $u(k)$ such that the tracking error approaching to zero, i.e., minimize the objective function $E(k)$. By using the SPSA algorithm, the parameters of IT2RFNS-A is adjusted such that the error defined in equation (27) is minimized. From the well-known gradient descent method and equation (5), the parameter update law can be written as

$$W(k+1) = W(k) + \Delta W(k) = W(k) + a_k\left(-\frac{\partial E(k)}{\partial W}\right) \quad (28)$$

where W is the tuning parameters of IT2RFNS-A. Then,

$$\frac{\partial E(k)}{\partial W} = -e(k)\frac{\partial e(k)}{\partial W}. \quad (29)$$

Herein, we adopt the SPSA algorithm to reduce the computational complexity of parameters update. The parameters update laws can be represented as

$$W(k+1) = W(k) + a_k e(k) g(W(k)) \quad (30)$$

where

$$g(W(k)) = \frac{e(W(k) + c_k\Delta_k) - e(W(k))}{c_k}\left[\Delta_{k1}^{-1} \; \Delta_{k2}^{-1} \; \ldots \; \Delta_{kp}^{-1}\right]^T. \quad (31)$$

$e(W(k) + c_k\Delta_k)$ denotes the tracking error between desired output and system output resulted by the IT2RFNS-A with perturbed tuning parameters. Note that equation (31) does not need to calculate the system gradient information, this simplifies the computational effort of nonlinear control.

D. Stability Analysis

Herein, we develop the stable theorem for selecting appropriate learning step length a_k. The choice of learning step length is very important for convergence. Hence, we employ the Lyapunov stability analysis approach to have convergence condition and the optimal learning step length for IT2RFNS-A.

Theorem 1. Let a_k be the learning step length of tuning parameters for the IT2RFNS-A. Consider the nonlinear control problem using IT2RFNS-A (shown in Fig. 3), the asymptotic convergence of the closed-loop system is guarantee if the learning step length is chosen satisfying

$$0 < a_k < \frac{2}{\left|g(k)\right|^2}, \text{ for all } k \quad (32)$$

where $g(W(k)) = \dfrac{e(W(k)+c_k\Delta_k)-e(W(k))}{c_k}\left[\Delta_{k1}^{-1}\ \Delta_{k2}^{-1}\ \ldots\ \Delta_{kp}^{-1}\right]^T$ is the gradient estimation using SPSA approach. In addition, the faster convergence can be obtained by using the following optimal time-varying learning step length

$$a_k^* = \frac{1}{\left|g(k)\right|^2}. \tag{33}$$

Proof: First, we define the discrete-time Lyapunov function as follows

$$V(k) = E(k) = \frac{1}{2}e^2(k) = \frac{1}{2}\left(y_r(k) - y(k)\right)^2 \tag{34}$$

where $e(k)$ represents the tracking error. Then, the change of the Lyapunov function is

$$\Delta V(k) = V(k+1) - V(k) = \frac{1}{2}\left(e^2(k+1) - e^2(k)\right). \tag{35}$$

According to the Lyapunov stability theorem, if the change of the positive definite Lyapunov function, denoted $\Delta V(k)$, satisfies the condition $\Delta V(k) < 0$, $\forall k$, then the asymptotical stability is guaranteed [1, 2]. Hence, our objective is to select the proper learning step length such that $\Delta V(k) < 0$, $\forall k$. This implies that $V(k)$ will converge to zero when k approaches to infinity. By [1, 2, 28], the error difference can be represented as

$$\Delta e(k) = e(k+1) - e(k) \cong \left[\frac{\partial e(k)}{\partial W}\right]^T \Delta W \tag{36}$$

where ΔW denotes the change of W. From equations (28) and (30), we obtain

$$\Delta W \equiv -a_k e(k)\frac{\partial e(k)}{\partial W} \cong a_k e(k) g(k). \tag{37}$$

Thus,

$$\begin{aligned}
\Delta V(k) &= \frac{1}{2}\left[e^2(k+1) - e^2(k)\right] \\
&= \frac{1}{2}\left[e(k+1) - e(k)\right]\cdot\left[e(k+1) + e(k)\right] \\
&= \frac{1}{2}\Delta e(k)\cdot\left[2e(k) + \Delta e(k)\right] \\
&= \Delta e(k)\cdot\left(e(k) + \frac{1}{2}\Delta e(k)\right) \\
&= \left[\frac{\partial e(k)}{\partial W}\right]^T a_k e(k) g(k)\cdot\left\{e(k) + \frac{1}{2}\left[\frac{\partial e(k)}{\partial W}\right]^T a_k e(k) g(k)\right\} \\
&= -a_k e^2(k)\left|g(k)\right|^2\left(1 - \frac{1}{2}a_k\left|g(k)\right|^2\right).
\end{aligned} \tag{38}$$

Note that $P(k)$ is positive for all k>0 and let $P(k) = a_k\left|g(k)\right|^2$. Thus,

$$\Delta V(k) = -e^2(k)P(k)\left(1 - \frac{1}{2}P(k)\right). \tag{39}$$

Recall that the asymptotical stability of the IT2RFNS-A is guaranteed if $\Delta V(k) < 0$, $\forall$ k>0. Thus, $\left(1 - \frac{1}{2}P(k)\right)$ should be positive such that $\Delta V(k) < 0$, $\forall k$. Therefore, we obtain the stability condition for a_k

$$0 < a_k < \frac{2}{|\,g(k)\,|^2}. \tag{40}$$

The asymptotic stability is guaranteed if a_k is chosen to satisfy equation (40). In addition, we would like to find a condition for a_k that guarantees the fast convergence. From (38) and (39), we have

$$\begin{aligned}
e^2(k+1) &= e^2(k) - e^2(k)P(k)\left(2 - P(k)\right) \\
&= e^2(k)\left[1 - 2P(k) + P^2(k)\right] \\
&= e^2(k)\left[P(k) - 1\right]^2.
\end{aligned} \tag{41}$$

The minimum of $e^2(k+1)$ is achieved when $P(k) = 1$. Hence, the time-varying optimal learning step length is

$$a_k^* = \frac{1}{\left|g(k)\right|^2}. \tag{42}$$

■

IV. Simulation Results

Consider the control problem of Chua's chaotic circuit. Our purpose is to develop an IT2RFNS-A controller to generate the proper control signal such that the system output y can follow a given reference trajectory y_r by the scheme as shown in the Fig. 3.

The typical Chua's chaotic circuit consists of one inductor, two capacitors, one linear resistor, and one piecewise-linear resistor [30, 31]. It has been shown that this circuit holds very rich nonlinear dynamics such as chaos and bifurcations. The dynamic equation of Chua's circuit are described as

$$\begin{aligned}
\frac{dv_{C_1}}{dt} &= (C_1)^{-1}\left(\frac{v_{C_2} - v_{C_1}}{R} - \lambda\right) \\
\frac{dv_{C_2}}{dt} &= (C_2)^{-1}\left(\frac{v_{C_1} - v_{C_2}}{R} - i_L\right) \\
\frac{di_L}{dt} &= (L)^{-1}\left(-v_{C_1} - R_O i_L\right)
\end{aligned} \tag{43}$$

where voltages v_{C_1}, v_{C_2}, and current i_L are state variables; R_O is a constant; λ denotes the nonlinear resistor which is a function of voltage across two terminals of C_1. The is λ defined as a cubic function as

$$\lambda = aV_{C_1} + c(v_{C_1})^3 \quad (a > 0, c < 0). \tag{44}$$

According to [31], equation (43) can be transferred into the canonical form as

$$\begin{bmatrix}\dot{x}_1\\ \dot{x}_2\\ \dot{x}_3\end{bmatrix}=\begin{bmatrix}0&1&0\\0&0&1\\0&0&0\end{bmatrix}\cdot\begin{bmatrix}x_1\\x_2\\x_3\end{bmatrix}+\begin{bmatrix}0\\0\\1\end{bmatrix}\cdot\left(f+g\cdot u+d\right)$$
$$y=x_1 \tag{45}$$

where $f=\frac{14}{1805}x_1-\frac{168}{9025}x_2+\frac{1}{38}x_3-\frac{2}{45}\left(\frac{28}{361}x_1+\frac{7}{95}x_2+x_3\right)^3$, $g=1$, and d is the external disturbance and is assumed to be a square-wave with amplitude ± 0.5 and period 2π. Herein, the objective is to track the reference trajectory $y_r=1.5\sin(t)$. We choose the initial state value as $x(0)=[0\ \ 0\ \ 1]^T$ and sampling time as 0.01 second.

For comparison, the same simulations are done by using IT2FNS-A and the case without optimal learning step length. The used coefficients are listed in Table I. The simulation results of trajectories are shown in Fig. 4. Figure 4(a) shows the phase plant trajectory after controlled, Fig. 4(b)-4(d) shows the state trajectories x_1, x_2, and x_3, respectively (solid line: actual system output; dashed line: reference trajectory). Figure 5 depicts the control effort of the IT2RFNS-A controller. The final fuzzy rules are

R^1: IF z_{11} is $\widetilde{F}_{11}$ and z_{21} is $\widetilde{F}_{21}$ and z_{31} is $\widetilde{F}_{31}$,
THEN $Y_1=[-7.6414\ -0.2130]+[-5.6236\ -0.3833]x_1$
$+[8.5389\ 9.0126]x_2+[-0.7853\ 1.6596]x_3$

where $\theta_{11}=[-4.3323\ 9.3274]$, $\theta_{21}=[-2.0292\ 2.6543]$, $\theta_{31}=[-8.0895\ 4.3461]$, $\overline{\omega}_1=[-10.0520\ -9.9033]$, and $\underline{\omega}_1=[-10.2740\ -9.3170]$.

where $\theta_{12}=[-10.2843\ 1.1492]$, $\theta_{22}=[-2.1777\ 9.1312]$, $\theta_{32}=[-6.9073\ -0.5194]$, $\overline{\omega}_2=[-9.6955\ 2.2647]$, and $\underline{\omega}_2=[-5.7276\ -7.5890]$.

R^3: IF z_{13} is $\widetilde{F}_{13}$ and z_{23} is $\widetilde{F}_{23}$ and z_{33} is $\widetilde{F}_{33}$,
THEN $Y_1=[-8.4356\ -6.3436]+[-9.0422\ -4.7307]x_1$
$+[4.5459\ 9.6610]x_2+[-9.1732\ 2.0163]x_3$

where $\theta_{13}=[-2.0828\ 3.3525]$, $\theta_{23}=[-6.9332\ -2.3628]$, $\theta_{33}=[-7.1283\ -7.4267]$, $\overline{\omega}_3=[-9.5861\ -0.3531]$, and $\underline{\omega}_3=[-9.9473\ -8.7061]$.

R^4: IF z_{14} is $\widetilde{F}_{14}$ and z_{24} is $\widetilde{F}_{24}$ and z_{34} is $\widetilde{F}_{34}$,
THEN $Y_1=[3.9646\ 11.7177]+[5.1486\ 9.3539]x_1$
$+[-4.5256\ 6.0764]x_2+[-0.9234\ 6.5402]x_3$

where $\theta_{14}=[-7.7789\ -7.6991]$, $\theta_{24}=[-8.7967\ -5.7106]$, $\theta_{34}=[-7.1095\ -6.3978]$, $\overline{\omega}_4=[-8.7774\ 1.2302]$, and $\underline{\omega}_3=[-7.3826\ -4.7145]$.

The corresponding MFs are depicted in Fig. 6.

We can observe that the proposed method is valid to control a nonlinear dynamic system. The comparison results are shown in Table II which is obtained by 10 independent runs. From Table II, we can easily find that the IT2RFNS-A performs better than IT2FNS-A. This result shows that the IT2RFNS-A has ability to cope with dynamic problems. Observe the performance of the case with optimal learning step length from Table II, we again demonstrate that adopting optimal learning step length guarantees the efficient training of IT2RFNS-A.

V. CONCLUSION

In this paper, we have proposed an interval type-2 recurrent fuzzy system with asymmetric membership functions (IT2RFNS-A) and its training scheme using the proposed stable SPSA algorithm. In addition, we adopt the Lyapunov theorem to derive the appropriate range of learning step length for SPSA to guarantee the stability of the closed-loop system for nonlinear control. In addition, we also derive the optimal learning step length which can ensure the efficient training for IT2RFNS-A. The feasibility and the effectiveness of the proposed method have been demonstrated by illustration example. The simulations on the control of the Chua's chaotic circuit are done and shows the following advantages of proposed approach; (a) The IT2RFNS-A can reduce the fuzzy rules, that is, only few rules can achieve the specific performance or even better; (b) The IT2RFNS-A can catch the dynamic response of the system, i.e., it is capable of coping with dynamic problems; (c) By using the proposed SPSA algorithm, the gradient information is unnecessary. In other words, a great deal of computational effort is saved. (d) For control problems, the proposed method avoids approximating the system sensitivity which leads to inaccuracy. (e) Adopting optimal learning step length improves the performance of training IT2RFNS-A.

***Abstract*—This paper provides root finding methods for the centroid computation of interval type-2 fuzzy sets and general type-2 fuzzy sets with linear secondary membership function. When the FOUs of the type-2 fuzzy sets are provided, the centroid computation methods in this paper is accurate and computational efficient, which provide new methods for the type-2 fuzzy systems computation.**

***Keywords*—Type-2 fuzzy set (IT2 FS) , Karnik-Mendel (KM) algorithms, centroid computation, root finding.**

I. Introduction

Type-2 fuzzy logic system (FLS) allows for better modeling of uncertainty as type-2 fuzzy set (T2 FS) encompass a Footprint of Uncertainty (FOU) which, associated with its third dimension, gives more degrees of freedom to T2 FS in comparison to type-1 fuzzy set (T1 FS) [1], [14], [20], [30]. Interval type-2 fuzzy set (IT2 FS) is a simplified version of general T2 FS where the membership grade is crisp interval rather than functions. Most applications on type-2 fuzzy FLS involve only interval type-2 systems applications, and it has been shown that interval type-2 FLSs can outperform their type-1 FLSs counterparts in a variety of fields including information processing, fuzzy control and decision making [10], [28], [21], [6], [16]. General type-2 FLSs has only recently been investigated in more detail [19], [25], [11], [3], [24], [4], [23]. It is expected that the general T2 FSs will have the ability to model uncertainty more accurately than IT2 FSs which in turn will result in the potential for a superior performance in comparison to type-1 and interval type-2 FLSs. But the high complexity associated with their design and their computational requirements made them appear unsuitable for real-world use. One of the major obstacles to the use of generalized type-2 FLSs on real-world problems is the type reduction of general T2 FSs [19], [25], [3], [11], which is consisted of the steps of type reduction from general T2 FS into T1 FS, and T1 FS defuzzification to the final crisp output. Calculating the centroid of a general T2 FS typically requires a large amount of computation.

To date, type-reduction methods have been developed by Karnik and Mendel [9] and are elaborated upon in [14]. The efficient algorithms, called the Karnik-Mendel (KM) algorithms, have been developed for centroid type reduction for interval type-2 FLSs. The KM algorithms have been applied to many applications of T2 FSs and play an important role in type-2 FLSs [20], [14], [7], [15], [16]. Mendel and Liu [18] proved monotonicity and super-exponential convergence of the algorithms. The iteration number of KM algorithm is usually less than seven for accuracies of 10^{-2}. Because of the iterative natures of the KM algorithms, there may be a computational bottleneck in real-time applications. So, Wu and Mendel [29] proposed an uncertainty bound method to approximate type reduction of ITS without computation burden. Greenfield, Chiclana, Coupland and Robert John [5] proposed a collapsing method of defuzzification for discretised IT2 FSs, which claimed can be outperformed the KM algorithms both in accuracy and speed. Finally, Wu and Mendel [27] proposed Enhanced KM (EKM) algorithms to reduce the computational cost of the standard KM algorithm.

However, no efficient strategies exist to date for centroid type-reduction of general T2 FLSs [11], [19], [25]. John and Czarnecki [8] and Lucas et al. [13] proposed the general centroid computation as the centroids of all vertical slices (each of which is a T1 FS). Liu [11] developed an efficient strategy to implement centroid type-reduction for general type-2 FLSs by decomposing a general T2 FS into IT2 FS α-planes with $\alpha \in [0, 1]$. Mendel, Liu and Zhai [19] use this method for the computation of general type-2 sets, which seems to be the first practical choices for extension of IT2 FSs to general T2 FSs. The centroid type reduction is performed using KM algorithms individually for each α-plane. A quasi-T2 fuzzy logic system with two α-plane sets are designed. Starczewski [24] also designed triangular type-2 fuzzy logic systems. A new efficient approximate iterative procedure based on the KM type-reduction is proposed. Wagner and Hagras [25] introduced the zSlices-based representation, and proposed a similar type reduction method with the repetitive KM algorithm for the centroid of general T2 FSs. Except the α-plane (zslice) based centroid computation method mentioned [19], [25], which takes samples from the two dimensional directions of the membership function, and obtains approximate solution with repetitive computation and iterations, Coupland and John [2], [3], [4] presented a geometric representation of general type-2 sets. The geometric method [4], [3], [2] uses more simplified

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

and rough approximation method than the α-plane method with KM-algorithm, and it is claimed faster than the KM algorithm in computation. More recently, Zhai and Mendel [31] proposed introduced a centroid-flow (CF) algorithm, which only utilizes the KM/EKM algorithms to compute the centroid of the general type-2 fuzzy sets, which only need to compute the α-plane of the beginning. It should be noted that in all of the general T2 FSs publications for the authors [19], [11], [10], [3], [25], [4], [24], the second membership function are often assumed linear (triangular or trapezoidal), there seems no much justification to adopt other forms of second membership functions forms in general type-2 FLSs, especially in control and decision applications.

Up till now, in contrast to the centroid defuzzification of type-1 fuzzy sets, that is usually computed integral of the membership function of the output fuzzy set, almost all the current type reduction methods of T2 FS are discrete based, that is we take sampling data from the T2 FS, and compute the general centroid values approximately. This not only make the computation accuracy becomes very low but also make the computation complexity increases very fast, e. g. for 100 samples on the α-plane and x-domain respectively, we should compute 100 times iterate computation with $10,000$ data; if we want a one more digit accuracy of the general centroid values, we have to take 1000 samples on two dimensions, and compute 1000 times iterate computation with $1,000,000$ data. Some computational analysis of these methods can be found in [19], [11], [25]. In the present paper, we will extend the KM algorithm to the general root finding method. The KM algorithm iteration process become a part of rooting finding with Newton-Raphson method. In which, the centroid values can be computed directly and the accurately, and can integrate other numerical integral and root finding techniques in practice. For general T2 FSs under linear second membership function, the centroid value computation is only two times of the case of IT2 FSs, the repetitive IT2 FS slices computation can be avoided, and the computation is accurate.

The organization of the paper is as follows. Section II gives preliminaries about T2 FSs and the centroid computation of T2 FSs. Section III provides the root finding methods for the centroid of IT2 FS and the analytical method for the centroid computation of general T2 FS. Section IV illustrates the proposed methods with numerical examples. Section **??** summarizes the main results and draws conclusions.

II. Preliminaries

A. The centroid of interval type-2 fuzzy set and general type-2 fuzzy set

Definition 1: [17] A T2 FS, denoted as $\tilde{A}$, is characterized by a type-2 membership function $\mu_{\tilde{A}}(x,u)$, where $x \in X$ and $u \in J_x \subseteq [0,1]$, i. e.

$$\tilde{A} = \{((x,u), \mu_{\tilde{A}}(x,u) | \forall x \in X, \forall u \in J_x \subseteq [0,1]\} \quad (1)$$

where $0 \leq \mu_{\tilde{A}(x,u)} \leq 1$, X is the domain of the fuzzy set, and J_x is the domain of the secondary membership function at x. $\tilde{A}$ can also be expressed as

$$\tilde{A} = \int_{x \in X} \int_{u \in J_x} \mu_{\tilde{A}}(x,u)/(x,u) \quad \forall u \in J_x \subseteq [0,1] \quad (2)$$

where $\int\int$ denotes union over all admissible x and u. J_x is called the primary membership of x in $\tilde{A}$. At each value of x say $x = x'$, the 2-D plane whose axes are u and $\mu_{\tilde{A}}(x',u)$ is called a vertical slice of $\tilde{A}$. Besides the vertical slice representation mentioned above, a general T2 FS can also be represented as a series of wavy slices where for discrete universes of discourse X and U [14] .

The footprint of uncertainty, denoted $FOU(\tilde{A})$ is the union of all primary memberships, i.e., $FOU(\tilde{A}) = \bigcup_x \in X J_x$, which represents the uncertainty in the primary memberships of a T2 FS $\tilde{A}$.

Definition 2: [14] An IT2 FS $\tilde{A}$ is completely described by its lower and upper MFs, $\underline{\mu}_{\tilde{A}}(x)$ and $\overline{\mu}_{\tilde{A}}(x)$, respectively. The footprint of uncertainty (FOU) of an IT2 FS is described in terms of these MFs:

$$FOU(\tilde{A}) = \bigcup_{x \in X} \left[\underline{\mu}_{\tilde{A}}(x), \overline{\mu}_{\tilde{A}}(x)\right]$$

Definition 3: [19] An α-plane FOU, i.e., $FOU(\tilde{A}_\alpha)$ is

$$FOU(\tilde{A}_\alpha) = \alpha I_{\tilde{A}_\alpha}(x,u|\alpha). \quad (3)$$

where $I_{\tilde{A}_\alpha}$ is an indicator function

$$I_{\tilde{A}_\alpha}(x,u|\alpha) = \begin{cases} 1 & (x,u) \in \tilde{A}_\alpha \\ 0 & (x,u) \notin \tilde{A}_\alpha \end{cases}$$

The α-plane representation (theorem) for $\tilde{A}$ is

$$\tilde{A} = \bigcup_{\alpha \in [0,1]} FOU(\tilde{A}_\alpha)$$

Definition 4: The centroid $c(A)$ of the T1 FS A is defined as

$$C(A) = \frac{\sum_{i=1}^{N} x_i \mu_A(x_i)}{\sum_{i=1}^{N} \mu_A(x_i)} \quad (4)$$

The centroid of a T2 FS, which was developed by Karnik and Mendel [9], has turned out to be a very important concept for IT2, as well as general T2 FSs and their associated FLSs.

Definition 5: [26] The centroid $C_{\widetilde{A}}$ of an IT2 FS $\widetilde{A}$ is the union of the centroids of all its embedded T1 FSs A_e, i.e.,

$$C(\widetilde{A}) = \bigcup_{\forall A_e} c(A_e) = [c_l(\widetilde{A}), c_r(\widetilde{A})] \quad (5)$$

where $\bigcup$ is the union operation, and

$$c_l(\widetilde{A}) = \min_{\forall A_e} c(A_e) \quad (6)$$

$$c_r(\widetilde{A}) = \max_{\forall A_e} c(A_e) \quad (7)$$

Definition 6: [19] The centroid of general T2 FS $\tilde{A}$, is the union of the centroids of all the embedded T1 sets. With the α-plane representation method [19], [11], $C_{\tilde{A}}$ can be computed using the α-plane decomposition of $\tilde{A}$, the centroid of general

T2 FS $C_{\tilde{A}}(x)$ is the union of a series of IT2 FS at every α-plane, i.e.,

$$C_{\tilde{A}}(x) = \bigcup_{\alpha \in [0,1]} \alpha / C_{\tilde{A}_\alpha}(x)$$

where $C_{\tilde{A}_\alpha}(x)$ is the centroid of the α-plane $\tilde{A}$. Because each $\tilde{A}_\alpha$ is an interval-valued set, its centroid is an interval set, i.e.,

$$C_{\tilde{A}_\alpha}(x) = [l_{\tilde{A}_\alpha}, r_{\tilde{A}_\alpha}]$$

B. The centroid computation with KM algorithms

Let $x_i (i = 1, 2 \ldots, N)$ represent the discretization of an IT2 FS $\widetilde{A}$; $\underline{\mu}_{\widetilde{A}}(x_i)$ and $\overline{\mu}_{\widetilde{A}}(x_i)$ are the lower and upper membership functions that are associated with $\widetilde{A}$ respectively. Using the representation theorem for a T2 FS [17], the centroid of IT2 FS $\widetilde{A}$, $c_{\widetilde{A}} = [c_l, c_r]$, can be computed as the optimal solutions of the following interval weighted average problems [9], [18]:

$$c_l = \min_{\forall \theta_i \in [\underline{\mu}_{\widetilde{A}}(x_i), \overline{\mu}_{\widetilde{A}}(x_i)]} \frac{\sum_{i=1}^{N} x_i \theta_i}{\sum_{i=1}^{N} x_i \theta_i} \tag{8}$$

$$c_r = \max_{\forall \theta_i \in [\underline{\mu}_{\widetilde{A}}(x_i), \overline{\mu}_{\widetilde{A}}(x_i)]} \frac{\sum_{i=1}^{N} x_i \theta_i}{\sum_{i=1}^{N} x_i \theta_i} \tag{9}$$

It is well known that c_l and c_r can be expressed, as:

$$c_l = \frac{\sum_{i=1}^{L} x_i \overline{\mu}_{\widetilde{A}}(x_i) + \sum_{i=L+1}^{N} x_i \underline{\mu}_{\widetilde{A}}(x_i)}{\sum_{i=1}^{L} \overline{\mu}_{\widetilde{A}}(x_i) + \sum_{i=L+1}^{N} \underline{\mu}_{\widetilde{A}}(x_i)} \tag{10}$$

$$c_r = \frac{\sum_{i=1}^{R} x_i \underline{\mu}_{\widetilde{A}}(x_i) + \sum_{i=R+1}^{N} x_i \overline{\mu}_{\widetilde{A}}(x_i)}{\sum_{i=1}^{R} \overline{\mu}_{\widetilde{A}}(x_i) + \sum_{i=L+1}^{N} \underline{\mu}_{\widetilde{A}}(x_i)} \tag{11}$$

where L and R are called switch points with $x_L \le c_l \le x_{L+1}$ and $x_R \le c_r \le x_{R+1}$. The determination of L and R can be performed by using the KM algorithms [20].

Currently, the centroid of general T2 FS $\tilde{A}$ is computed with α-plane (or zslices) [19], [25] with $\alpha \in [0, 1]$, which decomposes the general T2 FS into a series of IT2 FS. The centroid of T2 FS is computed by the process in Table I.

III. The Analytical Direct Centroid Computation of General Type-2 Fuzzy Set with Linear Secondary Membership Function

A. Direct centroid computation of Interval type-2 sets

We assume all the x_is are different, and they are bounded in $[a, b]$, where $a = \min_{1 \le i \le n} \{x_i\}$ and $b = \max_{1 \le i \le n} \{x_i\}$, which denote the smallest and the largest sampled values of x respectively*. Then, the continuous versions of (10) and (11) are

$$c_l = \frac{\int_a^{c_l} x \overline{\mu}_{\widetilde{A}}(x) dx + \int_{c_l}^{b} x \underline{\mu}_{\widetilde{A}}(x) dx}{\int_a^{c_l} \overline{\mu}_{\widetilde{A}}(x) dx + \int_{c_l}^{b} \underline{\mu}_{\widetilde{A}}(x) dx} \tag{12}$$

*As noted in [22, p. 363], if Gaussian MFs are used, one can extend the theoretical results to $a \to -\infty$, $b \to +\infty$; but, in practice, when truncations are used, a and b are again finite numbers.

$$c_r = \frac{\int_a^{c_r} x \underline{\mu}_{\widetilde{A}}(x) dx + \int_{c_r}^{b} x \overline{\mu}_{\widetilde{A}}(x) dx}{\int_a^{c_r} \underline{\mu}_{\widetilde{A}}(x) dx + \int_{c_r}^{b} \overline{\mu}_{\widetilde{A}}(x) dx} \tag{13}$$

From (12) and (13), we have

$$\int_a^{c_l} (c_l - x) \overline{\mu}_{\widetilde{A}}(x) dx + \int_{c_l}^{b} (c_l - x) \underline{\mu}_{\widetilde{A}}(x) dx = 0 \tag{14}$$

$$\int_a^{c_r} (c_r - x) \underline{\mu}_{\widetilde{A}}(x) dx + \int_{c_r}^{b} (c_r - x) \overline{\mu}_{\widetilde{A}}(x) dx = 0 \tag{15}$$

Let

$$\varphi(\xi) = \int_a^{\xi} (\xi - x) \overline{\mu}_{\widetilde{A}}(x) dx + \int_{\xi}^{b} (\xi - x) \underline{\mu}_{\widetilde{A}}(x) dx \tag{16}$$

$$\psi(\xi) = \int_a^{\xi} (\xi - x) \underline{\mu}_{\widetilde{A}}(x) dx + \int_{\xi}^{b} (\xi - x) \overline{\mu}_{\widetilde{A}}(x) dx \tag{17}$$

Consider (14), (15), then $\varphi(c_l) = 0$ and $\psi(c_r) = 0$. The computation of the centroid values of c_l and c_r can be transformed in the root finding problems of $\varphi(\xi) = 0$ and $\psi(\xi) = 0$. The equivalence of KM Algorithm and Newton-Raphson root-finding method and some more theoretical analysis were given in [12]. We can use the centroid finding equations (16) and (17) as the direct centroid computation methods.

B. Direct centroid computation of general type-2 sets

The centroid of general T2 FS is the combination of a series of α-plane IT2 FS with $\alpha \in [0, 1]$, which is in fact a normal type-1 fuzzy set with type reduction [19], [11]. It is natural that the centroid computation is the centroid of general T2 FS is more complicated, which is obtained by solving the centroids of a series of IT2 FS repeatedly [19], [25]. As the T2 FSs are obtained from T1 FS with an additional dimension, there is not common principle for the secondary membership determination. We often assume the secondary membership function of T2 FS to be assumed linear (triangular or trapezoidal membership function) [19], [11], [10], [3], [25], [4], [24]. It is very lucky that under such assumptions the centroid of a T2 FS can be obtained directly without solving every α-plane and we also get the type-1 centroid function analytically, which is convenient for final defuzzification.

If the second membership function of general T2 FS is linear, then α-plane decomposition of general T2 FS $\tilde{A}$ can be expressed as:

$$\underline{\mu}_{\widetilde{A}_\alpha}(x) = (1 - \alpha) \underline{\mu}_{\widetilde{A}_0}(x) + \alpha \underline{\mu}_{\widetilde{A}_1}(x) \tag{18}$$

$$\overline{\mu}_{\widetilde{A}_\alpha}(x) = (1 - \alpha) \overline{\mu}_{\widetilde{A}_0}(x) + \alpha \overline{\mu}_{\widetilde{A}_1}(x) \tag{19}$$

where $\underline{\mu}_{\widetilde{A}_\alpha}(x)$ and $\overline{\mu}_{\widetilde{A}_\alpha}(x)$ are the LMF and UMF of α-plane IT2 FS respectively.

We usually have $\forall x$, $\underline{\mu}_{\widetilde{A}_0}(x) \le \underline{\mu}_{\widetilde{A}_1}(x)$ and $\overline{\mu}_{\widetilde{A}_0}(x) \ge \overline{\mu}_{\widetilde{A}_1}(x)$, so that $\underline{\mu}_{\widetilde{A}_\alpha}(x)$ is increasing with α and $\overline{\mu}_{\widetilde{A}_\alpha}(x)$ is decreasing with α. We can compute the centroid values of IT2 FS with FOU $\underline{\mu}_{\widetilde{A}_\alpha}(x)$ and $\overline{\mu}_{\widetilde{A}_\alpha}(x)$, in which α is a parameter of the IT2 FSs.

TABLE I
THE CENTROID COMPUTATION OF GENERAL TYPE-2 FUZZY SET

Step	The computation process
1	Sample $\alpha \in [0,1]$ with $0 = \alpha_1 < \alpha_2 < \cdots < \alpha_m = 1$, where m can be determined by the tolerance error bound of the problem. Then the general T2 FS is decomposed into a serial of α-planes in the form of IT2 FS $\tilde{A}_{\alpha_j}$, $j = 1, 2, \ldots, m$.
2	For every $\tilde{A}_{\alpha_j}$, $j = 1, 2, \ldots, m$, compute the general centroid values $c_l(\alpha_j)$ and $c_r(\alpha_j)(j = 1, 2, \ldots, m)$ with the KM algorithms respectively.
3	Connect the points $c_l(\alpha_j)$ and $c_r(\alpha_j)$ for all $j = 1, 2, \ldots, m$ together, thereby obtaining any approximate solution for $c_l(\alpha)$ and $c_r(\alpha)$ for $\alpha \in [0,1]$.

With (16),

$$\begin{aligned}\varphi(\alpha, l) &= \int_a^l (l-x)\overline{\mu}_{\widetilde{A}_\alpha}(x)dx + \int_l^b (l-x)\underline{\mu}_{\widetilde{A}_\alpha}(x)dx \\ &= \int_a^l (l-x)\left((1-\alpha)\overline{\mu}_{\widetilde{A}_0}(x) + \alpha\overline{\mu}_{\widetilde{A}_1}(x)\right)dx \\ &\quad + \int_l^b (l-x)\left((1-\alpha)\underline{\mu}_{\widetilde{A}_0}(x) + \alpha\underline{\mu}_{\widetilde{A}_1}(x)\right)dx \\ &= -\alpha\left(\int_a^l (l-x)\left(\overline{\mu}_{\widetilde{A}_0}(x) - \overline{\mu}_{\widetilde{A}_1}(x)\right)dx \right. \\ &\quad \left. + \int_l^b (l-x)\left(\underline{\mu}_{\widetilde{A}_0}(x) - \underline{\mu}_{\widetilde{A}_1}(x)\right)dx\right) \\ &\quad + \left(\int_a^l (l-x)\overline{\mu}_{\widetilde{A}_0}(x)dx + \int_l^b (l-x)\underline{\mu}_{\widetilde{A}_0}(x)dx\right)\end{aligned}$$

Let $\varphi(\alpha, l) = 0$, we have

$$\begin{aligned}\alpha_l = &\left(\int_a^l (l-x)\overline{\mu}_{\widetilde{A}_0}(x)dx + \int_l^b (l-x)\underline{\mu}_{\widetilde{A}_0}(x)dx\right) \\ &\Big/ \left(\int_a^l (l-x)\left(\overline{\mu}_{\widetilde{A}_0}(x) - \overline{\mu}_{\widetilde{A}_1}(x)\right)dx \right. \\ &\left. + \int_l^b (l-x)\left(\underline{\mu}_{\widetilde{A}_0}(x) - \underline{\mu}_{\widetilde{A}_1}(x)\right)dx\right) \qquad (20)\end{aligned}$$

This expression shows the relationship between l and α, if we have an additional restrict value of α with $\alpha \in [0,1]$, then it can be regard the reverse function of $c_l(\alpha)$.

Similarly, with

$$\begin{aligned}\psi(\alpha, r) = &\int_a^r (r-x)\underline{\mu}_{\widetilde{A}_\alpha}(x)dx \\ &+ \int_r^b (l-x)\overline{\mu}_{\widetilde{A}_\alpha}(x)dx \qquad (21)\end{aligned}$$

Let $\psi(\alpha, r) = 0$, we can also get that

$$\begin{aligned}\alpha_r = &\left(\int_a^r (r-x)\underline{\mu}_{\widetilde{A}_0}(x)dx + \int_l^b (r-x)\overline{\mu}_{\widetilde{A}_0}(x)dx\right) \\ &\Big/ \left(\int_a^r (r-x)\left(\underline{\mu}_{\widetilde{A}_0}(x) - \underline{\mu}_{\widetilde{A}_1}(x)\right)dx \right. \\ &\left. + \int_r^b (r-x)\left(\overline{\mu}_{\widetilde{A}_0}(x) - \overline{\mu}_{\widetilde{A}_1}(x)\right)dx\right) \qquad (22)\end{aligned}$$

This provides a direct computation for the centroid of T2 FS with linear second membership function.

According to (20), solving $\alpha_l(l) = 0$ and $\alpha_l(l) = 1$ about l respectively. Suppose the solutions are l_0 and l_1, then $\alpha_l(l)$ with $l \in [l_0, l_1]$ will be the left centroid. Similarly, according to (22), solving $\alpha_r(r) = 0$ and $\alpha_l(r) = 1$ about r respectively. Suppose the solutions are r_0 and r_1, then $\alpha_r(r)$ with $r \in [r_1, r_0]$ will be the right centroid. The solution of $\alpha_l(l) = 0$ and $\alpha_l(l) = 1$, $\alpha_r(r) = 0$ and $\alpha_l(r) = 1$ can be obtained by the direct root finding method of Subsection III-A.

In summary, for general T2 FS with linear second membership function, the centroid function can be computed in a very simple way comparing to the α-plane method in Table I, which is given in Table II.

So, the type-1 centroid function of general T2 FS $\tilde{A}$ should be:

$$C_{\tilde{A}}(x) = \begin{cases}\alpha_l(x) & x \in [l_0, l_1] \\ 1 & x \in [l_1, r_1] \\ \alpha_r(x) & x \in [r_1, r_0]\end{cases} \qquad (23)$$

With the centroid defuzzification method of type-1 set, the final defuzzification value can be computed:

$$c(\tilde{A}) = \frac{\int_{l_0}^{l_1} x\alpha_l(x)dx + \int_{l_1}^{r_1} xdx + \int_{r_1}^{r_0} x\alpha_r(x)dx}{\int_{l_0}^{l_1} \alpha_l(x)dx + \int_{l_1}^{r_1} dx + \int_{r_1}^{r_0} \alpha_r(x)dx} \qquad (24)$$

IV. NUMERICAL EXAMPLES

Some numerical examples are provided to illustrate our proposed methods. If the membership functions is expressed with elementary function, the centroid function of T2 FS can even be expressed analytically. Here is an examples.

Example 1: Here is a T2 FS with non symmetrical FOU.

$$\overline{\mu}_{\widetilde{A}_0}(x) = -\frac{4}{9}x^2 + \frac{4}{3}x \qquad (25)$$

$$\underline{\mu}_{\widetilde{A}_0}(x) = -\frac{4}{9}x^2 + \frac{8}{9}x \qquad (26)$$

where $x \in [0, 2]$, which is shown in Figure 1.

The secondary MF of $\widetilde{A}$ is chosen to be a triangular membership function whose base equals $\overline{\mu}_{\widetilde{A}_0}(x) - \underline{\mu}_{\widetilde{A}_0}(x)$ and whose apex is determined by a randomly generated value $w(x) \in [0,1]$ as

$$Apex(x) = \underline{\mu}_{\widetilde{A}_0}(x) + w(x)\left[\overline{\mu}_{\widetilde{A}_0}(x) - \underline{\mu}_{\widetilde{A}_0}(x)\right] \qquad (27)$$

Here, we set $w = \frac{3}{5}$ and the domain is $x \in [0, 2]$.

TABLE II
THE CENTROID COMPUTATION OF GENERAL T2 FS WITH LINEAR SECOND MEMBERSHIP FUNCTION

Step	The computation process
1	Compute the centroid functions $\alpha_l(l)$ and $\alpha_r(r)$ without considering the domain of α-plane level value α with (20) and (22) respectively.
2	Find the corresponding bounds of l and r for $\alpha \in [0,1]$ by solving equations $\alpha_l(l) = 0$ and $\alpha_l(l) = 1$ about l, and $\alpha_r(r) = 0$ and $\alpha_l(r) = 1$ about r respectively. Suppose the solutions are l_0, l_1 and r_0, r_1 respectively.
3	Replacing $\alpha_l(l)$, $\alpha_r(r)$ with $\alpha_l(x)$, $\alpha_r(x)$, then $\alpha_l(x)$ with $x \in [l_0, l_1]$ and $\alpha_r(x)$ with $x \in [r_0, r_1]$ will be the left and right centroid functions of general T2 FS respectively.

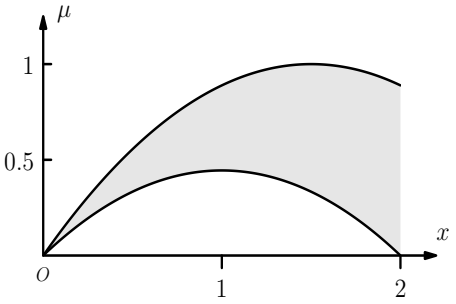

Fig. 1. The FOU of Example 1

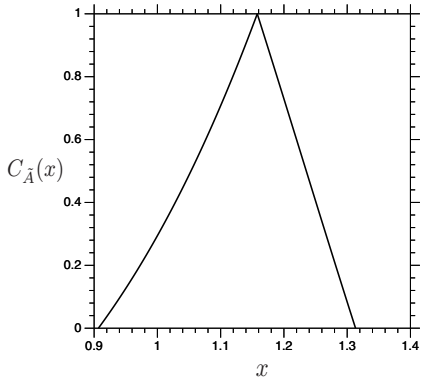

Fig. 2. The centroid function of Example 1

The left centroid function and right centroid function can be computed respectively:

$$\alpha_l(l) = \frac{5(l^3 + 8l - 8)}{5l^3 - 36l + 48} \tag{28}$$

$$\alpha_r(r) = \frac{5(r^3 - 20r + 24)}{5r^3 - 24r + 32)} \tag{29}$$

Find the solutions for $\alpha_l(l) = 0, \alpha_l(l) = 1$ for l and $\alpha_r(r) = 0, \alpha_r(r) = 1$ for r respectively. We can get that $l_0 = 0.907$, $l_1 = 1.158$, $r_1 = 1.158$, $r_0 = 1.313$.

Then the left centroid function of $\widetilde{A}$ is the function α_l in the domain $l \in [l_0, l_1]$. The right centroid function of $\widetilde{A}$ is the function α_r in the domain $r \in [r_1, r_0]$. The centroid of this T2 FS is in triangular shape, which can be expressed as (30) if the variables l and r are replaced with x.

$$\alpha(x) = \begin{cases} \frac{5(x^3+8x-8)}{5x^3-36x+48} & 0.907 \le x \le 1.158 \\ \frac{5(x^3-20x+24)}{5x^3-24x+32} & 1.158 \le x \le 1.313 \end{cases} \tag{30}$$

The results is plotted in Fig 2. It is shown that the centroid function is also in triangular shape. With (24), the final centroid defuzzification value is 1.1327.

Here are two more complicated examples.

Example 2: Piecewise linear LMF and UMF, and triangle secondary MFs [19], which is also similar to the example of [11]:

$$\underline{\mu}_{\widetilde{A}_0}(x) = \max\left\{ \begin{bmatrix} (x-1)/2, & 1 \le x \le 3 \\ (7-x)/4, & 4 \le x \le 7 \\ 0, & \text{otherwise} \end{bmatrix}, \begin{bmatrix} (x-2)/5, & 2 \le x \le 6 \\ (16-2x)/5, & 6 \le x \le 8 \\ 0, & \text{otherwise} \end{bmatrix} \right\} \tag{31}$$

$$\overline{\mu}_{\widetilde{A}_0}(x) = \max\left\{ \begin{bmatrix} (x-1)/6, & 1 \le x \le 4 \\ (7-x)/6, & 4 \le x \le 7 \\ 0, & \text{otherwise} \end{bmatrix}, \begin{bmatrix} (x-3)/6, & 2 \le x \le 5 \\ (8-x)/9, & 5 \le x \le 8 \\ 0, & \text{otherwise} \end{bmatrix} \right\} \tag{32}$$

which is shown in Figure 3. In this example, each secondary MF is chosen to be a triangle of height one whose base equals $\overline{\mu}_{\tilde{A}}(x) - \underline{\mu}_{\tilde{A}}(x)$ and whose apex location Apex(x) is parameterized as

$$Apex(x) = \underline{\mu}(\tilde{A})(x) + w[\overline{\mu}(\tilde{A})(x) - \underline{\mu}(\tilde{A})(x)] \tag{33}$$

where $w = 0, 0.25, 0.5, 0.75, 1$.

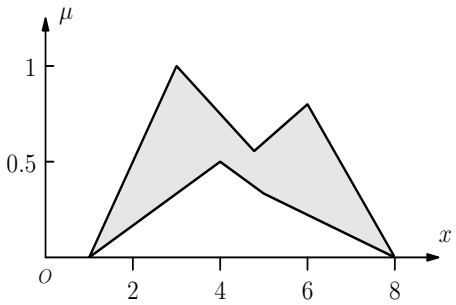

Fig. 3. The FOU of Example 2

Set $w = 0$, let $\alpha_l = 0, 1$ for (20), $\alpha_r = 0, 1$ for (22), then we can get $l_0 = 3.6605$, $l_1 = 4.2667$ and $r_0 = 4.9917, r_1 = 4.2667$, respectively. Then the left centroid function $\alpha_l(l)$ with $l \in [l_0, l_1]$ and right centroid function $\alpha_r(r)$ with $r \in [r_1, r_0]$

can be obtained. Replacing l, r with the same variable x, $\alpha_l(x)$ and $\alpha_r(x)$ can be plotted together.

The other cases for $w = 0.25, 0.5, 0.75, 1$ can also be obtained in a similar way. The two pairs of end points for the left centroid and right centroid functions for the different cases of w are listed in Table III. The left and right centroid functions are plotted in Fig. 4. These are almost the same as the results of [19] which are computed with $N = 10000$, $m = 100$ respectively.

TABLE III
THE CENTROID FUNCTIONS BOUNDS OF EXAMPLE 2

w	$[l_0, l_1]$	$[r_1, r_0]$
0	[3.6605, 4.2667]	[4.2667, 4.9917]
0.25	[3.6605, 4.3008]	[4.3008, 4.9917]
0.5	[3.6605, 4.3208]	[4.3208, 4.9917]
0.75	[3.6605, 4.3340]	[4.3340, 4.9917]
1	[3.6605, 4.3433]	[4.3433, 4.9917]

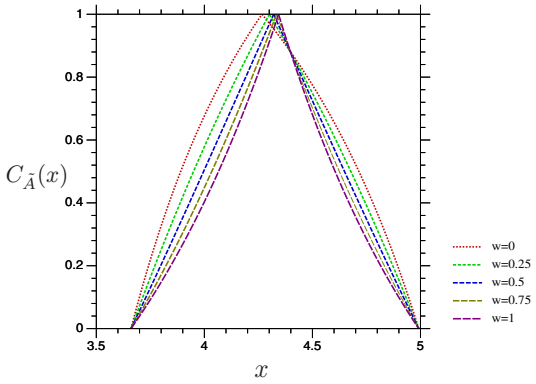

Fig. 4. The centroid functions of Example 2

All the centroid functions are kept in triangular shape with $l_1 = r_1$. With (24), the final centroid defuzzification values of these fuzzy sets are $4.4640, 4.4800, 4.4918, 4.5012, 4.5090$ respectively.

Example 3: Gaussian LMF and UMF, and trapezoidal secondary MFs [19], which is also similar to the example of [11]:

$$\overline{\mu}_{\widetilde{A}_0}(x) = \max\left\{\exp\left[-\frac{(x-3)^2}{8}\right], 0.8\exp\left[-\frac{(x-6)^2}{8}\right]\right\} \quad (34)$$

$$\underline{\mu}_{\widetilde{A}_0}(x) = \max\left\{0.5\exp\left[-\frac{(x-3)^2}{2}\right], 0.4\exp\left[-\frac{(x-6)^2}{2}\right]\right\} \quad (35)$$

which is shown in Figure 5. The secondary MF of $\widetilde{A}$ is chosen to be a trapezoid whose base equals $\overline{\mu}_{\widetilde{A}_0}(x) - \underline{\mu}_{\widetilde{A}_0}(x)$ and whose top is defined by left and right endpoints, which are $\underline{\mu}_{\widetilde{A}_1}(x)$ and $\overline{\mu}_{\widetilde{A}_1}(x)$, and both are parameterized as

$$\underline{\mu}_{\widetilde{A}_1}(x) = \underline{\mu}_{\widetilde{A}_0}(x) + 0.6w\left[\overline{\mu}_{\widetilde{A}_0}(x) - \underline{\mu}_{\widetilde{A}_0}(x)\right] \quad (36)$$

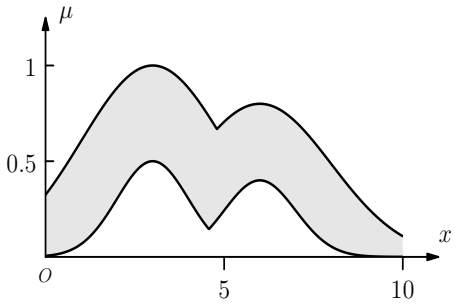

Fig. 5. The FOU of Example 3

$$\overline{\mu}_{\widetilde{A}_1}(x) = \overline{\mu}_{\widetilde{A}_0}(x) - 0.6(1-w)\left[\overline{\mu}_{\widetilde{A}_0}(x) - \underline{\mu}_{\widetilde{A}_0}(x)\right] \quad (37)$$

where $w = 0, 0.25, 0.5, 0.75, 1$, and the domain is $x \in [0, 10]$.

Set $w = 0$, let $\alpha_l = 0, 1$ for (20), $\alpha_r = 0, 1$ for (22), then we can get $l_0 = 3.156$, $l_1 = 3.680$, $r_1 = 5.059$, $r_0 = 5.675$, respectively. Then the left centroid function $\alpha_l(l)$ with $l \in [l_0, l_1]$ and right centroid function $\alpha_r(r)$ with $r \in [r_1, r_0]$ can be obtained. Replacing l, r with the same variable x, $\alpha_l(x)$ and $\alpha_r(x)$ can be plotted together.

The other cases for $w = 0.25, 0.5, 0.75, 1$ can also be obtained in a similar way. The two pairs of end points for the left centroid and right centroid functions for the different cases of w are listed in Table IV. The left and right centroid functions are plotted in Fig. 6. These are almost the same as the results of [19] which are computed with KM algorithms of $N = 10000$, $m = 100$ and Table I respectively.

TABLE IV
THE CENTROID FUNCTIONS BOUNDS OF EXAMPLE 3

w	$[l_0, l_1]$	$[r_1, r_0]$
0	[3.1557, 3.6800]	[5.0589, 5.6747]
0.25	[3.1557, 3.8281]	[4.9454, 5.6747]
0.5	[3.1557, 3.9286]	[4.8686, 5.6747]
0.75	[3.1557, 4.0013]	[4.8131, 5.6747]
1	[3.1557, 4.0565]	[4.7711, 5.6747]

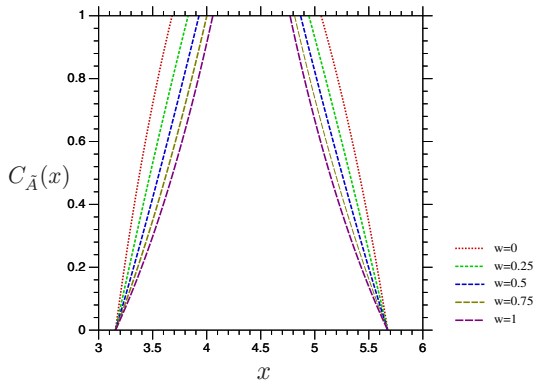

Fig. 6. The centroid functions of Example 3

All the centroid functions are kept in trapezoidal shape. With (24), the final centroid defuzzification values of these fuzzy sets are $4.9080, 4.8721, 4.8565, 4.8490, 4.8454$ respectively.

This general type-2 defuzzification method not only utilizes the rooting finding method in centroid computation of the IT2 FSs, and also avoid in the data sampling in the second membership function, the repetitive iterate computation can be avoided, which can greatly reduce the amount of computation in application. In fact, except the possible root finding iteration at the two end points $\alpha = 0, 1$, there is no iteration in our method at all, which is helpful to loose the computation bottleneck for defuzzification applications, even for realtime implementation requirements.

Another advantage of our method is that, we use the integral operation of the membership function instead of the sum operation of the sampling data, the centroid value is the exact solution of the original problem, which is different from current approximate data sampling methods in essence. We can also use numerical integral method from the same sampling data of current sampling methods where computation error can be greatly reduced, and the error bound can be estimated in advance with the theory in numerical analysis.

Note that, both in the IT2 FS and general T2 FS centroid computation, we do not pay much attention on the lower level implementation of the algorithms. As we have mentioned, this can be done through the proper use of software packages or the programming of computer languages directly. The numerical integration and root finding methods in numerical analysis and the computation cost reduction techniques such as Enhanced KM algorithms [27] can be applied, but this is beyond the main topic of this paper.

V. Conclusion

With the continuous form of the centroid computation of interval type-2 (IT2 FS) fuzzy sets (IT2 FSs), this paper transforms the centroid computation of IT2 Fs into root finding problems. When the FOUs of the IT2 FS are given, the centroid of the IT2 Fs can be computed directly and accurately. Then efficient methods for the centroid computation of general type-2 fuzzy sets with linear membership function are provided. Numerical examples illustrate the proposed approaches.

Type-2 Fuzzy Airplane Altitude Control:

A Comparative Study

Sheir Afgen Zaheer and Jong-Hwan Kim

{sheir, johkim}@rit.kaist.ac.kr

Abstract— **The standard fuzzy logic controllers, also known as type-1 fuzzy logic controllers, have often been criticized for their inability to handle uncertainties in the control processes. Therefore, a lot of attention is being focused on type-2 fuzzy logic controllers, especially, the interval type-2 fuzzy logic controllers. This paper aims at developing both type-1 and type-2 fuzzy logic controllers for an airplane altitude control problem and comparing their performances. Both the controllers have similar knowledge bases, and both of them are tested in two simulation setups, an ideally modeled setup and a setup with uncertainties. The results show that the type-2 fuzzy logic controller outperforms the type-1 fuzzy logic controller, especially, in the environment with uncertainties. Therefore, this research seems to validate the superiority of type-2 fuzzy logic control in making the controllers independent of uncertainties in intricate model details.**

Keywords — **Type-2 fuzzy logic control, altitude control, fuzzy airplane control.**

I. INTRODUCTION

The popularity of type-2 fuzzy systems has risen enormously during the past few years. Though the theoretical concepts of type-2 fuzzy sets date back to 1975 [1], the limitation of computational resources limited their practical applications. However, with the massive improvements in computational capabilities in the recent years, type-2 fuzzy systems are being widely used in various control and decision making problems.

Moreover, the type-2 fuzzy systems also answer the skepticism regarding the fuzziness of type-1 fuzzy systems. Type-1 fuzzy sets have a crisp membership value which means that each element in a set has a predefined fixed value; this violates the notion of fuzziness regarding uncertainties. A two-layered architecture to improve nonlinearity handling in type-1 fuzzy controller for the systems with dead-zones has been proposed [2]. However, the causes of nonlinearities and uncertainties in real systems are not always known. Such problems associated with uncertainties in systems or the fuzzy rules are solved in type-2 fuzzy systems by assigning a secondary membership function, to each element in the fuzzy set, rather than a crisp membership value [1], [3]. This type of type-2 fuzzy systems, known as the general type-2 fuzzy sets, are computationally very complex. Therefore, interval type-2 fuzzy systems (IT2FS) have been developed to provide a satisfactory compromise between the uncertainty handling of type-2 systems and the computational complexity [3], [4]. The IT2FS assigns a range of membership values to each element in such a way that every value in the specified range has a full secondary membership grade. Fig. 1 gives a graphical depiction of a typical triangular interval type-2 fuzzy set. The shaded region that defines the range of membership values for a particular element is called the foot of uncertainty (FoU) [3].

Type-2 fuzzy systems have been used in many research problems. Type-2 fuzzy logic has been widely used in mobile robot control and navigation applications [5]-[10]. A simplified real time controller for a coupled-tank liquid-level control has also been developed [11]. Moreover, type-2 fuzzy logic has also been used in medical diagnosis [12], [13]; human machine interaction [14]; traffic control systems [15], etc. Apart from the above mentioned contributions, type-2 fuzzy systems have also been used in management surveys [16] and human resource management [17]. However, there has been a very little research about the performance comparison of the type-1 and type-2 fuzzy systems developed through similar rules and membership functions, and subjected to identical testing conditions.

This paper compares the performances of the type-1 fuzzy and the interval type 2 fuzzy logic (IT2FLC) control systems for a multi-input multi-output (MIMO) airplane altitude control simulation. Type-1 fuzzy control systems have been widely used in the airplane altitude control problem. Different kinds of fuzzy altitude and/or flight controllers have been developed. Complete type-1 fuzzy flight control system has been developed [18]. Another research was aimed at developing decoupled PID controllers for speed and heading control, and a type-1 fuzzy altitude controller [19]. However, none of the

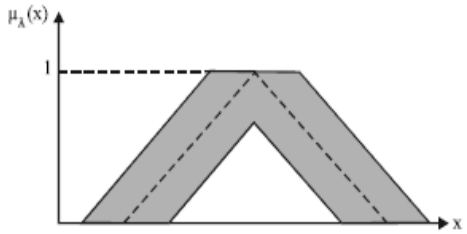

Fig. 1. Interval type-2 triangular fuzzy set.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology (2010-0000831)

previous researches at flight control systems have employed type-2 fuzzy control systems.

The proposed system aims at developing a fuzzy flight control system (FFCS) with two decoupled controllers: a fuzzy heading controller (FHC) and a fuzzy altitude controller (FAC). FHC is designed as a type-1 fuzzy control system and its major functions are to control airplane's heading and lateral stability. FAC, on the other hand, is developed, first by employing a type-1 fuzzy altitude controller (T1FAC) and then by an interval type-2 fuzzy altitude controller (IT2FAC). Two sets of simulations are conducted: one with ideally modeled system and the other with a system with uncertainties. These simulations put both the T1FAC and the IT2FAC under test for each of the simulation scenarios. The resulting responses are then compared.

The paper is organized as follows: Section II describes the airplane model. Section III gives an overview of the overall control scheme and the FHC, and section IV explains the two altitude controllers, T1FAC and IT2FAC. Section V describes the results of T1FAC and IT2FAC. Finally the discussions and conclusion follow in section VI.

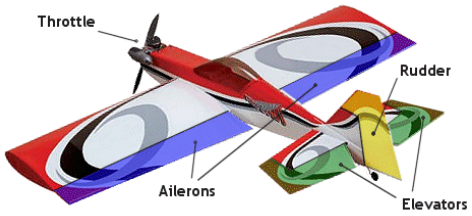

Fig. 2. Basic airplane controls.

II. The Airplane Model

In order to assess the performances of the developed controllers, an airplane model is required. A propulsion based RC airplane is modeled. The control surfaces for a typical RC airplane are shown in Fig. 2. The throttle is used to regulate the speed of the airplane by varying the rotational speed of the propeller, the elevator is used to control the airplane's ascent and descent, the ailerons are used for airplane's lateral stabilization and mid air turning, and the rudder is used for the on-ground taxiing of the airplane. The specific RC model used as a control problem in this research is the Kadet MK-II RC airplane model. The aerodynamic parameters for MK-II RC airplane used are the same as in the previous research [19].

Aerosim Blockset in Simulink environment is a simulation tool for modeling and control of airplanes [20]. The Aereosim Blockset is configured for the Kadet MK-II RC airplane by using the aerodynamic configuration file consisting of aerodynamic coefficients and parameters for the Kadet MK-II RC airplane [19]. A snapshot of the Simulink control model is shown in Fig. 3. As evident from Fig. 3, any airplane can be modeled by plugging in the corresponding airplane parameters to each block.

III. The Fuzzy Flight Control System

The fuzzy flight control system (FFCS) consists of two decoupled controllers: A fuzzy heading controller (FHC) and a fuzzy altitude controller (FAC). The goal of FFCS, schematically shown in Fig. 4, is to autonomously track the desired altitude and the heading, and then maintain the desired

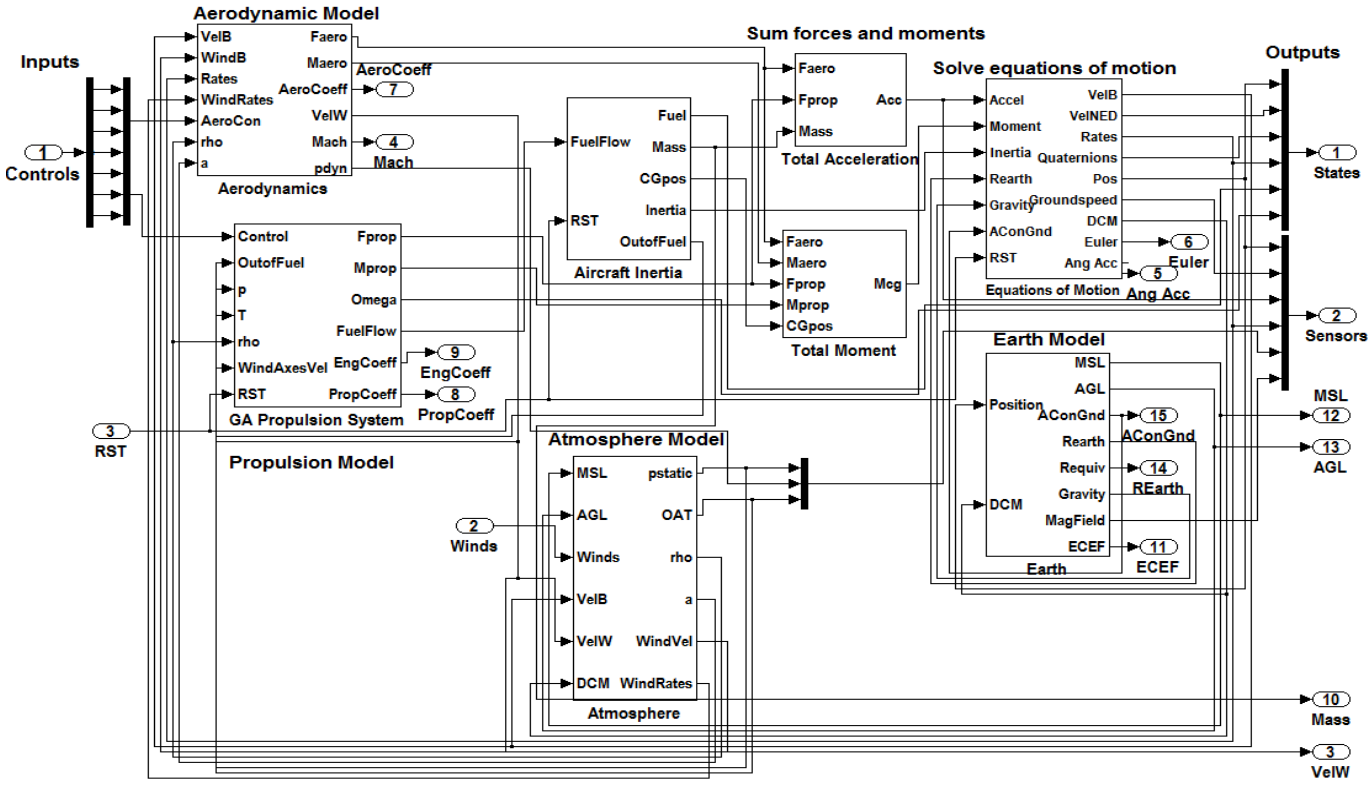

Fig. 3. The block diagram of Simulink based airplane model.

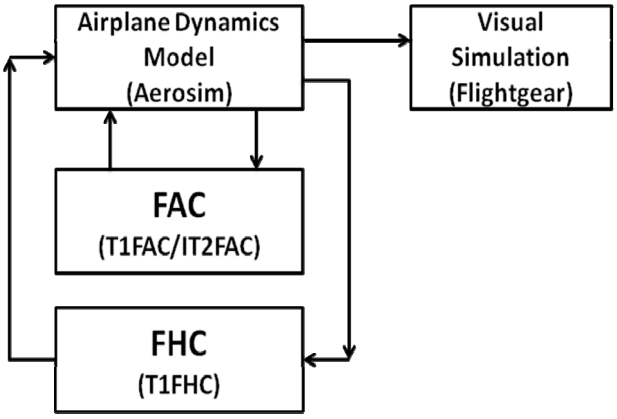

Fig. 4. Overall FFCS architecture.

values once they are achieved. The desired altitude and heading are calculated using the three desired position co-ordinates specified by the user. The overall system is also linked with Flightgear for the visual simulation of the airplane behavior.

A. *The Fuzzy Heading Controller*

Though this research is aimed at the performance comparison of type-1and type-2 fuzzy systems in altitude control, designing a heading controller is imperative because of the following two reasons:

- The heading controller is in charge of the ailerons, thus providing the in-flight lateral stability essential for the airplane to track the desired altitude.
- The airplane, while ascending, descending or maintaining altitude, also experiences some horizontal displacement; the heading controller ensures that the horizontal displacement is in the required direction.

The heading controller employed in this research is a FHC. The FHC is a type-1 fuzzy controller; the schematics along with the membership functions are shown in Fig. 5. The bank angle calculated by FHC is then transformed to the control surface level command to the ailerons by using the following proportional compensator:

$$Aeleron = (0.55\pi/180) * BankAngle. \quad (1)$$

IV. The Fuzzy Altitude Controllers

The FACs have been widely implemented by researchers for controlling the altitude of both manned and unmanned aerial vehicles. The altitude controller is a multi-input and multi-output (MIMO) system, generally developed by considering altitude error, change in altitude error and airspeed as the controller's inputs while elevator/angle of attack and throttle level are the controller's output. The throttle is linked with the FAC because throttle regulates the amount of thrust required by an ascending or descending airplane.

The similar control schematics are considered in this paper. The rule base for the controller is developed using the expert knowledge based on literature review and personal experiences with RC airplane control [19]. The fuzzy set representation and the membership functions for the inputs

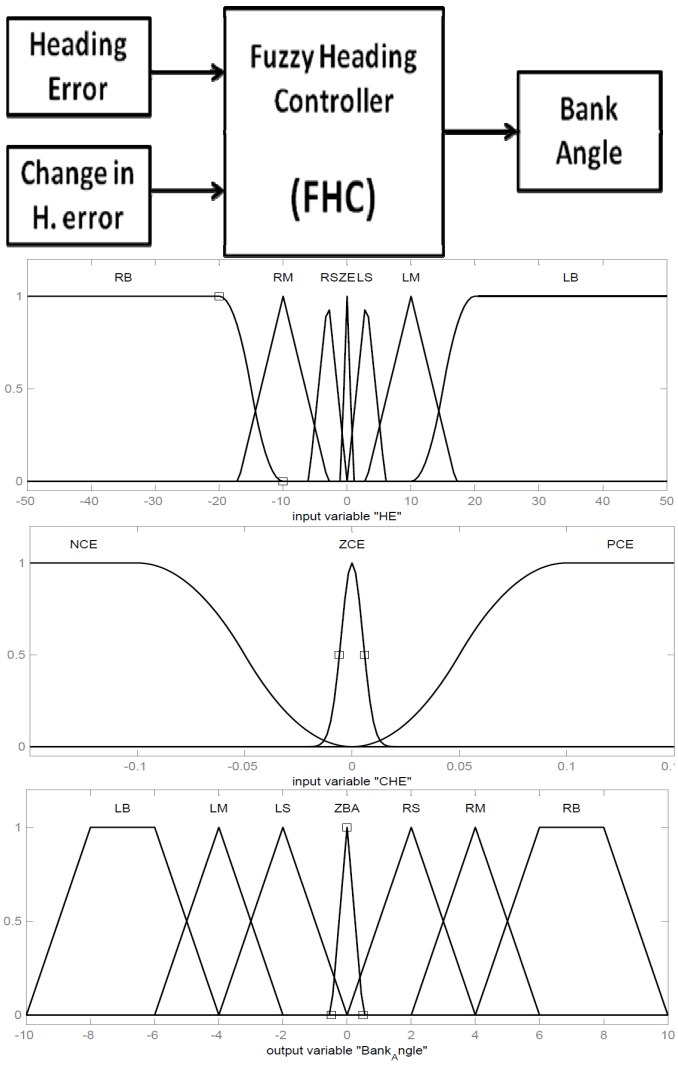

Fig. 5. (Top to Bottom) The schematics of FHC, and the membership functions of inputs and output respectively.

and outputs for the T1FAC and the IT2FAC are discussed in the following subsections.

A. *The Type-1 Fuzzy Altitude Controller*

The first controller developed for altitude control is T1FAC. T1FAC was developed as a Mamdani type-1 fuzzy logic controller. This 3-input 2-output controller was tuned via simulations. Fig. 6 shows the architecture of the T1FAC along with the membership functions for inputs and outputs, respectively. The t-Norm and s-Norm operators used are "min" and "max", respectively, with "min" implication and "max" aggregation. The centroid method is employed for defuzzification.

B. *The Interval Type-2 Fuzzy Altiude Control*

The layout of the IT2FAC and the membership functions for inputs and outputs, respectively are shown in Fig. 7. The interval type-2 fuzzy sets are defined using a principal membership function (similar to T1FAC) with a certain footprint of uncertainty (FoU). The principal membership

function and FoU are transformed into the left and right membership functions (LMF and RMF) according to the following membership definitions for triangular membership functions:

LMF = triangular MF [*A-FoU*N, B-FoU*N, C-FoU*N*]

RMF = triangular MF [*A+FoU*N, B+FoU*N, C+FoU*N*] (2)

where *A*, *B*, and *C* are the three index parameters for the primary triangular member ship functions. *N* is the normalization factor given as:

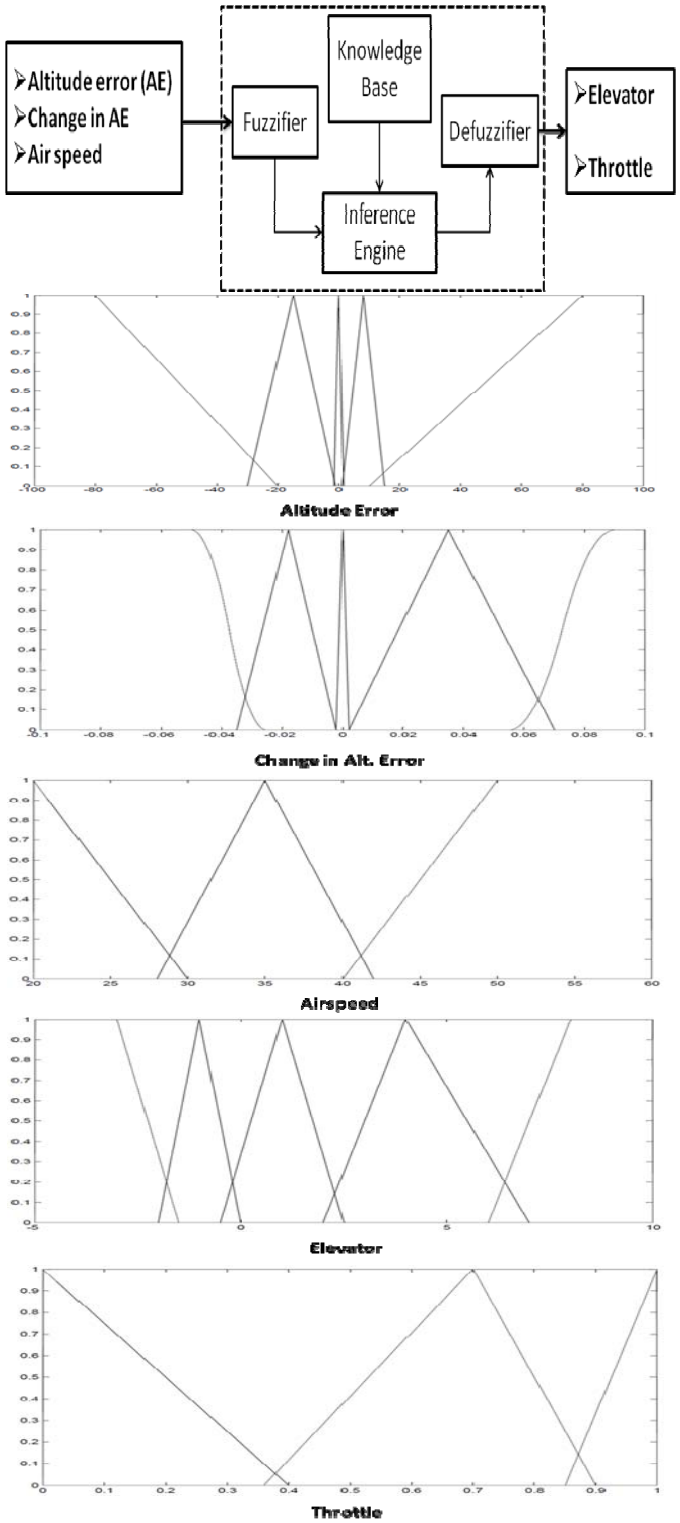

Fig. 6. (Top to Bottom) The schematics of T1FAC, and the membership functions of inputs and outputs respectively.

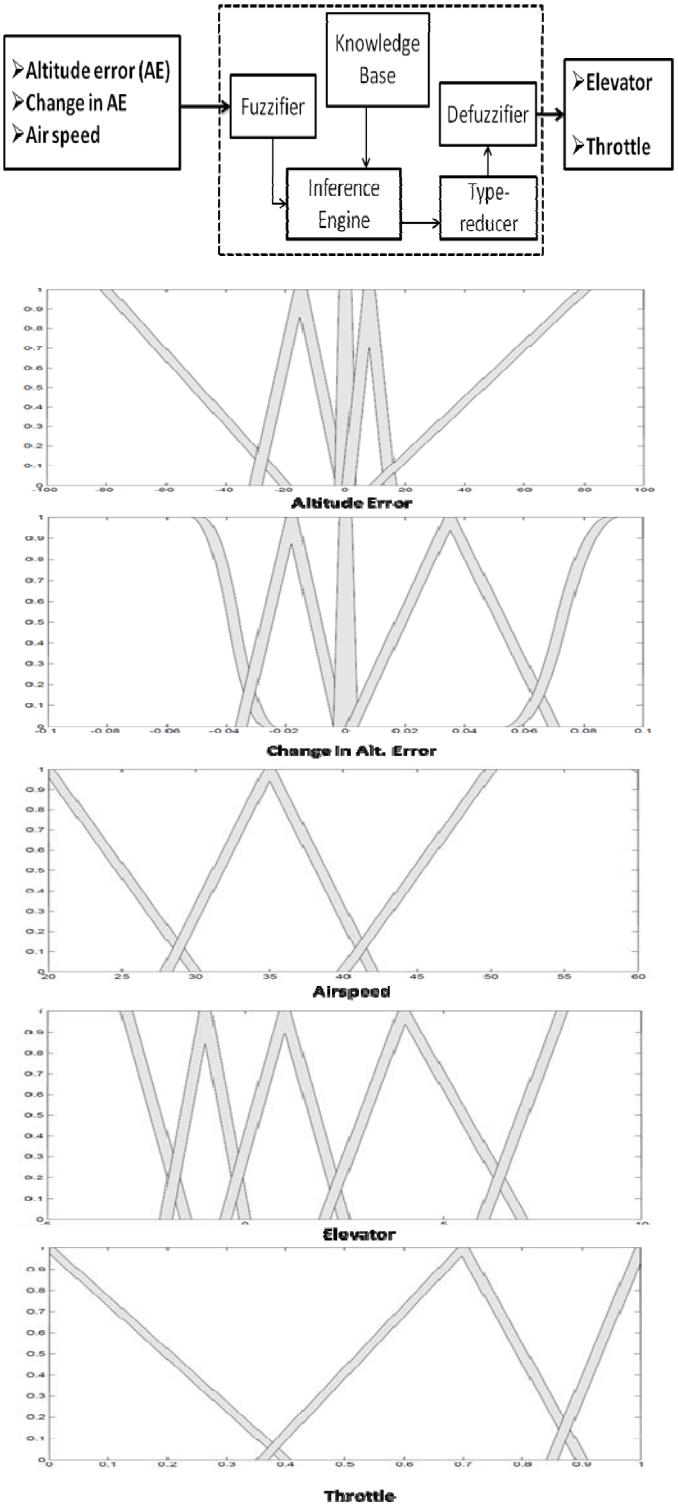

Fig. 7. (Top to Bottom) The schematics of IT2FAC, and the membership functions of inputs and outputs respectively.

$$N = (UoD_{max} - UoD_{min})/200 \quad (3)$$

where UoD_{max} and UoD_{min} are the maximum and minimum values, respectively, of the universe of discourse (UoD). Whereas, for Gaussian membership functions, the FoU defined is used to convert the membership functions to a pair of LMFs and RMFs with same variance but variable means. The conversion is defined by the following equations:

$$LMF = gauss\ MF\ [\sigma, \mu - FoU*N]$$
$$RMF = gauss\ MF\ [\sigma, \mu + FoU*N] \quad (4)$$

where σ and μ are the variance and the mean of the primary membership functions, respectively. The fuzzy operations used are similar to those used in T1FAC but with an addition of "KM type reduction" [3], [21].

V. Simulations and Results

Two types of simulations were conducted to gauge the performances of both the controllers. The first simulation setup was conducted under an ideal environment with no noises and uncertainties. However, the second setup had a level of random noise associated with both the actuator model and the sensory model. The introduction of this noise made the airplane model uncertain, i.e., the system no longer was exactly the same for which the altitude controller was designed. The performances in both the simulation setups were evaluated by their success in tracking the reference altitudes. In the particular scenario discussed here, the airplane, initially at an altitude of 500m, was required to ascend to a height of 700m. Once a steady state was achieved the airplane was then required to descend to an altitude of 300m. Additionally, simulations to observe the response of the developed IT2FAC under the ramp reference input were also conducted. The setup for this simulation scenario is explained in section V-D The simulation setup was also linked with a visual simulator to observe the airplane response in a 3D simulated environment. Flightgear was used as a visual simulator. Flightgear is an open-source flight simulator development project licensed under the GNU General Public Liscence. A snapshot of the visual simulation is shown in Fig. 8.

Fig. 8. A snapshot of the visual simulation in Flightgear.

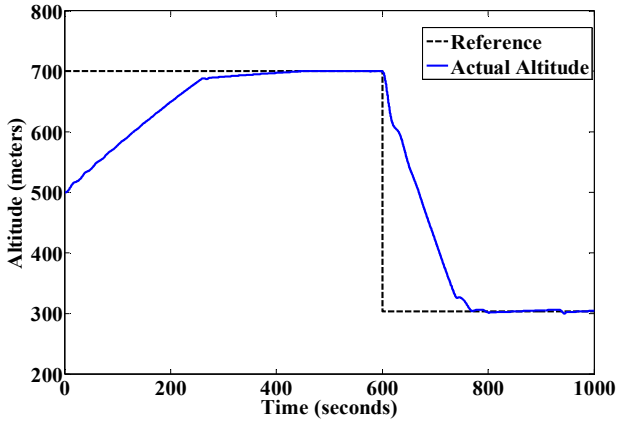

Fig. 9(a). Results of T1FAC in the ideal simulation setup.

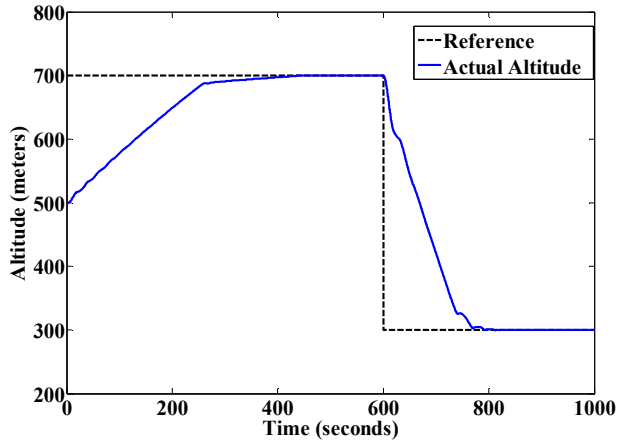

Fig. 9(b). Results of IT2FAC in the ideal simulation setup.

A. The Ideal Simulation Environment

The simulation results are shown in Fig. 9 (9(a) for T1FAC and 9(b) for IT2FAC). As evident from the figure, both the controllers were able to perform the job at the hand. However, when analyzed in detail, the steady state response under T1FAC had a slight measure of unwanted oscillations. Moreover, the mean steady state error over a number of simulations, in case of T1FAC, was up to 0.17 meter; while in case of IT2FAC, the steady state error was under 0.03 meter.

B. The Uncertain Simulation Environment

In this setup, a level of uncertainty was introduced in the plant model. This uncertainty was introduced to slightly perturb the airplane model and to propagate uncertainty to the actuator and sensor modules. This arrangement provided a system whose behavior differed from the actual model for which the controller was designed and tuned. Moreover, it also provided with the opportunity to validate the often advocated hypothesis about the superiority of the interval type-2 fuzzy logic controllers, as compared to the type-1 fuzzy logic controllers, in handling uncertainties. The results of these simulations are summarized graphically in Fig. 10 (10(a) for T1FAC and 10(b) for IT2FAC). It can be seen that the steady state response generated by T1FAC is not satisfactory.

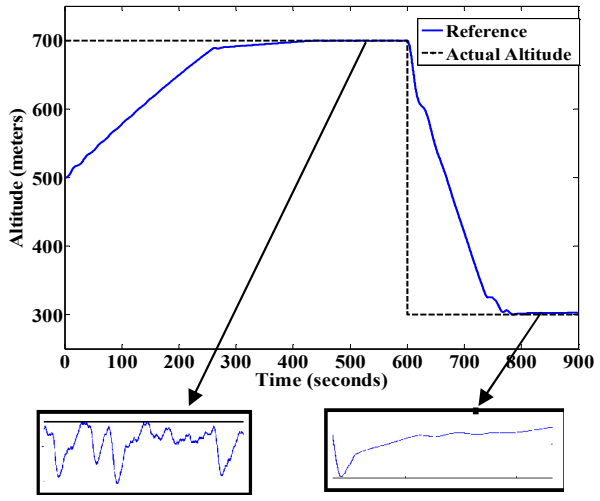

Fig. 10(a). Results of T1FAC in the simulation setup with uncertainties (Bottom blocks are the magnified steady state responses, (RMSE = 3.58 m)).

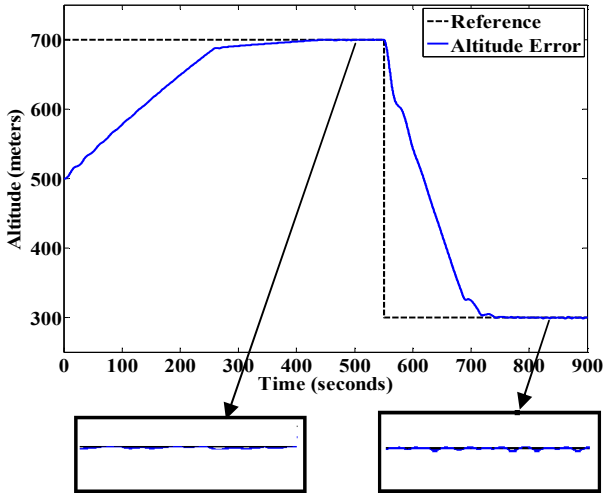

Fig. 10(b). Results of IT2FAC in the simulation setup with uncertainties (Bottom blocks are the magnified steady state responses (RMSE = 0.43 m)).

C. *Effects of Different Values for Footprint of Uncertainties*

The IT2FAC had an additional parameter that required tuning; this parameter was the footprint of uncertainty (FoU), given in (2). An appropriate value for FoU was thus needed. The optimization of FoU is out of the scope of this paper. However, the effects of different values of FoU, in the neighborhood of the FoU*s* in the previous simulations, on the steady state performance were studied. The study state performances, for different FoU values, in terms of steady state root mean squared errors (RMSE) are summarized in Fig. 11. In each of the cases in Fig. 11, the FoU was assumed to be the same for all the fuzzy membership functions. It is evident from these simulation results that a balanced level of FoU value is essential for the desired performance of the system. Therefore, the value of the FoU should not be too large to

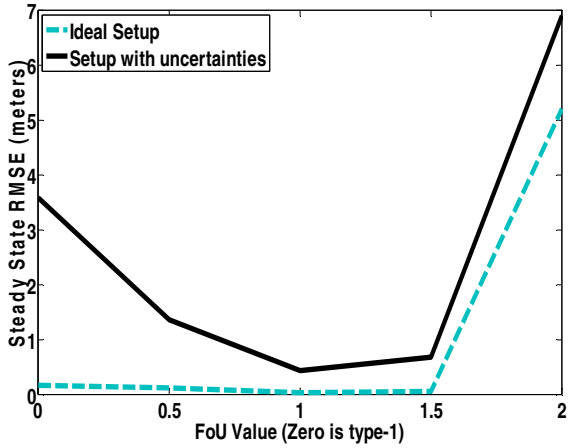

Fig. 11. Steady state RMSE as the result of simulations with different values of FoUs

vanquish the minimum level of preciseness required for the distinctive identifications of the fuzzy sets.

D. *Ramp response of the IT2FAC*

All the results and analysis in the previous subsections were based on the step response of the developed IT2FAC. This subsection deals with the response of the IT2FAC when subjected to a reference input with a ramp (sloped) profile. The results of the simulation, with ramp as a reference input, are shown in Fig. 12. In this setup, the airplane was made to track the reference altitude trajectory that linearly ascended to an altitude of 600 meters, then stayed there for a while, and finally, descended linearly to the altitude of 475 meters. As evident from the figure, a successful tracking response was observed.

VI. Discussions and Conclusion

The purpose of this paper was to compare the performances of the T1FAC and the IT2FAC in an airplane altitude control problem. In the ideal simulation environment, both the controllers were able to track the desired altitude. However in the second simulation environment that had some modeling uncertainties, IT2FAC was the clear winner because

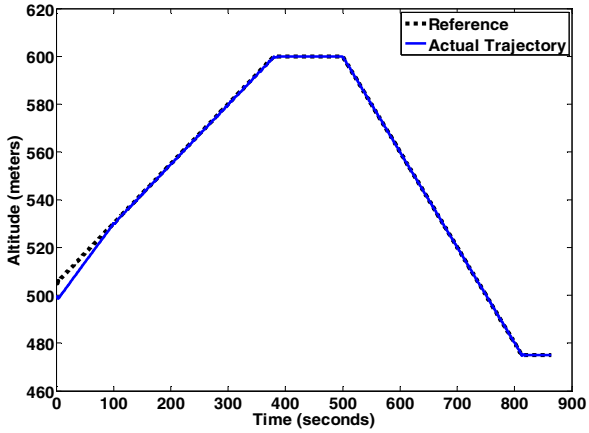

Fig. 12. Tracking response of IT2FAC to a ramp input

the system with T1FAC showed oscillatory behavior around the reference altitude set-points.

This success of IT2FAC can be attributed to its non-crisp membership functions. These non-crisp membership values make IT2FAC more robust than its simpler counterpart with crisp membership values, i.e., T1FAC. The control problem in this study, however, emphasized only on stability and steady state response. Therefore, the control problems and studies emphasizing transient response characteristics like rise time, settling time, etc., might limit the extent to which these results can be generalized. However, considering the current problem, it can be safely deduced that interval type-2 fuzzy logic controller outperforms type-1 fuzzy controller, especially, in handling uncertainties. This finding also seems to be consistent with most of the research done on type-2 fuzzy logic controllers.

The IT2FAC can be further improved by optimizing the controller for desired transient and steady state responses, such as rise time and settling time, etc. Moreover, the FHC can also be upgraded to type-2 fuzzy control for a complete type-2 fuzzy flight control system.

***Abstract*—In this paper, we present a solution to Zadeh's Magnus challenge problem on linguistic probabilities. First, we implement Zadeh's solution to this problem. Then, we use the intersection-product syllogism and a syllogism based on the entailment principle to interpret the problem so that it can be solved via Linguistic Weighted Averages. We show that the problem can be solved by calculation of pessimistic (lower) and optimistic (upper) probabilities via Linguistic Weighted Averages. Then, we choose vocabularies for quantifiers and linguistic probabilities that are involved in the problem statement. The vocabularies are modeled using interval type-2 fuzzy sets. We calculate optimistic (upper) and pessimistic (lower) probabilities, which naturally would be interval type-2 fuzzy sets. Finally, we map the pessimistic and optimistic probabilities to linguistic probabilities present in the vocabularies, so that the results can be comprehended by a human.**

***Index Terms*—Computing with words, interval type-2 fuzzy sets, linguistic weighted average, lower and upper probabilities**

I. Introduction

Computing with words (CWW) is believed to play a pivotal role in the mainstream of research on automation of everyday reasoning and decision-making [8], [10], [15], [32]. Everyday reasoning exploits information stated in natural language; therefore, pertinent techniques are needed to describe and interpret information stated in natural language propositions, combine information coming from multiple sources with different degrees of reliability, and make decisions based on such information.

In essence, CWW can be viewed as a computational theory of perceptions [29]. Human perceptions are about physical and mental objects like length, color, speed, time, direction, strength, likelihood, truth, intent, etc. The key challenge for building a computational theory of perceptions is that perceptions of such objects are imprecise, due to the limited accuracy of human's sensorimotor system. As a result, one of the central concepts of CWW is "precisiation of meaning," which calls for building a computational model pertinent to the semantics of a statement in a natural language. This is mainly performed by assigning fuzzy sets to linguistic attributes, be they possibilistic, probabilistic, or veristic [27]. It is also believed that for CWW, a viable method of completing this task is collecting data about a linguistic constraint from subjects, and building type-2 fuzzy sets based on the empirical data [11].

Recently, Zadeh proposed that two levels of CWW could be distinguished [13]: In *basic* (level 1) CWW, information carriers are numbers, intervals, and words. Propositions are usually simple "assignment" ones like: X *is between 3 and 4* ($X \in [3,4]$), X *is very small*, or *If* X *is high, then* Y *is low*. In *advanced* (level-2) CWW, information carriers can also be more complicated natural language propositions involving modifiers, truth values, possibilistic constraints, linguistic probabilities, usuality constraints, etc.

Essentially, in level-2 CWW, assignment of constraints in such statements can be implicit, e.g., using a modifier "Some" in the statement "Some PhD students at the University of Southern California are Iranian" implies assigning a linguistic value (Some) to the portion of USC's PhD students who are Iranian.

Zadeh asserts that in level-2 CWW, propositions (and not just words) are precisiated, i.e. the *whole statement* is reduced down to the assignment of generalized constraints to some variables; therefore, level-2 CWW must exploit techniques for capturing the semantics of a proposition in a natural language in terms of the semantics of its building blocks.

It is worth noting that the existing approaches to rule-based fuzzy systems mainly deal with level-1 CWW, since they employ the calculi of fuzzy if-then rules.

As stressed in [12], a scientifically correct first order model for a word is a type-2 fuzzy set. Zadeh also predicts that type-2 fuzzy sets will play a central role in level-2 CWW [13]; thus, it can be envisioned that type-2 fuzzy sets will be used as the rudiments of advanced CWW in the forthcoming years. In essence, we view CWW as the interactions between a group of people and at least another person (or computer). Henceforth,

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

the group's perception of a word needs to affect the uncertainty about the word in the word's fuzzy set model. This can be viewed as the main motivation for using type-2 fuzzy sets in CWW. Moreover, as will be seen in the sequel, type-2 fuzzy sets provide a natural framework to provide uncertain numeric values like "about 20% " as solutions to CWW problems, and the term "about" captures the inter-person and intra-person uncertainties propagated via information aggregation methods.

One of the most important problems in CWW is aggregation of linguistic information for hierarchical multi-criteria decision making. Linguistic Weighted Averages are believed to provide an appropriate framework for performing this task [19], [20], especially when we deal with words precisiated with type-2 fuzzy sets.

A set of challenge problems for testing CWW methodologies has been proposed in [25], [28], [30], [33]. Perhaps the most famous challenge problem in this set is the so-called "tall Swedes" problem: *Most Swedes are tall. What is the average height of Swedes?*

We examined the solution to the "tall Swedes" challenge problem in [18]. One of the most challenging problems in level-2 CWW is manipulation of propositions containing linguistic and imprecise probabilities [31], [13], and some of Zadeh's challenge problems deal with linguistic probabilities.

In this paper, we focus on the following problem (called the "Magnus problem") involving linguistic quantifiers: *Most Swedes are tall. Most tall Swedes are blond. What is the probability that Magnus (a Swede picked at random) is blond?*

It is worth noting that although these kinds of problems may appear to be "toy problems," serious consideration of them leads to solution of totally new classes of CWW problems. As will be seen in this paper, the solution of the Magnus problem calls for calculation of linguistic lower and upper probabilities, which are closely related to Dempster-Shafer theory of evidence [5]. We will demonstrate that the Linguistic Weighted Average method can contribute to the solution of this problem via manipulating linguistic probabilities.

It is worth noting that we believe that there is no unique solution to Advanced CWW problems, including the Magnus problem. There might be different methodologies for solving a particular problem, and additionally, one can choose different vocabularies to decode the solution so that it can be comprehended by humans. However, the solutions should be linguistically similar.

The rest of this paper is organized as follows: Section II elaborates on Zadeh's methodology for solving the Magnus problem; Section III implements Zadeh's solution to the Magnus problem, and maps it into a linguistic probability via linguistic approximation; Section IV is a critique of Zadeh's solution; Section V uses some standard reasoning tools to interpret the Magnus problem so that it can be solved via Linguistic Weighted Averages, and demonstrates that this gives rise to the calculation of type-2 fuzzy lower and upper probabilities; Section VI studies the effect of the size of the vocabularies on the solution, and shows that when the size of the vocabulary of linguistic probabilities is small, the linguistic lower and upper probabilities are translated to the same word through linguistic approximation; and, Section VII presents some conclusions and suggestions for future research.

II. Zadeh's Methodology for Solving The Magnus Problem

Zadeh solves the Magnus problem by utilizing the following intersection-product syllogism [28]:

$Q_1 A$'s are B's
$Q_2(A$ and $B)$'s are C's

$Q_1 \otimes Q_2 A$'s are (B and C)'s

At least $(Q_1 \otimes Q_2)$ A's are C's

in which Q_1 and Q_2 are linguistic quantifiers, A, B, C are linguistic attributes, and $\otimes$ denotes fuzzy multiplication determined by:

$$\mu_{Q_1 \otimes Q_2}(u) = \sup_{u=xy} (\min(\mu_{Q_1}(x), \mu_{Q_2}(y)) \tag{1}$$

At least is an operator acting on a fuzzy quantifier Q, and can be seen as the order relation $\leq$ extended by the extension principle as follows:

$$\mu_{At\ least(Q)}(x) = \sup_{y \leq x} \mu_Q(y), \quad x, y \in [0,1] \tag{2}$$

The intersection-product syllogism is a fuzzy extension of a simple calculation involving numeric quantifiers. Consider the following example: 50% of the students of the EE Department at USC are graduate students. 80% of the graduate students of the EE Department at USC are on F1 visa. Therefore, 50% $\times$ 80% of the graduate students of the EE Department at USC are on F1 visa. Consequently, *at least* 40% of the students of the EE Department at USC are on F1 visa (since some undergraduate students may be on F1 visa, we use the term *at least*).

It can easily be observed that in the Magnus problem, $Q_1 = Most$, $Q_2 = Most$, $A = Swede$, $B = tall$, and $C = blond$; therefore, it can be inferred that $At\ least$ $(Q = Most \otimes Most)$ Swedes are both tall and blond. On the other hand for a *(non-decreasing) monotonic quantifier* Q, i.e. one whose membership function $\mu_Q(u)$ is monotonically non-decreasing, $At\ least(Q) = Q$ [26]. For a proof of this proposition see Appendix A.

Zadeh views $Most$ as a monotonic quantifier, and hence $Most \otimes Most$ is monotonic. Therefore, the portion of Swedes who are both blond and tall is $Most \otimes Most$. Zadeh interprets a linguistic constraint on the portion of a population as a linguistic probability (LProb), and directly concludes that:

$$\text{LProb}(\text{Magnus is blond}) = Most \otimes Most \tag{3}$$

III. Implementation of Zadeh's Solution

Zadeh's elaboration on the Magnus problem does not include some components of CWW engines. He does not provide the exact membership functions of the fuzzy quantifier $Most$, the linguistic approximation method, or the vocabulary

of linguistic probabilities through which the result could be communicated with humans.

We believe that although a linguistic quantifier has the same mathematical nature as a linguistic probability (both of them are fuzzy subsets of the unit interval $[0, 1]$), they are semantically different: A linguistic quantifier imposes an elastic constraint on the *portion of a population having a specific attribute*, but a linguistic probability (e.g., *Very likely*) imposes a linguistic constraint on the more objective concept of *likelihood of a particular event*. This issue can be viewed as analogous to the difference between two ways of defining probability: the relative frequency definition and the axiomatic definition. The relative frequency approach defines the probability of an event in an experiment as the limit of the ratio of the number of occurrences of that event to the total number of repetitions of the experiment, when this number tends to infinity. The linguistic quantifier *Most* imposes a linguistic constraint on such a ratio. On the other hand, a set of linguistic probabilities (e.g., *Unlikely, Likely, Very likely, Very unlikely*) obeys a fuzzy version of axioms pertinent to probability theory [1]. The relative frequency approach is based on heuristics and the axiomatic approach bears more mathematical rigor.

In any solution of the Magnus problem (be it in a type-1 or a type-2 fuzzy logic framework) not only must one therefore construct a fuzzy set for modeling (precisiating) the quantifier $Most$, but one must also employ a vocabulary of fuzzy probabilities for linguistic approximation of the solution $Most \otimes Most$ containing a linguistic probability that is understandable by human beings. To do the latter, we choose a member of the vocabulary of linguistic probabilities whose Jaccard's similarity [4], [9] with $Most \otimes Most$ is the largest. Recall that the Jaccard's similarity measure between two type-1 fuzzy sets A and B, $s_J(A, B)$, is:

$$s_J(A, B) = \frac{\int_X \mu_{A \cap B}(x) dx}{\int_X \mu_{A \cup B}(x) dx} \tag{4}$$

We chose a right shoulder type-1 fuzzy set to model (precisiate) the linguistic quantifier $Most$[1], whose membership function is depicted in Fig. 1. We also constructed a nine word vocabulary of type-1 fuzzy sets to model the linguistic probabilities. The members of the vocabulary are: *Absolutely improbable, Almost improbable (AI), Very unlikely (VU), Unlikely (UL), Moderately likely (ML), Likely (L), Very likely (VL), Almost certain (AC), Absolutely certain*. Their membership functions are shown in Fig. 2. The extreme words *Absolutely improbable* and *Absolutely certain*[2] are naturally modeled via singletons, and hence are not shown in the figure.

Following Zadeh's philosophy of precisiation of $Most$ as a monotonic quantifier (which could be interpreted as $All \subset Most$), we chose the membership functions so that: $Almost\ improbable \subset Very\ unlikely \subset Unlikely$ and $Likely \subset Very\ likely \subset Almost\ certain$.

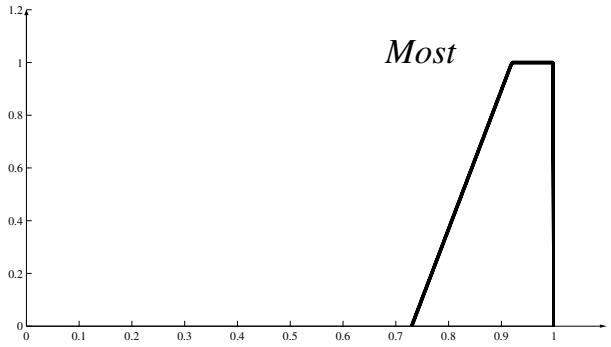

Fig. 1. The membership function of the type-1 fuzzy quantifier $Most$.

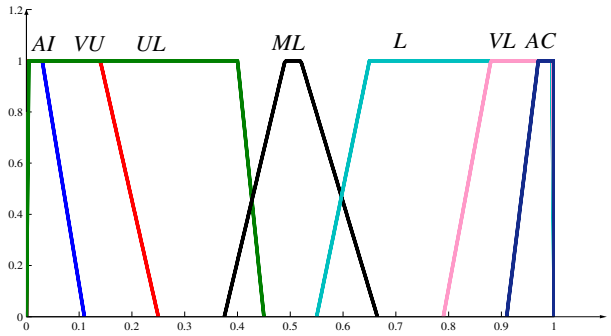

Fig. 2. The membership functions of the vocabulary of type-1 linguistic probabilities.

Computation of Zadeh's solution to the Magnus problem involves a fuzzy multiplication. Since we have chosen a trapezoidal membership function for $Most$, it is easy to compute $Most \otimes Most$ by (1). Assume that one has two trapezoidal fuzzy numbers $A = (a_1, b_1, c_1, d_1)$ and $B = (a_2, b_2, c_2, d_2)$; then, $A \otimes B = (a_1 a_2, b_1 b_2, c_1 c_2, d_1 d_2)$. The computed $Most \otimes Most$ corresponding to the membership function of Fig. 1 is shown in Fig. 3. Note that the center of gravity of the solution is 0.8304. Later, this will be compared to the average centroid of the type-2 solution(s).

In the next step of our interpretation of Zadeh's solution, we calculate Jaccard's similarity measure between $Most \otimes Most$ and each member of the vocabulary of type-1 linguistic probabilities P_i, $(i = 1, \ldots, 9)$, and denote them by $s_J(Most \otimes Most, P_i)$. The results are shown in Table I.

It can be concluded that decoding Zadeh's methodology yields the following solution to the Magnus problem, given

[1]In practice, we can collect data from a group of subjects about all words and then use the Interval Approach [11] or the Enhanced Interval Approach [2] to construct the IT2 FS models. Our hypothetical T1 FSs could then correspond to the upper membership functions of these IT2 FSs. The membership functions used here are for illustrative purposes only.

[2]Note that from (4), it is obvious that the Jaccard's similarity of a singleton and any fuzzy set is always zero. Hence, no solution would map to the extreme words in the decoding procedure. The extreme words are included in the vocabulary because their presence is crucial for an axiomatic approach to fuzzy probabilities, as will be seen in the sequel.

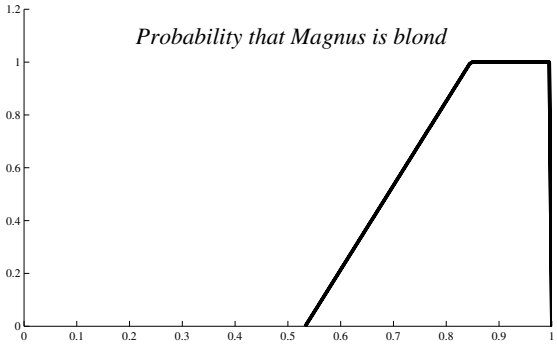

Fig. 3. The membership functions of $Most \otimes Most$.

the aforementioned fuzzy sets for the type-1 linguistic probabilities:

"It is *Likely* that Magnus (a Swede picked at random) is blond."

IV. Critique of Zadeh's Solution

As stressed by [7], although Zadeh's treatment of fuzzy probabilities is very interesting and can be applied to data-centered applications, it needs to be mathematically rigorized so that it is more appropriate from the viewpoint of a probability theorist. As a result, the following linguistic probability measure is defined in [7]: Assume that Ω is a sample space, and $\mathcal{B}$ is the σ-algebra of events associated with Ω, i.e:

1) $\mathcal{B} \subseteq \mathcal{P}_\Omega$
2) $\mathcal{B} \neq \emptyset$
3) $A \in \mathcal{B} \Rightarrow A' \in \mathcal{B}$
4) $\{A_i\}_{i=1}^{\infty} \subseteq \mathcal{B} \Rightarrow \bigcup_{i=1}^{\infty} A_i \in \mathcal{B}$

in which $\mathcal{P}_\Omega$ is the family of subsets of Ω, and $A' = \Omega - A$ is the complement of A.

A function $\mathrm{LProb} : \mathcal{B} \rightarrow \mathscr{N}_{[0,1]}$ is called a *linguistic probability measure* if and only if, for any $A \in \mathcal{B}$:

1) $0 \preceq \mathrm{LProb}(A) \preceq 1$
2) $\mathrm{LProb}(\emptyset) = 0$ and $\mathrm{LProb}(\Omega) = 1$
3) If $\{A_i\}_{i=1}^{\infty} \subseteq \mathcal{B}$ and $i \neq j \Rightarrow A_i \cap A_j = \emptyset$ (i.e. A_i's are mutually disjoint), then $\mathrm{LProb}\left(\bigcup_{i=1}^{\infty} A_i\right) \subseteq \bigoplus_{i=1}^{\infty} \mathrm{LProb}(A_i)$
4) $\mathrm{LProb}(A') = 1 \ominus \mathrm{LProb}(A)$

TABLE I
Similarities between Zadeh's solution $Most \otimes Most$ and linguistic probabilities

Linguistic probability (P_i)	$s_J(Most \otimes Most, P_i)$
Absolutely improbable	0
Almost improbable	0
Very unlikely	0
Unlikely	0
Moderately likely	0.0435
Likely	**0.7499**
Very likely	0.4857
Almost certain	0.1166
Absolutely certain	0

in which $\mathscr{N}_{[0,1]}$ is the set of all fuzzy numbers over the unit interval, $\preceq$ is the order relation induced by the fuzzy minimum operator (and is equivalent to the α-cut ranking method), $\oplus$ represents a special addition for fuzzy numbers [6], and $\ominus$ is the fuzzy subtraction operation.

Zadeh's approach to solving the Magnus problem does not obey the axioms of linguistic probability theory. In his approach, he only considers the events "tall" and "blond". Nevertheless, the above axiomatic approach requires the σ-algebra of events to contain the complement of those events (i.e. "not tall" and "not blond") as well. As will be seen in the sequel, using syllogisms proposed by Zadeh, we consider the events "not tall" and "not blond" and the linguistic probabilities assigned to them in our model. We solve the Magnus problem using type-2 fuzzy sets as models for linguistic probabilities, and we can show [17] that our treatment of linguistic probabilities obeys a set of axioms which are similar to those stated for type-1 fuzzy sets in above.

V. Fuzzy Reasoning and Calculation of Linguistic Upper and Lower Probabilities via Linguistic Weighted Averages

Heuristically, when one assigns a linguistic attribute to *Most of a population*, it can be concluded that the *rest* of that population does not have that attribute. Such an intuition can be derived formally from the following rule obtained from the entailment principle [26] :

QA's are B's

$\neg QA$'s are B''s

in which $\neg Q$ is the antonym of the fuzzy quantifier Q, and its membership function [26] is given by:

$$\mu_{\neg Q}(u) = \mu_Q(1-u),\ u \in [0,1] \tag{5}$$

and B' is the complement of the fuzzy set B, characterized by:

$$\mu_{B'}(u) = 1 - \mu_B(u) \tag{6}$$

Exploiting the aforementioned rule, we have: "A few Swedes are not tall," in which Few is an antonym of the linguistic quantifier $Most$. Consequently, applying this rule to the statement "Most tall Swedes are blond," one concludes that: "A few tall Swedes are not blond."

It is worth noting that the semantics of the fuzzy quantifier $Most$ suggests that it is more appropriately modeled by an interior fuzzy set. As we insisted earlier, when *Most of a population* have a linguistic attribute, it means that there are some members of that population who *do not* have such an attribute. It is reasonable, therefore, to assume that $\mu_{Most}(1) \neq 1$ (i.e. the membership value of 100% in $Most$ is not 1); thus, we choose an interior fuzzy set to model the quantifier $Most$, and its antonym to model the quantifier Few, as shown in Fig. 4.

One has linguistic information about the distribution of blond Swedes among those who are tall, i.e. one knows that most of tall Swedes are blond. Unfortunately, one does not know anything about the distribution of blond Swedes

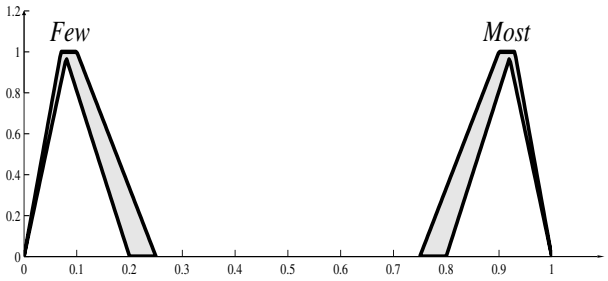

Fig. 4. Type-2 fuzzy sets for modeling $Most$ and Few.

among those (few) Swedes who are not tall. This situation is summarized in the tree of Fig. 5.

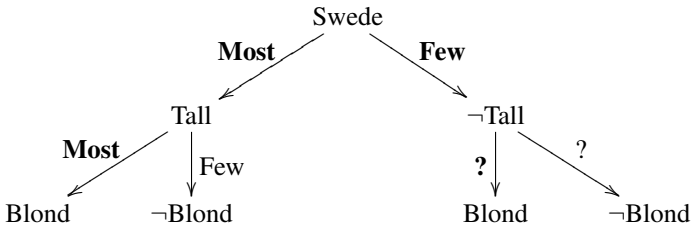

Fig. 5. Linguistic information about the distribution of blond people among Swedes.

Because of one's total ignorance about the distribution of blonds among the Swedes who are not tall, one can take two different approaches to calculate the linguistic probability that Magnus is blond: The first approach assumes that the distribution of blonds among Swedes who are not tall is similar to the case of tall Swedes i.e., *Most Swedes who are not tall are blond; few of them are not blond;* however, such a methodology does not seem to be quite plausible, because it completely neglects our total ignorance about the situation, and assumes additional *world knowledge*, which may not always be available.

The second approach calculates a linguistic lower and a linguistic upper probability corresponding respectively to the pessimistic case, when *none of Swedes who are not tall are blond* and the optimistic case when *all of Swedes who are not tall are blond*.

To calculate the linguistic lower and upper probabilities, we use a *normalized version* of the intersection-product syllogism, so that the problem can be solved using Linguistic Weighted Averages [19], [20]. The linguistic lower probability $\mathrm{LProb}^{-}(\cdot)$ is determined as:

$$\mathrm{LProb}^{-}(\text{Magnus is blond}) = \frac{\mathit{Most} \times \mathit{Most} + \mathit{Few} \times \mathit{None}}{\mathit{Most} + \mathit{Few}} \tag{7}$$

Similarly, the linguistic upper probability $\mathrm{LProb}^{+}(\cdot)$ is determined as:

$$\mathrm{LProb}^{+}(\text{Magnus is blond}) = \frac{\mathit{Most} \times \mathit{Most} + \mathit{Few} \times \mathit{All}}{\mathit{Most} + \mathit{Few}} \tag{8}$$

In (7) and (8), All and $None$ are singletons, respectively represented by:

$$\mu_{All}(u) = \begin{cases} 1 & u = 1 \\ 0 & \text{otherwise} \end{cases} \tag{9}$$

$$\mu_{None}(u) = \begin{cases} 1 & u = 0 \\ 0 & \text{otherwise} \end{cases} \tag{10}$$

A Linguistic Weighted Average $\widetilde{Y}_{LWA}$ of interval type-2 fuzzy sets $\widetilde{X}_i$ with interval type-2 fuzzy weights $\widetilde{W}_i$, $(i = 1, \cdots, n)$ is characterized by the following *expressive formula*[3] [14]:

$$\widetilde{Y}_{LWA} = \frac{\sum_{i=1}^{n} \widetilde{W}_i \times \widetilde{X}_i}{\sum_{i=1}^{n} \widetilde{W}_i} = [\underline{Y}_{LWA}, \overline{Y}_{LWA}] \tag{11}$$

in which:

$$\underline{Y}_{LWA} = \min_{\forall W_i \in [\underline{W}_i, \overline{W}_i]} \frac{\sum_{i=1}^{n} W_i \underline{X}_i}{\sum_{i=1}^{n} W_i} \tag{12}$$

$$\overline{Y}_{LWA} = \max_{\forall W_i \in [\underline{W}_i, \overline{W}_i]} \frac{\sum_{i=1}^{n} W_i \overline{X}_i}{\sum_{i=1}^{n} W_i} \tag{13}$$

in which the underlined and overlined quantities denote lower and upper membership values of $\widetilde{Y}_{LWA}$. Observe that LProb^{-} and LProb^{+} in (7) and (8) are Linguistic Weighted Averages that can be computed by (12) and (13).

By analogy with classical probability theory, one can observe that the weighted average solutions in (7) and (8) can be derived from the following conditional fuzzy probability calculation which is a generalization of the calculations of [7] to type-2 fuzzy sets:

$$\begin{aligned} &\mathrm{LProb}(\text{blond}|\text{Swede}) = \\ &\mathrm{LProb}(\text{tall}|\text{Swede}) \times \mathrm{LProb}(\text{blond}|\text{tall and Swede}) + \\ &\mathrm{LProb}(\neg\text{tall}|\text{Swede}) \times \mathrm{LProb}(\text{blond}|\neg\text{tall and Swede}) \end{aligned} \tag{14}$$

$\mathrm{LProb}^{-}(\text{Magnus is blond})$ is obtained by assuming in (14) that:

$$\mathrm{LProb}(\text{blond}|\neg\text{tall and Swede}) = \mathit{None} = 0 \tag{15}$$

and $\mathrm{LProb}^{+}(\text{Magnus is blond})$ is obtained by assuming in (14) that:

$$\mathrm{LProb}(\text{blond}|\neg\text{tall and Swede}) = \mathit{All} = 1 \tag{16}$$

It can be shown [16] that the intrinsic normalization present in the linguistic weighted average contributes to interactive addition of fuzzy probabilities, which avoids obtaining counter-intuitive linguistic probabilities whose membership functions are non-zero outside $[0, 1]$ [6], [24].

One can argue that when there is no assumption on the distribution of blonds among Swedes who are not tall, based

[3]This means that although $\widetilde{Y}_{LWA}$ can be expressed by (11), it is not computed by adding/multiplying interval type-2 fuzzy sets.

on the principle of maximum entropy [3], one should assume that:

$$\begin{aligned}&\text{LProb}(\text{blond}|\neg\text{tall and Swede}) = \\ &\text{LProb}(\text{not blond}|\neg\text{tall and Swede}) = 0.5\end{aligned} \quad (17)$$

It can easily be shown that the linguistic probability calculated by (17) is exactly $(\text{LProb}^+ + \text{LProb}^-)/2$. This is a direct result of the fact that $(All + None)/2 = 0.5$, and the nature of the average. The linguistic upper and lower probabilities provide more flexibility when such an assumption cannot be made.

We calculate LProb^- and LProb^+ exploiting a method based on alpha-cuts [21], [23]. The results are shown in Figs. 6 and 7, respectively. The centroid and average centroid of the lower probability are $[0.7966, 0.8150]$ and 0.8058, respectively. The centroid and average centroid for the upper probability are $[0.8888, 0.9002]$ and 0.8945, respectively. The centroid can be used to report a solution in terms of the uncertain numeric upper and lower probabilities for the problem: "the probability that Magnus is blond is between around 80% and around 89%." Note that 80% and 89% are the average centroids of the type-2 fuzzy lower and the upper probabilities, and the term "around" reflects the uncertainty represented by the centroids, and reflects the inter-person and intra-person uncertainties about the words. Such uncertainties are propagated by the linguistic weighted average, and can be captured when reporting a numeric value for the lower and the upper probabilities, by calculation of centroid and average centroid. This cannot be done by any solution involving type-1 fuzzy sets, including Zadeh's solution.

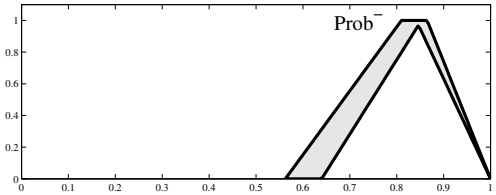

Fig. 6. Linguistic lower probability that Magnus is blond.

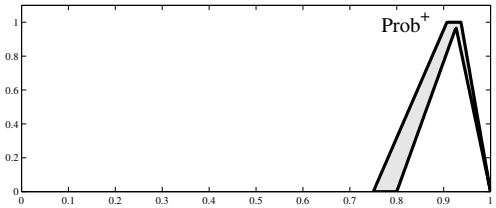

Fig. 7. Linguistic upper probability that Magnus is blond.

In order to communicate the results to people via linguistic probabilities (e.g., very likely), we computed Jaccard's similarities of the linguistic lower probability and the linguistic upper probability with the vocabulary of linguistic probabilities ($\widetilde{P}_i,\ i = 1, \cdots, 9$) whose membership functions are shown in Fig. 8. The results are shown in Table II. The vocabulary of type-2 linguistic probabilities contains the same words as the vocabulary of type-1 linguistic probabilities. As done previously, we modeled the extreme words *Absolutely improbable* and *Absolutely certain* as singletons, and hence they are not shown in the figure.

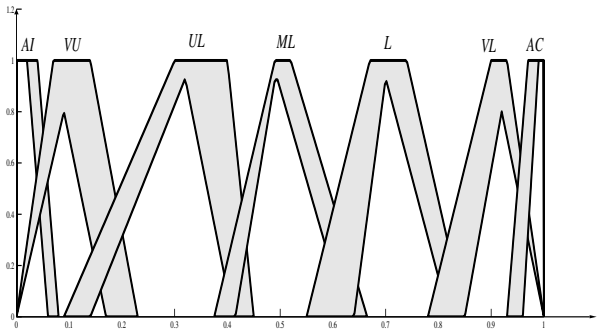

Fig. 8. The membership functions of the vocabulary of type-2 linguistic probabilities.

Note that the Jaccard's similarity between interval type-2 fuzzy sets $\widetilde{A}$ and $\widetilde{B}$ is calculated by [22], [23]:

$$s_J(\tilde{A}, \tilde{B}) = \frac{\int_X (\min(\bar{\mu}_{\tilde{A}}(x), \bar{\mu}_{\tilde{B}}(x)) + \min(\underline{\mu}_{\tilde{A}}(x), \underline{\mu}_{\tilde{B}}(x)))dx}{\int_X (\max(\bar{\mu}_{\tilde{A}}(x), \bar{\mu}_{\tilde{B}}(x)) + \max(\underline{\mu}_{\tilde{A}}(x), \underline{\mu}_{\tilde{B}}(x)))dx} \quad (18)$$

in which $\bar{\mu}_{\tilde{A}}(x)$ and $\underline{\mu}_{\tilde{A}}(x)$ are upper membership and lower membership functions of $\tilde{A}$.

Since we have obtained a pessimistic and an optimistic probability, we can make the following statement: "The probability that Magnus is blond is between likely and very likely."

TABLE II
SIMILARITIES BETWEEN THE LINGUISTIC LOWER AND UPPER PROBABILITIES WITH THE MEMBERS OF THE VOCABULARY OF LINGUISTIC PROBABILITIES

VI. A Study on The Effect of The Size of Vocabulary on The Results

Linguistic approximation is essentially the fuzzy counterpart of rounding numeric values. In conventional rounding, one approximates a numerical value with the "nearest" number that is meaningful for available computing machinery. In linguistic approximation, analogously, a member of the vocabulary that

is most similar to the result of a reasoning procedure is selected so that the result is perceivable by a person.

It is therefore appropriate to investigate the issue of "resolution," when performing linguistic approximation. More specifically in the Magnus problem, if the vocabulary of linguistic probabilities is not of a sufficient resolution, both the linguistic upper and lower probabilities map to the same word, removing the effect of considering total ignorance about the distribution of blonds among the Swedes who are not tall. On the other hand, precision makes communication more difficult, e.g. the statement " It is very likely that Magnus is blond" is more comprehensible by a human than the statement "The probability that Magnus is blond is between likely and very likely." Consequently, it is of interest to investigate the conditions which lead to a more precise linguistic answer.

The main factor affecting the resolution of a CWW system is the size of its vocabularies, because the size of the vocabulary is influential on the shape of the fuzzy set modeling a word [14]. As the size of a vocabulary increases, the "fuzziness" [34] of fuzzy sets modeling each word decreases.

To examine the dependence of the solution on the resolution of the vocabulary of the linguistic probabilities, we chose vocabularies containing 3, 5, and 7 words, and calculated Jaccard's similarities of the linguistic lower and the upper probabilities with the words of each vocabulary, in the following manner:

Vocabulary 1: *Absolutely improbable, Likely, Absolutely certain* (see Fig. 9). Vocabulary 2: *Absolutely improbable, Unlikely, Likely, Very likely, Absolutely certain* (see Fig. 10). Vocabulary 3: *Absolutely improbable, Almost Improbable, Unlikely, Likely, Very likely, Almost certain, Absolutely certain* (see Fig. 11). Note that the singletons are not shown in Figs. 9-11.

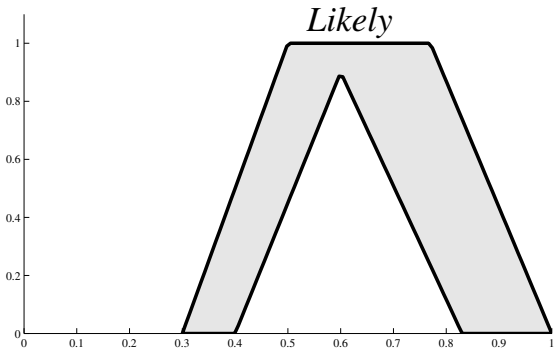

Fig. 9. The membership functions of the 3-word vocabulary of linguistic probabilities.

The similarities between the linguistic lower and upper probabilities with the members of each of the vocabularies are shown in Tables III-V. Interestingly, the linguistic lower and upper probabilities are decoded into the same word in the cases where we have 3, 5, and 7 words in the vocabulary. For the three-word vocabulary, the word is "Likely", whereas in the five-word and seven-word vocabularies, it is "Very likely".

VII. CONCLUSIONS

In this paper, we applied Linguistic Weighted Averages to the calculation of linguistic probabilities to solve Zadeh's "Magnus" challenge problem. We demonstrated that applying syllogisms related to linguistic quantifiers to this problem

gives rise to the derivation of linguistic upper and lower probabilities. This is in accord with the existing landscape of Dempster-Shafer theory of evidence, which has been used for manipulation of imprecise probabilities in decision making problems. Our forthcoming efforts will be devoted to developing a new linguistic evidence theory.

The use of Linguistic Weighted Averages appears to be promising in solving more complicated CWW problems which involve implicit assignment of linguistic constraints to variables like probability (and truth). This is mainly due to the inherent normalization done by them, which prevents them from resulting in fuzzy probabilities whose membership functions are non-zero outside the interval $[0, 1]$.

APPENDIX A
PROOF FOR $At\ least(Q) = Q$ WHEN Q IS MONOTONICALLY NON-DECREASING

The operator *At least* is defined by:

$$\mu_{At\ least(Q)}(x) = \sup_{y \le x} \mu_Q(y), \quad x, y \in [0, 1] \tag{19}$$

Since $\mu_Q(x)$ is non-decreasingly monotonic, $\forall y \le x,\ \mu_Q(y) \le \mu_Q(x)$. Therefore, $\sup_{y \le x} \mu_Q(y) = \mu_Q(x)$, and $\mu_{At\ least(Q)}(x) = \mu_Q(x)$.

***Abstract* – We have introduced the linguistic weighted power mean and its computation via a generalization of the Karnick-Mendel algorithm. This new family of aggregation operators admits interval type-2 fuzzy membership functions for both its inputs and its weights to account for imprecise knowledge of these quantities. The simplest member of this family, the linguistic weighted average, is the primary instantiation of a "perceptual computing" engine in Mendel and Wu's recent book by this title. This paper presents a comparison of the linguistic weighted power mean and the linguistic weighted average on one of the examples they describe in detail—the "investment judgment advisor". Our results illustrate the flexibility and range of logical inference provided by this very versatile aggregation operator for computing with words applications.**

Keywords-aggregation operators; type-2 fuzzy logic; computing with words; perceptual computing

I. INTRODUCTION

The recent book by Mendel and Wu entitled *Perceptual Computing* [1] presents an approach to "computing with words" (CWW), a problem area originally suggested by Zadeh [2] that remains of high interest. (See, for example, the recent special section of the *IEEE Transactions on Fuzzy Systems* on CWW [3] and publications [4]-[7].)

Mendel and Wu's approach to CWW is motivated by the premise that "words mean different things to different people," and therefore the inputs, computational engine and outputs of a perceptual computer (Per-C) must explicitly take account of this inherent imprecision. Inputs to the Per-C are modeled as interval type-2 (IT2) fuzzy membership functions (MFs) spanning an appropriate range (e.g., a 0-10 scale), which is perhaps the simplest method for representing imprecise knowledge of membership values.

The Per-C is proposed to have three components: an *encoder*, a *computational engine* and a *decoder*. Mendel and Wu's strategy for the encoder is to develop a code book of input and output *words* that are also represented by IT2 MFs. Inputs to the Per-C computational engine are selected from this vocabulary of input words. The IT2 fuzzy input variables and importance weights are mapped to code book words via similarity comparisons. The computational engine logically aggregates the imprecision represented in these word MFs into corresponding output IT2 MFs. These output IT2 MFs are decoded by an analogous similarity mapping into corresponding word outputs.

Two architectures for the Per-C computational engine are proposed in [1]: 1) a bank of parallel *if-then rules*, and 2) a "*linguistic weighted average*" (LWA). The first of these relies upon results summarized in Mendel's earlier book [8] on type-2 fuzzy rule-bases systems, where input variables are represented by IT2 MFs and the implication operation performed by the rules results in an output IT2 MF. In fuzzy control applications, this output MF is generally type-reduced to an interval whose midpoint describes the defuzzified scalar output of the computational engine. In CWW applications, the output IT2 MF is typically mapped into an output word in the code book vocabulary using the decoder described above.

The LWA Per-C architecture is employed in three of the four chapters in [1] presenting detailed examples of Per-C applications. It is a generalization of the traditional weighted average, first to a type-1 *fuzzy weighted average* (FWA) and then to a IT2 fuzzy weighted average in which all inputs and importance weights are represented by IT2 MFs. The latter generalization applies the celebrated Karnick-Mendel algorithm [9] for computing the centroid of an IT2 MF to the α-cuts of the upper and lower MFs (UMF and LMF, respectively) of the input variables and weights, resulting in the corresponding α-cuts of the LWA UMF and LMF. The output UMF and LMF are then constructed (in approximation) using the well-known α-cut Representation Theorem [10].

The LWA is perhaps the simplest aggregation operator $L(\tilde{\mathbf{x}}, \tilde{\mathbf{w}})$ mapping IT2 MFs of scores $\tilde{\mathbf{x}} = (\tilde{x}_1, ..., \tilde{x}_n)$ and associated importance weights $\tilde{\mathbf{w}} = (\tilde{w}_1, ..., \tilde{w}_n)$ into an output IT2 MF. These operators represent a form of data fusion in which both scores and weights are generally taken to lie within a common interval range and are characterized by IT2 MFs. Although the LWA is the primary computational method featured for computing with words in [1], it is limited in its ability to represent how humans aggregate preference scores. For example, it cannot model a mandatory requirement. Therefore it is highly desirable to develop more powerful and computationally feasible aggregation operators that can be applied to IT2 inputs.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

The LWA is but one member of the class of aggregation operators generally referred to as the p-norm [11]. When the power r in the p-norm is allowed to vary over the entire real line, it is called a weighted power mean (WPM), defined by

$$L_r(\tilde{\mathbf{x}},\tilde{\mathbf{w}}) \triangleq \lim_{q\to r}\left(\frac{\sum_{i=1}^{n}\tilde{w}_i\tilde{x}_i^q}{\sum_{i=1}^{n}\tilde{w}_i}\right)^{1/q}. \quad (1)$$

While it is no longer always a norm, the WPM is a flexible operator that is used in information retrieval and other ranked decision applications [12]. As r ranges over the real line, L_r ranges from logical conjunction $x_1\wedge\cdots\wedge x_n$ of the inputs (in the limit as $r\to-\infty$) to logical disjunction $x_1\vee\cdots\vee x_n$ (in the limit as $r\to\infty$). L_r is thus an *orand* operator. Other special cases of the weighted power mean include the LWA ($r=1$), geometric mean ($r=0$), harmonic mean ($r=-1$) and Euclidean mean ($r=2$). Dujmovi [13] suggests (in a type-1 setting) that the WPM performs best of a general class of parameterised aggregation operators that range continuously between the extremes of conjunction and disjunction.

In a current paper [14], we have generalized the Karnick-Mendel algorithm to compute the output interval of the WPM given input intervals for $\tilde{\mathbf{x}}$ and $\tilde{\mathbf{w}}$, for arbitrary values of the power r. We denote this as the Weighted Power Mean Enhanced Karnick-Mendel (WPMEKM) algorithm, since it makes use of performance enhancements over the original Karnick-Mendel algorithm as described in [15]-[16]. By employing the α-cut Representation Theorem, we use the WPMEKM algorithm to compute the output IT2 MF of $L_r(\tilde{\mathbf{x}},\tilde{\mathbf{w}})$, given IT2 MFs for the inputs and weights. We denote this new aggregation operator as the *linguistic weighted power mean* (LWPM).

The primary contribution of this paper is to provide a comparison of Per-C computational engines using the LWPM aggregation operator $L_r(\tilde{\mathbf{x}},\tilde{\mathbf{w}})$ with the LWA Per-C engine described by Mendel and Wu (which is $L_1(\tilde{\mathbf{x}},\tilde{\mathbf{w}})$), using the detailed example of an Investment Judgment Advisor presented in [1] and described below. This example illustrates the flexibility and range of logical inferences available using the LWPM as compared to the LWA. Thus the LWPM represents a significant generalization and extension of the choices of Per-C computational engines available for CWW applications.

The remainder of this paper is organized as follows: first, we summarize the WPMEKM algorithm of [14]. Then we review the Investment Judgment Advisor (IJA) example of [1]. Next, we compare the IJA outputs using the LWPM versus the LWA, and discuss the advantages of the LWPM. Finally, we describe how even more useful logical aggregation operators can be constructed hierarchically using combinations of LWPM components.

II. SUMMARY OF WPMEKM ALGORITHM

Suppose initially that we have interval-valued scores $[\underline{x}_i,\overline{x}_i]$ and weights $[\underline{w}_i,\overline{w}_i]$, where $\overline{x}_i,\underline{x}_i\in[0,1]$, $\overline{w}_i,\underline{w}_i\geq 0$, $i\in\{1,\ldots,n\}$ are inputs to the LWPM $L_r(\tilde{\mathbf{x}},\tilde{\mathbf{w}})$. We summarize below the WPMEKM algorithm for computing corresponding output intervals of the LWPM [14].

First we consider the exceptional cases $r=\pm\infty$, for which $L_r(\mathbf{x},\mathbf{w})$ is independent of w_i. The interval endpoints then are determined solely by the x_i interval boundaries, with

$$\begin{aligned}\underline{L}_{-\infty}(\mathbf{x},\mathbf{w}) &= \min_{i:\ w_i>0}\{\underline{x}_i\},\ \overline{L}_{-\infty} = \min_{i:\ w_i>0}\{\overline{x}_i\}\\ \underline{L}_{\infty}(\mathbf{x},\mathbf{w}) &= \max_{i:\ w_i>0}\{\underline{x}_i\},\ \overline{L}_{\infty} = \max_{i:\ w_i>0}\{\overline{x}_i\}\end{aligned}. \quad (2)$$

Next, consider the weighted power mean for a finite power r. Then (1) can be rewritten as

$$L_r(\mathbf{x},\mathbf{w}) = h_r\left(\sum_{i=1}^{n}w_i h_r^{-1}(x_i)\Big/\sum_{i=1}^{n}w_i\right) = h_r\left(y_r(\mathbf{x},\mathbf{w})\right) \quad (3)$$

where

$$h_r(z)=\begin{cases} z^{1/r}, & r\neq 0\\ \exp(z), & r=0\end{cases}, \quad (4)$$

$$y_r(\mathbf{x},\mathbf{w}) = \sum_{i=1}^{n}w_i h_r^{-1}(x_i)\Big/\sum_{i=1}^{n}w_i. \quad (5)$$

Note that h_r and h_r^{-1} are strictly increasing on the non-negative reals if $r\geq 0$ and are strictly decreasing if $r<0$.

With (3), the value of the weighted power mean applied to intervals $[\underline{x},\overline{x}_i],[\underline{w}_i,\overline{w}_i]$ can be written as the interval

$$[\underline{L}_r,\overline{L}_r] = \left[\min h_r\left(\sum_{i=1}^{n}w_i h_r^{-1}(x_i)\Big/\sum_{i=1}^{n}w_i\right), \max h_r\left(\sum_{i=1}^{n}w_i h_r^{-1}(x_i)\Big/\sum_{i=1}^{n}w_i\right)\right] \quad (6)$$

where min and max are taken over $\{x_1,\ldots x_n,w_1,\ldots w_n : x_i\in[\underline{x}_i,\overline{x}_i], w_i\in[\underline{w}_i,\overline{w}_i],\ i=1,\ldots,n\}$.

From (6), we have

$$[\underline{L}_r,\overline{L}_r] = \begin{cases}[h_r(\underline{y}_r),h_r(\overline{y}_r)] & r\geq 0\\ [h_r(\overline{y}_r),h_r(\underline{y}_r)] & r<0\end{cases}, \quad (7)$$

where

$$\left[\underline{y}_r, \overline{y}_r\right] = \left[\min\left\{ \frac{\sum_{i=1}^{n} w_i h_r^{-1}(x_i)}{\sum_{i=1}^{n} w_i} \right\}, \max\left\{ \frac{\sum_{i=1}^{n} w_i h_r^{-1}(x_i)}{\sum_{i=1}^{n} w_i} \right\} \right]. \quad (8)$$

Now for any $i \in \{1,...,n\}$, $h_r^{-1}\left(\underline{x}_i\right) \le h_r^{-1}\left(\overline{x}_i\right)$ if h_r is strictly increasing and $h_r^{-1}\left(\underline{x}_i\right) \ge h_r^{-1}\left(\overline{x}_i\right)$ if h_r is strictly decreasing. So to compute (8), we compute the LWA of input intervals $\left[h_r^{-1}\left(\underline{x}_i\right), h_r^{-1}\left(\overline{x}_i\right)\right]$ when $r \ge 0$ and $\left[h_r^{-1}\left(\overline{x}_i\right), h_r^{-1}\left(\underline{x}_i\right)\right]$ when $r < 0$. Then we apply h_r to the resulting interval LWA, where the upper and lower bounds are transposed at this step if h_r is strictly decreasing. Thus in all cases, the bounds in (7) are given by:

$$\begin{aligned} \underline{L}_r &= h_r\left(\sum_{i=1}^{n} \underline{z}_i h_r^{-1}\left(\underline{x}_i\right) \Big/ \sum_{i=1}^{n} \underline{z}_i \right), \\ \underline{z}_i &= \begin{cases} \overline{w}_i, & \underline{x}_i < h_r\left(y_r\left(\underline{\mathbf{x}}, \underline{\mathbf{z}}\right)\right) = \underline{L}_r \\ \underline{w}_i, & \underline{x}_i > h_r\left(y_r\left(\underline{\mathbf{x}}, \underline{\mathbf{z}}\right)\right) = \underline{L}_r \end{cases} \\ \overline{L}_r &= h_r\left(\sum_{i=1}^{n} \overline{z}_i h_r^{-1}\left(\overline{x}_i\right) \Big/ \sum_{i=1}^{n} \overline{z}_i \right), \\ \overline{z}_i &= \begin{cases} \underline{w}_i, & \overline{x}_i < h_r\left(y_r\left(\overline{\mathbf{x}}, \overline{\mathbf{z}}\right)\right) = \overline{L}_r, \\ \overline{w}_i, & \overline{x}_i > h_r\left(y_r\left(\overline{\mathbf{x}}, \overline{\mathbf{z}}\right)\right) = \overline{L}_r \end{cases} \end{aligned} \quad . \quad (9)$$

The EKM algorithms [15]-[16] can be adapted to compute $\left[\underline{y}, \overline{y}\right] = \left[\min h\left(\frac{\sum_{i=1}^{n} w_i h^{-1}(x_i)}{\sum_{i=1}^{n} w_i} \right), \max h\left(\frac{\sum_{i=1}^{n} w_i h^{-1}(x_i)}{\sum_{i=1}^{n} w_i} \right) \right]$ for any strictly monotonic function h, which in the present case we take to be h_r. We call the resulting algorithm WPMEKM for the special case of weighted power means, while recognizing the more general application.

WPMEKM Algorithm

1) If the minimum $L_r\left(\mathbf{x}, \mathbf{w}\right) = \underline{L}_r$ is to be computed, set $k = \left[n / 2.4 \right]$ where $[x]$ is the nearest integer to x. Set $x_i = \underline{x}_i$, $u_i = \underline{w}_i$ and $v_i = \overline{w}_i$ for each $i = 1,\ldots,n$. If the maximum $L_r(\mathbf{x}, \mathbf{w}) = \overline{L}_r$ is to be computed, set $k = \left[n / 1.7 \right]$, $x_i = \overline{x}_i$, $u_i = \overline{w}_i$ and $v_i = \underline{w}_i$ for $i = 1,\ldots,n$.

2) Sort the x_i for $i = 1,\ldots,n$ in ascending order so that $x_{i_1} \le x_{i_2} \le \cdots \le x_{i_n}$ where i_j, $j = 1,\ldots,n$ represents the original index values. Rearrange the weight interval endpoints u_i and v_i using the same permutation of index values i_j, $j = 1,\ldots,n$ that result from the x_i sort. Now refer to x_i, u_i, v_i, $i = 1,\ldots,n$ as the sorted sets of inputs and weights.

3) Compute

$$a = \sum_{i=1}^{k} h^{-1}(x_i) v_i + \sum_{i=k+1}^{n} h^{-1}(x_i) u_i, \quad (10)$$

$$b = \sum_{i=1}^{k} v_i + \sum_{i=k+1}^{n} u_i, \quad y = \left(\frac{a}{b} \right). \quad (11)$$

4) Find $k' \in \{0,1,...,n\}$ such that $x_{k'} \le h(y) < x_{k'+1}$. Check if $k' = k$. If yes, set $L_r(\mathbf{x}, \mathbf{w}) = h(y)$, stop. If no, continue.

5) Set $s = sign\left(k' - k\right)$, and compute

$$a' = a + s \sum_{i=\min(k,k')+1}^{i=\max(k,k')} h^{-1}(x_i)\left(v_i - u_i\right), \quad (12)$$

$$b' = b + s \sum_{i=\min(k,k')+1}^{i=\max(k,k')} \left(v_i - u_i\right), \; y = \left(\frac{a'}{b'} \right). \quad (13)$$

6) Set $a = a'$, $b = b'$ and $k = k'$. Go to step 4).

Note that because h is strictly monotonic, the sort on x_i results in either an ascending or descending sort on $h^{-1}(x_i)$ depending on whether h is increasing or decreasing.

With the WPMEKM algorithm, the weighted power mean interval boundaries can be computed for any value of r. These interval-valued results enable us directly to compute arbitrarily accurate approximations to the weighted power mean membership function for scores and weights that are fuzzy sets, using the α-cut representation theorem [10]. In this case the interval computation is applied to α-cuts of the input variables to determine the corresponding α-cuts of the output variable. In the IT2 case, this computation is applied to both the upper and lower bounding functions for the scores and weights to determine the corresponding upper and lower bounding functions of the global score.

III. INVESTMENT JUDGMENT ADVISOR REVIEW

The IJA example in [1] originated with Tong and Bonissone [17], who considered the decision confronting an individual with a moderately large amount of capital who wishes to select among five investment sector alternatives, using four investment criteria. The five alternatives are commodities (a_1), stocks (a_2), gold (a_3), real estate (a_4) and long-term bonds (a_5). The four investment criteria are:

risk of losing capital (c_1),inflation vulnerability (c_2), anticipated profit (c_3) and liquidity (c_4). The investor's goal is to rate each investment with respect to the four criteria and then aggregate these ratings into a decision statistic that can be used for ranking (or for capital allocation among the different alternatives to achieve an appropriately diversified portfolio.)

Through a process of interval analysis [18] using inputs from real subjects, Mendel and Wu derive three descriptive vocabularies of eight, seven and four words that are represented using IT2 MFs. The UMF and LMF of each vocabulary word MF is a trapezoid disposed on the domain interval $[0,10]$, with the extreme words in each vocabulary typically represented by left- or right-shoulder MFs, while the intermediate words are represented by mid-range MFs. (For details, see [1], Tables 7.13, 7.14 and 7.15.) The eight-word vocabulary expresses *amount*, characterized by None to Very Little (NVL) , Very Low (VL), Low (L), More or Less Low (MLL), Fair to More or Less High (FMLH), More or Less High (MLH), High (H) and Extremely High (EH). This vocabulary is used to grade each alternative with respect to the first three criteria, where in keeping with [1] a simple *antonym* $\mu_{10-\tilde{A}}(x)$ of the respective IT2 MF is used for criteria 1 and 2 in the aggregation, i.e., $\mu_{10-\tilde{A}}(x) = \mu_{\tilde{A}}(10-x)$. Alternative forms for the membership functions antonyms which exhibit more intuitive behaviour are discussed in [19].

The seven-word vocabulary expresses *quality*, characterized by Very Bad (VB), Bad (B), Somewhat Bad (SB), Fair (F), Somewhat Good (SG), Good (G) and Very Good (VG). This vocabulary is used in grading the alternatives with respect to criterion 4. The four-word vocabulary expresses *importance*, characterized by Unimportant (U), More or Less Unimportant (MLU), More or Less Important (MLI) and Very Important (VI). Table 1 (replicated from [1]) presents three hypothetical word evaluation matrices grading each investment alternative from the perspectives of speculative, conservative and in-between investors, respectively.

TABLE 1 LINGUISTIC RATINGS AND WEIGHTS OF INVESTMENT ALTERNATIVES WRT CRITERIA

(a) Speculative Investor

Ratings	c_1	c_2	c_3	c_4

a_5	L	L	L	F
Weight	MLI	MLI	VI	MLI

Mendel and Wu use the LWA to aggregate the criteria evaluations and importance evaluations for each alternative into corresponding output IT2 MFs, which are then ranked to determine the order of appropriateness of the investment categories for each of the three types of investors. In the next section we generalize these results using the LWPM with different power exponents on the same input data, which will illustrate the versatility of this aggregation operator as a function of the power exponent.

IV. COMPARISON OF AGGREGATION OPERATORS

When a parameterized aggregation operator such as the LWPM ranges between conjunction and disjunction, we define its similarity to conjunction as the degree of *andness* and its similarity to disjunction as the degree of *orness*, where andness is the complement to orness. The weighted arithmetic mean is equi-similar to conjunction and disjunction, with both andness and orness equal to 1/2. Andness of an aggregator L for which $x_1 \wedge \cdots \wedge x_n \le L(\mathbf{x},\mathbf{w}) \le x_1 \vee \cdots \vee x_n$ everywhere is defined in [13] to be:

$$\alpha_g = \frac{\overline{x_1 \vee \cdots \vee x_n} - \overline{L(\mathbf{x},\mathbf{w})}}{\overline{x_1 \vee \cdots \vee x_n} - \overline{x_1 \wedge \cdots \wedge x_n}} = \frac{n-(n+1)\left(\overline{L(\mathbf{x},\mathbf{w})}\right)}{n-1}, \quad (14)$$

where the overbar denotes averaging over the hypercube $[0,1]^n$ in which $\mathbf{x}$ lies. An aggregator L that is more similar to conjunction than disjunction is referred to as *partial conjunction*, and if vice versa, as *partial disjunction* [13]. Properties are partially substitutable if L is a partial

disjunction, and must be partially simultaneous if L is a partial conjunction.

When L is the weighted power mean with fixed weights and input scores, $L_r(\mathbf{x},\mathbf{w})$ is a continuous and increasing function of r. Therefore from (14), the andness $\alpha_g^{(r)}$ of $L_r(\mathbf{x},\mathbf{w})$ is a monotonically decreasing function of r. When $-\infty < r < 1$, $L_r(\mathbf{x},\mathbf{w})$ represents partial conjunction (i.e., $\alpha_g^{(r)} > 0.5$) whereas for $1 < r < +\infty$, $L_r(\mathbf{x},\mathbf{w})$ represents partial disjunction. For $r \le 0$, $L_r(\mathbf{x},\mathbf{w}) = 0$ if $x_i = 0$ for any $i \in \{1,\ldots,n\}$. Therefore $r = 0$ is the upper bound on r when all inputs are mandatory.

When the inputs are represented by IT2 MFs, the notions of substitutable and mandatory are no longer crisp, but the qualitative aspects of partial disjunction/conjunction are still preserved. To illustrate the range of behaviors for the LWPM as compared with the LWA, we plot in the following sequences of figures the output IT2 MF footprint of uncertainty (FOU) of the LWPM for different values of the power exponent r. In each figure we also plot the FOU of the LWA where $r = 1$, with andness $\alpha_g^{(1)} = 0.5$. The "+" crosshatch corresponds to the LWA MF, while the "x" crosshatch corresponds to the LWPM MF; the UMF is shown as a solid line, while the LMF is shown as a dashed line. The solid vertical line indicates the defuzzified centroid of the LWPM IT2 MF, and the two dashed vertical lines indicate the left and right endpoints of the LWPM centroid interval. Note that our purpose in the choices of alternatives shown below is to illustrate the cases where the LWPM is qualitatively the *most* similar and the *least* similar to the LWA results for a given value of the parameter r.

Consider first the extreme cases of $r = \pm\infty$, where the andness of the LWPM is 1 ($r = -\infty$) or 0 ($r = +\infty$). Figs. 1-6 are for $r = +\infty$, with andness $\alpha_g^{(\infty)} = 0$ (pure disjunction), where the LWPM MF lies generally to the right of the LWA MF. Odd numbered figures correspond to the alternatives for which the LWPM MF FOU is most similar qualitatively to that of the LWA, and even numbered figures correspond to alternatives for which it is most dissimilar to the LWA.

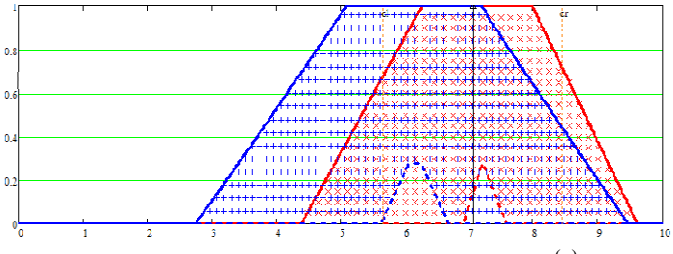

Figure 1 Speculative investor FOUs for a_4, $r = +\infty$, $\alpha_g^{(\infty)} = 0$

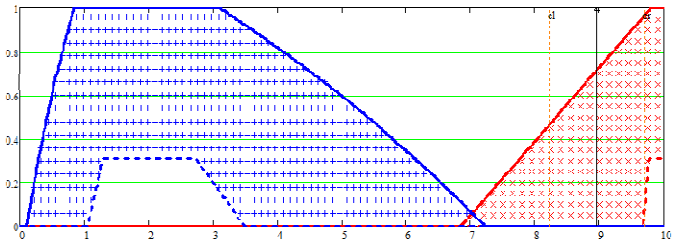

Figure 2 Speculative investor FOUs for a_5, $r = +\infty$, $\alpha_g^{(\infty)} = 0$

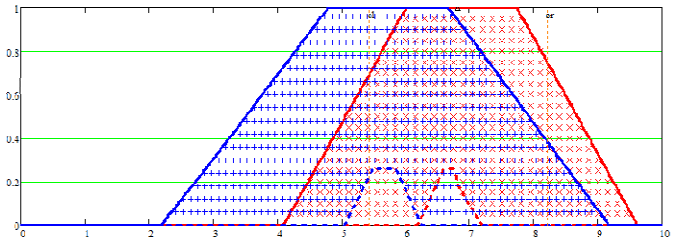

Figure 3 Conservative investor FOUs for a_3, $r = +\infty$, $\alpha_g^{(\infty)} = 0$

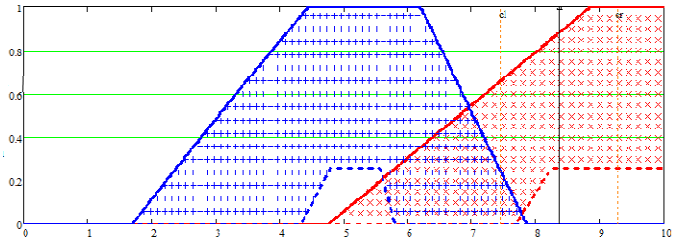

Figure 4 Conservative investor FOUs for a_4, $r = +\infty$, $\alpha_g^{(\infty)} = 0$

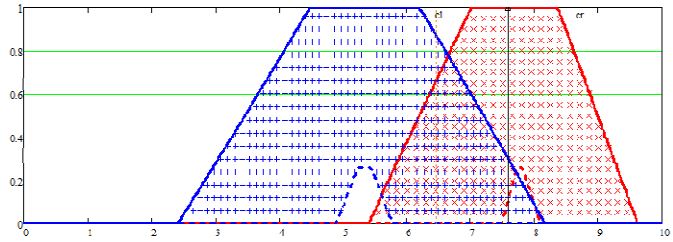

Figure 5 In-between investor FOUs for a_5, $r = +\infty$, $\alpha_g^{(\infty)} = 0$

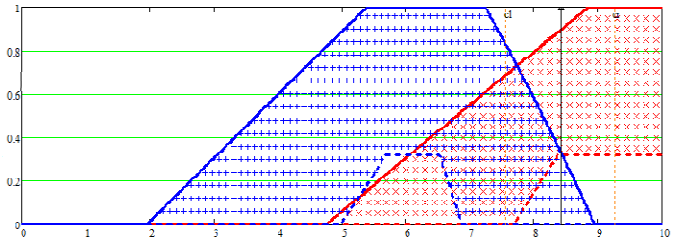

Figure 6 In-between investor FOUs for a_4, $r = +\infty$, $\alpha_g^{(\infty)} = 0$

We observe a dramatic range of differences between the LWPM and LWA over different alternatives, which is a function of the *dispersion* of the evaluation words' IT2 MFs over the 0-10 scale with respect to the various criteria. The LWA smooths these differences, resulting in an interior

trapezoidal IT2 MF in all cases, while the LWPM for $r = +\infty$ often results in a right-shoulder trapezoidal IT2 MF.

Figs. 7-12 show analogous results for the case $r = -\infty$ (pure conjunction), which corresponds to andness $\alpha_g^{(-\infty)} = 1$.

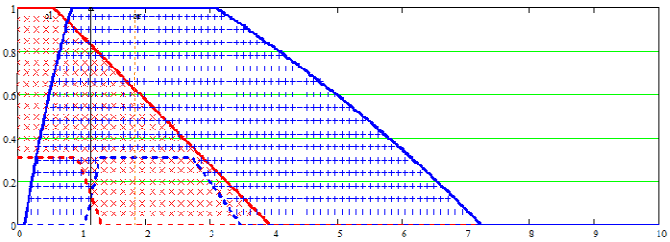

Figure 7 Speculative investor FOUs for a_5, $r = -\infty$, $\alpha_g^{(-\infty)} = 1$

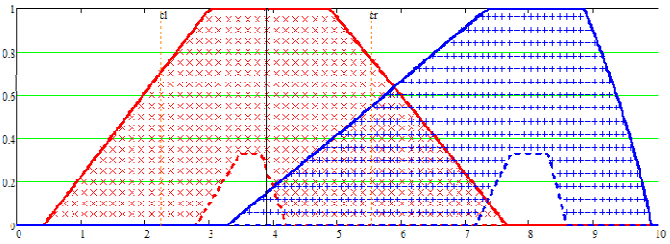

Figure 8 Speculative investor FOUs for a_1, $r = -\infty$, $\alpha_g^{(-\infty)} = 1$

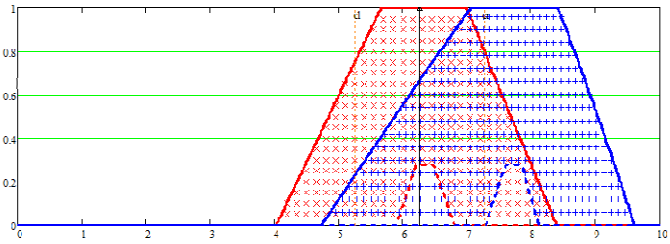

Figure 9 Conservative investor FOUs for a_5, $r = -\infty$, $\alpha_g^{(-\infty)} = 1$

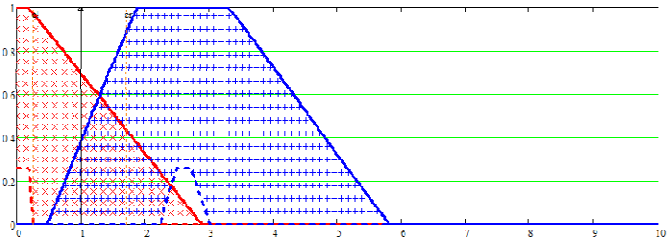

Figure 10 Conservative investor FOUs for a_1, $r = -\infty$, $\alpha_g^{(-\infty)} = 1$

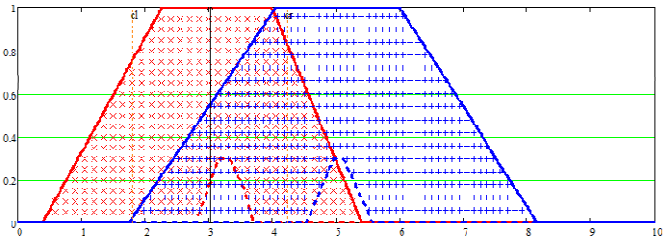

Figure 11 In-between investor FOUs for a_3, $r = -\infty$, $\alpha_g^{(-\infty)} = 1$

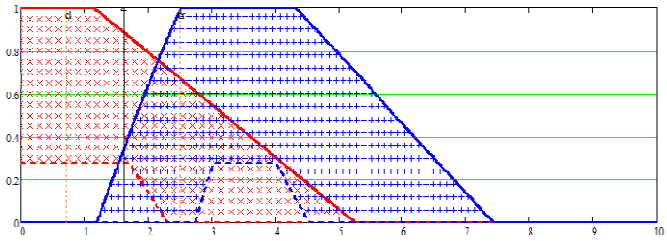

Figure 12 In-between investor FOUs for a_1, $r = -\infty$, $\alpha_g^{(-\infty)} = 1$

Here, the LWPM MF lies generally to the left of the LWA MF, since the LWPM for $r = -\infty$ selects the *minimum* left and right endpoints over the input MFs for each α-cut. Again we observe a substantial range of differences between the LWPM and LWA IT2 MFs, with the LWPM often transitioning to a left-shoulder trapezoidal IT2 MF.

These examples serve to illustrate the substantially greater aggregation versatility of the LWPM over the LWA. By the choice of r, we impart different perspectives to the fuzzy IT2 decision process, ranging from the most optimistic view having an orness of 1, to the most pessimistic view having an andness of 1, with a continuous range of andness/orness between these extremes. This compares with the single value of andness = orness = 0.5 available with the LWA, which averages out the more extreme inputs and thus might be termed a "consensus" view.

Figs. 13-18 show the analogous results for the case $r = -1$ (i.e., the harmonic mean), for which $\alpha_g^{(-1)} = 0.773$. Here, we observe considerably more overlap between the LWPM and LWA MFs, since the power exponents of the two aggregation operators are closer in value. However, even in this case, we observe instances (i.e., Figs. 16 and 18) where the LWPM transitions into a left-shoulder trapezoidal IT2 MF, whereas the LWA has a midrange trapezoidal IT2 MF in all cases.

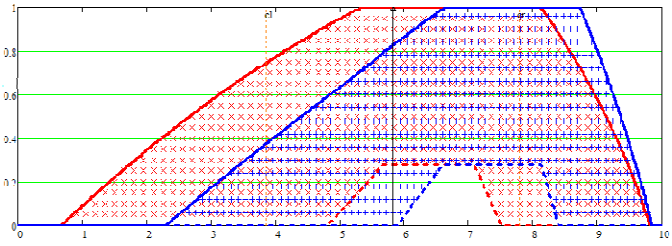

Figure 13 Speculative investor FOUs for a_2, $r = -1$, $\alpha_g^{(-1)} = 0.773$

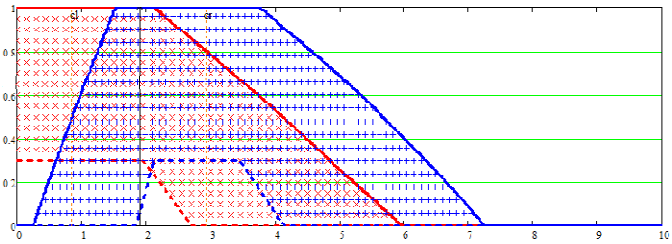

Figure 14 Speculative investor FOUs for a_3, $r = -1$, $\alpha_g^{(-1)} = 0.773$

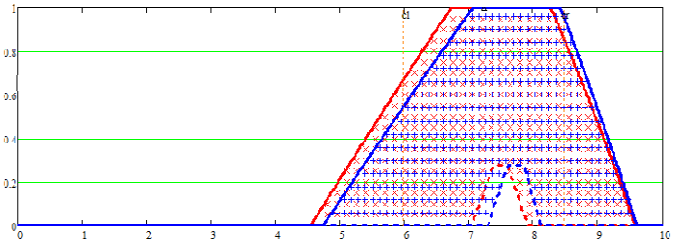

Figure 15 Conservative investor FOUs for a_5, $r=-1$, $\alpha_g^{(-1)}=0.773$

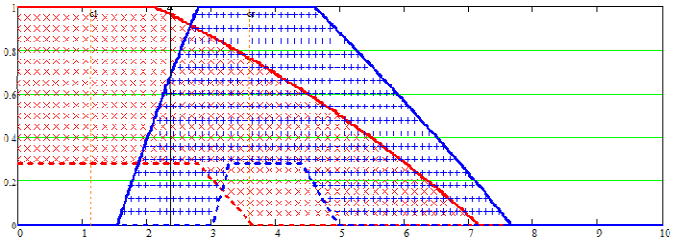

Figure 16 Conservative investor FOUs for a_2, $r=-1$, $\alpha_g^{(-1)}=0.773$

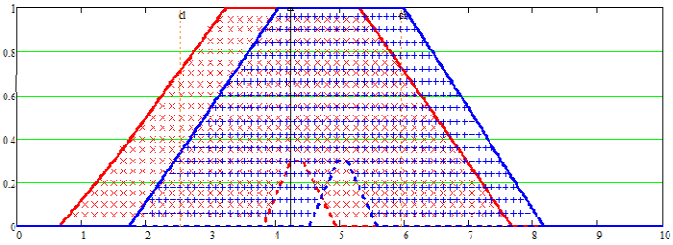

Figure 17 In-between investor FOUs for a_3, $r=-1$, $\alpha_g^{(-1)}=0.773$

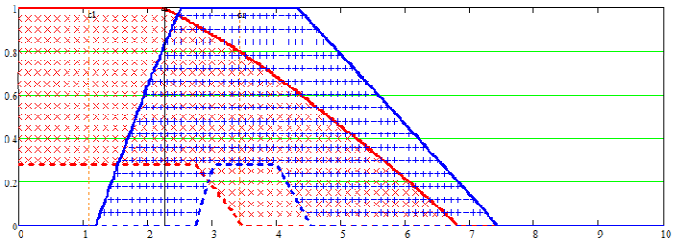

Figure 18 In-between investor FOUs for a_1, $r=-1$, $\alpha_g^{(-1)}=0.773$

In other examples in [1], Mendel and Wu employ hierarchical LWAs in a decision tree to aggregate subcategories of criteria scores into higher-level criteria. Use of the LWPM enables us further to generalize these hierarchical aggregations. For example, to aggregate a mandatory fuzzy input x_1 with a desired fuzzy input x_2, Dujmovi [20] composes bivariate operators denoted by $x_1\Delta(x_1\nabla x_2)$ and called *conjunctive partial absorption* (CPA) aggregators (see also [13]). CPA aggregators apply a WPM partial disjunction (denoted ∇, where $r\geq 1$) to the two inputs, and then take a partial conjunction (denoted Δ, where $r\leq 0$) of that output with the mandatory input.

In a type-1 fuzzy context, $x_1\Delta(x_1\nabla x_2)$ necessarily is zero if x_1 is zero, and $x_1\Delta(x_1\nabla x_2)-x_1$ is positive (resp. negative) when x_2 is greater (resp. less) than x_1. The absolute difference $\left|x_1\Delta(x_1\nabla x_2)-x_1\right|$ is called the *reward* when x_2 is greater than x_1, and is otherwise called a *penalty* [13]. We construct the operator $x_1\Delta(x_1\nabla x_2)$ from weighted power means as

$$CPA_2(\mathbf{x},\mathbf{w}',\mathbf{w})=L_r\left(\left(x_1,L_s(\mathbf{x},\mathbf{w})\right),\mathbf{w}'\right), \qquad (15)$$

with $r\leq 0, 1\leq s<\infty$. Here, $\left(x_1,L_s(\mathbf{x},\mathbf{w})\right)$ are 2-dimensional scores, and $\mathbf{w}'$ is a 2-dimensional weight vector. However $\mathbf{x}$ and $\mathbf{w}$ may be of higher dimension if we have multiple partially substitutable inputs.

As an illustration of the application of IT2 CPA operators, suppose the speculative investor places a mandatory (in a type-1 context) requirement on high investment returns (criterion c_3 in Table 1), making it analogous to x_1 in (15), with a LWPM aggregation of the remaining criteria scores constituting x_2 using a power exponent of -1, as in Figs. 13-18. Suppose further that we specify a maximum reward of +15%, with a maximum penalty of -25%, and set $r=-10$ and $s=1.449$ (the latter corresponding to an andness of 7/16) in (15). Using the techniques of [20], we compute corresponding type-1 weights $\mathbf{w}=(0.347,0.653)$ and $\mathbf{w}'=(0.935,0.065)$ in (15) that achieve these reward/penalty values, and then calculate the LWPMs for ∇ and Δ on the IT2 input variables, with singleton weights.

Fig. 19 shows the CPA IT2 FOU (X crosshatch) and the LWA FOU (+ crosshatch) for investment alternative a_1 (commodities). Comparing this with Fig. 20, where we used a LWPM on all four inputs with $r=-1$, we observe that the CPA FOU is substantially narrower, and is disposed over considerably higher values, than the LWPM FOU. This is understandable from inspection of Table 1, where we observe that the potential for high investment returns in commodities is graded as "extremely high" by a speculative investor. Thus we would expect an enhanced score for commodities when this criterion is elevated to mandatory.

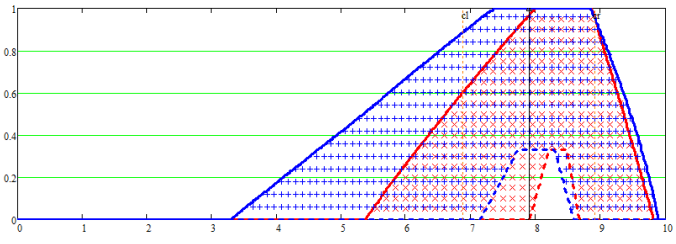

Figure 19 Speculative investor CPA for a_1, with c_3 mandatory.

On the other hand, Figs. 21-22 show the same comparison for investment alternative a_5 (long-term bonds), whose potential for high returns is graded "very low" by the speculative investor. The CPA FOU differs relatively little from the comparable LWPM FOU, since alternative a_5 is in fact scored relatively low with respect to *all* criteria by the speculative investor.

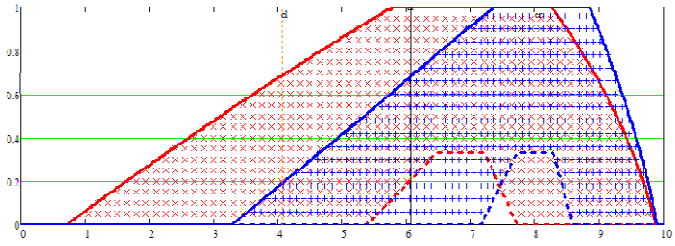

Figure 20 Speculative investor LWPM for a_1, $r=-1$, $\alpha_g^{(-1)}=0.773$.

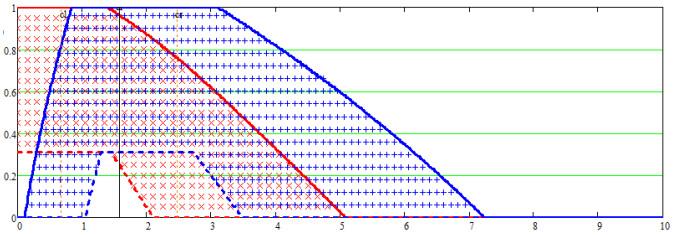

Figure 21 Speculative investor CPA for a_5, with c_3 mandatory.

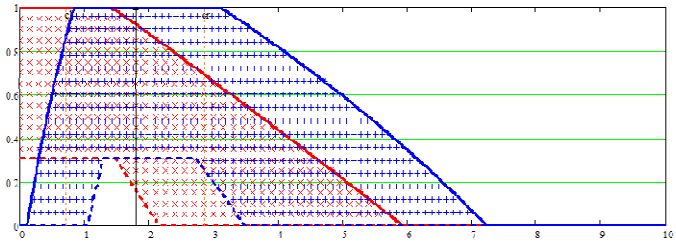

Figure 22 Speculative investor LWPM for a_5, $r=-1$, $\alpha_g^{(-1)}=0.773$.

V. CONCLUSION

We introduce a new family of Per-C computational engines based on the LWPM, and compare it with the LWA using an extended example described in [1]. The WPMEKM algorithm is presented for the computation of LWPM aggregations with interval input and weight variables. This can be extended to inputs and weights described by IT2 MFs using the α-cut Representation Theorem. The LWPM is shown to be a much more versatile aggregation operator, and thus it provides a significant extension to the suite of tools available for CWW applications. We also show how LWPM modules can be used to produce conjunctive partial absorption operators, and illustrate their differences with respect to a straightforward LWPM. These operators enable far more general hierarchical logic functions to be constructed than are available with simple hierarchies of LWAs.

***Abstract*—The capacity of Fuzzy Neural Network (FNN) is explored in this paper. The FNN is first transformed into an equivalent fully connected three layer neural network, or FFNN, via a new approach proposed in this paper. Then the lower and upper bounds of FNN can be found. To check the validity of the theoretical bounds, an example is illustrated with the trainings to yield excellent capacity matching with the theoretical bounds. This new finding has its emerging values in all engineering applications using FNN, such as intelligent adaptive control, pattern recognition, and signal processing, …, etc.**

Keywords-Neural Networks, Fuzzy Logic, Fuzzy Neural Networks, Back Propagations, Universal Approximation Theorem, Capacity of Neural Networks

I. INTRODUCTION

During the past decade, fuzzy neural networks (FNNs) have been proposed and successfully applied to solve problems in various fields, such as intelligent adaptive control, system identification, pattern classification and image processing,…, etc [1-4]. FNN can utilize human experience and knowledge by incorporating linguistic fuzzy information. FNN consists of a set of if-then fuzzy rules. The rules are built up by human experts as linguistic knowledge. To obtain better performance, some training algorithms such as back-propagation(BP) algorithm is adopted to tune the parameters of fuzzy system and the weights of neural network. Training algorithm attempts to minimize the training error, which is the difference between the desired and actual outputs [5]. If FNN is properly constructed, it follows Universal Approximate Theorem (UAT), i.e., the properly constructed FNN can approximate any functions [6-7]. However, the UAT does not point out how to properly construct the fuzzy system and neural network. This is to say that the FNN designed for certain applications by human experts cannot be ideal, which will lead to the discussion of the constraints of FNN, i.e., the capacity of FNN, so that engineering applications via FNN can be achieved. Similar to the discussions of the capacity of multilayer neural networks [8], the capacity of FNN is defined as the maximum number of desired input vectors that can be mapped to desired output vectors without error. This is also to say that the number of training samples has significant impact on training process. Excessive samples size may lead training process to be diverged. The capacity of associative memory and multilayer perceptron (MLP) has been conducted in the past decade, assuming a fully connected neural network [8-15]. However, the capacity of FNN has never been found in the literatures. This is due to fact that the FNN is not a fully connected directed graph and the intermediate layer is defined as a product layer, instead of a summing layer in a NN.

To apply the techniques in finding the capacity of three layers NN, a new approach is proposed to transform the four layers FNN into a fully connected directed graph with all summing nodes. This is achieved in this paper by also combining a systematic fuzzy rule generation for FNN [16] so as to obtain a fully indexed equivalent three layer NN for FNN, or FFNN. By using this new FFNN, the lower and upper bounds of the capacity of FNN can be found in this paper. An example is illustrated this paper to validate the theoretical bounds by back propagation trainings. Excellent matching is achieved between the theoretical bounds and training simulation.

II. THE FNN WITH SYSTEMATIC RULE GENERATION

Given the training input data vectors $\{x_q^*, q = 1, 2, 3, \cdots, n\}$, and the desired output vectors $\{y_p^*, p = 1, 2, \ldots, m\}$, the inference rules of simplified fuzzy reasoning can be established by the expert. The l^{th} control rule has the following form:

Rule l: IF x_1 is $A_1^{r_1}$ and ….. and x_n is $A_n^{r_n}$ THEN y_1 is W_{l1} and …. and y_m is W_{lm}

where l is a rule number, the $A_q^{r_i}$ are membership functions of antecedent part, and W_{lp} are real numbers of the consequent part. When the inputs are given, the truth value μ_l of the premise of the l^{th} rule is defined by

$$\mu_l = A_1^{r_1}(x_1)\times\cdots\times A_n^{r_n}(x_n); \{l = 0,1,2,\ \ldots, L;\ r_i = 0,1,2,\ldots,R_{i-1}\} \quad \text{趙} \tag{1}$$

where L is total number of fuzzy rules and R_i is the number of MFs for fuzzy variable x_i , and r_i is the ordinal index of MFs for fuzzy variable x_i . Among the commonly used defuzzification strategies, the simplified fuzzy reasoning yields a superior result. The output yp of the fuzzy reasoning can be derived from the following equation:

$$y_p = \frac{\sum_i \mu_i w_{ip}}{\sum_i \mu_i}, (p = 1,2,\cdots,m) \tag{2}$$

Where μ_l is the truth value of the premise of the l^{th} rule, equations (1) and (2) describe the simplified fuzzy reasoning methods, through which the membership functions of the antecedent part are chosen. Then the fuzzy neural network (FNN) can be constructed and is shown in Fig. 1. [1]

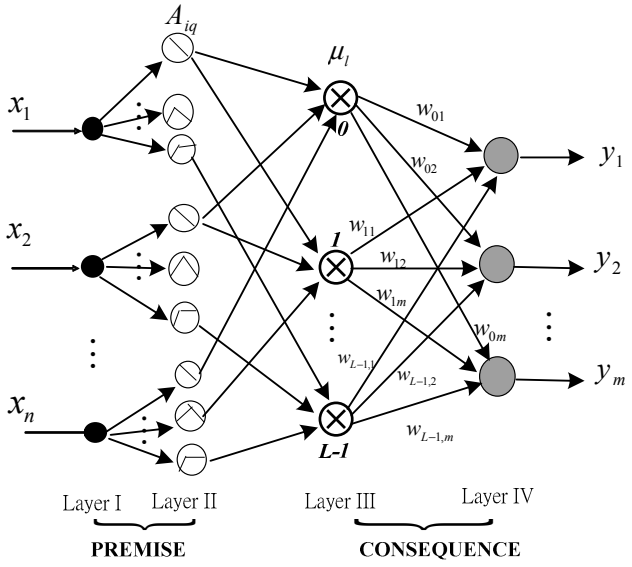

Figure. 1 The configuration of FNN

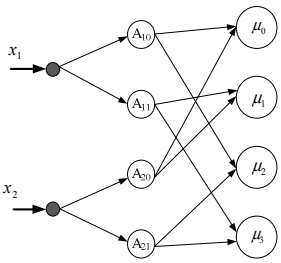

Figure. 2. Simple Illustration of Layers 1, 2 and 3 in FNN

TABLE I. SYSTEMATIC GENERATION OF RULES FROM MFS

r_1	r_2	$l(=r_1+2r_2)$	μ_l
0	0	0	$A_{10}(x_1)A_{20}(x_2)$
1	0	1	$A_{11}(x_1)A_{20}(x_2)$
0	1	2	$A_{10}(x_1)A_{21}(x_2)$
1	1	3	$A_{11}(x_1)A_{21}(x_2)$

Figure. 1 shows that the system has a total of four layers. Nodes at Layer I are input nodes, which represent input linguistic variables. Nodes at Layer II are term nodes, which represent the terms of the respective linguistic variables. Each node at Layer III is a fuzzy rule. All the layer-three nodes form the fuzzy rule base. Layer IV is the output layer. The links between Layer III and IV are fully connected by the weighting factors w_{lp}. Further a systematic generation of the fuzzy rule in Layer III has been derived in [16] which can reduce the programming effort with less execution time in real-time applications. In [16], a systematic generation of fuzzy rules in Layer III of the FNN in Figure 1 has been presented. In particular, the ordinal index l of the l^{th} fuzzy rule is:

$$l = r_1 + \sum_{i=2}^{n}\left(\prod_{j=1}^{i-1} R_j\right) r_i \tag{3}$$

where R_i is the total number of MFs for fuzzy variable x_i , and r_i ($0 \le r_i \le R_i - 1$) is the ordinal index for the r_i th MF for fuzzy variable x_i . Equation (3) can produce all the $l's$ in the range of $0 \le l \le (\prod_{i=1}^{n} R_i) - 1$ with a one-to-one mapping from MFs to fuzzy rules. This will provide us with a complete indexing of the equivalent fully connected fuzzy neural network for FNN in the following sections. For two fuzzy variables $\{x_1, x_2\}$ with two MFs for $\{x_1, x_2\}$, i.e., $\{A_{10}(x_1), A_{11}(x_1)\}$ for x_1 , $\{A_{20}(x_2), A_{21}(x_2)\}$ for x_2 , with $\{R_1 = R_2 = 2\}$, as shown in Fig. 2. From (3), the ordinal index of four fuzzy rules can be generated using $\{l = r_1 + 2r_2, l = 0,1,2,3\}$. Table I shows the result.

III. THE EQUIVALENT FULLY CONNECTED NEURAL NETWORK FOR FNN

As can be seen from the above discussion of FNN, the FNN is not a fully connected graph between Layer II and Layer III. This will hinder the discussion of the capacity of FNN. Therefore, in order to find the capacity of FNN, we need to convert the FNN into a fully connected neural network. There are two obstacles to be resolved. The first obstacle is that the links between Layer II and Layer III of FNN are not fully connected. The second obstacle is that computation unit in Layer III of FNN is a product unit rather than a summing unit. From Fig. 1, we can see the transitions from Layer II to Layer III can be simplified by arranging the links between Layer I to Layer III using equivalent weights. This can be more easily observed from Fig. 2 that there are links from each input node (x_1 or x_2) to every fuzzy rule, all through one of the MFs of every input node. Figures 3-1 & 3-2 show these cases for x_1 and x_2 with proper link weights. This is to say that we can suppress Layer II (MF layer) in the original FNN and replace new links between Layer I and Layer III, so that we can have a fully connected FNN (FFNN) as shown in Fig. 3-3.

This can be generalized to a general case of fully connected FNN, or FFNN as shown in Figure 4. This can resolve the first obstacle of not-fully connected property of the original FNN shown in Figure 1. The $\{V_{ij}(i=1,2,...,n; j=1,2,...,L)\}$ in Fig. 4 is defined as the link weight between the i^{th} node of Input Layer and the j^{th} node of Hidden Layer, or the fuzzy rule layer.

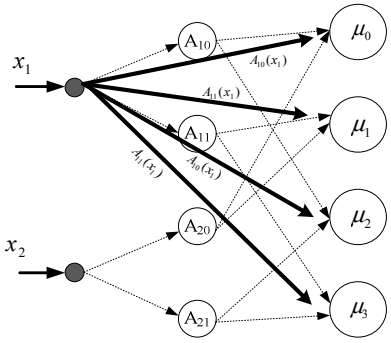

Figure. 3-1. Suppressing the MF Layer for x_1

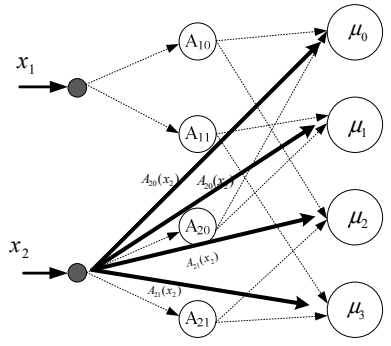

Figure. 3-2. Suppressing the MF Layer for x_2

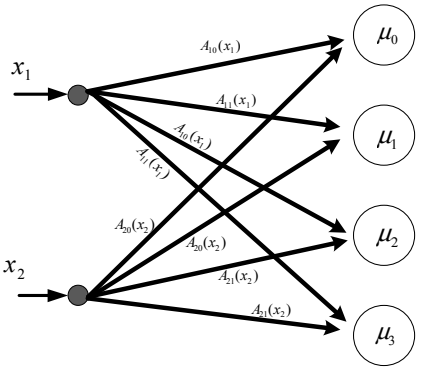

Figure 3-3. Suppressing the MF Layer with proper link weights

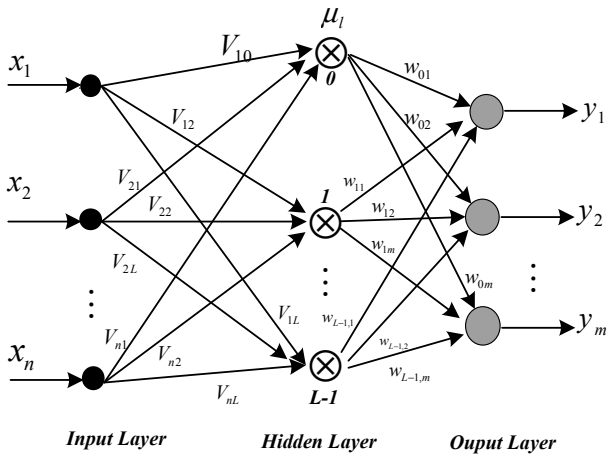

Figure 4. The equivalent fully connected neural network for FNN

However, the V_{ij} links between Input Layer and Hidden Layer in Figure 4 are still not well specified to yield μ_l in the Hidden Layer. We only know that each input node is only allowed to contribute one link weight form μ_l. Therefore μ_l is expressed in term of the product of n V_{ij} weights. Fortunately, a systematic way to generate the fuzzy rules in Hidden Layer has been proposed in [16]. This is to say that, given the fuzzy rule μ_l, we can determine its related links from all input nodes in a systematic way. From (3), we can reversely find all the r_i's for a specific l (fuzzy rule number in Layer III) as follows:

$$r_1(l) = l\%R_1;$$
$$r_i(l) = (l / \prod_{k=1}^{i-1} R_k)\%R_i, i = 2,...,n \quad (4)$$

where A % B represents the remainder of the division of A over B, A/B represents the quotient of the division of A over B. From (4) we can get n ordinal index $r_i(l)(i=1, 2, ..., n)$ of membership functions corresponding to rule l, then the $V_{ij}(i=1, 2, ..., n; j=1,2,...,L)$ can be set as:

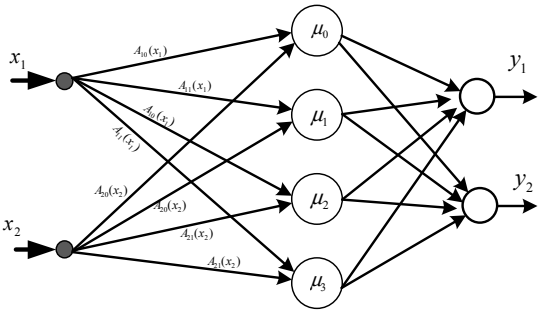

Figure 5. The FFNN with two input variables, two output variables

$$V_{ij} = A_{ir_i(j)}(x_i),\ i = 1, 2,\ ..., n; j = 1, 2, ..., L \qquad (5)$$

For two fuzzy variables $\{x_1, x_2\}$ with two MFs for each input variable i.e. $\{A_{10}(x_1), A_{11}(x_1)\}$ for x_1, $\{A_{20}(x_1), A_{21}(x_1)\}$ for x_2, then there are four hidden nodes (i.e., four rules), eight weights from input nodes to hidden nodes $V_{ij}(i = 1,\ 2; j = 1, 2, 3, 4)$. Table II shows the result. Fig. 5 shows the FFNN.

Therefore we have resolved the issue of not-fully connected MF layer in the original FNN, as shown in Figure 4. The next task will be to transform the product unit in Layer III (fuzzy rule layer) of FNN, or Layer II in Fig. 4 into an equivalent summing unit. To do so, we need to change the V_{ij} defined in (5) into the following new weight:

$$V_{ij} = Ln(A_{ir_i(j)}(x_i)) \qquad (6)$$

The output of hidden Layer is:

$$\mu_j = \sigma(\sum_{i=1}^{n} Ln(A_{ir_i(j)}(x_i))) = \sigma(Ln(\prod_{i=1}^{n} A_{ir_i(j)}(x_i)) \qquad (7)$$

where σ is any activation function, Ln is natural logarithm. If we take exponential function as activation function, we have

$$\mu_j = Exp(Ln(\prod_{i=1}^{n} A_{ir_i(j)}(x_i)) = \prod_{i=1}^{n} A_{ir_i(j)}(x_i) \quad 趙趙趙 \qquad (8)$$

Fig. 6 illustrates this transformation via (6) to (8).

It is important to note that the exponential activation function in Fig. 6 has limit zero when the input argument is a negative number, or the exponential activation function has limit at one infinite direction. This does match the requirement for finding the capacity of the three layers NN [15]. Figure 7 shows the complete fully connected FNN, or FFNN. It is obvious that the FFNN shown in Figure 7 is equivalent to the original FNN shown in Fig. 1. However, the FFNN is a fully connected three layer directed graph, which is the basis of finding the capacity of FFNN, or FNN. This will be discussed in the following sections.

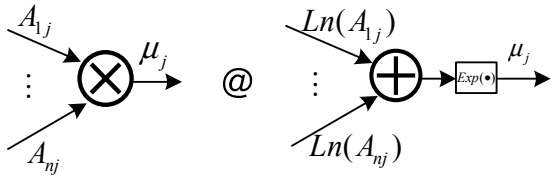

Figure 6. Transforming the product unit into summing unit in FNN

TABLE II FFNN WEIGHTS GENERATED FROM MFS AND RULE NUMBER

$l(=j-1)$	$r_1(l)$	$r_2(l)$	V_{1j}	V_{2j}
0	0	0	$A_{10}(x_1)$	$A_{20}(x_2)$
1	1	0	$A_{11}(x_1)$	$A_{20}(x_2)$
2	0	1	$A_{10}(x_1)$	$A_{21}(x_2)$
3	1	1	$A_{11}(x_1)$	$A_{21}(x_2)$

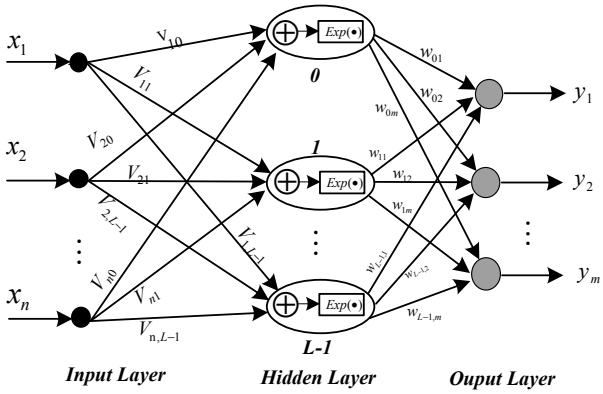

Figure 7. The complete fully connected FNN, or FFNN

IV. THE CAPACITY OF FNN OR FFNN

As mentioned in section 3, the original FNN has the same capacity as that of the equivalent FNNN with three layers. In this section, we will discuss the capacity of the three layers FNNN with exponential activation functions in the hidden layer. The following Theorem 1 shows lower and upper bounds of the FNN, or the three layer FFNN.

Theorem 1. For the FNN defined in Figure 1, where there are n inputs, m outputs, and L neurons in fuzzy layer (or hidden layer), each fuzzy variable x_i has R_i MFs, each MFs has N_{cp} control parameters, then the capacity P of the FNN can be bounded by the following inequality:

$$L \le P \le (\sum_{i=1}^{n} R_i N_{cp} + Lm) / m \qquad (9)$$

Proof:

In [15], it has been shown that standard single-hidden layer feed-forward networks (SLFN) with at most L hidden neurons and with any bounded nonlinear activation function which has a limit at one infinity can learn L distinct samples with zero

error. This implies that the SLFN with L hidden units can memorize at least L distinct patterns. For the FFNN, the exponential activation function in the hidden layer satisfies the condition of activation function in [15], so the lower bound on the capacity *P* is the number of hidden nodes L, i.e.,

$$P \geq L \tag{10}$$

Further, it has been shown in [8] that the upper bound for the capacity of feed-forward networks with arbitrary hidden unit activation functions can be found. For a feed-forward network (without bias) with n inputs, m outputs, *L* hidden units and arbitrary hidden activation functions, the number of patterns P that can be memorized with no error is less than or equal to $L(n+m)$, divided by the number of outputs m. Then the upper bound for the capacity P of SLFN is

$$P \leq L(n+m)/m \tag{11}$$

In the right hand side of (11), *nL* represents the number of links between input layer and hidden layer and *mL* represents the number of links between hidden layer and output layer. The *nL* and *mL* links should have the weights which are independent of input variables. However the link weights between layer I and layer II of FFNN depends on input variables, we should find another kind of control parameters between layer I and layer II to find the upper bound of the capacity of the FFNN. Assume that each MF in FNN has identical N_{cp} control parameters, such as the mean and variance in Gaussian MFs. In this popular case, $N_{cp} = 2$. So the total number of independent control parameters between layer I and layer II is $\sum_{i=1}^{n} R_i N_{cp}$. Replacing *nL* in (11) with $\sum_{i=1}^{n} R_i N_{cp}$, we have the following upper bound for the capacity *P* of FFNN:

$$P \leq (\sum_{i=1}^{n} R_i N_{cp} + Lm)/m \tag{12}$$

From (10) and (12), we can conclude that:

$$L \leq P \leq (\sum_{i=1}^{n} R_i N_{cp} + Lm)/m \qquad \text{Q.E.D.}$$

For Gaussian or any triangular membership functions, the number of control parameters N_{cp} is 2. From (1) we have $L = \prod_{i=1}^{n} R_i$, so if $n \geq 2$ and $R_i \geq 2$, then we have $nL = n\prod_{i=1}^{n} R_i > N_{cp}\sum_{i=1}^{n} R_i$. Therefore, from (11) and (12),

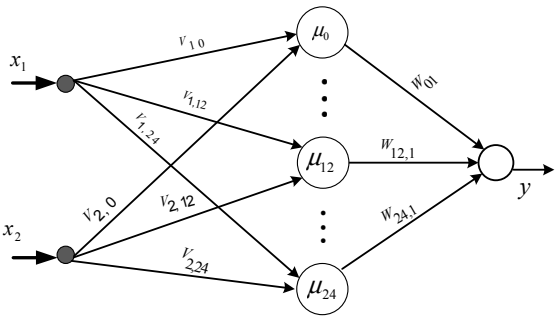

Figure. 8. FFNN with two input variables, each variable with five MFs

we find that the upper bound for capacity of FNN is less than that of MLP with the same configuration for larger *n*.

V. ILLUSTRATED EXAMPLE

In this section, Theorem 1 will be adopted to decide the theoretical upper and lower bounds of a particular FNN. In order to check the validity of the theoretical results, detailed BP trainings of the FNN are also conducted. The FFNN shown in Fig. 8 has two input nodes ($n = 2$) and one output node ($m = 1$), each linguistic variable has five items, so there are 25 nodes in hidden layer ($L = 25$). According to Theorem 1, the capacity P of the FNN should be bounded by $L \leq P \leq (\sum_{i=1}^{n} R_i N_{cp} + Lm)/m$, which is $25 \leq P \leq 45$. The membership functions are Gaussian functions (= $Exp(\frac{-(x-\mu)^2}{2\sigma^2})$), the output node is a linear unit. The training data is generated by $y = \sin(x_1\pi)\cos(x_2\pi)$, x_1 and x_2 are both in the range of [-1, 1] with 0.1 as the step-size. The FNN can be trained by the following BP algorithm as described in [5]:

$$\begin{cases} m_i(t+1) = m_i(t) - k_m \dfrac{\partial e_p}{\partial m_i}, i = 1,...,K \\ \sigma_i(t+1) = \sigma_i(t) - k_\sigma \dfrac{\partial e_p}{\partial \sigma_i}, i = 1,...,K \\ w_{jp}(t+1) = w_{jp}(t) - k_w \dfrac{\partial e_p}{\partial w_{jp}}, j = 1,...,L, p = 1,...,m \end{cases} \tag{13}$$

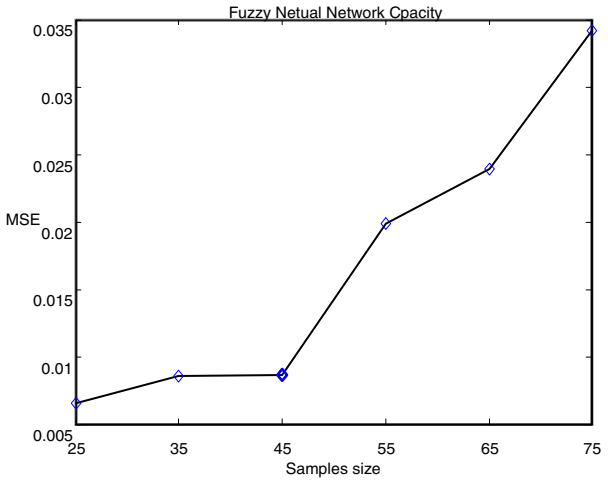

Figure 9. Relationship between training error and patterns number of FNN

Where $e_p = \frac{1}{2}(y_p - y_p^*)^2$, $K = \sum_{i=1}^{n} R_i$ is the number of MFs. From Fig. 9, we can see that if the number of training patterns is near the lower bound (=25),the MSE can be made as close as possible to zero. When the number of training patterns reach upper bound (=45),the MSE values start to deviate from zero rapidly, which will be very difficult for the training process to converge. Therefore the theoretical bounds are in excellent agreement with the real BP training results

VI. CONCLUSION

This paper proposes a new approach to find the lower and upper bounds of the capacity of FNN. By transforming the conventional four layers FNN into an equivalent fully connected three layer feed-forward NN, or FFNN, we can obtain the lower and upper bounds of FNN. An illustrated example is proposed to demonstrate the validity of theoretical bound using real BP trainings. Excellent agreement has been obtained between the theoretical bounds and real BP trainings. The impact of this paper is that all engineering application via FNN should have the capacity of their imperfect FNN in mind to complete the successful implementations. This will be our future research directions.

VII. ACKNOWLEDGEMENT

This research is supported by the research fund of the National Grand Fundamental Research 973 Program of China under Grant 2011CB302801.

***Abstract*—In recent years, cancer can be detected and recognized by analyzing the sample's expression profile. The cancer gene expression data are high dimensional, high variable dependent, and very noisy. The dimension reduction method is often used for processing the high dimensional data. In this study, a new statistical dimension reduction method called Expressive Value Distance (EVD) is developed and proposed for the practical high-dimensional gene expression cancer data. The feature genes data extracted by EVD are arranged for training the optimally trained Artificial Neural Network (ANN). The trained ANN is then used to classify whether the unseen gene data is cancer or not. In comparison of ANN classification with and without EVD, it is found that both of the ANN can classify the cancer data in good accuracy. With the EVD method, the great amount of data (2000 genes) can be effectively reduced to 16 genes. Therefore, EVD is an effective dimension reduction method. Even the EVD method is not used, the optimally trained ANN is also an advanced method for classifying the high dimensional and complicated cancer data. Briefly, it proves that optimally trained ANN is a very robust classification technique.**

Keywords-Gene expression profile; Dimension reduction; Artificial neural network; Expressive value distance; Classification of cancer;

I. INTRODUCTION

Classification has become one of the most promising learning techniques. It is crucial in many applications such as cancer classification [1]. Such classifications have an immense impact on cancer prognosis and therapy. In contrast with clustering, classification techniques start with a collection of labeled (pre-classified) expression patterns. The purpose is to train a classification model that would be able to classify a new expression pattern. In recent years, the development of microarray technology has allowed the simultaneous monitoring of thousands of genes [2, 3], which have motivated the progress in cancer classification by using gene expression [4, 5, 6].

Known as a parallel distributed processing network, artificial neural network is a robust tool recently used as classification. It has been applied to a very broad range of tasks in many different disciplines. It consists of interconnected processing elements called nodes or neurons that work together to produce an output function. The output of a neural network relies on the cooperation of the individual neurons within the network.

It becomes a reality to apply neural network with bioinformatics technology to cancer diagnosis for the development of DNA microarray technology. It has attracted tremendous interest in both the scientific community and in industry. Several studies have recently reported on the application of microarray gene expression analysis for the classification of cancer [7]. Most of these applications assumed a predefined network architecture (including connectivity and node transfer functions) and used a training algorithm to the learn weights.

In this study, 62 colon cells with 2000 genes expression data are analyzed (22 normal and 40 cancer cells). On the basis of the feature of gene expression data (high dimensional, high variable dependent, and very noisy), feature extraction by dimension reduction is necessary before the classification from the original data set [8, 9]. To classify the high dimensional gene expression cancer data, the dimension reduction methods were often used, such as principal component analysis (PCA), generalized topographic mapping, projection pursuit and so on [10]. After the dimension is reduced, the feature genes can be obtained and analyzed more easily. A new dimension reduction method (EVD) based on the concept of probability distribution and hierarchical clustering method is proposed for cancer data. After the feature gene data is obtained, the feature genes data will be arranged as the input for training the optimal trained Artificial Neural Network (ANN) [11]. The trained ANN is

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

used to classify whether the unseen gene data is cancer or not. The benchmark classification tests have been performed to show that the EVD can yield a slightly better result than that of the optimally trained ANN method. For computational complexity comparison, it is obvious that the optimally trained ANN has less computational complexity than that of EVD, and yet provides a very robust classification technique with good accuracy.

II. THE ALGORITHMS

2.1 Classification method

The structure of two layers ANN is shown in Fig. I, which will be used as a cancer gene classifier in this paper.

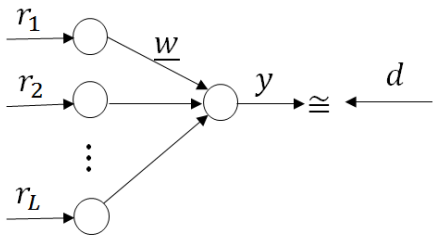

Fig. I. Two-layers ANN

Where

$$\underline{r} = [r_1, r_2, \dots, r_L]^T \in \mathbb{R}^L \quad (2.1)$$

is the input vector of the network

$$\underline{w} = [w_1, w_2, \dots, w_L]^T \in \mathbb{R}^L \quad (2.2)$$

is the weighting vector $y \in \mathbb{R}$ is the network output, and "T" is the transpose operator of matrices.

Hence, according to the structure of the two layers ANN, we obtain the following formula

$$y = \sum_{l=1}^{L} r_l w_l = \underline{r}^T \underline{w} \quad (2.3)$$

Given a training dataset with P samples

$$\{(\underline{r}_1, d_1), (\underline{r}_2, d_2), \dots, (\underline{r}_P, d_P)\},$$

We define the sum of square error which is a function of the weight vector $\underline{w}$ by

$$J(\underline{w}) = \frac{1}{2P}\left(\underline{y} - \underline{d}\right)^T \left(\underline{y} - \underline{d}\right)$$
$$= \tfrac{1}{2P}\left(R^T\underline{w} - \underline{d}\right)^T \left(R^T\underline{w} - \underline{d}\right) \quad (2.4)$$

Where

$$R = \left[\underline{r}_1, \underline{r}_2, \dots, \underline{r}_P\right] \in \mathbb{R}^{L\times P} \quad (2.5)$$
$$\underline{y} = [y_1, y_2, \dots, y_P] \in \mathbb{R}^P \quad (2.6)$$
$$\underline{d} = [d_1, d_2, \dots, d_P] \in \mathbb{R}^P \quad (2.7)$$

Indeed to train the ANN is to minimize the error function $J(w)$ in equation (2.4). The classical approach to find the minimum weight vector is using steepest descent method. Precisely, we will construct an iteration sequence which is expected to converge to the minimum weight vector as below:

$$\underline{\mathrm{w}}(t+1) = \underline{\mathrm{w}}(t) - \beta(t)\left.\frac{\partial J(\underline{w})}{\partial \underline{w}}\right|_{\underline{\mathrm{w}}(t)} \quad (2.8)$$

Where t denotes the t th iteration and the number $\beta(t)$is the learning rate. By chain rule, the gradient $\frac{\partial J(\underline{w})}{\partial \underline{w}}$ is equal to $\frac{1}{P}R(R^T\underline{w} - \underline{d})$. Hence, we have

$$\underline{w}(t+1) = \underline{w}(t) - \frac{\beta(t)}{P}R\left(R^T\underline{w}(t) - \underline{d}\right) \quad (2.9)$$

It was shown that the relatively large or small learning rates may affect the learning progress and even may lead to failure of the process [12]. So, to avoid these situations, dynamic optimal learning rate training for ANN is employed to train the two layers ANN in this paper. It is not only guaranteed that the maximum error reduction can be achieved by choosing the optimal learning rate for the next training iteration, but also that the initial choice of the weights become not essential. According to Theorem 1 in [11], the optimal learning rate $\beta_{opt}(t)$ can be found from the minimum of a quadratic polynomial $A\beta^2 + B\beta$ where

$$A = \frac{1}{2P^3}R^T R\underline{e}_t\underline{e}_t^T R^T R$$
$$B = \frac{1}{P^2}R^T\underline{e}_t^T\underline{e}_t R$$
$$\underline{e}_t = R^T\underline{w}(t) - \underline{d} \quad (2.10)$$

The dynamic optimal learning rate training is summarized as follow:

Algorithm 1: Classification by using ANN with Dynamic Optimal Learning Rates

1) Training the classifier

step1. Given P training data and obtain R and $\underline{d}$ as above.

step2. Set the iteration counter $t = 0$ and the initial weight to be $\underline{w}(0)$. Find the optimal learning rate $\beta_{opt}(0)$. Start the steepest descend to the error function $J(\underline{w})$.

step3. Find if the error function $J(\underline{w})$ is smaller than a given tolerant ε? If yes, go to Step 7.

step4. Update the weighting matrix to yield $\underline{w}(t+1)$ according to (2.9)

step5. Find the optimal learning rate $\beta_{opt}(t+1)$ for the next iteration.

step6. Set $t = t + 1$.Go back to Step 3.

step7. Store the current $\underline{w}(t)$ to $\underline{w}_{opt}$ and end.

2) Testing the classifier:

step8. Given another set of testing data and form R_{test} and $\underline{d}_{test}$ as if in step 1 of the training process.

step9. Obtain the trained network output vector $\underline{y}_{test}$ by using the formula $\underline{y}_{test} = R^T\underline{w}_{opt}$.

step10. Convert the output $\underline{y}_{test}$ into the classification label (1/-1).

step11. Compare $\underline{y}_{test}$ and $\underline{d}_{test}$ and have the diagnostic accuracy.

step12. End.

2.2 Dimension reduction method

Gene expression profile of a DNA is very complicated and it can be represented by a high dimensional vector. For example, in this paper, the dimension of such vector is up to 2000. However, most the genes within DNAs are not relevant

for cancer classification and they should be eliminated [13, 14]. Besides, the rest of the genes can be grouped into clusters. The genes within a cluster actually are highly correlated. Therefore, one of the genes in a cluster can be chosen as its representative. Based on this theory, we are able to reduce the dimension of the gene expression profile vectors. In our study, we have actually implemented such dimension reduction by vertical process and horizontal process. The vertical process is to eliminate those irrelevant genes by using EVD method, while the horizontal process is to classify the resulted genes from vertical process into clusters by the hierarchical clustering method and to choose one representative gene from each cluster [15].

A. *Vertical process*

First of all, we assume that the condition distribution of a gene expression given that it is from a normal DNA (or a cancer DNA) follows normal distribution. Therefore, the conditional probability density function of a gene expression is

$$f(x|normal) = \frac{1}{\sigma_1\sqrt{2\pi}} e^{-\frac{1}{2}(\frac{x-\mu_1}{\sigma_1})^2}$$

and

$$f(x|cancer) = \frac{1}{\sigma_2\sqrt{2\pi}} e^{-\frac{1}{2}(\frac{x-\mu_2}{\sigma_2})^2}$$

Note that practically, the mean and the variance can be replaced by its sample mean and sample variance respectively in order to obtain the above density functions.

Definition 1: The expressive value distance between $f(x|normal)$ and $f(x|cancer)$ of a gene expression is defined to be **EVD**:

$$EVD = \int_{min(x)-\delta}^{max(x)+\delta} |f(x|normal) - f(x|cancer)|dx \quad (2.11)$$

Where δ is called the generalization error of the distribution area and

$$\delta = \frac{\min(x) - \min(x)}{5} \quad (2.12)$$

Algorithm 2: Vertical process of EVD

step1. Calculate the EVD of all the gene expressions by using equation (2.11).

step2. Set the EVD threshold α.

step3. Select the i^{th} gene if its EVD is bigger than α to form a new feature gene set and its size is denoted by L_1.

step4. End.

B. *Horizontal process*

In order to have further reduction of the numbers of genes, we are going to group the genes with similar gene expression. Assume a gene expression profile x_k of the resulted dataset of vertical process. Therefore,

$$x_k = (x_{k1}, x_{k2}, \dots, x_{kL_1}) \in \mathbb{R}^{L_1}$$

Where $k = 1,2, \dots, n$ and n is the number of samples.

The correlation between i^{th} genes and j^{th} gene is defined as below

$$r_{ij} = \frac{\sum_{k=1}^{n}(x_{ki} - \bar{x_i})(x_{kj} - \bar{x_j})}{[\sum_{k=1}^{n}(x_{ki} - \bar{x_i})^2 \sum_{k=1}^{n}(x_{kj} - \bar{x_j})^2]^{\frac{1}{2}}} \quad (2.13)$$

Where $\bar{x_i}$ and $\bar{x_j}$ are the sample means of the gene expression of i^{th} and j^{th} genes respectively.

Then, we get the relation matrix of the feature genes as below (2.14):

$$RM = \begin{bmatrix} r_{11} & r_{12} & \cdots & r_{1L_1} \\ r_{21} & r_{22} & \cdots & r_{2L_1} \\ \vdots & \vdots & \ddots & \vdots \\ r_{L_1 1} & r_{L_1 2} & \cdots & r_{L_1 L_1} \end{bmatrix} \quad (2.14)$$

The average related value represent as (2.15)

$$\overline{RM}(C_1, C_2) = \frac{1}{n_{C_1} \times n_{C_2}} \sum_{x_k \in C_1} \sum_{x_m \in C_2} r_{km} \quad (2.15)$$

Where C_1 and C_2 stand for two classes of genes and n_{C_1} and n_{C_2} are the sizes of C_1 and C_2 respectively.

Algorithm 3: Horizontal process of EVD

step1. Fix a integer number L_2

step2. Clustering the output gene set of vertical process by classical hierarchical clustering method (bottom-up), refer to [15], with distance function $\overline{RM}(C_1, C_2)$ and $K = L_2$.

step3. Choose one gene from every sample of the final L_2 clusters to form a reduce list of genes for ANN classification.

step4. End.

III. EXAMPLE

In this paper, the expression of colon dataset of 62 cells were used, 22 normal cells and 40 cancer cells (Fig. II and Table I). The dataset was free for download in the website [16].

Fig. II. Colon cancer dataset

TABLE I

COLON CANCER DATASET

Name / Sample		1_Has.3004	…	2000_Hsa.9683
S1	**N**	12.77219	…	5.888287
S2	**N**	10.90289	…	4.252098
S3	**N**	11.83636	…	4.942221
⋮	⋮	⋮	⋮	⋮
S61	**C**	13.15361	…	5.007476
S62	**C**	12.60609	…	4.540089

Then 6 of 22 normal cells and 16 of 40 cancers randomly was selected as the training set. The remains were arranged into the testing set (see Fig. III).

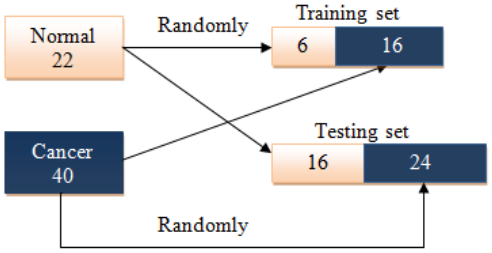

Fig. III. Colon cancer dataset

For comparison purpose, we did two kinds of methods experiments with ANN for classification in this study. The first method, the ANN was treated as the classifier directly. The second method, apply the dimension reduction method EVD before classification by ANN. (See Fig. IV).

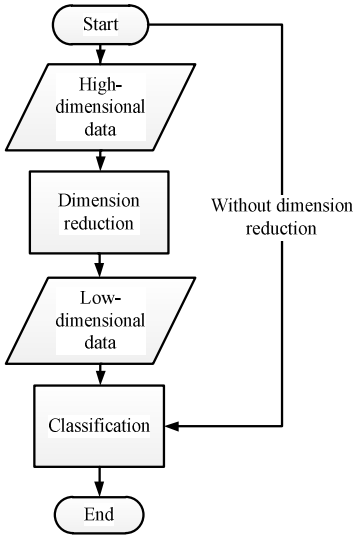

Fig. IV. Flow chart of two groups of classification

By using algorithm 1, the variables were listed as below:

R: refers to the expression dataset matrix of colon cancer, treated as the input matrix. And $L = 2000, P = 22$.

$\underline{d}$: refers to the desired output vector. $\underline{d} = [d_1, d_2, \ldots, d_P]$ $d_1 \sim d_6$ equal to 1, $d_7 \sim d_{22}$ equal to -1. 1 stand for normal, and -1 stands for cancer.

R_{test} : refers to the testing data. And $L = 2000, P_{test} = 40$.

$\underline{d}_{test}$: refers to desired output of the testing input R_{test}. $\underline{d}_{test} = [d'_1, d'_2, \ldots, d'_{40}]$, $d'_1 \sim d'_{16}$ equal to 1, $d'_{17} \sim d'_{40}$ equal to -1.

The tolerant ε=0.008, i.e. when $J(\underline{w})$<=0.008, $\underline{d}$ and y are closed enough. Then, the current $\underline{w}(t)$ was stored to $\underline{w}_{opt}$.

Thus, we test the classifier by comparing $\underline{y}_{test}$ and $\underline{d}_{test}$ we have the diagnostic accuracy of classification using ANN listed in Table IV.

By using dimension reduction method mentioned as EVD, we get the EVD bar chart (see Fig. V) of the initial genes.

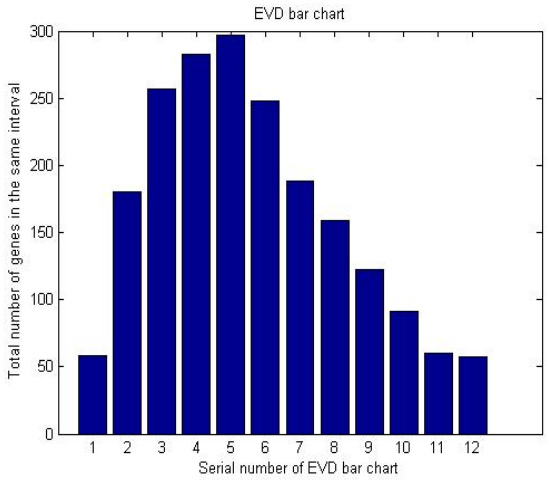

Fig. V. Statistical graph of EVD

Considering the statistical result of the EVD, in Table II, the threshold of the genes was set as α=0.8. Thus, L_1 (L_1 =330) genes (EVD>0.8) were selected and form the feature dataset in the vertical process.

TABLE II

THE STATISTICAL DATA OF EVD

EVD	0~0.1	0.1~0.2	0.2~0.3	0.3~0.4
Number of genes	58	180	257	283
EVD	0.4~0.5	0.5~0.6	0.6~0.7	0.7~0.8
Number of genes	297	248	188	159
EVD	0.8~0.9	0.9~1.0	1.0~1.1	1.1~1.5
Number of genes	122	91	60	57

In horizontal process, dimensions of the feature genes from the vertical process were reduced by using algorithm 3. Here, L_2 was set to be 16. That is to say, 16 clusters were clustered in the final. Then, choose the gene, whose EVD is the largest in each cluster.

Since the indexes of the genes have been stored in every step, the sequence number of the genes was lain out in Table III, i.e. these 16 genes form the feature genes dataset.

Then we apply algorithm 1 by using ANN as a cancer gene classifier. Here, $\underline{d'}$ and $\underline{d'}_{test}$ are same with $\underline{d}$ and $\underline{d}_{test}$ in the first experiment. However, L has been reduced to L_2 applying the EVD algorithm. Then, the variables were listed as below:

R': refers to the expression dataset matrix of colon cancer, treated as the input matrix. And $L_2 = 16, P' = 22$.

$\underline{d'}$: refers to the desired output vector. $\underline{d'} = \underline{d}$.

R'_{test} : refers to the testing data. And $L_2 = 16, P'_{test} = 40$.

$\underline{d'}_{test}$: refers to desired output of the testing input R'_{test}, $\underline{d'}_{test} = \underline{d}_{test}$.

Thus, the trained network output vector $\underline{y'}_{test}$ can be obtained by using the formula $\underline{y'}_{test} = R'^{T}\underline{w'}_{opt}$. By comparing $\underline{y'}_{test}$ and $\underline{d'}_{test}$ we have the diagnostic accuracy of classification using ANN with EVD. (Refer to Table IV).

IV. EXPERIMENTAL RESULTS

The program in this study was written in the Matlab® code and operated in the laptop PC with Windows® platform. The accuracy of classification is described as Table IV.

We compute 20 times by using optimal trained Artificial Neural Network (ANN) and ANN method with the Expressive Value Distance (EVD) algorithm separately. Then we get the results of the accuracy respectively (see Table IV). It suggests that both of the two kinds of methods could be used for colon cancer classification efficiently. By the comparison of these two ways of training methods, we found that the average accuracy is slightly better by using EVD. So, it has been shown that EVD is an effective method in the area of dimension reduction. For computational complexity comparison, it is obvious that the optimally trained ANN has less computational complexity, and yet provides a very robust classification technique with good accuracy.

V. CONCLUTION

In this study, the new statistical dimension reduction algorithm EVD is developed successfully. It is applied to the practical colon cancer dataset. After using the EVD method, the dimension of the input data to ANN was largely reduced from 2,000 to 16. The reduction of the number of inputs does not affect the subsequent optimally trained ANN approach because both of the ANNs with or without the EVD method can provide the very accurate classification results. It is also represented that the important feature of the data can be extracted by the EVD method, although the optimally trained ANN approach can provide less computational complexity.

Abstract— **An iterative bootstrapping-based data over-sampling strategy is presented in this paper together with an adaptive neural-fuzzy inference system (ANFIS) to deal with a severely imbalanced data modelling problem. As real industrial data are often very large, containing hundreds of process variables and a huge number of data records, the selection of a compact set of input variables becomes critical for any successful modelling and analysis operations. Significant efforts have been devoted to identifying the most relevant input variables through correlation analysis and neural network based forward input selection. An optimal majority to minority class data ratio, which controls the level of data imbalance for model training, is then determined through the iterative bootstrapping process such that the combined sensitivity and specificity performance is optimised. The iterative bootstrapping ANFIS modelling strategy is then applied to a real industrial case study for rail quality classification, with the original data being provided by Tata Steel Europe. Preliminary results show a good overall performance through the iterative bootstrapping data over-sampling ANFIS modelling.**

Keywords: Imbalance data; bootstrapping, data resampling; fuzzy c-means clustering, ANFIS, steel manufacturing, rail.

I. INTRODUCTION

Data-driven modelling has gathered pace and gained much popularity due the rapid growth in computing power and the wide availability of data/information. Modelling tools and algorithms have also evolved into more complex structures capable of dealing with highly non-linear and multi-dimensional input/output mappings. However, in many real-world modelling scenarios, the available data are often highly imbalanced, such as product quality data and patient-disease data, where the data ratio of the majority class (the 'good' data) towards the minority class (the 'bad' data) can be very high. The data imbalance problem is prevalent in many applications, including fraud detection, risk management, quality classification, and medical diagnosis. Due to the overwhelming dominance of the majority class, the resulting model is often heavily biased to the majority cases while ignoring the minority class if the imbalance is not adequately dealt with [1]. Research in imbalanced data modelling has grown rapidly [2-4] as more researchers realized that imbalance entails more often than not sub-optimal modelling. Research methods for imbalanced data modelling can be classified into two major categories: using data resampling so that the resampled data are more balanced [5]; and modifying the learning algorithm or the cost criteria so that the classifier is biased towards the minority class [6, 7].

In this paper, a modelling strategy of integrated bootstrapping [8] data resampling and adaptive neural-fuzzy inference system (ANFIS) is proposed. The core of the ANFIS model is developed using fuzzy C-means clustering [9] on the resampled data. This modelling strategy is then applied to a case study for a large scale industrial problem provided by Tata Steel Europe, relating through process manufacturing data to finished steel rail ultrasonic test results. The remainder of the paper is organized as follows. Section 2 provides an overview of the data which are extracted from the sequential steelmaking, casting, rolling and finishing processes of the large multi-product manufacturing complex. Section 3 is devoted to data pre-processing, which deals with data consolidation, input selection, and feature extraction. As the data set is very large, containing over two hundred process variables in more than sixty-five thousand data records, the data pre-processing task becomes essential and critical toward any successful modelling practices. In Section 4, an iterative bootstrapping data resampling algorithm is developed, together with an ANFIS based classification scheme. It is found that the majority to minority class data ratio, which controls the level of data imbalance in the bootstrapping resampled data, plays a pivotal role in optimising the overall classification performance over the two different categories. Finally, concluding remarks and discussions are outlined in Section 5.

II. Overview of the Rail Production Data

A. Brief Description of the Rail Production Route

The rail manufacturing data used for this study were collected from an integrated steel manufacturing complex belonging to Tata Steel Europe. The production line which manufactures a range of steel products including rail, consists of steelmaking, continuous casting, rolling, and finishing sub-processes, as sketched in Fig. 1. A basic oxygen furnace takes molten iron from upstream blast furnaces as well as additional scraps and refines them into steel by blowing high purity oxygen through the lance onto the surface of the hot metal. The oxidation process generates heat and removes excessive carbon and other chemical impurities (a batch process lasting approximately 30 minutes). The liquid steel is then tapped into a ladle, for further secondary steelmaking, going through a ladle metallurgical furnace where the steel chemical compositions are adjusted through alloy addition and desulphurization, and a vacuum de-gasser where harmful hydrogen and other gas inclusions are removed to improve steel cleanness. The rail grade liquid steel is then transferred to the multi-strand continuous casting machine where steel blooms of about 8-tonne are produced. These steel blooms are subsequently heated in a reheating furnace and processed to rail via multi-pass hot rolling and straightening operations to produce rails upto 120 metres in length. The final stage of manufacture entails comprehensive Non-Destructive Testing (NDT) of every rail to ensure adherence to strict standards for internal and surface quality, as well as for dimensional accuracy, before dispatch to customers. This study focuses on the small number of rails which are rejected due to internal flaws and analytical approaches to find root causes and thus by introduction of appropriate control measures, to improve product yields.

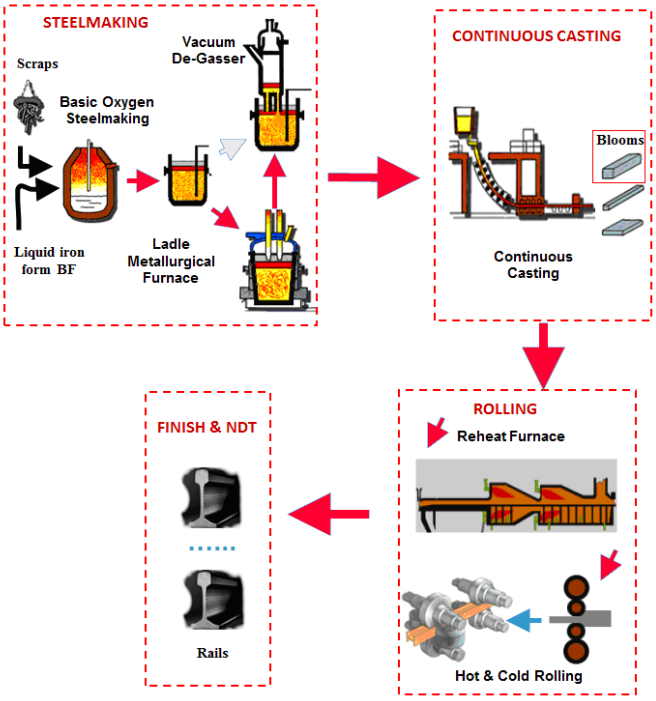

Figure 1. Overview of the rail production route

B. Overview of the Rail Manufacturing Data

In a modern rail production line, there exists extensive instrumentation for online process monitoring and control, as well as offline production management and administration. An integrated data infrastructure, which includes multiple online data servers for collecting real-time variables, process parameters, management information, key unit production time histories, and quality inspection data, is installed through the production line. These original data, which are stored in various databases, are further processed and aggregated before being stored in a master data mining server where higher level data analysis and mining tasks can be conducted. The data can also be easily accessed in this environment for other advanced modelling and optimisation tasks.

The data collected from the rail production route described above cover a two-year production period, including over 65000 data records with up to 200 variables. Preliminary investigations of the rail data revealed many challenges for modelling and analyses. Due to the large scale of the data, even simply processing the data can prove to be resource intensive, and algorithms and procedures need to be planned with great care. Basic tasks such as plotting, copying and paste are not straightforward, as they often break commonly used software specifications and norms. Often, responses become prohibitive sluggish, hence an adequate choice of analysis tools becomes a necessity as a single computing tool cannot best serve the diversified requirements demanded in the data modelling cycle. Hence, an integrated software environment has been established to deal with the large scale rail data modelling, as shown in Fig. 2.

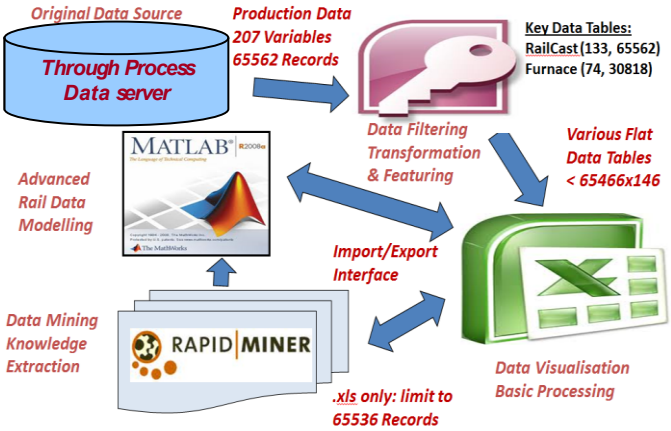

Figure 2. An integrated database and software environment

An initial inspection of the data revealed that some variables were redundant, and others contained conflicting information. A few records included also a significant amount of missing values and could not hence be used for modelling. Furthermore, many of the variables are primarily relevant to production management, hence should be eliminated for the rail quality analysis.

Based on this initial perspective, a data pre-processing strategy has been carefully designed in order to form a parsimonious model data set from the original rail production route data. As pointed out in [10-11], pre-processing is an

important step in any complicated data modelling process, and its function normally includes data cleaning, normalization, transformation, feature selection, etc. In this study, the focus of the data pre-processing operation is directed mainly towards identifying data outliers, correcting wrong data entries, checking data conflicts, missing value decision, and identifying relevant inputs. A process expert from Tata Steel was closely involved in the data pre-processing task providing essential knowledge input to explain and advise about inter variable correlations, apparent redundancy and relevance of data items. After the initial data pre-processing stage, the original rail data are reduced in both dimension and length by eliminating non-relevant variables and deleting data records with too many missing values or conflict data items. The resulting rail data set, after the pre-processing stage, consists of 140 process variables and 39687 records.

This pre-processed data set remained very large and the data dimension was still too high for any meaningful feature classification. The input dimension needed to be reduced further in order for a manageable data classification model to be elicited. Hence, the reduction of the input space dimension and the selection of the most suitable input variables will be tackled in the next section.

III. Model Input Selection

Input variable selection is a vital step in complex system modelling where the input–output relationship is often not too well understood. An unnecessarily large number of inputs can be detrimental to effective modelling, not only that the high dimensional space will cause the difficulty due to 'the curse of dimensionality', but also the irrelevant and redundant inputs tend to confuse and distort the true input-output outcomes. It is a well-known fact that the data examples needed to tune a model grow exponentially with the number of inputs, and the resources required for an increasing large data set soon become prohibitive. The central task in input selection is to identify and remove variables that have little influence on the output, so that the main emphasis can be put on the important input variables. As pointed out in [12], the objective of input variable selection is three-fold: improving the prediction performance of the predictors, providing faster and more cost-effective predictors, and providing a better understanding of the underlying process that generated the data. Many different methods have been proposed to deal with the input selection problem, including fuzzy logic based approaches [13-14], statistical test or correlation analysis [15-16], and direct objective optimisation based approaches [17].

A. Correlation Analysis

The correlation coefficient analysis can prove sufficient enough to help identify the input/output dependency if the process under investigation is linear [18]. Even though the rail production line is complex and certainly nonlinear, it is believed that some preliminary correlation analysis will be worthwhile. Correlation coefficient analysis can help to reach a better understanding of the data to be modelled. The Pearson's correlation coefficient can be calculated via the following equation:

$$\rho_{ij} = \frac{\sum_{k=1}^{N}(x_i(k)-\bar{x}_i)(x_j(k)-\bar{x}_j)}{\sqrt{\sum_{k=1}^{N}(x_i(k)-\bar{x}_i)^2 \sum_{k=1}^{N}(x_j(k)-\bar{x}_j)^2}} \quad (1)$$

Where $\rho_{ij} \in [-1, 1]$ is the correlation coefficient between variable x_i and x_j, $x_i(k)$ is the value of the kth x_i sample, N is the total number of samples, and $\bar{x}_i$ is the sample mean. When one of the variables is the output, ρ_{ij} represents the linear dependency between the output and the given input, otherwise it indicates the co-linearity between the two given inputs.

When a significant number of variables are involved in the data set, there will be a very large number of correlation coefficients. A compact form to summarize all the correlation coefficients is a correlation matrix $\boldsymbol{R}$, defined as follows:

$$\boldsymbol{R} = [\rho_{ij}]_{n\times n} = \begin{pmatrix} \rho_{11} & \cdots & \rho_{1n} \\ \vdots & \ddots & \vdots \\ \rho_{n1} & \cdots & \rho_{nn} \end{pmatrix} \quad (2)$$

Where ρ_{ij} is the correlation coefficient defined in (1), n is the total number of data variables in the data set. $\boldsymbol{R}$ is a symmetric and with $\rho_{ii} = 1$, $i = \{1, 2, \ldots, n\}$.

For this study, data variables are limited to steelmaking and continuous casting sub-processes (named as rail-cast data, with process variables $x_1 \sim x_{70}$), as it is known that these two sub-processes have strong influences on the internal rail quality. Correlation analysis of the rail-cast data revealed that there is little linear correlation between inputs and the output (the number of rejected rails), with the top-10 correlation coefficients being listed in Table I. The correlation coefficient values are rather small, with the maximum being 0.144 related to the 9th input. The results are not constructive enough to help identify the relevant inputs for data modelling. However, the resulting correlation matrix revealed significant correlations among various potential inputs, as many correlation coefficients exceeded 0.95, as outlined in the last two columns of Table 1. Highly correlated inputs indicate significant redundant information contained in the corresponding variables, which need to be eliminated for parsimonious data modelling.

TABLE I. Top 10 significant Correlation coefficients

Rank	*Output Corr.*	*Var*	*Input Corr.*	*Vars (I, J)*

B. Input Selection using a Neural Network Model

As is clear from the previous correlation analysis that the input-output relation is highly nonlinear, a neural network (NN) based forward selection procedure is proposed here to identify the most relevant input variables. A simple 3-layer feed-forward neural network possesses very powerful input-output mapping capability and can approximate any continuous non-linear function with arbitrary accuracy provided that enough hidden neurons have been used [19]. The output of such an NN can be expressed as follows [20]:

$$\hat{y}(k) = \sum_{j=1}^{M} w_j \varphi_j(\sum_{i=1}^{n} w_{ij} x_i(k) + w_{j0}) + w_0 \qquad (3)$$

where $\hat{y}(k)$ is the NN output prediction for the kth sample, w_j and w_{ji} are the relevant NN weighting coefficients at the output layer and hidden layer, respectively, w_0 and w_{j0} are the corresponding bias, ϕ_j is the nonlinear activate function of the jth hidden neuron, and M is the total number of hidden neurons.

A forward input selection procedure is proposed with the above NN model as a performance evaluator. The input selection is implemented through an iterative process, starting from selecting a single input for the NN modelling. All the potential inputs are sampled as the single input candidate, and the neural network model with the minimum root mean squared error (RMSE) is identified as NN*. The inputs corresponding to the ones used in NN* are ranked as the most important inputs identified so far. In the next round of input selection, the inputs of the NN is increased by one from the identified input set, with the newly increased input selected from all remaining potential input candidates. The above forward input selection procedure was repeated until either a sufficient number of inputs identified or no performance improvement achieved by adding more inputs. The NN training procedure used here is adapted from the one used in [22], with critical training parameters fixed via trial-and-error tuning. The number of hidden neurons is determined by the number of NN model inputs by using empirical rules, as optimisation in this scenario will be computationally too expensive. The iterative forward input selection algorithm is summarized as follows:

Step i: Initialisation of the forward input selection: i = 1, $\boldsymbol{x}^{\boldsymbol{0}} = \{\}$, put all the variables into the potential input candidate set $\boldsymbol{X}^0 = [x_1, x_2, \ldots, x_n]$

Step ii: Start a new round of input selection. For each of the potential input candidate $x_j \in \boldsymbol{X}^0$, perform neural network modelling with extended input $\boldsymbol{x}^{\boldsymbol{0}} = [\boldsymbol{x}^{\boldsymbol{0}}, x_j]$. Computing the corresponding model performance $J_j, j = \{1, 2, \ldots, dim(\boldsymbol{X}^0)\}$.

Step iii: Identify the best neural network model NN_{j*} using the corresponding RMSE (Root mean square error) performance, and electing x_{j*} as the most important input in the current round. Expanding the fixed input set $\boldsymbol{x}^{\boldsymbol{0}} = [\boldsymbol{x}^{\boldsymbol{0}}, x_{j*}]$, and eliminate it from $\boldsymbol{X}^0$ ($\boldsymbol{X}^0 = \boldsymbol{X}^0 \setminus x_{j*}$).

Step iv: If the best NN performance in the current round does not improve over the previous one, or if $dim(\boldsymbol{x}^{\boldsymbol{0}}) >= n_{max}$, or if $\boldsymbol{X}^0$ is empty, then go to Step v, otherwise return to Step ii.

Step v: The elements in $\boldsymbol{x}^{\boldsymbol{0}}$ are the most important input variables identified by the NN forward selection procedure. The importance ranking is the order of inclusion of the elements.

Table II summarises the results obtained from the aforementioned forward input selection procedure. As the neural network model is very powerful for input-output mapping, the nonlinear behaviour in the data set can be better dealt with. However, the computation involved in this NN based forward input ranking is quite heavy, especially when a large data set is involved. For the current input ranking task with 70 potential inputs, a maximum number of 2450 neural networks need to be trained via some kind of error back-propagation algorithm, and each neural network need to be trained over more than 20000 samples. Extra in-loop optimisations, for the hidden neuron number or learning parameters, are not computationally feasible. Hence, key training parameters and network structure parameters are fixed based on the modelling experience.

TABLE II. INPUT RANKING USING THE NN FORWARD SELECTION

No	Var	No	Var	No	Var	No	Var
1	x_8	11	x_{24}	21	x_{51}	31	x_{23}

9	x_{11}	19	x_{41}	29	x_1	39	x_7
10	x_{65}	20	x_6	30	x_{57}	40	x_{35}

IV. BOOTSTRAPPING RESAMPLING AND DATA CLASSIFICATION

The number of model inputs has been reduced to 39 by selecting the first 39 variables listed in Table 2 obtained by using the NN forward input ranking scheme described in Section 3. The original output, $y \in \{0, 1, 2, 3\}$, is chosen as the feature variable originating from the NDT ultrasonic testing, with y=0 representing a good rail and $y = \{1, 2, 3\}$ indicating a rejected rail. The non-zero discrete value of y indicates the presence of single or multiple flaws. An adaptive neural-fuzzy modelling approach was developed based on the *ANFIS* framework [21], however the success rate for the rejected rail classification is very poor with less that 10% correctly classified, when the imbalanced data is used for training the model. Further investigations revealed that the main cause of such poor classification is the severe data imbalance in the training data set.

A. Boostrapping for Data Resampling

Since samples belonging to the minority class are fewer than those belonging to the majority class in the current modelling scenario, a direct approach for data resampling is adopted here in order to change the class distributions. A more balanced data can be obtained through different resampling

strategies, such as under-sampling, over sampling, or the combination of both, as is briefly discussed in [22]. In order to avoid unnecessary information loss, the resampling scheme used here is over-sampling of the minority class data, with the resampling implemented via bootstrapping [23]. In order to carry out the over-sampling, the original rail-cast data are first segregated into two data subsets, each containing data samples from a single class. The data subset corresponding to the minority class is then fed into the bootstrapping resampling algorithm, which produces a multiple randomly resampled subsets, each with the same size as the original minority subset. Those resampled subsets are then combined into an over-sampled minority class data, and then mixed with the majority class data to form the final resampled training data. The level of imbalance for the resampled training data can be controlled via a design parameter R_{MM}, defined as the ratio of the number of samples belong to the majority class to that belong to the minority class. As a price paid to avoid information loss during the resampling, the size of the resampled training data set is increased. Fig. 3 shows the effect of the R_{MM} on the size of the resampled training data.

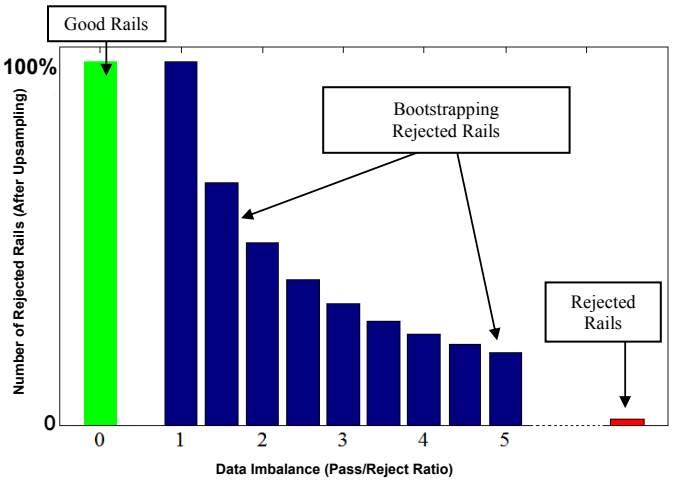

Figure 3. Effect of R_{MM} to the size of resampled training data

B. Fuzzy C-means Clustering based Classification

An adaptive neural-fuzzy inference system can be viewed as a fuzzy logic system whose rules are generated through fuzzy neural network training from a carefully assembled training data set [24-25]. A generic fuzzy inference model can be presented as a collection of fuzzy rules in the following form:

R_i: **If** x_1 is A_{i1} **and** x_2 is A_{i2} ... **and** x_n is A_{in} **then** $y = z_i(\boldsymbol{x})$

where $\boldsymbol{x} = [x_1, x_2, \ldots, x_n] \in U$ and $y \in V$ are linguistic variables, A_{ij} are fuzzy sets defined on the universe U, and $z_i(\boldsymbol{x})$ is a function of $\boldsymbol{x}$. Fig. 4 shows a simplified ANFIS architecture with two rules, where Layer 1 is for fuzzy membership mapping of the input, Layer 2 implements the fuzzy 'and' operation, Layer 3 normalises the firing strength of each fuzzy rule, Layer 4 performs the then part function $y = z_i(\boldsymbol{x})$ of the corresponding fuzzy rule, and Layer 5 computes the overall output of the fuzzy system for the given input.

In this study, the fuzzy membership takes a form of a Gaussian function, and the fuzzy rule is trained using fuzzy c-means clustering through a Matlab built-in fuzzy logic toolbox routine *genfis3* [21]. Fuzzy c-means clustering (FCM) is a well-recognized paradigm to generate fuzzy models, due to its efficiency and simplicity. After the number of clusters p (equivalent to the number fuzzy rules) is chosen, the FCM algorithm partitions all the data samples $\{\boldsymbol{x}(1), \boldsymbol{x}(2), \ldots, \boldsymbol{x}(N)\}$ into p fuzzy clusters such that the following objective function is minimized:

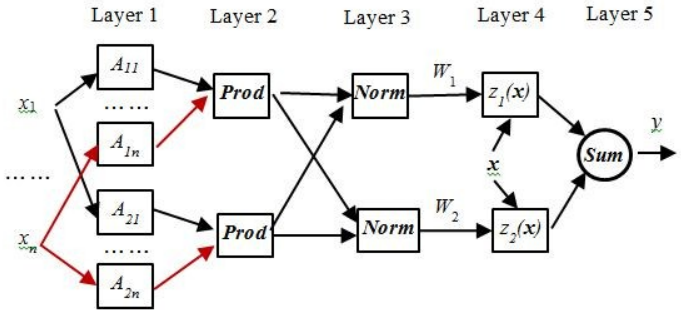

Figure 4. A simplified ANFIS architecture with 2 rules [21]

$$J_m = \sum_{k=1}^{N} \sum_{i=1}^{p} \mu_{ik}^{\alpha} ||\boldsymbol{x}(k) - \boldsymbol{c}_i||^2 \quad (4)$$

where $\boldsymbol{c}_i$ is the centre of the ith cluster generated by fuzzy clustering, μ_{ik} is the membership degree of the kth data belonging to the ith cluster, and α is the exponent of μ_{ik}. The fuzzy membership μ_{ik} normally satisfies the following constraints:

$$\sum_{i=1}^{p} \mu_{ik} = 1, \ \forall k \in \{1, N\}; \ 0 \le \mu_{ik} \le 1, \forall k, i \in \{1, p\} \quad (5)$$

In this study, a hybrid learning algorithm is used to optimise the parameters of the fuzzy inference systems. It applies a combination of the 'least-squares' method and the error back-propagation gradient descent method for training the membership function and other ANFIS parameters using the inputs-outputs in the training data set.

The number of fuzzy rules p and the majority-to-minority ratio R_{MM} are two critical parameters which will influence the ultimate modelling performance. We have developed an iterative optimisation procedure in order to identify the 'best' combination of these two critical design parameters under the paradigm of bootstrapping over-sampling and adaptive neural-fuzzy classification. Fig. 5 shows the diagram for the iterative optimisation scheme.

C. Preliminary Results

The pre-processed rail-cast data need to be divided into two data sets, one used for training and another for testing and with the training/testing data ratio set to 70:30. 39 inputs are used for modelling, as specified by the forward NN input selection scheme discussed in Section 3. The training data set will be used for bootstrapping resampling in order to generate a balanced training set for data modelling. The range of majority to minority case data ratio R_{MM} is selected as $[R_{min} \sim R_{max}] = [1.0, 5.0]$ with an increment step length of 0.5. The range for p, the number of fuzzy rules, is chosen as $[p_{min}, p_{max}] = [2, 10]$ with

incremental step of 1. The maximum training epoch is 100. Some preliminary modelling results are shown in Fig. 6.

In a classification problem, the performance of misclassification gives a better measure of the quality of the developed model than the RMSE based performance. In order to calculate such misclassification performance, the continuous outputs of the optimised ANFIS model are transformed into binary outputs, with 1 indicating the minority class ('Reject') and 0 for the majority class ('Good'). Specificity, sensitivity and accuracy performances originated in medical research [26] are adopted in this paper as the binary classification performances. 'Specificity' measures the proportion of 'negative' samples (majority class) which are correctly identified, while 'sensitivity' measures the proportion of 'positive' samples (minority class) which are correctly identified. In other words, sensitivity represents the true 'negative' rate, while specificity is the true 'positive' rate. 'Accuracy' is the overall percentage that both categories are correctly classified.

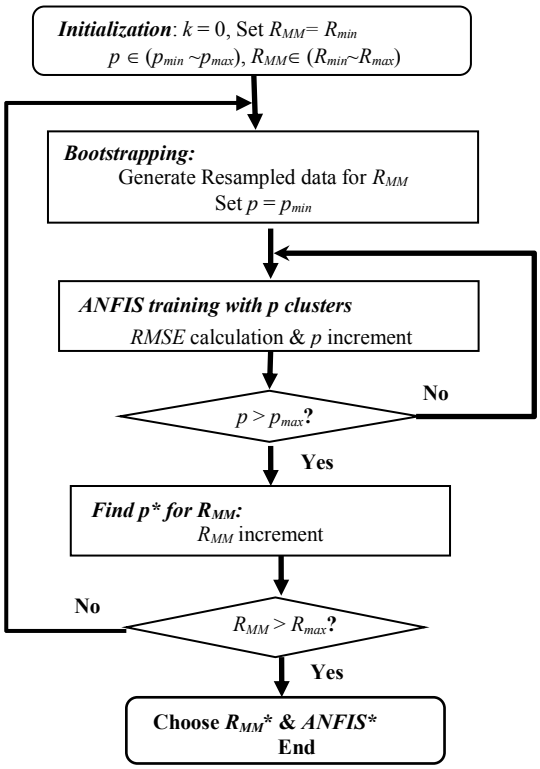

Figure 5. Iterative optimisation for p & R_{MM} in bootstrapping-ANFIS scheme

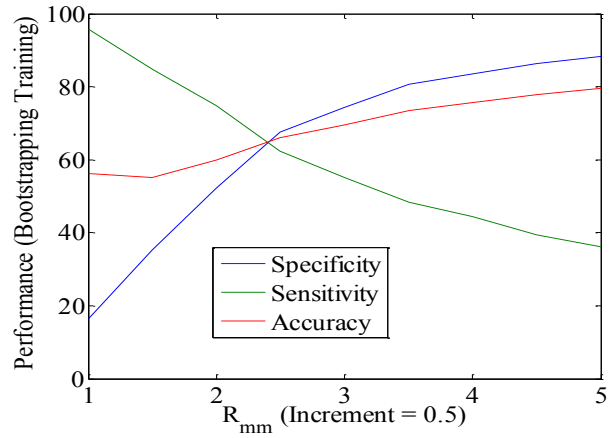
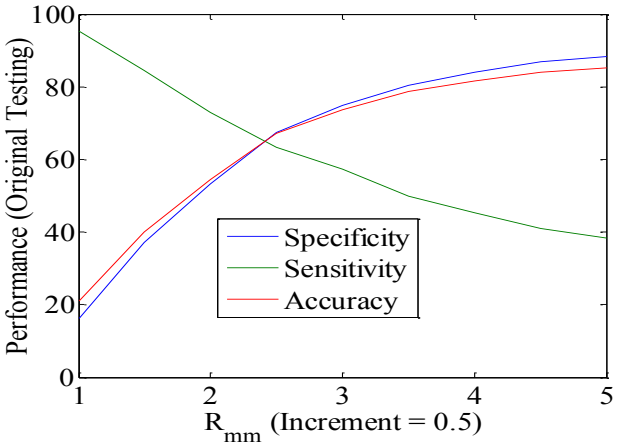
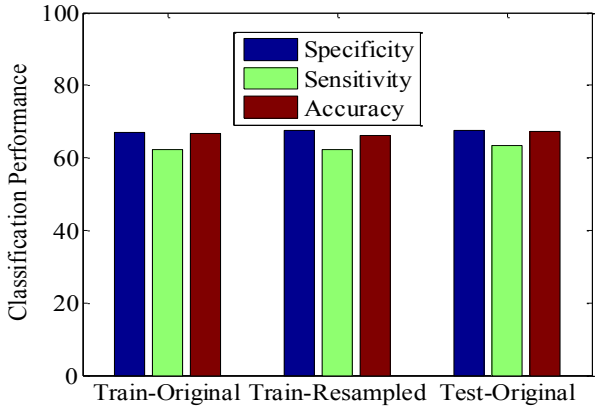
Fig. 6 shows a clear trend of the three different performances against the variation of the R_{MM} data ratio, which is used to control the data imbalance level in bootstrapping. The data over-sampling is carried out on the original training data alone, so the whole testing data remain to be 'unseen' for the model to be developed using the resampled training data. A large R_{MM} value indicates more dominance for the majority class in the resampled training data, and hence is beneficial to the performance related to the majority class, i.e., the specificity. In contrast, a small R_{MM} value indicates a reduced dominance of the majority class, and hence tends to benefit the performance for the minority class, i.e., sensitivity. There exists an optimal R_{MM} such that the overall classification performance reaches its optimum. Simulation results show that, the optima R_{MM} * value is approximately 2.5 for the current study.



(a). Measured by the over-sampled training data (Train-Original)



(b). Measured by the original testing data (Test-Original)



(c). Classification performance for R_{MM} *= 2.5

Figure 6. Performance of bootstrapping ANFIS scheme

The iterative bootstrapping ANFIS model produced a good balance between the data fitting and generalisation performance, as exemplified by the results shown in Fig. 6. In

the original data modelling without resampling applied (see Fig. 7), the success rate for rejected rail classification (sensitivity) was very poor at less than 10% for the testing data set and about 16% for the trainiing data set. Although in that case, the specificity performance was very good (over 96% for both the training and testing data sets), the model was of little practical value as the concern in the production route is to identify robust relationships that support identification and elimination of root causes for rail rejection. The sensitivity of the optimal model (discovered through the iterative procedure presented in Fig. 5) is much better at 65% for the resampled training data (Fig. 6a), and when this optimal model is applied to the original training data set (without resampling) similar results are observed. Furthermore, when the model is applied for the previously unused testing portion from the original data set the same performance results are observed (Fig. 6b) indicating that the matched performance for familiar data and for 'unseen' data are consistent. Fig. 6c shows the sensitivity, specificity and accuracy performances for the ANFIS model developed under the optimal resampled training data set corresponding to R_{MM} *= 2.5.

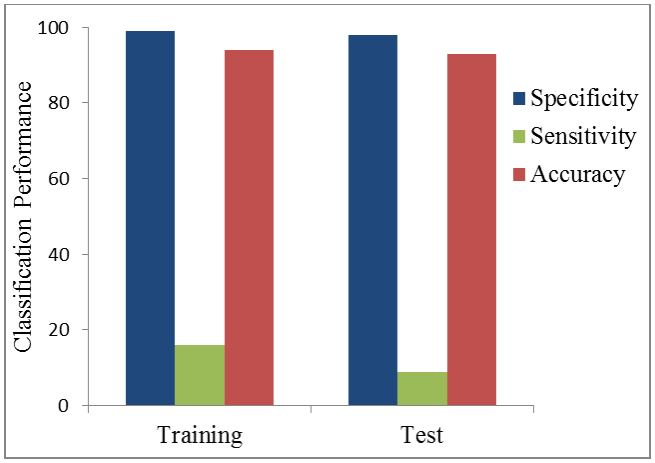


Figure 7. Classification performance using the rail data without resampling

V. Conclusions

In this paper an integrated bootstrapping-ANFIS modelling scheme has been developed to deal with severely imbalanced data classification. The fuzzy classification is implemented through an iterative process of generating oversampling training data and learning the ANFIS model parameters using the resampled training data through fuzzy c-means clustering. Since the case study involves large scale industrial data, data pre-processing plays a significant role for effective data modelling. One of the key objectives of the data pre-processing is to form a compact data set by selecting the most relevant optimal input variables, thus minimising redundancy and eliminating data conflicts. Correlation analysis and forward NN-based input ranking have been incorporated in the data pre-processing stage. Preliminary results show that the integrated bootstrapping-ANFIS modelling scheme developed is very promising, with significant performance improvement especially in terms of the sensitivity. Moreover, the developed classification model achieved a good balance between data fitting and data generalisation.

One disadvantage of using bootstrapping-based over-sampling is that the resampled training data set includes a significant level of redundancy related to the minority class data. The increase in the overall training data set size may also pose difficulties for large scale data modelling and classification, due to the relatively big increase in computing resources. We will investigate new methodologies to overcome these shortcomings in future research.

***Abstract*—This paper presents a passive fuzzy controller design method for stabilizing the uncertain nonlinear stochastic inverted pendulum robot system. Through Takagi-Sugeno (T-S) fuzzy modeling approach, the complex nonlinear properties can be described by combining several linear sub-systems and determined membership functions. The Itô stochastic differential equation is employed to represent dynamics of systems in this paper. Appling the modeling approach, the T-S fuzzy model with multiplicative noise can be built for describing the nonlinear stochastic system. Besides, the uncertainties of the controlled system are considered in this paper for dealing with molding errors and varying parameters. Hence, the robust control problem is also discussed and investigated in this paper. Finally, the numerical simulations are proposed to show the effectiveness of the present design approach.**

Keywords-passive; uncertain; T-S fuzzy model; multiplicative noise

I. INTRODUCTION

There have been many researches on control of a two wheeled inverted pendulum system. Over the past few years, the inverted pendulum robot control problem has been investigated in many literatures [1-2]. And, the researchers have applied the pendulum system to simulate human stance and walk behaviors. However, the human stance and walk behaviors control problem is a complicated and difficult problem due to the nonlinearities of system.

In some circumstances, we may encounter real systems with random noise which makes the systems stochastic. When the stochastic behavior exists in the system, the related model can be called as systems with multiplicative noise [3]. Since stochastic modeling approach plays important role, many efforts have been proposed for stochastic system. Furthermore, parameter uncertainty often also appears in the real system due to the model inaccuracies and/or changes in the environment. With the parameter uncertainties, the control problem of the system considered in this paper are more difficult and challenger to be solved and investigated, than the same problems of deterministic systems. Based on the above motivation, the control problem of the inverted pendulum robot model with multiplicative noise is studied in this paper.

As well known that the stability of complex nonlinear systems is hard to be analyzed and synthesized. Recently, the fuzzy logic has been widely applied to approximate the nonlinearities of the system. And then, since Takagi-Sugeno [4], proved a model-based fuzzy approximating matched called T-S model, there have been dramatic progress in stability analysis and control design of nonlinear systems this model-based fuzzy systems. Referring to [4], many practical nonlinear systems have been successful represented via T-S fuzzy model. Thus, the inverted pendulum robot system with multiplicative noise is represented by T-S fuzzy model in this paper. Besides, the Parallel Distributed Compensation (PDC) concept [5] is applied to design the fuzzy controller for T-S fuzzy models. Through the T-S fuzzy model and PDC design concept, the linear control criteria can be applied to analyze the complex nonlinear systems.

Furthermore, consider the attenuation performance, the passivity theory [6] provides a useful tool to discuss the effect of disturbance on the systems. With the passivity theory, many efforts [7-8] have been proposed to design fuzzy controller for T-S fuzzy model with external disturbance. And, based on Lyapunov function, the stability conditions were derived into Linear Matrix Inequality (LMI) problems. According to the literatures [9], we can find that passivity theory provides several kinds of the performance: for example, H_∞ control and L_2 control. Based on the definition of supply rate, the different performance can be determined with passivity theory.

The purpose of this paper is to concentrate on the passive fuzzy controller design problem for uncertain nonlinear stochastic inverted pendulum robot system with multiplicative noises. The proposed fuzzy controller design methodology is developed by using the concept of PDC and the Lyapunov stability criterion. And the passivity theory is employed to guarantee disturbance attenuation performance of the system. Based on the LMI technique [10], one can find a suitable common positive definite matrix and feedback gains for satisfying the derived stability conditions. Then, the PDC-based passive fuzzy controller can be designed by obtained feedback gains. Thus, according to the proposed stability criterion, the nonlinear stochastic inverted pendulum robot system driven by designed fuzzy controller is strictly input passive and robustly asymptotically mean square stable.

Finally, a simulations result is proposed to show the effectiveness and application of the proposed design method of this paper.

The organization of this paper is structured as follows. The dynamic model of simple human stance system with multiplicative noise is described in Section II. The discrete-time stochastic T-S fuzzy system of the nonlinear system is described in Section III. The fuzzy controller design method is proposed in Section IV. Through applying the proposed design approach, simulation results are provided in Section V. Finally, concluding remarks are made in Section VI.

II. The Dynamic Model of Simple Human Stance System

In this section, the inverted pendulum robot system is introduced. Referring to Fig. 1, a simplified mathematical dynamic model for describing inverted pendulum robot system is proposed to simulate the stance of human [11] as follows.

$$
\begin{aligned}
x_1(\mathrm{k}+1) &= x_1(\mathrm{k}) + T\,x_2(\mathrm{k}) + 0.1\,v(\mathrm{k}) \\
x_2(\mathrm{k}+1) &= x_2(\mathrm{k}) + \frac{T}{M + m\left(sin\,x_3(\mathrm{k})\right)^2}\Big(u(\mathrm{k}) + ml\,x_4^2(\mathrm{k}) \\
&\quad \times sin\,x_3(\mathrm{k}) - b\,x_2(\mathrm{k}) - mg\,cos\,x_3(\mathrm{k})\,sin\,x_3(\mathrm{k})\Big) \\
x_3(\mathrm{k}+1) &= x_3(\mathrm{k}) + T\,x_4(\mathrm{k}) \\
x_4(\mathrm{k}+1) &= x_4(\mathrm{k}) + \frac{T}{l\left(M + m\left(sin\,x_3(\mathrm{k})\right)^2\right)}\Big((M+m)\,g \\
&\quad \times sin\,x_3(\mathrm{k}) - u(\mathrm{k})\,cos\,x_3(\mathrm{k}) + b\,x_2(\mathrm{k})\,cos\,x_3(\mathrm{k}) \\
&\quad - ml\,x_4^2(\mathrm{k})\,sin\,x_3(\mathrm{k})\,cos\,x_3(\mathrm{k})\Big) \\
y(\mathrm{k}) &= x_1(\mathrm{k}) + v(\mathrm{k})
\end{aligned}
\tag{1}
$$

where

m	is the mass of black on the pendulum.
l	is the length of pendulum.
g	is the acceleration due to gravity.
b	is coefficient of viscous friction for motion of cart.
u	is the applied force.
v	is the external disturbance input.
M	is the mass of the cart.
T	is the sampling period.

The four state variables stand for $x_1(\mathrm{k}) = x$, $x_2(\mathrm{k}) = \dot{x}$, $x_3(\mathrm{k}) = \theta$, $x_4(\mathrm{k}) = \dot{\theta}$ with x the position of the cart, $y(\mathrm{k})$ is the system output, $v(\mathrm{k})$ is the external disturbance, and θ the angle of pendulum makes with vertical. This model is obtained by discretizing the continuous time model via Euler's method with $T = 0.1$ s, $b = 12.98$ Kg/s, $M = 1.378$ Kg, $l = 0.325$ m, $g = 9.8$ m/s^2, $m = 0.051$ Kg.

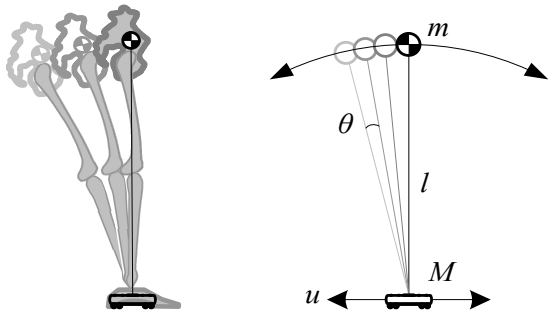

Fig. 1 Inverted pendulum robot system

Considering parameter uncertainties and stochastic behaviors, the modified dynamic model for the inverted pendulum robot system can be described as follows:

$$
\begin{aligned}
x_1(\mathrm{k}+1) &= x_1(\mathrm{k}) + 0.1\,x_2(\mathrm{k}) + 0.01\,x_1(\mathrm{k})\,w(\mathrm{k}) + \delta_1\,x_1(\mathrm{k}) \\
&\quad + 0.1\,v(\mathrm{k}) + 0.001\mathrm{v}(\mathrm{k})\,w(\mathrm{k}) + \delta_2\,u(\mathrm{k}) + \delta_3\,v(\mathrm{k}) \\
x_2(\mathrm{k}+1) &= x_2(\mathrm{k}) + \frac{0.1}{1.378 + 0.051\left(sin\,x_3(\mathrm{k})\right)^2}\Big(u(\mathrm{k}) - 12.98\,x_2 \\
&\quad + 0.0166\,x_4^2(\mathrm{k})\,sin\,x_3(\mathrm{k}) - 0.4998\,cos\,x_3(\mathrm{k}) \\
&\quad \times sin\,x_3(\mathrm{k})\Big) + 0.1\,x_2(\mathrm{k})\,w(\mathrm{k}) + 0.000726\,u(\mathrm{k})\,w(\mathrm{k}) \\
x_3(\mathrm{k}+1) &= x_3(\mathrm{k}) + 0.1\,x_4(\mathrm{k}) + 0.1\,x_3(\mathrm{k})\,w(\mathrm{k}) \\
x_4(\mathrm{k}+1) &= x_4(\mathrm{k}) + \frac{0.1}{0.4478\left(0.0166\left(sin\,x_3(\mathrm{k})\right)^2\right)} \\
&\quad \times\Big(14.0042\,sin\,x_3(\mathrm{k}) - u(\mathrm{k})\,cos\,x_3(\mathrm{k}) \\
&\quad + 12.98\,x_2(\mathrm{k})\,cos\,x_3(\mathrm{k}) \\
&\quad - 0.0166\,x_4^2(\mathrm{k})\,sin\,x_3(\mathrm{k})\,cos\,x_3(\mathrm{k})\Big) \\
&\quad + 0.1\,x_4(\mathrm{k})\,w(\mathrm{k}) - 0.002233\,u(\mathrm{k})\,w(\mathrm{k}) \\
y(\mathrm{k}) &= x_1(\mathrm{k}) + v(\mathrm{k})
\end{aligned}
\tag{2}
$$

where δ_1, δ_2 and δ_3 are the perturbation, which denoted by $\delta_1 \in [-0.001,\ \ 0.001]$, $\delta_2 = \delta_3 \in [-0.0002,\ \ 0.0002]$, and $w(\mathrm{k})$ is discrete Brownian Motion [12]. Using fuzzy modeling technique one can obtain T-S fuzzy model of (2) in the following section.

III. The Discrete Stochastic T-S Fuzzy Models

In order to build the T-S fuzzy model of the considered inverted pendulum robot system (2), two operating points are chosen to obtain the linearized models with the sector linearization technique [10]. The operating points are chosen as follows.

$\left(x_1(\mathrm{k}),\ x_2(\mathrm{k}),\ x_3(\mathrm{k}),\ x_4(\mathrm{k}),\ u(\mathrm{k})\right)_{\text{oper1}} = \left(0 \quad 0 \quad \pm 88^\circ \quad 0 \quad 0\right)$
and
$\left(x_1(\mathrm{k}),\ x_2(\mathrm{k}),\ x_3(\mathrm{k}),\ x_4(\mathrm{k}),\ u(\mathrm{k})\right)_{\text{oper2}} = \left(0 \quad 0 \quad 0 \quad 0 \quad 0\right)$.

In the points $\left(x_1(\mathrm{k}),\ x_2(\mathrm{k}),\ x_3(\mathrm{k}),\ x_4(\mathrm{k}),\ u(\mathrm{k})\right)_{\text{oper2}}$ is the equilibrium point and the others is the off-equilibrium point. According to the points, the membership function can be determined as Fig. 2. Through the above two linear subsystems and defining membership functions as Fig. 2, one can obtain the following T-S fuzzy model for the inverted pendulum robot system (2) such as.

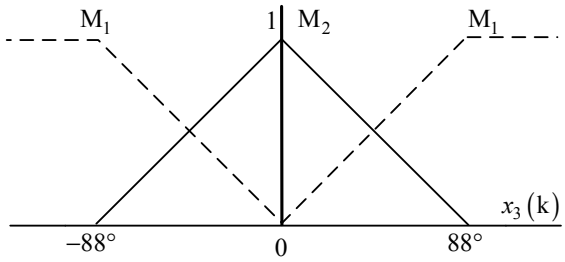

Fig. 2 Membership functions of $x_3(\mathrm{k})$

Rule 1: IF $x_3(\mathrm{k})$ is about M_1 THEN

$$x(\mathrm{k+1}) = \mathbf{A}_1(\mathrm{k})x(\mathrm{k}) + \mathbf{B}_1(\mathrm{k})u(\mathrm{k}) + \mathbf{D}_1(\mathrm{k})v(\mathrm{k}) + \left(\bar{\mathbf{A}}_1 x(\mathrm{k}) + \bar{\mathbf{B}}_1 u(\mathrm{k}) + \bar{\mathbf{D}}_1 v(\mathrm{k})\right) w(\mathrm{k})$$
$$y(\mathrm{k}) = \mathbf{C}_1 x(\mathrm{k}) + \mathbf{E}_1 v(\mathrm{k}) \tag{3}$$

Rule 2: IF $x_3(\mathrm{k})$ is about M_2 THEN

$$x(\mathrm{k+1}) = \mathbf{A}_2(\mathrm{k})x(\mathrm{k}) + \mathbf{B}_2(\mathrm{k})u(\mathrm{k}) + \mathbf{D}_2(\mathrm{k})v(\mathrm{k}) + \left(\bar{\mathbf{A}}_2 x(\mathrm{k}) + \bar{\mathbf{B}}_2 u(\mathrm{k}) + \bar{\mathbf{D}}_2 v(\mathrm{k})\right) w(\mathrm{k})$$
$$y(\mathrm{k}) = \mathbf{C}_2 x(\mathrm{k}) + \mathbf{E}_2 v(\mathrm{k}) \tag{4}$$

where $x(\mathrm{k}) = \left[x_1(\mathrm{k}) \quad x_2(\mathrm{k}) \quad x_3(\mathrm{k}) \quad x_4(\mathrm{k})\right]^{\mathrm{T}}$,
$\mathbf{A}_{\mathrm{i}}(\mathrm{k}) = \mathbf{A}_{\mathrm{i}} + \Delta\mathbf{A}_{\mathrm{i}}(\mathrm{k})$, $\mathbf{B}_{\mathrm{i}}(\mathrm{k}) = \mathbf{B}_{\mathrm{i}} + \Delta\mathbf{B}_{\mathrm{i}}(\mathrm{k})$,
$\mathbf{D}_{\mathrm{i}}(\mathrm{k}) = \mathbf{D}_{\mathrm{i}} + \Delta\mathbf{D}_{\mathrm{i}}(\mathrm{k})$,

$$\left[\Delta\mathbf{A}_{\mathrm{i}}(\mathrm{k}) \quad \Delta\mathbf{B}_{\mathrm{i}}(\mathrm{k}) \quad \Delta\mathbf{D}_{\mathrm{i}}(\mathrm{k})\right] = \mathbf{H}_{\mathrm{i}}\Delta(\mathrm{k})\left[\mathbf{R}_{\mathrm{i}} \quad \mathbf{R}_{\mathrm{Bi}} \quad \mathbf{R}_{\mathrm{Di}}\right], \tag{5}$$
$$\Delta(\mathrm{k})^{\mathrm{T}}\Delta(\mathrm{k}) \le \mathbf{I} \tag{6}$$

and

$$\mathbf{A}_1 = \begin{bmatrix} 1 & 0.1 & 0 & 0 \\ 0 & 0.0916 & -0.0008 & 0 \\ 0 & 0 & 1 & 0.1 \\ 0 & 0.0975 & 1.9622 & 1 \end{bmatrix},$$

$$\mathbf{A}_2 = \begin{bmatrix} 1 & 0.1 & 0 & 0 \\ 0 & 0.0581 & -0.0363 & 0 \\ 0 & 0 & 1 & 0.1 \\ 0 & 2.8983 & 3.127 & 1 \end{bmatrix},\ \mathbf{B}_1 = \mathbf{B}_2 = \begin{bmatrix} 0 \\ 0.0726 \\ 0 \\ -0.2233 \end{bmatrix},$$

$$\mathbf{D}_1 = \mathbf{D}_2 = \begin{bmatrix} 0.1 \\ 0 \\ 0 \\ 0 \end{bmatrix},\ \bar{\mathbf{A}}_1 = \bar{\mathbf{A}}_2 = \begin{bmatrix} 0.01 & 0 & 0 & 0 \\ 0 & 0.1 & 0 & 0 \\ 0 & 0 & 0.1 & 0 \\ 0 & 0 & 0 & 0.1 \end{bmatrix},$$

$$\bar{\mathbf{B}}_1 = \bar{\mathbf{B}}_2 = 0.01\times\begin{bmatrix} 0 \\ 0.0726 \\ 0 \\ -0.2233 \end{bmatrix},\ \bar{\mathbf{D}}_1 = \bar{\mathbf{D}}_2 = 0.01\times\begin{bmatrix} 0.1 \\ 0 \\ 0 \\ 0 \end{bmatrix},$$

$$\Delta\mathbf{A}_1 = \Delta\mathbf{A}_2 = \begin{bmatrix} \delta & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} = \mathbf{H}\Delta(\mathrm{k})\mathbf{R},\ \mathbf{E}_1 = \mathbf{E}_2 = 1$$
$$\mathbf{H} = [0.02 \quad 0 \quad 0 \quad 0]^{\mathrm{T}},\ \mathbf{R} = \left[0.05 \quad 0 \quad 0 \quad 0\right],$$
$$\mathbf{R}_{\mathrm{B1}} = \mathbf{R}_{\mathrm{B2}} = \mathbf{R}_{\mathrm{D1}} = \mathbf{R}_{\mathrm{D2}} = 0.01,\ \mathbf{C}_1 = \mathbf{C}_2 = \left[1 \quad 0 \quad 0 \quad 0\right]. \tag{7}$$

where $\mathbf{I}$ is identity matrix and the notation $\Delta(\mathrm{k})$ is time-varying matrix function. In this simulation, we assume that $\Delta(\mathrm{k}) = \sin(\mathrm{k})$. $E\{w(\mathrm{k})\} = 0$, $E\left\{w(\mathrm{k})^2\right\} = 1$, the noise $w(\mathrm{k})$ is assumed independent with $x(\mathrm{k})$. Furthermore, $E\{\bullet\}$ denotes standard expected operator. The uncertain matrices $\Delta\mathbf{A}_{\mathrm{i}}(\mathrm{k})$, $\Delta\mathbf{B}_{\mathrm{i}}(\mathrm{k})$, $\Delta\mathbf{D}_{\mathrm{i}}(\mathrm{k})$ are said to be admissible if both (5) and (6) hold. Given a pair of $\left(x(\mathrm{k}), u(\mathrm{k})\right)$, the final outputs of the fuzzy system can be inferred as follows.

$$x(\mathrm{k+1}) = \sum_{\mathrm{i}=1}^{2} h_{\mathrm{i}}\left(x_3(\mathrm{k})\right)\left(\mathbf{A}_{\mathrm{i}}(\mathrm{k})x(\mathrm{k}) + \mathbf{B}_{\mathrm{i}}(\mathrm{k})u(\mathrm{k}) + \mathbf{D}_{\mathrm{i}}(\mathrm{k})\mathrm{v}(\mathrm{k}) + \left(\bar{\mathbf{A}}_{\mathrm{i}}x(\mathrm{k}) + \bar{\mathbf{B}}_{\mathrm{i}}u(\mathrm{k}) + \bar{\mathbf{D}}_{\mathrm{i}}v(\mathrm{k})\right)w(\mathrm{k})\right)$$
$$y(\mathrm{k}) = \sum_{\mathrm{i}=1}^{2} h_{\mathrm{i}}\left(x_3(\mathrm{k})\right)\left(\mathbf{C}_{\mathrm{i}}x(\mathrm{k}) + \mathbf{E}_{\mathrm{i}}v(\mathrm{k})\right) \tag{8}$$

where $h_{\mathrm{i}}\left(x_3(\mathrm{k})\right) = \dfrac{M_{\mathrm{i}}\left(x_3(\mathrm{k})\right)}{\sum_{\mathrm{i}=1}^{2} M_{\mathrm{i}}\left(x_3(\mathrm{k})\right)}$, $h_{\mathrm{i}}\left(x_3(\mathrm{k})\right) \ge 0$,

$M_{\mathrm{i}}\left(x_3(\mathrm{k})\right) = \prod_{\mathrm{j}=1}^{\mathrm{r}} \mathrm{M}_{\mathrm{j}}\left(x_3(\mathrm{k})\right)$ and $\sum_{\mathrm{i}=1}^{2} h_{\mathrm{i}}\left(x_3(\mathrm{k})\right) = 1$. And the classical PDC law is given by

$$u(\mathrm{k}) = \sum_{\mathrm{i}=1}^{2} h_{\mathrm{i}}\left(x_3(\mathrm{k})\right)\mathbf{F}_{\mathrm{i}}x(\mathrm{k}) \tag{9}$$

Substituting (9) into (8), the closed-loop model can be written as

$$x(\mathrm{k+1}) = \sum_{\mathrm{i}=1}^{2}\sum_{\mathrm{j}=1}^{2} h_{\mathrm{i}}\left(x_3(\mathrm{k})\right) h_{\mathrm{j}}\left(x_3(\mathrm{k})\right)\left(\mathbf{G}_{\mathrm{ij}}(\mathrm{k})x(\mathrm{k}) + \mathbf{D}_{\mathrm{i}}(\mathrm{k})\right.$$
$$\left.\times v(\mathrm{k}) + \left(\bar{\mathbf{G}}_{\mathrm{ij}}x(\mathrm{k}) + \bar{\mathbf{D}}_{\mathrm{i}}v(\mathrm{k})\right)w(\mathrm{k})\right)$$
$$y(\mathrm{k}) = \sum_{\mathrm{i}=1}^{2} h_{\mathrm{i}}\left(x_3(\mathrm{k})\right)\left(\mathbf{C}_{\mathrm{i}}x(\mathrm{k}) + \mathbf{E}_{\mathrm{i}}v(\mathrm{k})\right) \tag{10}$$

where $\mathbf{G}_{\mathrm{ij}}(\mathrm{k}) = \mathbf{A}_{\mathrm{i}}(\mathrm{k}) + \mathbf{B}_{\mathrm{i}}(\mathrm{k})\mathbf{F}_{\mathrm{j}}$, $\bar{\mathbf{G}}_{\mathrm{ij}} = \bar{\mathbf{A}}_{\mathrm{i}} + \bar{\mathbf{B}}_{\mathrm{i}}\mathbf{F}_{\mathrm{j}}$. (11)

In the following, we introduce the following lemma and definition, which will be used in the derivation of our main results in the next sections.

Definition 1 [8]

Considering the system (1), then the disturbance $v(\mathrm{k})$ and output $y(\mathrm{k})$ are said to be strictly input passive if

$$E\left\{2\sum_{\mathrm{k}=0}^{\mathrm{k_q}} y^{\mathrm{T}}(\mathrm{k})v(\mathrm{k})\right\} > E\left\{\sum_{\mathrm{k}=0}^{\mathrm{k_q}} \gamma v^{\mathrm{T}}(\mathrm{k})v(\mathrm{k})\right\} \tag{12}$$

where $\gamma \geq 0$ and terminal time $\mathrm{k_q} > 0$. #

Lemma 1 [13]

Let $\mathbf{Q}$, $\mathbf{H}$, $\mathbf{S}$, $\boldsymbol{\beta}$ and $\boldsymbol{\psi}$ be real matrices with appropriate dimensions such that $\boldsymbol{\beta} > 0$ and $\boldsymbol{\psi}^{\mathrm{T}}\boldsymbol{\psi} \leq \mathbf{I}$. Then, for any scalar $\varepsilon > 0$ such that $\boldsymbol{\beta} - \varepsilon\mathbf{H}\mathbf{H}^{\mathrm{T}} > 0$, one has

$$\left(\mathbf{Q} + \mathbf{H}\boldsymbol{\psi}\mathbf{S}\right)^{\mathrm{T}}\boldsymbol{\beta}^{-1}\left(\mathbf{Q} + \mathbf{H}\boldsymbol{\psi}\mathbf{S}\right) \leq \mathbf{Q}^{\mathrm{T}}\left(\boldsymbol{\beta} - \varepsilon\mathbf{H}\mathbf{H}^{\mathrm{T}}\right)^{-1}\mathbf{Q} + \varepsilon^{-1}\mathbf{S}^{\mathrm{T}}\mathbf{S}. \tag{13}$$

#

IV. Robust Passive Control Design

In this section, for analyzing and synthesizing the stability of closed-loop system (10), the sufficient stability condition is developed via passivity theory and Lyapunov function.

Theorem 1

Given a dissipative rate $\gamma \geq 0$, if there exists a positive definite matrix $\mathbf{P} > 0$, and scalar $\varepsilon_{\mathrm{i}} > 0$ for satisfying the following conditions, then the closed-loop system (10) is strictly input passive and robustly asymptotically mean square stable.

$$\begin{bmatrix} \bar{\boldsymbol{\Phi}}_{11} & \bar{\boldsymbol{\Phi}}_{21}^{\mathrm{T}} \\ \bar{\boldsymbol{\Phi}}_{21} & \bar{\boldsymbol{\Phi}}_{22} \end{bmatrix} < 0 \text{ for } \mathrm{i, j} = 1, 2 \tag{14}$$

where

$$\bar{\boldsymbol{\Phi}}_{11} = \mathbf{G}_{\mathrm{ij}}^{\mathrm{T}}\left(\mathbf{P}^{-1} - \varepsilon_{\mathrm{i}}\mathbf{H}_{\mathrm{i}}\mathbf{H}_{\mathrm{i}}^{\mathrm{T}}\right)^{-1}\mathbf{G}_{\mathrm{ij}} + \varepsilon_{\mathrm{i}}^{-1}\mathbf{R}_{\mathrm{ij}}^{\mathrm{T}}\mathbf{R}_{\mathrm{ij}} + \bar{\mathbf{G}}_{\mathrm{ij}}^{\mathrm{T}}\mathbf{P}\bar{\mathbf{G}}_{\mathrm{ij}} - \mathbf{P}$$
$$\bar{\boldsymbol{\Phi}}_{21} = \boldsymbol{\Phi}_{21} - \mathbf{C}_{\mathrm{i}},\ \bar{\boldsymbol{\Phi}}_{22} = \boldsymbol{\Phi}_{22} - \mathbf{E}_{\mathrm{i}}^{\mathrm{T}} - \mathbf{E}_{\mathrm{i}} + \gamma\mathbf{I}$$
$$\boldsymbol{\Phi}_{21} = \mathbf{D}_{\mathrm{i}}^{\mathrm{T}}\left(\mathbf{P}^{-1} - \varepsilon_{\mathrm{i}}\mathbf{H}_{\mathrm{i}}\mathbf{H}_{\mathrm{i}}^{\mathrm{T}}\right)^{-1}\mathbf{G}_{\mathrm{ij}} + \varepsilon_{\mathrm{i}}^{-1}\mathbf{R}_{\mathrm{Di}}^{\mathrm{T}}\mathbf{R}_{\mathrm{ij}} + \bar{\mathbf{D}}_{\mathrm{i}}^{\mathrm{T}}\mathbf{P}\bar{\mathbf{G}}_{\mathrm{ij}}$$
$$\boldsymbol{\Phi}_{22} = \mathbf{D}_{\mathrm{i}}^{\mathrm{T}}\left(\mathbf{P}^{-1} - \varepsilon_{\mathrm{i}}\mathbf{H}_{\mathrm{i}}\mathbf{H}_{\mathrm{i}}^{\mathrm{T}}\right)^{-1}\mathbf{D}_{\mathrm{i}} + \varepsilon_{\mathrm{i}}^{-1}\mathbf{R}_{\mathrm{Di}}^{\mathrm{T}}\mathbf{R}_{\mathrm{Di}} + \bar{\mathbf{D}}_{\mathrm{i}}^{\mathrm{T}}\mathbf{P}\bar{\mathbf{D}}_{\mathrm{i}} \tag{15}$$

Proof :

Les us choose the Lyapunov function $V\left(x(\mathrm{k})\right) = x^{\mathrm{T}}(\mathrm{k})\mathbf{P}x(\mathrm{k})$. Firstly, by calculating difference and taking mathematical expectation of $V\left(x(\mathrm{k})\right)$ one has.

$$E\left\{\Delta V\left(x(\mathrm{k})\right)\right\} = E\left\{x^{\mathrm{T}}(\mathrm{k+1})\mathbf{P}x(\mathrm{k+1}) - x^{\mathrm{T}}(\mathrm{k})\mathbf{P}x(\mathrm{k})\right\}$$
$$= E\left\{\sum_{\mathrm{i}=1}^{2}\sum_{\mathrm{j}=1}^{2} h_{\mathrm{i}}\left(x_3(\mathrm{k})\right)h_j\left(x_3(\mathrm{k})\right)\left(\left(\mathbf{G}_{\mathrm{ij}}(\mathrm{k})x(\mathrm{k}) + \mathbf{D}_{\mathrm{i}}(\mathrm{k})v(\mathrm{k})\right)^{\mathrm{T}}\right.\right.$$
$$\times\mathbf{P}\left(\mathbf{G}_{\mathrm{ij}}(\mathrm{k})x(\mathrm{k}) + \mathbf{D}_{\mathrm{i}}(\mathrm{k})v(\mathrm{k})\right) + \left(\bar{\mathbf{G}}_{\mathrm{ij}}x(\mathrm{k}) + \bar{\mathbf{D}}_{\mathrm{i}}v(\mathrm{k})\right)^{\mathrm{T}}$$
$$\left.\left.\times\mathbf{P}\left(\bar{\mathbf{G}}_{\mathrm{ij}}x(\mathrm{k}) + \bar{\mathbf{D}}_{\mathrm{i}}v(\mathrm{k})\right) - x^{\mathrm{T}}(\mathrm{k})\mathbf{P}x(\mathrm{k})\right)\right\} \tag{16}$$

Using the Lemma 1, the following relations can be obtained.

$$\left(\mathbf{G}_{\mathrm{ij}}(\mathrm{k})x(\mathrm{k}) + \mathbf{D}_{\mathrm{i}}(\mathrm{k})v(\mathrm{k})\right)^{\mathrm{T}}\mathbf{P}\left(\mathbf{G}_{\mathrm{ij}}(\mathrm{k})x(\mathrm{k}) + \mathbf{D}_{\mathrm{i}}(\mathrm{k})v(\mathrm{k})\right)$$
$$\leq \xi^{\mathrm{T}}(\mathrm{k})\left(\begin{bmatrix}\mathbf{G}_{\mathrm{ij}}^{\mathrm{T}} \\ \mathbf{D}_{\mathrm{i}}^{\mathrm{T}}\end{bmatrix}\left(\mathbf{P}^{-1} - \varepsilon_{\mathrm{i}}\mathbf{H}_{\mathrm{i}}\mathbf{H}_{\mathrm{i}}^{\mathrm{T}}\right)^{-1}\begin{bmatrix}\mathbf{G}_{\mathrm{ij}} & \mathbf{D}_{\mathrm{i}}\end{bmatrix}\right.$$
$$\left.+\varepsilon_{1\mathrm{i}}^{-1}\begin{bmatrix}\mathbf{R}_{\mathrm{ij}}^{\mathrm{T}} \\ \mathbf{R}_{\mathrm{Di}}^{\mathrm{T}}\end{bmatrix}\begin{bmatrix}\mathbf{R}_{\mathrm{ij}}^{\mathrm{T}} \\ \mathbf{R}_{\mathrm{Di}}^{\mathrm{T}}\end{bmatrix}^{\mathrm{T}}\right)\xi(\mathrm{k}), \tag{17}$$

where $\mathbf{G}_{\mathrm{ij}}(\mathrm{k}) = \mathbf{G}_{\mathrm{ij}} + \mathbf{H}_{\mathrm{i}}\Delta\mathbf{R}_{\mathrm{ij}}$, $\mathbf{R}_{\mathrm{ij}} = \mathbf{R}_{\mathrm{i}} + \mathbf{R}_{\mathrm{Bi}}\mathbf{F}_{\mathrm{j}}$ and $\xi(\mathrm{k}) = \begin{bmatrix}x(\mathrm{k}) \\ v(\mathrm{k})\end{bmatrix}$.

From (17), one has following inequality from (16)

$$E\left\{\Delta V\left(x(\mathrm{k})\right)\right\}$$
$$\leq E\left\{\sum_{\mathrm{i}=1}^{2}\sum_{\mathrm{j}=1}^{2} h_{\mathrm{i}}\left(x_3(\mathrm{k})\right)h_{\mathrm{j}}\left(x_3(\mathrm{k})\right)\left\{\xi^{\mathrm{T}}(\mathrm{k})\begin{bmatrix}\bar{\boldsymbol{\Phi}}_{11} & \boldsymbol{\Phi}_{21}^{\mathrm{T}} \\ \boldsymbol{\Phi}_{21} & \boldsymbol{\Phi}_{22}\end{bmatrix}\xi(\mathrm{k})\right\}\right\} \tag{18}$$

Let us introduce the following performance function

$$J = E\left\{\sum_{\mathrm{k}=0}^{\mathrm{k_q}}\left(\gamma v^{\mathrm{T}}(\mathrm{k})v(\mathrm{k}) - 2y^{\mathrm{T}}(\mathrm{k})v(\mathrm{k})\right)\right\} \tag{19}$$

for all $v(k) \neq 0$ with zero initial condition. From (19), one has

$$J \le E\left\{\sum_{k=0}^{k_q}\left(\gamma v^{T}(k)v(k)-2y^{T}(k)v(k)+\Delta V(x(k))\right)\right\}$$
$$\equiv E\left\{\sum_{k=0}^{k_q}\Theta(k)\right\} \tag{20}$$

where

$$\Theta(k)=\Delta V(x(k))+\gamma v^{T}(k)v(k)-2y^{T}(k)v(k) \tag{21}$$

From (18) and (10), one has

$$\Theta(k)\le\sum_{i=1}^{r}\sum_{j=1}^{r}h_i(x_3(k))h_j(x_3(k))\{\xi^{T}(k)\Psi\xi(k)\} \tag{22}$$

where $\Psi=\begin{bmatrix}\bar{\Phi}_{11} & \bar{\Phi}_{12}\\ \bar{\Phi}_{21} & \bar{\Phi}_{22}\end{bmatrix}$. Obviously, if the stability condition (14) holds, then one has $\Psi<0$ and $\Theta(k)<0$. According to $\Theta(k)<0$, one has the following relations from (20).

$$J<0 \text{ and } E\left\{2\sum_{k=0}^{k_q}y^{T}(k)v(k)\right\}>E\left\{\sum_{k=0}^{k_q}\gamma v^{T}(k)v(k)\right\} \tag{23}$$

Since the (23) is equivalent to (12) of Definition 1, the closed-loop system (10) is strictly input passive. Besides, the stability of system is necessary performance for controlled system. Hence, in the following, the stability of system is discussed. If the condition (14) of Theorem 1 is held i.e., $\Psi<0$, thus $\Theta(k)<0$ from (22). By assuming the $v(k)=0$, the $\Delta V(x(k))<0$ can be found from (21) due to $\Theta(k)<0$. Referring to [14], one can find that the system is robustly asymptotically mean square stable due to $E\{\Delta V(x(k))\}<0$. So, if the stability condition (14) holds then the closed-loop system (10) is strictly input passive and robustly asymptotically mean square stable. The proof is completed.

#

In Theorem 1, the stability condition (14) is not strict LMI problem for applying convex optimization algorithm. For the reason, one can directly convert (14) into LMI form with Schur complement and variables setting technique. Since the limitation of paper, the convention process is omitted here. In the following section, the proposed method of this paper is employed to design PDC-based fuzzy controller for stabilizing system (2).

V. Simulation Results

Consider the closed-loop system (10), and choose the dissipative rate $\gamma=1$. Applying Theorem 1 and using the MATLAB LMI toolbox, one can obtain

$$\mathbf{P}=\begin{bmatrix}16.8513 & 6.4704 & 22.3447 & 4.3105\\ 6.4704 & 3.6448 & 12.0250 & 2.2749\\ 22.3447 & 12.0250 & 45.1505 & 8.6407\\ 4.3105 & 2.2749 & 8.6407 & 1.6566\end{bmatrix},$$

$\varepsilon_1=3.6974$ and $\varepsilon_2=3.4109$. Subsequently, one can obtain the feedback gain

$\mathbf{F}_1=[17.6175 \quad 3.5721 \quad 53.3833 \quad 11.3578]$ and
$\mathbf{F}_2=[17.5728 \quad 24.1477 \quad 61.6890 \quad 11.3458]$.

According to the PDC concept, the fuzzy controller can be structured via state feedback gains with control law (9) designed controller, the responses of considered system are stated in Figs. 3-6 with initial condition $x(0)=[0 \quad 0 \quad 0.8 \quad 0]^{T}$ and $v(k)$ is a zero-mean white nose with variance 0.01. From the simulation results of Figs. 3-6, one can find that the closed-loop system is robustly asymptotically mean square stable. Besides, the following equation is introduced to check the strictly input passive of system.

$$\frac{E\left\{\sum_{k=0}^{k_q}v^{T}(k)v(k)\right\}}{E\left\{2\sum_{k=0}^{k_q}y^{T}(k)v(k)\right\}}=0.4958 \tag{24}$$

Based on Definition 1, the strictly input passivity of system (2) can be achieved by fuzzy controller (9) due to the value in (24) is less than one. From the Figs. 3-6 and (24), the strictly input passivity and robustly asymptotically mean square stability of system (2) is achieved by employing the designed PDC-based fuzzy controller (9).

VI. CONCLUSIONS

In this paper, the control problem of nonlinear inverted pendulum system with multiplicative noises has been studied. The T-S fuzzy model was build to represent the original complex nonlinear system. In order to simulate the practical operation conditions, the stochastic behavior and uncertainties of system have been considered during investigation and discussion in this paper. Expect for stability of system, the attenuation performance was also concerned in this paper. Referring to the simulation results, the strictly input passivity and robustly asymptotically mean square stability of nonlinear inverted pendulum robot system with multiplicative noise can be achieved designed PDC-based fuzzy controller.

***Abstract*— In this paper, Differential Evolution (DE) that incorporates fuzzy control and k-nearest neighbors algorithm is proposed to tackle the economic load dispatch problem. To provide the self-terminating ability, a technique called Iteration Windows (IW) is introduced to govern the number of iteration in each searching stage during the optimization. The size of IW is controlled by a fuzzy controller, which uses the information provided by the k-nearest neighbors system to analyze the population during the searching process. The controller keeps controlling the IW till the end of the searching process. A wavelet based mutation process is embedded in the DE searching process to enhance the searching performance. The weight *F* of DE is also controlled by the fuzzy controller to further speed up the searching process. The proposed method is employed to solve the Economic Load Dispatch with Valve-Point Loading (ELD-VPL) Problem. It is shown empirically that the proposed method can terminate the searching process with a reasonable number of iteration and performs significantly better than the conventional methods in terms of convergence speed and solution quality.**

Keywords-Fuzzy Control, Economic Load Dispatch, Differential Evolution

I. INTRODUCTION

Differential Evolution (DE) [1] is a population based stochastic optimization algorithm that searches the solution space for the best solution by using a group of particles. It uses the weighted difference between two particles to determine the third particle. Because of the population based searching strategy, DE is less possibly getting trapped in local optima [3]. DE guides the particles to move toward the best solution by using evolutionary operations. Comparing with other optimization algorithms, DE is relatively easy to implement. It requires fewer parameters for tuning, and has a relatively fast convergence speed. It can also offer a high degree of exploration for the population, and has been successfully applied in many optimization problems such as data clustering [4], power plant control [5], optimization of non-linear functions [6], etc.

On applying DE to real-world problems, the maximum number of iteration is usually needed to be provided as the stopping criterion of the algorithm. Different problems might require different numbers of iteration and there is no strong proof for the best number of iteration for a given problem. The maximum number of iteration often is determined by trial and error and/or the user's experience. To tackle this problem, much research work have been done to test the convergence criteria for different search methods [7][8]. In this paper, a new technique called Iteration Windows is embedded into the searching process of DE. On searching, the searching stage of DE can be analyzed based on the distribution of the population in the search domain. By monitoring the distribution of the population, we can get an idea of the state of the searching process. One method for analyzing the population behavior is clustering. In this paper, an improved DE that incorporates fuzzy control and k-nearest neighbors to determine the terminating condition is proposed to handle the problem of Economic Load Dispatch with Valve-Point Loading (ELD-VPL).

ELD is a method to schedule or control the power generator outputs with respect to the load demands, and to operate the power system economically [9]. The goal is to minimize the operation cost of the power generating system. Because of the valve-point loadings and rate limits, the input-output characteristics of modern generators are nonlinear by nature. As a result, the characteristics of ELD-VPL problems are multimodal, discontinuous, and highly nonlinear. Owing to its complexity, we cannot determine the maximum number of iteration easily.

This paper is organized as follows: Section II presents the operation of the DE with self-terminating ability. The problem formulation of ELD-VPL is given in Section III. Experimental study and analysis are given in Section IV. A conclusion will be drawn in Section V.

II. DE WITH SELF-TERMINATING ABILITY

First, a population of solution vectors will be randomly generated over the solution space. They move on the solution space by addition, subtraction and component swapping; until the population converges to the best solution after a number of iteration. The pseudo code for the standard DE (SDE) process is shown in Fig.1. In this paper, DE with self-terminating ability using k-nearest neighbors and fuzzy control is proposed. The pseudo code is shown in Fig. 2.

```
begin
   Initialize the population;
   While (not the maximum number of iteration)
   {
         Mutation operation by equation (2);
         Crossover operation by equation (3);
         Evaluation of the fitness function;
         Selection of the best vector by equation (4);
   }
end
```

Figure 1. Pseudo code for SDE.

```
begin
Initialize the population;
   While (control not equal to 0) do
   {
        While (Iteration window not equal to 0)
        {
              Mutation operation by equation (2);
              Crossover operation by equation (3);
              Modifying the trial population vectors by
              equation (5);
              Evaluation of the fitness function;
              Select the best vector by equation (4);
              Iteration window =Iteration window – 1;
        }
        Analyze the population by k-NN by equation (10);
        Count the number of local clusters;
        Determine the new k , the new F and iteration
            window size by the fuzzy controller;
        If iteration window size> 6 then control = 1;
        If iteration window size< = 6 then control = 0;
          }
end
```

Figure 2. Pseudo code for the proposed system.

A. Standard Differential Evolution (SDE)

DE attempts to control a set of population of N_p vectors for each generation of evolution, with each vector contains D elements of parameters. Let $P_{x,g}$ be the population of the current generation g, and $\mathbf{x}_{i,g}$ be the i-th vector in this population:

$$\begin{aligned} P_{x,g} &= (\mathbf{x}_{i,g}), i = 0,1,...,N_p - 1; g = 0,1,...,g_{\max} \\ \mathbf{x}_{i,g} &= (x_{j,i,g}), j = 0,1,...,D-1. \end{aligned} \tag{1}$$

where $g_{\max}$ is the maximum number of generation. The population should be initialized as uniformly and randomly distributed over the solution space, which should have a specified boundary. DE generates a mutated vector $\mathbf{v}_{i,g}$ for each target vector $\mathbf{x}_{i,g}$ by using the mutation operation:

$$\mathbf{v}_{i,g} = \mathbf{x}_{i,g} + F \cdot (\mathbf{x}_{r_1,g} - \mathbf{x}_{r_2,g}) \tag{2}$$

where F is the scaling factor, which is a user-defined value; r_1 and r_2 are two different integers randomly generated from {0, 1, ..., N_p−1}. After the mutation operation, uniform crossover is employed to enhance the differential mutation search strategy and increase the diversity of the perturbed parameter vectors. Each vector element pair $x_{j,i,g}$ and $v_{j,i,g}$ generates a new trial vector element $u_{j,i,g}$:

$$\mathbf{u}_{i,g} = (u_{j,i,g}) = \begin{cases} (v_{j,i,g}) & \text{if } (rand_j(0,1) \le Cr \\ (x_{j,i,g}) & \text{otherwise.} \end{cases} \tag{3}$$

where $Cr \in [0, 1]$ is the crossover rate, which is a user-defined value that controls the number of parameters that are copied from the mutant. $rand_j(0,1)$ generates a random value between 0 and 1 for the j-th parameter. The algorithm also ensures $u_{j,i,g}$ gets at least one parameter value as $x_{j,i,g}$ [1]. Then the population is updated by comparing each trial vector to the corresponding target vector $\mathbf{x}_{i,g}$. For finding the global minimum, if the fitness value of the trial vector is lower than that the target vector, DE will replace the target vector in the next generation; otherwise the target vector retains its original place in the population for at least one generation. The selection operation is therefore given by:

$$\mathbf{x}_{i,g+1} = \begin{cases} \mathbf{u}_{i,g} & \text{if } f(\mathbf{u}_{i,g}) \le f(\mathbf{x}_{i,g}) \\ \mathbf{x}_{i,g} & \text{otherwise.} \end{cases} \tag{4}$$

where $f(\cdot)$ is the fitness function. When the condition to stop further evolution is satisfied, for example, the preset maximum number of iteration has been reached, the algorithm ends with the best solution as the final solution.

B. Wavelet mutation in crossover operation

To enhance the searching performance, we can embed a wavelet mutation in the DE crossover operation [19], which exhibits a fine-tuning ability. Let the i-th vector after crossover for the wavelet mutation be $\mathbf{u}_{i,g} = (u_{0,i,g}, u_{1,i,g}, ..., u_{D-1,i,g})$. Its element value is inside the vector element's boundary [$para^j_{\min}$, $para^j_{\max}$]. The mutated crossover vector is given by $\bar{\mathbf{u}}_{i,g} = (\bar{u}_{0,i,g}, \bar{u}_{1,i,g}, ..., \bar{u}_{D-1,i,g})$, and

$$\bar{u}_{j,i,g} = \begin{cases} u_{j,i,g} + \sigma \times (para^j_{\max} - u_{j,i,g}) \text{ if } \sigma > 0 \\ u_{j,i,g} + \sigma \times (u_{j,i,g} - para^j_{\min}) \text{ if } \sigma \le 0 \end{cases}, \tag{5}$$

$$\sigma = \frac{1}{\sqrt{a}} e^{-\left(\frac{\varphi}{a}\right)^2 / 2} \cos\left(5\left(\frac{\varphi}{a}\right)\right), \quad (6)$$

where

$$a = e^{-\ln(\lambda)\times\left(1-\frac{t}{T}\right)^{\zeta_{wm}}+\ln(\lambda)}. \quad (7)$$

T is the total number of iteration and t is the current iteration number; ζ_{wm} is the shape parameter of the monotonic increasing function, λ is the upper limit of the parameter a. At the early stage, a larger value of $|\sigma|$ gives a larger searching space; at the later stage, $|\sigma|$ is smaller and the algorithm gives a smaller searching space for fine-tuning. After the operation of the wavelet mutation, the population is updated by comparing each trial vector $\bar{\mathbf{u}}_{i,g}$ to the corresponding target vector $\mathbf{x}_{i,g}$ using the method of standard DE as given by (4). A new population is generated and the same DE evolution process is repeated.

C. K-Nearest Neighbors (K-NN)

The k-nearest neighbor algorithm (k -NN) algorithm is used to identify the number of groups of vectors (clusters) in the searching domain. It is a method for classifying and grouping data based on closest training data samples in a multidimensional feature space, and a class label is assigned with each training data sample [10][11][12]. By counting the majority class of its neighbors, a data element can be classified with a class label. The value of k is used to control the number of training data samples being considered in one group.

In the proposed system, a user-defined threshold T is introduced for controlling the size of the cluster. Firstly, the entire population is evaluated by the k-NN algorithm, where k is a value controlled by a fuzzy controller. Then, the k nearest vectors would be determined by k-NN. The total distance between those nearest vectors and the current test vector is:

$$D_{total} = \sum_{i=1}^{k} d_i(\mathbf{p}, \mathbf{q}_i) \quad (8)$$

where $d_i(\cdot)$ is the Euclidean distance between two points; $\mathbf{p}$ is the current testing point and $\mathbf{q}_i$ is one of the k nearest elements in the searching domain. The Euclidean distance is given by:

$$d_i(\mathbf{p},\mathbf{q}_i) = \sqrt{(p_1 - q_{i1})^2 + (p_2 - q_{i2})^2 + \cdots + (p_n - q_{in})^2} = \sqrt{\sum_{j=1}^{n} (p_j - q_{ij})^2} \quad (9)$$

The average distance d_{average} of a group (cluster) is:

$$d_{average} = \frac{D_{total}}{k} \quad (10)$$

If $d_{\text{average}} < T$, a local cluster is obtained. If $d_{\text{average}} \geq T$, a cluster is not present. The system will count the number of clusters obtained, which is passed to the fuzzy controller to determine the size of the next iteration window.

D. Iteration Windows

In the proposed system, the DE algorithm will first run for a small number of iteration (i.e. the first stage), and then the evolution will be paused (Fig. 3). After going through this iteration window, the population will be saved. The population distribution information (i.e. the number of local clusters) obtained from k-NN will be passed to the fuzzy controller to determine the size of the next-stage iteration window. One advantage of using the iteration window is that it can reduce the computation power for reaching the final solution, since the fuzzy controller is not operating during the evolution within a stage. It operates between stages only. Moreover, the total number of iteration is governed by the fuzzy controller instead of fixed by the user.

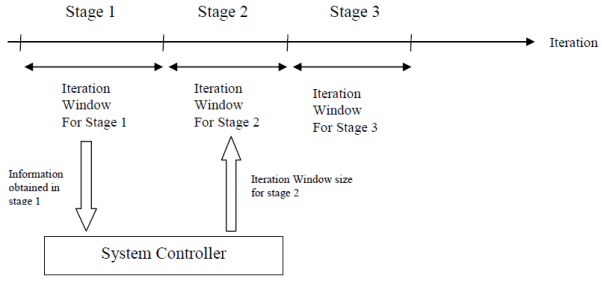

Figure 3. Operation of Iteration Windows.

The relation of the next iteration window's size (the next number of iteration) to the population distribution could be described by some heuristic rules. As a result, the fuzzy controller is modeling this relation. Hence, the total number of iteration could be controlled with respect to the nature of the problem. It does not require the user to determine the total number of iteration, but the system has its own ability to stop the system when it has reliably converged to the real optimum point.

E. Fuzzy Controller

A fuzzy controller realizes fuzzy inference [13]. Its applications include climate control [14], medicine [15], relational database [16], scheduling [17], etc. The process of fuzzy inference involves membership functions, logical operations and fuzzy if-then rules. Implementing fuzzy inference systems can be in Mamdani-type and Sugeno-type [18]. The Mamdani-type fuzzy inference method is used in this paper to construct the fuzzy controller. It uses linguistic control rules obtained from experienced human experts to perform decision making. The output variables must be fuzzy sets. To map the fuzzy set to some crisp output value, the system needs to do defuzzification. In this paper, the method

of center of gravity (COG) is used to perform defuzzification. Fig. 4 shows how the fuzzy inference system works.

The evolution of population-based searching algorithms, including DE, will not be the same for different experiments of a given problem because the algorithms themselves contain a lot of uncertainties. On analyzing the population distribution in the searching process, the derivation of the next iteration window's size from the population distribution should best be described as some heuristic rules. The aforementioned fuzzy controller can then be employed to determine the window's size together with the value of k for the k-NN in the next stage. The fuzzy controller takes the current k value and the population distribution information (i.e. the number of local clusters obtained) provided by k-NN as inputs, and maps this information into the fuzzy membership functions. The fuzzy controller also controls the value of F in the DE operation to enhance the searching process. An overview of the proposed system is shown in Fig. 5.

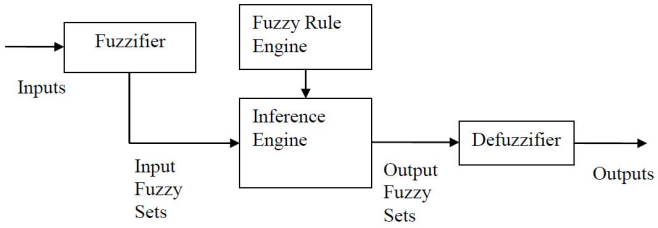

Figure 4. Operation of fuzzy inference system.

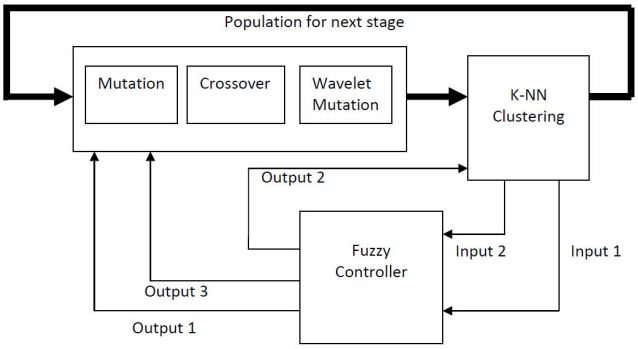

Figure 5. Overview of the proposed system.

III. ELD-VPL PROBLEM

The Economic Load Dispatch with Valve-Point Loading (ELD-VPL) is a method to control or schedule a group of power generator outputs with respect to the load demands, and operate a power system economically so as to minimize the operation cost of the power generating system. The problem can be formulated into the following objective function:

$$\min \sum_{i=1}^{n} C_i(P_{L_i}) \tag{11}$$

where $C_i(P_{L_i})$ is the operation fuel cost of generator i, and n denotes the number of generators. The problem is subject to balance constraints and generating capacity constraints:

$$D_L = \sum_{i=1}^{n} P_{L_i} - P_{Loss} \tag{12}$$

$$P_{L_{i,min}} \le P_{L_i} \le P_{L_{i,\max}}, i = 1,2,\cdots,n \tag{13}$$

where D_L is the load demand, P_{L_i} is the output power of the i-th generator, P_{Loss} is the transmission loss, and $P_{L_{i,\max}}$ and $P_{L_{i,min}}$ are the maximum and minimum output power of the i-th generator, respectively. The operation fuel cost function with valve-point loadings of the generators is given by

$$C_i(P_{L_i}) = a_i P_{L_i}^2 + b_i P_{L_i} + c_i + \left| e_i \times \sin(f_i \times (P_{L_{i,\min}} - P_{L_i})) \right| \tag{14}$$

where a_i, b_i, and c_i are the coefficients of the cost curve of the i-th generator, and e_i and f_i are the coefficients of the valve point loadings. The generating units with multivalve steam turbines exhibit a greater variation in the fuel cost functions. The valve-point effects introduce ripples in the heat-rate curves. To solve the ELD-VPL problem by using the proposed system, the solution representation of elements in the population is defined as follows:

$$\mathbf{P} = [P_{L_1} P_{L_2} P_{L_3} \cdots P_{L_{n-1}}] \tag{15}$$

where n is the number of generators. From (11), we have

$$P_{L_n} = D_L - \sum_{i=1}^{n-1} P_{L_i} + P_{Loss} \tag{16}$$

In this paper, the power loss is not considered, so

$$P_{L_n} = D_L - \sum_{i=1}^{n-1} P_{L_i} \tag{17}$$

To ensure that P_{L_n} falls within the range [$P_{L_{n,\min}}$, $P_{L_{n,\max}}$],

$$\text{If } P_{L_n} > P_{L_{n,\max}} \begin{cases} P_{L_1} = P_{L_1} + (P_{L_n} - P_{L_{n,\max}}) \\ P_{L_n} = P_{L_{n,\max}} \end{cases} \tag{18}$$

$$\text{If } P_{L_n} < P_{L_{n,\min}} \begin{cases} P_{L_1} = P_{L_1} - (P_{L_n} - P_{L_{n,\min}}) \\ P_{L_n} = P_{L_{n,\min}} \end{cases} \tag{19}$$

It should be noted that (18) and (19) are used to control each individual power generator. If the value of P_{L_1} is outside the constraint boundary (i.e. the safety range), the exceeding portion of the power required will be shared by other generators to ensure that the output power of all individual generators are working within the safety range.

IV. EXPERIMENT AND RESULT

Different kinds of DE methods are applied to a 40-generator system, which is adopted as an example in [19]. The load demand (D) of the problem is 10500 MW. Standard DE [20], DE/local-to-best/1 [20], DE/rand/1 with per-vector-dither [22] and the proposed system are used to solve the ELD-VPL problem. The following simulation conditions are used:

- The shape parameter of the wavelet mutation (ζ_{wm}): It is chosen by trial and error. ζ_{wm} = 1 is used in this paper;
- The parameter λ in (7): 10000;
- The number of population vectors: N_p = 30;
- Initial population: It is generated uniformly at random.
- Crossover rate: C_r= 0.5;
- The mutation weight factor (For standard DE, DE/local-to-best/1, DE/rand/1 with per-vector-dither): F=0.6;
- The number of iteration: 2000;
- Threshold T for k-NN: 5;
- Membership functions: As shown in Fig. 6 and Fig. 7;
- Fuzzy rule: Listed in Table 1. (Input 1 is the current number of local clusters; Input 2 is the k value of the current iteration window; Output 1 is the next F value for DE; Output 2 is k for the next stage; Output 3 is the next iteration window size.)

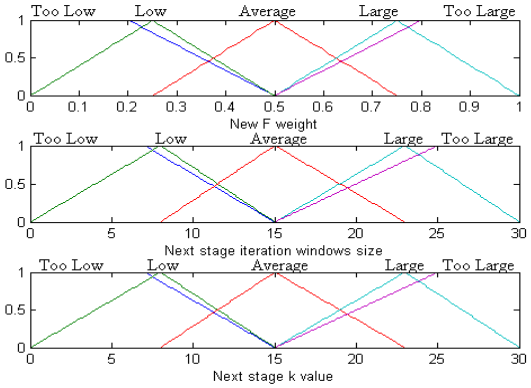

Figure 7. Input Membership Functions.

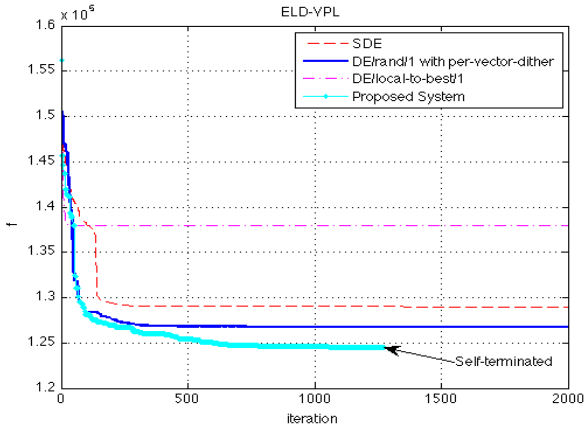

Figure 8. Fitness curve of ELD Problem

The dimension of ELD-VPL problem is 39. The result in terms of the cost value is shown in Table 2. All results shown are averaged data out of 50 trials. The convergence curves of different tested methods are shown in Fig. 8. We can see that the proposed system performs much better than the other methods in terms of convergence rate and cost value. The proposed system can offer the best (minimum) cost among the methods, which is $124559.87. The proposed system is able to terminate itself at the 1376-th iteration.

The comparison between the Delta method with standard DE, Delta method with DE/local-to-best/1, Delta method with

DE/rand/1 with per-vector-dither and the proposed system with Iteration Window is shown in Fig. 9. The Delta method is a common method for terminating the searching process in evolution algorithms. In the experiments, if the fitness value of the current iteration is less the 10^{-6} of the previous 10-th iteration, the searching process will be terminated. It shows that when using the Delta method, most of the algorithms will terminate very early with a very poor result, while the proposed system can terminate the searching process with much better solution quality.

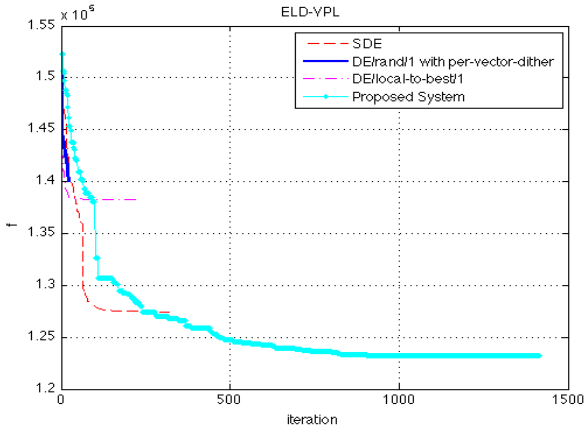

Figure 9. Comparison between the Delta method and the proposed system.

TABLE II. THE RESULT

	Proposed System	standard DE	DE/local-to-best/1	DE/rand/1 with per-vector-dither
Costs	**124559.87**	128982.54	137924.53	126753.64

V. CONCLUSION

In this paper, DE that incorporates fuzzy control and *k*-nearest neighbor algorithm has been proposed to handle the ELD-VPL Problem. To provide the self-terminating ability, the technique called Iteration Windows has been introduced to govern the number of iteration in each searching stage during the optimization. The size of the iteration windows is controlled by a fuzzy controller, which uses the information provided by the *k*-NN algorithm to analyze the population during the searching process. The controller keeps controlling the iteration windows until the end of the searching process. The wavelet based mutation process is embedded in the DE searching process to enhance the searching performance. The *F* weight of DE is also controlled by the fuzzy controller to further speed up the searching process. For the ELD-VPL problem, it is shown empirically that the proposed method out-performs significantly the conventional methods in terms of convergence speed and solution quality. The proposed system can terminate itself with a reasonable number of iteration.

***Abstract*—In this paper, we develope a genetic algorithm based fuzzy inference system to recognize hypoglycemic episodes based on heart rate and corrected QT interval of the electrocardiogram (ECG) signal. Genetic algorithm is introduced to optimize the membership functions and fuzzy rules. A practical experiment based on data from 15 children with T1DM is studied. All the data sets are collected from the Department of Health, Government of Western Australia. To prevent the phenomenon of overtraining (over-fitting), a validation strategy that may adjust the fitness function is proposed. Thus, the data are organized into a training set, a validation set, and a testing set randomly selected. The classification results in term of sensitivity, specificity, and receiver operating characteristic (ROC) analysis show that the proposed classification method performs well.**

***Index Terms*—Diabetes, Fuzzy logic, Genetic algorithm, Hypoglycemia.**

I. Introduction

Episodes of hypoglycemia for Type 1 diabetes mellitus (T1DM) patients, which can result in unconsciousness, seizures or even death, are common and can cause serious side effect in insulin therapy [1]. At least 50% of all severe episodes of hypoglycemia occur during night time [2] because usual insulin preparations do not adequately mimic the normal patterns of endogenous insulin secretion [3]. However, it is impossible in practice to monitor the episodes of hypoglycemia by measuring the blood glucose levels around the clock. Based on the physiological parameters of heart rate and QT interval of the ECG signal, the glucose levels of the T1DM patients can be determined and thus the episodes of hypoglycemia can be diagnosed [4].

A significant contribution is made by the use of fuzzy inferencing to realize the modeling and design of a non-invasive hypoglycemia monitoring system based on physiological responses. The classification models for numerous medical diagnosis such as diabetic nephropathy [5], acute gastrointestinal bleeding [6] and pancreatic cancer [7] have been developed by the use of the statical regression methods [8]. However, statical regression models are only accurate over the range of patients' data. In addition, it can only be applied if the patents' data are distributed based on the developed regression model, and the correlation between dependent and independent variables does not exist. If the patients' data are irregular, the developed regression models would have an unnaturally too wide possibility range.

To carry out modeling and classification for medical diagnosis purposes using the ECG and EEG signals [9]–[11], much attention has been devoted to computational technologies such as fuzzy system [12], support vector machine [13], and neural networks [14]. Apart from EEG and ECG classification, advanced computational intelligence techniques have been applied to cardiovascular response [15], breast cancer and blood cell [16], skull and brain [17], etc. Each technology has its own advantages; for example, fuzzy system is famous for its decision-making ability. Thanks to its ability of representing expert knowledge, the system's output can be determined by a set of linguistic rules which can be understood easily. As discussed in [18], neural networks (NNs) have been used as universal function approximators thanks to their good approximation capability. To develop classification models for medical diagnosis purpose [19], NNs are good to use because of their ability in addressing both the nonlinear and fuzzy nature of patients' data. In [20], the support vector machine (SVM) has shown good performance for doing classification. It has been used in many applications. Thanks to its capability of tackling binary classification problems, SVM has been used in classifying the features of the cardiac signal [21].

Since traditional optimization methods like the least square algorithm and gradient descent methods have the potential problem of trapping in local optima, evolutionary algorithms such as particle swarm optimization (PSO) [22], genetic algorithm (GA) [23], differential evolution (DE) [24], and ant colony optimization [25] were considered. They are efficient global optimization algorithms particularly good for handling multimodal problems. As discussed in [10], [26], [27], the combination of optimization methods and evolutionary algorithms can eventually give good performance in clinical applications.

In this paper, a genetic algorithm based fuzzy inference system is developed for the detection of hypoglycemic episodes using the physiological parameters of heart rate (HR), cor-

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

rected QT interval (QTc) of the electrocardiogram (ECG) signal, change of heart rate, (ΔHR), and change of corrected QT interval of the electrocardiogram signal (ΔQT_c). Fuzzy inference system (FIS) [12], [28] is good at representing expert knowledge in linguistic rules that can be easily understood by human beings. In this paper, we prove that the overall performance of the hypoglycemia detection system is distinctly improved in terms of sensitivity and specificity by using an FIS. To optimize the fuzzy rules and fuzzy membership functions of the FIS, the global searching algorithm of Genetic Algorithm (GA) [23] is investigated. GA is a powerful random global search technique to handle optimization problems. It can help find the globally optimal solution over a domain. A real application is given to show the proposed algorithm is useful to detect the hypoglycaemic episodes in T1DM children. Besides, a validation strategy is introduced to reduce the effects of overtraining [29].

The organization of this paper is as follows: In Section II, the details of the development of the genetic algorithm based fuzzy inference system are presented. To show the effectiveness of our proposed methods, the results of detecting nocturnal hypoglycemic episodes in T1DM patients are discussed in Section III. A conclusion is drawn in Section IV.

II. Methodology

To realize the detection of hypoglycemic episodes in T1DM patients, a GA based fuzzy inference system (FIS) is developed. The 4-input 1-output system is shown in Fig. 1. The physiological inputs are the heart rate (HR), corrected QT interval of the electrocardiogram signal (QT_c), change of heart rate (ΔHR), and change of corrected QT interval of the electrocardiogram signal (ΔQT_c). The output is the binary status of hypoglycemia (h), with +1 representing hypoglycemia and -1 representing non-hypoglycemia. The FIS plays a main role in modeling the correlation between the physiological parameters (HR, QT_c, ΔHR, and ΔQT_c) and the presence of hypoglycemia (h).

In this system, the fuzzy membership functions and fuzzy rules are optimized by GA. The details of the GA-based FIS, the performance measurement, and the fitness function that is associated with a validation strategy are discussed as follows:

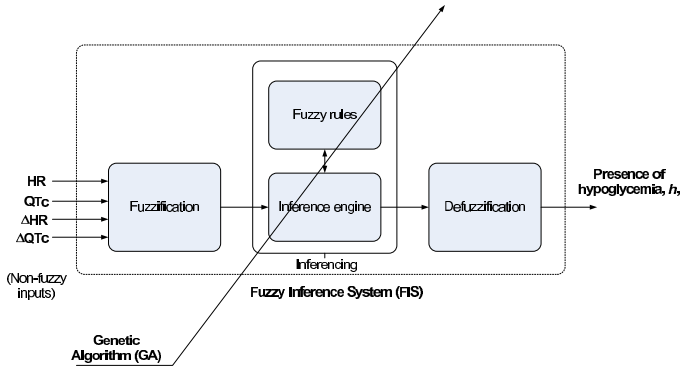

Fig. 1. Hypoglycemia detection system.

A. Fuzzy Inference System

Referring to Fig. 1, an FIS is used to model the hypoglycemic detection based on the physiological inputs (HR, QT_c, ΔHR, and ΔQT_c). The physiological inputs are treated as linguistic variables and given membership values that allow fuzzy detection. The fuzzy detection system consists of three components: fuzzification, inferencing, and defuzzification.

1) Fuzzification: The first step is to take the inputs, and determine the degree of membership they belong to each of the appropriate fuzzy sets. The membership function is defined as $\mu_{N_z^k}(z(t))$, which is a bell-shaped function given by:

$$\mu_{N_z^k}(z(t)) = e^{\frac{-(z(t)-m_z^k)^2}{2\varsigma_z^k}}, \tag{1}$$

where $z(t)$ is any one of the following 4 signals: $HR(t)$, $QT(t)$, $\Delta HR(t)$, $\Delta QT_c(t)$; $z(t)$ denotes the non-fuzzy input, $k = 1, 2, ..., m_f$; m_f denotes the number of membership functions, $t = 1, 2, ..., n_d$; n_d denotes the number of input-output data pairs. The parameters m_z^k and ς_z^k are the mean value and the standard deviation of the k-th membership function, respectively. If the input value is less than the minimum of the mean value or higher than the maximum of the mean value, the corresponding degree of membership is set as 1.

2) Inferencing: The task of the inferencing process is to map the fuzzified inputs to the rule base, and to produce a fuzzified output for each rule. The fuzzy if-then rules in the rule base are of the following format:

$$\begin{aligned} \text{Rule } \gamma : \textbf{IF} HR(t) \text{ is } N_{HR}^k(HR(t)) \textbf{ AND} \\ QT_c(t) \text{ is } N_{QT_c}^k(QT_c(t)) \textbf{ AND} \\ \Delta HR(t) \text{ is } N_{\Delta HR}^k(\Delta HR(t)) \textbf{ AND} \\ \Delta QT_c(t) \text{ is } N_{\Delta QT_c}^k(\Delta QT_c(t)) \textbf{ THEN } y(t) \text{ is } w_\gamma. \end{aligned} \tag{2}$$

where $N_{HR}^k(HR(t))$, $N_{QT_c}^k(QT_c(t))$, $N_{\Delta HR}^k(\Delta HR(t))$, and $N_{\Delta QT_c}^k(\Delta QT_c(t))$ are fuzzy terms, γ=1, 2, ...,n_r; n_r denotes number of rules and n_r is set to $(m_f)^{n_{in}}$, where $n_{in} = 4$ is the number of inputs to the FIS. From the fuzzification process, the inference engine obtains the values of $\mu_{N_{HR}^k}(HR(t))$, $\mu_{N_{QT_c}^k}(QT_c(t))$, $\mu_{N_{\Delta HR}^k}(\Delta HR(t))$, $\mu_{N_{\Delta QT_c}^k}(\Delta QT_c(t))$. Aggregation is then used to obtain the output of each rule γ as a fuzzy value. The output for each rule is defined as:

$$\begin{aligned} \mu_\gamma = (\mu_{N_{HR}^k}(HR(t))) \times (\mu_{N_{QT_c}^k}(QT_c(t))) \\ \times(\mu_{N_{\Delta HR}^k}(\Delta HR(t))) \times (\mu_{N_{\Delta QT_c}^k}(\Delta QT_c(t))), \\ \gamma = 1, 2, ..., n_r. \end{aligned} \tag{3}$$

3) Defuzzification: Defuzzification is the process of translating the outputs of the fuzzy rules into a value. The output of the defuzzication process is given by:

$$y(t) = \frac{\sum_{\gamma=1}^{n_r} w_\gamma \mu_\gamma}{\sum_{\gamma=1}^{n_r} \mu_\gamma}, \tag{4}$$

where $w_\gamma \in [0, 1]$ is the fuzzy singleton in Rule γ. If the output $y(t)$ is positive, hypoglycemia is present $(h(t) = +1)$.

B. Genetic Algorithm

To optimize the fuzzy membership functions and rules (the values of m, ς and w), the Genetic Algorithm (GA) is investigated. The GA process is shown in Algorithm II.1. First, a population of chromosomes P is created. Each chromosome $\mathbf{p}_i$ contains a set of genes p_{ij}, where $i = 1, 2, ..., n_p$, $j = 1, 2, ..., n_g$; n_p and n_g denote the population size (number of chromosomes) and the number of genes respectively. Second, the chromosomes are evaluated by a defined fitness function $f(\mathbf{p}_i)$. The form of the fitness function depends on the application. The better chromosomes are those returning higher fitness values in this process. Third, some of the chromosomes are selected to undergo genetic operations for reproduction by the method of normalized geometric ranking [30]. It is a selection based on a non-stationary penalty function which is a function of the generation number. As the number of generation increases, the penalty increases that puts more and more selective pressure on the GA to find the feasible solution. In general, a higher-rank chromosome will have a higher chance to be selected. Fourth, the genetic operation of crossover is performed. The crossover operation is mainly for exchanging information from the two parents, chromosomes $\mathbf{p}_1$ and $\mathbf{p}_2$, obtained in the selection process with a defined probability of crossover μ_c. This probability gives an expected number of chromosomes that undergo the crossover. In this paper, Blend-α [31] is used as the operation of crossover, which has a good searching ability and can handle multimodal and separability problem effectively. For the Blend-α crossover, the resulting offspring is chosen randomly from the interval $[X_j^1, X_j^2]$ following the uniform distribution, where

$$\begin{aligned} X_j^1 &= \min(p_{1j}, p_{2j}) - \alpha d_j \\ X_j^2 &= \max(p_{1j}, p_{2j}) + \alpha d_j \end{aligned}, \tag{5}$$

$d_j = |p_{1j} - p_{2j}|$, p_{1j} and p_{2j} are the j-th element of $\mathbf{p}_1$ and $\mathbf{p}_2$, respectively, and α is a positive constant.

After the crossover operation, the mutation operation follows. The mutation operation is to change the genes of the chromosomes in the population such that the features inherited from their parents can be changed. A probability of mutation, μ_m, is defined to govern the operation. It gives an expected number of genes that undergo the mutation. Non-uniform mutation [23] is used, which is an operation with a fine-tuning capability. The mutated gene is given by,

$$\hat{p}_{ij} = \begin{cases} p_{ij} + \Delta(\tau, \delta^j_{\max} - p_{ij}) & \text{if } r_d = 0 \\ p_{ij} + \Delta(\tau, p_{ij} - \delta^j_{\min}) & \text{if } r_d = 1 \end{cases}, \tag{6}$$

where r_d is a random number equal to 0 or 1 only. $\delta^j_{\max}$ and $\delta^j_{\min}$ are the upper and lower boundary of the gene. The function $\Delta(\tau, y)$ return a value in the range $[0, y]$ approaches 0 as τ increases. It is defined as follows.

$$\Delta(\tau, y) = y\left(1 - r^{(1-\tau/T)^{\zeta}}\right), \tag{7}$$

where r is a random number in range of [0,1], τ represents the current generation number, T represents the total number of iteration and ζ is a shape parameter that determines the degree of non-uniformity. After going through the mutation operation, the new offspring will be evaluated using the fitness function. The new population will be formed when the new offspring replaces the chromosome with the smallest fitness value. A global best chromosome $\hat{\mathbf{p}}_g$ that has the best fitness value will be stored if the current best chromosome $\hat{\mathbf{p}}(\tau)$ is better than the global one in the current generation. The newly formed population will repeat the same process. Such an iterative process will be terminated when a defined termination condition is met. Finally, the best chromosome (solution) $\hat{\mathbf{p}}_g$ will be found.

Algorithm II.1: PSEUDO CODE FOR GA()

```
τ ← 0
Initialize P(τ)
output (f(P(τ)))
while <not termination condition>
  do { τ ← τ + 1
       Select 2 parents, p_1 and p_2 from P(τ − 1)
       Perform crossover operation (5) with μ_c
       Perform mutation operation (6) − (7) with μ_m
       if p̂(τ) > p̂_g
         then p̂_g = p̂(τ)
       output (P(τ))
       output (f(P(τ)))
return (p̂_g)
comment: return the best chromosome (solution)
```

C. Performance Evaluation and Fitness Function

In this system, GA is employed to optimize the fuzzy rules and membership functions by finding out the best parameters m, ς and w. The function of the fuzzy inference system is to detect the hypoglycemic episodes accurately. To measure the performance of the biomedical classification test, sensitivity and specificity are introduced [32]. The sensitivity measures the proportion of actual positives which are correctly identified and the specificity measures the proportion of actual negatives which are correctly identified. The definitions of the sensitivity (ξ) and the specificity (η) are given as follows:

$$\xi = \frac{N_{TP}}{N_{TP} + N_{FN}}, \tag{8}$$

$$\eta = \frac{N_{TN}}{N_{TN} + N_{FP}}, \tag{9}$$

where N_{TP} is number of true positives which means the sick people are correctly diagnosed as sick; N_{FN} is number of false negative which means the sick people are wrongly diagnosed as healthy; N_{FP} is number of false positives which means healthy people are wrongly diagnosed as sick; and N_{TN} is number of true negatives which means the healthy people are correctly diagnosed as healthy. The values of ξ and η are within 0 to 1.

The objective of the system is to maximize the sensitivity and the specificity; thus, the fitness function is designed to maximize both values. A fitness function with a constant value and a penalty function is given in [33]. The constant value is used to control the balance between the sensitivity and specificity. The penalty function is used to force the sensitivity and the specificity to a required condition. However, on using this approach, only the training set and testing set are considered, which will risk the occurrence of overtraining [29]. Overtraining refers to the reduction of the generalization ability that can occur as the system is trained. To overcome this problem, a validation strategy that may adjust the fitness function is proposed in this paper to reduce the risk of overtraining.

Fig. 2 shows the idea of the proposed method to solve the overtraining problem. In this figure, the two curves represent the training performance and validation performance respectively. To overcome the overtraining problem, a validation set is introduced for the proposed fitness function. The x-axis represents the iteration number and T denotes the total number of iteration (as introduced in (7)), the y-axis represents the classification performance (in this paper, the performance is governed by sensitivity and specificity). The objective of the proposed validation strategy is to train the training set and test the trained results with the validation set with respect to a target region. The target region is a performance requirement related to sensitivity and specificity, for example, $\xi > 0.7$ and $\eta > 0.5$. As illustrated in Fig. 2 at T_a, we can see the performance of the training set has reached a very good result; however, the performance of the validation set cannot meet the minimum requirement of the target region. The testing performance will have a high chance to be out of the target region. It is an overtraining phenomenon; the model is over-fit with the training set and has the generalization performance reduced. At time T_b, the performance of both the training set and the validation set are within the target region; the testing result will have a good chance meeting the performance requirement. The parameters of the FIS will be stored at this time. In this paper, the termination condition of the GA is met when τ=T. When both sets have reached the target region and $\tau < T$, such as $\tau = T_b$, we will update the target region (increase the requirement level). For example, increase $\xi > 0.7$ to $\xi > 0.75$. At time T_c, both the training and validation performance are in the updated target region, the model parameters will then be updated.

Algorithm II.2: FITNESS FUNCTION($\bar{\xi}_t, \bar{\eta}_t, \bar{\xi}_v, \bar{\eta}_v$)

$\eta_l \leftarrow \eta_d$
$\xi_l \leftarrow \xi_d$
output $(\bar{\xi}_t, \bar{\eta}_t, \bar{\xi}_v, \bar{\eta}_v)$ based on (8) and (9)
output (f_{fit}) based on (10)
if $(\xi_t > \xi_l$ & $\eta_t > \eta_l$ & $\xi_v > \xi_l$ & $\eta_v > \eta_l)$
  then $\xi_d = \xi_d + \sigma$

Based on the above concept, the process of formulating the fitness function is shown in Algorithm II.2. First, a target region will be defined, the lower boundary of the sensitivity and specificity are defined as ξ_l and η_l respectively; the upper boundary for them is 1 (maximum performance). The initial values of the lower boundary for ξ_d and η_d are given. Second, based on (8) and (9), the training sensitivity ξ_t, the training specificity η_t, the validation sensitivity ξ_v, and the validation specificity η_v are evaluated. Referring to Fig. 2, the training performance is the result of ξ_t and η_t. Similarly, the validation performance is the result of ξ_v and η_v. Next,the fitness function, f_{fit} is calculated as follow:

$$f_{fit} = \bar{\xi}_t + \bar{\eta}_t + \bar{\xi}_v + \bar{\eta}_v, \tag{10}$$

where

$$\bar{\xi}_t = \begin{cases} 1 & \text{if } \xi_t \geq \xi_l \\ 1 - \frac{\xi_l - \xi_t}{\xi_l} & \text{if } \xi_t < \xi_l \end{cases},$$

and

$$\bar{\xi}_v = \begin{cases} 1 & \text{if } \xi_v \geq \xi_l \\ 1 - \frac{\xi_l - \xi_v}{\xi_l} & \text{if } \xi_v < \xi_l \end{cases},$$

and

$$\bar{\eta}_t = \begin{cases} 1 & \text{if } \eta_t \geq \eta_l \\ 1 - \frac{\eta_l - \eta_t}{\eta_l} & \text{if } \eta_t < \eta_l \end{cases},$$

and

$$\bar{\eta}_v = \begin{cases} 1 & \text{if } \eta_v \geq \eta_l \\ 1 - \frac{\eta_l - \eta_v}{\eta_l} & \text{if } \eta_v < \eta_l \end{cases}.$$

In (10), the maximum fitness value is equal to 4 (when $\bar{\xi}_t$, $\bar{\eta}_t$, $\bar{\xi}_v$, $\bar{\eta}_v$ all equal 1), which implies that both the training and validation performance have met the defined requirement. Finally, if the target region ($\xi_t > \xi_l$ and $\eta_t > \eta_l$ and $\xi_v > \xi_l$ and $\eta_v > \eta_l$) is reached, ξ_d will be updated by $\xi_d + \sigma$, where the value of σ is normally between 0.01 and 0.05. For finding out the optimal sensitivity with a fixed specificity value, only ξ_d will be updated during the training process.

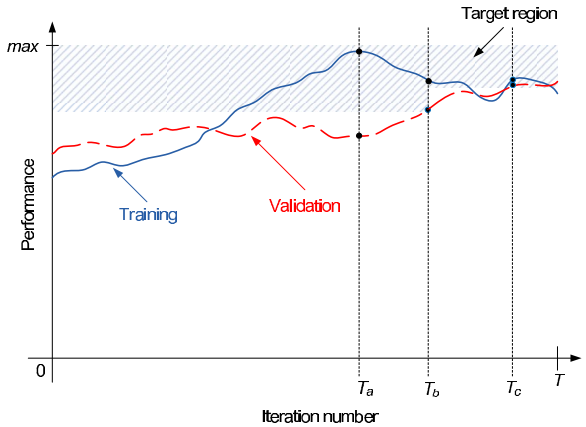

Fig. 2. Fitness function with validation strategy

III. Results and Discussion

Fifteen children with T1DM (14.6 ± 1.5 years) volunteered for the 10-hour overnight hypoglycemia study at the Princess Margaret Hospital for Children in Perth, Western Australia, Australia. Each patient was monitored overnight for the natural occurrence of nocturnal hypoglycemia. Data were collected with approval from Women's and Children's Health Service, Department of Heath, Government of Western Australia, and with informed consent.

A comprehensive patient information and consent form was formulated and approved by the Ethics Committee. The consent form included the actual consent and a revocation of consent page. Each patient received this information consent form at least two weeks prior to the start of the studies. He/She had the opportunity to raise questions and concerns with any medical advisers, researchers and the investigators. For the children participating in this study, the parent or guardian signed the relevant forms. We measured the required physiological parameters, while the actual blood glucose levels (BGL) were collected as reference using Yellow Spring Instruments. The main parameters used for the detection of hypoglycemia are the heart rate, corrected QT interval, change of heart rate and change of corrected QT interval. The responses from 15 T1DM children exhibited significant changes during the hypoglycemia phase against the non-hypoglycemia phase. Normalization is used to reduce patient-to-patient variability and to enable group comparison. The normalization is done by dividing the patient's heart rate and corrected QT interval by his/her corresponding values at time zero.

In this paper, the meaning of hypoglycemia is suggested as BGL $<$ 3.3 mmol/l. The detection of hypoglycemic episodes using these variables is based on the proposed GA-based fuzzy inference system developed using the obtained clinical data. In effect, it estimates the presence of hypoglycaemia at sample period k_s based on the data at sampling period k_s and the previous data at sampling period $k_s - 1$. In general, the sampling period is 5 minutes and approximately 35-40 data points are used for each patient. The whole data set consists of a training set, a validation set and a testing set, each with 5 patients randomly selected. With these 15 patients, the number of data points for training, validation, and testing is 199, 177, and 193 respectively. The whole data set, which includes both the hypoglycemia data part and non-hypoglycemia data part, is used to build the classification and measure the classification performance in terms of sensitivity and specificity.

For comparison and analysis purposes, 4 approaches are used to tackle the same T1DM problem. They are: i) Evolved fuzzy inference system with 4 inputs (EFIS4) (4 inputs: HR, QT_c, ΔHR, and ΔQT_c) with the proposed fitness function and validation strategy considered; ii) Evolved fuzzy inference system with 2 inputs (EFIS2) (2 inputs: HR and QT_c only) with the proposed fitness function and validation strategy considered; iii) Evolved fuzzy inference system with 4 inputs without the proposed fitness function and validation strategy (EFIS4-V), the fitness function in [33] is applied; and iv) Evolved multiple regression with 4 inputs (EMR4).

GA is used to find the optimized fuzzy rules and membership functions of EIFS4, EFIS2, EFIS4-V, and the model parameters of EMR4. The parameter values of the GA are shown as follows.

- Population size θ: 100;
- Probability of crossover μ_c: 0.8;
- Constant value of crossover α: 0.5;
- Probability of mutation μ_m: 0.3;
- Shape parameter of mutation ζ: 2;
- Number of iteration T : 1000;
- Number of runs : 20.

In the fuzzy inference system, the number of the membership functions is set at 3 (m_f = 3); thus, the total number of fuzzy rules n_r is equal to 81 ($n_r = {n_f}^{n_{in}} = 3^4 = 81$). The best training, validation and testing results in term of the sensitivity (ξ) and specificity (η) are tabulated in Table I. For the proposed fitness function, the initial ξ_l and η_l are set at 0.7 and 0.4 respectively. The σ for sensitivity is set at 0.02. From Table I, we can see that the testing performance of EFIS4 outperform the other approaches, and the testing sensitivity is 86.05% with 42.73% specificity. The sensitivity of EFIS4 (86.05%) is significantly better than the sensitivity of EMR4 (67.44%). To illustrate the effectiveness of the proposed fitness function and validation strategy, evolved fuzzy inference system with 4 inputs (EFIS4-V) without the proposed fitness function and validation strategy is used. In EFIS4-V, there are only 2 data set (training and testing), 10 patients (combining the training and validation set of EFIS4) are selected for training and 5 patients are selected for testing. We can see from the results that the testing sensitivity of EFIS4 shows an increase from 81.40% to 86.05%. Furthermore, on comparing EFIS4 and EFIS2, the testing sensitivity with 4 inputs is better, which reflects that ΔHR; ΔQT_c are useful physiological information to enhance the sensitivity.

The Receiver Operating Characteristic (ROC) [34] analysis is tabulated in Table II and the ROC plot is shown in Fig. 3. ROC analysis is commonly used in medical decision making, and is a useful technique for visualizing the diagnostic performance of a test. In an ROC curve the sensitivity is plotted against the false positive rate (1−specificity). A test with perfect discrimination has an ROC plot that passes through the upper left corner (100% sensitivity, 100% specificity). Thus, the closer the ROC plot is to the upper left corner, the higher the overall accuracy of the test. In Table II, the corresponding Area Under the Curve (AUC) of EFIS4 for testing is 0.7502 with a 95% confidence interval of (0.6578, 0.8426). With these results, we can see that the diagnostic performance of EFIS4 for testing is the best.

IV. Conclusion

A genetic algorithm based fuzzy inference system is developed to detect hypoglycemia. Experimental results indicate that hypoglycemia can be detected from the physiological responses of heart rate, corrected QT interval, change of heart rate and change of corrected QT interval. To optimize the fuzzy rules and membership functions, the genetic algorithm is

used. To avoid the over-training problem, a validation strategy that may adjust the fitness function is proposed. A clinical study is given to illustrate that the system with the proposed fitness function and validation strategy offers better results as compared with those from a fuzzy inference system of only 2 inputs, a fuzzy inference system without considering the over-training problem, and an evolved multiple regression algorithm in terms of sensitivity and specificity.

***Abstract*—Stability analysis of polynomial fuzzy model-based (PFMB) control systems under the parallel distributed compensation (PDC) design technique is investigated. A new polynomial fuzzy controller (PFC) is introduced to release conservativeness in the existing approaches. Compared to the conventional (PFC), the controller under consideration in this paper has a favorable property which introduces some more variables in the stability conditions such that, the solution of the derived stability conditions can be explored in a larger group of potential solutions. This property may lead to further relax stability conditions. However, the stability conditions will not be in the form of SOS conditions. Hence, particle swarm optimization (PSO) is employed to explore the solution of the derived stability conditions which are in the form of state-dependent BMI. It is shown that the conventional PFC is a special case of that of proposed one. Finally, a simulation example is given to illustrate the effectiveness of the proposed approach.**

***Index Terms*—polynomial fuzzy model(PFM), state-dependent Bilinear Matrix Inequality (BMI), stability conditions, sum of squares (SOS), particle swarm optimization (PSO).**

I. Introduction

Recently, fuzzy model-based (FMB) control approach has become a popular system control analysis methodology. It provides a systematic way for handling of nonlinear control systems [1]. To demonstrate complex nonlinear systems in a fuzzy frame, T-S fuzzy model [2], [3], introduces a mathematical framework. This model portrays a nonlinear system by a set of fuzzy rules. Each rule contains a linear model, so-called subsystem, that represents the dynamics of the nonlinear plant in a specific local operating domain. The overall T-S fuzzy model is constructed as an average weighted sums of some subsystems. To control a nonlinear plant, a fuzzy controller is employed to close the feedback loop. The design strategy of fuzzy controller is based on the T-S fuzzy model so that, a FMB control system [4]–[6] is formed.

At early stage of research on the FMB control approach, lack of a rigorous theoretical basis for stability analysis had drawn a great deal of attention to this area. Recently, based on the Lyapunov stability theory [7] for nonlinear control systems, sufficient conditions to guarantee the stability of the FMB control system are derived. In most of the proposed approaches, stability analysis and control design problems are formulated to Linear Matrix Inequality (LMI) problems [8]. Then, utilizing convex programming techniques, LMI MATLAB Toolbox [9], numerical solutions are obtained. Some of the well-known LMI-based stability conditions have been reported in [1], [5], [10]–[18]. *Parallel Distributed Compensation* (PDC) [5] design technique, for which the fuzzy controller shares the same membership functions as T-S fuzzy model, is employed to further relax the stability conditions [1], [11], [12], [18]. When the fuzzy controller does not follow the PDC design, it is called non-PDC fuzzy controller.

Very recently, nonlinear control systems have been represented by polynomial fuzzy model (PFM) [19], which is a generalized form of the T-S fuzzy model. PFMs have the same structure as the T-S fuzzy model, but polynomials are allowed to be considered in the subsystems. To close the feedback loop, polynomial fuzzy controller (PFC) which is similar to the traditional fuzzy controller [6], but with polynomials in its structure, is employed and polynomial fuzzy model-based (PFMB) control system is constructed.

To deal with the stability analysis and performance design of the PFMB control systems, sum of squares (SOS) approach is employed [19]. Based on the SOS approach, polynomials are allowed to be incorporated in the stability conditions. These conditions can be regarded as state-dependent LMI conditions. Semi-definite programming software SOSTOOLS [20] is the computational method to be employed to solve numerically these SOS (state-dependent LMI) conditions, based on the SOS decomposition. Compared to the LMI approach, SOS approach has some advantages in dealing with stability analysis of fuzzy control systems. Since, polynomials are allowed to be incorporated in the PFM, it is more effective in representing nonlinear control systems. Moreover, when various polynomials of state variables are allowed to be considered in the PFC, solution of stability conditions can be searched in a larger group of candidates, which may result in the relaxation of stability conditions. In addition, to investigate stability of these systems, polynomial Lyapunov function (PLF) which is a generalized form of quadratic Lyapunov function, can be implemented. It should be noted that PLF can be utilized in the LMI-based stability conditions.

Conservatism is one of the drawbacks that most of the existing stability conditions suffer from it. In [21], to relax

The work described in this paper was partially supported by COSMOS project grant from the European Communities Seventh Framework Programme (FP7-NMP-2009-SMALL-3, NMP- 2009-3.2-2) under grant agreement 246371-2, and a grant from the Modernisation Initiative with the support of the Guys and St Thomas Hospitals Charity.

the stability conditions under the non-PDC paradigm for FMB control systems, a fuzzy controller has been considered, for which the feedback gains were time-varying nonlinear functions. Due to introducing more decision variables in the structure of the stability conditions, feedback gains can be searched in a wider domain of potential solution for the conditions under consideration. However, the derived stability conditions were in the form of bilinear matrix inequality (BMI). Therefore, numerical solution were found by employing genetic algorithm (GA) [22] and LMI MATLAB Toolbox.

In this paper, stability of PFMB control systems under the PDC design technique is investigated. To release conservativeness resulting from considering conventional form for PFC [19], PFC with similar structure to the controller in [21] is introduced. Compared to the conventional PFC, the PFC under consideration introduces some more decision variables in the stability conditions such that, the solution of the derived stability conditions can be explored in a larger group of potential solutions which may lead to relaxed stability conditions. However, the resulting conditions will be in the form of state-dependent BMI. Then, utilizing searching algorithms say, particle swarm optimization (PSO) [23], the solution of derived conditions can be searched in a wider domain.

The rest of this chapter is organized as follows. In section II, PFM, PFC and PFMB control system are presented. In section III, stability analysis of PFMB control system is presented. In section IV, a simulation example is given to illustrate the validity of the proposed approach. Section V concludes this paper.

II. PFM, PFC AND PFMB CONTROL SYSTEM

Consider a nonlinear system described by

$$\dot{\mathbf{x}} = \mathbf{f}\big(\mathbf{x}(t), \mathbf{u}(t)\big), \tag{1}$$

where $\mathbf{f}\big(\mathbf{x}(t), \mathbf{u}(t)\big)$ is a nonlinear function in which $\mathbf{x}(t) \in \mathbb{R}^{\rho}$ is the system state vector and $\mathbf{u}(t) \in \mathbb{R}^{\omega}$ is the input vector. Using the sector nonlinearity concept [6], the nonlinear system (1) is represented by the following polynomial fuzzy model [19], [24],

Plant Rule *i*:

$$\begin{aligned} &\text{IF } z_1(\mathbf{x}(t)) \text{ is } M_1^i \text{ AND ... AND } z_p(\mathbf{x}(t)) \text{ is } M_p^i \\ &\text{THEN } \dot{\mathbf{x}}(t) = \mathbf{A}_i(\mathbf{x}(t))\hat{\mathbf{x}}(\mathbf{x}(t)) + \mathbf{B}_i(\mathbf{x}(t))\mathbf{u}(t) \\ &\qquad\qquad\qquad\qquad\qquad\qquad i = 1, \cdots, r, \end{aligned} \tag{2}$$

for which $z_{\alpha}(\mathbf{x}(t))$ is the premise variable; M_{α}^i is a fuzzy term corresponding to i^{th} rule; $\mathbf{A}_i(\mathbf{x}(t)) \in \mathbb{R}^{\rho \times N}$ and $\mathbf{B}_i(\mathbf{x}(t)) \in \mathbb{R}^{\rho \times \omega}$ are the polynomial system and polynomial input matrices respectively, for $i = 1, ..., r$, $\alpha = 1, ..., p$; In addition, $\hat{\mathbf{x}}(t) = [\hat{x}_1(t), \hat{x}_2(t), ..., \hat{x}_N(t)]^T \in \mathbb{R}^N$ is a vector of monomials in $\mathbf{x}(t)$ with assumption that $\hat{\mathbf{x}}(t) = \mathbf{0}$ *iff* $\mathbf{x}(t) = \mathbf{0}$. A monomial in $\mathbf{x}(t)$ is a function of the form $x_1^{\alpha_1}(t)x_2^{\alpha_2}(t)...x_n^{\alpha_{\rho}}(t)$, where $\alpha_1, \alpha_2, ..., \alpha_{\rho}$ are nonnegative integers. In this case, the degree of the monomial is given by $\alpha_1 + \alpha_2 + ... + \alpha_{\rho}$.

The overall system dynamics is represented by

$$\dot{\mathbf{x}}(t) = \sum_{i=1}^{r} \mu_i(\mathbf{z}(\mathbf{x}(t)))\Big(\mathbf{A}_i(\mathbf{x}(t))\hat{\mathbf{x}}(\mathbf{x}(t)) + \mathbf{B}_i(\mathbf{x}(t))\mathbf{u}(t)\Big). \tag{3}$$

where

$$\begin{aligned} &\mu_i(\mathbf{z}(\mathbf{x}(t))) \in [0, \ \ 1], \\ &\sum_{i=1}^{r} \mu_i(\mathbf{z}(\mathbf{x}(t))) = 1. \end{aligned}$$

To control nonlinear system represented by the polynomial fuzzy model (3), a polynomial fuzzy controller is introduced, which is described by following fuzzy rules.

Control Rule *j* :

$$\begin{aligned} &\text{IF } g_1(\mathbf{x}(t)) \text{ is } N_1^j \text{ AND ... AND } g_q(\mathbf{x}(t)) \text{ is } N_q^j \\ &\text{THEN } \mathbf{u}(t) = \frac{\mathbf{F}_j(\mathbf{x}(t))}{H(\mathbf{x}(t))}\hat{\mathbf{x}}(\mathbf{x}(t)) \\ &\qquad\qquad\qquad\qquad\qquad\qquad j = 1, ..., c, \end{aligned} \tag{4}$$

where $g_{\theta}(\mathbf{x}(t))$ is the premise variable; N_{θ}^j is a fuzzy term corresponding to the j^{th} control rule, $j = 1, ..., c$, $\theta = 1, ..., q$; $\mathbf{F}_j(\mathbf{x}(t)) \in \mathbb{R}^{\omega \times N}$ is the polynomial feedback gain of the j^{th} rule to be determined and $H(\mathbf{x}(t))$ is defined as follows.

$$H(\mathbf{x}(t)) = \sum_{k=1}^{c} \lambda_k(\mathbf{g}(\mathbf{x}(t)))a_k(\mathbf{x}) \tag{5}$$

in which

$$a_k(\mathbf{x}(t)) = a_k^1\hat{x}_1 + ... + a_k^{l-1}\hat{x}_{l-1} + a_k^l,$$

where $\hat{x}_1, ..., \hat{x}_{l-1}$ are monomials and $a_k^1, ..., a_k^l$ are scalars.

Then, regarding to (5), the overall PFC is defined as

$$\begin{aligned} \mathbf{u}(t) &= \sum_{j=1}^{c} \lambda_j(\mathbf{g}(\mathbf{x}(t)))\frac{\mathbf{F}_j(\mathbf{x}(t))}{H(\mathbf{x}(t))}\hat{\mathbf{x}}(\mathbf{x}(t)) \\ &= \sum_{j=1}^{c} \lambda_j(\mathbf{g}(\mathbf{x}(t)))\frac{\mathbf{F}_j(\mathbf{x}(t))}{\sum_{k=1}^{c} \lambda_k(\mathbf{g}(\mathbf{x}(t)))a_k(\mathbf{x}(t))}\hat{\mathbf{x}}(\mathbf{x}(t)) \end{aligned} \tag{6}$$

where

$$\begin{aligned} &\lambda_j(\mathbf{g}(\mathbf{x}(t))) \in [0, \ \ 1], \\ &\sum_{j=1}^{c} \lambda_j(\mathbf{g}(\mathbf{x}(t))) = 1. \end{aligned} \tag{7}$$

$$\dot{\mathbf{x}}(t) = \frac{\sum_{i=1}^{r}\sum_{j=1}^{c}\mu_i(\mathbf{x}(t))\lambda_j(\mathbf{x}(t))\Big(a_j(\mathbf{x}(t))\mathbf{A}_i(\mathbf{x}(t)) + \mathbf{B}_i(\mathbf{x}(t))\mathbf{F}_j(\mathbf{x}(t))\Big)}{\sum_{k=1}^{c}\lambda_k(\mathbf{x}(t))a_k(\mathbf{x}(t))}\hat{\mathbf{x}}(\mathbf{x}(t)). \tag{8}$$

Considering the PFM (3) and the PFC (6) connected in a closed loop, we have

$$\dot{\mathbf{x}}(t) = \sum_{i=1}^{r}\mu_i(\mathbf{x})(t)\Big(\mathbf{A}_i(\mathbf{x}(t))\hat{\mathbf{x}}(\mathbf{x}(t)) + \mathbf{B}_i(\mathbf{x}(t))\sum_{j=1}^{c}\lambda_j(\mathbf{x})(t) \times \frac{\mathbf{F}_j(\mathbf{x}(t))}{\sum_{k=1}^{c}\lambda_k(\mathbf{x}(t))a_k(\mathbf{x}(t))}\hat{\mathbf{x}}(\mathbf{x}(t))\Big)$$

Then, the PFMB control system is obtained as (8).

For brevity, $\mathbf{x}$, $\hat{\mathbf{x}}(\mathbf{x})$, $\mu_i(\mathbf{x})$, $\lambda_j(\mathbf{x})$ and $\mathbf{u}$ are used to denote $\mathbf{x}(t)$, $\hat{\mathbf{x}}(\mathbf{x}(t))$, $\mu_i(\mathbf{z}(t))$, $\lambda_j(\mathbf{s}(\mathbf{x}(t)))$, and $\mathbf{u}(t)$, respectively, in the following analysis.

III. Stability Analysis of PFMB Control Systems

Based on the Lyapunov stability theory, the stability of the PFMB control system (8) is investigated. Consider the following polynomial quadratic Lyapunov function candidate [19]

$$V(\mathbf{x}) = \hat{\mathbf{x}}(\mathbf{x})^T\mathbf{X}^{-1}(\tilde{\mathbf{x}})\hat{\mathbf{x}}(\mathbf{x}), \tag{9}$$

where $\mathbf{X}^{-1}(\tilde{\mathbf{x}}) \in \mathbb{R}^{N\times N}$ is a symmetric positive definite polynomial matrix and $\tilde{\mathbf{x}} = [x_{k_1}, x_{k_2}, ..., x_{k_d}]$ is a vector to be chosen such that $\mathbf{K} = \{k_1, k_2, ..., k_d\}$ denotes the indices of the corresponding zero rows in $\mathbf{B}_i(\mathbf{x})$ for all i. Denoting the k^{th} row in $\mathbf{A}_i(\mathbf{x})$ and $\mathbf{B}_i(\mathbf{x})$ as $\mathbf{A}_i^k(\mathbf{x})$ and $\mathbf{B}_i^k(\mathbf{x})$ respectively, we have

$$\mathbf{B}_i^k(\mathbf{x}) = \mathbf{0} \qquad \text{for } k \in \mathbf{K}. \tag{10}$$

To avoid introducing non-convex condition, we assume that $\mathbf{X}(\tilde{\mathbf{x}})$ only depends on state vector $\tilde{\mathbf{x}}$. Hence $\frac{\partial\mathbf{X}^{-1}(\tilde{\mathbf{x}})}{\partial x_k} = \mathbf{0}$ for $k \notin \mathbf{K}$. For more details readers are referred to [19], [25]. According to the Lyapunov stability theory, if $\mathbf{X}(\tilde{\mathbf{x}})$ and $\mathbf{X}^{-1}(\tilde{\mathbf{x}})$ are positive definite matrices in $\tilde{\mathbf{x}}$ and $\dot{V}(t) \leq 0$ (equality holds when $\mathbf{x} = \mathbf{0}$), then the polynomial FMB control system (8) is asymptotically stable. Following the approach in [19]:

$$\dot{V}(\mathbf{x}) = \dot{\hat{\mathbf{x}}}^T(\mathbf{x})\mathbf{X}^{-1}(\tilde{\mathbf{x}})\hat{\mathbf{x}}(\mathbf{x}) + \hat{\mathbf{x}}^T(\mathbf{x})\mathbf{X}^{-1}(\tilde{\mathbf{x}})\dot{\hat{\mathbf{x}}}(\mathbf{x}) + \hat{\mathbf{x}}^T(\mathbf{x})\dot{\mathbf{X}}^{-1}(\tilde{\mathbf{x}})\hat{\mathbf{x}}(\mathbf{x}) \tag{11}$$

in which

$$\begin{aligned}\dot{\hat{\mathbf{x}}}(\mathbf{x}) &= \begin{pmatrix}\dot{\hat{\mathbf{x}}}_1(\mathbf{x})\\ \vdots \\ \dot{\hat{\mathbf{x}}}_N(\mathbf{x})\end{pmatrix}\\ &= \begin{pmatrix}\frac{\partial\hat{x}_1}{\partial x_1} & \cdots & \frac{\partial\hat{x}_1}{\partial x_\rho}\\ \vdots & \ddots & \vdots \\ \frac{\partial\hat{x}_N}{\partial x_1} & \cdots & \frac{\partial\hat{x}_N}{\partial x_\rho}\end{pmatrix}\begin{pmatrix}\frac{\partial x_1}{\partial t}\\ \vdots \\ \frac{\partial x_\rho}{\partial t}\end{pmatrix}\\ &= \mathbf{\Phi}(\mathbf{x})\dot{\mathbf{x}}\end{aligned}$$

where $\mathbf{\Phi}(\mathbf{x}) \in \mathbb{R}^{N\times\rho}$ is a polynomial matrix defined as follows

$$\mathbf{\Phi}(\mathbf{x}) = \begin{pmatrix}\frac{\partial\hat{x}_1}{\partial x_1} & \cdots & \frac{\partial\hat{x}_1}{\partial x_\rho}\\ \vdots & \ddots & \vdots \\ \frac{\partial\hat{x}_N}{\partial x_1} & \cdots & \frac{\partial\hat{x}_N}{\partial x_\rho}\end{pmatrix}. \tag{12}$$

Then, (11) is derived as follows.

$$\dot{V}(\mathbf{x}) = \dot{\mathbf{x}}^T\mathbf{\Phi}^T(\mathbf{x})\mathbf{X}^{-1}(\tilde{\mathbf{x}})\hat{\mathbf{x}}(\mathbf{x}) + \hat{\mathbf{x}}^T(\mathbf{x})\mathbf{X}^{-1}(\tilde{\mathbf{x}})\mathbf{\Phi}(\mathbf{x})\dot{\mathbf{x}} + \hat{\mathbf{x}}^T(\mathbf{x}) \times \left(\sum_{k=1}^{\rho}\frac{\partial\mathbf{X}^{-1}(\tilde{\mathbf{x}})}{\partial x_k}\dot{x}_k\right)\hat{\mathbf{x}}(\mathbf{x}). \tag{13}$$

Since $\frac{\partial\mathbf{X}^{-1}(\tilde{\mathbf{x}})}{\partial x_k} = \mathbf{0}$ for $k \notin \mathbf{K}$, and according to (10), $\dot{V}(\mathbf{x})$ is written as follows.

$$\dot{V}(\mathbf{x}) = \dot{\mathbf{x}}^T\mathbf{\Phi}^T(\mathbf{x})\mathbf{X}^{-1}(\tilde{\mathbf{x}})\hat{\mathbf{x}}(\mathbf{x}) + \hat{\mathbf{x}}^T(\mathbf{x})\mathbf{X}^{-1}(\tilde{\mathbf{x}})\mathbf{\Phi}(\mathbf{x})\dot{\mathbf{x}} + \hat{\mathbf{x}}^T(\mathbf{x}) \times \left(\sum_{k\in\mathbf{K}}\frac{\partial\mathbf{X}^{-1}(\tilde{\mathbf{x}})}{\partial x_k}\sum_{i=1}^{r}\mu_i(\mathbf{x})\mathbf{A}_i^k(\mathbf{x})\hat{\mathbf{x}}(\mathbf{x})\right)\hat{\mathbf{x}}(\mathbf{x}). \tag{14}$$

Also, $\mathbf{X}(\tilde{\mathbf{x}})$ is invertible, then we have $\mathbf{X}^{-1}(\tilde{\mathbf{x}})\mathbf{X}(\tilde{\mathbf{x}}) = \mathbf{I}$. Differentiating both sides with respect to x_k yields

$$\frac{\partial\mathbf{X}^{-1}(\tilde{\mathbf{x}})}{\partial t}\mathbf{X}(\tilde{\mathbf{x}}) + \mathbf{X}^{-1}(\tilde{\mathbf{x}})\frac{\partial\mathbf{X}(\tilde{\mathbf{x}})}{\partial t} = \mathbf{0}.$$

Hence the following relation holds.

$$\frac{\partial\mathbf{X}^{-1}(\tilde{\mathbf{x}})}{\partial t} = -\mathbf{X}^{-1}(\tilde{\mathbf{x}})\frac{\partial\mathbf{X}(\tilde{\mathbf{x}})}{\partial t}\mathbf{X}^{-1}(\tilde{\mathbf{x}}) \tag{15}$$

Denoting $\mathbf{y}(\mathbf{x}) = \mathbf{X}^{-1}\hat{\mathbf{x}}(\mathbf{x})$ and according to (15), $\dot{V}(\mathbf{x})$ can be written in the following form.

$$\dot{V}(\mathbf{x}) = \sum_{i=1}^{r}\sum_{j=1}^{c} \mu_i(\mathbf{x})\lambda_j(\mathbf{x})\mathbf{y}^T(\mathbf{x}) \frac{\mathbf{T}_{ij}(\mathbf{x})}{\sum_{k=1}^{c}\lambda_k(\mathbf{x})a_k(\mathbf{x})}\mathbf{y}(\mathbf{x}), \quad (16)$$

where

$$\begin{aligned}\mathbf{T}_{ij}(\mathbf{x}) = &\Big(a_j(\mathbf{x})\mathbf{A}_i(\mathbf{x})\mathbf{X}(\tilde{\mathbf{x}}) + \mathbf{B}_i(\mathbf{x})\mathbf{M}_j(\mathbf{x})\Big)^T\mathbf{\Phi}^T(\mathbf{x}) \\ &+ \mathbf{\Phi}(\mathbf{x})\Big(a_j(\mathbf{x})\mathbf{A}_i(\mathbf{x})\mathbf{X}(\tilde{\mathbf{x}}) + \mathbf{B}_i(\mathbf{x})\mathbf{M}_j(\mathbf{x})\Big) \\ &- \sum_{k\in\mathbf{K}}\frac{\partial\mathbf{X}(\tilde{\mathbf{x}})}{\partial x_k}a_j(\mathbf{x})\mathbf{A}_i^k(\mathbf{x})\hat{\mathbf{x}}(\mathbf{x}) \quad (17)\end{aligned}$$

in which the local feedback gains are defined as

$$\mathbf{F}_j(\mathbf{x}) = \mathbf{M}_j(\mathbf{x})\mathbf{X}^{-1}(\tilde{\mathbf{x}}), \qquad j = 1, ..., c. \quad (18)$$

Utilizing the PDC design technique, (16) can be written as

$$\begin{aligned}\dot{V}(\mathbf{x}) &= \sum_{i=1}^{r}\sum_{j=1}^{r} \mu_i(\mathbf{x})\mu_j(\mathbf{x})\mathbf{y}^T(\mathbf{x}) \frac{\mathbf{T}_{ij}(\mathbf{x})}{\sum_{k=1}^{r}\mu_k(\mathbf{x})a_k(\mathbf{x})}\mathbf{y}(\mathbf{x}) \\ &= \sum_{i=1}^{r} \mu_i(\mathbf{x})\mu_i(\mathbf{x})\mathbf{y}^T(\mathbf{x}) \frac{\mathbf{T}_{ii}(\mathbf{x})}{\sum_{k=1}^{r}\mu_k(\mathbf{x})a_k(\mathbf{x})}\mathbf{y}(\mathbf{x}) \\ &+ \sum_{i=1}^{r}\sum_{i<j} \mu_i(\mathbf{x})\mu_j(\mathbf{x})\mathbf{y}^T(\mathbf{x}) \frac{\mathbf{T}_{ij}(\mathbf{x}) + \mathbf{T}_{ji}(\mathbf{x})}{\sum_{k=1}^{r}\mu_k(\mathbf{x})a_k(\mathbf{x})}\mathbf{y}(\mathbf{x}) \quad (19)\end{aligned}$$

Choosing $a_j(\mathbf{x}) > 0$, $j = 1, ..., c$ and regarding to the properties of the membership functions in (4),

$$\sum_{k=1}^{c}\lambda_k(\mathbf{x})a_k(\mathbf{x}) > 0. \quad (20)$$

Referring to the Lyapunov stability theory, the PFMB control system (8) is asymptotically stable if $\dot{V}(\mathbf{x}) < 0$. If $\mathbf{T}_{ii}(\mathbf{x}) < 0$ for $i = 1, ..., r$ and $\mathbf{T}_{ij}(\mathbf{x}) < 0$ for $i = 1, ..., r, i < j$ in (19), then $\dot{V}(\mathbf{x}) < 0$ and thus, resulting in asymptotically stability of PFMB control system (8).

The stability analysis result is proposed as the following theorem.

Theorem 1. *The PFMB control system* (8) *consisting of the PFM* (3) *and the PFC* (6) *is asymptotically stable if there exist pre-defined polynomials* $a_k(\mathbf{x}) > 0$ $k = 1, ..., r$, *and matrices* $\boldsymbol{X}(\tilde{\mathbf{x}})$ *and* $\boldsymbol{M}_j(\mathbf{x})$ *such that, the following SOS-based conditions are satisfied,*

$$\upsilon^T\Big(\mathbf{X}(\tilde{\mathbf{x}}) - \epsilon_1(\mathbf{x})\mathbf{I}\Big)\upsilon \text{ is SOS}, \quad (21)$$

$$-\upsilon^T\Big(\mathbf{T}_{ii}(\mathbf{x})) + \epsilon_{2ii}(\mathbf{x})\mathbf{I}\Big)\upsilon \text{ is SOS}, \qquad \text{for } i = 1, ..., r, \quad (22)$$

$$-\upsilon^T\Big(\mathbf{T}_{ij}(\mathbf{x}) + \mathbf{T}_{ji}(\mathbf{x}) + \epsilon_{2ij}(\mathbf{x})\mathbf{I}\Big)\upsilon \text{ is SOS}, \qquad \forall\, i < j, \quad (23)$$

where $\mathbf{T}_{ij}(\mathbf{x})$ *is defined in* (17), $\upsilon(t) \in \mathbb{R}^\rho$ *is an arbitrary vector independent of* $\mathbf{x}$ *and* $\epsilon_1(\mathbf{x}) > 0$, $\epsilon_{2ij}(\mathbf{x}) > 0$ *for* $\mathbf{x} \neq \mathbf{0}$ *are pre-defined polynomial scalars and the local feedback gains are defined in* (18).

Remark 1: To derive the numerical solution of state-dependent BMI conditions in Theorem 1, the searching algorithm, PSO technique, is exploited. The procedure for finding numerical solution is illustrated in Fig. 1 and summarized in the following stages:

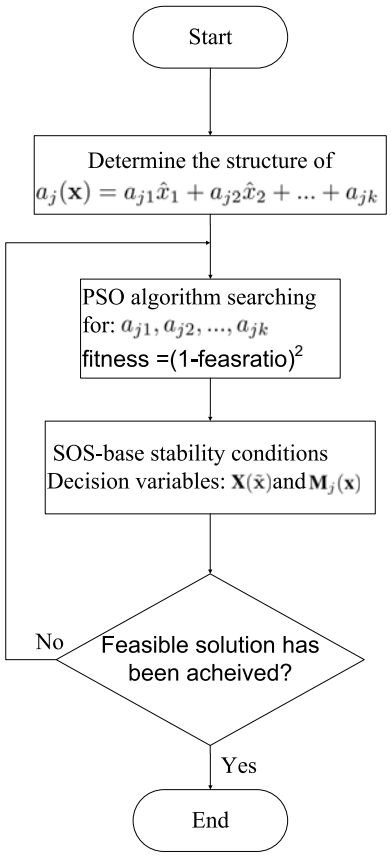

Fig. 1. Flowchart of the proposed PSO and SOS-based technique

Stage 1: The $a_j(\mathbf{x})$ $j = 1, ..., r$, are polynomials containing monomials with various degrees. As the first step, proper monomials which have contribution in relaxation of stability conditions are determined. The coefficients of these monomials

are considered as decision variables to be determined by the PSO in the next steps.

Stage 2: The PSO assigns initial values to the coefficients of $a_j(\mathbf{x})$ $j = 1, ..., r$. These values are kept fixed during stage 3.

Stage 3: Since the values of $a_j(\mathbf{x})$ are fixed then, the stability conditions in Theorem 1 convert to SOS-based stability conditions. Numerical solution for the derived SOS-based stability conditions are obtained by SOSTOOLS [25].

Stage 4: If the derived parameters for the SOSTOOLS show feasibility of solution for the SOS-based stability conditions then, the searching procedure will stop. Otherwise, if the stopping criterion, which is a predefined number of iteration has not been reached, return to *Step 2*. It should be noted that, in the PSO searching algorithm, finding of solution is formulated as a minimization problem for a fitness function. In this paper, fitness function for the PSO algorithm is chosen as $-(1-\text{feasratio})^2$. A more closer value of 'feasratio' to '1' leads to minimization of the fitness function and implies more accurate solution for the SOS-based stability conditions.

IV. Simulation Example

The effectiveness of the proposed stability analysis approach is illustrated by following simulation example.

Consider a three-rule PFM with the following system and input relations.

$$\mathbf{A}_1(\mathbf{x}) = \begin{pmatrix} 1.59 + x_1^2 - 2x_2^2 - x_1x_2 & -7.29 + 2x_1x_2 \\ 0.01 & -x_1^2 - x_2^2 \end{pmatrix},$$

$$\mathbf{A}_2(\mathbf{x}) = \begin{pmatrix} 0.02 + x_1^2 - 2x_2^2 - x_1x_2 & -4.64 + 2x_1x_2 \\ 0.35 & 0.21 - x_1^2 - x_2^2 \end{pmatrix},$$

$$\mathbf{A}_3(\mathbf{x}) = \begin{pmatrix} -\alpha + x_1^2 - 2x_2^2 - x_1x_2 & -4.33 + 2x_1x_2 \\ 0 & 0.05 - x_1^2 - x_2^2 \end{pmatrix},$$

$$\mathbf{B}_1(\mathbf{x}) = \begin{pmatrix} 1 + x1 + x1^2 \\ 0 \end{pmatrix},$$

$$\mathbf{B}_2(\mathbf{x}) = \begin{pmatrix} 8 + x1 + x1^2 \\ 0 \end{pmatrix},$$

$$\mathbf{B}_3(\mathbf{x}) = \begin{pmatrix} -\beta + 6 + x1 + x1^2; 0 \\ -1 \end{pmatrix},$$

where α and β are constant parameters. Based on the PDC design technique, a three-rule PFC in the form of (6) is employed to close the feedback loop. Then, the PFMB control system in the form of (8) is obtained.

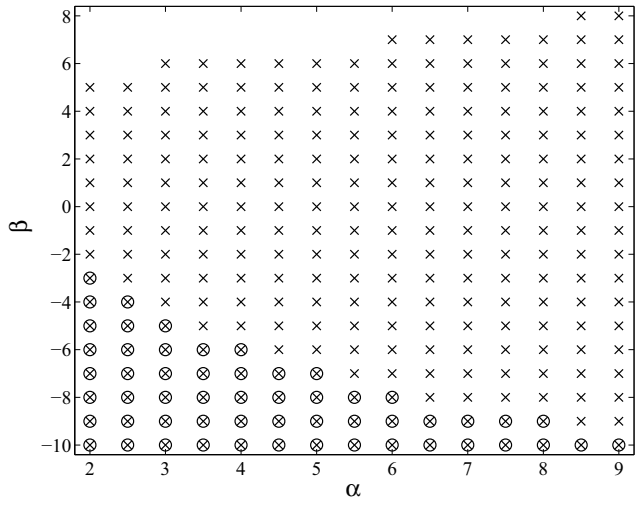

Fig. 2. Stability regions given by [19] (×), and Theorem 1 (○) for the Simulation Example.

To investigate the stability of the aforementioned PFMB control system, the stability conditions proposed in Theorem 1 are employed. However, as it mentioned in Remark 1, $a_j(\mathbf{x})$ are decision variables that means the derived stability conditions are in the form of state-dependent BMI. Then, implementing algorithm shown in Fig. 1, the solution for the derived stability conditions are achieved.

In this simulation example the following format is chosen for $a_j(\mathbf{x})$

$$a_j(\mathbf{x}) = a_j^1 x_1^2 + a_j^2, \tag{24}$$

where a_j^1 and a_j^2 are scalars to be chosen via PSO searching algorithms. The lower and upper bounds of a_j^1 and a_j^2, are chosen as 10^{-3} and 3 respectively.

For comparison purposes the stability conditions proposed in [19], is employed to investigate the system stability for $2 \leq a \leq 9$, $7.4 \leq b \leq 9$. The stability regions given by SOS-based stability conditions in [19] and Theorem 1 are demonstrated in Fig. 2. It can be seen that comparing to the stability conditions in [19], the proposed SOS-based stability conditions in Theorem 1 are able to offer a larger stability region.

For reference, according to Theorem 1 with considering the relaxation expressions, for $a = 5$ and $b = 6$, $\mathbf{X}(\tilde{\mathbf{x}})$ and the feedback gains are obtained as the above of this page.

V. Conclusion

Stability analysis of PFMB control systems has been proposed. Introducing a new form of PFC which is the generalized form of the conventional one, relaxed stability conditions have been achieved. Compared to the conventional PFC, the fuzzy controller under consideration has a favorable property which introduces some more variables in the stability conditions such that, the solution of the derived stability conditions can be explored in a larger group of potential solutions. The

$$\mathbf{X}(\tilde{\mathbf{x}}) = \begin{bmatrix} 10.807 & -1.5579 \\ -1.5579 & 1.4054 \end{bmatrix}$$

$$\mathbf{F}_1 = [-1.0414 - 0.5533x_1 + 0.0287x_1^2 + 0.1159x_1^3 - 0.1741x_1^4 - 0.0201x_1x_2 + 0.0450x_2 - 0.2055x_2^2 \\ 0.9848 - 1.6206x_1 + 0.0919x_1^2 + 0.1286x_1^3 - 0.1929x_1^4 - 0.0435x_1x_2 + 0.0393x_2 - 0.2276x_2^2],$$

$$\mathbf{F}_2 = [-2.7283 + 0.2983x_1 + 0.2779x_1^2 - 0.0339x_1^3 - 0.3559x_1^4 + 0.3844x_1x_2 - 0.0088x_2 - 0.3004x_2^2 \\ - 0.3482 - 0.0861x_1 + 0.2112x_1^2 - 0.0380x_1^3 - 0.3945x_1^4 + 0.0470x_1x_2 + 0.0137x_2 - 0.3329x_2^2],$$

$$\mathbf{F}_3 = [-0.7934 + 0.0610x_1 + 0.0461x_1^2 - 0.1019x_1^3 - 0.1316x_1^4 - 0.0088x_1x_2 - 0.0019x_2 - 0.1139x_2^2 \\ 0.5162 - 0.6742x_1 + 0.3559x_1^2 - 0.1129x_1^3 - 0.1459x_1^4 - 0.0731x_1x_2 + 0.0594x_2 - 0.1263x_2^2],$$

achieved stability conditions are in the form of state-dependent BMI conditions. The PSO algorithm has been employed to search for the numerical solution of the derived conditions. A simulation example has been presented to confirm the validity of the proposed approach.

Abstract— **The limited power consumption, as a major constraint, presents challenges in improving the network throughput for Wireless Sensor Networks (WSNs). Due to the limited computational power, the applications of WSNs in Terrestrial Networks require the capability to pre-process the observation data so as to remove irrelevant features or factors from multi-dimensional dataset. This paper proposes a intelligent distributed energy efficient routing algorithm inspired from natural learning and adaptation process with the aid of hybrid Neural Rough Sets theory, which is used to efficiently reduce the dimensionality of input dataset. The algorithmic implementation and experimental validation are described in this paper. Details of the algorithm and its testing procedures are presented in comparison with the other power-aware protocols, e.g., mini-hop. The validation of the proposed model is carried out via a wireless sensor network test-bed implemented in Castalia Simulator. The experimental results show the network performance measurements such as delay, throughput and packet loss that have been greatly improved as the outcome of applying this integration with Neural Rough Sets.**

I. INTRODUCTION

Wireless Sensor Networks (WSNs) have drawn considerable attention recently in both terrestrial and underwater network research community [1-2], [14-15]. Specifically, WSNs consist of a number of sensor devices (MOTEs), which are normally inexpensive, portable, having communication and limited computational power. It potentially enlists our daily life with such characteristics as required by pervasive computing, ubiquitous communication and monitoring, which enables to establish on-demand interactions with data devices, services and applications without spacial and time limitations. Portable wireless communication devices, microprocessors as well as communication protocols and wireless techniques including WiMAX all contribute to the construction of WSNs.

The MOTEs are interconnected to each other via the network grid. Routing schemes play an important role in maintaining efficient data communications across this network grid. Whereas, routing algorithms are required to consider the constraints of MOTEs such as limited energy supply, limited computational power. Huge amount of data are produced to be processed in this regard, it is desirable to have the reduced data dimensions in a pre-processing stage. In this paper, we explore the possibility of using a new Neural Rough Set process to fulfill this purpose.

Current and future computing environments will be of massive scale and complexity. They have heterogeneous products, services, devices and platforms of ever growing scale. Intensive research has recently gone into developing a robust distributed smart algorithms and protocols for decentralised cases.

At the meantime, there are a number of routing protocols that have been proposed so far, such as Low Energy Adaptive Clustering Hierarchy (LEACH), Data-centric SPIN and Direct diffusion. LEACH relies heavily on the regular routing structure, which cannot flexibly adapt to changeable network environment. While the Direct diffusion does not build up a regular routing structure and SPIN even does not maintain a structural hierarchy at all, even no state information. These protocols cannot satisfy the practical requirements with these disadvantages under various circumstances. In fact, there are two major aspects for a routing scheme to consider (1) energy efficiency and (2) self-healing. Based on this consideration, a *self-governed* bio-inspired routing scheme is proposed in this paper. This algorithm is designed to solve the *packet* routing problem with minimal energy consumption for each hop communication and aims to maximise the lifetime of nodes in the network. Meanwhile, the new self-healing algorithm well reduce the possibility of node failures and satisfy the need for various levels of dynamic packets routing when routing decisions can be made locally at each node.

The remainder of the paper is organized as follows: Section II reviews the background of Neural Rough Set theory and the new bio-inspired scheme initiated by the swarm behavior. Section III presents the new routing algorithm details including algorithmic steps, and its implementation details. Simulation results of the new algorithm are presented in Section IV. As a validation experiment, the performance analysis shows the efficiency of our proposed routing scheme that potentially to small sized networks in WSNs. Finally, we conclude the contributions of this paper and look into the future work.

II. PROPOSED NEURAL ROUGH SETS AND ANT COLONY BIOLOGICAL MODEL

A. Related Rough Set Preliminaries

The rough set theory is an extension of set theory for the study of intelligent system with indiscernible, ambiguous and imperfect data information. Rough-set theory appeared two decades ago. Its main thrust is used in attribute reduction, rule-generation and prediction. For instance, by applying a mathematical approach to solve the data reduction problem, it is good at finding out the discernity, vagueness and uncertainty in data analysis. The rough-set concept was introduced by Pawlak and his colleagues [16]. This theory became very popular among scientists around the world in the last decade, and it is now one of the most developed AI methods. The primary goal of this new emerging theory is to classify the information from incomplete information. Its successful application to a variety of problems has shown its usefulness and versatility[18].

As we know, the decision table in a rough set scheme plays an important role in clarifying a discretized feature values. Applying rough-neural bundled computation has proved to be more efficient in discovering emergence and hidden order of control area as an approach to knowledge discovery and data mining. The integration of such an approach with telecommunication complex scenario, the goal of having a more robust internet tolerating the nonstationary anomalies can be achieved. Below are some definitions and domain descriptions [18].

The information system is The information system is formed as a pair of IS=(U, A, V, f), where U is a *non-empty* finite set of objects (formed as an universe), and A is a set of finite attributes, V is the domain limitation of A, and $f:U\times A\rightarrow V$ is an information function. $\forall a\in A$, $x\in U$, $f(x,a)\in V$. Each non-empty subset $B\subseteq A$, Let $H\subseteq U\times U$ denote an indiscernibility relation on U that can be defined as:

$$H=\{(x,y)\in U\times U:b(x)=b(y),\forall b\in B\} \quad (1)$$

Objects x and y satisfying the relationship H are indiscernible by attributes from B.

Definition 1 *Given an information system S, let $B\subset A$, and $x(i), x(j)\in U$, a binary relation $[x]_B\triangleq\{(x(i), x(j))\in U\times U /\forall a\in B, f(x(i),a)=f(x(j),a)\}$ is an indiscernibility relationship.*

Let U/H denote the equivalent class of H.For any $x\in U$, we denote the set,$[x]_B\triangleq\{(x(i),x(j))\in U\times U|\forall a\in B,f(x(i),a)=f(x(j),a)\}$ is called the equivalent class in B. The empty set φ and the elements in U/H are called elementary sets. Any subsets $X\subset U$ from the given data can be approximated by the elementary sets. Let $X\in U$, We define two sets $S_{LB}(X)$ and $S_{HB}(X)$ as the *lower approximation* and *upper approximation* of the set of objects X as:

$$S_{LB}(X)=\{x\in U:[x]_B\subseteq X\} \quad (2)$$

$$S_{HB}(X)=\{x\in U:[x]_B\}\cap X\neq\varphi\} \quad (3)$$

where $[x]_B$ denotes the set of all objects indiscernible with x by attributes from B. In Pawlak's definition of indiscernibility relations, for $x,y\in U$, it is called that y is indiscernible to x with respect to $B\subseteq A$ if $f(x,a)=f(y,a)$, $\forall a\in B$. Where f(x,a) means a mapping of value x with respect to attribute a [18].

B. Neural Rough Sets and BP Training

The concept of lower and upper approximation has been applied in many applications of computational intelligence. Successive research shows that the general concepts of lower and upper bound offer a broader application field in various types of industrial fields. In particular, rough set theory has demonstrated the power of using these bounds in rule generation [18].

Although there are plenty of classifications of recurrent neural networks, Zhang, et al [19] make a good performance comparison among the main algorithm i.e. BP, Perceptron-Back propagation Hybrid (PBH), Fuzzy ARTmap and Radial-Basis Function Network (RBF), their results reveal that BP and PBH nets outperform Perceptron, Fuzzy ARTmap and RBF by the criteria of classification errors. Hence we will apply BP nets in our design. The input datasets with all features are filtered by rough-sets logic and subsequently the models based on the minimum feature sets are built with the integration of rough neurons into Neural Rough networks. In this part, our network architecture is Ninput : Nhidden:1 three layer feed-forward rough neural network for processing. During this process, the error in the output neuron is propagated back from one layer to the previous layer by altering the weights of the connections, i.e. Back-Propagation (BP) algorithm. A rule of thumb, known as the Baum-Haussler rule [17], is used to determine the number of hidden neurons to be used:

$$N_{\text{hidden}}=\frac{Ntrain*Etolerance}{Npts+Noutput} \quad (4)$$

where N_{train} is the number of hidden neurons, E_{tolerance} is the error tolerance, N_{pts} is the number of data points per training example, N_{output} is the number of output neurons, in our architecture, $N_{output}=1$. In our case, for example, Let $E_{tolerance}=0.001$; $N_{train}=4000\times N_{pts}$; then the above equation becomes:

$$N_{\text{hidden}}\leq\frac{4Npts}{Npts+1} \quad (5)$$

Hence, the number of neurons in the hidden layer should be no more than 4. Now, we are ready to start the rough neural multilayer sets process to reduce the dimensionality of inputs datasets [18].

C. Proposed Bio-inspired Algorithm

We apply the metaphor of ant food foraging behavior into network routing system. As stated in the literature, ant colony optimization metaheuristic (ACO) was first systematically

introduced by Dorigo in 1992 in his PhD dissertation [6]. ACO is a probabilistic technique for solving computational problems which can be reduced to finding good paths through graphs. They are inspired by the behavior of ants in finding paths from the colony to food. The early attempts of biological researches on ants were conducted by Dorigo and Gambardella [7] for routing in wired and wireless mobile environments.

In addition, Stutzle and Hoos proposed MAX-MIN ant system, namely MMAS, it is an improvement version of ACO. MMAS differs from standard ACO in that (i) only the best ant adds pheromone trails, and (ii) the minimum and maximum values of the pheromone are explicitly limited [8]. Agassounon 9], [10] proposed interesting work based on ACO to solve information retrieval and resource allocation issues. A good review of available ACO basis, models and new trends can be found in Oscar's work [11].

ACO algorithms can be applied to find the near-optimal multihop routing path in mobile ad hoc networks, namely AntHocNet, the experimental results indicate AntHocNet algorithm outperforms the other popular Ad hoc On-Demand Distance Vector Routing (AODV) algorithm in terms of *end-to-end delay* and *delivery* ratio. Related problems such as load-balance and routing in computer networks are also investigated in the work by Hsiao et. al, by use of ACO [12]. In sum, performance comparisons between ACO-based algorithm and other routing algorithm show better performance by use of ACO metaheuristics.

The most important feature of ACO metaheuristic is inspired from the *stigmergy,* which mimics the indirect communication behaviors adopted by social insects. The proposed algorithm, termed iACO, especially for WSNs, each packet are regarded as an individual ant, communicating with each other via "pheromone" values stored in each wireless sensor node's pheromone table.

Three main steps are included in the flowchat of the proposed algorithms for the routing scheme of WSNs. In brief, the steps include (1) Generate local solutions based on the path (i,j) selection probability; (2) Pheromone update; (3) Decision making.Maintaining the Integrity of the Specifications

Figure 2 depicts the overall integration process where Rough set process and the proposed algorithm are attached together to solve the routing path in network environment.

III. ROUTING ALGORITHM IN WSNS

Suppose the ant is randomly placed on node i, the probability of an ant k choosing the next adjacent node j is as depicted in Equation 6. And the pheromone table helps to choose the next neighbor in the process.

$$P_{ij} = \begin{cases} \dfrac{[\tau(i,j)]^{\alpha} \cdot [\eta(j)]^{\beta}}{\sum_{u \notin M_k} [\tau(i,j)]^{\alpha} \cdot [\eta(j)]^{\beta}} & if\ j \notin M_k \\ 0 & \text{otherwise} \end{cases} \qquad (6)$$

where P_{ij} = probability of packet going from node i to j,
τ (i,j) = pheromone level in the table of node i for node j,
η (j) = energy level of node j,
M_k = identifier of every visited node,
α = parameter that denotes pheromone level,
β = parameter that denotes energy level heuristics.

Two categories of ants are in use, they are termed as forward ants and backward ants. We adopted this concept from the relating work of ant algorithm routing such as T-ant, antNet [2] and EEABR [3]. We further develop the definitions as used in the literature. The forward ants are defined as the ants that are sent from the source. The forward ants will carry the information such as (1) the required sensor type, (2) the sensor region of interest, (3) the data rate and (4) the time period of the interest. More details can be seen in table I where both categories of ants are described in functions.

Parameters and variables formatted in the packet of the experiment are described here in Table I. The header and data are carried by each packet. The packet is sent from source node, taking the form as backward and forward ants

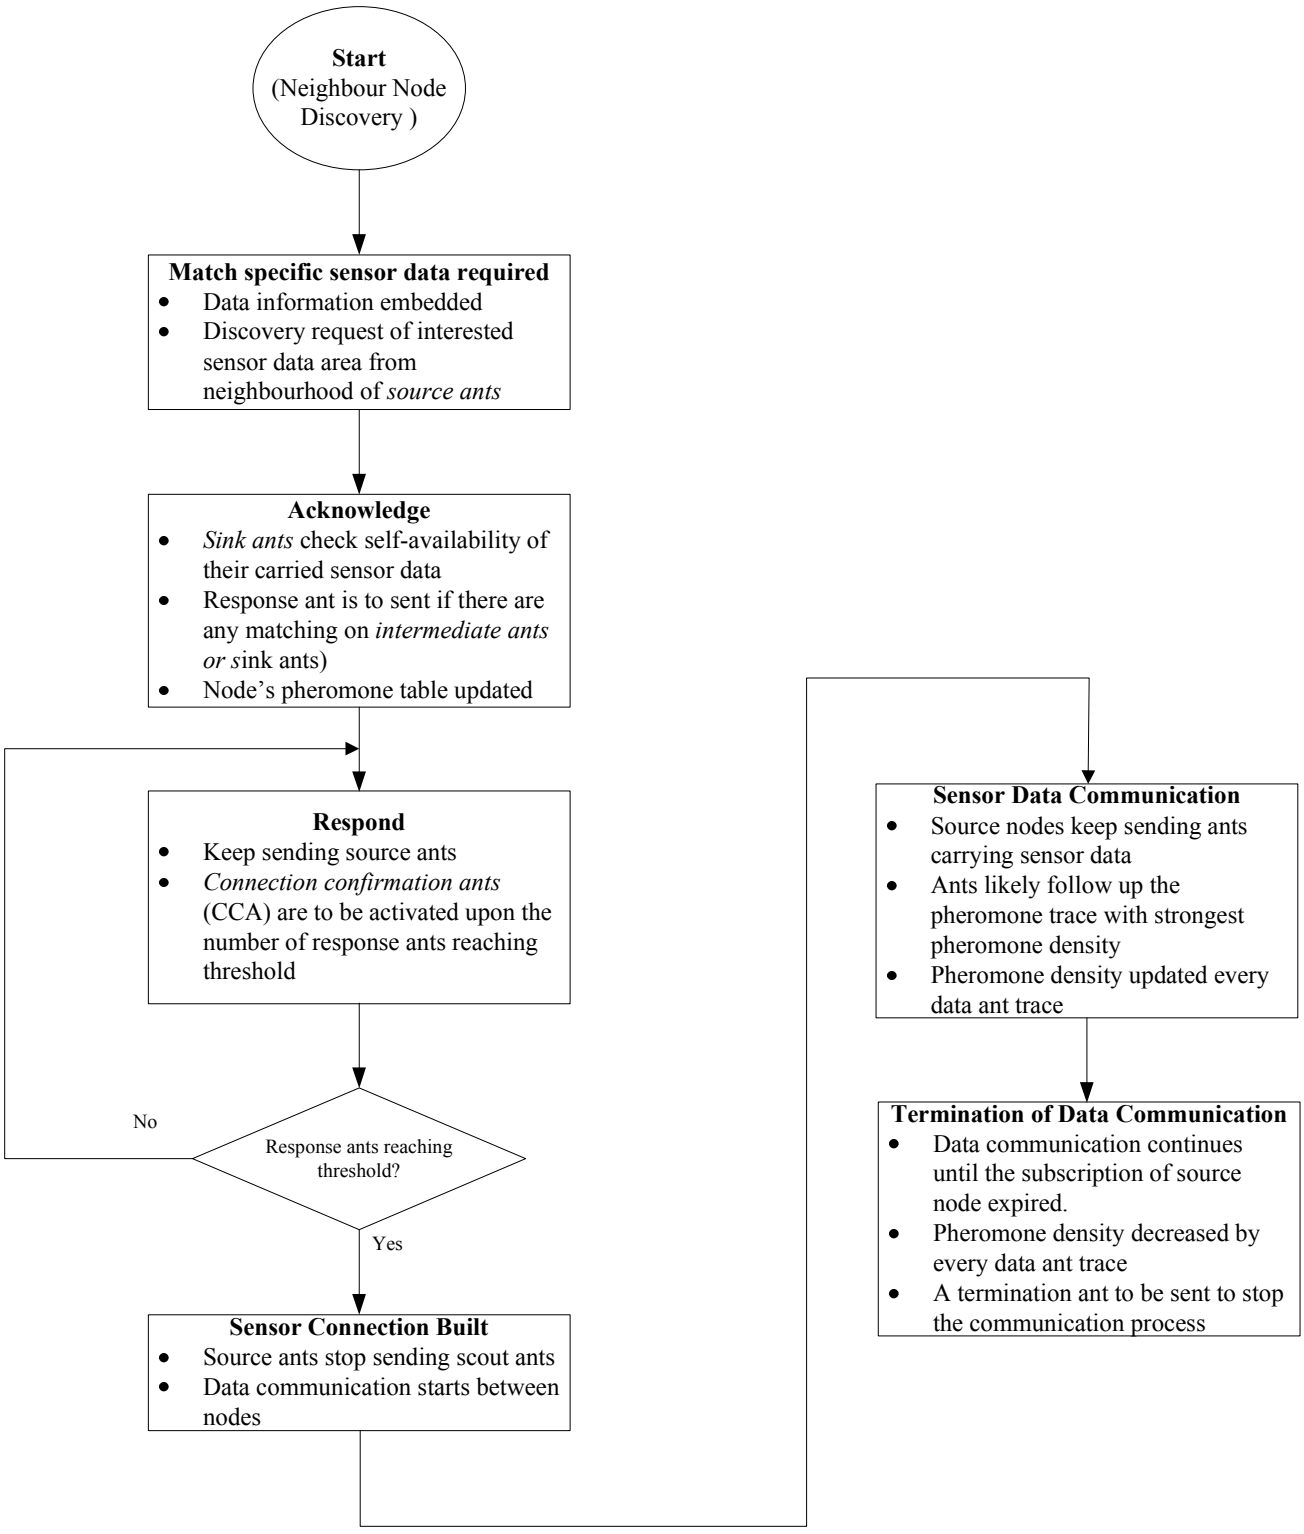

Figure 1. Flowchart of the proposed algorithms for the routing scheme of WSNs

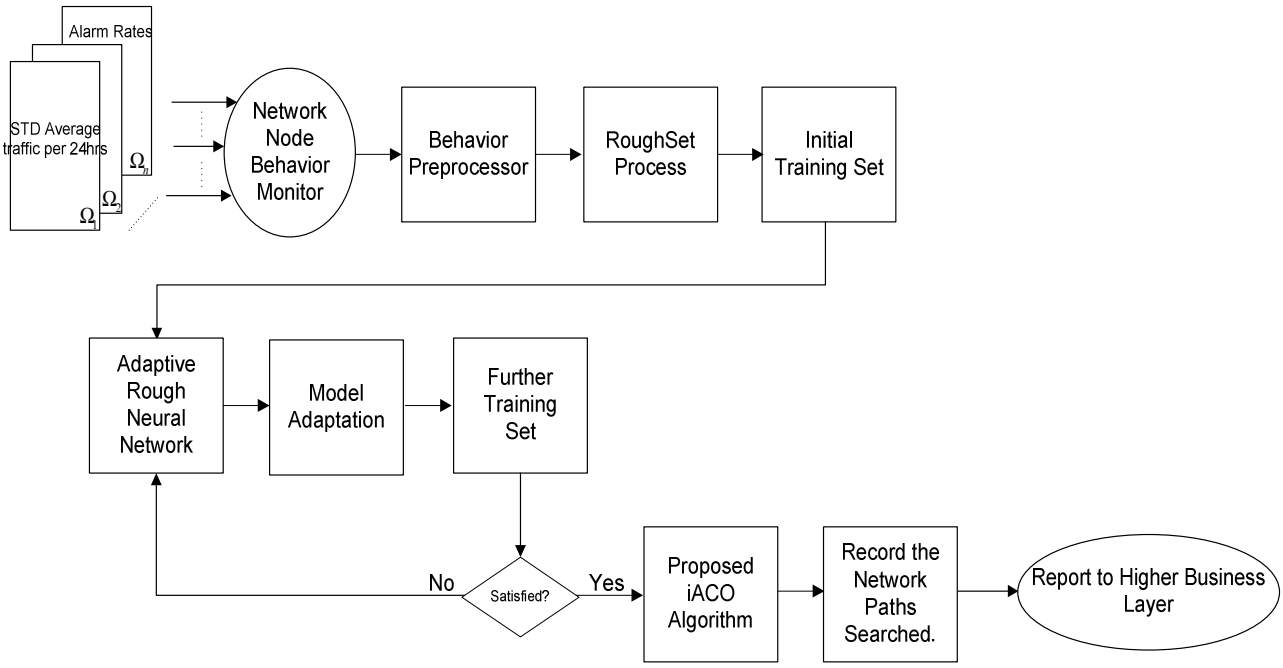

Figure 2. Illustration Schematic of The Overall Process

Pheromone Update:

Pheromone plays an important role in searching for a suitable node. In our algorithm, only the pheromone along our successfully recorded paths (usually more than one) is intensified, instead, pheromone in those incomplete paths evaporates. The pheromone increases and reductions will influence the searching process in next iteration. We adopt the conventional ACO pheromone update rule as [20]:

- Intensify pheromone: an absolute amount of pheromone $\Delta\tau_{i,j}^{k} > 0$ is added to the existing pheromone values on the paths completed by k -th ant

$$\Delta\tau_{i,j}^{k} = \begin{cases} \frac{Q}{Z_{\min(k)}} if \ (i, \ j) \in T_k \\ 0 \qquad if \notin T_k \end{cases} \qquad (7)$$

where T_k are the paths having been traversed by k -th ant. Q is a constant. More research on Q value have been done in Dorigo [6].

- Evaporate pheromone: pheromone on the edges of incomplete traversing paths is reduced in order to minimize the chances of being selected by other ants.

$$\tau_{i,j} = (1-\rho)\times\tau_{i,j} \qquad \forall i, \ j \in [1:52] \quad (8)$$

where $\rho \in [0, \ 1)$ is the pheromone evaporation rate. $\tau_{i,j}$ is the current pheromone density on the trail $a(i, \ j)$.

Mutate pheromone update process: In order to increase the convergence speed of the algorithm, we combine the *mutation* parameter into our pheromone update rules, where the concept of *threshold* is also involved. The mutation parameter in our algorithm are partly based on *Best-worst Ant Colony Algorithm* (BWACA) as well as *Max-min* Ant system.

IV. EXPERIMENT

A. Simulation Platform and Configuration Parameters

The simulation is conducted on the platform called Castalia network simulator [5]. Being a specially designed network simulator, Castalia contains models for realistic wireless channels, MAC layers, radio, physical sensor and resource management. Moreover, it contains modules that can simulate the different functionality and behaviours of wireless sensors and hence is regarded as a good simulation of the real behaviour in the research society for WSNs [4].

The dataset preprocessed by Neural Rough Set process is further processed in this simulation section.

The most commonly used algorithm for routing label witched Paths (LSPs) is the min-hop algorithm [13] The nature of this algorithm has been adopted by many routing protocols. Therefore, it is reasonable to compare our proposed algorithm with min-hop algorithm.

To evaluate two algorithms, we define the following parameter metrics in use in the simulation.

1) *Energy consumption*
2) *Delay*
3) *Throughput*

With regards to these metrics, Figure 3 and 4 depict the comparison view of *energy consumption* and *delay* exhibited by various node density levels. As shown, the small number of nodes would not make a significant impact on the energy consumption and delays.

When the interactive nodes increasing till 145, an energy peak occurs, and new routing algorithm proposed consumes less 1/3 energy than min-hop algorithm though the similar curve trend is observed. For the larger network, this difference tends to be more significant.

As shown in Figure 4, the impacts of delays for algorithms are trivial, though the proposed routing produces a slightly less delays than the min-hop. *Max-min* Ant system.

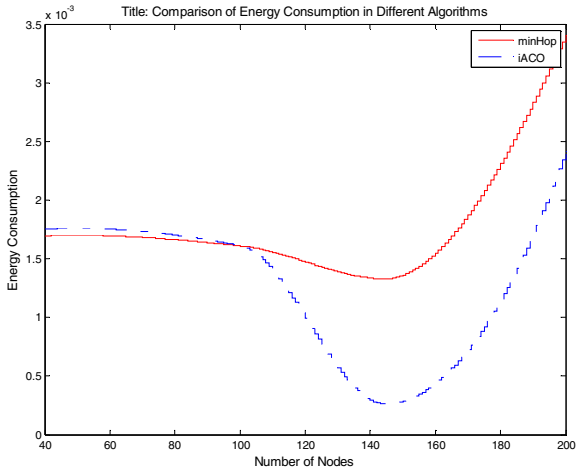

Figure 3 Comparison of Energy Consumption of Ant Population Levels

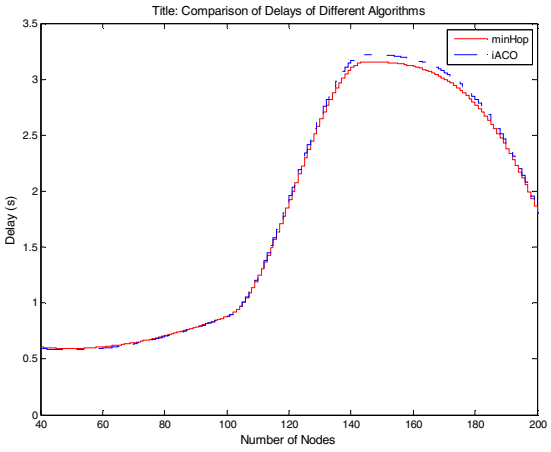

Figure 4 Comparison of Delays Between Two Algorithms

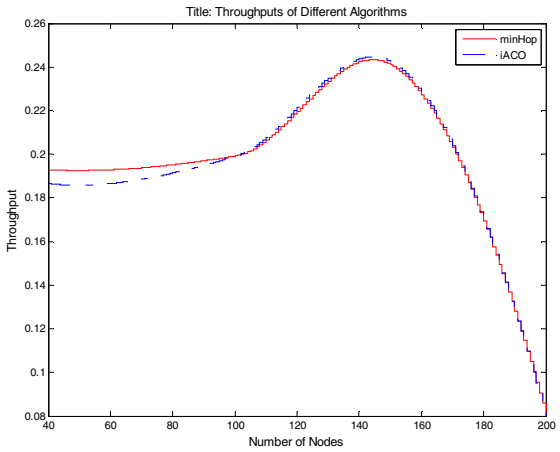

Figure 5 Comparison of Throughputs Between Two Algorithms

With regards to the throughput, as shown in Figure 5, when the number of nodes increase till 145, there are not much differences between min-hop algorithm and enhance ant-based protocol. The experience data and literature prove it is difficult for the traditional ACO achieve the marginal performance as min-hop routing scheme. The proposed protocol demonstrates the similar performance in this regard, so it can be regarded as a good improvement.

Figure 6, 7 and 8 shows the impacts of various node densities towards energy consumption, delays and throughput. It is shown there is an obvious effect on the efficiency of various node densities, but it seems not a linear relationship. There is a few optimal node densities at which the lowest energy consumption is observed. Similarly, it comes to the delay in Figure 7 and throughput in Figure 8. Specifically, the density is 0.005 when the minimum delay occurs, but the maximum delay occurs when the density is 0.1. This is also the case for throughput.

In particular, the minimum energy consumption, maximum

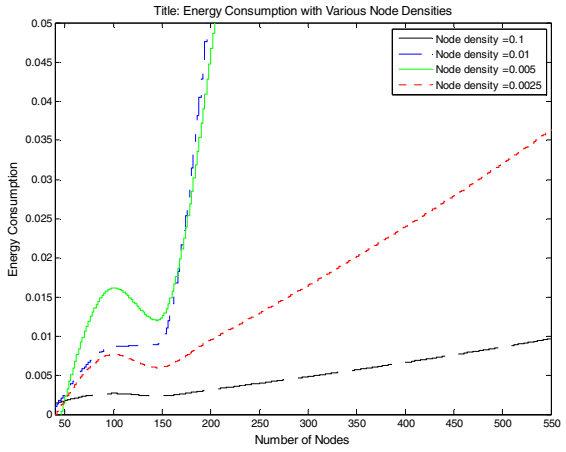

Figure 6 Energy Consumption with Various Node Densities

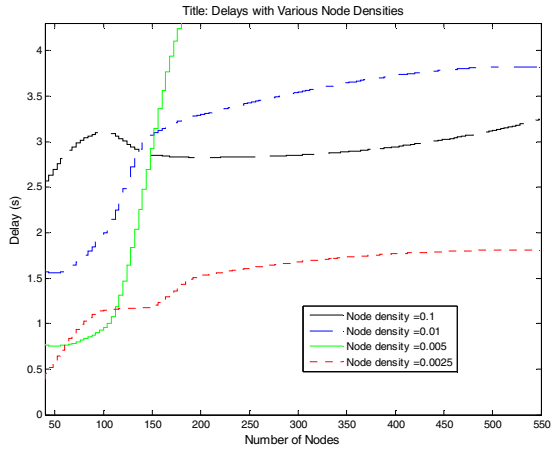

Figure 7 Delays with Various Node Densities

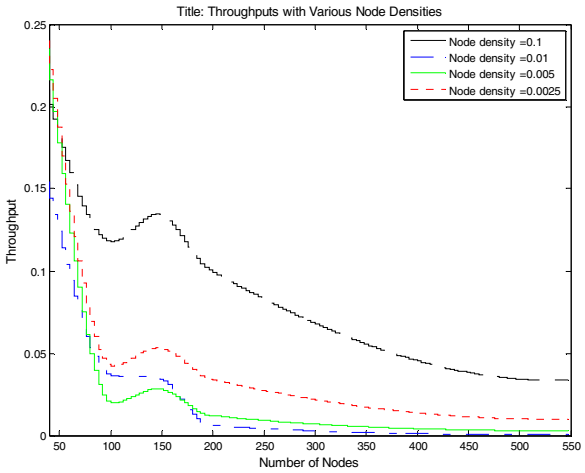

Figure 8 Throughputs with Various Node Densities

when the network has 50 nodes. The current good results are well compliance with the expected network size less than 100.

V. CONCLUSION AND FUTURE WORK

In this paper, a distributed, reliable nature-inspired routing algorithm for terrestrial sensor networks is presented. This routing process occurs after the dataset feature reduction via neural rough set theory. The swarm algorithm is partly based on the efficient *Max-Min* algorithm and it is suitable for flexible structure of wireless sensor networks. This new distributed scheme performs generally not worse than other standard routing algorithm, and in some occasions, it outperforms than conventional *min-hop* algorithm. More work in the future includes conducting further performance comparison work with other sensor network routing algorithms, as well as identifying and validating the best parameters configurations for the proposed algorithm under various network environment to guide real productive practices in the networking industry.

***Abstract*—Accurate identification of P2P traffic is critical for efficient network management and reasonable utilization of network resources, as P2P applications have been growing dramatically. Fuzzy clustering is more flexible than hard clustering and is practical for P2P traffic identification because of the natural treatment of data using fuzzy clustering. Fuzzy c-means clustering (FCM) is an iteratively optimal algorithm normally based on the least square method to partition data sets, which has high computational overhead. This paper proposes modifications to the objective function and the distance function that greatly reduces the computational complexity of FCM while keeping the clustering accurate. The proposed FCM clustering technology can be incorporated into a Fuzzy Inference System (FIS) to implement real-time network traffic classification by updating the training data set continuously and efficiently.**

Keywords-network traffic identification; peer-to-peer communications; machine learning; fuzzy c-means clustering; statistical analysis; data transformation

I. INTRODUCTION

Network traffic that could be administered through traffic measurement, traffic control, and traffic simulation consists of flows from a great variety of users using different applications on diverse utilities. Network traffic management plays a key role in optimizing network performance, improving latency, and scheduling network resources for adjusting bandwidth based on traffic engineering. Network traffic measurement measures the amount of different types of traffic on a specific device, an individual port, or a particular application; network control prioritizes and optimizes traffic. Both network measurement and control are key processes for network traffic management [1].

Internet protocol-based network traffic classification (also know as IP traffic identification or characterization) has become one of the major challenges in network management. The main roles of network management are to provide information for capacity planning and provisioning, traffic engineering, fault diagnosis, application performance optimization, anomaly detection and pricing to Internet Service Providers (ISPs) and their equipment vendors. Based on network traffic measurement, appropriate features selection, and classification methods, traffic classification relies on an in-depth understanding of the contents of Internet traffic dynamically [2].

Peer-to-peer (P2P) networking is a distributed application architecture that mainly relies on the computing power and bandwidth of the participants in the network and uses application software to search for shared files of users connected to the network. Every participant in the network plays both roles of provider (server) and consumer (client) without requiring to be coordinated by a central server or file hosting services. Compared to Web browsing, e-mail or many other non-P2P applications, where data is only transferred in short intervals and with relative small quantities, P2P file-sharing could utilize significant network resources, resulting in network jams and affecting the quality of service (QoS). Classifying P2P traffic could support ISPs to increase overall availability and reliability of connection by offering less bandwidth to specific users or definite P2P applications while maintaining QoS to other users or applications. P2P traffic classification is a key element for network traffic management, network resource scheduling, and performance enhancement.

P2P traffic classification is getting more sophisticated as P2P communications are continuously changing from TCP layers using well known ports to disguising themselves by using port numbers for commonly used protocols such as HTTP and FTP and implementing dynamic port numbers. The accurate identification is proved to be more complicated with the enormous emerging P2P applications. Traditional P2P traffic classification mechanisms depend on mapping applications to well-known port numbers and have been very successful in the past. However, they are becoming obsolete as new P2P applications began using dynamic port numbers. Payload based analyses which inspect application packet payloads to determine if they contain characteristic signatures of known applications overcome the shortcomings of port-based classification. However, their performance is greatly reduced and inefficient with P2P applications using plain-text ciphers, variable-length padding, and encryption. The payload-independent statistical identification based on network layer and data link layer utilizes machine learning techniques such as neural networks, unsupervised machine learning, support vector machine, and hybrid mechanism with much flexibility, self-learning and self-adaptive and is gained much attention in academic and industrial areas [3].

Clustering is one of the machine learning techniques that has been used for network traffic classification. Fuzzy

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

clustering is more flexible than hard clustering and is practical for P2P traffic identification because of the natural treatment of data [2]. Traditional FCM (Fuzzy c-means) clustering technique has the advantage of quantifying a level of membership of elements to detected clusters. GK-FCM (Gustafson-Kessel FCM) can generate clusters that adapt themselves to the shape and location of data [4]. However, the computational complexity of FCM or GK-FCM is high. Our proposed modification for the objective function and distance can decrease computational complexity greatly while keeping the classification accurate, which is crucial for high volume real-time P2P traffic applications.

The remainder of the paper is structured as follows: Section II discusses various network traffic analysis categories. Different machine learning techniques with supervised, un-supervised, and hybrid learning are described in Section III. Section IV illustrates FCM and the proposed method for P2P traffic identification. Some simulations and comparison of simulating results are provided in Section V. We conclude the research and outline future work in Section VI.

II. NETWORK TRAFFIC ANALYSIS

Network traffic analysis is the process of observing and identifying network traffic. The ultimate goal of traffic analysis is to classify the traffic into definite groups, which is defined by network administrators. The classification could be based on users recognized by sources or destinations, or applications identified by a protocol. Traffic classification typically starts with network measurements and extracts traffic attributes later, and finally groups the traffic based on the selected strategies. The following sub-sections briefly describe various techniques that have been used for traffic analysis.

A. Traffic Measurement

Network traffic measurement measures traffic flows of observing devices such as routers, switches and dedicated probes to capture traffic attributes such as port numbers, payload and statistical characteristics. Traffic measurements are conducted on a continuous basis and the results are used for network management and temporary routing, maintenance, or long-term network deployment depending on the sampling period. They can be categorized into active and passive measurements. External traffic is injected to the network during the measurement in active measurements, whereas no enhanced injection is adopted for passive measurements. Active measurements are mainly used to detect the vulnerability of a specific network or a device, and examine the performance of a network to a particular application. Active measurements are not suitable to check the influence by users because user-independent packets are injected to network continuously. Passive measurements based on users connected to a specific network observe network connections, packets and flows to find source and destination addresses, port numbers and transport protocols. Passive measurements are the fundamentals for traffic identification and optimization [2, 5, 6]. This paper focuses on passive network flow-level-based measurements.

B. Port Number Analysis

Port-based analysis rests on the fact that many traditional P2P applications have default ports (assigned by the Internet Assigned Numbers Authority (IANA) and can be classified by looking up the TCP SYN packets for TCP traffic). This is the most straightforward and most successful method in the early time for identifying P2P network traffic. This method is easy and fast because it only accesses the header of the packets to get the data required for classification. The port-based classification system does not apply sophisticated strategy and can be easily extended by adding new application-port match pairs to its database. For example, HTTP traffic uses port 80, FTP uses 20, 21, DNS uses 53, and E-mail uses 25, 110, and etc.

However, for P2P applications, the accuracy of port-based classification is decreased abruptly as modern networks exceedingly carry more and more traffic that use dynamically allocated port numbers. Some applications may not have their ports registered with IANA or use ports other than well-known ports to prevent them from being detected. IP layer encryption may confuse the traffic headers also, making it impractical to identify network traffic through port-based approaches [7].

C. Payload-based Analysis

To avoid total reliance on the port numbers, a more reliable approach, payload-based analysis, a.k.a. DPI (Deep Packet Inspection), is to inspect the packet payload for characteristic signature of known applications. Payload-based identification based on some knowledge about the payload formats of specific applications checks particular features present in the application traffic to see whether it contains some characteristic signatures or not.

Payload-based classification works well for Internet traffic, including P2P traffic, when the payload is not encrypted. But payload-based classification is gradually becoming ineffective or impossible as new P2P applications use encryption, variable-length padding and other more advanced routing techniques to avoid being detected. The lack of openly reliable protocol specifications, especially for enormous emerging applications, the demand for high computing and storage capacities, the application signatures changing with the corresponding applications, and their protocol evolution are key challenges for developing application signatures [8, 9].

D. Statistical Analysis

To overcome the drawbacks of heavily relying on fixed port numbers or deep inspection of packet contents of network traffic, the approaches that take advantage of the statistical properties at the network layer and data link layer are attracting much attention to academic researchers, industrial developers and network administrators. The statistical analysis relies on the fact that traffic at the network layer has statistical properties (such as the distribution of flow duration, flow idle time, packet inter-arrival time and packet lengths, and etc.) and that similar applications typically have similar behavior patterns. For example, FTP normally used for large file transferring have a longer connection duration and larger average packet size, while some P2P applications such as BitTorrent typically are persistent and send data bi-directionally.

Exploiting distinct characteristics of traffic flow for specific applications, network traffic classifier can identify network traffic using only flow statistics. P2P nodes are possibly located within a domain of common data link layer switch; however, detecting the traffic is a minor concern because it does not consume network resources outside the local switch.

Based on the statistical parameters, machine learning which automatically builds a classifier by learning the inherent structure of network traffic dataset can automatically identify traffic flows. The classifier has the ability of continually gaining new knowledge based on the data newly acquired and modifies the model structure to adapt to the whole data and get the overall performance optimized [10, 11].

E. Feature selection and reduction

Feature selection techniques normally based on the actual performance of the learning algorithms are critical to build a machine learning classifier by which the network traffic can be identified using the smallest necessary set of features to reduce the demand for storage capacity and computational complexity. It can be broadly classified into filter method based on general characteristics of traffic data and wrapper method based on the comparison of different subsets and selection of the best one using machine learning techniques. Transformations of features such as Log or Gaussian are sometimes very effective to get higher levels of classification accuracy.

Appropriate feature reduction algorithms can reduce the number of features needed to identify traffic flows drastically, which in turn can greatly reduce the computational complexity without affecting classification accuracy apparently. Feature reduction can be achieved by using machine learning techniques to get the best combination of attributes that provide the most contrasting application classes. Although the total number of packets in the flow, the average packets size of a flow, and the duration of the flow are all valid features, there is still a need to transform some features to increase classification accuracy and reduce feature sets as much as possible using correlation-based or consistency-based approaches to decrease the computation overhead [12].

III. MACHINE LEARNING TECHNIQUES

Machine learning techniques can map instances of network traffic flows into different traffic classes based on selected features. Features are descriptive statistic variables that can be calculated from one or more packets. For example, mean packet length is a scientific discipline that focuses on the design and development of solutions. The discipline allows computers to evolve characteristics based on empirical data. As a subset of the wider Artificial Intelligence, it is closely related to probability theory, statistics, and fuzzy systems and neural networks.

The application of machine learning approaches usually starts by defining features based on calculation of multiple packets to identify and distinguish future unknown IP traffic. The next step is to train the established classifier to match traffic classes and feature sets. Finally, the last step is to classify unknown traffic using previously learned rules. Machine learning techniques can be categorized into three subsets: *supervised learning* which generates a function that maps inputs to desired outputs, *unsupervised learning*, such as clustering which seeks the structure of data and organizes them orderly, and *hybrid* also called semi-supervised which combines supervised and unsupervised machine learning algorithms. The following sub-sections describe the three subsets briefly.

A. Supervised machine learning

In network traffic classification, supervised machine learning generates knowledge structures to classify new traffic flow into pre-defined classes based on the training of the classifier for the matches of known traffic to definite classes. The classifier is provided with a collection of traffic datasets and their pre-identified classes. The result of classifying the known traffic into specific classes becomes more accurate with the progress of training and the ultimate goal for the classifier is to classify the unknown traffic into the suitable classes as accurately as possible. Two major steps in supervised machine learning are matching training datasets with classes and classifying unknown new captured datasets into classes. Artificial neural network and Naïve Bayes classifier are two important algorithms used in traffic classification.

Based on independent presence and absence of distinct features, the Naïve Bayes classifier greatly simplifies the training procedure [12], although independence is generally a poor practice. The Naïve Bayes method calculates the Gaussian distribution of the features for each class based on labeled training dataset. The maximum likelihood algorithm classifies data into definite classes based on conditional probabilities.

Neural networks have attracted more attention compared to other approaches in many application areas, including network traffic classification. Neural networks with a built-in ability to modify their synaptic connections and weights to adapt in surrounding environment have the potential to address many of the problems encountered by rule-based algorithms. Their attributes of non-linearity and adaptiveness are especially desirable for P2P traffic identification. However, neural networks, like other supervised machine learning approaches, normally require a large diversity of training for real world operations since they need sufficient representative examples in order to capture the underling structure in which generalization of cases is occurred. The complexity of calculation may also limit its applications in some categories, especially in data pre-processing while clustering techniques have advantages on those [13].

B. Unsupervised machine learning (clustering)

Compared to supervised machine learning techniques in which training datasets match pre-defined classes before testing, unsupervised machine learning algorithms explore natural classes using internalized heuristics to group data. Clustering methods classify data based on the similarity which can be measured by distance functions such as Euclidean, Tchebychev, or City Block. A good set of clusters should have intra-similarity and inter-dissimilarity. As an algorithmic framework for data analysis and interpretation, clustering has been widely used in understanding data, revealing fundamental phenomenon, and visualizing major tendencies. Clustering can be categorized into two types: *hierarchical clustering* uses previously established clusters to find successive clusters; and

partitioning clustering determines all clusters at once based on iterative procedures. Subspace clusters, correlation clustering and bi clustering are new emerging algorithms and have been adapted to practical applications. Density-based algorithms, such as DBSCAN (Density Based Spatial Clustering of Applications with Noise), probabilistic model-based techniques, for instance, AutoClass and K-means clustering have become popular.

DBSCAN is based on density-reachability. Density-connectivity is an example of density-based algorithms which find clusters starting from the estimated density distribution of corresponding nodes. In this approach, all points in a specific cluster are mutually density-connected. It requires two parameters: epsilon (the distance around an object that defines its eps-neighborhood) and minPts (minimum number of points to classify data into distinct classes) [14].

Expectation Maximization (EM) approach focuses on finding maximum likelihood. EM is used to group data into a small number of classes and then generates classification rules from distinct classes. The probabilistic model-based AutoClass allows automatic selection of the number of classes and soft clustering of the data, which allows data to be fractionally assigned to more than one cluster. It is effective for first step of classification or individual applications identification in network traffic engineering [3].

K-means clustering approaches partition data into classes based on distances and try to maximize the homogeneity intra-cluster by minimizing the error overall and heterogeneity inter-cluster by maximizing the error. The distance and objective functions are fundamental elements for clustering. The iteration changes the clusters' centers and alters the belongingness of data to distinct clusters until specifications are met. It can classify different types of TCP-based applications using the first few packets of the traffic flow [11].

C. Hybrid approaches

Semi-supervised machine learning approaches (also called Hybrid approaches) combine unsupervised and supervised learning techniques. Hybrid approaches use both a small quantity of labeled and a large amount of unlabelled data. This approach partitions training dataset into classes first using clustering algorithms, then maps unlabelled traffic data into identified classes with the existence of empty classes for further use. The approach is flexible, especially for new emerging unknown network traffic classification [15].

IV. FUZZY C-MEANS CLUSTERING AND PROPOSED MODIFICATIONS

Conventional hard clustering methods classify each data point into one cluster. Nevertheless, the observation of P2P traffic characteristics could be imprecise because of the ever-changing nature of IP network traffic. Fuzzy clustering, however, can classify a piece of data point, such as network traffic data information, into two or more clusters with different belongingness. Based on the fuzzy logic, which has a great resemblance with human decision making ability, FCM generates precise solutions and results from either a certain or an approximate set of input information. It can achieve optimal through iterations with the simultaneous change of cluster centers and the membership values which are definitions of one data belonging to one class. Fuzzy clustering is more flexible than hard clustering and is practical for P2P traffic identification because of the natural treatment of data [2].

This section first describes FCM and GK FCM clustering methods. Both FCM and GK FCM methods can effectively generate clusters, but with high overhead. The modifications to FCM are then proposed to simplify the calculation and complexity, which is vital for real-time P2P applications that could consist of a large number of real-time traffic flows.

A. Fuzzy c-means clustering

Fuzzy c-means clustering has three requirements [16]:

1. Membership degree (pattern *k* belongs to cluster *i*):

$$0 \le \mu_{ik} \le 1, i = 1,..., C(clusters), k = 1,..., N(patterns)$$

2. Total Membership (the sum of all membership degrees is constrained to 1):

$$\sum_{i=1}^{C} \mu_{ik} = 1, k = 1,..., N \quad (1)$$

3. No empty clusters are allowed and no cluster may contain all the data examples.

$$0 < \sum_{k=1}^{N} \mu_{ik} < N, i = 1,..., C \quad (2)$$

The procedure of clustering is an iterative process of minimizing the objective function,

$$J(X;U,V) = \sum_{i=1}^{C}\sum_{k=1}^{N} (\mu_{ik})^m d^2(x_k, v_i) \quad (3)$$

Where m: [1, ∞] is a weighting exponent that determines the fuzziness of the clusters (fuzziness parameter). If m=1 the sets are crisp not fuzzy. $d^2(x_k,v_i)$is the distance measurement.

The data are typically in geometric forms, such as lines or points. When points are used, the general form of the distance measurement between a point x_k and a cluster center v_i is given by:

$$d_{ik}^2 = (x_k - v_i)^T A_i (x_k - v_i) \quad (4)$$

When A_i=I, the measurement is based on the Euclidean distance and the clusters are with the spherical shape (traditional FCM or FCM).

When $A_i=F_i^{-1}$, the measurement is based on the Mahalanobis distance and the clusters are with the ellipsoidal shape where F_i is the Fuzzy Covariance Matrix of cluster *i*. The method is called GK FCM [4].

The objective of the FCM clustering is to find spherical clusters of approximately the same size. Its input is a data matrix X = (N, M) and the number of clusters C; its outputs are cluster centers V and fuzzy partition matrix U. Cluster centers V are initialized randomly.

The iterative procedure of the FCM algorithm is as follows,

1) *Compute distances from x_k to each clsuter center v_i:*

$$d_{ik}^2 = (x_k - v_i)^T (x_k - v_i) \quad (5)$$

2) *Compute partition matrix U (membership values):*

$$\mu = \frac{1}{\sum_{i=1}^{C} (d_{ik}^2 / d_{jk}^2)^{1/(m-1)}} \quad (6)$$

3) *Compute new cluster centers V based on U:*

$$v_i = \frac{\sum_{k=1}^{N} (\mu_{ik})^m x_k}{\sum_{k=1}^{N} (\mu_{ik})^m} \quad (7)$$

These three steps will be repeated until a criterion is satisfied, typically a pre-configured threshold is reached.

B. Gustafson-Kessel FCM clustering

The Gustafson-Kessel (GK) clustering algorithm [4] is commonly used in various domains including image processing, classification and system identification. Contrast to the FCM algorithm, its main feature is the local adaptation of the distance metric to the shape of the cluster. In addition, it is relatively insensitive to the data scaling and initialization of the partition matrix.

The objective of the GK FCM clustering is to find ellipsoidal clusters of approximately the same size. Its inputs and outputs are exactly same with traditional FCM except the distance function.

The iterative procedure of the GK FCM algorithm is the same as the traditional FCM, except that the distance computation uses Equation (4) instead of (5). A_i used in Equation (4) is defined as:

$$A_i = \left|F_i^{1/M}\right| F_i^{-1} \quad (8)$$

$$F_i = \frac{\sum_{k=1}^{N} (\mu_{ik})^m (x_k - v_i)^T (x_k - v_i)}{\sum_{k=1}^{N} (\mu_{ik})^m}$$

The procedure repeats the computations with the simultaneous change of cluster centers, membership values, and belongingness until a criterion is satisfied.

C. Modification to FCM clustering

The FCM has been shown to be an effective data clustering algorithm [13]. It is an iteratively optimal algorithm usually based on the least square method to make a fuzzy partition of the data set. The objective function of the traditional FCM is described in (3). However, it was found out that the modified linear distance, suggested by Bezdek [17], and as shown in (9) produced almost the same results in practice, with the clustering center values identical to those from the least square method [18].

$$J(X;U,V) = \sum_{i=1}^{C} \sum_{k=1}^{N} (\mu_{ik})^m d(x_k, v_i) \quad (9)$$

Additionally, in this paper, the linear distance measurement using City Block distance instead of Euclidean distance is adopted to reduce the computational overhead. City Block distance is calculated as:

$$d_{ik} = \left|x_k - v_i\right| \quad (10)$$

for a data point x_k and a cluster center v_i.

The proposed modifications to FCM reduce the complexity of the objective function from quadratic in (3) to linear in (9). Moreover, the complexity of the distance function also is reduced from quadratic plus square root calculations used in Euclidean distance to simply linear used for City Block distance, as shown in (10). The calculation is needed for each data point. Therefore, the total computation overhead for the entire dataset could be significant. The reduction of calculation time is vital for real-time P2P traffic applications, as the number of P2P flows could be huge and the response time needs to be very short.

V. SIMULATIONS AND COMPARISONS

The major role of FCM is to cluster data into different groups (classes or clusters). When the objects in the same clusters share more similar characteristics and the objects in different clusters are with more different features, the clustering result is considered to be better. Our experiments showed that the proposed method using simplified objective function and distance function can generate results and classification accuracy similar to that of the conventional FCM, while the method improves the computational speed. For the traditional FCM, the time complexity is $O(\mathrm{NDC}^2\mathrm{I})$, where N is the number of patterns and C is the number of clusters (see section IV), D stands for data dimensions, and I equals the number of iterations of calculations. The modified FCM has time complexity of $O(\mathrm{NDCI})$. With more emerging P2P applications, the complexity reduction from proportional of C^2 to C would greatly enhance the efficiency of this approach. As a result, the proposed method has the potential to be used for online network traffic monitoring or pre-processing for network management [19].

The following two sub-sections demonstrate the results generated by traditional FCM and the modified FCM, respectively, for a comparison. The application of the proposed FCM to P2P traffic classification was then demonstrated.

A. Results of FCM clustering

The results produced by traditional FCM clustering are presented in Fig. 1. The quasi-random two-dimensional data, as depicted in Fig. 1(a), were used for demonstration. Fig. 1(b) shows the result for two clusters, while Fig. 1(c) present the result for three clusters. The black labels (×, ○, and Δ) in the figures are cluster centers.

The membership values of the data points to the cluster centers are shown in Fig. 2. The vertical axis illustrates the

membership values for data presented on the horizontal 2-dimensional plane. Fig. 2(a) presents the membership values for cluster 1 after those three clusters, as shown in Fig. 1(c), were generated; Fig. 2(b) is for cluster 2, and Fig. 2(c) is for cluster 3. Threshold values were to determine which cluster each data point belongs to.

B. Results of modified FCM

As stated in the previous section, this paper modifies the objective function from quadratic to linear, and changes the distance function from Euclidean distance to City Block. The modifications were implemented in Matlab by changing the related M-functions.

Using the same data as the FCM, the clustering results with three clusters for the modified FCM methods are shown in Fig. 3. In Fig. 3(a), only the objective function was changed from quadratic to linear; Fig. 3(b) only the distance function was altered from Euclidean to City Block; and Fig. 3(c) both the objective function and the distance function have been modified.

Compared with Fig.1(c) which depicts results generated from the traditional FCM, there is not much clustering difference. The cluster centers for the modified FCM remain unchanged, the belongingness of objects to clusters are almost the same as the traditional FCM. Only a few boundary points were grouped into different clusters. In addition, Fig. 3 also reveals that the difference between the variations (a), (b), and (c) is also small.

The experiments were used to study the feasibility of the proposed changes to FCM and to compare the results for both approaches. The results demonstrated that the proposed FCM is feasible from the clustering accuracy perspective; the next step is to apply the proposed FCM to P2P traffic classification.

C. P2P traffic classification using modified FCM clustering

We used the data captured in an empirical platform and extracted the features from traffic flows. Many features can be obtained directly from packet headers or their statistic characteristics such as average, min, max, and standard deviation. The dataset consists of 41 features. Some features are correlated with each other, while others are independent. Feature reduction was adapted to closely related features. Feature selection is crucial for clustering techniques. For P2P traffic clustering, after feature reduction, we grouped features into two categories: traffic flow and packet statistics.

From the traffic flow perspective, features that are essential for flow identification and flow characteristics include:

- number of packets sent for a flow
- number of packets received for a flow
- duration of the flow
- protocol
- source and destination ports (2 features)

From the perspective of packet statistics, we consider:

- total number of packets
- mean packet length
- mean payload length
- mean packet inter-arrival time the average sent packet size
- average received packet size
- variances of average sent packet size
- variances of average received packet size
- byte ratio of sent packets
- byte ratio of received packets

We examined those 15 features listed above and applied the clustering to the experimental data using those 15 features. We did not find significant clustering difference using the modified distance function from Euclidean to City Block and the changed objective function. This demonstrates that the proposed modifications to FCM would generate clusters that are comparable with those created with the traditional FCM. However, the computational speed has improved significantly.

On the other hand, when we used different feature combinations, we obtained apparently different clustering results, so feature selection can have direct impact not only on the efficiency for network traffic data clustering, but also clustering accuracy as well. This is also true for other clustering methods.

For Fuzzy clustering, the selection of the number of clusters is also crucial; otherwise the clustering results may be absurd. We applied the modified FCM on simulated P2P network traffic, as illustrated in Fig. 4 (a). The data consist of four simulated P2P traffic types: PPLive, BitTorrent, QQ, and Skype.

Fig. 4(b) shows the clustering results for four clusters, each representing one P2P traffic type. The results for four clusters were consistent for 8-10 experiments. Running the same data using the traditional FCM method generates similar results, i.e., there was no significant difference between the traditional and the modified approaches. This demonstrates that the modified FCM generates very comparable results to the traditional FCM.

On the other hand, the experiments also demonstrate that the selection of the number of clusters has a direct effect on the clustering outcome. For instance, Fig. 4(c) and 4(d) illustrate results of selecting five clusters for the simulated P2P traffic which has only four different traffic types: PPLive, BitTorrent, QQ, and Skype.

As presented in Fig. 4(c) and Fig. 4 (d), the results are very different if the number of clusters is set to five for the clustering process. Obtaining very different results using the same number of clusters is an indication that the number of clusters is incorrect or does not represent the actual data.

The effect of the number of clusters is further explained here. If Fig. 4(d) represents the actual traffic data and Fig. 4(b) is the results when we choose four clusters in the beginning of the clustering, then only the data in the yellow region of Fig. 4(d) would be misclassified. If Fig. 4(c) represents the actual traffic data and we obtain the results shown in Fig. 4(b) when four clusters are chosen, it means that more data have been misclassified. In both cases, the clustering errors are caused by

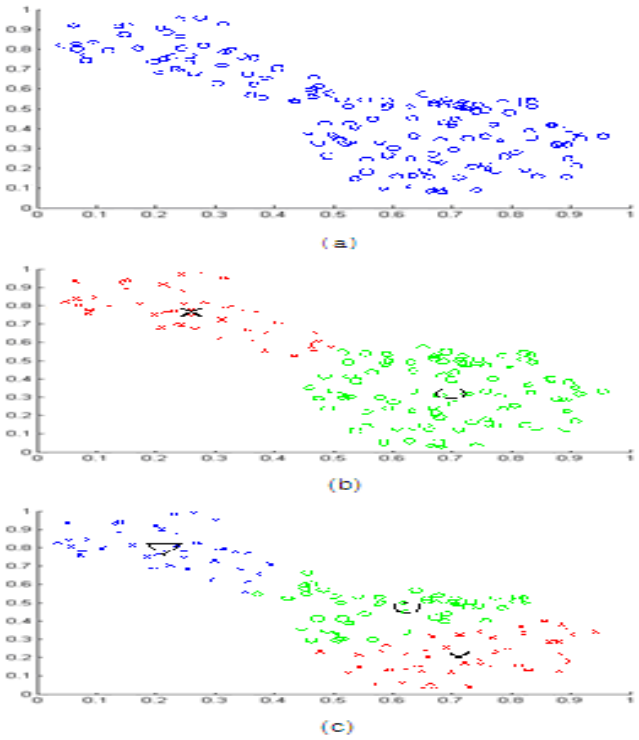

Figure 1. Clustering results of traditioal FCM: (a) quasi-random data to be clustered, (b) clustering result with 2 clusters, (c) clustering result with 3 clusters

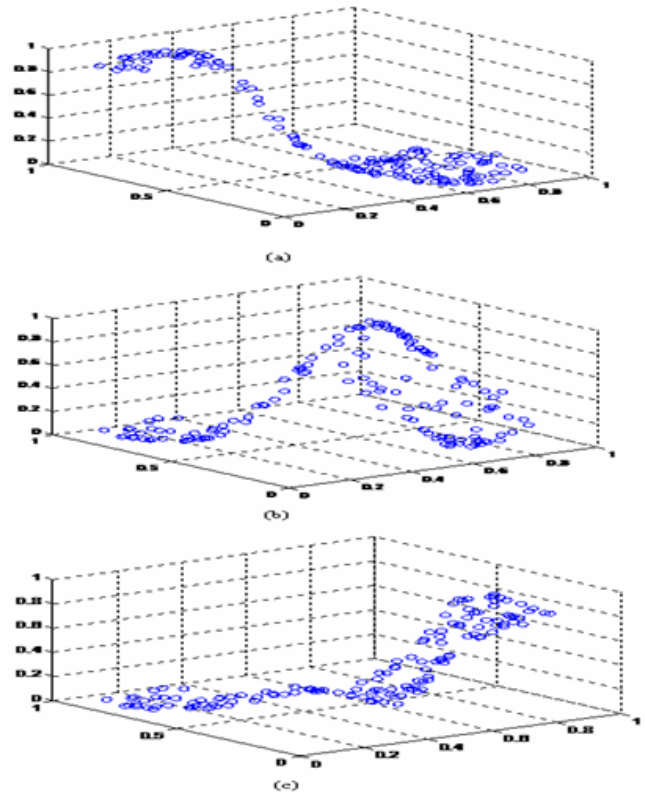

Figure 2. Membership values for: (a) cluster 1, (b) cluster 2, (c) cluster 3 after being grouped into 3 clusters

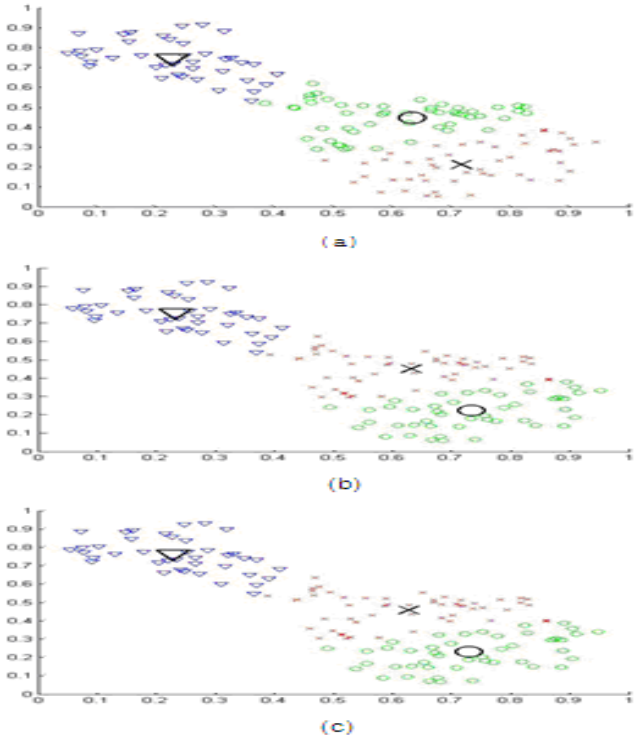

Figure 3. Clustering results of modified FCM: (a) modified objective function, (b) modified distance function, (c) modified objective and distance functions

the inappropriate selection of the number of clusters, which is crucial for FCM-based clustering.

If we obtain different results, e.g., results illustrated in Fig. 4(c) and Fig. 4(d), for different runs using the same number of clusters, cross-examination is needed. In this case, more data may be needed to validate the classification. Normally FCM does not generate reasonable or correct results if the number of clusters is wrong or inappropriate. We can also examine the membership values to determine if the clustering results should be accepted or rejected, or if more data are needed for verification.

In real-time classification for P2P traffic in which new applications are emerging, re-clustering is likely needed. With the modified FCM method, the speed is much faster than the traditional FCM, which is another important factor to consider for comparison for frequent re-clustering.

VI. CONCLUSIONS AND FUTURE WORK

The feasibility of automatic P2P traffic classification using machine learning techniques was explored in this paper. Classification accuracy and computational overhead are critical factors to consider for the high dimensional network traffic dataset. The fewer the features we select, the lower the computational overhead is with possibly lower accuracy. We compared different feature combinations for feature selection and reduced the feature set to 15 critical ones for analysis. Further, this paper modified the distance function from Euclidean (involving square and square root calculations) to City Block (linear calculations only) and changed the objective

function from quadratic to linear to decrease the computational complexity. Computational overhead is crucial for a large volume of real-time P2P traffic monitoring. With the proposed modifications to FCM, the efficiency is improved, while the results obtained from our data were very similar to the traditional FCM.

Performance estimation of the modified FCM clustering based on overall accuracy, precision, and recall can be conducted in the future. We are also working on getting real traffic data using tcpdump on campus for further investigation.

Abstract— **In this paper, process conditions of epoxy dispensing processes are determined by the proposed genetic algorithm based neural fuzzy networks, which consists of two tasks: a) the approach of neural fuzzy networks, which was shown to be better than the other existing approaches, is proposed to develop models in relating between process parameters and quality characteristics for the epoxy dispensing processes; b) the approach of genetic algorithm is used to determine process parameters with respect to pre-defined quality requirements based on the developed neural fuzzy network models. The results indicate that, based on the proposed genetic algorithm based neural fuzzy network, estimated process parameters can achieve specified requirements of microchip encapsulations with high and robust qualities.**

Keywords- Epoxy dispensing process, microchip encapsulation, neural fuzzy networks

I. INTRODUCTION

Epoxy dispensing is one of the most popular processes for microchip encapsulation on chip-on-board packages. In traditional semiconductor manufacturing, a trial-and-error method is usually used to identify proper process parameters setting so as to achieve the required quality characteristics. However, epoxy dispensing processes involve extremely complex inter-relationships among the fluid properties, process conditions, needle design parameters and overall encapsulation quality. Also cognitive uncertainties exist in the epoxy dispensing processes such as the human handling of substrate for measurement, insufficient data for process model development, and human judgment on qualities of the microchip encapsulation. Recently, various approaches have been attempted to model epoxy dispensing process including analytical approach [1], statistical regression [9], artificial neural networks [9] and fuzzy regression [7].

Statistical regression [14] is a commonly used empirical approach to develop manufacturing process models. However, statistical regression can only be applied if the given data are distributed along the developed statistical regression models, and the relationship between dependent and independent variables is crisp [2]. Artificial neural networks can transform a nonlinear mathematical model into simplified black-box structures for various manufacturing processes [10]. They can be used for modeling nonlinear, complex and noisy manufacturing processes, but they are not recommendable by engineering users, as the models developed are in black-box nature and no information can be obtained within the models. Unlike these two approaches which required certain amount of data to develop models, fuzzy regression [13] has a distinct advantage that it can develop models using incomplete data sets or smaller amount of data. However, linear fuzzy regression models, which can only address linearity but not address nonlinearity, can only be generated by the fuzzy regression approaches.

Neural fuzzy networks have been used to develop models for various manufacturing processes which are both nonlinear and complex [15, 11]. The approach has the capability to transform a nonlinear mathematical model into a simplified input-output structure. Kang et al. [8] have proved that neural fuzzy networks outperform statistical regression in modeling of highly nonlinear systems. Compared with conventional fuzzy logic modeling, neural fuzzy systems can achieve better performance in mathematical function approximations, while the same number of fuzzy sets is used in input variables [5].

In this paper, a genetic algorithm based neural fuzzy networks is proposed to determine process condition for epoxy dispensing process of microchip encapsulation. First the approach of neural fuzzy networks is used to model epoxy dispensing for microchip encapsulation based on a set of experimental data. Validation results show that the process models developed based on neural fuzzy networks outperform those developed based on statistical regression, neural network and fuzzy regression. The developed process models are then used to formulate an optimization problem, which aims at specifying the optimal process parameters for the required quality characteristics. The process optimization is performed

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

by a genetic algorithm, which involves with the developed process models. The solutions of the optimization problem allow the optimal settings for the parameters of the epoxy dispensing process to be obtained. Validation tests are performed to evaluate the proposed approach to the modeling and optimization of the fluid dispensing process, and the results indicate that effective process parameter settings can be obtained that achieve the specified product quality requirements.

II. EPOXY DISPENSING PROCESS

In electronic packaging, normally, silicon chips are covered using an X-Y numerically controlled dispensing system that delivers epoxy encapsulant through a needle. The epoxy material is commonly dispensed in a pattern, working from the center out. A fluid dam around the die site and second wire bond points can be made to contain the flow of material and make a more uniform looking part as shown in Figure 1. The process is called the epoxy dispensing of microchip encapsulation. Two quality characteristics of encapsulation were also identified as

a) encapsulation weight (mg), *y*

b) encapsulation thickness (mm), *z*.

Three significant process parameters and their normal operating ranges were identified by the company supporting this research as:

c) the compressed air pressure (1 bar to 4 bar) x_1;

d) the pump motor speed (400 rpm to 1000 rpm), x_2;

e) the height between the substrate and the needle (250 to 2000 steps of stepping motor), x_3.

96 experiments were carried out based on a full factorial design with 4 levels in x_1, 6 levels in x_2 and 4 levels in x_3. 88 of the 96 experimental data were used to develop the model in relating the process parameters and the quality characteristics, and the rest 8 experimental data were used for the validation test.

To evaluate prediction accuracy of the process model, the mean error (Me) was used as defined below:

$$\text{Merror} = \frac{1}{n}\sum_{k=1}^{n}\frac{\left|t(k) - y(x(k))\right|}{t(k)} \qquad (1)$$

where $t(k)$ is the actual value of the quality requirement for the *k-th* experimental data; $y(x(k))$ is the estimated quality requirement with the recommended process parameters $x(k)$ obtained from the process model; n is the number of experimental data sets used for the validation tests.

The variance of errors (Var) was also involved in the validation as shown below:

$$\text{Var} = \frac{1}{n-1}\sum_{k=1}^{n}\left(\frac{\left|t(k) - y(x(k))\right|}{t(k)} - \text{Merror}\right)^2 \qquad (2)$$

III. MODELLING OF EPOXY DISPENSING USING NEURAL FUZZY NETWORK

Figure 2 shows the structure of a neural fuzzy network (NFN) which was used to develop models of the epoxy dispensing process in which the relationship between process parameters (x_1, x_2 and x_3) and the quality characteristics (y and z) is addressed. NFN consists of an input layer which feds in an input vector containing x_1, x_2 and x_3, and the output layer which produces the output response, y or z. Two hidden layers are connected between the input and output layers. The functions of the four layers of the NFN are described below:

Input layer: Each node in this layer which corresponds to a process parameter transmits input values to the next layer.

Hidden layer 1: Each node in this layer corresponds to one linguistic label (i.e. small, medium or large) with respect to x_1, x_2 and x_3. The membership value which specifies the degree to which an input value belongs to fuzzy set, is calculated in Layer 2. The j^{th} membership function of the input variable x_i is a bell-shaped function and is given by

$$A_{ij}(x_i) = e^{\frac{-(x_i - \bar{x}_{ij})^2}{2\sigma_{ij}^2}} \qquad (3)$$

where parameters $\bar{x}_{ij}$ and σ_{ij} with i=1,2,3 and j=1,2,3 are the mean value and the standard deviation of the j^{th} membership function of the input variable x_i respectively.

Hidden layer 2: The node in this layer represents one fuzzy logic rule and performs precondition matching of a rule. For instance, a fuzzy rule $R_{g_1g_2g_3}$ can be given as:

$R_{g_1g_2g_3}$: IF x_1 is $A_{1g_1}(x_1)$ AND x_2 is $A_{2g_2}(x_2)$ AND x_3 is $A_{3g_3}(x_3)$ THEN $y(x_1,x_2,x_3)$ is $\mu_{g_1g_2g_3}$,

where $\mu_{g_1g_2g_3}$ is an output singleton y of the rule $R_{g_1g_2g_3}$, and it can be represented as:

$$\mu_{g_1g_2g_3} = A_{1g_1}(x_1)\cdot A_{2g_2}(x_2)\cdot A_{3g_3}(x_3) \qquad (4)$$

As the number of membership functions of each input variable is 3 and the number of input variables is 3, the total number of fuzzy rules is 27 (i.e. 3^3).

Output layer: The nodes in this layer corresponds to the output variable y. The node integrates all the outputs of hidden layer 2 and it acts as a defuzzifier with defined in (5).

$$y(x_1,x_2,x_3)=\frac{1}{\sum_{g_1,g_2,g_3=1}^{3}\mu_{g_1,g_2,g_3}}\cdot \sum_{g_1,g_2,g_3=1}^{3}\mu_{g_1,g_2,g_3}\left(w_1^{g_1,g_2,g_3}x_1+w_2^{g_1,g_2,g_3}x_2+w_3^{g_1,g_2,g_3}x_3+w_0^{g_1,g_2,g_3}\right) \quad (5)$$

where the weights $w_0^{g_1,g_2,g_3}$, $w_1^{g_1,g_2,g_3}$, $w_2^{g_1,g_2,g_3}$ and $w_3^{g_1,g_2,g_3}$ with $g_1,g_2,g_3=1,2,3$ are the neural fuzzy parameters.

$w_0^{g_1,g_2,g_3}$, $w_1^{g_1,g_2,g_3}$, $w_2^{g_1,g_2,g_3}$ and $w_3^{g_1,g_2,g_3}$ with $g_1,g_2,g_3=1,2,3$ $\bar{x}_{ij}$ and σ_{ij} with *i*=1,2,3 and *j*=1,2,3 (namely NFN parameters) were searched by using a genetic algorithm (GA) [6]. The objective of the genetic algorithm is to minimize the training error of the NFN model by searching the NFN parameters setting. The fitness function is defined as:

$$fitness=\frac{1}{1+err} \quad (6)$$

where $err=\frac{1}{N}\sum_{\mathbf{x}=X}\frac{\left|y(\mathbf{x})-y^t(\mathbf{x})\right|}{y^t(\mathbf{x})}\times 100\%$; $\mathbf{x}=(x_1,x_2,x_3)$, $y^t(\mathbf{x})$ is the actual output, **X** is the domain of all the training data, and *N* is the total number of training data. The range of *fitness* in (6) is between 0 and 1.

The GA starts with a population of randomly generated chromosomes, while each chromosome is set to be a set of neural fuzzy parameters. The length of each chromosome is equal to the number of neural fuzzy parameters which is 45. Thereafter, the GA further processes a fixed number of generations using the evolutionary operations (i.e. selection, crossover and mutation). The selection is performed in two steps, chromosome selection and survival. The selection on chromosomes decides who parents become and how many children the parents have. The children are created through crossover which exchanges information between parents, and the mutation which further perturbs the children. The fitness of each child is then evaluated based on the fitness function (6). Finally, the survival step decides who survives in the population. After the operations of selection, crossover and mutation, a new population is generated. The chromosome with the highest fitness is selected to be the setting of the neural fuzzy parameters.

The following parameter values have been used in the GA for searching the neural fuzzy parameters; crossover rate = 0.8; mutation rate =1/45, where 45 is the length of the chromosome; number of generations = 1000; population size = 200. The GA were implemented using Matlab programming software. The training errors of the NFNs for the encapsulation weight and encapsulation thickness were found as 6.0263% and 5.2591% respectively.

Eight validation tests were carried out in order to evaluate the effectiveness of the developed NFN models in modelling the epoxy dispensing process. Table 1 shows the validation results are compared with those based on our previously developed statistical regression, artificial neural networks and fuzzy regression for modelling the epoxy dispensing process [9]. Row 1 and Row 3 show the comparisons of the mean testing errors for the encapsulation weight and thickness respectively. Row 2 and Row 4 show that the comparisons of the variances of the testing errors for the encapsulation weight and thickness respectively. It can be seen that the NFN based process models can achieve the smallest mean testing errors and the smallest variance of mean errors compared with other methods. Therefore the NFN based process models for encapsulation weight and thickness predictions were used to perform the process optimization of the epoxy dispensing.

IV. PROCESS OPTIMIZATION USING GENETIC ALGORITHM

Process optimization aims at determining a setting of the process parameters so as to achieve the required encapsulation weight (β mg) and encapsulation thickness (γ mm). To determine the process parameter setting, the following objective function is used:

$$Min\ \ \rho=\lambda_1\frac{|y-\beta|}{\beta}+\lambda_2\frac{|z-\gamma|}{\gamma} \quad (7)$$

subject to: $1\le x_1\le 4$, $400\le x_2\le 1000$ and $250\le x_3\le 2000$, where λ_1 and λ_2 are the weights of the two quality characteristics, encapsulation weight and encapsulation thickness respectively. As the two quality characteristics are supposed to be equal importance, $\lambda_1=\lambda_2=0.5$ were used.

Figure 3 shows a GA for determining process parameters setting for the epoxy dispensing, and it shows how the GA is interconnected to the NFN for modeling the epoxy dispensing process. The GA aims at minimizing the objective function (7) from which the optimal values of x_1, x_2 and x_3 can be obtained to achieve the required encapsulation weight β mg and encapsulation thickness γ mm. The main operations of the GA are described below.

A. Representation of strings

The first step of GA is to randomly generate strings which represent the population of GA. Real and binary encoding representations are two commonly used approaches for representing strings in GA. In binary encoding representation, strings need to be encoded to real values for fitness evaluation and also they need to be decoded again for reproduction operation. However, in real encoding representation, there is no need for string encoding and decoding, which would save a considerable amount of computational time and would lead to a much faster searching process than that of the binary encoding representation. Therefore, real encoding was adopted in GA, and each string contains three real values, which correspond to x_1, x_2 and x_3. The generated random values have the ranges associated with the operating ranges of the process parameters.

B. Fitness function

The objective function (7) was formulated to determine how close the randomly generated strings are to the required values of encapsulation weight (β mg) and encapsulation thickness (γ mm). Based on a string with the three process parameters, the quality measures of encapsulation weight y and encapsulation thickness z can be predicted by the NFN based process models. The fitness function of the GA is defined as follows:

$$\text{fitness} = \frac{1}{1+\text{error}} \tag{8}$$

where $\text{error} = \lambda_1 \frac{|y-\beta|}{\beta} + \lambda_2 \frac{|z-\gamma|}{\gamma}$.

Based on the fitness function (8), the fitness of a string with x_1, x_2 and x_3 can be evaluated. The objective is to maximize the fitness value of the fitness function (8) by searching the optimal x_1, x_2 and x_3.

C. Crossover operation

The intermediate crossover [12] for real encoding representation is used in the GA. It is a method of producing a new string around and between the process parameters of the two selected parent strings. The new string $\left[x_1^3, x_2^3, x_3^3\right]$ is produced based on the following formulation:

$$\left[x_1^3, x_2^3, x_3^3\right] = \left[x_1^2, x_2^2, x_3^2\right] \times \alpha \left\{\left[x_1^2, x_2^2, x_3^2\right] - \left[x_1^1, x_2^1, x_3^1\right]\right\} \tag{9}$$

where α is a scaling factor chosen uniformly at random over some interval typically $[-0.25, 1.25]$, and $\left[x_1^1, x_2^1, x_3^1\right]$ and $\left[x_1^2, x_2^2, x_3^2\right]$ are the two selected parent strings. The process parameters in the new string are the result of combining the values of the process parameters in the parent strings according to (9) with a scaling factor α chosen for each process parameter. In geometric terms, intermediate crossover is capable of producing new parameter values within a slightly larger hypercube than that defined by the parent strings but constrained by the range of the scaling factor α.

D. Mutation operation

Mutation is carried out by randomly changing one or more process parameter values of the selected string between its pre-defined upper and lower bound. The mutation operator of Gaussian perturbation of individual parameters is used. For example, the parameter x_j is selected to be mutated. After performing mutation, its value becomes:

$$x_j' = x_j + \text{MutMx} \times R_j \times \delta \tag{10}$$

where MutMx = +1 or -1 with equal probability; R_j = 0.5 × searching domain of the process parameter x_j; δ = a value in the range [0,1] for shrinking the mutation range based on Gaussian perturbation.

E. Selection of strings

The population is evolved and improved iteratively until a stopping condition is met. In evolutionary computation, there are several stopping conditions. In this GA, the stopping criterion is met when the number of generations is equal to a pre-defined number of generations. Otherwise, the population is evolved in the next generation. The approach of roulette-wheel, which is one of the most common selection methods used for selecting strings to perform reproduction operations [6], is used for strings selection in the GA. For example, the fitness of the j-th string in a population is assigned a value $fitness_j$. The fitness values are used to assign a probability value prob_j to the j-th string. The probability value prob_j is defined as:

$$\text{prob}_j = \frac{\text{fitness}_j}{\sum_{j=1}^{\text{Popsize}} \text{fitness}_j} \tag{10}$$

where Popsize is the population size of GA. Equation (10) shows that the string with a larger fitness value has higher probability to be selected. The updated population is produced by reinserting the new reproduced strings into the old population. It can be produced by replacing the least fitness strings in the old population with the new reproduced strings. However, pre-mature convergence likely occurs in early generations of evolution. To avoid the problem, random reinserting approach is used in the GA.

The population size, crossover rate and the mutation rate of the GA are set as 200, 0.8 and 0.001 respectively, which are suggested by DeJong [4]. The pre-defined number of generations is set at 1000. The GA toolbox coded in Matlab [3], which exists in the public domain, has been employed to search the process parameters of the epoxy dispensing process.

Eight validation tests were performed to evaluate the effectiveness of the GA. For each test, required values of encapsulation weight and thickness are input and it is expected that a setting of process parameters can be obtained from the optimization model. Table 2 shows the eight settings of process parameters recommended by the GA corresponding to the eight sets of quality requirements. The second and third columns show the required values of encapsulation weight and encapsulation thickness. The last three columns show the settings of the process parameters recommended by the GA.

V. CONCLUSION

In this paper, a genetic algorithm based neural fuzzy networks was proposed to determine process parameters setting of epoxy dispensing process for microchip encapsulation. 96 experiments based on a full factorial design were conducted in which the parameters of compressed air pressure, pump motor speed, distance between substrate and needle, and two quality characteristics, encapsulation weights and encapsulation thickness, are involved. 88 experimental data were used to develop the NFN based process models. 8 validation tests were carried out to evaluate the effectiveness and robustness of the process parameters settings recommended by the GA. The validation results indicate that, for each test, a setting of process parameters can be obtained to achieve the required quality requirement based on the proposed approaches.

Further work involves the validation of the searched process parameters obtained by the genetic algorithm based

neural fuzzy networks in a real world environment using experiments.

Abstract— **Fuzzy regression is a commonly used approach for modeling manufacturing processes in which the availability of experimental data is limited. Fuzzy regression can address fuzzy nature of experimental data in which fuzziness is not avoidable while carrying experiments. However, fuzzy regression can only address linearity in manufacturing process systems, but nonlinearity, which is unavoidable in the process, cannot be addressed. In this paper, an evolutionary fuzzy regression which integrates the mechanism of a fuzzy regression and genetic programming is proposed to generate manufacturing process models. It intends to overcome the deficiency of the fuzzy regression, which cannot address nonlinearities in manufacturing processes. The evolutionary fuzzy regression uses genetic programming to generate the structural form of the manufacturing process model based on tree representation which can address both linearity and nonlinearities in manufacturing processes. Then it uses a fuzzy regression to determine outliers in experimental data sets. By using experimental data excluding the outliers, the fuzzy regression can determine fuzzy coefficients which indicate the contribution and fuzziness of each term in the structural form of the manufacturing process model. To evaluate the effectiveness of the evolutionary fuzzy regression, a case study regarding modeling of epoxy dispensing process is carried out.**

Keywords- fuzzy regression, manufacturing process modeling

I. INTRODUCTION

In manufacturing processes, process variables at each of the many processing steps in a manufacturing line need to be controlled, and all process variables related to the desired output need to be optimized to maintain tight control. Development of a manufacturing process model, which represents relationship between process variables and desired outputs, is essential.

While only a small amount of experimental data is available, fuzzy regression [1, 4, 10, 21-23] has the distinct advantage of being able to generate models in manufacturing process systems, which have a high degree of fuzziness. For examples, Schaiable and Lee used the fuzzy linear regression method to model the vertical CVD process [20]. Lai and Chang applied fuzzy regression to model the die casting process [1]. Ip et al. introduced the fuzzy linear regression to develop models for epoxy dispensing [8]. Three different approaches of fuzzy linear regression were summarized in Chang and Ayyub [2]. However, the existing fuzzy regression approaches cannot be used to develop manufacturing process models which are nonlinear in nature. In fact, nonlinear behaviors of manufacturing process commonly exist. If nonlinearities are integrated into the approach of fuzzy regression, more accurate models can be developed.

Furthermore, it is widely recognized that the quality of model development declines when outliers in experimental data exist, but very few studies have attempted to detect outliers when developing fuzzy regression models. Chen [6] proposed a method to detect outliers involving crisp inputs and fuzzy outputs. The method detects the difference in width between the spread of fuzzy data and the spread of fuzzy output. However, experimental data and the results of manufacturing processes involve crisp values of experimental settings and crisp values of experimental responses. Therefore, this method cannot be applied to manufacturing process modeling.

To overcome these deficiencies, we propose a genetic fuzzy regression, which can be used to generate manufacturing process models with nonlinear nature. The genetic fuzzy regression uses the general outcomes of genetic programming to construct models based on a tree structure representation in which both the interaction and higher order terms can be considered so as to address nonlinearity. Then it uses the mechanism of fuzzy regression to detect the outliers from experimental data sets based on an indicator of outliers. The fuzzy regression then estimates the contribution of each branch of the tree in order to determine the fuzzy coefficient of each term of the model by using the experimental data sets excluding the outliers. As nonlinear terms can be generated and represented in the branches of the tree based on the

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

genetic fuzzy regression, nonlinear terms can be generated in the manufacturing process models. Furthermore, as the fuzzy regression is used to determine fuzzy coefficients of the manufacturing process model, only a small amount of data is required, which is practical in the manufacturing process.

The effectiveness of the proposed genetic fuzzy regression approach is evaluated by modeling the epoxy dispensing process for electronic packages, which is used in various electronic packaging processes such as integrated circuit (IC) encapsulation and die-bonding [16]. Epoxy dispensing is a highly non-linear process that involves extremely complex inter-relationships among the epoxy properties, process conditions and overall encapsulation quality [7]. The genetic fuzzy regression is used to develop models for this manufacturing process. Modeling results based on genetic fuzzy regression is compared with those based on the fuzzy linear regression methods of Tanaka [9] and Peters [8], which have been employed to model the epoxy dispensing processes.

II. GENETIC FUZZY REGRESSION

The genetic fuzzy regression approach generates the manufacturing process model which relates output responses and process variables in fuzzy regression form. When defining, the genetic fuzzy regression needs to:

a) specify the form of the manufacturing process model in fuzzy regression form
b) determine the fuzzy coefficients which characterize the model
c) define the algorithm of genetic fuzzy regression

A. Form of process model

The general form of the manufacturing process models, which involves nonlinear terms between process variables are represented as fuzzy regression form as follows:

$$\tilde{y} = \tilde{f}_0 + \sum_{i=1}^{N} \tilde{f}_i(x_i) + \sum_{i=1}^{N}\sum_{j=1}^{N} \tilde{f}_{ij}(x_i, x_j) + \ldots + \tilde{f}_{1,2,\ldots N}(x_1, x_2, \ldots x_N) \tag{1}$$

where $\tilde{y}$ is the output response, x_i is the i-th process variable, $\tilde{f}_0$ is a fuzzy bias term and $\tilde{f}_i(x_i)$, $\tilde{f}_{ij}(x_i, x_j)$, … represent univariate fuzzy components and bivariate fuzzy components respectively. A higher order high-dimensional Kolmogorov-Gabor polynomial is one of the forms of (1), which can be written as follows:

$$\tilde{y} = \tilde{f}_{NR}(x) = \tilde{A}_0 + \sum_{i_1=1}^{N} \tilde{A}_{i_1} x_{i_1} + \sum_{i_1=1}^{N}\sum_{i_2=1}^{N} \tilde{A}_{i_1 i_2} x_{i_1} x_{i_2} + \ldots + \sum_{i_1=1}^{N} \ldots \sum_{i_d=1}^{N} \tilde{A}_{i_1 \ldots i_d} \prod_{j=1}^{d} x_j \tag{2}$$

where $\tilde{A}_0 = (a_0^c, a_0^s)$, $\tilde{A}_1 = (a_1^c, a_1^s)$, $\tilde{A}_2 = (a_2^c, a_2^s)$, … $\tilde{A}_N = (a_N^c, a_N^s)$, $\tilde{A}_{11} = (a_{11}^c, a_{11}^s)$, $\tilde{A}_{12} = (a_{12}^c, a_{12}^s)$, … $\tilde{A}_{NN} = (a_{NN}^c, a_{NN}^s)$, … $\tilde{A}_{N\ldots N} = (a_{N\ldots N}^c, a_{N\ldots N}^s)$.

The fuzzy regression model (2) can be rewritten as follows:

$$\tilde{y} = \tilde{A}'_0 x'_0 + \tilde{A}'_1 x'_1 + \tilde{A}'_2 x'_2 \ldots \tilde{A}'_{N_{NR}} x'_{N_{NR}} \tag{3}$$

or $$\tilde{y} = (a_0^c{}', a_0^s{}')x'_0 + (a_1^c{}', a_1^s{}')x'_1 + (a_2^c{}', a_2^s{}')x'_2 + \ldots (a_{N_{NR}}^c{}', a_{N_{NR}}^s{}')x'_{N_{NR}} \tag{4}$$

where $1+N_{NR}$ is the number of terms of (1), (2) and (3); $\tilde{A}'_0 = \tilde{A}_0$, $\tilde{A}'_1 = \tilde{A}_1$, $\tilde{A}'_2 = \tilde{A}_2$, … $\tilde{A}'_{N_{NR}} = \tilde{A}_{N\ldots N}$; $x'_0 = 1$, $x'_1 = x_1$, $x'_2 = x_2$, … $x'_{N_{NR}} = x_1 \cdot x_2 \cdot \ldots x_d$; and $\tilde{A}'_0 = (a_0^c{}', a_0^s{}')$, $\tilde{A}'_1 = (a_1^c{}', a_1^s{}')$, … $\tilde{A}'_{N_{NR}} = (a_{N_{NR}}^c{}', a_{N_{NR}}^s{}')$. $\tilde{A}'_i$ and x'_i are called the fuzzy coefficients and the transformed variables respectively, where i=0,1,2,…N_{NR}.

The vectors of the fuzzy coefficients are defined as follows:

$$\tilde{A}' = (\tilde{A}'_0, \tilde{A}'_1, \ldots \tilde{A}'_{N_{NR}}) = ((a_0^c{}', a_0^s{}'), (a_1^c{}', a_1^s{}'), \ldots (a_{N_{NR}}^c{}', a_{N_{NR}}^s{}')), \tag{5}$$

$$a^c{}' = (a_0^c{}', a_1^c{}', \ldots a_{N_{NR}}^c{}'), \tag{6}$$

and $$a^s{}' = (a_0^s{}', a_1^s{}', \ldots a_{N_{NR}}^s{}'). \tag{7}$$

The vector of the transformed variables is defined as follows:

$$x' = (x'_0, x'_1, x'_2, \ldots x'_{N_{NR}}). \tag{8}$$

Using the vectors of the fuzzy coefficients and the vector of the transformed variables, (3) can be rewritten as follows:

$$\tilde{y} = \tilde{A}' \cdot x'^T \tag{9}$$

B. Determination of fuzzy coefficients

The fuzzy regression is proposed to determine the fuzzy coefficients of the manufacturing process models which are structured in the form of (4). Based on Peters' fuzzy regression [19], the fuzzy coefficients of the manufacturing process model are determined by solving the linear programming (LP) problem formulated as (10a) to (10f):

$$\max \bar{\lambda} = \frac{1}{M} \sum_{i=1}^{M} \lambda_i \tag{10a}$$

$$\text{s.t. } (1 - \bar{\lambda}) p_0 - \sum_{i=1}^{M}\sum_{j=0}^{N} a_j^S{}' |x_{ij}| \geq -d_0 \tag{10b}$$

$$(1 - \lambda_i) p_i - \sum_{j=0}^{N} a_j^c{}' x_{ij} - \sum_{j=0}^{N} a_j^S{}' |x_{ij}| \leq y_i, i = 1,2,\ldots,M \tag{10c}$$

$$(1 - \lambda_i) p_i + \sum_{j=0}^{N} a_j^c{}' x_{ij} + \sum_{j=0}^{N} a_j^S{}' |x_{ij}| \geq y_i, i = 1,2,\ldots,M \tag{10d}$$

$$\lambda_i \leq 1, \; i=1,2,\ldots,M \tag{10e}$$

$$a_j^S{}' \geq 0, j = 0,1,\ldots,N_{NS} \tag{10f}$$

where d_0 represents the desired value of the objective function, p_0 is the tolerance of the desired lower bound and p_i is the width of the tolerance interval of y_i. $\bar{\lambda}$ is the arithmetic mean of all λ_i. The parameters p_0 and p_i are determined in a context-dependent way according to the decision maker's experience and knowledge. A very low value of the special λ_i

)

in a Peters' fuzzy linear regression model indicates that the corresponding data set y_i is far outside the interval and can be treated as an outlier. Therefore λ_i (i=1,2,…,M) can be employed to determine whether or not the ith data set is an outlier [11]. With a threshold value of λ_0, the y_i is defined as an outlier if $\lambda_i \le \lambda_0$ for i=1,2,…,M, and the outliers are removed one by one from the training data sets during the process of developing manufacturing process models. The pseudocode of the fuzzy regression is shown below:

Determine the values of d_0, p_0 and p_i;
Select an appropriate threshold value λ_0;
Solve the LP problem (10a)-(10f) using the 1-st to the M-th data sets;
While ($\min_{i=1,...M} \lambda_i \le \lambda_0$) **do {**
Solve the LP problem (10a)-(10f) using the 1-st to the M-th data sets excluding the k–th data set;
// where λ_k is the small one among all the λ_i with i=1, 2, …M;
Remove the k-th data set from the M data sets
M=M-1;
}
Return the final fuzzy coefficients

In the fuzzy regression, the first step is to determine the values of d_0, p_0 and p_i [19], which can be used to control the spread of the interval of the fuzzy regression model. A threshold value λ_0 is then defined as follows:

$$\lambda_0 = \frac{1}{2}\left(\max_{i=1,...,M} \lambda_i + \min_{i=1,...,M} \lambda_i\right) \qquad (11)$$

where $\max_{i=1,...,M} \lambda_i$ and $\min_{i=1,...,M} \lambda_i$ are calculated using all the data sets. In the while-loop of the fuzzy regression, all λ_i with i = 1,2, …M, are found by solving the linear programming problem (10a)-(10f). If all λ_i are larger than λ_0, the fuzzy coefficients are returned as the final solution, and the fuzzy regression is terminated. Otherwise, the LP problem (10a)-(10f) is solved by excluding the k-th data set, where λ_k are the smallest among all the λ_i with i=1,…M. The k-th data set is then removed from the M data sets, and the number of data sets becomes M-1. The operations in the while-loop continues until all λ_i with i=1,…M are larger than λ_0.

In the fuzzy regression, the dependent data belongs to a certain range based on the mechanism of Peters' fuzzy regression [19]. Outliers are compensated for by data that lies within the interval, and the estimated interval is determined by using all of the data rather than using only the "worst" data. Therefore a new variable is introduced to represent the degree to which the solution belongs to the set of "good solutions" (i.e. degree of membership).

Since some terms in (1) may be redundant, prudent selection of significant terms or orders is advisable if a more economical and adequate model is desired. In the intelligent fuzzy regression approach, genetic programming is used to generate the fuzzy regression model which consists of significant terms.

C. Pseudocode of Evolutionary Fuzzy Regression

Genetic programming is proposed to determine the structures of process models in the evolutionary fuzzy regression, and its pseudocode is shown as follows.

t=0
Initialize $\Omega(t)$=[$\theta_1(t)$, $\theta_2(t)$,… $\theta_{POP}(t)$]
Assign fuzzy coefficients to all $\theta_i(t)$
// $\Omega(t)$ is the population of the t-th generation.
// $\theta_i(t)$ is the i-th individual of $\Omega(t)$.
Evaluate all $\theta_i(t)$ according to a fitness function
while (termination condition not fulfilled) **do {**
Parent Selection $\Omega(t$+1)
Crossover $\Omega(t$+1)
Mutation $\Omega(t$+1)
Determine fuzzy coefficients in all $\theta_i(t$+1) by using
Fuzzy regression discussed in Section 2B
Evaluate all $\theta_i(t$+1)
$\Omega(t)$= $\Omega(t$+1)
t=t+1
}

The evolutionary fuzzy regression begins by creating a random initial population $\Omega(t)$ with POP individuals $\theta_i(t)$, while t=0. Each individual $\theta_i(t)$ is in the form of a tree structure [12, 13], which can be used to represent the structure of the manufacturing process model as defined in (4). Hierarchical trees are composed of functions F and terminals T [12, 13]. The manufacturing process model (4) contains only the three arithmetic operations, +, - and *, thus F is represented as F = {+, -, *}. The set of terminals is defined as T = { x_1, x_2, … x_N}. In the tree, operations from the function set F are used as internal nodes, and arguments from the terminal set T are used as terminal nodes. For example, a hierarchical tree can be expressed as:

(x_1*x_1) - (x_2*x_2) + $(x_1*x_2*x_4)$

which is equivalent to:

$x_1^2 - x_2^2 + x_1 x_2 x_4$

The fuzzy regression as described in Section IIB is used to assign the fuzzy coefficients to each individual $\theta_i(t)$. All individuals are evaluated according to a defined fitness function, which is aimed at evaluating the goodness-of-fitness of the manufacturing process model. The mean absolute error (MAE) of the *j-th* individual can be calculated based on (12).

$$MAE_j = 100\% \times \sqrt{\frac{1}{M}\sum_{k=1}^{M}\left|\frac{y_k - F_j(\mathbf{x_k})}{y_k}\right|}, \qquad (12)$$

where F_j is the fuzzy regression model represented by the *j-th* individual, $(y_k, \mathbf{x_k}) = (y_k, (x_{k1}, x_{k2}, ...x_{kN}))$ is the *k-th* training data set which excludes the outliers detected by the fuzzy regression, and M is the number of training data sets excluding the outliers used to develop the manufacturing process model.

(12) is commonly known as an indicator of training error in a model. It reflects how well the model fits the training data sets. However, a model may contain many unnecessary and complex terms. A complex over-parameterized model with a large number of parametrical terms reduces the transparency

and interpretation of the model. To prevent the evolutionary fuzzy regression from generating models that are too complex, a fitness function is designed to balance the trade-off between the reduction of complexity and the model accuracy. In this paper, penalty terms are introduced into the fitness function of the evolutionary fuzzy regressions [17]. The fitness of the *j-th* individual is denoted as follows:

$$fitness_j = \frac{1 - MAE_j}{\left(1 + \exp\left(c_1\left(L_j - c_2\right)\right)\right)} \quad (13)$$

where $fitness_j$ is the fitness value, L_j is the number of nodes of the *j-th* individual, and c_1 and c_2 are both penalty terms.

The parent selection process then uses the goodness-of-fitness of each individual to determine the selection of potential individuals to perform crossover or mutation. Finally, the new individuals with the determined fuzzy coefficients are evaluated using the fitness function to create a new population $\Omega(t+1)$. The process continues until the pre-defined termination condition has been fulfilled.

III. EVALUATION OF GENETIC FUZZY REGRESSION

In this section, the evaluation of the performance of the proposed evolutionary fuzzy regression is illustrated by modeling a fluid dispensing process [34] for the encapsulation of IC chips for electronic packages. The modeling results are compared with those based on Tanaka and Watada's fuzzy regression (FR-Tanaka) [43] and Peters' fuzzy regression (FR-Peters) [36]. All the algorithms, GP-FR, FR-Tanaka and FR-Peters were implemented using Matlab. The GP parameters in evolutionary fuzzy regression are shown as follows: population size =50; maximum number of evaluated individuals =5000; generation gap = 0.9; probability of crossover = 0.5; probability of mutation = 0.5.

Epoxy dispensing is a common process for performing the encapsulation of IC chips for electronic packages [15]. Modeling the epoxy dispensing process is critical to understanding the behavior of the process and to achieving optimization of the process. However, the epoxy dispensing process is difficult to characterize due to the complex behavior of the epoxy encapsulant and the existence of uncertainties inherent to epoxy dispensing systems [3, 5, 7]. In the following, the modeling of epoxy dispensing for IC chip encapsulation is described. In the epoxy dispensing machines for IC chip encapsulation, normally, silicon chips are covered using an X-Y numerically controlled dispensing system that delivers epoxy encapsulant through a needle by a pump. The material is commonly dispensed in a pattern, working from the center out. An epoxy dam around the die site and the second wire bond points can be made to contain the flow of material and produce a uniform-looking part as shown in Figure 1 in the appendix.

The epoxy dispenser consists of three essential parts, the syringe with epoxy, the time-pressure dispensing machine and the nozzle's head. The epoxy was injected from the syringe vertically by the time-pressure dispensing machine. The dropped epoxy paste was collected horizontally on the grinded plastic block. To minimize the discrepancies of the experiments, the vertical distance between the syringe and glass slides was kept identically at 1.5cm in all the experiments. The quality characteristic, encapsulation weight (mg), was investigated. The weights of the epoxy pastes were measured by a precise electronic weighing instrument.

With the assistance of the company supporting this research, three process parameters, which are significant to the encapsulation weight *y*, were identified as follows:

- the dispensing time (5s to 9s), x_1 , which is the duration of the air pressure controlled by the time-pressure dispensing machine;
- the compressed air pressure (0.4Mpa to 0.6Mpa), x_2 which is the amount of pressurized air compressed by the time-pressure dispensing machine; and
- the diameters of the nozzle head (0.61mm , 0.84 mm or 0.137 mm), x_3 .

Fifty-four experiments were carried out based on a 3^k full factorial design with 2. In the factorial design, 3 levels of dispensing time (x_1), 3 levels of compressed air pressure (x_2) and 3 levels of nozzle head diameters of (x_3) were adopted. Forty-eight out of the fifty-four experimental data sets and results were used to develop the process models of the epoxy dispensing process while the remaining seven were used to test the developed models. The outliers were included in all the training data sets. The 1st, 18th, 28th and 45th data sets were considered outliers in modeling the encapsulation weight. Both the training and testing data sets of the epoxy dispensing process are shown in Table 1 in the appendix.

Using the 47 training data sets for the encapsulation weight as shown in Table 4, the manufacturing process model for encapsulation weight as determined by FR-Tanaka is as follows:

$$y = (-0.70,-0.00) + (0.24,-0.00) \cdot x_1 + (0.03,0.16) \cdot x_2 + (0.63,0) \cdot x_3 \quad (14)$$

The manufacturing process model for encapsulation weight found by FR-Peters is as follows:

$$y = (-0.54, 0.15) + (0.20, 0.87) \cdot x_1 + (0.01,0.14) \cdot x_2 + (0.55,0.56) \cdot x_3 \quad (15)$$

Using the same experimental data sets shown in Table 4, the model for the encapsulation weight found by the GP-FR is shown as follows:

$$y = (-0.03,1.42) + (0.06, 0.01) \cdot x_1 \cdot x_2 \cdot x_3^4 \quad (16)$$

It can be found that only linear terms can be generated by the FR-Tanaka and FR-Peters, and the higher order and interaction terms of the process models can be generated by the proposed evolutionary fuzzy regression. Therefore nonlinearity can be addressed by the manufacturing process models generated the proposed evolutionary fuzzy regression. To evaluate the effectiveness of the three fuzzy regression methods, 6 validation tests were conducted. Tables 2 show the results of the validation tests yielded by the developed models for the epoxy dispensing process. From the table, it can be found that the smallest errors can be obtained by the proposed evolutionary fuzzy regression rather than the other two methods in all the validation tests of both models of the

encapsulation weight. In addition, the mean errors and variances of errors obtained by the evolutionary fuzzy regression are the smallest.

IV. CONCLUSION

In this paper, an evolutionary fuzzy regression approach which integrates the mechanisms of genetic programming and fuzzy regression is proposed for modeling manufacturing processes. The proposed evolutionary fuzzy regression intends to compensate the limitation of the traditional fuzzy regression which can only address linearity in manufacturing systems but cannot address nonlinearity. Apart from this, the proposed evolutionary fuzzy regression approach can also be used to detect outliers from data sets such that models with better capability of prediction can be developed. To evaluate the effectiveness of the proposed evolutionary fuzzy regression approach, the evolutionary fuzzy regression, FR-Tanaka and FR-Peters were all applied to model the epoxy-dispensing process in which outliers exist in the data sets. Modeling results based on the three approaches were compared. The results indicate that the smallest prediction errors and errors in variance can be achieved by evolutionary fuzzy regression than by the commonly used fuzzy regression methods, FR-Peters, and FR-Tanaka. The achievement of better results can be explained by the introduction of nonlinear terms in the manufacturing process models developed based on evolutionary fuzzy regression, and the exclusion of outliers.

***Abstract*—This paper introduces an abstract model of heuristic search for handling uncertainty. In the search, heuristic information and evaluation are precisely defined mathematically. As special cases, the model includes a previous probabilistic game-tree search and a pattern search. This paper also considers the relationship between the model and the rough set approach. Each rough set formulation can be reformulated as a special case of the abstract model.**

***Index Terms*—Heuristic information, game-tree search, pattern recognition, tolerance relation, tolerance representative, rough set.**

I. Introduction

This paper reports a preliminary result of a recent study on uncertainty based on probability theory. The study of uncertainty often includes search and evaluation([7]). For the evaluation, the information returned by the search usually is incomplete. In this paper, the incomplete information is called heuristic information and the corresponding search is called a heuristic search. This paper introduces an abstract model of heuristic search. Special cases include a probabilistic game-tree search and a pattern search in a pattern recognition. This paper also considers the relationship between the abstract model and the rough set approach in handling uncertainty.

The rough set approach ([8]) of handling uncertainty can be interpreted as a task of classifying some objects in a universe of discourse, denoted by U. The information for U is usually provided by a set of attributes. An indiscernibility relation R is an equivalent relation on U, which is usually defined by a subset of attributes. Each R-equivalent class $[x]_R$ is an R-exact elementary set. Any subset $Y \subseteq U$ is R-exact if it is a union of R-exact elementary sets. Any subset $X \subseteq U$ which is not R-exact is R-rough. The R-lower and R-upper approximation of X are defined, respectively, as follows:

$$\begin{aligned} \underline{R}X &= \{\omega \in \Omega \mid [\omega]_R \subseteq X\}. \\ \overline{R}X &= \{\omega \in \Omega \mid [\omega]_R \cap X \neq \emptyset\}. \end{aligned}$$

The rough set is extended by use of a tolerance relation instead of an equivalent relation ([9]). A tolerance relation ([19]) is a reflexive and transitive binary relation on U.

For a game-tree search, the goal is to estimate the game values at certain nodes of the game tree. The information provided by a search is usually incomplete to determine the game values. Intuitively, a deeper search returns more precise information and the decision can be improved. However, there is a pathological phenomenon ([6]), in which the minimax algorithm may degrade the information provided by a static evaluation in a deeper search.

A probabilistic formulation of heuristic information in game-tree search has been introduced ([11], [12]). The goal of the game search is to estimate the game values at a certain nodes for a given game $\omega \in \Omega$. The set Ω of all possible games is a probability space. Let M be one of the game values, which is a random variable. A search returns a piece of information about ω, which is a subset X ($\subset \Omega$) containing ω. The theoretical evaluation of M is the conditional expectation $E_X(M)$. A deeper search returns more precise information about ω, which corresponds to a more accurate estimation of M. The actual algorithm depends on each individual game structure. The minimax algorithm does not compute $M_X(M)$ in general, even if M is the minimax value of a node.

Uncertain information also appears in a pattern recognition, which is to classify certain objects. For a given element ω, a two-class recognition problem can be formulated as a determination of the predicate $\omega \in X$, where X is the set of all elements of one class.

The classical probabilistic formulation of pattern recognition on a Euclidean space $\Re^n$ ([3]) is extended to general probability spaces ([14], [15], [16]). This approach uses a tolerance relation as a similarity. The heuristic information is generated by a non-crispy ([18]) representative data clustering which is defined by a set of representative elements. The cluster of a representative is the set of all similar elements to the representative. A conditional probability given a piece of heuristic information is used to estimate the pattern of the given element.

This paper introduces a general abstract model for heuristic search based on probability theory. A search task consists of a probability space $(\Omega, \mu, \mathcal{F})$ and a random variable M. The goal is to approximate the random variable M. A heuristic search is to find heuristic information I about a given element ω. The heuristic information I is a measurable set containing ω: $\omega \in I$. The set of all such possible I's forms a partition of Ω. The partition generates a Borel subfield $F \subseteq \mathcal{F}$. The evaluation of M is the conditional expectation $E_F(M)$.

The heuristic game-tree search and the pattern recognition mentioned above are special cases of this abstract model. Each rough set formulation can also be formulated in a special heuristic search model.

The rest of this paper is organized as follows: Section 2 defines the abstract heuristic search model, using a game-tree search as an example. Section 3 discusses the relationship between this model and the rough set approach. Section 4 introduces a pattern recognition model by use of representative data clustering. Section 5 considers an example. The rough set properties in a representative data clustering are computed for different similarities in this section. Section 6 is the conclusion.

II. Heuristic Information and Evaluation

Based on probability theory, this section introduces a mathematical model for heuristic information and heuristic search. The heuristic information in a game-tree search ([11], [12]) and the heuristic search by use of representative coverings ([16]) are special cases.

Definition 2.1. A *search model* is a probability space with a random variable, denoted by $(\Omega, \mathcal{F}, \mu, M)$, where Ω is a sample space of all possible elements, $\mathcal{F}$ is a Borel field on Ω, μ is a probability measure on $\mathcal{F}$, and M is a random variable of the probability space $(\Omega, \mathcal{F}, \mu)$.

For simplicity, we assume that Ω is a finite set. Let $F \subseteq \mathcal{F}$ be any Borel subfield. A non-empty set $A \in F$ is F-minimal if there is no non-empty F-measurable set properly contained in A. Suppose that $P_F = \{I_1, .., I_n\}$ consists of all F-minimal sets. Then P_F forms a partition of Ω and any F-measurable set is a union of F-minimal sets.

Definition 2.2. A *heuristic search* of a search model $(\Omega, \mathcal{F}, \mu, M)$, is a pair (F, f) where F is a Borel subfield $F \subseteq \mathcal{F}$ and f is a function on Ω. For any given element $\omega \in \Omega$, f returns the F-minimal set I containing ω: $\omega \in I$. The function f is the *heuristic search function* and I is the *heuristic information* about the element ω.

In a heuristic search, we consider an evaluation of the random variable M.

Definition 2.3. The estimator of M, based on the heuristic search $S = (F, f)$, is the conditional expectation M_S of M with respective to F:

$$M_S = E_F(M). \tag{1}$$

The estimator is also a random variable. For any $\omega \in \Omega$, let $I = f(\omega)$, the heuristic information about ω. Then $M_S(\omega)$ is the conditional expectation of M relative to I:

$$M_S(\omega) = E_I(M) = \frac{1}{\mu(I)} \int_I M d\mu. \tag{2}$$

That is, M_S has a constant value in I, which is the average of M. Here we assume I has a positive measure.

Let $P_F = \{I_i \mid i = 1, ..., n\}$ be the partition corresponding to the heuristic search S. Then M_S is a linear combination:

$$M_S = \sum_i E_{I_i}(M) \mathbf{1}_{I_i}, \tag{3}$$

where $\mathbf{1}_{I_i}$ is the indicator function of I_i: $\mathbf{1}_{I_i}(\omega) = 1$ if $\omega \in I_i$, 0 otherwise.

Consider two heuristic searches $S_1 = (F_1, f_1)$ and $S_2 = (F_2, f_2)$. If F_1 is a subfield of F_2: $F_1 \subset F_2$, then we say that S_2 is *more precise* than S_1. In this case, each F_1-minimal set is a union of F_2-minimal sets. The corresponding estimators have the following property([2]).

Theorem 2.1. If S_2 is more precise than S_1, then the estimator M_{S_1} is also an estimator of M_{S_2}:

$$M_{S_1} = (M_{S_2})_{S_1}. \tag{4}$$

In each F_1-minimal set, the value of M_{S_1} is the average of M_{S_2}. That is, M_{S_2} is more accurate than M_{S_1} in estimating M.

To illustrate the idea of the heuristic information formulation, we consider a uniform binary game tree of four levels([11], [12]), where each terminal node has independently the value 1 (a win for MAX) or 0 (a loss for MAX) with a probability p $(0 < p < 1)$ and $1 - p$, respectively. The space $\Omega = \{0, 1\}^8$ of all leaf patterns forms a probability space. The game value at each internal node is the minimax value at that node, which is a random variable. We consider the task of estimating the minimax value at the root, denoted by M. Then the probability space Ω and M form a search model.

We consider two searches. First, consider the heuristic searches $S_1 = (F_1, f_1)$ where the function f_1 counts the number of 1's at the leaves under the root. The corresponding partition of F_1 consists of 9 members: $I_k = \{(x_1, .., x_8) \in \Omega \mid \sum_1^8 x_i = k\}$, $k = 0, 1, ..., 8$. For a given game $x' = (x'_1, .., x'_8)$, the heuristic information is I_k, where $k = \sum_1^8 x'_i$, based on which the estimation of M is the conditional probability:

$$M_{F_1}(x') = P(M = 1 \mid x' \in I_k).$$

The second heuristic search is $S_2 = (F_2, f_2)$. The function f_2 counts the numbers of 1's at the leaves under each of the two nodes of level 2. The Borel field F_2 is generated by the partition consisting of following 25 sets:

$$I_{ij} = \{(x_1, .., x_8) \in \Omega \mid \sum_1^4 x_k = i, \sum_5^8 x_k = j\}, 0 \le i, j \le 4.$$

For the given game $x' = (x'_1, .., x'_8)$, the heuristic information is I_{ij}, where $i = \sum_1^4 x'_k$ and $j = \sum_5^8 x'_j$, based on which the estimation of M is

$$M_{F_2}(x') = P(M = 1 \mid x' \in I_{ij}).$$

The search S_2 is more precise than S_1 because $I_k = \cup_{i+j=k} I_{ij}$ for each I_k in F_1. The both estimators have the following relation:

$$P(M = 1 \mid x' \in I_k) = \sum_{i+j=k} \mu(I_{ij}) P(M = 1 \mid x' \in I_{ij}).$$

III. Heuristic Search and Rough Set

This section shows that in a heuristic search any measurable set of probability space may be treated as a rough set ([8], [9]) . And each rough set formulation can be reformulated as a heuristic search.

Suppose that X is a measurable set in a given a probability space $(\Omega, \mathcal{F}, \mu)$. Let $M = \mathbf{1}_X$, the indicator of X, which is a random variable because X is measurable. Let $S = (F, f)$ be a heuristic search for the search model $(\Omega, \mathcal{F}, \mu, M)$. Consider the corresponding partition of Ω: $P_F = \{I_1, .., I_n\}$, which consists of all F-minimal sets. The partition defines an indiscernibility relation (also denoted by F) in the rough set terminology ([8], [9]), : two elements ω_1 and ω_2 are indiscernible if $f(\omega_1) = f(\omega_2)$; that is, for the two elements, the heuristic search returns the same heuristic information I_i: $\omega_1 \in I_i$ and $\omega_2 \in I_i$. Based on this indiscernibility relation, all F-exact elementary sets are those I_i's in P_F. The F-lower and F-upper approximations of X are, respectively,

$$\underline{F}X = \{\omega \in \Omega \mid M_F(\omega) = 1\} \tag{5}$$

$$\overline{F}X = \{\omega \in \Omega \mid M_F(\omega) > 0\} \tag{6}$$

That is, $\underline{F}X$ consists of all F-minimal sets contained in X and $\overline{F}X$ consists of all F-minimal sets which has a non-empty intersection with X and the intersection has a positive measure. If $\underline{F}X = \overline{F}X$, then X is F-exact. Any member in the Borel field F is F-exact.

Conversely, each rough set formulation ([8], [9]) can be treated as a special heuristic search. In a rough set formulation, let Ω be the universe of objects and R the equivalence relation on Ω. The R-exact elementary sets are the R-equivalence classes $[x]_R$, $x \in \Omega$. Any union of R-exact elementary sets is R-exact. Any set $X \subseteq \Omega$ which is not R-exact is R-rough. The lower and upper approximation of X are defined, respectively, as follows:

$$\underline{R}X = \{\omega \in \Omega \mid [\omega]_R \subseteq X\} \tag{7}$$

$$\overline{R}X = \{\omega \in \Omega \mid [\omega]_R \cap X \neq \emptyset\} \tag{8}$$

Consider the universe of objects (i.e., Ω) as a probability space, where the Borel field $\mathcal{F}$ is the set of all subsets of Ω and each object $\omega \in \Omega$ is measurable and has the same probability measure $\mu(\omega) = \frac{1}{|\Omega|}$. Then the indicator $M = \mathbf{1}_X$ of X is a random variable. For the search model $(\omega, \mathcal{F}, \mu, M)$, we consider the following heuristic search. Let F be the Borel field generated by the R-exact elementary sets. That is, the F-minimal sets are the R-exact elementary sets and the members of F are R-exact. The function $f(\omega) = [\omega]_R$ is a heuristic function. The lower and upper approximation of X are, respectively, $\underline{F}X = \{\omega \in \Omega \mid M_F(\omega) = 1\}$ and $\overline{F}X = \{\omega \in \Omega \mid M_F(\omega) > 0\}$. The estimator M_F at an element ω is the conditional probability $M_F(\omega) = P(\omega \in X \mid \omega \in [\omega]_R)$; that is, it is the rough membership function defined in ([9]):

$$M_F(\omega) = \mu(\omega, X) = \frac{|[\omega]_R \cap X|}{|[\omega]_R|}.$$

Therefore each rough set formulation is a special heuristic search for a search model.

IV. Heuristic Search Using Representatives

This section introduces a heuristic information computed by comparing an element with representatives. First, we consider a pattern recognition model on a probability space $(\Omega, \mathcal{F}, \mu)$, ([14], [15], [16]), which is an extension of the classical model ([3]).

A. Pattern Recognition and Classifiers

Pattern recognition is about guessing or predicting the unknown nature of an observation. Formally, we use ω to denote an observation and Ω to denote the space of all possible observations. For simplicity, we considers only two classes (e.g., normal and anomaly), denoted by 0 and 1.

We assume the observation is probabilistic. Consider the probability space $(\Omega, \mathcal{F}, \mu)$. Let (X, Y) be a random pair taking their respective values from Ω and $\{0, 1\}$. The random pair is defined by a pair (μ, η), where μ is the probability measure of X and η is the posterior probability, given the value of X. That is, for any $A \in \mathcal{F}$, $P(X \in A) = \mu(A)$, and for any $\omega \in \Omega$, $\eta(\omega) = P(Y = 1 \mid X \in [\omega]_{\mathcal{F}})$, where $[\omega]_{\mathcal{F}}$ is the $\mathcal{F}$-minimal set containing ω. Note that η is measurable (relative to $\mathcal{F}$) and the 4-tuple $(\Omega, \mathcal{F}, \mu, \eta)$ forms a search model defined in Section 1.

In pattern recognition, one creates a classifier $g : \Omega \to \{0, 1\}$ to represent one's guess of y, the class of a given observation ω. The classifier errs on ω when $g(\omega) \neq y$. We only consider measurable classifiers, which always assign indistinguishable observations (i.e., elements in the same $\mathcal{F}$-minimal set) to a same class.

Definition 4.1. A classifier on the search model $(\Omega, \mathcal{F}, \mu, \eta)$ is an F-measurable function $g : \Omega \to \{0, 1\}$, where $\{0, 1\}$ is treated as a discrete space.

The probability of error $L(g) = P(g(X) \neq Y)$ is the *error rate* of g:

$$L(g) = P(g(X) \neq Y) = \int_{\Omega} P(g(X) \neq Y | X \in [\omega]_{\mathcal{F}}) d\mu(\omega). \tag{9}$$

The *false positive rate* $L^{(0)}(g)$ and the *false negative rate* $L^{(1)}(g)$ are

$$L^{(0)}(g) = P(g(X) = 1 | Y = 0), \tag{10}$$

and

$$L^{(1)}(g) = P(g(X) = 0 | Y = 1). \tag{11}$$

The relation among the three types of error is

$$L(g) = L^{(0)}(g)P(Y = 0) + L^{(1)}(g)P(Y = 1).$$

Let $0 \leq \theta < 1$. The classifier g_θ is defined as follows

$$g_\theta(\omega) = \begin{cases} 1 \text{ if } \eta(\omega) > \theta, \\ 0 \text{ otherwise.} \end{cases} \tag{12}$$

Note that, if $\eta(\omega) \in \{0, 1\}$, then $L(g_\theta) = L^{(0)}(g_\theta) = L^{(1)}(g_\theta) = 0$ for $0 < \theta < 1$. The classifier $g_{0.5}$ is the *Bayes classifier* and $L(g_{0.5})$ is the *Bayes Error*. Similarly to the classical theory [3], we have following theorems.

Theorem 4.1. (Bayes) For any classifier g, $L(g_{0.5}) \leq L(g)$.

Theorem 4.2. (Neyman-Pearson) For any classifier g and θ $(0 < \theta < 1)$, if $L^{(0)}(g) \leq L^{(0)}(g_\theta)$, then $L^{(1)}(g) \geq L^{(1)}(g_\theta)$.

The Bayes classifier is an optimal classifier if we are required to minimize the error rate. If the false positive rate $L^{(0)}$ is required to be kept under a certain level, then g_θ minimizes the false negative rate $L^{(1)}$ for some θ.

B. Representative data clustering and heuristic information

First we consider a tolerance relation ξ on the search model $(\Omega, \mathcal{F}, \mu, \eta)$, which is a reflexive and symmetric binary relation; that is, $(\omega, \omega) \in \xi$ for any $\omega \in \Omega$, and $(\omega_1, \omega_2) \in \xi$ implies $(\omega_2, \omega_1) \in \xi$. A space with a tolerance relation is called a tolerance space.

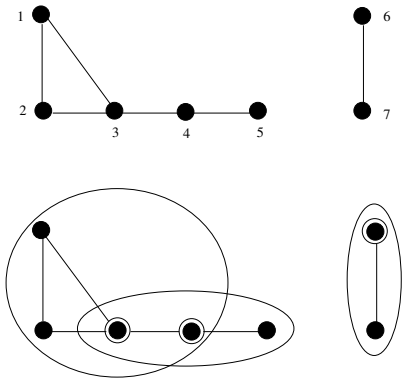

Fig. 1. A tolerance space and a minimal representative clustering.

We also use ξ as a predicate: $\xi(\omega_1, \omega_2)$ iff $(\omega_1, \omega_2) \in \xi$. If $\xi(\omega_1, \omega_2)$, we say that ω_1 is ξ-similar to ω_2, or ω_1 and ω_2 are ξ-similar. We may omit ξ when there is no ambiguity. Any undirected graph is a tolerance space (and vice versa), where Ω is the set of all vertices, and two vertices are similar if they are the same vertex or they are adjacent (e.g., Fig. 1).

For each $\omega \in \Omega$, the set $\xi(\omega) = \{u \in \Omega \mid \xi(\omega, u)\}$ is called the neighborhood of ω. Here we assume that each neighborhood is measurable (i.e., an element of $\mathcal{F}$). We consider a data clustering of the search model by use of the neighborhoods (e.g., [13], [15], [16]). Each $\omega \in \Omega$ is called a *representative* of its neighborhood $\xi(\omega)$. A set of elements $\{r_1, ..., r_k\}$ is a representative system of Ω if the corresponding neighborhoods cover the whole space Ω . The representative system is minimal ([4], [10]) if there is no other representative system with less than k members.

A representative system forms a clustering of Ω, in which the clusters are the corresponding neighborhoods. Note that each cluster is measurable. We call such a clustering a representative clustering. The clustering is in general not a partition (e.g., Fig. 1).

An element $\omega \in \Omega$ is called a *surprise* ([15], [16]) if ω is not similar to any other element in Ω; that is, $\xi(\omega) = \{\omega\}$. Therefore, each surprise is always in any representative system. Let the numbers of the surprises be denoted by α_ξ, which is independent of the choice of representative systems. The similarity ξ does not provide any pattern about surprises. In application, searching a similarity should eliminate or reduce the number of surprises.

Let $\mathbf{R}_\xi = \{r_1, ..., r_k\}$ be a minimal representative system. Let the neighborhoods of r_i's generate the Borel subfield D $(D \subseteq \mathcal{F})$, and the corresponding partition be $P_D = \{A_i \mid i = 1, ..., n\}$. For example, in Fig. 1 there are three representatives and the corresponding partition is $\{\{1, 2\}, \{3, 4\}, \{5\}, \{6, 7\}\}$. For an $\omega \in \Omega$, the member A_i containing ω, denoted by $f(\omega)$, is computed as follows. We compare ω with the k representatives. Let S_ω be the set of all representatives similar to ω and $N_\omega = \mathbf{R}_\xi - S_\omega$. Then

$$f(\omega) = A_i = \cap_{r \in S_\omega} \xi(r) - \cup_{r \in N_\omega} \xi(r). \tag{13}$$

The pair $S = (D, f)$ is a heuristic search for the search model $(\Omega, \mathcal{F}, \mu, \eta)$. The estimator of η is $\eta_D = E(\eta|D)$. Given ω, $\eta_D(\omega)$ is the conditional probability:

$$\eta_D(\omega) = \frac{1}{\mu(A_i)} \int_{A_i} \eta(t) d\mu(t) = P(Y = 1 | X \in A_i). \tag{14}$$

We define classifiers based on the heuristic search $S = (D, f)$. A *D-classifier* is a D-measurable function $g^D : \Omega \longrightarrow \{0, 1\}$. Note that g^D is constant on each A_i. As in Section 1, any *D-classifier* g^D is a linear combination of the indicators $\mathbf{1}_{A_i}$'s. Any D-classifier is also $\mathcal{F}$-measurable and hence a classifier on the search model $(\Omega, \mathcal{F}, \mu, \eta)$, but not vice versa.

For D-classifiers, we have following similar definitions and properties. The D-classifier $g^D_\theta = 1$ iff $\eta_D(x) > \theta$, $0 \leq \theta < 1$. The Bayes D-classifier $g^D_{0.5}$ minimizes the error rate of all $\mathcal{D}$-classifiers. The Neyman-Pearson Theorem is also true; that is, for any D-classifier g^D, if $L^{(0)}(g^D) \leq L^{(0)}(g^D_\theta)$, then $L^{(1)}(g^D) \geq L^{(1)}(g^D_\theta)$. Since the Bayes classifier $g_{0.5}$ minimizes the error rate, $L(g^D_{0.5}) \geq L(g_{0.5})$.

To search for a minimal representative system is intractable in general. A heuristic method to search for sub-minimal representative system has been introduced ([13], [14]).

C. Application in Supervised Learning

This subsection briefly summarizes an application of heuristic search in a supervised learning, which has been introduced in ([16]). Suppose a supervised learning process consists of two sets: a training data set and a testing data set. The goal of the process is to classify each element in the testing data set. We assume that there are two classes, 0 and 1. We treat the training data set as the space Ω. We assign each element in Ω the same probability measure $\frac{1}{|\Omega|}$ if there is no previously given probability. From the given class label in the training data set, the posterior probability η can be computed. That is, we formulate the training data set into a search model $(\Omega, \mathcal{F}, \mu, \eta)$, where $\mathcal{F}$ is the Borel field corresponding to the probability measure.

The training process is to search for a suitable similarity ξ (i.e., a tolerance relation) and to compute a sub-minimal representative system $\mathbf{R}_\xi$, which defines a heuristic search $S = (D, f)$. Based on $\mathbf{R}_\xi$ the estimator η_D is computed. Then the classifier g^D_θ $(0 \leq \theta < 1)$ is defined by use of η_D.

For each element ω in the testing data set, the heuristic information about ω in the training data set is computed by comparing ω with the representatives, as discussed above. Then we use the value of η_D on the searched heuristic information as an evaluation of the element: $\eta_D(\omega)$. Based on this evaluation, each classifier g_θ^D is extended to the testing data set. If ω is an unknown surprise (i.e, not similar to any representative), then the evaluation is not defined. In this case, ω may be evaluated by the distribution of surprises in the training data set.

The training result can be studied by use of different type of errors and the receiver operating characteristic analysis ([5]). In the training process, the Bayes error $L(g_{0.5}^D)$ should be as near to the original Bayes error $L(g_{0.5})$ as possible. To be a typical pattern, each representative should be similar to as many records as possible because surprising elements predict existence of unknown surprises in the testing data set which are not similar to any representatives. There is no heuristic information for the unknown surprise. One the other hand, for the computational purpose, the number of representatives should be small relative to the training data set size $|\Omega|$.

V. Examples

The section uses the Breast Cancer Wisconsin (Original) Data Set ([1], [17]) as an example data set. The data set consists of 699 Instances. The instances have 10 attributes and a class attribute. Except the first attribute which is the sample code number, there are 9 attributes to consider for a pattern search task. The domain for the attributes are integers from 1 to 10. There are few instances that contain a single missing (i.e., unavailable) attribute value. For the class attribue, there are two classes: 2 for benign and 4 for malignant. There are 458 benign instances and 241 malignant instances. Let X be the set of malignant instances. We consider the approximations of X in the rough set terminology by use of representative clusterings.

Let $(x_1^\omega, ..., x_9^\omega)$ represent the 9 attributes of an instance ω. We consider three different kinds of similarities. In the following we assume that $|x_i^{\omega_1} - x_i^{\omega_2}| = 5$ if one of the values is missing.

The first similarity is:

$$\xi_1(\omega_1, \omega_2) \text{ if } |x_i^{\omega_1} - x_i^{\omega_2}| \leq 3, \quad i = 1, ..., 9. \tag{15}$$

That is, for two instances if the difference of each attribute values is less than or equal to 3, then they are ξ_1-similar.

The second one is:

$$\xi_2(\omega_1, \omega_2) \text{ if } |x_i^{\omega_1} - x_i^{\omega_2}| \leq 2 \text{ for a least } 8 \text{ attributes.}$$

That is, ω_1 and ω_2 are ξ_2-similar if there are 8 attributes for which the differences are less than or equal to 2.

The third one is:

$$\xi_2(\omega_1, \omega_2) \text{ if } \sum_{i=1}^{9} |x_i^{\omega_1} - x_i^{\omega_2}| \leq 15. \tag{16}$$

That is, ω_1 and ω_2 are ξ_3-similar if the sum of of all differences is less than or equal to 15.

TABLE I
Summaries of the examples

	$\lvert\mathbf{R}_\xi\rvert$	α_ξ	$\lvert\mathbf{P}_\xi\rvert$	$\lvert L_\xi\rvert$	$\lvert\mathbf{B}_\xi\rvert$	b_ξ	m_ξ	B-error
ξ_1	97	36	229	167	7	20	10	0.0114
ξ_2	66	12	224	185	5	9	6	0.0027
ξ_3	32	3	176	153	10	59	24	0.0172

For each similarity ξ, we compute a sub-minimal representative system $\mathbf{R}_\xi$ and the corresponding partitions $\mathbf{P}_\xi$. The number of surprises is α_ξ. The set of the exact elementary sets in the lower approximation of X is represented by L_ξ. The set of boundary exact elementary sets is denoted by $\mathbf{B}_\xi$. A boundary exact elementary set is an exact elementary set which is in the upper approximation but not in the lower approximation. Let b_ξ and m_ξ be the numbers of benign and malignant instances in the boundary, respectively.

The results are summarized in the Table 1, where B-error represents the Bayes error. For example, in the first similarity ξ_1, there are 97 representatives, 229 exact elementary sets. There are 10 malignant instances in the boundary; that is 231 malignant instances are in the lower approximation of X. The similarity ξ_2 gives a better result, where 235 malignant instances are in the lower approximation of X and there are only 15 (i.e., $9+6$) instances in the boundary. The Bayes error is 0.0027.

VI. Conclusion

This paper introduces an abstract model of heuristic search based on probability. Both the previous probabilistic game-tree search and the pattern search are special cases of the abstract model. Each rough set formulation can also be reformulated as a special case of the abstract model. Further research on the abstract model is needed in order to understand more about the theoretical properties of heuristic search and heuristic information.

***Abstract*—Previously, we introduced a novel method to estimate adult skeletal age-at-death using the Sugeno fuzzy integral (FI). Specifically, we took a multi-hypothesis testing approach to make the classical FI yield a fuzzy set (FS)-valued result, which is not guaranteed to be normal or convex, based on interval-valued sources of information (aging methods). We showed quantitative results for summarizing the FS and comparing the single decision to a known age-at-death. In this article, we extend our prior work and present formulas to measure the uncertainty in the resultant FSs. We generate linguistic descriptions to establish domain standardization for the goal of assisting forensic and biological anthropologists. Specifically, we introduce fuzzy class definitions for age-at-death FSs and we present an OWA contrast approach to measure the degree of specificity in age-at-death FSs.**

Keywords; Sugeno fuzzy integral; linguisitic description; skeletal age-at-death; anthropology

I. INTRODUCTION

Age-at-death estimation of an individual skeleton is important to forensic and biological anthropologists for identification and demographic analysis. It has been shown that current individual aging methods are often unreliable because of skeletal variation and taphonomic factors. In [1], we demonstrated that the fuzzy integral (FI) can be used for age-at-death estimation. Our algorithm produces a decision regarding age-at-death using multiple interval-valued aging methods while taking into account the numeric accuracies of the methods and the condition of the bone being examined. Advantages of this FI approach are that it does not require a population, it can (quantitatively) produce a single age-at-death estimate and it (qualitative) produces a fuzzy set (FS).

Forensic and biological anthropology is rooted heavily in definitions, methods and standardization. It is important that techniques are well established and that their findings be reproducible and understandable by different scientists. Our prior work is based on a set of accepted aging methods, their documented reliabilities and the weathering or quality of the skeletal remains. However, while our quantitative procedure is well established in [1], the qualitative component, i.e. interpretation of the FSs, is currently based on a set of crisp rules. Herein, we assert that the (linguistic) anthropological desired results are not crisp but instead fuzzy. Therefore, we require a mathematical (fuzzy) way to model these concepts and their associated uncertainties. We focus on the FSs and we introduce a systematic way to interpret the discoveries.

This article is important to anthropology because it makes the qualitative FS analysis procedure explicit and researchers can therefore better understand how to interpret results acquired from different investigators on different types of skeletal remains. This article is important to the FS community because it demonstrates a real-world application of the classical number-valued FI to construct (potentially non-normal and non-convex) FSs. In addition, we present a feature-based method to determine different age-at-death FS anthropological classes and the degree of FS specificity. This work is a case in which it is useful to maintain as much uncertainty as possible throughout the entire analysis procedure, exemplifying Marr's Principle of Least Commitment [2]. That is, one should not stop with the production of a single quantitative result. Instead, we show that it is possible to generate linguistic descriptions of FSs, and that analysis of this information results in different knowledge than what the quantitative approach yields.

II. BACKGROUND

A. Related Work in the FS Community

In [1], we show how the classical FI with a number-valued integrand and number-valued fuzzy measure (FM) can be used to produce FS-valued results based on interval-valued sources of information. Our approach, which is summarized later in this article, is one of multiple hypotheses testing. Grabisch et al. [3] previously demonstrated a *literal* extension of the number-valued FI to FS-valued integrands and number-valued FMs. Grabisch's FI, for a FS-valued integrand and number-valued FM, is comprised of a series of interval-valued integrand and number-valued FM calculations (based on the work of Dubois [4]), which in return is decomposed into the classical FI for a number-valued integrand and FM. While it might initially appear to be possible to cast our anthropological problem into one of a FI with a FS-valued integrand and number-valued measure, the problem is that Grabisch's approach requires that the FSs be normal and convex. As we discuss later, while our FSs are usually convex they are generally not normal.

[1]Todd 1920 [2]Lovejoy et al. 1985b [3]Meindl and Lovejoy 1985

Yager and Klir [5, 6], to name two, have previously presented various specificity measures for FSs. To the best of our knowledge, our approach to linguistically measuring the specificity of an age-at-death FS, based on the OWA [7] and contrast in different regions of a FS is new.

B. *Aging Methods*

Forensic investigators rely on the accuracy of age indicators for personal identification purposes, whereas biological anthropologists generally have a broader area of applicability for accurate age estimation, such as paleodemographic studies [8]. In general, all skeletal remains are not guaranteed to be present in a forensic case. Different aging methods have been established in the field in order to approximate age-at-death based on the analysis of different skeletal remains. The aging methods used in our prior work and herein include the pubic symphysis morphology [9], auricular surface morphology [10], and ectocranial suture closure [11] used for adult age estimation. The intervals that these techniques produce are shown in table 1. For the methods used here, researchers compare the skeletal remains to a discrete set of stages, or use a composite score and lookup the age-range (interval) in a table.

C. *Uncertainity in Age-at-Death Estimation and Prior Work*

It is well known that there is uncertainty in age-at-death estimation [12, 13, 14, 15]. Causes of uncertainty come from actual death age, the amount of exposure to various unknown elements, and cause and timing of death. Even more specifically, we know: (1) skeletally immature and young adult individuals are likely to be aged more precisely than older adult individuals, (2) bones are in a continual process of change, usually degenerative and influenced by the habitual activities and health of the individual as well as the age of the individual, (3) skeletal age assessment produces (crisp) age ranges instead of a specific age or fuzzy intervals, and (4) aging methods have varying accuracies.

Due to the inherent uncertainty in this domain, some have developed procedures to aggregate information acquired from multiple aging methods in order to improve age-a-death estimation. Prior approaches in the field are all statistical and are generally based on populations. Existing multifactorial aging methods include Acsádi and Nemeskéri, [16]; Lovejoy et al. [17]; Boldsen et al. [18]. Our method, [1], however can incorporate more information. In addition to the (objective) strength in a hypothesis, we also take into account the variable (subjective) accuracies associated with each method and the weathering or quality of remains.

D. *Accuracy and Quality Indicies*

Because of the various stated uncertainties, it is important to include as much known or observable information as possible about the skeleton so that all factors available can be taken into consideration when determining skeletal age-at-death. The accuracy of the methods and condition or quality of the skeleton becomes important because they are related to the overall assessment of the skeleton.

Accuracy index. Accuracy in age estimation is defined as how well the estimated or biological age conforms to the real chronological age, and relies on how strongly correlated the biological and chronological ages are to each other. We use the correlation coefficient of the chronological and biological age indicator that is associated with each adult aging method (Katz and Suchey [18]; Meindl and Lovejoy [11]; Meindl et al. [15]).

Quality. Bone quality is an additional piece of information that can be taken into consideration when analyzing a skeleton. Because the condition of the skeleton is dependent on environmental factors, the quality of a skeleton affects determining age-at-death. Previously, we evaluated and scored the bone quality using a modified version of Behrensmeyer [19] weathering stages provided in Standards [20], but with a stage 6 added to take into account the absence of an age indicator. Quality values are assigned, based on the weathering stages, and are associated specifically with the part of the skeleton for which the aging methods are being applied. If the bone is deteriorated but can still be used, the aging method will still be applied but the decision reached will respectively be associated with a lower support value. The quality indices are ordinal and arbitrarily assigned values. They must be decreasing values and no greater than one and no less than 0. They were assigned in this manner to indicate the least weathering as producing the best results (1) and the most weathering as producing poor or no results (0). A score of 0 is assigned if the bone is not present. Previously, we assigned Stage 0 a quality value of 1.0, Stage 1 a value of 0.8, Stage 2 is 0.6, Stage 3 is 0.4, Stage 4 is 0.2, Stage 5 is 0.1, and Stage 6 is 0. However, the data used in this study were collected on museum specimens and therefore the quality index does not vary considerably.

E. Sugeno Fuzzy Integral

The fusion of information using the fuzzy integral (Sugeno or Choquet) has a rich history. Much of the theory and several applications can be found in [21, 3, 22]. With respect to this problem, we consider a finite set of sources of information, $X = \{x_1, x_2, \cdots, x_E\}$ and a function that maps X into some domain (initially [0,1]) that represents the partial support of a hypothesis from the standpoint of each source of information. Depending on the problem domain, X can be a set of experts, sensors, features, pattern recognition algorithms, etc. The hypothesis is usually thought of as an alternative in a decision process or a class label in pattern recognition. Both Sugeno and Choquet integrals take partial support for the hypothesis from the standpoint of each source of information and fuse it with the (perhaps subjective) worth of each subset of X in a non-linear fashion. This worth is encoded into a fuzzy measure [23]. Initially, the function $h: X \to [0,1]$, and the measure $g: 2^X \to [0,1]$ take real number values in [0,1]. Certainly, the output range for both function and measure can be (and have been) defined more generally, but it is convenient to think of them in the unit interval for confidence fusion.

More formally, for a finite set $X = \{x_1, x_2, \cdots, x_E\}$, a (numeric) fuzzy measure is a function $g: 2^X \to [0,1]$, (a real valued set function) such that

1. $g(\phi) = 0$ and $g(X) = 1$;
2. If $A, B \subseteq X$ with $A \subseteq B$, then $g(A) \leq g(B)$.

Note that if X is an infinite set, a third condition guaranteeing continuity is required, but it is a moot point for finite X. In this article, we use the Sugeno λ-fuzzy measure [23]. The Sugeno λ-fuzzy measure builds the measure, all 2^N-1 values, given a set of densities (the measure for all singletons). Alternatively, for a few number of sources, one can define the fuzzy measure by hand or learn it from training data.

Given a finite set X, a fuzzy measure $g: 2^X \to [0,1]$ and a function $h: X \to [0,1]$, the (numeric) Sugeno integral of h with respect to g is given by

$$\int h \circ g = \bigvee_{i=1}^{E} \left(h(x_{(i)}) \wedge g(\{x_{(1)}, \cdots, x_{(i)}\}) \right),$$

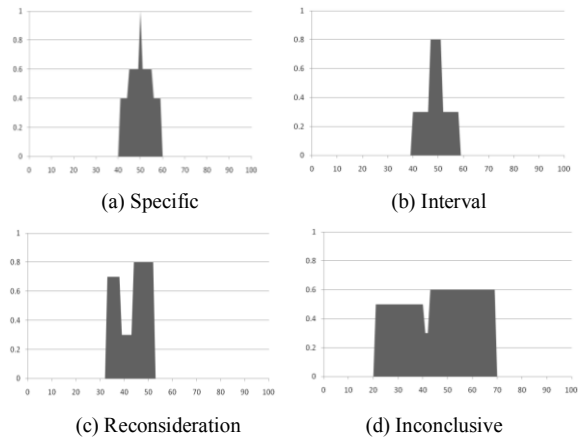
where $X = \{x_{(1)}, \cdots, x_{(E)}\}$ has been sorted so that $h(x_{(1)}) \geq h(x_{(2)}) \geq \cdots \geq h(x_{(E)})$. This finite realization of the actual definition highlights the fact that the Sugeno integral represents the best pessimistic agreement between the objective evidence in support of a hypothesis (h function) and the (possibly subjective) worth of the supporting evidence as provided by the fuzzy measure g.

F. Sugeno FI for Adult Skeletal Age-at-Death Estimation

After the age, accuracy, and quality indices are collected, a hypothesis is tested. The hypothesis is "the skeleton is age _ (a specific age, not range)". The Sugeno integral is repeatedly applied, once for each possible age using the respective accuracy, range and quality information. Every age, in discrete one year increments from 1 to 110 is tested. The age indicators provide input based on if the age tested is in their respective interval. The $h(x_i)$ values are a function (t-norm) of the quality, a [0,1] value, and if the aging method indicates that the age tested falls in the age interval, either a 0 for false or 1 for true. The result of this procedure is a collection of (age tested, FI result) pairs, which is a FS defined over the age domain. In this respect, we are able to address the case of sub-normal FSs.

G. Prior Method to Classify Age-at-Death FSs

As shown in figures 1 and 4, at least four different potential FS classes are possible; specific, figure 1(a), interval, figure 1(b), reconsideration, figure 1(c), and inconclusive, figure 1(d).



(a) Specific (b) Interval

(c) Reconsideration (d) Inconclusive

Fig. 1. Illustration of age-at-death FS classes for the FI results.

In [1], 'Specific' means that the procedure has identified an exact age-at-death, e.g. 25 years old. Class 'Interval' indicates that the procedure has identified a range (interval) of possible ages, e.g. 25-30. Class 'Reconsideration' means that there are multiple similar age-at-death ranges (intervals). Therefore, a researcher needs to decide how to resolve the conflict. Class 'Inconclusive' means that there is too little solid evidence to indicate any age-at-death.

Initially, an age-at-death FS was classified into one of the four just mentioned classes according to the characteristics of its intervals. A plateau is defined here to be an interval such that the interval directly before it and the interval directly after it (if they exist) have smaller FI values. For example, figure 1(a) has one plateau while figure 1(c) has two plateaus. The following tests, analyzed in the order specified below, were used in [1] to determine the type of FS. Each test is a yes or no question.

- *Test 1*: Is the length of the maximum plateau greater than or equal to 30 years? If the answer is yes, then the FS is placed in the category inconclusive, if not, then the next test is conducted.
- *Test 2*: Is there a single plateau and is its length equal to one? If yes, the result is specific age.

- *Test 3*: Is there a single plateau and is its length 29 or less years? If yes, the result is age interval.

In the case that the FS does not pass one of the above three tests then it is labeled as type reconsideration.

III. Fuzzy Set Approach to Class Determination

A shortcoming of [1] is it's crisp class definitions. Initially, this set of definitions appeared to be suitable. However, after investigating different results, it was discovered that these initial definitions do not capture the inherent fuzziness that exists in age-at-death FS classes. Figure 2 contains example age-at-death FSs illustrating the inherent fuzziness of the classes.

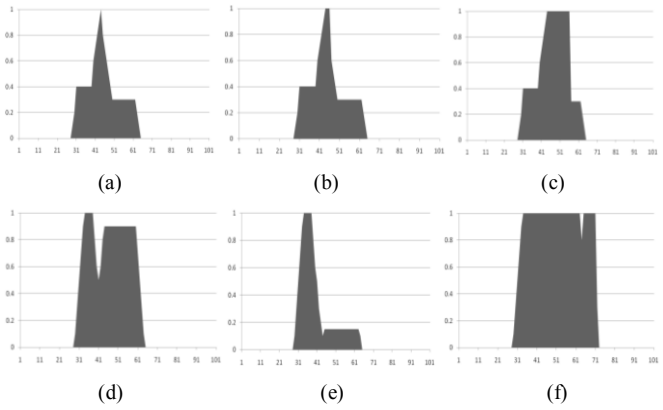


Fig. 2. FSs showing the fuzziness inherent to defining age-at-death FS classes.

We begin this discussion with the comparison of figure 2(a) to figure 2(b). In figure 2(a), the maximum plateau has a width of 1. In figure 2(b), the maximum plateau has a width of 3. The old definitions classify figure 2(b) as type 'Interval'. As it turns out, figure 2(a) is an interval, just with a small (length 1) width. We assert that there is little difference between figures 2(a) and 2(b). Figure 2(b) should instead have the highest membership in 'Specific' instead of 'Interval'. In comparison, figure 2(c) should have the highest membership in the class 'Interval'. The question is to what degree do these examples belong to these concepts?

Next, consider figures 2(d) and 2(e). The prior definitions in [1] classify these FSs as type 'Reconsideration'. However, the second (smaller) plateau in figure 2(e) has a very low (0.15) membership degree. Should these two FSs have the same membership degree in class 'Reconsideration'? Should figure 2(e) not have a higher degree in 'Interval' or 'Specific'?

On a final note, figure 2(f) is classified as 'Inconclusive' by the old set of definitions. The maximum plateau has a width of 30. Should this FS have the same membership degree as a FS with a maximum plateau with width 35, 40, or higher? What about a FS with a maximum plateau with width of 28? The recurring theme between these different examples is that the definitions provided prior do not accurately take into account the fuzziness that exists in determining the class of age-at-death FSs.

What is needed is a set of measurements of age-at-death FSs and FS class definitions. In this respect, a baseline for analysis can be established and a common understanding of age-at-death FS interpretation can take place.

First, we extract all plateau, $I = \{I_1,...,I_N\}$, where $I_n = [I_{n,start}, I_{n,end}]$ and $I_{n,start} \le I_{n,end}$. Herein, we restrict our analysis to a discrete set of ages, $I_{n,start}, I_{n,end} \in \{1,2,...,110\}$. Each interval is also associated with a membership degree, $\mu_{FI,n}$, which is the output of our FI procedure.

The first feature is the width, $|I_n|$, of the plateau that has the largest $\mu_{FI,n}$ value. The width of the maximum plateau is important for our understanding of how well the FI procedure singled out an age-at-death. The linguistic variable 'Maximum Plateau Width' (MPW) is defined and has the terms 'little', 'some', and 'big' (reported in table 2). The FSs used herein are trapezoidal membership functions (MFs), which are defined with respect to four ordered points, [a b c d]. These four numbers specify an interval in which the membership is value 1, i.e. between [b c], a linearly increasing interval, i.e. [a b], a linearly decreasing interval, i.e. [c d], and any point that is less than a, or greater than d, has a membership value of zero.

Table 2. Linguistic variable and terms for 'Maximum Plateau Width'.

	little	moderate	big
MF	[0 1 4 6]	[1 5 29 35]	[25 30 110 110]

The next feature is the distance (in terms of membership value) between the maximum plateau and the second largest plateau. The calculation is

$$\beta = \begin{cases} 1 & \text{if } |I| == 1 \\ (f_{max\,1} - f_{max\,2}) & \text{else} \end{cases},$$

where

$$f_{max\,1} = \max_{n} \mu_{FI,n},$$

$$f_{max\,2} = \max_{k \neq n} \mu_{FI,k}.$$

Table 3 reports the set of terms for the linguistic variable 'Plateau Separation' (PS), defined on the domain β.

Table 3. Linguistic variable and terms for 'Plateau Separation'.

	little	moderate	big
MF	[0 0 .3 .5]	[.3 .5 .7 .9]	[.5 .7 1 1]

Based on these two features, we are now able to define the four age-at-death FS classes. The definitions are no longer crisp. The confidence (membership degree) that an age-at-death FS belongs to the category (concept) 'Specific' is

$$\mu_{\text{Specific}} = \mu_{\text{little}}^{\text{MPW}} * \mu_{\text{big}}^{\text{PS}},$$

'Interval' is

$$\mu_{\text{Interval}} = \mu_{\text{moderate}}^{\text{MPW}} * \mu_{\text{big}}^{\text{PS}},$$

'Inconclusive' is

$$\mu_{\text{Inconclusive}} = \mu_{\text{big}}^{\text{MPW}},$$

and 'Reconsideration' is

$$\mu_{\text{Reconsideration}} = \mu_{\text{small}}^{\text{PS}}.$$

For the example FSs in figure 2, the membership values for the above four terms are provided in table 4.

Table 4. FS class memberships for the FSs in figure 2.

	$\mu_{Specific}$	$\mu_{Interval}$	$\mu_{Inconclusive}$	$\mu_{Reconsideration}$
2(a)	1*1=1	0*1=0	0	0
2(b)	1*1=1	0.5*1=0.5	0	0
2(c)	0*1=0	1*1=1	0	0
2(d)	0.5*0=0.5	1*0=0	0	1
2(e)	0.5*1=0.5	1*1=1	0	0
2(f)	0*0=0	0.83*0=0	1	0

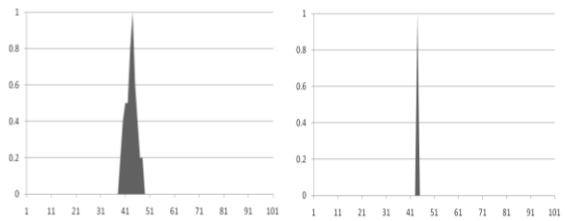
Table 4 shows what we expect. Figure 2(a) is 'Specific', figure 2(b) is more 'Specific' than 'Interval', figure 2(c) is 'Interval', figure 2(d) is somewhat 'Specific' but more of type 'Reconsideration', figure 2(e) is somewhat 'Specific', but mostly 'Interval', and figure 2(f) is 'Inconclusive'.

IV. Measuring Age-at-Death FS Specificitiy

While the last section detailed a feature and FS-based approach to determining the membership degree of an age-at-death FS in the four anthropological classes, a question still remains regarding how *specific* the FS is with respect to being able to narrow the age-at-death to a single value? For example, even if the method indicates a single age-at-death, i.e. class 'Specific', how specific are the findings in terms of there being evidence that the skeletal remains might be a different age? Figure 3 and figure 2(a) illustrate this concept.

Figure 3 illustrates what we already know. The smaller the area in the age-at-death FS, the greater our confidence is that the aging methods agreed on a specific age-at-death. That is, the less fuzzy the age-at-death FS, the more *specific* the age. In reality, figure 3(b) is unlikely because aging methods produce intervals and not a single age-at-death. Because a specific age is not expected to ever be encountered using current crisp aging methods, it is important that we include a measure of age-at-death FS specificity. The first thought was to use the standard FS scalar-cardinality to measure age-at-death specificity,

$$\text{sc}(A) = \sum_{i=1}^{110} A(x_i).$$



(a) (b)

Fig. 3. Differences in age-at-death *specificity* for age-at-death FSs. Compared to figure 2(a), figure 3(a) is more specific, while figure 3(b) is the most specific.

However, it turns out that we need something tailored specifically to age-at-death FSs. If the goal is to have a low sc(A), namely a FS with value 1 at one domain location and zero elsewhere, i.e. figure 3(b), then in return we open the door for other types of age-at-death FSs that could acquire a low sc(A) values. Namely, this can occur because our FI procedure can yield FSs that are not normal. For example, if there is significant disagreement between all of the aging methods, then sc(A) can have a near zero value.

Instead, we address age-at-death FS specificity using an ordered weighted average (OWA) approach [7]. The OWA begins by sorting (in descending order) the membership values. The OWA also takes a set of weights that generally sum to one (or the calculation is weighted by the sum of the weights). The first weight is for the largest sorted value, the second weight is for the second largest value, etc. The OWA is capable of producing many familiar order statistics, i.e. the weighted average, maximum, minimum, etc. For example,

$$\text{OWA}(0, \underbrace{\frac{1}{10}, \ldots, \frac{1}{10}}_{10}, \underbrace{0, \ldots, 0}_{99}))$$

is an OWA operator with a weight of 0 for the maximum value, the average of the next 10 largest values and weights of 0 for all the remaining values.

We use different OWAs to calculate the membership of the age-at-death specificity for the terms 'Exact', 'High', 'Moderate' and 'Low'. The membership of 'Exact' is

$$\mu_{\text{Exact}} = \text{OWA}(1, \underbrace{0, \ldots 0}_{109}) - \text{OWA}(0, \underbrace{\frac{1}{10}, \ldots, \frac{1}{10}}_{10}, \underbrace{0, \ldots, 0}_{99})),$$

'High' is

$$\mu_{\text{High}} = \text{OWA}(1, \underbrace{0, \ldots 0}_{109}) *$$

$$\frac{\left(\text{OWA}(0, \underbrace{\frac{1}{10}, \ldots, \frac{1}{10}}_{10}, \underbrace{0, \ldots, 0}_{99})\right) - \left(\text{OWA}(\underbrace{0, \ldots, 0}_{11}, \underbrace{\frac{1}{20}, \ldots, \frac{1}{20}}_{20}, \underbrace{0, \ldots, 0}_{79})\right)}{\left(\text{OWA}(0, \underbrace{\frac{1}{10}, \ldots, \frac{1}{10}}_{10}, \underbrace{0, \ldots, 0}_{99})\right)},$$

'Moderate is

$$\mu_{\text{Moderate}} = \text{OWA}(1, \underbrace{0,\ldots 0}_{109}) * \left(\frac{\left(\text{OWA}(\underbrace{0,\ldots,0}_{20}, \underbrace{\frac{1}{20},\ldots,\frac{1}{20}}_{20}, \underbrace{0,\ldots,0}_{70})) \right) - \left(\text{OWA}(\underbrace{0,\ldots,0}_{30}, \underbrace{\frac{1}{20},\ldots,\frac{1}{20}}_{30}, \underbrace{0,\ldots,0}_{50})) \right)}{\left(\text{OWA}(\underbrace{0,\ldots,0}_{20}, \underbrace{\frac{1}{20},\ldots,\frac{1}{20}}_{20}, \underbrace{0,\ldots,0}_{70})) \right)} \right),$$

and 'Low' is

$$\mu_{\text{Low}} = \text{OWA}(1, \underbrace{0,\ldots 0}_{109}) * \left(\text{OWA}(\underbrace{0,\ldots,0}_{30}, \underbrace{\frac{1}{10},\ldots,\frac{1}{10}}_{10}, \underbrace{0,\ldots,0}_{70}) \right).$$

These formulas take into the account the maximum membership value and 'contrast' between different parts of the FS. For the example FSs in figures 2 and 3, the membership values for the above four terms are provided in table 5.

Table 5. Age-at-death specificity value for the FSs in Figure 2.

	μ_{Exact}	μ_{High}	μ_{Moderate}	μ_{Low}
2(a)	0.36	0.6	0.78	0
2(b)	0.31	0.63	0.78	0
2(c)	0	0.34	0.81	0
2(d)	0.06	0.39	0.85	0
2(e)	0.2	0.84	0.75	0
2(f)	0	0.05	0.63	.89
3(a)	0.62	1	0	0
3(b)	1	0	0	0

Again, table 5 reports what we expect. Figure 2(a) is mostly 'Moderate' but also somewhat 'High', figure 2(b) is essentially the same as figure 2(a), figure 2(c) is more 'Moderate' and less 'High' than figure 2(a-b), figure 2(e) has a higher specificity than figure 2(d), figure 2(f) has a very low specificity, while figure 3(b) is the most specific.

V. Confidence

Formulas have now been presented for age-at-death FS classification and determination of the amount of specificity. The final component of this article is interpretation of the FI output degree. No new procedure is presented here in terms of measurements. The importance is establishing a vocabulary for the concept 'Confidence in Age-at-Death'. Table 6 reports the terms and their values.

Table 6. Linguistic variable and terms for 'Confidence in Age-at-Death'.

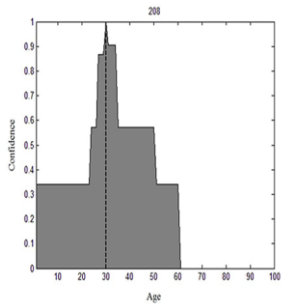
	High	moderate	low	no
MF	[.8 .9 1 1]	[.4 .6 .8 1]	[0 .2 .4 .6]	[0 0 .1 .2]

VI. Data Set and Experiments

Most of the skeletal aging methods are based on collections with known aged individuals, such as the Terry Anatomical Collection [24, 25]. This collection contains mainly black and white adult skeletons with dates of birth ranging from 1822-1943. It contains 1,728 individuals with the majority between 20 to 80 years of age. The data used here, which is the same data used in our prior FI article, was collected as part of another study by L. Konigsberg, N. Herrmann, and D. Wescott. It is available at http://konig.la.utk.edu/paleod.htm. Skeletal remains of known age from the Terry Collection were scored for pubic symphysis morphology [9], auricular surface morphology [10] and ectocranial suture closure [11]. Our data set is comprised of 735 individuals, specifically 323 females and 412 males. There are too many skeletons to report all findings, so a select set are shown to emphasize the proposed method. We use the same examples from our prior article [1]. The first four results in figure 4, (a-d), are the findings of the procedure introduced in this article for four skeletal cases from the Terry Anatomical Collection.

The Terry collection only contains skeletal remains with a quality value of 1. If any wearing is present, it is most likely due to researchers working on the skeletal remains. Because of this, in [1] we introduced 4 hypothetical cases (HCs) based on individuals from the Terry collection in which the quality value was varied and additional methods were simulated to test scenarios outside of the data set analyzed (figure 4 e-h). These experiments are summarized here, while the full information is contained in [1].

Figure 4 tells the following story. Skeleton 208 (4a) is clearly of type specific, has a low specificity, and there is a high FI confidence. This reinforces the class label that we found prior in [1]. Discoveries for skeletons 25R and 635 also reinforce what we found earlier (figures 4b and 4d). However, for skeleton 779R (4c), we now discover two class labels with high membership value, inconclusive and reconsideration. According to our definitions, it is inconclusive due to the length of the maximum plateau, however, there is also very little difference (in confidence) between the maximum plateau and the second largest. Even if one could reduce the width of the interval for the maximum plateau, there would still remain substantial disagreement between it and the second largest.



Skeleton	208
Chronological Age	30 yrs

Proximal Femur	18-45

h: class=(0,0,0,1), specificity=(0.03,0.21,0.3,0.52) and conf=(1,0.22,0,0)

Fig. 4. Four skeletal examples from the Terry Anatomical Collection (a-d) and four hypothetical examples from [1] (e-h). For each age-at-death FS, we present the membership values in (1) the type of FS, (Specific, Interval, Inconclusive, Reconsideration), (2) the specificity, (Exact, High, Moderate, Low), and (3) the confidence interpretation, (High, Moderate, Low, No).

In HC1 (figure 4e), numerous (8) aging methods are simulated and the result is a single plateau of FI value 1 between ages 37-39. The highest membership in 'Interval', but there is also support in 'Specific'. In HC2 (figure 4f), the qualities of the skeletal remains were varied and the result was a single plateau of FI value 0.7 and age between ages 35 to 39. We see the same basic trend for HC2 as seen in HC1. In HC3 (figure 4g), the quality of the skeleton 208 (figure 4a) were varied. The result is a value of 0.6 for the ages 27 to 30. For HC3, there is little support for any class label. The measurements do not match our models to any high degree. There is more support in 'Specific', however almost the same confidence amount in 'Interval'. Additionally, the specificity degree has decreased between HCs 2 and 3. In part, this is because our OWA approach takes into account the maximum

FI value. Thus, as the maximum FI value decreases, so does our confidence in the amount of attainable specificity of the FS.

Lastly, for HC4 (figure 4h), we showed a case in which the quality value is 1 but the aging methods were in extreme disagreement. Multiple plateaus are discovered. The maximum plateau has a FI value of 0.95 for the ages 33 to 36 and the second largest is of FI value 0.91 for ages 25 to 29. In this case, there is a distinct class label of 'Reconsideration' with a high confidence and indication of 'Low' FS specificity.

VII. Conclusions

In this article, we extended our previous anthropological FI-based adult skeletal age-at-death estimation research [1]. This work is important to anthropology because it makes the prior qualitative procedure of manually analyzing age-at-death FSs now explicit. Therefore, researchers can better understand how to interpret results acquired from different investigators on different types of skeletal remains. This work is important to the fuzzy set community because we show how the FI for a number-valued integrand and number-valued measure can produce FS-valued results We also demonstrate a feature-based method of defining and measuring classes of different FSs in the context of anthropology. Lastly, we demonstrate an OWA-based contrast approach to measure the amount of specificity in an age-at-death FS. The method proposed in this article both reinforces many findings from our earlier work as well as shedding light on new discoveries. The proposed method makes the previous process of qualitatively analyzing the FI produced FSs explicit and understandable by others.

***Abstract*—For a class of complex production processes, based on the actual running status data, a new modeling approach based on moving pattern is presented by constructing pattern moving space and defining moving variable-pattern class variable in it. The dynamics of a class of complex production processes is characterized by the movement of pattern class variable in pattern moving space. For characterizing pattern class variable quantitatively , in this paper, interval number is used as its metric form, and our previous proposed interval T-S fuzzy model (ITSFM) is adapted to model its movement in pattern moving space. Experimental results are then presented that indicate the validity and applicability of the proposed approach.**

Keywords: moving pattern, pattern moving space, pattern class variable, interval arithmetic, Takagi–Sugeno fuzzy model, interval time series

I. INTRODUCTION

In real world, there are many complex production processes in metallurgy, chemical industry and building materials etc （e.g. blast furnace, sintering machine, cement rotary kiln and so on.）For this class of production processes, there are the same characteristics as follows[1]. Therein, there is a series of physical chemistry reactions of heat transfer and matter transfer, burning thermodynamics and chemistry reaction dynamics, moving boundary, hydrodynamics and aerodynamics. It is difficult to characterize the dynamics. In addition, the mapping relationships between inputs and outputs can't be described by classic Newton's laws of mechanics, but be described only by statistics. For example, even under the same experimental conditions, the obtained data usually differ from one to another. Thus, the traditional modeling approach based on input/output data characterized in Euclidean space is not appropriate for modeling the relationship between inputs and outputs of a complex industrial process.

For this class of complex production process systems, there is lack of effective dynamics description methods. We try to give a new method to describe the movement law obeying statistics by using statistical principal, pattern recognition and control theory.

For modeling of complex dynamical systems, an pattern-based process identification approach emulating human in dealing with process response was originally introduced in [2]. Generally, the existing methods for pattern-based process identification can be divided into four classes [3], namely the key-values approach [4][5], the qualitative evaluation approach [6], the elementary pattern recognition approach [7], and the cure fitting approach [8] [9]. In these methods, Pattern recognition is mainly used to solve system model identification or system state estimation problems. After that, the design of control law is still based on the time-domain model. Here pattern is not considered as a moving variable.

In this paper, in contrast to traditional modeling approach to characterizing dynamical systems in Euclidean space, the dynamics of complex production processes is characterized by the moving of running status patttern from one pattern class to another in pattern moving space. First, the collected multi-dimensional actual running status data of complex production processes are reduced to one dimensional data . Then, the one dimensional data are partitioned into C pattern classes constructing the pattern moving space, and pattern class variable is defined in it. Each pattern class represented by an interval number can be considered as a scale value of pattern moving space. The pattern samples belonging to the same pattern class have the same scale value in pattern moving space, and are represented by the same interval number. That is, we view the considered systems at the level of pattern class and capature only the dominant characteristics of the process. We are not concerned about the exact value of the running status data of the complex production processes, but concerned about the pattern classes which the running status data of complex production processes belong to. After pattern moving space is constructed and pattern class variable is defined in this space, the prediction model is built as follows:

$$\begin{aligned} dx(k) &= F(d\tilde{x}(k)) \\ &= F(f(dx(k-1), dx(k-2)\cdots dx(k-m_y), \\ &\qquad u(k-1), u(k-2), \cdots, u(k-m_u))) \end{aligned} \tag{1}$$

Where $dx(k)$ is pattern class variable, $F(\cdot)$ denotes classification, $d\tilde{x}(k)$ is the initial prediction output of pattern class variable and $d\tilde{x}(k) = f(\cdot)$ is a kind of initial prediction model. This is a prediction process including two steps. The first step is to obtain the initial prediction output $d\tilde{x}(k)$ based

*Corresponding Author.

on the initial prediction model $d\tilde{x}(k) = f(\cdot)$ modeled by our previous proposed interval T-S fuzzy model (ITSFM). The second step is to obtain the finial output pattern class variable $dx(k)$ by classifying the initial prediction output $d\tilde{x}(k)$.

This paper is organized as follows. After the introduction the preliminary knowledege about interval arithmetic is presented in Section II. In Section III, moving pattern-based modeling approach of a class of complex production process is proposed. In Section IV, the example is considered to demonstrate the validity and applicability of the proposed approach. Finally, Section V concludes this paper.

II. PRELIMINARY KNOWLEDGE

In this section, we briefly look at some important formulations in interval arithmetic[10] .

A. Interval arithmetic

An interval number can be represented by its lower and upper bounds as $A=[a^L, a^U]$, or, equivalently, by its midpoint and radius as $A=(a^C, a^R)$, where $a^C=(a^L+a^U)/2$ and $a^R=(a^U-a^L)/2$. Let A and B be two intervals represented by its lower and upper bounds, the operations defined on the interval numbers are, respectively.

$$A+B=[a^L+b^L, a^U+b^U] \quad (2)$$

$$A-B=[a^L-b^U, a^U-b^L] \quad (3)$$

$$\lambda \cdot A=[\lambda \cdot a^L, \lambda \cdot a^U] \quad (4)$$

Where λ is a constant and $\lambda>0$.

If the interval number A and B are represented by its midpoint and radius, the operations defined on the interval numbers are respectively:

$$A+B=(a^C+b^C, a^R+b^R) \quad (5)$$

$$A-B=(a^C-b^C, a^R+b^R) \quad (6)$$

$$\lambda \cdot A=(\lambda \cdot a^C, |\lambda| \cdot a^R) \quad (7)$$

B. Hausdorff distance

The Hausdorff distance is often used to measure the distance between two interval data. The concept of Hausdorff distance is stated as follows. Assume that two interval numbers X_1 and X_2 , $X_1=(a_1, c_1)$, $X_2=(a_2, c_2)$, a_1 and c_1 are the center and radius of interval number X_1 , respectively, a_2 and c_2 are the center and radius of interval number X_2 , respectively. The distance between X_1 and X_2 is defined as:

$$D(X_1, X_2)=|a_1-a_2|+|c_1-c_2|$$

III. MODELING OF COMPLEX PRODUCTION PROCESSES BASED ON MOVING PATTERN

In this paper, the dynamics of complex production processes is characterized by the move of operating condition patterns in pattern moving space. So, we need to construct pattern moving space firstly.

A. Construction of pattern moving space

Firstly, the multi-dimensional running status data are reduced to one dimensional data using principal component analysis. This can be considered as a process of feature extraction. Then, by fuzzy c-mean (FCM) clustering algorithm, the one-dimensional running status samples are partitioned into C pattern classes, that is, $P_1, P_2, \cdots, P_C$. The collection of those classes forms pattern moving space which corresponds to the considered complex production process. An explanatory example for demonstrating the constructed pattern moving space is shown in Fig.1. Each pattern class in pattern moving space can be considered as a qualitative "scale". The pattern samples belonging to the same pattern class have same "scale" value in pattern moving space

If the data is collected in a long enough period of time, the pattern moving space constructed based on these actual running status data can be considered as the running subspace of the system. Dynamics description and control problems can be discussed in this space. When the actual running status sample is out of the pattern moving space, the pattern moving space can be expanded by using the following method.

When a new pattern sample is classified into its belonging class, the distance between the pattern sample and this class center is calculated. If this distance is more than the class radius, then a new pattern class generates. In this paper, the new pattern sample is used as a new class center and the membership function can be computed for the new pattern class.

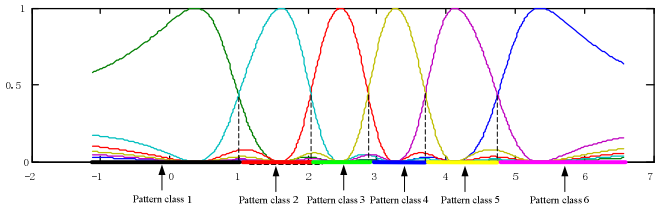

Fig.1 Pattern moving space composed of six pattern classes. The horizontal axis denotes the values of dimension reduced running status samples, and vertical axis denotes membership function values corresponding to dimension reduced running status samples.

B. The representation of pattern classes

In fact, each pattern class obtained in the above section is a qualitative description about pattern. In order to characterize quantitatively the dynamics of complex production processes in pattern moving space, each pattern class must be represented quantitatively. In this paper, we adopt interval numbers to represent pattern classes.

First, finding the maximum I_i^U and minimum I_i^L among the samples belonging to the same pattern class P_i , $i=1,\cdots,C$, where C is the number of pattern classes constructing the pattern moving space. Then, the maximum I_i^U and minimum I_i^L are used to construct an interval number

$I_i = [I_i^L, I_i^U]$. Thus, $I_i = [I_i^L, I_i^U]$ is the interval number characterizing pattern class P_i quantitatively. Let $I = \{I_1, I_2, \cdots, I_C\}$, it is the quantitative pattern moving space corresponding to pattern moving space P defined in above section. Here, quantified pattern classes are ordered from small to big in terms of the center values of I_i s. That is, $a_1 < a_2 < \cdots < a_C$, where $a_i = \dfrac{I_i^L + I_i^U}{2}$, $i = 1, \cdots, C$.

C. The definition of pattern class variable

In order to describe the movement of system in pattern moving space, a variable called pattern class variable is defined.

Assuming that $\{sx(k)\}$ and $\{mx(k)\}$ denotes measurement sample time series and pattern sample time series, respectively. Then pattern class variable must satisfy the following transformation:

$$mx(k) = T(sx(k)) \tag{8}$$

$$dx(k) = F(mx(k)) \tag{9}$$

Where $T(\cdot)$ and $F(\cdot)$ denote feature extraction and classification, respectively, $dx(k)$ is the pattern class variable.

Obviously, pattern class variable has two main characteristics:

(i) It is a variable over time.

(ii) It has the class attribute.

Pattern class variable is used to describe the variation of pattern class to which running status data belong over time in pattern moving space. And it together with pattern moving space forms the basis of the proposed modeling approach. The pattern class variable's metric form is not unique. In this paper, interval number is used as its metric form. That is, given at time instant *t*, $mx(k)$ is classified into pattern class i, and then let $dx(t) = I_i = [I_i^L, I_i^U]$. Thus, a pattern sample time series in Euclidean space is transformed into a pattern class variable time series in pattern moving space.

D. Modeling of Complex Production Processes based on moving pattern

In this paper, as interval numbers is used as the pattern class variable's metric form, so, in fact pattern class variable time series is an interval number time series. The dynamics of complex production processes is characterized by the transition of pattern class variable $dx(k)$ in pattern moving space. The dynamic model based on moving pattern is as follows:

$$\begin{aligned} dx(k) &= F(d\tilde{x}(k)) \\ &= F(f(dx(k-1), dx(k-2) \cdots dx(k-m_y) \\ &\qquad u(k-1), u(k-2), \cdots, u(k-m_u))) \end{aligned} \tag{10}$$

m_y and m_u, the orders of the considered dynamic systems; in this paper, m_y and m_u are assumed to be known priorly. $dx(t)$ is the pattern class variable, $F(\cdot)$ denotes classification, $d\tilde{x}(t)$ is the initial prediction output of pattern class variable and $d\tilde{x}(t) = f(\cdot)$ is a kind of initial prediction model. $u(k)$ is general system input represented by crisp real numbers, $u(k) \in R$.

The proposed moving pattern based modeling approach is composed of two steps.

1) Constructing the initial prediction model using the adapted interval T-S fuzzy model (ITSFM).

For modeling the moving of pattern class variable in pattern moving space, our previous proposed interval T-S fuzzy model (ITSFM) [11] is adapted and applied to moving pattern based modeling of complex production processes. The adapted ITSFM used to model of complex production complex in pattern moving space is as follows:

R^i : If $dx_c(k-1)$ is A_1^i and $dx_c(k-2)$ is A_2^i , $\cdots$, $dx_c(k-m_y)$ is $A_{m_y}^i$ and $u(k-1)$ is B_1^i , and $u(k-2)$ is B_2^i,…, $u(k-m_u)$ is $B_{m_u}^i$

then

$$\begin{aligned} dx^i(k) = \theta_0^i + \theta_1^i dx_c(k-1) + \cdots + \theta_{m_y}^i dx_c(k-m_y) + \\ + \theta_{m_y+1}^i u(k-1) + \theta_{m_y+2}^i u(k-2) + \cdots \\ + \theta_{m_y+m_u}^i u(k-m_u) \end{aligned} \tag{11}$$

Where A_j^i , B_q^i are the corresponding fuzzy sets. $dx_c(k-j)$ represents the center of pattern class variable $dx(k-j)$ at time instant $k-j$, that is, if the value of $dx(k-j)$ is equal to $I_i = [I_i^L, I_i^U]$ at time instant $k-j$, then $dx_c(k-j)$ is equal to $\dfrac{I_i^L + I_i^U}{2}$. $\theta_l^i = (a_l^i, c_l^i)$ is an interval number, a_l^i and c_l^i are the center and radius of θ_l^i , respectively. The membership grade $A_j^i(dx_c(k-j))$ and $B_q^i(u(k-q))$ are obtained by fuzzy *c*-means clustering algorithm in this paper, $l = 0,1,2,\cdots, m_y + m_u$, $j = 1,2,\cdots, m_y$, $q = 1,2,\cdots, m_u$, $i = 1,2,\ldots, r$, r denotes the number of rules.

The predicted interval output of the improved ITSFM, that is, $d\tilde{x}(k)$ is inferred as

$$d\tilde{x}(k) = \frac{\sum_{i=1}^{r} \omega_i dx^i(k)}{\sum_{i=1}^{r} \omega_i}, \tag{12}$$

Where $\omega_i = \prod_{j=1}^{m_y} A_j^i(dx_c(k-j)) \prod_{q=1}^{m_u} B_q^i(u(k-q))$

Let $\tilde{\omega}_i = \dfrac{\omega_i}{\sum_{i=1}^{r}\omega_i}$, then

$$
\begin{aligned}
d\tilde{x}(k) &= \sum_{i=1}^{r}\tilde{\omega}_i dx^i(k) \\
&= \sum_{i=1}^{r}\tilde{\omega}_i[\theta_0^i + \theta_1^i dx_c(k-1) + \cdots + \theta_{m_y}^i dx_c(k-m_y) \\
&\quad + \theta_{m_y+1}^i u(k-1) + \theta_{m_y+2}^i u(k-2) + \cdots \\
&\quad + \theta_{m_y+m_u}^i u(k-m_u)] \\
&= \sum_{i=1}^{r}\tilde{\omega}_i[(a_0^i, c_0^i) + (a_1^i, c_1^i)dx_c(k-1) + \cdots \\
&\quad + (a_{m_y}^i, c_{m_y}^i)dx_c(k-m_y) + (a_{m_y+1}^i, c_{m_y+1}^i)u(k-1) \\
&\quad + (a_{m_y+2}^i, c_{m_y+2}^i)u(k-2) + \cdots \\
&\quad + (a_{m_y+m_u}^i, c_{m_y+m_u}^i)u(k-m_u)] \\
&= \sum_{i=1}^{r}\omega_i(\mathbf{A}_i^t\mathbf{x}(k), \mathbf{C}_i^t \mid \mathbf{x}(k)\mid) \\
&= (\sum_{i=1}^{r}\omega_i\mathbf{A}_i^t\mathbf{x}(k), \sum_{i=1}^{r}\omega_i\mathbf{C}_i^t \mid \mathbf{x}(k)\mid)
\end{aligned}
\tag{13}
$$

Where

$$
\begin{aligned}
&\mathbf{A}_i = (a_0^i, a_1^i, \cdots, a_{m_y+m_u}^i)^t,\ \mathbf{C}_i = (c_0^i, c_1^i, \cdots, c_{m_y+m_u}^i)^t, \\
&\mathbf{x}(k) = (1, dx_c(k-1), dx_c(k-2), \cdots, dx_c(k-m_y), \\
&\qquad u(k-1), u(k-2), \cdots, u(k-m_u))^t, \\
&\mid \mathbf{x}(k)\mid = (1, \left|dx_c(k-1)\right|, \left|dx_c(k-2)\right|, \cdots, \left|dx_c(k-m_y)\right|, \\
&\qquad \left|u(k-1)\right|, \left|u(k-2)\right|, \cdots, \left|u(k-m_u)\right|)^t
\end{aligned}
$$

Furthermore, $\hat{p}(k)$ can be expressed as

$$
d\tilde{x}(k) = (\mathbf{A}^t\tilde{\mathbf{x}}(k),\ \mathbf{C}^t\left|\tilde{\mathbf{x}}(k)\right|) \tag{14}
$$

Where $\mathbf{A} = (\mathbf{A}_1^t, \mathbf{A}_2^t, \cdots, \mathbf{A}_r^t)^t$, $\mathbf{C} = (\mathbf{C}_1^t, \mathbf{C}_2^t, \cdots, \mathbf{C}_r^t)^t$

$$
\begin{aligned}
\tilde{\mathbf{x}}(k) &= (\tilde{\omega}_1\mathbf{x}(k)^t, \tilde{\omega}_2\mathbf{x}(k)^t, \cdots \tilde{\omega}_r\mathbf{x}(k)^t)^t \\
\left|\tilde{\mathbf{x}}(k)\right| &= (\tilde{\omega}_1\left|\mathbf{x}(k)\right|^t, \tilde{\omega}_2\left|\mathbf{x}(k)\right|^t, \cdots, \tilde{\omega}_r\left|\mathbf{x}(k)\right|^t)^t
\end{aligned}
$$

$\mathbf{A}^t\tilde{\mathbf{x}}(k)$ and $\mathbf{C}^t\left|\tilde{\mathbf{x}}(k)\right|$ are the center and radius of the initial predicted interval output $d\tilde{x}(k)$, respectively.

Different from our previous work [13], the parameters in (14) are obtained by minimizing the following objective function J in (15) subject to the constraints $c_j^i \geq 0$ as the radius of an interval is greater than or equal to zero, $i = 1, 2, \ldots, r$, $j = 0, 1, 2, \cdots, m_y + m_u$. Where $d\tilde{x}^L(k)$, $d\tilde{x}^U(k)$ are the lower and upper bound of the initial prediction output $d\tilde{x}(k)$, respectively, $dx^L(k)$, $dx^U(k)$ are the lower and upper bound of real pattern class variable $dx(k)$ at time instant k, respectively.

$$
\begin{aligned}
&\underset{\mathbf{A},\mathbf{C}}{Min} \quad J = \sum_{k=1}^{N}[dx^L(k) - d\tilde{x}^L(k)]^2 + \sum_{k=1}^{N}[dx^U(k) - d\tilde{x}^U(k)]^2 \\
&\text{subject to } c_j^i \geq 0, i = 1,2,\cdots,r,\ j = 0,1,2,\cdots,m_y + m_u
\end{aligned}
\tag{15}
$$

2) After obtaining the initial prediction output $d\tilde{x}(k)$, the finial prediction output $d\hat{x}(k)$ can be obtained by classifying the initial prediction output $d\tilde{x}(k)$ into the pattern class which is nearest to the initial prediction output $d\tilde{x}(k)$ by calculating the Hausdorff distance between the initial prediction output $d\tilde{x}(k)$ and each pattern class I_i in pattern moving space. That is, if $j = \underset{i=1,2,\cdots,C}{\arg\min}\left(D(d\tilde{x}(k), I_i)\right)$, then the final prediction output $d\hat{x}(k)$ is equal to I_j, where $I_i = [I_i^L, I_i^U]$ is the quantified value of pattern class i, $i = 1,2,\cdots,C$, C is the number of pattern class in pattern moving space. $D(d\tilde{x}(k), I_i)$ denotes the Hausdorff distance between interval number $d\tilde{x}(k)$ and I_i.

IV. NUMERICAL EXAMPLE

In this chapter, one practical example- sintering process of Anyang (one city of Henan Province of China) iron and steel plant is given to verify the validity of the proposed moving pattern-based modeling approach.

In the example, the actual running status data collected from sintering process of Anyang (one city of Shandong Province of China) iron and steel plant are used. The data consist of 864 pairs of input-output samples of a sintering process: the input $u(k)$ is the temperature of ignition hood and the output $y(k)$ is the first principal component of exhaust gas temperatures of three wind boxes, and the sampling time is 25s. In this example, the input and output data are normalized by statistical normalization, that is, $Z = \dfrac{X - \mu}{\sigma}$, where μ and σ are the mean and standard deviation of X, respectively. Fig.2 shows the 864 pairs of input-output samples. In this example, 864 running status samples $y(k)$ are used to constructing the pattern moving space by fuzzy c-means (FCM) clustering algorithm. Here, the cluster number is set to 20. The 20 pattern classes P_i represented by interval numbers are shown in Table I. The running status time series $y(k)$ in Euclidean space and the corresponding pattern class variable time series $\tilde{p}(k)$ characterized by intervals in pattern moving space are shown in Fig.3, $k = 1,2,\cdots,100$. From Fig.3, we can see that the transition of pattern class variable from one pattern class to another in pattern moving space can also characterize change of running status $y(k)$ in general.

In this example, the first 500 pairs of input-output samples are used to train the proposed initial prediction model, the

others are used to validate the model. The initial prediction model based on ITSFM is as follows:

R^i : If $dx_c(k-1)$ is A_1^i and $dx_c(k-2)$ is A_2^i and $dx_c(k-3)$ is A_3^i and $dx_c(k-4)$ is A_4^i and $u(k-1)$ is B_1^i

Then:

$$dx^i(k) = \theta_0^i + \theta_1^i dx_c(k-1) + \theta_2^i dx_c(k-2) + \theta_3^i dx_c(k-3) + \theta_4^i dx_c(k-4) + \theta_5^i u(k-1)$$

Where $dx_c(k-1)$ is the center of $dx(k-1)$. The membership grade $A_1^i(dx_c(k-1))$ and $B_1^i(u(k-1))$ is obtained by fuzzy *c*-means clustering algorithm which was adopted in [12] for determining the premise structure of T-S fuzzy model. $\boldsymbol{\theta}^i = [\theta_0^i, \theta_1^i, \theta_2^i, \theta_3^i, \theta_4^i, \theta_5^i]$ is the interval parameter vector in consequent part of ITSFM. Based on formula (15), the interval parameters in the consequent part of ITSFM are obtained and shown in Table II.

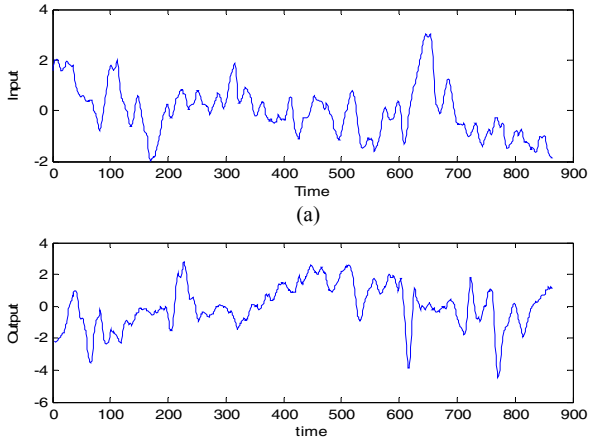

Fig.2 The input and output signals of the sintering process: (a) input $u(k)$; (b) output $y(k)$

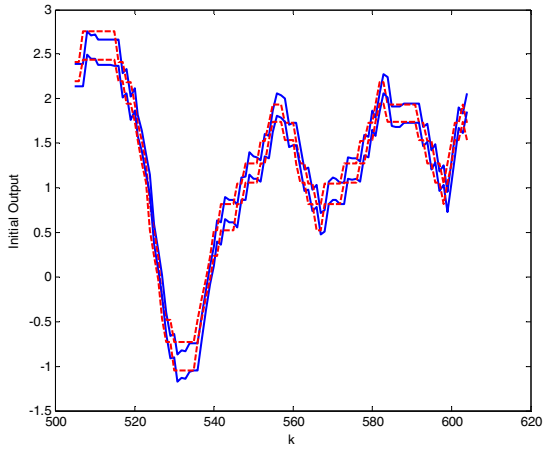

Fig.4 The initial prediction outputs $d\tilde{x}(k)$ (solid line) obtained by ITSFM and the real pattern class variable time series $dx(k)$ (dashed line).

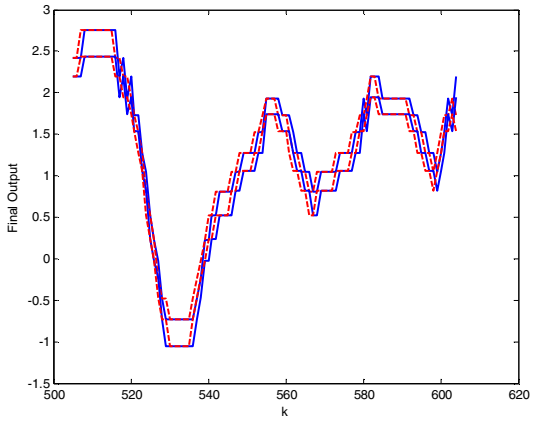

Fig.5 The final prediction outputs $d\hat{x}(k)$ (solid line) of the proposed model and the real pattern class variable time series $dx(k)$ (dashed line).

In Fig.4, the solid lines represent the initial prediction output $d\tilde{x}(k)$ obtained by the ITSFM with 4 fuzzy rules, and the dashed lines represent the real pattern class variable time series $dx(k)$ with time from 505 to 600. After the initial prediction output $d\tilde{x}(k)$ is classified, the final outputs $d\hat{x}(k)$ of the proposed model are obtained. In Fig.5, the solid lines represent the final outputs of the proposed model, the dashed lines represent the pattern class variable time series $dx(k)$ with time from 505 to 600. By comparing Fig.4 with Fig.5, we can see that the small difference between initial prediction output $d\tilde{x}(k)$ and the corresponding real pattern class variable time series $dx(k)$ at some time instant (for example *k*=508-515, 530-535, 585-591) is eliminated after $d\tilde{x}(k)$ is classified.

V. CONCLUSION

In this paper, in contrast to traditional modeling approach to characterizing dynamical systems in Euclidean space, the dynamics of complex production processes is characterized by

***Abstract*—Friction Stir Welding (FSW) is a relatively new solid-state joining technique, which is versatile, environment friendly, and energy and time efficient. For a comprehensive understanding of the effects of process conditions, such as tool rotation speed and traverse speed, on characterisations of welded materials, it is essential to establish prediction models for different aspects of the materials' behaviours. Because of the high complexity of the FSW process, it is often difficult to derive accurate and yet transparent enough mathematical models. In such a situation, a systematic data-driven fuzzy modelling approach is developed and implemented in this paper to model FSW behaviour relating to AA5083 aluminium alloy, consisting of microstructural features, mechanical properties, as well as overall weld quality. This methodology allows constructing transparent fuzzy models considering both accuracy and interpretability attributes of fuzzy systems. The elicited models proved to be accurate, interpretable and robust and can be further applied to facilitate the optimal design of process parameters, with the aim of finding the optimal combinations of process parameters to achieve desired welding properties.**

I. INTRODUCTION

Friction Stir Welding (FSW) is a practical solid-state joining technique, which was invented at The Welding Institute (TWI), UK in 1991 [1]. It was initially developed for welding aluminium alloys, and nowadays has been extended to be implemented in a variety of materials, including magnesium alloys [2], steels [3], copper alloys [4], titanium alloys [5], etc.

In a standard FSW process, a non-consumable rotating tool with a shoulder and a pin is inserted into the abutting edges of two rigidly clamped plates to be joined, as shown in Fig. 1 [6]. The tool moves along the joint line of the butting surfaces while the shoulder makes firm contact with the top surface of the work-piece. With the tool rotation, heat generated by friction between the tool and the work-piece softens the material being welded. Severe plastic deformation and flow of this plasticised metal occurs as the tool is rotating and travelling along the welding direction. Material is transported from the front of the tool to the trailing edge where it is forged into a joint.

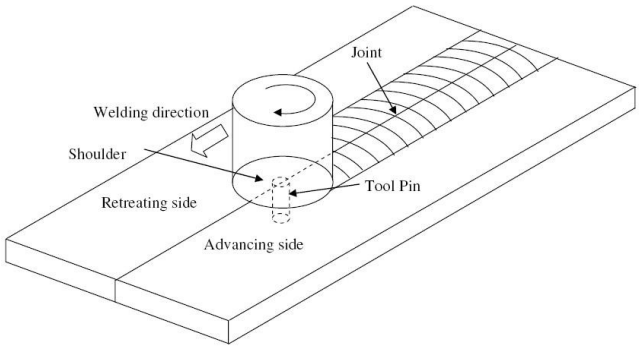

Figure 1. A schematic drawing of friction stir welding [6].

The FSW process involves intense plastic deformation and complex thermo-mechanical processes, which result in recrystallisation and development of texture within and around the stirred zone [7]. A typical cross-section of the FSW joint consists of three distinct zones, stirred (nugget) zone, Thermo-Mechanically Affected Zone (TMAZ), and Heat-Affected zone (HAZ), which can be identified in Fig. 2 [7].

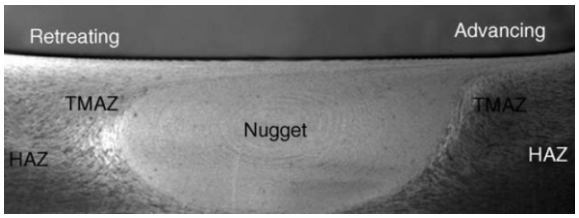

Figure 2. A cross-section macrograph of FSW showing various micro-structural zones [7].

During the FSW process, the material undergoes intense plastic deformation at elevated temperature, resulting in generation of fine and equiaxed recrystallised grains [8]. This fine microstructure produces good mechanical properties for the welded material. In addition, FSW demonstrates its

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

versatility as it is able to weld dissimilar alloys and dissimilar composites [9], for various types of joints, such as butt joints, lap joints, fillet joints, etc. FSW is also considered to be a "green" technology due to its energy efficiency and environment friendliness [7]. Compared to conventional welding methods, FSW consumes considerably less energy and it does not need shielding gas or flux, thereby making the process environmentally friendly. Since its invention in 1991 [1], FSW has found widespread applications in diverse industries, for example, aerospace, shipbuilding, automotive and railway industries [10].

For a comprehensive understanding of the effects of process conditions, such as tool rotation speed and traverse speed, on characterisations of welded materials, it is essential to construct accurate and reliable prediction models. Because of the high complexity of the FSW process, it is often 'tricky' to derive practical physical models. In such a situation, a systematic data-driven fuzzy modelling strategy is developed in this paper to elicit adequate prediction models based on experimental data, which include the micro-structural features, mechanical properties, as well as overall weld quality relating to AA5083 aluminium alloy.

Compared with analytically based methods, fuzzy systems are simpler in structure and easier to apply. They are capable of learning from data without needing much prior knowledge about the materials and processing [11], [12]. Fuzzy models are also convenient when combined with optimisation techniques to identify the input parameters that will provide a desirable behaviour profile [13], [14]. On the other hand, compared with black-box modelling approaches, such as Artificial Neural Networks (ANNs), fuzzy systems have transparent characteristics and the relationships between inputs and outputs are more interpretable, because of their use of descriptive language, such as linguistic 'IF-THEN' rules.

The proposed fuzzy modelling methodology allows to generate fuzzy models considering not only accuracy (precision) but also transparency (interpretability) of fuzzy systems via applying multi-objective optimisation techniques. As a result, a set of so-called 'Pareto-optimal' [15] models, in terms of different accuracy and interpretability levels, are constructed, which provide a wide range of choices for practitioners or users. In this paper, a hierarchical optimisation structure is proposed to improve the modelling efficiency, where two learning methods are systematically combined in order to improve various attributes of fuzzy systems: One multi-objective optimisation algorithm, the Non-dominated Sorting Genetic Algorithm II (NSGA-II) [16], is used to optimise the model's structure; Based on a fixed model structure, the other single-objective learning paradigm, the Gradient Descent (GD) method is employed to improve the model's parameters.

The remaining parts of this paper are organised as follows. Section II introduces the proposed modelling framework. Section III presents the experimental studies on modelling the FSW-related properties in detail. Finally, conclusions in relation to the whole study are drawn in Section IV.

II. THE MODELLING METHODOLOGY

A. Introduction to fuzzy systems

Fuzzy rule-based systems are viewed as robust 'universal approximators' capable of performing nonlinear mappings between inputs and outputs. It is an approach that allows a system to be represented using a descriptive language (linguistic 'IF-THEN' rules), which can easily be understood and explained by humans to allow them to gain a deeper insight into uncertain, complex and ill-defined systems.

Generally, a fuzzy system consists of four fundamental components: fuzzy rule-base, fuzzy inference engine, fuzzifier and defuzzifier. Fig. 3 shows the diagram of a fuzzy system. The central part of a fuzzy system is the knowledge-base (rule-base) consisting of the fuzzy rules. A fuzzy rule is an IF-THEN statement in which some words are characterised by continuous membership functions. Specifically, the fuzzy rule-base comprises the following fuzzy rules:

Rule$_l$: IF x_1 is A_1^l AND … AND x_n is A_n^l, THEN y is B^l,

where l = 1, 2, …, m; m is the number of rules in the fuzzy rule-base; A_i^l and B^l are fuzzy sets in $U_i \subset R$ and $V \subset R$, respectively, and $\boldsymbol{x} = (x_1, x_2, \ldots, x_i)^T \in U$ and $y \in V$ are the input and output (linguistic) variables of the fuzzy system, respectively.

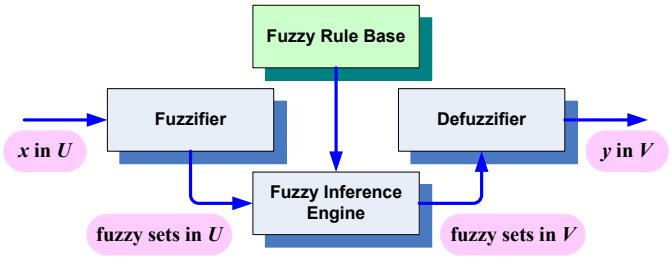

Figure 3. Basic configuration of fuzzy systems.

The fuzzifier is defined as a mapping from a real-valued point $\boldsymbol{x}^* \in U \subset R^i$ to a fuzzy set A^* in U. Normally, three types of fuzzifiers are used, which are singleton fuzzifier, Gaussian fuzzifier and triangular fuzzifier. They correspond to three types of fuzzy sets with different shapes of membership functions. In a fuzzy inference engine, fuzzy logic principles direct how to employ the fuzzy rules into a mapping from an input fuzzy set A^* to an output fuzzy set B^*. The defuzzifier is a mapping from the output fuzzy set B^* in $V \subset R$ to a real-valued point $y^* \in V$. Conceptually, the purpose of the defuzzifier is to specify a point in V that best represents B^*. Three widely used defuzzifiers are centre of gravity defuzzifier, centre average defuzzifier and maximum defuzzifier [17].

Fuzzy modelling is a systems modelling approach with fuzzy rule-based systems. In most of the fuzzy modelling methods, the fuzzy inference engine and the defuzzifier are predefined. Thus, the primary work is to generate appropriate fuzzy sets and right fuzzy rules.

B. A hierarchical multi-objective fuzzy modelling approach

Generally, data-driven fuzzy modelling can be viewed as a two-step process. The first step aims to generate a 'crude'

approximation of the fuzzy model. The second step consists of optimising the initial fuzzy rules and fuzzy sets to lead to a final 'optimised' fuzzy model.

For the first step, it can be achieved via two different methods: the grid-partitioning based method or the clustering based method. For the first method, the grid-partitioning defines a number of evenly distributed fuzzy sets for each variable. These fuzzy sets are shared by all the fuzzy rules. The main disadvantage of this method, in its basic version, lies in the large number of generated fuzzy rules when dealing with a high-dimensional modelling problem. In contrast, the second method employs data clustering information to define fuzzy sets. The fuzzy sets are not shared by all the rules, but each set is only mapped into one particular fuzzy rule. In this method, each fuzzy rule is associated to one cluster. In this paper, the clustering based method is employed, which includes a previously developed high-performance clustering algorithm, an agglomerative complete-link clustering algorithm [18].

For the second step, the main learning and optimisation techniques include linear least squares, gradient descent methods, neuro-fuzzy training methods, and some evolutionary optimisation techniques (evolutionary fuzzy systems). Compared with the fuzzy systems using other learning techniques, evolutionary fuzzy systems are able to realise improvements on not only the parameters but also the structure of the fuzzy systems. Moreover, multi-objective optimisation techniques within the evolutionary computation can prove very helpful in studying the trade-off between the accuracy and the interpretability of fuzzy systems. Some recent works in the literature [19], [20] have employed multi-objective optimisation techniques to tackle the trade-off issue of fuzzy models, while most of them were carried out based on grid-partitioning-type fuzzy sets.

In the previously proposed modelling approach [18], [21], a multi-objective optimisation algorithm was used to improve fuzzy models' structure and tune their parameters at the same time. This method would use relatively more calculation and would take longer to converge, where a large number of decision variables need to be adjusted and optimised simultaneously.

In this paper, a hierarchical optimisation structure is proposed, where two learning techniques conduct sequentially and iteratively to improve the different aspects of fuzzy systems: the multi-objective optimisation algorithm NSGA-II [16] is mainly employed to optimise the model's structure; while the gradient descent method is employed to improve the model's parameters. The NSGA-II algorithm has been demonstrated as one of the most efficient algorithms for multi-objective optimisation on a number of benchmark problems and applications. Two of the most important features in NSGA-II lie in its fast non-dominated sorting procedure and an elitist strategy. The detailed implementation procedure can be found in [16]. Gradient descent is a first-order optimisation algorithm that can quickly find a local minimum of a function. It has widely been employed in fuzzy modelling for tuning the membership functions [17] and shown to perform efficiently in improving the accuracy of fuzzy models.

Fig. 4 illustrates the proposed fuzzy modelling approach. This approach will be referred to throughout as a Fast Hierarchical Multi-Objective Fuzzy Modelling (FHMO-FM) approach. It can be divided into several components and the execution steps can be described as follows:

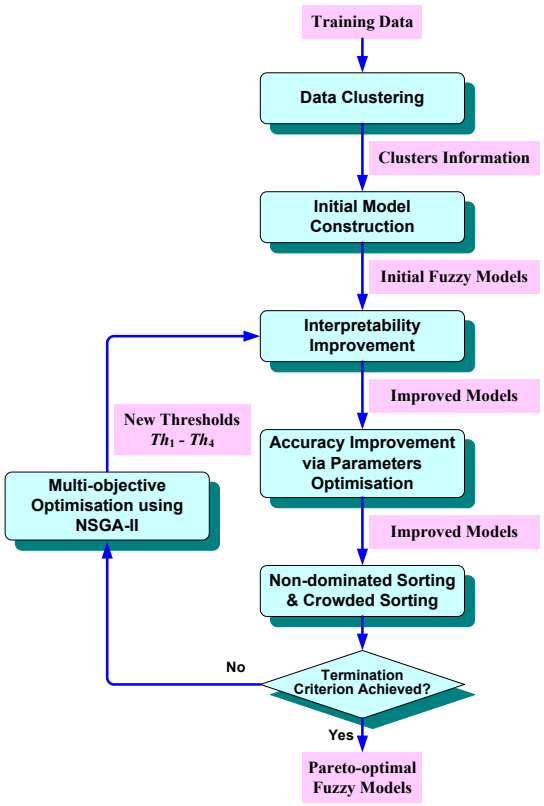

Figure 4. The flow chart of the proposed fuzzy modelling approach.

1. Data clustering: A modified agglomerative complete-link clustering algorithm [18] is employed to process training data in order to obtain the information relating to clusters. This algorithm has been shown to be more efficient and perform better than other well-known clustering algorithms, such as the fuzzy c-means (FCM) clustering algorithm [22].

2. Initial model construction: The information that these clusters provide is then used to construct an initial fuzzy model. In this approach, one cluster corresponds directly to one fuzzy rule; the centres of membership functions are defined using the information of their corresponding clusters' centre positions; other parameters relating to the membership functions are defined under the principle that one membership function must cover all the training data, which are included in its corresponding cluster. More details about this step have been introduced in [11].

3. Interpretability improvement: The fuzzy system is improved in structure, including the variation of the fuzzy rules and fuzzy sets, considering the interpretability issue. This task can be achieved using a four-step operation, including (1) removing redundant fuzzy rules, (2) merging similar fuzzy rules, (3) removing redundant fuzzy sets and (4) merging similar fuzzy sets. These four steps are controlled by 4

threshold parameters, Th_1 – Th_4. The details relating to the whole operation have been explained in [18], [21].

4. Accuracy improvement: The fuzzy models are improved by the gradient descent method [17] in terms of accuracy based on a fixed modelling structure.

5. Non-dominated sorting and crowed sorting: The non-dominated fuzzy models with a good diversity are found using the non-dominated sorting and crowed sorting mechanism, which are introduced in the algorithm NSGA-II [16].

6. Termination check: If the termination criterion is achieved, the modelling process is stopped and the final Pareto-optimal solutions are obtained; if not, all the modelling and performance information are passed to the algorithm NSGA-II. Normally, the termination criteria are designed so that the number of function evaluations achieves a predefined value.

7. Multi-objective optimisation using NSGA-II: The algorithm generates new control parameters (Th_1 – Th_4) for interpretability improvement based on the multi-objective optimisation strategy, then return to Step 3. It should been noted that the structure of a fuzzy model is not directly coded into the optimisation procedure, but is rather varied and optimised via controlling the thresholds. The accuracy of a fuzzy model can be evaluated using the Root Mean Square Error (RMSE) index, which is described as follows:

$$RMSE = \sqrt{\frac{\sum_{l=1}^{N}\left(y_l^m - y_l^p\right)^2}{N}} \tag{1}$$

where y_l^m is the measured output data and y_l^p is the predicted output data, l = 1, 2, …, N; N is the total number of data. The interpretability of a fuzzy model is affected by the number of fuzzy rules (*Nrule*), the number of fuzzy sets (*Nset*) and the total length of fuzzy rules (*Lrule*). To normalise these two objectives and make them similar and comparable in scale, they are formulated as follows:

$$\text{Objective 1: } \frac{RMSE}{RMSE_1} \tag{2}$$

$$\text{Objective 2: } \frac{Nrule}{Nrule_1} + \frac{Nset}{Nset_1} + \frac{Lrule}{Lrule_1} \tag{3}$$

where $RMSE_1$ is the root mean square error of the fuzzy model that is not optimised using the multi-objective optimisation mechanism; $Nrule_1$, $Nset_1$ and $Lrule_1$ represent the number of fuzzy rules, the number of fuzzy sets and the total rule length of this fuzzy model, respectively.

In the next section, this method will be further applied to predict the multiple properties for the friction stir welded materials. In those experiments, the initial number of clusters was set to 9, which means that the initial fuzzy model was generated using 9 rules. For the NSGA-II algorithm, the population size and the archive size were set to be 50 and the number of generation was set to be 200. Every single experiment was carried out over 20 runs. Only one set of typical results out of the 20 runs is selected and shown in the following paragraphs.

III. EXPERIMENTAL STUDIES

AA5083 is a non-heat treatable aluminium alloy that has excellent corrosion resistance and weldability combined with good strength and formability [23]. In this paper, 5.8 mm AA5083 plates were friction stir processed using the MX-Triflute^{TM} tool [24].

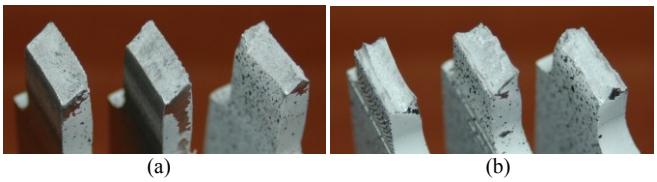
For FSW, two independent variables are used to control the process: tool Rotation Speed (RS) (rpm) in clockwise or counter-clockwise direction and Forward Movement per revolution (FM) (mm/rev) along the line of joint. The rotation of tool results in stirring and mixing of material around the rotating pin and the translation of tool moves the stirred material from the front to the back of the pin. Normally, a higher tool rotation speed generates higher temperature because of higher friction heating and results in more intense stirring and mixing of material. In this work, the welds were conducted at five different tool rotation speeds, typically between 200 and 600 rpm and five different traverse feed rates of 0.6, 0.8, 1.0, 1.2, and 1.4 mm/rev.

A. Mechanical properties

First, all the welds being tested for tensile properties at room temperature, including Yield Strength (YS), Ultimate Tensile Strength (UTS), Reduction Of Area (ROA) and elongation, where a two-dimensional Digital Image Correlation (DIC) system (LaVision 2D system running a 2MP monochrome camera) was used for data acquisition and displacement measurements. For each weld profile, 5 separate specimens were produced and tested. Based on these testing data, the intelligent modelling approach is then employed to construct the prediction models for the above mechanical properties.

Tensile specimens were machined from the nugget zone in transverse orientation to the weld. It should be emphasized that the strength obtained in the transverse tensile test represents the weakest region of the weld and the observed ductility is an average strain over the gage length including various zones.

In these tensile tests, failures mainly occurred as shear fracture in the HAZ (see Fig. 5 (a)), because the HAZ has the lowest strength due to significantly coarsened precipitates and the development of the Precipitate-Free Zones (PFZs) [7]. For the welds with defects, failures may also occur in the nugget zone (see Fig. 5 (b)), where porosity voids are produced.



(a) (b)

Figure 5. Fracture surfaces of tensile specimens: fracture occurring in the (a) HAZ and (b) nugget zone.

In the following case relating to the yield strength, 16 data were used for training and 4 data were used for final testing. Fig. 6 demonstrates the trade-offs among the Pareto-optimal models respect to the multiple objectives and various criteria, including the Root Mean Square Error (RMSE), the number of

fuzzy rules, the number of fuzzy sets and the total length of fuzzy rules.

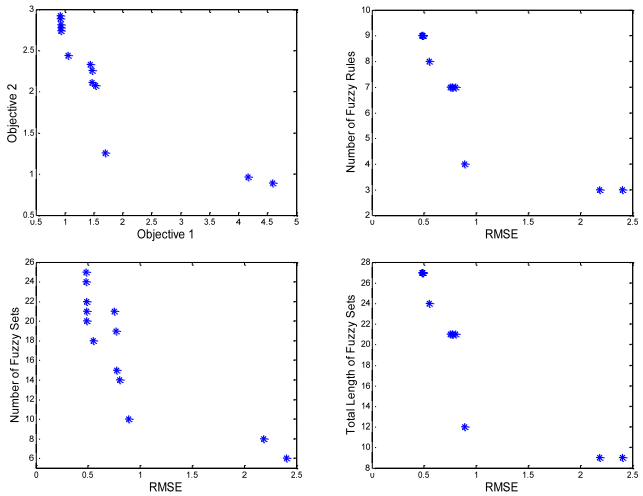


Figure 6. The performance of one set of optimised Pareto-optimal fuzzy models for the yield strength modelling problem.

Table I includes the main parameters of three optimised fuzzy models, which are selected from all the Pareto-optimal models and with 9, 7 and 4 rules respectively. Fig. 7 shows the prediction performance of these models. It can be seen that, for these optimised models, more fuzzy rules and more parameters will bring more accuracy while the models with fewer fuzzy rules and parameters are simpler in structure and easier to understand.

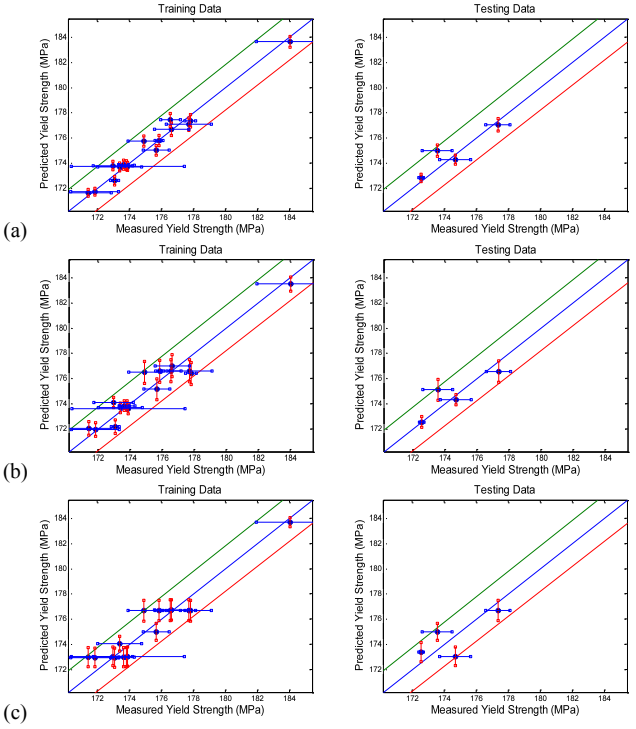

Figure 7. The yield strength models' predicted outputs versus measured outputs (with +1% and -1% error bands): (a) an optimised model with 9 rules, (b) an optimised model with 7 rules, and (c) an optimised model with 4 rules.

TABLE I. MAIN PARAMETERS OF SOME OBTAINED YIELD STRENGTH MODELS

Fuzzy model	*Number of fuzzy sets for each variable*	*Rule length of each fuzzy rule*	*RMSE of training*	*RMSE of testing*
Yield strength model with 9 rules	Inputs: [6; 7] Output: 9	[3; 3; 3; 3; 3; 3; 3; 3; 3]	0.4846	0.7676
Yield strength model with 7 rules	Inputs: [6; 7] Output: 6	[3; 3; 3; 3; 3; 3; 3]	0.7707	0.8878
Yield strength model with 4 rules	Inputs: [3; 4] Output: 3	[3; 3; 3; 3]	0.8901	1.2190

To provide more details about the obtained fuzzy models, Fig. 8 shows the fuzzy rule-base of the 4-fuzzy-rule model. For these fuzzy rules, they can be rewritten as the following approximate linguistic rules using the linguistic hedges approach [25]:

R_1: IF *RS* is *medium small* AND *FM* is *medium large*, THEN *YS* is *small*.
R_2: IF *RS* is *small* AND *FM* is *large*, THEN *YS* is *large*.
R_3: IF *RS* is *large* AND *FM* is *small*, THEN *YS* is *small*.
R_4: IF *RS* is *large* AND *FM* is *medium*, THEN *YS* is *medium*.

By inspecting these linguistic rules, one can understand more about the system's behaviour.

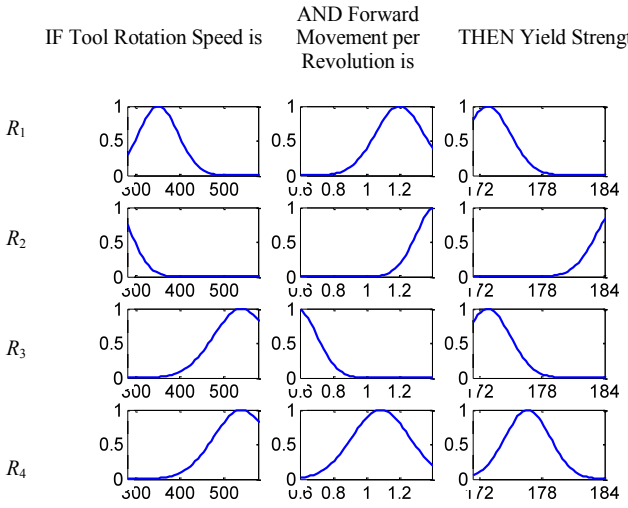

Figure 8. The rule-base of the 4-rule yield strength model.

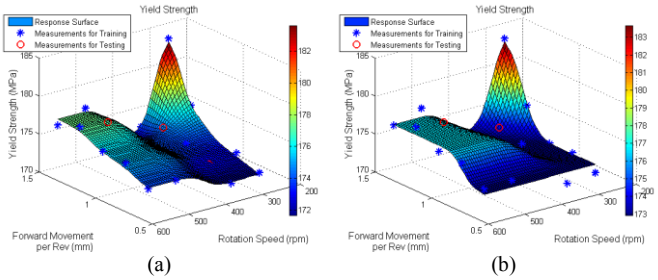
To verify the physical interpretation of the obtained model, Fig. 9 shows three-dimensional response surfaces of the obtained models. From these surfaces, it can be seen that the models with more fuzzy rules can catch more details from the training data. It can also be observed that, with increasing forward movement per revolution, the yield strength tends to increase. This trend is considered to be consistent with the expected behaviour from the knowledge experts.



(a) (b)

Figure 9. Response surfaces of the yield strength models: (a) the 9-rule model and (b) the 4-rule model.

B. *Weld quality*

Common defects in friction stir welds include porosity and surface defects [6]. To evaluate the quality of welds, three independent tests were conducted, including a bend test, a surface inspection, and a cross-section inspection. Based on these tests, four sub-indexes are designed to express the various aspects relating to the weld quality, i.e. the face flaws and root flaws in the bend test, the flaws on the surface, and the flaws within the cross-section. The values of such sub-indexes are integers from 0 to 3, where 0 means free from identifiable flaws and 3 represents complete failure or significant number of voids. By summing these sub-indexes together, an overall Weld Quality index (WQ) is obtained to represent the general situation for weld quality, whose value could be from 0 to 12 (0: excellent quality).

In this case, 20 overall weld quality index data were employed in the training phase and the remaining 5 data were used for testing. Fig. 10 demonstrates the trade-offs respect to the multiple criteria within these Pareto-optimal fuzzy models. It can be observed that these Pareto-optimal models exhibit fuzzy sets pattern behaviour, which means that they provide a wider choice of different solutions to users.

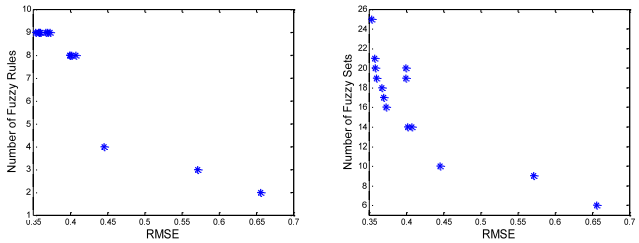


Figure 10. The performance of one set of optimised Pareto-optimal fuzzy models for the weld quality modelling problem.

Table II includes the main parameters of three optimised fuzzy models, which are selected from all the Pareto-optimal models and with 9, 8 and 4 rules respectively. Fig. 11 shows the prediction performance of these models. It can be seen that, for these optimised models, more rules and more parameters will bring more accuracy while the models with fewer rules and parameters are simpler in structure and easier to understand (interpret).

Fig. 12 shows the 3-D response surfaces of these models. From it, one can observe that, at a constant rotational speed, an increase in the travel speed favours the formation of wormhole defects. This shows a consistency with the phenomena reported in other literatures [6], [26].

TABLE II. MAIN PARAMETERS OF SOME OBTAINED WELD QUALITY MODELS

Fuzzy model	*Number of fuzzy sets for each variable*	*Rule length of each fuzzy rule*	*RMSE of training*	*RMSE of testing*
Weld quality model with 9 rules	Inputs: [5; 7] Output: 6	[3; 3; 3; 3; 3; 3; 3; 3; 3]	0.3751	0.3047
Weld quality model with 8 rules	Inputs: [4; 6] Output: 6	[3; 3; 3; 3; 3; 3; 3; 3]	0.3993	0.3313
Weld quality model with 4 rules	Inputs: [5; 4] Output: 5	[3; 3; 3; 3; 3]	0.4452	0.5165

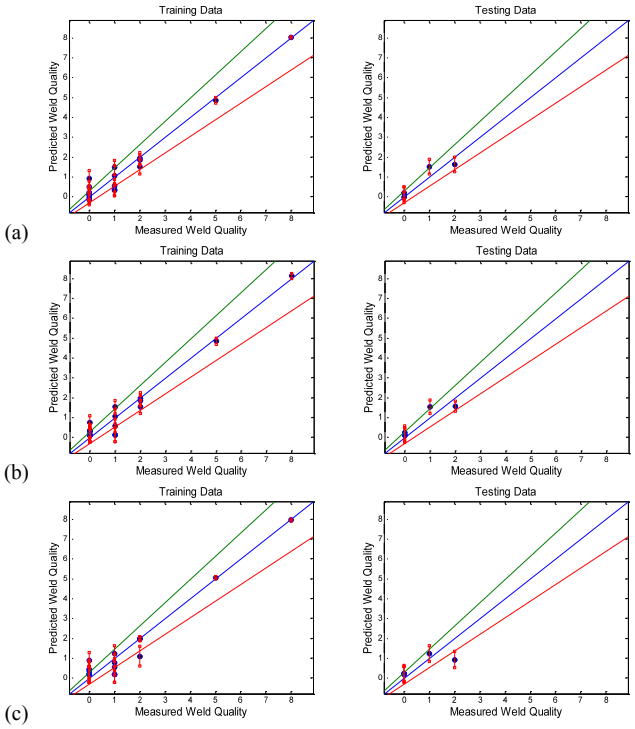

Figure 11. The weld quality models' predicted outputs versus measured outputs (with +10% and -10% error bands): (a) an optimised model with 9 rules, (b) an optimised model with 8 rules, and (c) an optimised model with 4 rules.

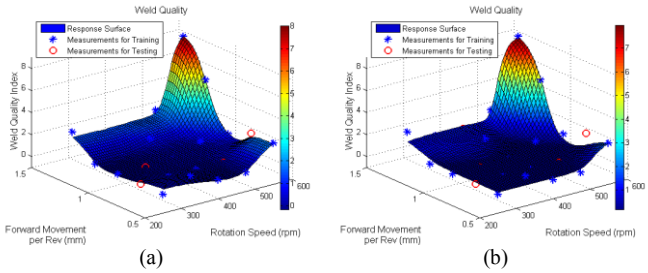

(a) (b)

Figure 12. Response surfaces of the weld quality models: (a) the 9-rule model, (b) the 8-rule model, and (c) the 4-rule model.

For more details about these Pareto-optimal models, Fig. 13 shows the rule-base of the 4-rule fuzzy model. It can be further represented as the following approximate linguistic rules using the linguistic hedges approach [25]:

R_1: IF *RS* is *medium small* AND *FM* is *large*, THEN *WQ* is *medium small*.
R_2: IF *RS* is *more or less medium large* AND *FM* is *medium small*, THEN *WQ* is *small*.
R_3: IF *RS* is *very large* AND *FM* is *small*, THEN *WQ* is *medium small*.
R_4: IF *RS* is *very large* AND *FM* is *large*, THEN *WQ* is *more or less large*.

It is clear that such linguistic fuzzy rules allow for a better insight into the FSW process.

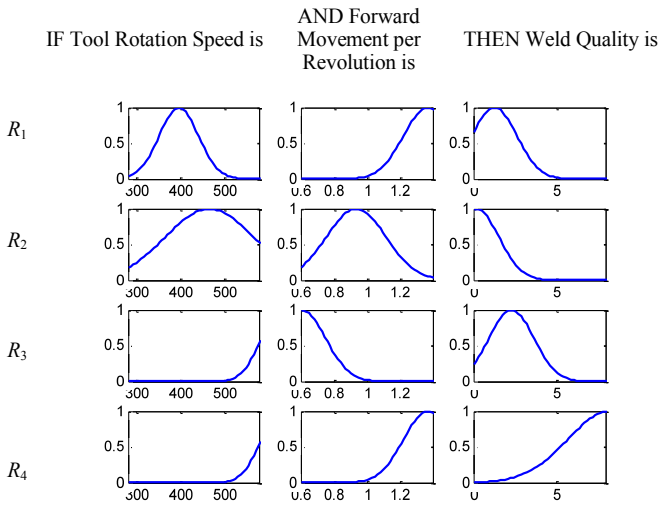

Figure 13. The rule-base of the 4-rule weld quality model.

C. *Grain size*

The FSW process results in significant micro-structural evolution, including grain size, grain boundary character, dissolution and coarsening of precipitates, breakup and redistribution of dispersoids, and texture [7]. In this paper, Average Grain Size (AGS) in the nugget zone is studied. Fig. 14 shows the micrographs of the pre-weld and post-weld materials, where one can identify different grain sizes.

In this experiment, 20 data points were used for training and 5 data points were reserved for testing. Fig. 15 shows the trade-offs among the multiple criteria within the non-dominated fuzzy solutions.

Fig. 16 shows the prediction performance of the model with 5 fuzzy rules and its response surface is displayed in Fig. 17. This surface has been confirmed to indeed follow the expected behaviour as predicted by theory and by knowledge experts. It should also be noted that the elicited fuzzy models reveal good generalisation ability from the smooth input-output response surface.

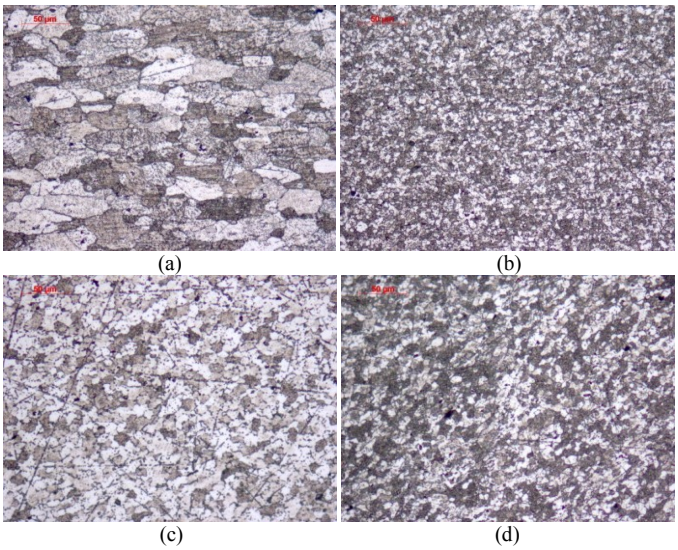

Figure 14. Micrographs of (a) the parent material, (b) the weld with *RS* = 280 rpm and *FM* = 1.4 mm/rev, (c) the weld with *RS* =580 rpm and *FM* =0.6 mm/rev, and (d) the weld with *RS* =580 rpm and *FM* =1.4 mm/rev.

IV. CONCLUSION

In spite of the relatively short history of friction stir welding, it has found widespread applications in various industries. FSW can also lead to significant improvements in the mechanical properties of the welded materials (weld and parent material) over the more conventional welding techniques. However, the fundamental physical understanding about the process is still lacking, as the material flow and micro-structural evolution within the weld is very complex. To achieve a comprehensive understanding of the effects of process conditions on characterisations of welded materials, a systems modelling framework, FHMO-FM, was successfully applied in this paper within the context of predicting multiple properties for the FSW processed material, including mechanical properties, weld quality, and average grain size. In the derived modelling method, the multi-objective optimisation technique has been employed to improve both the accuracy and the interpretability attributes of fuzzy models, and a hierarchical optimisation structure, including two learning techniques (NSGA-II and gradient descent), has also been included to improve the modelling efficiency. In future, the developed models will be exploited to serve as the core module for 'reverse-engineering' designs that are able to suggest optimal process conditions (process routes) by taking into account a set of desired objectives relating to achieving structurally sound, defect free, and reliable welds.

***Abstract*—Vasopressors belong to a powerful class of drugs used in the management of systemic shock in ill patients. The administration of a vasopressor involves the non-trivial process of inserting a central venous catheter. This procedure carries with it inherent risks which are increased when done under urgency such as in the case of unexpected systemic shock. The ability to predict the transition to vasopressor dependence could be expected to improve overall outcomes associated with the procedure. We use three different approaches combining fuzzy modeling with bottom-up (BU), top-town (TD) and ant feature selection (AFS), to classify requirements for vasopressors in shock. We observe that fuzzy models combined with BU feature selection return higher values of sensitivity; fuzzy models with no feature selection and fuzzy models with TD feature selection return higher values of AUC and specificity; features most commonly selected to classify impending use of vasopressores in pancreatitis patients include levels of Sodium and White Blood Cell counts, while for pneumonia patients include levels of Lactid Acid and White Blood Cell Count; and finally, fuzzy models combined with BU and fuzzy models combined with AFS demonstrate the lowest number of selected variables with no significant loss in accuracy.**

Keywords: Feature selection, Fuzzy models, Vasopressors, Shock

I. Introduction

Systemic shock is defined as "an acute clinical syndrome initiated by ineffective blood perfusion, resulting in severe dysfunction of organs vital to survival" [1]. The signs and symptoms of shock include hypotension, tachycardia, cool and clammy extremities, oliguria, dysglycemia, and delirium [1]. Depending on the etiology, mortality figures vary from 23% to 75% [2].

Early recognition and intervention are critical to prevent irreversible organ injury and failure. Unlike other conditions where the clinical diagnosis is made before the treatment is initiated, the treatment of shock often occurs concurrently or ahead of the diagnostic process [3]. This treatment entails three main steps - ventilate, infuse and pump [4] - consisting respectively of supplying oxygen to the patient until blood gas test results are available, infusion of fluids in order to increase plasma volume and cardiac output, and finally, when fluid administration fails to restore an adequate arterial pressure and organ perfusion, administration of vasopressors [5].

Vasopressors belong to a powerful class of drugs which are extremely useful for managing low blood pressure (hypotension) in patients with systemic shock. In critically ill patients, these drugs are often administered through central venous (CV) lines as they provide a fast and direct access to the central venous circulation [6]. However, inserting this type of line requires significant amounts of time (up to 1 hour, including radiologic imaging to evaluate placement), personnel resources, and can be associated with risks such as bloodstream infection. In the US only, catheter-related blood–stream infections have been reported to occur in 3 to 8% of inserted catheters and are the main cause of nosocomial bloodstream infection in intensive care units, with 80,000 cases annually at a cost of $300 million to $2.3 billion [7], [8]. Non-sterile central venous line insertion is more likely in urgent rather than elective scenarios. Simultaneously, there is a growing body of evidence supporting early commencement of vasopressor therapy as the key contributor to improved patient outcomes in certain disease states [9].

Bearing this in mind, being able to predict, within a certain time window, a patient's transition to vasopressor dependence could have great impact in a hospital, and particularly within the ICU environment, where patients are among the sickest in the hospital, for two main reasons: (i) a central line would only be inserted if the patient needs it in fact in the future (reduction in the performance of this procedure) (ii) the central line insertion protocol could be initiated with enough time, prior to the moment of need of vasopressors.

The present work will be a first step towards this major

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

goal. We will perform a classification task where, for a given set of clinical variables in a specific instant of the patient stay in the ICU, we will try to classify whether the patient was on vasopressors or not, as well as to find which subset of variables allows its better classification. This task will involve the application of soft computing techniques to a de-identified publicly available ICU database - MIMIC II [10]. As with other real-world databases, the dataset dealt with here, contains a relatively large number of non-linear features. Thus, from the engineering point of view, input selection is a crucial step in order to reduce models' complexity and remove inputs that do not improve the classification performance. From the clinical point of view, this feature selection process may bring to light new variables not been previously considered relevant to a given medical condition. In this paper, three different combinations of modeling and feature selection approaches are proposed and compared: fuzzy modeling with bottom-up tree search [11], with top-down tree search [11] and with ant colony feature selection [12].

Some studies have already explored this issue. In [13], a fuzzy-logic based algorithm was developed, taking arterial blood pressure and heart rate as inputs to generate a 'vasopressor advisability index'. In 2009, following Physionet/Computers in Cardiology Challenge, several algorithms were proposed to predict which patients would experience an acute hypotensive episode beginning within the forecast window. Finally, in [14] the application of some of the knowledge based methods as presented here was used to estimate outcomes in septic shock.

The paper is organized as follows. Section 2 briefly describes the modeling technique and proposed feature selection algorithms. A description of the database, its preprocessing as well as the obtained results are presented in Section 3. Conclusions are drawn in Section 4.

II. Methods

A. Fuzzy Modeling

Fuzzy modeling is a tool that allows an approximation of nonlinear systems when there is few or no previous knowledge of the system to be modeled [15]. Fuzzy models have several advantages compared to other non-linear modeling techniques. For clinical related classification systems, this approach is particularly appealing as it provides not only a more transparent model, but also a linguistic interpretation in the form of rules. These rules and logical connectives are used to establish relations between the defined features in order to derive a model. A fuzzy classifier contains a rule base consisting of a set of fuzzy if-then rules together with a fuzzy inference mechanism.

There are three general methods to design a fuzzy classifier that can be distinguished [16]: the regression method, the discriminant method and the maximum compatibility method. Given that the classification decision does not change by taking a monotonic transformation of the discriminant function [17], we used in this work the discriminant method. Here, the classification is based on the largest discriminant function, which is associated with a certain class, regardless of the values or definitions of other discriminant functions. In the discriminant method, a separate discriminant function $d_c(x)$ is associated with each class ω_c, $c = 1, \ldots, C$. The discriminant functions can be implemented as fuzzy inference systems. In this work, we use Takagi-Sugeno (TS) fuzzy models [18], which consist of fuzzy rules where each rule describes a local input-output relation. When TS fuzzy systems are used, each discriminant function consists of rules of the type

$$R_i^c : \textbf{If } x_{i1} \text{ is } A_{i1}^c \textbf{ and ... and } x_M \text{ is } A_{iM}^c$$

$$\textbf{then } d_i^c(\mathbf{x}) = f_i^c(\mathbf{x}),\ i = 1, 2, ..., K \tag{1}$$

where f_i^c is the consequent function for rule R_i^c. In these rules, the index c indicates that the rule is associated with the output class c. Note that the antecedent parts of the rules can be for different discriminants, as well as the consequents. Therefore, the output of each discriminant function $d_c(x)$ can be interpreted as a score (or evidence) for the associated class c given the input feature vector x. The degree of activation of the ith rule for class c is given by: $\beta_i = \prod_{j=1}^{M} \mu_{A_{ij}^c}(x)$, where $\mu_{A_{ij}^c}(x) : \mathbb{R} \rightarrow [0, 1]$. The discriminant output for each class c, is computed by aggregating the individual rules contribution: $d_c(x) = \frac{\sum_{i=1}^{K} \beta_i f_i^c(x)}{\sum_{i=1}^{K} \beta_i}$. The classifier assigns the class label corresponding to the maximum value of the discriminant functions, i.e

$$\max_c d_c(x). \tag{2}$$

The number of rules K, the antecedent fuzzy sets A_{ij}, and the consequent parameters $f_i^c(x)$ are determined using fuzzy clustering in the product space of the input and output variables. The number of fuzzy rules (or clusters) that best suits the data must be determined for classification. The following criterion, as proposed in [19], is used in this paper to determine the optimum number of clusters:

$$S(K) = \sum_{k=1}^{N} \sum_{i=1}^{K} (\mu_{ik})^m (\|x_k - v_i\|^2 - \|v_i - \bar{x}\|^2)^2 \tag{3}$$

Values of $S(K)$ were calculated by varying K from 2 to 20. The final number of clusters corresponded to a local minimum where the differences between the values of the criterion are minor. In our case we used a 10% threshold for this difference between two values. A fuzzy clustering and data analysis toolbox was used in this step [20].

B. Feature Selection

Feature selection is generally used to reduce computational complexity, to eliminate features with high mutual correlation [21], and required generalization properties of the model [22]. From the clinical point of view, this process may bring to light new variables that had not been previously considered for a given medical condition.

1) Bottom-up: A detailed description of the bottom-up approach used here is reported in [11]. Briefly, the bottom-up approach starts by looking for single features that may influence the process output and works to assemble these single relevant features, to achieve a model with the best performance. This approach deals with feature redundancy in a simple way. Once the features are added one by one, if a feature is redundant it means that it will not improve the model prediction, and for that reason it will not be incorporated in the previously selected subset of features. Considering X the vector containing n features, this feature selection process is described by Algorithm 1. The model evaluation method was generalized by using AUC – Area Under the ROC Curve – as the most suitable performance criteria.

According to [23], a Receiver–Operator Characteristics (ROC) curve can be used to study the behaviour of two–class classifiers. This is a function of the true positive ratio versus the false positive ratio. Consequently, in order to compare the performance of various classifiers, the AUC can be used. It corresponds to the total performance of a two-class classifier integrated over all thresholds:

$$AUC = 1 - \int_0^1 FP(FN)dFN \tag{4}$$

where FP and FN represent, respectively, the false positive rate the false negative rate. The true positive rate and true negative rate are respectively named as Sensitivity and Specificity and, in this particular scenario, correspond to the cases where the patient was correctly classified as being on vasopressors and the cases where the patient was correctly classified as not being on vasopressors.

Algorithm 1 Bottom-Up Feature Selection

For each feature in the feature vector X that does not belong to the features of the model:
repeat
  Build model using previous features of the model combined with each feature in the feature vector X that does not belong to the features of the model
  Compute AUC;
  Select the combination of features with the highest value of AUC as the new features of the model;
until AUC does not increase or the end of the feature vector is reached.
Select the final features;

2) Top-Down: A different approach based on a top-down tree search method was also used to select the most relevant features. This approach begins with all the available features, and removes those with the worst performance. The proposed top-down approach is described in Algorithm 2.

This algorithm differs from the bottom-up approach, as it begins with all the features and starts discarding features from stage to stage. Advantages include the reduction of the number of iterations per stage and, in some cases, of the number of stages, which, in lower dimension problems, ultimately leads to the overall reduction of the computational time. However, when the number of features is large, given that this approach will use more inputs to build each model from the beginning, the identification of each model can be computationally intensive.

Algorithm 2 Top-Down Feature Selection

$i = 0$, where i is the stage number;
repeat
  if $Stage = 0$ **then**
    Build a model using all the available features;
    $m = n$; where n is the number of initial features
  else
    $i = i + 2$
    Build a model using the features not discarded at the previous stage;
  end if
  Compute AUC_i;
  for $j = 1$ **to** m **do**
    Build model using all the features except feature j;
    Compute $AUC_{i+1,j}$
    if $AUC_{i+1,j} < AUC$ **then**
      Discard the feature j not used in modeling;
    end if
  end for
  $m = m - p$, where p is the number of discarded features;
until (no feature is discarded) OR (model has only one feature) OR ($AUC_i > AUC_{i-2}$)

3) Ant Colony: Ant Colony Optimization (ACO) a method suited to find minimum cost paths in optimization problems described by graphs [24]. This paper uses the ant feature selection algorithm (AFS) proposed in [12], where the best number of features is determined automatically by considering two objectives: minimizing the number of features (*feature cardinality* - N_f) and maximizing the prediction performance. Two cooperative ant colonies formed by g ants, optimize each objective. The first colony determines the number (cardinality) of features and the second selects the features based on the cardinality given by the first colony. Thus, two pheromone matrices and two different heuristics are used.

The objective function of this optimization algorithm aggregates both criteria, the maximization of the model performance and the minimization of the feature cardinality:

$$J^k = w_1(1 - AUC^k) + w_2 \frac{N_f^k}{n} \tag{5}$$

where $k = 1, \ldots, g$, AUC is the performance criterion previously defined in [23] and n is the total number of features. The weights w_1 and w_2 are selected based on experiments.

The heuristic value used for each feature (ants visibility) for the second colony, is computed as $\eta_{f_j} = AUC_j$ for $j = 1, \ldots, n$, where AUC_j quantifies the relevance of each feature in the prediction model.

For the feature cardinality (first colony), the heuristic value is computed using the Fisher discriminant criterion for feature

selection [25]. Considering a classification problem with two possible classes, class 1 and class 2, the Fisher discriminant criterion is described as

$$F(i) = \frac{|\mu_1(i) - \mu_2(i)|^2}{\sigma_1^2 + \sigma_2^2} \quad (6)$$

where $\mu_1(i)$ and $\mu_2(i)$ are the mean values of feature i for the samples in class 1 and class 2, and σ_1^2 and σ_2^2 are the variances of feature i for the samples in class 1 and 2. The score aims to maximize the between-class difference, minimize the within a given class spread and thus to limit the number of features chosen by the AFS algorithm, which can be particularly useful when the number of available features is large. Other currently proposed rank-based criteria generally come from similar considerations and show similar performance [25].

III. Results

A. MIMIC II Database

This paper used a de-identified publicly available ICU database named MIMIC II (Multiparameter Intelligent Monitoring in Intensive Care), containing data from 26,655 admitted patients. Data was collected over a six-year period, from Boston's Beth Israel Deaconess Medical Center, commencing in 2001. This database has two distinctive groups of data: the clinical database consisting of data integrated from different information systems in the hospital (patient demographics, medications, laboratory tests, etc), and a second group containing high resolution waveforms recorded from the bedside monitors in the intensive care units [10].

In this work we focused exclusively on the clinical data for two specific subsets of patients – pancreatitis and pneumonia. Given that these patients are usually treated differently – surgically and medically – we hypothesized that the circumstances related to the initiation of vasopressors are also distinct. In order to select these subsets, ICD9 (International Classification of Diseases) codes were used. These data included a total of 154 pancreatitis and 820 pneumonia patients, and 32 input variables, including vital signs, laboratory tests and urine output, sampled from one to every twelve hours, during the length of stay of the patient in the ICU. The output was formed as a binary classification with value one if, the patient was on vasopressors, and zero if not. The list of vasopressors for which the classification was performed included: phenylephrine, norepinephrine and dopamine. Their use represented 75% of all vasopressor administration events in the database. Other data inclusion criteria included: only data regarding the first stay of a patient in the ICU was considered; a period of at least six hours had to exist between the admission of the patient to the ICU (and commencement of the acquisition of data) and the administration of vasopressors; and only patients that were on vasopressors for more than two hours were included.

B. Data Preprocessing

Modern intensive care units are undergoing a significant evolution that is being driven by rapid improvements in technology as well as changes in healthcare policy. The growth of computer networking and information storage technologies has been accompanied by an increase in the complexity and number of biosensors used in the ICU, thus generating large amounts of data [26]. However, this has also contributed to issues of what to do when data are collected in different frequencies or when it is partially lost or absent. In this way, data preprocessing represents a crucial step since it defines the reliability of the information that will be used in later stages of the knowledge discovery process.

In the present work, in order to manage differences in frequency of collection, Heart Rate samples were used as a template to align the remaining variables. This choice is based on being the most frequently measured variable. A detailed description of this alignment process is presented in [27].

In general, ICU data can be missing either because they are perceived to be irrelevant for the current clinical problems (thus, not recorded), or because exogenous interventions or endogenous activities have rendered the data useless [26]. When it is possible to prove that a variable was not measured during a certain period of time because of an intentional reason (e.g. ventilator parameters when a patient is extubated), this missing segment is considered as non-recoverable. In this work, these non-recoverable missing segments were deleted. On the other hand, if the variable was suppose to exist, but for some unintentional reason (e.g. cable disconnection) it is missing, this absent segment is considered recoverable and thus, proper imputation techniques can be applied [27], [28]. In this work, a cubic interpolation was used to impute values to the recoverable missing segments.

C. Simulation and Results

The general goal of this work entailed classifying, for a specific time point of a patient stay in the ICU, whether vasopressors were being administered or not, as well as to find which subset of variables allows its better classification. Classification methods were used combining fuzzy modeling with three feature selection techniques: bottom-up (BU), top-down (TD) and ant feature selection (AFS). For purposes of comparison, a fourth method using fuzzy modeling without feature selection (No FS) was also used. In order to evaluate the performance of these models, three different criteria were used: AUC, specificity and sensitivity. The entire algorithm was run in two separate sections: feature selection and 10-fold cross-validation. Ten iterations were used during the feature selection step, thus obtaining ten different combinations of features. The combination returning the best value of AUC was selected and used on a 10-fold cross-validation step to assess how the built fuzzy model would perform. Final results are presented as an average of all these 10 folds.

Before analysing the obtained results, it is important to note some of the issues found during simulation. In determining the optimum number of fuzzy rules (clusters), in most cases, the number of clusters returned by the criterion described in equation 3 was between five and eight. However, in a few cases, the number of clusters was higher then eight, which also

Manual FS	2	1, 3	2	1, 3	2	1, 3

meant significantly higher computational times. Comparing the three feature selection methods regarding their execution times, fuzzy modeling combined with BU was the fastest (20 minutes in average for ten iterations), followed by fuzzy modeling combined with AFS and, finally, taking almost twice as the first, fuzzy modeling combined with TD.

In the first part of this work, we focused on comparing our results with other studies [13], where the classification of whether vasopressors were being administered or not, was made without distinguishing between them. In the second part of the work, we do distinguish and explore each of the vasopressors individually, i.e. a specific output was defined for each of the three vasopressors (phenylephrine, norepinephrine and dopamine).

1) Classification of general use of vasopressors: In [13], a fuzzy-logic based algorithm was developed to predict the need for vasopressor therapy, using the same MIMIC II database but with different criteria for patient selection. These models were built using as inputs two manually selected features - arterial blood pressure and heart rate. As shown in Table I, their algorithm achieved a specificity of 0.84 and a sensitivity of 0.69. The 0.77 value for AUC was estimated by us based on the respective values of specificity (0.84) and sensitivity (0.70). As mentioned, a comparison between the performance of our models with [13] was carried. However, it is important to note that it was not possible to identify which specific vasopressor(s) were included in their work, neither the criteria used to select patients. Furthermore, the conditions in which the values of specificity and sensitivity were obtained were not clear. Accordingly, some caution is needed when analysing and comparing the two approaches.

Main results follow: using the same two variables as in [13], the proposed fuzzy models returned lower values of AUC, specificity and sensitivity; however, when applying them to all variables or when combining them with any of the proposed automated feature selection processes, both AUC, specificity and sensitivity were shown to be significantly higher than in [13]. This indicates that for the specific models and data subsets chosen in this work, the two features used in [13], do not contain information that allows the correct classification of the outcome (the use of vasopressors). This is confirmed by Table II, where it is possible to observe that the features most commonly selected to classify impending use of vasopressores in pancreatitis patients include levels of Sodium (feature no. 14) and White Blood Cell counts (feature no. 12), while for pneumonia patients include levels of Lactid Acid (feature no. 28) and White Blood Cell Count (feature no. 12). These sets of features differ completely from the ones chosen in [13]. Despite the limitations, these results suggest that for the purpose of classifying whether vasopressors were being administered or not, both the proposed fuzzy model approach without feature selection and the fuzzy model approach combined with any of the automated feature selection processes, significantly outperformed previous approaches [13].

Additional comments can be made regarding the results obtained in Table I. First, higher values of AUC, specificity and sensitivity were in general obtained for the pancreatitis subset than for the pneumonia one. This might be related to the size of these subsets. As mentioned, the first contained 154 patients while the second contained 820. Most likely, the smaller subset contained a more homogeneous group of patients whose clinical condition was similar during the periods when vasopressors were being administrated or not. Secondly, it is also possible to observe that fuzzy modeling with No FS and fuzzy modeling combined with TD feature selection returned the highest values of AUC and specificity. However, these models did not return the best values of sensitivity. In other words, they performed the best in classifying when patients were not on vasopressors, but the worst in correctly classifying which patients were on vasopressors. The best values of sensitivity were given by fuzzy modeling combined with BU feature selection.

From the analysis of Table II, it can be pointed out that:

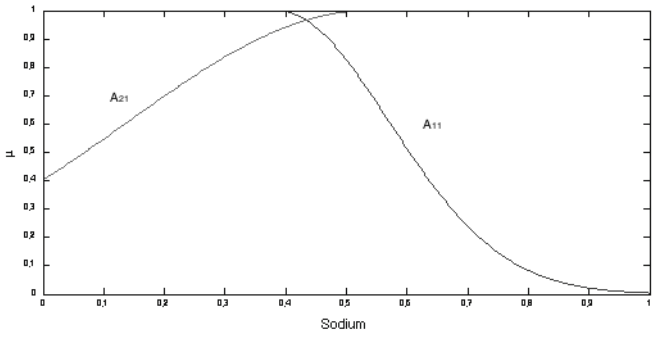

Fig. 1. Sodium's membership functions for cluster 1 (A_{11}) and 2 (A_{21})

BU and AFS techniques selected fewer features than the TD approach; in general, less features were selected for the pancreatitis subset than for the pneumonia subset; and finally, a certain consistency seems to exist between the variables most commonly selected by BU and AFS within each subset, but little or no agreement exists between the variables selected in the two subsets. In other words, this means that different variables were selected as being able to correctly classify the same outcome, between the pancreatitis and pneumonia subset of patients, thus pointing that the use of patient-specific models should be considered in future studies. In future works, it would be interesting to include a penalty for models with large numbers of features. This will reduce the number of features in the final model.

Finally, as an example, the rules built for the specific case of classifying the impending use of vasopressors in pancreatitis patients when using fuzzy modeling combined with BU, are presented:

1. **If** Sodium is A_{11} & White Blood Cell is A_{12} & BUN is A_{13} & Chloride is A_{14} **Then** $y(k) = 1.9 \cdot Sodium - 1.4 \cdot WhiteBloodCell - 3.2 \cdot BUN + 0.36 \cdot Chloride + 2.2$

2. **If** Sodium is A_{21} & White Blood Cell is A_{22} & BUN is A_{23} & Chloride is A_{24} **Then** $y(k) = -0.52 \cdot Sodium + 0.23 \cdot WhiteBloodCell + 0.073BUN + 0.55 \cdot Chloride - 0.094$

Given that two clusters were defined, two rules were obtained. The variables used to build the rules (Sodium, White Blood Cell, BUN and Chloride) were pre-selected by the BU feature selection process. A_{kj} corresponds to the membership function of cluster k for variable j. For example, in Figure 1, A_{11} and A_{21} correspond respectively to Sodium's membership functions for cluster 1 and 2. $y(k)$ corresponds the output of the model for cluster k. After the defuzzification step, all clusters outputs are combined into a single output, by averaging them. This final output takes a real value between 0 and 1 which, by using a pre-determined threshold (in this work defined as 0.12), is set to 1 if it is over this threshold, and 0 if it is below.

2) Classification of the specific use of phenylephrine, norepinephrine or dopamine: In the second part of this work, as previously mentioned, we tried to explore the individual use of each of the three vasopressors. First, in accordance to what was found in Table I, by comparing Table III and IV it is possible to observe that better results were obtained for the pancreatitis than for the pneumonia subset of patients. Second, developed models seem to perform the best in classifying when dopamine is administered, followed by phenylephrine and lastly in classifying the use of norepinephrine. Finally, fuzzy modeling with No FS and fuzzy modeling combined with TD returned again the best values of AUC and specificity, while fuzzy modeling combined with BU returned the best values of sensitivity.

From Tables V and VI several comments can be made regarding the set of selected features. First, contrarily to what was expected, having more features selected did not mean that models would perform better. For example, in classifying if dopamine was being administered to a pneumonia patient, after ten iterations of fuzzy modeling combined with BU, an average of two to four variables were selected. However, the model with the best values of AUC was the one where only two variables allowed to classify this outcome. Another interesting finding is that there is a certain agreement between the variables most commonly selected by BU and AFS. Most obvious examples include levels of Sodium (Table VII - Feature no. 14) and BUN (Table VII - Feature no. 10) in explaining the use of phenylephrine in pacreatitis patients, and levels of INR (Table VII - Feature no. 21) in explaining the use of dopamine in pneumonia patients. However, there are still a few cases (e.g. norepinephrine in pneumonia patients) where

a total disagreement exists between the two sets of selected features. This may be an indicator that for this specific problem of classifying the use of vasopressors, different and specific rules should be determined in order to explain the use of each of the three vasopressors. This highlights the importance and applicability of combining feature selection techniques with predictive models.

IV. CONCLUSIONS

Evidence based medicine firstly requires medicine based evidence. Modern intensive care units fill databases with large amounts of data which go some way to addressing this. However, these databases commonly contain large amounts of data acquired from different sources, and require reliable tools to process the information and integrate results in a human-understandable way. Given the particularly appealing feature for clinicians of providing transparent models and a linguistic interpretation in the form of rules, fuzzy models were used in the present work. In order to reduce the number of rules and bring to light new variables not previously thought relevant, a feature selection process was added to the models.

A classification task was performed to determine which set of clinical variables best predicted the likely administration of vasopressors. It was demonstrated that all the proposed approaches outperform previous works. Fuzzy models combined with BU feature selection returned higher values of sensitivity (i.e. perform better in classifying when a vasopressor was being administered), while fuzzy models with No FS and fuzzy models with TD feature selection returned higher values of AUC and specificity (i.e. performed better in classifying when a vasaprossor was not being administered). The fact that different features were selected to classify the same vasopressor in two different subsets of patients (pancreatitis and pneumonia), points to the future exploration of patient-specific models. Finally, fuzzy models combined with BU and fuzzy models combined with AFS utilize less variables with no significant loss in accuracy. Given the advantage of model ease of interpretation while maintaining high levels of accuracy, we believe that fuzzy modeling combined with these last two feature selection techniques provide opportunities for further studies in this area.

ACKNOWLEDGMENT

The author would like to acknowledge the assistance of the Division of Clinical Informatics at Beth Israel Medical Center. Both human and technical resources were made available and were critical for the development of this work.

Abstract: **Due to the rapid changing marketplace, technology, equipment and raw materials, companies pursuit competitiveness by the new product and new product development (NPD) process for the purpose of innovation, high quality, and speed to the market. It is a gradual trend that the product life cycle is becoming shorter. The product manager intends to achieve the highest customer satisfaction, product value and product continuity. Therefore, to evaluate performance of NPD becomes a critical issue on the NPD process selection which is considered in many different uncertain aspects. Thus, this situation can be regarded as a fuzzy multiple criteria decision-making (FMCDM) problem, so the vagueness and uncertainty of subjective perception could be considered. In this paper, the non-additive (called super-additive) fuzzy integral is used to deal with evaluation of fuzzy MCDM problems particularly while there is dependence among the selected criteria. We can evaluate the quality performance of NPD process according to the result of empirical analysis. Consequently, DEMATEL is used to explore the relevance for the selected criteria of NPD process which is used to find the directions of problem-solving. The results of this study will provide NPD project team a guidance to satisfy the customer needs and creative the value of enterprise business.**

Keywords: New product development (NPD), fuzzy multiple criteria decision-making (FMCDM), fuzzy integral, DEMATEL

I. INTRODUCTION

Due to the rapid changing marketplace, technology, equipment and raw materials, companies try to seek competitiveness by the product and new product development (NPD) process for the purpose of innovation, high quality, and speed to the market. It is a gradual trend that the product life cycle is becoming shorter. The manager intends to achieve the highest customer satisfaction, product value and product continuity. For the company, to select and evaluate is greatly critical on the NPD process which needs to be considered in different aspects [1]. As a result the high quality of NPD process has become the critical success factors of new product development.

Garvin (1984) thinks quality improvement is beneficial for market expansion and cost reduction, so the appropriate and high quality NPD process can provide the enterprise sustainable business. Its can increase the sense of reliance of product for obtaining the positive impression to create a good product (brand) image [5]. In 1987, the International Organization for Standardization (ISO) released ISO 9000 series of quality management system and quality assurance standards, most companies are using this standard to improve the process quality of enterprise. The enterprises of various fields that can review standard of ISO quality management through the procedures and conduct a series mission of the "process quality" for supervision, control, tracking and continuous improvement according to the design review standards and ISO quality management.

The development of new products and services involves an integrated set of unique activities. U.S. Product Development and Management Association (PDMA) proposed the NPD process with a clear definition as "a clear mission and the steps show that is from the concept to the marketable products or services required standardized methods". The manager should plan, check and execute a formal written review of the mission results under the appropriate stage of NPD process [27].

This study is based on ISO 9000:2008 quality management system to explore the evaluation indexes for the quality of NPD process [25]. The purpose here is to construct a model that not only considers in the presence of intangible attributes and uncertainty such has inter-dependent characteristics between attributes. First, a fuzzy integral is applied to integrate the performance rating of attributes in each criterion. The results can obtain the total performance of each dimension for the case study. Second, DEMATEL is used to construct the relevance for the evaluated criteria. Then, the manager can find the direction of problem-solving from DEMATEL. The results of this study will provide NPD team a guidance to satisfy the customer needs and create the value of sustainable business.

The reminder of this paper is organized as follows. In Section 2, literature review on quality of NPD process is introduced. In Section 3, NPD process performance evaluation model is developed. An empirical case analysis for NPD process is illustrated to show our proposed model in Section 4. The result and discussions is in Section 5. Finally, conclusion is presented in Section 6.

II. LITERATURE RELATED ON NPD PROCESS

This section is aimed to understand the evaluation indexes related to NPD process. It is collected, selected, analyzed, simulated and tested by the literature of the past new product development with expert questionnaires to find problems that requires strict quality management as a basis. We use ISO9000 series of quality management system standards to explore the related evaluation indexes of process quality.

A. The new product development (NPD)

Sampson (1970) proposed the view of consumer to explain the new product that is defined as "it has to meet new demands, requirements or desires that is more significant than other products" [2]. Souder (1988) defined the new product is based

on the view of business as "it has never owned products in previous" [7]. Kolter (1994) proposed the view of product characteristic to explain the new product who divided the types of new product as: (1) internal development of original product; (2) improved product; (3) modified product; (4) new brand. Overview of the scholar defines the new product to explain that opens up an entirely new market and adapts or replaces an existing product [8]. In addition, it is including an old product introduced in a new market or packaged and marketed in different way.

According to above all, the new product development (NPD) is a process which is designed to develop, test and consider the viability of products which are new to the market in order to ensure the growth or survival of the organization. The primary impact of the environment is to drive the types of new product changes which help speed products through development, and improve process efficiency and overall NPD effectiveness [12].

NPD involves a series of organization and connects the activities closely which is significantly for the input of manpower and financial capability. They believe the quality and up to 80% of NPD costs that has decided in the product design stage [13]. Therefore, the managers reduce and control the uncertainty activities before the next phase is implemented according to the integrity of information. It can ensure to improve the performance and quality of NPD.

B. New product development (NPD) process

From the past product idea to the new product development starts with the cumulative ideas. The idea generation is a NPD process in which creative thinking is used to produce large amount of ideas for new products. Therefore, NPD process may be accepted as a dynamic process in which each decision-making on each stage must be evaluated, selected, and prioritized. All the stages of the process are affected by uncertain, changing information and dynamic opportunities [18]. It is greatly complex and widely which is combined by many different aspects. The NPD process not only evaluates the gathered ideas but also has a specific purpose, which involve the whole of the enterprise including its customer, cost, time, technical, raw materials, regulatory requirement and the person in charge. Furthermore, the management of ideas is also very important at this stage due to the large number of ideas to be selected and their diversity.

Urban and Hauser (1980) defined the NPD process as: (1) opportunity identification phase; (2) design phase; (3) testing phase; (4) listed phase [4]. Cooper (1994, 1996) proposed the definition of NPD process as: (1) the ideas of product; (2) initial assessment; (3) concept design; (4) product development; (5) product testing; (6) engineering trial production; (7) mass production and listed [9][11]. To overview of the NPD process concept which is extended by the concept of stage and gate. A "Stage-Gate Process" is a conceptual and operational roadmap for moving a new-product project from idea to launch. Stage-Gate divides the effort into distinct stages separated by management decision gates. Cross-functional teams must successfully complete a prescribed set of related cross-functional tasks in each stage prior to obtaining management approval to proceed to the next stage of product development [14].

Today organizations have developed many different variations and varieties from the original concept of NPD process. In this paper, we propose a critical NPD process according to the NPD process definition from the concept of stage and gate, which is divided into five parts for ten phases as: (1) customer needs analysis; (2) conceptual design; (3) conceptual development; (4) preliminary design; (5) design and evaluation; (6) detail design; (7) product run and test; (8) pre-mass production run and test; (9) mass production listing; (10) transference, these NPD phases combine with the design review [3,10,13,14].

C. The evaluation indexes for NPD process

We explore the evaluation indexes of NPD process according to the ISO 9000:2008 quality management system [23][15]. Through the expert questionnaires select and evaluate the evaluation indexes according to its properties which is selected and divided into fifteen criteria, the result as shown in Table 1.

III. DEVELOPING AN EVALUATION MODEL FOR NPD PROCESS

In this paper, the fuzzy integral is used to combines the efficient value of those related attributes and to develop a new combining performance value [20]. Then, DEMATEL is used to explore the affect and relevance for the criteria of each dimension respectively which can provide the product manager to find the directions of problem-solving for the performance gaps of NPD process [28].

A. Regrouping the evaluation indexes of NPD process by fuzzy integral

The traditional multi-criteria decision-making evaluation is based on the assumption that each attribute is independent with the evaluation of multiple attributes executed by simply weighting the relative importance and performance of each [20][10]. The integrated performance is measured by weighting and performance for each attribute. In the real world, there are some inter-dependent characteristics between attributes. Therefore, partitioning the type of fuzzy integral has to be applied on these related attributes to regroup a new hierarchy system [20][3].

TABLE I. THE EVALUATION INDEXES OF NPD PROCESS [23][15]

Criteria for the process quality
C_1 Product specifications and customer needs analysis
C_2 Compatibility of safety and environment
C_3 The regulatory requirements of business practices, national and international standards
C_4 To compare with the competitive products
C_5 Consideration of improper use and misuse
C_6 The requirements of reliability, service and maintainability
C_7 The allowed tolerance and process capability assessment
C_8 The criteria of product acceptance and rejection
C_9 Installable features and easy assembly
C_{10} To review and use the standard components
C_{11} The manufacturability of product design and development
C_{12} The examination and experimentation of product design and development
C_{13} The specification of materials and components
C_{14} The requirements of packaging, handling, storage and storage life
C_{15} Confirmation of customer needs and assessment of production costs

B. λ-Fuzzy measure

Fuzzy measure is a set function, let g_λ be a λ fuzzy measure which is defined on a power set $P(x)$, for the finite set $X=\{x_1,x_2,\ldots,x_n\}$ [16].The fuzzy measure has the following property [19] [22]:

$$\forall A,B\in P(x),\quad A\cap B=\varnothing,$$
$$g_\lambda(A\cup B)=g_\lambda(A)+g_\lambda(B)+\lambda g_\lambda(A)g_\lambda(B) \quad \text{for } -1<\lambda<\infty \tag{1}$$

The density of the fuzzy measure $g_i=g_\lambda(\{x_i\})$ can be formulated as

$$\begin{aligned} g_\lambda(\{x_1,x_2,\ldots,x_n\}) &= \sum_{i=1}^{n} g_i+\lambda\sum_{i_1=1}^{n-1}\sum_{i_2=i_1+1}^{n} g_{i_1}g_{i_2} \\ &\quad +\cdots+\lambda^{n-1}g_1,g_2,\ldots,g_n, \\ &= \frac{1}{\lambda}\left|\prod_{i=1}^{n}(1+\lambda g_i)-1\right| \\ &\quad \text{for } -1<\lambda<\infty \end{aligned} \tag{2}$$

Base on these properties, one of the three following situations will be sustained for a specific case with two attributes, x_1 and x_2.

(a) If $\lambda>0$, then $g_\lambda(A\cup B)>g_\lambda(A)+g_\lambda(B)$: this implies that x_1 and x_2 have multiplicative effect in $\{A,B\}$.

(b) If $\lambda=0$, then $g_\lambda(A\cup B)=g_\lambda(A)+g_\lambda(B)$: this implies that x_1 and x_2 have additive effect in $\{A,B\}$.

(c) If $\lambda<0$, then $g_\lambda(A\cup B)<g_\lambda(A)+g_\lambda(B)$: this implies that x_1 and x_2 have substitutive effect in $\{A,B\}$.

C. Fuzzy integral

Let h be a measurable set function defined on the fuzzy measurable space, and supposing that $h(x_1)\ge h(x_2)\ge\cdots\ge h(x_n)$, then the fuzzy integral of fuzzy measure $g(\cdot)$ with respect to $h(\cdot)$ can be defined as Eq. (3) [6] and the concept of fuzzy integral as shown in Fig. 1 [20][22]:

$$\begin{aligned} \int h\,\mathrm{d}g &= h(x_n)g(H_n)+[h(x_{n-1})-h(x_n)] \\ &\quad g(H_{n-1})+\cdots+[h(x_1)-h(x_2)]g(H_1) \\ &= h(x_n)[g(H_n)-g(H_{n-1})]+h(x_{n-1}) \\ &\quad [g(H_{n-1})-g(H_{n-2})]+\cdots+h(x_1)g(H_1), \end{aligned} \tag{3}$$

where $H_1=\{x_1\}, H_2=\{x_1,x_2\},\ldots,H_n=\{x_1,x_2\ldots,x_n\}=X$.

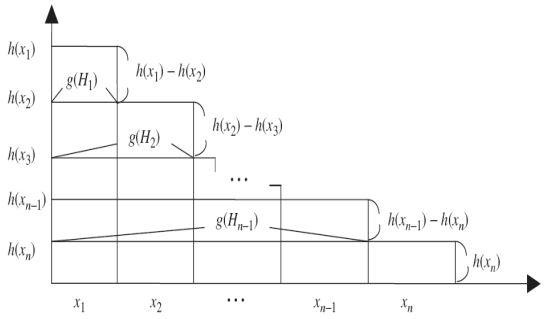

Figure 1. Concept of fuzzy integral [20] [22]

Using the fuzzy integral to formulae the original data, not only can fewer and more representative factors be extracted to describe the system, but the interactions between attributes can be considered. Furthermore, we used $\int h\,\mathrm{d}g=a_i(d)$ as the integrated performance value of the common-factor C_d for the case study.

D. Building a network relationship by DEMATEL

DEMATEL is an analytical method of structural model. It is mainly used to solve all kinds of complex problems to clarify the essential of the problem that can effectively understand the complex structure and provide viable options of problem-solving [21].

DEMATEL is divided into five steps. The first step is to confirm the system has n elements and develop the evaluating scale, using pair of dimensions to compare and also using evaluating scale 0, 1, 2, 3, 4, which in turn represents no effect (0), low effect (1), medium effect (2), high effect (3), and extremely high effect (4) as measuring standard. The second step is to calculate initial matrix, using pair of degree of interaction to obtain directly effecting matrix $\boldsymbol{Z}=[z_{ij}]_{n\times n}$, where z_{ij} represents the degree of effect on i factor effects j factor [24][26].

$$\boldsymbol{Z}=\begin{bmatrix} z_{11} & \cdots & z_{1j} & \cdots & z_{1n} \\ \vdots & & \vdots & & \vdots \\ z_{i1} & \cdots & z_{ij} & \cdots & z_{in} \\ \vdots & & \vdots & & \vdots \\ z_{n1} & \cdots & z_{nj} & \cdots & z_{nn} \end{bmatrix} \tag{4}$$

When the elements of *i* have a direct effect on the elements of *j*, then $z_{ij}\neq 0$, opposite $z_{ij}=0$. The third step is to normalize the matrix. It can be obtained from Eqs. (2) and (3). Its diagonal is 0, and maximum sum of row or column is 1.

$$\boldsymbol{X}=s\,\boldsymbol{Z} \tag{5}$$

$$s=\min\left[\frac{1}{\max_i\sum_{j=1}^{n}|z_{ij}|},\frac{1}{\max_j\sum_{i=1}^{n}|z_{ij}|}\right] \quad i,j=1,2,\ldots,n \tag{6}$$

The forth step is to obtain the total influence matrix $\boldsymbol{T}$. Its can be obtained by $\boldsymbol{T}=\boldsymbol{X}+\boldsymbol{X}^2+\cdots+\boldsymbol{X}^m=\boldsymbol{X}(\boldsymbol{I}-\boldsymbol{X})^{-1}$, where $\boldsymbol{I}$ is the identity matrix. The fifth step is to obtain prominence and

relation. To sum of each row and column of the total influence matrix $\boldsymbol{T}=[t_{ij}]$. Its will obtain the sum of all rows (vector $\boldsymbol{r}=(r_1,...,r_i,...,r_n)$) and the sum of all columns (vector $\boldsymbol{d}=(d_1,...,d_j,...,d_n)$).

If r_i represents the sum of all rows of the total influence matrix $\boldsymbol{T}$, meaning directly or indirectly influence degree; d_j represents the sum of all columns of the total influence matrix $\boldsymbol{T}$, meaning influence or be influenced other criteria. r_i represents the factor *i* which will influence other factors, d_j represents the factor *j* that is influenced by other factors. According to the definition, r_i+d_j presents the degree of relationship between the factors, meaning "prominence"; r_i-d_j presents the degree of influence and influenced for the factors, meaning "relation" [21][17].

IV. Empirical analysis for the case study

In this section, we evaluate the performance of NPD processes within a case study of company A. We will consider the overall impact in product manufacturing and developing that may have potential problems and risks in the NPD process. Through the expert questionnaires, we classify the evaluation indexes according to its properties which is selected and divided into five dimensions of fifteen criteria, as shown in Fig.2.

A. To obtain the assessment value by fuzzy measure

Here fuzzy measure and fuzzy integral are used to determine the problem of NPD performance evaluation for human subjective decision-making issues. In the table2, we obtain the results of fuzzy measure which illustrates that the criterion "Confirmation of customer needs and assessment of production costs (C_{13})" is most important attribute of customer needs included (C_{13}=0.74). And the set values are obtained respectively according to those evaluated value of attributes.

Consequently, the non-additive fuzzy integral model is used to calculate the assessment value (C_d) for each dimension. Furthermore, the performance value for each dimension is calculated as shown in Table 3. The result shows dimension "Customer needs (D_1)" is the highest performance value (D_1=0.920) than others; "Product design (D_3)" is the lowest performance value than others (D_3=0.865). The priority of performance value for each dimension is following: D_1 (Customer needs) > D_4 (Process planning) > D_5 (Product Logistics) > D_2 (Environment) > D_3 (Product design).

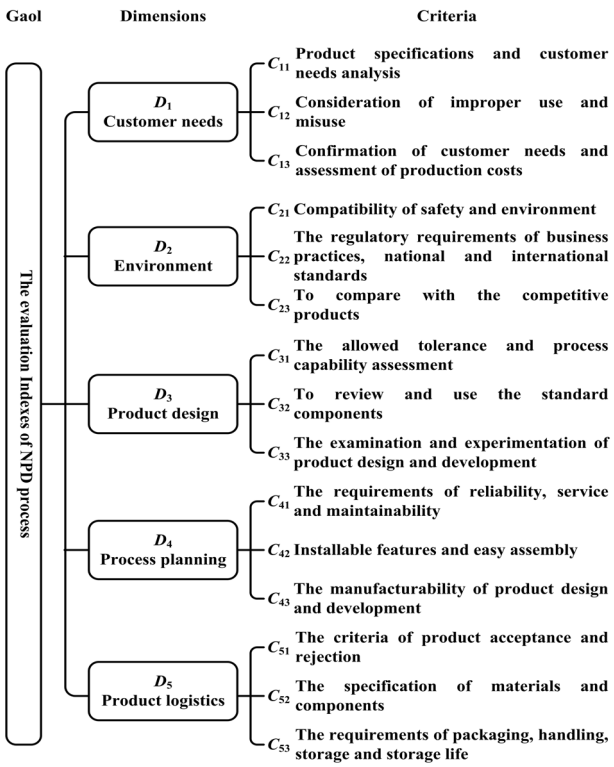

Figure 2. The assessment hierarchy system

TABLE II. FUZZY MEASURE $g(\cdot)$ OF EACH CRITERIA

Fuzzy measure of criteria	
D_1 Customer needs (λ =-0.91)	
$C_{11}=0.63$	$\{C_{11},C_{12}\}=0.79$
$C_{12}=0.38$	$\{C_{12},C_{13}\}=0.87$
$C_{13}=0.74$	$\{C_{11},C_{13}\}=0.95$
	$\{C_{11},C_{12},C_{13}\}=1$
D_2 Environment (λ =-0.85)	
$C_{21}=0.57$	$\{C_{21},C_{22}\}=0.82$
$C_{22}=0.49$	$\{C_{22},C_{23}\}=0.84$
$C_{23}=0.60$	$\{C_{21},C_{23}\}=0.88$
	$\{C_{21},C_{22},C_{23}\}=1$
D_3 Product design (λ =-0.81)	
$C_{31}=0.62$	$\{C_{31},C_{32}\}=0.83$
$C_{32}=0.43$	$\{C_{32},C_{33}\}=0.77$
$C_{33}=0.52$	$\{C_{31},C_{33}\}=0.88$
	$\{C_{31},C_{32},C_{33}\}=1$
D_4 Process planning (λ =-0.92)	
$C_{41}=0.65$	$\{C_{41},C_{42}\}=0.90$
$C_{42}=0.63$	$\{C_{42},C_{43}\}=0.87$
$C_{43}=0.58$	$\{C_{41},C_{43}\}=0.88$

Fuzzy measure of criteria	
	$\{C_{41}, C_{42}, C_{43}\} = 1$
D_5 Product logistics (λ =-0.94)	
$C_{51} = 0.55$	$\{C_{51}, C_{52}\} = 0.87$
$C_{52} = 0.66$	$\{C_{52}, C_{53}\} = 0.93$
$C_{53} = 0.72$	$\{C_{51}, C_{53}\} = 0.90$
	$\{C_{51}, C_{52}, C_{53}\} = 1$

B. To obtain the total performance by fuzzy integral

We used fuzzy integral to obtain the total performance base on the assessment value from fuzzy measure. The result demonstrates that dimensions "Environment (D_2)" and "Product design (D_3)" are the performance gaps with total performance 0.907 from Fuzzy Integral as illustrated in Table 3.

TABLE III. TO OBTAIN THE TOTAL PERFORMANCE BY FUZZY INTEGRAL

The case study of company A			
Dimensions	***Fuzzy measure of dimensions***	***Assessment value (C_d)***	***Performance ranking***
	λ=-0.99		
D_1	0.584	0.920	1
D_2	0.556	0.874	4
D_3	0.524	0.865	5
D_4	0.619	0.890	2
D_5	0.642	0.887	3
Total performance	**0.907**		
{D1,D2}=0.82	{D2,D4}=0.84		
{D1,D3}=0.81	{D2,D5}=0.85		
{D1,D4}=0.85	{D3,D4}=0.82		
{D1,D5}=0.86	{D3,D5}=0.83		
{D2,D3}=0.79	{D4,D5}=0.87		
{D1,D2,D3}=0.92	{D2,D3,D5}=0.93		
{D1,D2,D4}=0.94	{D3,D4,D5}=0.94		
{D1,D2,D5}=0.94	{D1,D2,D3,D4}=0.94		
{D1,D3,D4}=0.93	{D1,D2,D3,D5}=0.94		
(D1,D3,D5)=0.93	{D1,D2,D4,D5}=0.99		
{D1,D4,D5}=0.95	{D2,D3,D4,D5}=0.77		
{D2,D3,D4}=0.93	{D1,D2,D3,D4,D5}=1		

C. Constructing the network by DEMATEL

In this section, DEMATEL is applied to explore the inter-relationship between the criteria. According to the empirical analysis, we obtain the influence degree of each criterion as shown in Table 4. Based on the results of fuzzy integral, we build the network about "Environment (D_2)" and "Product design (D_3)" which are proved by the empirical analysis from DEMATEL as illustrated in Fig. 3 and Fig. 4.

TABLE IV. THE DEGREE OF INFLUENCE FOR EACH CRITERION

T	r	d	$r + d$	$r - d$
C_{11}	8.861	8.701	17.562	0.160
C_{12}	8.378	8.096	16.474	0.282
C_{13}	8.636	7.846	16.482	0.791
C_{21}	8.426	8.643	17.069	-0.218
C_{22}	7.737	9.209	16.947	-1.472
C_{23}	9.083	8.506	17.589	0.577
C_{31}	9.310	8.571	17.881	0.739
C_{32}	8.074	8.282	16.357	-0.208
C_{33}	8.418	8.504	16.922	-0.086
C_{41}	9.038	9.446	18.484	-0.409
C_{42}	8.848	8.564	17.412	0.285
C_{43}	8.351	8.818	17.169	-0.468
C_{51}	8.873	8.443	17.316	0.429
C_{52}	7.028	9.225	16.253	-2.197
C_{53}	8.563	6.770	15.333	1.793

Within the dimension "environment (D_2)", criterion C_{23} is the highest impact of the strength of relation that means the most important influencing factors; C_{22} is all the factors that affects the least degree of other factors according to the total influential prominence $(r_i + d_i)$. Furthermore, we also found that C_{23} is the highest degree of impact relationship which affects other factors directly; and C_{22} is the most vulnerable influence factor to compare with other criteria according to the influential relation $(r_i - d_i)$.

The result also illustrates that criterion "The regulatory requirements of business practices, national and international standards (C_{22})" needs for prior improvement. The product manager can improve the performance gap form the criterion "To compare with the competitive products (C_{23})" which could then effectively improve the entire performance of this dimension.

In the dimension "product design (D_3)", the criterion C_{31} is the highest impact of the strength of relation that means the most important influencing factors; C_{32} is all the factors that affects the least degree of other factors according to the total influential prominence $(r_i + d_i)$. Furthermore, we also found that C_{31} is the highest degree of impact relationship that affect

other factors directly; and C_{32} is the most vulnerable impact factor to compare with other criteria according to the influential relation $(r_i - d_i)$.

The result illustrates that criterion "To review and use the standard components (C_{32})" needs for prior improvement. The product manager can improve the performance gap begin with the criterion "The allowed tolerance and process capability assessment (C_{31})" which can effectively improve the entire performance of this dimension D_3.

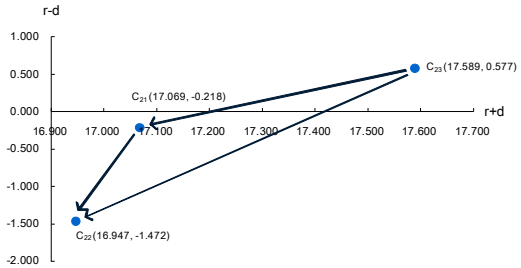

Figure 3. the Shown the interrelationship of D_2

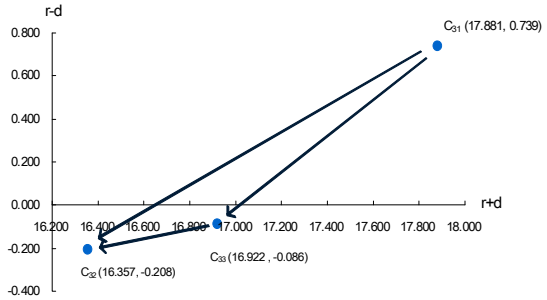

Figure 4. the Shown the interrelationship of D_3

V. Results and discussions

In this paper, we use fuzzy integral to integrate the performance rating of attributes for performance evaluation quality of the NPD process. Furthermore, we combine with the results of to obtain the total performance of NPD process for the case study. Consequently, we use DEMATEL to explore the relevance for the considered criteria of NPD process which is used to find the directions of problem-solving respectively.

According to the results of empirical analysis and the literature review to the past research, the study illustrates that shows "customer needs (D_1)", "process planning (D_4)" and "product logistics (D_5)" are the critical dimensions in NPD process quality [28]. In addition, we can know D_2 (Environment) and D_3 (Product design) both are the lowest performance value than others. The manager can improve the performance through the criteria of "To compare with the competitive products (C_{23})" and "The allowed tolerance and process capability assessment (C_{31})" which can improve the performance efficiency.

VI. Conclusion

In our study, we find that "customer needs", "process planning" and "product logistics" are still the critical indexes for performance assessment of the NPD process according to the empirical analysis. In case study of company A, we obtain the total performance is greatly near to the highest expect value, but the performance for the dimension of "environment (D_2)" and "product design (D_3)" are low. In the real word, the manager may take into those dimensions which can support the company to improve the entire NPD process efficiency in order to exceed the aspire level. The results from this study will provide an NPD project team a guidance to satisfy the customer needs and create the value of sustainable business.

***Abstract*—This paper presents an intelligent control scheme that uses an adaptive self-organizing cerebellar model articulation controller with general basis function (CMAC_GBF) in aircraft automatic landing system (ALS). During landing phase if the flight condition is out of the desired or preset environments, such as encountering severe turbulence, the ALS is disabled. The proposed intelligent controller can act as an experienced pilot and guide the aircraft landed safely in the serious condition. Lyapunov theory is applied to obtain adaptive learning rule and stability analysis is also provided. The performance of the proposed controller is better than conventional CMAC_GBF.**

Keywords-self-organizing CMAC; automatic landing system; general basis function; turbulence; PID control

I. INTRODUCTION

On March 1, 2008, at Hamburg airport, a Lufthansa Airbus A320 tried to land in crosswind conditions which exceeded the limit for the aircraft and made the left wing touch ground. The pilots then performed a go around and successfully saved the aircraft from crashing. The atmospheric disturbance causes the problem of flight safety and reduces the flying quality. According to International Air Transport Association (IATA) classification, aircraft accident contributing factor is divided into five categories as human factor, technical, environment, organization factor and insufficient. An aircraft accident survey of 19562 aircraft accidents from 1994 through 2003, weather was a contributing factor. The percentage of weather related to total accidents is 21.3% [1]. Percentage of weather related accidents by weather conditions is shown in Fig. 1. The first automatic landing system (ALS) was developed in England during 1965. Since then, most aircraft have had this system installed. The ALS relies on the instrument landing system (ILS) to guide the aircraft into the proper altitude, position, and approach angle during the landing phase. According to Federal Aviation Administration (FAA) regulations [2], environmental conditions considered in the determination of dispersion limits are: headwinds up to 25 knots, tailwinds up to 10 knots, crosswinds up to 15 knots, moderate turbulence, and wind shear of 8 knots per 100 feet from 200 feet to touchdown. Conventional automatic landing systems can provide a smooth landing, which is essential to the comfort of passengers. However, these systems work only within a specified operational safety envelope. When the conditions, such as turbulence or wind shear, are beyond the envelope, they often cannot be used. Most conventional control laws generated by the ALS are based on the gain scheduling method [3]. Control parameters are preset for different flight conditions within a specified safety envelope, which is relative defined by FAA regulation. When the conditions, such as turbulence, are beyond the envelope, the ALS is disabled and manual operation is engaged. An inexperience pilot may not be able to guide the aircraft safely. Therefore it is desirable to develop an intelligent ALS that expands the operational envelope to include more safe responses under a wider range of conditions. The goal of this study is to show that the proposed intelligent ALS can relieve human operation and guide the aircraft to a safe landing in wind-disturbance environment.

In recent years, intelligent control is more and more popular in control engineering applications. Many intelligent concepts have been applied into various scientific and engineering researches. There are also obvious achievements in flight control domain [4]-[9]. CMAC_GBF has attracted researchers' attentions for the following advantages: rapid learning speed, guarantee of learning convergence, good generalization, and low computational load. A simplified addressing technique procedure, S_CMAC_GBF, is presented by C.T. Chiang [10]. The simplified model not only provides fixed addressing procedure for CMAC_GBF but also reduces the usage of memory. The S_CMAC_GBF still posses the same learning convergence characteristics of CMAC_GBF, but with more enhanced accurate system performance. The calculation speed of S_CMAC_GBF is faster than conventional CMAC_GBF. It is very useful in on-line control system. But it is hard to decide the number of layers and the value of learning rate of the S_CMAC_GBF. In this study, we utilize a self-organizing CMAC_GBF (SOCM) [11] by judging error rate to add or delete layer and introduce a SOCM with adaptive learning rate to automatic landing system. Because adaptive control theory has been successfully employed in various fields, more and more researchers integrated the adaptive concept into the intelligent control system. The performance of the intelligent ALS under severe environment can be improved by the advantages of the SOCM with adaptive learning rate, and

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

the advantages are local generalization, rapid learning convergence, and environment adaptive capability.

II. LANDING SYSTEM MODEL

At the aircraft landing phase, the pilot descends from the cruise altitude to an altitude of approximately 1200 ft above the ground. The pilot then positions the aircraft so that the aircraft is on a heading towards the runway centerline. When the aircraft approaches the outer airport marker, which is about 4 nautical miles from the runway, the glide path signal is intercepted, as shown in Fig. 2 [12]. As the airplane descends along the glide path, its pitch, attitude, and speed must be controlled. The descent rate is about 10 ft/sec and the pitch angle is between -5 to +5degrees. Finally, as the airplane descends 20 to 70 feet above the ground, the glide path control system is disengaged and a flare maneuver is executed. The vertical descent rate is decreased to 2 ft/sec so that the landing gear may be able to dissipate the energy of the impact at landing. The pitch angle of the airplane is then adjusted, between 0 to 5 degrees for most aircraft, which allows a soft touchdown on the runway surface.

A simplified model of a commercial aircraft that moves only in the longitudinal and vertical plane is used in the simulations for implementation ease [7]. The motion equations of the aircraft are given as follows:

$$\Delta\dot{u} = X_u(\Delta u - u_g) + X_w(\Delta w - w_g) + X_q\Delta q - g(\frac{\pi}{180})\cos(\gamma_0)\Delta\theta + Z_E\delta_E + Z_T\delta_T \quad (1)$$

$$\Delta\dot{w} = Z_u(\Delta u - u_g) + Z_w(\Delta w - w_g) + (Z_q - \frac{\pi}{180}U_0)\Delta q - g(\frac{\pi}{180})\sin(\gamma_0)\Delta\theta + Z_E\delta_E + Z_T\delta_T \quad (2)$$

$$\Delta\dot{q} = M_u(\Delta u - u_g) + M_w(\Delta w - w_g) + M_q\Delta q + M_E\delta_E + M_T\delta_T \quad (3)$$

$$\Delta\dot{\theta} = \Delta q \quad (4)$$

$$\Delta\dot{h} = -\Delta w + \frac{\pi}{180}U_0\Delta\theta \quad (5)$$

where u is the aircraft longitudinal velocity (ft/sec), w is the aircraft vertical velocity (ft/sec), q is the pitch rate (rate/sec), θ is the pitch angle (deg), h is the aircraft altitude (ft), δ_E is the incremental elevator angle (deg), δ_T is the throttle setting (ft/sec), γ_o is the flight path angle (-3deg), and g is the gravity (32.2 ft/sec^2). The parameters X_i , Z_i and M_i are the stability and control derivatives.

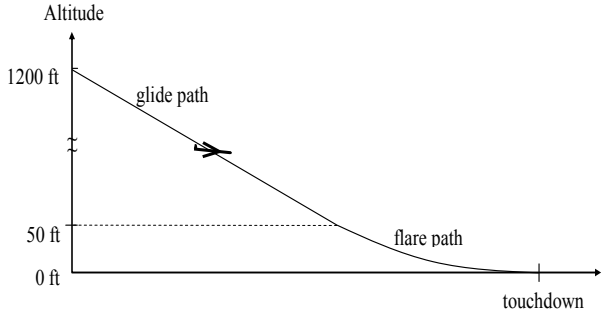

Figure 2. Glide path and flare path.

To make the ALS more intelligent, reliable wind profiles are necessary. Two spectral turbulence models by von Karman and Dryden are mostly used for aircraft response studies. In this study the Dryden form [7] was used for its demonstration ease. The model is given by:

$$u_g = u_{gc} + N(0,1)\sqrt{\frac{1}{\Delta t}\left(\frac{\sigma_u\sqrt{2a_u}}{s+a_u}\right)} \quad (6)$$

$$w_g = N(0,1)\sqrt{\frac{1}{\Delta t}\left(\frac{\sigma_w\sqrt{3a_w}(s+b_w)}{(s+a_u)^2}\right)} \quad (7)$$

where $u_{gc} = -u_{wind\,510}[1 + \frac{\ln(h/510)}{\ln(51)}]$, $a_u = \frac{U_o}{L_u}$, $L_w = h$, $a_u = \frac{U_o}{L_u}$, $a_w = \frac{U_o}{L_w}$, $b_w = \frac{U_o}{L_w\sqrt{3}}$, $L_u = 100h^{1/3}$ for $h > 230$, $L_u = 600$ for $h \le 230$, $\sigma_u = 0.2|u_{gc}|$ for $h > 500$, $\sigma_w = 0.2|u_{gc}|(0.5 + 0.00098*h)$ for $0 \le h \le 500$. The parameters are: u_g is the horizontal wind velocity (ft/sec), w_g is the vertical wind velocity (ft/sec), u_0 is the nominal aircraft speed (ft/sec), $u_{wind510}$ is the wind speed at 510 ft altitude, L_u and L_w are scale lengths (ft), σ_u and σ_w are RMS values of turbulence velocity (ft/sec), Δt is the simulation time step (sec), $N(0,1)$ is the Gaussian white noise with zero mean and unity standards deviation, u_{gc} is the constant component of u_g, and h is the aircraft altitude (ft). Fig. 3 shows a turbulence profile with a wind speed of 30 ft/sec at 510 ft altitude.

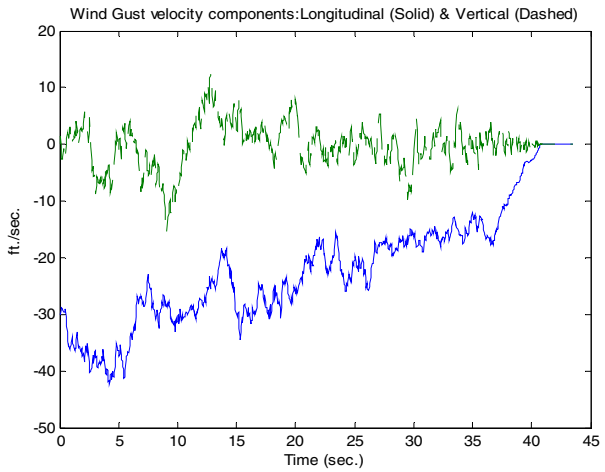

Figure 3. Turbulence profile.

III. INTELLIGENT CONTROL

A simplified PID control structure is applied to aircraft landing control as shown in Fig. 4. Its inputs consist of altitude and altitude rate commands along with aircraft altitude and altitude rate. Via aircraft landing controller we can obtain the pitch command θ_c. Then, the pitch autopilot is controlled by pitch command. The pitch autopilot is shown in Fig. 5. Detail descriptions can be found in [7]. In order to enable aircraft to land more steady when an aircraft approaches to the flare path, a constant pitch angle is added to the controller. In general, the PID controller is simple and effective but there are some drawbacks such as apparent overshoot and sensitive to external noise and disturbance. When severe turbulence is encountered the PID controller may not be able to guide the aircraft to land safely. With SOCM compensator the proposed controller can overcome these disadvantages. The control scheme utilizes a conventional PID controller to stabilize the controlled system and train the SOCM to provide precise control. The gains of PID controller are adjusted based on experiences, what it provides are tolerable solutions, not desired solutions. The SOCM can effectively meliorate these disadvantages.

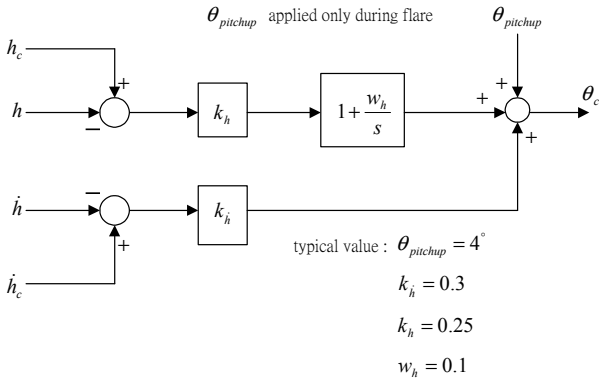

Figure 4. PID-controller.

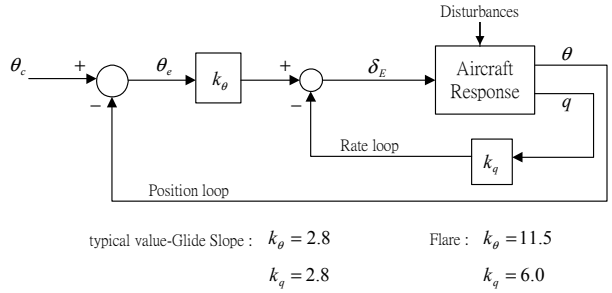

Figure 5. Pitch autopilot.

The output of CMAC is the sum of several values of hypercube and the input vector is the values of the aircraft status. The overall control scheme is described in Fig. 6, in which the control signal U is the sum of the PID controller output and the SOCM output. The inputs of the SOCM and PID controller are: altitude, altitude command, altitude rate, and altitude rate command. The PID controller provides tolerable solutions. In each time step k, the SOCM involves a recall process and a learning process. In the recall process, it uses the desired system output of the next time step and the actual system output as the address to generate the control signal U_{SOCM}. In the learning process, the control signal of the pitch autopilot, U, is treated as a desired output. It is used to modify the weights of SOCM stored at desired location which is addressed by the actual system output and the system output of the next time step. The output of the SOCM is the compensation for pitch command. When the wind turbulence is too strong, the ALS can not control the aircraft to land safely. In here we use a SOCM control scheme to improve the ability of turbulence resistance of the ALS.

A. CMAC_GBF

The CMAC represents one kind of associative memory technique. In the addressing technique, each input space (state variable) is quantized and the output space is divided into discrete states. A quantized input vector specifies a discrete state and is used to generate addresses for retrieving information from memory for this state. There is no big difference on the structure and quantization method and the mapping process between CMAC-GBF and original CMAC. The difference is that while the input vector maps the hypercube by way of the association in Fig. 7, the stored data can be the differential basis function value. Fig. 8 illustrates the block division of the CMAC-GBF for a two-variable case. This simple example has two state variables (x_1 and x_2) with each quantized into four discrete regions, called blocks. For instance, x_1 can be divided into *A*, *B*, *C,* and *D* and x_2 can be divided into *a*, *b*, *c,* and *d*. Areas *Aa*, *Ab*,...*Dd* formed by quantized regions are called hypercubes. By shifting each block a small interval (called an element) different hypercubes can be obtained. For instance, *E*, *F*, *G*, and *H* in the second row for x_1 and *e*, *f*, *g*, and *h* in the second row for x_2 are possible shifted regions. *Ee*, *Ef*, ...*Hh* are new hypercubes from the shifted regions. With this kind of decomposition, if there are *Ne* elements in a complete block, we will have *Ne* layers of hypercubes. In the given example there are four

layers as shown in Fig. 8. The state is covered by *Ne* different hypercubes, one from each layer. In the original CMAC, a constant value is assigned to each hypercube. By inputting these values into hypercubes, no matter what the positions are, they are treated as memory addresses. Therefore, the output is irrelevant to input and the differential of output to input is also not obtainable. Thus, in the CMAC-GBF, a general basis function (GBF) is used to replace constants in every hypercube. In this way, the positions of input vectors are related to output value, and the learning precision is also increased.

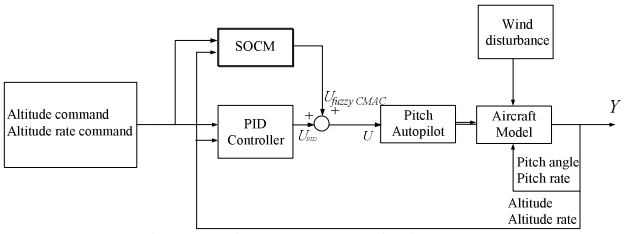

Figure 6. The SOCM control scheme.

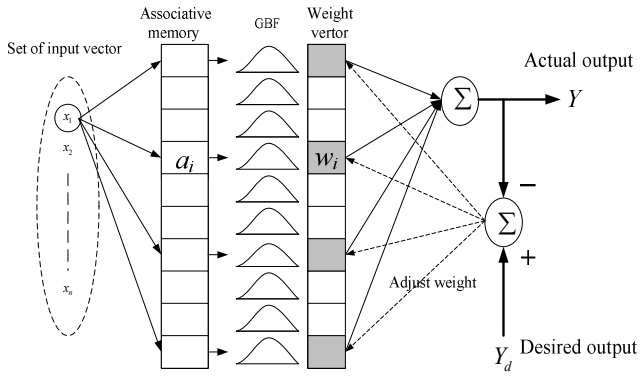

Figure 7. The structure of CMAC-GBF.

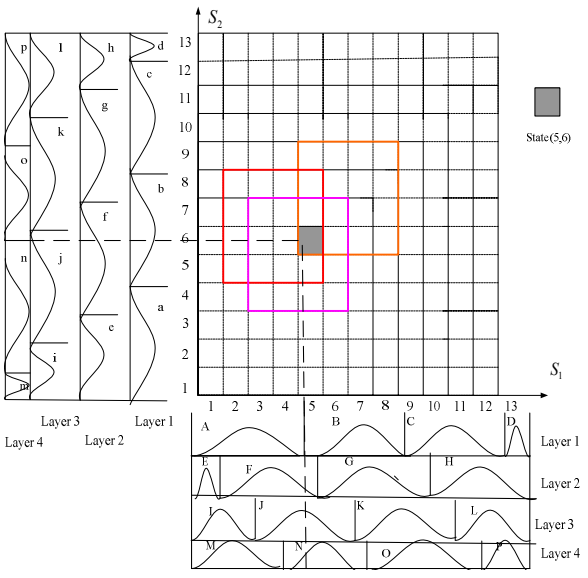

Figure 8. Block division of CMAC-GBF for a two-variable case.

In the CMAC_GBF, the content of hypercube can be expressed as $w_i(x_s) = v_i b_i(x_s)$, where $b_i(x_s)$ is a general basis function and v_i is a weight to be obtained through learning. The output of the CMAC-GBF can be written as below.

$$y(x_s) = \boldsymbol{a}_s^T w(x_s) = \sum_i^N [a_{s,i} v_i . b_i(x_s)] \tag{8}$$

where $\boldsymbol{a}_s^T = [a_{s,1} \quad a_{s,2} ..... a_{s,N}]$ is a basis function selection vector (or so-called association cells) and $W^T = [w_1 \quad w_2 ..... w_N]$ is the vector of memory contents of CMAC_GBF. The Gaussian functions are employed as the basis functions

$$b_i(x_s) \equiv \prod_{j=1}^N \phi_{ij}(x_{s,j}) \tag{9}$$

with

$$\phi_{ij}(x_{s,j}) = \exp[-\frac{(x_{s,j} - m_{ij})^2}{\sigma_{ij}^2}] \tag{10}$$

m_{ij} is the mean, σ_{ij} is the variance and N is the number of variables in the target function. Consequently, the weight function is

$$w_i(x_s) = v_i \prod_{j=1}^N \phi_{ij}(x_{s,j}) \tag{11}$$

The output from the CMAC with Gaussian basis functions can be mathematically expressed as

$$E = \frac{1}{2}(\hat{y}_s - y_s)^2 \tag{12}$$

The updated amount for v_i can be set to

$$\begin{aligned} \Delta v_i &= -\frac{\alpha_v}{N_e}\frac{\partial E}{\partial v_i} \\ &= -\frac{\alpha_v}{N_e}\frac{\partial E}{\partial e_s}\frac{\partial e_s}{\partial y(x_s)}\frac{\partial y(x_s)}{\partial w_i(x_s)}\frac{\partial w_i(x_s)}{\partial v_i} \\ &= \frac{\alpha_v}{N_e}(\hat{y}_s - \boldsymbol{a}_s^T w(x_s)) a_{s,i} b_i(x_s) \end{aligned} \tag{13}$$

where α_v is the learning rate for v. The mean and variables of the Gaussian function can also be adjusted to increase the approximation capability. The updating rules for these parameters can be derived as

$$\begin{aligned} \Delta m_{ij} &= -\frac{\alpha_m}{N_e}\frac{\partial E}{\partial m_{ij}} \\ &= -\frac{\alpha_m}{N_e}\frac{\partial E}{\partial e_s}\frac{\partial e_s}{\partial y(x_s)}\frac{\partial y(x_s)}{\partial w_i(x_s)}\frac{\partial w_i(x_s)}{\partial \phi_{ij}}\frac{\partial \phi_{ij}}{\partial m_{ij}} \\ &= \frac{\alpha_m}{N_e}(\hat{y}_s - \boldsymbol{a}_s^T w(x_s)) a_{s,i} v_i b_i(x_s) \frac{2(x_{s,i} - m_{ij})}{\sigma_{ij}^2} \end{aligned} \tag{14}$$

$$\Delta\sigma_{ij} = -\frac{\alpha_\sigma}{N_e}\frac{\partial E}{\partial \sigma_{ij}}$$
$$= -\frac{\alpha_\sigma}{N_e}\frac{\partial E}{\partial e_s}\frac{\partial e_s}{\partial y(x_s)}\frac{\partial y(x_s)}{\partial w_i(x_s)}\frac{\partial w_i(x_s)}{\partial \phi_{ij}}\frac{\partial \phi_{ij}}{\partial \sigma_{ij}} \quad (15)$$
$$= \frac{\alpha_\sigma}{N_e}(\hat{y}_s - \boldsymbol{a}_s^T w(x_s))a_{s,i}v_i b_i(x_s)(\frac{2(x_{s,i}-m_{ij})^2}{\sigma_{ij}^3})$$

where α_m and α_σ are the learning rates for mean and variance.

B. Self Organizing CMAC_GBF (SOCM)

The learning method for S_CMAC_GBF [10] and CMAC_GBF are the same, but they are different in the structures. The quantified method of input variables is different from the quantified conventional CMAC_GBF. In S_CMAC_GBF, each layer has only one block, and each block has different basis function. The weighting of each layer can be obtained by multiplying basis function of each layer with its height. Fig. 9 shows a two variables case, from recall process of S_CMAC_GBF, the output is the sum of the weights of 20 layers. The learning method of S_CMAC_GBF is just like the one for CMAC_GBF. In S_CMAC_GBF, the output equation is the same as CMAC_GBF. $a_{s,i}$ (element of selection vector) is either 1 (selected) or 0 (not selected) for CMAC_GBF, but in S_CMAC_GBF each element in the hypercube selection vector is equal to 1. It is noted that the learning rules of S_CMAC_GBF are also the same as CMAC_GBF. Adjust the required parameters in the recall process, and after repeated learning processes, the output of S_CMAC_GBF can reach the same accurate level as of CMAC_GBF.

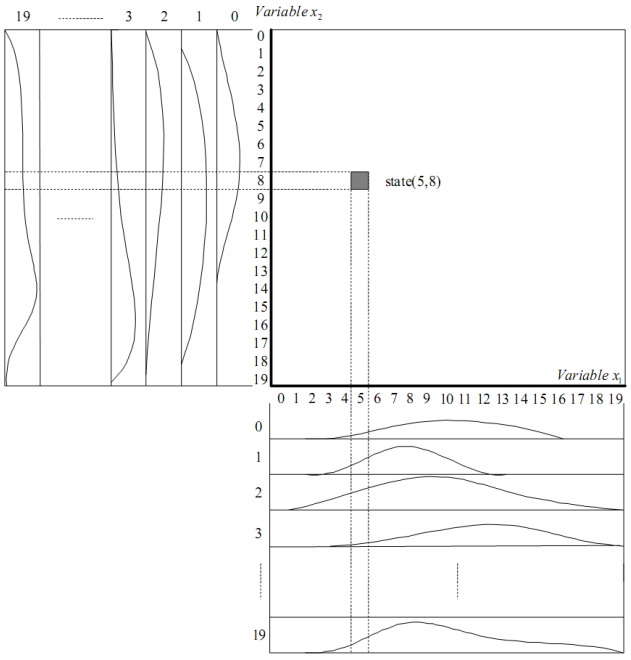

Figure 9. Block division of S_CMAC_GBF for two-variable case [10].

The difference of S_CMAC_GBF and SOCM [11] is that SOCM can create a new layer and delete a layer. The first process of the structure learning is to determine whether to add a new layer in association memory and to create its hypercube and weight memory, simultaneously. In the layer generating process, the mathematical description of the existing layers can be expressed as clusters. The firing strength of a rule for each incoming data can be represented as the degree to which the incoming data belong to the cluster. If a new input data falls within the boundary of clusters, SOCM will not generate a new layer but update parameters of the existing rules. Before SOCM decides which layer should be added or deleted, we have to choose the upper threshold (UT) (layer should be added) and lower threshold (LT) (layer should be deleted). The error rate can be expressed as

$$E_{rate} = \left|\frac{E(t)}{E(t-1)}\right| \quad (16)$$

If $E_{rate} > UT$ then $n_k(t+1) = n_k(t)+1$ (17)

where $n_k(t)$ is the number of the existing layers at time t. In the meanwhile, for the new layer, the initial mean and variance of Gaussian basis function in association memory space are defined as $m_{ink} = x_s$ and $\sigma_{ink}(t) = \sigma_{ink}(t\text{-}1)$, respectively.

If $E_{rate} < LT$ then $n_k(t+1) = n_k(t)\text{-}1$ (18)

We choose the least contribution layer of the SOCM output to be deleted. Using the ratio of the output from every layer

$$LO_i = \frac{v_i . b_i(x_s)}{v_{SOCM}}, \; i = 1 \; \ldots\ldots\ldots n_k \quad (19)$$

The layer which has minimum output ($\min_{i=1\sim nk} LO_i$) should be deleted.

IV. Stability Analysis of SOCM

In order to improve the shortcoming of conventional CMAC-GBF on the crisp relation, adaptive learning rule is introduced. Here, we use the discrete-time Lyapunov function to define the adaptive learning rate α. Let the tracking error e_s be

$$e_s(t) = \hat{y}_s - y_s \quad (20)$$

where t is the time index. A discrete-type Lyapunov function can be expressed as

$$V = \frac{1}{2}e_s^2(t) \quad (21)$$

Thus, the change in the Lyapunov function is obtained by

$$\Delta V = V(t+1) - V(t) = \frac{1}{2}\left[e_s^2(t+1) - e_s^2(t)\right] \quad (22)$$

The error difference can be represented by [13]

$$\Delta e_s(t) = e_s(t+1) - e_s(t) \approx \left[\left(\frac{\partial e_s(t)}{\partial v_i(t)}\right) \left(\frac{\partial e_s(t)}{\partial m_{ij}(t)}\right) \left(\frac{\partial e_s(t)}{\partial \sigma_{ij}(t)}\right) \right] \begin{bmatrix} \Delta v_i(t) \\ \Delta m_{ij}(t) \\ \Delta \sigma_{ij}(t) \end{bmatrix} \tag{23}$$

From (13) to (15) we have

$$\frac{\partial e_s(t)}{\partial v_i(t)} = \frac{\partial e_s}{\partial y}\frac{\partial y}{\partial w_i}\frac{\partial w_i}{\partial v_i} = -a_{s,i} b_i(x_s) \tag{24}$$

$$\frac{\partial e_s(t)}{\partial m_{ij}(t)} = \frac{\partial e_s}{\partial y}\frac{\partial y}{\partial w_i}\frac{\partial w_i}{\partial \phi_{ij}}\frac{\partial \phi_{ij}}{\partial m_{ij}} = -a_{s,i} v_i b_i(x_s)\frac{2(x_{s,i} - m_{ij})}{\sigma_{ij}^2} \tag{25}$$

$$\frac{\partial e_s(t)}{\partial \sigma_{ij}(t)} = \frac{\partial e_s}{\partial y}\frac{\partial y}{\partial w_i}\frac{\partial w_i}{\partial \phi_{ij}}\frac{\partial \phi_{ij}}{\partial \sigma_{ij}} = -a_{s,i} v_i b_i(x_s)\frac{2(x_{s,i} - m_{ij})^2}{\sigma_{ij}^3} \tag{26}$$

From (22) to (24), with respect to v_i, we have

$$\Delta V = \frac{1}{2}\left[e_s{}^2(t+1) - e_s{}^2(t) \right]$$
$$= \frac{1}{2}\left[e_s(t+1) - e_s(t) \right]\left[e_s(t+1) + e_s(t) \right]$$
$$= \frac{1}{2}\left[\Delta e_s(t) \right]\left[2 \cdot e_s(t) + \Delta e_s(t) \right]$$
$$= \Delta e_s(t)\left[e_s(t) + \frac{1}{2}\Delta e_s(t) \right]$$
$$= \left[-a_{s,i} b_i(x_s)\frac{\alpha_v}{N_e} e_s(t) a_{s,i} b_i(x_s) \right]$$
$$\left\{ e_s(t) + \frac{1}{2}\left[-a_{s,i} b_i(x_s)\frac{\alpha_v}{N_e} e_s(t) a_{s,i} b_i(x_s) \right] \right\}$$
$$= \left\{ -\frac{1}{2}\frac{\alpha_v}{N_e} e_s(t)\left[a_{s,i} b_i(x_s) \right]^2 \right\}$$
$$\left[2e_s(t) - \frac{\alpha_v}{N_e} e_s(t)\left[a_{s,i} b_i(x_s) \right]^2 \right]$$
$$= \left[-\frac{1}{2}\frac{\alpha_v}{N_e} e_s{}^2(t)\left[a_{s,i} b_i(x_s) \right]^2 \right]\left[2 - \frac{\alpha_v}{N_e}\left[a_{s,i} b_i(x_s) \right]^2 \right] \tag{27}$$

Let $\left[2 - \frac{\alpha_v}{N_e}\left[a_{s,i} b_i(x_s) \right]^2 \right] > 0$ then $\Delta V < 0$, i.e., we can select the learning rate α_v in the following range

$$\frac{2N_e}{\left[a_{s,i} b_i(x_s) \right]^2} > \alpha_v > 0 \tag{28}$$

From (22), (23), and (25), with respect to m_{ij}, we have

$$\Delta V = \frac{1}{2}\left[e_s{}^2(t+1) - e_s{}^2(t) \right] = \Delta e_s(t)\left[e_s(t) + \frac{1}{2}\Delta e_s(t) \right]$$
$$= \left\{ -\frac{1}{2}\frac{\alpha_m}{N_e} e_s(t)\left[a_{s,i} v_i b_i(x_s)\frac{2(x_{s,i} - m_{ij})}{\sigma_{ij}^2} \right]^2 \right\}$$
$$\left[2e_s(t) - \frac{\alpha_m}{N_e} e_s(t)\left[a_{s,i} v_i b_i(x_s)\frac{2(x_{s,i} - m_{ij})}{\sigma_{ij}^2} \right]^2 \right] \tag{29}$$
$$= \left[-\frac{1}{2}\frac{\alpha_m}{N_e} e_s{}^2(t)\left[a_{s,i} v_i b_i(x_s)\frac{2(x_{s,i} - m_{ij})}{\sigma_{ij}^2} \right]^2 \right]$$
$$\left[2 - \frac{\alpha_m}{N_e}\left[a_{s,i} v_i b_i(x_s)\frac{2(x_{s,i} - m_{ij})}{\sigma_{ij}^2} \right]^2 \right]$$

Let $\left[2 - \frac{\alpha_m}{N_e}\left[a_{s,i} v_i b_i(x_s)\frac{2(x_{s,i} - m_{ij})}{\sigma_{ij}^2} \right]^2 \right] > 0$ then $\Delta V < 0$, i.e., we can select the learning rate α_m in the following range

$$\frac{2N_e}{\left[a_{s,i} v_i b_i(x_s)\frac{2(x_{s,i} - m_{ij})}{\sigma_{ij}^2} \right]^2} > \alpha_m > 0 \tag{30}$$

From (22), (24), and (26), with respect to σ_{ij}, we have

$$\Delta V = \frac{1}{2}\left[e_s{}^2(t+1) - e_s{}^2(t) \right] = \Delta e_s(t)\left[e_s(t) + \frac{1}{2}\Delta e_s(t) \right]$$
$$= \left\{ -\frac{1}{2}\frac{\alpha_\sigma}{N_e} e_s(t)\left[a_{s,i} v_i b_i(x_s)\left(\frac{2(x_{s,i} - m_{ij})^2}{\sigma_{ij}^3}\right) \right]^2 \right\}$$
$$\left[2e_s(t) - \frac{\alpha_\sigma}{N_e} e_s(t)\left[a_{s,i} v_i b_i(x_s)\left(\frac{2(x_{s,i} - m_{ij})^2}{\sigma_{ij}^3}\right) \right]^2 \right] \tag{31}$$
$$= \left[-\frac{1}{2}\frac{\alpha_\sigma}{N_e} e_s{}^2(t)\left[a_{s,i} v_i b_i(x_s)\left(\frac{2(x_{s,i} - m_{ij})^2}{\sigma_{ij}^3}\right) \right]^2 \right]$$
$$\left[2 - \frac{\alpha_\sigma}{N_e}\left[a_{s,i} v_i b_i(x_s)\left(\frac{2(x_{s,i} - m_{ij})^2}{\sigma_{ij}^3}\right) \right]^2 \right]$$

Let $\left[2 - \frac{\alpha_\sigma}{N_e} \cdot \left[a_{s,i} v_i b_i(x_s)\left(\frac{2(x_{s,i} - m_{ij})^2}{\sigma_{ij}^3}\right) \right]^2 \right] > 0$ then $\Delta V < 0$, i.e., we can select the learning rate α_σ in the following range

$$\frac{2N_e}{\left[a_{s,i} v_i b_i(x_s)\left(\frac{2(x_{s,i} - m_{ij})^2}{\sigma_{ij}^3}\right) \right]^2} > \alpha_\sigma > 0 \tag{32}$$

ΔV becomes negative definite. This implies that $E(t) \to 0$ for $t \to \infty$. The convergence of the adaptive SOCM learning process is then guaranteed. The aircraft landing control system is locally asymptotically stable.

V. Simulations

The aircraft starts the initial states of the ALS as follows: the flight height is 500 ft, the horizontal position before touching the ground is 9240 ft, the flight angle is -3 degrees, the speed of the aircraft is 234.7 ft/sec. Successful touchdown landing conditions are defined as follows:

$$-3 \le \dot{h}_{TD} \text{ ft/sec} \le 0, \quad 200 \le V_{TD}(t) \text{ ft/sec} \le 270,$$
$$-300 \le x_{TD} \text{ ft} \le 1000, \quad -1 \le \theta_{TD} \text{ degree} \le 5,$$

where T is the time at touch down, $\dot{h}_{TD}$ is the vertical speed of the aircraft at touch down, x_{TD} is the position at touch down, $V_{TD}(t)$ is horizontal speed, θ_{TD} is the pitch angle at touch down.

Table I shows the result of conventional PID controller with different wind turbulence speeds. The conventional controller can only successfully guide an aircraft flying through wind speeds of 0 ft/sec to 30 ft/sec. The situations at wind turbulence 30 ft/sec are that the pitch angle is -0.1115 degrees, vertical speed is -2.1704/sec, horizontal velocity is 234.6779 ft/sec, and horizontal position at touchdown is 902.6000 ft, as shown in Fig. 10 to Fig. 12. If the wind speed is higher than 30 ft/sec, the ALS will be unable to guide the aircraft to land safely.

TABLE I. Results from using conventional PID controller (k1=2.8; k2=2.8; k3=11.5; k4=6.0)

Wind Speed (ft/sec)	Landing Point (ft)	Vertical Speed (ft/sec)	Pitch angle (degree)
0	785.2610	-2.8449	-1.3511
10	853.9561	-2.5786	-0.9523
20	910.0164	-2.3443	-0.4800
30	902.6000	-2.1704	-0.1115
40	1090.3424	-1.7348	0.3873

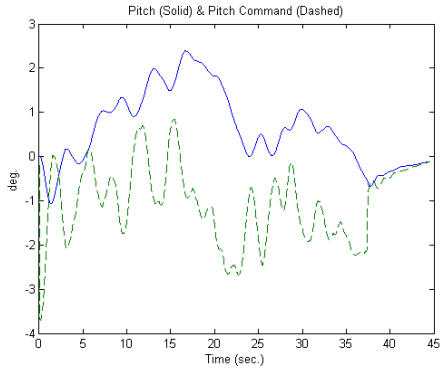

Figure 10. Aircraft pitch and pitch command.

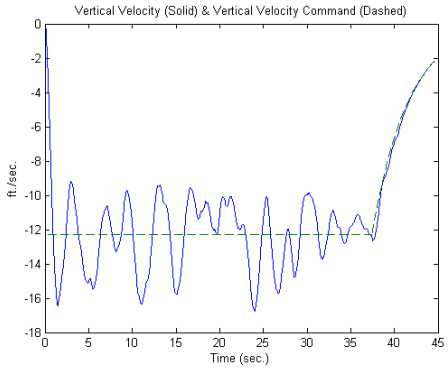

Figure 11. Aircraft vertical velocity and command.

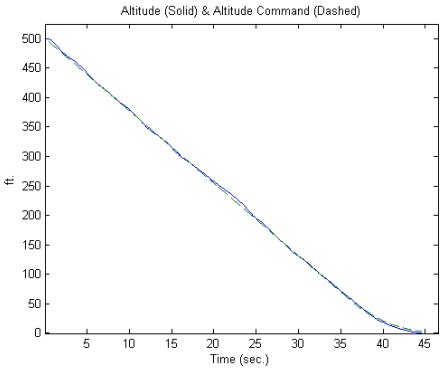

Figure 12. Aircraft altitude and command.

For the safe landing of an aircraft using the adaptive SOCM control scheme under different wind turbulence speeds are tested. The simulations show that the adaptive SOCM controller has well adaptive capability against severe wind disturbance. It is more robust than conventional PID type controller, as shown in Table II. The adaptive SOCM control scheme can successfully guide the aircraft flying through wind speeds of 0 ft/sec to 96 ft/sec. The situations at wind turbulence 96 ft/sec are that the pitch angle is 1.5011 degrees, vertical speed is -1.4125 ft/sec, horizontal velocity is 234.6779 ft/sec, and horizontal position at touchdown is 937.8017 ft, as shown in Fig.13 to Fig. 15. The layer variance is shown in Fig. 16.

TABLE II. Results from using adaptive SOCM control scheme (k1=2.8; k2=2.8; k3=11.5; k4=6.0)

Wind Speed (ft/sec)	Landing Point (ft)	Vertical Speed (ft/sec)	Pitch angle (degree)
20	937.8017	-1.9125	-0.3762
40	867.3983	-1.8542	-0.1497
60	949.5356	-1.4679	1.0374
80	738.3255	-1.4031	2.4873
90	926.0678	-1.5081	1.8440
96	937.8017	-1.4125	1.5011
97	1278.085	-0.7979	2.0038

VI. CONCLUSION

The purpose of this paper is to investigate the use of adaptive SOCM in aircraft automatic landing system and to make the automatic landing system more intelligent. Current flight control law is adopted in the intelligent controller design. Tracking performance and adaptive capability are demonstrated through software simulations. For the safe landing of an aircraft using a conventional controller, CMAC or a conventional fuzzy CMAC, the wind speed of turbulence limits are 30, 58, and 90 ft/sec [14], respectively. In this study, a well-trained adaptive SOCM control scheme can reach 96 ft/sec. The proposed controllers have better performance than previous works, and it can act as an experienced pilot and guide the aircraft to a safe landing in severe wind turbulence environment.

Abstract — **In this paper, necessary conditions are investigated for a single input/single output (SISO) Mamdani fuzzy systems as function approximators of continuous functions within a given accuracy. Since general SISO Mamdani fuzzy systems are monotonic on subintervals, the optimal configuration of fuzzy systems is that the number of division points is at least the times of its monotonicity changes. Thus with the extreme of the desired continuous function, necessary conditions are obtained through generating intervals that contain division points and pruning redundant intervals. Furthermore, a dynamically constructive method is proposed to show the conditions are optimal. It has been shown that existing results concerning necessary conditions are only special cases of our results. Finally, simulation examples are given to illustrate the conclusions, the strength of the fuzzy systems as function approximators are analyzed.**

Keywords- fuzzy systems; necessary conditions; fuzzy rules; approximation accuracy

I. INTRODUCTION

In the past decades, fuzzy systems were widely used and extensively studied for a variety of applications, especially in control applications because of their excellent performance in representing nonlinear functions in an intuitive and informative manner. In many applications of fuzzy theory, fuzzy systems involved can be viewed as rule-based function approximators. Many scholars have proved that fuzzy systems are universal approximators in different aspects [1-5]. To our knowledge, the smaller the approximation accuracy, the more fuzzy rules are required in order to approximate a certain continuous function, especially in high dimensions. Large numbers of rules render difficulty in designing fuzzy systems, such as high storage consumption, increased computational complexity, etc.

One always wants to construct a fuzzy system using less fuzzy rules to approximate a continuous function within a given accuracy. Therefore, many efforts have been made to reduce fuzzy rules. Some methods of these include orthogonal transformation, singular value decomposition[6-8] and heuristic methods such as genetic algorithms[9-10], clustering methods [11,12], and tree search[13], etc. Sufficient conditions for fuzzy systems have also been defined and solved by many scholars in term of the function approximation, which are mainly based on the uniform approximate polynomial [14-16] and the derivative of the object function[17-18, 23]. However, from a practical viewpoint, necessary conditions for fuzzy systems are more important since they place restrictions on selection components for fuzzy systems. Despite its importance, only a few papers [19-22] have dealt with this problem. Generally, the number of the fuzzy rules needed increases with the number of extreme of the desired function. However, the existing conclusions are only available for the fuzzy system with perfect approximation to a continuous function. In most cases of fuzzy system applications, the core part is to design a fuzzy system to approximate a prospective continuous function within certain accuracy. As a result, necessary conditions for fuzzy systems as function approximators within a given accuracy deserve deep study.

In this paper, we will establish new necessary conditions for general SISO Mamdani fuzzy systems as function approximator within a prescribed accuracy. By generating the intervals that contain division points and pruning redundant intervals, a novel constructive algorithm is proposed to obtain the necessary conditions. Furthermore, it has been shown that the conditions are optimal and the existing results given in [19] are only a special case of ours. Finally, illustrative examples are used to demonstrate the strength and limitation of the general SISO Mamdani fuzzy systems.

II. PROBLEM FORMULATION

A. Configuration of general SISO Mamdani fuzzy systems

The interval $[a,b]$, on which the object function $f(x)$ is defined, is divided into N subintervals (S_i is endpoint of sub-intervals):

$$a = S_0 < S_1 < S_2 < \cdots < S_N = b$$

Then there are $N+1$ normal, consistent and continuous input fuzzy sets defined on $[a,b]$ to fuzzify the input variable (Fig. 1). Each input fuzzy set denoted by A_i ($0 \le i \le N$) has a membership function $\mu_i(x)$ defined as follows:

This work was jointly supported by the National Science Foundation of China (Grants No.60625304, 60716021) and the National Key Project for Basic Research of China (Grants No.G2007cb311003, 2009cb724002).

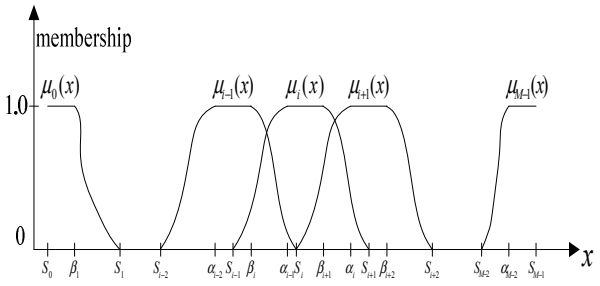

Figure 1. Illustrative definitions of input fuzzy sets.

$$\mu_i(x)=\begin{cases} I_i(x) & x\in[S_{i-1},\alpha_{i-1}] \\ 1 & x\in[\alpha_{i-1},\beta_{i+1}] \\ D_i(x) & x\in[\beta_{i+1},S_{i+1}] \\ 0 & x\in[a,b]/[S_{i-1},S_{i+1}] \end{cases} \tag{1}$$

where $I_i(x)$ equals to zero at $x=S_{i-1}$ and increases monotonically to one at $x=\alpha_{i-1}$, $D_i(x)$ equals to one at $x=\beta_{i+1}$ and decreases monotonically to zero at $x=S_{i+1}$, and

$$S_{-1}=S_0, S_{N+1}=S_N,\ S_{i-1}<\alpha_{i-1}\le S_i, S_i\le\beta_{i+1}<S_{i+1}.$$

The $N+1$ fuzzy rules used in the fuzzy system are in the form:

$$R_i: \text{IF } x \text{ is } A_i, \text{ THEN } y \text{ is } B_i,\ i=0,1,\cdots,N. \tag{2}$$

where B_i is a singleton output fuzzy set, whose membership function is one only at $y=y_i$ (an arbitrary constant) and is zero elsewhere. Using product inference engine and center-average defuzzifier, the output of the SISO Mamdani fuzzy system is

$$F(x)=\sum_i \mu_i(x)y_i \Big/ \sum_i \mu_i(x) \tag{3}$$

B. The approximation problems for fuzzy systems

The objective function $f(x)$ is defined on the compact domain Θ, which can be approximated by a fuzzy system $F(x)$ defined in sub-section II. A. The necessary condition of the fuzzy system for universal approximation is to find the minimal system configuration that the fuzzy system $F(x)$ can approximate the continuous function $f(x)$ within a given accuracy $\varepsilon\ge 0$ using smallest fuzzy rules, i.e.

$$\left\|F(x)-f(x)\right\|_\infty \le \varepsilon \tag{4}$$

III. Necessary Conditions for General SISO Mamdani Fuzzy Systems

A. Necessary Conditions for General SISO Mamdani Fuzzy Systems

The following lemmas are given for the subsequent development of necessary conditions for general SISO Mamdani fuzzy systems.

Lemma 1[19]: The fuzzy system $F(x)$ defined in (3) is continuous, and monotonic on $[S_{i-1},S_i]$ for all $i=1,2,\cdots,N$.

Lemma 2: Suppose $F(x)$ defined in (3) can approximate $f(x)$ within a given accuracy ε, for each subinterval $[S_j,S_{j+1}]$ there does not exist $S_j\le\xi_1<\xi_2<\xi_3\le S_{j+1}$ (ξ_1, ξ_2 and ξ_3 are extremes of $f(x)$ on $[S_j,S_{j+1}]$), such that

$$\begin{aligned} &f(\xi_1)-f(\xi_2)>2\varepsilon,\ f(\xi_2)-f(\xi_3)<-2\varepsilon \\ \text{or}\ &f(\xi_1)-f(\xi_2)<-2\varepsilon,\ f(\xi_2)-f(\xi_3)>2\varepsilon \end{aligned} \tag{5}$$

Proof: Without losing generality, assume that there exists $S_j\le\xi_1<\xi_2<\xi_3\le S_{j+1}$, such that

$$f(\xi_1)-f(\xi_2)>2\varepsilon,\ f(\xi_2)-f(\xi_3)<-2\varepsilon \tag{6}$$

Firstly, using reduction to absurdity, it can be proved that there exists $[x_{t1},x_{t2}]\subseteq[\xi_1,\xi_2]$, such that $F(x)$ strictly decreases on $[x_{t1},x_{t2}]$. It is assumed that the interval $[x_{t1},x_{t2}]$, on which $F(x)$ strictly decreases, does not exist. Then $F(x)$ increases monotonically on $[\xi_1,\xi_2]$ so that we can get

$$F(x_2)\ge F(x_1) \tag{7}$$

for arbitrary $\xi_1\le x_1<x_2\le\xi_2$. Since $F(x)$ can approximate $f(x)$ within a given accuracy $\varepsilon>0$, we have

$$-\varepsilon\le f(x_1)-F(x_1)\le\varepsilon \tag{8}$$

$$-\varepsilon\le f(x_2)-F(x_2)\le\varepsilon \tag{9}$$

Subtracting (9) from (8) yields

$$f(x_1)-f(x_2)\le 2\varepsilon+F(x_1)-F(x_2) \tag{10}$$

Similarly, subtracting (7) from (10) leads to

$$f(x_1)-f(x_2)\le 2\varepsilon \tag{11}$$

Eq. (11) is contradictory with Eq. (6). This contradiction means that there exists $[x_{t1},x_{t2}]\subseteq[\xi_1,\xi_2]$, on which $F(x)$ strictly decreases. Similarly, we can also prove that there exists $[x_{t3},x_{t4}]\subseteq[\xi_2,\xi_3]$, such that $F(x)$ strictly increases. Therefore, there exists two subintervals $[x_{t1},x_{t2}]$ and $[x_{t3},x_{t4}]$ in $[S_j,S_{j+1}]$, such that $F(x)$ strictly decreases and increases

respectively. By derivative's property, there must exist division points on $[S_j, S_{j+1}]$, which contradicted with Lemma 1. The proof is completed.

Lemma 2 has established some necessary conditions for Mamdani fuzzy systems as function approximators within a given approximation accuracy. In order to construct the necessary conditions in an intuitive manner, the construction algorithm is presented as follows, which consists of generating the intervals that contain division points and pruning redundant intervals.

Construction algorithm:

Step 1: Calculate the object function's extreme set $\boldsymbol{\xi}$ and create an empty set P.

Step 2: Traverse the extreme set $\boldsymbol{\xi}$,

WHILE there exist $\xi_p, \xi_e, \xi_q \in \xi$ with $\xi_p < \xi_e < \xi_q$ such that

$$f(\xi_p) - f(\xi_e) > 2\varepsilon,\ f(\xi_e) - f(\xi_q) < -2\varepsilon$$
$$\text{or } f(\xi_p) - f(\xi_e) < -2\varepsilon,\ f(\xi_e) - f(\xi_q) > 2\varepsilon$$

DO $P = P \bigcup \{[\xi_p, \xi_q]\}$.

Step 3: $Q = P$,

WHILE there exists $C_1, C_2 \in Q$, such that $C_1 \subset C_2$.

DO remove C_2 from Q.

Step 4: The algorithm ends and the characteristic set Q is got.

The characteristic set Q determined by construction algorithm above has the following properties:

(i) Given the extreme set $\boldsymbol{\xi}$, Q is unique.

(ii) There does not exist $C_j \in Q$ such that $P_i \subset C_j$ for arbitrary $P_i \in P$.

(iii) There also does not exist $C_1, C_2 \in Q$ such that $C_1 \subset C_2$.

To analyze the characteristics of the elements in set Q, the following definitions are given.

Definition 1: For an interval $C_t = [\xi_j, \xi_k]$, let $C_t^{\min} = \xi_j$, $C_t^{\max} = \xi_k$.

Definition 2 (interval correlation): For arbitrary $C_1, C_2 \in Q$, C_1 and C_2 are said to be correlative if there exist extremes ξ_1 and ξ_2 with $\xi_1 < \xi_2$ such that $\xi_1, \xi_2 \in C_1$, $\xi_1, \xi_2 \in C_2$,

Definition 3 (interval consistency): For arbitrary $C_1, C_2 \in Q$, C_1 and C_2 are said to be consistent if there exist extremes $\xi_1 \in C_1$ and $\xi_2 \in C_2$ such that

$$f(C_1^{\min}) - f(\xi_1) > 2\varepsilon,\ f(C_1^{\max}) - f(\xi_1) > 2\varepsilon$$
$$f(C_2^{\min}) - f(\xi_2) > 2\varepsilon,\ f(C_2^{\max}) - f(\xi_2) > 2\varepsilon$$
$$\text{or } f(\xi_1) - f(C_1^{\min}) > 2\varepsilon,\ f(\xi_1) - f(C_1^{\max}) > 2\varepsilon$$
$$f(\xi_2) - f(C_2^{\min}) > 2\varepsilon,\ f(\xi_2) - f(C_2^{\max}) > 2\varepsilon;$$

or else inconsistent.

Definition 4: For arbitrary $C_1, C_2 \in Q$, it is said $C_1 < C_2$ if $C_1^{\min} < C_2^{\min}$.

According to the construction algorithm, the following four corollaries could be obtained easily.

Corollary 1: For arbitrary $C_1, C_2 \in Q$, C_1 and C_2 could only be consistent or inconsistent exclusively.

Corollary 2: $C_1^{\min} \neq C_2^{\min}$, $C_1^{\max} \neq C_2^{\max}$ for arbitrary $C_1, C_2 \in Q$.

Corollary 3: For arbitrary $C_1, C_2 \in Q$, $C_1^{\max} < C_2^{\max}$ if $C_1^{\min} < C_2^{\min}$.

Corollary 4: For the elements $C_1, C_2, \cdots, C_n$ in Q, there exists a new sorting $C_{i_1}, C_{i_2}, \cdots, C_{i_n}$, such that $C_{i_1} < C_{i_2} < \cdots < C_{i_n}$

$$C_{i_1} < C_{i_2} < \cdots < C_{i_n} \tag{12}$$

In the following, relationship among elements in Q would be analyzed using reduction to absurdity.

Lemma 3: For arbitrary $C_1, C_2 \in Q$ with $C_1 < C_2$, C_1 and C_2 are not correlative if C_1 and C_2 are consistent.

Proof: Suppose C_1 and C_2 are correlative, we have $C_1^{\min} < C_2^{\min} < C_1^{\max} < C_2^{\max}$ by Corollary 3. Without losing generality, there exist extremes $\xi_1 \in C_1$, $\xi_2 \in C_2$ such that

$$f(C_1^{\min}) - f(\xi_1) > 2\varepsilon,\ f(C_1^{\max}) - f(\xi_1) > 2\varepsilon;$$
$$f(C_2^{\min}) - f(\xi_2) > 2\varepsilon,\ f(C_2^{\max}) - f(\xi_2) > 2\varepsilon \tag{13}$$

Let $\xi_e = \arg_{\xi_i} \min\{f(\xi_1), f(\xi_2)\}$. If $\xi_e \in [C_1^{\min}, C_2^{\min}]$, we have

$$f(C_1^{\min}) - f(\xi_e) > 2\varepsilon, f(C_2^{\min}) - f(\xi_e) > 2\varepsilon.$$

Thus $[C_1^{\min}, C_2^{\min}] \in P$ is obtained. This contradicted with $[C_1^{\min}, C_2^{\min}] \subset C_1$ and $C_1 \in Q$ based on property (ii). Assuming $\xi_e \in [C_2^{\min}, C_1^{\max}]$ or $\xi_e \in [C_1^{\max}, C_2^{\max}]$ yields a similar contradiction. Therefore C_1 and C_2 are not correlative.

Lemma 4: For arbitrary $C_1 < C_2 \in Q$, if C_1 and C_2 are correlative,

(1) C_1 and C_2 are inconsistent.

(2) Extremes ξ_1 and ξ_2 defined in Definition 3 satisfy $C_1^{\min} < \xi_1 \le C_2^{\min} < C_1^{\max} \le \xi_2 < C_2^{\max}$.

(3) There exist at least two division points in $[C_1^{\min}, C_2^{\max}]$ to achieve the approximation accuracy requirement in Eq. (4).

Proof: Conclusion (1) is obvious by Lemma 3. We now use a contradiction argument to show the other conclusions are also satisfied. Since C_1 and C_2 are correlative and $C_1 < C_2$, we can easily get

$$C_1^{\min} < C_2^{\min} < C_1^{\max} < C_2^{\max} \tag{14}$$

according to Corollary 3, Without losing generality, there is extreme $\xi_1 \in C_1$ such that

$$f(C_1^{\min}) - f(\xi_1) > 2\varepsilon,\ f(C_1^{\max}) - f(\xi_1) > 2\varepsilon \tag{15}$$

Because C_1 and C_2 are inconsistent, there exists $\xi_2 \in C_2$ such that

$$f(\xi_2) - f(C_2^{\min}) > 2\varepsilon,\ f(\xi_2) - f(C_2^{\max}) > 2\varepsilon \tag{16}$$

Assuming $C_2^{\min} < \xi_1 < C_1^{\max}$ and $\xi_1 < \xi_2$, we have

$$\begin{aligned} &\max\{f(C_1^{\max}), f(\xi_2)\} - f(\xi_1) > 2\varepsilon, \\ &\max\{f(C_1^{\max}), f(\xi_2)\} - f(C_2^{\max}) > 2\varepsilon \end{aligned} \tag{17}$$

Thus $[\xi_1, C_2^{\min}] \in P$ is obtained. This contradicted with $[\xi_1, C_2^{\min}] \subset C_2$ and $C_2 \in Q$ based on property (ii). Assuming $C_2^{\min} < \xi_2 < C_1^{\max}$ yields a similar contradiction. As a result, the conclusion (2) is satisfied.

Subsequently, let us analyze the conclusion (3). Without losing generality, there exist extremes $\xi_1 \in C_1$, $\xi_2 \in C_2$ such that

$$\begin{aligned} &f(C_1^{\min}) - f(\xi_1) > 2\varepsilon,\ f(C_1^{\max}) - f(\xi_1) > 2\varepsilon \\ &f(\xi_2) - f(C_2^{\min}) > 2\varepsilon,\ f(\xi_2) - f(C_2^{\max}) > 2\varepsilon \end{aligned} \tag{18}$$

By conclusion (2), we have

$$\begin{aligned} &f(C_1^{\min}) - \min\{f(\xi_1), f(C_2^{\min})\} > 2\varepsilon, \\ &\min\{f(\xi_1), f(C_2^{\min})\} - \max\{f(C_1^{\max}), f(\xi_2)\} < -2\varepsilon, \\ &\max\{f(C_1^{\max}), f(\xi_2)\} - f(C_2^{\max}) > 2\varepsilon. \end{aligned}$$

As a result, there exists at least two division points in $[C_1^{\min}, C_2^{\max}]$ according to Lemma 2.

From Lemma 4, we can conclude that two correlative intervals in Q could not have a common division point. Furthermore, the following Lemma which will help founding the relationship between the number of the elements in Q and the number of the division points for fuzzy systems could be obtained.

Lemma 5: Each element in Q determined by the construction algorithm has division point of its own if the fuzzy system $F(x)$ defined in (3) can approximate $f(x)$ within a given approximation accuracy ε.

Proof: For arbitrary $C_i \in Q$, if C_i is not correlative with the other element in Q, there exists division point in C_i according to Lemma 2. If C_i is correlative with $C_k \in Q$, C_i and C_k have their own division points by Lemma 4. Hence each element in Q determined by the proposed construction algorithm has division point of its own.

Suppose that the objective function $f(x)$ is defined on the interval $[a, b]$ in the framework of SISO Mamdani fuzzy system. If there are n elements in Q which is determined by the construction algorithm with respect to the function $f(x)$ above, n division points exist in the interval $[a, b]$ based on Lemma 5.

Furthermore, the interval is divided into at least $n+1$ subintervals, and at least $n+2$ fuzzy rules are needed to approximate the object function within a given approximation accuracy ε. Thus the necessary conditions for general SISO Mamdani fuzzy systems could be established intuitively.

Theorem 1: (Necessary conditions for fuzzy systems) Suppose there are n elements in Q determined by the construction algorithm. In order to approximate the object function within a given approximation accuracy, the input interval of the fuzzy system should be divided into at least $n+1$ subintervals; at least $n+2$ fuzzy rules are needed.

We will prove that the conditions established in Theorem 1 are also optimal.

Lemma 6: If $f(x_1) - f(x_2) \geq -2\varepsilon$ or $f(x_1) - f(x_2) \leq 2\varepsilon$ for arbitrary x_1, $x_2 \in [S_j, S_{j+1}]$ with $x_1 < x_2$, there exists a fuzzy system $F(x)$ in Eq.(4) which can approximate the object function $f(x)$ within a given approximation accuracy ε on subinterval $[S_j, S_{j+1}]$.

Proof: A constructive method will be used here to prove this lemma.

(a) If $f(x_1) - f(x_2) \geq -2\varepsilon$ for arbitrary $x_1, x_2 \in [S_j, S_{j+1}]$ with $x_1 < x_2$, the output $F(x)$ of a fuzzy system that can approximate $f(x)$ within a given accuracy ε on $[S_j, S_{j+1}]$ can be constructed as Fig. 2. And the output $F(x)$ of a fuzzy system can be constructed in details as follows.

Step 1 Calculate the extremes $\xi_0, \xi_1, \cdots, \xi_{n+1}$ of the object function $f(x)$ on $[S_j, S_{j+1}]$ with $\xi_0 = S_j, \xi_{n+1} = S_{j+1}$. Let $i = 0$, $e = \xi_0$.

Step 2 WHILE $i < n$ DO

$$F(x) = \min(f(x) + \varepsilon, f(e) + \varepsilon),\ x \in [\xi_i, \xi_{i+1}].$$

If $f(e) - f(\xi_{i+1}) \geq 0$

$e = \xi_{i+1}$.

$i = i + 1$.

Step 3 If $f(\xi_n) - f(\xi_{n+1}) \geq 0$, on $[\xi_n, \xi_{n+1}]$

$$F(x) = f(x) - \varepsilon + \frac{\xi_{n+1} - x}{\xi_{n+1} - \xi_n}(f(e) - f(\xi_n) + 2\varepsilon),$$

else

$$F(x) = f(e) + \varepsilon + \frac{x - \xi_n}{\xi_{n+1} - \xi_n}(f(\xi_{n+1}) - f(e) - 2\varepsilon).$$

(b) If $f(x_1) - f(x_2) \leq 2\varepsilon$ for arbitrary x_1, $x_2 \in [S_j, S_{j+1}]$ with $x_1 < x_2$. The corresponding fuzzy system output $F(x)$ on $[S_j, S_{j+1}]$ can be constructed in a similar way:

Step 1. Calculate the extremes $\xi_0, \xi_1, \cdots, \xi_{n+1}$ of the object function $f(x)$ on $[S_j, S_{j+1}]$ with $\xi_0 = S_j, \xi_{n+1} = S_{j+1}$. Let $i = 0$, $e = \xi_0$.

Step 2. WHILE $i < n$ DO

$F(x) = \max(f(x) - \varepsilon, f(e) - \varepsilon)$ on $x \in [\xi_i, \xi_{i+1}]$.

If $f(e) - f(\xi_{i+1}) \leq 0$

$e = \xi_{i+1}$.

$i = i + 1$.

Step 3. If $f(\xi_n) - f(\xi_{n+1}) \leq 0$, on $[\xi_n, \xi_{n+1}]$,

$$F(x) = f(x) + \varepsilon + \frac{\xi_{n+1} - x}{\xi_{n+1} - \xi_n}(f(e) - f(\xi_n) - 2\varepsilon).$$

else

$$F(x) = f(e) - \varepsilon + \frac{x - \xi_n}{\xi_{n+1} - \xi_n}(f(\xi_{n+1}) - f(e) + 2\varepsilon).$$

Furthermore, the input/output fuzzy sets can be constructed as: $\mu_1(x) = (\sup F - F(x)) / (\sup F - \inf F)$, $\mu_2(x) = 1 - \mu_1(x)$, $y_1 = F(S_j)$ and $y_2 = F(S_{j+1})$. The proof is completed.

Remark 1: The constructive methods in Lemma 6 just show that there exists fuzzy system that can approximate the object function within a given approximation accuracy in Eq. (4). Since the output constructed above in the first case is $f(S_j) - \varepsilon$ at $x = S_j$ and decreases monotonically to $f(S_{j+1}) + \varepsilon$ at $x = S_{j+1}$, while the second output constructed above is $f(S_j) + \varepsilon$ at $x = S_j$ and increases monotonically to $f(S_{j+1}) - \varepsilon$ at $x = S_{j+1}$, this two cases can be used alternately on subintervals to form a continuous output on the whole domain.

Lemma 7: Arbitrary two adjacent $C_{i_j}, C_{i_{j+1}} \in Q$ $(1 \leq j < n)$ in Corollary 4 are inconsistent.

Proof: If C_{i_j} and $C_{i_{j+1}}$ are correlative, C_{i_j} and $C_{i_{j+1}}$ are inconsistent according to Lemma 5. Otherwise, we have

$$C_{i_j}^{\max} \leq C_{i_{j+1}}^{\max} \tag{19}$$

If C_{i_j} and $C_{i_{j+1}}$ are consistent. Without losing generality, assume there exist extremes $\xi_1 \in C_1$, $\xi_2 \in C_2$ such that

$$\begin{aligned} &f(C_{i_j}^{\max}) - f(\xi_1) > 2\varepsilon,\ f(C_{i_j}^{\min}) - f(\xi_1) > 2\varepsilon \\ &f(C_{i_{j+1}}^{\max}) - f(\xi_2) > 2\varepsilon,\ f(C_{i_{j+1}}^{\min}) - f(\xi_2) > 2\varepsilon \end{aligned} \tag{20}$$

With (19) and (20),

$$\begin{aligned} &\max\{f(C_{i_j}^{\max}), f(C_{i_{j+1}}^{\min})\} - f(\xi_1) > 2\varepsilon, \\ &\max\{f(C_{i_j}^{\max}), f(C_{i_{j+1}}^{\min})\} - f(\xi_2) > 2\varepsilon. \end{aligned}$$

Thus $[\xi_1, \xi_2] \in P$ is obtained. It means there exists $C_s \in Q$ and $C_s \subseteq [\xi_1, \xi_2]$ such that $C_{i_j} < C_s < C_{i_{j+1}}$. It contradicted with Corollary 4. Therefore C_{i_j} and $C_{i_{j+1}}$ are inconsistent.

With Lemma 6 and Lemma 7, the optimal necessary condition for SISO Mamdani fuzzy systems is established as follows.

Theorem 2 (Optimal necessary conditions for fuzzy systems): To approximate a continuous function within a given accuracy, a general SISO Mamdani fuzzy system established on the number n of the characteristic set Q is optimal.

Proof: Let $C_j \in Q$ ($j = 1, \cdots, n$), where Q is determined by the construction algorithm with respect to the function $f(x)$ defined on $[a, b]$. n division points exist in the interval $[a, b]$ by Lemma 5. Without losing generality, we select all the division points $S_j \in C_j$ ($j = 1, \cdots, n$) at extremes of the function $f(x)$. And S_j satisfies

$$\begin{aligned} &f(C_j^{\min}) - f(S_j) > 2\varepsilon,\ f(C_j^{\max}) - f(S_j) > 2\varepsilon, \\ &\text{or } f(S_j) - f(C_j^{\min}) > 2\varepsilon,\ f(S_j) - f(C_j^{\max}) > 2\varepsilon. \end{aligned}$$

Suppose that the approximation accuracy ε can't be achieved on subinterval $[S_j, S_{j+1}]$. With Lemma 6, there exist extremes of $f(x)$ ξ_1, ξ_2, ξ_3 on $[S_j, S_{j+1}]$ with $S_j \leq \xi_1 < \xi_2 < \xi_3 \leq S_{j+1}$ such that

$$\begin{aligned} &f(\xi_1) - f(\xi_2) > 2\varepsilon,\ f(\xi_2) - f(\xi_3) < -2\varepsilon \\ &\text{or } f(\xi_1) - f(\xi_2) < -2\varepsilon,\ f(\xi_2) - f(\xi_3) > 2\varepsilon \end{aligned} \tag{21}$$

Thus $[\xi_1, \xi_3] \in P$ is obtained. It means there exists $C_t \in Q$, $C_t \subseteq [\xi_1, \xi_3]$ such that $C_j < C_t < C_{j+1}$ .This contradicted with Corollary 4. Therefore the fuzzy system can achieve approximation accuracy on each subinterval. In other words , the inequality $f(x_1) - f(x_2) \geq -2\varepsilon$ or $f(x_1) - f(x_2) \leq 2\varepsilon$ holds for arbitrary $x_1, x_2 \in [S_j, S_{j+1}]$ with $x_1 < x_2$.

According to Lemma 7, if there exist $x_1, x_2 \in [S_j, S_{j+1}]$ with $x_1 < x_2$ such that $f(x_1) - f(x_2) > 2\varepsilon$, there must exist $x_3, x_4 \in [S_j, S_{j+1}]$ with $x_3 < x_4$ such that $f(x_3) - f(x_4) < -2\varepsilon$.

Hence, for arbitrary two adjacent subintervals $[S_{j-1}, S_j]$ and $[S_j, S_{j+1}]$, if $f(x_1) - f(x_2) \geq -2\varepsilon$ holds for arbitrary $x_1, x_2 \in [S_j, S_{j+1}]$ with $x_1 < x_2$; $f(x_3) - f(x_4) \leq 2\varepsilon$ holds for arbitrary $x_3, x_4 \in [S_j, S_{j+1}]$ with $x_3 < x_4$. A continuous output for fuzzy system can be constructed using the constructive methods in Lemma 6 alternately. It means that there exists a fuzzy system which can achieve the given approximation accuracy in Eq. (4). Therefore the necessary conditions are optimal under the same condition.

Remark 2: If *n* division points in Theorem 1 are selected appropriately, none other division points are necessary for the fuzzy systems to achieve the given approximation accuracy in Eq. (4).

Remark 3: In Theorems 1 and 2, the following assumptions are assumed to be known for the necessary conditions of the SISO Mamdani fuzzy system on a given approximation accuracy ε:

(a) Approximation accuracy $\varepsilon \geq 0$;

(b) The values of $f(x) \in C[a,b]$ at extremes $\xi_i : v_i = f(\xi_i)$, $1 \leq i \leq m$;

(c) The values of $f(x)$ at endpoints: $v_0 = f(a)$, $v_{m+1} = f(b)$.

These prerequisite conditions (a)-(c) will be the minimum information required to describe a well-behaved continuous function so that the fuzzy systems performs more efficiently than other classical functional approximators. And these conditions can be gained easily in practical process.

B. Comparision study on necessary conditions

Ying [19, 20] pointed out that, a fuzzy system as approximator, the number of division points is at least the number of extremes of the continuous function for the necessary condition. However, these results are not available for the fuzzy system as universal approximator within a given accuracy. In most cases, the necessary conditions for the fuzzy system as universal approximator within a given accuracy are more practical and useful. Here we will show that Ying's conclusion is only a special case of our results given above.

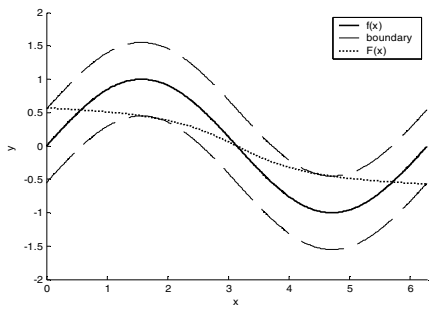

Figure 2. The fuzzy system using only two rules approximates $f(x)$.

Consider the function $f(x) = \sin x$, $x \in [0, 2\pi]$ in Fig. 3 with error bound 0.55 (dashed lines). A fuzzy system $F(x)$ with 2 fuzzy rules could be constructed (the dotted line) to achieve the given approximation accuracy by Lemma 7. However, according to Ying's conclusion, the fuzzy system requires at least 4 rules to achieve the given approximation accuracy. Consequently, necessary conditions proposed by Ying hold no longer when the approximation accuracy is prescribed.

In the construction algorithm, when the given approximation accuracy $\varepsilon \to 0$, we have

$$f(\xi_{i-1}) - f(\xi_i) > 2\varepsilon, f(\xi_i) - f(\xi_{i+1}) < -2\varepsilon$$
$$\text{or } f(\xi_{i-1}) - f(\xi_i) < -2\varepsilon, f(\xi_i) - f(\xi_{i+1}) > 2\varepsilon \quad (23)$$

for arbitrary $\xi_{i-1}, \xi_i, \xi_{i+1} \in \xi$, $i = 1, 2, \cdots, m$, and $Q = \{[\xi_0, \xi_2], [\xi_1, \xi_3], \cdots, [\xi_{m-1}, \xi_{m+1}]\}$.

According to Theorem 1, the input interval $[a,b]$ must be divided into at least $m+1$ subintervals, and the number of the fuzzy rules is $m+2$. This is just the necessary conditions for fuzzy systems as universal approximates proposed in [19]. As a result, the approach in [19] is a special case of our necessary conditions when ε approaches zero.

IV. ILLUSTRATIVE EXAMPLES

In this section, the developed approaches above will be illustrated by examples.

Example: Design a Mamdani fuzzy system to uniformly approximate the continuous function shown in Fig. 4. We can find easily that the extreme set of $f(x)$ is $\{0, 4, 6, 8, 12, 12.5, 13, 14.5, 16, 20, 21, 22, 26\}$ whose values are $\{1, -1, -0.4, -1, 1, 0.9, 1, 0.7, 1, -1, -0.8, -1, 1\}$.

The necessary conditions for a fuzzy system on various kinds of approximation accuracy are given as follows:

(1) $0 \leq \varepsilon < 0.05$

Using the construction algorithm, the characteristic set Q is

$$Q=\{[0,6],[4,8],[6,12],[8,12.5],[12,13],[12.5,14.5],[13,16],$$
$$[14.5,20],[16,21],[20,22],[21,26]\}.$$

By using the necessary conditions for fuzzy systems in Theorem 1, 13 fuzzy rules are required to achieve approximation accuracy.

(2) $0.05 \le \varepsilon < 0.1$

Using the construction algorithm, the characteristic set Q is

$$Q=\{[0,6],[4,8],[6,12],[8,14.5],[13,16],[14.5,20],$$
$$[16,21],[20,22],[21,26]\}.$$

We can conclude that 11 fuzzy rules can be used to achieve the given approximation accuracy by Theorem 1. Take $\varepsilon = 0.08$ as an example, the upper and lower boundaries of $f(x)$ are obtained by moving it vertically by ε upwards and downwards (the dashed lines in Fig. 5). A fuzzy system output whose monotonicity changes 9 times, is constructed in the tunnel encircled by the boundaries to approximate $f(x)$ (dotted line). Therefore 11 fuzzy rules are necessary for achieving the given accuracy.

(3) $0.1 \le \varepsilon < 0.15$

Using the construction algorithm, the characteristic set Q is

$$Q=\{[0,6],[4,8],[6,12],[8,14.5],[13,16],[14.5,20],[16,26]\}$$

And 9 fuzzy rules are required to achieve the given approximation accuracy by Theorem 1.

(4) $0.15 \le \varepsilon < 0.2$

The construction algorithm is used to determine the characteristic set as

$$Q=\{[0,6],[4,8],[6,12],[8,20],[16,26]\}.$$

And 7 fuzzy rules are required to achieve the given approximation accuracy by Theorem 1. Take $\varepsilon = 0.18$ as an example, the upper and lower bounds of $f(x)$ are obtained by moving it vertically by ε upwards and downwards (the dashed lines in Fig. 6). A fuzzy system output whose monotonicity changes 5 times, is constructed in the tunnel encircled by the boundaries to approximate $f(x)$ (dotted line). Therefore 7 fuzzy rules are necessary for achieving the given accuracy.

(5) $0.2 \le \varepsilon < 0.5$

Using the construction algorithm, the characteristic set Q is

$$Q=\{[0,12],[8,20],[16,26]\}.$$

5 fuzzy rules are required to achieve the given approximation accuracy by Theorem 1.

(6) $\varepsilon \ge 0.5$

The construction algorithm is used to determine the characteristic set Q as $Q=\Phi$. 2 fuzzy rules are required to achieve approximation accuracy by Theorem 1.

The strength as well as limitation of the general SISO Mamdani fuzzy system as function approximator is showed in the example. It is observed that the minimal number of fuzzy rules M increases with the number Ω of the desired continuous function's extremes whose swings are larger than the approximation accuracy. That is to say, on one hand, a small number of fuzzy rules suffice to achieve the approximat ion if Ω is a small number, even the desired function has a complicated formulation. On the other hand, large numbers of fuzzy rules are required to approximate a simple function with large Ω. It means that fuzzy systems are not ideal function approximators for applications involving highly oscillatory continuous functions with large amplitudes. And the necessary conditions are local constant with accuracy. These may be used to explain practical fuzzy models only use a small number of fuzzy rules to achieve successful applications.

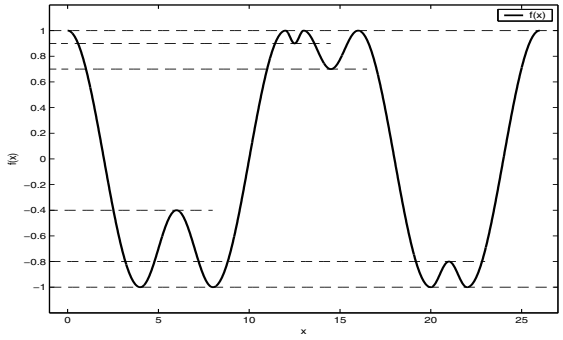

Figure 3. The desired function $f(x)$ in example 2.

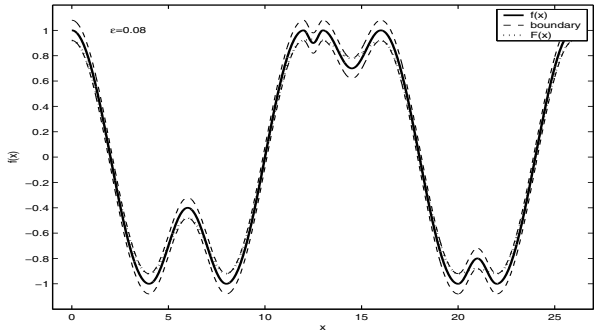

Figure 4. A fuzzy system $F(x)$ is constructed to approximate $f(x)$ in example 2 with accuracy 0.08.

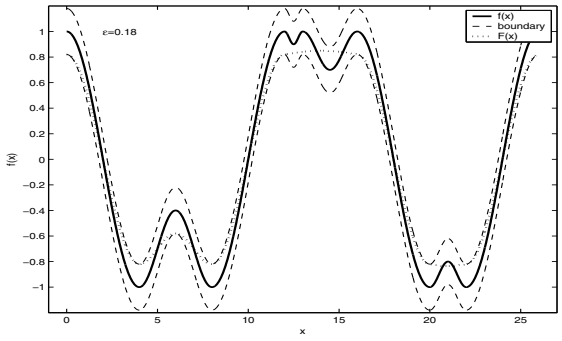

Figure 5. A fuzzy system $F(x)$ is constructed to approximate $f(x)$ in example 2 with accuracy 0.18.

V. CONCLUSIONS

This paper is concerned with the necessary conditions for general SISO Mamdani fuzzy systems as approximators within a given accuracy. The necessary conditions proposed in this paper expand the existing ones so that new conclusions are suitable for more practical cases. It has been proved that the proposed conditions are optimal. Finally, some examples are used to demonstrate the strength and limitation of the general SISO Mamdani fuzzy systems.

Abstract— **This paper develops a fuzzy stochastic multi-objective linear programming (FSMOLP) model for a multi-level, multi-item capacitated lot sizing problem (CLSP) in a multi assembly shop. The proposed model attempts to minimize the total cost consisting of total production variation cost, inventory cost, backlog cost and total setup cost while maximizing the resource utilization simultaneously. To cope with the uncertainty associated with the most of the input data, e.g., the demand and process-related parameters they are treated as fuzzy stochastic parameters with identical stochastic membership function during the planning horizon. To show the usefulness of the proposed solution method, a numerical example is first solved. Then, the usefulness of the proposed model is validated over a set of randomly generated test problems.**

Keywords; Multi-level, multi-item capacitated lot sizing problem, Fuzzy Stochastic Multi-Objective Linear Programming, Multi assembly shop

I. INTRODUCTION

Shops, in which several assembly products are mounted simultaneously, are called Multi-Assembly Shops (MSA). In these shops, the raw material after being converted to sub-components by initial operations enters the main assembly line with different lot sizes. In such environments, many products with various sub-assemblies are assembled in different levels and then changed into final products (see [1]-[3]). MSA production planning models involves multiple items, restrictive capacities and setup times and/or cost. In this multi-level, multi-item production system, assumes a serial item structure with one or more final products that requires a multiple component. Each item is produced on a resource.

The multi-item multi-period CLSP with dynamic demand is a well known optimization problem that finds a wide variety of applications in real-world problems. Due to its vast industrial applicability, researchers have devoted special attention to it (see [4]-[5]). The problem arises in production environments where the changeover of a resource from one product type to another causes setup time and/or setup costs. Numerous models to support dynamic lot sizing for multi-level production systems have been presented over the last decades. Reviews of the literature on dynamic lot sizing are given by [6]-[8]. Big-bucket model formulations multi-level CLSP determines production quantities and periods only, without consideration of the actual production sequence of the orders within a time period [9]. The problem is complicated by the existence of setup costs as well as inventory holding costs [10].

The deterministic multi-item dynamic capacitated lot-sizing problem has been studied for a long time (For recent overviews see [11]-[13]). However, only a limited number of researchers have considered dynamic capacitated lot sizing under imprecise parameters. Industrial planning practice usually applies a forecasting procedure that provides a deterministic time series of expected future parameters. Uncertainty is taken into consideration by developing stochastic or fuzzy programming methods.

However, only a limited number of researchers have considered dynamic CLSP under uncertain demand. A literature overview is presented in Sox et al. [14]. Sox and Muckstadt [15] solve a variant of the stochastic dynamic CLSP, where item and period specific backorder costs as well as extendible production capacities are considered. Brandimarte [16] considers the stochastic CLSP where the uncertainty of the demand is represented through a scenario tree. In this case, the period demands are modeled as discrete random variables. Tempelmeier [17] consider the stochastic version of the dynamic multi-item CLSP. The problem is to determine lot sizes to satisfy demands for multiple products over a finite discrete time horizon.

Another imprecision is that, in actual practice, the capacity is frequently vague and difficult to predict. Moreover only a limited amount of (production, space, or budget) capacity might be available for a type of product, and this capacity might vary over time due to its own or other products seasonality. The fuzzy set theory, which can represent this vague future capacity easily, is an ideal approach. Pai [18] extended the work of Florian and Klein [l9] by using fuzzy capacity. Various investigators have used fuzzy set theory to investigate the lot-sizing problem. Lee and Yao [20] used the fuzzy concept to deal with lot sizing problem while demand and production quantity are uncertain. Chang et al. [21] modified the economic reorder point problem by introducing a fuzzy backorder quantity. The results offered a better sense of using economic fuzzy quantities. Chen and Wang [22] proposed a functional principle to deal with the lot sizing problem in a fuzzy environment. Yao and Lee [23] used a triangular fuzzy number to represent the fuzzy order quantity. Pappis and Karacapilidis [24] derived an appropriate number of production runs and lot sizes for multi-products with fuzzy

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

demands. Several methods have been developed in the literature to deal with the possibilistic models involving the imprecise coefficients in both objective functions and constraints. Notably, the main part of proposed method is based on Jimenez et al. [25], Jimenez, [27] and Torabi and Hassini [26] because of their several advantages as follow:

1. Jimenez, [27] introduced general ranking method which can be applied to different kinds of membership functions such as triangular, trapezoidal and nonlinear ones in both symmetric and a symmetric forms.
2. The Jimenez et al. [25] method is based on the strong mathematical concepts such as expected interval and expected value of fuzzy numbers.
3. By increasing the size of problem, the complexity of proposed model should not be increased exponentially.
4. TH method [26] is very promising fuzzy multi-objective approach which can produce efficient solutions based on the decision maker's preferences along with offering appropriate flexibility to provide different solutions to help the decision maker in selecting the final preferred compromise solution.

However, the most popular approach to convert the fuzzy linear program (FLP) into the conventional deterministic linear program (LP) is the method of ordering fuzzy numbers such as area compensation method [28], the expected mid-point of fuzzy numbers [29], the grade of possibility and necessity [30] and the signed distance method [31].

Similarly, the fuzzy stochastic linear program has also been handled by defuzzifying and derandomizing fuzzy stochastic variables in two manner as sequential or simultaneously. In the sequential approaches, the defuzzifying process is performed first. Then the derandomizing process is done later (see [32]-[33]).

In this paper, we develop a fuzzy stochastic formulation for CLSP in which an optimal production plan is provided for multi products with imprecise dynamic demands over a given planning horizon. The production system is capacitated and setup times/costs occur when changing from one product to another while the model's parameters are vague. The objective is to find an optimal production plan that minimizes production variation, setup, and backlog and inventory cost while maximizes the resource utilization. Compared with deterministic models, fuzzy stochastic CLSP models are even more important in practice. In many real-world problems, customer demands, inventory bounds, and costs are all subject to uncertainty, and to make things worse, they could be dependent on each other in consecutive periods. The study of lot-sizing began with Wagner and Whitin [33], and there is now a sizeable literature in this area extending the basic model to consider capacity constraints, multiple items, multiple levels, etc. However, most previous work on lot-sizing has been directed towards the deterministic case. The practical problem is that in general much, if not all, of the future demands, capacity, resource consumption and costs (i.e. setup, production variation, holding and backorder cost) have to be forecast. However, the existence of forecast errors radically affects the behavior of the lot sizing procedures [34]. In contrast to the deterministic CLSP, we assume that every parameters such as cost multiple, demand, available resource and consumption resource are fuzzy stochastic variable. The period demands are non stationary (to permit dynamic effects such as seasonal variations, promotions, or general mixtures of known customer orders with random portions of period demands). Because they depend on many factors. Thus, it is difficult to determine exactly the values of these parameters. Moreover, the factors, which are fluctuating due to uncertain environment, could make these parameters vary. These circumstances often happen in long term planning, development strategies and engineering design, in which the described conditions (objectives, constraints, and coefficients) cannot be determined precisely and certainly.

In addition, we developed a new fuzzy stochastic multi-objective linear programming (FSMOLP) approach to solve the proposed model. We first convert the imprecise constraints into the crisp ones by using the expected value of corresponding imprecise parameters as well as the imprecise nature of the objective function by using upper and lower bound of the fuzzy stochastic objective functions coefficients. Then, after applying appropriate strategies for converting this possibilistic model into an auxiliary crisp multi-objective linear model (MOLP), we apply an interactive fuzzy approach to solve this MOLP and finding a preferred compromise solution. The main contributions of this paper could be highlight as follows:

1. Proposing a new bi-objective multi item, multi level CLSP model.
2. Developing a new CLSP model based on the structure of multi assembly shops.
3. Considering the imprecision and ambiguousness of CLSP parameters and modeling a fuzzy stochastic CLSP.
4. Proposing a new algorithm to find the efficient solutions of the proposed fuzzy stochastic CLSP.

II. PROPOSED MODEL

We classified the parameters of the proposed CLSP into two categories as supplier-related and demand-related parameters. Demand-related parameters include demand, backorder cost which are related (or set) to the costumers, while supplier-related parameters are determined by the supplier. Production variation, holding and setup cost, the amount of needed resource to produce one item and the available resource at each level in each period are fallen in the second category. CLSP is a multi period, big-time bucket, production planning problem that lot sizes of the product should be determined for long planning horizon. Thus, it is difficult to determine exactly the values of supplier-related and demand –related parameters. Moreover, the factors, which are fluctuating due to uncertain environment, could make these parameters vary. These circumstances often are different for each category that could introduce as follows:

1. Long planning horizon

2. Risk
3. Impact of the environmental factors
4. Change shops and workers situation
5. Vagueness and imprecise parameters

According to the above mentioned, many researchers focus on the stochastic or fuzzy techniques to deal with the vagueness and imprecision nature of the real case problems. Although both of stochastic and fuzzy approach separately are worthful techniques. According to the nature of problem parameters, fuzzy stochastic parameters are more desirable than stochastic or fuzzy parameters, because the parameters of the model determined based on the incomplete historical data (or ill-known data). In addition considering the input parameter as fuzzy stochastic variable could help the decision makers to close into the real problem. Consequently, due to the unavailability or incompleteness of data in real world circumstances, especially in big-time bucket production planning problem, every parameters embedded in such CLSP model have an imprecise and vague nature. So, in order to model the lack of knowledge about these parameters we use appropriate fuzzy stochastic membership function. The following assumption has been considered to formulate proposed CLSP model.

A. Assumptions

1. Each item needs just an identical resource.
2. The amounts of available resources in shop floor are imprecise and consider as fuzzy stochastic variable.
3. At the end of each period available resource will be retrieved.
4. Several products are produced, each of which is assembled from two or more item from upper level.
5. The considered CLSP problem is a multi period big-time bucket problem.
6. When all tasks of a level are finished, the tasks of the lower level could be started.
7. The demand of the product is non deterministic parameter with identical fuzzy stochastic membership function.
8. Costumers demand should be satisfied completely at the end of planning horizon.
9. The backorder and inventory holding is allowed, while both of them are equal to zero at the begging and ending of the planning horizon.
10. The production system has been designed as multi-level that in each level various item should be assembled.
11. In terms of number of products is a multi-item production planning that there are several products should be organized during planning horizon.
12. The capacity constraint is considered on available resource.
13. Setup time is considered as constraint in model and setup cost appeared as cost in objective function.

The following notations are used in the formulation of the proposed CLSP model:

B. Notations

Indices:

i: End product, $i=1,\ldots,P$
v: Item, $v=1,\ldots,V$
l: level. $l=1,\ldots,L$
j: Machine, $j=1,\ldots,J$
h: period(Time bucket), $h=1,\ldots,H$

Parameters:

$\widetilde{\widetilde{C}}_{ihj}^{Sh}$: Setup cost of item *v* of level *l*, from end product *i* on machine *j* in period *h*

$\widetilde{\widetilde{C}}_{i}^{Hh}$: Holding cost of end product *i* in period *h*

$\widetilde{\widetilde{C}}_{i}^{Bh}$: Back order cost of product *i* in period *h*

$\widetilde{\widetilde{d}}_{i}^{h}$: Demand of end product *i* at the end of period *h*

RT_{ihj} : The rate of production item *v* at level *l* of end product *i* on machine *j*

t_{ihj}^{h} : The processing time of item *v* at level *l* of end product *i* on machine *j* at period *h*

b_{ilv} : The number of item *v* at level *l* needed for producing product *i*.

ST_{ihj} : Setup time of item *v* at level *l* of end product *i* on machine *j*

$\widetilde{\widetilde{a}}_{ihv}$: The amount of resource needed to produce one unit of item *v* of level *l* from end product *i*

$\widetilde{\widetilde{R}}_{j}$: The accessible amount of resource *j*

λ_{ihj} :1, If item *v* of level *l*, from end product *i is* need machine j,0 otherwise

Decision variable:

I_{i}^{h} : Inventory level of end product i at the end of period h

B_{i}^{h} : Back order level of end product i at the end of period h

Q_{i}^{h} : The lot size of end product i at period h

C. Fuzzy Stochastic CLSP formulation

The objective of the proposed CLSP model is to determine the lot-sizes of the products whereas satisfying the cost and utility of the multi assembly shop. There are two objectives associated with the model: one is to minimize the costs related to the assembling operations, resource setups, backorder and inventory holding; the other is to maximize the utilization of the available resource. The two objectives are described below.

The first objective function is:

$$\text{Min} \sum_{h=1}^{H}\sum_{i=1}^{P}\sum_{l=1}^{L}\sum_{v=1}^{V}\widetilde{\widetilde{C}}_{ihv}^{Sh}.Y_{i}^{h}+\sum_{h=1}^{H}\sum_{i=1}^{P}\widetilde{\widetilde{C}}_{i}^{Hh}.I_{i}^{h}+\sum_{h=1}^{H}\sum_{i=1}^{P}\widetilde{\widetilde{C}}_{i}^{Bh}.B_{i}^{h}+\sum_{h=1}^{H}\sum_{i=1}^{P}\sum_{l=1}^{L}\sum_{v=1}^{V}\widetilde{\widetilde{C}}_{ihv}^{Ph}.Q_{i}^{h}.b_{ilv} \quad (1)$$

The four terms indicate, respectively, resource setup cost, inventory holding cost, backorder cost and production variation cost. In the first term, $\widetilde{\widetilde{C}}_{ihj}^{Sh}$ is the setup cost of

resource j and Y_i^h is an auxiliary 0-1 integer variable which assumes a value of one if product i is produced in period, and zero otherwise. In the second and third term, $\widetilde{\widetilde{C}}_i^{Hh}$ and $\widetilde{\widetilde{C}}_i^{Bh}$ are the holding and backorder cost for a unit of product i that holding or non delivery at the end of period. In the forth term, $\widetilde{\widetilde{C}}_{ilv}^{Ph}$ is per unit cost of performing operation item (ilv). This includes both the assembling and consumed resource cost.

The second objective function is formulated as follows:

$$\text{Min} \sum_{h=1}^{H}\sum_{l=1}^{L}\sum_{j=1}^{J}\left(\widetilde{\widetilde{R}}_j - R_{lj}^h\right) \tag{2}$$

where,

$$R_{lj}^h = \sum_{i=1}^{P}\sum_{v=1}^{V} b_{ilv}.Q_i^h.\widetilde{\widetilde{a}}_{ilv}.\lambda_{ilvj} \qquad \forall h,l,j$$

The $\widetilde{\widetilde{R}}_j$ is the total amount of resource j that is available during planning horizon. We split the multi assembly shop into a number of the level including various item from different products. When any level is started, all related item will be assembled until the next level begin. At the start of next level all resources will be retrieved and $\widetilde{\widetilde{R}}_j$ resource is available again. In the second objective, we try to close the amount of total available resource with consuming resource ($\widetilde{\widetilde{R}}_{lj}^h$) for each resource at each level in each period. The following constraint sets are in effect:

The demand of the customers should be satisfied during planning horizon, while according to the assumption the backorder and holding are allowed. So the demand balance constraints are defined as three equations.

$$I_i^{h-1} - B_i^{h-1} + Q_i^h = I_i^h - B_i^h + \widetilde{\widetilde{d}}_i^h \qquad \forall i, h \geq 2,3,...,H \tag{3}$$

$$Q_i^1 - I_i^1 + B_i^1 - \widetilde{\widetilde{d}}_i^h = 0 \qquad \forall i \tag{4}$$

$$I_i^H = B_i^H = I_i^0 = B_i^0 = 0 \qquad \forall i \tag{5}$$

The first and second equation balance the amount of the backorder, holding and lot sizes of all products from h=2 to end of the planning horizon and h=*1* respectively. The third formulation shows that at the start and end of the planning horizon backorder and holding is equal to zero.

The capacity constraint, ensure that the overall consumption must remain lower than the available capacity. The available resource $\widetilde{\widetilde{R}}_j$ would be retrieve at the end of each level for each resource at each level in each period.

$$\sum_{i=1}^{P}\sum_{v=1}^{V} b_{ilv}.Q_i^h.\widetilde{\widetilde{a}}_{ilv}.\lambda_{ilvj} \leq \widetilde{\widetilde{R}}_j \qquad \forall h,l,j \tag{6}$$

Production equation, grantee that if any product is produced in each period ($Q_i^h > 0$) the decision variable Y_i^h is become one, and zero otherwise.

$$Q_i^h \leq M.Y_i^h \qquad \forall i,h \tag{7}$$

$$Y_i^h = \{0,1\} \qquad \forall i,h \tag{8}$$

$$Q_i^h, B_i^h, I_i^h \in \text{Integer} \qquad \forall i,h \tag{9}$$

Variable constraint, show the type of each decision variable

$$Y_i^h = \{0,1\} \qquad \forall i,h \tag{10}$$

$$Q_i^h, B_i^h, I_i^h \in \text{Integer} \qquad \forall i,h \tag{11}$$

III. RANKIN OF FUZZY STOCHASTIC VARIABLE

There are several types of definition of fuzzy stochastic variable. Here, the attention is restricted to the concepts of Luhandjula [35] for the definition of the fuzzy stochastic variable and its characteristics (see [36]) as shown in figure 1.

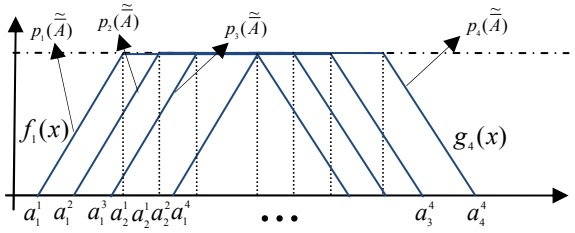

Figure 1. Fuzzy Stochastic number

When $\widetilde{A}$ is an uncertain value parameter, the membership degree $\mu_{\widetilde{A}}(x)$ can be viewed as the credibility degree of $\widetilde{A}$ taking value x [37]. $\widetilde{A}$ ($\widetilde{A} = (a_1, a_2, a_3, a_4)$) is a trapezoidal fuzzy number with membership degree $\mu_{\widetilde{A}}(x)$ as (12) if $f_a(x)$ and $g_a(x)$ are the linear function.

$$\mu_{\widetilde{A}}(x) = \begin{cases} 0 & (-\infty, a_1] \\ f(x) & [a_1, a_2] \\ 1 & [a_2, a_3] \\ g(x) & [a_3, a_4] \\ 0 & [a_4, +\infty) \end{cases} \tag{12}$$

According to the $\widetilde{A}$ definition, the expected interval of $\widetilde{A}$ was define by Heilpern, [38] as (13).

$$EI(\widetilde{A}) = [E_1^{\widetilde{A}}, E_2^{\widetilde{A}}] \tag{13}$$

where

$$E_1^{\widetilde{A}} = \int_0^1 f_{\widetilde{A}}^{-1}(y)dy = \int_0^1 ((a_2 - a_1).y + a_1)dy = \frac{a_2 + a_1}{2}$$

$$E_2^{\widetilde{A}} = \int_0^1 g_{\widetilde{A}}^{-1}(y)dy = \int_0^1 ((a_3 - a_4).y + a_4)dy = \frac{a_3 + a_4}{2}$$

From (13), the expected interval of fuzzy stochastic variable $\widetilde{\widetilde{A}}$ is obtained by (14). Moreover the expected value is define as the average of the $E_1^{\widetilde{A}}$ and $E_2^{\widetilde{A}}$.

$$EI(\widetilde{\widetilde{A}}) = [E_1^{\widetilde{\widetilde{A}}}, E_2^{\widetilde{\widetilde{A}}}] = [\frac{\overline{a}_1 + \overline{a}_2}{2}, \frac{\overline{a}_3 + \overline{a}_4}{2}] \tag{14}$$

where

$$\overline{a}_i = E(a_i) = \sum_k p_k(\widetilde{\widetilde{A}}) \times a_i$$

While there is existed wide range of ranking approach to rank fuzzy numbers in the literature, notably some issued should be considered to choose efficient ranking method as follow:

1. Due to the complicated structure of the mathematical models, the applied method should not increase the size of the problem (neither variable nor constraints).
2. The ranking method should not be approximated approach while we prefer to find the best solution if possible.

Definition 1. Assuming $\tilde{\tilde{A}}_1$ and $\tilde{\tilde{A}}_2$ are two fuzzy stochastic variable. The membership degree $\mu_{\tilde{\tilde{A}}_1 \geq \tilde{\tilde{A}}_2}(x)$ can be viewed as the credibility degree of $\tilde{\tilde{A}}_1 \geq \tilde{\tilde{A}}_2$ taking value x and as follow:

$$\mu_{\tilde{\tilde{A}}_1 \geq \tilde{\tilde{A}}_2} = \begin{cases} 0 & E_2^{\tilde{\tilde{A}}_1} - E_1^{\tilde{\tilde{A}}_2} < 0 \\ \dfrac{E_2^{\tilde{\tilde{A}}_1} - E_1^{\tilde{\tilde{A}}_2}}{E_2^{\tilde{\tilde{A}}_1} - E_1^{\tilde{\tilde{A}}_2} - (E_1^{\tilde{\tilde{A}}_1} - E_2^{\tilde{\tilde{A}}_2})} & 0 \in [E_1^{\tilde{\tilde{A}}_1} - E_2^{\tilde{\tilde{A}}_2}, E_2^{\tilde{\tilde{A}}_1} - E_1^{\tilde{\tilde{A}}_2}] \\ 1 & E_1^{\tilde{\tilde{A}}_1} - E_2^{\tilde{\tilde{A}}_2} > 0 \end{cases} \quad (14)$$

where $[E_1^{\tilde{\tilde{A}}_1}, E_2^{\tilde{\tilde{A}}_1}]$ and $[E_1^{\tilde{\tilde{A}}_2}, E_2^{\tilde{\tilde{A}}_2}]$ are the expected interval of $\tilde{\tilde{A}}_1$ and $\tilde{\tilde{A}}_2$. When $\mu_m(\tilde{\tilde{A}}_1, \tilde{\tilde{A}}_2) \geq \chi$ we will say that $\tilde{\tilde{A}}_1$ is bigger than, or equal, to $\tilde{\tilde{A}}_2$ at least in a degree a and we will represent it by $\tilde{\tilde{A}}_1 \geq_\chi \tilde{\tilde{A}}_2$.

Definition 2 [36]. Given a decision vector $x \in R^n$ we will say that it is feasible in degree χ if

$$\min_{m=1,\ldots,M} \{\mu_m(\tilde{\tilde{A}}_1 x, \tilde{\tilde{A}}_2)\} = \chi \quad (15)$$

That is to say

$$\tilde{\tilde{A}} x_1 \geq_\chi \tilde{\tilde{A}}_2 \quad (16)$$

It is equivalent to (from (14)),

$$[\chi E_1^{\tilde{\tilde{A}}_1} + (1-\chi) E_2^{\tilde{\tilde{A}}_1}] x \leq \chi E_2^{\tilde{\tilde{A}}_2} + (1-\chi) E_1^{\tilde{\tilde{A}}_2} \quad (17)$$

IV. OBJECTIVE FUNCTION WITH FUZZY STOCHASTIC COEFFICIENT

In this section we try to convert the fuzzy stochastic coefficient of the objective functions into the crisp ones such that using maximum performance of the fuzzy stochastic number. Assumed that P is a fuzzy stochastic programming problem as follow:

$$P: \min \ Z_h = \tilde{\tilde{c}}_n x \quad \text{for } n = 1,\ldots,N$$
$$\text{s.t.}$$
$$x \in X$$

$\tilde{\tilde{c}}_n$ is a fuzzy stochastic coefficient of the objective function (n^{th}) and X is feasible space of the problem.

Definition 3. For fuzzy stochastic number ($\tilde{\tilde{c}}_h$) we define the upper and lower bound of $\tilde{\tilde{c}}$ ($\tilde{c}_n^l$ and $\tilde{c}_n^u$) as follow:

Lower bound of $\tilde{\tilde{c}}_n$ *(*$\tilde{c}_n^l$*):* The maximum movement that $\tilde{\tilde{c}}_n$ could move to left hand side as follows:

$$\tilde{c}_n^l = \min a_{ni}^k = (\min a_{n1}^k, \min a_{n2}^k, \min a_{n3}^k, \min a_{n4}^k) \quad (18)$$

Upper bound of $\tilde{\tilde{c}}$ *(*$\tilde{c}_n^u$*):* The maximum movement that $\tilde{\tilde{c}}$ could move to right hand side as follows:

$$\tilde{c}_n^l = \max a_{ni}^k = (\max a_{n1}^k, \max a_{n2}^k, \max a_{n3}^k, \max a_{n4}^k) \quad (19)$$

According to $\tilde{c}_n^l$ and $\tilde{c}_n^u$ the membership function of each objective function would be obtained (20) and (21) for minimizing and maximizing respectively.

$$\mu_n^z(z) = \begin{cases} 0 & Z > z_u^{n(NIS)} \\ \dfrac{z_l^{n(PIS)} - Z}{z_u^{n(NIS)} - z_l^{n(PIS)}} & z_l^{n(PIS)} \leq Z \leq z_u^{n(NIS)} \\ 1 & Z \leq z_l^{n(PIS)} \end{cases} \quad (20)$$

$$\mu_n^z(z) = \begin{cases} 1 & Z > z_u^{n(PIS)} \\ \dfrac{Z - z_u^{n(PIS)}}{z_u^{n(PIS)} - z_l^{n(NIS)}} & z_l^{n(NIS)} \leq Z \leq z_u^{n(PIS)} \\ 0 & Z \leq z_l^{n(NIS)} \end{cases} \quad (21)$$

Often the researchers to find the positive ideal solution (PIS) and negative ideal solution (NIS) solve the MOLP problem 2N time (N number of the objective functions). To avoid iterative procedure and reduce running time, we define $z_l^{n(PIS)}$ and $z_u^{n(NIS)}$ and $z_u^{n(PIS)}$ and $z_l^{n(NIS)}$ for minimizing and maximizing objective functions respectively as definition 6 and 7.

Definition 4. Define $z_l^{n(PIS)}$ and $z_u^{n(NIS)}$ for minimization:

$z_l^{n(PIS)} = \min z_l^n(x)$ (For each *h* individually)

$z_u^{n(NIS)} = \max_{\hat{x}_n} \{z_u^n(\hat{x}_n)\}$ ($\hat{x}$ is the solution of z_u^n, for maximizing each n individually)

Definition 5. Define $z_u^{n(PIS)}$ and $z_l^{n(NIS)}$ for maximization:

$z_u^{n(PIS)} = \max z_u^n(x)$ (For each *h* individually)

$z_l^{n(NIS)} = \min_{\hat{x}_n} \{z_l^n(\hat{x}_n)\}$ ($\hat{x}$ is the solution of z_l^n, for minimizing each *n* individually)

where z_l^n and z_u^n is formulated as (22) and (23).

$$Z_\cdot^n = \min \ E\mathrm{V}(\tilde{\tilde{c}}_l^n).x$$
$$\text{s.t.} \quad (22)$$
$$x \in X$$

$$Z_\cdot^n = \min \ E\mathrm{V}(\tilde{\tilde{c}}_u^n).x$$
$$\text{s.t.} \quad (23)$$
$$x \in X$$

Torabi and Hassini, [26], proposed a novel interactive fuzzy approach to solve multi objective linear programming (MOLP) problem and finding a preferred compromise solution. We applied their aggregate function to solve P as follow:

$$\max \ \eta(z) = \varsigma\eta_0 + (1-\varsigma)\sum_n \theta_n \mu_n(z)$$
$$s.t.$$
$$\eta_0 \leq \mu_n(z) \quad n = 1,\ldots,N \quad (24)$$
$$z \in F(z)$$
$$\varsigma \in [0,1]$$

where $\mu_n(z)$ and $\eta_0 = \min_n \{\mu_n(z)\}$ denote the satisfaction degree and minimum satisfaction degree of objective functions, respectively. This formulation has a new achievement function defined as a convex combination of the lower bound for satisfaction degree of objectives (η_0), and the weighted sum of these achievement degrees ($\mu_n(z)$) to ensure yielding an adjustably balanced compromise solution.

Moreover, θ_n and ς indicate the relative importance of the n^{th} objective function and the coefficient of compensation, respectively. The θ_n parameters are determined by the decision maker based on her/his preferences such that $\sum_n \theta_n = 1,\ \theta_n > 0$. Also, ς controls the minimum satisfaction level of objectives as well as the compromise degree among the objectives implicitly. That is, the proposed formulation is capable of yielding both unbalanced and balanced compromised solutions for a given problem instance based on the decision maker's preferences through adjusting the value of parameter ς [17].

By defining upper and lower bound of fuzzy stochastic coefficient (definition 3) we convert the imprecision objective function into crisp one for single or multi objective fuzzy stochastic programming problem.

V. THE PROPOSED FUZZY SOLUTION APPROACH

To solve the proposed MOLP models with fuzzy stochastic parameters several methods have been developed in the literature. By considering the imprecision situation as fuzzy stochastic parameters, both experimentally nature of the data and satisfaction level of decision makers are take into account simultaneously. But it would increase the complexity of the solution method. Hop, [16] convert the fuzzy stochastic MOLP into the corresponding deterministic MOLP problem by using superiority and inferiority measures of the fuzzy stochastic variables. In another work, he presented a model to measure attainment value of fuzzy stochastic goals and then applied it to de-randomize and defuzzify the fuzzy stochastic goal programming problem and obtain a standard linear program [39]. Although in both paper he obtained acceptable results, two issues could be discussed A) he consider fuzzy stochastic number as different fuzzy number with identical probability (discrete distribution). B) He changed the structure of the model by adding the imprecise constraint into objective function. However, in this paper to solve the proposed fuzzy stochastic MOLP model of CLSP, we proposed an interactive fuzzy stochastic solution approach by combining the [25], [26], [36]. The proposed hybrid approach is as follows:

Step 1: Determine the appropriate fuzzy stochastic membership function for imprecise parameters and forming the fuzzy stochastic CLSP model.

Step 2: Convert the uncertain constraints into the crisp ones by using the expected value of corresponding imprecise parameters as equation (17).

Step 3: Convert fuzzy stochastic coefficient of the objective functions into the fuzzy ones by using upper and lower bound of coefficient (equations (18) and (19)).

Step 4: Convert fuzzy objective functions into the crisp ones by using the expected value of the upper and lower bound of the coefficients and find the Z_*^n , Z_*^n

Step 5: Determine the membership function of the objective functions by using (20)-(21) and definition 6 and 7.

Step 6: Convert the equivalent crisp MOLP model into a single ones using TH aggregation functions [26], (24) which resulting the efficient solutions.

To run the proposed algorithm the decision maker should specify the value of the: feasibility degree of the constraints (χ); the deviation of the objective function coefficient (γ); coefficient of compensation (ς); relative importance of the fuzzy goals θ_n . Jimenez, [25] proposed a three steps procedure to maximize the satisfaction (feasibility) degree. The deviation of the objective function coefficient (γ) is set by the DM. Also, the coefficient of compensation and relative importance of the fuzzy goals are specified by decision makers generally. If the decision makers are not satisfied with the obtained results, another solution will be provided by changing these values.

VI. NUMERICAL ILLUSTRATION

To illustrate the efficiency of the proposed method, we consider Luhandjula's example. The results are compared with Luhandjula [35] and Hop [36] results. In this example a triangular fuzzy number ($(m-0.5, m, m+0.5)$) with a discrete distribution $p_1 = 0.25$ and $p_2 = 0.75$ has been considered. The results show the capability of the proposed model in against of existed method [36] and [35] as reported in table 1.

$$\max \quad \left(\begin{matrix}\tilde{3}\\ \tilde{4}\end{matrix}\right)x_1 + \left(\begin{matrix}\tilde{2}\\ \tilde{3}\end{matrix}\right)x_2$$
$$s.t.$$
$$\tilde{\tilde{A}}x \le \tilde{\tilde{b}}$$
$$x \ge 0,$$

$$(\tilde{\tilde{A}}, \tilde{\tilde{B}}) = \begin{cases} (\tilde{A}_1, \tilde{B}_1) = \left\{\left(\begin{matrix}\tilde{1} & \tilde{1}\\ \tilde{2} & \tilde{1}\end{matrix}\right), \left(\begin{matrix}\tilde{3}\\ \tilde{4}\end{matrix}\right)\right\} \\ (\tilde{A}_2, \tilde{B}_2) = \left\{\left(\begin{matrix}\tilde{1} & \tilde{3}\\ \tilde{1} & \tilde{2}\end{matrix}\right), \left(\begin{matrix}\tilde{5}\\ \tilde{4}\end{matrix}\right)\right\} \end{cases}$$

According to the step 1 to 6 the model would be rewritten as follow:

$$\max \quad \eta_0$$
s.t.
$$\eta_0 \le \mu_n(z) \quad n = 1$$
$$[0.75\chi + (1-\chi)1.25]x_1 + [2.25\chi + (1-\chi)2.75]x_2 \le [4.25\chi + (1-\chi)4.75]$$
$$[\chi + (1-\chi)1.5]x_1 + [1.5\chi + (1-\chi)2]x_2 \le [3.75\chi + (1-\chi)4.25]$$

where

$$\mu_1(z) = \begin{cases} 1 & z > 15 \\ \dfrac{x - 11.25}{3.75} & 11.25 \le z \le 15 \\ 0 & z < 11.25 \end{cases}$$

Table 1. Obtained results

Method	Decision vector	Objective function
Proposed method	$x_1 = 3.6\ x_2 = 0.1$	15
Hop [16]	$x_1 = 4\ x_2 = 1$	14
Luhandjula [25]	$x_1 = 1.34\ x_2 = 1$	6.02

From the obtained results, it is clear that the proposed method gives acceptable solution based on the Luhandjula [35] and Hop [36] results. In addition, the proposed methodology is also superior considering the amount of calculations and complexities embedded in other methodology, especially, the Hop's method because of a few number of constraints and the simplicity of conversion. Moreover, the proposed method compares fuzzy stochastic variables based on their relative relationships. This comparison will relax the constraints from the deterministic ones. Thus, the larger spreads of fuzzy numbers led to the more relaxation amount [36].

To illustrate the validity of the proposed model, a numerical experiment is solved and results are reported in table 2. The characteristics of the problem are as follows:

1. Membership function of each fuzzy stochastic parameter (FSP) is trapezoidal with discrete uniform distribution.
2. Setup and production variation costs are a FSP with trapezoidal fuzzy membership function and are generated randomly with uniform distribution. Similarly, Backorder and holding cost of product are $\tilde{\tilde{C}}_{ilv}^{Hh} = 0.55 \times \tilde{\tilde{C}}_{ilv}^{Ph}$ and $\tilde{\tilde{C}}_{ilv}^{Bh} = 1.2 \times \tilde{\tilde{C}}_{ilv}^{Ph}$ respectively.
3. b_{ilv} were generated from a uniform distribution U [1,5].
4. $\tilde{\tilde{a}}_{ilv}$ were generated randomly from uniform distribution U [3,5].
5. $\tilde{\tilde{R}}_{j}$ were generated randomly from uniform distribution U [4000,16000].

Based on the structure of the proposed CLSP model, problem dimensions has been obtained according to five parameters as period, product, level, item and resource and is equal to $(h \times i \times l \times v \times j) = (3 \times 3 \times 4 \times 3 \times 3)$.

The test problem is carried out with a branch-and-bound (B&B) method by using the LINGO 9.0 software. We have considered a problem with three products, four levels, three item which should be produced during three periods with three resources. According to the step 1 to 4 of proposed method the Fuzzy stochastic CLSP model is reformulated and the solution of $Z_{\cdot}^{n}$, $Z_{\cdot}^{n}$, $z_{l}^{n(PIS)}$, $z_{u}^{n(NIS)}$ has been calculated firstly. We determine the membership function of the each objective function and then convert the equivalent MOLP model into a single crisp ones based on the step 6 and obtaining results as Z_1=6971 and Z_2=288 with $\varsigma = 0.1$, $\vec{\theta} = (0.7, 0.3)$ as reported in table 2.

VII. CONCLUSION

We develop a fuzzy stochastic multi-objective linear programming model for big bucket multiple periods lot-sizing problems in which an optimal production plan is provided for multiple products with dynamic demands over a given planning horizon. The significance of accounting for uncertainty and risk in such networks spurs an interest to develop appropriate production planning tools to cope with uncertain and imprecise parameters in multi assembly shop lot sizing. To deal with imprecise and ambiguous nature of data, we introduce appropriate fuzzy stochastic membership functions for imprecise parameters.

Then an interactive fuzzy stochastic approach has been developed. Uncertain constraints as well as imprecise objective functions are converted into their crisp one by using the expected interval and value of the ill-known parameters, respectively. Finally, the equivalent crisp MOLP model is transferred into a single objective model using an appropriate aggregation function which ensures yielding efficient solutions. The proposed solution method is validated over a number of test problem and the corresponding results seem to be promising. This approach can also be used for solving other fuzzy stochastic MOLP models due to its computationally advantages.

***Abstract*—Improving fuel efficiency in vehicles can reduce the energy consumption concerns associated with operating the vehicles. This paper presents a model for a parallel hybrid electric vehicle. In the model, the flow of energy starts from wheels and spreads toward engine and electric motor. A fuzzy logic based control strategy is implemented for the vehicle. The controller manages the energy flow from the engine and the electric motor, controlling transmission ratio, adjusting speed, and sustaining battery's state of charge. The controller examines the vehicle speed, demand torque, slope difference, state of charge of battery, and engine and electric motor rotation speeds. It then determines the best values for continuous variable transmission ratio, speed, and torque. A slope window method is formed that takes into account the look-ahead slope information, and determines the best vehicle speed. The developed model and control strategy are simulated using real highway data relating to Nowra-Bateman Bay in Australia, and SAE Highway Fuel Economy Driving Schedule. The simulation results are presented and discussed. It is shown that the use of the proposed fuzzy controller reduces the fuel consumption of the vehicle.**

Keywords: Hybrid electric vehicles, backward modeling, look-ahead fuzzy control system, fuel efficiency.

I. INTRODUCTION

The demand for petroleum continues to increase whilst oil supplies remain finite [1]. According to a report published in 2006 [2], 80 million barrels of petrol is used per day around the world. The transportation sector consumes 66% of this petrol, and the portion of the land transportation is 56% of this quantity. Consuming this amount of fuel continues to aggravate the economical and environmental concerns around the world.

When it comes to energy utilisation and climate change concerns, cars and trucks are considered one of the principal problems. They consume a large portion of the oil and emit a large amount of greenhouse gas. In response to the impacts of the vehicles on environment and energy security, improving fuel efficiency in vehicles can play a massive role. There exist many techniques to improve the fuel efficiency in vehicles. Over the past few decades, there has been significant development in automobile engine and body technology. Thus, there are little gains achievable in fuel economy through vehicle engine and body. This has resulted in the emergence of innovative technologies for automotive industry. Since pure electric vehicles do not have adequate source of energy for propulsion in relatively long distance ranges, and because their recharging process requires several hours, hybrid electric vehicles (HEVs) can be considered as a better means of transportation. In comparison with conventional vehicles, fuel economy and reduced emissions have been achieved by HEVs [3-5]. The general concept of a HEV is the combination of an electric drive with an internal combustion engine (ICE), where both engine and motor can work in their optimal operating range.

A HEV is a complex system consisting of many components. The necessary propulsion energy is generated and converted in the component known as powertrain or propulsion system. The ways of arrangement of these components determine the configuration of the powertrain. There are a vast range of feasible configurations for a HEV. Based on the configuration of its powertrain, a HEV can be classified into series hybrid, parallel and series parallel hybrid. In this study, a parallel hybrid electric configuration is considered.

Although HEVs have made it possible to improve fuel efficiency and reduce emissions, considerable energy effectiveness can be achieved also by using driving profile, environmental effects, driving behaviour and control strategy. In this study, a control strategy that takes into account road geometry is developed.

II. ENERGY MANAGEMENT AND CONTROL IN HYBRID ELECTRIC VEHICLES

The overall performance of a HEV depends on how its individual components are efficiently designed and how the operation of the components is coordinated with each other.

Respectively, the control in HEVs can be classified in two levels: coordinate control and component control. In a HEV, the driver demand via accelerator is translated into power as the input of the coordinate control. Accordingly, the coordinate control system manages the components to achieve certain objectives.

There are two approaches in HEVs coordinate control, heuristic methods and classical optimal methods. The major feature of the former is its success in real-time control. The deterministic rule based control and fuzzy logic control can be classified in the heuristic approaches. The applied rules are designed based on heuristic knowledge of expert and even mathematical model.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Usually the rule based coordinate controllers in HEVs benefit from "load-leveling" concept. This approach is applied by Hochgraf et al. [6]. They used engine, alternator and battery characteristics for determining an appropriate engine control strategy for a series hybrid electric vehicle. Their examination revealed that a load-levelling strategy applied to the engine would provide better fuel economy than a power-tracking scheme. Their idea became a fundamental for some other works. Jalil et al. [7] defined a rule-based control strategy based on the engineering knowledge. Rule-based control is the foundation of the fuzzy logic which translates linguistic representation of control inputs into numerical representation with membership function in the fuzzification and defuzzification process. The knowledge of expert in controlling the process is expressed in the form of rules. Schouten et al. [8] proposed a fuzzy-logic control system in order to optimise the fuel consumption in a parallel HEV. Accordingly, the power-split strategy through fuzzy rules is formulated to manage the possible ways of power to wheels: (1) only the ICE; (2) only the EM; (3) both the ICE and the EM at the same time; (4) charge the battery, using portion of the ICE power to drive the EM as a generator and using the remainder power to drive the wheels; and (5) regenerative braking by slowing down the vehicle and letting the wheels drive the EM as a generator that provides power to the battery.

Despite the fact that, the applied controllers have enhanced the fuel efficiency the effects of in-advance information from the road has not been used in the existing works. Thereafter, we will show how real road data can be applied in a HEV model, and the impact of in-advance knowledge of road slope on fuel economy will be investigated.

III. PARALLEL HYBRID ELECTRIC POWER TRAIN

HEVs usually consist of two sources of energy. In order to achieve the part of energy which in conventional vehicle is wasted in the form of heat, the electrical part of drive train has bidirectional energy sources and converters. In a parallel hybrid electric vehicle (PHEV), the engine supplies the mechanical power to the wheels and generator during the charge of battery. The power can be supplied by only electric motor to the wheels, or engine can be assisted by the electric motor. The engine and electric motor are coupled together by mechanical coupling. A configuration and power flow in a PHEV is illustrated in Fig. 1.

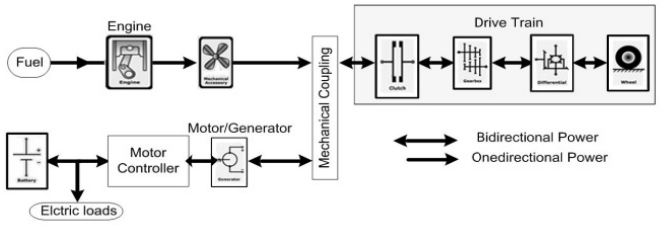

Figure 1. Parallel hybrid vehicle configuration and power flow diagram.

For a given HEV and road, the speed and torque at the output of mechanical coupling for providing the required force in the wheels can be calculated from the forces acting on vehicle.

The various longitudinal forces in a vehicle are expressed as acceleration, rolling, gravitational and drag. Accordingly, the traction force, F_{tr} is derived from the equation of solid body motion in the following form:

$$F_{tr} = M\dot{v}(t) + C_{rr}MgCos\alpha + MgSin\alpha + \frac{1}{2}C_D A\rho(v(t) + v_w(t))^2 \quad (1)$$

where the traction force parameters are listed in Table I.

TABLE I. TRACTION FORCE PARAMETERS

M vehicle mass	C_{rr} rolling Coe.	C_D drag Coe.
v vehicle speed	g gravitational acc.	A frontal area
v_w wind speed	α road slope	ρ air density

Equation (1) describes the dynamic of vehicle, and determines the amount of power that can be provided by the two sources of energy, battery and petrol. In the quasi-static HEV model, the engine can be modeled by the efficiency map model. The engine model is described by the following equation and Fig. 2.

$$\eta_{ice} = \frac{P_m}{P_{ch}} = \frac{P_m}{\dot{m}\,(T_m,\omega)\,Q_{lhv}} = \frac{3600\times10^3}{Q_{lhv}BSFC(T_m,\omega)} \quad (2)$$

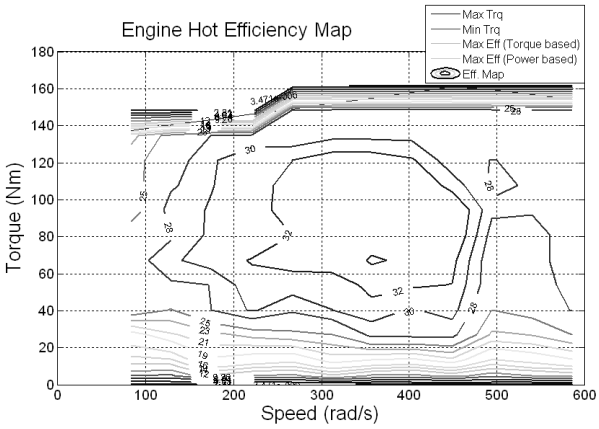

Figure 2. Engine efficiency map.

where ηice is the engine efficiency, which is a function of internal combustion engine torque and crankshaft rotational speed, Pm is the mechanical power at the crankshaft, Pch is the delivered mechanical power to the engine, and Qlhv [J/g] is chemical energy of fuel which is defined as "the amount of heat released by combusting a specified quantity (initially at 25 °C or another reference state) and returning the temperature of the combustion products to 150 °C". Typically, Qlhv=42.5[kJ/g] for petrol [9].

Similar to the engine efficiency map, there exists an efficiency map for an electric machine (EM) which presents empirical data of its efficiencies as a function of torque and speed. These efficiencies can be presented as contours on a torque-speed map. The applied motor/generator efficiency map in this study is illustrated in the Fig. 3.

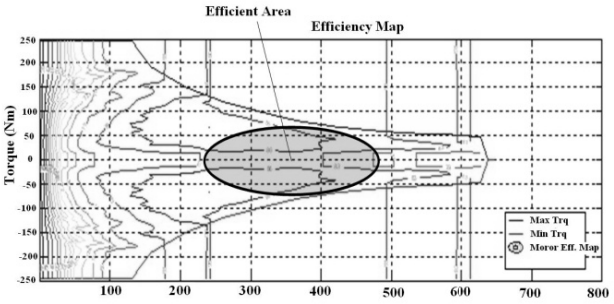

Figure 3. Efficiency map of a 33 kW (peak power) induction AC motor.

The input-output power in EM can be calculated as follows:

$$P_{in}(t) = V(t)I(t) \quad (3)$$

$$P_{out}(t) = T_{em}(t)\omega_{em}(t) \quad (4)$$

$$\eta_{em}(T_{em}(t), \omega_{em}(t)) = \frac{P_{out}(t)}{P_{in}(t)} \quad (5)$$

Where I is the EM input current in ampere, V is the input voltage in volt, and η_{em} is the EM efficiency. As presented in Fig. 3, according to the speed and the torque, there is an efficient area. Respectively, EM should be controlled to operate in this region. Consequently, in order to obtain the maximum efficiency when we are using the engine to charge the battery, the optimal speed range is considered in the applied fuzzy controller of this study.

Many types of battery have been modeled thus far. An overview of the battery models is available in literature [10]. Typically used batteries in HEVs are the lead acid and the Nickel metal batteries. In our modeling, we used the introduced lead acid model in [11].

IV. POSITIONING METHOD

In the proposed model, the drive train is represented by using the backward looking method. An overview of the different approaches in HEV modelling is available in literature [12]. A desired speed is fed to the longitudinal block. The desired speed can be a constant speed as the input of a conventional cruise control or a variable speed. The variable speed can be a drive cycle, an optimiser output or an adaptive cruise controller output [13]. We consider that the origin and destination of travel is known in advance and its information can be obtained from GIS. In order to simplify the problem, the road points are considered in a plane in two dimensions, x and y (distance and altitude) [14]. From the variation of altitude and distance, the slopes are determined for the entire path.

Assume that a moving vehicle at time t is at place $\vec{x_i}(t)$ and its velocity is $\vec{v_i}(t)$. The position vector between two consequent points can be calculated from following relation:

$$\vec{r}_i(t) = \vec{x_i}(t + \Delta t) - \vec{x_i}(t) \quad (6)$$

where, $\vec{x_i}$ is the position vector in the x-y coordinates. The distance between two consequent points can be written as:

$$s_i(t) = \|\vec{x_i}(t + \Delta t) - \vec{x_i}(t)\| \quad (7)$$

where $\| \ \|$ represent the norm of the specified vector.

The direction toward the forward point can be easily calculated from the following equation:

$$\vec{e}_i(t) = \frac{\vec{x_i}(t+\Delta t) - \vec{x_i}(t)}{\|\vec{x_i}(t+\Delta t) - \vec{x_i}(t)\|} \quad (8)$$

The velocity, $\vec{v_i}(t)$ can be found as follow:

$$\vec{v}_i(t) = \frac{s_i(t)}{\Delta t}\vec{e}_i(t) \quad (9)$$

Therefore, instantaneous velocity has two orthogonal terms in vertical and horizontal directions whose scalar can be presented in the following form:

$$v_x(t) = \left\|\frac{s_i(t)}{\Delta t}\vec{e}_i(t)\right\| Cos\alpha(t) = \|\vec{v}_i(t)\| Cos\alpha(t) \quad (10)$$

$$v_y(t) = \left\|\frac{s_i(t)}{\Delta t}\vec{e}_i(t)\right\| Sin\alpha(t) = \|\vec{v}_i(t)\| Sin\alpha(t) \quad (11)$$

where α(t) is the instantaneous slope angle between the direction vector, $\vec{e}_i(t)$ and x axis, and can be calculated from following relation:

$$\alpha(t) = \tan^{-1}\left(\frac{y(t+\Delta t) - y(t)}{x(t+\Delta t) - x(t)}\right) \quad (12)$$

A moving average method is used, and the samples are averaged to estimate the future slopes. With the movement of vehicle in each meter, a new sample is entered to the look-ahead window and the oldest sample is eliminated from the sampling space (see Fig. 4).

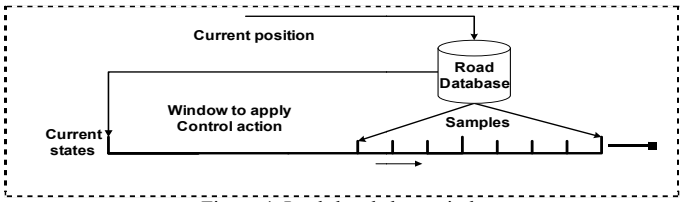

Figure 4. Look-head slope window.

$$\alpha(look_{ahead}) = \frac{\sum_{K=1}^{n}(\text{sampled date})}{n} - \frac{\text{oldest sample}}{n} + \frac{\text{new sample}}{n} \quad (13)$$

As in the backward facing model, the flow of energy starts from wheels and spreads toward ICE and EM. This facilitates the necessary calculations.

V. LOOK-AHEAD FUZZY LOGIC CONTROLLER

This section presents the proposed control strategy and the fuzzy controller, whose rules are based on the empirical knowledge of the expert, which is developed in this study. The main objectives of the controller are to manage the energy flow between ICE and EM, control the transmission ratio, adjust the optimal speed and sustain the battery state of charge (SOC) at an optimal level. The advantage of this system is its robustness, since it is tolerant to imprecise measurements and component variations. The fuzzy rules can be easily tuned, if required, therefore adaptation is an additional benefit of this controller. The main idea behind the fuzzy-logic controller is to employ logic-based control strategy. The look-ahead control is a strategy that relies on logical reasoning of how the vehicle should behave in certain circumstances.

In this paper, it is assumed that the environment is represented by the road slope. The longitudinal forces on a vehicle, "(1)" is associated with road slopes. Since the required propulsive energy is provided by ICE, EM or both using the road slope, making intelligent decisions can improve the fuel economy.

The operation of the modeled PHEV based on the controller commands can be electric only, engine traction, hybrid propulsion, regenerative braking and battery charging using the energy due to gravity. The controller acts such that the required torque is always met. Control in HEVs can be divided in two levels: coordinate control and components control. The coordinate controller (CC) is at the higher level and should mange the lower level controllers such as ICE controllers, EM controller, speed controller, mechanical brake controller and battery SOC controller. The inputs to CC are the demand torque, the difference between the existing slope and the future slope, SOC, the engine speed, the motor speed, and the resistive force.

From the stand point of the control problem, it is desired to find such control outputs that optimize the fuel consumption. In the proposed CC, there are inputs such as future slope, vehicle speed, demand torque, SOC, rotational speed and resistive force. From the expert knowledge, it is known that fuel saving can be made during uphill or downhill. During moderate uphill travel, vehicle loses speed and engine works in its inefficient region. During downhill travel because of the gravity, the acceleration of vehicle will increase. An expert driver will speed up before an uphill and slow down before a downhill drive. Therefore, driving can be classified into three main states: driving on level, uphill or downhill roads. This classification is not crisp (or precise) and can be best modeled using fuzzy logic. Therefore, the difference of current slope and the calculated one from the look-ahead slope estimator is considered as an input to CC. With respect to the engineering considerations of the road structure, and in order to generate the geographical fuzzy set of the road, the linguistic interpretation of slope is considered from a very high negative (-30%) to a very high positive (30%) slope. Based on the variation of this input, the controller output is the speed that manipulates the current speed with respect to the future slopes. The range of operation is from -10 to 10 km/h.

The design criteria for controlling the power split between ICE, EM and charging of battery is based on the efficiency maps. In other words, ICE and EM are confined to operate in the high efficiency area of the map. The inputs to the controller such as demand torque, shaft rotational speed and resistive force are converted to fuzzy values. These fuzzified inputs are demonstrated in Fig. 5. The fuzzy logic controller maps the inputs to the outputs with a set of logic rules. Fuzzy control rules are characterized as a collection of fuzzy IF-THEN rules whose conditions and consequences involve linguistic variables. The IF-part of the rules refers to attributes that express fuzzy set of the input variables. A particular input value, which belongs to this set to a certain degree, is demonstrated by the degree of membership. For instance, the membership functions that define the degree of membership of the speed are Pi functions. They determine the degree of memberships to the fuzzy set, from very low speed to very high speed. The defined membership functions for road slope are Gaussians which show the degree of membership to the fuzzy set from very steep down to very steep up. Fuzzy speed is considered from zero speed to very high speed (150 km/h). Taking into consideration the linguistic representation of all of the numerical inputs, the fuzzifications which have been done are illustrated in Fig. 5.

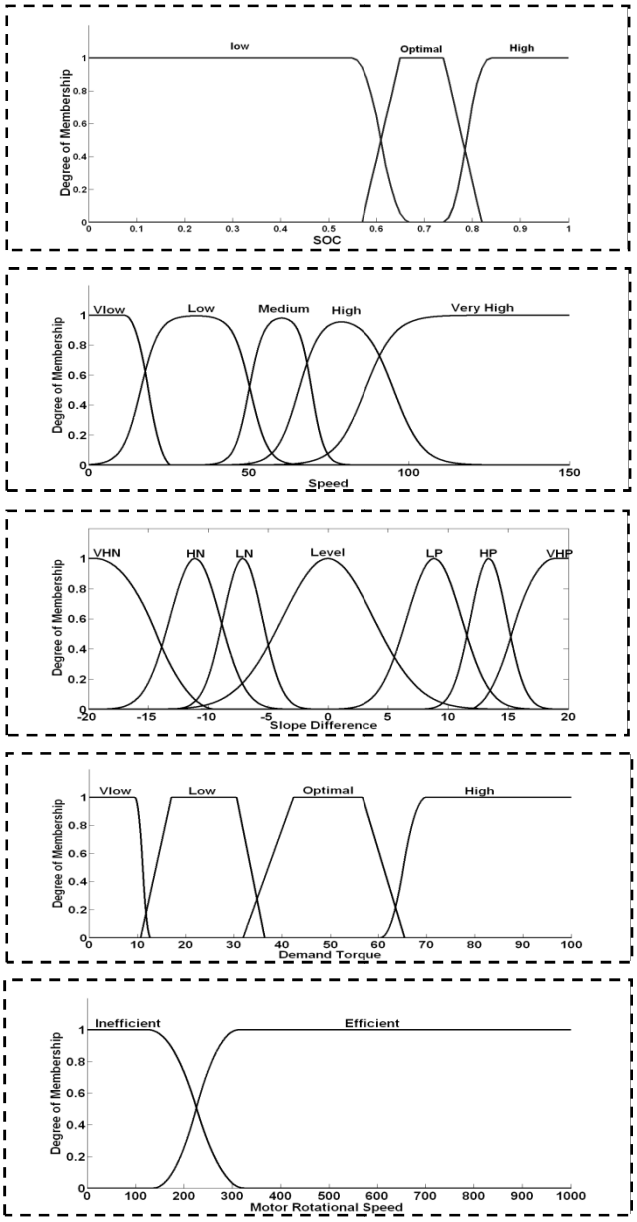

Figure 5. Input membership functions.

The THEN-part of the rules of the controller refers to the values of the output variable. To achieve the output of the controller, the degrees of membership of the IF-parts of rules are evaluated, and the THEN-parts of the rules are weighted by these degrees of membership. For example, in the membership functions that define this degree of membership for the input speed are Pi functions which establish the degree of membership to the fuzzy set, from very high shift to low shift. We implemented the most frequently used method generally known as the Mamdani's minimum operation [15]. In this

method, if the inputs are fuzzy singletons, A'=u0 and B'=v0, then the results C' can be obtained from the following relation:

$$\mu_{C'}(w) = \bigvee_{i=1}^{n}[\mu_{A_i}(u_0) \wedge \mu_{B_i}(v_0)] \wedge \mu_{C_i}(w) \quad (14)$$

In order to obtain a crisp control output from an inferred fuzzy inference engine, the most common method called the centroid area is used:

$$Z_{COA} = \frac{\int_z \mu_C(z) Z dz}{\int_z \mu_C(z) dz} \quad (15)$$

where Z is the output from the given inputs and their fuzzy relation, and μC(Z) is the aggregated output membership function. For instance, the crisp output of the fuzzy controller to the adaptive cruise controller increases the vehicle speed before an uphill or decreases it before a downhill. The extended or diminished speed is proportional to the fuzzified angle of slope.

For the engine considered in this model, from the ICE efficiency map, the optimal operation of engine occurs from the rotational speed of 250 rad/sec to 400 rad/sec and torque of 45 Nm to 60 Nm. Maintaining the crankshaft rotational speed in the efficient section can be achieved by the gear ratio transmission which is controlled by the controller according to the fuzzified vehicle speed. EM can be used as a load regulator to sustain ICE in the efficient torque area. Since there are two stages in the energy conversion, EM should be controlled to operate in the efficient speed range. This mater has been considered in the control strategy so far. When we are using the regenerative braking, or the energy from the gravitational force, SOC is the only parameter which is considered. During battery's charging and discharging, the efficiency of the battery can be defined as:

$$\eta_{discharge} = \frac{V}{V_o} \quad (16)$$

$$\eta_{charge} = \frac{V_o}{V} \quad (17)$$

where V is the cell operating voltage, and Vo is the thermodynamic voltage. In the discharging mode, a higher efficiency is obtained in high SOC, and in the charging mode, a higher efficiency is obtained in lower SOC. Enhancing net cycle efficiency and considering the state of health of battery, the fuzzy controller controls the battery in its middle SOC range of 0.6 - 0.8.

Beside the shift ratio and adaptive speed, the engine torque is the other output of the fuzzy controller. The membership functions of the fuzzy outputs are shown in Fig. 6.

If the vehicle speed is very low, or the demand torque is very low, SOC will be examined. If SOC is in its normal condition, the vehicle will work in electric only mode. The negative resistive force and brake will also be examined, and with the condition of SOC less than 0.8, the battery will be charged. Because of the certainty in these situations, regenerative braking and electric only mode of operation of the HEV have been controlled with crisp rules. For the other states of the fuzzy controller outputs, the engine is maintained in its optimal operation mode. Correspondingly, the fuzzy controller rules are performed. For instance, when SOC is not high and the demand torque is low and the motor rotational speed is efficient, the engine is controlled to deliver optimal torque, EM will be controlled to work in the generator mode, and the difference between the engine torque and the demand torque will be used in the generator to produce electrical energy. The produced electrical energy will be stored in the battery.

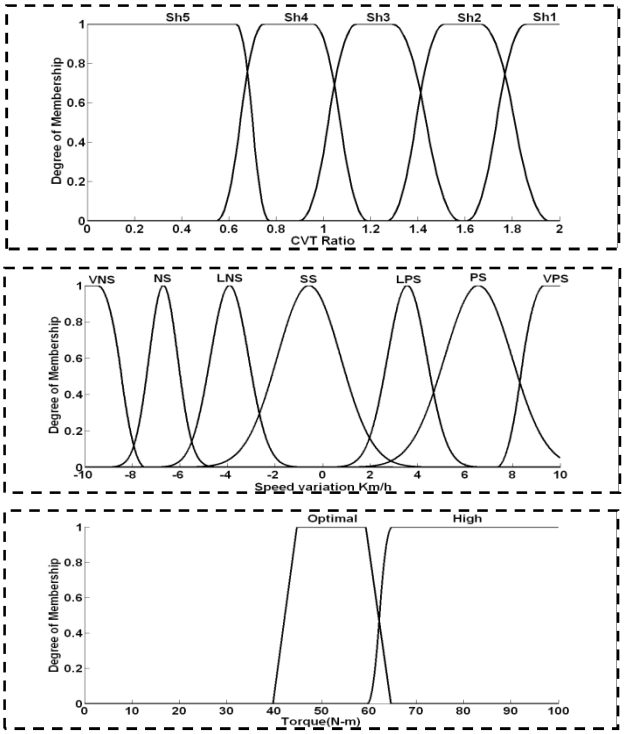

Figure 6. Output membership functions.

VI. SIMULATION AND RESULTS

The described controller and the PHEV are modeled in SIMULINK. The recommended Highway Fuel Economy Driving Schedule (HFEDS) by SAE J1711 standard [16] and real road data are applied to evaluate the proposed model.

To present the simulation results, the information of a highway, 50km of Nowra-Bateman Bay in Australia, is implemented in the model. The Cartesian coordinate's of the data is presented in Table II.

TABLE II. REAL CARTESIAN COORDINATES FOR NOVARA TO BATMAN BAY, AUSTRALIA

Road location	DIST D(km)	EAST X(km)	NORTH Y(km)	ALT Z(km)
R[1,10,C1,0.009]	0.0085	9687.63	4421.904	0.0155
R[1,10,C1,0.019]	0.0188	9687.599	4421.895	0.0158
R[1,10,C1,0.029]	0.0291	9687.596	4421.885	0.0162
R[1,10,C1,0.039]	0.0386	9687.592	4421.876	0.0164

Accordingly, the slope is calculated based on the rate of change in altitudes of distances. The graph of the used slope data is demonstrated in Fig. 7.

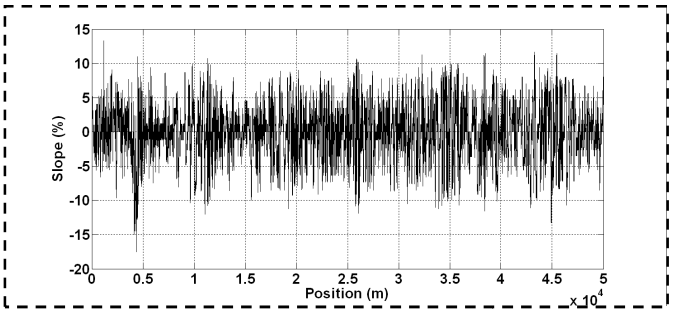

Figure 7. Slope of highway.

The use of real road data in the model distinguishes this approach from the former ones which use only the drive cycle and a constant grade. In order to evaluate the model and its fuzzy controller, simulation is run through the highway fuel economy test (HWFET). Three circumstances are considered: look-ahead information and adaptation the speed based on the future slope on the applied drive cycle, fuzzy controller with the applied drive cycle, and the default control strategy in PSAT [17]. As can be seen from the operating points of the engine on the efficiency map, which are presented in Fig. 8 for the first controller, the operation points are more controlled in the efficient area than the second and the third controllers. It means that the fuzzy controller with adaptive cruise control leads a better fuel consumption than the other controllers. Define abbreviations and acronyms the first time they are used in the text, even after they have been defined in the abstract. Abbreviations such as IEEE, SI, MKS, CGS, sc, dc, and rms do not have to be defined. Do not use abbreviations in the title or heads unless they are unavoidable.

The results of the proposed controller in comparison with the other controllers, from the standpoint of fuel economy are summarised in the Table III.

VII. CONCLUSIONS

This paper presented an approach for PHEV modelling based on the real road geographical data. From the model, the dynamic position of vehicle is achievable. The applied method uses a combination of the calculated data (distance, altitude and slope) and the static information from GIS. Instantly, the calculated data is compared with the road geographical information (length and altitude). The instantaneous position and slope are extracted. The new information is applied to determine various longitudinal forces, rolling resistance, gravitational and aerodynamic drags. The future states for a look-ahead window are extracted. Accordingly, a moving average calculator is implemented to estimate the future slopes. The deference between future and instant slopes is expressed as a fuzzy value which is applied to a fuzzy controller. The control output from the fuzzy inference engine is the amount of speed change with respect to the alteration of slope ahead. The control output is added to the reference speed which is the HWEFT drive cycle.

Considering the optimal operation of ICE, EM and SOC of battery, the fuzzy controller commands PHEV to achieve optimal fuel consumption. Simulations were carried out. The results show that good improvements on fuel consumption (6%) in comparison with the PSAT default controller. The comparison has been done with the fuzzy controller without look-ahead information, where fuel saving of 2.62% was recorded.

***Abstract*—Elliptic curve cryptosystem (ECC) was proposed by Miller [10] and Koblitz [9] which relies on the difficulty of elliptic curve discrete logarithmic problem (ECDLP). It is gaining wide acceptance as an alternative to the conventional public key cryptosystem such as RSA [24], DSA [25], DH [26]. Also it is noted that the wireless sensor networks (WSN) based on the rapid progress of wireless communications and embedded micro electro mechanical systems technologies are becoming important part in our daily life. The security of the WSN becomes one of the major concerns in its applications. Even ECC prominently offers great potential benefits for WSN security there is still a lot of work needs to be done due to WSN has very restraint running conditions such as limited energy source, capability of computing, etc. It is well known that scalar multiplication operation in ECC accounts for about 80% of key calculation time on wireless sensor network motes. In this paper we present an optimized dynamic window based on our previous research works. The whole quality of service (QoS) has been improved under this algorism in particularly the power consuming is more efficiently. The simulation results showed that the average calculation time, due to fuzzy conditions decreased from previous 26 to current 9 as a whole the calculation time, decreased by approximately 18% in comparison to our previous algorithms in an ECC wireless sensor network [23].**

Keywords-Elliptic curve cryptography (ECC), scalar multiplication, non-adjacent form, slide window, fuzzy control

I. INTRODUCTION

The high demand for various applications shows the fact that the rapid progress of wireless sensor networks has become popular in our daily life. With the growth in very large scale integrated (VLSI) technology, embedded systems and micro electro mechanical systems (MEMS) has enabled production of inexpensive sensor nodes, which can transmit data over a distances with free media and efficient use of power [1, 22, 23]. In the WSN systems, the sensor node will detect the interested information, processes it with the help of an in-built microcontroller and communicates results to a sink or base station. Normally the base station is a more powerful node, which can be linked to a central station via satellite or internet communication to form a network. There are many deployments for wireless sensor networks depending on various applications such as environmental monitoring e.g. volcano detection [2,3], distributed control systems [4], agricultural and farm management [5], detection of radioactive sources [6], and computing platform for tomorrows' internet [7]. Generally speaking, a typical WSN architecture can be shown in Figure 1.

Contrast to traditional networks, a wireless sensor network normally has many resource constraints [4] due to the limited size. As an example, the MICA2 mote consists of an 8 bit ATMega 128L microcontroller working on 7.3 MHz. As a result nodes of WSN have limited computational power. Radio transceiver of MICA motes can normally achieve maximum data rate of 250 Kbits/s, which restricts available communication resources. The flash memory that is available on the MICA mote is only 512 Kbyte. Apart from these limitations, the on board battery is 3.3.V with 2A-Hr capacity. Therefore, the above restrictions with the current state of art protocols and algorithms are expensive for sensor networks due to their high communication overhead.

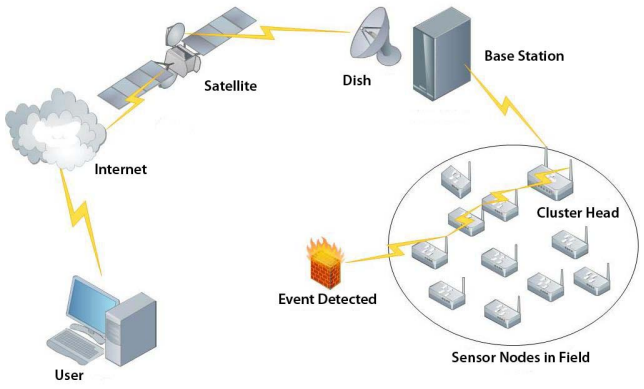

Figure 1: A Typical WSN architecture

Recalled that the Elliptic Curve Cryptography was first introduced by Neal Koblitz [9] and Victor Miller [10] independently in the early eighties. The advantage of ECC over other public key cryptography techniques such as RSA, Diffie-Hellman is that the best known algorithm for solving elliptic curve discrete logarithm problem (ECDLP) which is the underlying hard mathematical problem in ECC which will take the fully exponential time. On the other hand the best algorithm for solving RSA and Diffie-Hellman takes sub exponential time [11]. ECC offers the same level of security with smaller key size and it leads to the better performance in limited environments like cellular phones, PDA, sensor networking, etc. For example, ECC with a key size of 160 bits provides the same level of security as RSA [24], DSA [25] and DH [26] with a key size of 1024 bits. In summary, the ECC problem can only be solved in exponential time and, to date, there is a lack of sub exponential methods to attack ECC.

An elliptic curve E over $GF(p)$ can be defined by

$$y^2 = x^3 + ax + b$$

where $a, b \in GF(p)$ and

$$4a^3 + 27b^2 \neq 0$$

in the $GF(p)$.

The point (x, y) on the curve satisfies the above equation and the point at infinity denoted by ∞ is said to be on the curve.

If there are two points on the curve namely, $P(x_1, y_1)$, $Q(x_2, y_2)$ and their sum is given by point $R(x_3, y_3)$ the algebraic formulas for point addition and point doubling are given by following equations:

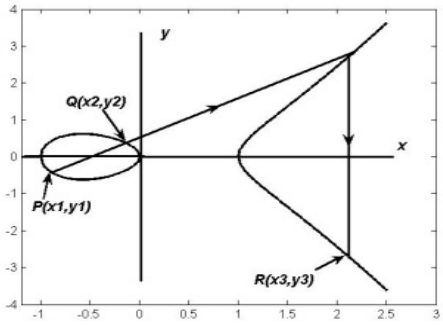
We have:

$$x_3 = \lambda^2 - x_1 - x_2$$

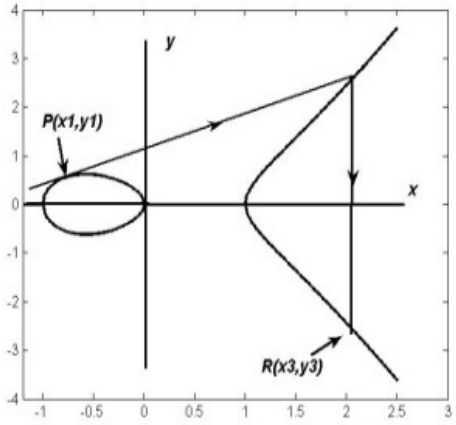
$$y_3 = \lambda(x_1 - x_3) - y_1$$

$$\lambda = \frac{y_2 - y_1}{x_2 - x_1}, \quad \text{if } P \neq Q$$

$$\lambda = \frac{3x^2 + a}{2y_1}, \quad \text{if } P = Q$$



(a) Addition: $P + Q = R$



(b) Doubling: $P+P = R$

Figure 2: Point addition and point doubling on elliptic curve.

Here, the addition, subtraction, multiplication and inverse are the arithmetic operations over $GF(p)$, which can be shown in Figure 2.

II. Elliptic Curve Diffie-Hellman Scheme Proposed for WSN

Before we get into our innovation method, we need to have a closer look at the popular legacy scheme for WSN. As per [13] the original Diffie-Hellman algorithm with RSA requires a key of 1024 bits to achieve sufficient security but *Diffie Hellman based on ECC* can achieve the same security level with only 160 bit key size.

The classical Elliptic Curve Diffie Hellman scheme operates as shown in the Figure 3.

Initially Alice and Bob agree on a particular curve with base point P. They generate their public keys by multiplying P with their private keys namely K_A and K_B. After sharing public keys, they generate a shared secret key by multiplying public keys by their private keys. The secret key is $R = K_A * Q_A = K_B * Q_B$. With the known values of Q_A, Q_B and P, it is computationally intractable for an eavesdropper to calculate K_A and K_B which are the private keys of Alice and Bob. As a result, adversaries cannot calculate R the shared secret key.

In ECC, two heavily used operations are involved: scalar multiplication and modular reduction. Gura *et. al.* [14] showed that 85% of execution time is spent on scalar multiplication. Scalar Multiplication is the operation of multiplying point P on an elliptic curve E defined over a field $GF(p)$ with positive integer k which involves point addition and point doubling. Operational efficiency of kP is affected by the type of coordinate system used for point P on the elliptic curve and the algorithm used for recoding of integer k in scalar multiplication.

This research paper proposes an innovative algorithm based on one's complement for representation of integer k which

accelerates the computation of scalar multiplication in wireless sensor networks.

The number of point doubling and point addition operations in scalar multiplication depends on the recoding of integer *k*. Expressing integer *k* in binary format highlight this dependency.

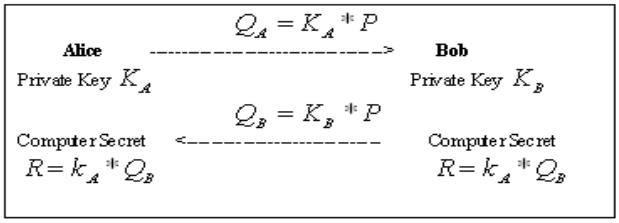


Figure 3: Diffie-Hellman protocol based on ECC

The number of zeros and number of ones in the binary form, their places and the total number of bits will affect the computational cost of scalar multiplications. The Hamming weight as represented by the number of non-zero elements, determines the number of point additions and bit length of integer *K* determines the number of point doublings operations in scalar multiplication.

One point addition when $P \neq Q$ requires one field inversion and three field multiplications [13]. Squaring is counted as regular multiplication. This cost is denoted by $1I + 3M$, where *I* denotes the cost of inversion and *M* denotes the cost of multiplication.

One point doubling when $P = Q$ requires $1I + 4M$ as we can neglect the cost of field additions as well as the cost of multiplications by small constant 2 and 3 in the above formulae.

Binary Method

Scalar multiplication is the computation of the form $Q = kP$, where *P* and *Q* are the elliptic curve points and *k* is positive integer. This is obtained by repeated elliptic curve point addition and doubling operations. In binary method the integer *k* is represented in binary form:

$$k = \sum_{j=0}^{l-1} K_j 2^j, \; K_j \in \{0,1\}$$

The binary method scans the bits of *K* either from left-to-right or right-to-left. The binary method for the computation of *kP* is given in the following *algorithm 1*, as shown below:

The cost of multiplication when using binary method depends on the number of non-zero elements and the length of the binary representation of *k*. If the representation has $k_{l-1} \neq 0$ then binary method require $(l - 1)$ point doublings and $(W-1)$ where *l* is the length of the binary expansion of *k*, and *W* is the Hamming weight of *k* (i.e., the number of non-zero elements in expansion of *k*). For example, if $k = 629 = (1001110101)_2$, it will require $(W-1) = 6 - 1 = 5$ point additions and $l - 1 = 10 - 1 = 9$ point doublings operations.

Algorithm 1: Left to right binary method for point multiplication

Input: A point $P \in E(F_q)$, an

$$k = \sum_{j=o}^{l-1} K_j 2^j, \;\; K_j \in \{0,1\}$$

l bits integer

Output: $Q = kP$

1. $Q \leftarrow \infty$
2. For $j = l$ □ 1 to 0 do:
   2.1 $Q \leftarrow 2Q$,
   2.2 if $k_j = 1$ the $Q \leftarrow Q + P$.
3. Return Q.

Signed Digit Representation Method

The subtraction has virtually the same cost as addition in the elliptic curve group. The negative of point (x, y) is $(x, -y)$ for odd characters. This leads to scalar multiplication methods based on addition–subtraction chains, which help to reduce the number of curve operations. When integer *k* is represented with the following form, it is a *binary signed digit representation*.

$$k = \sum_{j=0}^{l} S_j 2^j, \;\; S_j \in \{1,0,-1\}$$

When a signed-digit representation has no adjacent non zero digits, i.e. $S_j S_{j+1} = 0$ for all $j \geq 0$ it is called a non-adjacent form (NAF).

The following *algorithm 2* computes the NAF of a positive integer given in binary representation.

Algorithm 2: Conversion from Binary to NAF

$$k = \sum_{j=0}^{l-1} K_j 2^j, \; K_j \in \{0,1\}$$

Input: An integer

$$k = \sum_{j=0}^{l} S_j 2^j, \;\; S_j \in \{1,0,-1\}$$

Output: NAF

1. $C_0 \leftarrow 0$
2. *For j = 0 to l do:*
3. $C_{j+1} \leftarrow [(K_j + K_{j+1} + C_j)/2]$
4. $S_j \leftarrow K_j + C_j - 2C_{j+1}$
5. *Return* $(S_l \ldots S_0)$

NAF usually has fewer non-zero digits than binary representations. The average hamming weight for NAF form is $(n-1)/3.0$. So generally it requires $(n-1)$ point doublings and $(n-1)/3.0$ point additions. The binary method can be revised accordingly and is given another algorithm for NAF, and this modified method is called the *Addition Subtraction* method.

III. FUZZY CONTROLLER FOR DYNAMITIC WINDOW IN ECC- PROPOSED ALGORITHM BASED

We are going to use the algorithm, based on *subtraction by utilization of the 1's* complement, is most common in binary arithmetic. The 1's complement of any binary number may be found by the following equation [19-22]:

$$C_1 = (2^a - 1) - N \quad (1)$$

where C_1 = 1's complement of the binary number, a = number of bits in N in terms of binary form, N = binary number.

From a closer observation of the equation (1), it reveals that any positive integer can be represented by using minimal non-zero bits in its 1's complement form provided that it has a minimum of 50% Hamming weight. The minimal non-zero bits in positive integer scalar are very important to reduce the number of intermediate operations of multiplication, squaring and inverse calculations used in elliptical curve cryptography as we have seen in previous sections.

The equation (1) can therefore be modified as per below:

$$N = (2^a - C_1 - 1) \quad (2)$$

For example, we may take N =1788 then it appears

N= $(11011111100)_2$ in its binary form

C_1= 1's Complement of the number of N= $(00100000011)_2$

a is in binary form so we have a = 11

After putting all the above values in the equation (2) we have:

$1788 = 2^{11} - 00100000011 - 1$, this can be reduced as below:

$$1788 = 100000000000 - 00100000011 - 1 \quad (3)$$

So we have

$1788 = 2048 - 256 - 2 - 1 - 1$

As is evident from equation (3), the Hamming weight of scalar N has reduced from 8 to 5 which will save 3 elliptic curve addition operations.

The above recoding method based on one's complement subtraction combined with sliding window method provides a more optimized result.

Let us compute [763] P (in other words k = 763) as an example, with a *sliding window algorithm* with K recoded in binary form and window sizes ranging from 2 to 10. It is observed that as the window size increases the number of pre-computations also increases geometrically. At the same time number of additions and doubling operations decrease.

Now we present the details for the different window size to find out the optimal window size using the following example:

Window Size w = 2

$763 = (1011111011)_2$

No of pre-computations = $2^w - 1 = 2^2 - 1 = [3]\ P$

763 = 10 11 11 10 11

The intermediate values of Q are

P, 2P 4P, 8P, 11P, 22P, 44P, 47P, 94P, 95P, 190P, 380P, 760P, 763P

Computational cost = 9 doublings, 4 additions, and 1 pre-computation.

Window Size w = 3

No of pre-computations = $2^w - 1 = 2^3 - 1 = [7]\ P$

So all odd values: [3]P, [5]P, [7]P

763 = 101 111 101 1

= [5]P [7]P [5]P [1]P

The intermediate values of Q are

5P, 10P, 20P, 40P, 47P, 94P, 188P, 376P, 381P, 762P, 763P

Computational cost = 7 doublings, 3 additions, and 3 pre-computations.

We continue to derive the remaining calculations for Window Size w = 6, Window Size w = 7, Window Size w = 8, Window Size w = 9, and Window Size w = 10. The results for all calculations are presented in Table 1.

Table 1: WINDOW SIZE VS NO OF DOUBLINGS, ADDITIONS AND PRE COMPUTATIONS

Window Size	No of Doublings	No of Additions	No of Pre computations
2	9	4	1
3	7	3	3
4	6	2	7
5	5	1	15
6	4	1	31
7	3	1	61
8	3	1	127
9	1	1	251
10	0	0	501

It is interesting to have some information from Figure 4, which shows the charts obtained from table 1 (in order to see the relation clearly, we used so-called amplified chart because of the range is only limited 0 to 10 in window size).

As we are interested in the further details about the relations between "Doubling" and "Addition", from Figure 4 it clearly shows that the "Pre-computation" and "doubling" are the dominated factors hence we need to focus on this factor in our future discussion for the window size.

Algorithm for sliding window scalar multiplication on elliptic curves.

1. $Q \leftarrow P_{\infty}$ *and* i $\leftarrow l$ - 1
2. while i $\geq$ 0 do
3. if $n_i = 0$ then Q $\leftarrow$ [2]Q and i $\leftarrow$ i - 1
4. else
5. s $\leftarrow \max(i - k + 1, 0)$
6. *while* $n_s = 0$ do s $\leftarrow$ s + 1
7. for h = 1 to i - s + 1 do Q $\leftarrow$ [2]Q
8. u $\leftarrow (n_i \ldots\ldots n_s)_2$ [$n_i = n_s = 1$ and i - s + 1 $\leq$ k]
9. Q $\leftarrow$ Q $\oplus$ [u]P [u is odd so that [u]P is precompute d]
10. i $\leftarrow$ s - 1
11. return Q

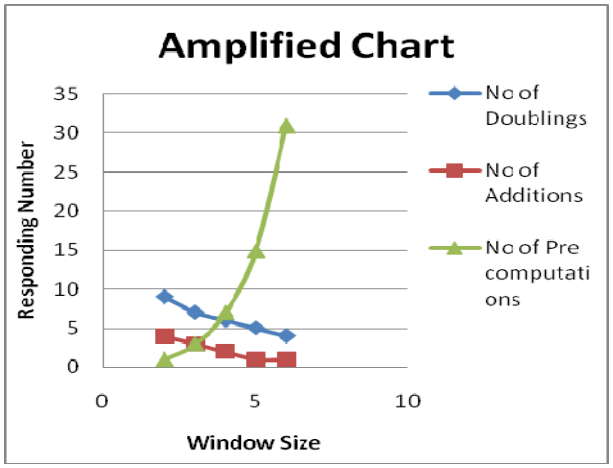

Fig. 4: amplified chart (focus on limited range) for the Table 1

IV. FUZZY CONTROLLER SYSTEM IN ECC

It is clear, from above description, that there is a tradeoff between the computational cost and the window size as shown in Table 1. However, this tradeoff is underpinned by the balance between computing cost (or the RAM cost) and the pre-computing (or the ROM cost) of the node in the network.

It is obviously to observe that the variety of wireless network working states will make this control complex and calculations could be relatively more expensive.

Therefore, we propose a fuzzy dynamic control system, to provide dynamic control to ensure the optimum window size is obtained by tradeoff between pre-computation and computation cost.

The fuzzy decision problem introduced by Bellman and Zadeh has as a goal the maximization of the minimum value of the membership functions of the objectives to be optimized.

Accordingly, the fuzzy optimization model can be represented as a multi-objective programming problem as follows [21]:

$$Max : \min\{\mu_s(D)\} \,\&\, \min\{\mu_l(U_l)\} \quad \forall s \in S \,\&\, \forall l \in L$$

$$\text{such that} \quad A_l \le C_l \qquad \forall l \in L,$$

$$\sum_{r \in R_p} x_{rs} = 1 \qquad \forall p \in P \,\&\, \forall s \in S,$$

$$x_{rs} = 0 \text{ or } 1 \qquad \forall r \in R \,\&\, \forall s \in S$$

In above equation, the objective is to maximize the minimum membership function of all delays, denoted by D, and the difference between the recommend value and the measured value, denoted by U.

The Fuzzy control system is extended from our previous design and shown in Figure 5. For the accurate control, we designed a three inputs fuzzy controller. The first input is *storage room*, which has three statuses, showing storage room in one of the three, namely (a) low, (b) average, and (c) high. The second input is pre-computing working load (*PreComputing*) in one of three states, namely (a) low, (b) average, and (c) high. The third input is *Doubling*, expressing how much working load for the calculation "doubling" which has three cases, namely (a) low, (b) average, and (c) high. The output is one, called *WindowSize,* to express the next window size should be moved in which way, which has three states for the window sizes, namely (a) down, (b) stay, and (c) up.

There are 26 *Fuzzy Rules* listed as shown in Table 2 (weights are unit). Note: H=high; A=average; L= low; U=up; S= stay; D1= down.

TABLE 2 26 Fuzzy rules for Figure 1

StorgeRoom	PreComputing	Doubling	WindSize
L	L	L	U
L	L	A	U
L	L	H	S
L	A	L	U
L	A	A	U
L	A	H	S
L	H	L	U
L	H	A	S
L	H	H	S
A	L	L	U
A	L	A	U
A	L	H	S
A	A	L	U
A	A	A	S
A	A	H	D1
A	H	A	S
A	H	H	S
H	L	L	S
H	L	A	S
H	L	H	D1
H	A	L	S
H	A	A	S
H	A	H	D1
H	H	L	D1
H	H	A	D1
H	H	H	D1

It is noted that above 26 fuzzy rules did work in our previous designed system, but it is noted that there are only 9 *Fuzzy Rules* listed in above table will be dominated the whole fuzzy control procedure (if we still keep the weights are unit) due to the fact that *StorageRoom* in Figure 5 can be ignored because of that the results shown in Figure 4 even it is a factor (with little impact on the outcome of this fuzzy system) needs to be appeared in this control system.

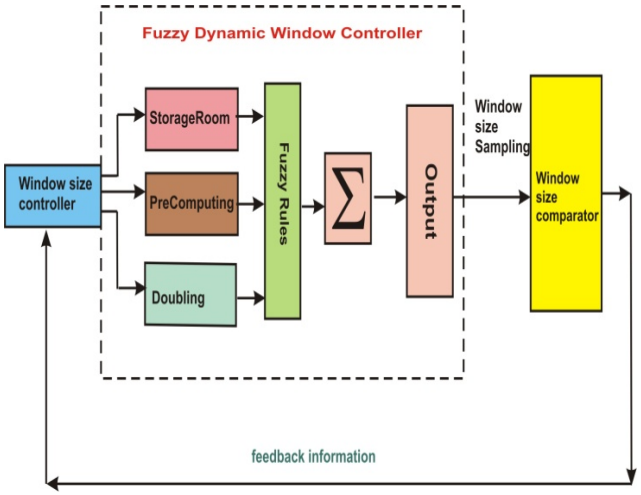

Figure 5: Three inputs fuzzy window control system

Therefore, the above 26 fuzzy rules become the major 9 fuzzy rules, which will decrease the system latency and improve the quality of service (QoS). The 9 fuzzy rules can be described as below:

1. If 1·(PreComputing is low) and 1·(Doubling is low) then 1·(WindowSize is Up)
2. If 1·(PreComputing is low) and 1·(Doubling is average) then 1· (WindowSize is Up)
3. If 1·(PreComputing is low) and 1·(Doubling is high) then 1· (WindowSize is stay)
4. If 1·(PreComputing is average) and 1·(Doubling is low) then 1· (WindowSize is Up)
5. If 1·(PreComputing is average) and 1·(Doubling is average) then 1· (WindowSize is Up)
6. If 1·(PreComputing is average) and 1·(Doubling is high) then (WindowSize is stay)
7. If 1·(PreComputing is high) and 1·(Doubling is low) then 1· (WindowSize is Up)
8. If 1·(PreComputing is high) and 1·(Doubling is average) then 1· (WindowSize is stay)
9. If 1·(PreComputing is high) and 1·(Doubling is high) then 1· (WindowSize is stay)

The number at each fuzzy condition being with a bracket is defined as "the weight number", currently it is unit. Later we shall change it with different weight according to the running situations as described in the next. The three inputs with 9 fuzzy rules in *Mamdani model* running fuzzy controller part. The three inputs are *StorageRoom*, *PreComputing* and *Doubling* as shown in Figure 6.

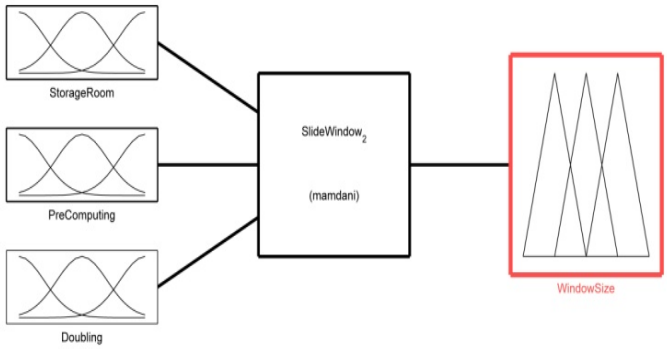

Figure 6: The block diagram of current fuzzy controller

As our target is to making window size at closer to or sitting on the optimum "window size," the output is taking *WindowSize*. It is noted that the "*StorageRoom*" has low, average, high with other two parameters's combinations.

The output with *StorageRoom* and *PreComputing* is shown in Figure 7. The surface *StorageRoom* vs. *Doubling* is shown in Figure 8.

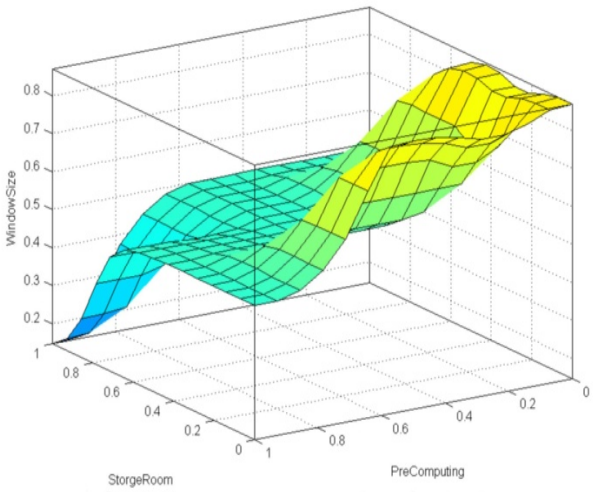

Figure 7: The output of the surface for the *StorageRoom* vs. *PreComputing*.

From above figures, it is clearly observed that in the low window size side, if the storage room is low the dominated function of "doubling" will play role as Figure 7 shown but if the window size is at the high side, the storage room will be fairly stay at the middle either for PreComputing or Doubling, which is the doubling will sharply increased when window size a little bit larger that also can be shown from Table 1.

From Figure 8 it is clearly to show when the storage room is getting big, it would be nice to have larger window size for the "doubling".

Now if we change the weight for above fuzzy rules as such the rules 1,5 10, 13, 14, 15, 16, 18, 20 ,21, 22, 23, 25, and 26 are set in 0.5 (the rest will keep the same) due to the major functions are controlled by the storage room, and doubling

will rapidly increasing by the window size larger. The outputs will changed as the average storage room will increased 0.04% and the other two inputs are decreased by 0.02% the output become window staying a little wider side by 0.003%.

It is clear that this fuzzy controller for the dynamic window is also involved a tradeoff between accuracy and control costs. For example the same system may go further for the second order parameters, i.e. not just check the changes about the input variables but also check the change tendencies of the variables, which will be discussed in another paper.

If we keep the *StorageRoom* constant, e.g. *StorageRoom* = 0.4, and the output of the "*PreComputing*" vs. "*Doubling*" is shown in Figure 9. Now in order to show the "StorageRoom" is not dominated factor as we discussed above, we took another value, "StorageRoom" = 0.8 and the output of the "*PreComputing*" vs. "*Doubling*" is shown in Figure 10.

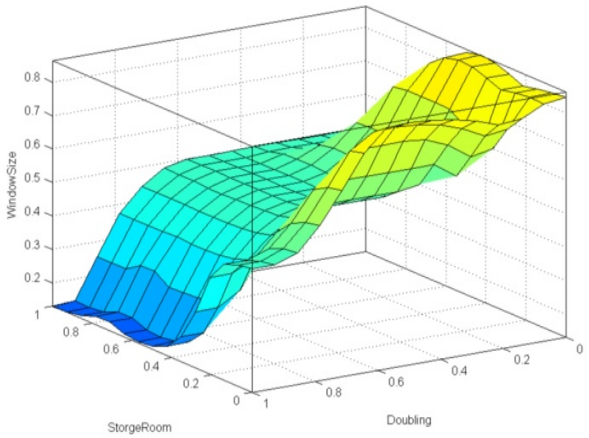

Figure 8: The output of the surface for the *StorageRoom* vs. *Doubling*.

It is observed that the output of the "*PreComputing*" vs. "*Doubling*" is not much difference between Figures 8 and 9.

From Figures 7 and 8 we can observe that the "dominated factor" is not the members of the "*StorageRoom*" in Figure 8 due to the fact that the *StorageRoom* goes to large than 40% (or 0.4) the factors *PreComputing* and *Doubling* are dominated in Figure 7 and Figure 8 separately.

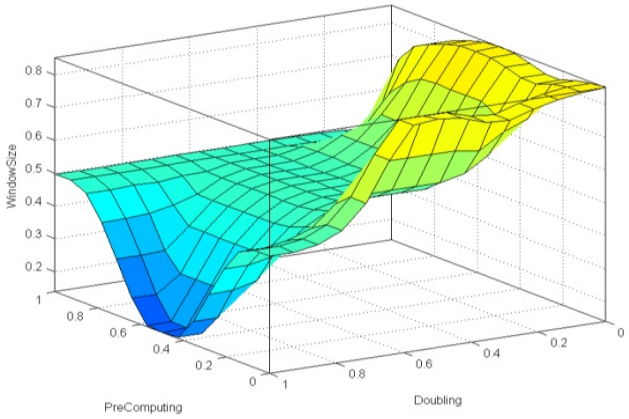

Figure 9: The output of the surface for the *StorageRoom* = constant (0.4) and *PrecComputing* vs. *Doubling*.

The *StorageRoom* cannot play a role in the process of the dynamic window, which is underpinned by the fact that has been shown in Figures 4. The simulations of the example described in above were implemented. Also it is noted that with equation (2), the computational cost has been reduced from 3 additions as in the binary method to only 1 addition in one's complement subtraction form. The number of pre-computations has remained the same.

In our simulations, the proposed method together with a fuzzy window size controller makes the ECC calculation in the current algorism is about 18% more efficient (in terms of average) than the methods in [23] with the same QoS level.

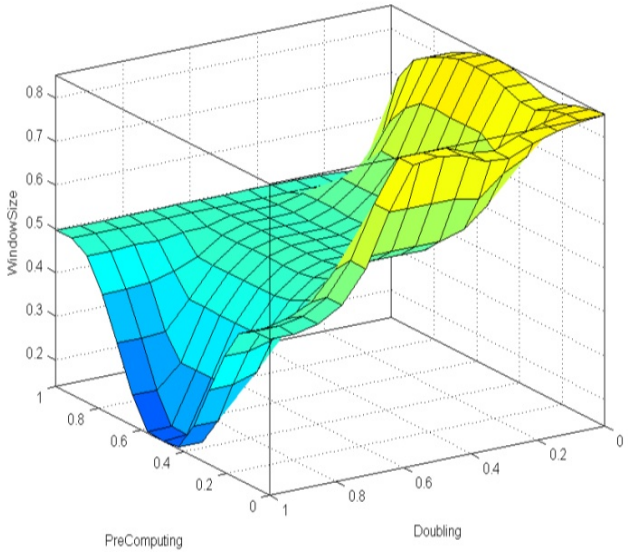

Figure 10: The output of the surface for the *StorageRoom* = constant (0.8) and *PreComputing* vs. *Doubling*.

V. CONCLUSION

In this paper, it has been investigated that the positive integer in point multiplication may be recorded with *one's complement subtraction* to reduce the computational cost involved in this heavy mathematical operation for wireless sensor network platforms. As the NAF method involves modular inversion operation to get the NAF of binary number, the one's complement subtraction can provide a very simple way of recoding the integer. There is always a decision between pre-computing and computing, the former is related to the storage and the latter is associated with computing capability and capacity. The window size may be the subject of trade-off between the available RAM and ROM at a particular instance on a sensor node, which can be controlled by fuzzy controller. The final simulation in a sensor wireless network shows that about 18% more efficient than our previous method [23] can be obtained with an ECC sensor network.

Abstract— **This paper introduces a new tuning technique for the PID control scheme that is adopted for regulating the magnitude and frequency of the wind energy conversion system (WECS) output voltage which presents interesting control demands and exhibits intrinsic non-linear characteristics. The developed technique is stem from blending the ant system optimization method with Takagi Sugeno fuzzy system approach. The optimum relationship between the PID controller gains and the parameters of fuzzy modules is explored using Ant system algorithm; hence a satisfactory dynamic performance of the WECS is obtained.**

Keywords-Takagi - Sugeno fuzzy control; PID control; Ant system optimization; Wind energy conversion systems

I. INTRODUCTION

In the world of today there is a need for alternatives to the large coal and oil fired power plants. Renewable energy is one way to go, and in particular wind turbines have proven to be a solution [1]. The arrival of the new power devices technologies, new circuit topologies and novel control strategies are contributing to the success of the wind generation technology.

In wind energy standalone generation systems, the frequency and the magnitude of the terminal voltage for the Self Excited Induction generators (SEIG) vary with load even when the rotor speed is maintained constant. An increase in the rotor speed due to the increase of wind speed will result in a proportionate increase in frequency, often accompanied by severe overvoltage and excessive current.

Although the slip-ring machine is more expensive and requires more maintenance, it permits rotor slip-power control when driven by a variable-speed turbine. When a grid connection is permissible, the slip-ring machine may be operated as a double-output induction generator (DOIG) using the slip-energy recovery technique. In the case of Self Excited Slip Ring Induction Generator (SESRIG), the system cost can be further reduced by the use of a simple rotor resistance controller [2], [3]. Since only a capacitor bank needs to be connected to the stator terminals, the SESRIG provides a good quality ac source with little harmonic distortion to the stator load. Another advantageous feature of the SESRIG is that independent control of the voltage and frequency can be achieved easily. Even with a wide variation in speed, the generator frequency can be maintained reasonably constant by rotor resistance control, while the voltage can be controlled by varying the excitation capacitance. The rating of the rotor resistance controller is small compared with the generator rating; hence, the cost saving is quite significant.

Fuzzy control and tuning methodologies have emerged in last years as promising ways to approach nonlinear control problems and to deal with difficulties of conventional PID controllers [4]. The area of auto-tuning of PID controller using fuzzy systems has attracted many authors [5][6]. However, a common bottleneck encountered in fuzzy controller design is that derivation of fuzzy rules is often difficult and time-consuming, and relies on expert knowledge. To overcome this disadvantage, many automatic methods for fuzzy system design and optimization algorithms have been proposed, such as neural fuzzy systems [7]and evolutionary fuzzy systems [8].

Recently, the social inspired optimization algorithms become a successful alternative for the conventional tuning method to adapt the PID controllers. Using these new methods, the global optimal or suboptimal solutions of the optimized control scheme are found. These algorithms are adopted by many researchers for tuning PID controller in its classical and intelligent forms. One such approach is Ant System Optimization (ASO) which is founded on the foraging behavior of ants and their indirect communication based on pheromones see for instance [9]. ASO has been applied to several combinatorial problems such as job scheduling, routing optimization in data communication networks and telephone networks [10].

One of the widely used methods for optimizing a fuzzy logic controller is to modify the rule base using this self-organizing algorithm automatically according to previous responses until the desired control performance is achieved. Many works studied this problem such as [11], [8] and [12]. In [11], a tracking control problem is assumed to develop a self tuning PID control scheme with application to antilock braking system via combinations of fuzzy and genetic algorithms. While in [13], the approximation of analytical test function is performed using ant colony algorithm to tune the parameters of Takagi Sugeno (T-S) fuzzy rule base. The authors simplified their work by assuming constant

Deanship of Scientific Research – University of Tabuk. *(sponsors)*

consequence part instead of the ordinary linear function consequent part of T-S fuzzy system. In [12], incremental fuzzy PID controller is used which is slightly different from the T-S fuzzy PID controller where, the scaling factors for input/output Macvicar-Whelan based fuzzy system are addressed in the ant colony optimization framework. In T-S fuzzy systems design, one challenging design task is the determination of the parameters of the consequent part. In this paper, ASO is employed to design the consequent part of a Takagi Sugeno fuzzy PID controller. The paper presents design procedures for a model free T-S fuzzy PID controller. Three independent T-S fuzzy systems are combined to tune different gains of PID controller. The optimum relationship between the PID controller parameters and the parameters of T-S fuzzy modules is explored. Using Ant system algorithm, the parameters of each T-S fuzzy system are optimally determined. The idea is to start with a tuned, conventional PID controller, replace it with an equivalent Takagi-Sugeno fuzzy PID controller and eventually fine-tune the T-S fuzzy tuner. This is relevant whenever a PID controller is possible or already implemented.

In the proposed T-S Fuzzy Ant System PID, structure of T-S fuzzy system is well adapted via defining the optimum parameters of its consequence part. Once new rules are generated, the PID controller parameters are calculated from the defuzzification process. This paper has two main contributions. Firstly, a PID controller has been designed for WECS using a blending tuning mechanism namely Takagi – Sugeno fuzzy Ant system algorithm. Secondly, a satisfactory closed loop performance is achieved with respect to the conventional ZN frequency response tuning method. The objective of Ant System Optimization in this paper is to improve both the design efficiency of Takagi – Sugeno fuzzy systems and its performance to get optimal PID parameters. In this paper the voltage and frequency control of a three phase SESRIG is investigated by varying the external rotor resistance and the excitation capacitance using the proposed Ant Takagi Sugeno Fuzzy PID controller.

This paper is organized as follows: section II shows the main feature of the control characteristic for SESRIG used in the proposed standalone WECS. Takagi Sugeno fuzzy tuner for PID controller is presented in section III. Section IV introduces ant system optimization algorithm for optimal parameter determination for Takagi Sugeno fuzzy systems. The proposed control strategy is applied to WECS in section V. Finally, a conclusion is set in section VI.

II. SESRIG VOLTAGE AND FREQUENCY CONTROL

Normalized equivalent circuit of the steady state model of SESRIG can be proposed as seen in Fig. 1 [14]. Where a is per unit frequency (actual frequency/base frequency), b per-unit speed (rotor speed/synchronous speed) corresponding to base frequency, C excitation capacitance per phase, E_1 air-gap voltage per phase referred to base frequency, R_1 & R_2 stator and rotor winding resistances per phase. R_L stator load resistance per phase. V_1 Load voltage per phase, X_1& X_2 Stator and rotor leakage reactances per phase, X_c Excitation capacitive reactance per phase and X_L Load reactance per phase.

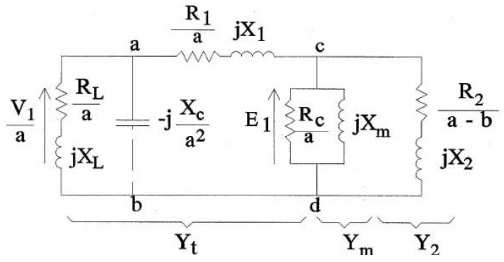

Figure 1 Normalized equivalent circuit of SESRIG[14]

For convenience, all of the machine parameters, except the excitation capacitance, are expressed in per unit. The solution of the SEIG equivalent circuit have been developed using various methods. Among them, the nodal admittance method [15], is considered very simple and easy to follow, hence it will be adopted in this paper. The main feature of the control characteristic for SESRIG used in standalone WECS is deduced in this section by performing laboratory experiments on 1.1 KW machine. The effect of changing the external rotor resistance with constant excitation capacitance and vice versa on the output terminal voltage and frequency at loading condition is presented. Fig's. 2 &3 show the effect of changing the external rotor resistance with constant excitation capacitance at loading conditions (R_L = 8 p.u) on the SESRIG output terminal voltage and frequency.

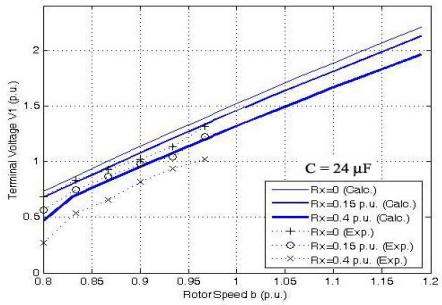

Figure 2 Terminal Voltage (V_1) versus Rotor Speed (b) at different external resistance (R_x) at R_L= 8 p.u.

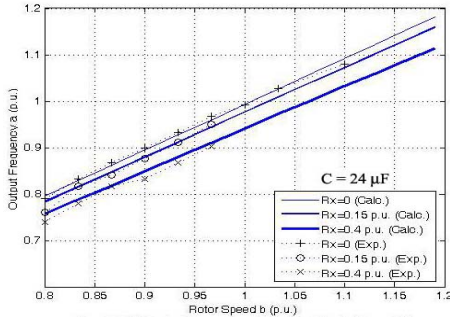

Figure 3 Output Frequency (a) versus Rotor Speed (b) at different external resistance (R_x) at R_L= 8 p.u.

Fig. 4, shows that as the rotor speed (b) increase the external rotor resistance (R_x) required to maintain the frequency constant at 1 p.u. increases. It is noted that unity per-unit frequency is only achievable at rotor speeds above 1 p.u.

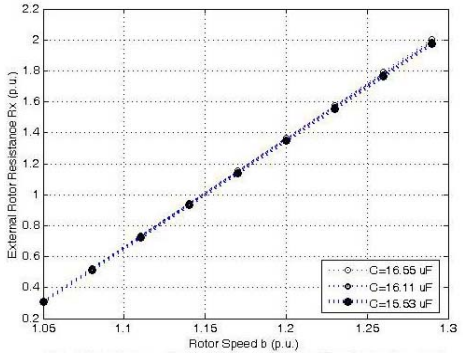

Figure. 4 External Rotor Resistance (R_x) required to maintain rated frequency as the rotor speed varies at different excitation capacitance (R_L=8)

Fig. 5 shows the corresponding terminal voltage. The terminal voltage (V_1) is constant as the rotor speed increases. At the same rotor speed, increasing the excitation capacitance increases the voltage. At a certain value of excitation capacitance, unity per-unit voltage can be obtained. For example, at rotor speed b = 1.1 p.u. and load resistance R_L= 8 p.u., the external rotor resistance required to achieve a = 1 p.u. is 0.66 p.u. To keep the voltage at 1 p.u. at the same time, the external capacitance is adjusted to 16.11 μF.

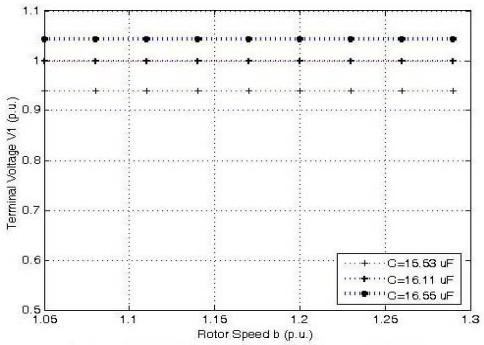

Figure 5 Terminal voltage (V_1) at rated frequency as the rotor speed varies at different excitation capacitance (R_L=8)

Fig.'s 6&7, show the external resistance and excitation capacitance needed to maintain nominal voltage and frequency at a constant rotor speeds (b) of 1.1 p.u. and 1.2 p.u. as the load current increases. For example, when rotor speed (b) is 1.1 and load current (I_L) is 0.25 p.u., the values of the external resistance and excitation capacitance which are needed to maintain the frequency and voltage at 1 p.u. are 0.7 p.u. and 16.55 μF respectively.

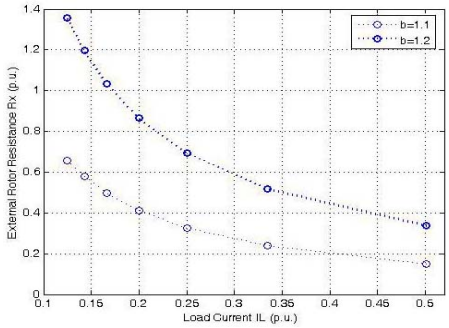

Figure 6 Variation of external resistance (R_x) to operate at rated voltage and frequency as the load current increases

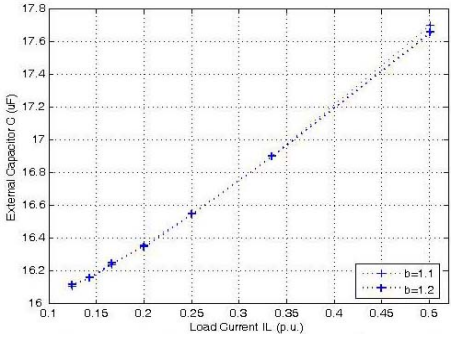

Figure 7 Variation of excitation capacitance (C) to operate at rated voltage and frequency as the load current increases

From the above figures and discussions the following points can be concluded:

Remark 1:

(1) Comparison between the computed and experimental results reflects their close matching that reflects the adequateness of the circuit model and the solution method proposed in [16] and [17].

(2) At constant load conditions, changing the external rotor resistance will affect the standalone WECS terminal output voltage and frequency while the excitation capacitance remains unchanged (i.e. increasing rotor speed (i.e. wind speed) should accompany with increasing the external rotor resistance while the excitation remains nearly constant)

(3) At variable load conditions, simultaneous change in the external rotor resistance and the excitation capacitance is required in order to keep the standalone WECS working at the rated voltage and frequency (i.e. increasing the loading condition (the output power required from the standalone WECS) to be delivered to the load) should accompany with decreasing the external rotor resistance and increasing the excitation capacitance).

III. T – S FUZZY TUNER FOR PID CONTROLLER

Many PID controllers were presented in literature, the expression of PID control law for a continuous time system is given as follows:

$$\boldsymbol{u(t) = K_p e(t) + \frac{K_p}{T_i}\int_0^t e(t)dt + K_p T_d \frac{de(t)}{dt}} \quad (1)$$

where *e(t)* is the error between the input and the output of the system; *u(t)* is the control action generated by the PID controller; K_p is the proportional gain; T_i is the integral time constant; and T_d is the derivative time constant.

In this section, three independent T-S fuzzy systems are used to tune different gains of PID controller. Each fuzzy module is assigned to obtain each PID gains. The typical T-S fuzzy systems studied in this paper have two inputs and one output. The input variables are error and rate of change of the error. We denote *e(t)*, $\dot{e(t)}$ and *y(t)* as error, rate of change of error and system output, respectively. A fuzzy set for *e(t)* (or $\dot{e}(t)$) is denoted as *M* (or *L*) and the corresponding membership is designated as $\mu_i(e(t))$ or ($\mu_i(\dot{e}(t))$). Throughout this work, a Gaussians membership functions for the two inputs of the premise part of T-S fuzzy system are used. The error *e(t)* and the rate of change of the error $\dot{e}(t)$ are normalized using three Gaussian membership functions; negative *N*, zero *Z*, and positive *P*, so that nine rules constitute the rule base for each module. For simplicity, the consequent part has been chosen to be a first order function of *e(t)* and $\dot{e}(t)$. The rule bases have the following form:

Rule j: **If *e(t)* is *M* and $\dot{\mathbf{e}}(\mathbf{t})$ is *L* then $k_i = a_{ij}e(t) + b_{ij}\dot{e}(t)$**

where $k_i = f(e(t), \dot{e}(t))$ is the gain to be tuned, i.e. K_p , K_i or K_d . a_{ij} and b_{ij} are the constants, and *j=1, 2, ...9* is the rule number. In this paper, the weighted average technique is utilized to get the overall fuzzy output as follows:

Given a pair of *e(t)*, $\dot{e}(t)$, the final output of the fuzzy system is inferred as follows [18]:

$$\boldsymbol{k^i = \frac{\sum_{j=1}^{r} w_j(e(t), \dot{e}(t))\left(a_{ij}e(t) + b_{ij}\dot{e}(t)\right)}{\sum_{j=1}^{r} w_j(e(t), \dot{e}(t))}}$$

$$k^i = \sum_{j=1}^{r} h_j\left(e(t), \dot{e}(t)\right)\left(a_{ij}e(t) + b_{ij}\dot{e}(t)\right) \quad (2)$$

$$w_j\left(e(t), \dot{e}(t)\right) = \prod_{j=1}^{2} \mu_{A_j^i}(e(t), \dot{e}(t)),$$

$$\boldsymbol{h_j\left(e(t), \dot{e}(t)\right) = \frac{w_j\left(e(t), \dot{e}(t)\right)}{\sum_{j=1}^{r} w_j\left(e(t), \dot{e}(t)\right)}}$$

Where $\mu_{A_j^i}(e(t), \dot{e}(t))$ is the grade of membership of $(e(t), \dot{e}(t))$ in *A* and *B*. In this paper, we assume that,

$w_j\left(e(t), \dot{e}(t)\right) \geq 0 \quad for\ j = 1,2, \dots, r$

$\sum_{j=1}^{r} w_j(e(t), \dot{e}(t)) > 0$ for all *t*. Therefore we obtain

$h_j\left(e(t), \dot{e}(t)\right) \geq 0 \quad for\ j = 1,2, \dots, r$ and

$\sum_{j=1}^{r} h_j\left(e(t), \dot{e}(t)\right) = 1$

Remark 3: Our approach is different from those of [11], [13] and [12] in the following ways.

i. A Takagi – Sugeno type of the fuzzy PID control system is assumed instead of incremental fuzzy PID control system.
ii. The input Gaussian membership functions of T-S fuzzy tuner are assumed to be constant (i.e. the membership function's center *"c"* and its spread *"σ"* are constant over each rules and fuzzy system).
iii. The total no. of free parameters to be tuned in is 117 parameters while in our proposed design procedures are 54 parameters (i.e. smaller computational burden).

IV. ASO ALGORITHM BASED T-S FUZZY OPTIMAL PARAMETER DETERMINATION

A. Ant System Optimization

The ant system is the first member of a class of algorithms called Ant Colony Optimization (ACO) that was initially proposed by Colorni, Dorigo and Maniezzo [19]. This technique is adopted in this paper due to its simplicity. The main underlying idea, loosely inspired by the behavior of real ants, is that of a parallel search over several constructive computational threads based on local problem data and on a dynamic memory structure containing information on the quality of previously obtained result. In this algorithm, computational resources are allocated to a set of artificial ants that exploit a form of indirect communication mediated by the environment to find the shortest path from the ant nest to a set target. Ant algorithms have been proved to be a quick global optimal solution finder when compared to other heuristic methods such as simulated annealing and genetic algorithms. It also states that the ant algorithms have the quality to find new optimal solution without reinitiating the computations from scratch.

B. T-S Fuzzy PID optimization problem

Usually, the optimization process consists of finding the controller parameters such as to minimize or maximize a given cost function of the closed loop system consisting of a fuzzy PID controller and an unknown plant. The optimization of step response of the system under control by minimizing a suitable performance criterion is the aim of this work.

Each T-S fuzzy module consists of constant premise parameters (that is needn't to be optimized) and 18 free consequence parameters (that will be optimized). The total number of free parameters to be optimized for the overall fuzzy system is 54. The AS algorithm is applied to optimize two different parameter matrices (*A* & *B*). These parameters matrices are driven by the consequence parts of fuzzy rule base. The dimension of both parameter matrices is "*3x9*". The effectiveness of the proposed T-S Fuzzy controller is quantified by the following performance criteria that are evaluated at the end of a step response experiment. It includes the overshoot ζ, settling time t_s and steady state error e_{ss} of the system unit step response. The performance criterion of the system F is designed as follows:

$$\boldsymbol{F = \lambda_\zeta f_1 + \lambda_{t_s} f_2 + \lambda_{e_{ss}} f_3} \quad (3)$$

where $\lambda_\zeta, \lambda_{t_s} and\ \lambda_{e_{ss}}$ are three weighting coefficients and f_1, f_2 & f_3 are defined as follows:

$$f_1 = \frac{\zeta}{\zeta_o}, f_2 = \frac{t_s}{t_{so}}\ and\ f_3 = \begin{cases} \frac{e_{ss}}{e_{sso}}\ if\ e_{sso} \neq 0 \\ 0\ ,\quad if\ e_{sso} = 0 \end{cases}, \quad (4)$$

Where $\zeta_o, t_{so}\ and\ e_{sso}$ are the performance values obtained from ZN tuning formula. The parameters matrices for the problem of tuning T-S fuzzy PID controller are defined as:

$$\boldsymbol{A} = \begin{bmatrix} \boldsymbol{a_{11}} & \cdots & \boldsymbol{a_{19}} \\ \vdots & \ddots & \vdots \\ \boldsymbol{a_{31}} & \cdots & \boldsymbol{a_{39}} \end{bmatrix} \& B = \begin{bmatrix} \boldsymbol{b_{11}} & \cdots & \boldsymbol{b_{19}} \\ \vdots & \ddots & \vdots \\ \boldsymbol{b_{31}} & \cdots & \boldsymbol{b_{39}} \end{bmatrix} \quad (5)$$

Now, the control problem in this paper can be formulated as follows:

Given a plant *G(s)* to be controlled (Fig.8), ***determine*** the optimum values of the parameters in (2) using ant system algorithm, hence, ***find*** the optimal PID parameters K_p, T_i and T_d ***so that*** the control system has the minimum value of given performance criterion "*F*" (3).

Fig. 8 depicts the closed loop control system used in this paper.

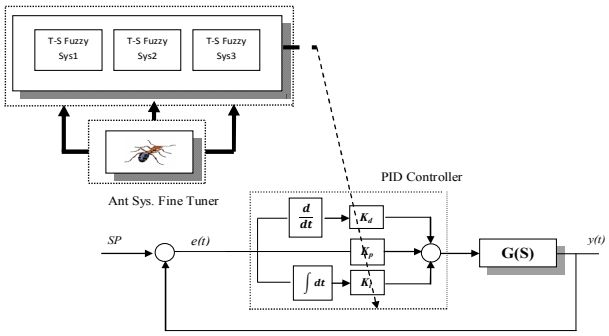

Figure 8 The Proposed Closed loop Control System

A. Proposed Algorithm

Using the same technique used in [20] or the ant system optimization, we can modify the design algorithm presented in [12] to take into account the presence of T-S fuzzy system. The proposed AS Algorithm based T-S Fuzzy optimal PID parameter determination can be summarized as follows:

Step 1: Determine K_{po}, K_{io} and K_{do} using the classical Ziegler-Nichols tuning formula for a given control system with a PID controller and compute the system's performance indexes $\zeta_o, t_{so}\ and\ e_{sso}$.

Step 2: Specify the initialization parameters of our proposed problem that contain the following:

- Values of $\alpha, \beta, \rho, \tau_o\ and\ m$.
- The maximum number of iterations t_{max}.
- A one-dimensional array $Path_k$ with 108 elements. Array $Path_k$ can be used to denote the moving path of ant *k*.

Step 3: Set the iteration counter *t=1* and then place all of the m ants at the origin O.

Step 4: Set *i=1*.

Step 5: Set *k=1*.

Step 6: Compute the transition probability of each node on line L_i using the following formula

$$P_k(i,j,t) = \frac{\tau^\alpha(i,j,t)\eta^\beta(i,j,t)}{\sum_{j=0}^{9}\tau^\alpha(i,j,t)\eta^\beta(i,j,t)}$$

Where $\eta(i,j,t)$ is the visibility of node *(i, j)* and defined as:

$$\eta(i,j,t) = \frac{10 - |j - j^*|}{10}$$

Where the values of j^* are set in the following way:

- In the first iteration of the AS algorithm, the values of j^* (*i=1-108, j=0-9*) are assigned from the different values of the one dimensional array $Path_{k\text{-}initial}$.
- In each of the following iterations, j^* are determined from the calculated one dimensional array $Path_k$ (it contains different entities of matrices *A* & *B*) that is corresponding to optimal traveling path generated in the previous iteration by the ant

$\alpha\&\beta$ represent respectively the relative importance of the pheromone concentration and visibility in transition probability

Step 7: Based on the calculated transition probability in the previous step and using Roulette wheel selection method, select a node on line L_i for ant *k* and move ant *k* to this node, then save the *y* coordinate of the node into the i^{th} element of $Path_k$.

Step 8: Set *k*←*k+1*. If $k \leq m$, go to Step 6; Otherwise, continue.

Step 9: Set *i*←*i+1*. If $i \leq 108$, go to Step 5; Otherwise, continue.

Step 10: For each ant *k* (*k=1, 2, ..., m*): according to Pathk, compute different entities values of matrices *A* & *B* using formula (5).

Step 11: For each ant *k* (*k=1, 2, ..., m*): evaluate the PID gain values from the T-S fuzzy system according to formula (2).

Step 12: For each ant *k* (*k=1, 2, ..., m*): perform a simulation experiment using the calculated matrices *A* & B and compute the system's performance indexes $\zeta^k, t_s^k\ and\ e_{ss}^k$ then compute the performance criterion F_k using formula (3).

Step 13: Compare all of the obtained F_k values and find the optimal ant path of this iteration ($Path_{k\text{-}optimal}$), that has minimum value of the performance criterion (i.e. $min_k F_k$, *k=1,2,...,m*). Save the $Path_{k\text{-}optimal}$ and the corresponding optimal PID gains.

Step 14: Set each element of $Path_k$ to zero, *k=1, 2,..., m*.

Step 15: Update the pheromone concentration of each node on the moving ant path using the following updating rule:

$$\tau(i,j,t+1) = \rho\tau(i,j,t) + \Delta\tau(i,j)$$

$$\Delta\tau(i,j) = \sum_{k=1}^{m}\Delta\tau(i,j)$$

Where $0 < \rho < 1$ is the pheromone decay parameter; $\tau(i,j)$ is the amount of pheromone laid at n_{ij} by ant *k* in the iteration just completed and computed by the following formula:

$$\Delta\tau_k(i,j) = \begin{cases} \frac{Q}{F_k}\ if\ ant\ k\ passed\ through\ n_{ij}\ in\ previous\ iterat. \\ 0 \qquad\qquad\qquad\qquad\qquad Otherwise \end{cases}$$

Where Q is a positive constant, F_k is the value of performance criterion of ant k in the iteration just completed and computed by (3).

Step 16: Set $t \leftarrow t+1$. If $t < t_{max}$ and all of the m ants do not make the same tour, place all the ants at the origin O and go to Step 4; if $t < t_{max}$ but all of the m ants make the same tour or $t = t_{max}$, ; stop.

V. Standalone WECS Simulation Using the Proposed Technique

In this section, based on the results drawn from the above sections, the proposed technique namely Ant System based Takagi Sugeno Fuzzy PID (ASTSFPID) Control is applied to the standalone WECS configured in Fig. (9) to automatically control the terminal output voltage and frequency of SESRIG when either the stator load impedance or the rotor speed changes. The goal is to keep the voltage and frequency at the value of 1 p.u. This is achieved by simultaneously changing the excitation capacitor and the added rotor resistance.

A. Closed loop control

The stator terminal voltage and the output frequency are chosen as the feedback variable since any change in speed and stator load impedance will result in a corresponding change in the terminal voltage and output frequency. The stator terminal voltage signal is compared with the voltage reference signal. The voltage error signal is fed to a proportional-plus-integral (PI) controller that outputs a signal for the firing angle of the thyristor controlled inductor (TCR). The output frequency signal is compared with the frequency reference signal. The frequency error signal is fed to another PI controller that outputs a signal for the duty cycle of the chopper controlled resistance.

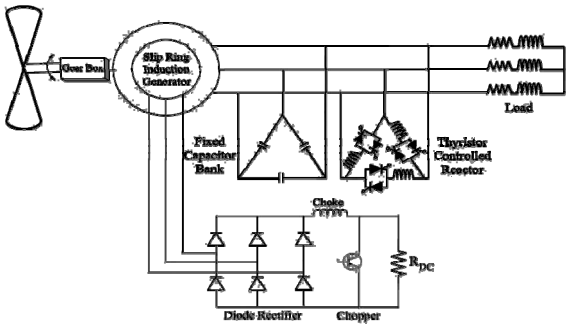

Figure 9 Schematic Diagram for the system configuration

In [17], since no electrical dynamics is involved the SESRIG was approximated as a first-order delayed system, the parameters of the proposed transfer function were determined using the open-loop step response method. Proper tuning of the PI controller is required in order to give satisfactory dynamic performance of the proposed standalone WECS. Hence, same approximation for SESRIG performed in [17] will be adopted in this paper.

Among different traditional tuning methods, the Ziegler-Nichols (ZN) technique has been very influential. The idea is to start the proposed algorithm with ZN PI gains then enhance the dynamic response of the closed loop system according to the performance index in (3) via the steps of the algorithm. Finally, the algorithm will reach to the optimal parameters of the PI controller that can be used in controlling the voltage and the frequency of the standalone WECS.

B. Closed Loop Control Simulation Results

This section contains the results of three simulation experiments using MATLAB/SIMULINK environment to study the dynamic response of SESRIG based standalone WECS with Takagi Seguno Fuzzy based Ant System PI closed loop control. For the sack of comparison, the results with ZN-PI controller designed in [17] are also presented. Firstly the response for changing the rotor speed (b) while the stator load resistance kept constant is presented. Secondly the response for changing the stator load resistance (R_L) while the rotor speed (b) kept constant is studied. Thirdly the response for changing the rotor speed (b) followed with a change in the stator load resistance (R_L) is introduced. Fig's. (10-15) show the dynamic response (output voltage and frequency) of the standalone WECS subjected to the proposed and traditional control method. The proposed PI controllers (ASTSFPI) after a short transient time restored both the output terminal voltage and frequency to the reference value (i.e. 1 p.u.) with reasonable overshoot and zero steady state error irrespective of changing the rotor speed and the stator load resistance. As seen from the following figures, the proposed control method outperforms the traditional control method.

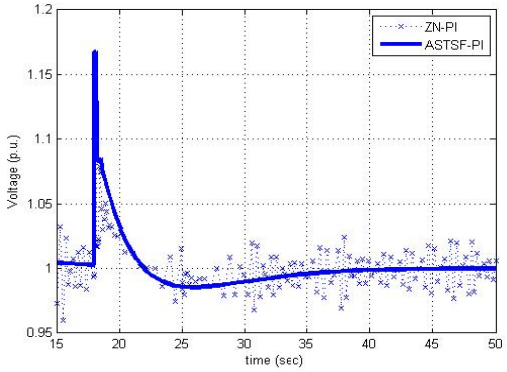

Figure 10 Dynamic Response of the voltage as the rotor speed increases from 1.2 to 1.3 p.u at R_L= 4 p.u. with the proposed and the traditional control

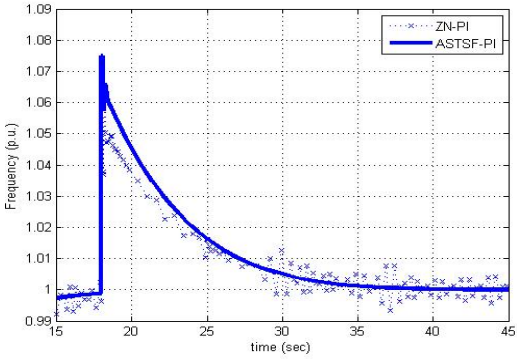

Figure 11 Dynamic Response of the frequency as the rotor speed increases from 1.2 to 1.3 p.u at R_L= 4 p.u. with the proposed and the traditional control

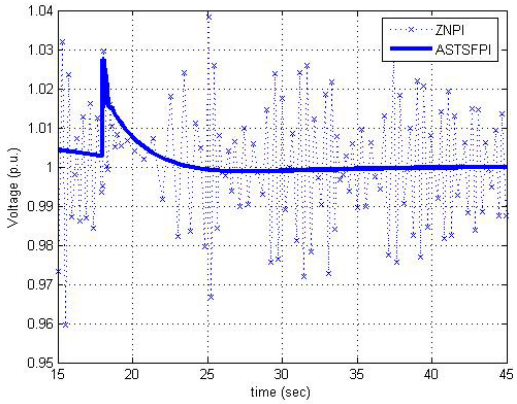

Figure 12 Dynamic Response of the voltage as the load increases from 4 to 4.3 p.u at *b*= 1.2 p.u. with the proposed and the traditional control

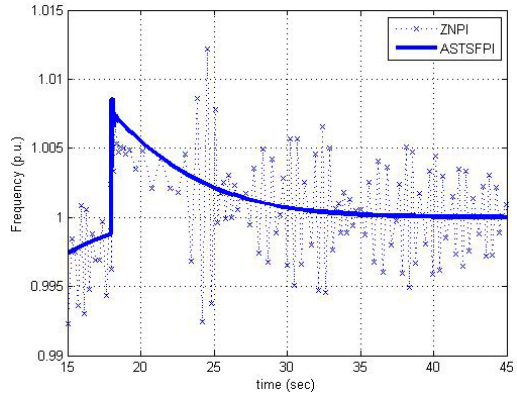

Figure 13 Dynamic Response of the frequency as the load increases from 4 to 4.3 p.u at *b*= 1.2 p.u. with the proposed and the traditional control

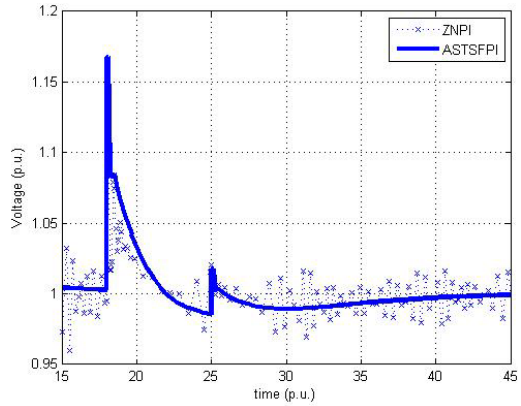

Figure 14 Dynamic response for the voltage as rotor speed & Stator load resistance change from b = 1.15 to 1.3 p.u and from R_L= 4.5 to R_L= 4.3 p.u. with the proposed and the traditional control

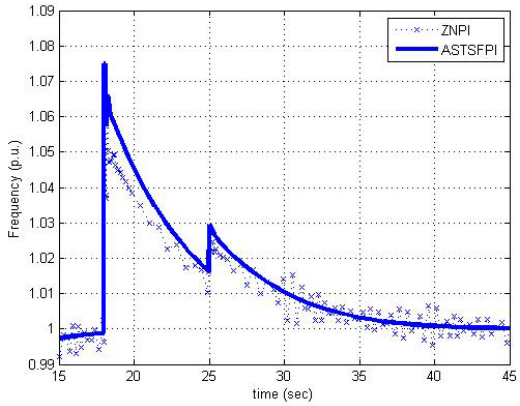

Figure 15 Dynamic response of the frequency as rotor speed change &stator load resistance change from *b*= 1.15 to 1.3 p.u and from R_L= 4.5 to R_L= 4.3 p.u. with the proposed and the traditional control

VI. CONCLUSION

In this paper, an optimal Takagi Seguno fuzzy PID controller is determined using ant system algorithm. The proposed controller is used to control the output voltage and frequency for standalone WECS at the sending end of self-excited slip-ring induction generator. The ant system algorithm search for the optimal parameters of the consequent part of the Takagi Seguno fuzzy system that is in turn produces the optimal PID gains. It is shown that with varying rotor speed and load impedance both the frequency and the output voltage of the SESRIG can be maintained constant by rotor resistance control and excitation capacitance control over a wide range of speeds without exceeding the stator current limit. The proposed algorithm is easily implemented, has a good convergence property and has an efficient searching ability for the optimal PID controller. Moreover the proposed technique is very effective and useful for making the self excited induction generator feasible for remote windy areas.

***Abstract*—This paper focuses on fuzzy H_∞ controller design for uncertain active suspension systems with actuator delay based on Takagi-Sugeno (T-S) model approach. This dynamic system is presented by taking into account the sprung and unsprung mass variations, the actuator delay, and the suspension performance. The fuzzy H_∞ controller is designed such that the resulting T-S fuzzy system is asymptotically stable and guarantees H_∞ performance, and simultaneous satisfying the constraint performance. The existence condition of fuzzy H_∞ control is obtained in terms of linear matrix inequalities (LMIs) and can be solved by using the standard software. A quarter-car suspension model is provided to validate the effectiveness of the proposed design procedures.**

Keywords: Fuzzy control, T-S model, H_∞ control, actuator delay, uncertain active suspension systems.

I. Introduction

The vehicle suspension is a crucial component that is used to support the vehicle weight, to provide effective isolation of the chassis from road excitations, to keep tyre contact with the ground, and to maintain the wheels in appropriate position on the road surface. Recently, considerable attention has been paid to the hot issue how to achieve the required suspension performances, namely, ride comfort, road handling, and suspension deflection [1]. Recently, many active suspension control approaches have been presented to handle the tradeoff [2]–[7]. It has been proved that H_∞ control method is feasible to achieve a compromised vehicle performance in [6], [7].

For active suspension systems, the vehicle sprung and unsprung masses may vary according to the different loading conditions, such as the payload and number of vehicle passengers. If we do not take into account the varying vehicle sprung and unsprung masses in the control design process, the performance of the vehicle suspension systems will be affected. More recently, the authors in [8], [9] used the polytopic parameter uncertainties to model the varying vehicle sprung or unsprung masses. Among [8], [10], the parameter-dependent controllers has been proposed for the quarter-car suspension systems with sprung mass variation. The parameter-independent sampled-data H_∞ controller design strategy has been provided in [9] for quarter-car suspension systems with both sprung and unsprung mass variations. In particular, the authors in [11] presented T-S model-based fuzzy control design approach for electrohydraulic active suspension systems with input constraint.

This paper is concerned with the problem of fuzzy H_∞ control for uncertain active suspension systems with actuator delay based on T-S model approach. The parallel-distributed compensation (PDC) scheme is used to develop fuzzy H_∞ performance analysis condition for the proposed T-S fuzzy systems presenting the uncertain active suspension systems. Then, the fuzzy H_∞ controller is designed to ensure the resulting T-S fuzzy system is asymptotically stable and satisfy H_∞ performance, and guarantee the suspension performance. The linear matrix inequality (LMI)-based condition of fuzzy H_∞ controller is derived and can be solved by using the standard software. Finally, a quarter-car suspension model is provided to demonstrate the effectiveness of the proposed design approach.

II. Problem Formulation

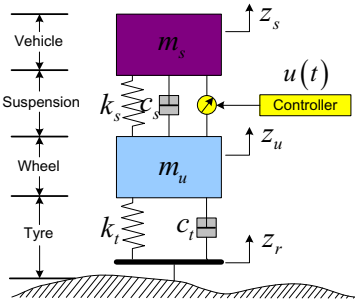

Fig. 1. Quarter-car model

Over the past years, many researchers became to investigate the modeling and control design for active suspension systems since these systems play an important role in guaranteeing the suspension performance, such as ride comfort, road holding, and suspension deflection. A quarter-car model has been used widely for the research in the literature and is shown in Fig. 1, in which m_s is used to denote the sprung mass, which represents the car chassis; m_u is the unsprung mass, which represents mass of the wheel assembly; $u(t)$ is used to stand for the active input of the suspension system; z_s and z_u are used to

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

denote the displacements of the sprung and unsprung masses, respectively; z_r is used to denote the road displacement input; c_s and k_s are damping and stiffness of the suspension system, respectively; k_t and c_t stand for compressibility and damping of the pneumatic tyre, respectively. Then, the dynamic equation of the suspension model is established as:

$$\begin{aligned} & m_u\ddot{z}_u(t)+c_s[\dot{z}_u(t)-\dot{z}_s(t)]+k_s[z_u(t)-z_s(t)] \\ & +k_t[z_u(t)-z_r(t)]+c_t[\dot{z}_u(t)-\dot{z}_r(t)] \\ = \; & -u\left(t\right), \\ & m_s\ddot{z}_s(t)+c_s[\dot{z}_s(t)-\dot{z}_u\left(t\right)]+k_s[z_s(t)-z_u(t)] \\ = \; & u\left(t\right). \end{aligned} \tag{1}$$

Denote $x_1(t)=z_s(t)-z_u(t)$ as the suspension deflection, $x_2(t)=z_u(t)-z_r(t)$ as the tire deflection, $x_3(t)=\dot{z}_s(t)$ as the sprung mass speed, $x_4(t)=\dot{z}_u(t)$ as the unsprung mass speed, and $w(t)=\dot{z}_r(t)$ as the disturbance input, respectively. The equations in (1) can be rewritten as:

$$\dot{x}(t)=A\left(t\right)x(t)+B_1\left(t\right)w(t)+B\left(t\right)u\left(t\right), \tag{2}$$

where

$$\begin{aligned} A\left(t\right) &= \begin{bmatrix} 0 & 0 & 1 & -1 \\ 0 & 0 & 0 & 1 \\ -\frac{k_s}{m_s} & 0 & -\frac{c_s}{m_s} & \frac{c_s}{m_s} \\ \frac{k_s}{m_u} & -\frac{k_t}{m_u} & \frac{c_s}{m_u} & -\frac{c_s+c_t}{m_u} \end{bmatrix}, \\ B\left(t\right) &= \begin{bmatrix} 0 \\ 0 \\ \frac{1}{m_s} \\ -\frac{1}{m_u} \end{bmatrix}, \quad B_1\left(t\right)=\begin{bmatrix} 0 \\ -1 \\ 0 \\ \frac{c_t}{m_u} \end{bmatrix}, \\ x(t) &= \begin{bmatrix} x_1(t) & x_2(t) & x_3(t) & x_4(t) \end{bmatrix}^T. \end{aligned}$$

For suspension systems control design problems, their performance, such as ride comfort and suspension deflection, road holding should be taken into account. For quarter car suspension model showed in Fig. 1, it is extensively accepted that ride comfort can be generally quantified by the body acceleration in the vertical direction, hence it is practically acceptable to choose body acceleration, $\ddot{z}_s(t)$, as the first control output. Therefore, one of our main objectives is to minimize the vertical acceleration $\ddot{z}_s(t)$, which means that the passengers feel comfortable. Here we recall H_∞ control method since the value of H_∞ norm is defined as an upper bound of the root-mean-square gain. Our main goal is to minimize the H_∞ norm of the transfer function from the disturbance $w(t)$ to the control output $z_1(t)=\ddot{z}_s(t)$ with an emphasis on ride comfort improving. Meanwhile the following required performance should be taken into account:

I) The suspension deflection cannot exceed a maximum value constrained due to mechanical structure, that is,

$$|z_s(t)-z_u(t)|\le z_{\max}, \tag{3}$$

where $z_{\max}$ is the maximum suspension deflection.

II) The dynamic tyre load has to be less than the static tyre load in order to ensure a firm uninterrupted contact of the wheels on the road,

$$k_t\left(z_u(t)-z_r(t)\right)<\left(m_s+m_u\right)g. \tag{4}$$

Based on the above discussion, we choose the body acceleration $\ddot{z}_s(t)$ as performance control output, the suspension stroke $z_s(t)-z_u(t)$ and relative dynamic tire load $k_t\left(z_u(t)-z_r(t)\right)/\left(m_s+m_u\right)g$ as constrained control output $z_2(t)$. Therefore, we can use the following system to present the active vehicle suspension system:

$$\begin{aligned} \dot{x}(t) &= A\left(t\right)x\left(t\right)+B_1\left(t\right)w\left(t\right)+B\left(t\right)u\left(t\right), \\ z_1(t) &= C_1\left(t\right)x(t)+D_1\left(t\right)u\left(t\right), \\ z_2(t) &= C_2\left(t\right)x(t), \end{aligned} \tag{5}$$

where $A\left(t\right)$, $B_1\left(t\right)$ and $B\left(t\right)$ are defined in (2), and

$$\begin{aligned} C_1\left(t\right) &= \begin{bmatrix} -\frac{k_s}{m_s} & 0 & -\frac{c_s}{m_s} & \frac{c_s}{m_s} \end{bmatrix}, \\ D_1\left(t\right) &= \frac{1}{m_s}, \\ C_2\left(t\right) &= \begin{bmatrix} \frac{1}{z_{\max}} & 0 & 0 & 0 \\ 0 & \frac{k_t}{(m_s+m_u)g} & 0 & 0 \end{bmatrix}. \end{aligned}$$

It can be found that the suspension suspension system in (5) is an uncertain model in that the sprung mass m_s and the unsprung mass m_u vary in given ranges. When carrying out the modeling the suspension systems, the actuator time delay should be taken into account, which can be expressed as:

$$\begin{aligned} \dot{x}(t) &= A\left(t\right)x\left(t\right)+B_1\left(t\right)w\left(t\right)+B\left(t\right)u\left(t-d\left(t\right)\right), \\ z_1(t) &= C_1\left(t\right)x(t)+D_1\left(t\right)u\left(t-d\left(t\right)\right), \\ z_2(t) &= C_2\left(t\right)x(t), \\ x(t) &= \phi(t), \quad t\in\left[-\bar{d},0\right], \end{aligned} \tag{6}$$

where $\phi(t)$ is a vector-valued initial continuous function defined on $t\in\left[-\bar{d},0\right]$. $d\left(t\right)$ denotes the time-varying delay satisfying

$$0\le d\left(t\right)\le\bar{d}, \quad d\left(t\right)\le\mu. \tag{7}$$

The sprung mass m_s and the unsprung mass m_u are assumed to be uncertainties and replaced by $m_s\left(t\right)$ and $m_u\left(t\right)$, which vary in a given range, i.e. $m_s\left(t\right)\in\left[m_{s\min},m_{s\max}\right]$ and $m_u\left(t\right)\in\left[m_{u\min},m_{u\max}\right]$. This means the uncertain mass $m_s\left(t\right)$ is bounded by its minimum value $m_{s\min}$ and its maximum value $m_{s\max}$. In addition, the uncertain mass $m_u\left(t\right)$ is bounded by its minimum value $m_{u\min}$ and its maximum value $m_{u\max}$. Next, we can obtain the values of $\frac{1}{m_s(t)}$ and $\frac{1}{m_u(t)}$ from $m_s\left(t\right)\in\left[m_{s\min},m_{s\max}\right]$ and $m_u\left(t\right)\in\left[m_{u\min},m_{u\max}\right]$. Then we have

$$\begin{aligned} \text{maximum}\frac{1}{m_s\left(t\right)} &= \frac{1}{m_{s\min}}=:\hat{m}_s, \\ \text{minimum}\frac{1}{m_s\left(t\right)} &= \frac{1}{m_{s\max}}=:\check{m}_s, \\ \text{maximum}\frac{1}{m_u\left(t\right)} &= \frac{1}{m_{u\min}}=:\hat{m}_u, \\ \text{minimum}\frac{1}{m_u\left(t\right)} &= \frac{1}{m_{u\max}}=:\check{m}_u. \end{aligned}$$

We can represent $\frac{1}{m_s(t)}$ and $\frac{1}{m_u(t)}$ by

$$\begin{aligned}\frac{1}{m_s(t)} &= M_1(\xi_1(t))\hat{m}_s + M_2(\xi_1(t))\check{m}_s,\\ \frac{1}{m_u(t)} &= N_1(\xi_2(t))\hat{m}_u + N_2(\xi_2(t))\check{m}_u,\end{aligned}$$

where $\xi_1(t) = \frac{1}{m_s(t)}$ and $\xi_2(t) = \frac{1}{m_u(t)}$,

$$\begin{aligned}M_1(\xi_1(t)) + M_2(\xi_1(t)) &= 1,\\ N_1(\xi_2(t)) + N_2(\xi_2(t)) &= 1.\end{aligned}$$

The membership functions can be calculated as

$$\begin{aligned}M_1(\xi_1(t)) &= \frac{\frac{1}{m_s(t)} - \check{m}_s}{\hat{m}_s - \check{m}_s}, \quad M_2(\xi_1(t)) = \frac{\hat{m}_s - \frac{1}{m_s(t)}}{\hat{m}_s - \check{m}_s},\\ N_1(\xi_2(t)) &= \frac{\frac{1}{m_u(t)} - \check{m}_u}{\hat{m}_u - \check{m}_u}, \quad N_2(\xi_2(t)) = \frac{\hat{m}_u - \frac{1}{m_u(t)}}{\hat{m}_u - \check{m}_u}.\end{aligned}$$

We name the member functions **Heavy**, **Light**, **Heavy** and **Light**. Then, the uncertain systems in (6) is represented by the following fuzzy model.

Model Rule 1: **IF** $\xi_1(t)$ is **Heavy** and $\xi_2(t)$ is **Heavy**, **THEN**

$$\begin{aligned}\dot{x}(t) &= A_1x(t) + B_1u(t-d(t)) + B_{11}w(t),\\ z_1(t) &= C_{11}x(t) + D_{11}u(t-d(t)),\\ z_2(t) &= C_{21}x(t),\end{aligned}$$

matrices A_1, B_1, B_{11}, C_{11}, D_{11} and C_{21} are obtained by replacing $\frac{1}{m_s(t)}$ and $\frac{1}{m_u(t)}$ with matrices $A(t)$, $B(t)$, $B_1(t)$, $C_1(t)$, $D_1(t)$ and $C_2(t)$ with $\hat{m}_s$ and $\hat{m}_u$ respectively.

Model Rule 2: **IF** $\xi_1(t)$ is **Heavy** and $\xi_2(t)$ is **Light**, **THEN**

$$\begin{aligned}\dot{x}(t) &= A_2x(t) + B_2u(t-d(t)) + B_{12}w(t),\\ z_1(t) &= C_{12}x(t) + D_{12}u(t-d(t)),\\ z_2(t) &= C_{22}x(t),\end{aligned}$$

matrices A_2, B_2, B_{12}, C_{12}, D_{12} and C_{22} are obtained by replacing $\frac{1}{m_s(t)}$ and $\frac{1}{m_u(t)}$ with matrices $A(t)$, $B(t)$, $B_1(t)$, $C_1(t)$, $D_1(t)$ and $C_2(t)$ with $\hat{m}_s$ and $\check{m}_u$ respectively.

Model Rule 3: **IF** $\xi_1(t)$ is **Light** and $\xi_2(t)$ is **Heavy**, **THEN**

$$\begin{aligned}\dot{x}(t) &= A_3x(t) + B_3u(t-d(t)) + B_{13}w(t),\\ z_1(t) &= C_{13}x(t) + D_{13}u(t-d(t)),\\ z_2(t) &= C_{23}x(t),\end{aligned}$$

matrices A_3, B_3, B_{13}, C_{13}, D_{13} and C_{23} are obtained by replacing $\frac{1}{m_s(t)}$ and $\frac{1}{m_u(t)}$ with matrices $A(t)$, $B(t)$, $B_1(t)$, $C_1(t)$, $D_1(t)$ and $C_2(t)$ with $\check{m}_s$ and $\hat{m}_u$ respectively.

Model Rule 4: **IF** $\xi_1(t)$ is **Light** and $\xi_2(t)$ is **Light**, **THEN**

$$\begin{aligned}\dot{x}(t) &= A_4x(t) + B_4u(t-d(t)) + B_{14}w(t),\\ z_1(t) &= C_{14}x(t) + D_{14}u(t-d(t)),\\ z_2(t) &= C_{24}x(t),\end{aligned}$$

matrices A_4, B_4, B_{14}, C_{14}, D_{14} and C_{24} are obtained by replacing $\frac{1}{m_s(t)}$ and $\frac{1}{m_u(t)}$ with matrices $A(t)$, $B(t)$, $B_1(t)$, $C_1(t)$, $D_1(t)$ and $C_2(t)$ wit $\check{m}_s$ and $\check{m}_u$ respectively.

By fuzzy blending, the overall fuzzy model is inferred as follows:

$$\begin{aligned}\dot{x}(t) &= \sum_{i=1}^{4} h_i(\xi(t))\left[A_ix(t) + B_iu(t-d(t)) + B_{1i}w(t)\right],\\ z_1(t) &= \sum_{i=1}^{4} h_i(\xi(t))\left[C_{1i}x(t) + D_{1i}u(t-d(t))\right],\\ z_2(t) &= \sum_{i=1}^{4} h_i(\xi(t))C_{2i}x(t),\end{aligned} \tag{8}$$

where

$$\begin{aligned}h_1(\xi(t)) &= M_1(\xi_1(t)) \times N_1(\xi_2(t)),\\ h_2(\xi(t)) &= M_1(\xi_1(t)) \times N_2(\xi_2(t)),\\ h_3(\xi(t)) &= M_2(\xi_1(t)) \times N_1(\xi_2(t)),\\ h_4(\xi(t)) &= M_2(\xi_1(t)) \times N_2(\xi_2(t)).\end{aligned}$$

It is obvious that the fuzzy weighting functions $h_i(\xi(t))$ satisfy

$$h_i(\xi(t)) \geq 0, \quad \sum_{i=1}^{4} h_i(\xi(t)) = 1.$$

In this study, we consider the design of fuzzy controllers. By using parallel distributed compensation, we suppose the following fuzzy controller:

Control Rule j: **IF** $\xi_1(t)$ is **Heavy** (**Light**) and $\xi_2(t)$ is **Heavy** (**Light**),

THEN $u(t) = K_jx(t)(j = 1, 2, 3, 4)$.

Hence, the overall fuzzy control law is represented by

$$u(t) = \sum_{j=1}^{4} h_j(\xi(t))K_jx(t) \tag{9}$$

where K_j $(j = 1, 2, 3, 4)$ are the local control gains and $u(t-d(t)) = \sum_{j=1}^{4} h_j(\xi(t-d(t)))K_jx(t-d(t))$. Therefore, in this paper, we assume that $h_j(\xi(t-d(t)))$ is well defined for $t \in \left[-\bar{d}, 0\right]$, and $h_j(\xi(t-d(t))) \geq 0$, $(j = 1, 2, 3, 4)$ $\sum_{j=1}^{4} h_j(\xi(t-d(t))) = 1$. For simplicity, the following notations will be used:

$$h_i =: h_i(\xi(t)), \quad h_j^d =: h_j(\xi(t-d(t))).$$

Applying the fuzzy controller (9) to system (8) yields the closed-loop system:

$$\begin{aligned}\dot{x}(t) &= \sum_{i=1}^{4}\sum_{j=1}^{4} h_ih_j^d\left[A_ix(t) + B_iK_jx(t-d(t)) + B_{1i}w(t)\right],\\ z_1(t) &= \sum_{i=1}^{4}\sum_{j=1}^{4} h_ih_j^d\left[C_{1i}x(t) + D_{1i}K_jx(t-d(t))\right],\\ z_2(t) &= \sum_{i=1}^{4} h_iC_{2i}x(t).\end{aligned} \tag{10}$$

It should be pointed out that the T-S fuzzy system in (10) can be established due to the sprung $m_s(t)$ and unsprung $m_u(t)$ can be measured in practice. In our study, the sector nonlinearity method [12] is used to analysis the variations of the sprung $m_s(t)$ and unsprung $m_u(t)$ to present the T-S fuzzy system in (10).

Without loss of generality, It is assumed, $w \in L_2[0,\infty)$, and $\|w\|_2^2 \leq w_{\max} < \infty$. The main object of this subsection is just to design the feedback gain matrices K_j $(j = 1,2,3,4)$ such that the following requirements are satisfied: the closed-loop system is asymptotically stable; under zero initial condition, the closed-loop system guarantees that $\|z_1\|_2 < \gamma \|w\|_2$ for all nonzero $w \in L_2[0,\infty)$, where $\gamma > 0$ is a prescribed scalar; the following control output constraints are guaranteed:

$$|\{z_2(t)\}_q| \leq 1, \quad q = 1,2. \tag{11}$$

III. Fuzzy Controller Design

In this section, fuzzy H_∞ state-feedback controller is derived for the active suspension system with actuator delay such that the closed-loop system in (10) is asymptotically stable and can also guarantee a prescribed gain from disturbance $w(t)$ to performance output z_1 while keeping the suspension stroke and tire deflection constraints satisfied. Based on the Lyapunov stability, we have the following theorem.

Theorem 1: Consider the closed-loop system in (10). For given scalars $\bar{d} > 0$, μ and matrices K_j, if there exist matrices $P > 0$, $Q > 0$, $S > 0$, $R > 0$, N_j, and M_j with appropriate dimensions $(j = 1,2,3,4)$ such that the following LMIs hold for $q = 1,2$:

$$\begin{bmatrix} \Phi_{11}^{ij} & \Phi_{12}^{1ij} & \Phi_{13}^{ij} & \Phi_{14}^{ij} \\ 0 & -R & 0 & 0 \\ 0 & 0 & -I & 0 \\ 0 & 0 & 0 & -R \end{bmatrix} < 0, \tag{12}$$

$$\begin{bmatrix} \Phi_{11}^{ij} & \Phi_{12}^{2ij} & \Phi_{13}^{ij} & \Phi_{14}^{ij} \\ 0 & -R & 0 & 0 \\ 0 & 0 & -I & 0 \\ 0 & 0 & 0 & -R \end{bmatrix} < 0, \tag{13}$$

$$\begin{bmatrix} -P & \sqrt{\rho}\{C_{2i}\}_q^T \\ * & -I \end{bmatrix} < 0, \tag{14}$$

where

$$\Phi_{11}^{ij} = \begin{bmatrix} \Xi_{11}^{ij} & \Xi_{12}^{ij} & \Xi_{13}^{ij} & \Xi_{14}^{ij} \\ * & \Xi_{22}^{ij} & \Xi_{23}^{ij} & \Xi_{24}^{ij} \\ * & * & \Xi_{33}^{ij} & -N_4^T \\ * & * & * & -\gamma^2 I \end{bmatrix},$$

$$\Phi_{12}^{1ij} = \begin{bmatrix} \sqrt{\bar{d}}M_1 \\ \sqrt{\bar{d}}M_2 \\ \sqrt{\bar{d}}M_3 \\ \sqrt{\bar{d}}M_4 \end{bmatrix}, \Phi_{12}^{2ij} = \begin{bmatrix} \sqrt{\bar{d}}N_1 \\ \sqrt{\bar{d}}N_2 \\ \sqrt{\bar{d}}N_3 \\ \sqrt{\bar{d}}N_4 \end{bmatrix},$$

$$\Phi_{13}^{ij} = \begin{bmatrix} C_{1i}^T \\ K_j^T D_{1i}^T \\ 0 \\ 0 \end{bmatrix}, \Phi_{14}^{ij} = \begin{bmatrix} \sqrt{\bar{d}}A_i^T R \\ \sqrt{\bar{d}}K_j^T B_i^T R \\ 0 \\ \sqrt{\bar{d}}B_{1i}^T R \end{bmatrix},$$

$$\begin{aligned} \Xi_{11}^{ij} &= PA_i + A_i^T P + Q + S + M_1 + M_1^T, \\ \Xi_{12}^{ij} &= PB_iK_j - M_1 + M_2^T + N_1, \\ \Xi_{13}^{ij} &= M_3^T - N_1, \Xi_{14}^{ij} = PB_{1i} + M_4^T, \\ \Xi_{22}^{ij} &= -(1-\mu)S + N_2 + N_2^T - M_2 - M_2^T, \\ \Xi_{23}^{ij} &= N_3^T - N_2 - M_3^T, \Xi_{24}^{ij} = N_4^T - M_4^T, \\ \Xi_{33}^{ij} &= -Q - N_3 - N_3^T. \end{aligned}$$

Then,

(1) the closed-loop system is asymptotically stable;

(2) the performance $\|T_{z_1 w}\|_\infty < \gamma$ is minimized subject to output constraints (11) with the disturbance energy under the bound $w_{\max} = (\rho - V(0))/\gamma^2$, where $T_{z_1 w}$ denotes the closed-loop transfer function from the road disturbance $w(t)$ to the control output $z_1(t)$.

Proof. Considering the Lyapunov-Krasovskii functional as follows:

$$\begin{aligned} V(t) &= x^T(t)Px(t) + \int_{t-\bar{d}}^{t} x^T(s)Qx(s)\,\mathrm{d}s \\ &\quad + \int_{t-d(t)}^{t} x^T(s)Sx(s)\,\mathrm{d}s \\ &\quad + \int_{-\bar{d}}^{0}\int_{t+\alpha}^{t} \dot{x}^T(s)R\dot{x}(s)\,\mathrm{d}s\mathrm{d}\alpha. \end{aligned} \tag{15}$$

For any appropriately dimensioned matrices M and N, the following equalities hold directly according to Newton-Leibniz formula:

$$\begin{aligned} \eta_1(t) &= 2\bar{\xi}^T(t)M \\ &\quad \left(x(t) - x(t-d(t)) - \int_{t-d(t)}^{t} \dot{x}(s)\,\mathrm{d}s\right) = 0, \\ \eta_2(t) &= 2\bar{\xi}^T(t)N \\ &\quad \left(x(t-d(t)) - x\left(t-\bar{d}\right) - \int_{t-\bar{d}}^{t-d(t)} \dot{x}(s)\,\mathrm{d}s\right) = 0, \end{aligned}$$

where

$$\begin{aligned} M &= \begin{bmatrix} M_1^T & M_2^T & M_3^T & M_4^T \end{bmatrix}^T, \\ N &= \begin{bmatrix} N_1^T & N_2^T & N_3^T & N_4^T \end{bmatrix}^T \\ \bar{\xi}^T(t) &= \begin{bmatrix} x^T(t) & x^T(t-d(t)) & x^T\left(t-\bar{d}\right) & w^T(t) \end{bmatrix}. \end{aligned}$$

We first establish the H_∞ performance of the system in (10) under zero initial conditions. Adding $\eta_1(t)$ and $\eta_2(t)$ into $\dot{V}(t)$, we have

$$\begin{aligned} &\dot{V}(t) + z_1^T(t)z_1(t) - \gamma^2 w^T(t)w(t) \\ \leq\ & \sum_{i=1}^{4}\sum_{j=1}^{4} h_i h_j^d \bar{\xi}^T(t) \left[\frac{d(t)}{\bar{d}}\left(\bar{\Xi}_{ij} + \bar{d}MR^{-1}M^T\right)\right. \\ & \left. + \frac{\bar{d}-d(t)}{\bar{d}}\left(\bar{\Xi}_{ij} + \bar{d}NR^{-1}N^T\right)\right]\bar{\xi}(t), \end{aligned}$$

where

$$\breve{\Xi}_{ij} = \begin{bmatrix} \Xi_{11}^{ij} & \hat{\Xi}_{12}^{ij} & \Xi_{13}^{ij} & \Xi_{14}^{ij} \\ * & \Xi_{22}^{ij} & \Xi_{23}^{ij} & \Xi_{24}^{ij} \\ * & * & \Xi_{33}^{ij} & -N_4^T \\ * & * & * & -\gamma^2 I \end{bmatrix} + \begin{bmatrix} C_{1i}^T \\ K_j^T D_{1i}^T \\ 0 \\ 0 \end{bmatrix} \begin{bmatrix} C_{1i}^T \\ K_j^T D_{1i}^T \\ 0 \\ 0 \end{bmatrix}^T + \begin{bmatrix} A_i^T \\ K_j^T B_i^T \\ 0 \\ B_{1i}^T \end{bmatrix} \bar{d}R \begin{bmatrix} A_i^T \\ K_j^T B_i^T \\ 0 \\ B_{1i}^T \end{bmatrix}^T.$$

According to Schur complement and the above method, we develop

$$\dot{V}(t) + z_1^T(t) z_1(t) - \gamma^2 w^T(t) w(t) < 0, \tag{16}$$

for all nonzero $w \in L_2[0,\infty)$. Under zero initial conditions, we have $V(0) = 0$ and $V(\infty) \geq 0$. Integrating both sides of (16) yields $\|z_1\|_2 < \gamma \|w\|_2$ for all nonzero $w \in L_2[0,\infty)$, and the H_∞ performance is established. Then, we can show that system (10) is stable with $w(t) = 0$ after using above similar proof.

The rest proof of Theorem 1 is cut off due to space limitation. Please refer to the proof of [9].

In what follows, the fuzzy H_∞ controller existence condition for the active suspension system in (10) is presented based on fuzzy H_∞ performance analysis criterion in Theorem 1.

Theorem 2: Consider the closed-loop system in (10). For given scalars $\bar{d} > 0$ and μ, if there exist matrices $\bar{P} > 0$, $\bar{Q} > 0$, $\bar{S} > 0$, $\bar{R} > 0$, Y_j, $\bar{N}_j$, and $\bar{M}_j$ with appropriate dimensions such that the following LMIs hold for $q = 1, 2$:

$$\begin{bmatrix} \bar{\Phi}_{11}^{ij} & \bar{\Phi}_{12}^{1ij} & \bar{\Phi}_{13}^{ij} & \bar{\Phi}_{14}^{ij} \\ 0 & \bar{R} - 2\bar{P} & 0 & 0 \\ 0 & 0 & -I & 0 \\ 0 & 0 & 0 & -R \end{bmatrix} < 0, \tag{17}$$

$$\begin{bmatrix} \bar{\Phi}_{11}^{ij} & \bar{\Phi}_{12}^{2ij} & \bar{\Phi}_{13}^{ij} & \bar{\Phi}_{14}^{ij} \\ 0 & \bar{R} - 2\bar{P} & 0 & 0 \\ 0 & 0 & -I & 0 \\ 0 & 0 & 0 & -R \end{bmatrix} < 0, \tag{18}$$

$$\begin{bmatrix} -\bar{P} & \sqrt{\rho}\bar{P}\{C_{2i}\}_q^T \\ * & -I \end{bmatrix} < 0, \tag{19}$$

where

$$\bar{\Phi}_{11}^{ij} = \begin{bmatrix} \bar{\Xi}_{11}^{ij} & \bar{\Xi}_{12}^{ij} & \bar{\Xi}_{13}^{ij} & \bar{\Xi}_{14}^{ij} \\ * & \bar{\Xi}_{22}^{ij} & \bar{\Xi}_{23}^{ij} & \bar{\Xi}_{24}^{ij} \\ * & * & \bar{\Xi}_{33}^{ij} & -\bar{N}_4^T \\ * & * & * & -\gamma^2 I \end{bmatrix},$$

$$\bar{\Phi}_{12}^{1ij} = \begin{bmatrix} \sqrt{\bar{d}}\bar{M}_1 \\ \sqrt{\bar{d}}\bar{M}_2 \\ \sqrt{\bar{d}}\bar{M}_3 \\ \sqrt{\bar{d}}\bar{M}_4 \end{bmatrix}, \bar{\Phi}_{12}^{2ij} = \begin{bmatrix} \sqrt{\bar{d}}\bar{N}_1 \\ \sqrt{\bar{d}}\bar{N}_2 \\ \sqrt{\bar{d}}\bar{N}_3 \\ \sqrt{\bar{d}}\bar{N}_4 \end{bmatrix},$$

$$\bar{\Phi}_{13}^{ij} = \begin{bmatrix} \bar{P}C_{1i}^T \\ Y_j^T D_{1i}^T \\ 0 \\ 0 \end{bmatrix} \bar{\Phi}_{14}^{ij} = \begin{bmatrix} \sqrt{\bar{d}}A_i^T \\ \sqrt{\bar{d}}Y_j^T B_i^T \\ 0 \\ \sqrt{\bar{d}}B_{1i}^T \end{bmatrix},$$

$$\begin{aligned} \bar{\Xi}_{11}^{ij} &= A_i\bar{P} + \bar{P}A_i^T + \bar{Q} + \bar{S} + \bar{M}_1 + \bar{M}_1^T, \\ \bar{\Xi}_{12}^{ij} &= B_i Y_j - \bar{M}_1 + \bar{M}_2^T + \bar{N}_1, \\ \bar{\Xi}_{13}^{ij} &= \bar{M}_3^T - \bar{N}_1, \bar{\Xi}_{14}^{ij} = B_{1i} + \bar{M}_4^T, \\ \bar{\Xi}_{22}^{ij} &= -(1-\mu)\bar{S} + \bar{N}_2 + \bar{N}_2^T - \bar{M}_2 - \bar{M}_2^T, \\ \bar{\Xi}_{23}^{ij} &= \bar{N}_3^T - \bar{N}_2 - \bar{M}_3^T, \bar{\Xi}_{24}^{ij} = \bar{N}_4^T - \bar{M}_4^T, \\ \bar{\Xi}_{33}^{ij} &= -Q - \bar{N}_3 - \bar{N}_3^T. \end{aligned}$$

Then a controller in the form of (9) exists, such that

(1) the closed-loop system is asymptotically stable;

(2) the performance $\|T_{z_1 w}\|_\infty < \gamma$ is minimized subject to output constraint (11) with the disturbance energy under the bound $w_{\max} = (\rho - V(0))/\gamma^2$.

Moreover, if inequalities (17)–(19) have a feasible solution, then the control gain K_j in (9) is given by $K_j = Y_j \bar{P}^{-1}$.

The proof is cut off due to space limitation. Contact the authors for the detailed proof.

IV. Simulation Results

In this section, a quarter vehicle active suspension system is exploited to demonstrate the effectiveness of the proposed approach. The quarter-car suspension model parameters are listed in Table I for the following controller design. The sprung

TABLE I
QUARTER-CAR MODEL PARAMETERS

k_s	k_t	c_s	c_t
42720N/m	101115N/m	1095Ns/m	14.6Ns/m

mass $m_s(t)$ is assumed to belong to the range $[873\text{kg}, 1073\text{kg}]$ and the unsprung mass $m_u(t)$ is assumed to belong to $[104\text{kg}, 124\text{kg}]$. In this study, the maximum allowable suspension stroke is assumed as $z_{\max} = 0.08$ m with $\rho = 1$. For the actuator delay $d(t) = 5 + 5\sin(\frac{1}{50})$ms satisfying $\bar{d} = 10$ms and $\mu = 0.1$, we consider fuzzy H_∞ controller design for the uncertain active suspension systems in (10). By using the convex optimization, it is found that the minimum guaranteed closed-loop H_∞ performance index γ_{min} is 5.9805 and the fuzzy controller gain matrices

$$K_j = 10^4 \times \begin{bmatrix} -8.0250 & 4.0130 & -3.3667 & 0.2256 \end{bmatrix}, \tag{20}$$

where $j = 1, 2, 3, 4$.

It is expected that the desired the fuzzy H_∞ controller with the parameters in (20) can be designed such that: 1) the sprung mass acceleration $z_1(t)$ is as small as possible; 2) the suspension deflection is below the maximum allowable suspension stroke $z_{\max} = 0.08$m, which means that $x_1(t)/z_{\max}$ below 1; 3) the relation dynamic tire load $k_t x_2(t)/(m_s(t) + m_u(t))g < 1$. We first consider the following test road disturbance as

$$z_r(t) = 0.0254\sin 2\pi t + 0.005\sin 10.5\pi t + 0.001\sin 21.5\pi t(\text{m}) \tag{21}$$

As discussed in [11], this road disturbance is close to the car body resonance frequency (1Hz), with high-frequency disturbance added to simulate the rough road surface. In order to carry out the simulation for the fuzzy H_∞ controller for the system in (10), the variational sprung mass $m_s(t)$ and the variational unsprung mass $m_u(t)$ are regards as $m_s(t) = 973+100\sin(t)$kg and $m_u(t) = 114+10\cos(t)$kg for deriving the fuzzy membership functional $h_i(\xi(t))$ $(i = 1, 2, 3, 4)$. By using the fuzzy H_∞ controller with the parameters in (20), we derive the corresponding closed-loop fuzzy system. Fig. 2 (a) depicts the responses of body vertical accelerations for the open- (passive) and closed-loop (active) systems and Fig. 2 (b) plots the responses of suspension stroke and tire deflection constraint for the passive and active systems. It is observed from Fig. 2 (a) that the proposed fuzzy H_∞ control strategy reduces the sprung mass acceleration significantly compared to the passive suspension under the same road disturbance. The designed fuzzy H_∞ controller can achieve the less value of the maximum body acceleration for the active suspension system than the passive system, and passenger acceleration in the active suspension system is reduced significantly, which guarantee better ride comfort. In addition, we can see from Fig. 2 (b) that the suspension deflection constrain $x_1(t)/z_{\max} < 1$ and the relation dynamic tire load $k_t x_2(t)/(m_s(t)+m_u(t))g < 1$ are guaranteed, which implies the road holding capability is ensured by the desired fuzzy controller. These two figures confirm that the designed standard state-feedback fuzzy H_∞ controller can achieve much better ride comfort and road handling, guarantee constrain suspension deflection for the active suspension system.

V. Conclusions

This paper has investigated the problem of fuzzy H_∞ control for T-S fuzzy-model-based active suspension systems with actuator delay. The sprung and unsprung mass variations, the actuator delay, and the suspension performance have been taken into account to establish the T-S fuzzy system for the control design objective. Based on the PDC scheme and stability theory, the fuzzy H_∞ performance analysis condition has been presented for the proposed T-S fuzzy system presenting the uncertain active suspension system. Then, the fuzzy H_∞ controller has been designed such that the resulting closed-loop T-S fuzzy system is asymptotically stable with H_∞ performance, and simultaneous satisfy the constraint suspension performance. A quarter-car suspension model has been given to validate the effectiveness of the proposed design method.

***Abstract*—This paper is concerned with the disturbance attenuation problem of fuzzy large-scale systems which consist of N interconnected subsystems which are represented by Takagi-Sugeno fuzzy models. Using Lyapunov function and linear matrix inequalities (LMIs), a criterion is proposed to have a prescribed level of disturbance attenuation. A numerical example is given to illustrate the control design procedure and its effectiveness.**

***Index Terms*—Fuzzy large-scale systems, Stability, Disturbance attenuation, Linear matrix inequalities (LMIs).**

I. Introduction

A "large-scale system" could be considered as a system which consists of several subsystems. These subsystems serve particular functions, share resources, and are usually connected by a set of interconnections [1]-[3]. Electrical power system, nuclear reactors, aerospace systems, economic systems, and process control systems, etc., are examples of large-scale systems. Since most of the real systems are complex and huge in size, many researchers are interested to study the stability problem of large-scale systems [4]-[12].

Nowadays, most complex systems are modeled as a fuzzy system with IF-THEN rules. By using fuzzy modeling, we can model complex nonlinear systems to arbitrary degrees of accuracy [13],[14]. There are too many approaches to model a process using fuzzy rules. One of them is the so-called T-S fuzzy model which is proposed by Takagi and Sugeno [15],[16]. Suppose that the large-scale system consists of a number of subsystems with interconnections, the nonlinear model of each subsystem can be modeled as a T-S fuzzy model such that each subsystem has a number of fuzzy regions having local linear dynamic in each region. The global model of large-scale system can be then achieved by connecting these local models by the use of membership functions.

Motivated from the work in [17],[18], the main task of this paper is to investigate the disturbance attenuation problem of fuzzy large-scale systems. Instead of conventional fuzzy parallel distribute compensation (PDC) design [19], nonlinear state feedback controllers are used in the stabilization of the whole system with a good disturbance attenuation.

This paper is organized as follows. Section II introduces the fuzzy large-scale model. An H_∞ controller design method for fuzzy large-scale systems is presented in Section III. An example which illustrate the effectiveness of the proposed approach is given in Section IV. Finally, some concluding remarks are given in Section V .

II. Fuzzy Large-scale Systems Model

Consider a fuzzy large-scale system (S) which consists of N interconnected subsystems $S_i (i = 1,2,\ldots,N)$. The ith fuzzy subsystem S_i can be described by:

$$S_i^l = \begin{cases} \dot{x}_i(t) = \sum_{l=1}^{r_i} \mu_i^l (A_i^l x_i(t) + B_i^l u_i(t) + E_i^l v_i(t)) \\ \qquad\qquad + \sum_{\substack{j=1 \\ j\neq i}}^{N} \sum_{l=1}^{r_i} \mu_i^l f_{ij}^l (x_j(t)) \\ y_i(t) = \sum_{l=1}^{r_i} \mu_i^l C_i^l x_i(t) \end{cases} \quad (1)$$

where S_i^l is the lth rule of S_i, $u_i(t) \in \mathbb{R}^{m_i}$ is the control input of S_i at time t with appropriate dimension, $x_i(t) \in \mathbb{R}^{n_i}$ is the state vector of the ith subsystem, $v_i(t) \in \mathbb{R}^{q_i}$ is the disturbance that belongs to $L_2[0,\infty)$, $f_{ij}^l(x_j(t))$ is the interconnection between the ith and jth subsystem in the lth rule of S_i, r_i is the number of rules in subsystem S_i, $(A_i^l, B_i^l, E_i^l, C_i^l)$ is the system matrices of rule l, in subsystem S_i, such that (A_i^l, B_i^l) is controllable, and μ_i^l is normalized membership function defined in in the following, in which $M_i^k(x_{ik}(t))$ is the grade of membership of $x_{ik}(t)$ in M_i^k.

$$\begin{aligned} &\mu_i^l(x_i(t)) = {}^{w_i^l}\!/_{\sum_{k=1}^{n_i} w_i^j} \\ &w_i^j = \prod_{k=1}^{n_i} M_i^k(x_{ik}(t)) \geq 0 \end{aligned} \quad (2)$$

As it can be seen in Fig. 1, $\sum_{l=1}^{r_i} \mu_i^l = 1, i = 1,2,\ldots,N$.

The jth rule of the isolated subsystem S_i, which is represented by a T-S fuzzy model, is of the following form:

$$\begin{aligned} &\text{Rule } j: \\ &\text{if } x_{i1}(t) \text{ is } M_i^l \text{ and } \ldots\ x_{in_i}(t) \text{ is } M_i^{n_i} \\ &\text{then } \dot{x}_i = A_i^l x_i(t) + B_i^l u_i(t) + E_i^l v_i(t) \\ &\qquad\qquad + \sum_{\substack{j=1 \\ j\neq i}}^{N} f_{ij}^l (x_j(t)) \\ &y_i(t) = C_i^l x_i(t) \end{aligned} \quad (3)$$

where $x_i(t) = [x_{i1}(t), x_{i2}(t), \ldots, x_{in_i}(t)]^T$, and M_i^ls are the fuzzy sets.

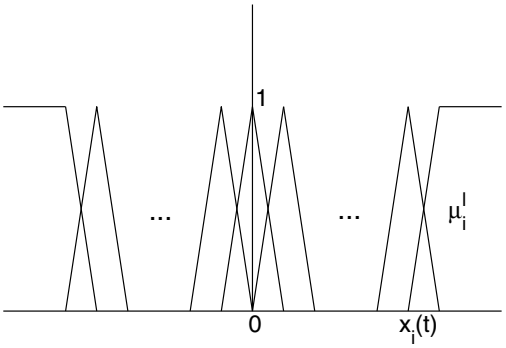

Fig. 1. Normalized membership function

III. H_∞ Controller Design with Nonlinear State Feedback Controller

In this section, based on Lyapunov functions we consider the H_∞ controller design for the large-scale fuzzy system (1). The objective is to find a fuzzy control law $u_i(t)$ such that the system (1) has a good level of disturbance attenuation, i.e., to have a good level of performance in the H_∞ sense. The H_∞ norm of a transfer function like $F(s)$, with output $y(t)$ and input $v(t)$, can be defined as follows [20]:

$$\|F(s)\|_\infty := \sup_{Re(s)>0} \bar{\sigma}[F(s)] = \sup_{\omega \varepsilon R} \bar{\sigma}[F(j\omega)] \tag{4}$$

Now, by defining the H_2 norm of $y(t)$ and $v(t)$ as

$$\|y\|_2^2 = \int_{-\infty}^{+\infty} y^T(t)y(t)dt$$
$$\|v\|_2^2 = \int_{-\infty}^{+\infty} v^T(t)v(t)dt$$

it can be concluded that

$$\frac{\|y\|_2}{\|v\|_2} \leq \|F\|_\infty$$

In the large-scale fuzzy system (1), by defining $F(s)$ the transfer function from the disturbance $v(t)$ to the output as $y(t)$, having a disturbance attenuation γ is equal to have $\|F\|_\infty \leq \gamma$, or equally:

$$\|y(t)\|_2 < \gamma \|v(t)\|_2 \tag{5}$$

for all non-zero $v(t) \in L_2$, where $y(t) = [y_1^T(t), y_2^T(t), \ldots, y_N^T(t)]^T$ and $v(t) = [v_1^T(t), v_2^T(t), \ldots, v_N^T(t)]^T$. Now, the closed-loop control system is said to be stable with disturbance attenuation γ. For this purpose, a nonlinear state feedback controller is considered as follows

$$u_i(t) = -\sum_{k=1}^{c_i} m_i^k(t) K_i^k(t) x_i(t) \tag{6}$$

in which

$$\sum_{k=1}^{c_i} m_i^k(t) = 1 \quad , \quad 0 \leq m_i^k(t) \leq 1$$

$$(i = 1,2,\ldots,N)(k = 1,2,\ldots,c_i) \tag{7}$$

and K_i^k is the state feedback gain with appropriate dimension. $m_i^k(t)$ is a nonlinear function defined by (9) and (10), c_i is an optimal number of controller in each subsystem. $M_i^{l,\acute{l},h}$s and $|M_i^{l,\acute{l},h}|$s are given in (11) and (12), in which, P_is are symmetric positive definite matrices, ε_{i1} and ε_{i2} are positive scalars, $f_{ij}^l(x_j(t)) = G_{ij}^l x_j(t)$, and n_{ij} is either 0 or 1. Now, by proposing the nonlinear state feedback controller, the closed-loop fuzzy subsystem becomes

$$\dot{x}_i(t) = \sum_{l=1}^{r_i}\sum_{k=1}^{c_i} \mu_i^l(t) m_i^k(t) \left\{ (A_i^l - B_i^l K_i^k) x_i(t) + E_i^l v_i(t) \right\} + \sum_{l=1}^{r_i}\sum_{\substack{j=1 \\ j\neq i}}^{N} \mu_i^l(t) f_{ij}^l(x_j(t))$$

$$y_i(t) = \sum_{l=1}^{r_i} \mu_i^l C_i^l x_i(t) \tag{8}$$

in which

$$m_i^1(t) = \begin{cases} 1 - \frac{\sum_{k=2}^{c_i} M_i^{l,\acute{l},k}}{\sum_{h=2}^{c_i} abs(M_i^{l,\acute{l},h})} & ,if \ \sum_{h=2}^{c_i} |M_i^{l,\acute{l},h}| \neq 0 \\ \frac{1}{c_i} & ,if \ \sum_{h=2}^{c_i} |M_i^{l,\acute{l},h}| = 0 \end{cases} \tag{9}$$

and

$$m_i^k(t) = \begin{cases} \frac{\sum_{k=2}^{c_i} M_i^{l,\acute{l},k}}{\sum_{h=2}^{c_i} |M_i^{l,\acute{l},h}|} & ,if \ \sum_{h=2}^{c_i} |M_i^{l,\acute{l},h}| \neq 0 \\ \frac{1}{c_i} & ,if \ \sum_{h=2}^{c_i} |M_i^{l,\acute{l},h}| = 0 \end{cases} \tag{10}$$

where

$$M_i^{l,\acute{l},k} = \sum_{l=1}^{r_i} \mu_i^l \mu_i^{\acute{l}} x_i^T(t) \Big(\left(A_i^l - B_i^l K_i^k\right)^T P_i + P_i \left(A_i^l - B_i^l K_i^k\right) + C_i^{lT} C_i^{\acute{l}} + \varepsilon_{i1}^{-1} P_i^T P_i + \sum_{j=1}^{N} \varepsilon_{i2}^{-1} n_{ij} P_i^T P_i + \sum_{j=1}^{N} \varepsilon_{i2} n_{ji} G_{ji}^{lT} G_{ji}^l \Big) x_i(t) \tag{11}$$

and

$$|M_i^{l,\acute{l},k}| = \sum_{l=1}^{r_i} |\mu_i^l \mu_i^{\acute{l}} x_i^T(t) \Big(\left(A_i^l - B_i^l K_i^k\right)^T P_i + P_i \left(A_i^l - B_i^l K_i^k\right) + C_i^{lT} C_i^{\acute{l}} + \varepsilon_{i1}^{-1} P_i^T P_i + \sum_{j=1}^{N} \varepsilon_{i2}^{-1} n_{ij} P_i^T P_i + \sum_{j=1}^{N} \varepsilon_{i2} n_{ji} G_{ji}^{lT} G_{ji}^l \Big) x_i(t)| \tag{12}$$

Now, our task is to design K_i^k in such a way that the whole fuzzy large-scale system satisfies the condition (5). This condition is summarized by the following theorem.

Theorem 3.1: The fuzzy large-scale system (1) has a guaranteed performance in H_∞ sense, if there exist symmetric positive definite matrices P_i, positive scaler ε_{i1} and ε_{i2}, and state gain K_i^1, such that the following condition is satisfied:

$$\begin{bmatrix} \Omega_1 & 0 \\ 0 & \Omega_2 \end{bmatrix} < 0 \tag{13}$$

where

$$\begin{aligned}\Omega_1 &= m_i^1\left(A_i^l - B_i^l K_i^1\right)^T P_i + P_i\left(A_i^l - B_i^l K_i^1\right)\\ &\quad + C_i^{lT} C_i^{\acute{l}} + \varepsilon_{i1}^{-1} P_i^T P_i + \textstyle\sum_{j=1}^N \varepsilon_{i2} n_{ji} G_{ji}^{lT} G_{ji}^l \\ \Omega_2 &= \varepsilon_{i1} E_i^{lT} E_i^l - \gamma^2 I.\end{aligned} \tag{14}$$

Proof: Consider a Lyapunov function $V(t)$ for the fuzzy large-scale system (1), given by

$$V(t) = \sum_{i=1}^N V_i(t) = \sum_{i=1}^N x_i^T(t) P_i x_i(t) \tag{15}$$

Now, by taking the derivative of $V_i(t)$ along the trajectories of ith subsystem, we get

$$\dot{V}_i(t) = \dot{x}_i^T P_i x_i(t) + x_i^T(t) P_i \dot{x}_i(t) \tag{16}$$

where, under zero conditions

$$\begin{aligned}&\textstyle\int_0^{+\infty}\left\{y^T(t)y(t) - \gamma^2 v^T(t)v(t)\right\}dt\\ &= \textstyle\int_0^{+\infty}\left\{y^T(t)y(t) - \gamma^2 v^T(t)v(t) + \frac{d}{dt}V(t)\right\}dt\\ &\quad - V(+\infty)\\ &\le \textstyle\int_0^{+\infty}\left\{y^T(t)y(t) - \gamma^2 v^T(t)v(t)\right.\\ &\quad \left. + \textstyle\sum_{i=1}^N\left[\dot{x}_i^T P_i x_i(t) + x_i^T(t) P_i \dot{x}_i(t)\right]\right\}dt\\ &\le \textstyle\int_0^{+\infty}\sum_{i=1}^N\left\{\sum_{\acute{l}=1}^{r_i}\mu_i^l\mu_i^{\acute{l}} x_i^T(t) C_i^{lT} C_i^{\acute{l}} x_i(t)\right.\\ &\quad - \gamma^2 v_i^T(t) v_i(t)\\ &\quad + \textstyle\sum_{l=1}^{r_i}\sum_{k=1}^{c_i}\mu_i^l m_i^k x_i^T(t)\left(\left(A_i^l - B_i^l K_i^k\right)^T P_i\right.\\ &\quad \left. + P_i\left(A_i^l - B_i^l K_i^k\right)\right) x_i(t)\\ &\quad + \textstyle\sum_{l=1}^{r_i}\mu_i^l\left(v_i^T(t) E_i^{lT} P_i x_i(t) x_i^T(t) P_i E_i^l v_i(t)\right)\\ &\quad \left. + 2\textstyle\sum_{l=1}^{r_i}\sum_{j=1}^N \mu_i^l f_{ij}^{lT} P_i x_i(t)\right\}dt\end{aligned} \tag{17}$$

Using the following matrix inequalities for all $a, b \in \mathbb{R}^n$, and any positive constant $\varepsilon > 0$

$$2a^T b \le \varepsilon a^T a + \varepsilon^{-1} b^T b \tag{18}$$

Now, let $f_{ij}^l(x_j(t)) = G_{ij}^l x_j(t)$, then we get

$$\begin{aligned}&\le \textstyle\int_0^{+\infty}\sum_{i=1}^N\left\{\sum_{\acute{l}=1}^{r_i}\sum_{k=1}^{c_i}\mu_i^l\mu_i^{\acute{l}} m_i^k x_i^T(t)\left(\left(A_i^l\right.\right.\right.\\ &\quad \left.\left.\left. - B_i^l K_i^k\right)^T P_i + P_i\left(A_i^l - B_i^l K_i^k\right)\right.\right.\\ &\quad \left.\left. + C_i^{lT} C_i^{\acute{l}}\right) x_i(t) - \gamma^2 v^T(t) v(t)\right.\\ &\quad + \textstyle\sum_{l=1}^{r_i}\mu_i^l \varepsilon_{i1} v_i^T(t) E_i^{lT} E_i^l v_i(t)\\ &\quad + \textstyle\sum_{l=1}^{r_i}\mu_i^l \varepsilon_{i1}^{-1} x_i^T(t) P_i^T P_i x_i(t)\\ &\quad + \textstyle\sum_{l=1}^{r_i}\sum_{j=1}^N \mu_i^l \varepsilon_{i2} x_j^T(t) G_{ij}^{lT} G_{ij}^l x_j(t)\\ &\quad \left. + \textstyle\sum_{l=1}^{r_i}\sum_{j=1}^N \mu_i^l \varepsilon_{i2}^{-1} x_i^T(t) P_i^T P_i x_i(t)\right\}dt\end{aligned} \tag{19}$$

By defining n_{ij} as follows

$$n_{ij} = \begin{cases} 1 & \text{if } G_{ij}^l \neq 0 \\ 0 & \text{if } G_{ij}^l = 0 \end{cases} \tag{20}$$

we get

$$\begin{aligned}&= \textstyle\int_0^{+\infty}\sum_{i=1}^N\left\{\sum_{l=1}^{r_i}\sum_{k=1}^{c_i}\mu_i^l\mu_i^{\acute{l}} m_i^k x_i^T(t)\left(\left(A_i^l\right.\right.\right.\\ &\quad \left.\left.\left. - B_i^l K_i^k\right)^T P_i + P_i\left(A_i^l - B_i^l K_i^k\right)\right.\right.\\ &\quad \left.\left. + C_i^{lT} C_i^{\acute{l}} + \varepsilon_{i1}^{-1} P_i^T P_i\right.\right.\\ &\quad \left.\left. + \textstyle\sum_{j=1}^N \varepsilon_{i2}^{-1} n_{ij} P_i^T P_i\right.\right.\\ &\quad \left.\left. + \textstyle\sum_{j=1}^N \varepsilon_{i2} n_{ji} G_{ij}^{lT} G_{ij}^l\right) x_i(t)\right.\\ &\quad \left. + \textstyle\sum_{l=1}^{r_i}\mu_i^l v_i^T(t)\left(\varepsilon_{i1} E_i^{lT} E_i^l - \gamma^2 I\right) v_i(t)\right\}dt\end{aligned} \tag{21}$$

Now, by using the definition of m_i^k, we have

$$\begin{aligned}&\textstyle\int_0^{+\infty}\left\{y^T(t)y(t) - \gamma^2 v^T(t)v(t)\right\}dt\\ &\le \textstyle\int_0^{+\infty}\sum_{i=1}^N\sum_{\acute{l}=1}^{r_i}\mu_i^l\mu_i^{\acute{l}} \times \left\{\begin{bmatrix} x_i(t) \\ v_i(t)\end{bmatrix}^T\right.\\ &\quad \left.\times \begin{bmatrix} \Omega_1 & 0 \\ 0 & \Omega_2\end{bmatrix} \times \begin{bmatrix} x_i(t) \\ v_i(t)\end{bmatrix}\right\}dt\end{aligned} \tag{22}$$

where

$$\begin{aligned}\Omega_1 &= m_i^1\left(A_i^l - B_i^l K_i^1\right)^T P_i + P_i\left(A_i^l - B_i^l K_i^1\right)\\ &\quad + C_i^{lT} C_i^{\acute{l}} + \varepsilon_{i1}^{-1} P_i^T P_i + \textstyle\sum_{j=1}^N \varepsilon_{i2} n_{ji} G_{ji}^{lT} G_{ji}^l \\ \Omega_2 &= \varepsilon_{i1} E_i^{lT} E_i^l - \gamma^2 I\end{aligned} \tag{23}$$

now if $\begin{bmatrix} \Omega_1 & 0 \\ 0 & \Omega_2\end{bmatrix} < 0$, we get

$$\int_0^{+\infty}\left\{y^T(t)y(t) - \gamma^2 v^T(t)v(t)\right\}dt < 0 \tag{24}$$

which implies that when $x_i(0) = 0; i = 1, 2, \ldots, N$, $\|y(t)\|_2 < \gamma\|v(t)\|_2$. ■

Now, it can be easily seen that if inequality (13) is satisfied, then the closed-loop fuzzy large-scale system is asymptotically stable, with disturbance attenuation γ.

According to the above theorem, the following algorithm can be developed for designing the controller.

Algorithm

1) Set a value for $\varepsilon_{ij}; j = 1, 2$.
2) Solve the matrix inequality (13). This can be solved by using the MATLAB LMI toolbox.
3) If the solution is feasible, the controller parameter K_i^1 will be obtained and the procedure can be stopped. In this case $K_i^k; k \neq 1$ can be chosen according to the type of the response. That is, $K_i^k; k \neq 1$ affects the response features, like: settling time, overshoot , etc. If the solution is not feasible, set $\varepsilon_{ij} = \frac{\varepsilon_{ij}}{2}$ [18], and go to step 2.

IV. Numerical Example

Here, an example is presented to verify the results of the proposed stabilization procedure of fuzzy large-scale system composed of two subsystems described by

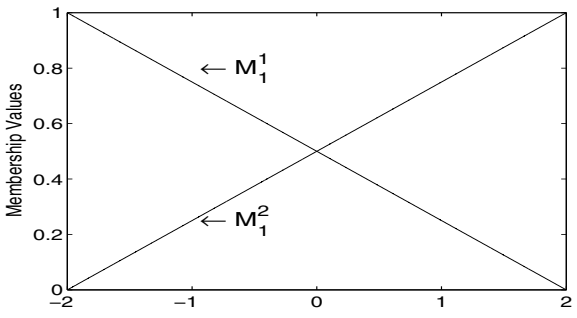

Fig. 2. Membership functions of subsystem S_1

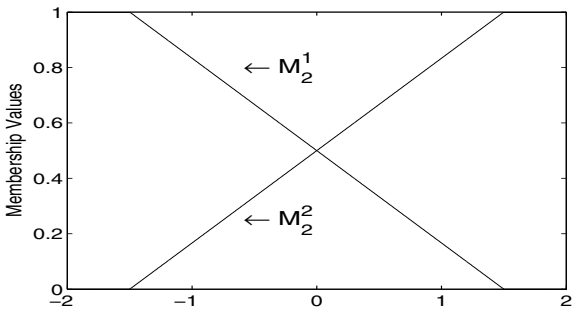

Fig. 3. Membership functions of subsystem S_2

Subsystem S_1

$$
\begin{aligned}
\text{Rule1}: \ & \text{if } x_{11}(t) \text{ is } M_1^2 \text{ and } x_{12}(t) \text{ is } M_1^1 \\
& \text{then } \dot{x_1}(t) = A_1^1 x_1(t) + B_1^1 u_1(t) \\
& \quad + E_1^1 v_1(t) + \textstyle\sum_{j=1}^{2} G_{1j}^1 x_j(t) \\
& y(t) = C_1^1 x_1(t) \\
\text{Rule2}: \ & \text{if } x_{11}(t) \text{ is } M_1^2 \text{ and } x_{12}(t) \text{ is } M_1^2 \\
& \text{then } \dot{x_1}(t) = A_1^2 x_1(t) + B_1^2 u_1(t) \\
& \quad + E_1^2 v_1(t) + \textstyle\sum_{j=1}^{2} G_{1j}^2 x_j(t) \\
& y(t) = C_1^2 x_1(t)
\end{aligned}
$$

in which $A_1^1 = \begin{bmatrix} -0.1 & 0 \\ 0 & -1 \end{bmatrix}$, $A_1^2 = \begin{bmatrix} 0 & 1 \\ -1.2 & -1 \end{bmatrix}$, $B_1^1 = \begin{bmatrix} 2.2 \\ 0 \end{bmatrix}$, $B_1^2 = \begin{bmatrix} 1.2 \\ -0.6 \end{bmatrix}$, $D_1^1 = D_1^2 = \begin{bmatrix} 0 \\ 0.5 \end{bmatrix}$, $C_1^1 = C_1^2 = \begin{bmatrix} 1 & 0 \end{bmatrix}$. Moreover, the interconnection matrices among the two subsystems are given by $G_{12}^1 = \begin{bmatrix} 0.1 & 0 \\ 0 & 0 \end{bmatrix}$, $G_{12}^2 = \begin{bmatrix} 0.1 & 0.1 \\ 0.1 & 0.1 \end{bmatrix}$. Membership functions of subsystem S_1 are shown in Fig. 2.

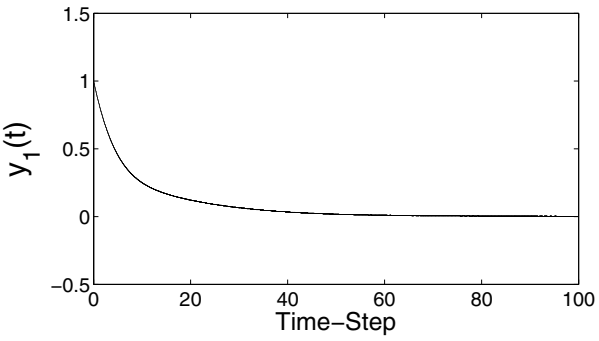

Fig. 4. $y_1(t)$, the output of the subsystem S_1

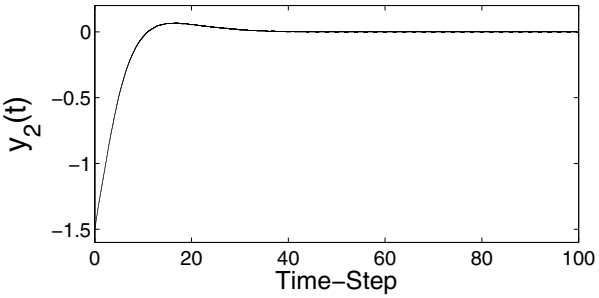

Fig. 5. $y_2(t)$, the output of the subsystem S_2

Subsystem S_2

$$
\begin{aligned}
\text{Rule1}: \ & \text{if } x_{21}(t) \text{ is } M_2^1 \text{ and } x_{22}(t) \text{ is } M_2^1 \\
& \text{then } \dot{x_2}(t) = A_2^1 x_2(t) + B_2^1 u_2(t) \\
& \quad + E_2^1 v_2(t) + \textstyle\sum_{j=1}^{2} G_{2j}^1 x_j(t) \\
& y(t) = C_2^1 x_2(t) \\
\text{Rule2}: \ & \text{if } x_{21}(t) \text{ is } M_2^2 \text{ and } x_{22}(t) \text{ is } M_2^1 \\
& \text{then } \dot{x_2}(t) = A_2^2 x_2(t) + B_2^2 u_2(t) \\
& \quad + E_2^2 v_2(t) + \textstyle\sum_{j=1}^{2} G_{2j}^2 x_j(t) \\
& y(t) = C_2^2 x_2(t)
\end{aligned}
$$

in which $A_2^1 = \begin{bmatrix} -1 & 0 \\ -0.8 & -2 \end{bmatrix}$, $A_2^2 = \begin{bmatrix} 0.08 & 1 \\ -2.5 & -0.6 \end{bmatrix}$, $B_2^1 = \begin{bmatrix} 1.2 \\ 1.2 \end{bmatrix}$, $B_2^2 = \begin{bmatrix} 2.2 \\ -0.8 \end{bmatrix}$, $D_2^1 = D_2^2 = \begin{bmatrix} 0 \\ 0.4 \end{bmatrix}$, $C_2^1 = C_2^2 = \begin{bmatrix} 1 & 0 \end{bmatrix}$. Moreover, the interconnection matrices among the two subsystems are given by $G_{21}^1 = \begin{bmatrix} 0 & 0.1 \\ 1 & 0 \end{bmatrix}$, $G_{21}^2 = \begin{bmatrix} 0.3 & 0 \\ -0.9 & 0 \end{bmatrix}$. The normalized membership functions of subsystem S_2 are shown in Fig. 3. To design, first, we design a nonlinear state feedback controller for each subsystem so to make the fuzzy large-scale have a good performance in H_∞ sense. By choosing $\varepsilon_{11} = \varepsilon_{21} = 2$ and $\varepsilon_{12} = \varepsilon_{22} = \frac{100}{0.15}$ and

using the above procedure, we can have

$$Q_1 = P_1^{-1} = \begin{bmatrix} 0.162 & 0.0066 \\ 0.0066 & 0.1626 \end{bmatrix},$$
$$Q_2 = P_2^{-1} = \begin{bmatrix} 0.1137 & 0.0157 \\ 0.0157 & 0.1851 \end{bmatrix},$$
$$K_1^1 = K_2^1 = \begin{bmatrix} 1 & 0 \end{bmatrix}$$

Since K_1^2 and K_2^2 don't affect the stability, by choosing $K_1^2 = \begin{bmatrix} 1 & 1 \end{bmatrix}$ and $K_2^2 = \begin{bmatrix} 0.01 & 0.01 \end{bmatrix}$, the procedure is completed. The initial conditions are $x_1(0) = \begin{bmatrix} 1 & -1.5 \end{bmatrix}^T$, $x_2(0) = \begin{bmatrix} -1.5 & 1 \end{bmatrix}^T$.

The simulation results using $v_1(t) = 5\sin(2\pi t)$, $v_2(t) = 5\sin(\pi t)$, 100 steps of $\Delta t = 0.01$, and $\gamma = 0.0036$ are shown in Figs. 4 and 5. It can be observed that the controller proposed in this paper based on the fuzzy dynamic model not only stabilizes the original nonlinear system but also effectively attenuates the disturbances as expected.

V. Conclusion

This paper investigates the disturbance attenuation problem of fuzzy large-scale systems. Under some sufficient conditions, the nonlinear state feedback controller is designed to have a desired disturbance attenuation. LMI tools play a key role to find the symmetric positive matrices P_i. It is shown that using the method presented in this paper, the stability condition can be checked by K_i^1. That is, K_i^k (for $k \neq 1$) does not affect the stability. An example is also presented to illustrate the effectiveness of the proposed method.

***Abstract*—Given a T-indistinguishability operator, the corresponding set H_E of extensional sets and the operators ϕ_E and ψ_E that provide upper and lower approximations of a fuzzy subset by extensional ones can be defined. Reciprocally, given any of these, the initial indistinguishability operator can be retrieved. In order to understand in depth how this relation works, it will be shown that there is an isomorphism between the corresponding lattices and how this isomorphism acts over the operations and orderings of the lattices will be studied.**

Keywords*: *indistinguishability operator; extensional set; upper approximation, lower approximation; transitive closure; extensional closure

I. Introduction

The set H_E of extensional fuzzy subsets of an indistinguishability operator E has been widely studied in the literature. In [1] it has been studied from an algebraic point of view and in [2] its topological behaviour has been analyzed. It has also been characterized as the set of generators of E [3], the set of logical states and the set of fixed points of two operators known as ϕ_E and ψ_E [2]. These two operators give upper and lower approximations respectively of a fuzzy subset by extensional ones with respect to E. Although the results obtained in relation to H_E, ϕ_E and ψ_E show a very similar family of properties these concepts fulfill separately, up to this point a real study of the depth of this relation has not been done yet.

In [4] the operators that can be upper and lower approximations of an indistinguishability operators have been characterized and [1] did the same for a set of fuzzy subsets of a universe to be the extensional set of an indistinguishability operator providing as a consequence bijections between the set $\mathcal{E}$ of indistinguishability operators on a given universe X, the set $\mathcal{H}$ of sets of extensional sets with respect to indistinguishability operators on X and the sets $\mathcal{U}$ and $\mathcal{L}$ of upper and lower approximations of fuzzy subsets by extensional ones with respect to an indistinguishability operator on X. Taking this into account and also the fact that these concepts verify a very similar collection of properties, it seems natural to ask if the connection between these sets is more than a simple bijection or if some kind of structure is kept.

This work has focused on this point and the results obtained have been that these bijections are actually isomorphisms, as the ordering and the structure given by the operations is kept. Furthermore, these sets can be regarded as lattices and, therefore, what we obtain is that all these lattices are isomorphic.

This fact has both a theoretical and practical relevance. It is theoretically interesting because this work provides some order and relation between the studies on indistinguishability operators, extensional sets, and upper and lower approximations that have been done up to this point. Furthermore, as all these concepts are isomorphic, the result shows that the only difference between them is the way in which are approached and the notation; this fact allowing us to translate all the results obtained on one lattice to the others through the isomorphisms presented on this paper.

From a practical point of view these isomorphisms are interesting too because several times multiple attributes are considered in a given problem and some kind of aggregation has to be done between them. This problem has been studied in [8] restricted to the aggregation of different indistinguishability operators. What if some attributes are more easily modelled by an indistinguishability operator, as they come from matching objects with a prototype, for instance, while other attributes are better seen as extensional sets because they come from direct observation? The isomorphisms we present in this paper allow us to codify different attributes into the concept that shows less difficulty to do so, and translate them into the same concept through these isomorphisms.

This work is structured in the following way:

In the next section of preliminaries the concepts related with the work are defined and the main properties and results related to them are given.

In Section III the main results of this work are proved. It is separated into three subsections that will show separately the isomorphisms between the sets $\mathcal{E}$, $\mathcal{H}$, $\mathcal{U}$ and $\mathcal{L}$.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

The isomorphisms will be explicitly given and how they work on the operations will be showed.

Finally, the main results of this work are summarized at the Conclusion.

II. Preliminaries

In this section the basic definitions and results that underly the present work will be provided. Firstly the concepts related to indistinguishability operators will be given: the definition of an indistinguishability operator and the transitive closure of a reflexive and symmetric fuzzy relation. Furthermore, the definition and basic properties of the set H_E of extensional fuzzy subsets sets of an indistinguishability operator E and the upper and lower approximations (ϕ_E and ψ_E respectively) related to E will be given.

Definition II.1. *Let T be a t-norm.*

- *The residuation $\overrightarrow{T}$ of T is defined for all $x, y \in [0,1]$ by*
$$\overrightarrow{T}(x|y) = \sup\{\alpha \in [0,1] | T(\alpha, x) \leq y\}.$$
- *The birresiduation $\overleftrightarrow{T}$ of T is defined for all $x, y \in [0,1]$ by*
$$\overleftrightarrow{T}(x,y) = \min\{\overrightarrow{T}(x|y), \overrightarrow{T}(y|x)\} = T(\overrightarrow{T}(x|y), \overrightarrow{T}(y|x)).$$

Definition II.2. *Let T be a t-norm. A fuzzy relation E on a set X is a T-indistinguishability operator if and only if for all $x, y, z \in X$*

a) $E(x,x) = 1$ *(Reflexivity)*
b) $E(x,y) = E(y,x)$ *(Symmetry)*
c) $T(E(x,y), E(y,z)) \leq E(x,z)$ *(T-transitivity).*

It is well known that given two indistinguishability operators E, F, the intersection $E \cap F$ is also an indistinguishability operator. On the contrary, the union $E \cup F$ is not generally an indistinguishability operator. The concept of transitive closure will prove to be useful further to be able to use the union operator as well.

Definition II.3. *Let T be a t-norm and R a fuzzy proximity (a reflexive and symmetric fuzzy relation) on a set X. The transitive closure $\overline{R}$ of R is the T-indistinguishability operator defined by*

$$\overline{R} = \bigcap_{E \in A} E$$

where A is the set of T-indistinguishability operators on X greater than or equal to R.

Now we can give a lattice structure to the set $\mathcal{E}$ of T-indistinguishability operators on a set X, with the natural ordering $\leq$, and two operations: the intersection $E \cap F$ and the closed union $\overline{E \cup F}$.

Indistinguishability operators can be generated in several ways. The simplest way is by obtaining the indistinguishability related to a fuzzy subset.

Definition II.4. *Let X be a set, T a t-norm and μ a fuzzy subset of X. The fuzzy relation E on X defined by*

$$E_\mu(x,y) = \overleftrightarrow{T}(\mu(x), \mu(y))$$

for all $x, y \in X$ is a T-indistinguishability operator.

One of the main results of the theory of indistinguishability operators is the Representation Theorem. This theorem proves that any family of fuzzy subsets on a set X generates a T-indistinguishability operator E on X and, reciprocally, that every T-indistinguishability operator on X can be generated by a family of fuzzy subsets.

Theorem II.5. [12] *Representation Theorem. Let R be a fuzzy relation on a set X and T a continuous t-norm. Then R is an T-indistinguishability operator if and only if there exists a family $(\mu_i)_{i \in I}$ of fuzzy subsets of X such that for all $x, y \in X$*

$$R(x,y) = \inf_{i \in I} E_{\mu_i}(x,y).$$

An indistinguishability operator E determines a set of observable sets or granules. These are given by the generators of E in the sense of the Representation Theorem and it is well known that they coincide with the set of extensional sets we define now.

Definition II.6. *Let X be a set and E a T-indistinguishability operator on X. A fuzzy subset μ of X is called extensional if and only if:*

$$\forall x, y \in X \quad T(E(x,y), \mu(y)) \leq \mu(x).$$

We will denote H_E the set of all extensional fuzzy subsets of X with respect to E.

Proposition II.7. *Let X be a set, E a T-indistinguishability operator on X and μ a fuzzy subset of X. Then:*

$$\mu \in H_E \Leftrightarrow E_\mu \geq E$$

As it has been proved in [1], extensional fuzzy subsets verify the properties of the next proposition. Furthermore, these properties completely determine the set of extensional fuzzy subsets.

Proposition II.8. *Let E be a T-indistinguishability operator and H_E its set of extensional fuzzy sets. Then, $\forall \mu \in H_E, (\mu_i)_{i \in I}$ a family of extensional sets and $\forall \alpha \in [0,1]$ the following properties hold:*

1) $\bigvee_{i \in I} \mu_i \in H_E$
2) $\bigwedge_{i \in I} \mu_i \in H_E$
3) $T(\alpha, \mu) \in H_E$
4) $\overrightarrow{T}(\mu|\alpha) \in H_E$
5) $\overrightarrow{T}(\alpha|\mu) \in H_E$

Given a fuzzy subset $\mu \in [0,1]^X$, it is an interesting topic to find the closest extensional set that contains μ. This is done using the operator ϕ_E, defined below. This operator can be also seen as a topological closure operator on the set $[0,1]^X$ [2].

Definition II.9. *Let X be a set and E a T-indistinguishability operator on X. The map ϕ_E: $[0,1]^X \to [0,1]^X$ is defined $\forall x \in X$ by:*

$$\phi_E(\mu)(x) = \sup_{y \in X} T(E(x,y), \mu(y)).$$

The operator ϕ_E verifies the following properties.

Proposition II.10. *For all μ, $\mu' \in [0,1]^X$ the following properties are satisfied:*

1) $\mu \leq \mu' \Rightarrow \phi_E(\mu) \leq \phi_E(\mu')$
2) $\mu \leq \phi_E(\mu)$
3) $\phi_E(\mu \vee \mu') = \phi_E(\mu) \vee \phi_E(\mu')$
4) $\phi_E(\phi_E(\mu)) = \phi_E(\mu)$
5) $\phi_E(\{x\})(y) = \phi_E(\{y\})(x)$
6) $\phi_E(T(\alpha, \mu)) = T(\alpha, \phi_E(\mu))$

Analogously, given a T-indistinguishability operator E, the operator ψ_E can be defined that provides extensional lower approximations of fuzzy subsets of X with respect to E. The operator ψ_E is dual to ϕ_E and can be seen topologically as an opening or interior operator.

Definition II.11. *Let E be a T-indistinguishability operator on a set X. The map ψ_E: $[0,1]^X \to [0,1]^X$ is defined $\forall x \in X$ by:*

$$\psi_E(\mu)(x) = \inf_{y \in X} \overrightarrow{T}(E(x,y) | \mu(y)).$$

ψ_E satisfies the properties below (dual to Properties II.10) and is determined by them.

Proposition II.12. *For all μ, $\mu' \in [0,1]^X$ the following properties are satisfied:*

1) $\mu \leq \mu' \Rightarrow \psi_E(\mu) \leq \psi_E(\mu')$
2) $\psi_E(\mu) \leq \mu$
3) $\psi_E(\mu \wedge \mu') = \psi_E(\mu) \wedge \psi_E(\mu')$
4) $\psi_E(\psi_E(\mu)) = \psi_E(\mu)$
5) $\psi_E(\overrightarrow{T}(x|\alpha)(y) = \psi_E(\overrightarrow{T}(y|\alpha)(x)$
6) $\psi_E(\overrightarrow{T}(\alpha|\mu)) = \overrightarrow{T}(\alpha, \psi_E(\mu))$

An interesting issue concerning the operators ϕ_E and ψ_E is that $Im(\phi_E) = Im(\psi_E) = H_E$, and hence the set of extensional fuzzy subsets H_E can also be characterized as the set of fixed points of ϕ_E and ψ_E. This fact is actually a direct consequence of the definitions and is very natural when ϕ_E and ψ_E is regarded from the topological approach.

Finally, we remind the concept of Galois connection between two ordered sets, as it will be used further to understand the relations between the concepts introduced previously:

Definition II.13. *Let $(A, \leq)$, $(B, \leq)$ two partially ordered sets. A Galois connection between these sets is a pair (F, G) of functions $F : A \to B$ and $G : B \to A$ satisfying:*

$$F(a) \leq b \quad \Leftrightarrow \quad a \leq G(b) \text{ (monotone Galois connection)}$$
$$b \leq F(a) \quad \Leftrightarrow \quad a \leq G(b) \text{ (antitone Galois connection)}$$

III. Isomorphisms and Dualities between Indistinguishability Operators, Extensional Sets, Upper and Lower Approximations

It is noticeable that the three concepts introduced (extensional sets, upper approximations and lower approximations) related to an indistinguishability operator E satisfy very similar families of properties. It is natural to ask then what is exactly the relation between these concepts.

In this section it will be shown that there actually exist bijections between the four stated concepts ($\mathcal{E}$, $\mathcal{H}$, $\mathcal{U}$, $\mathcal{L}$) and furthermore the structure of these is preserved through these bijections. This will lead us to the final fact that there are isomorphisms of lattices between the stated concepts, and these isomorphisms will be explicitly given.

This section is divided intro three subsections. The first one will study the isomorphism between indistinguishability operators and extensional sets. The second one will face indistinguishability operators and upper approximations and the third one will deal with lower approximations.

A. Indistinguishability Operators and Extensional Sets

This section will focus on studying the isomorphism between the lattice $\mathcal{E}$ of indistinguishability operators on a set X and the lattice $\mathcal{H}$ of sets of extensional fuzzy subsets.

Analogously as in the case of indistinguishability operators, given H_E and H_F two collections of extensional sets, the intersection of them $H_E \cap H_F$ is also the set of extensional sets of a certain indistinguishability operator, but the union of them $H_E \cup H_F$ is not. In order to close the set of extensional sets under the union operator, and therefore give to it the structure of a lattice, we have to introduce, as done with indistinguishability operators, the concept of extensional closure of a subset of $[0,1]^X$.

Definition III.1. *Let $J \subseteq [0,1]^X$. Its extensional closure $\overline{J}$ is defined by:*

$$\overline{J} := \bigcap_{H \in [0,1]^X, J \subseteq H} H$$

where H is a set of fuzzy subsets of X satisfying the properties of Proposition II.8:

1) $\bigvee_{i \in I} \mu_i \in H$
2) $\bigwedge_{i \in I} \mu_i \in H$
3) $T(\alpha, \mu) \in H$
4) $\overrightarrow{T}(\alpha|\mu) \in H$
5) $\overrightarrow{T}(\mu|\alpha) \in H$

The lattice $\mathcal{E}$ of indistinguishability operators on a set X has a natural ordering given by $\leq$, while the lattice $\mathcal{H}$ of sets extensional fuzzy subsets is ordered by the inclusion $\subseteq$. The following proposition states how these orders are inverted when we pass from one lattice to the other one.

Proposition III.2. *Let E, F be two indistinguishability operators on X with extensional sets H_E and H_F respectively. Then:*

$$E \leq F \Leftrightarrow H_F \subseteq H_E$$

Proof: $E \leq F \Leftrightarrow \forall x,y \in X\ E(x,y) \leq F(x,y)$, which is equivalent to $\forall x,y\ \forall \mu \in H_F\ T(E(x,y),\mu(y)) \leq T(F(x,y),\mu(y)) \leq \mu(x) \Leftrightarrow H_F \subseteq H_E$ ∎

The following theorem proves that there is a bijection between both lattices. This theorem was proved in [1].

Theorem III.3. *Let H be a subset of $[0,1]^X$ satisfying the properties of Proposition II.8. Then there exists a unique T-indistinguishability operator E such that $H = H_E$.*

Proof: Let E be the indistinguishability operator generated by H using the Representation Theorem (Theorem II.5).

Let us proof first that $H = H_E$.

Since H is a generating family, its fuzzy subsets are extensional with respect to E and $H \subseteq H_E$.

Let us see the other inequality.

Given $\mu \in H_E$ and $y \in X$, we define the fuzzy subset $\mu_y(x) = T(E(x,y),\mu(y))$. We will show that $\mu = \sup_{y\in X} \mu_y$.

$$\begin{aligned}\mu_y(x) &= T(\inf_{\nu\in H} E_\nu(x,y),\mu(y)) \\ &= \inf_{\nu\in H} T(\min\{\overrightarrow{T}(\nu(x)|\nu(y)),\overrightarrow{T}(\nu(y)|\nu(x))\},\mu(y)).\end{aligned}$$

Since $\mu(y)$ and $\nu(y)$ are constants, applying properties 2, 3, 4 and 5 of Proposition II.8 we have $\mu_y \in H$.

Since μ is extensional, $\mu_y(x) = T(E(x,y),\mu(y)) \leq \mu(x)$. As $\mu_y(y) = \mu(y)$ we obtain $\mu = \sup_{y\in x} \mu_y$ which belongs to H due to property 1 of Proposition II.8. So, $H_E \subseteq H$).

The uniqueness is a direct consequence of Proposition III.2. ∎

Corollary III.4. *$(\Gamma : E \to H_E, \Sigma : H_E \to E)$ define an antitone Galois connection between $\mathcal{E}$ and $\mathcal{H}$.*

We have shown that there is a bijection between $\mathcal{E}$ and $\mathcal{H}$ and how the orderings of the lattices are affected by it. Let us finally show how the structure is preserved (inverting the order) and therefore we will have proved that the bijection is an isomorphism of lattices. In fact we will have proved that given an indistinguishability operator E on X, H_E is actually its dual space.

Theorem III.5. *Let E, F be two indistinguishability operators on a set X with sets of extensional fuzzy subsets sets H_E and H_F respectively. Then:*

1) $H_{\overline{E\cup F}} = H_E \cap H_F$
2) $H_{E\bigcap F} = \overline{H_E \cup H_F}$

Proof:

1) $\mu \in H_E \cap H_F \Leftrightarrow \mu \in H_E$ and $\mu \in H_F$. This is equivalent to $E_\mu \geq E$ and $E_\mu \geq F$ or $E_\mu \geq E \cup F$ and by the definition of the extensional closure, this is equivalent to $E_\mu \geq \overline{E \cup F} \Leftrightarrow \mu \in H_{\overline{E\cup F}}$
2) $\supseteq$)
   $E \cap F \leq E \Rightarrow H_E \subseteq H_{E\cap F}$.
   $E \cap F \leq F \Rightarrow H_F \subseteq H_{E\cap F}$.
   Then $H_E \cup H_F \subseteq H_{E\cap F} \Rightarrow \overline{H_E \cup H_F} \subseteq H_{E\cap F}$.
   $\subseteq$)
   Let $\mu \in H_{E\cap F}$. Let us suppose $\mu \notin \overline{H_E \cup H_F}$. Then there exists an extensional set H_G with indistinguishability operator G such that $H_G \supseteq H_E \cup H_F$ and $\mu \notin H_G \Rightarrow \exists (x,y)$ such that $E_\mu(x,y) < G(x,y)$. Without loss of generality we can assume $E(x,y) \leq F(x,y)$. As $H_G \supseteq H_E \cup H_F$, $H_E \subseteq H_G$ and $H_F \subseteq H_G \Rightarrow G \leq E$ and $G \leq F$. So
   $E_\mu(x,y) < G(x,y) \leq E(x,y) \leq F(x,y)$. Hence
   $E_\mu(x,y) < (E \cap F)(x,y)$.
   Therefore, $\mu \notin H_{E\cap F}$ which contradicts our hypothesis!
   So $\mu \in \overline{H_E \cup H_F}$.

∎

B. Indistinguishability Operators and Upper Approximations

This subsection will be faced on proving that the lattice $\mathcal{U}$ is isomorphic to the lattice $\mathcal{E}$ of indistinguishability operators on a set X. The path that will take us to this result will be analogous to the one followed in the previous subsection.

As we did with $\mathcal{E}$ and $\mathcal{H}$, to give the set $\mathcal{U}$ of upper approximations ϕ_E ($E \in \mathcal{E}$) a lattice structure, we have to define a ϕ-closure.

Definition III.6. *Let f be a map defined on $[0,1]^X \to [0,1]^X$. The ϕ-closure $\overline{f}$ of f is defined as:*

$$\overline{f} = \bigwedge_{f\leq\phi,\phi\in U} \phi$$

where U is the set of maps $\phi : [0,1]^X \to [0,1]^X$ satisfying the properties of Proposition II.10:

1) $\mu \leq \mu' \Rightarrow \phi(\mu) \leq \phi(\mu')$
2) $\mu \leq \phi(\mu)$
3) $\phi(\mu \vee \mu') = \phi(\mu) \vee \phi(\mu')$
4) $\phi(\phi(\mu)) = \phi(\mu)$
5) $\phi(\{x\})(y) = \phi(\{y\})(x)$
6) $\phi(T(\alpha,\mu)) = T(\alpha,\phi(\mu))$

On the contrary with respect to what happened with extensional sets, in the case of upper approximations the ordering relation is directly preserved, instead of dually.

Proposition III.7. *Let E, F be two T-indistinguishability operators on X with upper approximations ϕ_E and ϕ_F respectively. Then:*

$$E \leq F \Leftrightarrow \phi_E \leq \phi_F$$

Given a ϕ operator, one can define an indistinguishability operator in the following way.

Proposition III.8. *Let $\phi : [0,1]^X \to [0,1]^X$ be a map satisfying the properties of Proposition II.10. Then the fuzzy relation E_ϕ defined by*

$$E_\phi(x,y) = \phi(\{x\})(y)$$

is a T-indistinguishability operator on X.

Proof: Straightforward ■

The following theorem proves that there is a bijection between indistinguishability operators and upper approximations.

Theorem III.9. *There is a bijection between the set $\mathcal{E}$ of T-indistinguishability operators on X and the maps $\phi : [0,1]^X \to [0,1]^X$ satisfying the properties of Proposition II.10.*

Proof: We have to prove that $\phi_{E_\phi} = \phi$ and $E_{\phi_E} = E$

- Let ϕ be a map satisfying the properties of Proposition II.10. For all $x, y \in X$ and for any fuzzy subset $\mu \in [0,1]^X$ we have:

$$\begin{aligned} \phi_{E_\phi}(\mu)(x) &= \sup_{y\in X} T(E_\phi(x,y), \mu(y)) \\ &= \sup_{y\in X} T(\phi(\{y\})(x), \mu(y)) \\ &= \phi(\mu)(x). \end{aligned}$$

- Let E be a T-indistinguishability operator. Then for all $x, y \in X$ we have:

$$\begin{aligned} E_{\phi_E}(x,y) &= \phi(\{x\})(y) \\ &= \sup_{z\in X} T(E(y,z), \{x\}(z)) \\ &= E(x,y). \end{aligned}$$

■

Corollary III.10. *$(\Gamma : E \to \phi_E, \Sigma : \phi_E \to E)$ define a monotone Galois connection between $\mathcal{E}$ and $\mathcal{U}$.*

Proof: Trivial due to the monotonicity of a t-norm ■

We have construct a bijection between $\mathcal{E}$ and $\mathcal{U}$ and analyzed how the order was affected by it. Again, let us finish by studying how the structure of the operations is directly preserved and therefore by proving that the bijection is an isomorphism.

Theorem III.11. *Let E, F be two indistinguishability operators with upper approximations ϕ_E and ϕ_F respectively. Then:*

1) $\phi_{\overline{E\cup F}} = \overline{\phi_E \vee \phi_F}$
2) $\phi_{E\cap F} = \phi_E \wedge \phi_F$

Proof:

1) $\geq$)
   Let $\mu \in [0,1]^X$.
   $\phi_{\overline{E\cup F}}(\mu)(x) = \sup_{y\in X} T(\overline{E \cup F}(x,y), \mu(y))$.
   As $\overline{E \cup F} \geq E, F \Rightarrow \phi_{\overline{E\cup F}}(\mu)(x) \geq \phi_E(\mu)(x)$ and $\phi_{\overline{E\cup F}}(\mu)(x) \geq \phi_F(\mu)(x)$. Hence:
   $\phi_{\overline{E\cup F}}(\mu)(x) \geq (\phi_E \vee \phi_F)(\mu(x)) \Rightarrow \phi_{\overline{E\cup F}} \geq \overline{\phi_E \vee \phi_F}$.
   $\leq$)
   By Definition III.6 and Proposition II.10, there exists a T-indistinguishability operator G on X such that $\overline{\phi_E \vee \phi_F} = \phi_G$. We have to prove that $\overline{E \cup F} \leq G$.
   Indeed, $\phi_E \leq \overline{\phi_E \vee \phi_F} = \phi_G$ and by Lemma III.7 $E \leq G$. Analogously we get $F \leq G$, and then $E \cup F \leq G \Rightarrow \overline{E \cup F} \leq G$, which proves the inequality.
2) $\phi_{E\cap F}(\mu)(x) = \sup_{y\in X} T(\min\{E(x,y), F(x,y)\}, \mu(y))$
   $= \sup_{y\in X} \min\{T(E(x,y), \mu(y)), T(F(x,y), \mu(y))\}$.
   And, as the min and the sup operators are interchangeable in the previous expression, this is equal to $(\phi_E \wedge \phi_F)(\mu)(x)$

■

C. Indistinguishability Operators and Lower Approximations

This subsection will deal with indistinguishability operators and lower approximations. The final result of the subsection will be, analogously as the previous subsections, the construction of the isomorphism between both lattices.

Firstly, to give the set $\mathcal{L}$ of lower approximations a lattice structure we have to introduce the ψ-closure of a map.

Definition III.12. *Let f be a map defined on $[0,1]^X \to [0,1]^X$. The ψ-closure $\widetilde{f}$ of f is defined as:*

$$\widetilde{f} = \bigwedge_{\psi\in L, f\leq\psi} \psi$$

where L is the set of maps $\psi : [0,1]^X \to [0,1]^X$ satisfying the properties of Proposition II.12:

1) $\mu \leq \mu' \Rightarrow \psi_E(\mu) \leq \psi_E(\mu')$
2) $\psi_E(\mu) \leq \mu$
3) $\psi_E(\mu \wedge \mu') = \psi_E(\mu) \wedge \psi_E(\mu')$
4) $\psi_E(\psi_E(\mu)) = \psi_E(\mu)$
5) $\psi_E(\overrightarrow{T}(x|\alpha)(y) = \psi_E(\overrightarrow{T}(y|\alpha)(x)$
6) $\psi_E(\overrightarrow{T}(\alpha|\mu)) = \overrightarrow{T}(\alpha, \psi_E(\mu))$

This way, the lattice structure is obtained with the ordering $\leq$, and the operations $\wedge$ and $\widetilde{\vee}$.

Let us prove now that the ordering of the lattices is directly preserved when we pass from one to the other.

Proposition III.13. *Let E, F be two indistinguishability operators on X with upper approximations ψ_E and ψ_F respectively. Then:*

$$E \leq F \Leftrightarrow \psi_E \leq \psi_F.$$

Analogously to the case of upper approximations, an indistinguishability operator can be defined given a lower approximation ψ.

Proposition III.14. *Let $\psi : [0,1]^X \to [0,1]^X$ be a map satisfying the properties of Proposition II.12. Then the fuzzy relation E_ψ defined by*

$$E_\psi(x,y) = \inf_{\alpha\in[0,1]} \overrightarrow{T}(\psi(\overrightarrow{T}(\{x\}|\alpha)(y)|\alpha)).$$

is a T-indistinguishability operator on X.

From this proposition, it can be proved that there is a bijection between the lattices $\mathcal{E}$ and $\mathcal{L}$.

Theorem III.15. [4] *There is a bijection between the set of T-indistinguishability operators and the maps ψ satisfying the properties of Proposition II.12.*

Corollary III.16. *($\Gamma : E \to \psi_E, \Sigma : \psi_E \to E$) define a monotone Galois connection between $\mathcal{E}$ and $\mathcal{L}$.*

Proof: Trivial by applying the properties of the residuation. ∎

We finally have to see that the stated bijection between the lattice of indistinguishability operators on X and the lattice of lower approximations on X preserves the structure given by $\wedge$ and $\overline{\vee}$. This is proved in the following Theorem. With this result, we have the stated isomorphism between both lattices.

Theorem III.17. *Let E, F be two T-indistinguishability operators on X with lower approximations ψ_E and ψ_F respectively. Then:*

1) $\psi_{\overline{E\cup F}} = \widetilde{\psi_E \vee \psi_F}$
2) $\psi_{E\cap F} = \phi_E \wedge \psi_F$

Proof:

1) $\geq$)
   $E \leq \overline{E \cup F} \Rightarrow \psi_E \leq \psi_{\overline{E\cup F}}$
   $F \leq \overline{E \cup F} \Rightarrow \psi_F \leq \psi_{\overline{E\cup F}}$
   Therefore, $\psi_E \vee \psi_F \leq \psi_{\overline{E\cup F}} \Rightarrow \widetilde{\psi_E \vee \psi_F} \leq \psi_{\overline{E\cup F}}$
   $\leq$)
   Let us assume that there exist $x \in X$ and a fuzzy subset μ of X such that:
   $\psi_{\overline{E\cup F}}(\mu)(x) > \widetilde{\psi_E \vee \psi_F}(\mu)(x)$. Then there exists a T-indistinguishability operator G on X such that $\widetilde{\psi_E \vee \psi_F} \leq \psi_G$ and $\psi_G(\mu)(x) < \psi_{\overline{E\cup F}}(\mu)(x)$.
   But $\psi_E \leq \widetilde{\psi_E \vee \psi_F} \leq \psi_G$. By Lemma III.13 we have $E \leq G$. Analogously $F \leq G$. So $E \cup F \leq G \Rightarrow \overline{E \cup F} \leq G$, which contradicts $\widetilde{\psi_G}(\mu)(x) < \psi_{\overline{E\cup F}}(\mu)(x)$. So we have $\psi_{\overline{E\cup F}} \leq \widetilde{\psi_E \cup \psi_F}$.
2) $(\psi_E \wedge \psi_F)(\mu)(x) =$
   $\min\{\inf_{y\in X} \overrightarrow{T}((E(x,y)|\mu(x)),$
   $\quad \inf_{y\in X} \overrightarrow{T}((F(x,y)|\mu(x)))\}$
   $= \inf_{y\in X} \overrightarrow{T}(\min\{E(x,y), F(x,y)\}|\mu(x)) =$
   $\psi_{E\cap F}(\mu)(x)$.

∎

IV. Conclusion

In this work, the relation between the set $\mathcal{E}$ of T-indistinguishability operators on a set X, the set $\mathcal{H}$ of sets of extensional fuzzy subsets with respect to a T-indistinguishability operator E on X and the sets $\mathcal{U}$ and $\mathcal{L}$ of upper and lower approximations of fuzzy subsets by extensional ones with respect to a T-indistinguishability operator respectively has been studied and stated. It has been proved that these sets are in fact isomorphic lattices and the isomorphisms have been given explicitly. These results are summarized bellow.

$$\begin{array}{ccccccc} \mathcal{L} & \approx & \mathcal{U} & \approx & \mathcal{E} & \approx & \mathcal{H} \\ \psi_E \wedge \psi_F & \leftrightarrow & \phi_E \wedge \phi_F & \leftrightarrow & E \cap F & \leftrightarrow & \overline{H_E \cup H_F} \\ \widetilde{\psi_E \vee \psi_F} & \leftrightarrow & \overline{\phi_E \vee \phi_F} & \leftrightarrow & \overline{E \cup F} & \leftrightarrow & H_E \cap H_F \end{array}$$

***Abstract*—In the classical set theory, there is the well known correspondence between the equipollence of finite sets and the equality of natural numbers expressing their cardinalities. In the fuzzy set theory, an equivalent correspondence between the equipollence of finite fuzzy sets and the equality of generalized cardinals has been proposed in [1]. This paper is devoted to the situation when we consider the mentioned relations to be graded, that means, the crisp equipollence of fuzzy sets is replaced now by the graded equipollence of fuzzy sets and the equality of fuzzy sets by their similarity.**

***Index Terms*—residuated-dually residuated lattice; graded equipollence; fuzzy c-measure**

I. Introduction

In the classical set theory, two sets have the same number of elements if and only if there exists a one-to-one mapping of one set onto the second one. Thus, there is a nice relation between the functional approach to the cardinality of sets, which does not suppose any knowledge about the numbers of elements in sets, and the approach based on the ordinal numbers expressing the numbers of elements of sets.

The above two mentioned approaches to the cardinality for (finite) fuzzy sets have been also studied in the fuzzy set theory. Nevertheless, for fuzzy sets, the situation is much more complicated by the graduation of membership of elements of fuzzy sets.

The classical-like approaches to the cardinality of fuzzy sets based on the notion of the equipollence of fuzzy sets were proposed by D. Klaua [2] and S. Gottwald [3], [4]. In the second case, a degree in which two fuzzy sets are equipollent is defined using fuzzy uniqueness of fuzzy mappings. Equivalence classes (fuzzy sets) are *fuzzy cardinals*. Note that fuzzy mappings are here defined as special fuzzy relations. Since these approaches are purely theoretical, a further substantial research in this direction has not been realized yet. Another approach was suggested by M. Wygralak [5], where the notion of equipollence of fuzzy sets is introduced using the cardinality of α-cuts of fuzzy sets. More precisely, two fuzzy sets A and B are equipollent, if

$$\bigvee\{\alpha \in [0,1] \mid |A_\alpha| \geq i\} = \bigvee\{\alpha \in [0,1] \mid |B_\alpha| \geq i\} \quad (1)$$

for any cardinal number i. Some modifications of (1) can be found in [1], [6], [7], [8]. In [9] (see also [10], [11]), we proposed a new approach to the equipollence of fuzzy sets over a universe of sets (e.g., a universe of all finite or countable sets, or all sets, or a Grothendieck universe). Analogously to the Gottwald's approach, a graded equipollence is considered, where, however, the degrees of being equipollent are obtained by a simpler way than in the Gottwald's approach. More precisely, this approach is based on a graded one-to-one correspondence between fuzzy sets where the crisp mappings between universes are considered.

The approaches to the cardinality of finite fuzzy sets based on objects expressing the number of elements in fuzzy sets can be divided to two directions, namely, to the scalar and fuzzy approaches. In this contribution, we are interested in the second approach, where the cardinality of fuzzy sets is expressed by special fuzzy sets defined over the set of natural numbers $\mathbb{N}$ or over universes containing a class of cardinal numbers. In this case, convex fuzzy sets over a class of cardinals have a dominant role. These fuzzy sets are usually called *generalized natural numbers* or *generalized cardinals* (see e.g. [12], [13], [14]). This type of cardinality of fuzzy sets is usually referred to the *fuzzy cardinality*.

Let us mention that the first definition of fuzzy cardinality of finite fuzzy sets, by means of functions from $\mathbb{N}$ to $[0,1]$, was done by L.A. Zadeh in [15]. A substantial improvement of the original definition was done again by L.A. Zadeh in [16] and gave rise to three types of cardinality, namely, $FGCount$, $FLCount$ and $FECount$. A generalization of FGCount, FLCount and FECount using t-norms and t-conorms was proposed by M. Wygralak in [14] and further developed in [1]. Both publications are an attempt to develop the cardinal theory for fuzzy sets including a relation between equipollence and equality of cardinal numbers. An axiomatic approach to fuzzy cardinality of finite fuzzy sets covering some of the well-known definition, defined by means of the generalized natural numbers, was proposed by J. Casasnovas and J. Torrens [17].

In [18], we generalized the Casasnovas-Torrens axiomatic approach and defined "fuzzy measures" extending the cardinality of finite sets to a cardinality finite fuzzy sets.[1] Although, the proposed system of fuzzy measures generalizes the cardinality of sets, some properties like the valuation property or, as will be seen later, the fundamental correspondence between the graded equipollence of fuzzy sets and the equality of their generalized cardinals are failed in general. Therefore, we call these measures as the *c-measures*, where the letter "c" is an

[1]Note that, in contrast to the cardinality of finite sets, we can define a large scale of fuzzy measures expressing the number of elements of finite fuzzy sets.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

abbreviation of "cardinal".

The aim of this contribution is to show relations between functional approach based on the graded equipollence introduced in [9] (see also [10], [11]) and the approach based on the fuzzy c-measures proposed in [18], where the cardinality of finite fuzzy sets is expressed by generalized cardinals.

The paper is structured as follows. In Preliminaries, we propose a residuated-dually residuated lattice as an algebraical structure of membership degrees of fuzzy sets and (countable and finite) fuzzy sets defined in the class of all countable sets. The graded equipollence of (countable) fuzzy sets is introduced in Section III. The section IV is devoted to fuzzy c-measures including the important properties as a representation of fuzzy c-measures by suitable homomorphisms between reducts of the rdr-lattices. In Section V, we shows the relation between the graded equipollence of finite fuzzy sets and the similarity of generalized cardinals obtained by fuzzy c-measures. The last section is the conclusion.

II. Preliminaries

A. Algebraic Structures of Membership Degrees of Fuzzy Sets

In this paper, the membership degrees of fuzzy sets are interpreted in a complete residuated lattice which is, moreover, extended by an adjoint pair of dual operations. We shall say that an algebra $\mathbf{L} = \langle L, \wedge, \vee, \otimes, \rightarrow, \oplus, \ominus, \bot, \top \rangle$ with six binary operations and two constants is a *residuated-dually residuated lattice* (shortly, an rdr-lattice), if

(i) $\langle L, \wedge, \vee, \bot, \top \rangle$ is a bounded lattice, where $\bot$ is the least element and $\top$ is the greatest element of L, respectively,
(ii) $\langle L, \otimes, \top \rangle$ and $\langle L, \oplus, \bot \rangle$ are commutative monoids,
(iii) the pairs $\langle \otimes, \rightarrow \rangle$ and $\langle \oplus, \ominus \rangle$ form adjoint pairs, i.e.

$$a \leq b \rightarrow c \quad \text{if and only if} \quad a \otimes b \leq c, \tag{2}$$
$$a \leq b \oplus c \quad \text{if and only if} \quad a \ominus b \leq c \tag{3}$$

hold for each $a, b, c \in L$ ($\leq$ denotes the corresponding lattice ordering).

The operations $\otimes$, $\rightarrow$, $\oplus$ and $\ominus$ are called *multiplication*, *residuum*, *addition* and *difference*, respectively.[2] We shall say that an rdr-lattice is *complete* (*linearly ordered*), if $\langle L, \wedge, \vee, \bot, \top \rangle$ is a complete (linearly ordered) lattice, respectively. Further, an rdr-lattice is *divisible*, if $a \otimes (a \rightarrow b) = a \wedge b$ holds for all $a, b, c \in L$, and *dually divisible*, if $(a \ominus b) \oplus b = a \vee b$ holds for all $a, b, c \in L$.

EXAMPLE 1 Let T and S be a left continuous t-norm and a right continuous t-conorm, respectively, and define $\rightarrow_T$ and $\ominus_S$ by

$$a \rightarrow_T b = \bigvee \{c \in [0,1] \mid T(a,c) \leq b\},$$
$$a \ominus_S b = \bigwedge \{c \in [0,1] \mid S(b,c) \geq a\}.$$

The algebra $\mathbf{L} = \langle [0,1], \min, \max, T, \rightarrow_T, S, \ominus_S, 0, 1 \rangle$ is a complete rdr-lattice. If T and S is the product (or the Łukasiewicz conjunction) and the probabilistic sum (or the Łukasiewicz disjunction), respectively, then we shall use $\mathbf{L}_\Pi$ ($\mathbf{L}_Ł$) to denote the Goguen (Łukasiewicz) rdr-lattice.

Let us define the following additional operations for any $a, b \in L$ and set $\{a_i \mid i \in I\}$ of elements from L over a countable (possibly empty) index set I:

$$a \leftrightarrow b = (a \rightarrow b) \wedge (b \rightarrow a), \qquad \textit{(biresiduum)}$$
$$\neg a = a \rightarrow \bot, \qquad \textit{(negation)}$$
$$\bigotimes_{i \in I} a_i = \begin{cases} \top, & I = \emptyset, \\ \bigwedge_{K \in \mathfrak{Fin}(I)} \bigotimes_{i \in K} a_i, & \text{otherwise}, \end{cases} \qquad \textit{(countable multiplication)}$$
$$\bigoplus_{i \in I} a_i = \begin{cases} \bot, & I = \emptyset, \\ \bigvee_{K \in \mathfrak{Fin}(I)} \bigoplus_{i \in K} a_i, & \text{otherwise}, \end{cases} \qquad \textit{(countable addition)}$$

where $\mathfrak{Fin}(I)$ denotes the set of all finite subsets of I. If $|I| = n$ is a finite index set and $a_i = a$ for any $i \in I$, then we will write $a^n = \bigotimes_{i \in I} a_i$ or $na = \bigoplus_{i \in I} a_i$.

To integrate some of alternative constructions based on the operations of $\wedge$ and $\otimes$, we shall use the common symbol $\odot$ (or $\bigodot$) for them. Analogously, we shall use $\overline{\odot}$ (or $\overline{\bigodot}$) to denote one of the operations $\vee$ or $\oplus$.

B. Fuzzy Sets

Since we are interested in finite fuzzy sets and consequently also denumerable fuzzy sets, let us consider the class $\mathfrak{Count}$ of all countable sets as a framework for our theory.[3] Further, we shall use $\mathfrak{Fin}$ to denote the class of all finite sets. A fuzzy set in $\mathfrak{Count}$ is defined as follows.

DEFINITION 1 A mapping $A : x \rightarrow L$ is called a fuzzy set in $\mathfrak{Count}$, if x is a set in $\mathfrak{Count}$.

In what follows, we shall use $\mathfrak{Fcount}$ to denote the class of all fuzzy sets in $\mathfrak{Count}$. Although, the fuzzy sets in $\mathfrak{Fcount}$ may be referred to "countable" fuzzy sets, we shall not use this notation and say only fuzzy sets. Notice that, for example, each fuzzy set or pair of fuzzy sets belong to $\mathfrak{Count}$. Hence, we obtain that $\mathfrak{Fcount} \subseteq \mathfrak{Count}$ and $\mathfrak{Fcount} \times \mathfrak{Fcount} \subseteq \mathfrak{Count}$.

Let us summarize several well known notions of the fuzzy set theory and suppose that $A : z \rightarrow L$ is a fuzzy set from $\mathfrak{Fcount}$. The set $z = \mathrm{Dom}(A)$ is called a *universe of discourse of* A, $\mathrm{Supp}(A) = \{x \in z \mid A(x) > \bot\}$ is called a *support of fuzzy set* A and $A_a = \{x \in z \mid A(x) \geq a\}$ is called an *a-cut of fuzzy set* A. The fuzzy set A is *crisp*, if $A(x) \in \{\bot, \top\}$ for any $x \in z$, and is called a *singleton*, if $A(x) > \bot$ for some $x \in z$ and $A(y) = \bot$ for any $y \in z$ with $y \neq x$. For simplicity, we shall use the same symbol to denote a crisp set as a fuzzy set (e.g., $\emptyset$ denotes the empty set as well as the empty fuzzy

[2] Notice that if the adjoint pair $\langle \oplus, \ominus \rangle$ (or $\langle \otimes, \rightarrow \rangle$) is forgotten in the rdr-lattice $\mathbf{L}$ we obtain the *residuated lattice* (or *dually residuated lattice*).

[3] Note that we need to deal with the set $\mathbb{N}$ of all natural numbers and fuzzy sets defined on it, and, therefore, the countable sets are considered. In general, we can consider an arbitrary universe of sets containing $\mathbb{N}$ satisfying the axioms U1-U5 of the definition of a universe of sets over $\mathbf{L}$ (see e.g. [9], [18], [10]). Note that the entire set theory can be introduced inside such universes of sets.

set) and $\{a/x\}$ to denote a singleton A with $A(x) = a > \bot$. Finally, if $f : z \to z'$ and $A : z \to L$ be a fuzzy set, then the *image of A under f* is denoted by $f^{\rightarrow}(A)$ and defined by $f^{\rightarrow}(A)(y) = \bigvee_{x \in z : f(x) = y} A(x)$ for any $y \in z'$.

An essential predicate in our theory is a binary relation saying that two fuzzy sets are the same or equivalent fuzzy sets. In the classical set theory, we say that two sets are the same sets, if they have the same elements. In our theory, we define the analogical notion as follows.

DEFINITION 2 We shall say that fuzzy sets A and B are *equivalent* (symbolically, $A = B$), if $\mathrm{Supp}(A) = \mathrm{Supp}(B)$ and $A(x) = B(x)$ for any $x \in \mathrm{Supp}(A)$.

For example, $A = \{0.9/a, 0/b\}$ and $B = \{0.9, /a\}$ are the equivalent fuzzy sets. We shall use $\mathrm{cls}(A)$ to denote the class of all fuzzy sets from $\mathfrak{Fcount}$ which are equivalent with A. A graded generalization of this relation may be given as follows.

DEFINITION 3 We shall say that fuzzy sets A and B are *the equivalent fuzzy sets* in the degree a (symbolically, $[A \approx B] = a$), if

$$a = \bigwedge_{x \in \mathrm{Dom}(A) \cup \mathrm{Dom}(B)} (A'(x) \leftrightarrow B'(x)), \tag{4}$$

holds for $A' \in \mathrm{cls}(A)$, $B' \in \mathrm{cls}(B)$ with $\mathrm{Dom}(A') = \mathrm{Dom}(B') = \mathrm{Dom}(A) \cup \mathrm{Dom}(B)$.

One can simply prove that $[A \approx B] = [A' \approx B']$ holds for any $A' \in \mathrm{cls}(A)$ and $B' \in \mathrm{cls}(B)$ and, hence, the previous definition is correct. Moreover, $[A \approx B] = \top$ if and only if $A = B$. For our investigation, we need only the operations of union and intersection defined as follows.[4] Let $A, B \in \mathfrak{Fcount}$, $x = \mathrm{Dom}(A) \cup \mathrm{Dom}(B)$ and $A' = A$, $B' = B$ such that $\mathrm{Dom}(A') = \mathrm{Dom}(B') = x$. Then

- *the union* of A and B is a mapping $A \cup B : x \to L$ defined by

$$(A \cup B)(a) = A'(a) \vee B'(a) \tag{5}$$

  for any $a \in x$,
- *the intersection* of A and B is a mapping $A \cap B : x \to L$ defined by

$$(A \cap B)(a) = A'(a) \wedge B'(a) \tag{6}$$

  for any $a \in x$,

One can check easily that our definition is correct, i.e., there is no dependence on the choice of fuzzy sets A' and B' in the previous definitions.

As one could notice, the major object of our theory is a finite fuzzy set. We propose the following definition based on the finiteness of universes of discourse (cf. [1], [14]).

DEFINITION 4 We shall say that a fuzzy set A from $\mathfrak{Fcount}$ is *finite*, if there exists $A' \in \mathrm{cls}(A)$ such that $\mathrm{Dom}(A')$ is a finite set.

[4]Further definitions of operations between fuzzy sets and also a definition of a fuzzy power set can be found in [10].

We shall use $\mathfrak{Ffin}$ to denote the class of all finite fuzzy sets in $\mathfrak{Count}$. Obviously, A is a finite fuzzy set if and only if $\mathrm{Supp}(A)$ is a finite set, $\mathfrak{Ffin}$ is a subclass of $\mathfrak{Fcount}$, the union or intersection of finite fuzzy sets is again a finite fuzzy set.

To define measures of finite fuzzy sets which are similar to the cardinality for finite sets, we need to introduce a concept of generalized cardinal over $\mathbb{N}$. A reasonable condition (see e.g. [1], [14]) for this concept is a "convexity" of fuzzy sets. The convexity of fuzzy sets may be defined over linearly ordered sets as follows. Recall that $\odot \in \{\wedge, \otimes\}$.

DEFINITION 5 Let x be a set in $\mathfrak{Count}$ equipped with a linear ordering $\leq$. We shall say that $A : x \to L$ is an *$\odot$-convex fuzzy set*, if $A(a) \odot A(c) \leq A(b)$ holds for any $a, b, c \in x$ with $a \leq b \leq c$.

DEFINITION 6 *A generalized cardinal* A (over $\mathbb{N}$) is an $\odot$-convex fuzzy set $A : \mathbb{N} \to L$.

One can see that generalized cardinals need not be finite fuzzy sets. We shall use $\mathfrak{N}$ to denote the set of all generalized cardinals. To be able to manipulate with generalized cardinals, we establish, by the Zadeh' extension principle, the operation of addition on $\mathfrak{N}$ as

$$(A + B)(i) = \bigvee_{\substack{k,l \in \mathbb{N} \\ k+l=i}} (A(k) \odot B(l)). \tag{7}$$

Let us define $\mathbf{0} : \mathbb{N} \to L$ by $\mathbf{0}(k) = \top$, if $k = 0$, and $\mathbf{0}(k) = \bot$, otherwise. One can easily prove the following statement saying that our definition of addition is correct.

THEOREM 1 *The triplet $(\mathfrak{N}, +, \mathbf{0})$ is a commutative monoid, where the divisibility of the rdr-lattice $\mathbf{L}$ has to be supposed for $\odot = \wedge$.*

III. GRADED EQUIPOLLENCE OF FUZZY SETS

In order to introduce a graded equipollence for fuzzy sets, we shall follow the classical idea and use "one-to-one mappings between fuzzy sets". Nevertheless, contrary to the classical approach, it seems to be reasonable to distinguish what one-to-one mapping is better than another one. This motivates us to introduce a degree in which a one-to-one mapping between suitable sets is a one-to-one mapping between fuzzy sets as follows.

DEFINITION 7 Let $A, B \in \mathfrak{Fcount}$, $x, y \in \mathfrak{Count}$ and $f : x \to y$ be a one-to-one mapping of x onto y in $\mathfrak{Count}$. We shall say that f is a *one-to-one mapping of A onto B in the degree a* with respect to $\odot$, if $\mathrm{Supp}(A) \subseteq x \subseteq \mathrm{Dom}(A)$ and $\mathrm{Supp}(B) \subseteq y \subseteq \mathrm{Dom}(B)$ and

$$a = \bigodot_{z \in x} (A(z) \leftrightarrow B(f(z))). \tag{8}$$

We shall write $[A \sim_f^{\odot} B] = a$, if f is a one-to-one mapping of A onto B in the degree a with respect to $\odot$. Before we introduce the definition of being equipollent in

the degree α, let us denote $\mathrm{Bij}(A,B)$ the set of all one-to-one correspondences between A and B. Obviously, the set $\mathrm{Bij}(A,B)$ can be characterized as follows.

THEOREM 2 *Let $A, B \in \mathfrak{Fcount}$. A mapping $f : x \to y$ belongs to the set $\mathrm{Bij}(A,B)$, if*

(i) f is a one-to-one mapping of x onto y,
(ii) $\mathrm{Supp}(A) \subseteq x \subseteq \mathrm{Dom}(A)$, and
(iii) $\mathrm{Supp}(B) \subseteq y \subseteq \mathrm{Dom}(B)$.

In what follows, we shall use some results on the graded equipollence for fuzzy sets to simplify the original definition (see [9], [11]). Moreover, we shall consider a more general case, when the operation $\bigwedge$ is replaced by $\bigodot$.[5]

Let $z \in \mathfrak{Count}$. We shall use $\mathrm{Perm}(z)$ to denote the set of all permutations on z, that is, the one-to-one mappings of z onto z.

DEFINITION 8 Let $A, B \in \mathfrak{Fcount}$. We shall say that A is equipollent with B in a degree a with respect to $\odot$ (symbolically, $[A \sim^{\odot} B] = a$), if

$$a = \bigvee_{f \in \mathrm{Perm}(z)} [C \sim_f^{\odot} D] \tag{9}$$

where $C \in \mathrm{cls}(A)$, $D \in \mathrm{cls}(B)$ are arbitrary fuzzy sets with $z = \mathrm{Dom}(C) = \mathrm{Dom}(D)$ such that $|\mathrm{Supp}(A)| \leq |z \setminus \mathrm{Supp}(B)|$ and $|\mathrm{Supp}(B)| \leq |z \setminus \mathrm{Supp}(A)|$.

One could be surprised that the degree in which fuzzy sets are equipollent is not dependent on the choice of fuzzy sets C and D. As we have mentioned above, the previous definition uses the results presented in [9], [11]. More precisely, we use the fact (described for the case $\odot = \wedge$) that the degree of equipollence of A and B can be obtained by fuzzy sets C and D being equivalent with A and B, respectively, for which it is sufficient to suppose that their domains have the same cardinality, or even, their domains are identical (after a suitable extension). Analogously, one could prove the sufficiency of this presumption on $\mathrm{Dom}(C) = \mathrm{Dom}(D)$ for $\odot = \otimes$.

The following useful lemma shows that the degree in which finite fuzzy sets are equipollent can be derived from finite sets.

THEOREM 3 *Let $A, B \in \mathfrak{Ffin}$ and $C \in \mathrm{cls}(A)$, $D \in \mathrm{cls}(B)$ be such that $z = \mathrm{Dom}(C) = \mathrm{Dom}(D)$ and $|z| = n$. Then*

$$[A \sim^{\odot} B] = \bigvee_{f \in \mathrm{Perm}(z)} [C \sim_f^{\odot} D]. \tag{10}$$

As we have mentioned above, the class $\mathfrak{Fcount} \times \mathfrak{Fcount}$ is a subclass of $\mathfrak{Count}$. Hence, we can define the following "fuzzy class" (or also "fuzzy class relation") in $\mathfrak{Count}$, which is analogous to the equivalence relation "to be equipollent" on the class of all sets (for details about fuzzy classes in a universe of sets, we refer to [9], [10]).

[5]For interesting readers, we refer to [9], [10], [11].

THEOREM 4 *The fuzzy class relation $\sim^{\odot}$: $\mathfrak{Fcount} \times \mathfrak{Fcount} \to L$ is a similarity relation ($\otimes$-equivalence) on the class $\mathfrak{Fcount}$, i.e.,*

$$[A \sim^{\odot} A] = \top, \tag{11}$$
$$[A \sim^{\odot} B] = [B \sim^{\odot} A], \tag{12}$$
$$[A \sim^{\odot} B] \otimes [B \sim^{\odot} C] \leq [A \sim^{\odot} C] \tag{13}$$

hold for arbitrary finite fuzzy sets $A, B, C \in \mathfrak{Fcount}$.

The fuzzy class relation $\sim^{\odot}$ is called the *graded equipollence* of finite fuzzy sets.

The rest of this section is devoted to the mappings (fuzzy classes) which can well characterize under some condition the finite fuzzy sets from the graded equipollence perspective.

Let $A \in \mathfrak{Ffin}$ be a finite fuzzy set and define a fuzzy class $p_A^{\odot} : \mathbb{N} \times \mathfrak{Fin} \to L$ by

$$p_A^{\odot}(i,y) = \bigvee_{\substack{z \subseteq y, \\ |z| = i}} \bigodot_{x \in z} A(x) \tag{14}$$

for any $i \in \mathbb{N}$. For simplicity, we shall omit the symbol $\odot$ in $p_A^{\odot}(-,y)$ in such cases, when we consider both interpretations of $\odot$, and thus no confusion can arise. Several properties of the fuzzy sets $p_A(-,y)$ are summarized in the following lemma.

LEMMA 5 *Let $A \in \mathfrak{Ffin}$. Then, for $i, j \in \mathbb{N}$, we have*

$$p_A(i,y) \leq p_A(j,y), \text{ if } i \geq j, \tag{15}$$
$$p_A(i,y) = \bot, \text{ if } i > \min(|y|, |\mathrm{Supp}(A)|), \tag{16}$$
$$p_A(0,y) = \top, \tag{17}$$
$$p_A(1,y) = \bigvee_{x \in y \cap \mathrm{Supp}(A)} A(x). \tag{18}$$

According to the previous lemma, one can see that $p_A(-,y)$ is a generalized cardinal which is a finite fuzzy set. The following statement shows an interesting relation between the equipollence of finite fuzzy sets and the equivalence of generalized cardinals derived from them.

THEOREM 6 *Let $A, B \in \mathfrak{Ffin}$ and $y \in \mathfrak{Fin}$ such that $\mathrm{Supp}(A) \cup \mathrm{Supp}(B) \subseteq y$. Then*

$$[A \sim^{\odot} B] \leq [p_A^{\odot}(-,y) \approx p_B^{\odot}(-,y)]. \tag{19}$$

Simple consequences of the inequality (19) are

$$p_A^{\odot}(-,y) = p_B^{\odot}(-,y), \tag{20}$$
$$[p_A^{\odot}(-,y) \sim^{\odot} p_B^{\odot}(-,y)] = \top, \tag{21}$$

whenever $A \in \mathrm{cls}(B)$ and $\mathrm{Supp}(A) \subseteq y$.

Let us suppose in the rest of this section that $\mathbf{L}$ be a complete linearly ordered rdr-lattice. Then one may simply prove the following equality for $\odot = \wedge$.

THEOREM 7 *Let $\mathbf{L}$ be a complete linearly ordered rdr-lattice, $A, B \in \mathfrak{Ffin}$ and $y \in \mathfrak{Fin}$ such that $\mathrm{Supp}(A) \cup \mathrm{Supp}(B) \subseteq y$. Then*

$$[A \sim^{\wedge} B] = [p_A^{\wedge}(-,y) \approx p_B^{\wedge}(-,y)]. \tag{22}$$

A straightforward consequence of the previous theorem is the following lemma shows that under some presumption on domains of considered finite fuzzy sets there exists a permutation determining the degree in which these fuzzy sets are equipollent.

COROLLARY 8 *Let* $\mathbf{L}$ *be a linearly ordered residuated lattice and* $A, B \in \mathfrak{Ffin}$ *be such that* $z = \mathrm{Dom}(A) = \mathrm{Dom}(B)$. *Then there exists a permutation* f *on* z *such that*

$$[A \sim^{\wedge} B] = [f^{\rightarrow}(A) \approx B]. \tag{23}$$

EXAMPLE 2 Let $\mathbf{L}$ be the Łukasiewicz algebra and $z = \{c_1 \ldots, c_5\}$ be a set of criterion. Let us suppose that the following fuzzy sets

$$A = \{0.3/c_1, 0.8/c_2, 0.4/c_3, 0/c_4, 0/c_5\}$$
$$B = \{0/c_1, 0.6/c_2, 0.9/c_3, 0/c_4, 0.7/c_5\}$$

express the satisfaction of all criterion by two applicants and our goal is to determine, whether the numbers of satisfied criterion are more or less the same for both applicants. According to (14), we can establish

$$p^{\wedge}_A(-, z) = \{1/0, 0.8/1, 0.4/2, 0.3/3, 0/4, 0/5, \ldots\},$$
$$p^{\wedge}_B(-, z) = \{1/0, 0.9/1, 0.7/2, 0.6/3, 0/4, 0/5, \ldots\}$$

and, using Theorem 7, we obtain

$$[A \sim^{\wedge} B] = \bigwedge_{i \in N} (p^{\wedge}_A(i, z) \leftrightarrow p^{\wedge}_B(i, z)) = 0.7.$$

Hence, we can conclude that both applicants have more or less the same number of satisfied criterion.

In the end of this section, we shall introduce an analogous notion to $p^{\odot}_A(i, y)$ for $\overline{\odot}$. Let $A \in \mathfrak{Ffin}$ be a finite fuzzy set and define a fuzzy class $p^{\overline{\odot}}_A : \mathbb{N} \times \mathfrak{Ffin} \to L$ by

$$p^{\overline{\odot}}_A(i, y) = \bigwedge_{\substack{z \subseteq y, \\ |z| = i}} \overline{\bigodot_{x \in z}} A(x) \tag{24}$$

for any $i \in \mathbb{N}$. Again, for simplicity, we shall omit the symbol $\overline{\odot}$ in $p^{\overline{\odot}}_A$ in such cases, when we consider both interpretations of $\overline{\odot}$, and thus no confusion can arise.

LEMMA 9 *Let* $A \in \mathfrak{Ffin}$. *Then, for* $i, j \in \mathbb{N}$, *we have*

$$p_A(i, y) \geq p_A(j, y), \ \textit{if} \ \ i \geq j, \tag{25}$$
$$p_A(i, y) = \top, \ \textit{if} \ \ i > \min(|y|, |\mathrm{Supp}(A)|), \tag{26}$$
$$p_A(0, y) = \bot, \tag{27}$$
$$p_A(1, y) = \bigwedge_{x \in y \cap \mathrm{Supp}(A)} A(x). \tag{28}$$

In contrast to $p^{\odot}_A(-, y)$, the mappings $p^{\overline{\odot}}_A(-, y)$ are denumerable fuzzy sets, i.e., $|\mathrm{Supp}(p^{\overline{\odot}}_A(-, y))| = \aleph_0$. Nevertheless, one can simply check that

$$[p^{\overline{\odot}}_A(-, y) \approx p^{\overline{\odot}}_B(-, y)] = \top, \tag{29}$$

whenever $A \in \mathrm{cls}(B)$ and $\mathrm{Supp}(A) \subseteq y$.

IV. FUZZY C-MEASURES

In the following text, we shall suppose that $\mathbf{L}$ is a complete rdr-lattice which is, moreover, divisible, whenever $\wedge$ is considered as $\odot$.

DEFINITION 9 A class mapping $\mathfrak{C} : \mathfrak{Ffin} \to \mathfrak{N}$ is a *fuzzy c-measure of finite fuzzy sets* with respect to $\odot$, if, for arbitrary $A, B \in \mathfrak{Ffin}$, it satisfies the following axioms

C1: if $A \cap B = \emptyset$, then $\mathfrak{C}(A \cup B) = \mathfrak{C}(A) + \mathfrak{C}(B)$,
C2: if $i, j \in N$ and $i > |\mathrm{Supp}(A)|$, $j > |\mathrm{Supp}(B)|$, then $\mathfrak{C}(A)(i) = \mathfrak{C}(B)(j)$,
C3: if A is a crisp set, then $\mathfrak{C}(A)$ is a crisp set and $\mathfrak{C}(A)(|A|) = \top$,
C4: if $a \in L$, $x, y \in \mathcal{U}$ and $i \in N$, then $\mathfrak{C}(\{a/x\})(i) = \mathfrak{C}(\{a/y\})(i)$,
C5: if $a, b \in L$ and $x \in \mathcal{U}$, then

$$\mathfrak{C}(\{a \,\overline{\odot}\, b/x\})(0) = \mathfrak{C}(\{a/x\})(0) \odot \mathfrak{C}(\{b/x\})(0),$$
$$\mathfrak{C}(\{a \odot b/x\})(1) = \mathfrak{C}(\{a/x\})(1) \odot \mathfrak{C}(\{b/x\})(1).$$

The axioms C1-C5 are called the *additivity, variability, consistency, singleton independency, preservation of non-existence* and *existence*, respectively. In the following text, for simplicity, we shall often speak only about "c-measure" instead of "fuzzy c-measure of finite fuzzy sets" and we shall omit "with respect to $\odot$", when no confusion can arise.

The first three axioms are adopted from [17] and their motivation is as follows. The additivity of c-measure is the standard property of cardinality of sets. The variability states that the c-measure of fuzzy sets is not influenced by the elements that do not belong to supports. A consequence of this axiom is correctness of our axiomatic system, it means, the equivalent finite fuzzy sets[6] have the same c-measure. The axiom of consistency ensures the fact that the c-measures are extensions of the cardinality measure (for finite sets). The singleton independency ensures that a form of elements does not influence the value of a c-measure. Finally, a value $\mathfrak{C}(\{A(x)/x\})(0)$ expresses a degree to which $\{A(x)/x\}$ may be considered as the empty set $\{0/x\}$, i.e. x does not belong to A. Analogously, a value $\mathfrak{C}(\{A(x)/x\})(1)$ determines a degree to which $\{A(x)/x\}$ may be considered as a singleton $\{1/x\}$, i.e. x belongs to A. Since $a \,\overline{\odot}\, b \geq a \vee b$, then one could deduce that the singletons $\{a/x\}$ and $\{b/x\}$ are closer to the empty set $\{0/x\}$ than the singleton $\{a \,\overline{\odot}\, b/x\}$ and, hence,

$$\mathfrak{C}(\{a \,\overline{\odot}\, b/x\})(0) \leq \mathfrak{C}(\{a/x\})(0) \wedge \mathfrak{C}(\{b/x\})(0).$$

Since $a \odot b \leq a \wedge b$, we may obtain

$$\mathfrak{C}(\{a/x\})(0) \odot \mathfrak{C}(\{b/x\})(0) \leq \mathfrak{C}(\{a \,\overline{\odot}\, b/x\})(0),$$

but this is in a contradiction with the relation mentioned above. A compromise is the first "strong" relation of the axiom C5.

[6] See Definition 2.

Analogously, one could deduce the second "strong" relation of the axiom C5. [7]

The following proposition shows the FGCount, FLCount and FECount by means of c-measures of finite fuzzy sets for $\odot = \wedge$ (cf. [17], [8], [1]). Define a complement of A by $\overline{A}(x) = A(x) \to \bot$ for any $x \in \mathrm{Supp}(A)$ and $\overline{A}(x) = \bot$ for any $x \in \mathrm{Dom}(A) \setminus \mathrm{Supp}(A)$.[8]

PROPOSITION 10 *The mappings $\mathfrak{C}_k : \mathfrak{Ffin} \to \mathfrak{N}$, $k = 1, 2, 3$, defined by*

$$\mathfrak{C}_1(A)(i) = \bigvee\{a \mid a \in L \text{ and } |A_a| \geq i\}, \tag{30}$$

$$\mathfrak{C}_2(A)(i) = \mathfrak{C}_1(\overline{A})(\bar{i}), \tag{31}$$

$$\mathfrak{C}_3(A)(i) = \mathfrak{C}_1(A)(i) \wedge \mathfrak{C}_2(A)(i) \tag{32}$$

are c-measures of finite fuzzy sets with respect to $\wedge$, where $\bar{i} = \max(0, |\mathrm{Dom}(A)| - i)$.

EXAMPLE 3 Let $\mathbf{L}$ be the Łukasiewicz algebra, i.e. $a \otimes b = \max(0, a + b - 1)$ and $A = \{0.5/a, 0.8/b, 0.1/c, 0.4/d, 0/e\}$. Then

$$\mathfrak{C}_1(A) = \{1/0, 0.8/1, 0.5/2, 0.4/3, 0.1/4, 0/5, 0/6 \dots\},$$
$$\mathfrak{C}_2(A) = \{0/0, 0.2/1, 0.5/2, 0.6/3, 0.9/4, 1/5, 1/6, \dots\},$$
$$\mathfrak{C}_3(A) = \{0/0, 0.2/1, 0.5/2, 0.4/3, 0.1/4, 0/0, 0/6 \dots\}.$$

Note that $\mathfrak{C}_1$ does not define a c-measure with respect to $\otimes$ in general. Two examples of c-measures with respect to $\otimes$ are given below.

PROPOSITION 11 *Let $\mathfrak{C}_1$ be the c-measure with respect to $\wedge$ defined above. Then mappings $\mathfrak{C}_k : \mathfrak{Ffin} \to \mathfrak{N}$ defined by*

$$\mathfrak{C}_4(A)(i) = \mathfrak{C}_1(A_\top)(i), \tag{33}$$

$$\mathfrak{C}_5(A)(i) = \begin{cases} \top, & i = 0, \\ \mathfrak{C}_5(A)(i-1) \otimes \mathfrak{C}_1(A)(i), & i > 0 \end{cases} \tag{34}$$

are c-measures with respect to $\otimes$.

EXAMPLE 4 Let A be the fuzzy set from Example 3. Then

$$\mathfrak{C}_4(A) = \{1/0, 0/1, 0/2, \dots\},$$
$$\mathfrak{C}_5(A) = \{1/0, 0.8/1, 0.3/2, 0/3, 0/4, 6 \dots\},$$

where, for example, $0.3 = 0.8 \otimes 0.5 = \max(0, 0.8 + 0.5 - 1)$.

The following proposition shows that the form of the c-measure can be various. Recall that $\mathbf{0}$ is the neutral element in the monoid $(\mathfrak{N}, +, \mathbf{0})$ and $\mathbb{N}$ can also denote the fuzzy set of all natural numbers, i.e., $\mathbb{N}(n) = \top$ for any $n \in \mathbb{N}$.

[7]Note that one could imagine a weaker relation, where the equalities in C5 are replaces by the inequality $\leq$. Nevertheless, this inequality does not lead to nicer results.

[8]One can verify that $A = B$ implies $\overline{A} = \overline{B}$ and thus $=$ is a congruence with respect to the complement in $\mathcal{U}$. Note that the same result cannot be obtained for a definition of $\overline{A}$ where $\overline{A}(x) = \top$ for any $x \in \mathrm{Dom}(A) \setminus \mathrm{Supp}(A)$.

PROPOSITION 12 *Let $\mathfrak{C} : \mathfrak{Ffin} \to \mathfrak{N}$ be a c-measure. Then $\mathfrak{C}(\emptyset) = \mathbf{0}$ or $\mathfrak{C}(\emptyset) = \mathbb{N}$. If $\mathfrak{C}(\emptyset) = \mathbb{N}$, then $\mathfrak{C}(A)$ is a non-decreasing mapping.*

A simple consequence of this proposition is the fact that $\mathfrak{C}(A)(i) \in \{\bot, \top\}$ for any $i \in \mathbb{N}$ such that $i > |\mathrm{Supp}(A)|$.

A consequence of the additivity of c-measure is the following theorem.

THEOREM 13 *Let $\mathfrak{C} : \mathfrak{Ffin} \to \mathfrak{N}$ be a c-measure and $A \in \mathfrak{Ffin}$ such that $\mathrm{Supp}(A) = \{x_1, \dots, x_m\}$. Then*

$$\mathfrak{C}(A)(i) = \bigvee_{\substack{i_1, \dots, i_m \in \{0,1\} \\ i_1 + \cdots + i_m = i}} \bigodot_{k=1}^{m} \mathfrak{C}(\{A(x_k)/x_k\})(i_k) \tag{35}$$

for each $i \in N$. Moreover, $\mathfrak{C}(A)(i) = \bot$ or $\mathfrak{C}(A)(i) = \top$ hold for any $m < i$.

In [17], a representation of cardinalities of finite fuzzy sets using two monotonic mappings $f, g : [0,1] \to [0,1]$ was shown. In order to introduce an analogical representation for the c-measures, we need to establish a generalization of monotonic mappings.

Let $\mathbf{L}_1, \mathbf{L}_2$ be complete rdr-lattices. We shall say that $h : L_1 \to L_2$ is an *$\odot$-homomorphism* of $\mathbf{L}_1$ to $\mathbf{L}_2$, if h is a homomorphism of the reduct $(L_1, \odot_1, \top_1)$ of $\mathbf{L}_1$ to the reduct $(L_2, \odot_2, \top_2)$ of $\mathbf{L}_2$, i.e., $h(a \odot_1 b) = h(a) \odot_2 h(b)$ and $h(\top_1) = \top_2$.[9] Further, we shall say that $h : L_1 \to L_2$ is an *$\overline{\odot}_{\mathrm{d}}$-homomorphism*, if h is a homomorphism from the reduct $(L_1, \overline{\odot}_1, \bot_1)$ of $\mathbf{L}_1$ to the reduct $(L_2, \odot_2, \top_2)$ of $\mathbf{L}_2$, i.e. $h(a \,\overline{\odot}_1\, b) = h(a) \odot h(b)$ and $h(\bot_1) = \top_2$.

The following lemma gives a characterization of c-measures using $\odot$- and $\overline{\odot}_{\mathrm{d}}$-homomorphisms.

LEMMA 14 *Let $f, g : L \to L$ be $\odot$- and $\overline{\odot}_{\mathrm{d}}$-homomorphisms from $\mathbf{L}$ to $\mathbf{L}$ such that $f(\bot) \in \{\bot, \top\}$ and $g(\top) \in \{\bot, \top\}$, respectively. Let $\mathfrak{C}_{f,g} : \mathfrak{Ffin} \to \mathfrak{N}$ be a mapping defined by the induction:*

$$\mathfrak{C}_{f,g}(\{a/x\})(0) = g(a),\ \mathfrak{C}_{f,g}(\{a/x\})(1) = f(a),$$
$$\mathfrak{C}_{f,g}(\{a/x\})(k) = f(\bot),\ k > 1$$

hold for each singleton $\{a/x\} \in \mathfrak{Ffin}$ and

$$\mathfrak{C}_{f,g}(A) = \mathfrak{C}_{f,g}(\{A(x_1)/x_1\}) + \cdots + \mathfrak{C}_{f,g}(\{A(x_m)/x_m\})$$

holds for each $A \in \mathfrak{Ffin}$ with $\mathrm{Supp}(A) = \{x_1, \dots, x_m\}$. Then $\mathfrak{C}_{f,g}$ is a c-measure of finite fuzzy sets with respect to $\odot$.

THEOREM 15 (REPRESENTATION OF C-MEASURES) *Let $\mathfrak{C} : \mathfrak{Ffin} \to \mathfrak{N}$ be a mapping satisfying the additivity axiom. Then the following statements are equivalent:*

(i) $\mathfrak{C}$ is a c-measure of finite fuzzy sets with respect to $\odot$,

[9]Note that each homomorphism between rdr-lattices (or residuated lattices which are the reducts of original rdr-lattices) is also an $\odot$-homomorphism.

(ii) there exist an $\odot$-homomorphism $f : L \to L$ and an $\overline{\odot}_{\mathrm{d}}$-homomorphism $g : L \to L$, such that $f(\bot) \in \{\bot, \top\}$, $g(\top) \in \{\bot, \top\}$ and

$$\mathfrak{C}(\{a/x\})(0) = g(a),\ \mathfrak{C}(\{a/x\})(1) = f(a),$$
$$\mathfrak{C}(\{a/x\})(k) = f(\bot)$$

hold for arbitrary $a \in L$, $x \in \mathfrak{Count}$ and $k \in \mathbb{N}$, $k > 1$.

We shall use $\mathfrak{C}_{f,g}$ to denote a c-measure which is determined by an $\odot$-homomorphism $f : L \to L$ and an $\overline{\odot}_{\mathrm{d}}$-homomorphism $g : L \to L$ satisfying (ii). Moreover, we shall use $\mathfrak{C}_f$ or $\mathfrak{C}_g$, if g or f are the trivial $\overline{\odot}_{\mathrm{d}}$-homomorphism or $\odot$-homomorphism (i.e., $g(a) = \top$ or $f(a) = \top$ for any $a \in L$), respectively. Note that the trivial homomorphisms have no influence on the form of a c-measure.

V. Graded equipollence and c-measures

Let $\mathbf{L}$ be a complete rdr-lattice, $f : L \to L$ be a mapping and $A : x \to L$ be a fuzzy set. We shall use $f(A)$ to denote a fuzzy set of x to L defined by $f(A)(z) = f(A(z))$ for any $z \in x$. Note that $f(A) = f \circ A$ and thus $\mathrm{Dom}(A) = \mathrm{Dom}(f(A))$.

The first theorem shows a relation between the degrees in which there exist one-to-one correspondences between fuzzy sets (under f and g) and the similarity of generalized cardinals obtained by the corresponding c-measure.

Theorem 16 *Let $\mathfrak{C}_{f,g} : \mathfrak{Ffin} \to \mathfrak{N}$ be a c-measure determined by $\odot$- and $\overline{\odot}_d$-homomorphisms f and g, respectively, $A, B \in \mathfrak{Ffin}$ and $h \in \mathrm{Bij}(A, B)$. Then*

$$a_{gh} \odot a_{fh} \leq [\mathfrak{C}_{f,g}(A) \approx \mathfrak{C}_{f,g}(B)], \tag{36}$$

where a_{gh} and a_{fh} are the degrees in which h is a one-to-one mapping of $g(A)$ and $f(A)$ onto $g(B)$ and $f(B)$, respectively.

A straightforward consequence of the previous theorem is the following corollary.

Corollary 17 *Let $f : L \to L$ be a $\odot$-homomorphism and $g : L \to L$ be a $\overline{\odot}_d$-homomorphism. Then*

(i) $[f(A) \sim^{\odot} f(B)] \leq [\mathfrak{C}_f(A) \approx \mathfrak{C}_f(B)]$,
(ii) $[g(A) \sim^{\odot} g(B)] \leq [\mathfrak{C}_g(A) \approx \mathfrak{C}_g(B)]$

hold for any $A, B \in \mathfrak{Ffin}$.

Let $\mathbf{L}$ be a complete rdr-lattice and $h : L \to L$ be a mapping. We shall say that h is $(k, \odot)$-compatible with $\leftrightarrow$, if

$$\underbrace{(a \leftrightarrow b) \odot \cdots \odot (a \leftrightarrow b)}_{\text{k-times}} \leq h(a) \leftrightarrow h(b). \tag{37}$$

Obviously, h is $(k, \wedge)$-compatible with $\leftrightarrow$, if $(a \leftrightarrow b) \leq h(a) \leftrightarrow h(b)$. For example, $h(a) = (\neg a)^k$ is $(k, \otimes)$-compatible with $\leftrightarrow$.

Corollary 18 *Let $\mathfrak{C}_{f,g} : \mathfrak{Ffin} \to \mathfrak{N}$ be a c-measure determined by $\odot$- and $\overline{\odot}_d$-homomorphisms f and g which are $(k, \odot)$- and $(l, \odot)$-compatible with $\leftrightarrow$, respectively, $A, B \in \mathfrak{Ffin}$ and $h \in \mathrm{Bij}(A, B)$. Then*

$$a_h^{k+l} \leq [\mathfrak{C}_{f,g}(A) \approx \mathfrak{C}_{f,g}(B)], \tag{38}$$

where a_h is the degree in which h is a one-to-one mapping of A onto B and $a^n = a$ for $\odot = \wedge$. Especially, we have

$$(A \sim^{\odot} B)^k \leq [\mathfrak{C}_f(A) \approx \mathfrak{C}_f(B)] \tag{39}$$
$$(A \sim^{\odot} B)^l \leq [\mathfrak{C}_g(A) \approx \mathfrak{C}_g(B)], \tag{40}$$

where $a^n = a$ for $\odot = \wedge$.

In the previous section, we have introduce the fuzzy classes $p_A^{\odot}$ and $p_A^{\overline{\odot}}$. The following theorems show the relation between the c-measures and some expressions obtained by the fuzzy sets $p_A^{\odot}(-, y)$ and $p_A^{\overline{\odot}}(-, y)$.

Theorem 19 *Let $\mathfrak{C}_{f,g} : \mathfrak{Ffin} \to \mathfrak{N}$ be a c-measure determined by $\odot$- and $\overline{\odot}_d$-homomorphisms f and g, respectively, $A \in \mathfrak{Ffin}$ and $y \in \mathfrak{Fin}$ such that $\mathrm{Supp}(A) \subseteq y$ and $|y| = m$. Then*

$$\mathfrak{C}_{f,g}(A)(i) \leq g(p_A^{\overline{\odot}}(m - i, y)) \odot f(p_A^{\odot}(i, y)) \tag{41}$$

holds for any $i = 0, \ldots, m$.

Theorem 20 *Let $\mathbf{L}$ be linearly ordered, $\mathfrak{C}_{f,g} : \mathfrak{Ffin} \to \mathfrak{N}$ be a c-measure determined by $\odot$- and $\overline{\odot}_d$-homomorphisms f and g, respectively, $A \in \mathfrak{Ffin}$ and $y \in \mathfrak{Fin}$ such that $\mathrm{Supp}(A) \subseteq y$ and $|y| = m$. Then*

$$\mathfrak{C}_{f,g}(A)(i) = g(p_A^{\overline{\odot}}(m - i, y)) \odot f(p_A^{\odot}(i, y)), \tag{42}$$
$$\mathfrak{C}_{f,g}(A)(i) = p^{\overline{\odot}}_{g(A) \cap y}(m - i, y) \odot p^{\odot}_{f(A)}(i, y) \tag{43}$$

hold for any $i = 0, \ldots, m$ and $\mathfrak{C}_{f,g}(A)(i) = f(\bot)$ for any $i > m$.

Corollary 21 *Let $\mathbf{L}$ be linearly ordered, $\mathfrak{C}_{f,g} : \mathfrak{Ffin} \to \mathfrak{N}$ be a c-measure determined by $\odot$- and $\overline{\odot}_d$-homomorphisms f and g, respectively, and $A \in \mathfrak{Ffin}$ such that $|\mathrm{Supp}(A)| = m$. Then*

$$\mathfrak{C}_{f,g}(A)(i) = g(p_A^{\wedge}(i + 1)) \wedge f(p_A^{\wedge}(i)) \tag{44}$$

holds for any $i = 0, \ldots, m$ and $\mathfrak{C}_{f,g}(A)(i) = f(\bot)$ for any $i > m$, where $p_A^{\wedge}(i) = p_A^{\wedge}(i, \mathrm{Supp}(A))$ for any $i \in \mathbb{N}$.

In the following example, we shall introduce three c-measures based on Theorem 20.

Example 5 Let us suppose that the membership degrees of fuzzy sets are interpreted in the Goguen rdr-lattice $\mathbf{L}_{\mathrm{P}}$ or Łukasiewicz rdr-lattice $\mathbf{L}_{\mathrm{Ł}}$ (see Ex. 1) and

$$A = \{0.5/x_1, 0.2/x_2, 0.9/x_3, 1/x_4,$$
$$0.8/x_5, 0.9/x_6, 1/x_7, 0.6/x_8\}$$

is a finite fuzzy set. Further, let us define $f, g : [0, 1] \to [0, 1]$ by $f(a) = a$ (the identity mapping) and $g(a) = 1 - a$ for any $a \in [0, 1]$. Obviously, both mappings are homomorphisms

between the corresponding structures. Let us put $\odot = T_{\mathrm{M}}$, $\odot = T_{\mathrm{P}}$ and $\odot = T_{\mathrm{L}}$ (the minimum, product and Łukasiewicz conjunction). Then we can construct three c-measures of finite fuzzy sets denoted by $\mathfrak{C}_{T_{\mathrm{M}}}$, $\mathfrak{C}_{T_{\mathrm{P}}}$ and $\mathfrak{C}_{T_{\mathrm{L}}}$. In particular, if T is one of the mentioned t-norms, then c-measure determined by the corresponding homomorphisms has the following form (due to Theorem 20)

$$\mathfrak{C}_T(A)(i) = T(1 - p_A^S(8-i, y), p_A^T(i, y)), \tag{45}$$

where $y = \{x_1, \ldots, x_8\}$, S is the corresponding t-conorm to T and $i = 1, \ldots, 8$. One can simply verify that $p_A^T(-, y)$ and $p_A^S(-, y)$ can be expressed by

$$p_A^T(i, y) = T(p_A^{T_{\mathrm{M}}}(0), \ldots, p_A^{T_{\mathrm{M}}}(i)),$$
$$p_A^S(i, y) = S(p_A^{S_{\mathrm{M}}}(0), \ldots, p_A^{S_{\mathrm{M}}}(i)),$$

where S_M denotes the maximum, for any $i = 0, \ldots, 8$, and $p_A^T(i, y) = \bot$ and $p_A^T(i, y) = \top$ for any $i \in \mathbb{N}$ such that $i > 8$ (see Lemmas 5 and 9). Hence, we can write the sequences

$$p_A^{T_{\mathrm{M}}} = \{1, 1, 1, 0.9, 0.9, 0.8, 0.6, 0.5, 0.2, 0, 0, \cdots\},$$
$$p_A^{S_{\mathrm{M}}} = \{0, 0.2, 0.5, 0.6, 0.8, 0.9, 0.9, 1, 1, 1, 1, \cdots\}$$

and, after a simple computation, we obtain

$$\mathfrak{C}_{T_{\mathrm{M}}}(A) = \{0/0{,}0/1, 0.1/2, 0.1/3, 0.2/4, 0.4/5, 0.5/6, 0.5/7, 0.2/8, 0/9, \ldots\},$$

$$\mathfrak{C}_{T_{\mathrm{P}}}(A) = \{0/0{,}0/1, 0.00032/2, 0.00288/3, 0.02592/4, 0.10368/5{,}0.15552/6, 0.15552/7, 0.03888/8, 0/9, \ldots\},$$

$$\mathfrak{C}_{T_{\mathrm{L}}}(A) = \{0/0{,}0/1, 0/2, 0/3, 0/4, 0/5, 0/6, 0/7, 0/8, \ldots\}.$$

Up till now all relationships between the graded equipollence and the similarity of c-measures of finite fuzzy sets have been in the form of the inequality. The following corollary shows that the equality can arise only in very special cases.

COROLLARY 22 *Let* $\mathbf{L}$ *be linearly ordered and* $\mathfrak{C}_{f,g} : \mathfrak{Fin} \to \mathfrak{Count}$ *be a c-measure determined by* $\odot$*- and* $\overline{\odot}_{\mathrm{d}}$*-homomorphisms* f *and* g*, respectively. Then*

$$(g(A) \sim^{\odot} g(B)) \odot (f(A) \sim^{\odot} f(B)) \leq [\mathfrak{C}_{f,g}(A) \approx \mathfrak{C}_{f,g}(B)] \tag{46}$$

for any $A, B \in \mathfrak{Fin}$*. Especially, we have*

$$g(A) \sim^{\wedge} g(B) = [\mathfrak{C}_g(A) \approx \mathfrak{C}_g(B)], \tag{47}$$
$$f(A) \sim^{\wedge} f(B) = [\mathfrak{C}_f(A) \approx \mathfrak{C}_f(B)] \tag{48}$$

for any $A, B \in \mathfrak{Fin}$*.*

VI. CONCLUSION

In this paper, we presented two approaches to the cardinality of finite fuzzy sets. In the first approach, the cardinality of fuzzy sets was expressed using the fuzzy (class) relation called the graded equipollence. In the second one, the number of elements in fuzzy sets was obtained by a fuzzy c-measure with respect to an operation $\odot$ as a generalized cardinal. Although, both approaches seem to be different, we showed that there exist several natural relations between them. Nevertheless, a desired relation which interconnects both approaches analogously to the classical relations between the equipollence of finite sets and finite ordinals can be proved only in the special cases, when $\odot = \wedge$ and some other presumptions on the form of fuzzy c-measures have to be satisfied (see Corollary 22).

***Abstract*—In this contribution, we study a very important semantic property of generalized quantifiers called the monotonicity for fuzzy quantifiers of type $\langle 1, 1\rangle$ defined using fuzzy measures and Sugeno type of fuzzy integrals. We show that fuzzy integrals can ensure under some natural conditions the monotonicity of fuzzy quantifiers. Finally, we propose the concept of concave fuzzy quantifiers and prove that each concave fuzzy quantifier is expressible as the conjunction of a non-increasing and a non-decreasing fuzzy quantifier.**

***Index Terms*—fuzzy quantifier; fuzzy measure; residuated lattice operation; monotonicity of fuzzy quantifiers**

I. Introduction

This contribution continues our study of semantic properties of type $\langle 1, 1\rangle$ fuzzy quantifiers defined by fuzzy integrals published in [7] (see also [4]) and presents some results on the monotonicity which belongs among the basic semantic properties as, e.g., the isomorphism invariance, extension, conservativity, investigated in the theory of generalized quantifiers (Boolean theory) as well as fuzzy quantifiers theory (many valued theory). For more information, we refer to [8], [13], [26].

Generalized quantifiers evolved, from pioneering works of Mostowski [20], Lindström [17], Barwise and Cooper [1], into quite large research field with deep results. For overview as well as new results see the recent monograph [26].

Research in the field of fuzzy quantifiers started with works of Zadeh [31], Thiele [29], Ralescu [28] and others, see also [18], [19], [22]. Important contribution was made by Hájek in [12], where he considers especially quantifier "many" using relative frequencies. He also points out interconnections between generalized quantifiers and modalities. A comprehensive study of fuzzy quantifiers was undertaken by Glöckner [8] (see also [9]). In paper [24], Novák studies so-called intermediate quantifiers, mainly from syntactic point of view in the frame of fuzzy type theory [23]. This research has been continued in [21], where all of generalized Aristotelian syllogisms (from Peterson's book [27]) has been syntactically proved using slightly different definition of fuzzy quantifiers than ours.

The semantic interpretation of many generalized quantifiers is often connected to measurement of "size" of sets in concern. Consider e.g. the quantifier "many". The truth value of proposition "many books have a red cover" clearly depends on the "size" of the set of red books. Therefore, it is natural to consider measures (and integrals) of (fuzzy) sets as natural tools for the modeling of important classes of generalized quantifiers. This motivated us to introduce fuzzy quantifiers of type $\langle 1\rangle$, which are denotations of important noun phrases of natural language, e.g. "something" in "Something is broken.", "everyone" in "Everyone likes Bob.", "nobody" in "Nobody knows everything.", using tools of fuzzy measure theory ([30], see also [10], [15]). More precisely, we used a Sugeno type of fuzzy integrals and defined fuzzy integrals of type $\langle 1\rangle$ in [5].

A natural extension of this research was to study quantifiers of type $\langle 1, 1\rangle$, e.g. "every" in "Every book has leaves.", "most" in "Most birds fly.", which take two arguments. These type $\langle 1, 1\rangle$ quantifiers are claimed to be the most important from the point of view of natural language semantics [26]. To introduce this type of fuzzy quantifiers by fuzzy integrals, we had to work with slightly different definition of fuzzy measures and integrals than in [5]. Note that the first argument of $\langle 1, 1\rangle$ quantifier is called *restriction* and the second one is *scope* (i.e., in "Every book has leaves", "to be a book" is the restriction and "to have leaves" is the scope). It is natural to think of the restriction as of a *new universe* for the quantifier (in our example, for the determination of truth value of this sentence, only these objects fulfilling the restriction condition are important, i.e., books). Because we are working with fuzzy subsets of some universe M, we in effect should be able to define quantifiers on *fuzzy universes*. Therefore, we defined a new type of fuzzy measure spaces on algebras of subsets of a *fuzzy* set A and a fuzzy integral on these fuzzy measure spaces (see [3], [6], [7]).

In [5], we have showed that type $\langle 1\rangle$ fuzzy quantifiers determined by fuzzy measures are monotone fuzzy quantifiers. The type of monotonicity, i.e., whether a fuzzy quantifier is monotone increasing (non-decreasing) or monotone decreasing (non-increasing), depends on the type of the fuzzy integral,[1] e.g., the fuzzy quantifier "many" defined using a fuzzy measure is monotone increasing, but the fuzzy quantifier "few" defined using complementary fuzzy measure is monotone decreasing. For type $\langle 1, 1\rangle$ fuzzy quantifiers, the situation is more complicated, since operations between restriction and scope are used in our modeling.

[1] In [5], we proposed two types of fuzzy integrals defined on fuzzy and complementary fuzzy measure spaces to model, e.g., "many" and "few". Note that under some conditions both types can be interconnected by the operation of negation.

The paper is structured as follows. In the following section, we recall basic notions from the fuzzy set theory and fuzzy measures and integrals. The third section is devoted to the residuated lattice operations using them operations between fuzzy sets are defined. Such operations between fuzzy sets are subsequently used as a means for a combination of two arguments of type $\langle 1,1\rangle$ fuzzy quantifiers. Fuzzy quantifiers defined using fuzzy integrals are introduced in the fourth section. The monotonicity of fuzzy quantifiers is studied in the fifth section. The last section is a conclusion.

II. Preliminaries

A. Structures of truth values

In this paper, we suppose that the structure of truth values is a *complete residuated lattice* (see e.g. [2]), i.e., an algebra $\mathbf{L} = \langle L, \wedge, \vee, \to, \otimes, \bot, \top\rangle$ with four binary operations and two constants such that $\langle L, \wedge, \vee, \bot, \top\rangle$ is a complete lattice, where $\bot$ is the least element and $\top$ is the greatest element of L, respectively, $\langle L, \otimes, \top\rangle$ is a commutative monoid (i.e., $\otimes$ is associative, commutative and the identity $a \otimes \top = a$ holds for any $a \in L$) and the adjointness property is satisfied, i.e.,

$$a \le b \to c \quad \text{iff} \quad a \otimes b \le c \tag{1}$$

holds for each $a, b, c \in L$, where $\le$ denotes the corresponding lattice ordering. A residuated lattice is *divisible*, if $a \otimes (a \to b) = a \wedge b$ holds for arbitrary $a, b \in L$, and satisfies the *law of double negation*, if $(a \to \bot) \to \bot = a$ holds for any $a \in L$. A divisible residuated lattice satisfying the law of double negation is called an *MV-algebra*. For more information about residuated lattices we refer to [2], [25].

Example 1 One can easily prove (see also [12]) that the algebra

$$\mathbf{L}_{\mathrm{T}} = \langle [0,1], \min, \max, T, \to_T, 0, 1\rangle,$$

where T is a left continuous t-norm and $a \to_T b = \bigvee\{c \in [0,1] \mid T(a,c) \le b\}$ defines the residuum, is a complete residuated lattice. Moreover, if T is the Łukasiewicz t-norm, i.e., $T(a,b) = \max(a+b-1, 0)$ for all $a, b \in [0,1]$, then $\mathbf{L}_{\mathrm{T}}$ is a complete MV-algebra called a *Łukasiewicz algebra (on* $[0,1]$*)*.

Let us define two additional operations for all $a, b \in L$:

$$a \leftrightarrow b = (a \to b) \wedge (b \to a), \qquad \text{(\textit{biresiduum})}$$
$$\neg a = a \to \bot. \qquad \text{(\textit{negation})}$$

B. Fuzzy sets

Let $\mathbf{L}$ be a complete residuated lattice and M be a universe of discourse (possibly empty). A mapping $A : M \to L$ is called an *fuzzy set on* M. A value $A(m)$ is called a *membership degree of* m *in the fuzzy set* A. The set of all fuzzy sets on M is denoted by $\mathcal{F}(M)$. Obviously, if $M = \emptyset$, then the empty mapping $\emptyset$ is the unique fuzzy set on $\emptyset$ and thus $\mathcal{F}(\emptyset) = \{\emptyset\}$. A fuzzy set A on M is called *crisp*, if there is a subset X of M such that $A = 1_X$, where 1_X denotes the characteristic function of X. Particularly, $1_\emptyset$ denotes the empty fuzzy set on M, i.e., $1_\emptyset(m) = \bot$ for any $m \in M$. This convention will be also kept for $M = \emptyset$. The set of all crisp fuzzy sets on M is denoted by $\mathcal{P}(M)$. A fuzzy set A is *constant*, if there is $c \in L$ such that $A(m) = c$ for any $m \in M$. For simplicity, a constant fuzzy set is denoted by the corresponding element of L, e.g., a, b, c.[2] Let us denote $\mathrm{Supp}(A) = \{m \mid m \in M \ \&\ A(m) > \bot\}$ and $\mathrm{Core}(A) = \{m \mid m \in M \ \&\ A(m) = \top\}$ the *support* and *core* of a fuzzy set A, respectively. Obviously, $\mathrm{Supp}(1_X) = \mathrm{Core}(1_X) = X$ for any crisp fuzzy set. A fuzzy set A is called *normal*, if $\mathrm{Core}(A) \neq \emptyset$.

Let $\{A_i \mid i \in I\}$ be a non-empty family of fuzzy sets on M. Then the *union of* A_i is defined by

$$\left(\bigcup_{i\in I} A_i\right)(m) = \bigvee_{i\in I} A_i(m) \tag{2}$$

for any $m \in M$ and the *intersection of* A_i is defined by

$$\left(\bigcap_{i\in I} A_i\right)(m) = \bigwedge_{i\in I} A_i(m) \tag{3}$$

for any $m \in M$. Let A, B be fuzzy sets on M. The *difference* of A and B is a fuzzy set $A \setminus B$ on M defined by

$$(A \setminus B)(m) = A(m) \otimes (B(m) \to \bot) \tag{4}$$

for any $m \in M$ and the *complement* of A is a fuzzy set $\overline{A} = 1_M \setminus A$. Finally, an extension of the operations $\otimes$ and $\to$ on L to the operations on $\mathcal{F}(M)$ is given by

$$(A \otimes B)(m) = A(m) \otimes B(m), \tag{5}$$
$$(A \to B)(m) = A(m) \to B(m) \tag{6}$$

for any $A, B \in \mathcal{F}(M)$ and $m \in M$, respectively.

Since we will deal with fuzzy sets over different universes, let us introduce the ordering relation between fuzzy sets on arbitrary universes. We say that a fuzzy set A on M is an *fuzzy subset of* a fuzzy set B on M' and denote by $A \subseteq B$, if $A(m) \le B(m)$ for any $m \in \mathrm{Supp}(A)$. The set of all fuzzy subsets of A on M is denoted by $\mathcal{F}(A)$. Thus

$$\mathcal{F}(A) = \{B \mid B \in \mathcal{F}(M) \text{ and } B \subseteq A\}. \tag{7}$$

Further, we say that a fuzzy set A on M is *equal* to a fuzzy set B on M' and denote by $A = B$, if $A \subseteq B$ and $B \subseteq A$. Obviously, if A and B are fuzzy sets on the same universe M, then the proposed relations coincide with the common definitions of the ordering and equality relations.

C. Fuzzy measures and integrals

In the following, we will consider algebras of fuzzy sets as a base for defining fuzzy measures of fuzzy sets.

Definition 1 Let A be a non-empty fuzzy set on M. A subset $\mathcal{F}$ of $\mathcal{F}(A)$ is an *algebra of fuzzy sets on* A, if the following conditions are satisfied

[2]We suppose that the meaning of this symbol will be unmistakable from the context, that is, it should be clear when an element of L is considered and when a constant fuzzy set is assumed.

(i) $1_\emptyset, A \in \mathcal{F}$,
(ii) if $X \in \mathcal{F}$, then $A \setminus X \in \mathcal{F}$,
(iii) if $X, Y \in \mathcal{F}$, then $X \cup Y \in \mathcal{F}$.

We denote $\mathbf{Alg}(A)$ the set of all algebras of fuzzy sets on A. A pair $(A, \mathcal{F})$ is called a *fuzzy measurable space* (on A), if $\mathcal{F}$ is an algebra of fuzzy sets on A. Let $(A, \mathcal{F})$ be a fuzzy measurable space and $X \in \mathcal{F}(A)$. We say that X is $\mathcal{F}$-*measurable*, if $X \in \mathcal{F}$.

REMARK 2 In order to refer to the universe of discourse M of A, we will sometimes write $\mathrm{Dom}(A)$ instead of M.

REMARK 3 For a non-empty set M, one checks easily that the proposed definition of algebra of fuzzy sets on 1_M coincides with the standard definition of algebra of fuzzy sets on M (cf. [30]).

EXAMPLE 4 $\{1_\emptyset, A\}$ and $\mathcal{F}(A)$ are trivial examples of algebras of fuzzy sets on A. The set of all crisp subsets of a fuzzy set A is not, in general, an algebra of fuzzy sets on A.

Let us introduce the concept of fuzzy measure as follows. The definition is a modification of the definition of a normed measure with respect to truth values (see e.g. [10]).

DEFINITION 2 Let $(A, \mathcal{F})$ be a fuzzy measurable space. A mapping $\mu : \mathcal{F} \to L$ is called a *fuzzy measure* on $(A, \mathcal{F})$, if
(i) $\mu(1_\emptyset) = \bot$ and $\mu(A) = \top$,
(ii) if $B, C \in \mathcal{F}$ such that $B \subseteq C$, then $\mu(B) \leq \mu(C)$.
A triplet $(A, \mathcal{F}, \mu)$ is called the *fuzzy measure space*, if $(A, \mathcal{F})$ is a fuzzy measurable space and μ is a fuzzy measure on $(A, \mathcal{F})$.

In the following text, a fuzzy measure space $(A, \mathcal{F}, \mu)$ may be shortly denoted by the same bold symbol $\mathbf{A}$, i.e. $\mathbf{A} = (A, \mathcal{F}, \mu)$. We denote $\mathbf{Fms}(M)$ the class of all fuzzy measure spaces defined on a non-empty universe M, i.e. a fuzzy measure space $(A, \mathcal{F}, \mu)$ belongs to $\mathbf{Fms}(M)$, if $A \in \mathcal{F}(M)$.

EXAMPLE 5 Let $\mathbf{L}_\mathrm{T}$ be an algebra from Example 1, where T is a continuous t-norm. Let M be a finite non-empty set and $A \in \mathcal{F}(M)$, $A \neq 1_\emptyset$. Then we can define fuzzy measure space $\mathbf{A}^\sigma = (A, \mathcal{F}(A), \mu^\sigma)$, where

$$\mu^\sigma(X) = \frac{\sum_{m \in M} X(m)}{\sum_{m \in M} A(m)}$$

for all $X \in \mathcal{F}(A)$. For motivation and more general definition of this fuzzy measure, we refer to Example 3.5 of our paper [5].

Now, we can introduce a type of fuzzy integral that is definable on an arbitrary fuzzy measure space $(A, \mathcal{F}, \mu)$. The integrated functions are fuzzy sets on $\mathrm{Dom}(A)$. For a convention with the classical measure theory, we will prefer, in this part, the denotation f, g for the integrated functions instead of X, Y. This integral is defined over a general operation $\odot$ which substitutes one of the operations $\wedge$ and $\otimes$, i.e., $\odot \in \{\wedge, \otimes\}$. This integral will be used as a basis for the definition of fuzzy quantifiers of type $\langle 1, 1\rangle$ determined by fuzzy measures.

DEFINITION 3 Let $(A, \mathcal{F}, \mu)$ be a fuzzy measure space with $M = \mathrm{Dom}(A)$, $f : M \to L$ be a mapping and X be an $\mathcal{F}$-measurable fuzzy set. Then $\odot$-fuzzy integrals of f on X is given by

$$\int_X^\odot f \, d\mu = \bigvee_{Y \in \mathcal{F}_X^-} \bigwedge_{m \in \mathrm{Supp}(Y)} (f(m) \odot \mu(Y)), \qquad (8)$$

where $\mathcal{F}_X^- = \{Y \mid Y \in \mathcal{F} \text{ and } 1_\emptyset \neq Y \subseteq X\}$. If $X = A$, then we write $\int^\odot f \, d\mu$.

One may see that no measurability of the mapping f is supposed in the definition, in contrast to the standard definition of fuzzy integral (cf. [16], [15]).

III. OPERATIONS BETWEEN FUZZY SETS DETERMINED BY RL-OPERATIONS

In this section, we will define so-called residuated lattice (rl-)operations and operations between fuzzy sets determined by them, which will subsequently be used as a means for a combination of two arguments (the restriction and scope, see Introduction) of a type $\langle 1, 1\rangle$ fuzzy quantifier. For example, the standard quantifier some is defined using the intersection operation, i.e.,

$$\mathsf{some}(A, B) = \bigvee_{m \in M} (A \cap B)(m), \qquad (9)$$

and every by the residuum operation $\to$, i.e.,

$$\mathsf{every}(A, B) = \bigwedge_{m \in M} (A \to B)(m). \qquad (10)$$

Hence, for the modeling of various natural language quantifiers we need different operations on fuzzy sets (cf. [11]).

DEFINITION 4 Let L be a set of constants. The set $\mathbf{P}(L)$ of *binary (residuated lattice) polynomials* with constants from L is the smallest set satisfying the following conditions
(i) $c \in \mathbf{P}(L)$ for any $c \in L$,
(ii) $x, y \in \mathbf{P}(L)$,
(iii) if $\psi_1, \psi_2 \in \mathbf{P}(L)$, then $\psi_1 \,\square\, \psi_2 \in \mathbf{P}(L)$ for any $\square \in \{\wedge, \vee, \otimes, \to\}$.

REMARK 6 In the previous definition, we refer the polynomials to a set L of constants. In our work, the set L will be identified with a support of a residuated lattice to deal with its elements and, hence, to extend the scale of models of fuzzy quantifiers.

Polynomials are abstract expressions of functions in all residuated lattices in which the considered constants are interpretable. As we have mentioned above, we identify a set L of

constants with a support L of a residuated lattice. Thus, if we write $\mathbf{P}(L)$, then we understand that all values of the support L are constants used in the constructions of polynomials of $\mathbf{P}(L)$. For simplicity, the support of a residuated lattice will be always denoted by the italic letter corresponding to the bold denotation of the residuated lattice. For example, the support of $\mathbf{L}$ is denoted by L. Using polynomials we can define operations on residuated lattices as follows (cf. [11]).

DEFINITION 5 Let $\mathbf{L}$ be a residuated lattice (with the support L). A binary residuated lattice polynomial $\psi \in \mathbf{P}(L)$ defines a binary *residuated lattice operation* (shortly rl-operation) on L by the following rules ($a, b, c \in L$)

(i) if $\psi = c$, then $\psi(a, b) = c$,
(ii) if $\psi = x$ or $\psi = y$, then $\psi(a, b) = a$ or $\psi(a, b) = b$, respectively,
(iii) if $\psi = \psi_1 \,\square\, \psi_2$, then $\psi(a, b) = \psi_1(a, b) \,\square\, \psi_2(a, b)$ for any operation $\square \in \{\wedge, \vee, \otimes, \rightarrow\}$.

The set of all rl-operations in a residuated lattice $\mathbf{L}$ will be denoted by $\mathbf{Ldo}(\mathbf{L})$ or shortly $\mathbf{Ldo}$, if the residuated lattice $\mathbf{L}$ is unmistakably determined by the context and thus no confusion can occur.

DEFINITION 6 Let $\psi_1, \psi_2 \in \mathbf{P}(L)$. We say that ψ_1 *is equal to* ψ_2 *in* $\mathbf{L}$ and denote it by $\psi_1 = \psi_2$, if $\psi_1(a, b) = \psi_2(a, b)$ holds for any $a, b \in L$.

EXAMPLE 7 The unary operation of the negation can be defined by the polynomial $\psi_1 = x \rightarrow \bot$ and thus $\neg a = \psi_1(a, b) = a \rightarrow \bot$ for any $a, b \in L$. The binary operation of the meet can be obtained from the polynomial $\psi_2 = x \wedge y$ and thus, $\psi_2(a, b) = a \wedge b$ for any $a, b \in L$. The difference between a and b can be defined using $\psi_3 = x \otimes (y \rightarrow \bot)$ and $a \setminus b = \psi_3(a, b) = a \otimes (b \rightarrow \bot)$.

DEFINITION 7 Let M be a non-empty universe and $\psi \in \mathbf{Ldo}(\mathbf{L})$. We say that an operation $\varphi_M : \mathcal{F}(M) \times \mathcal{F}(M) \rightarrow \mathcal{F}(M)$ is *determined by* ψ, if

$$\varphi_M(A, B)(m) = \psi(A(m), B(m)) \tag{11}$$

holds for any $A, B \in \mathcal{F}(M)$ and $m \in M$.

In this paper, we will suppose that all operations between fuzzy sets are determined by rl-operations.

IV. TYPE $\langle 1, 1\rangle$ FUZZY QUANTIFIERS DETERMINED BY $\odot$-FUZZY INTEGRALS

This section is devoted to fuzzy quantifiers that are defined using fuzzy measures and integrals introduced in [3] and summarized in Subsection II-C. Before commencing our introduction of fuzzy quantifiers, let us recall a common definition of limited and unlimited type $\langle 1, 1\rangle$ fuzzy quantifiers presented in [8], [9], [13].

In general, a mapping $Q_M : \mathcal{F}(M) \times \mathcal{F}(M) \rightarrow L$ is called the *monadic fuzzy quantifier of type* $\langle 1, 1\rangle$ *limited to* M, where M is a (possibly empty[3]) universe. A value of a fuzzy quantifier on fuzzy sets $A, B \in \mathcal{F}(M)$ is written as $Q_M(A, B)$.[4] A type $\langle 1, 1\rangle$ *unlimited (finite, countable) monadic fuzzy quantifier* is a functional Q assigning to each (finite, countable) universe M a type $\langle 1, 1\rangle$ monadic fuzzy quantifier Q_M limited to M.

In order to define fuzzy quantifiers determined by fuzzy measures in a reasonable generality, let us consider a functional $\mathcal{S}$ assigning to each non-empty universe M a mapping

$$\mathcal{S}(M) : \mathcal{F}(M) \times \mathcal{F}(M) \rightarrow \mathbf{Fms}(M). \tag{12}$$

For example, we can define $\mathcal{S}(M)(A, B) = (M, \mathcal{M}, \mu)$, where $(M, \mathcal{M}, \mu)$ is an arbitrary fuzzy measure space from $\mathbf{Fms}(M)$. One can see that $\mathcal{S}(M)$ is a constant mapping and the fuzzy sets A, B do not play any role in this definition. Further examples are $\mathcal{S}(M)(A, B) = (A, \mathcal{M}_A, \mu_A)$ or $\mathcal{S}(M)(A, B) = (A \cap B, \mathcal{M}_{A\cap B}, \mu_{A\cap B})$. Here, the fuzzy sets A, B have an active role in the definition of these fuzzy measure spaces.

To exclude a confusion, let us denote by

$$\int^{\odot}_{(A,\mathcal{F},\mu)} f \; d\mu \quad \text{or simply} \quad \int^{\odot}_{\mathbf{A}} f \; d\mu$$

the fuzzy integral from Subsection II-C defined on a fuzzy measure space $\mathbf{A} = (A, \mathcal{F}, \mu)$.

DEFINITION 8 Let M be a non-empty universe, $\mathcal{S}(M)$ be a mapping of the form (12) and φ_M be an operation on $\mathcal{F}(M)$ determined by an rl-operation ψ. A *fuzzy quantifier of type* $\langle 1, 1\rangle$ *limited to* M *determined by* $(\mathcal{S}(M), \varphi_M)$ is a mapping

$$Q_M : \mathcal{F}(M) \times \mathcal{F}(M) \rightarrow L$$

defined by

$$Q_M(A, B) = \int^{\odot}_{\mathcal{S}(M)(A,B)} \varphi_M(A, B) \; d\mu. \tag{13}$$

Since there is no fuzzy measure space on the empty (fuzzy) set, an extension of limited quantifiers to quantifiers over arbitrary universes cannot comprise a reasonably general stipulation how the quantifiers have to look for the empty universe. Therefore, we omit this situation in the following definition and introduce unlimited fuzzy quantifiers determined by fuzzy measures for the non-empty universes, whereas these fuzzy quantifiers can take arbitrary values for the empty universe.

[3]To define the behavior of generalized quantifiers for the empty universe is important in some situations. It happens, for example, when we study type $\langle 1, 1\rangle$ quantifiers which are obtained from type $\langle 1\rangle$ quantifiers by means of *relativization*. Then it is vital to have values of e.g. $\mathsf{some}_\emptyset(1_\emptyset)$ defined, see discussion in [26], p. 137.

[4]Note that, in the literature (see e.g. [13], [26]), we can also find the denotation $Q_M(A)(B)$ to emphasize what is the property modifying a common noun like "*to be a young student*" (A) and what is the considered predicate like "*to have a good result*" (B) in the sentence "*Many young students have good results*". In this conception, a type $\langle 1, 1\rangle$ fuzzy quantifier limited to M is a mapping $Q_M : \mathcal{F}(M) \rightarrow [\mathcal{F}(M) \rightarrow L]$, where $[\mathcal{F}(M) \rightarrow L]$ denotes the set of all mappings (type $\langle 1\rangle$ fuzzy quantifiers) of $\mathcal{F}(M)$ to L characterizing the predicates like "*to have a good result*".

DEFINITION 9 Let $\mathcal{S}$ and φ be functionals assigning to each non-empty universe M a mapping $\mathcal{S}(M)$ of the form (12) and an operation φ_M determined by an rl-operation ψ, respectively. An *unlimited fuzzy quantifier of type* $\langle 1,1\rangle$ *determined by* $(\mathcal{S},\varphi)$ is an unlimited fuzzy quantifier Q of type $\langle 1,1\rangle$ assigning a fuzzy quantifier Q_M limited to M determined by $(\mathcal{S}(M),\varphi_M)$ to each *non-empty* universe M.

Let us consider the sentence *"Many young students have good results"*,. Obviously, the fuzzy quantifier "many" expresses a quantity on the fuzzy set of "young students" and would be independent, in some sense, from the property "to have good results". More precisely, if we replace the property "to have good results" by "to have bad results", the interpretation of the fuzzy quantifier "many" would stay the same. This motivate us to establish the fuzzy quantifiers definable by fuzzy measures as follows.

DEFINITION 10 We say that an unlimited fuzzy quantifier Q is *definable by fuzzy measures*, if there exists a pair of functionals $(\mathcal{S},\varphi)$ such that Q is determined by $(\mathcal{S},\varphi)$ and $\mathcal{S}(M)(A,-)$ is a constant mapping for any non-empty universe M and $A\in\mathcal{F}(M)$.

REMARK 8 We can see that the class of fuzzy quantifiers definable by fuzzy measures is a subclass of the class of fuzzy quantifiers determined by $(\mathcal{S},\varphi)$. Hence, if a property is satisfied by fuzzy quantifiers determined by $(\mathcal{S},\varphi)$, then it is also satisfied by fuzzy quantifiers definable by fuzzy measures. In what follows, we will usually formulate statements for fuzzy quantifiers determined by $(\mathcal{S},\varphi)$.

Before we show several examples and start our study of monotonicity of fuzzy quantifiers definable by fuzzy measures (or determined by a pair of functionals $(\mathcal{S},\varphi)$ in general), let us introduce two important notions saying when one fuzzy quantifier is less than or equal to the second one, and when two fuzzy quantifiers are equal.

DEFINITION 11 Let P,Q be two quantifiers. We say that Q is *less than or equal to* P and denote it by $Q\le P$, if

$$Q_M(A,B)\le P_M(A,B) \tag{14}$$

holds for arbitrary non-empty universe M and $A,B\in\mathcal{F}(M)$. Further, we say that Q is *equal to* P and denote it by $Q=P$, if $Q\le P$ and $P\le Q$.

A reason why the empty universe is omitted in the previous definition is that fuzzy quantifiers determined by $(\mathcal{S},\varphi)$ are not a priori defined for the empty universe. In the following part, for simplicity, we will write only "Q is determined by $(\mathcal{S},\varphi)$" instead of "Q is a fuzzy quantifier of type $\langle 1,1\rangle$ determined by $(\mathcal{S},\varphi)$".

EXAMPLE 9 Let M be a non-empty universe and $\mathcal{S}_i(M)(A,B)=\{(M,\mathcal{F}(M),\mu_i)\}$, where, for $i=1,2$, we have

$$\mu_1(X)=\begin{cases}\bot, & \text{if } X=1_\emptyset,\\ \top, & \text{otherwise}\end{cases} \tag{15}$$

and

$$\mu_2(X)=\begin{cases}\top, & \text{if } X=M,\\ \bot, & \text{otherwise.}\end{cases} \tag{16}$$

If Q is determined by (S_1,φ_1), where $\varphi_{M,1}(A,B)=A\cap B$, then $Q=\mathsf{some}$, i.e., it is the interpretation of the standard quantifier some A are B. If Q is determined by (S_2,φ_2) for all $M\neq\emptyset$, where $\varphi_{M,2}(A,B)=A\to B$, then it is equal to every.

EXAMPLE 10 Let φ be a functional assigning φ_M to each non-empty universe and $\mathcal{S}_i$, $i=1,2$, be functionals defined in the previous example. We may introduce "boundary" fuzzy quantifiers $\forall_\varphi$ and $\exists_\varphi$ as follows

$$\forall_{\varphi,M}(A,B)=\bigwedge_{m\in M}\varphi_M(A,B)(m), \tag{17}$$

$$\exists_{\varphi,M}(A,B)=\bigvee_{m\in M}\varphi_M(A,B)(m). \tag{18}$$

Obviously, $\mathsf{every}=\forall_\varphi$ for $\varphi_M(A,B)=A\to B$ and $\mathsf{some}=\exists_\varphi$ for $\varphi_M(A,B)=A\cap B$. One can see that $\forall_\varphi\le\exists_\varphi$.

EXAMPLE 11 Let $\mathbf{L}_Ł$ be the Łukasiewicz algebra from Example 1. Let M be a finite non-empty set and $A\in\mathcal{F}(M)$, $A\neq 1_\emptyset$ and $\mathbf{A}^\sigma=(A,\mathcal{F}(A),\mu^\sigma)$ be a fuzzy measure space from Example 5. Let us define $S(M)(A,B)=\mathbf{A}^\sigma$ for $A\neq 1_\emptyset$, $S(M)(1_\emptyset,B)=(M,\mathcal{F}(M),\mu_2)$ and $\varphi_M(A,B)=A\to B$. Then, for any $A,B\in\mathcal{F}(M)$, we may define an interpretation of fuzzy quantifier many as

$$\begin{aligned}Q_M^{\mathsf{many}}(A,B)&=\int^{\otimes}_{S(M)(A,B)}\varphi_M(A,B)\;d\mu^\sigma=\\ &=\int^{\otimes}_{(A,\mathcal{F}(A),\mu^\sigma)}A\to B\;d\mu^\sigma=\\ &=\bigvee_{Y\in\mathcal{F}(A)^-}(\mu^\sigma(Y)\otimes\bigwedge_{m\in\mathrm{Supp}(Y)}(A\to B)(m)),\end{aligned}$$

if $A\neq 1_\emptyset$, and $Q_M^{\mathsf{many}}(1_\emptyset,B)=1$.

EXAMPLE 12 We can construct important fuzzy quantifiers, e.g., *few, no, at most half, etc.*, from already defined quantifiers using so-called external and inner negations (see [13], Definition 14). Let Q be a fuzzy quantifier of type $\langle 1,1\rangle$. The external or inner negation of Q is the fuzzy quantifier $\sim Q$ or $Q\sim$ defined as $(Q\sim)_M(A,B)=\neg Q_M(A,B)$ or $(Q\sim)_M(A,B)=Q_M(A,\overline{B})$, respectively. Hence, we can define fuzzy quantifiers, e.g., $\mathsf{no}=\sim\mathsf{some}$ and $\mathsf{few}=\mathsf{many}\sim$, where some and many are defined in Examples 9 and 11, respectively.

V. MONOTONICITY

The concept of monotonic quantifiers belongs among the basic properties which is observed for a large scale of natural language quantifiers as *all, some, few, many, nearly all, at least five, at most ten* etc. Of course, not all fuzzy quantifiers are monotonic. Typical examples are *about half, at least one and at most ten*. The monotonicity for the type $\langle 1,1\rangle$ fuzzy quantifiers is defined as follows.[5]

DEFINITION 12 Let Q be a fuzzy quantifier. We say that Q is monotonically non-decreasing in its first (second) component, if

$$Q_M(A,C) \leq Q_M(B,C) \quad (Q_M(C,A) \leq Q_M(C,B)) \quad (19)$$

holds for any universe M, $A,B,C \in \mathcal{F}(M)$, $A \subseteq B$, and Q is monotonically non-increasing in its first (second) component, if

$$Q_M(A,C) \geq Q_M(B,C) \quad (Q_M(C,A) \geq Q_M(C,B)) \quad (20)$$

holds for any universe M, $A,B,C \in \mathcal{F}(M)$, $A \subseteq B$.

REMARK 13 Notice that the mentioned inequalities are trivially satisfied for the empty universe. Hence, the empty universe can be excluded from our investigation of the monotonicity of fuzzy quantifiers.

One can see that *all, some, many, at least k* are monotonically non-decreasing and *not all, no, few, at most k* are monotonically non-increasing in the second component. Analogously to [26], we will use, for simplicity, the denotation $\uparrow$Mon, $\downarrow$Mon and Mon$\uparrow$, Mon$\downarrow$ to denote that a fuzzy quantifier is monotonically non-decreasing, non-increasing in the first component and monotonically non-decreasing, non-increasing in the second component, respectively. Sometimes it is useful a combination of the previous denotations as $\uparrow$Mon$\downarrow$ saying that a quantifier is non-decreasing in the first component and non-increasing in the second one. In general, the monotonicity of fuzzy quantifiers determined by $(\mathcal{S},\varphi)$ is closely related to the monotonicity of φ. Let us denote the monotonicity of the functional φ analogously by Mon$\uparrow$, Mon$\downarrow$ and $\uparrow$Mon, $\downarrow$Mon and similarly for their combinations, e.g. $\uparrow$Mon$\downarrow$.

THEOREM 1 *A fuzzy quantifier definable by fuzzy measures determined by $(\mathcal{S},\varphi)$ is Mon$\uparrow$ (Mon$\downarrow$) if and only if φ is Mon$\uparrow$ (Mon$\downarrow$).*

Proof: Let Q be a fuzzy quantifier definable by fuzzy measures determined by $(\mathcal{S},\varphi)$ which is Mon$\uparrow$. Let M be a non-empty universe and suppose that φ_M is determined by an rl-operation ψ. From the definition of φ, one can derive that the monotonicity of ψ implies the same form of the monotonicity of φ. Moreover, if a and b denote the constant fuzzy sets in $\mathcal{F}(M)$ with values a and b, respectively, then we may write $\varphi(a,b)(m) = \psi(a,b)$ for any $m \in M$. Recall that $\mathcal{S}(A,-)$ is a constant mapping from $\mathcal{F}(M)$ to $\mathbf{Fms}(M)$. Let a,b,c be constant fuzzy sets such that $b \leq c$. Since $\int^{\odot} c\ d\mu = c$, we obtain

$$\psi(a,b) = \varphi_M(a,b)(m) = \int^{\odot}_{\mathcal{S}(M)(a,b)} \varphi_M(a,b)\ d\mu =$$

$$Q_M(a,b) \leq Q_M(a,c) =$$

$$\int^{\odot}_{\mathcal{S}(M)(a,c)} \varphi_M(a,c)\ d\mu = \varphi_M(a,c)(m) = \psi(a,c),$$

where m is an arbitrary element of M. Hence, ψ is a monotonically non-decreasing mapping and, from the consideration above, we obtain that φ is Mon$\uparrow$. Analogously, we can prove Mon$\downarrow$ of φ under the presumption that Q is Mon$\downarrow$.

The opposite implication is a trivial consequence of the fact that the fuzzy integral is a non-decreasing mapping. ■

In the previous theorem, we cannot suppose the cases of $\uparrow$Mon and $\downarrow$Mon, since $\mathcal{S}(M)(b,-)$ and $\mathcal{S}(M)(c,-)$ are different fuzzy measure spaces and thus the presented inequality cannot be guarantied here. Nevertheless, supposing that $\mathcal{S}(M)(-,-)$ is a constant mapping, we may state the analogous result also for $\uparrow$Mon and $\downarrow$Mon.

THEOREM 2 *A fuzzy quantifier determined by $(\mathcal{S},\varphi)$ such that $\mathcal{S}(-,-)$ is a constant mapping for any non-empty universe M is $\uparrow$Mon ($\downarrow$Mon) if and only if φ is $\uparrow$Mon ($\downarrow$Mon).*

Proof: This is analogous to the proof of the cases Mon$\uparrow$ and Mon$\downarrow$. ■

REMARK 14 It is easy to see that the operations $\wedge$, $\vee$, $\otimes$ are $\uparrow$Mon$\uparrow$ and $\rightarrow$ is $\downarrow$Mon$\uparrow$. One can simply verify that, for example, $\varphi_1 \Box \varphi_2$ is Mon$\uparrow$, whenever φ_1 and φ_2 are Mon$\uparrow$ and $\Box$ is $\uparrow$Mon$\uparrow$.

REMARK 15 Obviously, the external negation and the inner negation of fuzzy quantifiers mentioned in the first part of our contribution (see also [8], [9], [13], [14], [26]) change the polarity of monotonicity in both components and in the second component, respectively. For example, let us consider every and some defined in Example 3.2. of the first part. Then every is $\downarrow$Mon$\uparrow$ and some is $\uparrow$Mon$\uparrow$, but $\sim$every $=$ some$\sim$ $=$ not every is $\uparrow$Mon$\downarrow$ and every$\sim$ $=\sim$ some $=$ no is $\downarrow$Mon$\downarrow$.

In [5], we showed that each type $\langle 1\rangle$ fuzzy quantifier determined by a fuzzy measure lays among the fuzzy quantifiers all and some. The question is, which boundaries hold for fuzzy quantifiers determined by $(\mathcal{S},\varphi)$, especially, for fuzzy quantifiers definable by fuzzy measures.

THEOREM 3 *For each fuzzy quantifier Q determined by $(\mathcal{S},\varphi)$, we have $\forall_\varphi \leq Q \leq \exists_\varphi$.*

Proof: This is a straightforward consequence of the definition of fuzzy measures on which the fuzzy quantifiers $\forall_\varphi$ and $\exists_\varphi$ are defined. ■

[5] A more general definition for monadic fuzzy quantifiers of type $\langle 1^n,1\rangle$ can be found in [13]. .

Naturally, we can find out fuzzy quantifiers (definable by fuzzy measures) which are not monotonic. For example, let us consider the Łukasiewicz algebra and operations between fuzzy sets determined by the following rl-operations

$$\psi_1(a,b) = a \otimes (a \rightarrow (b \vee \neg b)),$$
$$\psi_2(a,b) = a \leftrightarrow b.$$

Then fuzzy quantifiers which use the operations ψ_1 and ψ_2 are not monotonic. In fact, it is sufficient to consider the constant fuzzy sets $0 \subset 0.5 \subset 1$ defined on a non-empty universe. Since $\int^{\odot} c \, d\mu = c$, we may write, for ψ_1,

$$Q_M(1,0) = Q_M(1,1) = 1 > 0.5 = Q_M(1,0.5)$$

and, for ψ_2,

$$Q_M(0.5,0) = Q_M(0.5,1) = 0.5 < 1 = Q_M(0.5,0.5).$$

The proposed operations could be used in the evaluation of the quantified sentences:

"Every students is or is not prepared on the exam."
"Only blondes are pretty."

Obviously, the first statement is trivially fulfilled in the classical logic, but practically there are many students who know something but we cannot say that they are perfectly prepared on the exam. Hence, this statement has a sense in fuzzy logic.

Although, we are able to find some "reasonable" models of non-monotonic linguistic quantifiers definable by fuzzy measures, much more natural it is to define non-monotonic fuzzy quantifiers as a conjunction of two fuzzy quantifiers (definable by fuzzy measures), where one is Mon↑ (↑Mon) and the second one is Mon↓ (↓Mon). For example, a fuzzy quantifier *roughly between eight and ten* is a conjunction of *about eight or more than eight* (Mon↑) and *about ten or less than ten* (Mon↓).

An interesting question is, which non-monotonic fuzzy quantifiers can be described by the conjunction of two fuzzy quantifiers (not necessary definable by fuzzy measures) having the opposite polarity, i.e., one is Mon↑ and the second one Mon↓. In the generalized quantifier theory, such quantifiers are called *continuous*.[6] A generalization of the continuity for fuzzy quantifiers is a concavity defined as follows.

DEFINITION 13 We say that a fuzzy quantifier Q is concave in the first or the second component, if

$$Q_M(A',B) \wedge Q_M(A'',B) \leq Q_M(A,B) \tag{21}$$

or

$$(Q_M(B,A') \wedge Q_M(B,A'') \leq Q_M(B,A) \tag{22}$$

hold for any non-empty universe M and fuzzy sets $A, A', A'', B \in \mathcal{F}(M)$ such that $A' \subseteq A \subseteq A''$, respectively.

Let Q be a fuzzy quantifier and denote $Q_{M,a} : \mathcal{F}(M) \times \mathcal{F}(M) \rightarrow \{\bot, \top\}$ a fuzzy quantifier defined by $Q_{M,a}(A,B) = \top$ if and only if $Q_M(A,B) \geq a$. A fuzzy quantifier Q_a is the a-cut of the fuzzy quantifier Q.[7] The following lemma shows a relation between the concavity of fuzzy quantifiers and the continuity of a-cut fuzzy quantifiers.

LEMMA 4 *A fuzzy quantifier Q is concave in the first (second) component if and only if each a-cut fuzzy quantifier Q_a is continuous in the first (second) component.*

Proof: Here, we will prove only the concavity in the first component. The proof for the second component is analogous. Let Q be a concave in the first component fuzzy quantifier, $a \in L$, M be a non-empty universe and B be arbitrary fuzzy set of $\mathcal{F}(M)$. If $Q_{M,a}(A',B) = Q_{M,a}(A'',B) = \top$ and $A' \subseteq A \subseteq A''$, then $Q_M(A',B) \wedge Q_M(A'',B) \geq a$ and using the concavity of Q we obtain $Q_M(A,B) \geq a$ which implies $Q_{M,a}(A,B) = \top$. Hence, Q is continuous in the first component for any $a \in L$.

On the contrary, let Q_a be continuous fuzzy quantifier for any $a \in L$, $A' \subseteq A \subseteq A''$ and B be arbitrary fuzzy sets of $\mathcal{F}(M)$. Denote $a = Q_M(A',B) \wedge Q_M(A'',B)$. From the definition of Q_a, we obtain $Q_{M,a}(A',B) = Q_{M,a}(A'',B) = \top$. Since Q_a is continuous in the first component for any $a \in L$, then also $Q_{M,a}(A,B) = \top$. Hence, $Q_M(A,B) \geq a = Q_M(A',B) \wedge Q_M(A'',B)$ which means that Q is concave. ■

THEOREM 5 *Let Q and Q' be ↑Mon and ↓Mon (Mon↑ and Mon↓). Then $Q \wedge Q'$ is concave in the first (second) component.*

Proof: We restrict ourselves to the proof of the case of the first component. For any non-empty universe M and $A, A', A'', B \in \mathcal{F}(M)$ such that $A' \subseteq A \subseteq A''$, we have $Q_M(A',B) \leq Q_M(A,B) \leq Q_M(A'',B)$ and $Q'_M(A'',B) \leq Q'_M(A,B) \leq Q'_M(A',B)$. Hence, we obtain

$$(Q \wedge Q')_M(A',B) \wedge (Q \wedge Q')_M(A'',B) =$$
$$Q_M(A',B) \wedge Q'_M(A',B) \wedge Q_M(A'',B) \wedge Q'_M(A'',B) \leq$$
$$Q_M(A',B) \wedge Q'_M(A'',B) \leq Q_M(A,B) \wedge Q'_M(A,B) =$$
$$(Q \wedge Q')_M(A,B).$$

and thus $Q \wedge Q'$ is concave fuzzy quantifier. ■

THEOREM 6 *Let $\mathbf{L}$ be a distributive residuated lattice. Each concave in the first (second) component fuzzy quantifier is expressible as the conjunction of fuzzy quantifiers which are ↑Mon and ↓Mon (Mon↑ and Mon↓).*

Proof: Again, we restrict ourselves to the proof of the case of the first component. Let Q be concave in the first

[6] Note that a quantifier Q of type $\langle 1 \rangle$ is continuous, if the following holds: if $Q_M(A) = Q_M(C) = \top$ for a non-empty universe M and $A, C \in \mathcal{F}(M)$ such that $A \subseteq C$, then $Q_M(B) = \top$ for any $B \in \mathcal{F}(M)$ with $A \subseteq B \subseteq C$ (cf. [26]). For other types, one can analogously define the continuity of quantifiers in the given component as in the definition for the type $\langle 1 \rangle$.

[7] Obviously, each fuzzy quantifier can be simply derived from its a-cuts by $Q_M(A,B) = \bigvee \{a \mid a \in L \text{ and } Q_{M,a}(A,B) = \top\}$.

component. Put

$$P_M(A,B) = \bigvee_{A' \in \mathcal{F}(M),\ A' \subseteq A} Q_M(A',B).$$

$$P'_M(A,B) = \bigvee_{A'' \in \mathcal{F}(M),\ A \subseteq A''} Q_M(A'',B).$$

One can verify easily that P and P' are $\uparrow$Mon and $\downarrow$Mon, respectively. Moreover, $P \wedge P'$ is a concave fuzzy quantifier in the first component according to the previous theorem. Let M be an arbitrary non-empty universe and $A' \subseteq A \subseteq A''$ be arbitrary fuzzy sets from $\mathcal{F}(M)$. Obviously, we have

$$(P \wedge P')_M(A,B) = P_M(A,B) \wedge P'_M(A,B) =$$

$$\bigvee_{\substack{A' \in \mathcal{F}(M) \\ A' \subseteq A}} Q_M(A',B) \wedge \bigvee_{\substack{A'' \in \mathcal{F}(M) \\ A \subseteq A''}} Q_M(A'',B) \geq Q_M(A,B).$$

Since $\mathbf{L}$ is a distributive residuated lattice and $Q_M(A,B) \geq Q_M(A',B) \wedge Q_M(A'',B)$ for any $A' \subseteq A \subseteq A''$, then we may write

$$Q_M(A,B) \geq \bigvee_{\substack{A' \in \mathcal{F}(M) \\ A' \subseteq A}} \bigvee_{\substack{A'' \in \mathcal{F}(M) \\ A \subseteq A''}} (Q_M(A',B) \wedge Q_M(A'',B))$$

$$= \bigvee_{\substack{A' \in \mathcal{F}(M) \\ A' \subseteq A}} Q_M(A',B) \wedge \bigvee_{\substack{A'' \in \mathcal{F}(M) \\ A \subseteq A''}} Q_M(A'',B) =$$

$$P_M(A,B) \wedge P'_M(A,B) = (P \wedge P')_M(A,B).$$

Hence, Q is expressible as the conjunction $P \wedge P'$, where P is Mon$\uparrow$ and P' is Mon$\downarrow$. ■

VI. Conclusion

In this contribution, we defined fuzzy quantifiers of type $\langle 1,1 \rangle$ using fuzzy integrals and studied their monotonicity. Aside from the theoretical importance of generalized fuzzy quantifiers, we are also motivated by the applications of fuzzy logic e.g. in time series analysis, decision making and other fields where it can be advantageous to be able to use other than classical quantifiers "for all" and "exists". For example, in time series analysis and modeling, we can use quantifiers like "many" for filtering off of outliers, i.e. values that are numerically distant from (the course of) the data.

***Abstract*—Our aim in this paper is to introduce and study the new type of fuzzy ideals of a ring called generalized fuzzy imaginary right (resp . left) ideals and the direct products of them . The equivalence relation of them is given , besides , the properties of their intersection, union and level sets are discussed . Finally, we also give the properties of their homomorphic preimage.**

Keywords-fuzzy imaginary ideals ;generalized fuzzy imaginary ideals ; $(\in,\in\vee q_{(\lambda,\mu)})-$ ***fuzzy imaginary ideals ; level sets ;homomorphic preimage***

I. INTRODUCTION

The theory of fuzzy sets which was introduced by Zadeh in 1965[1] is applied to many mathematical branches. Rosenfeld inspired the fuzzification of algebraic structures and introduced the notion of fuzzy subgroups in 1971 [2] . Since then, many scholars studied the theory of fuzzy algebra and have published a series of papers [3-6]. In 1982, W. J. Liu defined and studied fuzzy subrings as well as fuzzy ideals in rings [7]. In 1990, H.C.Ma gave the definition of imaginary ideals of rings and obtained some results[8] , then in 1992, he discussed the relation between the imaginary ideals, pseudo ideals and ideals of rings [9], besides, some relevant examples were also given by him.

In 1992, Indian scholar S. K. Bhakat and P. Das introduced the concept of (α,β) -fuzzy subgroup[10] by using "belong to ($\in$)" relation and "quais-coincident with(q)"relation between the fuzzy point and the fuzzy sets. In fact ,it's an important and useful generalization of Rosenfeld's fuzzy subgroup. In 1996, S. K. Bhakat and P .Das introduced the concept of (α,β) -fuzzy subring in [11], B . J .Zhao and H. G .Chi has introduced the concept of (λ,μ) -generalized fuzzy subring in [12]. Z . H. Liao et al extended Rosenfeld's fuzzy algebra, Bhakat and Das's fuzzy algebra and $(\overline{\in},\overline{\in}\vee\overline{q})$ -fuzzy algebra to ($\in$, $\in\vee q_{(\lambda,\mu)}$)- fuzzy algebra, and do series of researches [13-16] .

This paper is the continuation of the above work, we give the definition of $(\in,\in\vee q_{(\lambda,\mu)})-$ fuzzy imaginary right (resp. left) ideals of rings, generalized fuzzy imaginary right (resp. left) ideals of rings.The properties of their intersection, union and level sets et al are also discussed. Besides , we find the equivalence relation between $(\in,\in\vee q_{(\lambda,\mu)})-$ fuzzy imaginary right (resp. left) ideals and generalized fuzzy imaginary right (resp. left) ideals . Finally ,the property of homomorphic preimage is given .

II. PRELIMINARIES

From now on , we write R and H for rings.

Definition 2.1[8] Let A be a subring of R , then A is said to be a imaginary right (resp. left) ideal of R if for all $x\in A$ and $y\in R$, $xy\in A$ (resp. $yx\in A$) implies $y\in A$.

We say A a imaginary ideal of R if A is both a imaginary right ideal and a imaginary left ideal of R .

Definition2.2[14] Let $\alpha,\lambda,\mu\in[0,1]$ and $\lambda<\mu$, if $A(x)\geq\alpha$ then a fuzzy point x_α belongs to a fuzzy subset A , denoted by $x_\alpha\in A$; if $\lambda<\alpha$ and $A(x)+\alpha>2\mu$ then a fuzzy point x_α generalized quasicoincident with a fuzzy subset A , denoted by $x_\alpha q_{(\lambda,\mu)}A$ .If $x_\alpha\in A$ or $x_\alpha q_{(\lambda,\mu)}A$, then $x_\alpha\in\vee q_{(\lambda,\mu)}A$.

Definition2.3 [3] Let $R_i(1\leq i\leq n)$ be rings and the direct product:

$$\prod_{1\leq i\leq n}R_i=\{(a_1,a_2,....a_n)|a_i\in R_i\}\ .$$

Then $\prod_{1\leq i\leq n}R_i$ is a ring under the operations as follows:

$(a_1,a_2,....a_n)+(b_1,b_2,...b_n)=(a_1+b_1,a_2+b_2,...a_n+b_n)$;

$(a_1,a_2,....a_n)(b_1,b_2,...b_n)=(a_1b_1,a_2b_2,...a_nb_n)$.

Definition2.4 [3] Let $A_i(1\leq i\leq n)$ be fuzzy subsets of R_i ,then a fuzzy subset $\prod_{1\leq i\leq n}A_i$ is defined as $(\prod_{1\leq i\leq n}A_i)(x_1,x_2,...x_n)=\inf_{1\leq i\leq n}A_i(x_i)$ called fuzzy direct product.

Definition 2.5[3] A fuzzy subset A of R is called a generalized fuzzy subring of R if for all $x,y\in R$, the following conditions are satisfied ,

(1) $A(x+y)\vee\lambda\geq A(x)\wedge A(y)\wedge\mu$;

(2) $A(-x)\vee\lambda\geq A(x)\wedge\mu$;

(3) $A(xy)\vee\lambda\geq A(x)\wedge A(y)\wedge\mu$.

Theorem 2.1[3] Let A be a fuzzy subset of R , then A is a generalized fuzzy subring of R if and only if $A_\alpha\neq\Phi$ is a sub - ring of R for all $\alpha\in(\lambda,\mu]$.

Theorem 2.2[6] Let A and B be generalized fuzzy subrings of R , then $A\cap B$ is a generalized fuzzy subring of R.

Theorem 2.3 [6] A is a subring of R if and only if χ_A is a generalized fuzzy subring of R.

Theorem 2.4[3] Let $f: R \to H$ be a homomorphism, if B is a generalized fuzzy subring of H, then $f^{-1}(B)$ is a generalized fuzzy subring of R.

III. $(\in, \in \vee q_{(\lambda,\mu)})$- FUZZY IMAGINARY IDEALS OF RINGS

Definition 3.1 Let A be a generalized fuzzy subring of R, then A is called a generalized fuzzy imaginary right (resp. left) ideal of R if for all $x, y \in R$, $A(y) \vee \lambda \geq A(x) \wedge A(xy) \wedge \mu$ ($A(y) \vee \lambda \geq A(x) \wedge A(yx) \wedge \mu$).

We say A a generalized fuzzy imaginary ideal of R if A is both a generalized fuzzy imaginary right ideal and a generalized fuzzy imaginary left ideal of R.

Definition 3.2 Let A be an $(\in, \in \vee q_{(\lambda,\mu)})$ – fuzzy subring of R, $\alpha \in (\lambda, 1]$, then A is called an $(\in, \in \vee q_{(\lambda,\mu)})$ – fuzzy imaginary right (resp. left) ideal of R, if $x_\alpha \in A$, $y \in R$ and $(xy)_\alpha \in A$ (resp . $(yx)_\alpha \in A$)implies $y_\alpha \in \vee q_{(\lambda,\mu)} A$.

We say A an $(\in, \in \vee q_{(\lambda,\mu)})$ – fuzzy imaginary ideal of R if A is both an $(\in, \in \vee q_{(\lambda,\mu)})$ – fuzzy imaginary right ideal and an $(\in, \in \vee q_{(\lambda,\mu)})$ – fuzzy imaginary left ideal of R.

Theorem 3.1 A fuzzy subset A is an $(\in, \in \vee q_{(\lambda,\mu)})$ – fuzzy subring of R if and only if A is a generalized fuzzy subring of R.

The proof is omitted .

Theorem 3.2 Let A be a fuzzy subset of R, then the following conditions are equivalent:

(1) A is an $(\in, \in \vee q_{(\lambda,\mu)})$ – fuzzy imaginary right (resp. left) ideal of R ;

(2) A is a generalized fuzzy imaginary right (resp. left) ideal of R ;

(3) Nonempty set A_α is a imaginary right (resp . left) ideal of R for all $\alpha \in (\lambda, \mu]$.

Proof. We prove the theorem for imaginary right ideal. Analogous arguments apply to imaginaryleft ideal.

$(1) \Rightarrow (2)$

We obtain that A is a generalized fuzzy subring of R based on theorem 3.1. Assume that there exists $x_0, y_0 \in R$ such that $A(y_0) \vee \lambda < A(x_0) \wedge A(x_0 y_0) \wedge \mu$,choose α such that $A(y_0) \vee \lambda < \alpha < A(x_0) \wedge A(x_0 y_0) \wedge \mu$,then $A(y_0) < \alpha$, $A(x_0) > \alpha$, $A(x_0 y_0) > \alpha$ and $\lambda < \alpha < \mu$,so $(x_0)_\alpha \in A$, $(x_0 y_0)_\alpha \in A$,thus $(y_0)_\alpha \in \vee q_{(\lambda,\mu)} A$ based on definition 3.2 .But $A(y_0) < \alpha$,therefore $A(y_0) + \alpha < \alpha + \alpha \leq 2\mu$, a contradiction . So A is a generalized fuzzy imaginary right ideal of R .

$(2) \Rightarrow (1)$

From theorem 3.1 , we know that A is an $(\in, \in \vee q_{(\lambda,\mu)})$ – fuzzy subring of R. For all $x, y \in R$ and $\alpha \in (\lambda, 1]$,if $x_\alpha \in A$ and $(xy)_\alpha \in A$,then $A(x) \geq \alpha$ and $A(xy) \geq \alpha$ .Since A is a generalized fuzzy imaginary right ideal of R, then $A(y) \vee \lambda \geq A(x) \wedge A(xy) \wedge \mu \geq \alpha \wedge \mu$ .If $\alpha > \mu$,then $A(y) \vee \lambda \geq \mu$, by $\lambda < \mu$,so $A(y) \geq \mu$,then $A(y) + \alpha \geq \mu + \alpha > 2\mu$,i.e., $y_\alpha q_{(\lambda,\mu)} A$. On the other hand , if $\alpha \leq \mu$,then we can obtain that $A(y) \geq \alpha$,i.e., $y_\alpha \in A$, so $y_\alpha \in \vee q_{(\lambda,\mu)} A$. Thus A is an $(\in, \in \vee q_{(\lambda,\mu)})$ – fuzzy imaginary right ideal of R.

$(2) \Rightarrow (3)$

we know that A_α is a subring of R based on theorem 2.1 . For all $x \in A_\alpha$ and $y \in R$,if $xy \in A_\alpha$,then $A(x) \geq \alpha$ and $A(xy) \geq \alpha$ .Since A is a generalized fuzzy imaginary right ideal of R , then for all $\alpha \in (\lambda, \mu]$,we have $A(y) \vee \lambda \geq A(x) \wedge A(xy) \wedge \mu \geq \alpha \wedge \mu = \alpha$, by $\lambda < \alpha$, so $A(y) \geq \alpha$,i.e., $y \in A_\alpha$. Thererore A_α is a imaginary right ideal of R for all $\alpha \in (\lambda, \mu]$.

$(3) \Rightarrow (2)$

We obtain that A is a generalized fuzzy subring of R based on theorem 2.1 . Assume that there exists $x_0, y_0 \in R$ such that $A(y_0) \vee \lambda < A(x_0) \wedge A(x_0 y_0) \wedge \mu$,choose α such that $A(y_0) \vee \lambda < \alpha < A(x_0) \wedge A(x_0 y_0) \wedge \mu$,then $A(y_0) < \alpha$, $A(x_0) > \alpha$, $A(x_0 y_0) > \alpha$ and $\lambda < \alpha < \mu$ i.e., $x_0 \in A_\alpha$ and $x_0 y_0 \in A_\alpha$, since A_α is a imaginary right ideal of R, then $y_0 \in A_\alpha$, i.e., $A(y_0) \geq \alpha$, a contradiction to $A(y_0) < \alpha$. Therefore A is a generalized fuzzy imaginary right ideal of R .

Theorem 3.3 Let A and B be generalized fuzzy imaginary right

(resp. left) ideals of R,then $A \cap B$ is a generalized fuzzy imaginary right (resp. left) ideals of R.

Proof. We prove the theorem for imaginary right ideal. Analogous arguments apply to imaginary left ideal.

We obtain that $A \cap B$ is a generalized fuzzy subring of R based on theorem 2.2, for all $x, y \in R$,we have $(A \cap B)(y) \vee \lambda = (A(y) \wedge B(y)) \vee \lambda = (A(y) \vee \lambda) \wedge (B(y) \vee \lambda) \geq (A(x) \wedge A(xy) \wedge \mu) \wedge (B(x) \wedge B(xy) \wedge \mu) = (A \cap B)(x) \wedge (A \cap B)(xy) \wedge \mu$ .Therefore $A \cap B$ is a generalized fuzzy imaginary right ideal of R.

Corollary 3.1 Let $A_i (i \in I)$ be generalized fuzzy imaginary right (resp. left) ideals of R,then $\bigcap_{i \in I} A_i$ is a generalized fuzzy imaginary right (resp. left) ideal of R.

Theorem 3.4 Let $A_i (i \in I)$ be generalized fuzzy imaginary right (resp . left) ideals of R and for all $i, j \in I$, $A_i \subseteq A_j$ or $A_j \subseteq A_i$,then $\bigcup_{i \in I} A_i$ is a generalized fuzzy imaginary right (resp. left) ideal of R .

Proof. We prove the theorem for imaginary right ideal. Analogous arguments apply to imaginary left ideal.

Firstly , we prove that $\vee_{i \in I}(A_i(x) \wedge A_i(y) \wedge \mu) = (\bigcup_{i \in I} A_i)(x) \wedge (\bigcup_{i \in I} A_i)(y) \wedge \mu$. Obviously , $\vee_{i \in I}(A_i(x) \wedge A_i(y) \wedge \mu) \leq (\bigcup_{i \in I} A_i)(x) \wedge (\bigcup_{i \in I} A_i)(y) \wedge \mu$ .Assume that $\vee_{i \in I}(A_i(x) \wedge A_i(y) \wedge \mu) \neq (\bigcup_{i \in I} A_i)(x) \wedge (\bigcup_{i \in I} A_i)(y) \wedge \mu$, then there exists r such that $\vee_{i \in I}(A_i(x) \wedge A_i(y) \wedge \mu) < r < (\bigcup_{i \in I} A_i)(x) \wedge (\bigcup_{i \in I} A_i)(y) \wedge \mu$ .Since $A_i \subseteq A_j$ or $A_j \subseteq A_i$ for all $i, j \in I$,then exists $k \in I$ such that $r < A_k(x) \wedge A_k(y) \wedge \mu$ .On the other hand , $A_i(x) \wedge A_i(y) \wedge \mu < r$ for all $i \in I$,a contradiction . Therefore $\vee_{i \in I}(A_i(x) \wedge A_i(y) \wedge \mu) = (\bigcup_{i \in I} A_i)(x) \wedge (\bigcup_{i \in I} A_i)(y) \wedge \mu$.

Next , for all $x, y \in R$,

(1) $(\bigcup_{i \in I} A_i)(x + y) \vee \lambda = \vee_{i \in I} A_i(x + y) \vee \lambda = \vee_{i \in I}(A_i(x + y) \vee \lambda) \geq \vee_{i \in I}(A_i(x) \wedge A_i(y) \wedge \mu) = (\bigcup_{i \in I} A_i)(x) \wedge (\bigcup_{i \in I} A_i)(y) \wedge \mu$;

(2) $(\bigcup_{i \in I} A_i)(-x) \vee \lambda = \vee_{i \in I} A_i(-x) \vee \lambda = \vee_{i \in I}(A_i(-x) \vee \lambda) \geq \vee_{i \in I}(A_i(x) \wedge \mu) = (\bigcup_{i \in I} A_i)(x) \wedge \mu$;

(3) $(\bigcup_{i \in I} A_i)(xy) \vee \lambda = \vee_{i \in I} A_i(xy) \vee \lambda = \vee_{i \in I}(A_i(xy) \vee \lambda) \geq \vee_{i \in I}(A_i(x) \wedge A_i(y) \wedge \mu) = (\bigcup_{i \in I} A_i)(x) \wedge (\bigcup_{i \in I} A_i)(y) \wedge \mu$;

(4) $(\bigcup_{i \in I} A_i)(y) \vee \lambda = \vee_{i \in I} A_i(y) \vee \lambda = \vee_{i \in I}(A_i(y) \vee \lambda) \geq \vee_{i \in I}(A_i(x) \wedge A_i(xy) \wedge \mu) = (\bigcup_{i \in I} A_i)(x) \wedge (\bigcup_{i \in I} A_i)(xy) \wedge \mu$. Therefore $\bigcup_{i \in I} A_i$ is a generalized fuzzy imaginary right ideal of R.

Theorem 3.5 Let A_1 and A_2 be generalized fuzzy imaginary right (resp . left) ideals of R_1 and R_2 respectively , then $A_1 \times A_2$ is a generalized fuzzy imaginary right (resp . left) ideal of $R_1 \times R_2$.

Proof. We prove the theorem for imaginary right ideal. Analogous arguments apply to imaginary left ideal.

Firstly,we prove that $A_1 \times A_2$ is a generalized fuzzy subring of $R_1 \times R_2$ .For all $x, y \in R_1 \times R_2$, where $x = (x_1, x_2)$ and $y = (y_1, y_2)$ .Since A_1 and A_2 are generalized fuzzy subrings of R_1 and R_2 respectively,so we have $(A_1 \times A_2)(x + y) \vee \lambda = (A_1 \times A_2)((x_1, x_2) + (y_1, y_2)) \vee \lambda = (A_1 \times A_2)((x_1 + y_1, x_2 + y_2)) \vee \lambda = (A_1(x_1 + y_1) \wedge A_2(x_2 + y_2)) \vee \lambda = (A_1(x_1 + y_1) \vee \lambda) \wedge (A_2(x_2 + y_2) \vee \lambda) \geq (A_1(x_1) \wedge A_1(y_1) \wedge \mu) \wedge (A_2(x_2) \wedge A_2(y_2) \wedge \mu) = (A_1 \times A_2)((x_1, x_2)) \wedge (A_1 \times A_2)((y_1, y_2)) \wedge \mu = (A_1 \times A_2)(x) \wedge (A_1 \times A_2)(y) \wedge \mu$ .Similarly,we can prove that $(A_1 \times A_2)(-x) \vee \lambda \geq (A_1 \times A_2)(x) \wedge \mu$ and $(A_1 \times A_2)(xy) \vee \lambda \geq (A_1 \times A_2)(x) \wedge (A_1 \times A_2)(y) \wedge \mu$ .So $A_1 \times A_2$ is a generalized fuzzy subring of $R_1 \times R_2$.

Next, for all $x, y \in R_1 \times R_2$, where $x = (x_1, x_2)$ and $y = (y_1, y_2)$, $(A_1 \times A_2)(y) \vee \lambda = (A_1 \times A_2)((y_1, y_2)) \vee \lambda = (A_1(y_1) \wedge A_2(y_2)) \vee \lambda = (A_1(y_1) \vee \lambda) \wedge (A_2(y_2) \vee \lambda) \geq (A_1(x_1) \wedge A_1(x_1 y_1) \wedge \mu) \wedge (A_2(x_2) \wedge A_2(x_2 y_2) \wedge \mu) = (A_1 \times A_2)((x_1, x_2)) \wedge (A_1 \times A_2)((x_1 y_1, x_2 y_2)) \wedge \mu = (A_1 \times A_2)((x_1, x_2)) \wedge (A_1 \times A_2)((x_1, x_2)(y_1, y_2)) \wedge \mu = (A_1 \times A_2)(x) \wedge (A_1 \times A_2)(xy) \wedge \mu$.

Therefore $A_1 \times A_2$ is a generalized fuzzy imaginary right ideal of $R_1 \times R_2$.

Theorem 3.6 Let A_i be generalized fuzzy imaginary right (resp . left) ideals of R_i , then $\prod_{1 \leq i \leq n} A_i$ is a generalized fuzzy imaginary right (resp . left) ideal of $\prod_{1 \leq i \leq n} R_i$.

Proof. We prove the theorem for imaginary right ideal. Analogous arguments apply to imaginary left ideal.

Firstly ,we prove that $\prod_{1 \leq i \leq n} A_i$ is a generalized fuzzy subring of $\prod_{1 \leq i \leq n} R_i$ .For all $x, y \in \prod_{1 \leq i \leq n} R_i$,where $x = (x_1, x_2, \ldots x_n)$ and $y = (y_1, y_2, \ldots y_n)$,then $(\prod_{1 \leq i \leq n} A_i)(x + y) \vee \lambda = \inf A_i(x_i + y_i) \vee \lambda = \inf(A_i(x_i + y_i) \vee \lambda) \geq \inf(A_i(x_i) \wedge A_i(y_i) \wedge \mu) = \inf A_i(x_i) \wedge \inf A_i(y_i) \wedge \mu$

$= (\prod_{1\le i\le n} A_i)(x) \wedge (\prod_{1\le i\le n} A_i)(y) \wedge \mu$ .Similarly , $(\prod_{1\le i\le n} A_i)(-x) \vee \lambda = \inf A_i(-x_i) \vee \lambda = \inf(A_i(-x_i) \vee \lambda) \ge \inf(A_i(x_i) \wedge \mu) = \inf A_i(x_i) \wedge \mu = (\prod_{1\le i\le n} A_i)(x) \wedge \mu$. We can prove $\prod_{1\le i\le n} A_i(xy) \vee \lambda \ge (\prod_{1\le i\le n} A_i)(x) \wedge (\prod_{1\le i\le n} A_i)(y) \wedge \mu$ using the same method.Therefore $\prod_{1\le i\le n} A_i$ is a generalized fuzzy subring of $\prod_{1\le i\le n} R_i$.

Next , For all $x, y \in \prod_{1\le i\le n} R_i$,where $x = (x_1, x_2, ...x_n)$ and $y = (y_1, y_2, ...y_n)$, then $(\prod_{1\le i\le n} A_i)(y) \vee \lambda = \inf A_i(y_i) \vee \lambda = \inf(A_i(y_i) \vee \lambda) \ge \inf(A_i(x_i) \wedge A_i(x_i y_i) \wedge \mu) = \inf A_i(x_i) \wedge \inf A_i(x_i y_i) \wedge \mu = (\prod_{1\le i\le n} A_i)(x) \wedge (\prod_{1\le i\le n} A_i)(xy) \wedge \mu$.

Thus $\prod_{1\le i\le n} A_i$ is a generalized fuzzy imaginary right ideal of $\prod_{1\le i\le n} R_i$.

Theorem 3.7 Let A be a subset of R ,then χ_A is a generalized fuzzy imaginary right (resp . left) ideal of R if and only if A is a imaginary right (resp . left) ideal of R.

Proof. We prove the theorem for imaginary right ideal . Analogous arguments apply to imaginary left ideal.

We know that A is a subring of R based on theorem 2.3 .

For all $x \in A$ and $y \in R$,if $xy \in A$,then $\chi_A(xy) = 1$ and $\chi_A(x) = 1$ .Since χ_A is a generalized fuzzy imaginary right ideal of R , so $\chi_A(y) \vee \lambda \ge \chi_A(x) \wedge \chi_A(xy) \wedge \mu = \mu$, by $\lambda < \mu$,so $\chi_A(y) \ge \mu = 1$,then $y \in A$ .Therefore A is a imaginary right ideal of R.

Conversely , we can easily obtain that χ_A is a generalized fuzzy subring of R based on theorem 2.3 . Assume that there exists $x_0, y_0 \in R$ such that $\chi_A(y_0) \vee \lambda < \chi_A(x_0) \wedge \chi_A(x_0 y_0) \wedge \mu$, choose α such that $\chi_A(y_0) \vee \lambda < \alpha < \chi_A(x_0) \wedge \chi_A(x_0 y_0) \wedge \mu$,then $\chi_A(y_0) < \alpha$, $\chi_A(x_0) > \alpha$, $\chi_A(x_0 y_0) > \alpha$ and $\lambda < \alpha < \mu$ i.e., $x_0 \in A$ and $x_0 y_0 \in A$, since A is a imaginary right ideal of R , then $y_0 \in A$, so $\chi_A(y_0) = 1 > \alpha$, a contradiction . Thus χ_A is a generalized fuzzy imaginary right ideal of R.

Theorem 3.8 Let A be a generalized fuzzy imaginary right (resp . left) ideal of R , then $A_{\underline{\lambda}} = \{x \mid A(x) > \lambda\}$ is a imaginary right (resp . left) ideal of R .

Proof. We prove the theorem for imaginary right ideal . Analogous arguments apply to imaginary left ideal.

Since A is a generalized fuzzy imaginary right ideal of R , then for every $x, y \in A_{\underline{\lambda}}$,we have $A(x+y) \vee \lambda \ge A(x) \wedge A(y) \wedge \mu > \lambda$, $A(-x) \vee \lambda \ge A(x) \wedge \mu > \lambda$, and $A(xy) \vee \lambda \ge A(x) \wedge A(y) \wedge \mu > \lambda$,i.e., $A(x+y) > \lambda$, $A(-x) > \lambda$ and $A(xy) > \lambda$,so $x+y, xy, -x \in A_{\underline{\lambda}}$. Therefore $A_{\underline{\lambda}}$ is a subring of R .

For all $x \in A_{\underline{\lambda}}$ and $y \in R$, if $xy \in A_{\underline{\lambda}}$,then $A(xy) > \lambda$ and $A(x) > \lambda$ .Since A is a generalized fuzzy imaginary right ideal of R , then $A(y) \vee \lambda \ge A(x) \wedge A(xy) \wedge \mu > \lambda$,so $A(y) > \lambda$,i.e., $y \in A_{\underline{\lambda}}$ .Therefore $A_{\underline{\lambda}} = \{x \mid A(x) > \lambda\}$ is a imaginary right ideal of R.

Theorem 3.9 Let $f : R \to H$ be a homomorphism , if B is a generalized fuzzy imaginary right (resp . left) ideal of H , then $f^{-1}(B)$ is a generalized fuzzy imaginary right (resp . left) ideal of R.

Proof. We prove the theorem for imaginary right ideal. Analogous arguments apply to imaginary left ideal.

Based on theorem 2.4 , we obtain that $f^{-1}(B)$ is a generalized fuzzy subring of R . For all $x, y \in R$, $f(x), f(y) \in H$, since B is a generalized fuzzy imaginary right ideal of H, then

$$\begin{aligned} & f^{-1}(B)(y) \vee \lambda \\ &= B(f(y)) \vee \lambda \\ &\ge B(f(x)) \wedge B(f(x)f(y)) \wedge \mu \\ &= B(f(x)) \wedge B(f(xy)) \wedge \mu \\ &= f^{-1}(B)(x) \wedge f^{-1}(B)(xy) \wedge \mu \end{aligned}$$

Therefore $f^{-1}(B)$ is a generalized fuzzy imaginary right ideal of R .

IV. CONCLUSIONS

In this paper,we gave the definition of $(\in, \in \vee q_{(\lambda,\mu)})$ – fuzzy imaginary right (resp . left) ideals of rings and generalized fuzzy imaginary right (resp . left)ideals of rings. Moreover , we found the equivalence relation between $(\in, \in \vee q_{(\lambda,\mu)})$ – fuzzy imaginary right (resp . left) ideals and generalized fuzzy imaginary right (resp . left) ideals. The properties of their intersection, union and level sets were also discussed. Finally , we gave the properties of their homomorphic preimage.

***Abstract*—A formal representation of the mutual information processing among the cognitive processes of the brain provides a real impression of the mechanisms of a Natural Intelligence (NI) system. The nature of information processing in the human brain is fuzzy. In this article, a new formal model, namely Cellular Fuzzy Networks (CFNs), is introduced to model the real characteristics of NI-Systems and especially the human mind. CFNs can effectively manipulate the interactions among natural concepts in an NI-system. The detailed definitions of CFNs and related theorems are provided. Then, CFNs are exploited to model a feasibility analysis of the human brain in the cognitive process of decision making. Finally, it is posited that CFNs have great potential to be applied in modeling the complex interrelationships in large-scale natural systems.**

Keywords- Cognitive informatics; natural intelligence system; fuzzy sets theory; cellular fuzzy networks; human mind

I. INTRODUCTION

The contemporary form of cybernetics is known as Cognitive Informatics (CI), which attempts to discover the mechanisms of natural intelligence and the cognitive processes of the brain [1]. CI applies many disciplines such as philosophy, physiology, psychology, and computer science to study the human brain as the most complicated organism in the universe [2, 3]. Natural intelligence, like other natural phenomena, is involved with vague concepts. An average brain in daily life thinks and proceeds with imprecise information and facts, and the nature of information processing in the human brain is fuzzy. Fuzzy sets theory provides a formal method to capture and process vague data from the natural world in a precise form [4].

The human brain proceeds through nonstop performance causal relationships among cognitive functions. Imitation of the real characteristics of the human mind requires the composition of an ultimately accurate harmony among the cognitive functions of the brain [5]. Subsequently, analyzing the complex interactions among a set of cognitive processes requires a formal method that can be easily adapted to the nature of information processing in an NI-System. The method can be exploited more effectively as one of the most vital issues in CI and AI research through the representation of mind flows [6].

In this paper, the concept of CI is used to make a relevant connection between psychological studies of NI and methodological models in computer engineering to develop a casual network in light of fuzzy sets theory. In this way, a new concept of cellular fuzzy networks is proposed to manipulate the mutual information processing among cognitive processes of the brain. The idea comes from the theorems of Cellular Bayesian Networks (CBNs) proposed in [7] and the fuzzy sets theory. Actually, CFNs acquire and merge the structure and mathematical background of CBNs and the principles of fuzzy inference systems [8].

This paper is arranged as follows: in Section II, a brief description of fuzzy sets theory is proposed, and then in Section III the cellular fuzzy network is developed on the basis of casual network and fuzzy sets theory. In Section IV, feasibility testing in NI-systems is modeled and simulated according to CFN in a MATLAB workspace. In this case, the psychological models for integrating new information into the existing knowledge are exploited to manipulate the feedback information to the NI-system. Finally, the paper is concluded in Section V.

II. FUZZY SETS THEORY

In cognitive psychology, vagueness and uncertainty regarding perception are properties of concepts which are inevitable in human thought processes. The origin of fuzzy concepts is due partly to the fact that the nature of information processing in the human brain is fuzzy.

The theory of fuzzy sets was proposed by L.A. Zadeh and provides an efficient basis for the model the cognitive capabilities of the human brain under uncertain circumstances. Currently, fuzzy sets is an extension of the classical notion of sets in which the membership of elements or objects in a set is assessed in binary terms according to a bivalent condition [9, 10]. In contrast, fuzzy sets theory permits the gradual assessment of the membership of elements in a set, which is determined by a membership function valued in the real unit interval [0, 1].

Fuzzy sets theory can be used in a wide range of domains in which information is incomplete or imprecise, such as bioinformatics [11]. In this way, fuzzy sets theory provides fuzzy production rules in order to reason and infer properly

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

with real world information. Fuzzy systems apply linguistic identifiers and rules to mimic NI-System behaviors and thought mechanisms more effectively.

III. CELLULAR FUZZY NETWORKS

In this section, cellular fuzzy networks and their related theorems are defined and explained in detail to determine a formal framework for representing an accurate depiction of the information flow in an NI-system.

A *causal network* is an acyclic digraph arising from an evolution of a substitution system, and representative of its history. In the evolution of a multi-way system, each substitution event is a vertex in a causal network. The existence of an edge between two vertices in the casual network indicates the order of the corresponding events, which are related by causal dependence. More precisely, the edge is a directed edge leading from the past event to the future event [11]. In a causal network, if the variables A and B become the parents of the variable C independently, there is no information on how impacts from variable A and variable B interact, and more specification is required. In addition, causal networks do not support the domain to be modeled contains feedback cycles. In this way, to eliminate these restrictions, some modifications to the structure of causal networks are performed according to the following definitions.

Definition 1. A *Fuzzy Network* (FN) is a fuzzy graphical model that represents a set of natural variables and their causal dependencies via a Directed Acyclic Graph (DAG). More particularly, an FN is a kind of casual network with the following characteristics:

- There is a set of variables and a set of directed edges between the variables;
- Each set contains a finite set of mutually exclusive states;
- The variables coupled with the directed edges construct a directed acyclic graph;
- Each variable A with parents $B_1, B_2 \ldots B_n$ is associated with a set of fuzzy production rules table comprised of the fuzzy rules in the form of IF B_1 AND B_2 AND…B_n THEN A.

In fact, each node in an FN presents a fuzzy inference system. If the variable A has no parent, then the table can be replaced by the degree of membership. A fuzzy network provides a graphical model of information passing among nodes to mimic the behaviors of an NI-system.

In a directed acyclic graph $G = (V, E)$, a node $C \in V$ is called a *center node* if and only if for any node $X \in V \backslash \{C\}$, the condition $\langle X, C \rangle \in E$ is satisfied. For example, in Fig. 1, the node n_3 in graph G_1 and the node n_2 in G_2 are the center nodes in their graphs, respectively. A directed acyclic graph is a *centered graph* if and only if it has only one center node, and there are no edges ending at non-center nodes [7].

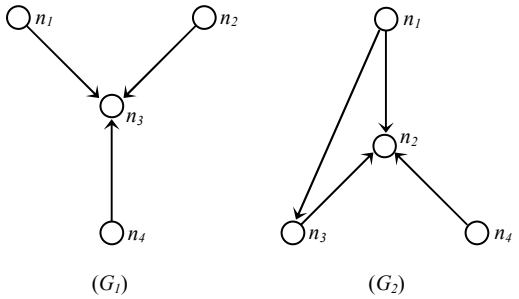

Figure 1. The sample graphs

For example, graph G_1 is a centered graph, and graph G_2 is not due to its containing extra edges between non-center nodes. The center node of a centered graph is specified shortly to C (G). Hence, in Fig. 1, we have $C(G_1) = n_3$.

Definition 2. A *cellular fuzzy network* is a pair (G, R), where $G = (V, E)$ is a centered graph, and R is a set of fuzzy production rules for the center node of G given its parents. For convenience, the center of G is also called, C (G), the center of the CFN, short for C (CFN).

In a CFN, each node acts as a fuzzy inference system, following five steps: (1) fuzzification of the input variables from the parents, (2) application of the fuzzy operator (AND or OR) in the antecedent, (3) implication from the antecedent to the consequent, (4) aggregation of the consequents across the rules, and, finally, (5) defuzzification and the outputs their passing onto the childs. For any two given cellular fuzzy networks $F_1 = (G_1, R_1)$ and $F_2 = (G_2, R_2)$, if C (B_1) ≠ C (B_2), the *union* $F = F_1 \cup F_2$ of the CFN F_1 and CFN F_2 is a pair (G, R), where G is the union of G_1 and G_2, and R is the union of R_1 and R_2. As shown in Fig. 2, two fuzzy cells (i.e. F_1, F_2) are linked through their center nodes (i.e. n_2, n_4) with directed edges. The union of two CBNs is also a graph model but according to the definitions it is no longer a CBN.

Definition 3. A *Cellular Fuzzy Networks* (CFNs) is a union, CFNs = $F_1 \cup F_2 \cup \ldots \cup F_n$, where F_i (i = 1, …, n) is cellular fuzzy network, and they are subject to the following constraints:

$$C(F_i) \neq C(F_j),\ 1 \leq i < j \leq n \tag{1}$$

and

$$C(F_i) \in (\bigcup_{i \neq j} V_j),\ i = 1, ..., n, \tag{2}$$

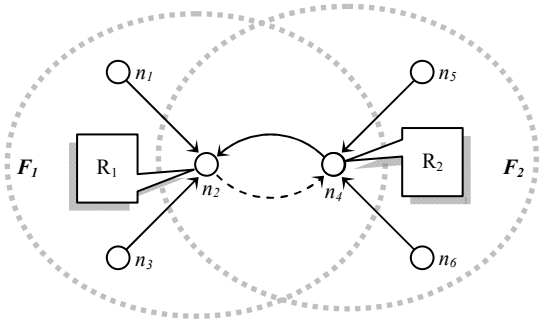

Figure 2. The union of cellular fuzzy networks (F_1andF_2)

where V_j is the node set of F_j. The first constraint indicates the uniqueness of every cell in the networks and the second constraint indicates that the center nodes are the only path for connection among the cells. CFNs can be developed like fractals by substituting every node with CFNs and so on. This attribute makes CFNs more flexible to model natural systems with dynamic scales.

IV. THE NATURAL INTELLIGENCE SYSTEM

An artificial mind system attempts to imitate cognitive mechanisms of the human brain in dealing with a wide variety of physical and mental incidents in the natural world. In cognitive psychology, vagueness and uncertainty are inevitable in human thought processes [12]. In many everyday situations, an average person thinks largely in an intuitive and associative manner, which is calculated or identified by qualitative or verbal measures within the range of interpretation for a given phrase. Particularly, it is recognized that people's internal representations of uncertainty are verbal.

Human brain as the most complex organism in the universe is the faculty of any kind of intelligent behaviors. Human behavior is directly generated by behavioral intensions, which are controlled by the attitude consisting of personal experiences and social norms [7].

Attitude or perceptual feasibility in which uncertainty is a substantial issue generally focuses on decision making processes. Attitude has a considerable impact on behavior and influences the ways a person thinks and feels. The direct relationship between attitude and behavior intention is shown in Table II. Furthermore, attitude of a person is affected by the environmental results of the related behavior. In this case, in order to manage the feedback of new information, in [18], a psychological model was developed which adjusted membership functions toward predicting the impact of new information on the existing body of knowledge. According to this model, newly acquired information from the environment about the possibility of doing an action has an impact on the modification of the perceptual feasibilities, as can be seen in Table I.

Now, the interactions between perceptual feasibility and behavior intention [18] as two fuzzy concepts in an NI-Sys are modeled with CFNs. Fuzzy concepts are characterized by generalized bell-shaped membership functions according to prevalent psychological and linguistic disciplines, as seen in Fig. 3 [8]. Psychological experiments [19] indicate that the amount of above-mentioned specifications is sufficient for practical purposes. As shown in Fig. 4, a CFNs model is developed which accounts for the verbal thinking orientation for decision making, or behavior modeling through logically describing the imprecision of the mind's activities ([10], [19]).

Tables I and II indicate the production rules of the fuzzy inference system on each node in the model in Fig. 4. As mentioned before, some natural and psychological attributes are extracted for the purpose of defining fuzzy rules. In fact, in the proposed model, perceptual feasibility is in charge of the evaluation or belief of a person about the difficulty of carrying out a designated behavior.

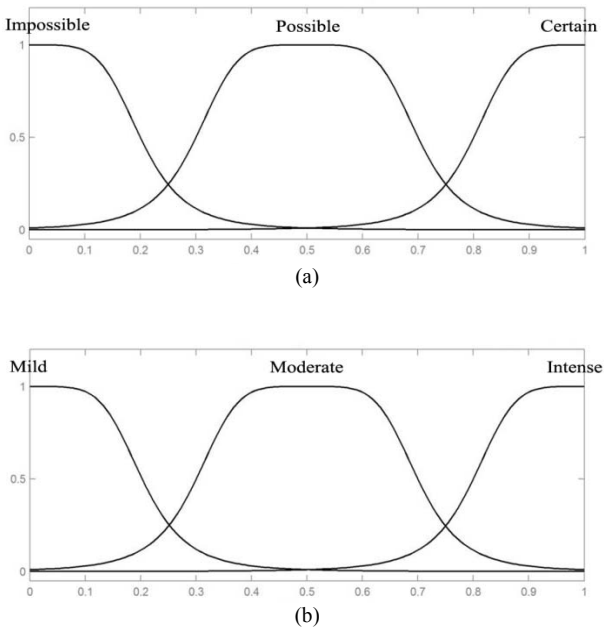

Figure 3. Diagrams of the membership functions of (a) feasibility analysis, and (b) behavior intention

For simulation, the fuzzy logic toolbox of Matlab was used to describe each node (in Fig. 4) efficiently as a fuzzy inference system and the plots of the fuzzy inference systems are shown in Figs. 5 and 6 [14]. In Fig. 5, the effect of the outcome of the behavior (i.e. the feedback) on the current belief about the feasibility of success in carrying out the behavior can be seen.

TABLE I. THE EFFECT OF FEEDBACK OF NEW INFORMATION ON OLD KNOWLEDGE

	New information		
Old knowledge	Impossible	Possible	Certain
Impossible	Impossible	Impossible	Possible
Possible	Impossible	Possible	Certain
Certain	Possible	Certain	Certain

TABLE II. THE EFFECT OF A FEASIBILITY ANALYSIS ON BEHAVIOR INTENTION

Feasibility analysis	Behavior intention
Impossible	Mild
Possible	Moderate
Certain	Intense

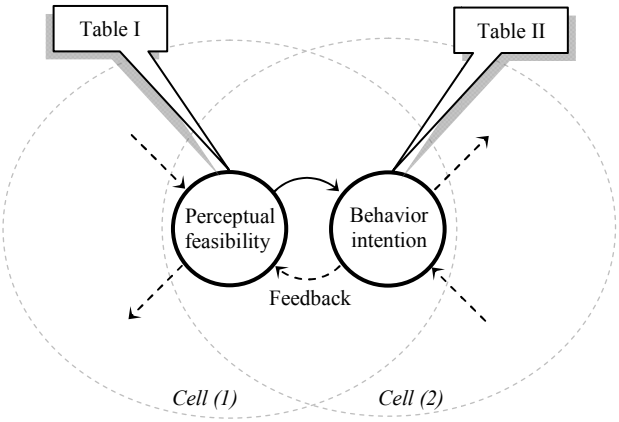

Figure 4. CFNs model of the interactions between feasibility analysis and behavior intention

In this case, the fuzzified inputs from the natural world are processed through IF-THEN rules and the Mamdani's max-min composition [17]. The simulated CFNs model provides a formal explanation for the mechanism and relationship between attitude and behavior. Also, it can be used for describing the way attitude helps to regulate the behavioral intention with a positive or negative judgment.

As a result, CFNs provide relevant specifications to freely determine the relationships among fuzzy inference systems, whether as aforementioned, a causal network has some restrictions in this way, such as a lack of information on how impacts from parent systems interact, and also the domain which contains feedback cycles are not supported. In addition, the model can be easily expanded to cover other factors involved in forming behavior in natural intelligent systems, like emotion and motivation. The designed CFNs can be used to control the behavior of an intelligent system with autonomous decision making ability according to the rules of feedback information and natural intelligence [15, 16].

V. CONCLUSION

A formal method is required to analyze the complex interactions among a set of cognitive processes of the brain

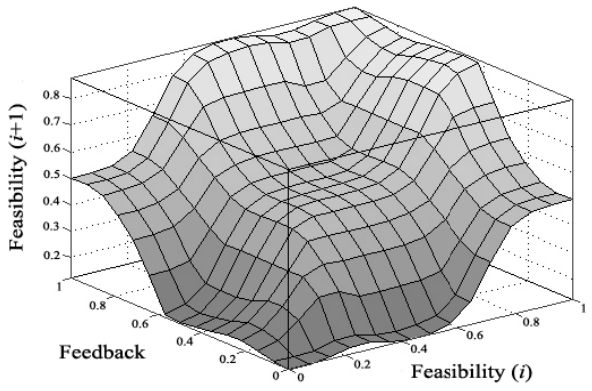

Figure 5. Surface plot of the fuzzy inference system of the left node in the CFNs model (in Fig. 4) that illustrates the influence of feedback as new information on the current feasibility analysis

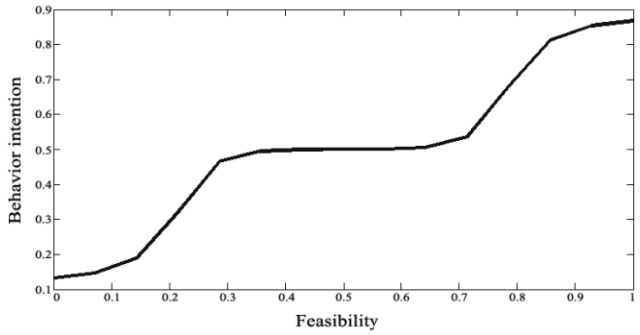

Figure 6. The plot of the fuzzy inference system of the right node in the CFNs model (in Fig. 4) that illustrates the influence of the feasibility analysis on the behavior intention

that can be easily adapted to the nature of information processing in a natural intelligence system. The brain works continuously through a life time; in such a dynamic organism, considering the effects of every stimulus and process becomes very complicated.

In the present work, a new concept of cellular fuzzy networks is proposed to model the real characteristics of NI-Systems, especially those of the human mind. The detailed definitions of CFNs and related theorems are provided. Subsequently, CFNs are exploited to model the feasibility analysis of the human brain in the cognitive process of decision making and behavior intention. The proposed model can be applied to simulate the transmission of mind flows toward implementing an intelligent humanoid behavior mechanism and other mental phenomena as well. The model offers the real possibility of humanoid behavior through developing an artificial mind system and future generation intelligent systems.

The authors propose future research on the theme, including the concepts of learning and inference in cellular fuzzy networks. CFNs have great potential to be applied to model the complex interrelationships in large-scale natural systems. Finally, it is expected that such methods will be able to establish more natural characteristics of the human mind and brain in the operation of artificial intelligence systems.

Abstract — **The human resources is playing a daily important role in modern globalized firms. Appropriate staffing strategies are critical for coordinating and controlling international human resource management related issues across widely distributed business units or subsidiaries over various geographic areas. However, very few researches tried to uncover how the expatriate managers can be selected, especially when the evaluation criteria influence each other. Thus, this research aims to develop a decision framework for selecting appropriate expatriate managers. A multiple criteria decision making (MCDM) framework consisting of the Decision Making Trial and Evaluation Laboratory (DEMATEL) for structuring the decision problem, the Analytical Network Process (ANP) for deriving weights versus each criterion, and finally, the VlseKriterijumska Optimizacija I Kompromisno Resenje (VIKOR) for ranking the alternatives have been proposed. An empirical study based on a globalized high technology firm will be leveraged for verifying the usefulness of this proposed analytic framework on staff selections.**

Keywords - Multinational Enterprises (MNE); ***International Human Resource Management***; ***Staffing Strategies***; ***Multiple Criteria Decision Making (MCDM)***; ***Decision Making Trial and Evaluation Laboratory (DEMATEL)***; ***Analytic Network Process (ANP)***; ***VlseKriterijumska Optimizacija I Kompromisno Resenje (VIKOR).***

I. INTRODUCTION

In the era of globalization, multinational enterprises (MNEs) have gradually expanded their operations in order to maximize the profitability and enhance the competitive advantages. International trade may occur anywhere in the value chain. Meanwhile, new technologies are enabling global manufacturing activities and service deliveries with the world-class quality and prices [9].

Due to the local and global competitions, MNEs are always seeking lower costs, higher quality as well as products or service discrepancy [2]. The lower costs are including lower-cost materials and lower-cost inputs such as land, utilities, and labor. In addition, the matured markets and limited opportunities in the developed countries further drive many MNEs to seek markets in other countries [22]. Therefore, MNEs in general and high technology MNEs in special usually set up different functional units, including manufacturing, marketing and R&D overseas. Appropriate human resources for managing overseas operations are essential for the final success.

The major purposes for establishing overseas operations of a high technology MNE are three folds: (1) limitations by strict host country government's regulations, higher labor consciousness, and scarce raw materials, (2) attractiveness being provided by foreign countries' preferential policies, well potential markets or plenty raw materials, and (3) leading the relating industries to create the competitive advantage and reduce the managing cost [14]. Consequently, in order to compete in the global marketplace, high technology MNEs must develop business strategies which can take advantage of global resources and markets. Since high technology MNEs differ in the scale and scope of their international operations, international human resource managers must assist in the global operations no matter what their scale and scope are [20].

However, the international human resource management is not easy. The challenges include of how the thousands of MNE employees in many different countries can effectively be attracted, engaged and retained to achieve the strategic objectives [24]. Therefore, appropriate strategies, including expatriates, inpatriates, and flexpatriates [2] should be designed and executed

To achieve this purpose, a hybrid multiple criteria decision making (MCDM) framework consisting of the Decision Making Trial and Evaluation Laboratory (DEMATEL), the Analytic Network Process (ANP) and the VlseKriterijumska Optimizacija I Kompromisno Resenje (VIKOR) will be proposed. At first, literature being related to high technology MNEs, international human resource management strategies for MNEs, and criteria for expatriate manager selections will be reviewed. The validity of the derived criteria will be confirmed by using the Delphic Oracle's Skills of Interpretation and Foresight (Delphi). The structure of the entire decision making problem will be developed based on the influence relationships between the criteria by using the DEMATEL. Weights versus the criteria will be derived based on the influence relation map (IRM) being derived by using the ANP. Finally, the VlseKriterijumska Optimizacija I Kompromisno Resenje (VIKOR) will be leveraged to rank the criteria.

The rest of this research is organized as follows. In Section 2, literature on MNE and criteria definitions for staffing policies will be reviewed. In Section 3, the hybrid MCDM framework for selecting the appropriate expatriate managers will be defined and demonstrated. In Section 4, an empirical study on a world-leading information technology (IT) company with several overseas manufacturing sites will be illustrated. Discussion and implications will be presented in Section 5. The last section is the conclusion in Section 6.

II. LITERATURE REVIEW

A MNE can be defined as a firm which produces and/or distributes products and/or services across national borders. MNEs have repeatedly been identified as the drivers of globalization [23]. MNEs achieve future successes based on appropriate international assignments. First this section takes a look at a number of criteria that are used by various global firms to select their international assignees [30]. Then the section examines the consequences of making mistakes either

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

in choosing international assignees or in preparing and supporting their assignments or in helping them make a successful return to home at the end of their international assignments [3].

Most MNEs base their choices for international assignments on candidates' technical expertise. The primary focus is on their ability to perform the target job requirements [9]. MNE makes the choice of individual to be sent on an international assignment and that choice is usually based on the individual's perceived ability to fill a perceived functional or technical need in the foreign operation [2]. The cultural adaptability is at least as important to the successful completion of an overseas assignment as is the individual's technical ability. Expatriates must be able to adjust to their new and often alien environments while effectively delivering their technical and managerial expertise [30]. They must graciously accept their new cultures but not at the expense of not getting their job done. While technical expertise is usually important, the principal difficulty faced by most expatriates lies in the inability of the managers and their families to adapt to the foreign cultures. Since adaptation to the foreign culture is so important to an international assignees performance, his desire for that foreign assignment is critical to their willingness to make the necessary efforts to adjust [17]. Sometimes MNEs need to recruit such people from the outside or acquire the expertise from consulting firms and the expertise could be recruited from overseas countries.

The selection decision for international assignees is critically important. Errors in the selection can have a major negative impact on the success of overseas operations as well as on the careers of relocated managers [17]. From the perspective of headquarters, it is most important that potential international assignees be seen as able to perform both the specific tasks to which they are assigned as well as to perform well in a different national culture. Because of the nature of most international assignments, selections for international transfer are most successful when based on factors such as the following: the maturity of the candidate; ability to handle foreign language; possession of a favorable outlook on the international assignment and locale by the expatiate and his family; possessing appropriate personal characteristics [13]. In order to convince the expatiates to take on the international assignments, some issues like dual families, disruption of their lives, work-life balance issues, and the uncertainty about the impact of the assignment on their careers, employees are becoming increasing reluctant. MNEs should pay attention to these factors when making selections for international assignments [21].

III. Research Methods

The analytical framework consists of five phases: reviewing related literature on MNEs staffing policy, establishing evaluation criteria for MNEs staffing policy by using the modified Delphi and the Cronbach's alpha coefficient; building the structure between evaluation criteria by using the DEMATEL; analyzing and ranking the interrelationship among the factors by using the VIKOR and finally, and deciding the strategies being suitable for each category of MNEs.

A. Modified Delphi

The modified Delphi method was designed by Dalkey and Helmer [19], try to identify issues and problems were collected from a group of technology education professionals using the modified-delphi Technique [12]. The primary objective of a Delphi inquiry is to obtain a consensus as a minimum of 75 percent agreement on any particular item at of opinion from a group of respondents. Meanwhile, it is possible to develop consensus on a common core of management assessment criteria which, when combined with the institution, unit, and position-specific criteria, can form a comprehensive management audit instrument.

B. DEMATEL

The DEMATEL method was developed by the Battelle Geneva Institute (1) to analyze complex 'world problems' dealing mainly with interactive man-model techniques; and (2) to evaluate qualitative and factor-linked aspects of societal problems [1]. The applicability of the method (e.g. [4; 5; 11; 31]) is widespread. Furthermore, a hybrid model combining the two methods has been widely used in various fields, for example, e-learning evaluation [7], airline safety measurement [11], and innovation policy portfolios for Taiwan's SIP Mall [5]. Therefore, in this paper we use DEMATEL not only to detect complex relationships and build a NRM of the criteria, but also to obtain the influence levels of each element over others; we then adopt these influence level values as the basis of the normalization supermatrix for determining ANP weights to obtain the relative importance. To apply the DEMATEL method smoothly, the authors refined the definitions based on above authors, and produced the essential definitions indicated below. The DEMATEL method is based upon graph theory, enabling us to plan and solve problems visually, so that we may divide multiple criteria into a relationship of cause and effect group, in order to better understand causal relationships. Directed graphs (also called digraphs) are more useful than directionless graphs, because digraphs will demonstrate the directed relationships of sub-systems. A digraph typically represents a communication network, or a domination relationship between individuals, etc. Suppose a system contains a set of elements, $S = \{s_1, s_2, \ldots, s_n\}$, and particular pair-wise relationships are determined for modeling, with respect to a mathematical relationship, MR. Next, portray the relationship MR as a direct-relation matrix that is indexed equally in both dimensions by elements from the set S . Then, extract the case for which the number 0 appears in the cell (i, j) , if the entry is a positive integral that has the meaning of: the ordered pair (s_i, s_j) is in the relationship MR; it has the kind of relationship regarding that element such that s_i causes element s_j . The digraph portrays a contextual relationship between the elements of the system, in which a numeral represents the strength of influence. The elements s_1 , s_2 , s_3 and s_4 represent the factors that have relationships in Fig. 1. The number between factors is influence or influenced degree. For example, an arrow from s_1 to s_2 represents the fact that s_1 influences s_2 and its influenced degree is two. The DEMATEL method can convert the relationship between the causes and effects of criteria into an intelligible structural model of the system [2].

Definition 1: The pair-wise comparison scale may be designated as eleven levels, where the scores 0,1,2,…,10 represent the range from 'no influence' to 'very high influence'.

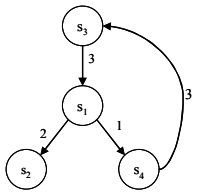

Fig. 1. An example of the directed graph

Definition 2: The initial direct relation/influence matrix $\boldsymbol{A}$ is an $n \times n$ matrix obtained by pair-wise comparisons, in terms of influences and directions between the determinants, in which a_{ij} is denoted as the degree to which the i^{th} determinant affects the j^{th} INC.

$$\mathrm{A} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \vdots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}$$

Definition 3: The normalized direct relation/influence matrix $\boldsymbol{N}$ can be obtained through Equations (1) and (2), in which all principal diagonal elements are equal to zero.

$$\boldsymbol{N} = z\mathrm{A}. \tag{1}$$

$$\text{where } z = 1 \Big/ \max_{1 \le i \le n} \sum_{j=1}^{n} a_{ij}. \tag{2}$$

In this case, $\boldsymbol{N}$ is called the normalized matrix. Since $\lim_{k \to \infty} \boldsymbol{N}^k = [0]$.

Definition 4: Then, the total relationship matrix $\boldsymbol{T}$ can be obtained using Equation (3), where $\boldsymbol{I}$ stands for the identity matrix.

$$\boldsymbol{T} = \boldsymbol{N} + \boldsymbol{N}^2 + \ldots + \boldsymbol{N}^k = \boldsymbol{N}(\boldsymbol{I} - \boldsymbol{N})^{-1}, \tag{3}$$

where $k \to \infty$ and $\boldsymbol{T}$ is a total influence-related matrix; $\boldsymbol{N}$ is a direct influence matrix and $\boldsymbol{N} = [x_{ij}]_{n \times n}$; $\lim_{k \to \infty} \left(\boldsymbol{N}^2 + \cdots + \boldsymbol{N}^k \right)$ stands for a indirect influence matrix and $0 \le \sum_{j=1}^{n} x_{ij} < 1$ or $0 \le \sum_{i=1}^{n} x_{ij} < 1$, and only one $\sum_{j=1}^{n} x_{ij}$ or $\sum_{i=1}^{n} x_{ij}$ equal to 1 for $\forall i, j$. So $\lim_{k \to \infty} \boldsymbol{N}^k = [\boldsymbol{0}]_{n \times n}$. The (i, j) element t_{ij} of matrix $\boldsymbol{T}$ denotes the direct and indirect influences of factor i on factor j.

Definition 5: The row and column sums are separately denoted as $\boldsymbol{r}$ and $\boldsymbol{c}$ within the total-relation matrix $\boldsymbol{T}$ through Equations (4), (5), and (6).

$$\boldsymbol{T} = [t_{ij}], \quad i, j \in \{1, 2, \ldots, n\} \tag{4}$$

$$\boldsymbol{r} = [r_i]_{n \times 1} = \left[\sum_{j=1}^{n} t_{ij} \right]_{n \times 1} \tag{5}$$

$$\boldsymbol{c} = [c_j]_{1 \times n} = \left[\sum_{i=1}^{n} t_{ij} \right]_{1 \times n} \tag{6}$$

where the $\boldsymbol{r}$ and $\boldsymbol{c}$ vectors denote the sums of the rows and columns, respectively.

Definition 6: Suppose r_i denotes the row sum of the i^{th} row of matrix $\boldsymbol{T}$. Then, r_i is the sum of the influences dispatching from factor i to the other factors, both directly and indirectly. Suppose that c_j denotes the column sum of the j^{th} column of matrix $\boldsymbol{T}$. Then, c_j is the sum of the influences that factor i is receiving from the other factors. Furthermore, when $i = j$ (i.e., the sum of the row sum and the column sum $(r_i + c_i)$ represents the index representing the strength of the influence, both dispatching and receiving), $(r_i + c_i)$ is the degree of the central role that factor i plays in the problem. If $(r_i - c_i)$ is positive, then factor i primarily is dispatching influence upon the strength of other factors; and if $(r_i - c_i)$ is negative, then factor i primarily is receiving influence from other factors [5; 11; 18].

C. Analytic Network Process (ANP)

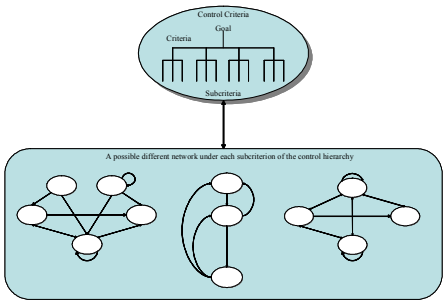
The ANP method, a multi criteria theory of measurement developed by Saaty [26] provides a general framework to deal with decisions without making assumptions about the independence of higher-level elements from lower level elements and about the independence of the elements within a level as in a hierarchy. Compared with traditional MCDM methods [26], e.g. AHP (Analytic Hierarchy Process), TOPSIS, ELECTRE, etc [26; 27], which usually assume the independence between criteria, ANP, a new theory that extends AHP to deal with dependence in feedback and utilizes the supermatrix approach [28], is a more reasonable tool for dealing with complex MCDM problems in the real world. In this section, concepts of the ANP are summarized based on Saaty's earlier works [26-29].

The ANP is a coupling of two parts. The first consists of a control hierarchy or network of criteria and subcriteria that control the interactions. The second is a network of influences among the elements and clusters. The network varies from criterion to criterion and a different supermatrix of limiting influence is computed for each control criterion. Finally, each of these supermatrices is weighted by the priority of its control criterion and the results are synthesized through addition for all the control criteria [26]. A control hierarchy is a hierarchy of criteria and subcriteria for which priorities are derived in the usual way with respect to the goal of the system being considered.

The criteria are used to compare the components of a system, and the subcriteria are used to compare the elements. The criteria with respect to which influence is presented in individual supermatrices are called control criteria. Because all such influences obtained from the limits of the several supermatrices will be combined in order to obtain a measure of the priority of overall influences, the control criteria should be grouped in a structure to be used to derive priorities for them. These priorities will be used to weight the corresponding individual supermatrix limits and add. Analysis of priorities in a system can be thought of in terms of a control hierarchy with dependence among its bottom-level alternatives arranged as a network as shown in Fig. 2. Dependence can occur within the components and between them.

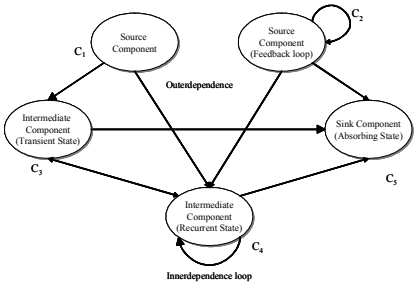
A control hierarchy at the top may be replaced by a control network with dependence among its components, which are

collections of elements whose functions derive from the synergy of their interaction and hence has a higher-order function not found in any single element. The criteria in the control hierarchy that are used for comparing the components are usually the major parent criteria whose subcriteria are used to compare the elements need to be more general than those of the elements because of the greater complexity of the components.



Source: [26]
Fig. 2. The control hierarchy

A network connects the components of a decision system. According to size, there will be a system that is made up of subsystems, with each subsystem made up of components, and each component made up of elements. The elements in each component interact or have an influence on some or all of the elements of another component with respect to a property governing the interactions of the entire system, such as energy, capital, or political influence. Figure 3 demonstrates a typical network. Those components which no arrow enters are known as source components such as $\boldsymbol{C}_1$ and $\boldsymbol{C}_2$. Those from which no arrow leaves are known as sink component such as $\boldsymbol{C}_5$. Those components which arrows both enter and exit leave are known as transient components such as $\boldsymbol{C}_3$ and $\boldsymbol{C}_4$. In addition, $\boldsymbol{C}_3$ and $\boldsymbol{C}_4$ form a cycle of two components because they feed back and forth into each other. $\boldsymbol{C}_2$ and $\boldsymbol{C}_4$ have loops that connect them to themselves and are inner dependent. All other connections represent dependence between components which are thus known to be outer dependent.



Source: [26]
Fig. 3. Connections in a network

A component of a decision network which was derived by the DEMATEL, it will be denoted by $\boldsymbol{C}_i, i=1,\cdots,m,$ and assume that it has n_h elements, which we denote by $e_{h1}, e_{h2},\cdots, e_{hm}$. The influences of a given set of elements in a component on any element in the decision system are represented by a ratio scale priority vector derived from paired comparisons of the comparative importance of one criterion and another criterion with respect to the interests or preferences of the decision makers. This relative importance value can be determined using a scale of 1–9 to represent equal importance to extreme importance [26-29]. The influence of elements in the network on other elementsin that network can be represented in the following supermatrix:

$$\boldsymbol{W} = \begin{array}{c} \\ \boldsymbol{C}_1 \\ \\ \\ \boldsymbol{C}_2 \\ \\ \\ \boldsymbol{C}_2 \\ \\ \end{array} \begin{array}{c} \begin{array}{cccccccccc} \boldsymbol{C}_1 & & & \boldsymbol{C}_2 & & & \cdots & \boldsymbol{C}_m & & \\ e_{11} & \cdots & e_{1n_1} & e_{21} & \cdots & e_{2n_2} & \cdots & e_{m1} & \cdots & e_{mn_m} \end{array} \\ \begin{bmatrix} \boldsymbol{W}_{11} & & \boldsymbol{W}_{12} & & \cdots & \boldsymbol{W}_{1m} \\ \boldsymbol{W}_{21} & & \boldsymbol{W}_{22} & & \cdots & \boldsymbol{W}_{2m} \\ \vdots & & \vdots & & \ddots & \vdots \\ \boldsymbol{W}_{m1} & & \boldsymbol{W}_{m2} & & \cdots & \boldsymbol{W}_{mm} \end{bmatrix} \end{array}$$

A typical entry $\boldsymbol{W}_{ij}$ in the supermatrix, is called a block of the supermatrix in the following form where each column of $\boldsymbol{W}_{ij}$ is a principal eigenvector of the influence of the elements in the i^{th} component of the network on an element in the j^{th} component. Some of its entries may be zero corresponding to those elements that have no influence.

$$\boldsymbol{W}_{ij} = \begin{bmatrix} w_{i_1 j_1} & w_{i_1 j_2} & \cdots & w_{i_1 j_{n_j}} \\ w_{i_2 j_2} & w_{i_2 j_2} & \cdots & w_{i_2 j_{n_j}} \\ \vdots & \vdots & \ddots & \vdots \\ w_{i_{n_i} j_1} & w_{i_{n_i} j_2} & \cdots & w_{i_{n_i} j_{n_j}} \end{bmatrix}$$

After forming the supermatrix, the weighted supermatrix is derived by transforming all columns sum to unity exactly. This step is very much similar to the concept of the Markov chain in terms of ensuring that the sum of these probabilities of all states equals 1. Next, the weighted supermatrix is raised to limiting powers, such as Equation (5) to get the global priority vector or called weights [4].

$$\lim_{\theta\to\infty} \boldsymbol{W}^{\theta} \tag{7}$$

In addition, if the supermatrix has the effect of cyclicity, the limiting supermatrix is not the only one. There are two or more limiting supermatrices in this situation, and the Cesaro sum would need to be calculated to get the priority. The Cesaro sum is formulated as follows.

$$\lim_{\psi\to\infty} (\frac{1}{\nu}) \sum_{j=1}^{\nu} \boldsymbol{W}_j^{\psi} \tag{8}$$

To calculate the average effect of the limiting supermatrix (i.e. the average priority weights) where $\boldsymbol{W}_j$ denotes the j^{th} limiting supermatrix. Otherwise, the supermatrix would be raised to large powers to get the priority weights [10] The weights of the k^{th} criterion derived by using the above ANP processes, namely ω_k, $k \in \{1,2,...,n\}$, will be regard as the weight of the k^{th} criterion.

D. VIKOR

VIKOR was proposed by Opricovic [6] and is a method to develop for multi-criteria optimization of complex systems. It determines the compromise ranking list and the compromise solution obtained with the initial (given) weights [16]. For

example from Figure 3-6, f_1^* (the ideal value of the first assessment criterion) and f_2^* (the ideal value of the second criterion) cannot reach f^* (ideal solution) at the same time. And the compromised solution is a point on the curve. f^c is closest to the ideal solution (f^*) among all non-inferior solutions. And therefore, the optimum compromised solution is: $f^c = f_1^c, f_2^c$. The steps of applying VIKOR are shown as follows [25]:

Step 1: Determine the ideal (best) solution (f_1^*) and the negative (worst) ideal solution (f_i^-) values of all criterion functions, $i = 1,2,\ldots n$. If the i th function represents a benefit then:

$$f_i^* = [(\max_j f_{ij} | i \in I_1) , (\min_j f_{ij} | i \in I_2)] , \forall_i \quad (9)$$

$$f_i^- = [(\min_j f_{ij} | i \in I_1) , (\max_j f_{ij} | i \in I_2)] , \forall_i \quad (10)$$

Step 2: Compute the values S_j and R_j , $j = 1,2,\ldots J$, by the relations

$$S_j = \sum_{i=1}^{n} w_i (f_i^* - f_{ij}) / (f_i^* - f_i^-) \quad (11)$$

$$R_j = \max_i \left[w_i (f_i^* - f_{ij}) / (f_i^* - f_i^-) \right] , \ j = 1,2,\ldots.J \quad (12)$$

where w_i are the weights of criteria, expressing their relative importance.

Step 3: Compute the values Q_j , $j = 1,2,\ldots J$, by the relation

$$Q_j = v(S_j - S^*) / (S^- - S^*) + (1-v)(R_j - R^*) / (R^- - R^*) \quad (14)$$

where $S^* = \min_j S_j$ $S^- = \max_j S_j$, $R^* = \min_j R_j$, $R^- \max_j R_j$

and v is introduced as a weight for the strategy of maximum group utility, whereas 1- v is the weight of the individual regret.

Step 4: Rank the alternatives, sorting by the values S , Q and R , in decreasing order. The results are three ranking lists.

Step 5: Propose as a compromise the alternative ($a^{'}$) which is ranked the best by the measure Q (minimum) if the following two conditions are satisfied:

C1. Acceptable advantage: $Q(a'')-Q(a') \geqq DQ$ where $a^{''}$ is the alternative with second position in the ranking list by Q ; $DQ = 1/(J-1)$; J is the number of alternatives.

C2. Acceptable stability in decision making: Alternative a′ must also be the best ranked by S or/and R . This compromise solution is stable within a decision making process, which could be: "voting by majority rule" (when $v > 0.5$ is needed), or "by consensus" $v \approx 0.5$, or "with veto" $v < 0.5$ .Here, v is the weight of the decision making strategy "the majority of criteria" (or "the maximum group utility").

If one of the conditions is not satisfied, then a set of compromise solutions is proposed, which consists of:

- Alternatives a′ and a″ if only condition C2 is not satisfied.
- Alternatives a′, a″,… $a^{(M)}$ if condition C1 is not satisfied; and $a^{(M)}$ is determined by the relation $Q(a^{(M)}) - Q(a^{'}) < DQ$ for maximum M (the positions of these alternatives are "in closeness").

According to Tzeng [8], the compromise solution is determined by the compromise-ranking method; the obtained compromise solution could be accepted by the decision makers because it provides maximum group utility of the majority (represented by min S , Eq. (11)), and minimum individual regret of the opponent (represented by min Q , Eq. (12)). The VIKOR algorithm determines the weight stability intervals for the obtained compromise solution with the input weights given by the experts.

IV. EMPIRICAL STUDY IN R&D FUNCTION

Following, an empirical study based on one of the world's leading IT company will be used for demonstrating the feasibility of the proposed hybrid MCDM framework. Managers for manufacturing sites will be evaluated and expatriated.

Ten experts with more than five years working experiences in globalized IT firms were invited to evaluate each of the first sixteen criteria. Those sixteen criteria include work experience (c_1), educational degree (c_2), language skill (c_3), age and sexuality (c_4), creativity (c_5), execution (c_6), communication (c_7), leadership (c_8), personal willingness (c_9), personal health (c_{10}), compensation (c_{11}), family support (c_{12}), loyalty (c_{13}), integrity (c_{14}), social skill (c_{15}) and cross-culture skill (c_{16}). The IRM can be derived then based on the DEMATEL. Furthermore, based on the ANP being introduced in Section 3, the weights versus each criterion can be derived. Based on the IRM being derived by the DEMATEL, the ANP method can be applied for calculating the weight versus each criterion. Pair-wise comparison results for the importance level of criteria being connected to the same goal are deprived according to experts' opinions and were provided as inputs for the ANP. The Super Decision [26] was used for deriving the weights (TABLE I).

TABLE I. The weights versus the criteria

Criteria	c_1	c_2	c_3	c_4	c_5	c_6	c_7	c_8
Weight	0.061	0.059	0.138	0.000	0.039	0.105	0.109	0.082
Criteria	c_9	c_{10}	c_{11}	c_{12}	c_{13}	c_{14}	c_{15}	c_{16}
Weight	0.113	0.037	0.000	0.021	0.056	0.054	0.126	0.000

Finally, the manager for an overseas manufacturing site can be evaluated and prioritized. According to Table II, the ranking results between all alternatives. The candidate C is the best one due to its lowest value in R-measure.

TABLE II. Results of ranking alternatives

Candidate	A	B	C
S	0.582	1.065	0.466
Q	0.138	0.808	0.109
R	0.118	1.000	0.000
Rank	2	3	1

V. DISICUSSION

In order to develop and sustain the global competitive advantage, appropriate international human resources management strategies should be adopted by MNEs. The appropriate expatriate manager selection is the very beginning step for the success of the international human resources management.

Based on the empirical study results, the language skill (0.138), social skills (0.126), personal willingness (0.113), communication skills (0.109), and execution capabilities (0.105) were regarded as the most important criteria. Except for the well-recognized including language skill et al., execution was selected as one of the important criteria albeit very little literature mentioned this criterion.

The criteria being neglected are worth discussing also. In this research, age, sexuality, creativity, personal health, compensation, as well as cross-culture skill was neglected. For the high technology firms being located in both Taiwan and China, since most managers got graduate degrees, their tendency to despise younger or female managers are less significant. Further, since the most Taiwanese IT company mainly focuses on process innovation aiming at cost reduction instead of product innovation, creativity is regarded as an non-important factor. For the neglect of health, compensation and family support, since most Taiwanese or mainland Chinese IT firms usually adopt the low cost strategy instead of differentiation, since there is almost nothing to be differentiated. Managers in such Asian firms usually neglected their personal health and family life.

Based on the results, the expatriates need to constantly enhance their professional skills and develop the potential energy by MNE training. The integrated training of the expatriates should be included manpower development, management development, career development, pre-departure training, and preview of the expatriate position, cultural awareness, language training and pre-departure practices.

In comparison with the traditional Fuzzy AHP based MCDM framework, the hybrid MCDM model consisting of the Delphi, the DEMATEL, the ANP, and the VIKOR was designed to overcome (1) the global expatriate selection issue, (2) traditional MCDM approaches for evaluating the global expatriate selection problem based on the wrong assumptions on the independence between the determinants, (3) the concept of the VIKOR which can be used to derive the optimal strategy which is closest to the ideal solution. Through the case study, we found the hybrid MCDM model to be applicable.

VI. CONCLUSSIONS

In the era of globalization, appropriate expatriate manager selections are critical conditions for the success of overseas operations. In this research, a hybrid MCDM framework consisting of the DEMATEL, the ANP and the VIKOR was proposed for selecting an appropriate expatriate manager for overseas manufacturing sites. An empirical study being modified from a real situation of a leading IT firm was introduced for verifying the feasibility of the proposed framework. In the future, the proposed framework can be applied on other expatriate selection problems. Meanwhile, further researches on the criteria being neglected during the evaluation process, including age, sexuality, compensation, cross-culture skill and etc. worth investigations.

***Abstract*—The union and intersection of general type-2 fuzzy sets (T2 FSs) are fundamental computations for such FSs. In the past, algorithms were developed for the union and intersection computations using vertical-slice and horizontal-slice representations of T2 FSs. The vertical-slice representation of a T2 FS traces its origins back to Zadeh [32] and requires computing the join or meet, whereas the horizontal-slice representation of a T2 FS is very recent, traces its origins to Liu [14], and requires computing the join and meet only for interval T2 FSs that are raised to level alpha, for which closed-form formulas are available [15]. In this paper, by studying the join and meet geometrically for general T2 FSs, we show that for many situations closed-form formulas exist for them. We also show that the formulas for computing the union and intersection of general T2 FSs that were derived from the horizontal-slice representation of a T2 FS [19] can also be obtained directly from geometrical interpretations of formulas that were derived by Karnik and Mendel [12] for the vertical-slice representation of a T2 FS.**

Keywords-Type-2 fuzzy sets, union, intersection, join, meet

I. INTRODUCTION

The use of general type-2 fuzzy sets (T2 FSs) in T2 fuzzy systems has the potential to let such fuzzy systems outperform comparable T2 fuzzy systems that only use interval type-2 fuzzy sets (IT2 FSs). This is because a general T2 FS makes full use of its third dimension, whereas an interval T2 FS does not. Consequently, there is now renewed attention at all aspects of general T2 FSs and fuzzy systems, including the computations of the three basic set-theoretic operations of intersection, union and complement [1]-[32]. This paper focuses only on the intersection and union operations, because they can be difficult to compute for general T2 FSs, whereas the complement is straightforward to compute.

Consider two T2 FSs sets [1] $\tilde{A}$ ($\mu_{\tilde{A}}: X\times[0,1]\rightarrow[0,1]$) and $\tilde{B}$ ($\mu_{\tilde{B}}: X\times[0,1]\rightarrow[0,1]$). $\tilde{A}$ and $\tilde{B}$ are described by 3D membership functions $\mu_{\tilde{A}}(x,u)$ ($x\in X$, $u\in U=[0,1]$) and $\mu_{\tilde{B}}(x,w)$ ($x\in X$, $w\in W=[0,1]$), respectively. They can also be expressed in terms of their respective *secondary membership functions*, $\mu_{\tilde{A}}(u\,|\,x)$ and $\mu_{\tilde{B}}(w\,|\,x)$, and *secondary grades*, $f_x(u)$ and $g_x(w)$, as:

$$\tilde{A}=\int_X \mu_{\tilde{A}}(u\,|\,x)/x=\int_X\left[\int_{U=[0,1]} f_x(u)/u\right]/x \tag{1}$$

and[1]

$$\tilde{B}=\int_X \mu_{\tilde{B}}(w\,|\,x)/x=\int_X\left[\int_{W=[0,1]} g_x(w)/w\right]/x \tag{2}$$

Note that $\mu_{\tilde{A}}(u\,|\,x)$ and $\mu_{\tilde{B}}(w\,|\,x)$ are T1 FSs, and are also called *vertical slices* of $\tilde{A}$ and $\tilde{B}$, respectively; hence (1) and (2) are called *vertical-slice representations of* $\tilde{A}$ and $\tilde{B}$.

It is well-known[2] [20] that the union of $\tilde{A}$ and $\tilde{B}$ is another T2 FS whose MF can be computed from:

$$\tilde{A}\cup\tilde{B}=\int_X \mu_{\tilde{A}\cup\tilde{B}}(v\,|\,x)/x \tag{3}$$

where

$$\begin{aligned}\mu_{\tilde{A}\cup\tilde{B}}(v\,|\,x)&=\int_{U=[0,1]}\int_{W=[0,1]} f_x(u)\bigstar g_x(w)/(v=u\vee w)\\ &\equiv \mu_{\tilde{A}}(u\,|\,x)\sqcup\mu_{\tilde{B}}(w\,|\,x)\quad x\in X\end{aligned} \tag{4}$$

in which $\sqcup$ denotes the *join* operation. The use of the notation $\mu_{\tilde{A}}(u\,|\,x)\sqcup\mu_{\tilde{B}}(w\,|\,x)$ to indicate the join between the secondary MFs $\mu_{\tilde{A}}(u\,|\,x)$ and $\mu_{\tilde{B}}(w\,|\,x)$ is, of course, a *shorthand notation* for the operations in the middle of (4). What (4) says is that to perform the join between two secondary MFs, $\mu_{\tilde{A}}(u\,|\,x)$ and $\mu_{\tilde{B}}(w\,|\,x)$, $v=u\vee w$ must be computed between every possible pair of primary memberships u and w, such that $u\in U$ and $w\in W$, and that the secondary grade of $\mu_{\tilde{A}\cup\tilde{B}}(v\,|\,x)$ must be computed as the *t*-norm operation between the corresponding secondary grades of $\mu_{\tilde{A}}(u\,|\,x)$ and $\mu_{\tilde{B}}(w\,|\,x)$, $f_x(u)$ and $g_x(w)$, respectively. Note that at each value of x the join involves T1 FSs (i.e.,

[1] When a secondary MF, e.g. $\mu_{\tilde{A}}(u\,|\,x)$, has support that does not have gaps (the support of a T1 FS is the set of values of its primary variable for which that MF is > 0), then it has been customary in the past to denote that support as J_x^u, and to call it the *primary membership*. This notation, which has been called into question in [1], is not used herein because it is not needed. Note, also, that in the past the notation $\mu_{\tilde{A}}(x)$ has been used (e.g., [15]) as a shorthand notation for $\mu_{\tilde{A}}(u\,|\,x)$. We now prefer to use $\mu_{\tilde{A}}(u\,|\,x)$ because it shows the explicit dependence of $\mu_{\tilde{A}}$ on its functional argument u.

[2] Some of the material in this section is taken from [16] and [19].

secondary MFs), and that the join must be computed for $\forall x \in X$. If more than one combination of u and w gives the same point $u \vee w$, then in the join we keep the one with the largest membership grade. Usually, the maximum *t*-conorm is used, as suggested in [32] and [20].

In general, evaluating the join is difficult to do for arbitrary T2 FSs. Karnik and Mendel [12] have shown that for n convex and normal (secondary) T1 FSs, $F_1,...,F_n$, characterized by MFs $f_1(\theta \mid x)$,...,$f_n(\theta \mid x)$, respectively, where $f_1(v_1 \mid x) = \ldots = f_n(v_n \mid x) = 1$, and the $f_i(\theta \mid x)$ are re-ordered so that $v_1 \le v_2 \le \cdots \le v_n$, the MF of $\sqcup_{i=1}^{n} F_i$, using maximum *t*-conorm ($\vee$) and either minimum or product *t*-norm (T), can be expressed as ($\forall x \in X$):

$$\mu_{\sqcup_{i=1}^{n} F_i}(\theta \mid x) = \begin{cases} T_{i=1}^{n} f_i(\theta \mid x) & \theta < v_1 \\ T_{i=k+1}^{n} f_i(\theta \mid x) & v_k \le \theta \le v_{k+1} \\ \vee_{i=1}^{n} f_i(\theta \mid x) & \theta > v_n \end{cases} \quad 1 \le k \le n-1 \quad (5)$$

Coupland and John [4]-[8] have taken a very new and novel approach to computing the join. Because their approach is also used for computing the meet, we describe it later in this section.

It is also well known [20] that the intersection of $\tilde{A}$ and $\tilde{B}$ is another T2 FS whose MF can be computed from:

$$\tilde{A} \cap \tilde{B} = \int_X \mu_{\tilde{A} \cap \tilde{B}}(v \mid x) / x \quad (6)$$

where

$$\begin{aligned} \mu_{\tilde{A} \cap \tilde{B}}(v \mid x) &= \int_{U=[0,1]} \int_{W=[0,1]} f_x(u) \bigstar g_x(w) / (v = u \wedge w) \\ &\equiv \mu_{\tilde{A}}(u \mid x) \sqcap \mu_{\tilde{B}}(w \mid x) \quad x \in X \end{aligned} \quad (7)$$

in which $\sqcap$ denotes the *meet* operation. The use of the notation $\mu_{\tilde{A}}(u \mid x) \sqcap \mu_{\tilde{B}}(w \mid x)$ to indicate the meet between the secondary MFs $\mu_{\tilde{A}}(u \mid x)$ and $\mu_{\tilde{B}}(w \mid x)$ is another *shorthand notation*, but this time for the operations in the middle of (7). What (7) says is that to perform the meet between two secondary MFs, $\mu_{\tilde{A}}(u \mid x)$ and $\mu_{\tilde{B}}(w \mid x)$, $v = u \wedge w$ must be performed between every possible pair of primary memberships u and w, such that $u \in U$ and $w \in W$, and the secondary grade of $\mu_{\tilde{A} \cap \tilde{B}}(v \mid x)$ must be computed as the *t*-norm operation between the corresponding secondary grades of $\mu_{\tilde{A}}(u \mid x)$ and $\mu_{\tilde{B}}(w \mid x)$, $f_x(u)$ and $g_x(w)$, respectively. This must be done for $\forall x \in X$. If more than one combination of u and w gives the same point $u \wedge w$, then in the meet (just as in the join) we keep the one with the largest membership grade.

Note that in (7) there are two t-norms, $\bigstar$ and $\wedge$. Although they are usually chosen to be the same, they do not have to be. See Starczewski [23] for very interesting discussions about this.

In general, evaluating the meet is also difficult to do for arbitrary T2 FSs, especially when the product *t*-norm is used in both places in (7). Karnik and Mendel [20] have also shown that for n convex and normal T1 FSs, $F_1,...,F_n$, characterized by MFs $f_1(\theta \mid x)$,...,$f_n(\theta \mid x)$, respectively, where $f_1(v_1 \mid x) = \ldots = f_n(v_n \mid x) = 1$, and the $f_i(\theta \mid x)$ are re-ordered so that $v_1 \le v_2 \le \cdots \le v_n$, the MF of $\sqcap_{i=1}^{n} F_i$ using maximum *t*-conorm and minimum *t*-norm can be expressed as ($\forall x \in X$):

$$\mu_{\sqcap_{i=1}^{n} F_i}(\theta \mid x) = \begin{cases} \vee_{i=1}^{n} f_i(\theta \mid x) & \theta < v_1 \\ \wedge_{i=1}^{k} f_i(\theta \mid x) & v_k \le \theta \le v_{k+1} \\ \wedge_{i=1}^{n} f_i(\theta \mid x) & \theta > v_n \end{cases} \quad 1 \le k \le n-1 \quad (8)$$

The usual derivations of (4) and (7) utilize Zadeh's extension principle. Mendel and John [18] show how (4) and (7) can easily be derived without having to use the Extension Principle.

Because (4) and (7) compute the join and meet of T2 FSs one vertical slice at a time, we shall refer to them as *vertical-slice computations*.

Coupland and John [7, 8] have shown how to compute the join and meet of $\tilde{A}$ and $\tilde{B}$ using methods from computational geometry (e.g., a modified Weiler-Atherton clipping algorithm, and a Bentley-Ottman plane sweep algorithm). Their approach is based on modeling a secondary MF geometrically as a [9] "set of connected straight line segments that need not be equally-spaced across the domain," and is limited so far to the minimum t-norm and the maximum *t*-co-norm.

Even more recently, Greenfield and John [9] presented an optimized grid method for computing the join and meet, one that is much more computationally efficient than a direct approach to using (5) and (8).

A limitation of the geometric and grid methods is they do not obtain closed-form formulas for the join and meet operations. Such formulas can be very useful when a type-2 fuzzy logic system is designed by optimizing an objective function with respect to MF parameters, and explicit derivatives of that function have to be computed so that optimal values of those parameters can be found.

When secondary MFs are triangular (an interesting compromise between interval secondary MFs and general secondary MFs, and one that is also considered by Coupland and John [7]) then Starczewski [22, 24] has shown that "extended *t*-norms[3] of triangular fuzzy truth values may be approximated by triangular fuzzy truth values as well." One of the most interesting aspects of Starczewski's [24] approach is it "… reduces calculations of extended *t*-norms (a similar approach can be rearranged for *s*-norms) to computing only the three characteristic functions: principal, upper and lower. Arbitrary traditional *t*-norms (or *s*-norms) can be used to calculate these functions. A tremendously useful feature of this approach is that the resultant MF preserves triangular shapes of the two arguments, and this way the approximate *t*-norms can be expanded to multi-argument form. Moreover, for

[3] An extended *t*-norm is a *t*-norm obtained by applying the Extension Principle to a T1 *t*-norm. It was the basis for Mizumoto and Tanaka's [20] works.

each triangular fuzzy membership grade only three parameters have to be stored and processed by [a] FLS, instead of tabularized functions as in the general approach." Another very useful feature of this approach is that formulas are given for the operations, so that explicit derivative formulas can be obtained if a triangular T2 FLS is designed (optimized) using a method that requires such derivatives (e.g., steepest descent).

Recently, Liu [14] presented a horizontal-slice[4] α-plane representation for a general T2 FS. This was further elaborated upon in [19, 17]. Related works are in [27], [29] and [30]. Using this new representation, described next, it is possible to compute the union and intersection of general T2 FSs one α-plane at a time.

Definition 1. An *α-plane* for the general T2 FS $\tilde{A}$, denoted $\tilde{A}_\alpha$, is the union of all primary memberships of $\tilde{A}$ whose secondary grades are greater than or equal to α ($0 \le \alpha \le 1$), i.e. [14]

$$\begin{aligned}\tilde{A}_\alpha &= \left\{(x,u), \mu_{\tilde{A}}(x,u) \ge \alpha \,\middle|\, \forall x \in X, \forall u \in U = [0,1]\right\} \\ &= \int_{\forall x \in X} \int_{\forall u \in U=[0,1]} \{(x,u) \,|\, f_x(u) \ge \alpha\}\end{aligned} \quad \blacksquare \quad (9)$$

Let[5] $S_{\tilde{A}_\alpha}(x)$ denote an α-cut of the secondary MF $\mu_{\tilde{A}}(u \,|\, x)$, i.e.,

$$S_{\tilde{A}_\alpha}(x) = [\underline{\mu}_{\tilde{A}_\alpha}(x), \overline{\mu}_{\tilde{A}_\alpha}(x)] \quad (10)$$

where $\underline{\mu}_{\tilde{A}_\alpha}(x)$ is the lower MF of $\tilde{A}_\alpha$ at x and $\overline{\mu}_{\tilde{A}_\alpha}(x)$ is the upper MF of $\tilde{A}_\alpha$ at x, i.e.:

$$\underline{\mu}_{\tilde{A}_\alpha}(x) = \inf\left\{u \,|\, u \in [0,1], \mu_{\tilde{A}}(x,u) \ge \alpha\right\} \quad (11)$$

$$\overline{\mu}_{\tilde{A}_\alpha}(x) = \sup\left\{u \,|\, u \in [0,1], \mu_{\tilde{A}}(x,u) \ge \alpha\right\} \quad (12)$$

Then, another way to express $\tilde{A}_\alpha$ is:

$$\tilde{A}_\alpha = \int_{\forall x \in X} S_{\tilde{A}_\alpha}(x)/x = \int_{\forall x \in X} \left(\int_{\forall u \in [\underline{\mu}_{\tilde{A}_\alpha}(x), \overline{\mu}_{\tilde{A}_\alpha}(x)]} u \right) / x \quad (13)$$

Definition 2. The *α-plane Representation* for $\tilde{A}$ is [14]:

$$\tilde{A} = \bigcup_{\alpha \in [0,1]} \alpha / \tilde{A}_\alpha \quad \blacksquare \quad (14)$$

In (14), $\alpha / \tilde{A}_\alpha$ denotes $\tilde{A}_\alpha$ raised to level α, is called[6] an α-level T2 FS, and is an IT2 FS whose secondary grades equal α instead of 1 (as would be the case for the usual IT2 FS). This suggests, and is indeed the case, that operations involving T2 FSs can be performed using readily available operations for IT2 FSs. Note that $\alpha / \tilde{A}_\alpha$ is called a *zSlice* by Wagner and Hagras [29, 30].

Let $(\tilde{A} \cup \tilde{B})_\alpha$ and $(\tilde{A} \cap \tilde{B})_\alpha$ be the α-planes of $\tilde{A} \cup \tilde{B}$ and $\tilde{A} \cap \tilde{B}$, respectively. For the minimum t-norm [i.e., the star in (4) and (7)], it is true that [14], [19]:

$$\tilde{A} \cup \tilde{B} = \bigcup_{\alpha \in [0,1]} \alpha / (\tilde{A} \cup \tilde{B})_\alpha = \bigcup_{\alpha \in [0,1]} \alpha / \tilde{A}_\alpha \cup \tilde{B}_\alpha \quad (15)$$

$$\tilde{A} \cap \tilde{B} = \bigcup_{\alpha \in [0,1]} \alpha / (\tilde{A} \cap \tilde{B})_\alpha = \bigcup_{\alpha \in [0,1]} \alpha / \tilde{A}_\alpha \cap \tilde{B}_\alpha \quad (16)$$

To-date, comparable results for other star t-norms, such as the product, are not available; however, any conjunction can be used in the meet, e.g., minimum or product.

To compute, e.g., $\tilde{A}_\alpha \cup \tilde{B}_\alpha$, for each value of α and $\forall x \in X$:

1. Compute $\tilde{A}_\alpha$ and $\tilde{B}_\alpha$, the results of which are two planes that are bounded by their respective lower and upper MFs, $\underline{\mu}_{\tilde{A}_\alpha}(x)$, $\overline{\mu}_{\tilde{A}_\alpha}(x)$, $\underline{\mu}_{\tilde{B}_\alpha}(x)$ and $\overline{\mu}_{\tilde{B}_\alpha}(x)$
2. *Compute $\tilde{A}_\alpha \cup \tilde{B}_\alpha$, as:*

$$\tilde{A}_\alpha \cup \tilde{B}_\alpha = [\underline{\mu}_{\tilde{A}_\alpha \cup \tilde{B}_\alpha}(x), \overline{\mu}_{\tilde{A}_\alpha \cup \tilde{B}_\alpha}(x)] \quad (17)$$

where

$$\underline{\mu}_{\tilde{A}_\alpha \cup \tilde{B}_\alpha}(x) = \underline{\mu}_{\tilde{A}_\alpha}(x) \vee \underline{\mu}_{\tilde{B}_\alpha}(x) \quad (18)$$

$$\overline{\mu}_{\tilde{A}_\alpha \cup \tilde{B}_\alpha}(x) = \overline{\mu}_{\tilde{A}_\alpha}(x) \vee \overline{\mu}_{\tilde{B}_\alpha}(x) \quad (19)$$

To compute $\tilde{A}_\alpha \cap \tilde{B}_\alpha$, simply replace $\tilde{A}_\alpha \cup \tilde{B}_\alpha$ in (17) – (19) by $\tilde{A}_\alpha \cap \tilde{B}_\alpha$, and $\vee$ in (18) and (19) by $\wedge$.

Because (15) and (16) compute the union and intersection of T2 FSs one horizontal slice at a time (i.e., one α-plane at a time), we shall refer to them as either *horizontal-slice* or *α-plane computations*.

In this paper we connect results that can be obtained from using (5) and (15) for the union of two T2 FSs, and (8) and (16) for the intersection of two T2 FSs, i.e. we connect the vertical-slice and horizontal-slice computations. In order to do this, we first study the geometry of the join and meet when (5) and (15) are used. Our purpose for doing these things is to *provide more insight into computations of the join and meet* and to *provide a new derivation of (15) and (16) directly from (5) and (8)*.

[4] Because a horizontal slice is analogous to an α-cut of a T1 FS, it is called the *α-plane representation* for a T2 FS.

[5] [19] uses the notations $S_{\tilde{A}}(x \,|\, \alpha)$, $s_L(x \,|\, \alpha)$ and $s_R(x \,|\, \alpha)$ for $S_{\tilde{A}_\alpha}(x)$, $\underline{\mu}_{\tilde{A}_\alpha}(x)$ and $\overline{\mu}_{\tilde{A}_\alpha}(x)$, respectively. Our notation is more consistent with the notation that has been proposed in [1], which is why we use it.

[6] In [19] $\alpha / \tilde{A}_\alpha$ is called the *footprint of uncertainty (FOU) of the α-plane*. As explained in [17], this is a misnomer, because an FOU lies on the 2D support of the MF of $\tilde{A}$, which corresponds to the $\tilde{A}_0$-plane.

II. GEOMETRY OF THE JOIN AND MEET: VERTICAL-SLICE COMPUTATIONS

It is straightforward to re-express (5) and (8) recursively, so that their computations are done two type-2 fuzzy sets at a time; hence, in order to study the geometry of join and meet, we focus on (5) and (8) at *any* $x \in X$ for two T2 FSs, $\tilde{A}$ and $\tilde{B}$, as defined in (1) and (2), respectively. For two T2 FSs, letting $F_1 \equiv F$ and $F_2 \equiv G$, and using the minimum[7] t-norm, minimum for the conjunction operation and maximum for the disjunction operation, (5) and (8) simplify[8] to:

$$\mu_{F \sqcup G}(\theta) = \begin{cases} \min[f(\theta), g(\theta)] & \theta < v_0 \\ g(\theta) & v_0 \le \theta \le v_1 \\ \max[f(\theta), g(\theta)] & \theta > v_1 \end{cases} \tag{20}$$

$$\mu_{F \sqcap G}(\theta) = \begin{cases} \max[f(\theta), g(\theta)] & \theta < v_0 \\ f(\theta) & v_0 \le \theta \le v_1 \\ \min[f(\theta), g(\theta)] & \theta > v_1 \end{cases} \tag{21}$$

A. Geometry of the Join

To illustrate the geometry of the join, we chose triangle MFs for both $f(\theta)$ and $g(\theta)$, and then used (20) to compute $\mu_{F \sqcup G}(\theta)$. Note, however, that *our results are valid for all convex secondary MFs*.

It is easy to use (20) to obtain $\mu_{F \sqcup G}(\theta)$ for the (e.g.) nine different relative locations of $f(\theta)$ and $g(\theta)$ that are summarized in Table I. Additional cases can be obtained by interchanging $f(\theta)$ and $g(\theta)$, and this is left to the reader. Observe from these nine cases, that:

1. When $v_1 > v_0$, and $f(\theta)$ and $g(\theta)$ either do not intersect [cases (a) and (e)], or have exactly one intersection [cases (b) and (f)], then $\mu_{F \sqcup G}(\theta) = g(\theta)$, the right-most secondary MF.
2. When $v_1 = v_0 = 0$, and $g(\theta) \subseteq f(\theta)$ [case (d)], then $\mu_{F \sqcup G}(\theta) = f(\theta)$, the right-most secondary MF; if $f(\theta) \subseteq g(\theta)$ re-label $f(\theta)$ as $g(\theta)$ and vice-versa.
3. When $v_1 = v_0 \neq 0$, and $g(\theta) \subseteq f(\theta)$ [case (h)], then $\mu_{F \sqcup G}(\theta)$ involves both $f(\theta)$ and $g(\theta)$.
4. When $v_1 = v_0 \neq 0$, and the left leg of $f(\theta)$ is to the left of the left leg of $g(\theta)$, and the right leg of $f(\theta)$ is to the left of the right leg of $g(\theta)$ [case (i)], then $\mu_{F \sqcup G}(\theta) = g(\theta)$, the right-most secondary MF.
5. When $v_1 > v_0$ and $f(\theta)$ and $g(\theta)$ intersect at exactly two points [cases (c) and (g)], then $\mu_{F \sqcup G}(\theta)$ involves both $f(\theta)$ and $g(\theta)$. This is also true if $f(\theta)$ and $g(\theta)$ intersect at three points (see Fig. 2(a)).

Situations 1, 2 and 4 are interesting because solutions for the join are completely given and require no further computation. While this is interesting from an educational point of view, it may not be possible to easily carry out the tests for these cases in order to use these results in a computer implementation of these cases.

Situations 3 and 5 are also interesting because they let us focus on the situations when a computer solution for $\mu_{F \sqcup G}(\theta)$ will be required. It is only these situations that will be examined in Section III.

B. Geometry of the Meet

Table II summarizes $\mu_{F \sqcap G}(\theta)$ (computed from (21)) for triangle MFs for both $f(\theta)$ and $g(\theta)$, and for the same nine different relative locations of these MFs as in Table I. Observe from these nine cases, that:

1. When $v_1 > v_0$, and $f(\theta)$ and $g(\theta)$ either do not intersect [cases (a) and (e)], or have exactly one intersection [cases (b) and (f)], then $\mu_{F \sqcap G}(\theta) = f(\theta)$, the left-most secondary MF.
2. When $v_1 = v_0 = 0$, and $g(\theta) \subseteq f(\theta)$ [case (d)], then $\mu_{F \sqcap G}(\theta) = g(\theta)$, the left-most secondary MF; if $f(\theta) \subseteq g(\theta)$ re-label $f(\theta)$ as $g(\theta)$ and vice-versa.
3. When $v_1 = v_0 \neq 0$, and $g(\theta) \subseteq f(\theta)$ [case (h)], then $\mu_{F \sqcap G}(\theta)$ involves both $f(\theta)$ and $g(\theta)$.
4. When $v_1 = v_0 \neq 0$, and the left leg of $f(\theta)$ is to the left of the left leg of $g(\theta)$, and the right leg of $f(\theta)$ is to the left of the right leg of $g(\theta)$ [case (i)], then $\mu_{F \sqcap G}(\theta) = f(\theta)$, the left-most secondary MF.
5. When $v_1 > v_0$ and $f(\theta)$ and $g(\theta)$ intersect at exactly two points [cases (c) and (g)], then $\mu_{F \sqcap G}(\theta)$ involves both $f(\theta)$ and $g(\theta)$. This is also true if $f(\theta)$ and $g(\theta)$ intersect at three points (see Fig. 2(b)).

As for the join, Situations 1, 2 and 4 are interesting because solutions for the meet are completely given and require no further computation; however, it may not be possible to easily carry out the tests for these cases in order to use these results in a computer implementation of these cases.

Situations 3 and 5 are also interesting because they let us focus on the situations when a computer solution for $\mu_{F \sqcap G}(\theta)$

[7] It is straightforward to use the product t-norm in (5), something we leave to the readers [see also [26], in which (20) and (21) are re-derived; they are also extended to the product t-norm, but (21) is not extended to both the product t-norm and conjunction, a very difficult case that is considered in [12] but for which simple formula like (21) does not exist].

[8] In the rest of this paper, in order to be consistent with the notation in [15, Appendix A], we let $v_1 \to v_0$ and $v_2 \to v_1$. Additionally, f_x and g_x are shortened to f and g, and $\theta \mid x$ is shortened to θ, because we are focusing on (5) and (8) at *any* $x \in X$.

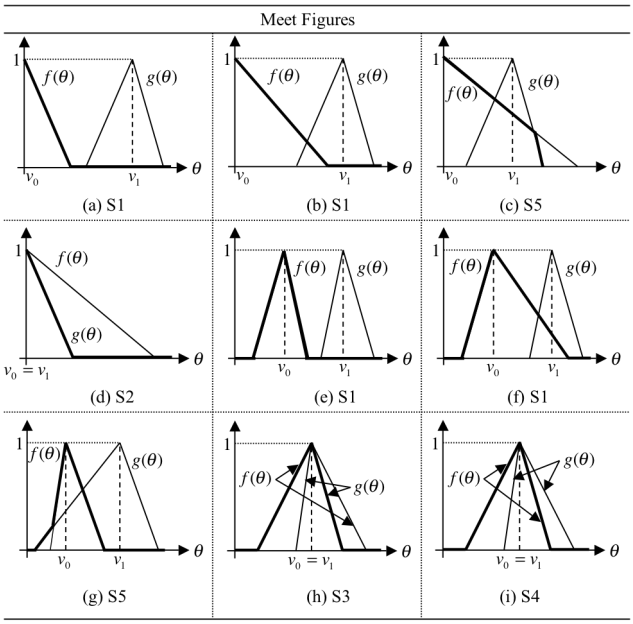
TABLE II

GEOMETRY OF THE MEET: THE HEAVY LINES DENOTE $\mu_{F \sqcap G}(\theta)$



will be required. It is only these situations that will be examined in Section III.

C. Simple Rules

Based on the results in Tables I and II and the rules extracted from their figures that are given in Sections A and B, it is possible to arrive at the following simple rules:

1. If $v_1 > v_0$ and $f(\theta)$ and $g(\theta)$ do not intersect or only have one intersection, or, if $v_1 = v_0 = 0$ and $f(\theta) \subseteq g(\theta)$ [if $f(\theta) \subseteq g(\theta)$ re-label $f(\theta)$ as $g(\theta)$ and vice-versa], or if $v_1 = v_0 \neq 0$, and the left leg of $f(\theta)$ is to the left of the left leg of $g(\theta)$, and the right leg of $f(\theta)$ is to the left of the right leg of $g(\theta)$, then:

$$\begin{cases} \mu_{F \sqcup G}(\theta) = g(\theta) \\ \mu_{F \sqcap G}(\theta) = f(\theta) \end{cases} \tag{22}$$

2. If $v_1 = v_0 \neq 0$, and $g(\theta) \subseteq f(\theta)$, then, although $\mu_{F \sqcup G}(\theta)$ and $\mu_{F \sqcap G}(\theta)$ involve both $f(\theta)$ and $g(\theta)$, no computer solutions are needed to compute them.
3. If $v_1 > v_0$ and $f(\theta)$ and $g(\theta)$ intersect at exactly two or more points, that $\mu_{F \sqcup G}(\theta)$ and $\mu_{F \sqcap G}(\theta)$ involve both $f(\theta)$ and $g(\theta)$, and require computer solutions.

Although these rules are obtained above for triangle secondary MFs, it is straightforward to show that they are applicable for all convex T1 FSs (Klir and Yuan (1995)).

III. CONNECTING VERTICAL-SLICE CALCULATIONS TO HORIZONTAL-SLICE (α-PLANE) COMPUTATIONS

In Section II.C, Rule 3 establishes when it is necessary to pursue the computations of $\mu_{F \sqcup G}(\theta)$ and $\mu_{F \sqcap G}(\theta)$ in more detail. In this section we study these detailed computations from different perspectives so as to connect the vertical-slice and horizontal slice computations. This is done geometrically, first for the join and then for the meet, both for the two T1 secondary MFs that intersect each other at three points, as depicted in Fig. 1. We leave it to the reader to verify that our conclusions are also applicable to two convex secondary T1 MFs that intersect at exactly two points, or for two convex secondary T1 MFs for which $v_1 = v_0 \neq 0$, and $g(\theta) \subseteq f(\theta)$ (Rule 2).

A. Join Computations

Using (20), the join of the two secondary MFs in Fig. 1 is depicted in Fig. 2a using heavy lines.

Next, we show how $\mu_{F \sqcup G}(\theta)$ can be obtained using the α-cuts of $f(\theta)$ and $g(\theta)$ raised to level α, denoted $f(\theta \mid \alpha)$ and $g(\theta \mid \alpha)$, respectively. From Fig. 3, for $\alpha_0 = 0$, observe the following:

$$\begin{cases} f(\theta \mid \alpha_0) = [a_0, b_0] \\ g(\theta \mid \alpha_0) = [c_0, d_0] \end{cases} \tag{23}$$

$$\mu_{F \sqcup G}(\theta \mid \alpha_0) = [a_0, b_0] = \left[\max(a_0, c_0), \max(b_0, d_0)\right] \tag{24}$$

For α_1, observe that:

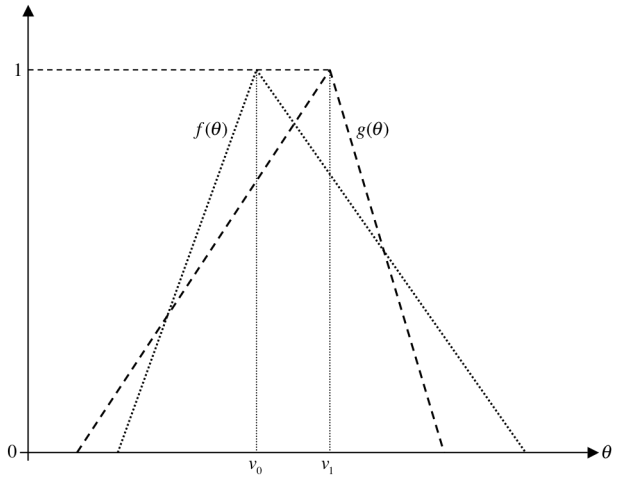


Figure 1. Two overlapping T1 secondary MFs.

$$\begin{cases} f(\theta \mid \alpha_1) = [a_1, b_1] \\ g(\theta \mid \alpha_1) = [c_1, d_1] \end{cases} \tag{25}$$

$$\mu_{F \sqcup G}(\theta \mid \alpha_1) = [a_1, b_1] = \left[\max(a_1, c_1), \max(b_1, d_1)\right] \tag{26}$$

Proceeding in a similar manner for the remaining α_i that are depicted on Fig. 3, it is straightforward to show that:

$$\begin{cases} f(\theta \mid \alpha_i) = [a_i, b_i] \\ g(\theta \mid \alpha_i) = [c_i, d_i] \end{cases}, \forall \alpha_i \tag{27}$$

$$\mu_{F \sqcup G}(\theta \mid \alpha_i) = \left[\max(a_i, c_i), \max(b_i, d_i)\right], \forall \alpha_i \tag{28}$$

The results in (27) and (28) are the same as the results that would be obtained from computing $\tilde{A}_\alpha \cup \tilde{B}_\alpha$, when (17)-(19) are used.

B. Meet Computations

Using (21), the meet of the two secondary MFs in Fig. 1 is depicted in Fig. 2b using heavy lines.

Next, we show how $\mu_{F \sqcap G}(\theta)$ can be obtained using $f(\theta \mid \alpha)$ and $g(\theta \mid \alpha)$. $f(\theta \mid \alpha_i)$ and $g(\theta \mid \alpha_i)$, for i = 0 and 1 are given in (23) and (25). From Fig. 4, for $\alpha_0 = 0$, observe that

$$\mu_{F \sqcap G}(\theta \mid \alpha_0) = [c_0, d_0] = \left[\min(a_0, c_0), \min(b_0, d_0)\right] \tag{29}$$

and, for α_1, observe that:

$$\mu_{F \sqcap G}(\theta \mid \alpha_1) = [c_1, d_1] = \left[\min(a_1, c_1), \min(b_1, d_1)\right] \tag{30}$$

Proceeding in a similar manner for the remaining α_i that are depicted on Fig. 4, it is straightforward to show that:

$$\mu_{F \sqcap G}(\theta \mid \alpha_i) = \left[\min(a_i, c_i), \min(b_i, d_i)\right], \forall \alpha_i \tag{31}$$

The result in (31) is the same as the result that would be obtained from computing $\tilde{A}_\alpha \cap \tilde{B}_\alpha$, when the well - known

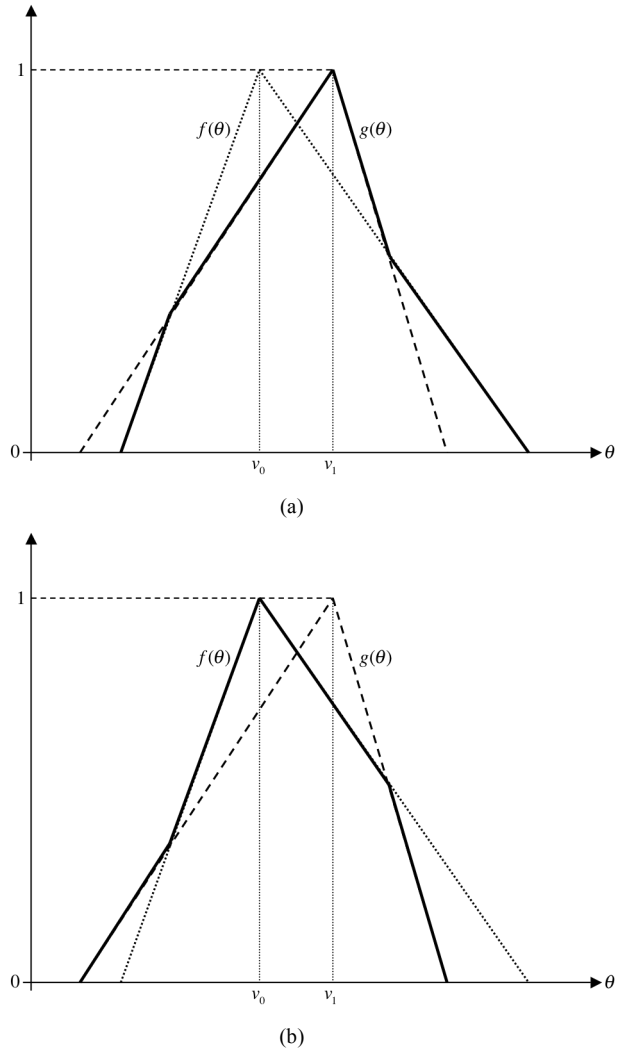

Figure 2. (a) Join and (b) meet of the two overlapping secondary MFs in Figure 1.

results for computing the intersection of IT2 FSs are used [described just below (19)].

C. Discussion

The results in (28) and (31) are, of course, not new. What is new is that they have been derived directly from the well-known vertical-slice computational results instead of from the α-plane representation. This provides an alternative way to obtain these results, which may be useful when teaching about general T2 FSs when time is limited.

IV. Conclusions

The union and intersection of general type-2 fuzzy sets (T2 FSs) are fundamental computations for such FSs. In the past, algorithms were developed for the union and intersection computations using vertical-slice and horizontal-slice representations of T2 FSs. The vertical-slice representation of a T2 FS traces its origins back to Zadeh [32] and requires computing the join or meet, whereas the horizontal-slice representation of a T2 FS is very recent, traces its origins to Liu [14], and requires computing the join and meet only for

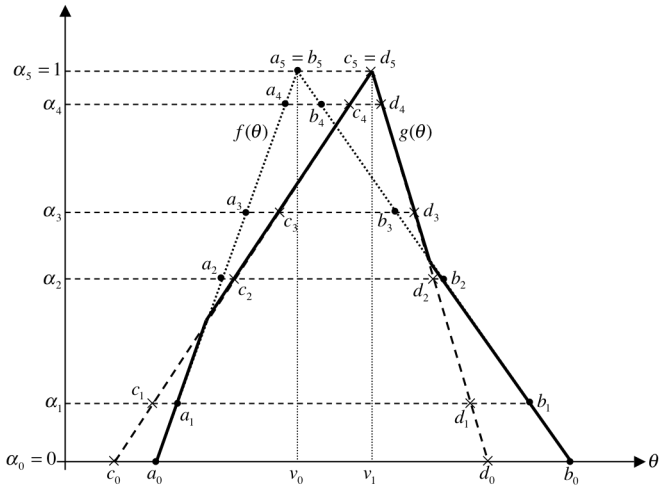

Figure 3. Join of the two overlapping secondary MFs in Fig. 1 and some α-cuts raised to level-α [9].

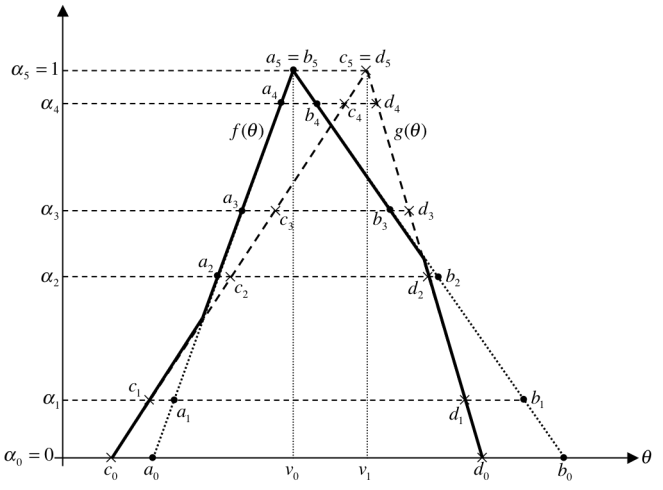

Figure 4. Meet of the two overlapping secondary MFs in Fig. 1 and some α-cuts raised to level-α. See footnote 9.

interval T2 FSs that are raised to level alpha, for which closed-form formulas are available [15]. In this paper, by studying the join and meet geometrically for general T2 FSs, we have shown that for many situations closed-form formulas exist for them. We have also shown that the formulas for computing the union and intersection of general T2 FSs that were derived from the horizontal-slice representation of a T2 FS [19] can also be obtained directly from geometrical interpretations of formulas that were derived by Karnik and Mendel [12] for the vertical-slice representation of a T2 FS.

How to turn the simple rules that are given in Section II.C into practical algorithms for computing the join and meet remains to be done. It was not done in this paper, because the purpose of this paper was to provide an alternative way to obtain these results, which may be useful when teaching about general T2 FSs when time is limited. We believe that this purpose has been accomplished.

Abstract— **This paper presents a fuzzy-based output power smoothing method for a wind energy conversion system (WECS) using short-term ahead prediction of wind speed. The WECS is based on a permanent magnet synchronous generator (PMSG) and transmits its electrical power to an AC grid through an IGBT pulse-width modulation (PWM) converter. The power converter controls the torque of the PMSG according to the torque command, which is determined by using the fuzzy logic. The inputs of the fuzzy logic are the predicted wind speed and the difference between the wind turbine torque and the generator torque. By means of the proposed method, the generator torque is smoothed and the kinetic energy stored by the inertia of the wind turbine can be utilized to smooth the output power fluctuations of the PMSG. In addition, the wind turbine's shaft stress is mitigated compared to a conventional maximum power point tracking (MPPT) control. The effectiveness of the proposed method is verified by numerical simulations.**

keywords–fuzzy logic, power smoothing, wind energy conversion system, wind speed prediction, wind turbine inertia.

I. Introduction

In recent years, there have been problems such as exhaustion of fossil fuels, e.g., coal and oil, and environmental pollution resulting from consumption of these fuels. For cleaner and economical energy characteristics, the world has been turning to alternatives of fossil fuels and wind energy conversion systems (WECS) have received increasing attention. Especially, variable speed wind turbine (VSWT) systems with power electronics interfaces have attracted interest. VSWT systems are usually based on doubly fed induction generators (DFIG) and permanent magnet synchronous generators (PMSG) [1]-[6]. Currently, the use of PMSGs has increased because of its simple structure and efficient energy production. Therefore, it is expected that more large size wind turbine generator (WTG) systems will adopt the PMSG [1]-[4]. Usually, the WECS with a PMSG is connected to the grid via an AC-DC-AC converter system. In this system, the WECS does not need to synchronize its rotational speed with the grid frequency. Besides, the gearbox can be omitted due to the low rotational speed of the WTG. On the other hand, wind energy is not constant and the wind turbine's power fluctuates. Since the output power fluctuations may cause grid frequency deviations, several literatures regarding the output power smoothing have been published such as the use of pitch angle control or the inertia of VSWTs [3]-[7].

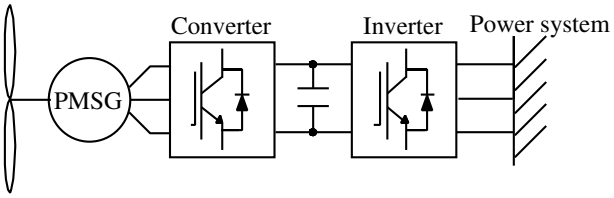

Fig. 1. Wind energy conversion system using PMSG.

This paper presents a fuzzy-based output power smoothing method for a WECS using short-term ahead prediction of wind speed. The WECS is based on a PMSG and transmits its electrical power to an AC grid through a IGBT pulse-width modulation (PWM) converter. The power converter controls the torque of the PMSG according to the torque command, which is determined by using the fuzzy logic. The inputs of the fuzzy logic are the predicted wind speed and the difference between the wind turbine torque and the generator torque. The short-term ahead wind speed is predicted by using least-squares method [7] and it is used to achieve more effective torque control of the PMSG for the wind speed variations. For high wind speed condition, the power fluctuations of the PMSG is smoothed with the pitch angle control. By using the proposed method, the torque of the PMSG is smoothed and the kinetic energy stored by the inertia of the wind turbine can be utilized to smooth the output power fluctuations of the PMSG. In addition, the wind turbine's shaft stress and the pitch action are mitigated compared to a conventional maximum power point tracking (MPPT) control. The effectiveness of the proposed method is verified by numerical simulations.

II. Conventional WECS

A. System Configuration

The system of the WECS is shown in Fig. 1. Wind energy obtained from the wind turbine is sent to the PMSG. To generate maximum power, rotational speed of the PMSG is controlled by a pulse width modulation (PWM) converter. The output power of the PMSG is supplied to the grid through a generator-side converter and a grid-side inverter.

B. Wind Turbine Model

Wind turbine output power, P_w, and wind turbine torque, T_w, are given by the following equations:

$$P_w = 0.5 C_p(\lambda, \beta) \rho \pi R^2 V_w^3 \tag{1}$$

$$T_w = 0.5 C_p(\lambda, \beta) \rho \pi R^3 V_w^2 / \lambda \tag{2}$$

where V_w is the wind speed, ρ is the air density, R is the radius of the wind turbine, C_p is the wind turbine power coefficient, $\lambda = \omega_w R / V_w$ is the tip speed ratio, ω_w is the angular rotor speed of the wind turbine and β is the pitch angle. C_p is given by the following equations [3]:

$$C_p = 0.22 \left(\frac{116}{\Gamma} - 0.4\beta - 5 \right) \exp^{-\frac{12.5}{\Gamma}} \tag{3}$$

$$\Gamma = \frac{1}{\frac{1}{\lambda + 0.08\beta} - \frac{0.035}{\beta^3 + 1}}. \tag{4}$$

C. Maximum Power Point Tracking Control

The output power characteristics of the wind turbine are depicted in Fig. 2. Here, the pitch angle, $\beta = 2°$. From this figure, it can be seen that there is a rotational speed, ω_{opt}, dotted by the black circles, for any particular wind speed. ω_{opt} is called the optimum rotational speed and generates the maximum power, P_{max} (MPPT control). ω_{opt} is approximated as follows [1]-[3]:

$$\omega_{opt} = 0.1874 V_w. \tag{5}$$

Generally, the MPPT control is applied when the wind speed, V_w, is smaller than the rated speed. If V_w is greater than the rated speed, then output power of the PMSG is controlled by the pitch angle control system as shown in Fig. 3 [3]. The pitch angle is controlled in the region between the rated wind speed (12m/s) and the cut-out wind speed (24m/s). Subtraction of the output power command the the PMSG, P_g^*, from the output power of the PMSG, P_g, gives the output error of the PMSG, ΔP_g, that evaluates the pitch angle command, β_{CMD}, via the pitch angle control system. The output power of the PMSG is controlled by a hydraulic servo system that drives the blades according to the pitch angle command, β_{CMD}. The output power command of the PMSG, P_g^*, is constant at the rated power (2MW).

D. PMSG Model

Basically, the mass model of a PMSG is the same as that of a permanent magnet synchronous motor (PMSM). The voltage and torque equations of the PMSM in the d-q reference frames are given by the following equations:

$$v_d = R_a i_d + L_d \frac{di_d}{dt} - \omega_g L_q i_q \tag{6}$$

$$v_q = \omega_g L_d i_d + R_a i_q + L_q \frac{di_q}{dt} + \omega_g K \tag{7}$$

$$T_g = p\{K i_q + (L_d - L_q) i_d i_q\} \tag{8}$$

where v_d and v_q are the d-q axis voltages, i_d and i_q are the d-q axis currents, R_a is the stator resistance, L_d and L_q are the d-q axis inductances, ω_g is the generator rotational speed, K is the permanent magnetic flux, and p is the number of pole pairs. Generating operation starts when the electromagnetic torque, T_g, is negative. The motion equation of the PMSG is given as

follows:

$$J_{eq}\frac{d\omega_g}{dt} = T_w - T_g. \tag{9}$$

where $J_{eq}(= J_g + J_w)$ is the equivalent inertia, T_w is the wind turbine torque.

E. Configuration of Power Converter System

The configuration of the power converter control system is shown in Fig. 4(a). The power converter is standard 3-phase two-level unit, composed of six IGBTs and controlled by triangle-wave PWM law.

The conventional configuration of the power converter is shown in Fig. 4(b). By using vector control scheme, the power converter controls the rotational speed of the PMSG to achieve variable speed operation with the MPPT control. The speed control of the PMSG is realized on a rotating reference frame, where the rotational speed error is used as the input to a speed controller which produces q axis stator current command, i_q^*. A salient-pole synchronous machine is used in this paper. To achieve efficient operation of the PMSG, d axis stator current command, i_d^*, is determined by [8] and given as follows:

$$i_d^* = \frac{K}{2(L_d - L_q)} - \sqrt{\frac{K^2}{4(L_q - L_d)^2} + i_q^2}. \tag{10}$$

The error between the command d-q axis currents, i_d^*, i_q^*, and the actual d-q axis currents are used as inputs to the current controllers. The current controllers produce d-q axis voltage commands v_d^*, v_q^* after the decoupling. The angle θ_g, for the Park transformation, is calculated from the rotational speed of the PMSG.

III. Proposed WECS

This section presents the proposed fuzzy-based output power smoothing method using the inertia of the wind turbine.

A. Power and Torque Characteristics in WECS

The wind turbine output, P_w, the wind turbine torque, T_w, and the generator torque, T_g, versus the wind turbine speed, ω_w, curves are shown in Figs. 5 and 6, respectively [2, 5, 6]. Here, the wind speed is assumed as 12m/s. If a constant output power command, $P_{ref} = kP_{rated}$, is given for the PMSG, then the generator torque is expressed as $T_g = P_{ref}/\omega_g$, where, k is a multiplying factor. The generator torque for $k = 1.0$ and 0.7 is shown in Fig. 6. In the conventional MPPT control, the operating point of the wind turbine speed becomes the optimum rotational speed, ω_{opt}, as shown in Fig. 5. However, in the output power smoothing method using the inertia of the wind turbine, the wind turbine speed changes around ω_{opt} according to the actual wind speed. In Fig. 6, if the rotational speed of the wind turbine changes from ω_{min} to ω_{max}, then the kinetic energy stored by the wind turbine, ΔE, is expressed as follows [2]:

$$\Delta E = \frac{1}{2}J_{eq}(\omega_{max}^2 - \omega_{min}^2). \tag{11}$$

By controlling the rotational speed of wind turbine in the region of $\omega_{min} \sim \omega_{max}$, ΔE can be used for output power smoothing. Since stable operation of the wind turbine is

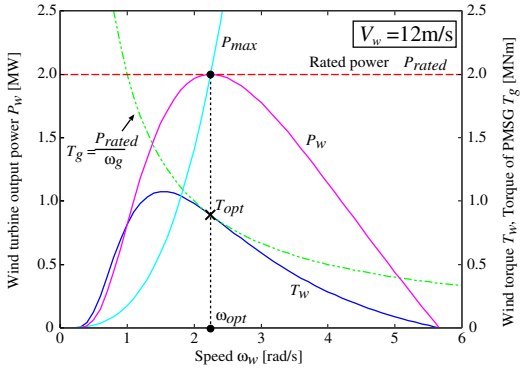

Fig. 5. Speed characteristics of WECS.

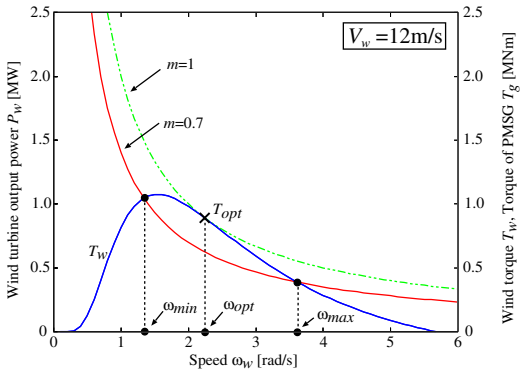

Fig. 6. Torques of PMSG for each output power.

achieved within a proper range, the upper and lower limits of the operation region are set to 0.6 pu and 1.4 pu. The rotational speed of the wind turbine is controlled within this region. Although Figs. 5 and 6 show the wind turbine characteristics at V_w=12m/s, wind turbine characteristics at $V_w = 5 \sim$12m/s can be obtained by using a lookup table which has prestored values of T_g and T_w as described in Fig. 6. Here, for the case of the constant power control, the rotational speed variations of the wind turbine will become large and will lead to the unstable operating of the WECS, increase of wind turbine's shaft stress. Therefore, this paper aims at the smoothing and controlling of the generator torque, T_g.

B. Torque Control Method using Fuzzy Logic

As described before, the generator-side converter smooths the generator torque for output power smoothing. The power fluctuations of the WECS can be leveled by smoothing the generator torque. For the proposed method, the generator torque command is determined by using the fuzzy logic. The fuzzy rules and membership functions are shown in Table 1 and Fig. 7, respectively. The inputs of the fuzzy logic are given by the following equations:

$$\Delta T = T_w - T_{g_opt} \tag{12}$$

$$\Delta \hat{V}_w = \frac{1}{T}\int_{t-T}^{t} \hat{V}_w dt - \hat{V}_w \tag{13}$$

where $\hat{V}_w$ is the predictive wind speed and it will be explained in next section. The output of the fuzzy logic is the torque

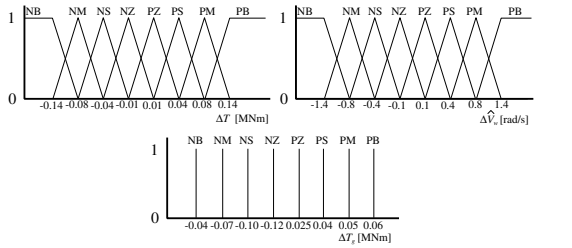

Fig. 7. Membership functions.

fluctuation index, ΔT_g. The increase and decrease of ΔT_g is determined by the input of ΔT, while the amount of ΔT_g is determined by the input of $\Delta\hat{V}_w$.

The reason for the use of (12) is based on (9) which is the system dynamics equation [6]. For (9), operating points, ω_{g0}, V_{w0}, T_{g0}, and T_{w0} are assumed. At the operating speed, ω_{g0}, if $d\omega_{g0}/dt = 0$ then $T_{w0} - T_{g0} = 0$. If the operating point, V_{w0}, increases and $T_{w0} - T_{g0} > 0$, then ω_{g0} should increase. The acceleration continues until $T_{w0} - T_{g0} = 0$. When $T_{w0} - T_{g0} = 0$, the operating speed, ω_{g0}, should remain at the operating point. If a decrease in wind speed occurs and $T_{w0} - T_{g0} < 0$, then ω_{g0} should decrease. The deceleration continues until $T_{w0} - T_{g0} = 0$. From these operations, by (12), if ΔT is increases, it means that the wind turbine torque, T_w, increases due to a increase in the wind speed. Therefore, the generator speed, ω_g, should increase, i.e., the generator torque, T_g, should decrease. On the other hand, if ΔT decreases, it means that T_w decreases due to a decrease in the wind speed. Therefore, ω_g should decrease, i.e., T_g should increase. Here, T_{g_opt} of (12) is the optimum generator torque in the MPPT control and can be calculated by the following equation [1]:

$$T_{g_opt} \approx T_{w_opt} = 1453.3\omega_g^2 \tag{14}$$

Here, T_{w_opt} is the optimum torque of wind turbine. (14) is derived assuming the wind rotor and the generator characteristics are at steady-state.

Equation (13) is used to evaluate the amount of ΔT_g. The first term of (13) is an average value of the predicted wind speed. To smooth the power fluctuations in the high frequency domain (above 0.1Hz), the value of T is set to 10s [2, 6]. If $\Delta\hat{V}_w$ is large, then it is seen that the wind speed variation is also large. Therefore, the amount of ΔT_g should be increased, and *vice-versa*. By using the predicted wind speed as the input of the fuzzy logic, more effective torque control can be achieved. Finally, the generator torque command, T_g^*, is determined by adding ΔT_g with T_{g_opt} as

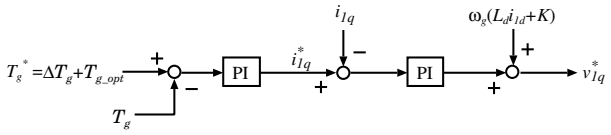

Fig. 8. Proposed configuration of converter.

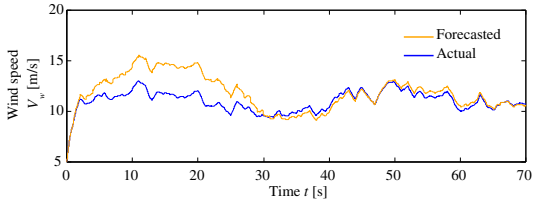

Fig. 9. Predicted and actual wind speeds.

shown in Fig. 8. In the proposed method, the fuzzy control is determined based on the motion equation of PMSG and the operating rotational speed. These are the fundamentals for the operations of WECS, and therefore, the fuzzy control can be used regardless of the kind of WECSs. On the other hand, the membership functions are needed to tune according to the specifications of generators and turbines. However, this is simple and flexible. The torque fluctuation index, ΔT_g, is determined by using several wind speed profiles in simulations. When using the proposed method in practical systems, one can simply determine the membership functions and the values of ΔT_g according to WECS's specifications and wind profiles.

C. Wind Speed Prediction by Least-Squares Method

In this paper, a short-term ahead wind speed is predicted by using the least-squares method [7].

The wind speed slope, $a(k)$, is derived by the wind speed from the past T_{pre} seconds (the sampling-period is 1s) as the following equation:

$$a(k) = \frac{T_{pre}\sum_{n=1}^{T_{pre}} nV_w(k-n) - \sum_{n=1}^{T_{pre}} n \sum_{n=1}^{T_{pre}} V_w(k-n)}{T_{pre}\sum_{n=1}^{T_{pre}} n^2 - \left(\sum_{n=1}^{T_{pre}} n\right)^2} \tag{15}$$

where k is the present time and $V_w(k-n)$ is the wind speed value of n intervals ago. If T_{pre} is set to 30s, then (15) is calculated as follows:

$$a(k) = \sum_{n=1}^{30} \frac{29 - 2(n-1)}{4495} V_w(k-n). \tag{16}$$

The predicted wind speed, $V_{wf}(k+T_f)$, is expressed as

$$V_{wf}(k+T_f) = V_w(k) + T_f a(k) \tag{17}$$

where T_f is the prediction time and set to 5s.

To investigate the effectiveness of the proposed prediction method, the simulation result of wind speed prediction is shown in Fig. 9. From this figure, it is seen that the prediction error is large by around $t = 30$ s because of the past wind

data is less than 30 points. After that, however, the prediction accuracy is improved and the percentage error becomes small.

IV. Power Smoothing Simulation

A. Simulation Model

The system model used for the simulation is shown in Fig. 10. Here, the grid-side inverter is connected to an infinite bus through a LC filter, three-phase transformer, and single circuit transmission line in parallel with load. The parameters of the PMSG and the power converters are listed in Table II.

B. Simulation Results

To evaluate the effectiveness of the proposed method, WECS operation is examined by using the both methods (conventional and proposed). In the conventional method, the MPPT control described in Section II is employed. In the proposed method, the WECS initially operates as the MPPT control by regulating the optimum generator torque. At $t = 40$ s, the WECS starts the proposed method for output power smoothing. The simulation results are shown in Fig. 11. The wind speed shown in Fig. 9 is used for the both methods. Figs. 11(a)$\sim$(d) show the generator torque and the input-output of the fuzzy logic, respectively. From these figures, it is confirmed that the generator torque is smoothed by the proposed torque control method compared with that of the MPPT control. Around $t = 40 \sim 60$ s, short term variations of the wind speed frequently occur. However, the predicted wind speed is used as the input of the fuzzy logic, and therefore, the control performance is improved as shown in Fig. 11(d). The generator speed and its d-q axis currents are shown in Figs. 11(e) and (f). By smoothing the generator torque, the generator speed accelerates/decelerates according to the wind speed increasing/decreasing. The kinetic energy of wind turbine, the pitch angle, the power coefficient, the active power of the PMSG and its maximum energy function with the both methods are shown in Figs. 11(g)$\sim$(k), respectively. Here, the maximum energy function, P_{max}, is expressed as follows [10]:

$$P_{max} = \int_0^t P_g(t)dt. \tag{18}$$

In the conventional MPPT method, the pitch action increases when the wind speed fluctuates around the rated speed (see Fig. 11(h)). This results is the reduction of the power coefficient as shown in Fig. 11(i). On the other hand, the kinetic energy stored by the wind turbine is utilized for power smoothing, and therefore, the pitch action can be decreased. Consequently, as can be seen in Fig. 11(k), the maximum energy function, P_{max}, increases compared with the MPPT control. Fig. 11(l) shows the torque difference between the wind turbine and the generator. From this figure, it is found that the torque difference is smaller than that of the MPPT control and the mitigation of the wind turbine's shaft stress is achieved.

V. Conclusion

This paper presents a fuzzy-based output power smoothing method for a WECS using short-term ahead prediction of wind speed. In the WECS, the power converter controls the generator torque according to the torque command, which is determined by using the fuzzy logic. By using the proposed method, the generator torque is smoothed and the kinetic energy stored by the inertia of the wind turbine can be utilized for power smoothing. The effectiveness of the proposed method is verified by numerical simulations.

***Abstract*— In recent years, amount of renewable energy facilities using wind turbine generator and photovoltaic power system have been increased due to natural environment and resource depletion. Moreover, all electrification apartment houses or residences and electric vehicles have been increased. However, due to the fluctuating power from renewable energy sources and loads, fluctuations of grid frequency and voltage become problematic. This paper presents a methodology of control system frequency and voltage by distributed controllable loads such as heat pump and electric vehicles. By applying power consumption controller using distributed fuzzy control for HP and H_∞ control for battery, fluctuations of grid frequency and voltage are suppressed around a desired value. In order to verify the effectiveness of the proposed system, MATLAB/Simulink is used for computed simulations.**

keywords–frequency and voltage fluctuation, autonomous control, heat pump, distributed control, battery, H_∞ control.

I. Introduction

The amount of power generation utilizing renewable energy has shown an upward trend due to depletion of energy sources and consideration about environment [1, 2]. But, there are important issues of electric power quality due to change conditions of the weather. Additionally, the relation between power supply and demand becomes more complex by installing photovoltaic equipment in house and transition to all electric equipments. In small power system such as island, diesel generator is used as major source of electricity but it has high environmental issue and high unit price of power energy. Diesel generators have their limits with respect to maintaining the balance of supply and demand because diesel generators with governors have mechanical constraint. Moreover, due to the fluctuating power generation from renewable energy sources, frequency and voltage fluctuation are problematic in island power systems. Therefore provision is needed to control the system frequency and voltage.

As provision in supply side, installation of storage equipment and pitch angle control for wind generator have been proposed to control dispersed power system [3, 4]. However the installation of storage equipment that needs large storage capacity, and the cost of maintenance with quality degradation is expensive. In addition, wind generator is an obstacle for output power leveling due to mechanical constraint of control mechanism and irregularity of energy. Hence, in case of large amount of renewable energy is connected to the power system, the electricity quality degrades by measuring only supply side.

In recent years, smart grid technology with power consumption control at the power demand side becomes an active area of new research. This technology allows bidirectional information transmission between supply side and demand side [5∼7]. On the demand side, the transition to all-electritication in consideration of economy, safety, and use of heat pump water heater (HP) and electric vehicle (EV) that is suitable for the environment. Thus, power conditioning ability is increasing by these large capacity load connected to power system in the demand side [8, 9]. In addition, increase of equipment capacity for frequency and voltage control are not used for the electric power supplier.

This paper presents a method for system frequency control and voltage control using decentralized loads in a small power system based on smart grid. Decentralized controllable loads (HP, battery) are controlled to maintain the supply-demand balance, thereby suppressing frequency deviation. Also, terminal voltage control becomes possible by reactive power control of inverter connected to controllable loads that is introduced on the demand side. Since HP is limited by heating medium stabilization, it is necessary for each HP to starts and stops separately at different timing. As the control method, HP is controlled with the probability distribution of storage water temperature and system frequency that are local information. By applying H_∞ control theory which makes controller design possible by considering a response characteristic of frequency domain of battery operate in super high-frequency domain. On frequency domain, diesel generator operates in low-frequency domain because of mechanical constraint. Within the low-frequency domain, HP operates separately at different timing, and suppressing frequency fluctuations. That helps to diesel generator is operated with rated output power, and it can operate with high efficiency. In addition, controllable load is operated with system frequency, terminal voltage and storage water temperature. Thus the control method are achieved without any communications. The effectiveness of the pro-

II. MODELING

Fig. 1 illustrates a small power system. There are diesel generator, wind farm and photovoltaic in power system which supply electricity for load demand. They operate independently without communication large-scale power system. The system capacity is 10MW which is the base rule in Per Unit method. The system frequency is maintained constant at 60Hz by a diesel generator with governor. The diesel generator is modeled as a synchronous generator. The electrical and mechanical characteristics of the synchronous generator can be described by the following differential equations:

$$2H\frac{d\Delta\omega}{dt} = P_m - P_e \tag{1}$$

$$\frac{d\delta}{dt} = \Delta\omega \tag{2}$$

$$\frac{de'_q}{dt} = \frac{1}{T'_{do}}\left[e_{fd} - (x_d - x'_d)i_d - e'_q\right] \tag{3}$$

$$\frac{de'_d}{dt} = \frac{1}{T'_{q0}}\left[e'_d - (x_q - x'_q)i_q\right] \tag{4}$$

where H is the inertia constant, T_m is the mechanical input into generator, P_e is the generator output, δ is the angular phase difference, $\Delta\omega$ is the angular speed deviation, e'_d, e'_q are the transient voltage for the direct and quadrature-axis

of synchronous generator, e_{fd} is the excitation voltage converted to the q-axis, x_d, x_q are the d-and q-axis synchronous reactances, x'_d, x'_q are the d- and q-axis transient reactances, i_d, i_q are the generator terminal currents for the d-q axes, T'_{do}, T'_{qo} are the d-and q-axis open circuit transient time constant, respectively. The parameter values for each element are shown in Table 1. Fig. 2 illustrates control block diagram of diesel generator. Excitation using automatic voltage regulator (AVR) is modeled by first-order lag element shown in Fig. 2(a). Control composition of governor of diesel generator is shown in Fig. 2(b). System frequency control is achieved by mechanical input T_m of generator. The wind turbine generator and photovoltaic are modeled as fluctuation source because of output power is fluctuated by weather conditions. On supply side, wind farm (2MW) is introduced, and 800 photovoltaic panels (2MW) are introduced on demand side. As controllable load, heat pump (HP) group (8MW) and battery group (2MW) are introduced in power system, and its control system is explained in the next chapters.

Fig. 8. Membership functions.

III. Controllable Load

The system frequency and terminal voltage fluctuations are suppressed by active and reactive power control with controllable loads. HPs and batterise are used as controllable load in this research. These electric appliances can be used as controllable load because their power consumption are adjustable and expend only during a given period of time. The decentralized HP model for houses is illustrated in Fig. 3(a). The water temperature of HP is controlled by feedback control with integral of power consumption under COP (coefficient of performance) is 4.0. The control block diagram is explained in the next section. The decentralized battery model is illustrated in Fig. 3(b). The discharge and charge operation are modeled as a first-order lag system, and charging rate is calculated by feedback control with integral of discharge and charge power consumption.

IV. Decentralized Autonomous Control of HP

A. Cumulative Distribution of Water Temperature

Each decentralized HP hold a unique water temperature, respectively, in power system. Those water temperature are produced by normal distribution random numbers shown in Fig. 4 as an average of 70 degrees °C. It can express the distribution of water temperature as a normal probability density distribution. The normal probability density distribution of water temperature is described by the following equation, and the normal probability density and its cumulative distribution are shown in Fig. 5.

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \tag{5}$$

where σ is the standard deviation ($\sigma > 0$), x (C_{HP}) is sample, and μ is the mean value.

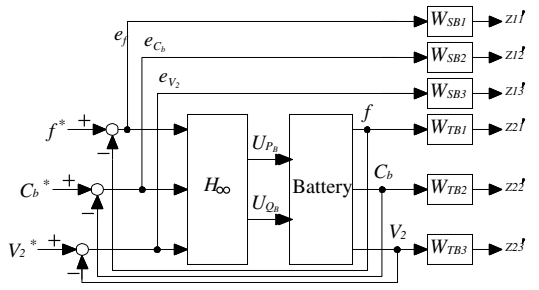

Fig. 9. Controller design of battery.

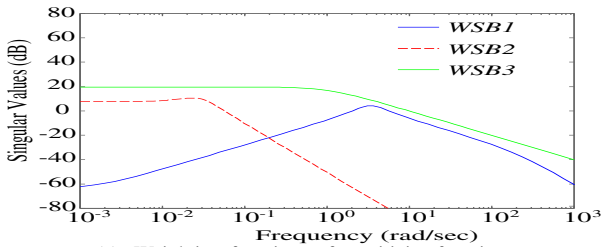
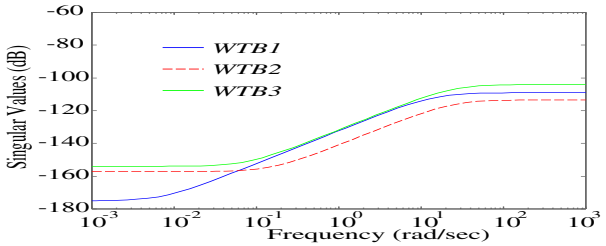


(a) Weighting functions of sensitivity function



(b) Weighting functions of complementary sensitivity function

Fig. 10. Weighting function for control of battery.

B. Control System of HP

First, it is necessary to show property of HP before saying about control method. HP provides heat to the storage water with compressing and inflating heating medium. Because of this process, HP needs a time that heating medium stabilize. In fact, it cannot be turn off for 10 minutes if it turns on once. For above-mentioned constrained behavior, each HP is switched on/off separately at different timing, and control frequency. In this study, decentralized autonomous control of HP is entertained by Fuzzy Logic Toolbox$^{\mathrm{TM}}$. By two input function of water temperature C_{HP} and passing time after switching T_P, each HP decides a maximum frequency deviation Δf_M shown in Fig. 6. Each HP switch to frequency fluctuation based on these maximum frequency deviations, and control frequency. And these passing time are produsedby uniformly distributed pseudorandom numbers from 0 s to 1,200 s. Fuzzy output response is shown in Fig. 7. It is seen that switching priority is so high that water temperature is low, and passing time is long. Maximum frequency deviations respectively are decided as above, and when a signal $\Delta f'$ from Δf is approached to the maximum frequency deviation, HP control system of Fig.6 commands HP to switch. With this system, each HP is switched separately at different timing, and suppress frequency fluctuation. Fig. 8 illustrate fuzzy membership functions. Fig. 8(a) is designed to analogizing

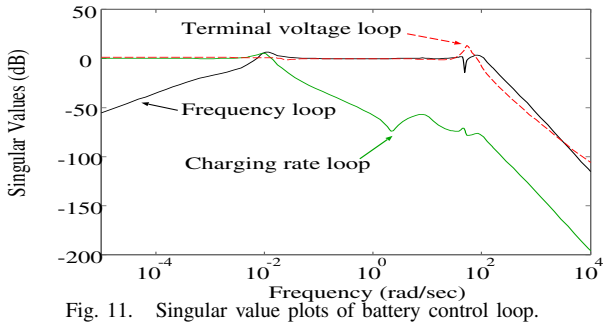


Fig. 11. Singular value plots of battery control loop.

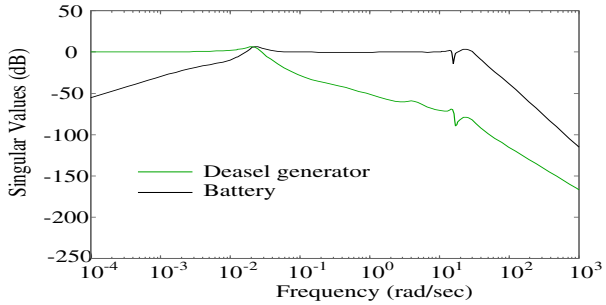

Fig. 12. Singular value plots of each control loop.

to cumulative distribution curve of water temperature, and it corresponds to distribution of water temperature. And Fig. 8(b) is designed that a maximum frequency deviation becomes smaller with increasing passing time.

V. Battery Control Method

H_∞ control block diagram of battery is shown in Fig. 9. The weighting function W_{SB1}, W_{SB2} and W_{SB3} for frequency deviation e_f, the charging rate deviation e_{C_B} and terminal voltage deviation V_2 in battery are shown in Fig. 10(a). To suppress only high frequency component of frequency deviation, W_{SE1} for battery discharge and charge behavior is designed to have high gain in high frequency domain and is designed low in low frequency domain. W_{SB2} for charging rate control of battery is designed to have low gain against W_{SB1}. W_{SB3} is designed to suppress the terminal voltage. Where charging rate reference and terminal voltage reference are 50% and 1.0 pu, respectively. Weighting functions of complementary sensitivity function is decided the robustness against the disturbance as illustrated in Fig. 10(b). The linear matrix inequality (LMI) approach is applied to the design of the H_∞ controller [10∼12]. The singular value plots of diesel generator and battery are illustrated in Fig. 11. It is seen that battery operates in high-frequency domain. Frequency loop of each controller are shown in Fig. 12. It is seen that diesel generator and battery operate in low-frequency and high-frequency domain, respectively.

VI. Simulation Results

The simulation results show the effectiveness of system frequency control and voltage control by the power consumption control of decentralized controllable loads in demand side. Because of a simulation time, 160 HP operate in simulation, and all output of HP are adjusted to the realistic value

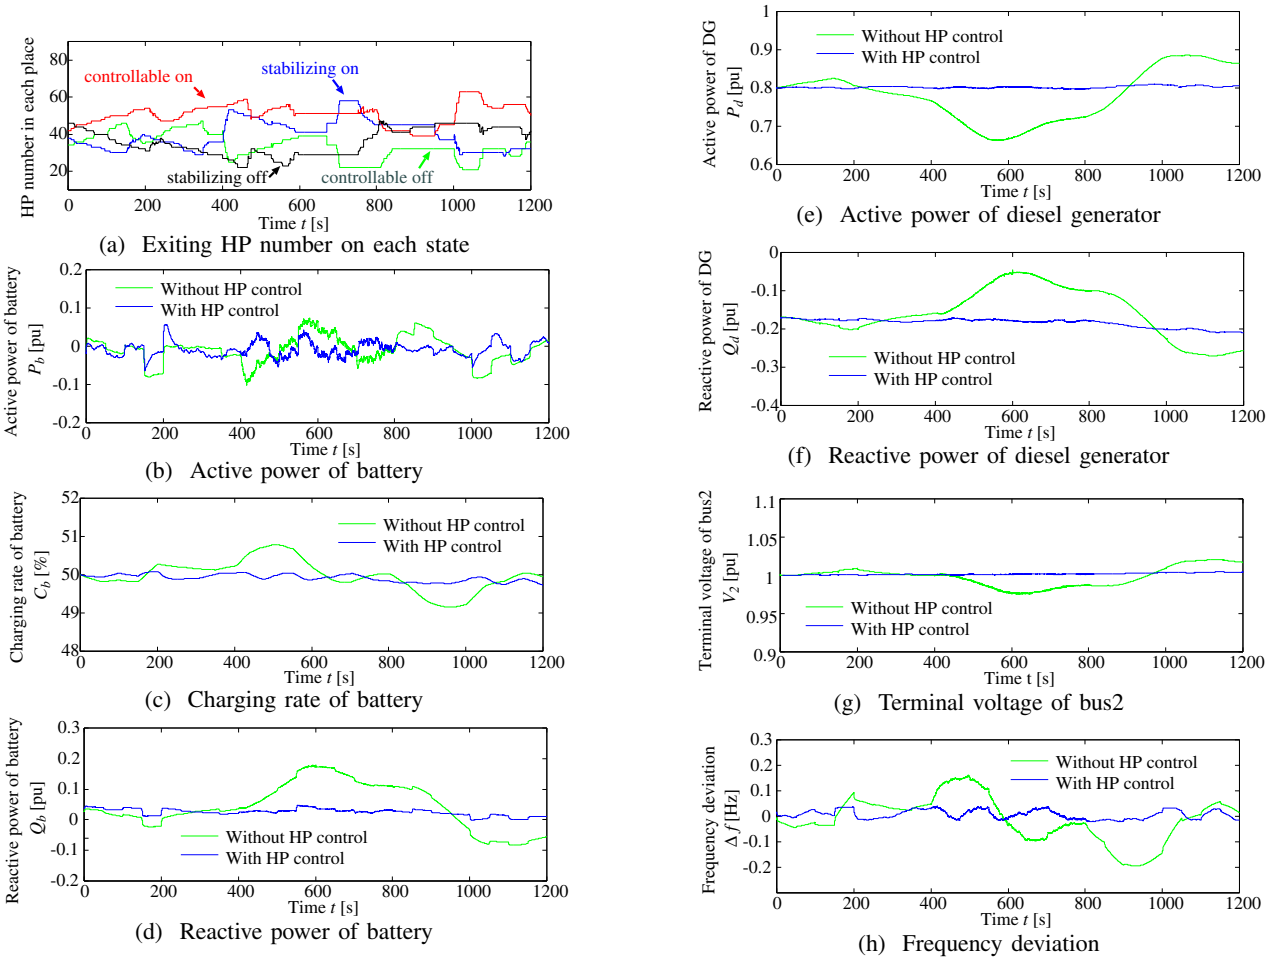
with gain multiple. The variation of wind farm output, non-controllable loads and photovoltaic outputs are assumed in this paper are shown in Fig. 13 (a)∼(e), respectively. The wind farm output is assumed by long-period fluctuation in 40-minute and short-period fluctuation in seconds as shown in Fig. 13(a), (b). The non-cantrollable load power consumptions P_l, Q_l are changed to assume the on/off operation of electric appliance as shown in Fig. 13(c), (d). The white noise is used to represent drastic change of photovoltaic output P_{pv} as shown in Fig. 13(e). The power consumption P_{HP} of HP is changed to suppress low-frequency component of frequency fluctuation in power system as seen in control results of Fig. 13(f). The reactive power Q_{HP} of HP is changed to suppress voltage fluctuation at bus 2 as shown in Fig. 13(g). Also the water temperature C_{HP} of 10 HPs are raised up respectively as seen in control result of Fig. 13(h). Fig. 14(a) show number of HP on each states that waiting states to stabilized and controllable states. The discharge and charge power P_b of battery are changed to suppress high-frequency component of frequency fluctuation in power system as seen in control results of Fig. 14(b). It can be seen that charged rate of battery stays constant as shown in Fig. 14(c). The reactive power Q_b of battery is changing to suppress voltage fluctuation at bus 2 as shown in Fig. 14(d). In case of without control, the active power P_d and reactive power Q_d of diesel generator fluctuate due to wind farm, photovoltaic and load variation are shown in Figs. 14(e), (f). Alternatively, when controllable loads are controlled, the diesel generator output P_d becomes smooth. The reactive power Q_d (Fig. 14(f)) also becomes smooth as well as active power. Therefore, it is seen that HP suppresses frequency fluctuation from low-frequency domain of diesel generator to low-frequency component in battery operating domain. Terminal voltage V2 of bus 2 is illustrated in Fig. 14(g). Although theterminal voltage fluctuates for the case where controllable load withoutcontrol and with control, the voltage becomes smooth and are kept in rated range as seen in same figure. It can be seen that the system frequency deviation df stays constant in Fig. 14(h). Therefore, the effectiveness of system frequency control and voltage control by power consumption control of decentralized controllable load in demand side is confirmed.

VII. Conclusion

This paper presents a control system to achieve suppression of frequency deviation and voltage fluctuation by using controllable load that may steadily increase in demand side in future. The power fluctuation occurred due to disperse power system is suppressed by active and reactive power control of controllable loads. Therefore, controllable loads are



(a) Exiting HP number on each state

operated to suppress the power fluctuation, and the following are achieved without any communication: balancing of the supply-demand, generating power leveling of output power of diesel generator, and suppressing frequency fluctuation. There are advantages that wind turbine generator and photovoltaic generation enable to operate in maximum power point, equipment cost of battery is reduced and the ability to control the frequency is ensured. Consequently, electricity companies can expect to supply the high quality power and to reduce the capital cost.

***Abstract*–Due to the lack of natural resources, the majority of energy in many countries must depend on import, and the corresponding cost is expensive and affected by international market fluctuation and control. In recent years, an intelligent micro- grid system composed of renewable energy sources is becoming one of the interesting research topics. The forecasting of short-term loads enables the intelligent micro-grid system to manipulate an optimized loading and unloading control by measuring the electrical supply each hour for achieving the best economical and power efficiency. Therefore, this study investigates a fuzzy neural network (FNN) with varied learning rates for the short-term load forecasting (STLF), and compares its better forecasting performance with a conventional neural network (NN) by numerical simulations of a real case in Taiwan campus.**

***Keywords*–Fuzzy neural network, varied learning rates, short-term load forecasting.**

I. INTRODUCTION

Nowadays, the research topic of short-term load forecasting (STLF) becomes an important issue for power system operations. In general, the objective of high-precision STLF is difficult to reach due to complex effects on load by a variety of factors. In the past researches, various STLF methods have been investigated [1], including exponential smoothing [2], regression [3], Box-Jenkins models [4], Kalman filter [5], state space model [6], and time series techniques [6]. These frameworks were developed based on statistical methods and proven to work well under normal conditions. However, these methods show some deficiency in the presence of an abrupt change in environment or sociological variables, which are believed to affect load patterns. Besides, the employed techniques for these models in [1]–[6] use a large number of complex relationships and require a long computational time, so that the desired forecasting accuracy can not be achieved.

In recent years, artificial intelligent methods have attracted more attention in application to load forecasting, such as pattern recognition [7], expert system techniques [8]–[10], neural network (NN) [11]–[14] and fuzzy logic system [15], [16]. Amjady, Daraeepour, and Keynia [11] comprised a modified version of a relief algorithm for the feature selection and a hybrid neural network to forecast the day-ahead electricity price. Bashir and El-Hawary [12] proposed adaptive artificial neural networks with particle swarm optimization to forecast the hourly load. In the previous literatures [15], [16], fuzzy logic was designed for short-term and midterm load forecasting. Unfortunately, the detailed action behavior in the NN is difficult to handle clearly, and how to build appropriate rules in the fuzzy system is the major problem to be solved. Therefore, the concept of incorporating fuzzy logic into a neural network has grown into a popular research topic [17]. The integrated fuzzy-neural-network (FNN) system possesses the merits of both fuzzy systems (e.g., humanlike IF-THEN rules thinking and ease of incorporating expert knowledge) and neural networks (e.g., learning and optimization abilities, and connectionist structures). By this way, one can bring the low-level learning and computational power of neural networks into fuzzy systems and also high-level, humanlike IF-THEN rule thinking and reasoning of fuzzy systems into neural networks [18]–[20].

This study investigates a FNN forecaster with varied learning rates for the STLF model, and compares its better forecasting performance with a conventional NN forecaster. The back-propagation algorithm is used to train the FNN on line. Moreover, to guarantee the convergence of forecasting error, analytical methods based on a discrete-type Lyapunov function are proposed to determine the varied learning rates of the FNN. This study is organized into five sections. Following the introduction, the network structure of a four-layer FNN is described, and the on-line training algorithm for the FNN with varied learning rates is derived in Section II. Moreover, the proposed STLF model via the FNN forecaster is illustrated in Section III. In Section IV, numerical simulations are given to verify the effectiveness of the proposed strategy in terms of mean average percentage error (MAPE). Finally, some conclusions are drawn in Section V.

II. FUZZY NEURAL NETWORK

A. Description of Network Structure

A general four-layer fuzzy neural network (FNN) as shown in Fig. 1, which is composed of the input (the *i* layer), membership (the *j* layer), rule (the *k* layer) and output layers (the *o* layer), is adopted to implement the proposed FNN forecaster. Nodes in the input layer represent the input linguistic variables. Nodes in the membership layer act as the membership functions. Moreover, all the nodes in the rule layer form a fuzzy rule base. The signal propagation and the basic function of each layer are introduced as follows.

This work was supported by the Institute of Nuclear Energy Research of Taiwan, R.O.C. through grant number 1002001INER065.

Layer 1: input layer

For every node *i* in this layer, the net input and the net output can be represented as

$$net_i^1 = x_h^1, \quad y_i^1 = f_i^1(net_i^1) = net_i^1 \tag{1}$$

where x_h^1 represents the *i*th input to the node of layer 1.

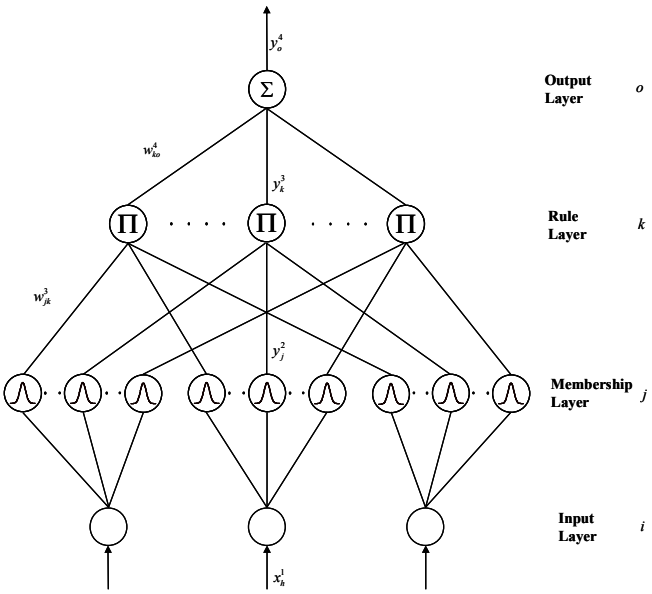

Fig. 1. Structure of four-layer fuzzy neural network (FNN).

Layer 2: membership layer

In this layer, each node performs a membership function. The Gaussian function is adopted as the membership function. For the *j*th node

$$net_j^2 = -\frac{(x_i^2 - m_{ij})^2}{(\sigma_{ij})^2}, \quad y_j^2 = f_j^2(net_j^2) = exp(net_j^2) \tag{2}$$

where m_{ij} and σ_{ij} are, respectively, the mean and the standard deviation of the Gaussian function in the *j*th term of the *i*th input linguistic variable x_i^2 to the node of layer 2.

Layer 3: rule layer

Each node *k* in this layer is denoted by $\prod$, which multiplies the incoming signal and outputs the result of product. For the *k*th rule node

$$net_k^3 = \prod_j w_{jk}^3 x_j^3, \qquad y_k^3 = f_k^3(net_k^3) = net_k^3 \tag{3}$$

where x_j^3 represents the *j*th input to the node of layer 3, and w_{jk}^3 is assumed to be unity.

Layer 4: output layer

The single node *o* in this layer is labeled as Σ, which computes the overall output as the summation of all incoming signals.

$$net_o^4 = \sum_k w_{ko}^4 x_k^4, \qquad y_o^4 = f_o^4(net_o^4) = net_o^4 \tag{4}$$

where the link weight w_{ko}^4 is the output action strength of the *o*th output associated with the *k*th rule; x_k^4 represents the *k*th input to the node of layer 4, and y_o^4 is the output of the FNN forecaster.

B. On-Line Learning Algorithm

The central part of the learning algorithm for an FNN concerns how to recursively obtain a gradient vector in which each element in the learning algorithm is defined as the derivative of an energy function with respect to a parameter of the network. This is done by means of the chain rule, and the method is generally referred to as the back-propagation learning rule, because the gradient vector is calculated in the direction opposite to the flow of the output of each node [17]. To describe the on-line learning algorithm of the FNN using the supervised gradient decent method, first the energy function *E* is defined as

$$E = (x_f - x_l)^2 / 2 = e^2 / 2 \tag{5}$$

where x_f and x_l represent the forecasting load and the actual load, and *e* denotes the output error between the forecasting load and the actual load. Then, the learning algorithm is described as follows.

Layer 4:

The error term to be propagated is given by

$$\delta_o^4 = -\frac{\partial E}{\partial y_o^4} = \left[-\frac{\partial E}{\partial e}\frac{\partial e}{\partial y_o^4}\right] = \left[-\frac{\partial E}{\partial e}\frac{\partial e}{\partial x_l}\frac{\partial x_l}{\partial y_o^4}\right] \tag{6}$$

and the weight is updated by the amount

$$\Delta w_{ko}^4 = -\eta_w \frac{\partial E}{\partial w_{ko}^4} = \left[-\eta_w \frac{\partial E}{\partial y_o^4}\right]\left(\frac{\partial y_o^4}{\partial net_o^4}\frac{\partial net_o^4}{\partial w_{ko}^4}\right) = \eta_w \delta_o^4 x_k^4 \tag{7}$$

The weights of the output layer are updated according to the following equation:

$$w_{ko}^4(N+1) = w_{ko}^4(N) + \Delta w_{ko}^4 \tag{8}$$

where the factor η_w is the learning-rate parameter of the weight, and N denotes the number of iteration.

Layer 3:

Since the weights in this layer are unity, only the error term needs to be calculated and propagated.

$$\delta_k^3 = -\frac{\partial E}{\partial net_k^3} = \left[-\frac{\partial E}{\partial y_o^4}\right]\left(\frac{\partial y_o^4}{\partial net_o^4}\frac{\partial net_o^4}{\partial y_k^3}\frac{\partial y_k^3}{\partial net_k^3}\right) = \delta_o^4 w_{ko}^4 \tag{9}$$

Layer 2:

The multiplication operation is done in this layer. The error term is computed as follows:

$$\begin{aligned}\delta_j^2 &= -\frac{\partial E}{\partial net_j^2} \\ &= \left[-\frac{\partial E}{\partial y_o^4}\frac{\partial y_o^4}{\partial net_o^4}\frac{\partial net_o^4}{\partial y_k^3}\frac{\partial y_k^3}{\partial net_k^3}\right]\left[\frac{\partial net_k^3}{\partial y_j^2}\frac{\partial y_j^2}{\partial net_j^2}\right] = \sum_k \delta_k^3 y_k^3\end{aligned} \tag{10}$$

Moreover, the variations of m_{ij} and σ_{ij} can be expressed as

$$\Delta m_{ij} = -\eta_m \frac{\partial E}{\partial m_{ij}} = \eta_m \delta_j^2 \frac{2(x_i^2 - m_{ij})}{(\sigma_{ij})^2} \tag{11}$$

$$\Delta \sigma_{ij} = -\eta_\sigma \frac{\partial E}{\partial \sigma_{ij}} = \eta_\sigma \delta_j^2 \frac{2(x_i^2 - m_{ij})^2}{(\sigma_{ij})^3} \tag{12}$$

where η_m and η_σ are the learning-rate parameters of the mean and the standard deviation of the Gaussian function. The mean and standard deviation of the membership layer are updated as follows:

$$m_{ij}(N+1) = m_{ij}(N) + \Delta m_{ij} \tag{13}$$

$$\sigma_{ij}(N+1) = \sigma_{ij}(N) + \Delta \sigma_{ij} \tag{14}$$

C. Convergence Analyses

Selection of the values for the learning-rate parameters has a significant effect on the network performance. In order to train the FNN effectively, three varied learning rates, which guarantee convergence of the output error based on the analyses of a discrete-type Lyapunov function, are derived in this section. The convergence analyses in this study are to derive specific learning-rate parameters for specific types of network parameters to assure convergence of the output error.

Theorem 1: Let η_w be the learning-rate parameter of the FNN weights and let P_{wmax} be defined as $P_{wmax} \equiv max_N \left\| P_w(N) \right\|$, where $P_w(N) = \partial y_o^4 / \partial w_{ko}^4$ and $\|\cdot\|$ is the Euclidean norm in $\Re^n$. The convergence is guaranteed if η_w is chosen as $\eta_w = \lambda / (P_{wmax}{}^2) = \lambda / R_u$, in which λ is a positive constant gain, and R_u is the number of rules in the FNN.

Proof: Since

$$P_w(N) = \frac{\partial y_o^4}{\partial w_{ko}^4} = x_k^4 \tag{15}$$

Thus

$$\left\| P_w(N) \right\| < \sqrt{R_u} \tag{16}$$

Then, a discrete-type Lyapunov function is selected as

$$V(N) = e^2(N)/2 \tag{17}$$

The change in the Lyapunov function can be obtained by

$$\Delta V(N) = V(N+1) - V(N) = [e^2(N+1) - e^2(N)]/2 \tag{18}$$

The error difference can be represented by

$$e(N+1) = e(N) + \Delta e(N) = e(N) + \left[\frac{\partial e(N)}{\partial w_{ko}^4} \right]^T \Delta w_{ko}^4 \tag{19}$$

where Δw_{ko}^4 represents a weight change in the output layer. By using (6), (7) and (19), then

$$\frac{\partial e(N)}{\partial w_{ko}^4} = \frac{\partial e(N)}{\partial y_o^4} \frac{\partial y_o^4}{\partial w_{ko}^4} = -\frac{\delta_o^4}{e(N)} P_w(N) \tag{20}$$

$$e(N+1) = e(N) - \left[\frac{\delta_o^4}{e(N)} P_w(N) \right]^T \eta_w \delta_o^4 P_w(N) \tag{21}$$

Then

$$\left\| e(N+1) \right\| \le \left\| e(N) \right\| \left\| 1 - \eta_w \left(\delta_o^4 / e(N) \right)^2 P_w^T(N) P_w(N) \right\| \tag{22}$$

If η_w is chosen as $\eta_w = \lambda / (P_{wmax}{}^2) = \lambda / R_u$, the term $\left\| 1 - \eta_w \left(\delta_o^4 / e(N) \right)^2 P_w^T(N) P_w(N) \right\|$ in (22) is less than 1. Therefore, the Lyapunov stability of $V > 0$ and $\Delta V < 0$ is guaranteed. The output error between the forecasting load and the actual load will converge to zero as $t \to \infty$. This completes the proof of Theorem 1.

In order to prove Theorem 2, the following lemmas [18] will be used.

Lemma 1 : Let $p(z) = z\, exp(-z^2)$. Then $|p(z)| < 1$, $\forall z \in \Re$.

Lemma 2 : Let $q(z) = z^2\, exp(-z^2)$. Then $|q(z)| < 1$, $\forall z \in \Re$.

Theorem 2: Let η_m and η_σ be the learning-rate parameters of the mean and the standard deviation of the Gaussian function for the FNN; let P_{mmax} be defined as $P_{mmax} \equiv max_N \left\| P_m(N) \right\|$, where $P_m(N) = \partial y_o^4 / \partial m_{ij}$; let $P_{\sigma max}$ be defined as $P_{\sigma max} \equiv max_N \left\| P_\sigma(N) \right\|$, where $P_\sigma(N) = \partial y_o^4 / \partial \sigma_{ij}$; $\|\cdot\|$ is the Euclidean norm in $\Re^n$. The convergence is guaranteed if η_m and η_σ is chosen as $\eta_m = \eta_\sigma = \eta_w [\left| w_{ko\,max}^4 \right| (2/\sigma_{ij\,min})]^{-2}$, in which $\eta_w = \lambda / R_u$; λ is a positive constant gain; $w_{ko\,\max}^4 = max_N [w_{ko}^4(N)]$; $\sigma_{ij\,\min} = max_N [\sigma_{ij}(N)]$; $|\cdot|$ is the absolute value.

Proof: According to lemma 1, $\left| [(x_i^2 - m_{ij})/\sigma_{ij}] exp\{ -\left[(x_i^2 - m_{ij})/\sigma_{ij} \right]^2 \} \right| < 1$. Since

$$\begin{aligned} P_m(N) &= \frac{\partial y_o^4(N)}{\partial m_{ij}} = w_{ko}^4 \frac{\partial y_j^2}{\partial m_{ij}} \\ &< w_{ko}^4 \left\{ max \left(\frac{2}{\sigma_{ij}} \right) \right\} = w_{ko}^4 \left(\frac{2}{\sigma_{ij\,min}} \right) \end{aligned} \tag{23}$$

Thus,

$$\left\| P_m(N) \right\| < \sqrt{R_u} \left| w_{ko\,max}^4 \right| (2/\sigma_{ij\,min}) \tag{24}$$

The error difference can also be represented by

$$e(N+1) = e(N) + \Delta e(N) = e(N) + \left[\frac{\partial e(N)}{\partial m_{ij}} \right]^T \Delta m_{ij} \tag{25}$$

where Δm_{ij} represents a change of the mean of the Gaussian function in the membership layer. By using (6), (11) and (25), then

$$\frac{\partial e(N)}{\partial m_{ij}} = \frac{\partial e(N)}{\partial y_o^4} \frac{\partial y_o^4}{\partial m_{ij}} = -\frac{\delta_o^4}{e(N)} P_m(N) \tag{26}$$

$$e(N+1) = e(N) - \left[\frac{\delta_o^4}{e(N)} P_m(N) \right]^T \eta_m \delta_o^4 P_m(N) \tag{27}$$

Then

$$\left\| e(N+1) \right\| \le \left\| e(N) \right\| \left\| 1 - \eta_m \left(\delta_o^4 / e(N) \right)^2 P_m^T(N) P_m(N) \right\| \tag{28}$$

If η_m is chosen as $\eta_m = \lambda / R_u [\left| w_{ko\,max}^4 \right| (2/\sigma_{ij\,\min})]^{-2} = \eta_w [\left| w_{ko\,max}^4 \right| (2/\sigma_{ij\,\min})]^{-2}$, $\left\| 1 - \eta_m \left(\delta_o^4 / e(N) \right)^2 P_m^T(N) P_m(N) \right\|$ in (28) is less than 1. Therefore, the Lyapunov stability of $V > 0$ and $\Delta V < 0$ by (17) and (18) is guaranteed. The output error between the forecasting load and the actual load will converge to zero as $t \to \infty$.

According to lemma 2, $\left\| [(x_i^2 - m_{ij}) / \sigma_{ij}]^2 \, exp\{-[(x_i^2 - m_{ij}) / \sigma_{ij}]^2\} \right\| < 1$. Since

$$\begin{aligned} P_\sigma(N) &= \frac{\partial y_o^4(N)}{\partial \sigma_{ij}} = w_{ko}^4 \frac{\partial y_j^2}{\partial \sigma_{ij}} \\ &< w_{ko}^4 \left\{ max\left(\frac{2}{\sigma_{ij}} \right) \right\} = w_{ko}^4 \left(\frac{2}{\sigma_{ij\,min}} \right) \end{aligned} \tag{29}$$

Thus,

$$\left\| P_\sigma(N) \right\| < \sqrt{R_u} \left| w_{ko\,max}^4 \right| (2/\sigma_{ij\,min}) \tag{30}$$

The error difference can also be represented by

$$e(N+1) = e(N) + \Delta e(N) = e(N) + \left[\frac{\partial e(N)}{\partial \sigma_{ij}} \right]^T \Delta \sigma_{ij} \tag{31}$$

where $\Delta \sigma_{ij}$ represents a standard deviation change of the Gaussian function in membership layer. By using (6), (12) and (31), then

$$\frac{\partial e(N)}{\partial \sigma_{ij}} = \frac{\partial e(N)}{\partial y_o^4} \frac{\partial y_o^4}{\partial \sigma_{ij}} = -\frac{\delta_o^4}{e(N)} P_\sigma(N) \tag{32}$$

$$e(N+1) = e(N) - \left[\frac{\delta_o^4}{e(N)} P_\sigma(N) \right]^T \eta_\sigma \, \delta_o^4 \, P_\sigma(N) \tag{33}$$

Then

$$\left\| e(N+1) \right\| \le \left\| e(N) \right\| \left\| 1 - \eta_\sigma \left(\delta_o^4 / e(N) \right)^2 P_\sigma^T(N) P_\sigma(N) \right\| \tag{34}$$

If η_σ is chosen as $\eta_\sigma = \lambda / R_u [\left| w_{ko\,max}^4 \right| (2/\sigma_{ij\,\min})]^{-2} = \eta_w [\left| w_{ko\,max}^4 \right| (2/\sigma_{ij\,\min})]^{-2}$, $\left\| 1 - \eta_\sigma (\delta_o^4 / e(N))^2 P_\sigma^T(N) P_\sigma(N) \right\|$ in (34) is less than 1. Therefore, the Lyapunov stability of $V > 0$ and $\Delta V < 0$ by (17) and (18) is guaranteed. The output error between the forecasting load and the actual load will converge to zero as $t \to \infty$. This completes the proof of Theorem 2.

III. Short-Term Load Forecasting Model

In general, the historical load data are usually used as the input for the short-term load forecasting (STLF) model. However, how to properly select characteristic data is a key question. To forecast the load at the next hour, the common practice is to use the most recently available load data, i.e., the yesterday load on the same hour. In the past research, the load data at the closed hour was selected to be the input for the STLF model. But, this selection method is not enough to completely appear the features for the forecasting hour. In order to improve the forecasting performance, a similar hour method is used to select the input variable for the STLF model.

The load patterns for weekdays are almost similar while those for weekends are different from weekdays due to social activities. Therefore, load information data for an entire week are considered. Moreover, all hours for a day will be considered because the daytime and night have different load features. In addition, a sudden load variation has a large influence for the forecasting performance. In order to prevent decreasing the forecasting accuracy from the sudden load variation, the data at the closed hours have to be considered.

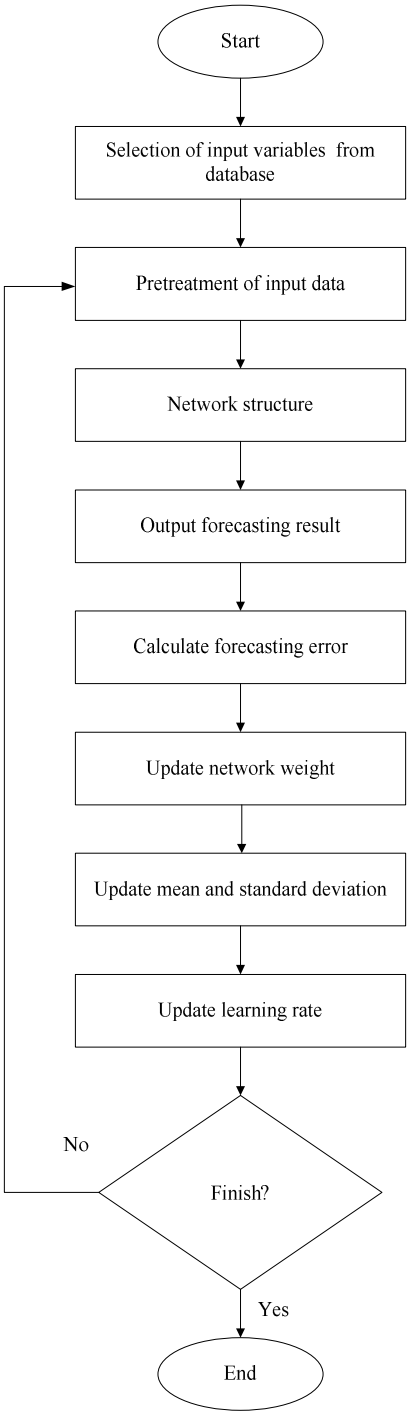

Fig. 2. Flowchart of neural-network-based short-term load forecasting (STLF).

According to the aforementioned consideration, a similar hour-based fuzzy neural network (FNN) forecaster as shown in Fig. 1 is designed to forecast the next hour's load. The flowchart of the proposed STLF model is depicted in Fig. 2. Three major factors including the load data at the same hour with the forecasting hour for yesterday, the load data at the same hour with the forecasting hour for the last week, and the load data at the closed hour with the forecasting hour are considered for the FNN forecaster. It will be helpful for simplifying the FNN structure and reducing the computation burden. In the proposed STLF model, the pretreatment of input data is to use the corresponding change rate in place of real data for normalizing input signals.

In this study, there are three input signals including the load data at the same hour with the forecasting hour for yesterday, and the load data at the same hour with the forecasting hour for the last two week, and one output signal for the FNN forecaster.

$$x_1^1 = [x_l(t-24) - x_l(t-25)] / x_l(t-25) \quad (35)$$

$$x_2^1 = [x_l(t-168) - x_l(t-169)] / x_l(t-169) \quad (36)$$

$$x_3^1 = [x_l(t-336) - x_l(t-337)] / x_l(t-337) \quad (37)$$

where t is the present hour. Because the main target in the proposed STLF model is to forecast the change rate between $x_l(t-1)$ and $x_l(t)$, the forecasting load $x_f(t)$ at the next hour can be represented as

$$x_f(t) = (1 + y_1^4)\, x_l(t-1) \quad (38)$$

The output error between $x_f(t)$ and $x_l(t)$ is continuously calculated to update the weights, the means, the standard deviations and the learning rates of the FNN forecaster until this program is finished. The effectiveness of the proposed STLF model is verified by the following numerical simulations.

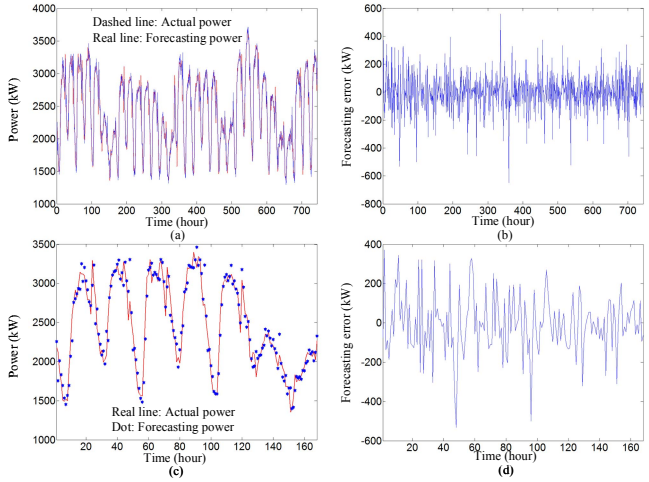

Fig. 3. Numerical simulations of STLF model with FNN forecaster in March: (a) Month forecasting performance; (b) Month forecasting error; (c) Week forecasting performance; (d) Week Forecasting error.

IV. Numerical Simulations

Numerical simulations of the proposed short-term load forecasting (STLF) model are implemented via the MATLAB software based on the schemes as shown in Figs. 1 and 2. In this study, the following mean absolute percentage error (MAPE) is adopted to measure the forecasting performance:

$$MAPE = \frac{1}{M}\sum_{t=1}^{M}\left[\frac{|x_f(t) - x_l(t)|}{x_l(t)}\right] \times 100\% \quad (39)$$

where M is the number of forecasting loads. In the numerical simulations, real data came from the energy management system in Yuan Ze University, Taiwan is used for examining the forecasting performance. In the fuzzy neural network (FNN) forecaster, there are three inputs in the input layer, nine neurons in the membership layer, twenty-seven neurons in the rule layer, one output in the output layer, and the learning rates are tuned according to Theorems 1 and 2 in Section II-C. For exhibiting the superiority of the proposed FNN forecaster with varied learning rates, a conventional neural network (NN) with the back-propagation learning algorithm is also examined here. In the NN forecaster, there are three inputs in the input layer, nine neurons in the hidden layer, one output in the output layer, and the learning rates are fixed at 0.5. The input and output signals of the NN forecaster are the same as the FNN forecaster as shown in (35)–(38).

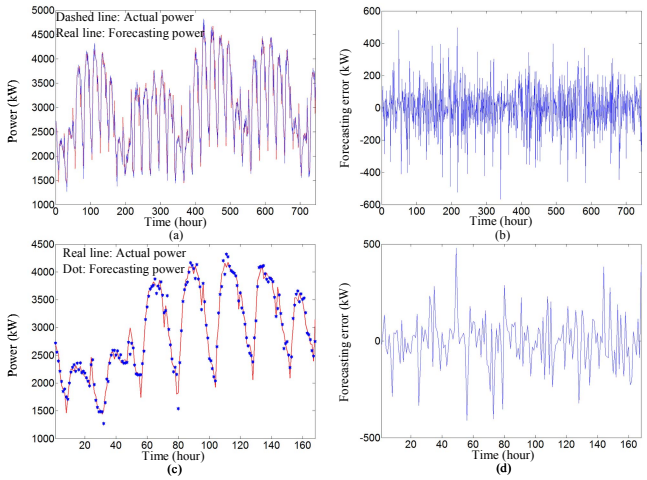

Fig. 4. Numerical simulations of STLF model with FNN forecaster in May: (a) Month forecasting performance; (b) Month forecasting error; (c) Week forecasting performance; (d) Week Forecasting error.

According to season factor and campus environment, the load data at four months (March, May, October and November in 2010) are selected. Numerical illustrations of the STLF model with the proposed FNN forecaster are depicted in Figs. 3–6. For all illustrations given in Figs. 3–6, the sub-figure (a) is the forecasting performance for a month; the sub-figure (b) is the forecasting error for a month; the sub-figure (c) is the forecasting performance for a week; the sub-figure (d) is the forecasting error for a week. The corresponding MAPE records of the STLF model with the conventional NN forecaster and the proposed FNN forecaster for different months are summarized in Table I. From these records, the MAPE value of the proposed STLF model with the FNN forecaster at different testing months is lower than 4.1%, and the average improvement rate in comparison with the conventional NN forecaster is 13.2%.

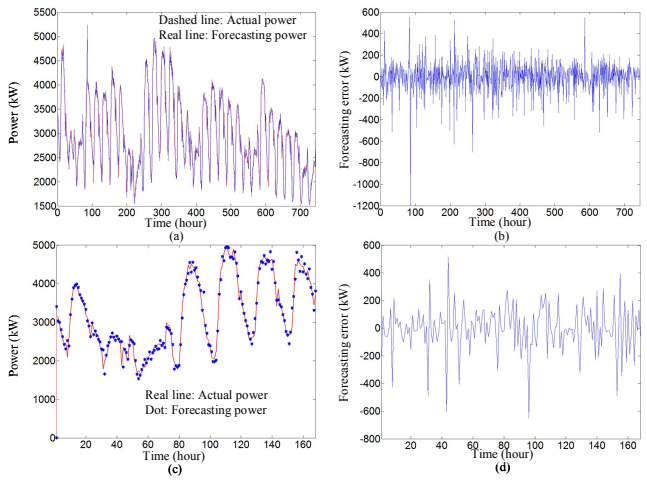

Fig. 5. Numerical simulations of STLF model with FNN forecaster in October: (a) Month forecasting performance; (b) Month forecasting error; (c) Week forecasting performance; (d) Week Forecasting error.

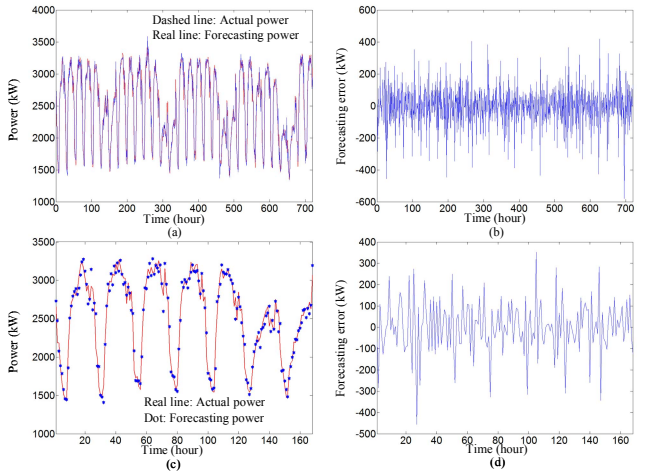

Fig. 6. Numerical simulations of STLF model with FNN forecaster in November: (a) Month forecasting performance; (b) Month forecasting error; (c) Week forecasting performance; (d) Week Forecasting error.

TABLE I. MAPE OF FORECASTING RECORDS FOR DIFFERENT MONTHS

Network structure	March	May	October	November
Fuzzy neural network	3.97%	4.04%	3.69%	3.98%
Neural network	4.8%	4.38%	4.41%	4.48%

V. CONCLUSIONS

This study has successfully developed a short-term load forecasting (STLF) model with a fuzzy neural network (FNN), and applied well to a real case in Taiwan campus. Due to the selection of similar hour data, the network structure can be simplified, and the computation time can be shortened. In order to guarantee the convergence of forecasting error, analytical methods based on a discrete-type Lyapunov function are proposed to determine varied learning rates for the on-line learning algorithm of the FNN forecaster. According to simulated results, the proposed STLF model with the FNN forecaster indeed yields better performance than the one with the conventional NN forecaster, and the average improvement rate is 13.2%. In the future, the proposed STLF model could be modified and extended to midterm and long-term load forecasting.

***Abstract* -- Conventional maximum power point tracking (MPPT) method, e.g. perturbation and observation (P&O) and incremental conductance (INC), have the drawbacks such as oscillation at the MPP during power fast tracking and power divergence under rapidly changing atmospheric condition. Thus, a fuzzy logic controller (FLC) is implemented in the PV system to avoid the conventional problem. FLC method has not only fast response under rapidly changing atmospheric conditions but also small oscillation at the maximum power point (MPP). However, FLC presents tuning difficulty of membership function, scaling factor and control rules. The FLC disadvantages can be reduced using single-fuzzy logic controller (S-FLC) without degrading its performance. The experiment results are shown to verify the studied S-FLC MPPT method.**

Keywords: Maximum Power Point Tracking, Photovoltaic Module, Single-Fuzzy Logic Control

I. INTRODUCTION

Worldwide energy consumption has increased rapidly due to world population growth. Since amount of fossil energy source has no longer enough, renewable energy sources such as solar power, wind power, geothermal power, and fuel cell are considered to meet the global demand for energy. Aside from the unlimited amount of the sources, renewable energy has advantages such as no or low pollution emissions compared with fossil energy. Among these renewable energy sources, solar energy is one of the most appropriate and primary renewable energy [1, 2]. Although the first PV cell was developed in 1954 [3], the researcher began to conduct its further development in the 1970s. They have improved device efficiency and reliability with lowered cost by using new material and fabrication process [4]. Currently, improvement of PV system performance is the goal of the development.

Development of PV system is generally focused on two areas: the PV cell manufacturing process and materials and the PV power management strategy. Techniques in manufacturing have had significant progress in terms of higher efficiency with lower cost. Regarding to PV power management, implementation of PV system with inappropriate strategy will result in low efficiency. Thus, PV power management strategy including energy conversion system is a very important part in efficiency improvement. One of the energy conversion strategies being developed is method to find maximum power of the PV module that known as maximum power point tracking (MPPT) method. The MPPT method automatically finds the maximum voltage or maximum current of a PV module at which it will operate to reach the maximum power output under certain temperature and irradiance. To obtain good performance, numerous methods are proposed to be implemented in the PV system. Based on the control algorithm, these proposed MPPT methods can be categorized into conventional and intelligent methods. The conventional MPPT method includes perturbation and observation (P&O), incremental conductance (INC), voltage-feedback methods, and so on. Fuzzy logic control (FLC), neural network, genetic algorithm, and so on is based on intelligent algorithm, thus it categorized into intelligent method.

The P&O and INC method are commonly used in the MPPT system because of their simple implementation. However, the P&O method has two drawbacks regarding its performance. The first is power oscillation at the maximum power point (MPP) and the other one is divergence of the MPP under rapid atmospheric change [5, 6, 7, 8]. The problem of power oscillation at the MPP also occurs in the INC method when fast tracking of the maximum power is desired. In the case of solar vehicle which its load consist mainly of batteries, these two methods are not suitable to be implemented. Therefore, an appropriate MPPT method that can quickly converge to MPP without oscillation problem is needed to maximize load current or voltage. One of alternative method to be implemented in this case is FLC MPPT method [8]. The implementation of FLC method in the MPPT system is referred to [9, 10, 11]. Some Improvements of FLC MPPT method has been proposed but it still with complex control rules [10, 11]. Consequently, FLC presents difficulty of modification and tuning of control rules. Due to this reason, B.J. Choi e.t. [12, 13] simplified the inputs of FLC to only one input that known as single-fuzzy logic controller (S-FLC). Besides simplicity of tuning of membership function, scaling factor and control rules, S-FLC present some other advantages such as the control rule table is built in one-dimensional space, the computational complexity is reduced, it is equivalent to the sliding mode control with a boundary layer and so on [13].

II. PV MODULE CHARACTERISTIC

A PV module is composed of PV cells connected in series to achieve required output voltage within a certain range of the system voltage under condition of average irradiance and temperature. The simplest circuit model of PV cell is represented by a current source paralleled with an ideal diode as shown in Fig.1. The current source I_p represents a current source generated by solar radiation. This current source is also called as the photo generated current.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

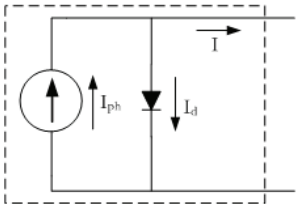

Fig.1. The equivalent circuit of ideal PV cell

The corresponding *I-V* characteristic can be described by the Kirchhoff's Current Law (KCL) where the output current I is the subtraction result of the current source I_p and the diode saturation current I_d. This characteristic can be written as:

$$I = I_p - I_d\left(e^{\frac{qV}{k_B T}} - 1\right) \quad (1)$$

where k_B is the Boltzman constant (1.381×10^{-23} J/K), T is the absolute temperature (in Kelvin), q(>0) is the electron charge (1.602×10^{-19}C), and V is the voltage at the terminal of the cell (in Volt).

In an ideal case, the open circuit voltage V_{oc} is calculated where the short circuit current I_{sc} is equal to the current source I_p. It can be written as:

$$V_{oc} = \frac{k_B T}{q} \ln\left(1 + \frac{I_p}{I_d}\right) \quad (2)$$

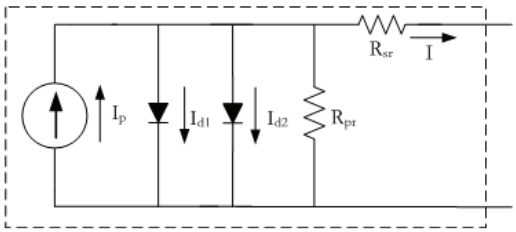

Fig.2. The equivalent circuit of non-ideal PV cell

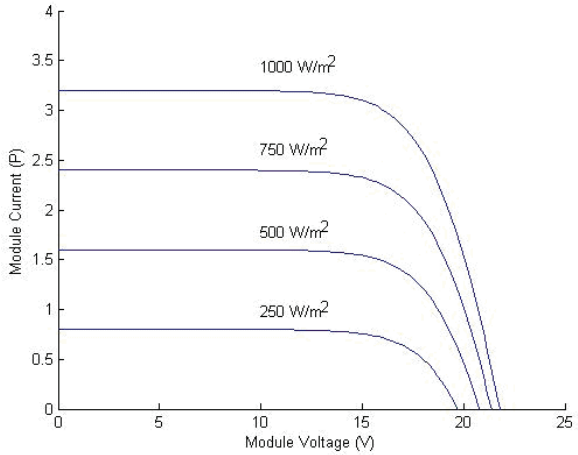
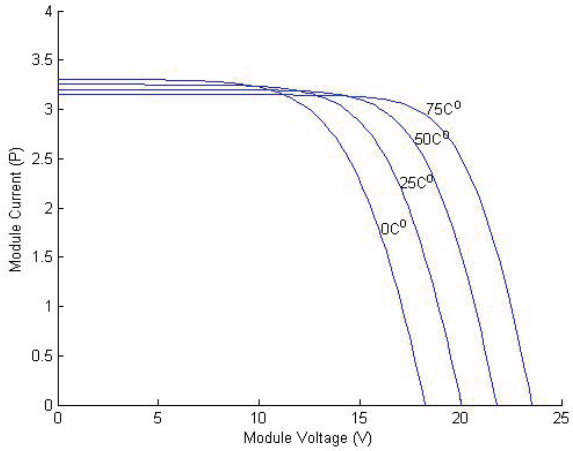
In practice, a non-ideal circuit is used to model the PV cell represented by a two-diode, shunt resistance R_{pr}, and series resistance R_{sr} as shown in Fig. 2. These components relates to the maximum power which can be generated by the PV cell. In details, the two-diode is used to correct an ideal characteristic curve and the two-resistor is leading to a characteristic of the form where the photo generated current may depend on the voltage. Instead of the equation (1), the characteristic equation is now written by incorporating ideality factor of two which appeared in the exponential term of the second diode. The equation becomes [14]:

$$I = I_p - I_{d1}\left\{\exp\left(\frac{V + IR_{sr}}{k_B T}\right) - 1\right\} - I_{d2}\left\{\exp\left(\frac{V + IR_{sr}}{2k_B T}\right) - 1\right\} - \frac{V + IR_s r}{R_{pr}} \quad (3)$$



(a)



(b)

Fig.3. The *I-V* characteristic of BP350 PV module (a) under different levels of irradiance and (b) under different levels of temperature

The relationship among power P, current I and voltage V produced by the PV module is shown in Fig. 3. The figure shows if the PV module generates power maximum P_{max} at the maximum voltage V_{max} and the maximum current I_{max} and it is varying with present temperature and irradiance.

III. Fuzzy-Logic MPPT Controller

A. Conventional Fuzzy-Logic Controller

Based on fuzzy-logic system (FLS) as shown in Fig.4, fuzzy logic controller (FLC) MPPT method consists of four components: fuzzification, rules and inference engine, and defuzzifier [15, 16, 17]. The input signal is measured from the output of PV power and then processed to generate signal control in the FLS. In the process, each of these signal, either input signal or output signal, are defined by one or more variable (s).

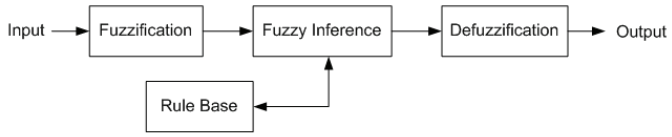


Fig.4. Fuzzy logic system (FLS)

Generally, FLC MPPT method has two input variables, error e and change in error Δe, and an output variable. The two input variables are described by:

$$e(k) = \frac{P_p(k) - P_p(k-1)}{I_p(k) - I_p(k-1)} \tag{4}$$

$$\Delta e(k) = e(k) - e(k-1) \tag{5}$$

where $P_{pk}(k)$ and $I_{pk}(k)$ are the power and current of the PV module, respectively [9]. Therefore, a fast convergence with a small oscillation at the steady state can be achieved. As for the output variable, the output of duty cycle step is expressed by dD.

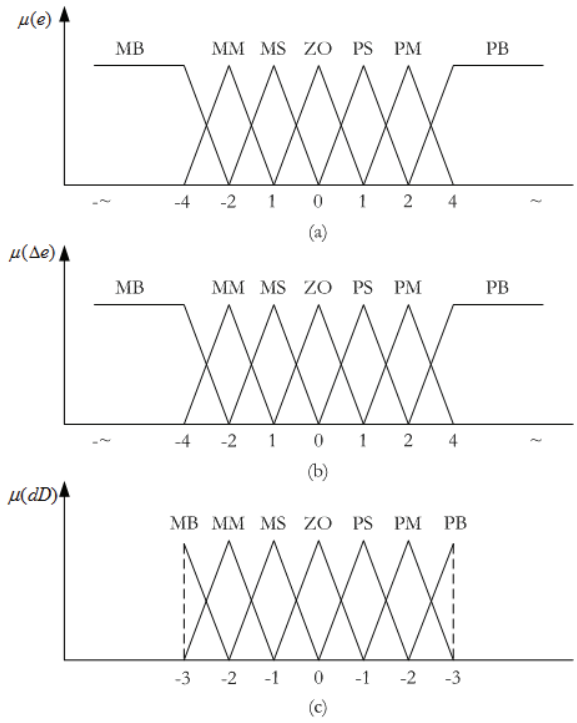

Fig.5. Membership function for (a) input, (b) input $e\Delta$ and (c) output dD

These two input and output variables are represented by fuzzy subsets. As shown in Fig.5, each fuzzy set has seven basic fuzzy subsets for variables of input and output which declared in terms of linguistic variables such as PB (plus big), PM (plus medium), PS (plus small), ZO (zero), MS (minus small), MM (minus medium), NB (minus big).

Fuzzy rules are designed to achieve zero error at the steady state of the MPP. As shown in the Table 1, the main idea of the rule is to bring operating point to the MPP by increasing or decreasing the duty ratio depending on the position of the operating point from the MPP. If the operating point is distant from the MPP, the duty ratio will be increased or decreased largely.

TABLE 1. FUZZY RULES BASE

Δe \ e	ML	MM	MS	ZO	PS	PM	PB
MB	MB	MB	MB	MB	MM	MS	ZO
MM	MB	MB	MB	NM	MS	ZO	PS
MS	MB	MB	MM	MS	ZO	PS	PM
ZO	MB	MM	MS	ZO	PS	PM	PB
PS	MM	MS	ZO	PS	PM	PB	PB
PM	MS	ZO	PS	PM	PB	PB	PB
PB	ZO	PS	PM	PB	PB	PB	PB

Since the rules table has seven linguistic variables of error e and change in error Δe respectively. The fuzzy-logic system has 49 rules as follows:

Rule^{1}*:* IF e is *MB* and Δe is *MB* THEN dD is *MB*

Rule^{2}*:* IF e is *MM* and Δe is *MB* THEN dD is *MB*

...

Rule^{49}*:* IF e is *PB* and Δe is *PB* THEN dD is *PB*

To get the output of inference, many methods are proposed by the researchers. There are some known methods such as Mandani, Sugeno, Larsen, and so on but the Mandani's method is commonly used. Its description is shown in Fig.6.

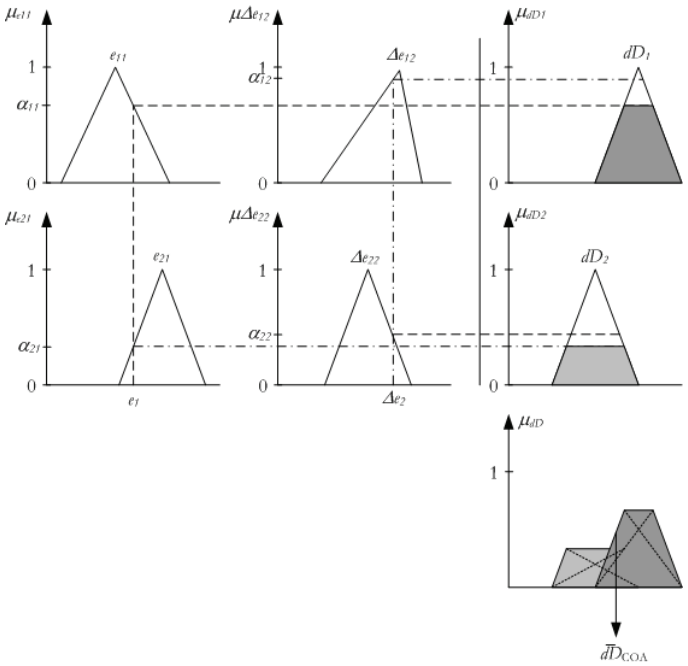

Fig.6. Mandani's inference method with COA defuzzification [17]

The output of fuzzy inference is a fuzzy control subset, such that it must be converted to the crisp value. By using the centroid (COA) defuzzifier, the output control *dD* can be calculated by:

$$dD = \frac{\sum_{k=1}^{I} dD_k \mu_{dD}(dD_k)}{\sum_{k=1}^{I} \mu_{dD}(dD_k)} \quad (6)$$

The value of *dD* is the duty step added to the previous duty cycle of PWM control signals.

B. Single Fuzzy-Logic Controller

S-FLC was published in [12, 13] as the controller of the inverted pendulum system tracking. The experiment proves that the performance and stability of S-FLC are similarly to that of FLC. The standalone MPPT system with S-FLC MPPT method is shown in Fig.7.

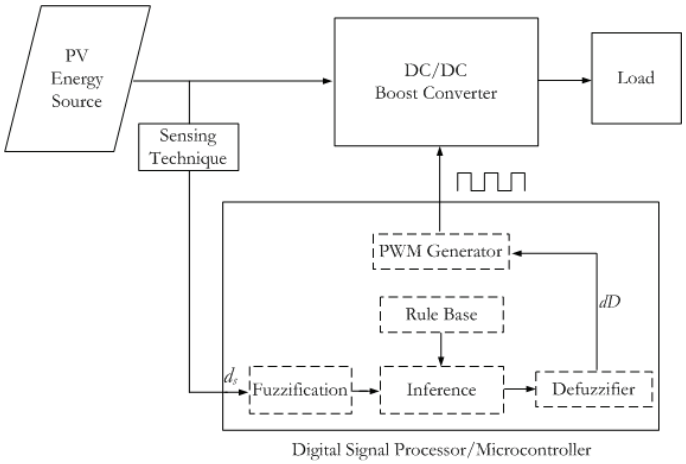

Fig.7. Stand-alone MPPT system with S-FLC MPPT method

As shown in Table 1, The FLC rules have a skew-symmetric property, thus the diagonal lines can be drawn following output variable shapes. The quantization level of the independent variables can be divided into two parts, such that the number of boundaries of control region is two times the numbers of output variables. Because the quantization level of the independent variables becomes infinitesimal, the boundaries become straight lines. Also the absolute magnitude of the input variables is proportional to the distance from the main diagonal line called the switching line *s*. It is written by [12, 13]:

$$s: \Delta e + \quad e = 0 \quad (7)$$

The value of the control input is measured as the distance from the main diagonal line or the distance between *H(e,Δe)* and *P(e,Δe)* called as the signed distance. It is described clearly in Fig. 8. This signed distance is written by:

$$d_s = \mathrm{sgn}(s) \frac{|\Delta e + \lambda e|}{\sqrt{1+\lambda^2}} = \frac{|\Delta e + \lambda e|}{\sqrt{1+\lambda^2}} \quad (8)$$

where:

$$\mathrm{sgn}(s) = \begin{cases} 1 & for\ s > 0 \\ -1 & for\ s < 0 \end{cases} \quad (9)$$

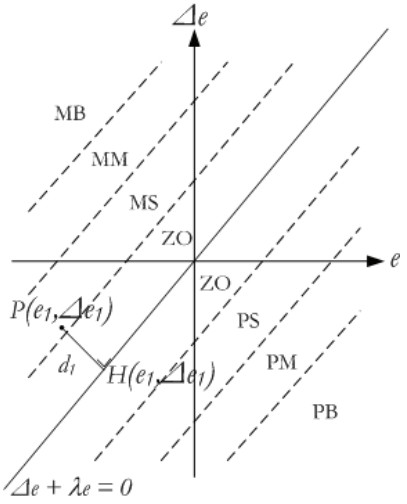

Fig.8. Derivation of a signed distance [12, 13]

Since the sign of a control input depends on the value of switching line *s* as described by equation (9), the absolute magnitude of control input is proportional to the distance from main diagonal line (*s*=0). It can be concluded that:

$$dD \sim -d_s \quad (10)$$

Instead of the fuzzy rules in Table 1, the single-fuzzy rules can be constructed to one dimensional space of d_s as shown in Table 2.

TABLE 2. SINGLE-FUZZY RULES BASE

d_s	MB	MM	MS	ZO	PS	PM	PB
dD	PB	PM	PS	ZO	MS	MM	MB

As shown in Table 2, the fuzzy-logic system has only 7 rules instead of 49 rules of Table 1. These 7 rules of S-FLC is shown as follows:

$Rule^1$: IF d_s is MB THEN *dD* is *PB*

$Rule^2$: IF d_s is MM THEN *dD* is *PM*

...

$Rule^7$: IF d_s is PB THEN *dD* is *MB*

Now, each of input variable *ds* and output variable *dD* is represented by seven basic fuzzy subsets as shown in Fig.9.

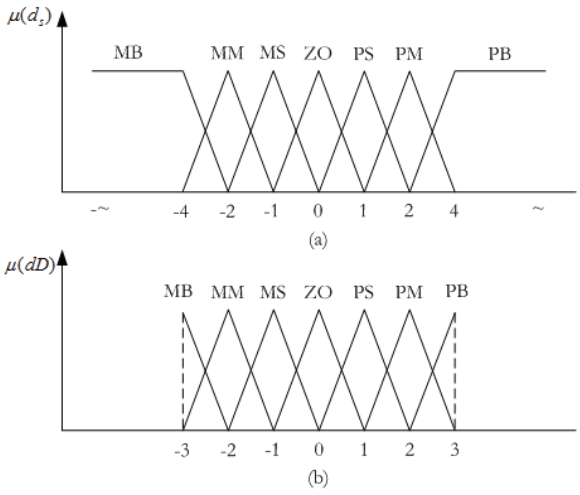

Fig.9. Membership functions for (a) input d_s and (b) output dD

IV. System Design

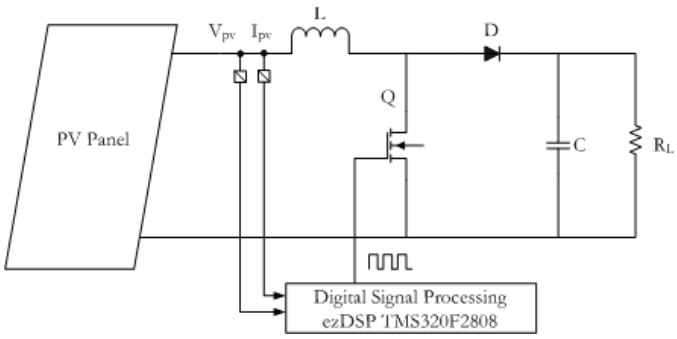

Fig.10. MPPT system with the boost converter and ezDSP TMS320F2800 controller

A design example of the studied MPPT PV system is shown in Fig.10. The design of standalone PV system consists of a PV panel, DC/DC boost converter and DSP controller. The design includes the boost converter which its component selection following the specification in Table 3. As the controller, DSP TMS320F2808 is used where a MPPT algorithm is implemented.

TABLE 3. Design Specifications of the Boost Converter

Specifications	
Nominal input voltage	17.5V
Maximum input voltage	21.8V
Nominal output voltage	24V
Maximum output voltage	50V
Maximum solar power	50Watt
Switching frequency	50kHz
Maximum inductor current ripple	10%
Maximum output voltage ripple	0.50%
Efficiency	>90%

To meet the specification required in Table 3, inductance L and output capacitance value C follows the calculation in Table 4 [18].

TABLE 4. List of the Selection Components: Inductance and Capacitance

Description	Values
Inductance L	$L = \frac{V_{pv} D}{2\Delta i_L f_s} = 165.885 \mu H$
Output capacitance C	$C = \frac{I_o D}{2\Delta v_o f_s} = 47.02 \mu F$

Regarding to diode selection, diode reverse voltage rating is one of the considerations. The diode is used as a current path for the inductor to the output at the off-state power switch and its forward current rating is calculated from the maximum output current. Therefore, a Schottky diode is chosen because it has fast switching characteristics, low reverse–recovery, and low forward voltage drop. The super fast recovery diode rectifier D10LC20U, with $200V$ maximum off-state voltage stresses and $10A$ average current handling, meets the requirement.

In selecting a power MOSFET and driver, the requirements is related to the ability to handle the maximum current and voltage stresses. This maximum voltage stress and the maximum current stress is considered from the maximal PV output voltage, and the maximum output current of PV module with its ripple, respectively. MOSFET IRFZ44N with $55V$ maximum drain-source voltage and $49A$ maximum drain current is selected in this design.

V. Experimental Result

A laboratory prototype of MPPT system is built to validate the performance of the S-FLC MPPT method. The prototype setup consists of a boost DC/DC converter, DSP controller, resistive load and a solar array simulator SAS Agilent E4360 (instead of PV module). The SAS Agilent E4360 simulates PV power source following the specification of BP350 solar module as shown in Table 5.

TABLE 5. The Specification of BP350 Solar Module [19]

Specifications	
Maximum Power (Pmax)	50W
Voltage at Pmax (Vmp)	17.5V
Current at Pmax (Imp)	2.9A
Short-circuit current (Isc)	3.17A
Open-circuit voltage (Voc)	21.8V

The experimental results include not only comparison between S-FLC MPPT method and FLC MPPT method, but also comparison between P&O methods and INC MPPT method. In detail, the results of measurement are described as follows:

a) No MPPT controller

The characteristics of MPPT system when the controller is not activated are shown in Fig. 11. A load of 50 Ω is connected to the system. The SAS voltage and current delivered to the converter is around 21.3*V* and 0.4*A,* respectively. Consequently, the SAS power reached by the system is only 8.7*W* or in the other hand 83% of PV maximum power is lost.

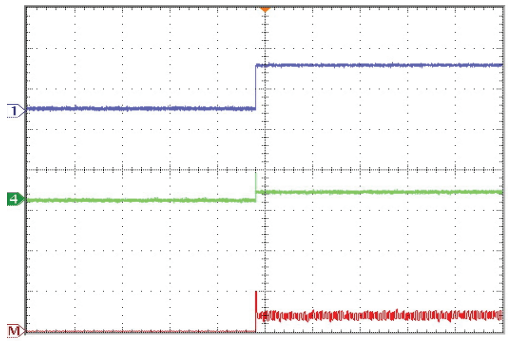

Fig.11. Maximum power reached by the system without any MPPT controller; Scale: [1]-Voltage (20V/div), [4] - Current (2A/div), [M]-Power (20W/div), Time 2s/div.

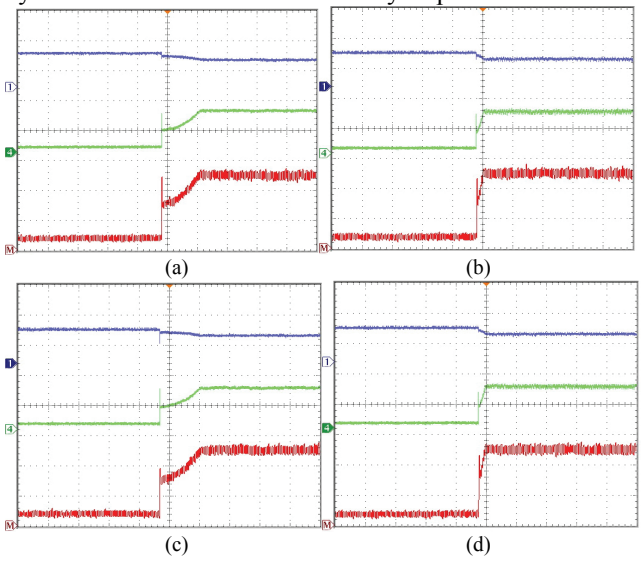
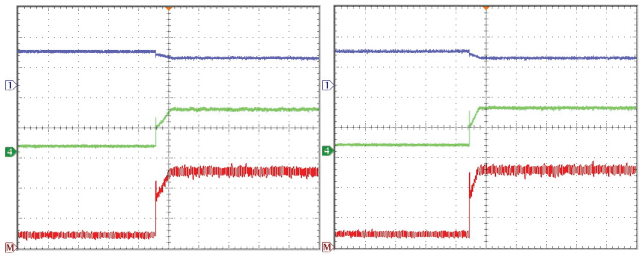
b) MPPT response time to the steady state

The characteristic of system response to the steady state (MPP) is shown is Fig. 12 when the controller is activated. The initial PWM duty cycle of 50% is set in the controller and a resistive load of 50Ω is connected to the system. It shows that the P&O and INC with 0.2% duty step are slower to reach the MPP than the others. The time required by the S-FLC method to reach the steady state of the MPP is close to the time needed by the P&O and INC with 0.9% duty step.



(a) (b) (c) (d)



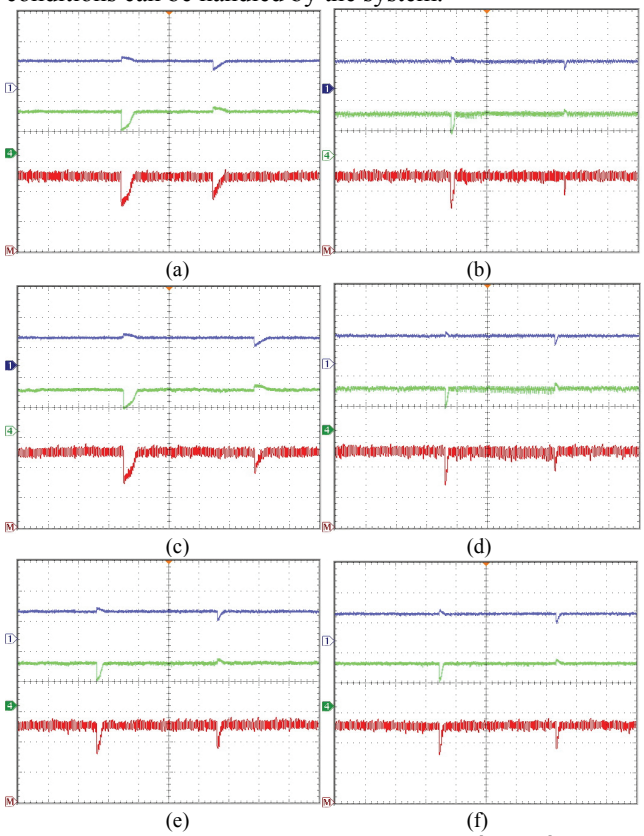
(e) (f)

Fig.12. Time response from no-MPPT to Load R=50Ω (a) P&O with duty step 0.2% (b) P&O with duty step 0.9% (c) INC with duty step 0.2% (d) INC with duty step 0.9% (e) FLC with duty step 0%-0.9% (f) S-FLC with duty step 0%-0.9%; Scale: [1]-Voltage (20V/div), [4]- Current (2A/div), [M]-Power (20W/div), Time 2s/div.

c) MPPT response time to load changing at the steady state

To validate the MPPT system response to the changing atmospheric condition, the system is tested by changing the loads. The value of load changing is 50 Ω to 100Ω and then 100Ω to 50Ω. Both FLC and S-FLC method have a fast response to reach the steady state condition. Fig. 13 shows the characteristics of the response time.

The response time of the MPPT system with respect to big load changing is shown in Fig. 14. The load changing of 25-110Ω is connected to the system. As shown in the Fig. 14, FLC and S-FLC methods are robust to handle big load changing that it means an extreme change in atmospheric conditions can be handled by the system.



(a) (b) (c) (d) (e) (f)

Fig.13. Time response to small load change R=50Ω→100Ω→50Ω (a) P&O with duty step 0.2% (b) P&O with duty step 0.9% (c) INC with duty step 0.2% (d) INC with duty step 0.9% (e) FLC with duty step 0%-0.9% (f) S-FLC with duty step 0%-0.9%; Scale: [1]-Voltage (20V/div), [4]- Current (2A/div), [M]-Power (20W/div), Time 2s/div.

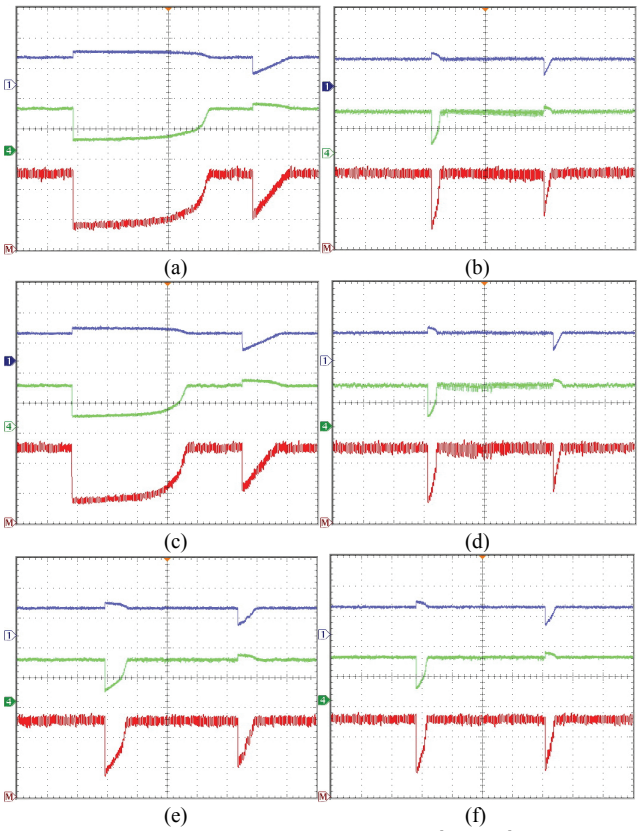


Fig.14. Time response to big load change R=25Ω→110Ω→25Ω (a) P&O with duty step 0.2% (b) P&O with duty step 0.9% (c) INC with duty step 0.2% (d) INC with duty step 0.9% (e) FLC with duty step 0%-0.9% (f) S-FLC with duty step 0%-0.9%; Scale: [1]-Voltage (20V/div), [4]- Current (2A/div), [M]-Power (20W/div), Time 2s/div.

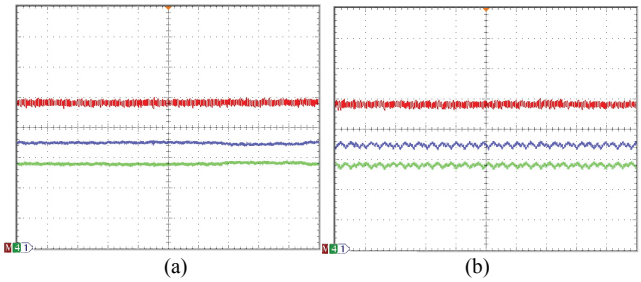
d) MPPT oscillation at the steady state

Small oscillation at the steady state of the MPP is one of the criterions of the MPPT method. Regarding to this criteria, experimental comparison of all methods is shown in Fig.15. The system is connected to resistance load of 50Ω, and then the oscillation is measured at the MPP. It can be seen in the figure, similar to P&O and INC method with 0.2% duty step, the FLC and S-FLC method has a small power oscillation at the MPP. However, a big power oscillation at the MPP cannot be avoided by the P&O and INC method with 0.9% duty step.



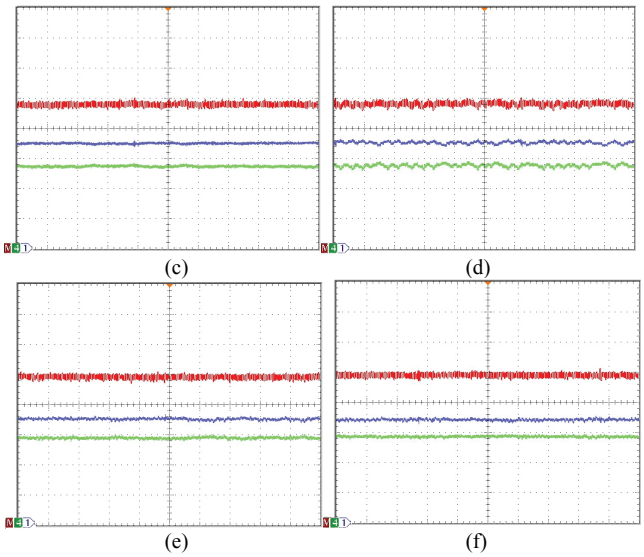


Fig.15. Power oscillation at the MPP (a) P&O with duty step 0.002% (b) P&O with duty step 0.009% (c) INC with duty step 0.2% (d) INC with duty step 0.9% (e) FLC with duty step 0%-0.9% (f) S-FLC with duty step 0%-0.9%; Scale: [1]-Voltage (5V/div), [4]- Current (1A/div), [M]-Power (10W/div), Time 400ms/div.

VI. Conclusion

A single-fuzzy logic controller (S-FLC) MPPT method is successfully implemented in a MPPT PV system. Due to control algorithm simplicity, it is easier to implement, modify and tune the control rules. The performance of S-FLC method has been validated in the MPPT system with a boost DC/DC converter and resistive load. A fast convergence with small oscillation at the MPP can be achieved by this method such that it has similar performance to FLC MPPT method. At the MPP tracking, both S-FLC and FLC, has a characteristic which similar to the conventional method, P&O and INC, with a high duty step and at the steady state of the MPP, they have a characteristic which similar to the conventional method with a low duty step.

To achieve more robust performance of S-FLC MPPT method, it is necessary to find appropriate membership function and sampling strategy without avoiding computation simplicity. Therefore, it is the most difficult part in the S-FLC design as well as the FLC design.

Abstract—**This paper presents a fuzzy based frequency control strategy by grid-connected MW class PV generation. The frequency control is proposed from the view point of the frequency fluctuation problem produced by the large penetration of PV power. The fuzzy control has three inputs: average insolation, change of insolation and system frequency deviation. Following these three inputs, a frequency control system of the PV inverters is proposed. For the case of different insolations, a coordinated inverter and battery control method is presented. The proposed method is simulated in three control area power system by considering dual power and information flows between supply and demand sides and is found satisfactory to provide frequency control and to reduce tie-line power fluctuations.**

Keywords-fuzzy control, frequecny deviations, MW-class PV, tie-line power fluctuations

I. INTRODUCTION

PV systems are expected to play a vital role in the future energy efficient and zero emission society. Recently, along with the smart grid, large PV power generation is getting enormous attraction. The penetration of PV systems in Japan is rising. Two factors have been boosting this: improved generation efficiency of PV modules and governmental subsidies [1]. However, PV power fluctuates depending on the weather conditions, season, and geographic location and causes problems like voltage fluctuation and large frequency deviation in an electric power system operation [2]-[4].

The integration of a large number of embedded PV generators will have far reaching consequences not only on the distribution networks but also on the national transmission and generation system. If the PV generators are built on the roof and sides of buildings, most of them will be located in urban areas and will be electrically close to loads. On the other hand, these PV generating units may be liable to common mode failures that might cause the sudden or rapid disconnection of a large proportion of operating PV capacity. However, considering the recent grid codes in Germany and Spain [5], PV generators should provide dynamic grid support e.g. voltage stability during voltage drops which is often referred to as Fault-Ride-Through (FRT) capability and frequency control.

Whether many studies are dedicated to the voltage control by PV inverters, this paper provides a strategy of frequency control by the grid-connected PV systems. The frequency control strategy is developed based on fuzzy logic [6] and is tested by simulation in a three control area power system and is compared with a conventional energy storage system (ESS) based smoothing method of PV output power fluctuations [1]. From the simulation results, it is found that the proposed frequency control method shows satisfactory performances and reduces the tie-line power fluctuations.

II. SYSTEM DESCRIPTION AND METHODOLOGY

To illustrate, frequency control performance by MW-class PV generation in a multi-area power system, three identical interconnected control areas are considered and is shown in Fig. 1. A generalized load frequency model in the presence of frequency control from PV generation is shown in Fig. 2[7]. The simulation parameters are given in Table I.

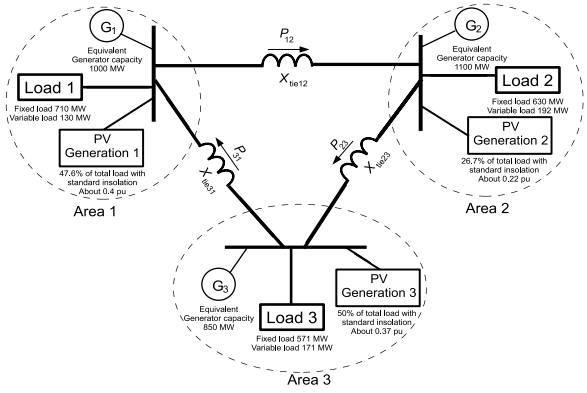

Fig 1. Three control area power system.

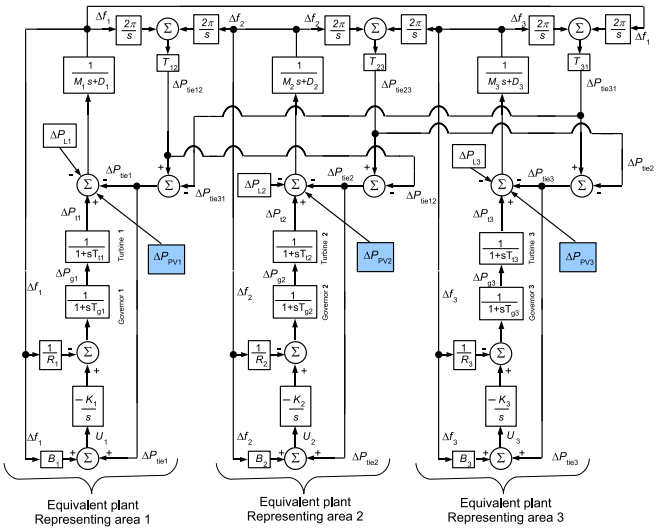

Fig. 2. Frequency control model with considering frequency control from PV generation.

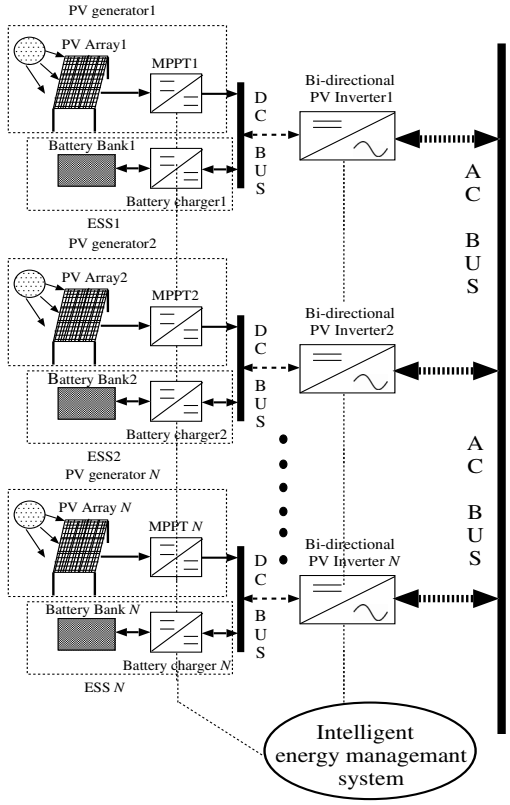

Fig. 3. Multiple PV generators are connected in coordinated control mode.

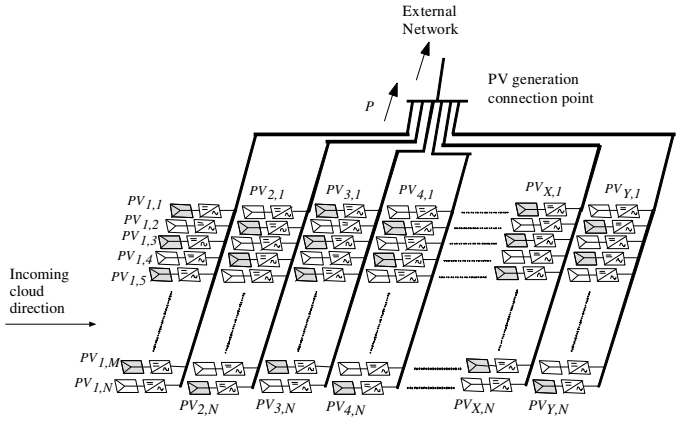

Fig. 4. The aggregate model of large PV plant connected to the power grid.

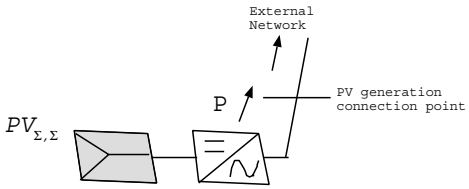

Fig. 5. One-PV generator equivalent.

A. Simplification of aggregate model of grid-connected PV generation

Commonly, grid-connected PV generation consist of a large number of relatively small PV units. This distributed generation can be represented by an equivalent PV generation plant whose rating is equal to the sum of the ratings of the individual PV generating units. A distributed PV generation systems with multiple PV generators is show in Fig. 3. An individual PV generator is consisted of a large PV array, a MPPT controller, and an ESS. The operational points of the individual PV generating units are determined by the insolation value and the frequency control algorithm. The aggregate model of the large-scale PV plant thus comprises $N \times Y$ PV generating units of G MW power capacity each where N is the number of PV generating unit in row and Y is the number of PV generating unit in column. The installed capacity of the equivalent PV plant is thus $N \times Y \times G$ MW. The model is shown in Fig. 4. However, the MPPT module and battery module of each PV system are not shown.

Uniform Insolation Distribution

In this case the PV generating units within the plant are assumed to have the same operating points. When reducing the

aggregate model of the large PV plant, the following assumptions are made:

- The MVA rating of the large PV plant equivalent, $S_{\Sigma,\Sigma}$ is the sum of the MVA ratings of the PV generating units:

$$S_{\Sigma,\Sigma} = \sum_{i=1}^{Y}\sum_{j=1}^{N} S_{i,j} \tag{1}$$

  Where $S_{i,j}$ is the MVA-rating of the PV generating unit j being in the column i.
- The equivalent PV generating plant supplies the same amount of electric power to the grid:

$$P_{\Sigma,\Sigma} = \sum_{i=1}^{Y}\sum_{j=1}^{N} P_{i,j} \tag{2}$$

  where $P_{i,j}$ is the electric power supplied by the PV generating unit j being in the column i and $P_{\Sigma,\Sigma}$ is the electric power supplied by the whole PV plant.

(1) and (2) imply that the equivalent PV plant can be defined by a simple addition of the MVA ratings and an addition of the electric power output of the individual generating units. Fig. 5 shows this one-PV generator equivalent. The incoming cloud shown in Fig. 4 is assumed to cover all the individual PV generating units in the equivalent plant at the same time.

Non-uniform Insolation Distribution

In this case the incoming cloud is such that:

- Its direction is as shown in Fig. 4.
- The cloud takes k seconds time to move from the first column to the second column of the PV generating units. In other words, the insolation is shifted by k seconds for each column of PV generating units.

Since the operating points of the PV units in each column are identical, the outputs of the PV units in each column are added and a multi-machine equivalent comprising of Y PV generating units is obtained. This multi-generators equivalent is shown in Fig. 6. The MVA ratings, $S_{\Sigma,\Sigma}$ the electric powers, $P_{\Sigma,\Sigma}$ of the equivalent PV plants are given by:

$$S_{\Sigma,\Sigma} = \sum_{i=1}^{Y} S_{i,\Sigma} \tag{3}$$

$$P_{\Sigma,\Sigma} = \sum_{i=1}^{Y} P_{i,\Sigma} \tag{4}$$

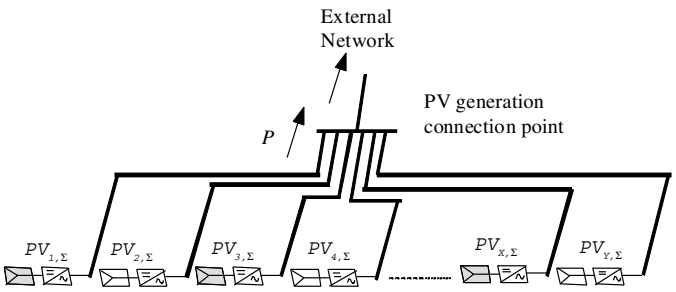

Fig. 6. The multi-PV generator equivalent.

B. Fuzzy based command power generation consdering uniform insolation to all PV inverters

In order to control output power of all PV systems considering power system condition, output power command P_{inv}^{*} is decided by output power command system shown in Fig. 7. Output power command system consists mainly of two fuzzy control blocks and the rate of rated output power for PV system is decided by these fuzzy controls. Fuzzy reasoning is described by a set of "if-then" rules based on fuzzy rules. Fuzzy reasoning is effective when mathematical expressions are difficult by inherent complexity or nonlinearity.

Firstly, fuzzy control I is explained. There are two inputs of fuzzy control I. One is frequency deviation Δf and the other is average insolation $\overline{S}_i$. Average insolation $\overline{S}_i$ is defined by

$$\overline{S}_i = \frac{1}{T}\int_{t-T}^{t} S_i dt \,. \tag{5}$$

where t is present time, T is integral interval, and S_i is instantaneous insolation. Fuzzy rules and membership functions of fuzzy control I are shown in TABLE II and Fig. 8, respectively. Fuzzy rules and membership functions that yield an output to reduce frequency deviations are defined by trial-and-error. The ith fuzzy rule is expressed as

$$\text{Rule } i: \text{if } \Delta f \text{ is } L_x \text{ and } \overline{S}_i \text{ is } M_y \text{ then } \gamma_I \text{ is } Z_l \tag{6}$$
$$x = 1,2,\cdots,7,\ y = 1,2,\cdots,7,\ l = 1,2,\cdots,7$$

where L_x , M_y denote the antecedents and Z_l are consequent part.

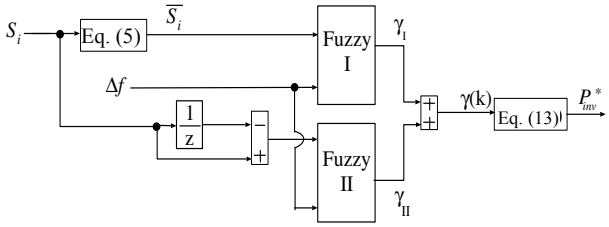

Fig. 7. Output power command generation system.

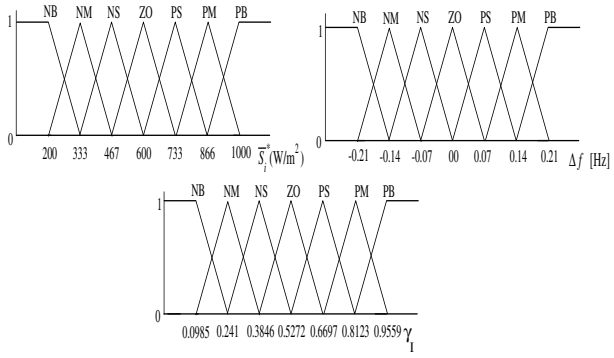

Fig. 8. Membership Functions of fuzzy control I.

TABLE II. FUZZY RULES OF FUZZY CONTROL I

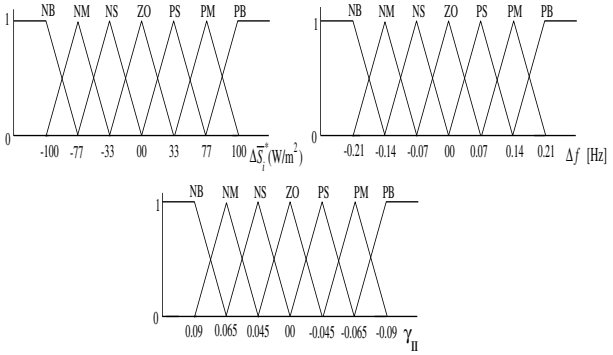

Fig. 9. Membership Functions of fuzzy control II.

TABLE III. FUZZY RULES OF FUZZY CONTROL II

ΔS_i \ Δf	NB	NM	NS	ZO	PS	PM	PB
NB	NB	NB	NB	NM	NM	NS	ZO
NM	NB	NB	NM	NM	NS	ZO	PS
NS	NB	NM	NM	NS	ZO	PS	PM
ZO	NM	NM	NS	ZO	PS	PM	PM
PS	NM	NS	ZO	PS	PM	PM	PB
PM	NS	ZO	PS	PM	PM	PB	PB
PB	ZO	PS	PM	PM	PB	PB	PB

NB=Negative Big NM=Negative Medium NS=Negative Small
PB=Positive Big PM=Positive Medium PS=Positive Small
ZO=Zero

Fuzzy reasoning output γ_I is calculated by

$$\gamma_I = \sum_{i=1}^{49} w_i Z_I \Big/ \sum_{i=1}^{49} w_i \tag{7}$$

where w_i denotes the grade for the antecedent and is obtained by

$$w_i = w_{\Delta fi} w_{\overline{s}_i i} \tag{8}$$

where $w_{\Delta fi}$ and $w_{\overline{s}_i i}$ are the grade of antecedents for each rule.

Secondly, fuzzy control II is explained. Frequency deviation Δf and change of insolation ΔS_i are used as inputs of Fuzzy control II, where change of insolation ΔS_i is expressed as

$$\Delta S_i = S_i(t-1) - S_i(t) \tag{9}$$

Output power command that depends on power system condition rather than insolation condition is decided by using frequency deviation Δf as input for both fuzzy reasoning I and fuzzy reasoning II. Fuzzy rules and membership functions of fuzzy control II are shown in TABLE III and Fig. 9, respectively. Setup of fuzzy rules and parameters of membership functions are determined by prioritizing to prevent boosting of frequency deviation. The *o*th of fuzzy rules is expressed as

$$\text{Rule } o: \text{if } \Delta f \text{ is } H_c \text{ and } \Delta S_i \text{ is } I_z \text{ then } \gamma_{II} \text{ is } Q_h \tag{10}$$

$$c = 1,2,\cdots,7,\ z = 1,2,\cdots,7,\ h = 1,2,\cdots,7$$

where H_c , I_z denote the antecedents and Q_h are consequent part. Fuzzy reasoning output γ_I is calculated by

$$\gamma_{II} = \sum_{i=1}^{49} w_o Q_h \Big/ \sum_{i=1}^{49} w_o \tag{11}$$

where w_o denotes the grade for the antecedent and is obtained by

$$w_o = w_{\Delta fo} w_{\Delta S_i o} \tag{12}$$

where $w_{\Delta fo}$ and $w_{\Delta S_i o}$ are the grade of antecedents for each rule.

The sum of outputs of fuzzy control I, γ_I , and fuzzy control II, γ_{II} become output power command by using the following equation:

$$P_{inv}^* = P_{rated}\left\{\gamma(k) + \frac{\gamma(k+1)-\gamma(k)}{T_s} f(t)\right\} \tag{13}$$

where P_{rated} is the rated output power of PV power generation system, T_s is sampling time, *f(t)* is periodic function such that $f(t) = t(0 < t < T_s)$.

C. Fuzzy based coordinated command power generation consdering different insolations todifferent PV inverters

In order to control the combined output power of multiple PV systems considering power utility and different insolation conditions, output power command is generated in two levels: central and local. Individual local output power commands are given to each of the PV power systems by maintaining coordination between central and local levels to produce combined PV output power same as the central output power command. Central output power command P_{inv}^* is decided by the previously described fuzzy based central output power command generation system and shown in Fig. 10. This central output power command system consists of mainly two fuzzy controls. There are two inputs of fuzzy control I. One is frequency deviation Δf and the other is average insolation $\overline{S}_i^*$. Average insolation $\overline{S}_i^*$ is defined by

$$\overline{S}_i^* = \frac{1}{T} \int_{t-T}^{t} S_i^* dt \tag{14}$$

where $S_i^* = \frac{1}{N}\sum_{N=1}^{N} S_{iN}$, t is present time, T is integral interval, N is the total number of PV power generation systems, S_{iN} is instantaneous insolation of each PV power generation system, and $\overline{S}_i^*$ is summation of insolation of each PV power generation system divided by N.

Frequency deviation Δf and change of insolation $\Delta\overline{S}_i^*$ are used as inputs of Fuzzy control II, where variance $\Delta\overline{S}_i^*$ is expressed as

$$\Delta\overline{S}_i^* = \overline{S}_i^*(t-1) - \overline{S}_i^*(t) \tag{15}$$

The sum of outputs of Fuzzy control I, γ_I , and Fuzzy control II, γ_{II} become central output power command by using the following equation:

$$P_{inv}^* = NP_{rated}\left\{\gamma(k) + \frac{\gamma(k+1)-\gamma(k)}{T_s} f(t)\right\} \tag{16}$$

where P_{rated} is the rated output power of a single PV power generation system, N is the total number of PV power generation systems, T_s is sampling time, *f(t)* is periodic function such that $f(t) = t(0 < t < T_s)$.

After generating central output power command, local output power command for each of the PV power generation systems is produced by a simple coordinated control. The N PV power generation systems with coordinated control are shown in Fig. 11. Here the combined PV output power P_A is expressed as

$$P_A = \sum_{N=1}^{N} P_{AN} \tag{17}$$

where P_{AN} is the output power of each PV power generation system. In order to achieve combined output power P_A equal to the central output power command P_{inv}^* coordinated control method for each of the PV power generation systems is needed.

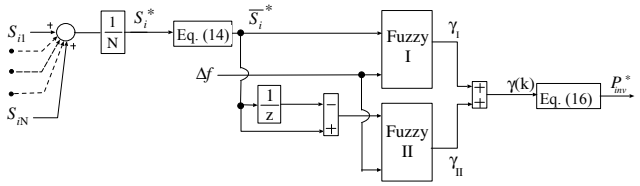

Fig. 10. Fuzzy based central output power generation.

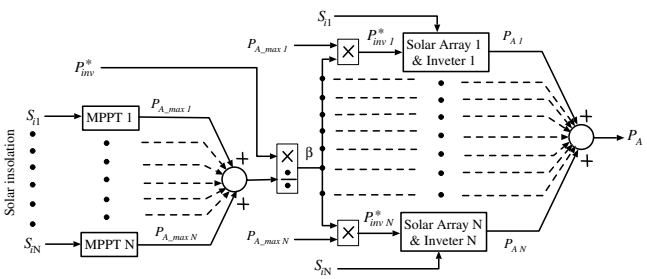

Fig. 11. Proposed coordinated control.

To generate coordination between central power command and individual local power command, a common tuning factor β is formulated. The tuning factor β can be expressed as

$$\beta = \frac{P_{inv}^*}{\sum_{N=1}^{N} P_{A\max\ N}} \tag{18}$$

where $P_{A\max N}$ is maximum power point tracking (MPPT) command of each PV power generation system. The P& O algorithm is used to generate the MPPT output power command considering instant insolation, PV array voltage, and PV array current. The individual local output power command for each of the PV power generation systems can be obtained by the following equation

$$P_{invN}^* = P_{A\max N} \times \beta \tag{19}$$

D. ESS charging/discharging

ESS power command P_{ESSi}^* for charging, discharging, and neutral modes can be expressed as follows

$P_{ESSi}^* = P_{\max i}^* - P_{invi}^*$ (Charging mode, if $P_{\max i}^* > P_{invi}^*$),

$P_{ESSi}^* = P_{invi}^* - P_{\max i}^*$ (Discharging mode, if $P_{\max i}^* < P_{invi}^*$),

$P_{ESSi}^* = 0$ (Neutral mode, if $P_{\max i}^* = P_{invi}^*$)

III. NUMERICAL SIMULATION RESULTS

Numerical simulation results of control area 1, 2, and 3 are shown in Figs. 12, 13, and 14 respectively. Figs. 12(a), 13(a), and 14(a) show the insolations. Different insolations are used for each of the control areas. Figs. 12(b), 13(b), and 14(b) show the average insolations. Figs. 12(c), 13(c), and 14(c) show the change of insolations. Figs. 12(d), 13(d), and 14(d) show the load of each area.

Figs. 12(e), 13(e), and 14(e) show the generator powers with the conventional smoothing method. Figs. 12(f), 13(f), and 14(f) show the generator powers with the proposed method. From Figs. 12(e), 12(f), 13(e), 13(f), and 14(e), 14(f), it is observed that the generator powers with the proposed method are smoother than those of the conventional method as PV inverters are taken part in the frequency control. As conventional generators stay far away from consumer loads and typically the PV systems are installed at the consumers' side, less fluctuating generator powers are easy to be produced by the conventional generators. This will also helps to reduce burden on the energy storages available on the consumer side.

Figs. 12(g), 13(g), and 14(g) show the PV powers with the conventional smoothing method. Figs. 12(h), 13(h), and 14(h) show the PV powers with the proposed method. From Figs. 12(g), 12(h), 13(g), 13(h), and 14(g), 14(h), it is seen that the PV powers with the proposed method are varying according to the load variation to provide frequency control. However, PV powers with the conventional method are smooth which means they cannot take part in frequency regulation and they are just trying to reduce the fluctuation of PV power by smoothing.

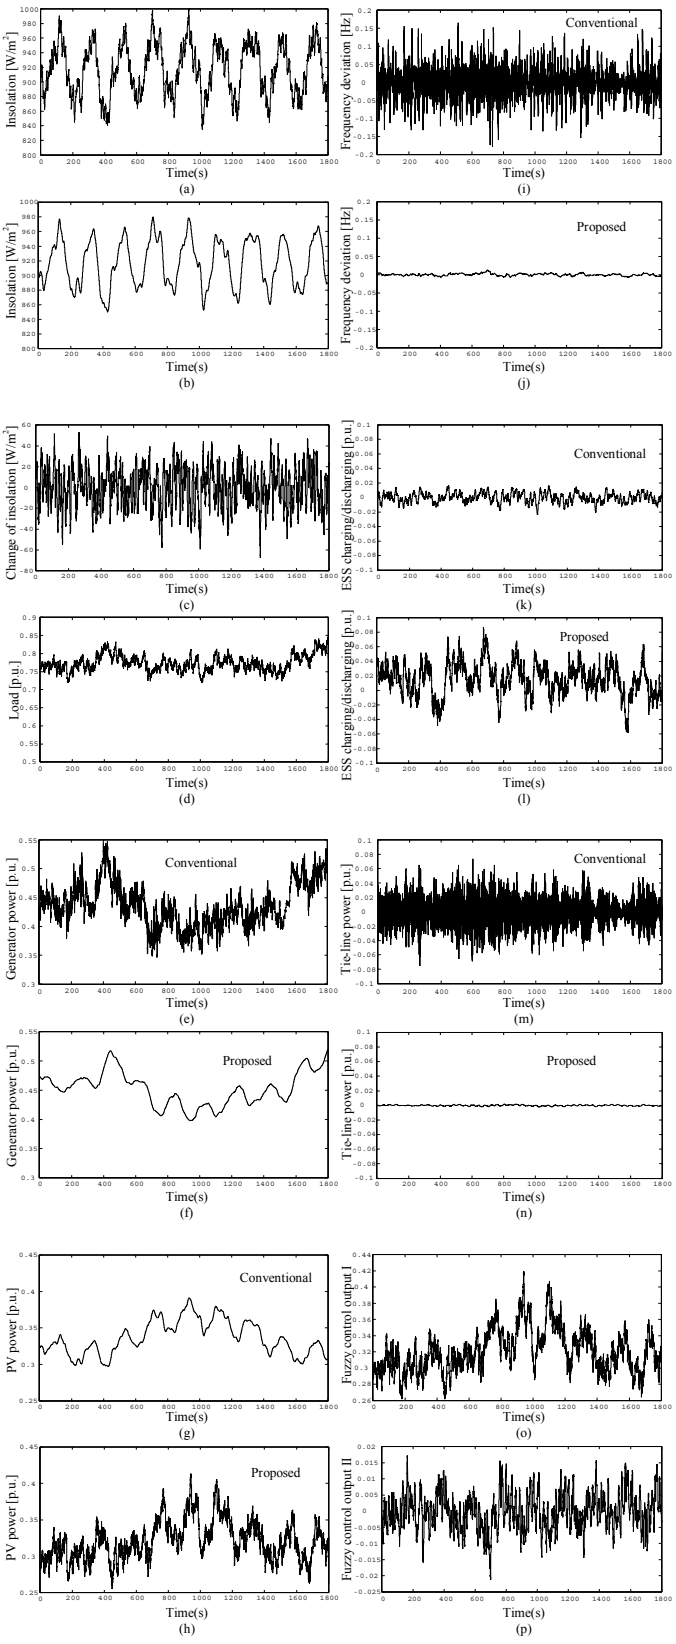

Fig. 12. Comparative simulation results of the proposed methods and the conventional smoothing based method [1] for control area 1.

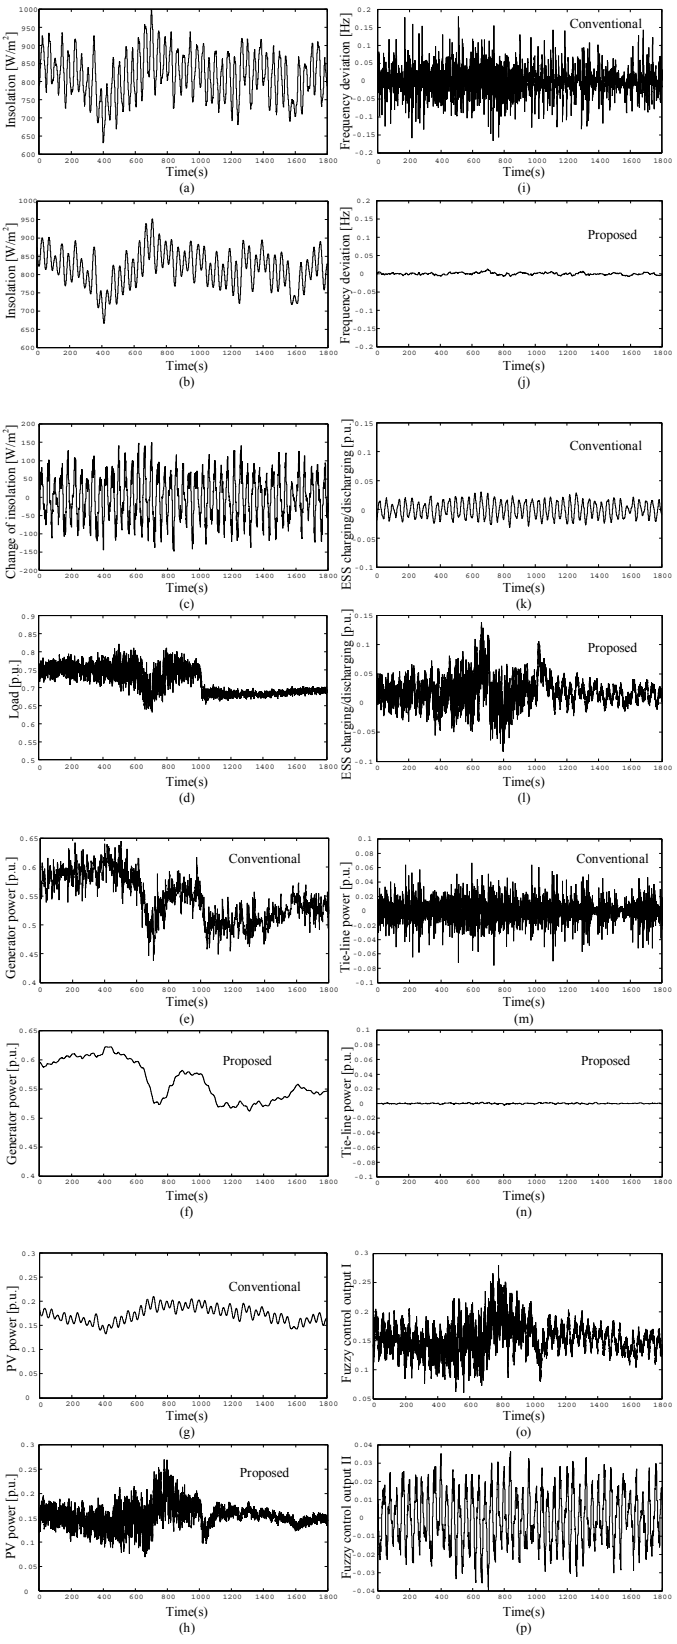

Fig. 13. Comparative simulation results of the proposed methods and the conventional smoothing based method [1] for control area 2.

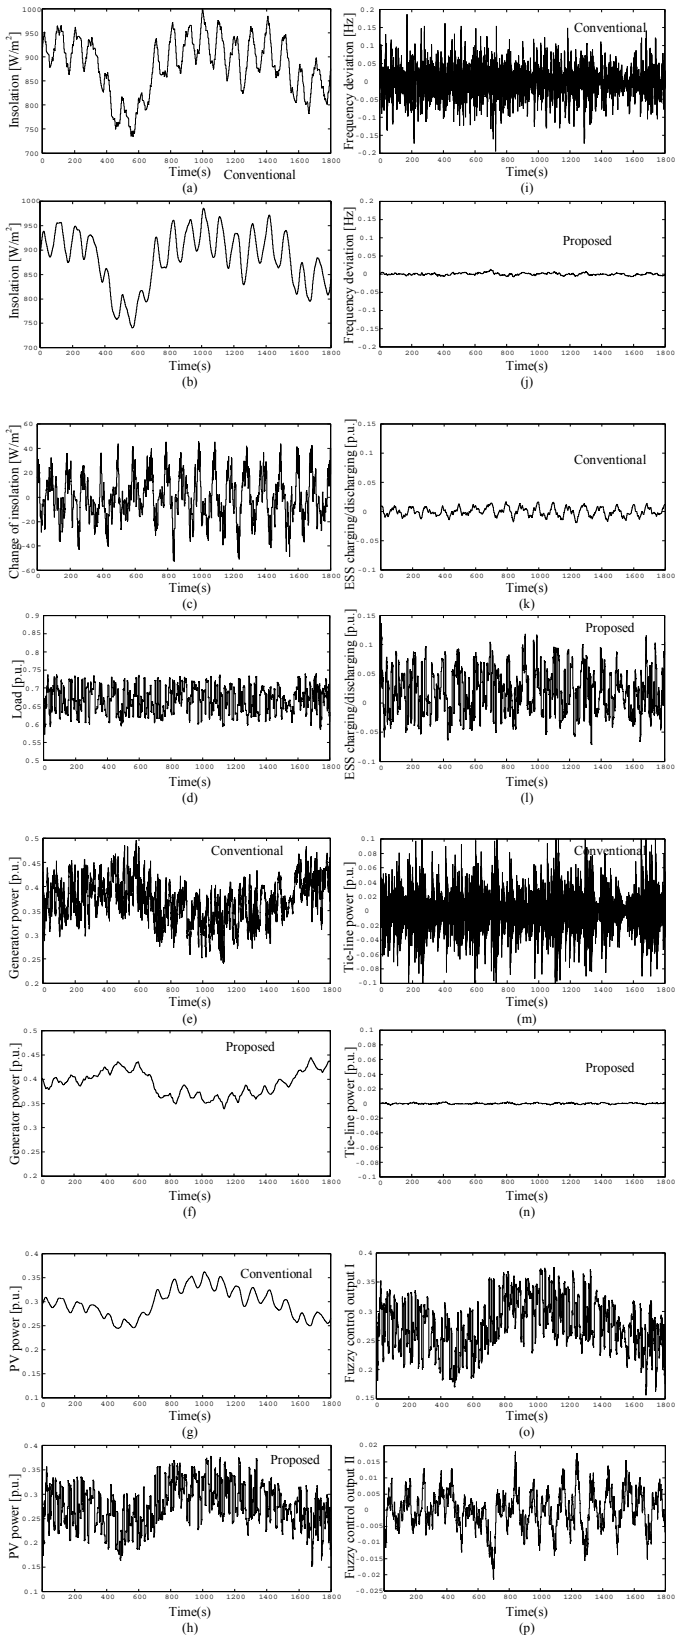

Fig. 14. Comparative simulation results of the proposed methods and the conventional smoothing based method [1] for control area 3.

Figs. 12(i), 13(i), and 14(i) show the frequency deviations with the conventional smoothing method. Figs. 12(j), 13(j), and 14(j) show the frequency deviation with the proposed method. From Figs. 12(i), 12(j), 13(i), 13(j), and 14(i), 14(j), it can be said the frequency control performances are better achieved by the proposed method as the frequency deviations with the proposed method are almost zero. This happens as the PV inverters acted like virtual generators by responding to a low frequency with the increase in their active power output and to a high frequency with the decrease in their active power output.

Figs. 12(k), 13(k), and 14(k) show the ESS charging/discharging powers with the conventional smoothing method. Figs. 12(l), 13(l), and 14(l) show the ESS charging/discharging powers with the proposed method. From Figs. 12(k), 12(l), 13(k), 13(l), and 14(k), 14(l), it can be said that the ESS powers required for the proposed method are higher than those of the conventional method. Considering the plug-in-electric vehicles and other energy storage systems, these can easily be maintained in the future smart power systems.

Figs. 12(m), 13(m), and 14(m) show the tie-line power fluctuations with the conventional smoothing method. Figs. 12(n), 13(n), and 14(n) show tie-line power fluctuations with the proposed method. From Figs. 12(m), 12(n), 13(m), 13(n), and 14(m), 14(n), it can be said that tie-line power fluctuations reduction are better achieved by the proposed method as the tie-line power fluctuations with the proposed method are almost zero. This happens as the PV inverters acted like virtual generators and try to address the issue of tie-line power fluctuations.

Figs. 12(o), 13(o), and 14(o) show the outputs of the fuzzy control I. Figs. 12(p), 13(p), and 14(p) show the outputs of the fuzzy control II. It can be observed that the outputs are changed in accordance to their inputs.

IV. CONLCUSIONS

This paper presents a fuzzy based frequency control approach by the grid-connected MW class PV generators. From the simulation results, it is seen that the proposed method works efficiently in the case of insolation and load variations.

In the proposed method, fuzzy controls are used as fuzzy controls are effective when mathematical expressions are difficult by inherent complexity or nonlinearity or uncertainty. Load and insolation variations are typical problems to be solved for large penetration of PV power in the utility. So, fuzzy control of PV inverters can be an intelligent solution towards the smart grid.

The current practice of smoothing PV power with the help of batteries cannot provide frequency control or ramp control according to the frequency deviations. Therefore by using the proposed method power consumers can play a vital role in the control of power system and can also reduce the burden on conventional generators far away.

In the proposed method, only active power controls of OV inverters for the purpose of frequency control are shown. In the future research, voltage control will also be included with the proposed frequency control and the response of the proposed frequency and voltage controller in the case of power system fault will be presented.

ACKNOWLEDGMENT

***Abstract*—Based on heuristic fuzzy rules, a new power restoration approach is presented in this paper. The restoration approach developed can be used to deal with different fault cases in a distribution system (DS) with sources of renewable energies. This paper introduces "Load Path" as the main framework for restoration. The proposed strategy can achieve the advantages of simple decision criterions, balance of backup feeders, fast execution time, and applicability for different fault cases. Depending on fault situations, the number of load paths is different. With more than two load paths existing, the proposed fuzzy rules infer the best main load path with one of its switches operated as the restoration strategy (RS) for the specific case. To consider the distributed generations (DGs) of renewable energies, the proposed approach has been validated in a test system adapted from Taipower distribution system for different scenario studies.**

Keywords-Restoration Strategies, Fuzzy Rules, Renewable Energies, Distribution System

I. INTRODUCTION

Due to rapid increases in demand and consumption of electrical energy, safe and reliable power supplies in an electrical system are drawing much more important than before. However, the growing size of power systems increases the complexity of its supervision, control, and energy demand supply management, especially as the DGs of renewable energies are taken into account.

Effective service RSs are very important when there is a fault occurring in the power system. The primary task of restoration is to find appropriate backup feeders to restore the outage zones (loads) as much as possible. For a large system, as a fault happens, the outage zones would be large and restoration of the outage zones appears relatively complicated.

There have been many studies focused on the RSs for the power systems. Heuristics based search methods [1-3] collect the operators' practical manipulation experiences to derive the restoration scheme. Expert system approaches [4-7] build a rule-based data system composed of operators' empirical rules and documents. Under occurrence of a fault, RSs would be automatically generated via the inference engine. Fuzzy theory [8-12] translates the problem's variables and objective functions into membership functions. By using the fuzzy inference value, feasible RSs are obtained. Petri-net algorithm [13, 14] constructs into a net the feeders of a distribution system and the switches' states and the locations. With combination of empirical rules and evaluation function, the searching process infers a restoration plan. These methods above can be roughly regarded as heuristic-based restoration strategies. They can find appropriate RSs fast; however it needs a large data base to handle different fault cases, and it can't ensure if the obtained RS is the best one for the fault case.

On the other hand, the RSs are derived on the basis of optimization algorithms. Genetic algorithm [15-18] has been employed to generate optimal restoration plan through imitating the evolution process. Particle-swarm optimization [19-21] and ant-colony optimization [22] are alternative optimization approaches. They are all inspired from the swarm or colony of creatures, such as fish, birds, and ants. Though these methods can deal with multi-objective optimization problem and achieve a near-optimal solution, the results are influenced by different parameters given. Besides, far more computational time is needed to generate an optimal restoration plan. Plus, in the optimization process, most of the switches considered as variables to determine may be unrelated to the restoration of the outage zones, a fact which wastes the searching time a lot.

In this paper, a fuzzy-rule based power restoration approach is proposed. For different types of faults occurring, a corresponding inference procedure is performed to create the restoration strategies. By using the "Load Path" notion, the developed RS transfers appropriate amount of outage loads to backup feeders based on backup feeders' capacity and their loads at the instance of restoration. Balanced loads of the backup feeders are expected with overloads avoided as much as possible. As more than one load paths are considered, a fuzzy-rule based inference process is used to achieve an appropriate restoration scheme. Load transferring or shedding would be used, as there is no enough margin of capacity on the backup feeders. With DGs of renewable energies existing in the distribution system, the developed RS can also take the influences of DGs into consideration.

II. PROPOSED FUZZY RULE BASED RESTORATION APPROACH

The proposed restoration approach to be detailed in this section is based on simple decision fuzzy rules. The algorithm developed is described in the flowchart of Figure 1. The

This work supported in part by National Science Council of R.O.C. under Grant NSC 100-3113-E-194 -001 is greatly acknowledged.)

following assumption is made before the restoration algorithm proceeds:

- The fault and the outage zones have been identified and isolated from the grid.
- The loads of each zone and the available output of DGs of renewable energy are well known enough at the instance of restoration in a smart-grid system.

In the proposed approach described below, the load transferring process will be used to make the backup feeder have more capacity to supply the loads. The load transferring process is to choose the secondary backup feeder with the largest capacity margin to supply appropriate amount of loads originally belonging to some backup feeder. The secondary backup feeders with smaller capacity margin are then considered. If capacity margin of the secondary backup feeder is smaller than the amount of loads needed to transfer, the transferring load process would not be performed.

A. Proposed Restoration Approach

The proposed restoration algorithm is described step by step as follows.

Step 1) Detect the fault, and open the isolation switch(es) to isolate the fault. The outage zones are recognized.

Step 2) Find out the set of available tie switches for restoring the outage zones.

Step 3) Based on the number of available tie switches, the sub-steps next are followed:

Step 3-1) For number of available tie switches, n_{TSW}**=1.**

Step 3-1-1) Check if the backup feeder has enough capacity margin. If it is, then go to **Step 3-1-5**; otherwise go to **Step 3-1-2**.

Step 3-1-2) Execute the load transferring process of the backup feeder.

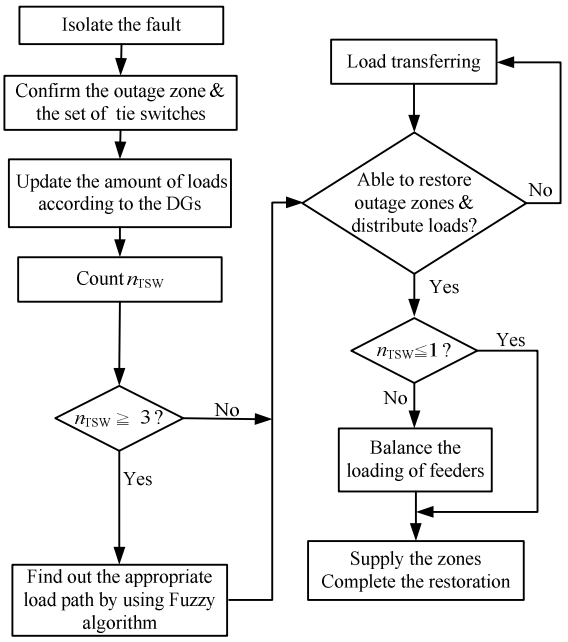

Figure 1. Flowchart of the proposed RS

Step 3-1-3) Check again whether the backup feeder has enough capacity margin. If it is, then go to **Step 3-1-5**; otherwise go to **Step 3-1-4**.

Step 3-1-4) Supply the loads in the outage zones by the backup feeder as much as possible; shed the loads still not restored in the remaining outage zones.

Step 3-1-5) Restore the outage zones by the backup feeder and finish the restoration process.

Step 3-2) For number of available tie switches**,** n_{TSW}**=2**

Step 3-2-1) Construct the only one load path between the two tie switches (for example, the load path is Z_5-Z_6-Z_7-Z_8-Z_9 in Figure 5).

Step 3-2-2) Identify and integrate the outage zones which would be integrated into a load path (for example, Z_4 in Figure 5).

Step 3-2-3) Check if the total capacity margin of the two backup feeders is enough to supply the outage loads. If it is, then go to **Step 3-2-6**; otherwise go to **Step 3-2-4**.

Step 3-2-4) Perform the load transferring process.

Step 3-2-4-1) Perform load transferring of the backup feeder with less capacity margin until the total capacity margin of the two backup feeders can meet the outage loads. If it cannot meet, then go to Step 3-2-5; otherwise go to Step 3-2-6.

Step 3-2-4-2) Perform load transferring of the backup feeder which cannot supply its corresponding loads. After the load transferring, if the backup feeder still doesn't have enough capacity margin, then go to **Step 3-2-5**; otherwise go to **Step 3-2-6**.

Step 3-2-5) Supply the outage zones as much as possible by the backup feeders individually; shed the remaining outage loads in the zones, if there still are.

Step 3-2-6) According to backup feeders' loading ratios of capacity margin, as shown in (1), divide appropriately the loads into two parts by opening a switch on the load path to be supplied by individual backup feeders.

$$\text{Min}\left(\left|\frac{LS_1}{MC_1}-\frac{LS_2}{MC_2}\right|\right) \quad (1)$$

where LS_i is the load supplied by backup feeder i, and MC_j is the capacity margin of backup feeder i. If both backup feeders can supply the corresponding loads individually, finish the restoration process; otherwise go to **Step 3-2-4-2**.

Step 3-3) For number of available tie switches, $n_{TSW} \geqq 3$

Step 3-3-1) Determine and integrate the outage zones into load paths.

Step 3-3-2) Determine the main load path based on the

proposed fuzzy inference rules, to be illustrated further below.

Step 3-3-3) Integrate the remaining outage zones other than those on the main load path into the main load path.

Step 3-3-4) Check whether the total capacity margin of the two backup feeders on the main load path is enough to supply all the outage loads. If it is, then go to **Step 3-3-9**; otherwise go to **Step 3-3-5**.

Step 3-3-5) Have the integrated outage zones (not belonging to the original main load path) be supplied by the other backup feeder as much as possible.

Step 3-3-6) Check again whether the total capacity margin of the two backup feeders on the main load path is enough to supply the outage loads. If it is, then go to **Step 3-3-9**; otherwise go to **Step 3-3-7**.

Step 3-3-7) Perform the load transferring process.

Step 3-3-7-1) Perform load transferring of the backup feeder with less capacity margin until the total capacity margin of backup feeders can supply the outage loads. If it cannot, go to **Step 3-3-8**; otherwise go to **Step 3-3-9**.

Step 3-3-7-2) Perform load transferring of the backup feeder which cannot supply its corresponding loads. After the load transferring, if the backup feeder still doesn't have enough capacity margin, go to **Step 3-3-8**; otherwise go to **Step 3-3-9**.

Step 3-3-8) Supply the outage zones as much as possible individually by two backup feeders; shed the remaining outage loads of the zones, if there are.

Step 3-3-9) According to backup feeders' loading ratios of capacity margin as shown in Eq. (1), allocate appropriate amounts of loads into two parts to open a switch on the load path. If both backup feeders can supply the corresponding loads individually, finish the restoration process; otherwise **Step 3-3-7-2**.

B. Update of Loads and DGs in Outage Zones

DGs of renewable energies may have discontinuous output due to weather conditions, such as PV, wind-turbine (WT), combined heat and power (CHP), and fuel cell (FC) generation systems in the DS. To restore the loads in the outage zones, the loads of the still energized area and the available power output of the DGs can be updated before the restoration process under the assumption of an established smart-grid system. At the same time, information on number of available tie switches n_{TSW} in the outage zone is needed.

C. Restoration Process

Figure 2 shows the example DS diagram used for illustration of the restoration process. In description of the proposed restoration approach below, cases of different numbers of available tie switches that can be used in restoration are discussed.

1) Case 1: Number of available tie switch = 1

In Figure 3, suppose there was a fault occurring at Z7, switches S_9 and S_{10}, therefore, were opened to isolate the fault. Then, the load path of Z_8-Z_9 is defined. This is the simplest case where to close S12 is the strategy to restore the outage zones. If the backup feeder, Feeder4, doesn't have enough capacity to supply the outage zones, the backup feeder transfers load to the other feeder (secondary backup feeder) to obtain more capacity.

However, if it still fails to restore outage zones after the load transferring process, the restoration process will start to shed the loads. As many loads as possible are supplied by the backup feeder (Feeder4) with the remaining loads in the outage zones being shed.

2) Case 2: Number of available tie switches = 2

a) Type 1: No outage zones to be integrated

Suppose there was a fault occurring in Z_4 as shown in Figure 4. Switches S_5 and S_6 were opened to isolate the fault. Load path of Z_5-Z_6-Z_7-Z_8-Z_9 is defined. It is clear to see that the outage zones have two backup feeders: Feeder2 and Feeder4. The RS will choose one switch of S_8, S_9, S_{10}, and S_{11} to separate the load path into two parts. Appropriate amount of loads is allocated to the two backup feeders according to the loading ratios of capacity margin of the individual backup feeder as shown in Eq. (1).

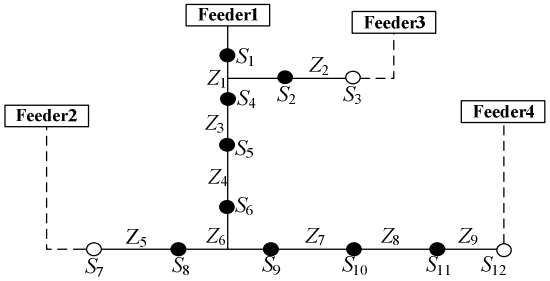

Figure 2. An example DS diagram

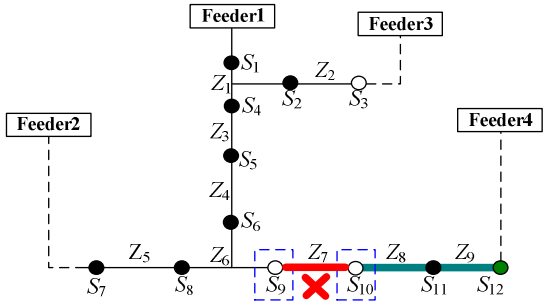

Figure 3. The DS diagram with one tie switch

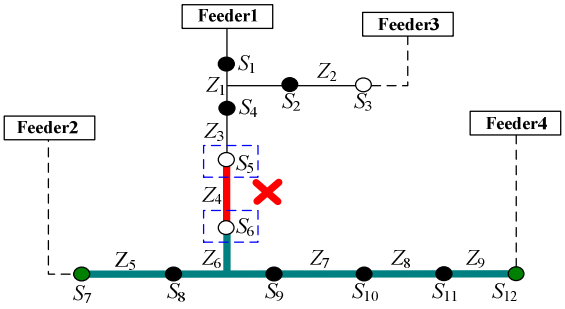

Figure 4. The DS diagram with two tie switches & no outage zones be integrated

The purpose is to make the loads of backup feeders balanced to avoid overloading for either of the backup feeders.

If the backup feeders, Feeder2 or Feeder4, don't have enough capacity margin to supply the outage zones, the backup feeders will proceed to the load transferring process trying to obtain more capacity. If it still fails to restore outage zones after their own load transferring process, the strategy will start to shed the loads to have as most loads supplied.

b) Type 2: Outage zones to be integrated

If the fault occurred at Z_3 as shown in Figure 5, S_4 and S_5 were opened to isolate the fault. The load path of Z_5-Z_6-Z_7-Z_8-Z_9 is defined. However, it is noted that Z_4 should be integrated into the load path, otherwise it cannot be restored. In this case, the outage zones also have two backup feeders: Feeder2 and Feeder4. The same steps are followed as in Type 1 above to restore the outage zones.

3) Case 3: Number of available tie switches ≧3

Suppose a fault occurred at Feeder1 as shown in Figure 6, S1 was opened to isolate the fault. Based on the proposed algorithm, three tie switches of S3, S7, and S12 are available for the restoration in this case. Accordingly, three load paths in Figure 6are defined below:

- Load Path 1 (S_3 to S_7): Z_2-Z_1-Z_3-Z_4-Z_6-Z_5
- Load Path 2 (S_3 to S_{12}): Z_2-Z_1-Z_3-Z_4-Z_6-Z_7-Z_8-Z_9
- Load Path 3 (S_7 to S_{12}): Z_5-Z_6-Z_7-Z_8-Z_9

The RS will find out the main load path by using the following fuzzy inference process. Two membership functions of the following fuzzy variables are used as illustrated in Figure 7 for the fuzzy inference rules.

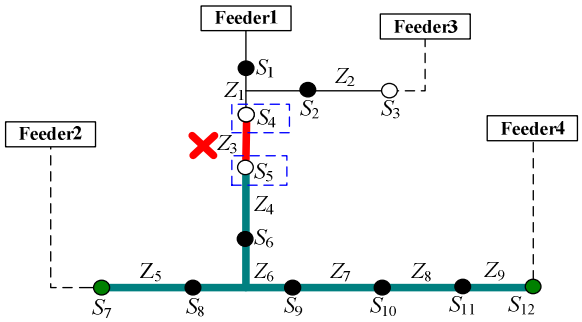

Figure 5. The DS diagram with two tie switches & outage zones to be integrated

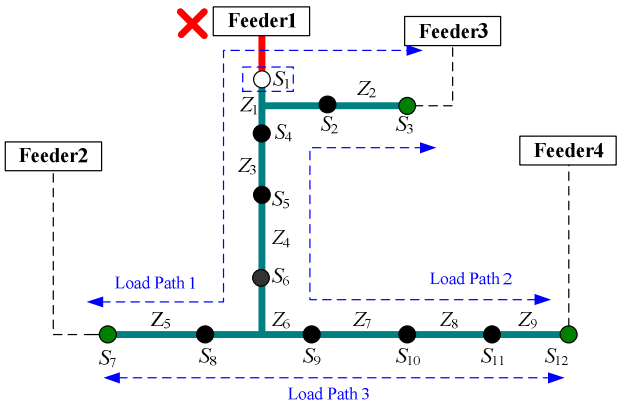

Figure 6. The DS diagram with more than three tie switches

- The total capacity margin of two backup feeders on the load path
- The total outage loads of the load path

The fuzzy rules are showed in Table. I. Take "Load Path 1" in Figure 6 for example, the inputs of the fuzzy inference engine are defined as the total capacity margin of Feeder3 and Feeder2 and the total outage loads of "Load Path 1." Based on the fuzzy inference and defuzzification process, the main load path with highest output value will be determined, whose outage zones will be restored with priority.

With the main load path determined, loads of the rest outage zones are integrated into the zone of the main load path. For example, if the "Load Path 2" is the determined main load path, the restoration process will integrate Z_5 into Z_6, and the outage zones will be restored by Feeder3 and Feeder4. Then, the restoration process will choose one switch among S_2, S_4, S_5, S_6, S_9, S_{10}, S_{11}, or S_{12} to separate the load path into two parts. The objective is to allocate appropriate amount of loads to different backup feeders.

If the backup feeders have no enough capacity margin , the proposed algorithm will check whether the integrated outage zones (e.g. Z_5) can be supplies by its connecting backup feeder (e.g. Feeder2) or not. In case the margin for restoration of the outage loads is still not enough, the load transferring process will proceed. However, if the load transferring process fails restoration of all the outage zones, the algorithm will start to shed the loads of the remaining outage zones, as the backup feeders (Feeder3 & 4) supply as many loads as they can.

III. Simulation Results

The proposed algorithm is implemented in MATLAB 7.1 on a windows-XP based PC with Intel Core 2, Duo E7200, 2.53-GHz CPU and 2GB of RAM. The proposed restoration approach was applied to a practical 6-feeder DS of Taipower Company (TPC) [23].

A. Scenario 1: Large Outage Zone Situation

Suppose that there was a fault occurring at Feeder5 as in Figure 8. The system opened S_{59} (CB_5) first to isolate the fault. Because the number of corresponding available tie switches is three, including S_{38}, S_{41} and S_{44}, with three load paths existing.

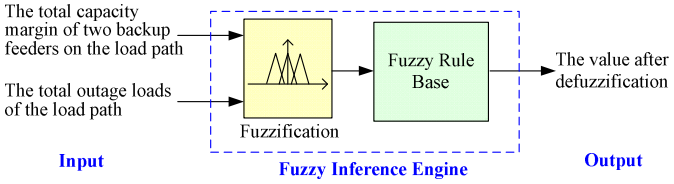

Figure 7. The fuzzy inference process in determining the main load path

TABLE I. THE FUZZY RULES USED IN THE INFERENCE ENGINE

B \ A	Low	Medium	High
Low	Medium	Low	Medium
Medium	Medium	Medium	High
High	Low	Medium	High

Note: A: total capacity margin of the backup feeders on the load path
B: the total outage loads on load path

The proposed algorithm determined the main load path based on the fuzzy inference rules described. Then the process proceeded to restore the outage zones to have balanced loading of feeders. The final result is showed in TABLE II. Through this scenario, it shows that the proposed restoration can deal with serious fault cases with large outage zones and achieve load balancing as much as possible.

B. *Scenario 2: Comparison with the Method in* [23]

In this scenario, the proposed approach was compared with the method in [23]. It was assumed that there was a fault occurring at Z_{43} as shown in Figure 9. The restoration algorithm opened S_{47} and S_{48} first to isolate the fault. The corresponding two available tie switches are S_4 and S_{41} for only one load path existing.

The proposed restoration approach determined whether outage zones were needed to be integrated or not. In this scenario, Z_{44} and Z_{45} must be integrated into Z_{46} for restoration. Then the process proceeded to restore the outage zones and balance the loading of feeders as much as possible simultaneously. The final result is showed in TABLE III, the proposed approach can achieve a solution with all outage zones restored with balanced loads of the backup feeders.

In comparison, the solution obtained by the expert system proposed in [23] still has the outage zones of Z_{49} and Z_{50} un-restored, and all the restored zones are supplied by single feeder instead of balancing the loads via two backup feeders as in the proposed method.

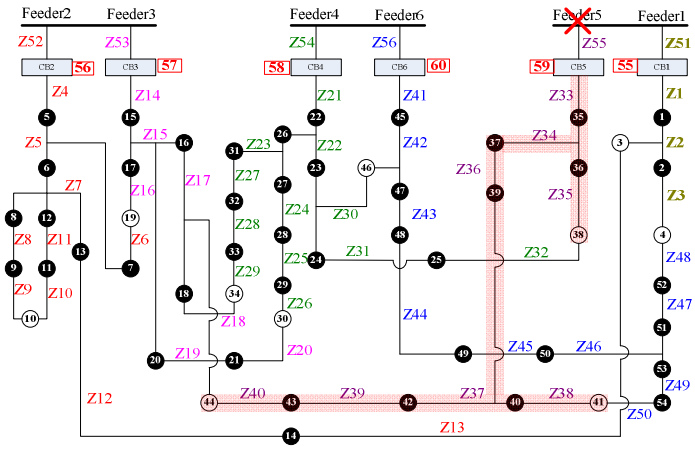

Figure 8. TPC 6-feeder system with fault at Feeder5

TABLE II. THE FINAL RESULTS FOR SCENARIO 1 AFTER RESTORATION

Items \ Scenario	Scenario 1	
Fault Location	Feeder5	
Isolation Switch	CB5 (S_{59})	
Total Outage Zones Before Restoration	Z_{33}, Z_{34}, Z_{35}, Z_{36}, Z_{37}, Z_{38}, Z_{39}, Z_{40}	
Backup Feeder (FD)	Feeder3	Feeder4
Supplied Zones	Z_{37}, Z_{38}, Z_{39}, Z_{40}	Z_{33}, Z_{34}, Z_{35}, Z_{36}
Switch Operation	Close: S_{44}, S_{38}; Open: S_{39}	
Outage Zones After Restoration	None	
Execution Time (s)	1.367136	

C. *Scenario 3: Comparison with/without DGs Considered*

In this scenario, the purpose is to find out influence of DGs considered on restoration strategies. The DS without DGs considered was compared with that with DGs. To consider the DGs, the fault situation is assumed the same as Scenario 1 as shown in Figure 8, but having some zones installed generators of renewable energies.

TABLE IV summarizes the zone conditions with DGs considered for Scenario 3. Accordingly, capacities of all feeders were also adjusted to lower values to make the restoration more difficult in recovering the loads.

TABLE V show the results obtained with and without DGs considered. It was supposed in a smart-grid system the loading conditions are updated periodically. Different switching operations for the two cases are shown in TABLE V. The case without DGs considered needs more switching operations to transfer the loads for the system restoration.

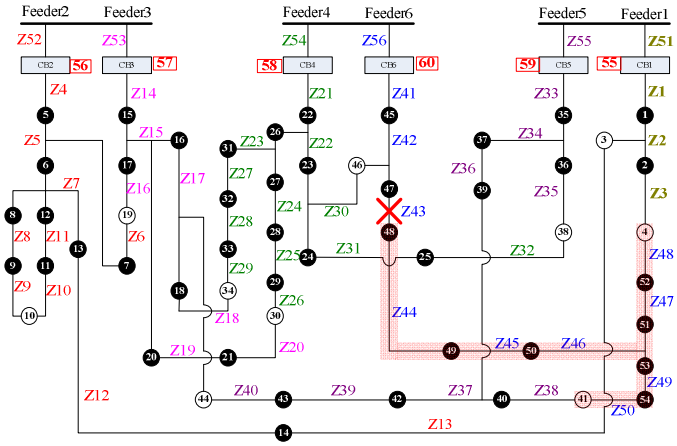

Figure 9. TPC 6-feeder system with fault at Z_{43}

Remark	None		Z_{38} is transferred to Feeder6	

IV. CONCLUSIONS

In this paper, a heuristic fuzzy-rule based system was proposed for restoration of a DS with/without existing DGs of renewable energies. Based on the concept of load path, loads in the outage zones are supplied as much as possible by backup feeders. Through the proposed process, balanced feeders' loading can thus be achieved. For large outage zones, the main load path is determined for more than two load paths via the proposed fuzzy inference rules. With different types of DGs and fault conditions existing in the DS, the proposed algorithm can also deal with the corresponding restoration problem easily based on the simple fuzzy decision rules.

The test results by using a practical Taipower distribution system showed different faulty situations can be well dealt with by using the proposed approach. Further, the proposed approach can have better restoration results (without loads un-restored in the outage zones) as compared with the expert system tested on the same system. The influence of DGs of renewable energies on restoration of a DS was also evaluated through the proposed approach.

***Abstract*—This paper introduces an evolutionary optimization algorithm as a tool for training an Artificial Neural Network used for production forecasting of solar energy PV plants. This optimized procedure essentially represent a bio-inspired heuristic search technique which is used to solve complex forecasting problems modeled on the concepts of biological neurons. Some simulation results are reported to highlight advantages and drawbacks of the proposed method in order to suitably apply this algorithm to a neuro-fuzzy system application in solar energy production. The weather forecast data related to the PV plants are supplied by the airport service close to the production site and relative data are pre-processed using Fuzzy Logic techniques.**

***Index Terms*—PV energy prediction, Neural Networks.**

I. Introduction

In recent years solar power is getting more and more important as an alternative and renewable energy source, especially for small autonomous electrical power systems, villages and also rural areas. Photo-voltaic (PV) plants can also be connected to the traditional grid for energy distribution, but variations in solar power can cause, in general, voltage and frequency fluctuations.

Load and energy production forecasting has always been crucial for the effectiveness of power system planning and operation. Lots of electric power companies are now forecasting power load based on traditional prediction methods [1]. However, since the relationship between power load and factors influencing power production is nonlinear, it is difficult to identify its nonlinearity by using traditional prediction methods.

Moreover, renewable energy sources have increased the complexity of this scenario, thus requiring the capability to predict the dynamics of the system and to offer an optimal management; therefore, it has been proposed the application of advanced forecasting techniques integrated with an optimization algorithm in order to create a predictive model of the physical system and to provide an efficient control of resources and information. To implement this approach, evolutionary optimization procedures adaptively and dynamically analyzing consumer profiles have been defined in the so called digital energy environment [2].

Advanced forecasting techniques provide utilities with reliable production predictions and the opportunity to plan for additional power supply and to make proactive actions. This aspect can have an impact on the economic balance of the systems especially in an integrated smart grid solution perspective. In fact, in this way the system-plant management is capable for example to plan appropriate preventive maintenance strategies in order to minimize energy losses due to unproductive suspensions. It can be estimated in the order of million dollars per MW per year adopting predictive strategies in the renewable energy sector and just the 10% of these are due to an optimized operating efficiency [3].

Increased solar power penetration is possible if measures are taken concerning solar radiation forecasting. This procedure may also affect the energy efficiency of the conventional power stations, since it affects the operation point of the power units. Prediction of solar power is therefore of importance for efficient load management and operation of the system. It has been suggested in literature [4], [5], [6] that solar power forecast could be based on the use of Artificial Neural Networks (ANNs). They are particularly appealing because of their ability to model an unspecified nonlinear relationship between production and weather variables.

II. Artificial Neural Networks

Computation techniques play an important role in most engineering applications in which optimization problems have to be solved. Usually the complex nature of many practical problems involves an effective use of Artificial Neural Networks to solve them. ANNs are useful tools when it is necessary to understand the complex and nonlinear relationships among data, without any a-priori assumption concerning the nature of these correlations.

ANN is an effective computing method, in order to easily process the dynamic behavior of time-varying variable, as previously presented by the authors in [7]. It is a computational model that simulates the features and behavior of the human brain neural networks. It consists of an interconnected group of artificial neurons that suitably processes information according to the strength of connections among them. In more practical terms neural networks are non-linear statistical data modeling tools used to model complex relationships between inputs and outputs or to find patterns in data.

For the considered forecasting application, a multilayered

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

perceptron (MLP) has been utilized. The MLP is a well-known universal approximator and has been extensively used in engineering applications, as well as other kind of ANN.

Training algorithms are used to train the network by learning the nonlinear behavior between input and output data. Therefore the learning process should result in finding the weights configuration associated to the minimum output error, namely the optimized weights configuration.

In other words, since ANN wish to infer the mapping implied by the data, the weights of the network have to be optimized in order to reach a good and accurate desired output: usually these tasks are associated to an objective function to be optimized. This function, called cost or energy function, provides the interface between the physical problems and the optimization algorithm itself. The cost function, in particular, is related to the mismatch between the proposed mapping and the data and for this reason it must contains prior knowledge about the problem domain.

A commonly used cost is the mean-squared error which tries to minimize the average squared error between the network's output, $f(x)$, and the target value y over all the example pairs.

There are often many problems related to this task: generally finding a solution in an optimization process means to reach a balance among different and often conflicting goals; as a consequence such a search could be extremely difficult. The huge number of variables is the first difficulty when dealing with one of these optimizing issues. Secondly, there are lots of weights configurations with different values of the cost function which are quite similar each other and very close to the global optimum case, even if these configurations are sub-optimal.

In particular, the approaches used to optimize and train a MLP may be divided into two main categories: the ones that need to calculate derivatives in order to optimize the objective function, such as gradient descent based strategies, e.g. the Error Back-Propagation (EBP) algorithm, and those that, starting from an initial position in the solution space, explore iteratively this space without requiring any derivatives calculation, e.g. evolutionary methods, like Genetic Algorithm (GA) or Particle Swarm Optimization (PSO) [7].

Error Back Propagation algorithm is a well known analytical algorithm used for neural networks training. In literature, there are several forms of back-propagation, all of them requiring different levels of computational efforts; the conventional back-propagation method is, however, the one based on the gradient descent algorithm.

One of the drawbacks of this method is the strong dependence upon the initial guess. A bad choice of the starting point may result in the possibility to get stuck in a local minimum and consequently to find a solution that is not the best one. Besides, most of the typical problems requiring optimization often have non-differentiable or/and discontinuous regions in the solution domain and this fact introduces difficulties in the application of these traditional methods based on derivatives calculations. These aspects are often overcome by evolutionary methods, like the one chosen by the authors, the Genetical Swarm Optimization (GSO) algorithm [8].

GSO essentially represent a bio-inspired heuristic search technique, which can be used to solve combinatorial optimization problems, modeled on the concepts of natural selection and evolution (GA), but also based on cultural and social behaviours derived from the analysis of the swarm intelligence and interaction among particles (PSO) [9]. Previously performed analyses highlighted some advantages of the proposed technique in order to suitably apply this algorithm to neural network applications in engineering problems [10].

III. Implementation

As shown in Figure 1, weather forecasts are a key input when the ANN is used for forecasting. Nevertheless in case of rapid changes in solar radiation or temperature at the forecast day, produced power changes greatly and forecast error would sensibly increase. In traditional prediction methods the ANN uses all similar days data to learn the trend of similarity. However, learning all similar days' data is quite complex, and it does not help if weather conditions change suddenly during the same day. Therefore, it is necessary to integrate into the neuro-fuzzy system real time information coming from local meteorological stations and, in particular, from surrounding regions and cities, where the weather change has already occurred.

In this paper a real-world case study with a proposed approach of fuzzy filtering is suitable for dealing with the complexity of inputs involved in the available weather forecast data. Over the last decades fuzzy models have been used to replace conventional methods for engineering applications, especially in control systems, making easier the solution to many problems by introducing an unconventional set of rules. System analysis and control design for nonlinear systems based on fuzzy system approaches have been very active in the scientific community [11], [12], [13]. In this context fuzzy models, due to their intrinsic capability of approximating nonlinear data mappings, could be exploited for the preprocessing of a subset of weather data in order to filter the inputs for the ANN. As shown in detail in Figure 1 a fuzzy preprocessing toolbox is introduced into the neural system to find data correlation between UV index, cloud cover and specific time/season with irradiance value useful to perform production forecast.

IV. Simulation Results

In order to compare the different optimization approaches for training the ANN, a production forecasting problem has been considered with a different perspective compared to [1]. The focus is to highlight how fast and accurate the methods are in determining and optimizing the neural networks weights associated to the considered problem.

After a trial campaign, the network architecture which have provided better results present two hidden layers, as shown in Figure 1. In particular, the number of neurons in the input layer is 16, as reported in Table I, which describes the meteorological parameter provided from the weather forecast service.

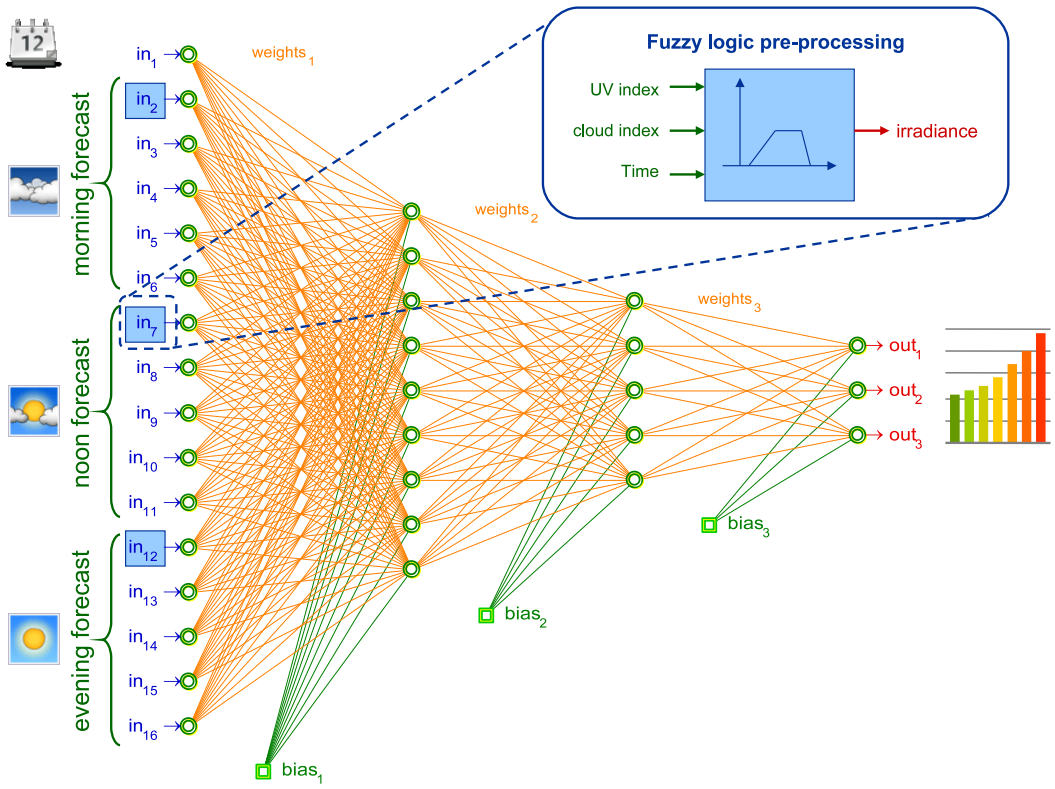

Fig. 1. Simplified view of the implemented feed-forward ANN with Fuzzy pre-processing.

i_{16}	Air pressure	”	(1000–1040) mbar

The neurons in the two hidden layers are, respectively, 9 and 5, while the output layer is composed of 3 neurons, since 3 different produced-power forecasts are considered: in fact, the authors performed simulations for three different photovoltaic power plants in order to test their method at various scale, since they have different productive capacity, as shown in Table II. To compare the numerical results it is important to underline that the three plant locations present exactly the same GPS reference points. Therefore the weather conditions can be assumed identical for the three PV plants at each time.

Different time horizons was considered in load forecasting: short term (day and several days), medium term (week and several weeks), long term (year and several years), and forecasts for different lead time can potentially be used for different aims. We finally chose a short term time base for this specific application. The neuro-fuzzy system optimized by GSO exhibit good predictive performances in all the operative conditions, in a complete sunny day, a partly cloudy one and even a plant

TABLE II
STRUCTURE OF OUTPUT LAYER

Neuron	Variable name	Range
o_1	SM 4200S-2 Produced power	(0–4) kW
o_2	SM 4200S-3 Produced power	(0–4) kW
o_3	SM 35C-4 Produced power	(0–35) kW

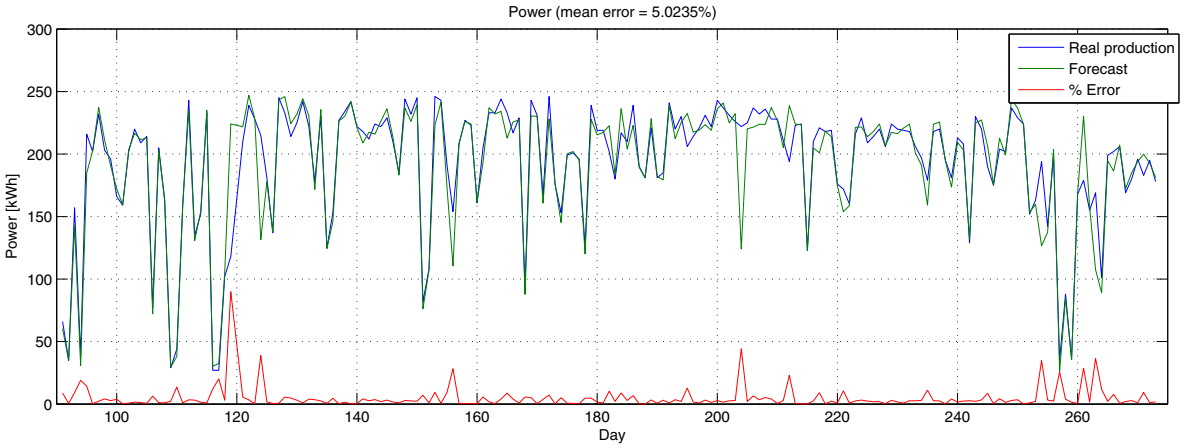

Fig. 2. Results of the forecasting over a six-months time frame and comparison with actual data.

maintenance day.

Figure 2 shows the complete data set simulations around six months and the average error is around 5% . The considered ANN behaviour does not change with respect to the plant power size.

V. Conclusions

Energy plant prediction is very important in industrial applications. An accurate prediction enables to mitigate the price risk associated with the power exchange, for instance signing more bilateral contracts. Besides, a good estimate of the load profile results in avoiding economic penalties on the balancing market. In this work the authors presented an effective and robust implementation of an Neuro-fuzzy model for forecasting of photo-voltaic energy production.

***Abstract*—Software development time and cost estimation are the process of estimating the most realistic use of time and cost required for developing a software. It is one of the biggest challenges in the area of software engineering and project management, in the last decades. The software estimates are difficult to obtain due to incomplete software information is available in the early phase of software development process. Insufficient software information causes inaccuracy in software attributes. Thus, the vagueness and uncertainty of the software attributes is the main reason of inaccuracy of software estimates. Software cost estimation models such as regression model, expert judgment, SLIM, and COCOMO require accurate software attributes and long term estimation process, which are not completely achievable in early phase of software development process. Soft computing techniques such as fuzzy logic can reduce the vagueness and uncertainty of software attributes. Therefore, it may consider as alternative to decrease the inaccuracy of software estimates. This research aims to utilise an adaptive fuzzy logic model to improve the accuracy of software time and cost estimation. Using advantages of fuzzy set and fuzzy logic can produce accurate software attributes which result in precise software estimates. The Two-Dimension Gaussian Membership Function (2-D GMF) was used in the fuzzy model to make software attributes smoother in terms of the range of values. The COCOMO I, NASA98 data sets; and four project data from a software company in Malaysia were used in the evaluation of the proposed Fuzzy Logic COCOMO II (FL-COCOMO II). The evaluation of the obtained results, using Mean of Magnitude of Relative Error (MMRE) and PRED(25%) evaluation techniques, showed that the FL-COCOMO II produced the MMRE less than the original COCOMO and the value of PRED(25%) in the Fuzzy-COCOMO II is higher than the original COCOMO. Furthermore, the FL-COCOMO II showed 8.03% improvement in terms of estimation accuracy using MMRE when compared with the original COCOMO. Using advantages of fuzzy logic such as accurate estimation; adaption; understandability, and etc., can improve the accuracy of software estimates.**

Keyword—Software project management, software cost estimation models, COCOMO II, soft computation techniques, fuzzy logic

I. INTRODUCTION

The number of project failures and those projects completed over cost and over schedule has been a significant issue for software project managers. Poor estimates have not only led projects to exceed budget and go over schedule but also, in many cases, to be terminated entirely. Although between 30% and 40% of software projects are ultimately completed despite going over budget or schedule, and many more projects are cancelled or failed [1]. Among the many reasons for failure, inaccuracy in software estimates has been identified as a root cause of a high percentage of failures in the software development [1, 2]. Software cost estimation is the set of techniques and procedures that organisations use to arrive at an estimate for proposal bidding, project planning, and probability estimates [3, 4]. As such, estimation accuracy is a very significant issue for executives, managers, technical staff, and, particularly, practitioners who perform or rely on cost estimation [5]. Accurate estimation of software development cost also continues to challenge software engineering researchers due to the continued lack of accurate estimates [2]. The reasons that software cost estimation is difficult and error prone include [3]:

- Software cost estimation requires a significant amount of cost to perform correctly;
- The process is often done hurriedly, without an appreciation for the cost required to perform the estimate;
- Experience is required for developing estimates, especially for large projects, and;
- Human bias

There are several software cost estimation models which can be classified as algorithmic and non-algorithmic models. The algorithmic models are based on the statistical analysis of historical data [6, 7], for example, Software Life Cycle Management (SLIM) [8] and Constructive Cost Model (COCOMO) [9]. Non-algorithmic techniques are based on new approaches such as, Parkinson, Expert Judgment, Price-to-Win, and Machine Learning approaches [10, 11]. The Machine learning approach is used to group together a set of techniques that represent some of the facts of human mind [12], for example regression trees, rule induction, fuzzy systems, genetic algorithms, artificial neural networks, Bayesian networks, and evolutionary computation. The last five of these approaches are classified as soft computing group. The importance of algorithmic and non-algorithmic estimation techniques discuss in the following sections, briefly.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

A. Algorithmic models

The famous algorithmic cost estimation models are: Boehm's COCOMO I and II [10]; Albrecht's Function Point; and Putnam's SLIM [8]. These models require inputs, accurate estimate of specific attributes, such as source line of code (SLOC), number of user screen, interfaces, complexity, etc. which are not easy to obtain in the early phase of software development. The formula and calculation of these models are easy to understand, also, they provide fast estimates when compared with non-algorithmic models. Besides, attributes and relationships used to estimate software development cost could change over time, and/or differ for software development environments [9]. The limitations of the algorithmic models led to the exploration of the non-algorithmic models.

B. Non-algorithmic models

In 1990's, the non-algorithmic models was born and have been proposed to software cost estimation. Software researchers have turned their attention to the new approaches that were based on soft computing approach such as artificial neural networks, fuzzy logic, and genetic algorithms. Fuzzy Logic (FL) offers a powerful linguistic representation that able to represent imprecision in the model inputs and outputs, while providing a more knowledge base approach to establish an effective model. Research shows that using FL can result in good performance in terms of reducing imprecision of inputs and outputs parameters.

This paper proposed an effective fuzzy logic model for embedding in the COCOMO II to overcome the vagueness and uncertainty of software attributes which resulted in producing more accurate estimation results.

II. Related work

Gray and MacDonell [2] compared popular techniques in software cost estimation such as regression techniques, function point analysis (FPA), fuzzy logic, and artificial neural networks. Their results showed that fuzzy logic model produced better performance than the other models. They introduced an application of fuzzy logic to cost estimation which resulted in developing a tool, FUzzy logic SOftware MEasuring (FULSOME) [2], to assist software managers in decision making. In the FULSOME model, the two important variables were selected: complexity adjustment factor and unadjusted function point. Then a triangular membership functions were defined for the small, medium, and large intervals of size, complexity, and software effort. Fei and Liu attempted to apply fuzzy logic to the algorithmic cost estimation models in order to handle uncertainty and imprecision problems in such models [13]. They proposed a fuzzy software size model for the COCOMO I. They found that it is unreasonable to assign determinate values for the software size attributes in the COCOMO I, because an accurate estimate of delivered source instruction (KDSI) cannot be made before starting the project. Ryder [14] applied fuzzy modeling technique to the COCOMO I and Function Points model. Idri et al and Huang et al [15, 16] investigated the application of fuzzy logic to the EMs in the intermediate COCOMO I. Also, the fuzzification of the COCOMO I without considering the adjustment factor, then they introduced the f-COCOMO. They assigned a new software size to the COCOMO I, also, the coefficients related to the development mode were assigned to a fuzzy set. In another research, Kumar et al [17] applied fuzzy logic to manpower buildup index (MBI) of Putnam estimation model. The MBI is based upon 64 different rules. The results showed that fuzzy logic can be effectively applied to software cost estimation.

Fuzzy logic also had been applied to the non-algorithmic models to overcome the uncertainly of the models. Molokken and Jorgensen, proposed a combination of a fuzzy logic model with the estimation by analogy technique [1]. Estimation by analogy is one of the classified techniques of expert-based estimation. It is a type of Case-based Reasoning (CBR) method. Besides, the fuzzy analogy for software cost estimation had also been applied to web-based software.

In summary, fuzzy logic has been applied to algorithmic and non-algorithmic cost estimation models in the pursuit of achieving better estimation results. Nevertheless, there is still much uncertainty as to what estimation technique suits which type of estimation problem [16]. Choosing between the different techniques is a difficult decision that requires the support of a well-defined evaluation method to show each estimation technique as it applies to any estimation problem.

III. Problem Statement

Inaccurate software cost estimation has plagued software projects for decades. Poor estimates have not only led projects to exceed budget and schedule but also, in many cases, be terminated entirely. The ability to accurately estimate software development time, cost, and manpower, changes as newer methodologies replace old ones. Therefore, an accurate software cost estimation model is highly required in software project management.

IV. Research Method

This section, first, introduces the characteristics and strength of the COCOMO II and fuzzy logic, briefly, then the new FL-COCOMO II is explained.

A. The COCOMO II

The COCOMO I model is a regression-based software cost estimation model, which was developed by Boehm in 1981 [9] and thought to be the most cited, best known, and the most plausible model among all traditional cost estimation models. The COCOMO I was a stable model on that time. One of the problems with the use of COCOMO I today is that it does not match the development environment of the late 1990's. Therefore, in 1997, Boehm was developed the COCOMO II to solve most of the COCOMO I problems [11]. Equation (1) and

Figure 1 show the formula and the process of software schedule, cost, and manpower estimation in the COCOMO II. The COCOMO II includes several software attributes such as: 17 Effort Multipliers (EMs), 5 Scale Factors (SFs), Software Size (SS), and Effort estimation that are used in the Post Architecture Model of the COCOMO II [20]. The description of the 17 EMs and 5 SFs based upon their numerical values and productivity ranges are shown in Table 1 [11].

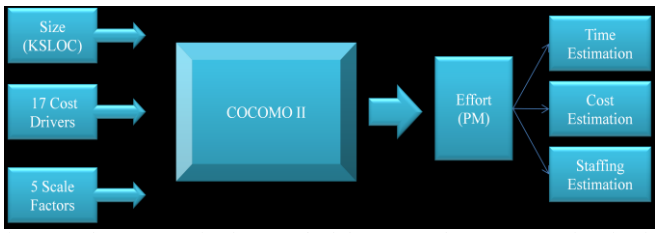

Figure 1: The process of software schedule, cost, and manpower estimation in the COCOMO II

$$\begin{cases} \text{Effort}_{\text{PM}} = \text{A} \times [\text{Size}]^{\text{B}+0.01\times\sum_{j=1}^{5}\text{SF}_j} \times \prod_{i=1}^{17}\text{EM}_i \\ \text{Schedule}_{\text{Months}} = \text{C} \times (\text{Effort})^{\text{D}+0.2\times 0.01\times\sum_{j=1}^{5}\text{SF}_j} \\ \text{Average staffing}_{\text{People}} = \dfrac{\text{Effort}}{\text{Schedule}} \\ \text{COST} = \text{Effort} \times (\text{Payment}_{\text{Month}}) \\ \text{A} = 2.94;\quad \text{B} = 0.91;\quad \text{C} = 3.67;\quad \text{D} = 0.28 \\ \text{Size: Software Size (SLOC)} \end{cases} \quad (1)$$

Vagueness and uncertainty of the software attributes can impact the software estimates. Thus, accurate software attributes resulted in producing accurate software estimates that is most desired for software project managers and organisations.

Table 1: The range of COCOMO II EMs

Effort Multiplier	Range
Required software reliability (RELY)	0.82-1.26
Database size (DATA)	0.90-1.28
Product complexity (CPLX)	0.73-1.74
Developed for reusability (RUSE)	0.95-1.24
Documentation match to life-cycle needs (DOCU)	0.81-1.23
Execution time constraint (TIME)	1.00-1.63
Main storage constraint (STOR)	1.00-1.46
Platform volatility (PVOL)	0.87-1.30
Analyst capability (ACAP)	1.42-0.71
Programmer capability (PCAP)	1.34-0.76
Personnel continuity (PCON)	1.29-0.81
Applications experience (APEX)	1.22-0.81
Platform experience (PLEX)	1.19-0.85
Language and tool experience (LTEX)	1.20-0.84
Use of software tools (TOOL)	1.17-0.78
Multi site development (SITE)	1.22-0.80
Required development schedule (SCED)	1.43-1.00

The value of SFs, are based on the rationale that they are a significant source of exponential variation on a project's effort or productivity variation.

B. *Fuzzy Logic*

In 1965, Lofti Zadeh formally developed multi-value set theory, and introduced the term fuzzy into the technical literature [18]. Fuzzy Logic (FL) starts with the concept of fuzzy set theory. It is a theory of classes with un-sharp boundaries, and considered as an extension of the classical set theory [19]. The membership $\mu_A(x)$ of an element x of a classical set A, as subset of the universe X, is defined by (2), as follows:

$$\mu_A(x) = \begin{cases} 1 & if \quad x \in A \\ 0 & if \quad x \notin A \end{cases} \quad (2)$$

A system based on FL has a direct relationship with fuzzy concepts (such as fuzzy sets, linguistic variables, etc.) and fuzzy logic. The popular fuzzy logic systems can be categorised into three types: Pure fuzzy logic systems, Takagi and Sugeno's fuzzy system, and fuzzy logic system with fuzzifier and defuzzifier [19]. Since most of the engineering applications produce crisp data as input and expects crisp data as output, the last type is the most widely used type of fuzzy logic systems. Fuzzy logic system with fuzzifier and defuzzifier, first, proposed by Mamdani and it has been successfully applied to a variety of industrial processes and consumer products [19]. The main three steps of applying fuzzy logic to a model are:

- Step 1:
  - Fuzzification: It converts a crisp input to a fuzzy set
- Step 2:
  - Fuzzy Rule-Based System: Fuzzy logic systems use fuzzy IF-THEN rules
  - Fuzzy Inference Engine: Once all crisp input values are fuzzified into their respective linguistic values, the inference engine accesses the fuzzy rule base to derive linguistic values for the intermediate and the output linguistic variables
- Step 3:
  - Defuzzification: It converts fuzzy output into crisp output

C. *The Fuzzy Logic COCOMO II (FL-COCOMO II)*

The new FL-COCOMO II is established based on the COCOMO II and FL. The COCOMO II includes a set of input software attributes: 17 EMs, 5 SFs, 1 SS and one output, Effort estimation. The architecture of the FL-COCOMO II is shown in Figure 2.

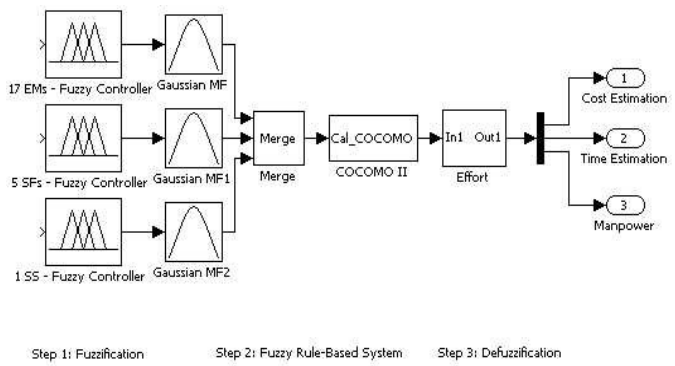

Figure 2: The architecture of the FL-COCOMO II includes: 17 EMs, 5SFs, 1 SS, and effort estimation

In the COCOMO II effort is expressed as Person Months (PM). It determines the efforts required for a project based on software project's size in Thousand Source Line of Code (KSLOC). Traditionally, the problem of software effort estimation relies on the single (numeric) values of the EMs, SFs, and software size that given as software attributes to estimate the effort. However, the size of the software may compute based on previously developed software that are similar to the current one (especially at the beginning of the project). Obviously, correctness and precision of such estimates are limited. It is essentially important to recognise this situation and come up with a technique which can evaluate the associated imprecision residing within the final results of cost estimation. Using fuzzy sets in EMs, SFs, and software size attributes can be specified by distribution of their possible values instead of using fixed values. Commonly, this form of distribution is represented in the form of a fuzzy set. It is important to clarify that vagueness and uncertainty at the input level of the COCOMO II yields uncertainty at the output level [10]. Converting the software attributes to respective fuzzy set causes improving the accuracy of the software attributes which resulted in estimation accuracy. Obviously, a certain monotonicity property holds, which is less precise estimate of inputs give rise to less detailed effort estimates. Overlapped symmetrical the Two-Dimension Gaussian Membership Function (2-D GMF) improves fuzzy model to a precise model.

Furthermore, there is a possibility when using the 2-D GMF that some attributes are assigned the maximum degree of compatibility instead of assigning to lower degrees. In order to avoid this linearity it is proposed to use more superior function, the 2-D GMF, for representing inputs of the model. The 2-D GMF is represented by (3) as follows:

$$\mu_{A_i}(x) = Gaussian\,(x, c_i, \sigma_i) = e^{\frac{-(x-c_i)^2}{2\sigma_i^2}} \quad (3)$$

Where c_i is the center of the i^{th} fuzzy set and σ_i is the width of the i^{th} fuzzy set.

The processes involved in applying fuzzy logic to the COCOMO II to establish the FL-COCOMO II are described as follows. The three main processes in the FL-COCOMO II are: Fuzzification, Fuzzy Rule-Based/ Fuzzy Inference Engine, and Defuzzification. The software attributes in the COCOMO II converted to the fuzzy variables based on the fuzzification process and terms Extra Low (XL), Very Low (VL), Low (L), Nominal (N), High (H), Very High (VH), and Extra High (XH) were defined for the 23 software attributes (17 EMs, 5 SFs, and 1 SS) were defined for each software attribute. The fuzzy sets corresponding to the various associated linguistic values for each software attribute were defined using the 2-D GMF. For example, the fuzzification of the Applications Experience (AEXP) EM based on the 2-D GMF function μ, using Fuzzy Inference System tool in the MATLAB software, is defined as shown in Table 2 and Figure 3. The Fuzzy Inference System (FIS) is a fuzzy tool in the MATLAB software which was used in the fuzzification, fuzzy calculations, fuzzy rule generation, and defuzzification process of the FL-COCOMO II. The FIS supports Mamdani and Sugeno fuzzy methods. The FL-COCOMO II was established based upon the Sugeno fuzzy interface system which is more accurate than the Mandani FIS method.

Table 2: Applications Experience (AEXP) EM Description

Effort Multiplier: Applications Experience (AEXP)						
Descriptors	2 months	6 months	1 year	3 years	6 years	-
Effort Multipliers	1.42	1.19	1	0.85	0.71	-
Rating	VL	L	N	H	VH	EX

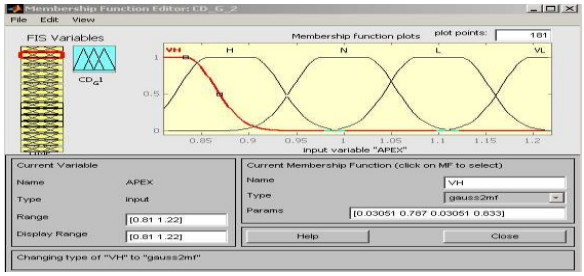

Figure 3: The fuzzification of the AEXP EM using FIS tool in the MATLAB software

At the first step, all the software attributes of the COCOMO II converted to the responding fuzzy sets and variables ($Fuzzy_{EMij}$) rather than using the fixed values of EM_{ij}. The $Fuzzy_{EMij}$ were calculated using equation (4) and the original EM_{ij} values and the 2-D MGF μ was defined for the various fuzzy sets associated with the EMs, SFs, and SS. This process helps to reduce the vagueness and uncertainty of the software attributes at this level.

$$Fuzzy_{EM_{ij}} = F\left(\mu^{V_1}{}_{A1}, \ldots \mu^{V_i}{}_{Ai}, EM_{i1} \ldots EM_{ij}\right) \quad (4)$$

For ease, F is taken as a linear function, where the $\mu^{Vi}{}_{Aj}$ is the membership function of the fuzzy set Aj associated with the cost driver V_i as shown in equation (5).

$$Fuzzy_{EM_{ij}} = \sum_{j=1}^{k_i} \mu_{A_i}{}^{v_i} * EM_{ij} \quad (5)$$

The fuzzy rules for the FL-COCOMO II were defined through the linguistic variables in the fuzzification process. It

is important to take note that these fuzzy rules were adjusted as well as all pertinence level functions, in accordance with the tests and the characteristics of the project. The fuzzy rules were defined based on the connective "AND" and "OR" or combination of them between input variables, as shown as follows.

Fuzzy rules:
IF TOOL is Low TEHN effort is Low
IF PCAP is Very Low THEN effort is Very High
IF RESUE is Nominal THEN effort is Nominal
IF DATA is Very High THEN effort is Very High
…

The number of rules which were defined for the FL-COCOMO II is more than 193 based on the input variables. In the process of fuzzy rule generation of the FL-COCOMO II, the FIS tool in the MATLAB software was used as shown in Figure 4.

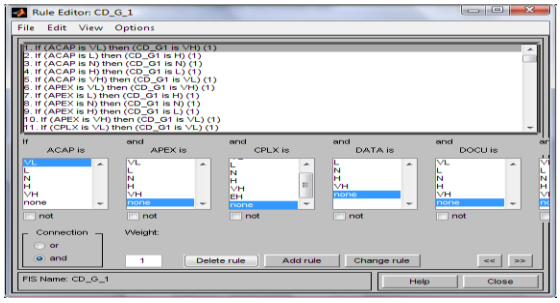

Figure 4: The fuzzy rule generation using FIS tool in the MATLAB software

The last step is defuzzification of the effort variable using defuzzification techniques such as Mean of Maximum (MOM), Center of Area (COA), and First of Maximum (FOM). The defuzzification of the output "Effort" performed using the Mean of Maximum (MOM) technique because the results obtained are more accurate when compared with the other defuzzification techniques.

V. RESULTS AND DICUSSION

The FL-COCOMO II was evaluated through three sources: two public domain data sets (Data set 1 and 2) and 4 software project data from software companies in Malaysia (Data set 3). The descriptions of these data sets are discussed as follows.

A. Data set 1

The COCOMO I data set—Boehm [10] was the first researcher which looked at software engineering from an economic point of view then he came up with a cost estimation model from a dataset, the COCOMO I data set. The COCOMO I dataset includes 63 historical project data. This data set is in public domain and available in http://promisedata.org.

B. Data set 2

The NASA93 data set—the NASA93 data set includes 93 project data from NASA Manager Measurement Benchmarking Element. This data set is in public domain and available in http://promisedata.org.

C. Data set 3

Four real project data from two software companes A and B in Malaysia. These project data were collected through a direct data collection from software companes A and B in the COCOMO data set fromat.

Therefore, in this research three different data sets (160 project data) were used for evaluation of the FL-COCOMO II.

D. Evaluation Method

In the evaluation of software cost estimation models, the most widely used evaluation criterion are the Mean Magnitude of Relative Error (MMRE) and the probability of a project having a relative error of less than or equal to L (PRED(L)). The Magnitude of Relative Error (MRE) is defined in equaton (6) as follows:

$$MRE_i = \frac{|Actual\ Effort_i - Predicted\ Effort_i|}{Actual\ Effort_i} \quad (6)$$

The MRE value was calculated for each observation i that effort is estimated at that observation. The aggregation of MRE over multiple observations (N) can be achieved through the Mean MRE (MMRE) in equation (7) as follows:

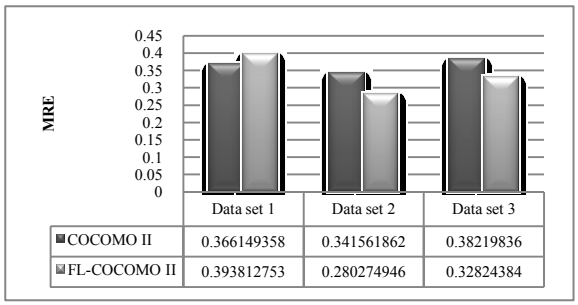
$$MMRE = \frac{1}{N} \sum_i^N MRE_i \quad (7)$$

A complementary criterion is the prediction at level L, PRED(L) = k/N, where k is the number of observations where MRE is less than or equal to L, and N is the total number of observations. Thus, PRED(25%) gives the percentage of projects which are predicted with a MRE less or equal than 25%. This value, 25%, is a realistic value for evaluation of models.

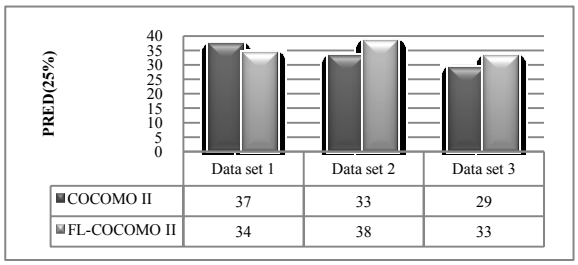
The FL-COCOMO II was evaluated through the three data sets (1, 2, and 3), separately, using the MMRE and PRED (25%). These data sets were applied to the COCOMO II and FL-COCOMO II, separately, and then the value of MRE and PRED (25%) were calculated for each data set. The comparison between obtained results from the COCOMO II and FL-COCOMO II using data set 1 to 3 are shown in Table 3 and Figure 5.

Table 3: Comparison between obtained results from the COCOMO II and FL-COCOMO II using the MRE and PRED(25%)

Data set	Model	Evaluation	
		MMRE	PRED(25%)
Data set 1	COCOMO II	0.366149358	37%
	FL-COCOMO II	0.393812753	34%
Data set 2	COCOMO II	0.341561862	33%
	FL-COCOMO II	0.280274946	38%
Data set 3	COCOMO II	0.38219836	29%
	FL-COCOMO II	0.32824384	33%
Mean	COCOMO II	0.363303193	33%
	FL-COCOMO II	0.334110513	35%



(a)



(b)

Figure 5: Comparison between the COCOMO II and FL-COCOMO II using the (a) MRE and (b) PRED (25%) evaluation techniques

The row labelled in "Mean" represents the average result for the data sets 1 to 3 based upon the evaluation criterion in the models.

For the data set 1, the value of MRE and PRED(25%) evaluation criterion for the COCOMO II and FL-COCOMO II are 0.366149358 and 0.393812753; 37 and 34, respectively. These values show that in terms of MRE, the COCOMO II shows less value for MRE and higher value for PRED (25%) when compared with the FL-COCOMO II. Therefore, in this case, the COCOMO II produced more accurate results for data set 1.

For the data set 2, the value of MRE and PRED(25%) evaluation criterion for the COCOMO II and FL-COCOMO II are 0.341561862 and 0.280274946; 33 and 38, respectively. These values show that in terms of MRE, the FL-COCOMO shows less value for MRE and higher value for PRED (25%) when compared with the COCOMO II. Therefore, in this case, the FL-COCOMO II produced more accurate results than the COCOMO II.

For the data set 3, the value of MRE and PRED(25%) evaluation criterion for the COCOMO II and FL-COCOMO II are 0.38219836 and 0.32824384; 29 and 33, respectively. These values show that in terms of MRE, the FL-COCOMO shows less value for MRE and higher value for PRED (25%) when compared with the COCOMO II.

Finally, The values of MMRE for COCOMO II and FL-COCOMO II based upon data sets 1 to 3 are 0.363303193 and 0.334110513, respectively, and the value of PRED (25%) are 33 and 35, respectively.

By comparing these results, a software cost estimation model with a lower value of MMRE gives better estimates than a model with a higher value. The best cost estimation model shows a value 0 for MMRE evaluation criterion. Also, a software cost estimation model with a higher value of PRED(25%) gives better estimates than a model with a lower value. The best cost estimation model shows a value 0 for MMRE and 100% for PRED(25%) evaluation criterion. Between these two estimation models (COCOMO II and FL-COCOMO II), the use of FL-COCOMO II for software development cost estimate can produce better estimates in terms of MMRE, and PRED (25%) than the COCOMO II based on the data sets 1 to 3.

The percentage of improvement of FL-COCOMO II is calculated based on the difference between the two models divided by the value of the COCOMO II. Table 4 shows the comparison of the improvement based upon estimation accuracy in COCOMO II and FL-COCOMO II.

Table 4: Comparison of improvement of the COCOMO II and FL-COCOMO II

Model		Evaluation	
		MMRE	PRED (25%)
COCOMO II vs. FL-COCOMO II			
	COCOMO II	0.363303193	33
	FL-COCOMO II	0.334110513	35
	Improvement (%)	8.03	6.06

According to the Table 4, in terms of MMRE, the percentage of improvement based upon estimation accuracy for the FL-COCOMO II is 8.03% and based on PRED (25%) is 6.06% when compared to the COCOMO II, respectively. It shows that using FL can improve the estimation accuracy and it can be used as alternative to apply to the other software cost estimation models to improve estimation accuracy.

VI. CONCLUSION

One of the important issues in software project management is accurate and reliable estimation of software time, cost, and manpower, especially in the early phase of software development. Software attributes usually have properties of uncertainty and vagueness when they are measured by human judgment. A software cost estimation model incorporates fuzzy logic can overcome the uncertainty and vagueness of software attributes. However, determination of the suitable fuzzy rule sets for fuzzy inference system plays an important role in coming up with accurate and reliable software estimates. The objective of this research was to examine the application of applying fuzzy logic in software cost estimation that can perform more accurate result. This paper presented an adaptive software cost estimation model incorporates fuzzy logic technique to handle imprecision and uncertainty of software attributes. The results obtained from applying three different data sets 1 to 3 to the models, showed that the FL-COCOMO II produced better estimation results than the COCOMO II using evaluation criterion MMRE=0.334110513 and PRED(25%)=35. Furthermore, the percentage of improvement for the FL-COCOMO is from 6.06 to 8.03, which shows the performance of the FL-COCOMO

when compared with the COCOMO II based on the estimation accuracy. The application of fuzzy logic in other software cost estimation models can also be explored in the future.

***Abstract*—Much work has been carried out in the area of fuzzy-rough sets for supervised learning. However, very little has been accomplished for the unsupervised or semi-supervised tasks. For many real-word applications, it is often expensive, time-consuming and difficult to obtain labels for all data objects. This often results in large quantities of data which may only have very few labelled data objects. This paper proposes a novel fuzzy-rough based semi-supervised self-learning or self-training approach for the assignment of labels to unlabelled data. Unlike other semi-supervised approaches, the proposed technique requires no subjective thresholding or domain information. An experimental evaluation is performed on artificial data and also applied to a real-world mammographic risk assessment problem with encouraging results.**

***Index Terms*—Rough sets, fuzzy sets, mammographic analysis, semi-supervised learning**

I. Introduction

Each year worldwide, more and more data is collected. In fact, it is estimated that the amount of data collected and stored at least doubles every two years. This collection and storage is facilitated by the fact that the actual process of doing so has become easier in recent times. The result is enormous collections of data. Of this data, a large percentage is unlabelled or has labels which are incomplete or missing. It is because this data is so large that it becomes very difficult, time-consuming and expensive for humans to manually assign labels to data objects. Additionally, many real-world application datasets (such as gene expression data, text classification, etc.) are also of large dimensionality. This further frustrates the process of label assignment for domain experts as large dimensionality can make the task of label assignment intractable.

Supervised learning operates on labelled data and attempts to learn its underlying functional relationships. It is the most common paradigm in machine learning and is typically concerned with the learning of classifiers which can accurately reflect the predictive regularities of the underlying model from the feature values and decision class labels. In unsupervised learning, decision class labels are unavailable and the task is to construct/reconstruct the class information from some inherent structure in the data (also known as cluster analysis). These techniques attempt to find groups in the data such that objects in the same group are similar to each other in some way. The notion of similarity is however subjective and as such unsupervised learning approaches are forced to make subjective assumptions about groupings as well as the number of groups into which objects belong. Semi-supervised learning (SSL) [1] lies somewhere between supervised learning and unsupervised learning. SSL is typically employed when some (but not all) of the data is labelled. The primary aim of SSL is to try to combine both the labelled and the unlabelled data. SSL has attracted much interest in the field of machine learning due (as mentioned previously) to the abundance of unlabelled data which is available for many real-world problems. The problem with of course with traditional classification methods is that they cannot use unlabeled data to train classifiers. SSL can also play an important part as a quantitative method in trying to reason about human category-learning, where most of the data is obviously unlabelled [24].

There have been many attempts to adapt existing supervised and unsupervised methods for use in the semi-supervised paradigm. These include typical approaches such as neural networks [3], EM algorithm [4], FCM clustering [5], Support Vector Machines [6], Fuzzy Systems [7], and others [8]. One of the main drawbacks of many of the existing semi-supervised approaches however is that they require the specification of at least one additional subjective tunable parameter.

Rough sets [9] and fuzzy-rough sets [10] have enjoyed much attention for the task of supervised learning [11], due to their domain independence and in the case of fuzzy-rough sets the additional ability to handle real-valued data. The vast majority of the work that has been carried out in the areas of rough sets and fuzzy-rough sets has been focused on supervised learning approaches, i.e. where the class labels are known. Very little work has been carried out which employs fuzzy-rough sets for the task of unsupervised learning, and even less still for that of semi-supervised learning. Although there has been some use of rough sets for the task of semi-supervised learning [12] as well as the use of fuzzy sets and rough sets in isolation of each other [13], no use has been made of *fuzzy-rough* sets. The motivation for a fuzzy-rough based semi-supervised approach is based on the success of the supervised approaches [11], [14], and the fact that no additional user-supplied thresholding is required.

This paper presents a novel fuzzy-rough based semi-supervised algorithm for the task of predicting labels for unlabelled data. The algorithm is based on the well-known self-training approach [15], [16], and uses the upper and lower approximation membership values of fuzzy-rough sets for each of the concepts of the labelled objects to iteratively label

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

unlabelled objects.

The remainder of this paper is structured as follows. Section 2 summarises the theoretical basis and concepts of rough sets and fuzzy-rough sets. Section 3 describes the fuzzy-rough semi-supervised self learning approach and corresponding algorithm. Section 4 shows the results of applying the fuzzy-rough semi-supervised self-learning approach to a number of artificial datasets, as well as a real-world mammographic risk assessment task. Section 5 concludes the paper with some suggestions, as well as a discussion of ideas for future work.

II. Rough Set and Fuzzy Set Hybridisation

Rough set theory (RST) [9] provides a means by which knowledge can be extracted from a domain in a concise manner. RST can retain information content whilst reducing the amount of information involved. At the core of RST is the concept of indiscernibility. Let $I = (\mathbb{U}, \mathbb{S})$ be an information system, where $\mathbb{U}$ is a non-empty set of finite objects (the universe of discourse) and $\mathbb{S}$ is a non-empty finite set of attributes so that $a : \mathbb{U} \rightarrow V_a$ for every $a \in \mathbb{S}$. V_a is the set of values that a can take. For any $P \subseteq \mathbb{S}$, there exists an associated equivalence relation $IND(P)$:

$$IND(P) = \{(x, y) \in \mathbb{U}^2 | \forall a \in P, a(x) = a(y)\} \quad (1)$$

The partition generated by $IND(P)$ is denoted $\mathbb{U}/IND(P)$ and is calculated as follows:

$$\mathbb{U}/IND(P) = \otimes\{\mathbb{U}/IND(\{a\}) : a \in P\} \quad (2)$$

where,

$$P \otimes Q = \{X \cap Y : \forall X \in P, \forall Y \in Q, X \cap Y \neq \emptyset\} \quad (3)$$

If $(x, y) \in IND(P)$, then x and y are indiscernible by attributes from P. The equivalence classes of the P-indiscernibility relation are denoted $[x]_p$. Let $X \subseteq \mathbb{U}$. X can be approximated using only the information contained in P by constructing the P-*lower* and P-*upper* approximations of X:

$$\underline{P}X = \{x | [x]_p \subseteq X\} \quad (4)$$

$$\overline{P}X = \{x | [x]_p \cap X \neq \emptyset\} \quad (5)$$

The tuple $\langle \underline{P}X, \overline{P}X \rangle$ is known as a rough set. The problem with RST however, is that because of the definite equivalence imposed by the equivalence relation, it cannot be used effectively on real-valued data. As most data is real-valued, this usually involves a discretisation step prior to the application of RST. Discretisation usually results in a loss of information however and this has prompted the development of a more intuitive and flexible approach by hybridising fuzzy sets and rough sets to give fuzzy-rough sets [10].

A fuzzy-rough set [10] is defined by two fuzzy sets, fuzzy lower and upper approximations, obtained by extending the corresponding crisp rough set notions. In the crisp case, elements that belong to the lower approximation (i.e. have a membership of 1) are said to belong to the approximated set with absolute certainty. In the fuzzy-rough case, elements may have a membership in the range [0,1], allowing greater flexibility in handling uncertainty.

Definitions for the fuzzy lower and upper approximations can be found in [17], where a T-transitive fuzzy similarity relation is used to approximate a fuzzy concept X:

$$\mu_{\underline{R_P}X}(x) = \inf_{y \in \mathbb{U}} \mathcal{I}(\mu_{R_P}(x, y), \mu_X(y)) \quad (6)$$

$$\mu_{\overline{R_P}X}(x) = \sup_{y \in \mathbb{U}} \mathcal{T}(\mu_{R_P}(x, y), \mu_X(y)) \quad (7)$$

Here, $\mathcal{I}$ is a fuzzy implicator and $\mathcal{T}$ a t-norm. A fuzzy implicator is any $[0, 1]^2 \rightarrow [0, 1]$-mapping $\mathcal{I}$ satisfying $\mathcal{I}(0, 0) = 1, \mathcal{I}(1, x) = x$ for all x in $[0, 1]$. R_P is the fuzzy similarity relation induced by the subset of features P:

$$\mu_{R_P}(x, y) = \mathcal{T}_{a \in P}\{\mu_{R_a}(x, y)\} \quad (8)$$

$\mu_{R_a}(x, y)$ is the degree to which objects x and y are similar for feature a, and may be defined in many ways, for example:

$$\mu_{R_a}(x, y) = 1 - \frac{|a(x) - a(y)|}{|a_{max} - a_{min}|} \quad (9)$$

$$\mu_{R_a}(x, y) = \max(\min(\frac{(a(y) - (a(x) - \sigma_a))}{\sigma_a}, \frac{((a(x) + \sigma_a) - a(y))}{\sigma_a}, 0) \quad (10)$$

where ${\sigma_a}^2$ is the variance of feature a. As these relations do not necessarily display $\mathcal{T}$-transitivity, the fuzzy transitive closure can be computed for each attribute [2]. The choice of relation is largely determined by the intended application. For example, for the task of feature selection, a relation such as (10) may be best suited, as this allows only small differences between feature values of differing objects. For the task of classification however, a more gradual and inclusive relation such as (9) can be employed. Indeed, this is the relation which is used in the semi-supervised approach described in this paper.

III. Fuzzy-Rough Semi-Supervised Learning

The algorithm employed in this paper is a variation of the popular semi-supervised self-learning or self-training approach [15], [16]. Self learning has been widely employed for the task of semi-supervised learning in text mining applications [8], [12], [15], [16]. It is fast and converges sooner than most other semi-supervised approaches. The basis for the algorithm is that given a set of labelled objects and a set of unlabelled objects, the labelled objects are used to make predictions about the class membership of the unlabelled objects. In self learning/training a classifier (or induction method) is initially trained with a (usually small) amount of labelled data. The classifier is then used to predict labels for the unlabelled data. Typically the most 'confident' unlabelled points, along with their corresponding predicted labels, are then added

to the training set. The classifier is then re-trained and the procedure is repeated. Notice that the classifier uses its own predictions in order to 'train' itself. One of the criticisms that is often levelled at self-learning approaches is that they can reinforce classification errors that are made early-on in the label assignment. However, it is shown in [15] that this is not strictly the case and the self-learning algorithm can perform equally as well as co-training [18] - another well-known SSL approach. In this paper, a variation of self-learning is employed in that only objects which belong fully to the fuzzy-rough lower approximation of any of the decision classes are added to the labelled data at each iteration, and therefore no subjective confidence level threshold is employed. It should be emphasised at this point that the task at hand is the labelling of unlabelled data using a semi-supervised learning method rather than the building of models for unseen objects.

A. Fuzzy-Rough Semi-supervised Self Learning Algorithm

The rationale behind the fuzzy-rough self learning (FRSL) algorithm is that the fuzzy-rough lower and the upper approximation memberships of each of the (labelled) decision classes, (calculated by means of all of the labelled objects) to the unlabelled test object y, provide good clues in order to predict class membership.

In practice, the algorithm starts out by examining each object in the unlabelled data. If the unlabelled object belongs to the lower approximation of a given class with fuzzy-rough dependency equal to 1.0, then the label of that class is assigned to that object. The object is then added to the training data and will be included when generating the fuzzy-rough partitions in the following iterations. The algorithm continues until either: 1) all unlabelled objects have been labelled, or 2) until any of the remaining unlabelled objects do not belong to the lower approximation of any of the labelled decision classes with certainty (fuzzy-rough dependency < 1.0). If there are remaining unlabelled objects, a naive approach is adopted in order to assign labels by calculating the combination of lower and upper approximation memberships and using this value to assign class labels. Adopting such a strategy means that labels are (as far as possible) propagated via only those objects which are 'certain' thus minimising the risk of reinforcement of classification errors at an early stage in the algorithm.

It is important to note that the propagation of labels happens through the addition of previously unlabelled objects to the labelled training data. This has the effect of altering the fuzzy-rough lower and upper approximation memberships of the remaining unlabelled objects.

B. Worked Example

In order to demonstrate the fuzzy-rough concepts employed in the previous section, a small worked example is presented. Note that only a small dataset is included in this example, and as such the formal concepts are only demonstrated rather than the execution of the algorithm. The example dataset has 3 real-valued conditional attributes (a,b, and c) and a single crisp discrete-valued decision attribute (q) as the *labelled training data*, shown in Table I. A further dataset shown in Table II containing 2 objects is used as the *unlabelled* data, again with the same number of conditional attributes but with unknown decision attribute values.

FRSL(L, UL, C, y)
L, the set of all labelled data objects; UL, the set of all unlabelled data objects; C, the set of decision classes in L; y, the unlabelled data object to be labelled

```
(1)  while (∃y ∈ UL : μ_RC(y) == 1.0)
(2)     buildFuzzyRoughPartition(L)
(3)      ∀C ∈ L
(4)        if (μ_RC(y) == 1.0)
(5)          y ← y ∪ {C}
(6)          L ← L ∪ {y}
(7)  while UL ≠ ∅
(8)     buildFuzzyRoughPartition(L)
(9)     γ_best ← 0, γ_prev ← 0, bestClass ← ∅
(10)     ∀C ∈ L
(11)       if (μ_RC(y) + μ_R̄C(y))/2 > γ_best)
(12)       γ_best ← γ_prev, C ← bestClass
(13)       y ← y ∪ {bestClass}
(14)       L ← L ∪ {y}
(15)  end
```

Fig. 1. The FRSL Algorithm

TABLE I
EXAMPLE LABELLED TRAINING DATA

Object	a	b	c	q
1	-0.4	-0.2	-0.5	yes
2	-0.4	0.1	-0.1	no
3	0.2	-0.3	0	no
4	0.2	0	0	yes

TABLE II
UNLABELLED DATA

Object	a	b	c	q
$ul1$	0.3	-0.3	0	-
$ul2$	-0.4	0	-0.3	-

Referring to the FRSL algorithm described in the previous section, the first step is to calculate the fuzzy upper and lower approximations for all decision classes. In Table I there are 4 objects and as noted previously a decision attribute which has 2 classes ($\{yes\}$, and $\{no\}$).

Using the fuzzy similarity measure as defined in 9 the similarity of each unlabelled object is compared to all of the objects in the training data. For instance, consider the unlabelled object $ul1$:

$$\mu_{R_P}(ul1, 1) = T(\mu_{R_{\{a\}}}(ul1, 1), \mu_{R_{\{b\}}}(ul1, 1), \mu_{R_{\{c\}}}(ul1, 1)) = 0$$

$$\mu_{R_P}(ul1, 2) = T(\mu_{R_{\{a\}}}(ul1, 2), \mu_{R_{\{b\}}}(ul1, 2), \mu_{R_{\{c\}}}(ul1, 2)) = 0$$

$$\mu_{R_P}(ul1, 3) =$$

$$T(\mu_{R_{\{a\}}}(ul1,3), \mu_{R_{\{b\}}}(ul1,3), \mu_{R_{\{c\}}}(ul1,3)) = 0.83$$

$$\mu_{R_P}(ul1,4) =$$
$$T(\mu_{R_{\{a\}}}(ul1,4), \mu_{R_{\{b\}}}(ul1,4), \mu_{R_{\{c\}}}(ul1,4)) = 0.23$$

These similarity values can then be used to generate the lower and upper approximations. Note that the fuzzy connectives chosen for this example are the Lukasiewicz t-norm ($\max(x+y-1,0)$), and Lukasiewicz fuzzy implicator ($\min(1-x+y,1)$). For the labelled data decision concept $X = yes$ these are:

$$\mu_{\underline{R_P}}X(ul1) = \inf_{y\in\mathbb{U}} \{I(\mu_{R_P}(ul1,y), \mu_X(y)\}$$
$$= \inf\{I(0,1), I(0.0,0), I(0.83,0), I(0.23,1)\} = 0.17$$

and,

$$\mu_{\overline{R_P}}X(ul1) = \sup_{y\in\mathbb{U}} \{I(\mu_{R_P}(ul1,y), \mu_X(y)\}$$
$$= \sup\{T(0,1), T(0,0), T(0.83,0), T(0.23,1)\} = 0.23$$

Similarly for the decision concept $X = no$:

$$\mu_{\underline{R_P}}X(ul1) =$$
$$\inf\{I(0,0), I(0,1), I(0.83,1), I(0.23,0)\} = 0.77$$

$$\mu_{\overline{R_P}}X(ul1) =$$
$$\sup\{T(0,0), T(0,1), T(0.83,1), T(0.23,0)\} = 0.83$$

Note that for each of the unlabelled test objects, the object is allowed to belong to the class under consideration to degree 1.0 as the 'true' class is unknown. It can be seen that the upper and lower approximation membership values for test object $ul1$ for the class label $X = yes$ are equal to 0.17, and 0.23 respectively. When $X = yes$ the corresponding values are 0.77 and 0.83. Note that the FRSL algorithm in the first instance will only label objects with membership $\mu_{\underline{R_P}}$ X = 1.0 and that the example employed here is to show how these membership values are obtained. If we are to assume that ul1 and ul2 are remaining objects after all others have been labelled then, the algorithm will therefore label $ul1$ naïvely. This is done using the upper and lower approximation memberships and given that: (0.77 + 0.83)/2 = 0.80 for $X = no$ and (0.17 + 0.23)/2 = 0.20 for $X = yes$. Data object $ul1$ will be therefore labelled as belonging to the class $X = no$.

Similarly, the procedure is then repeated for object $ul2$ which results in the following upper and lower approximation values for $X = no$:

$$\mu_{\underline{R_P}}X(ul2) =$$
$$\inf\{I(0.2,1), I(0.4,0), I(0,0), I(0,1)\} = 0.6$$

$$\mu_{\overline{R_P}}X(ul2) =$$
$$\sup\{T(0.2,1), T(0.4,0), T(0,0), T(0,1)\} = 0.2$$

And, $X = yes$:

$$\mu_{\underline{R_P}}X(ul2) =$$
$$\inf\{I(0.2,0), I(0.4,1), I(0,1), I(0,0)\} = 0.8$$

$$\mu_{\overline{R_P}}X(ul2) =$$
$$\sup\{T(0.2,0), T(0.4,1), T(0,1), T(0,0)\} = 0.4$$

IV. Experimental Evaluation

There is no clear consensus or commonly agreed benchmark datasets for the comparison of semi-supervised learning techniques. The most common way of testing new techniques involves taking the labelled datasets available in [19] and removing labels from a percentage of the data objects. The problem with such an approach is that well-distributed absent labels are rarely the case in the real-world. Indeed, the removal of labels in such a manner may not demonstrate sufficiently the true utility of most semi-supervised approaches.

In light of the above statement, two different approaches have been adopted for the experimental evaluation: (i) Two artificial datasets are examined and compared with some existing methods (ii) a real-world labelling problem for mammographic risk assessment is presented along with some prototype labelled examples.

1) Experimental Setup: For the artificial data, two datasets have been generated which reflect some common realistic problems, and demonstrate how the FRSL method copes with such problems. The data objects contained in the datasets have 2 conditional attributes and belong to two separate classes. The labels of only 5% of the objects are known for the problem shown in Fig. 2 (and represented by ■ for class + and ● for class ○) - thus 2.5% for one class and 2.5% for the other, giving a total of 410 labelled and unlabelled objects. For problem 2 in Fig.6, 10% of the labels are known (again represented by ■ and ●), thus giving a total of 420 labelled and unlabelled objects for this dataset. In the case of the mammographic data there are 322 objects in total, and four decision classes based on the BIRADS [20] labelling scheme to reflect risk of development of breast cancer. 10% of the data (32 data objects) has been labelled using the consensus of three expert radiologists - i.e. where all three agree completely on the classification for a given mammogram.

The FRSL method is compared with some common SSL techniques - SSFCM [5] and another self-learning technique based on FNN [21]. SSFCM was proposed as an extension to the popular FCM clustering algorithm. It uses the labelled data as seed points for the cluster prototypes which are essentially ignored when the clusters are updated. The rationale behind the approach is that all labelled examples should be trusted, which is a reasonable assumption but this can affect the objective function of FCM.

The FNN-based self-learning approach uses a fuzzy classifier to estimate class membership for unlabelled examples and learns in an iterative fashion by adding learned examples to the classifier training data at the end of each iteration and

then retraining. This approach has a number of parameters which must be tuned however: number of nearest neighbours, fuzzifier value, and threshold for class membership. For the experimental evaluation carried out in this paper, the fuzzifier value (m) was set to 2.0, the labelling threshold was varied between 0.8-0.95, and the number of nearest neighbours was varied between 1 and 20. The parameter settings which resulted in the best performance are presented here. No restrictions were imposed algorithm itself in terms of number of iterations, number of examples selected from the unlabelled data for labelling (per iteration), or number of most confidently labelled examples that are added at each iteration to the labelled data.

Although the FRSL approach does not have any subjective tunable parameters, a similarity relation must be selected. The fuzzy similarity relation defined in (9) is employed here as this has been shown to produce good results for the task of supervised learning.

A. Artificial Data

The first artificial dataset as shown in Fig. 2, represents two clusters of data, and has only two conditional features. The problem is that for the given class labels, the clusters do not characterise the classes very well and a supervised classifier will be easily misled. The labelled data objects have been chosen at random from the distribution.

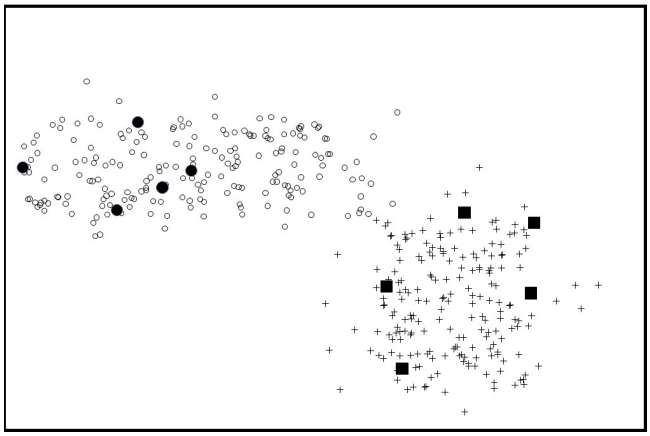

Fig. 2. Artificial Data - Problem 1

SS-FCM was applied to this problem and the results are shown in Fig.3. It can be seen that SS-FCM manages to classify 76% of the objects correctly and fails mostly around the decision boundary between the two classes. Given that the two concepts are very close at this point, and there is some overlap between classes, this performance is quite good.

The FNN wrapper method seems to produce better results that that of SS-FCM but still suffers from poor performance around the decision boundary. It manages to increase classification accuracy to 88% correct classification however.

FRSL manages to label 92% of all objects correctly. Once again the objects are at the boundary between two classes which demonstrates that the overlapping boundary presents a challenge for all methods.

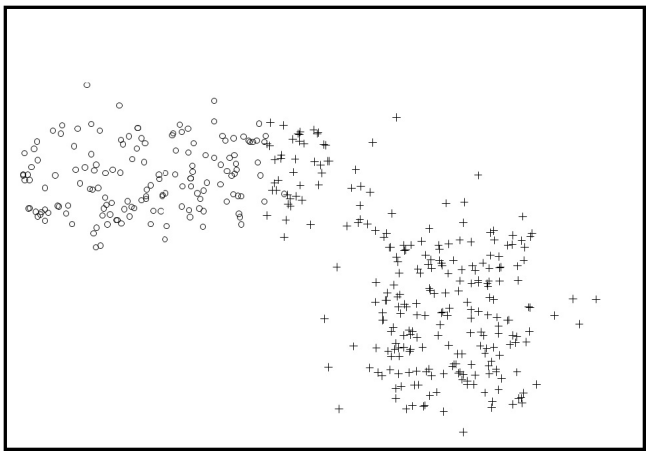

Fig. 3. Artificial Data Problem 1 - SS-FCM

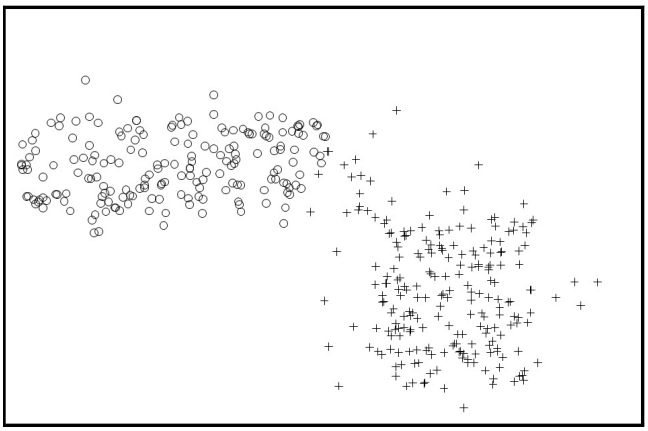

Fig. 4. Artificial Data Problem 1 - FNN Wrapper

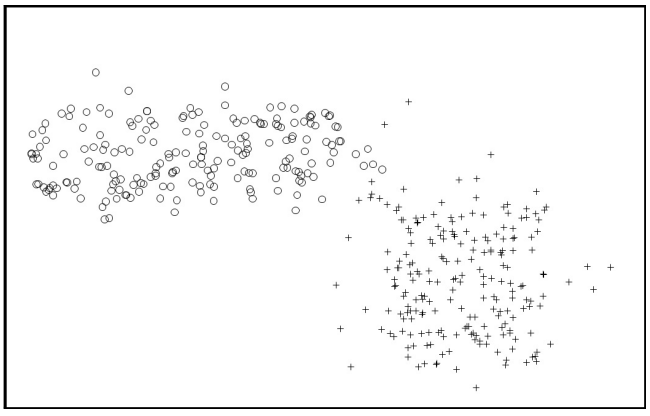

Fig. 5. Artificial Data Problem 1 - FRSL

The second artificial dataset shown in Fig.6 is more complex than that of the previous example. In this case one of the classes has been split into two regions. Once again the labelled objects have been chosen at random, although they now represent 10% of the overall data (20 objects) rather than 5% used in the previous example. This dataset has particularly badly defined decision boundaries and it is certain that a completely unsupervised method would fail in this case.

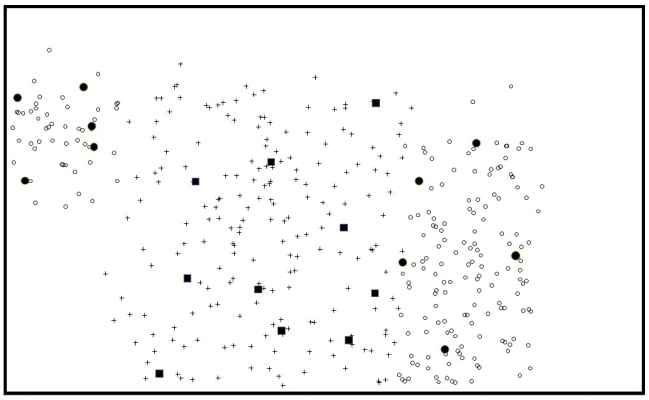

Fig. 6. Artificial Data Problem 2

The SS-FCM method failed completely to correctly label any of the unlabelled data objects that lie in the second cluster which is part of class 1 represented by "O" in Fig.7. The reason for this failure is that SS-FCM does not allow for the induction of more than one cluster for each concept. It also manages to mis-label a number of objects on the decision boundary which is to be expected to a certain degree as the boundary is extremely cluttered. The overall accuracy of the method for correctly labelled instances is 66%.

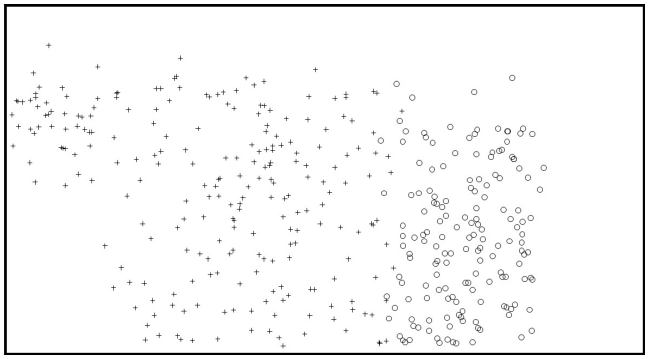

Fig. 7. Artificial Data Problem 2 - SS-FCM

In the case of the FNN wrapper method, performance is quite good and both clusters are identified. However there is a significant amount of mis-labelling of objects. Despite this, the method correctly labels 78% of all objects. Interestingly, some of the assignments appear to be quite strange around the boundaries, with some objects that are distant from the relevant labelled examples. This may be more to do with the sequence of self-learning and value for the number of neighbours than any inherent properties of FNN however.

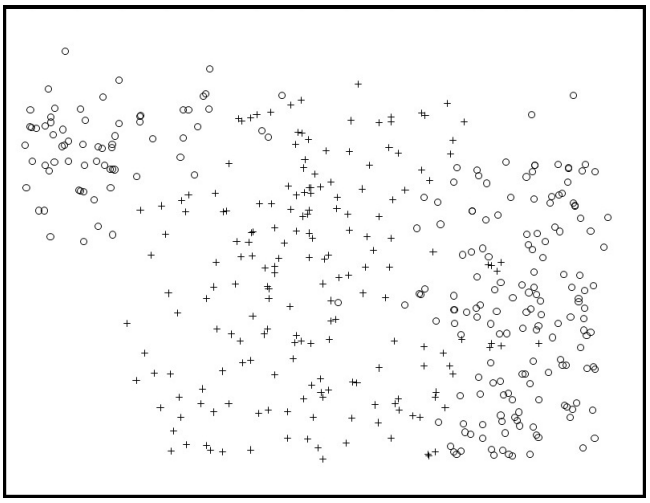

Fig. 8. Artificial Data Problem 2 - FNN

FRSL correctly labels 83% of all of the unlabelled objects for problem 2. Perhaps more importantly however, it manages to label all of those objects represented by the class "O" correctly, the only confusion that arises is with regard to incorrectly labelling objects of the other class.

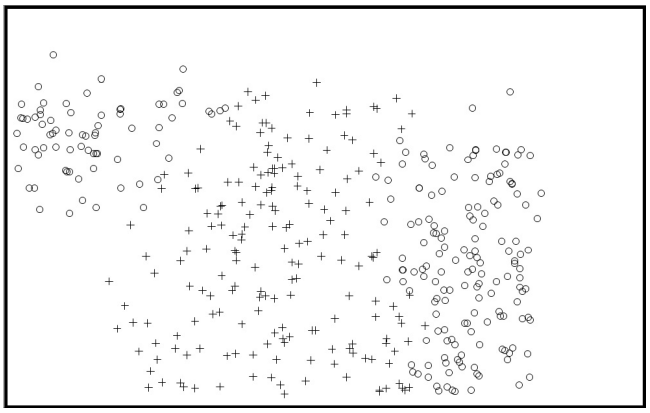

Fig. 9. Artificial Data Problem 2 - FRSL

B. Mammographic Risk Assessment Data

Although artificial data examples often provide useful performance indicators, a mammographic risk assessment problem has been included here in order to demonstrate that FRSL is also useful for such real-world tasks.

Breast cancer is a major health issue, and perhaps the most common amongst women in the EU. It is estimated that between 8% and 13% of all women will develop breast cancer at some point during their lives. Breast tissue characteristics are widely accepted as important indicators of the likelihood of the developing breast cancer [22]. The BIRADS [20] classification scheme allows the division of breast tissue density into 4 distinct classes where 1 represents tissue that is fatty and 4 represents tissue that is dense. The data that is used here has been obtained from [23] and the features have been extracted

TABLE III
CONFUSION MATRICES AND LABEL CLASSIFICATION ACCURACIES FOR THE MIAS DATASET.

FNN
(*Classification accy* = 51.50%)

Consensus opinion	*1*	*2*	*3*	*4*
1	62	15	8	2
2	40	48	15	0
3	32	22	35	6
4	6	4	6	21

FRSL
(*Classification accy* = 65.22%)

	1	*2*	*3*	*4*
1	74	13	0	0
2	15	68	17	3
3	0	36	44	15
4	0	7	6	24

using the method described in [22]. Each of the labelled objects has been labelled using the consensus of three expert radiologists (i.e. where they *all* agree on the classification).

The confusion matrices in Fig. III show the results obtained by both the FNN Wrapper method and the FRSL method. The results for SS-FCM method was not presented for this problem as it fails almost completely to identify any distinct classes. This probably due in the most part to the fact that this is not a clustering task.

The true accuracy for this dataset is 68% when all of the objects have been annotated by experts, FRSL manages 65.21% correct label assignment which is close to this figure. FNN seems to fail to label classes 1 and 2 in particular, whereas one would expect the confusion to lie between classes 2 & 3 as these are conceptually close and are the classes upon which experts disagree most. FNN however shows a large amount of confusion between classes 1 and 3, and also between 1 and 4 which of course are not neighbouring classes. FRSL demonstrates results which do seem to follow a diagonal trend with low non-neighbouring class confusions and a better correct number of label assignments.

V. CONCLUSION

This paper has presented a novel algorithm for the semi-supervised labelling of unlabelled data based on the fuzzy-rough upper and lower approximation membership. Note that no user-defined thresholds are required for the FRSL method, although a choice must be made regarding fuzzy similarity relations and connectives.

Further work in this area will include a more in-depth experimental investigation of the proposed method and the impact of the choice of fuzzy relations, connectives as well as the learning speed of FRSL and number of instances labelled at each iteration etc. Another area worthy of investigation is the combination of the use fuzzy discernibility matrices on the unlabelled data and the use of the fuzzy-rough method on the labelled data, such that the information in both could be aggregated to build classifiers. This may help to address the current assumption for the FRSL method that the labelled objects are fully representative of the class distribution which of course may not be the case. One area is particular which may yield improvements in performance is that of multi-view learning or ensemble semi-supervised classification, where a number of weakly supervised classifiers are aggregated in order to label unlabelled data.

***Abstract*—Wireless sensor networks (WSNs) are composed of sensor nodes in order to detect and transmit features from the physical environment. Generally, the sensor nodes transmit information to a special node called sink. Some recent researches have led to the selection of routes in sensor networks with multiple sink nodes. The approach proposed by this paper presents the application of Genetic Fuzzy System (GFSs) for the selection of routes in WSNs, in order to make the communication between multiple sensor nodes and sink nodes. The results obtained through simulations demonstrated a sensor network with a longer lifetime, through the choice of the adequate sink used for sending packets through the network in order to find the best routes.**

***Index Terms*—Fuzzy Inference System, Genetic Algorithms, Wireless Sensor Networks, Mamdani, Sink Nodes.**

I. Introduction

In recent years we have witnessed a considerable increase in researches involving Wireless Sensor Networks (WSNs) due to their applicability to various areas like safety, health, agriculture, smart environments, industrial automation, among others [1],[2]. Some of the most common paradigms of communication in WSNs involve the communication of multiple sensor nodes placed in an observation area reporting information to a special node named sink (many-to-one). In [3] it is said that the use of a unique sink represents a bottleneck in a network, especially for applications in real-time and continuous data flow. In this sense, some researches have directed studies to the use of multiple sinks, in which communication addresses an alternative paradigm composed of multiple sensor nodes to multiple sinks (many-to-many). For instance, we can cite some papers that address the aspects of WSN with multi-sinks: Tradeoff Between Security and Communication Cost [4], Data Dissemination of Emergency Messages in Mobile Multi-sink Wireless Sensor Networks [5], Topology Control Algorithm Based on Bottleneck Node for Large-Scale WSNs [6], Data Caching Based Queries in Multi-sink Sensor Networks [7].

The approach used in this work focuses on the communication between the sensor nodes and the multiple sink nodes of a WSN. This scenario was chosen because of the growing popularization of applications that require networks with multiple sinks, for example, applications using multimedia wireless sensor networks [8] applications using acting nodes [9], as well as other applications where there might be more than one sink node. Some of these applications intended to promote the selection of routes in WSN, such as: An Energy Efficient Load-Balanced Multi-Sink Routing Protocol for Wireless Sensor Networks [10], Routing in Wireless Sensor Networks Using an Ant Colony Optimization (ACO) Router Chip [11], NSN based Multi-Sink Minimum Delay Energy Efficient Routing in Wireless Sensor Networks [12].

One approach often used to deliver data to multiple sink nodes involves the technique of load balancing [13]. In this approach the data collected by the sensors are distributed throughout the network in order to use all the paths available for routing algorithm. However, the isolated use of the technique of load balancing does not guarantee the energy efficiency of the network, because the path may serve more than one sensor node and thus can have paths with different energy levels. Thus, this technique can force a particular sensor node using a route with low energy capacity.

The methodology implemented in this work for routes selection in WSN combines fuzzy inference systems (FIS) of Mamdani [14] and Genetic Algorithms (GA) [15]. We employed a FIS of Mamdani, in that we tried to model approximate reasoning [16] in order to imitate the human ability to make reasonable decisions in an environment of imprecision, uncertainties and noise. This is because FIS are potentially able to express and process qualitative information. In this paper, fuzzy inference systems of Mamdani are used to determine the most appropriate sink node through consideration of some characteristics of the sensors network, such as energy and number of hops. The production rules in an inference model have linguistic variables both in their antecedents as in their consequents. Genetic Algorithms are employed to obtain the optimal adjustment of fuzzy inference system parameters. By applying GAs, we intend to achieve both a fuzzy database and a fuzzy rules base to maximize performance of the application of Mamdani's inference system in the selection of routes in Wireless Sensor Networks. Therefore, the obtained fuzzy system should be able to help the routing algorithm to choose the best communication path between the sensor nodes and the

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

sink nodes so as to maximize the network lifetime. The design of a fuzzy inference system can be seen as an optimization problem in a high-dimensional search space where each point represents a specific fuzzy rule base and a fuzzy data base. The performance of the FIS forms a hypersurface in the search space. Implementing the optimal FIS corresponds to obtain the optimal location of this hypersurface. However this hypersurface is infinitely large, nondifferentiable, complex, noisy, multimodal and deceptive [17]. It is important to highlight that GAs are global optimization algorithms, based on natural selection mechanisms and genetics, which have shown themselves efficient in a wide variety of problems, in that they override many limitations found in the traditional search/optimization methods [18]. The systems achieved from the integration between the fuzzy inference models and genetic algorithms are called Genetic Fuzzy Systems (GFSs) [19].

II. Related Works

In [3] we have a wireless sensors network consisting of multiple sinks arranged in a cluster that use a database management system distributed in each sink of the network. This proposal requires two modifications in the routing protocol: the first is that the protocol should enable the creation and storage of the multiple routes during message propagation, and the second requires that the network offer QoS (Quality of Service), for the delivery of event notification messages. While the message is propagated through the network, the paths are created and stored in each clusterhead (CH).

The research in [20] proposes a scheme based on Fuzzy Logic to select a better path and increase survival time in MANETs (Mobile Ad hoc Networks). This proposal presents, as contributions, an adaptive path selection scheme and protocol independent. In addition, the correlation of the network characteristics and the safety criterion are made through the use of Fuzzy Logic, to improve the path selection in order to minimize safety limitations found in routing protocols.

In [21], the scenario is of a flat WSN that has only one sink and investigates problems of optimization of the data routing to the sink, based on metrics to choose the best path. In this proposal, a fuzzy inference system is used to select the best candidate node to send packets to the sink at any given time. One drawback to this protocol is the fact that it does not approach the use of multiple sinks, what makes it vulnerable to problems such as bottlenecks and greater energy waste of the nodes next to the sink.

Our work differs from the ones mentioned, since it was proposed to use a Genetic Fuzzy approach to enable choosing the best path for sending data. We propose an algorithm that works together with a routing protocol, in order to help the sensor node in the selection process of the best path among the various possible routes at a given time. This route selection process is made through the use of a Mamdani's fuzzy inference system responsible for classifying routes based on criteria, like energy and number of hops, with the aim of increasing the uptime of the network, since bad ways, such as longer paths, with little energy, should be avoided.

III. The algorithm proposed to assist the Choice of the Best Route in Multi-Sink Environments

A. General Aspects

In our proposal we consider a network in which the sensor nodes are positioned so as to reach the coverage of the whole area and the multiple sinks are arranged according to the network design. It is noteworthy that the sink nodes are devices with superior characteristics to the sensor nodes, having no energy limitations.

Each sink node is responsible for receiving notification messages of events occurring anywhere on the network. For such, each sensor node must select the most appropriate sink at a given moment, taking characteristics of the network into consideration, such as energy, number of hops, collisions and delay. We must emphasize that on this paper we considered initially only two characteristics, energy and number of hops, main metrics considered in WSNs [22].

It is important to highlight that choosing a routing protocol is necessary, since our solution will work together with it. The choice of the routing protocol is made according to the needs of the network designer, being required only that the protocol be capable of providing multiple paths (multipath). To test, we used the routing protocol Directed Diffusion [23] whose operation is detailed in section 5.

B. The Solution Proposed

We present the steps of the implemented algorithm by means of Figure 1. After the positioning stage of all nodes in the network, they are started and the sinks generate a *V*-list containing their neighbor nodes. This list is used by the sinks to send a signalling message β^n, as illustrated in Figure 1. The signalling message sent by the sinks is propagated through the network by the neighbor sensor nodes.

At receiving a signalling message a sensor node *X* will check the following fields:

- *Energy*: this field is used to store the lowest energy value found on the course so far;
- *Base_station*: indicates which sink originated the signalling message;
- *Number_of_hops*: distance traveled in hops from the sink which originated the message to the current sensor node;
- *Predecessor_node*: identifies the node from which *X* node received the message;
- *Last_sequence*: identifies the signalling message. Every time sinks need to reconstruct the routes, a new signalling message is generated and the field *Last_sequence* will be incremented, so that the nodes may distinguish the current message from the messages sent previously.

If a given node *Y* receives a signalling message whose value of the field Predecessor_node is different from some of the neighbor nodes that it uses as the current route it will disregard this message discarding it, so as to save resources of the sensor node such as: processing, storage and energy used. Figure 2 illustrates a situation of signalling message discard in which the network interconnection has already been established at

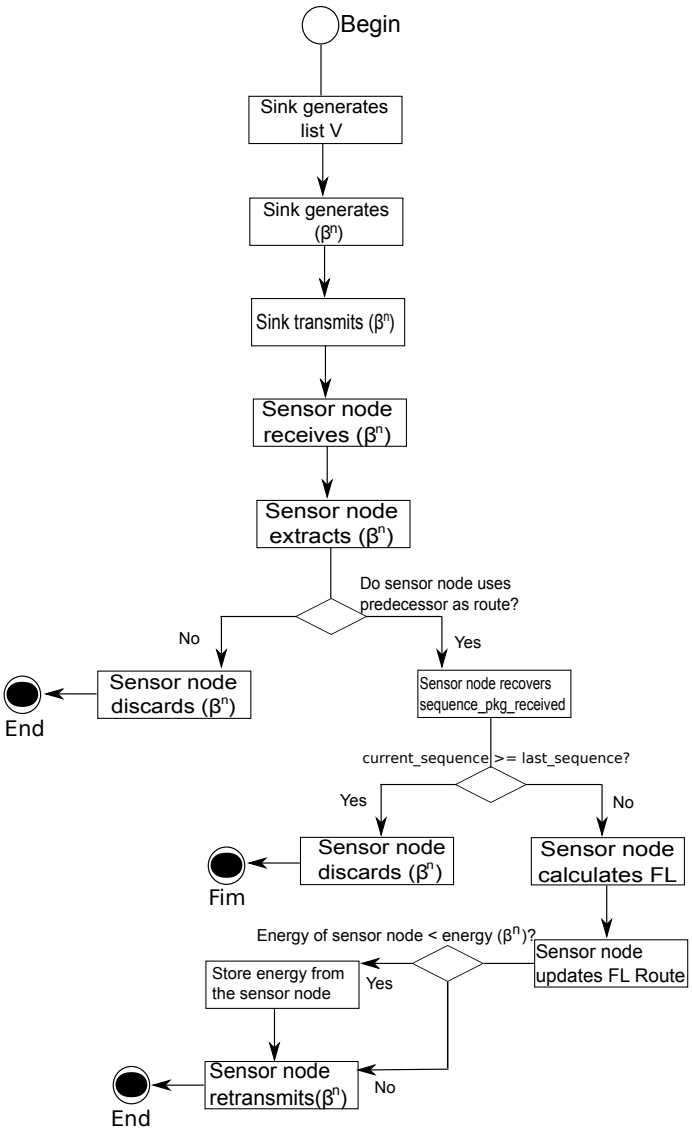

Fig. 1. Flowchart that represents the algorithm.

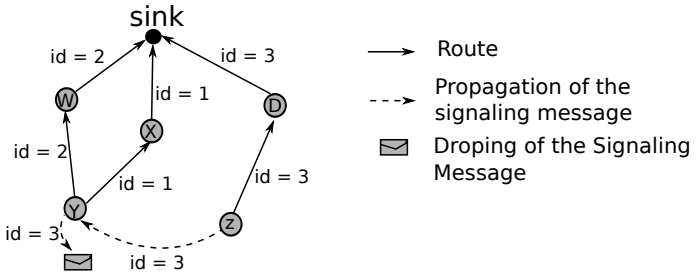

Fig. 2. Droping of the signalling message.

the boot by the routing algorithm used and the sensor nodes have multiple routes. Thus, the sensor node *Y* has two routes to reach the sink node established through the nodes *X*, id = 1 and *W*, id = 2. When the signalling message β^n is transmitted by the sink node, the neighbor nodes propagate the message through the network. Thus, when node *Z* receives the message β^n, it passes it on to all neighbor nodes it can reach, including sensor nodes that are not part of its route, as it is the case of node *Y*, when receiving the message β^n from node *Z* will discard it immediately.

In order to avoid old messages from remaining traveling through the network, some routines are established according to algorithm presented in Figure 1. A given node *X* at receiving a signalling message checks the field Last_Sequence to verify whether it refers to a new signalling message, or if it is only the propagation of a message received previously. The next step is to calculate the fuzzy level (FL) associated with each route. This parameter allows the node to select the best route at a given moment, according to the last signalling message received. For each route that a node may use, there is an FL associated with it. Routes with higher FL value are regarded as preferential. The FL value is obtained through Mamdani's fuzzy inference model, whose entries correspond to the values of energy and number of hops. Finally, node *X* tests if its energy is lower than the energy contained in the received message, if so, it updates the field energy signalling message with the value of its remaining power, if not, it goes to the next step and relays the message over the network.

In our work, we consider that each sink node will send signalling messages β^n periodically to the network, in order to update the FL of each route set up by the routing algorithm. Thus, there will be a better use of the energy of the sensor nodes, in that the routes are chosen at each transmitted signalling message. We call α window the period in which signalling messages are transmitted. The value attributed to α cannot be very small so that the network is overcharged with the constant transmission of signalling messages nor can it be a value large enough to affect the choice of routes. Details related to the α value determination will be submitted in section 7.

IV. Genetic Fuzzy System

A. Fuzzy Inference Systems

Fuzzy Inference Systems are able to handle very complex processes, based on imprecise, uncertain and qualitative information. Fuzzy Inference Systems are very suitable for modelling complex systems where it is very complicated to describe the system mathematically. Generally, the fuzzy inference systems are based on linguistic rules of type "if ... then" in which the fuzzy set theory [24] and the Fuzzy Logic [25], [26] provide the mathematical basis.

In general, fuzzy inference systems operate based on three steps: Fuzzification, inference procedures, and defuzzification. In fuzzy inference systems, generally, non fuzzy (quantitative, accurate, crisp) inputs are taken into consideration, derived from observation or measurement, which is the case of most practical applications. Fuzzification is a mapping of the domain of the entrance variable to the fuzzy domain, representing the attribution of linguistic values defined by membership

functions to the input variables of the Fuzzy Inference System. The fuzzy inference procedure is responsible for evaluating the primary terms (linguistic labels) of the input variables applying the production rules so as to obtain the value of the fuzzy output from the inference system. Once the fuzzy output set has been obtained at the step of defuzzification an interpretation of that information is made. This step is necessary because in practical applications, quantitative outputs are generally required. Defuzzification is typically used to assign a numeric value to the output fuzzy set.

B. Genetic Algorithms

Genetic Algorithms are search and/or optimization algorithms based on the mechanisms of genetics and natural selection. Their operation follows biologic inspiration, which presupposes that in a given population individuals with "good" characteristics are more likely to survive and to beget even stronger individuals (fit), while the less fit individuals tend to disappear during the evolutionary process. When using GAs, each individual of the population, called chromosome, represents a potential solution to the problem to be solved. Each piece of the chromosome is called the gene. GAs emphasize combination of the most promising candidates for the solution of the problem. This combination of the fittest individuals is obtained through the application genetic operators that manipulate the genetic composition of chromosomes in order to explore and to exploit the search space so as to find better solutions to the problem. The genetic operators mentioned are computational aproximations of phenomena seen in nature, such as genetic mutation and sexual reproduction.

Though apparently simple, in part due to their bioinspired foundation, GAs are able to solve complex problems in very elegant way. Moreover, they are not affected by suppositions about differentiability or continuity of the objective function of the problem, in that GAs do not use information from derivatives in the evolutionary process, nor do they need information about the individuals' neighborhood. This implies that GAs can be very appropriate to deal with problems with non-differential and non-continuous functions. In addition, GAs differ themselves from randomic search and/or optimization techniques, since they apply the fitness index, which is important information relevant to the search space obtained by the use of the evaluation function.

C. Genetic Fuzzy System Implementation Aspects

The implemented fuzzy inference system has two input linguistic variables, Energy and number of hops, and a output linguistic variable, the Fuzzy Level (FL). The syntax of the rules of the fuzzy system is represented by the following linguistic conditional declarations:

- Rule 1: If (Energy is A_1) and (Number of hops is B_1), Then (FL is C_1) or
- ...
- Rule n_r: If (Energy is A_p) and (Number of hops is B_q), Then (FL is C_r)

where: n_r is the number of rules; A_j, B_k, C_l are the primary terms (linguistic values) associated with the linguistic variables, Energy, number of hops and FL, respectively; *p*, *q* and *r* correspond to the number of primary terms of the linguistic variables Energy, Number of hops and FL, respectively.

Thus, we have a Mamdani's fuzzy system, consisting of N_r disjunctive inference rules. The rules are inferred in a parallel way, without considering the order in which they are implemented. The inference of each rule consists of the evaluation of the antecedent, followed by the application of the implication operator to determine the consequent fuzzy set. The defuzzification procedure obtains the FL's numeric value. The implication operator used was Mamdani's minimal operator; the aggregation of the consequents was performed by the maximum operator and the defuzzification method employed was the area center method (or centroid method) [27], [28].

The approach adopted in this paper proposes the use of GAs to determine the number of primary terms for the linguistic variables, the adjustment of the membership functions associated with each primary term, and the set of linguistic rules of Mamdani's fuzzy system, simultaneously.

The first aspect to be considered in the use of GAs for the solution of a problem is the chromosomal representation of the problem, so that the GAs can solve it appropriately [17]. In this study the chromosomes have information related to the number of primary terms and the membership functions of the input and output linguistic variables, as well as information on the rules bases of the fuzzy inference system.

The chromosome structure to store the parameters of the fuzzy inference system was divided into three parts. The first part codifies the amount of primary terms of the linguistic variables. This part of the chromosome has 9 bits, where each set of 3 bits represents the number of primary terms of a linguistic variable. The second part stores information of the fuzzy rules base. According to experience of authors in relation to the behavior of WSNs, the top number of primary terms of each linguistic variable was defined as being equal to 5, and the amount of rules is then set by a multiplication between the numbers of primary terms of the input linguistic variables (Energy and Number of hops). Thus, the maximum number of rules in the system is equals to 25. Therefore, the second part is represented by 75 bits, and each set of 3 bits represents the primary term associated with a rule of the inference system. The third part codifies the parameters of the membership functions of each linguistic variable of the system. As membership functions have continuous parameters that require a great precision, the representation of the chromosome by real numbers was adopted [29], instead of binary representation [30] used in the two first parts. The membership functions used for the linguistic variables are triangular (Figure 3).

However, instead of the chromosomes storing the values a_i, m_i and b_i for each membership function, they store the adjustment coefficients (parameters) δ_i and η_i. Each membership function i can be assembled from the following equations [31]:

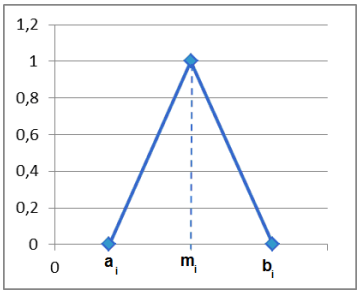

Fig. 3. Triangular membership function.

- $a_i = (a_i + \delta_i) - \eta_i$;
- $m_i = (m_i + \delta_i)$;
- $b_i = (b_i + \delta_i) + \eta_i$.

The coefficient δ_i is responsible for moving the membership function to the right or to the left, while the coefficient η_i can expand or shrink the support of the membership function [28] in relation to its universe of discourse. As each linguistic variable has 5 primary terms at most, and each membership function associated with a primary term is represented by the two parameters δ_i and η_i, 10 genes, at most, are necessary to represent the membership functions of a linguistic variable of the applied fuzzy inference system. Therefore, the third part of the chromosome has size 30. As each chromosome stores the information about the parameters of the inference fuzzy system (fuzzy database and fuzzy rule base), we have one chromosome of 114 (9 + 75 + 30) genes. The GA implemented has adopted a population of 80 individuals (chromosomes).

After the chromosome representation definition, the GA design focuses on the specification of an evaluation function. Since the goal of the fuzzy system is to help the routing algorithm choose the best way to communicate between the sensor nodes and the sink nodes, this work employed the time it takes for the first sensor node of the network to die as evaluation function. Therefore, this is a maximization problem whose objective is to tune the Mamdani's fuzzy inference system that selects the best routes to maximize the lifetime of the network.

After the attribution of the fitness index by the evaluation function, the selection process chooses a subset of individuals of the current population to compose an intermediate population in order to apply the genetic operators. The selection method adopted in this work was the tournament method. It is worth mentioning that the size of the adopted tournament was set equal to 2. In combination with the selection module an elitist strategy was used with the maintenance of the best individual from one generation to the other.

To evolve the population go through an evolution one should apply the genetic operators (crossover and mutation). Crossover is the process for sharing information through of the exchange of portions (genes) of the parent chromosomes. The crossover operator has always been considered as the primary search operator in GAs because it exploits the available information from chromosomes about the search space. As this operator combines the features of parent chromosomes to form offsprings, it is highly probable that good chromosomes may generate better ones. Therefore the crossover can be considered one of the main components for improving the behavior of the GA [32]. In this study, we used discrete crossover [33]. The mutation genetic operator [34] is necessary to introduce and maintain genetic diversity of the population through randomic changes of genes within the chromosomes, what provides a means for incorporation of new genetic characteristics within the population. Therefore, mutation ensures the possibility of reaching any point of the search space, besides to avoid to get trapped in local minima. However, mutation is applied less frequently than crossover in order to preserve the exploration-exploitation-relationship [35].

Several criteria may be applied to finalize the execution of a GA. In this work the maximum limit of generations fixed in 100 interactions was adopted as stopping criterion.

As a result of the GAs operation in the adjustments of fuzzy systems, Figures 4 and 5 show the membership functions associated with the linguistic variable energy and number of hops.

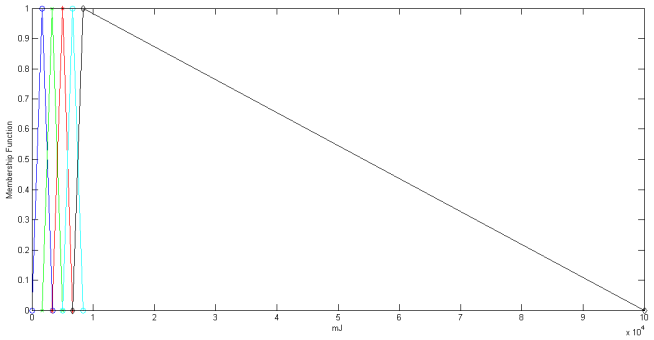

Fig. 4. Membership function of the energy variable.

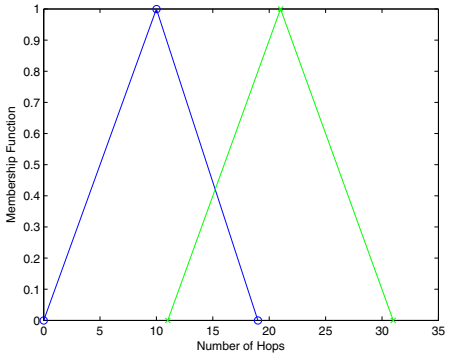

Fig. 5. Membership function of the number of the hops variable.

V. Simulation

This section presents comments about the simulations carried out to validate the routes selection algorithm using the implemented Genetic Fuzzy System.

A. Simulator

In our experiments, we use the Sinalgo simulator [36]. Sinalgo is a framework implemented in Java language, for testing and validating the networks algorithms. Contrary to other tools such as the *Network Simulator* 2 [37], which allows the simulation of networks in several layers of the protocol stack, our approach focuses the use of Sinalgo to verificate the efficiency of the algorithms to selection of routes.

B. Network Characteristics

The main characteristics of the network are:

1) Topology: the simulated network is steady and includes only two types of nodes: sink nodes and sensor nodes. The sensor nodes have similar characteristics, featuring a flat network, where each node of the network has a single identifier and steady radio range.
2) Scenarios used: in our simulations we used four scenarios with similar environment. All scenarios are usually composed of 100 sensor nodes distributed uniformly throughout the network and for the scenarios that use multiple sinks we used 4 sink nodes located at the end of the network initially, with a range area of 700 m x 700 m. We configured a sensor node located in the center of the network to transmit packets continuously at a ratio of one packet per second in the four scenarios.

Next we describe the simulated scenarios:

- Scenario 1: in this scenario we used the Directed Diffusion routing protocol in its traditional form, without the use of fuzzy inference systems and without multiple sinks.
- Scenario 2: we used the Directed Diffusion routing protocol with multiple sinks and applyed the load balancing among the existing multiple paths. It is important to emphasize that we did not use Fuzzy Inference Systems.
- Scenario 3: the application through Mamdani's fuzzy inference system influences the routes formation through the Directed Diffusion protocol, in order to choose the best route to one of the sinks. Nevertheless, the design of the fuzzy inference system is made in an empiric way, in which the adjustments of the fuzzy database and the fuzzy rule base are made manually, based on tests with various different configurations.
- Scenario 4: just as in scenario 3, the application through Mamdani's fuzzy inference system influences the formation of routes through the Directed Diffusion protocol, in order to choose the best route to one of the sinks. However, in this scenario, the parameters of the fuzzy inference system are not adjusted empirically anymore, but by using Genetic Algorithms, characterizing the approach as fuzzy-genetic.

C. The Routing Algorithm

For the communication of the nodes with the sinks, we used the Direct Diffusion routing protocol, which is designed for wireless sensor networks, where the network designer is responsible for defining the type of event that should be observed by the sensor nodes and the area of interest.

VI. Results and Discussions

The results of the proposed approach application are presented based on three metrics. The metrics are:

- First node death time: it expresses the death time of the first node in the network. Here, we intend to analyze how long sensor nodes remain living;
- Network death time: it records how long the network remains alive, that is, how long the network will be able to keep the necessary communications active.
- Sink nodes number: in this metric, we evaluate how the amount of sink nodes influences our work;

Although our solution is aimed at environments with multiple sinks, we firstly analyzed the network behavior through simulations in the same scenarios described in section V using only one sink node, as illustrated by the figures 6 and 7. We conducted these experiments with the purpose of verifying the feasibility and efficiency of the proposed solution, since an environment with a single sink did not receive satisfactory results, possibly the realization of these simulations environments with multiple sinks would be unsatisfactorily similar.

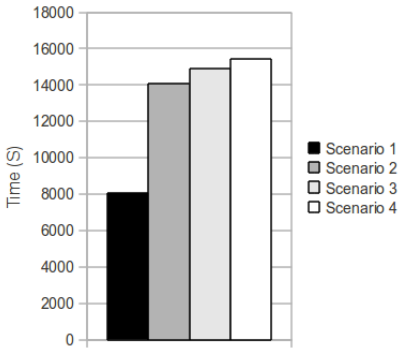

Fig. 6. Death time of the first node of the network.

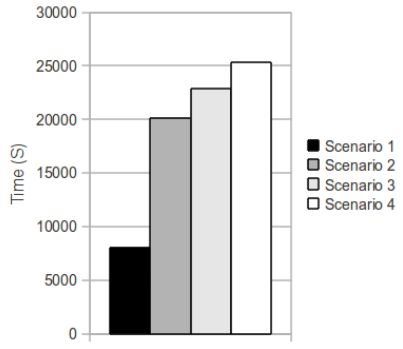

Fig. 7. Death Time the Network.

We also evaluated the behavior of the sensors in a WSN with multiple sink nodes for each scenario according to the three metrics addressed. For the first metric, first node death time

in the network, we can see from Figure 8 that in scenario 1, where we used the Directed Diffusion protocol in its traditional form, without the use of fuzzy inference systems and without multiple sinks. The results showed weakness in the lifetime of the network, where a sensor node participates actively in a route in use. In scenario 2, without using Fuzzy Inference Systems, with multiple sinks and the usage of load balancing. We obtained an improvement of approximately 11% compared to scenario 1. In scenario 3 we have a solution that uses fuzzy inference systems adjusted empirically, associated with the use of multiple sinks. In this scenario, the gain compared with scenario 1 is approximately 234%. Finally, in scenario 4 we have the representation of the proposed solution that uses a genetic fuzzy system and multiple sinks in which the gain when compared with scenario 1, approaches 373%. This gain was due to the use of multiple sinks, increasing the number of routes each node can use for the transmission of data over the network and the use of the genetic fuzzy system which makes the node avoid the bad routes (low energy, long distances).

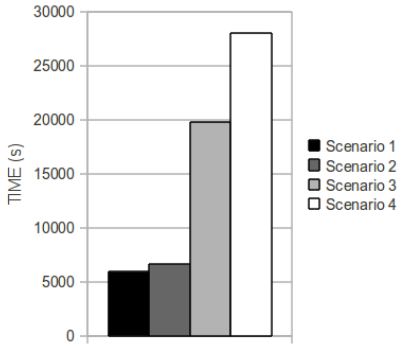

Fig. 8. Death time of the first node of the network.

We represented in Figure 9 the network death time, time when the network communication is discontinued due to the death of some sensor nodes that compose the routes of the sender. In the column representing scenario 1 (without fuzzy inference system and without multiple sinks), we have that the network death time corresponds to the network's first node death time because this network does not have multiple routes and multiple sinks. In scenario 2, due to load balancing across multiple paths to network remains active around 104% more than scenario 1. In scenario 3, the network remains active for a long period of time. Approximately 478% higher than the scenario 1, this gain was achieved by using multiple routes, associated with the use of empirical fuzzy inference in the best routes selection process at a certain moment. The great difficulty encountered in this simulation scenario was due to the empirical adjustment of the inference system that consumed much time, in that they were carried out based on trial and errors. Still, it was not possible to firmly tell whether the chosen parametres of fuzzy inference system were the best. We obtained in scenario 4, an uptime of the network higher than all simulated scenarios; about 541% higher than scenario 1, this gain was promoted through the use of genetic fuzzy system and multiple sinks.

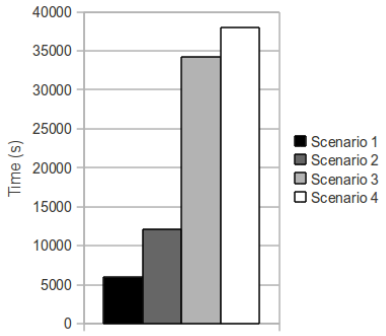

Fig. 9. Death Time the Network.

VII. α Window

As mentioned previously, in our algorithm, we consider that each sink node waits for an α time window to send signalling messages so that the sensor nodes update their fuzzy levels.

We conducted simulations with different α values and we evaluated the performance based on the network's first node death time (Figure 10). We could realize that the values close to the desired are between 800 and 900 seconds.

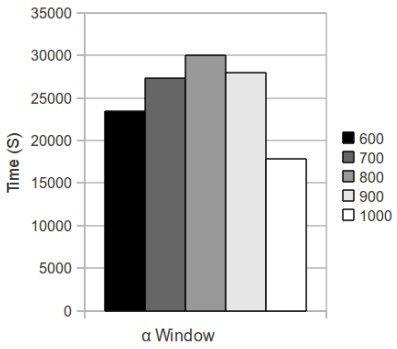

Fig. 10. Window α.

VIII. Conclusions

This paper proposes a fuzzy genetic system-based algorithm for the selection of routes in WSN with multiple sinks. Fuzzy inference systems of Mamdani are used to determine the most appropriate sink node through consideration of some characterstics of the sensors network, such as energy and number of hops. However, the optimal design of a Mamdani's fuzzy inference system is a complicated task due to some characteristics of the search space. Generally, this search space is characterized as infinitely large, nondifferentiable, complex, noisy, multimodal and deceptive. These characteristics induce the authors to apply Genetic Algorithms on tuning of Mamdani's fuzzy inference system. The main objective of the algorithm is to extend the network's lifetime which can be achieved by making the nodes avoid bad routes during the sending of packets through the network. For such, we applied

fuzzy inference systems in order to build a knowledge base which makes the process of finding the best routes possible.

Results obtained through simulations, demonstrated that our approach is feasible increasing the network's lifetime satisfactorily. In future works we intend to analyze the behavior of algorithms in more complex scenarios, as well as select new linguistic variables for the fuzzy inference.

When you opt for a fuzzy inference system to determine the selection of routes in a wireless sensor network with multiple sink nodes, you have an action/control strategy that can be monitored and interpreted, even from the linguistic viewpoint. Another advantage found in using fuzzy inference systems during the development of this work refers to the inclusion of the authors' experience in the definition of some parameters of the implemented fuzzy system. That experience could be used directly to aid the construction of the rules base and the initial definition of the primary terms (fuzzy sets) of the linguistic variables.

Abstract— **Oscar is a conversational intelligent tutoring system (CITS) which dynamically predicts and adapts to a student's learning style throughout the tutoring conversation. Oscar aims to mimic a human tutor to improve the effectiveness of the learning experience by leading a natural language tutorial and adapting material to suit an individual's learning style. Prediction of learning style is undertaken through capturing independent variables during the conversation. The variable with the highest value determines the individuals learning style. This paper proposes a new method which uses a fuzzy classification tree to build a fuzzy predictive model using these variables which are captured through natural language dialogue Experiments have been undertaken on two of the learning style dimensions: perception (sensory-intuitive) and understanding (sequential-global). Early results show the model has substantially increased the predictive accuracy of the Oscar CITS and discovered some interesting relationships amongst these variables.**

Keywords- Fuzzy classification tree, conversational agent; intelligent tutoring systems;

I. INTRODUCTION

Intelligent Tutoring Systems (ITS) are computer-based educational systems which employ intelligent technologies to provide individualised instruction [1]. In order to personailise the students learning experience, a number of factors can be used such as user affect, such as emotion [2], personality [3] and learning style [4]. Learning styles recognise that people have instructional preferences in how they absorb and process information. One of the most established learning style models is known as the Index of Learning Styles model (ILSM). ILSM was proposed by Felder and Silverman [5] to describe the learning styles in engineering education and suggested different teaching styles to address learners' needs. Each person has their own learning strategy for learning specific subject matter in a particular context [5]. If the teacher knows the students' learning styles then delivery of a subject can be adapted.

Existing ITS capture learning styles using a formal questionnaire [6], [7] or by analysing a student's behaviour within the ITS [8], [9]. The main problem with questionnaires is that they are time consuming and onerous and people do not tend to complete them accurately. Predicting learning style using a history of student behaviour means adaptation is delayed until several modules have been completed, and also a student's learning style may change over time or for different topics. EDUCE [10] and WELSA [11] both estimate learning style dynamically for curriculum sequencing, but do not include a conversational interface or incorporate other intelligent tutoring technologies.

Most ITS do not have a natural language interface but rely instead on navigation around the tutoring material through buttons and hyperlinks. This is due to the fact that conversational interfaces are complex to develop [6..11]. However, to adequately mimic a human tutor, an ITS should support the construction of knowledge through discussion [12]. One way of providing a natural language interface is through the incorporation of a Conversational Agent (CA) [13]. A CA uses natural language dialogue to communicate with users [14] and will have the ability to reason and pursue a course of action based on its interactions with humans and other agents. Some work has been done in incorporating CAs with ITS but this has been to help the learning management system, rather than undertake a tutorial with a learner [15,16]. AutoTutor [16] is a conversational intelligent tutoring system (CITS), which helps students construct knowledge about computer literacy and physics. CIRCSIM-tutor [16] engages students in discussion to solve physiology problems. Discussions that take place in either system do not consider learning styles during tutoring. Knowledge of an individual's learning style is essential when developing a CITS which can adapt its teaching style to individual learner preferences [12].

Oscar is a CITS that dynamically predicts learning style throughout the tutoring conversation and adapt its intelligent tutoring style to suit an individual's learning style [12]. Prediction of learning style occurs during the conversational tutoring session by capturing the values independent variables. The variable with the highest value determines the individuals learning style in accordance with the Index of Learning Styles Model (ILSM) [5]. The current method has had some degrees of success but its fundamental weakness is that it does not consider the relationships between these variables in predicting the learning style.

Fuzzy models have been developed for educational learning since 1996 when Hawkes and Derry [18] proposed

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

a model that captured the way in which human tutor's evaluated borderline tutoring decisions in accordance with student behavior. One of the most recent areas of research is in making learning object recommendations for a specific domain based on an individual's learning style [19..22]. In [20] a fuzzy inference system comprising of six rules is applied to a recommender system in order to assign a student a suitable learning object in the field of computer networks. Cabada et al [21] used a combined fuzzy-neuro approach to recommend learning objects. The approach learns student behavior based upon types of tutoring materials students have previously used and their learning styles. In [22] a fuzzy-neuro approach was used to infer the learning characteristics of a student in an interactive learning environment. This method was used to obtain an optimal learning path both instructor and learner through the tutoring domain. Whilst each of the above systems have shown degrees of success using small experimental groups none attempt to predict the learning style through obtaining variables captured through natural language dialogue which occurs naturally through a tutoring conversation.

This paper proposes an approach to modeling these variables using fuzzy classification trees in order to improve the predictive accuracy. The concepts of fuzzy decision trees are well established [23..27].The main features of fuzzy trees, compared with crisp trees, are the gradual transitions that exist between continuous attribute values and the inference process that allows all branches within the tree to be fired to some degree. Existing methodologies for creating fuzzy trees present different approaches on how to determine fuzzy regions at nodes within the tree [28] and the fuzzy inference strategy which is applied [23-24]. In this paper, a modified version of the Fuzzy Inference Algorithm (FIA) [24] is used to produce a fuzzy predictive model using variables extracted through natural language dialogue during the tutoring conversation.

The paper is organized as follows: Section II describes Oscar, the conversational intelligent tutoring system used within this paper. Section III describes the modified FIA and how it has been applied to the learner's data set. Section IV explains the experimental process which was undertaken on two of the learners dimensions: perception (sensory-intuitive) and understanding (sequential-global) [5]. Finally section V presents the results and discussion.

II. OSCAR: A CONVERSATIONAL INTELLIGENT TUTORING SYSTEM

The Oscar CITS is a conversational intelligent tutoring system designed to dynamically predict a student's learning style during a tutoring conversation, and to adapt the tutoring style to suit the individual learner [17]. Oscar's pedagogical aim is to provide the learner with the most appropriate learning material for their learning style leading to a more effective learning experience and a deeper understanding of the topic. Rather than being designed with the purpose of picking up learning styles (such as [5]), the Oscar CITS attempts to mimic a human tutor by leading a two-way discussion and using cues from the student dialogue and behaviour to predict and adapt to their learning style. Oscar's natural dialogue interface and classroom tutorial style are intuitive to learners, enabling them to draw on experience to feel more comfortable and confident in using the CITS. Oscar CITS is a personalised tutor which can answer questions, provide hints and assistance using natural dialogue, and which favours learning material to suit each individual's learning style. The Oscar CITS offers 24-hour personalised learning support at a fixed cost. Oscar's intelligent approach includes presenting learning material in the sequence and style most suited to the individual's learning style (curriculum sequencing [15]), analysing and giving feedback on incomplete and erroneous solutions (intelligent solution analysis [29]) and giving intelligent hints and discussing questions (problem solving support [30]). By combining all three intelligent technologies with a conversational interface, Oscar's intelligent support aims to build the confidence of the learner and improve motivation and deep understanding of the subject.

A. The Index of Learning Styles

In their Index of Learning Styles (ILS) model [5], Felder and Silverman described the learning styles in engineering education and suggested different teaching styles to address learners' needs. The ILS model defines four separate dimensions of preferred learning style, each relating to a step in the process of receiving and processing information as follows:

- *Perception* – this dimension categorises learners as *sensory* (SNS) or *intuitive* (INT) and relates to the type of information a student prefers to perceive (e.g. external, by observation (sensory) or internal, by speculation (intuitive)).
- *Input* – this dimension classes learners as *visual* or *verbal* by considering the way in which learners prefer to receive external information (e.g. by looking at diagrams (visual) or by listening to explanations (verbal)).
- *Processing* – this dimension groups learners as *active* or *reflective* according to the way perceived information is converted into knowledge (e.g. by the active discussion (active) or introspective consideration (reflective) of a topic).
- *Understanding* – this dimension categorises learners as *sequential* (SEQ) or *global* (GLO) depending on the way they progress towards understanding (e.g. by continual steps (sequential) or holistically in large jumps (global)).

Learning styles are central to the decision making within Oscar CITS. Following an initial study, a subset of the best ILS predictor questions for each learning style dimension was identified [31] and this was used to generate tutoring material for each learning style within Oscar.

For the purpose of this work, a conversational tutorial on structured query language (SQL) was developed. The target audience for the pilot study would be undergraduate computing students, for whom a Databases course including SQL is compulsory. Tutoring revision scenarios were designed based around the syllabus and the database

lecturers' experience of revision tutorials. Each revision question was mapped to the ILS model using the model's descriptions of indicative behaviour, such as a preference for theoretical questions.

B. Prediction and Adaptation

The Oscar CITS aims to mimic a human tutor by using knowledge of learning styles and cues from student behaviour to predict individual learning style. During a tutorial, information is recorded about learner behaviours and then used to predict learning style. The experiments reported in [12, 31] compared the results of the formal ILS questionnaire to student behaviour to compute an accuracy of prediction based on 17 hypotheses. Three of the 17 hypotheses are shown as an example below.

H1: a student's learning path through the tutorial is indicative of learning style.

H2: choosing to be guided through a process (or not) is indicative of learning style.

H3: The amount of discussion a student enters into with the tutor is indicative of learning style.

The variables with the best accuracy for an ILS dimension are then used to predict student learning style and adapt the tutoring style accordingly.

Oscar CITS uses an algorithm to determine the best adaptation for each tutoring question based on the student learning style strengths. The algorithm is fairly complex in that it considers all four learning style dimensions. Rather than simply adapting to the strongest student learning style, the algorithm separately considers each question and its ability to adapt for certain learning styles as well as a student's learning styles. This allows for tutorial questions where it is not possible to include adaptive learning material for all learning styles, as occur in real life. The development of the adaptive Oscar CITS is reported in [17].

Figure 1 shows two examples of logic rules used by the system to increment learning style values during tutoring. Learning styles are held in eight values within the student model, representing each pole of the four dimensions (perception (sensory-intuitive), input (visual-verbal), processing (active-reflective) and understanding (sequential-global) [17].

1. Example rule to test whether presenting information visually helps the student's information perception:

```
IF    student does not know the answer
THEN show student image/diagram;
IF    student shown image/diagram
AND   student gives correct answer
THEN increase VISUAL;
```

2. Example rule to test how comfortable the student is with words and with detail:

```
IF    answer is given in the explanation text
AND   student does not know the answer
THEN increase INTUITOR
AND   increase VISUAL;
```

Fig. 1. Example of logic rules used to adjust student learning style based on tutoring conversation

C. Conversational Agent and Dialogue Design

Oscar was developed using a type of conversational agent (CA) known as a goal-orientated conversational agent (GO-CA) [13]. GO-CA's are a specific family of conversational agents that are designed to converse with humans through the use of natural language dialogue to achieve a specific task. In this case to act as an intelligent tutor to guide the learner through the tutorial based upon their learning style. The GO-CA used in this work utilised pattern matching algorithms to capture the values of specific attributes through dialogue interaction with a user. This is achieved through the use of scripts which contain sets of rules about the domain (SQL) and a knowledge base to guide the conversation towards achieving a specific goal (Oscar adaptation rules). In the Oscar CITS, the dialogue for each tutorial was scripted using Convagent's GO-CA [19]. Overall, there were 38 contexts containing around 400 rules. The full architecture and methodology for developing Oscar CITS is described in [32]. Throughout tutoring, the CITS records and logs information about the behaviour of the student, such as timing of interactions, the number of words used, the number of times FAQs are asked and the type of tutor resource accessed. The tutoring conversation is also recorded, along with information about the student knowledge of the topic being discussed and the adaptation employed.

Figure 2 shows a screenshot of the Oscar CITS user interface showing a user interaction where the student is being asked to write an SQL query with the results limited by two values. Oscar is guiding the student through each step of writing the query. The chat window shows the student's previous utterance, which is incorrect, and Oscar's response, followed by a reminder of the question. An image relevant to the stage of the query is shown to the right, and movies pop up in a new window if appropriate. Oscar's response helps the student by hinting at the solution by recommending an approach to writing the WHERE clause, rather than simply showing the answer. By adopting the constructivist style of teaching like human tutors, Oscar endeavors to provoke a deeper understanding of a topic.

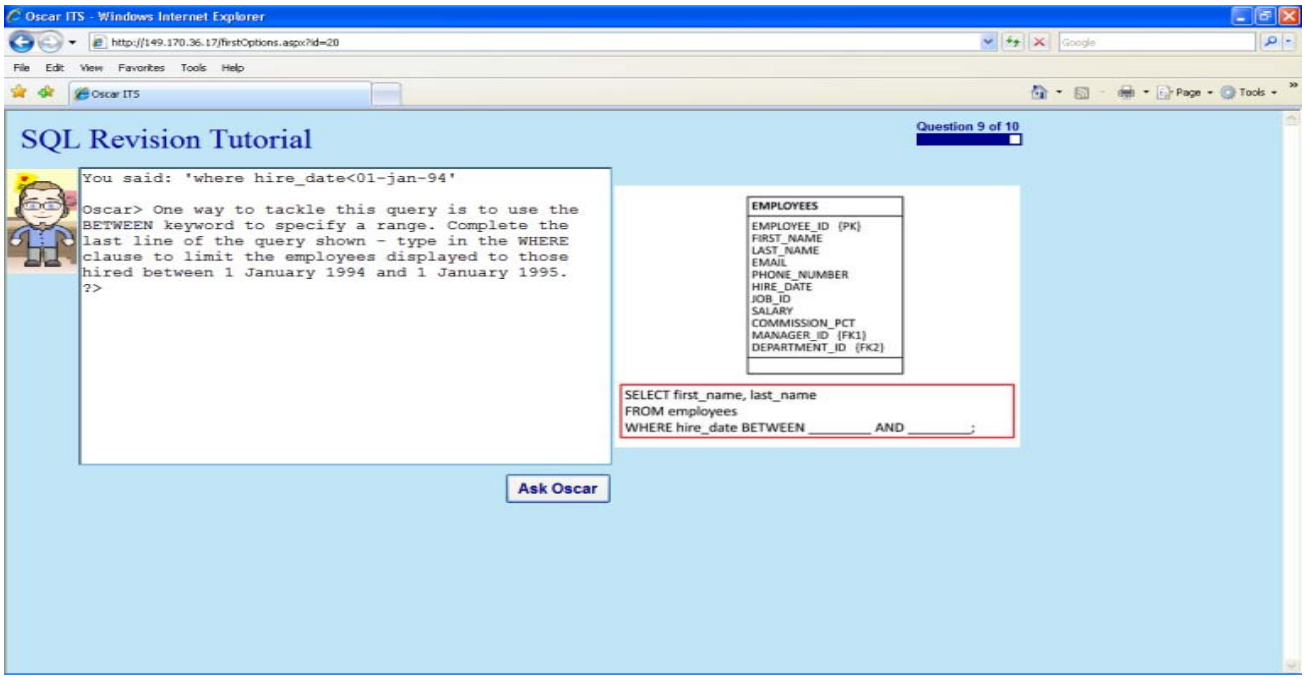

Fig. 2. Oscar CITS

D. *Example Learner Dialogue*

Table I shows part of a student's tutoring dialogue logged during experiments used for this work. In utterance 33, Oscar continues a question about data types. The student gives the wrong data type in utterance 34, and next Oscar indicates that the answer is wrong and gives the student a second chance to answer in case of spelling errors, repeating the question. In utterance 36 the student tries again, still with the wrong answer. Oscar gives feedback that the answer is wrong (utterance 37), and helps by showing an image of the most common data types to see if the student is able to pick out the required answer. In this action, Oscar is helping the student learn by reminding them of the common data types and asking them to think about the correct data type rather than simply telling them the answer. In utterance 38 the student enters the correct data type, extended to include the decimal places, and Oscar then confirms that they have the right answer and repeats the solution to reinforce the knowledge.

TABLE I. EXAMPLE TUTORING DIALOGUE SNIPPET LOGGED DURING THE EXPERIMENT.

Utterance	Dialogue
33. Oscar>	Now, in our books table suppose we want to store the price of the book where the maximum price of a book is 99.99. What would be the datatype?
34. Student>	VARCHAR2
35. Oscar>	I'm sorry, that's wrong. Check your spelling and try again - type in the datatype for book price (with a maximum of 99.99).
36. Student>	VARCHAR2 MAX 99.99
37. Oscar>	That's still wrong. Take a look at the table of common datatypes - can you now type in the datatype for book-price where the maximum price is 99.99?
38. Student>	NUMBER(2,2)
39. Oscar>	That's correct - we need a datatype of NUMBER(2,2) in order to show the decimal point in book-price, with a maximum of 99.99.

III. GENERATING FUZZY CLASSIFICATION TREES

Previous work [23,24,28] has shown that the generation of a fuzzy classifier from crisp induced trees produces a generalized and robust rule set without the need for human expert intervention during the fuzzification process. For the purpose of this paper the fuzzy classification trees will be constructed using the FIA algorithm [24] which will now be briefly described. FIA is an algorithm designed to build fuzzy classification trees from raw datasets. One of the strengths of the algorithm is that no pre-fuzzification of the data is required. FIA provides a mechanism for the direct fuzzification of both discrete and continuous attributes and the ability to use any T-norm/ T-conorm pair for determining fuzzy inference

A. *Fuzzy Inference Algorithm (FIA)*

A high level description of the stages of FIA is as follows:

1. Generate a crisp classification decision tree using pre-defined pruning criteria (in this work Quinlan's C4.5 decision tree algorithm was used [32]).
2. For each node, *i* within the tree identify whether discrete or continuous attributes and define an opposing membership function pair. Each membership function will have an associated domain (dm_i, dn_i) whose scope is determined by the attribute at that specific branch which is defined as

$$dm_i = dt_i - n_j\sigma_i \quad \text{and} \quad dn_i = dt_i + n_{j+1}\sigma_i \qquad (1)$$

Where σ_i is the standard deviation of attribute *i*,

n is a real number $n \rightarrow [0,5]$ used to extend fuzziness

across the domain of the attribute,

dt is the decision threshold and

dm and *dn* are the lower and upper bounds respectively of membership function *i*.

3. Select T-norm pair with inference strategy.

Let a set of data ***S*** consist of ***i***-attributes $\{A_1,A_2....A_i\}$ of domain D which are used to describe a single object. The process of learning from ***S*** involves a transformation function ***F*** which accepts as input ***S*** and produces a defuzzified outcome ***O***, which is a mapping

$$\boldsymbol{F(S) \rightarrow O} \tag{2}$$

Applying an inference technique onto an existing tree consisting of ***x*** branches involves the combination of ***V*** membership function values $\{\mu_1, \mu_2,...\mu_v\}$ of all root to leaf node paths. Let ***T*** be a set of all possible outcomes $\{t_1,t_2,..t_y\}$ defined from an existing crisp tree where ***y*** is the total number of outcomes. Fuzzy inference of ***S*** will involve an inference mechanism, ***IM*** which consists of an intersection function $f\wedge$, which takes in ***V*** and a t-norm ***TMin*** , which produces a set of minimum outcomes $\{TMin_1,TMin_2.....T.Min_j\}$ where *j* is the number of leaf nodes, and a union function $f\vee$, which combines output from $f\wedge$ to produce a maximum membership grade ***O***. Let $f\wedge, f\vee$ $\boldsymbol{O} \in \{0.0,1\}$ consisting of real numbers, $\Re$.

i. Applying the fuzzy intersection function, $f\wedge$

This involves combining membership grades down all paths, from root to leaves within the tree.

$$f\wedge\ (\{\mu_1, \mu_2,...\mu_v\}) \rightarrow \boldsymbol{TMin}\ \{TMin_1,TMin_2.....T.Min_j\} \tag{3}$$

ii. Apply possibilistic strength of leaf node

The possibilistic strength of a leaf node represents the possibility that an example reaching a leaf node will have the same outcome as the leaf. Let ***P*** be a set of leaf possibilities $\{p_1,p_2...p_y\}$ where ***y*** is the total number of leaf outcomes then

$$f\wedge\ (\{\mu_1, \mu_2,...\mu_v\}) \rightarrow TMin \{(TMin_1*p_1),(TMin_2*p_2).....(TMin_j*p_y)\} \tag{4}$$

Each leaf possibility p_y is applied to the corresponding membership grade at each leaf node $TMin_j$, after the intersection operation has been applied to combine grades of membership down one tree path.

iii. Applying fuzzy union function $f\vee$

The fuzzy union operator is applied in-order to combine the membership grades from all leaf nodes in order to produce a representative final grade of membership.

$$f\vee\ (\{(TMin_1*p_1),(TMin_2*p_2).....(TMin_j*p_y)\rightarrow \boldsymbol{O} \tag{5}$$

O is the fuzzy singleton used to determine the success of correct classification having taken place for ***S***.

4. Interpret and implement the tree as a set of Fuzzy IF-THEN rules. Each rule within the classifier may be defined as:

$$R\,j_1..j_n : IF\ x_1\ is\ A_{1j1}\ .....\ AND\ X_n\ is\ A_{njn}$$
$$THEN\quad y\ is\ b_{\,j1.jn},$$
$$Where\ \ j1 = 1,2,...K_1;\quad jn = 1,2,...,Kn \tag{6}$$

$R\,j_1..j_n$ is the label of each fuzzy if-then rule,
$b_{\,j1.jn}$, is the consequent real number and
K is the number of fuzzy sub-spaces.

5. Optimize membership function and inference weightings (if applicable)

A full description of the original FIA can be found in [24].

B. Defuzzification

The unique characteristics of a specific classification problem will often determine the defuzzification strategy used. The experiments in this paper have been undertaken using discrete outcome data set. In this instance the fuzzy singleton is first used to construct the consequence part of the rule after the min intersection operator has been applied. Each consequence is then combined using the max fuzzy union operator to produce a real valued outcome.

IV. GENERATING A FUZZY DECISION TREE FROM CONVERSATIONAL TUTORIALS

A. Data Set

75 undergraduate university students who had previous experience of SQL completed the formal ILS questionnaire and the Oscar CITS SQL Revision tutorial. During the tutorial their behavior and test scores were logged. Information relevant to the prediction of learning styles was captured in 41 different variables during the tutorial. The value of each variable in table II was determined by a series of logic rules (see Section II, B) being fired during the tutoring conversation. Table II shows all 41 variables within the data set that were captured. Each variable is associated with predicting at least one learning style dimension. For example, one variable, *no_interactions*, captured the number of conversational interactions the user had with Oscar during the session. The variables *Q5_choice* and *Q5steps2* captured the student's approach to writing queries (i.e. whether they try all at once or want to try one step at a time). These two variables along with *Q9_choice* and *Q9_steps2* are indicative of the SEQUENTIAL/GLOBAL and SENSORY/INTUTIVE learning dimensions. Most learning

style dimensions had an approximately even split of students, apart from the Visual/Verbal dimension where most students were Visual. This was not unexpected and in accordance with the ILS model [5] for students studying science and engineering based subjects.

TABLE II. OSCAR DATA SET DESCRIPTION

Variable name	Type	Values / Range	Mean	Standard Deviation
Rules_VIS	Numeric	1 to 11	6.733	2.767
Rules_VRB	Numeric	0 to 11	3.400	2.427

Mean_interact	Discrete	2		
Class	Discrete	2		

B. Experimental Methodology

For each experiment set, stratified 10-fold cross validation was used. For the purpose of this work, experiments were undertaken on two of the learning style dimensions: perception (sensory-intuitive) and understanding (sequential-global). Following the FIA methodology, first crisp decision trees were created from the data set using the statistical chi-square pruning technique with significance levels of 0.1% in order to produced highly optimized crisp trees which would allow good generalization to take place. Figure 3 shows a sample crisp decision tree for the sequential-global learning dimension. Table III, provides a high level description of variables used within the tree in Figure 3.

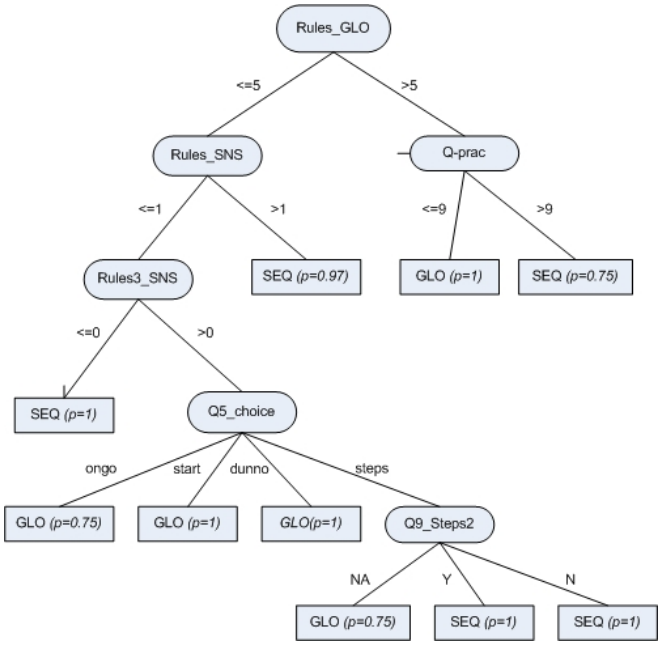

Fig. 3. Crisp tree representing sequential-global dimension

TABLE III. VARIABLE DESCRIPTION

Variable	Description
Rules_GLO	The number of user interactions which mapped to Global logic rules that fired during the tutoring conversation.
Rules_SNS	The number of user interactions which mapped to Sensory logic rules that fired during the tutoring conversation.
Rules3_SNS	The number of Sensory rules that fired during user interaction AND whether the student got the answer right directly afterwards.
Q5_choice	Records the approach taken by the student in the first attempt in answering a complex query (Q5).
Q9_Steps2	Records a change in approach taken by the student during their answer to complex query Q9.
Q_prac	Records the number of correct practical based questions during the tutorial.

Fuzzy membership functions were generated for both discrete and continuous attributes. Initial membership functions were selected to be equivalent to crisp sets with the initial fuzzy classifier system becoming an alternative representation of the decision tree. For experiments reported in this paper the amount of fuzzification either side of each tree node was increased linearly. Figure 4 shows an example

membership function generated from the training data for the attribute RulesSen.

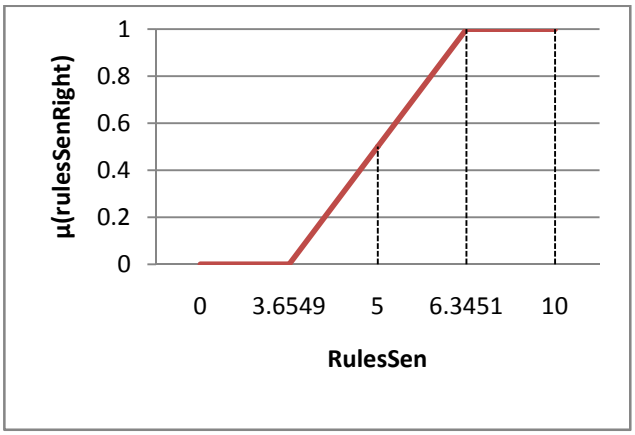

Fig. 4. μ(rulesSenRight)

Using a one-to-one mapping, each tree was then transformed into a set of Fuzzy IF-THEN rules. For example, the tree in figure 3 would be transformed into 10 rules. Zadeh's Min-Max inference technique [33] was to combine grades of memberships of all rules within the fuzzy classification trees. In each experiment, results were generated using 10-fold cross validation. The classification accuracy of the fuzzy classification tree can be defined as

$$F_1 = \frac{\sum_{i=1}^{i=n} \frac{\text{Number of Correctly Classified Records in Class } i}{\text{Total Number of Records in Class } i}}{n} \quad (7)$$

where i = Class i, and n= Number of classes.

Accuracy was measured by comparing the system predicted learning style to the ILS questionnaire result of the same participant.

V. Results and Discussion

Tables IV and V present the results of the sequential-global and sensory-intuitive dimensions respectively using three methods. In each table the average results of 10 fold cross validation are shown. For the sequential-global dimension (Table IV), columns %AVG SEQ and %AVG GLO show the %accuracy of predicting sequential learners and global learners respectively, with the overall prediction accuracy for the sequential-global learning dimension being shown in the %AVG SEQ/GLO column. Table V presents the results for the sensory-intuitive dimension in a similar way. In tables IV and V; OneVar gives the classification accuracy of using one variable predictor to classify the learning style; DT(C4.5) provides the classification accuracy of a crisp decision tree model where multiple variables are combined based upon their effect on the outcome; Fuzzy DT show the results obtained by the fuzzy classification trees generated by FIA.

TABLE IV Sequential - Global

Method	%AVG SEQ	% AVG GLO	% AVG SEQ/GLO
OneVar (Q5choice)	70	59	65
DT (C4.5)	80	70	76
Fuzzy DT	93	83	88

TABLE V Sensory-Intuitive

Method	%AVG SEN	% AVG INT	% AVG SEN/INT
OneVar(Q5choice)	70	59	65
DT (C4.5)	84	80	82
Fuzzy DT	98	73	86

The results in tables IV and V show that in the case of both learning dimensions, when only one variable is used (OneVar); the same variable (Q5choice) was identified as being the most significant in terms of prediction accuracy. An initial observation of the results shows that correlation does exist between the two learning dimensions as sequential people like to learn step by step and sensory people like to go slowly and carefully, whereas global people like to jump straight in and intuitive people are fast and careless. The results in Tables IV for OneVar show that 70% of students who choose to answer the Question 9 query in the tutorial, one step at a time are Sequential learners. Using this variable (Q5choice) the Oscar CITS would predict that students in this group are Sequential learners and be accurate 70% of the time.

The results of inducing fuzzy classification trees yielded some interesting results with regards to the models that were produced. In modeling the sequential-global dimension, the attribute Rules_GLO (representing the number of global related rules that had fired during the conversation) was seen to be the most significant detector of learning style. However, what was surprising was the number of sensory attributes (Rules_SNS and Rules3_SNS) that were also included in the model. This again supported the correlation between sequential-global and sensory-intuitive dimensions.

The results in Tables IV and V also show that combining the attributes from the dataset generates a model which can be used to improve the prediction accuracy of the learner through the conversational agent tutorial. For the sequential-global dimension, the fuzzy classification trees produced gave a 23% improvement over prediction using one variable and a 12% increase over the crisp C4.5 decision tree. For the sensory–intuitive dimension, a 21% improvement was obtained over the one variable predictor and a 4% improvement over the crisp C4.5 decision tree.

VI. CONCLUSION

This paper proposes a new method which uses fuzzy classification trees to build a fuzzy predictive model in order to predict a students learning style through a conversational intelligent tutoring system. Using a dataset of 41 independent variables captured during the tutorial, experiments were carried out on two of the learning style dimensions: perception (sensory-intuitive) and understanding (sequential-global). The results have shown that the fuzzy predictive model has substantially increased the predictive accuracy of the Oscar CITS compared with the one variable predictor currently used within the system. Further work will incorporate the fuzzy predictive model into the adaptive Oscar CITS in order to provide an improved and more personalized learning experience.

***Abstract*—Signal transduction plays an important role in biological organisms. Here, we proposed a method to access the information of the signal transduction ability of signal transduction pathway in the cells. Due to the nonlinear signal transduction pathway model, we have to solve the Hamilton-Jacobi inequalities (HJIs) to get the measurement. Instead of directly solving HJIs, fuzzy interpolation method was employed such that we can systematically measure signal transduction ability by solving the linear matrix inequalities (LMIs). The measurement will provide an insight to the characteristics of the signal transduction networks.**

Keywords-signal transduction ability, fuzzy interpolation, T-S fuzzy model, MAP kinase cascades, linear matrix inequalities (LMIs)

I. INTRODUCTION

Metabolic processes (homeostasis) [1], the growth and differentiation of tissues (endocrine signaling) [2], the synthesis and secretion of proteins (blood clotting, immune-responses) and the composition of intracellular and extracellular fluids (photoreception, olfaction) are all closely related to signaling pathways. It is apparent that signaling pathways are indispensable for life. In general, a signaling pathway is initiated by protein-protein interaction between ligands and receptors. Conformation changes of a receptor usually occurs when a ligand binds to its specific receptor. This change ultimately induces specific cellular responses. Such converting processes from ligand binding to specific cellular response are termed as signal transductions. On molecular level, signaling pathways involve production or degradation of substances, molecular modification and activation or inhibition of chemical reaction. Thus there are many researches on the signaling pathways have focused on signaling molecules, cell-surface receptors, or the second messengers. Besides mass transferring, signaling pathways can be viewed as the information processing and transferring systems [3]. There are also many researches on the properties of signaling pathways, such as amplification [1], specificity, adaption, ultrasensitivity [4], oscillation [4], or synchronization. In this paper, we investigated the amplification of signaling pathways.

Signaling pathways need an amplification mechanism to reduce expense of signaling molecules and to respond as soon as possible. From the viewpoint of energy expedition, signal amplification can effectively reduce the initial key substances and can cause significant effects. Also, signaling pathways are responsible for the responses to the environmental variation that means the response should be as soon as possible if some deleterious stress was presented to organisms. There are many researches indicated the importance of signal amplification as well as the functional role of signal amplification. In osmo-adaptation in yeast under osmotic stress, Klipp and et al. provided an integrated mathematical model of the signaling pathway which indicated the relationship between rate constants of kinases and phosphatases and signal amplification [5]. In liver glycogenolysis and release of glucose, 10^{-10}M epinephrine in blood can generate an intracellular cAMP concentration of 10^{-6}M, an amplification of 10^{4} [6].

In electrical engineering, there are several electrical components having the property of signal amplification, such as transistors. The analysis of amplification property of those gadgets had been done. The same analysis may be performed on the amplification property of a signaling pathway [7]. However, because of nonlinearity of signaling pathways, knowledge about the systematic properties of signaling pathways is still limited and incomplete. The interpretation of experimental data of signaling pathway is still context and knowledge-dependent. In this study, the signaling pathway is studied from the dynamic system perspective for which a signal transduction ability measurement is proposed based on signal and system theory from the systematic point of view. It is according to the ratio of output to input signal energy of the studied signaling pathway. This measurement is only dependent on the system characteristics of the studied signaling pathway.

Nevertheless, the proposed measurement scheme for nonlinear signaling pathways needs to solve the corresponding nonlinear Hamilton-Jacobi inequalities (HJIs). At present, we still have no analytic or numerical solution for HJIs, except some simple cases. Recently, Takagi-Sugeno (T-S) fuzzy systems have efficiently interpolated several local linear systems via fuzzy bases to approximate a nonlinear system [8].

Then the nonlinear signal transduction ability measurement problem can be solved via a set of linear matrix inequalities (LMIs) based on a set of fuzzy local linear signaling systems, which could be easily solved via LMI toolbox in Matlab® [9]. Based on fuzzy system theory and signal transmission method, the transduction ability of nonlinear signal transduction pathway could be investigated from these local linear signal transduction pathways. In this situation, more biological transduction insight can be investigated from linear signal system point of view. In near future, the transduction ability measurement may be as the characterization of the signal transmission systems for biotechnological, therapeutic applications and development of drug design.

The following sections include description of the generalized nonlinear signal transduction model, proposed measurement of signal transduction ability, fuzzy approximation of the nonlinear signal transduction model, and simulation example of MAP kinase and JAK/STAT signaling pathways, which are widely involved in eukaryotic signal transduction of cellular growth and differentiation and immune-responses respectively.

II. Methods And Results

A. Dynamic model of signaling pathways

Mathematical modeling for metabolic networks has been studied extensively and is useful for describing experimental data, deducing regulatory principle and understanding more complex dynamic phenomena such as oscillation. However, in modeling of signaling pathways, there are few examples have been studied since no available experimental data. According to the structure of signaling pathways which is consisted of consecutive activations and deactivations of proteins, we still can model the signaling pathways as series of chemical reactions. That means the signaling pathways can be modeled by a system of rate equations. The choice of the expressions for the rates is a matter of the elaborateness of experimental knowledge and of modeling taste. Linear and bilinear expressions or Michaelis-Menten kinetics have been used to model the signaling pathway [3]. A ubiquitous signaling pathway, mitogen-activated protein (MAP) kinase cascades, which regulate fundamental cellular functions including cell growth and death, differentiation, transformation and motility, is used here to demonstrate the proposed measurement scheme. A general scheme of a MAP kinase cascade (Fig.1) consists of general levels (three or more), where the activated kinase at

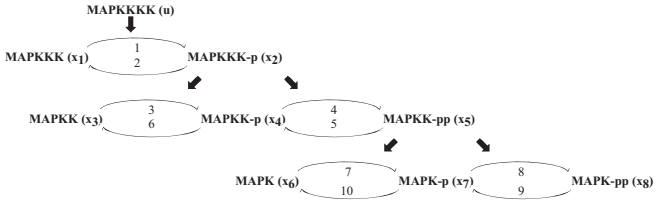

Figure 1. The general scheme of mitogen-activated protein (MAP) kinase cascade.

each level phosphorylates the kinase for the next level. The MAP kinase (MAPK) is at the terminal level of the whole cascade. It is activated by MAPK kinase (MAPKK), which is activated by MAPKK kinase (MAPKKK). Those sequential phosphorylations can be referred as activation of the signaling pathway. Dephosphorlyation of those kinases is thought to inactivate the signaling pathway. At each level, protein phosphatases can inactivate the corresponding kinase. The dynamics of a MAP kinase cascade can be represented by the following ODE system.

$$\begin{aligned}
\frac{d}{dt}MAPKKK &= -v_1 + v_2 \\
\frac{d}{dt}MAPKKKP &= v_1 - v_2 \\
\frac{d}{dt}MAPKK &= -v_3 + v_6 \\
\frac{d}{dt}MAPKKP &= v_3 - v_6 - v_4 + v_5 \\
\frac{d}{dt}MAPKKP_2 &= v_4 - v_5 \\
\frac{d}{dt}MAPK &= -v_7 + v_{10} \\
\frac{d}{dt}MAPKP &= v_7 - v_{10} - v_8 + v_9 \\
\frac{d}{dt}MAPKP_2 &= v_8 - v_9
\end{aligned} \tag{1}$$

where $v_i, i = 1,2,\ldots,10$ are reaction rates. The assumed values for the constants and rate equations are listed in Table 1.

TABLE I. Rate equations and parameters' values of the MAP kinase cascade model.

Reaction number	Rate equation	Constant
v_1	$\frac{k_1 x_1 u}{K_1 + x_1}$	$k_1 = 0.025, K_1 = 15$
v_2	$\frac{k_2 x_2}{K_2 + x_2}$	$k_2 = 0.25, K_2 = 8$
v_3	$\frac{k_3 x_2 x_3}{K_3 + x_3}$	$k_3 = 0.025, K_3 = 15$
v_4	$\frac{k_4 x_2 x_4}{K_4 + x_4}$	$k_4 = 0.025, K_4 = 15$
v_5	$\frac{k_5 x_5}{K_5 + x_5}$	$k_5 = 0.75, K_5 = 15$
v_6	$\frac{k_6 x_4}{K_6 + x_4}$	$k_6 = 0.75, K_6 = 15$
v_7	$\frac{k_7 x_5 x_6}{K_7 + x_6}$	$k_7 = 0.025, K_7 = 15$
v_8	$\frac{k_8 x_5 x_7}{K_8 + x_7}$	$k_8 = 0.025, K_8 = 15$
v_9	$\frac{k_9 x_8}{K_9 + x_8}$	$k_9 = 0.5, K_9 = 15$
v_{10}	$\frac{k_{10} x_7}{K_{10} + x_7}$	$k_{10} = 0.5, K_{10} = 15$

In general, the scheme of a signaling cascade can be represented by the following nonlinear dynamic system:

$$\begin{aligned} \dot{x} &= f(x) + g(x) \cdot u \\ y &= C \cdot x \end{aligned} \tag{2}$$

where the vector $x = \begin{bmatrix} x_1 & \cdots & x_n \end{bmatrix}^T$ denote states of protein involved in the signaling pathway. $f(x)$ denotes the interaction among these proteins. $g(x)$ denotes the coupling between m input signals $u = \begin{bmatrix} u_1 & \cdots & u_m \end{bmatrix}^T$ and the signaling pathway. y denotes the outputs of the signaling pathway. For example, if x_n is the output signal to be discussed, then $C = \begin{bmatrix} 0 & \cdots & 0 & 1 \end{bmatrix}$.

B. Signal transduction ability measurement

There are many properties of the signaling way to be investigated such as the signaling time, the signal duration or the signal amplitude. As we mentioned previously, our interest is in the signal amplification that is, the signal amplitude. We define the transduction ability from the system gain point of view as follows:

$$T_a = \sup_{u(t) \in L_2[0,t_f]} \frac{\|y(t)\|_2}{\|u(t)\|_2} \tag{3}$$

where $u(t)$ and $y(t)$ are the inputs and outputs of the signaling pathway respectively. The physical meaning of transduction ability is the maximum ratio of signal energy of output to the signal energy of all possible bounded input signals within the time interval $[0, t_f]$. The reason why we consider the maximum energy ratio of output signal to all input signals is that input signals may change under different conditions and the signal energy ratio may change depending on those input signals. However, transduction ability is based on the worst-case effect of all input signals on outputs and is dependent on the characteristics of dynamic systems. Actually, the transduction ability cannot be measured directly by trying each possible bounded input signal which is a measure of system characteristics of the signaling pathway. In general, the maximization problem for measurement of signal transduction ability of a signal transduction pathway cannot be solved directly. It can only be solved indirectly by a systematic analysis method in the following.

Let us denote an upper bound of transduction ability as follows:

$$\frac{\|y(t)\|_2^2}{\|u(t)\|_2^2} \le \rho^2, \forall u(t) \in L_2[0, t_f] \tag{4}$$

or

$$\|y(t)\|_2^2 \le \rho^2 \|u(t)\|_2^2, \forall u(t) \in L_2[0, t_f] \tag{5}$$

Therefore, we can find an upper bound them decrease the upper bound as small as possible to approach the transduction ability, i.e., to minimize the upper bound to estimate the signal transduction ability.

Theorem 1

If there exists a positive function $V(x)$ with $V(0) = 0$ satisfying the following Hamilton-Jacobi inequality (HJI):

$$\left(\frac{\partial V(x)}{\partial x}\right)^T f(x) + \frac{1}{4\rho^2}\left(\frac{\partial V(x)}{\partial x}\right)^T g(x) g(x)^T \frac{\partial V(x)}{\partial x} + x^T C^T C x \le 0 \tag{6}$$

then the signal transduction ability of the signal pathway is less than ρ.

C. Fuzzification

In general, it is still very difficult to solve the nonlinear HJI-constrained optimization problem in proposition 1. Fuzzy interpolation method is employed to overcome this situation and simplify the procedure to solve the transduction ability measurement problem.

Recently, fuzzy dynamic model has been widely employed to interpolate several local linear dynamic systems to approximate a nonlinear dynamic system to simplify nonlinear control problem [10], [11]. Takagi-Sugeno (T-S) fuzzy dynamic model [8] is described by fuzzy If-Then rules and employed here to efficiently deal with the problem of transduction ability measurement of the signaling pathway. The *i*-th rule of fuzzy model of nonlinear signal transduction pathway is proposed as the following form: [10],[11]

Rule i

If $x_1(t)$ is F_{i1}, $x_2(t)$ is F_{i2},..., $x_l(t)$ is F_{il}, then

$$\begin{aligned} \dot{x} &= A_i x(t) + B_i u(t) \\ y &= Cx(t) \end{aligned}$$

where $i = 1, 2, \ldots, L$, F_{ij} is the fuzzy set, A_i and B_i are known constant matrices, L is the number of fuzzy rules, and l is the number of premise variables. If all state variables are used as premise variables then $l = n$. The physical meaning of fuzzy rule i is that if the state variables $x_1(t), x(t), \ldots, x_l(t)$ are with fuzzy sets $F_{i1}, F_{i2}, \ldots F_{il}$, then the nonlinear signaling pathway could be represented by the linear systems. The fuzzy system is referred as follows:[10], [11], [8]

$$\begin{aligned} \dot{x} &= \frac{\sum_{i=1}^{L} \mu_i(x(t)) \left[A_i x(t) + B_i u(t)\right]}{\sum_{i=1}^{L} \mu_i(x(t))} \\ &= \sum_{i=1}^{L} m_i(x(t)) \left[A_i x(t) + B_i u(t)\right] \\ y &= Cx(t) \end{aligned} \tag{7}$$

where $\mu_i\left(x\left(t\right)\right)=\prod_{i=1}^{l}F_{ij}\left(x_j\left(t\right)\right)$, and $m_i\left(x\left(t\right)\right)=\dfrac{\mu_i\left(x\left(t\right)\right)}{\sum_{i=1}^{L}\mu_i\left(x\left(t\right)\right)}$. $F_{ij}\left(x_j\left(t\right)\right)$ is the grade of membership of $x_j\left(t\right)$ in F_{ij} and $m_i\left(x\left(t\right)\right), i=1,2,\ldots,L$ are called the fuzzy bases. The denominator $\sum_{i=1}^{L}\mu_i\left(x\left(t\right)\right)$ is only for normalization so that the total fuzzy sum of fuzzy bases $\sum_{i=1}^{L}m_i\left(x\left(t\right)\right)=1$. The physical meaning of the fuzzy system is local linear signaling pathways are interpolated through nonlinear bases $m_i\left(x\left(t\right)\right)$ to approximate the nonlinear signaling pathway. Actually, except fuzzy bases, other interpolation bases could be also employed to interpolate linear signaling pathways to approximate a nonlinear signaling pathway.

By fuzzy approximation, the nonlinear signaling pathway can be represented by the following fuzzy interpolated signaling pathway:

$$\begin{aligned}\dot{x}&=f\left(x\right)+g\left(x\right)u\\&=\sum_{i=1}^{L}m_i\left(x\left(t\right)\right)\left[A_ix\left(t\right)+B_iu\left(t\right)\right]\\&\quad+\Delta f\left(x\right)+\Delta g\left(x\right)u\left(t\right)\end{aligned}\tag{8}$$

where $\Delta f\left(x\right)=f\left(x\right)-\sum_{i=1}^{L}m_i\left(x\left(t\right)\right)A_ix\left(t\right)$ and $\Delta g\left(x\right)=g\left(x\right)-\sum_{i=1}^{L}m_i\left(x\left(t\right)\right)B_i$ denote fuzzy approximation errors. There are many methods to find A_i and B_i for the fuzzy model identification. We would use fuzzy toolbox in Matlab® to find A_i and B_i easily. After finding A_i and B_i, we could easily find bounds of fuzzy approximation error as follows:

$$\left\|\Delta f\left(x\right)\right\|_2^2\le a\left\|x\left(t\right)\right\|_2^2\tag{9}$$

$$\left\|\Delta g\left(x\right)\right\|_2^2\le b\tag{10}$$

for some positive constants a and b. Then based on fuzzy approximation, we get the following transduction ability measurement for the nonlinear signaling pathway.

Theorem 2:

For the nonlinear signaling pathway, there exists a positive definite symmetric matrix P by solving the following Riccati-like inequalities.

$$\begin{aligned}&A_i^TP+PA_i+\frac{2}{\rho^2}PB_iB_i^TP+\frac{2}{\rho^2}PP\\&\qquad+\frac{\rho^2a}{2}I+\frac{2b}{\rho^2}PP+C^TC\le 0,\\&i=1,2,\cdots,L\end{aligned}\tag{11}$$

In order to solve the above Riccati-like inequalities by the conventional LMI method, we let the positive definite symmetric matrix $W=P^{-1}$. Then above Riccati-like inequalities can be equivalent to

$$\begin{aligned}&A_iW+WA_i^T+\frac{2}{\rho^2}\left[B_iB_i^T+I+bI\right]\\&\qquad+WC^TCW+\frac{\rho^2a}{2}WW\le 0,\\&i=1,2,\ldots,L\end{aligned}\tag{12}$$

By the Schur complements, the Riccati-like inequalities is equivalent to the following LMIs:

$$\begin{aligned}&\begin{bmatrix}A_iW+WA_i^T+\frac{2}{\rho^2}\left(B_iB_i^T+I+bI\right) & WC^T & W\\ CW & -I & 0\\ W & 0 & -\frac{2}{\rho^2a}I\end{bmatrix}\le 0,\\&i=1,2,\ldots,L\end{aligned}\tag{13}$$

Then the signal transduction ability of nonlinear signaling pathway is less than ρ, i.e., is an upper bound of the signal transduction ability.

By fuzzy approximation, the HJI is approximated by a set of algebraic inequalities. Therefore, the signal transduction ability of the nonlinear signaling pathway could be obtained by solving the following constrained optimization.

$$T_a=\min_{\substack{\text{subject to } W>0\\ \rho>0 \text{ and } (12)}}\rho\tag{14}$$

which could be solved by decreasing until no positive definite symmetric matrix exists.

Remark 1. The Riccati-like inequalities are an approximation of HJI at local linear systems. Similarly, the constrained optimization problem for signal transduction ability measurement of nonlinear signaling pathway is also a conventional method based on fuzzy interpolation method to replace the very difficult constrained optimization subject to HJI by the constrained optimization subject to LMIs. In general, the constrained optimization problem for signal transduction ability measurement is called "eigenvalue problem", which can be efficiently solved by Matlab® LMI toolbox.

Remark 2. If ρ is smaller, then the last term in (11) should be larger so that the eigenvalues of A_i would be in the far left hand complex plane (i.e. with more negative real part) and then the total sums would be negative. If ρ is larger, then the eigenvalues of A_i would be near the imaginary axis (i.e. with smaller negative real part). In general, the signaling pathways always amplify the input signals (i.e. $T_a > 1$). In this situation, the eigenvalues of A_i would be near the imaginary axis, in order to amplify the extracellular signals to activate the corresponding genes in the cell.

III. Experimental Simulations

A. Simulation 1

Here we took into account that enzymes catalyze all steps and therefore consider Michaelis-Menten kinetics for the individual step. In these expressions, the concentrations of the donor and acceptor of the transferred phosphate group, ATP and ADP, are not explicitly expressed but are included in the rate constants. The dynamic of the nonlinear model and the fuzzy model of MAPK kinase cascade were shown in Fig.2 and Fig.3 respectively. The performance of MAPK kinase cascade, i.e., the ability to amplify the signal and to notably enhance the concentration of double-phosphorylated MAPK and the speed of activation, depends on the dynamic system of the signaling pathway and their rate constants. The simulation procedure started from fuzzy interpolation for the nonlinear model and the parameters of the fuzzy model, A_i and B_i , can be identified. Then, the approximation errors, a and b , can be determined. Next, according to *Theorem 2*, the augmented LMIs can be solved via LMI toolbox in Matlab®. Finally, signal transduction ability can be obtained by decreasing the prescribed ρ until no positive definite symmetric matrix solutions for the augmented LMIs exist.

First, using method of least-squares estimator, the parameters, A_i and B_i , of the fuzzy model can be identified. Since there are 8 substances or state variables in the ODE model, and by choosing 2 fuzzy sets for each variable, we have totally 256 fuzzy rules for the fuzzy model. By comparing the fuzzy model with the original ODE model, the approximation errors, $a = 2.35 \times 10^{-16}$ and $b = 1.86 \times 10^{-7}$ were determined. In the end, by solving the eigenvalue problem with LMI toolbox in Matlab®, the signal transduction ability of the fuzzy signaling pathway is $T_a = 6.39 \times 10^6$ and the corresponding positive definite symmetric matrix is

$$W = \begin{bmatrix} 0.9988 & -0.9988 & -0.0156 & 0.0083 & 0.0073 & + & - & - \\ & 0.9988 & 0.0156 & -0.0083 & -0.0073 & - & + & + \\ & & 0.1165 & -0.0613 & -0.0552 & - & + & + \\ & & & 0.0987 & -0.0374 & + & - & - \\ & & & & 0.0926 & - & + & + \\ & & & & & + & - & - \\ & & & & & & + & - \\ & & & & & & & + \end{bmatrix}$$

where $+$ and $-$ mean the very small positive and negative numbers (~10^{-12}), respectively. (The elements in the lower triangular matrix were not shown for symmetry).

IV. DISCUSSION

In this work, the proposed measurement provided a new way to access the ability of signal transduction in intracellular communication from a systematic view. The signal transduction ability is not easy to be quantified or determined by a single biological experiment on measuring the concentration of the input and output signals. Hence, a way to quantify the ability which is independent to the measurement of the concentration of the input and output signals is demanded. According to the concept of a system gain, our proposed method can determine the ability of signal transduction and is only dependent on the structure of the signaling pathway and the components involved in. Our result said that the signal transduction ability of MAP kinase cascade is about 10^6. That matched the description from the textbook [12] which says each level of a signaling pathway can cause about 10^2 times concentration amplification since the cascade is consisted of three-level cascade. It implied the usefulness of our proposed method. However, for a more precise estimation of the signal transduction ability, it needs to be confirmed by biological experiments. Also with the improvement of the knowledge on the structure of the signaling pathway, this method can give a better estimation on the ability of signal transduction.

Moreover, in this study, the nonlinear ODE equations are adopted to describe the signaling pathway, which also have been widely used in quantitative description to metabolism. However, we have to notice the difference between these two modules in the biology. First, signaling pathways serve for information processing and transfer of information, while metabolism provides mainly mass transfer. Second, the metabolic network is determined by the present set of enzymes catalyzing the reactions. Third, the different amounts of components have an effect on the concentration ration of catalysts and substrates.[3] The models for signaling pathway can always be improved according to the improvement on the experimental techniques and the knowledge about signaling pathways. Nevertheless, based on our purposed measurement, the signal transduction ability can always be accessed no matter which model is used to describe the whole signaling pathways.

In reality, the modules operated in a living system always have inherent noise due to random events. The amount of noise is a property of the system itself, and it may or may not cause significant deviation from the deterministic model. Some stochastic models [13] have been developed due to the consideration of the nature of the signaling pathways, that is, signaling pathways execute their functions under external disturbances and internal noises. One way to improve the estimation is to modify our proposed measurement with noise term $v(t)$, i.e.,

$$T_a = \sup_{u(t)\in L_2[0,t_f]} \frac{\|y(t)\|_2}{\|u(t)\|_2 + \|v(t)\|_2} \qquad (15)$$

Then, the signal transduction ability can also be investigated under such noisy environments, which is more real. Hence we can also investigate the robustness of signaling pathways with this proposed measurement [14]. The more robust the signaling pathway is the smaller variation the signal transduction ability is.

This methodology characterize the output-to-input energy ratio of the signal transduction systems and can apply on the biological modular device, such as amplifiers, logic elements, and actuators, or biochemical circuit designs to estimate signal transduction ability. Through the measurement, the signaling pathways can be analyzed and the importance of each component in the pathway can also be estimated. In the end, through the analysis of the signal transduction ability, each step in the signaling pathway can be analyzed and calculated its signal transduction ability which may be determined by the properties of reactants (for example: kinases or phosphatases) and the state of the interested cell. According to the conception of the BioBrick, we can also build the library of the building bricks of signaling pathways, and then the signaling pathway with desired signal transduction ability can be designed.

***Abstract*—Long-term business cycle forecasting is a very important issue in economic evaluation. This study presents a novel intuitionistic fuzzy least-squares support vector regression (IFLS-SVR) model for accurately forecasting long-term index of business cycle. Traditional support vector regression (SVR) and least-squares support vector regressions (LS-SVR) have been successfully applied in forecasting problems especially complex/nonlinear system. In this paper, the prediction model adopts two least-squares support vector regressions with intuitionistic fuzzy sets to approach fuzzy upper and lower bounds respectively, and then approach the crisp predict values. Genetic algorithms (GAs) are also employed in order to select two parameters of IFLS-SVR models. In this study, IFLS-SVR, LS-SVR and SVR are employed for the Taiwan business index forecasting. Empirical results indicate that the IFLS-SVR has better performance in terms of forecasting accuracy. Therefore, the IFLS-SVR model can efficiently provide credible long-term prediction for the Taiwan business index forecasting**

Keywords- long-term business cycle forecasting; intuitionistic fuzzy support vector regression; support vector regression; least-squares support vector regressions

I. INTRODUCTION

Accuracy forecasting long-term business cycle is an important issue in economic research. Business cycle is often determined by a panel of macroeconomic experts from analyzing movements in the set of components making up the Commerce Department's coincident variables of economic activity. Index of business cycle can be easily observes that has nonregular business cycle in past serial time, and index of business cycle belongs nonlinear data set especially in Taiwan. For accuracy measuring/forecasting, stochastic/statistics method is usually employed to analysis business cycle. Many researches have devoted to study of business cycle ([17], [18], [4], [32], [33], [27], and [20]). However, it is difficult to predict the business cycle with time serial, and many researches forecast short-term index of business cycle for reducing complexity. The difficulty derives from assumptions made by the probability distributions and a lack of adequate business cycle models for long-term prediction. Moreover, in real world information usually belongs vague, uncertain, imprecise and incomplete. In Taiwan the index of business cycle is composed of nine exogenous variables. This may make the index of business cycle exist some uncertain factors. Hence, to overcome the problem intuitionistic fuzzy sets (IFSs) and generalization of fuzzy interval data is employed to represent Taiwan business cycle which uses five lights/intervals to represent different economic actives. In order to handle the uncertain situation and insufficient vague information, a concept IFSs developed by [1] is introduced in this paper. The fundamental characteristics of IFSs are that the values of its membership function and non-membership vague values rather than exact numbers. Therefore, it could be used to simulate any activities and process requiring human expertise and knowledge, which are inevitably imprecise values.

In this paper, we discuss multivariate fuzzy nonlinear regression by support vector regression (SVR). SVR [30] has been extended so as to solve forecasting problems and has provided many exciting results especially nonlinear regression and time series problems with the introduction of Vapnik's ε-insensitive loss function. Unlike most of the traditional technology SVR implement neural network models, and SVR adopts the structural risk minimization principle which seeks to minimize an upper bound of the generalization error rather than minimize the training error. In recent years, SVR schemes have been extended to cope with forecasting problems, and have provided many promising results in customer demand [19], finance ([29], [16], and [14]) intermittent demand [13], tourism demand [25], air quality ([22] and [21]), wind speed [24], plant control systems [31], rainfall [12], prices for the electricity market [8] and flood control [35]. Furthermore, for representing fuzzy data the support vector fuzzy regression machines have been proposed by[11]. This method modified the principle of SVR which changes convex optimization problems to multivariate fuzzy linear regression models. And the support vector interval regression networks (SVIRNs) are proposed by [15] which can efficiently handle interval output data. Yao and Yu [34] develop a fuzzy regression based on asymmetric support vector machines which extend the support vector fuzzy regression machines. Chuang [7] extended SVIRNs develops

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

interval support vector interval regression networks (ISVIRNs) which can handle interval input/output data. Hao and Chiang [9] develops a fuzzy regression analysis by support vector learning. In this paper we proposed a novel IFLS-SVR to forecast index of business cycle. Our proposed method find upper and lower bound by LS-SVR respectively, and use intuitionistic fuzzy sets technology to approach training data. Our proposed method can get benefit LS-SVR. In addition to our method adopts genetic algorithms (GAs) to search optimal parameters of LS-SVR. This make our method can obtain better performance.

A. IFSs Theroy

Fuzzy sets theory, proposed by Zadeh [36], has shown successful applications in various fields. In this theory, the membership of an element to a fuzzy set is a single value between zero and one. But in reality, it may not always be certain that the degree of non-membership of an element to a fuzzy set is just equal to 1 minus the degree of membership, i.e. there may be some hesitation degree. Thus, as a generalization of fuzzy sets, the concept of IFSs was introduced by [1]. Bustince and Burillo [6] showed that this notion coincides with the notion of vague sets (VSs).

The IFSs is as an extension of fuzzy sets. An IFSs A in a fixed set E is an objective with the expression

$$A=\left\{\left\langle x,\mu_A(x),\nu_A(x)\right\rangle\middle|x\in E\right\}, \tag{1}$$

where the functions $\mu_A: E\to[0,1]$ and $\nu_A: E\to[0,1]$ denote the degree of membership and the degree of non-membership of the element $x\in E$, respectively. For every $x\in E$,

$$0\le\mu_A(x)+\nu_A(x)\le 1 \tag{2}$$

when $\mu_A(x)+\nu_A(x)=1$, for every $x\in E$, then the IFSs will degenerate to a fuzzy set. Hence, we can consider a fuzzy set with its membership function $u_A(x)$, having the IFSs expression as

$$A=\left\{\left\langle x,\mu_A(x),1-\mu_A(x)\right\rangle\middle|x\in E\right\} \tag{3}$$

under the condition of $v_A(x)=1-u_A(x)$, for every $x\in E$.

For each IFSs A in E, "hesitation degree" has consideration. We call the hesitation degree of an element $x\in E$ in A by the following expression:

$$\pi_A(x)=1-\mu_A(x)-\nu_A(x), \tag{4}$$

We can consider $\pi_A(x)$ as a hesitancy degree of x to A. From (4) it is evident that

$$0\le\pi_A(x)\le 1 \text{ for all } x\in E. \tag{5}$$

Therefore, to describe an intuitionistic fuzzy set completely; we need at least two functions from the triplet ([2][3]): (1) membership function; (2) non-membership function; (3) hesitation degree.

B. Least-squares Support Vector Regressions with Genetic Algorithm

A successful method for regression problem is the least squares support vector regression ([26] and [28]), which attempts to minimize the sum square errors (SSEs) of training data set while simultaneously minimizing the margin error. The LS-SVR approach is to approximate an unknown function by a training data set $\{(x_i, y_i), i=1, \ldots, N\}$. The regression function can be formulated as follows:

$$y=f(x)=w^T\varphi(x_i)+b \tag{6}$$

where $\varphi(x_i)$ denotes the feature of the inputs, and w and b indicate coefficients. LS-SVR introduces a least squares version to SVR by formulating the regression problem as

$$\begin{aligned}&Min\ J_1(w,b,e)=\frac{1}{2}\|w\|^2+\frac{1}{2}C\sum_{i=1}^{N}e_i^2\\&subjective\ to\\&y_i=w^T\varphi(x_i)+b+e_i,\ i=1,2,\cdots,N\end{aligned} \tag{7}$$

Introduce the Lagrangian as

$$L_1(w,b,e,\alpha)=J_1(w,b,e)+\sum_{i=1}^{N}\alpha_i(y_i-w^T\varphi(x_i)-b-e_i). \tag{8}$$

where α is the Lagrangian multiplier vector. The conditions for optimality are

$$\begin{aligned}&\frac{\partial L_1}{\partial w}=0\Rightarrow w=\sum_{i=1}^{N}\alpha_i\varphi(x_i),\\&\frac{\partial L_1}{\partial b}=0\Rightarrow\sum_{i=1}^{N}\alpha_i=0,\\&\frac{\partial L_1}{\partial e_i}=0\Rightarrow e_i=\frac{1}{C}\alpha_i,\ i=1,\ldots,N,\\&\frac{\partial L_1}{\partial \alpha_i}=0\Rightarrow y_i=w^T\varphi(x_i)+b+e_i,\ i=1,\ldots,N.\end{aligned} \tag{9}$$

Herein, $k(x_i, x_j)$ denotes a Kernel function whose value equals the inner product of two vectors, x_i and x_j, in the feature space $\varphi(x_i)$ and $\varphi(x_j)$, meaning that $k(x_i, x_j)=\varphi^T(x_i)\ \varphi(x_j)$. Any function that satisfies Mercer's condition [23] can act as the Kernel function. This work uses the Gaussian function. Hence, we can denote the $K=(k_{ij})_{N\times N}$, $k_{ij}=k(x_i, x_j)$, and $V=\mathrm{diag}\{1/C,1/C,\ldots,1/C\}$, LS-SVR can be described as

$$\begin{bmatrix}A & 1\\ 1^T & 0\end{bmatrix}\begin{bmatrix}\alpha\\ b\end{bmatrix}=\begin{bmatrix}y\\ 0\end{bmatrix}, \tag{10}$$

where $A=K+V$. Hence, the regression model (see (6)) is found by solving (10). The resulting LS-SVR becomes then

$$f(x)=\sum_{i=1}^{N}\alpha_i k(x,x_i)+b. \tag{11}$$

Note that in the case of Gaussian kernels, one has only two additional tuning parameters (C, σ), which is less than for standard SVR.

The experiment uses genetic algorithms (GA) [10] to search optimal parameter of LS-SVR. In this study, binary encoding is specified in GA search. The size of the population is set fifty. The roulette wheel selection principle is used to select chromosomes for reproduction. In the crossover operation,

chromosomes are paired randomly. The single-point-crossover principle is employed in the GA search. In this study, the probabilities of crossover and mutation are set to 0.5 and 0.1, respectively. By the GA search the optimal parameters C andσ can be obtained. To minimize forecasting error of the LS-SVR model, the negative values of *MAPE* were treated as the objective values of the GA; thus, each iteration generates a smaller MAPE value. The parameter search procedure is conducted until the stop criterion is reached. The two parameters resulting in the smallest validation error are then used to develop a appropriate LS-SVR model. Finalized forecasting vales are obtained by LS-SVR. Finally, after comparison with the testing data, the testing errors are obtained.

III. INTUITIONISTIC FUZZY LEAST-SQUARES SUPPORT VECTOR REGRESSIONS

The IFLS-SVR approach has mainly different with LS-SVR/SVR which constructs the intuitionistic fuzzy sets to represent uncertain degree of data. IFSs D_i in a fixed set E is an objective with the expression

$$D_i = \left\{ \left\langle X_i = (x_i, y_i), \mu_D(y_i), \nu_D(y_i) \right\rangle \middle| X \in E \right\}, i \in 1, ..., N. \quad (12)$$

In this paper, intuitionistic fuzzy generator or fuzzy complement is created from Yager generating function [5]. The fuzzy complement functional is defined as:

$$N(\mu(y_i)) = g^{-1}(g(1) - g(\mu(y_i))) \quad (13)$$

where $g(.)$ is an increasing function and g:[0,1]→[0,1].

Yager class can be generated by using the following function in the above (13)

$$g(y_i) = y_i^{\alpha} \quad (14)$$

So, Yager's intuitionistic fuzzy complement is written as:

$$N(y_i) = (1 - y_i^{\alpha})^{1/\alpha}, \alpha > 0 \text{ where} N(1)=0, N(0)=1. \quad (15)$$

Non-membership values are calculated from Yager's intuitionistic fuzzy complement $N(y_i)$. Thus, with the help of Yager's intuitionistic fuzzy complement, IFSs becomes:

$$D_i = \left\{ \left\langle X_i = (x_i, y_i), \mu_D(y_i), (1 - \mu_D(y_i)^{\alpha})^{1/\alpha} \right\rangle \middle| X \in E \right\}. \quad (16)$$

and the hesitation degree is :

$$\pi_D(Y_i) = 1 - \mu_D(y_i) - (1 - \mu_D(y_i)^{\alpha})^{1/\alpha} \quad (17)$$

In IFLS-SVR, based on the expert's viewpoints the membership function can be determined, and then the hesitation degree can be obtained by (16). Following we can use definition of triangular fuzzy numbers (TFNs) to approach the intuitionistic fuzzy lower (IY_{Li}) and upper bounds (IY_{Ui}) with α=0.5 which can be formulated as following:

$$IY_{Li} = Y_{Li} + (Y_{Ci} - Y_{Li}) \times (\mu_D(y_i) + \pi_D(y_i)) \quad (18)$$

$$IY_{Ui} = Y_{Ui} - (Y_{Ui} - Y_{Ci}) \times (\mu_D(y_i) + \pi_D(y_i)) \quad (19)$$

where Y_{Li} is lower bound of TFNs, Y_{Ci} is the mode of TFNs, and Y_{Ui} is upper bound of TFNs. Fig. 1 shows that the data point construct intuitionistic fuzzy lower and upper bounds.

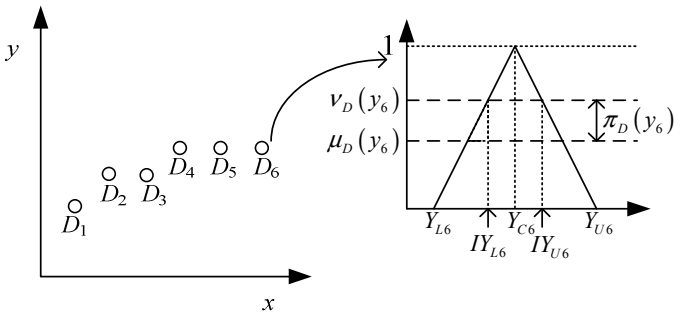

Figure 1. Illustration of construction of the intuitionistic fuzzy sets.

Then, in the IFLS-SVR model the intuitionistic fuzzy lower and upper regression lines must be constructed by the LS-SVR method with the lower bound of $\{(x_i, IY_{Li}), i=1, 2, \ldots, N\}$ and the upper bound of $\{(x_i, IY_{Ui}), i=1, 2, \ldots, N\}$, respectively, which can be written as follows:

$$Y_L(x_i) = w_{Li}^* + b_L = \sum_{i=1}^{N} \alpha_{Li} k(x, x_i) + b_L. \quad (20)$$

where the Lagrange multipliers, α_{Li} and an optimal weight vector w_{Li}^* of the lower bound regression hyperplane can be estimated by (6):

$$Y_U(x_i) = w_{Ui}^* + b_U = \sum_{i=1}^{N} \alpha_{Ui} k(x, x_i) + b_U. \quad (21)$$

where the Lagrange multipliers, α_{Ui} , and an optimal weight vector w_{Ui}^* of the upper bound regression hyperplane can be estimated by (7). Then the fuzzy prediction model uses (20) and (21) to estimate the estimated central vale $Y_C(x_i)$ by a simple calculation as follows:

$$Y_C(x_i) = \sum_{i=1}^{N} ((\alpha_{Li} + \alpha_{Ui}) K(x, x_i) + b_L + b_U)/2. \quad (22)$$

Furthermore, the IFLS-SVR model uses GA algorithms to select the two parameters of LS-SVR. Fig. 2 shows the flowchart of the proposed IFLS-SVR model.

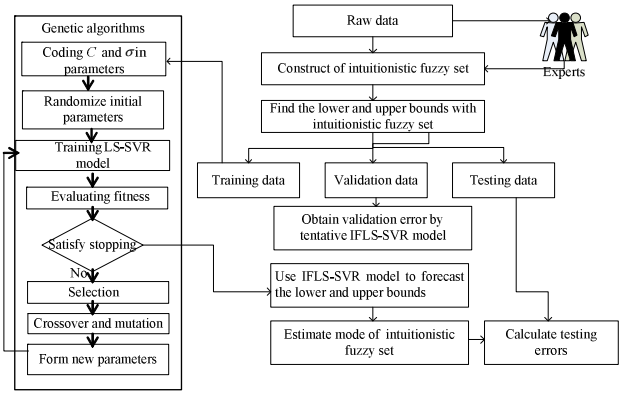

Figure 2. A flowchart of the IFLS-SVR

IV. NUMERICAL EXAMPLES AND EXPERIMENTAL RESULTS

To represent the vague characteristics of business cycles index in Taiwan, the Council of Economic Planning and Development uses five business lights to indicate the various degrees of business cycles. Table I shows the lights, intervals, and meanings of economic activities of the different degrees of business cycles from the Council of Economic Planning and Development. These intervals can be regarded as TFNs. Fig. 3 shows the monthly Taiwanese business index from October 1990 to November 2010. The monthly data were divided into three sets: the training set (October 1990 to December 2008), the validation set (January 2009 to December 2009), and the testing set (from January 2010 to November 2010). Moreover, Fig. 3 also shows IFSs of business cycles index in October 2008. The training data were used to design the forecasting model, and the testing data were employed to measure the forecasting performance of the different forecasting models. In addition, the root mean square error (*RMSE*) and mean absolute percentage error (*MAPE*) were used to measure the forecasting accuracy of the two models. (23) to (24) illustrate the expression of RMSE, MAPE respectively.

$$RMSE = \left\{ \frac{1}{M} \sum_{t=1}^{M} \left(Y_{Ct} - Y_C(x_t) \right)^2 \right\}^{0.5} \tag{23}$$

$$MAPE(\%) = \frac{100}{M} \sum_{t=1}^{M} \left| \frac{Y_{Ct} - Y_C(x_t)}{Y_{Ct}} \right| \tag{24}$$

where M is the number of forecasting periods; Y_{Ct} is the actual value, and $Y_C(x_t)$ is the forecasting value at period t.

TABLE I. THE INDEX OF BUSINESS CYCLES IN TAIWAN

Lights	Intervals of business cycle	Meanings of business activities
Red	[38, 45]	Excellent
Yellow-Red	[32, 37]	Good
Green	[23, 31]	Medium
Yellow-Blue	[17, 22]	Retrieving
Blue	[9 , 16]	Not good

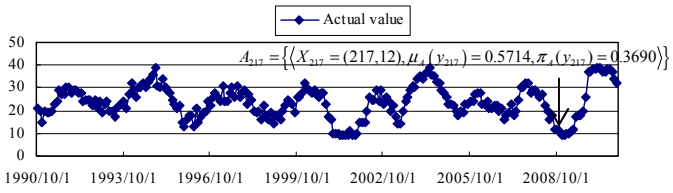

Figure 3. Illustration of actual values from October 1990 to November 2010

Table II illustrates the actual values and experimental results of the IFLS-SVR model from January 2010 to November 2010. In addition, Table II shows the optimal parameters of the proposed IFLS-SVR model. Fig. 4 makes a point-to-point comparison of actual values and predicted values of IFLS-SVR. Fig. 4 shows that the IFLS-SVR model can efficiently capture the trend of data. From observing the Fig. 4 we can find that the LS-SVR and SVR have lower forecasting values from January 2010 to November 2010. This may be because that LS-SVR and SVR have over fitting phenomenon in the forecasting index of business cycles. The forecasting values are similarity the validation set by using LS-SVR and SVR technologies. The Table III shows and ranks the performances of three models. Again, the IFLS-SVR outperforms others models in terms of forecasting accuracy.

Finally, the Wilcoxon signed rank test was implemented to test the forecasting result. The test results, presented in Table IV, show significant differences among the IFLS-SVR, the LS-SVR and SVR models, indicating the forecasting result of IFLS-SVR is better than those of the traditional LS-SVR and SVR approaches based on *MAPE* and *RMSE*.

V. CONCLUSIONS

Due to the recent global economic recession, analysis of business cycles is increasingly crucial. This study develops a novel IFLS-SVR model to exploit the unique strength of the intuitionistic fuzzy set theory and the LS-SVR technique, in order to predict long-term business cycles in Taiwan.

Simulation results indicate that the IFLS-SVR model offers a promising alternative in business cycles in uncertain circumstances. The superior performance of the IFLS-SVR model can be ascribed to two causes. First, the LS-SVR can efficiently capture trends of nonlinear data. Second, the IFLS-SVR model can provide creditable predictions for long-term Taiwanese business cycle predictions. For future work, forecasting other types of uncertain time series data by the IFLS-SVR model is a challenging issue for study. Future studies can also consider using data preprocessing techniques to improve the forecasting accuracy of the IFLS-SVR model.

***Abstract*—Recently, mining interrelated data among multiple types of objects attracts a lot of attention due to its importance in many real-world applications. Despite of extensive study on fuzzy clustering of vector space data and homogeneous relational data, very limited exploration has been made on fuzzy clustering of relational data involving several object types. In this paper, we propose FC-SMR, a fuzzy approach for clustering star-structured multi-type relational data, where the central type is related to multiple attribute types. In FC-SMR, objects of the central type are clustered based on the rankings of objects of different attribute types. We formulate the clustering problem as a constrained maximization problem and give an efficient algorithm for finding local solutions of the defined objective function. Experimental studies conducted on real-world document data show the effectiveness of the new approach.**

***Index Terms*—Fuzzy clustering; co-clustering; multi-type; heterogeneous relational data; document categorization**

I. Introduction

Compared with hard clustering, fuzzy clustering which allows overlaps among clusters is generally agreed to be able to provide a more accurate and natural description of the underlying structure of real-world data. The same as k-means, most existing studies on fuzzy clustering such as fuzzy c-means (FCM) [1] deal with vector space data, of which each object is represented as a vector in some feature space, e.g. a document is represented as a vector where each feature or dimension of the vector is a distinctive word. Other than the vector-feature represented data, the pairwise relational data also has been studied for a long time [2], [3], [4]. Most typically, the relationships are similarities or dissimilarities between each pair of objects from a given data set, e.g. similarity between two documents. These document-document relation is referred as homogeneous as it exist between objects of the same type, i.e., document. Although the vector space data and homogeneous relational data are two basic data representation models based on which extensive studies have been carried out, new challenges come out when the technique of clustering is applied to the data mining domain for handling various real-world data sets, which is more natural to be represented as multi-type relational data, where inter-relations exist among objects of several types.

In some recent studies [5], [6], fuzzy co-clustering approaches have been proposed for document categorization which simultaneously cluster documents and words. Different from the two basic data representations, in co-clustering, *document* and *word* are treated as two object types, and the *document-word* co-occurrence data is a bi-type heterogeneous relational data. While traditional clustering generates clusters of one type of objects, co-clustering simultaneously clusters objects of each of the two types. It has been shown in the literature that co-clustering approaches are always more effective and informative than those traditional one-side clustering approaches [7].

However, co-clustering is not applicable on data involving more than two object types. For document data sets, other than *document* and *word*, which form the *document-word* relation, document may also be related to other object types. For example, in hierarchical taxonomy mining, each document belongs to a category, which forms a *document-category* relation. The relations among objects of different types may form different structures. A star-structure is a special case where the central type is related to several attribute types as illustrated in Fig. 1. For document clustering, *document* is the central type and other object types, such as *word* and *category* are attribute types, and the *document-word* relation corresponds to a bi-type star-structure, while the *document-word* together with the *document-category* relations form a tri-type star-structure. It is possible to transform multi-type relational data to one of the basic data representation forms with respect to the object type that is interested, and then use an existing approach to get the clusters of the objects of this type. For example, a vector representation for the central-type objects may be obtained by concatenating all attribute-type objects as its features. However, this leads to a very sparse data in a high dimensional space which is a very difficult problem for most clustering approaches to solve.

To fully make use of those central-attributes relations, multi-type relational clustering approaches have been proposed in [8], [9], [10], [11], [12], [13], [14]. Most of these approaches are formulated as high-level co-clustering approaches, where [9], [11], [15], [12] formulate clustering as matrix factorization problems, [14], [13] are model-based approaches solved by the EM algorithm, [8] solves the problem with semi-definite programming and [10] is an iterative spectral clustering which needs eigenvalue decomposition at each iteration. In this paper, we develop a fuzzy clustering approach for star-structured multi-type relational data mining (FC-SMR). The proposed approach is a natural extension of the fuzzy co-clustering

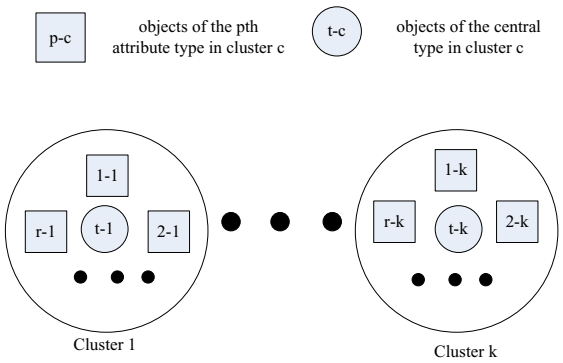

Fig. 2. The clustering problem for multi-type star-structured relational data.

approach (FCoDok) in [5]. In FCoDok, a co-cluster is a document cluster associated with a word cluster, while in FC-SMR, each document cluster is associated with r clusters with each of them corresponding to an attribute type. This multi-type relational clustering problem has some similarity to the multi-view clustering [16] and collaborative clustering [17] in the sense that all these three problems make use of more than one data descriptions or views, i.e. relational matrices between the central type and different attribute types, views by different feature sets or data source distributed in multiple places. However, in [16] and [17], clustering is performed locally on each data view during which the partition information on other views are collaborated to some degree, while in the problem of this study, only a global partition of the documents is produced as an optimal solution for taking care of all relations. Moreover, the clusters of objects of each of the attribute types are also obtained.

The rest of the paper is arranged as follows: we first review some related work in Section 2. The detailed formulation of the proposed approach is then presented in Section 3. Experimental results on benchmark document data sets are reported and discussed in Section 4. Finally, we make the conclusion of this paper in Section 5.

II. Fuzzy co-clustering for documents

Several fuzzy co-clustering approaches have been proposed in the literature, and here we only review the most related one referred as FCoDok proposed in [5]. This approach is an improved version of [18] for document categorization. Given the document-word co-occurrence matrix $r_{ij} \in \mathbf{R}_{n\times m}$ of n documents and m words, the objective of FCoDok is to maximize the following criterion:

$$J_{FCoDok} = \sum_{c=1}^{k}\sum_{i=1}^{n}\sum_{j=1}^{m} u_{ic} r_{ij} v_{jc} - T_u \sum_{c=1}^{k}\sum_{i=1}^{n} u_{ic}^2 - T_v \sum_{c=1}^{k}\sum_{j=1}^{m} v_{jc}^2 \quad (1)$$

subject to

$$\forall c, i, j, \quad u_{ic} \geq 0, v_{jc} \geq 0 \quad (2)$$

$$\forall i, \sum_{c=1}^{k} u_{ic} = 1; \quad \forall c, \sum_{j=1}^{m} v_{jc} = 1 \quad (3)$$

where k is the number of clusters, u_{ic} is the membership of document i with respect to cluster c, and v_{jc} is the membership of word j with respect to cluster c. From (3), it can be observed that u_{ic} is the standard fuzzy membership as for each document, the sum of its u values in all clusters is 1; differently, for each word j, the sum of its v values in all clusters is not required to be 1, instead, the sum of v values over all words in each cluster is 1. To differentiate these two kinds of measures, from now on, we refer u the membership while v the ranking. The first term of (1) called degree of aggregation measures the quality of the clustering and the second and third terms of (1) are quadratic regularization of u and v, respectively. This quadratic regularization has also been used as an alternative way to generate the fuzziness of memberships in fuzzy c-means [19].

The updating equations of u_{ic} and v_{jc} are derived by the method of Lagrange Multiplier, which is shown as below [5]:

$$u_{ic} = \frac{1}{2T_u} g_{ic} + \frac{1}{k}\left(1 - \frac{1}{2T_u}\sum_{f=1}^{k} g_{if}\right) \quad (4)$$

$$v_{jc} = \frac{1}{2T_v} h_{jc} + \frac{1}{m}\left(1 - \frac{1}{2T_v}\sum_{p=1}^{m} h_{pc}\right) \quad (5)$$

where $g_{ic} = \sum_{j=1}^{m} v_{jc} r_{ij}$ and $h_{jc} = \sum_{i=1}^{n} u_{ic} r_{ij}$. Since the above updating formulas do not guarantee nonnegativity of u_{ic} and v_{jc}, during each iteration, negative values of u_{ic} and v_{jc} are set to 0, and re-normalization is performed accordingly to satisfy the summation constraints in (3). Solutions that guarantee nonnegativity are also derived in [5] with the KKT (Karush-Kuhn-Tucker) conditions.

III. Fuzzy Clustering for Star-Structured Multi-Type Relational Data (FC-SMR)

The FCoDok handles the *document-word* co-occurrence data, which can be regarded as bi-type star-structured relational

data, where *word* is the only attribute type. Now, we present the proposed approach FC-SMR for star-structured relational data with $r > 1$ attribute types.

A. Problem Formulation

Given a document data involving $r > 1$ attribute types, we have r matrices $\{\mathbf{R}_p\}_{p=1}^r$, where $r_{ij}^p \in \mathbf{R}_p$ is the relationship between the ith object of the central type, i.e., document x_i, and the jth object of the pth attribute type denoted as y_j^p. We assume that each relation matrix is weighted by β_p. As illustrated in Fig. 2, the problem is to produce k document clusters based on r relation matrices $\{\mathbf{R}_p\}_{p=1}^r$, and each document cluster is associated with a cluster of objects of each of the attribute types. We use u_{ic} to represent the fuzzy membership of x_i in cluster c, and v_{jc}^p the ranking of y_j^p in cluster c. The proposed approach is to maximize the following objective:

$$J_{FC-SMR} = \sum_{p=1}^{r}\sum_{c=1}^{k}\sum_{i=1}^{n}\sum_{j=1}^{m_p}\beta_p u_{ic} r_{ij}^p v_{jc}^p \tag{6}$$

$$-\frac{\rho}{2}\sum_{c=1}^{k}\sum_{i=1}^{n}(u_{ic})^2 - \frac{\eta_p}{2}\sum_{p=1}^{r}\sum_{c=1}^{k}\sum_{j=1}^{m_P}(v_{jc}^p)^2 \tag{7}$$

subject to

$$\forall i, c, \quad u_{ic} \geq 0; \quad \forall p, j, c, \quad v_{jc}^p \geq 0; \tag{8}$$

$$\forall i, \sum_{c=1}^{k} u_{ic} = 1, \quad \forall p, j, \quad \sum_{j=1}^{m_p} v_{jc}^p = 1. \tag{9}$$

where n and m_p are the number of documents and the number of objects of the pth attribute type, respectively. The document clusters obtained as the solution of the above problem may not be the optimal with respect to the relation between *document* and each individual attribute type, but it is an overall optimum considering the relations between *document* and all attribute types. We use the classic method of Lagrange multiplier to derive the local solutions of the constrained optimization problem formulated above. The Lagrangian is formed as

$$L = J_{FC-SMR} + \sum_{i=1}^{n}\gamma_i(\sum_{c=1}^{k}u_{ic} - 1) + \sum_{p=1}^{r}\sum_{c=1}^{k}\lambda_c^p\sum_{j=1}^{m_p}(v_{jc}^p - 1)$$
$$+\sum_{c=1}^{k}\sum_{i=1}^{n}\alpha_{ic}u_{ic} + \sum_{p=1}^{r}\sum_{c=1}^{k}\sum_{j=1}^{m_p}\theta_{jc}^p v_{jc}^p \tag{10}$$

where all γ_i and λ_c^p, α_{ic}, θ_{jc}^p are Lagrange multipliers. According to the KKT (Karush-Kuhn-Tucker) conditions, after some algebraic manipulations, u_{ic} can be derived as

$$u_{ic} = \begin{cases} \frac{1}{\rho}g_{ic} + \frac{1}{|\mathcal{K}_i^+|}(1 - \frac{1}{\rho}\sum_{f\in\mathcal{K}_i^+} g_{if}), & \text{for } \ c \in \mathcal{K}_i^+ \\ 0, \quad otherwise \end{cases} \tag{11}$$

with

$$g_{ic} = \sum_{p=1}^{r}\sum_{j=1}^{m_p}\beta_p v_{jc}^p r_{ij}^p \tag{12}$$

where

$$\mathcal{K}_i^+ = \{f : u_{if} > 0\}$$

is the set that consists of cluster ids of which the memberships of x_i is positive, and

$$v_{jc}^p = \begin{cases} \frac{1}{\eta_p}h_{jc}^p + \frac{1}{|\mathcal{N}_c^+|}(1 - \frac{1}{\eta_p}\sum_{l\in\mathcal{N}^+} h_{lc}^p), & \text{for } \ j \in \mathcal{N}_c^+ \\ 0, \quad otherwise \end{cases} \tag{13}$$

with

$$h_{jc}^p = \beta_p \sum_{i=1}^{n} r_{ij}^p u_{ic} \tag{14}$$

where

$$\mathcal{N}_c^+ = \{l : v_{lc}^p > 0\}$$

is the set of object ids of which the rankings in cluster c is positive. The derivation is similar as in FCoDok and we can use Procedure-K and Procedure-N in [4] to decide $\mathcal{K}_i^+$ and $\mathcal{N}_c^+$.

The first term of (11) decides the membership distribution of each x_i in k clusters while the second term is a normalization to ensure the summation constraint to be satisfied. From (12), it can be observed that given the rankings of attribute objects in each cluster, the membership of x_i in a cluster c is larger than in cluster f if more objects of r attribute types related to x_i have large ranking values in cluster c than in cluster f. Similarly, the first term in (13) decides the distribution of rankings among objects of the pth attribute type in cluster c, and the second term is there to ensure the satisfaction of the summation constraints on the ranking values. From (14), we may know that the rankings of objects of the same attribute type are only decided by the memberships of the documents. Given the memberships of documents in a cluster c, the ranking of attribute object y_i^p in this cluster is larger than that of another attribute object y_j^p if more documents related to y_i^p have larger memberships in this cluster.

B. Algorithm

For implementation, we can update $u_{ic} \in \mathbf{U}_{n\times k}$ and $v_{jc}^p \in \mathbf{V}_p(m_p \times k)$ in matrix form as below and use the same simplified way as in [5] to deal with negative memberships and rankings.

Calculate $\mathbf{U}$:

$$\mathbf{U} = \frac{1}{\rho}\mathbf{G} + \frac{1}{k}(\ -\frac{1}{\rho}\ \mathbf{G}) \tag{15}$$

$$\mathbf{G} = \sum_{p=1}^{r}\beta_p\mathbf{R}_p\mathbf{V}_p \tag{16}$$

For each row i of $\mathbf{U}$, find

$$\mathcal{K}_i^+ = \{f : u_{if} > 0\} \tag{17}$$

modify

$$u_{ic} = \begin{cases} 0, & \text{for} \quad c \notin \mathcal{K}_i^+ \\ \frac{u_{ic}}{\sum_{f\in\mathcal{K}_i^+} u_{if}}, & \text{for} \quad c \in \mathcal{K}_i^+ \end{cases} \tag{18}$$

for each p, calculate $\mathbf{V}_p$:

$$\mathbf{V}_p = \frac{1}{\eta_p}\mathbf{H}_p + \frac{1}{m_p}(\quad -\frac{1}{\eta_p}\quad \mathbf{H}_p) \tag{19}$$

$$\mathbf{H}_p = \beta_p \mathbf{R}_p^T \mathbf{U} \tag{20}$$

For each column c of $\mathbf{V}_p$, find

$$\mathcal{N}_c^+ = \{l : v_{lc}^{\mu} > 0\} \tag{21}$$

modify

$$v_{jc}^p = \begin{cases} 0, & \text{for} \quad j \notin \mathcal{N}_c^+ \\ \dfrac{v_{jc}^p}{\sum_{l \in \mathcal{N}_c^+} v_{lc}^p}, & \text{for} \quad j \in \mathcal{N}_c^+ \end{cases} \tag{22}$$

where is a matrix with a proper size, of which every entry is 1. The detailed algorithm is given as below:

Algorithm 1 FC-SMR

Input: $n \times m_p$ Relation matrix $\{\mathbf{R}_p\}_{p=\{1,2,\ldots,r\}}$, the number of clusters k, parameter ρ, $\{\eta_p\}_{p=\{1,2,\ldots,r\}}$, and positive weights $\{\beta_p\}_{p=\{1,2,\ldots,r\}}$.

Output: Fuzzy memberships of the central objects $\mathbf{U}$ and rankings of the attribute objects $\mathbf{V}_p$ for each $p = \{1, 2, \ldots, r\}$.

Method:

1: Initialize $\mathbf{U}^{(0)}$ with nonnegative values.
2: **repeat**
3: **for** each $p = \{1, 2, \ldots, r\}$ **do**
4: Update $\mathbf{V}_p^{(l)}$ as (19) with $\mathbf{H}_p^{(l)}$ calculated from (20).
5: Modify $\mathbf{V}_p^{(l)}$ according to (21) and (22).
6: **end for**.
7: Update $\mathbf{U}^{(l+1)}$ as (15) with $\mathbf{G}^{(l+1)}$ calculated from (16).
8: Modify $\mathbf{U}^{(l+1)}$ according to (17) and (18).
9: **until** convergence

IV. Experimental Results

This section presents experimental studies of the proposed FC-SMR approach for document clustering. We use the benchmark data set 20newsgroups [20].

A. Data

The original data of 20newsgroups downloaded at http://people.csail.mit.edu/jrennie/20Newsgroups/ contains 18828 non-duplicated documents, which are categorized into 20 topics. Following [8] and [10], we generate three subsets consisting of different subtopics as listed in Table I. For example, data set TM1 consists of clusters C_1 and C_2, where C_1 is the *rec.sport* cluster which contains two subtopics or categories on *baseball* and *hockey*, and C_2 is the *talk.politics* cluster that has three subtopics on *guns*, *mideast* and *misc*. Each of the three data sets is formed by randomly selecting 100 documents from each of the chosen subtopics. For each data set, we obtain two relation matrices *document-word* and *document-category* which are denoted as $\mathbf{R}_1$ and $\mathbf{R}_2$, respectively. The *rainbow* toolkit [21] is used to get the *document-word* occurrence data. Stop-words have been removed and 2000 words with the largest information gain are kept. Non-text documents are skipped by *rainbow*. After preprocessing, documents consisting of less than two words are removed and finally we have 497, 598 and 794 documents for TM1, TM2 and TM3, respectively. The *tf-idf* weighting [22] is used for weighting the words in each document. Each subtopic is a category and $\mathbf{R}_2$ is a binary matrix with an entry is 1 if the document is from that subtopic otherwise is 0.

TABLE I
Structure of Newsgroup Datasets

TM1	C_1: {rec.sport.baseball, rec.sport.hockey} C_2: {talk.politics.guns, talk.politics.mideast, talk.politics.misc}
TM2	C_1: {comp.graphics, comp.os.ms-windows.misc} C_2: {rec.autos, rec.motorcycles} C_3: {sci.crypt, sci.electronics}
TM3	C_1: {comp.sys.ibm.pc.hardware, comp.sys.mac.hardware} C_3: {rec.autos, rec.motorcycles} C_3: {sci.med, sci.space} C_4: {talk.politics.guns, talk.politics.mideast}

B. Setting Up

We tested the proposed approach FC-SMR on the TM1, TM2 and TM3 three data sets. For comparison, we also implemented four existing approaches: Hyperspherical Fuzzy c-Means (HFCM) [23], fuzzy co-clustering (FCoDok) [5], Non-negative matrix factorization approach referred as (NMF-H) [12] and spectral relational clustering (SRC) [10]. HFCM is a modified fuzzy c-means clustering with cosine distance for documents; NMF-H and SRC are two existing multi-type relational clustering approaches. The results of HFCM and FCoDok are obtained based on $\mathbf{R}_1$, the *document-word* bi-type relational data. Three multi-type relational clustering approaches, FC-SMR, NMF-H and SRC are based on $\mathbf{R}_1$ and $\mathbf{R}_2$, i.e. the *word-document-category* tri-type relational data.

In our experiment, the number of clusters k is set to be equal to the real number of classes for each data set. We set $T_u = 0.001, T_v = 1$ for FCoDok and $\rho = 0.01, \eta_1 = \eta_2 = 1$ for FC-SMR. The fuzzifier $m = 1.02$ is used for HFCM. We let $\beta_1 + \beta_2 = 1$ in FC-SMR. For all fuzzy approaches, truncated clusters are obtained by assigning each object to the cluster with the largest membership.

C. FC-SMR vs. HFCM and FCoDok

We first compare the performance of the proposed FC-SMR with existing fuzzy approaches HFCM and FCodok. Table II to Table IV give the best clustering results that HFCM, FCoDok and FC-SMR can achieve among 30 trials with random initializations on the three data sets, respectively.

It can be seen from these contingency tables that with the additional *document-category* relation, FC-SMR is able to achieve 100% accuracy on all the three data sets. The results of FCoDok and HFCM on TM1 and TM2 are close, but FCoDok performs better than HFCM on TM3. Although FCoDok and HFCM make use of the same *document-word* matrix, HFCM treats each document as a vector and use the cosine similarity to measure the closeness of two documents, while FCoDok

treats document and word as two different object types and documents are clustered based the ranking of words. There is no explicit similarity measure defined in FCoDok and FC-SMR.

Fig. 3 plots $\mathbf{u}_1 = \{u_{1,1}, u_{2,1} \ldots, u_{500,1}\}$, the membership values of documents in C_1 of TM1 produced by HFCM and FC-SMR, respectively. According to the summation constraints, the memberships in the other cluster follow $\mathbf{u}_2 = 1 - \mathbf{u}_1$. For TM1, the ground truth partition is that the first 198 documents are in C_1: *rec.sport* and the rest are in C_2: *talk.politics*. It can be seen from Fig. 3a that in HFCM, for the 21th document, $u_{21,1} < u_{21,2}$, although this document should be in C_1. At the same time, six documents (labeled by circles) which should be in C_2 are assigned larger memberships in C_1. These results indicate that the representation of these documents in terms of word frequency is not sufficient enough for correctly assigning those documents into the right clusters. The *document-category* relation help to clarify the uncertainty or correct the misleading information in the *document-word* relation. This can be seen from Fig. 3b that, when the *document-category* relation are further incorporated, those previously mis-clustered documents are now assigned reasonable memberships in two clusters which are consistent with the ground truth. Although it can be told from the document-category matrix that which documents are in the same subtopic, this matrix alone delivers no information on the hierarchy structure of the subtopics, i.e. which subtopics should be combined into a high-level cluster. Therefore, clustering only based on the *document-category* relation does not produce any meaningful result as it merely combines those subgroups into the specified number of clusters in a random way.

D. Comparison of NMI Values

Now we compare FC-SMR with four other approaches in terms of *Normalized Mutual Information* (NMI) [24]. The higher the NMI value, the more closer of the algorithm generated results to the ground truth. The NMI value equals to 1 only when the partition produced by an algorithm is identical to the ground truth of the partition. Each approach is run 30 trials on each data set. Random initializations are used for HFCM, and other approaches are initialized with document fuzzy memberships produced by HFCM. Table V shows the mean and standard deviation (numbers in brackets) of NMI values over 30 trials. For FC-SMR, we give results with different values of β_1 and β_2.

It can be seen that FC-SMR achieves significant better results than other approaches on all three data sets. Generally, three multi-type relational clustering approaches making use of both $\mathbf{R}_1$ and $\mathbf{R}_2$ perform better than HFCM and FCoDok where $\mathbf{R}_2$ is not used. FCoDok and HFCM give close results on TM2 but HFCM outperforms FCoDok on TM1, while FCoDok performs better than HFCM on TM3. Among three multi-type relational approaches, FC-SMR is the best and NMF-H is better than SRC. Like FC-SMR, NMF-H also produces the ideal result on TM1, but its performances on the other two data sets are not as good as those of FC-SMR.

TABLE V
COMPARISON OF NMI VALUES

	TM1	TM2	TM3
HFCM	0.8862 (0.0149)	0.7183 (0.0076)	0.7862 (0.0395)
FCoDok	0.8506 (0.0138)	0.7127 (0.0024)	0.8129 (0.0408)
NMF-H	1.0000 (0.0000)	0.8008 (0.1757)	0.8925 (0.1032)
SRC	0.9595 (0.1541)	0.7207 (0.1679)	0.8053 (0.1331)
FC-SMR ($\beta_2 = 1 - \beta_1$)			
($\beta_1 = 0.1$)	1.0000 (0.0000)	1.0000 (0.0000)	0.9866 (0.0525)
($\beta_1 = [0.2, 0.8]$)	1.0000 (0.0000)	1.0000 (0.0000)	0.9917 (0.0455)
($\beta_1 = 0.9$)	1.0000 (0.0000)	1.0000 (0.0000)	1.0000 (0.0000)

It also shows that the results of FC-SMR on three data sets do not change much with respect to β_1 in [0.1, 0.9].

E. Ranking of Words and Categories

Together with the documents clusters, we also obtain the word rankings and category rankings. The ranking values of each category in each cluster is shown in the three matrices given in (23) to (25) for TM1, TM2 and TM3, respectively, where each row indicates a category and each column indicates a cluster or a topic. Top 10 words of each cluster are also listed in Table VI. As attribute types, *category* and *word* can be used for description or characterization of the document cluster. We can see that those key categories and key words which have large ranking values provide meaningful information to tell what topic each document cluster possibly related to. If we take C_1 of TM1 for example, from its associated key categories named *basedball* and *hockey*, and key words, such as *game*, *hockey*, *team*, *players*, *baseball*, we may guess that documents of this cluster are about sports, possibly on hockey and baseball. Such kind of information can be used as a short summary of the cluster which provides a quick sense of the whole document cluster without looking through each of the long documents.

$$\begin{array}{c} \\ \textit{baseball} \\ \textit{hockey} \\ \textit{guns} \\ \textit{mideast} \\ \textit{misc} \end{array} \begin{array}{c} \begin{array}{cc} \textit{rec.sport} & \textit{talk.politics} \end{array} \\ \begin{pmatrix} 0.4327 & 0 \\ 0.5673 & 0 \\ 0 & 0.3067 \\ 0 & 0.3506 \\ 0 & 0.3428 \end{pmatrix} \end{array} \tag{23}$$

$$\begin{array}{c} \\ \textit{graphics} \\ \textit{os.ms-windows.misc} \\ \textit{autos} \\ \textit{motorcycles} \\ \textit{crypt} \\ \textit{electronics} \end{array} \begin{array}{c} \begin{array}{ccc} \textit{comp} & \textit{rec} & \textit{sci} \end{array} \\ \begin{pmatrix} 0.4716 & 0 & 0 \\ 0.5284 & 0 & 0 \\ 0 & 0.4579 & 0 \\ 0 & 0.5421 & 0 \\ 0 & 0 & 0.7018 \\ 0 & 0 & 0.2982 \end{pmatrix} \end{array} \tag{24}$$

$$

V. Conclusion

In this paper, we work on a fuzzy clustering approach for star-structured multi-type relational data analysis, where relations exist between the central type and r attribute types. The main idea of the new approach is to estimate the fuzzy memberships of the central-type objects based on the rankings of all related attribute-type objects, and the memberships of central-type objects are in turn used for updating the rankings of all attribute-type objects. Our experimental study on benchmark document data sets demonstrates the benefit of using information from multiple relation matrices for clustering as well as the feasibility and effectiveness of the proposed approach.

Abstract – **Real-world databases often contain missing data and existing correction algorithms deliver varying performance. Also, most modeling techniques are not suitable to deal with them automatically. In this study we examine different approaches to predicting septic shock in the presence of missing data. Some pre-processing techniques for managing missing data include disregarding data, or replacing it with information that by design introduces bias. In this study, we show that predictive performance improves by employing a minimum pre-processing technique, the Zero-Order-Hold (ZOH) method, by applying a Fuzzy C-Means clustering technique based on the partial distance calculation strategy (FCM-PDS) and by computing the final classification regarding the samples from each patient. Performance improvements continue to occur where up to approximately 60% of the data is missing, though for higher percentage the classification performance still is statistically improved. We further validate this approach by making comparisons with previous studies.**

Missing Data; Septic Shock; Fuzzy C-Means; Partial Distance Strategy; Zero-Order-Hold

I. INTRODUCTION

Severe sepsis remains both an important clinical challenge and an economic burden in intensive care. This is especially so for septic shock, which is characterized by the persistence of a hypotensive state, despite adequate fluid resuscitation [1]. The mortality rate among septic shock patients is very high (about 50%), as are the comparative costs of treatment. Cost-of-illness studies in the US focusing on direct costs per sepsis patient support the premise of, and attention to, increasing global health care costs [2]. Prevention and quality are therefore embraced as cost efficient contributors to a solution, and it so the ability to predict and prevent expensive septic shock hospitalizations.

A review of the literature highlights previous studies in this area that have applied knowledge-based soft computing techniques to various scenarios associated with septic shock [3, 4, 5, 6]. In [5], however, feature selection is applied in order to reduce data dimensionality by removing inputs that do not improve the prediction performance of the model.

The aim of this study is explore the influence of pre-processing and new modeling techniques for the prediction of septic shock. By using two sets of 12 and 28 selected features from the pre-processed MEDAN database [6] described in [4] and [5], respectively, results were compared to these studies.

Real-world databases often contain many missing values and artifacts, either due to lack of sampling or post-acquisition processing techniques (e.g. re-sampling). Most learning rule-based algorithms deal poorly with this. However, different pre-processing techniques can be applied to minimize this issue. In some cases, if the amount of missing data is small, it is possible to delete all incomplete data. In other cases, it can be more useful to attempt to find suitable replacement values.

This work is supported by the Portuguese Government under the programs: Project PTDC/SEM-ENR/100063/2008, Fundação para a Ciência e Tecnologia (FCT), and by the MIT-Portugal Program and FCT grants SFRH/BD/51028/2010, SFRH/43043/2008 and SFRH/43081/2008.

There are two types of missing data: missing not at random (MNAR) and missing at random (MAR) [7]. The second group can be further divided into missing completely at random (MCAR) and general MAR. MCAR values can be interpreted as a random reduction of the dataset, because their probability does not depend on the observed data or the unobserved data [8, 9]. Thus, they provide no further information for assigning incomplete features vectors to clusters. Alternatively, MAR values are not randomly distributed across all observations, but are randomly distributed within one or more subsamples instead. This is the scenario for the database used in this study.

Having discussed the unsatisfactoriness of disregarding missing data, replacing missing values creates problems of bias with the introduction of new data [10]. An alternative then to these two methods is to extend the data analysis method so that the method can deal directly with incomplete data. In this work we use a modified fuzzy c-means (FCM) clustering method that allows the identification of Takagi-Sugeno fuzzy models from incomplete data by means of product-space clustering [11]. This method uses the extension of the Fuzzy C-Means algorithm with the Partial Distance Strategy (FCM-PDS), discussed in [12, 13], and does not require any kind of imputation or iterative guess-estimation of the missing values. The algorithm possesses all the standard convergence properties of FCM. Additionally, both the global convergence theory and the local alternating optimization convergence theory are applicable [13]. Previous works [11] showed that the performance of these models is comparable to the one obtained when using a complete data set [11] making it a suitable tool for the present study.

The modeling technique used will be briefly discussed in Section II. In Section III the methodology is described followed by results and discussion in Section IV. Section V concludes the paper.

II. MODELING

Takagi-Sugeno (TS) fuzzy models can be used as universal approximators in non-linear studies as this.

A. Takagi-Sugeno Fuzzy Modeling

A TS fuzzy model [14] is a fuzzy rule-based model where the rule consequents are crisp functions of the model input:

$$R^k : \text{If } \mathbf{x} \text{ is } A^k \text{ then } y^k = f^k(\mathbf{x}),\ k = 1,\ 2,\ ...,\ K, \qquad (1)$$

where R^k denotes the k-th rule, K is the number of rules, $\mathbf{x}$ is the antecedent variable, y is the one dimensional consequent variable and A^k are the (multidimensional) antecedent fuzzy sets of the k-th rule. Each rule k has a different function f^k yielding a different value y^k for the output. The most simple consequent function f^k in (1) is the linear affine form:

$$R^k: \text{If } \mathbf{x} \text{ is } A^k \text{ then } y^k = \left(\mathbf{a}^k\right)^T \mathbf{x} + b^k \qquad (2)$$

where $\mathbf{a}^k$ is a vector of parameter and b^k is a scalar offset. This model is called an affine TS model.

B. Fuzzy Modeling with Missing Values

Several techniques can be used in fuzzy identification. One possibility is to use identification by product-space clustering [15]. This principle involves approximating a nonlinear problem by decomposing it into several sub-problems. In general, the identification of fuzzy models is solved in two steps: structure identification and parameter estimation. Structure identification can be obtained by fuzzy clustering. Parameter identification consists of determining the parameters for the antecedent functions and the parameters of the rule consequents.

With missing values, product-space clustering can also be used as long as the distance metric is modified in order to deal with those values. It is possible to calculate partial distances using all non-missing feature values, and scaling afterwards this quantity by the reciprocal of the proportion of components used [16]. An example of the D^2_{ik} calculation of the Euclidean distance is [13]:

$$\begin{aligned} D_{ik}^2 &= \|z_k - v_i\|_2^2 \\ &= \left\|(?\,2\,?\,?\,5)^T - (6\,7\,8\,9\,10)\right\|_2^2 \\ &= \frac{5}{5-3}\left((2-7)^2 - (5-10)^2\right) \end{aligned} \qquad (3)$$

The general formula for the partial distance calculation of D^2_{ik} is given by:

$$D_{ik}^2 = \frac{n}{I_k}\sum_{j=1}^{n}\left(x_{kj} - v_{ij}\right)^2 I_{kj} \qquad (4)$$

where

$$I_{kj} = \begin{cases} 0, if\ x_{kj} \in X_M \\ 1, if\ x_{kj} \in X_P \end{cases}, for\ 1 \le j \le n \text{ and } 1 \le k \le N \qquad (5)$$

and $I_k = \sum_{j=1}^{n} I_{kj}$

X_M and X_P are the subsets of X containing the missing and the present values from the total datum, respectively. This is the partial distance strategy (PDS) mentioned before and the operational basis of modified FCM the algorithm used in this study. The FCM-PDS is the regular FCM algorithm where the calculation of the distance D^2_{ik} is substituted by (4) and also the cluster prototype centers, v_{ij}, are calculated according to:

$$v_{ij} = \sum_{k=1}^{N}(\mu_{ik})^m I_{kj} x_{kj} \Big/ \sum_{k=1}^{N}(\mu_{ik})^m I_{kj} \qquad (6)$$

where μ_{ik} is the membership degree of x_k to the cluster center v_i.

The antecedent membership functions can be obtained by projecting the multidimensional fuzzy sets defined point wise in the rows of the partition matrix of the model onto the individual antecedent variables of the rules. However, by computing the membership degrees directly in the space of the antecedent variables, each cluster represents one fuzzy rule, as in (2). The multidimensional membership functions A^k are given analytically by computing the distance from the projection of the cluster center v_i onto X, and then computing the membership degree, $\beta_i(\mathbf{x})$, in an inverse proportion to the distance, with the form:

$$\beta_i(\mathbf{x}) = \left[\sum_{j=1}^{c} \left(D_{ik}^2 \left(\mathbf{x}, v_i^x \right) / D_{jk}^2 \left(\mathbf{x}, v_j^x \right) \right)^{\frac{2}{m-1}} \right]^{-1} \quad (7)$$

The consequent parameters for each rule are estimated by the least-squares method. The set of optimal parameters with respect to the model output is estimated by minimizing the global prediction error, taking into account the aggregation of the rules [11].

III. METHODOLOGY

A. MEDAN Database Pre-processing

The pre-processed MEDAN database [6] originates from 71 German intensive care units (ICUs) using several data quality techniques [3] (e.g. data re-sampling, errors filtration, standardization of measuring units). However, to use the database for our objectives, several pre-processing methodologies are required such as identification and removal of outliers and management of missing data.

In [4], data from a suitable normal distribution (noise) was inserted randomly so that the algorithms could not learn from the added noise data. In particular, the aim was to prevent situations where data with missing value replacements might be alternatively classified [17]. Contrastingly, a linear regression strategy followed by the Zero-Order-Hold (ZOH) method was used in [5]. The ZOH method can be applied causally by holding in time a sample value until a new one is acquired. This was done for each feature along the time. In the case where no value is present in the initial time stamp of a patient, the dataset will contain missing values until one value is acquired for that feature. This method constitutes a suitable pre-processing technique for medical data records as we are dealing with time-dependent signals series, many of them with low changing frequencies [5]. Schematically, the dataset preprocessing will happen as follows:

(Without ZOH pre-processing)

$$original\ dataset = \begin{bmatrix} ? & ? & ? & 13 & 17 & 21 & ? & 29 \\ 2 & ? & 10 & ? & ? & 22 & ? & ? \\ 3 & 7 & ? & ? & 19 & ? & ? & ? \\ 4 & 8 & 12 & 16 & ? & ? & 28 & ? \end{bmatrix} \quad (8)$$

(With ZOH pre-processing)

$$ZOH\ dataset = \begin{bmatrix} ? & ? & ? & 13 & 17 & 21 & ? & 29 \\ 2 & ? & 10 & 13 & 17 & 22 & ? & 29 \\ 3 & 7 & 10 & 13 & 19 & 22 & ? & 29 \\ 4 & 8 & 12 & 16 & 19 & 22 & 28 & 29 \end{bmatrix} \quad (9)$$

Approximately 24h spaced samples were used for comparison with [4]. Though in [4] the daily mean values (after input of missing data) were used, comparison with this work still is valid. Two studies were performed here: Predicting septic shock by applying the FCM-PDS method without any pre-processing of the dataset (FCM-PDS); and predicting septic shock by applying the FCM-PDS method with the ZOH pre-processing method (ZOH-FCM-PDS). Thus, for the first study the datasets contain all the missing data from the original MEDAN database. For the second, the datasets will only contain missing data until at least one value is acquired in every feature, in the original database.

From these studies we can compare the use of the FCM-PDS algorithm with the results obtained in [4] and evaluate the differences in performance when using a suitable pre-processing technique.

B. Experimental Setup

This study makes use of a publicly available database [6], containing data from a total of 382 patients with septic shock associated with abdominal causes. For each patient, the database holds personal records, physiological parameters, diagnoses/therapies, medication, and respective outcomes (survived or deceased).

As in previous works we focused exclusively on the physiological parameters (a total of 103 features). However, only 139 patients were found to meet initial inclusion criteria and not all of them have entries for the 103 features [3, 4]. From the total features available then, two different datasets of 12 features [4] and 28 features [5] were selected to perform the studies, resulting in a total of 121 patients and 81 patients in each set, respectively.

The models were iteratively built (100 times for statistical purposes) for the two sets of features and the performance of the models was evaluated in terms of accuracy (correct classification rate), sensitivity (true positive classification rate) and specificity (true negative classification rate), and area under the ROC (Receiver Operating Characteristic) curve (AUC):

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN} \quad (10)$$

$$Sensitivity = \frac{TP}{TP + FN} \quad (11)$$

$$Specificity = \frac{TN}{TN + FP} \tag{12}$$

Where *TP* is the number of true positive classifications obtained, *FP* is the number of false positive classifications, *TN* is the number of true negative classifications and *FN* is the number of false negative classifications. The ROC curve is obtained by plotting the true positive classifications rate (TPR, or sensitivity) against the false positive classifications rate (FPR, or 1-specificity) obtained for a binary classifier system as its discrimination threshold is varied. The area under that curve is calculated as:

$$AUC = \int_0^1 ROC = \int_0^1 TPR.dFPR \tag{13}$$

The train and test sets in each set of features were obtained by randomly dividing the available data (50% train and 50% test). These subsets were maintained the same throughout the simulation.

The results were then compared with [4], where a neural-network-based modeling approach is used to classify abdominal septic shock patients using the same subset of 12 features that was used in this work.

C. Computing Classification

When performing the first tests with the FCM-PDS algorithm the accuracy obtained was very similar to that obtained in [4] (in contrast, sensitivity and specificity were balanced). This is not unexpected as neither of the pre-processing techniques adds any additional information to the missing dataset. Therefore, after testing the model created with the test set, the results were aggregated so that the predicted classification for each patient results from the mean of all its predicted classifications for each time samples. Schematically, consider the dataset configuration used:

$$\begin{bmatrix} id & time & feature1 & \dots & featureN & Classification \\ id_{p1} & t_{p1,1} & x_{1,p1,1} & \dots & x_{N,p1,1} & class_{p1} \\ \dots & \dots & \dots & \dots & \dots & \dots \\ id_{p1} & t_{p1,T1} & x_{1,p1,T1} & \dots & x_{N,p1,T1} & class_{p1} \\ id_{p2} & t_{p2,1} & x_{1,p2,1} & \dots & x_{N,p2,1} & class_{p2} \\ \dots & \dots & \dots & \dots & \dots & \dots \\ id_{p2} & t_{p2,T2} & x_{1,p2,T2} & \dots & x_{N,p2,T2} & class_{p2} \\ \dots & \dots & \dots & \dots & \dots & \dots \\ id_{pk} & t_{pk,1} & x_{1,pk,1} & \dots & x_{N,pk,1} & class_{pk} \\ \dots & \dots & \dots & \dots & \dots & \dots \\ id_{pk} & t_{pk,Tk} & x_{1,pk,Tk} & \dots & x_{N,pk,Tk} & class_{pk} \end{bmatrix} \tag{14}$$

Where id_{pk} is the identifier of patient *pk*, x_N is the value of feature *N*, *Tk* is the number of time stamps for patient *pk*, and $class_{pk}$ is the observed classification. The clustering method treats each time sample individually. Consequently, we can compute the predicted classification of each patient using the predicted classification for each of its time stamps:

$$\hat{class}_{pk,final} = \frac{1}{Tk}\sum_{i=1}^{Tk} \hat{class}_{pk}(t_{pk,i}) \tag{15}$$

This procedure maintains some of the time series information by not treating each time sample as an individual sample. This method was used in both approaches (with and without pre-processing) presented in this work.

IV. Results and Discussion

The 12 feature and 28 feature datasets created without pre-processing contained approximately 54% and 67% missing data, respectively. In contrast, same datasets obtained using the ZOH method only contained 2% and 4% missing data, respectively (the remaining missing values are placed in the initial positions of each feature (9)).

In Fig.1 one can observe the performance test of the ZOH-FCM-PDS method for the 12 feature dataset. The threshold value selected for comparison was one for which accuracy is near the maximum, and sensitivity and specificity are relatively balanced. In this case we selected 0.35.

Table I presents the percentage of correct classifications achieved by each of the approaches. Although the ZOH-FCM-PDS approach performs better than the other methods for the 12 feature dataset, the differences between this method and the FCM-PDS method become faded for the 28 feature dataset. In Table II, sensitivity and specificity are presented for the 12 features dataset studies and, again, the best results for these criteria are achieved by the ZOH-FCM-PDS method. This method performs well overall as the missing data percentage decreases. In Table III, where the results for sensitivity and specificity for the studies using the 28 feature dataset are presented, the clearest differences between the two approaches are the standard deviations. The mean values are very similar which means that the FCM-PDS approach is not as robust as it is when preceded by the pre-processing. This is also observed in Table I and is due to the fact that we are not dealing with MCAR values, and therefore the configuration of the dataset influences the results drastically. This effect is best observed when dealing with the 28 feature dataset (67% missing values downgraded to 4%) where, by replacing the great majority of the missing values using the ZOH method, the model becomes more robust maintaining its prediction power. This means that the information contained in each time sample is related to the previous ones, as expected by physicians, otherwise the ZOH-FCM-PDS method would perform worse overall. Additionally, this reinforces the observations that for percentages of missing data up to approximately 70% the FCM-PDS model can perform well though the mean error increases as one approaches upper limits [11].

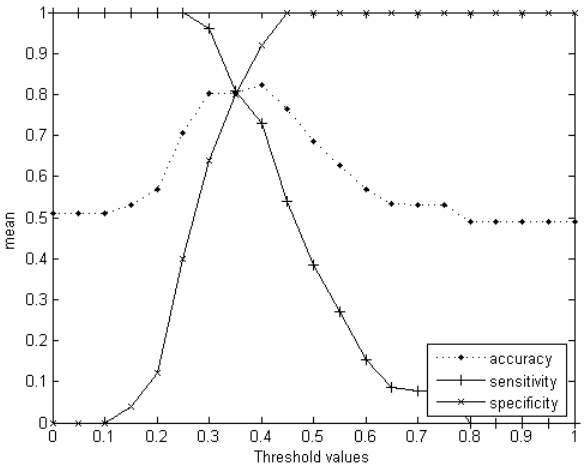

Figure 1. Performance of the ZOH-FCM-PDS method using the 12 feature dataset. The threshold value chosen for presenting the results here was 0.35.

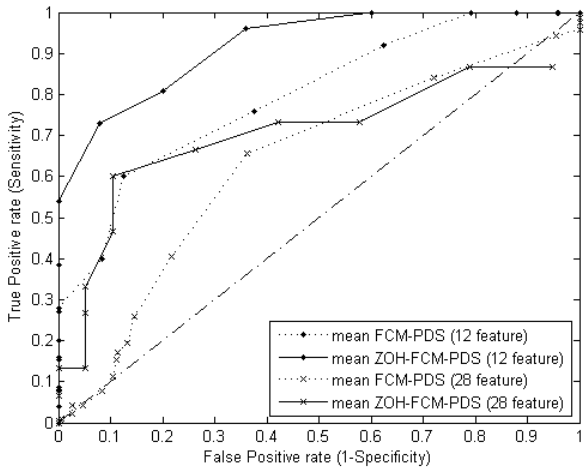

Figure 2. ROC curves obtained for the 12 and 28 feature datasets studies.

TABLE I. ACCURACY (PERCENTAGE OF CORRECT CLASSIFICATIONS)

	12 feature		28 feature	
	Mean	***Std***	***Mean***	***Std***
NN [4]	69.00	4.37	-	-
ZOH-FCM-PDS	80.39	0.00	70.59	0.00
FCM-PDS	69.39	0.00	64.76	7.73

TABLE II. SENSITIVITY AND SPECIFICITY USING 12 FEATURES

	12 feature			
	Sensitivity		Specificity	
	Mean	***Std***	***Mean***	***Std***
NN [4]	15.01	-	92.26	-
ZOH-FCM-PDS	80.77	0.00	80.00	0.00
FCM-PDS	76.00	0.00	62.50	0.00

TABLE III. SENSITIVITY AND SPECIFICITY USING 28 FEATURES

	28 feature			
	Sensitivity		Specificity	
	Mean	***Std***	***Mean***	***Std***
ZOH-FCM-PDS	66.67	0.00	73.68	0.00
FCM-PDS	65.67	12.98	63.75	24.03

The method used in [4] performs similarly in terms of accuracy to FCM-PDS method. However, for sensitivity and specificity the approach used in this study clearly performs better.

In Table IV the AUC values obtained for the two datasets of features when using the two approaches discussed are presented. Again, the use of the ZOH pre-processing method constitutes a significant difference for the 12 feature dataset, resulting in better AUC values. The variability of the results due to the high percentage of missing data is noticeable for the 28 feature dataset. Fig.2 permits graphical comparison of the ROC curves obtained for all the studies. Both methods perform similarly for the 28 feature dataset.

The technique used in this study to compute the predicted classification of each patient clearly improves the classification when compared to results in [4]. Although the accuracy of both is similar, the differences can be seen in Table II as the balance between sensitivity and specificity. As mentioned before, both [4] and the FCM-PDS approach do not use pre-processing techniques that could bias the information contained in the dataset.

TABLE IV. AUC

	12 feature		28 feature	
	Mean	***Std***	***Mean***	***Std***
ZOH-FCM-PDS	89.85	0.00	64.91	0.00
FCM-PDS	78.58	0.00	63.14	11.73

In [4], a potential improvement to the classification performance was to use only the three last 24h time samples from each patient. However, this work demonstrates a viable alternative method, and notes that other techniques could also be used in order to favor the positive or negative classifications, for example, as in the "balanced accuracy". Computing the classification of each patient after using the FCM-PDS method in datasets containing limited time windows (e.g. last three days) could constitute a better improvement to the septic shock prediction study.

In reference [17] missing values are replaced by centers of gravity associated with fuzzy rules. This procedure unjustly improves the statistical properties of the original data by replacing the missing values in the best possible manner for the system [3, 4]. However, such a replacement strategy, like performing a linear regression in the existing values [5], offers some advantages that warrant further examination and comparison in the development of more robust models (e.g. applications in data-based knowledge extraction).

V. CONCLUSIONS

Real-world databases usually contain missing values. Using the MEDAN database we studied the application of a modified fuzzy c-means (FCM) clustering method that allows the identification of Takagi-Sugeno fuzzy models from incomplete data, without using complex pre-processing methods. This paper demonstrates a real-time modeling strategy for medical data that is reliable, with high fidelity and non-complex interpretability. Applying the models developed in this study with time limited physiological datasets and suitable pre-processing techniques demonstrates the opportunities to improve classification performance and risk prediction in clinical settings.

***Abstract*—This article addresses the problem of the construction of concordance measures between two crisp, fuzzy and possibilistic partitions from their coincidence matrices. Two existing approaches are reviewed and their advantages and drawbacks are exhibited so that a new Rand index taking profits of both is proposed. Numerous experimental results show that it outperforms other extensions of the Rand index.**

***Index Terms*—Soft partitions, similarity measure, Rand index**

I. Introduction

A partition of a dataset $X = \{\mathbf{x}_1, ..., \mathbf{x}_n\}$ of n objects is a set of c non-empty subsets of X. These subsets, called *clusters* thereafter, generally regroup objects along common properties they share. Partitions can be represented by a $(c \times n)$ partition matrix U, whose general term u_{ik} represents the membership degree of each $\mathbf{x}_k$ $(k = 1, n)$ to the ith cluster $(i = 1, c)$. Each column of U is then the membership vector $\mathbf{u}_k$ of the object $\mathbf{x}_k$. For the sake of clearness and simplicity, a partition will be identified with its corresponding partition matrix in the following. Depending on whether or not clusters are mutually exclusive and on whether or not objects of X totally belong to each cluster, partitions can be of different nature. We distinguish the three main categories [1], called the sets of *possibilistic*, *fuzzy* and *crisp* partitions, respectively defined as :

- $\mathcal{M}_{pcn} = \{U \in \mathbb{R}^{c\,n} : u_{ik} \in [0, 1]\}$,
- $\mathcal{M}_{fcn} = \{U \in \mathcal{M}_{pcn} : \sum_{i=1}^{c} u_{ik} = 1\}$,
- $\mathcal{M}_{hcn} = \{U \in \mathcal{M}_{fcn} : u_{ik} \in \{0, 1\}\}$.

Moreover, we will refer to the set $\mathcal{M}_{pcn} - \mathcal{M}_{hcn}$ as the set of *soft partitions*, according to the definition in [2].

In many fields, figuring out how close are two partitions of the same dataset X is a problem of great interest. Generally speaking, it can indeed be useful to confront how different experts class different objects. In clustering, and more precisely in cluster validity, it also enables to evaluate and compare the quality of different algorithms, or the same algorithm with different parameters. This important problem has been tackled since decades by attempting to define concordance measures assessing the degree of agreement between partitions, so that a large number of measures exist in the literature. One can distinguish two kinds of measures, depending on the use made of them, see [3] : an *external index* will be used when one wants to assess the quality of a partition compared to a reference one, while a *relative index* will be used to only evaluate how close two partitions are. Since the frontier between these two categories is thin, we will more generally refer to both of them as *comparison indices* in this paper.

Early comparison indices have been dedicated to crisp partitions, and a new interest has recently emerged for this topic thanks to the definition of the new class of soft partitions mentioned above. Many fuzzy or soft concordance measures have been recently proposed, and one can distinguish between them those relying on direct approaches from those extending historical crisp ones. Among the formers, one can cite measures based on the comparison of the whole set of α-cuts of the two partitions [4], or on a measure of uncertainty of both partitions [5]. The latters, such as the fuzzy transfert distance [6], extend existing crisp indices in the sense they reduce to crisp ones while comparing two crisp partitions. This category of soft indices also regroup a class of propositions called *coincidence-based indices*, extending well known indices such as the Rand, Jaccard and Fowlkes-Mallow ones [7]. Such soft indices solve most of the intrinsic problems of the comparison of partitions, and specifically :

- the *correspondance* or *cluster matching* problem, as discussed in [2],
- the problem of comparing partitions with different number of clusters.

Indeed, by comparing how objects are paired, i.e. belong or not belong to the same cluster in both partitions, no preliminary cluster matching is required, and the number of clusters has computationally no importance with these indices. The comparison is based on the construction, for each partition to be compared, of a coincidence matrix crossing the partition with itself. Many propositions have been made to compute and compare such matrices. Most of them are based on fuzzy set-theoretic tools, extending thus directly the set-theoretic approach used for the crisp indices, *e.g.* in [8], [9] and [10]. Another approach is possible, as proposed in [11]. It consists in using a similarity measure between the two coincidence matrices based on a distance between the membership vectors of the partitions. Because each of these constructions presents drawbacks and advantages, we propose in this paper a new

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

soft Rand index taking profits of both approaches.
This paper is organized as follows. A review of existing soft Rand indices is presented in section II and their strengths and weaknesses are confronted. In section III, the new Rand index is proposed. Its main characteristics are investigated in section IV through an intensive comparative experimental study. A conclusion is given in section V.

II. Some existing coincidence-based soft Rand Indices

Let $U \in \mathcal{M}_{hcn}$ be a crisp partition of a dataset X. The *coincidence matrix* Ψ_U of U is a symmetric $(n \times n)$ matrix whose general term

$$\psi_{U,kl} = \sum_{i=1}^{c} u_{ik} \wedge u_{il} = \begin{cases} 1 & \text{if } \mathbf{u}_k = \mathbf{u}_l \\ 0 & \text{else} \end{cases} \tag{1}$$

describes the degree to which the objects $\mathbf{x}_k$ and $\mathbf{x}_l$ of X belong to the same cluster in U. Given a second partition V of the same dataset and its coincidence matrix Ψ_V, the crisp Rand Index measuring the concordance between U and V is defined as follows:

$$RI(U,V) = \frac{n_{11} + n_{00}}{n_{11} + n_{10} + n_{01} + n_{00}}. \tag{2}$$

As defined, the Rand index takes values in $[0,1]$ and equals 1 when $U \equiv V$. The number of pairs of objects $(\mathbf{x}_k, \mathbf{x}_l)$ belonging to the same cluster (respectively to different clusters) in both U and V is given by n_{11} (respectively n_{00}), so that the numerator in (1) represents the agreement of U and V. On the other side, disagreement between both partitions is represented by the numbers of pairs belonging to the same cluster in U (respectively V) and in different clusters in V (respectively U), namely n_{10} and n_{01}. Let us assume $\alpha, \beta \in \{0,1\}$, the different numbers of pairs $n_{\alpha\,\beta}$ are given:

$$n_{\alpha\,\beta} = \sum_{k=2}^{n} \sum_{l=1}^{k-1} \big((1-\alpha) + (2\,\alpha - 1)\ \psi_{U,kl}\big) \wedge \big((1-\beta) + (2\,\beta - 1)\ \psi_{V,kl}\big). \tag{3}$$

This index, as many other crisp indices constructed on the same principle, *e.g.* in [7], can be equally computed from the contingency matrix crossing the two partitions to be compared, see [12]. This equivalence, that do not generally holds in the soft case, has led to two different classes of soft extensions, namely the *contingency-based*, see the recent work by Anderson et al [2], and the *coincidence-based* ones we are interested in. We recall hereafter two recent extensions of the Rand index belonging to this latter class to which we will compare our proposition.

A. The fuzzy set-theoretic approach

Since the crisp Rand index as defined by (2) is built on a logical and set-theoretic approach, some authors have proposed to extend it by use of fuzzy set-theoretic tools. Namely, the t-norm and the sum (or Σ-count) operators are used to extend the classical concepts of intersection (or conjunction) and cardinality, respectively. Briefly, a t-norm is a commutative, associative and monotonic function $\top : [0,1]^2 \to [0,1]$ having 1 for neutral element. The most common t-norms are given in table I and an interest reader can refer to [13] for a complete review.

TABLE I
Basic triangular norms and some parametrized families of t-norms.

Standard	$\top_M(a,b) = \min(a,b)$
Product	$\top_P(a,b) = a\,b$
Łukasiewicz	$\top_L(a,b) = \max(a+b-1, 0)$
Frank $\lambda \in \mathbb{R}_+^\star \backslash \{1\}$	$\top_{F_\lambda}(a,b) = \ln_\lambda\left(1 + \frac{(\lambda^a - 1)\,(\lambda^b - 1)}{\lambda - 1}\right)$
Hamacher $\lambda \in \mathbb{R}_+$	$\top_{H_\lambda}(a,b) = \frac{a\,b}{\lambda + (1-\lambda)\,(a+b-a\,b)}$

Extending (1) to the soft domain results in defining the elements of the soft coincidence matrix $\Psi_U^\top$ of a soft partition matrix U by [3]:

$$\psi_{U,kl}^\top = \sum_{i=1}^{c} \top(u_{ik}, u_{il}). \tag{4}$$

However, it has been recently shown that such a direct extension leads to counterintuitive values for the diagonal elements $\psi_{U,kk}^\top$ of the soft matrix, see [9], [10]. Indeed, these elements, which represent the degree to which each object $\mathbf{x}_k$ belongs to the same cluster as itself, is generally not 1, and can moreover be much less than 1 because of the $\top$ aggregation operator. The authors thus recommend to normalize the matrix $\Psi_U^\top$ to bring its diagonal terms to ones. A generic solution can be found in [10], leading to a soft normalized coincidence matrix $\Phi_U^\top$ whose general term is defined by:

$$\phi_{U,kl}^\top = \frac{\psi_{U,kl}^\top}{\top\left(K_\top\left(\psi_{U,kk}^\top\right), K_\top\left(\phi_{U,ll}^\top\right)\right)} \tag{5}$$

where $K_\top : [0,1] \to [0,1]$ is a t-norm dependant function such that $\top\big(K_\top(a), K_\top(a)\big) = a$. Given another soft normalized coincidence matrix $\Phi_V^\top$ computed from another soft partition V, the numbers $n_{\alpha\beta}$ (3) are extended to the soft domain by:

$$n_{\alpha\,\beta}^\top = \sum_{k=2}^{n} \sum_{l=1}^{k-1} \top\big((1-\alpha) + (2\,\alpha - 1)\ \phi_{U,kl}^\top, (1-\beta) + (2\,\beta - 1)\ \phi_{V,kl}^\top\big). \tag{6}$$

The derived *Normalized Soft Rand Index* ($NSRI$) is then computed directly from (2), and it is easy to show it reduces to its crisp counterpart when U and V are crisp.

B. The distance-based measure of equivalence approach

In [11], Hüllermeier and Rifqi propose another extension of the Rand index lying on a distance-based measure of equivalence between the membership vectors $\mathbf{u}_k$ of a soft partition U, so that the terms of the coincidence matrix Ψ_U^{HR} of U are defined as:

$$\psi_{U,kl}^{HR} = 1 - \frac{||\mathbf{u}_k - \mathbf{u}_l||}{\sqrt{2}}. \tag{7}$$

Given another soft partition V, the *Soft Equivalence Rand Index* ($SERI$) is then given by:

$$SERI(U,V) = \frac{1}{q}\sum_{k=2}^{n}\sum_{l=1}^{k-1} 1 - |\psi_{U,kl}^{HR} - \psi_{V,kl}^{HR}| \qquad (8)$$

where $q = \frac{n(n-1)}{2}$ is the number of different pairs of objects in X. It is shown that $SERI$ reduces as well to the crisp Rand index when comparing two crisp partitions. Furthermore it presents the great advantage to take its maximum value of 1 when $U \equiv V$ whatever the space in which U and V are defined ; which is not the case for the previously presented $NSRI$. This lead to an interesting discussion about how the two coincidence matrices are aggregated to build the index, depending on the approach. Indeed, keep in mind the terms of the coincidence matrices describe the degree to which two elements belong to the same cluster in a given partition, and remember the Rand index is meant to assess how much the two partitions are in agreement. Then, while $\psi_{U,kl}$ is close to $\psi_{V,kl}$, one can intuitively conclude in an agreement between U and V concerning the $(\mathbf{x}_k, \mathbf{x}_l)$ pair of objects. As a direct consequence, the given pair should then have a high contribution to the value of the Rand index. However, this is not the case with the $NSRI$ presented in section II-A. As an example, let $a = 0.3$ and $b = 0.29$ be the degrees to which two objects $\mathbf{x}_k$ and $\mathbf{x}_l$ are paired in two partitions. With the standard t-norm $\top_M$, and according to (6) and (2), the contribution of a and b to the agreement $n_{11} + n_{00} = \min(0.3, 0.29) + \min(1-0.3, 1-0.29) = 0.99$, which is a value one can expect. Nevertheless, their overall impact on the Rand index is drastically pulled down by their contribution to the disagreement $n_{10} + n_{01} = \min(0.3, 1-0.29) + \min(1-0.3, 0.29) = 0.59$. At the opposite, the contribution of a and b to the $SERI$, given by $s^{HR}(a,b) = 1 - |a-b| = 0.99$ in (8), is total and avoid the previously exposed drawback.
It is interesting to point out that this s^{HR} function, called *degree of concordance* by its authors, is actually a *similarity measure* since it satisfies the following axioms:

$$s(a,b) = s(b,a) \qquad \text{(symmetry)} \qquad (9)$$
$$s(a,a) \geq s(a,b),\ \forall\ b \qquad \text{(maximality)} \qquad (10)$$
$$s(a,a) = 1 \qquad \text{(unity)} \qquad (11)$$

This remark lies at the heart of this paper. On one hand, by preserving the set-theoretic sense of the original Rand index, $NSRI$ presents the strong advantage to lie on a strong and admitted theory, and its well behaviour has been shown in [10]. However, as exhibited above, it also presents a serious drawback because of the way the terms of the coincidence matrices are aggregated. On the other hand, the $SERI$, by redefining the original Rand index formula by means of a similarity measure, correct this. In the next section, we propose a new Rand index which takes profit of both approach, based on a new family of similarity measures.

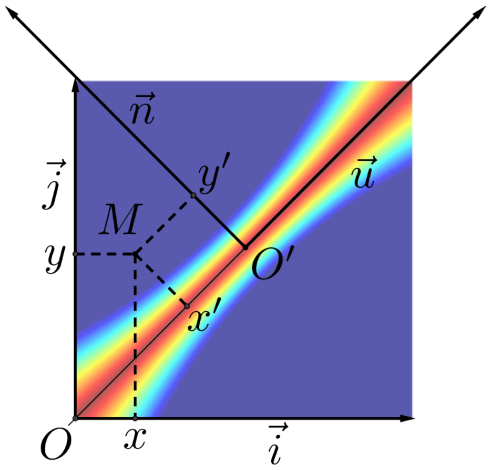

Fig. 1. Isosurface of s_p^w computed with w_T, $t = 0.1$, $r = 0.3$ and $o = \frac{1}{2}$ and geometrical explanation of its construction

III. The Normalized Soft Window-based similarity Rand Index

Let $O' = {}^t(o,o)$ be a point lying on the diagonal line $\Delta : x = y$ of the unit square and let $\vec{u}$ and $\vec{n}$ be two unit orthogonal vectors as shown in Fig. 1. Each point $M = {}^t(x,y) \in [0,1]^2$, whose coordinates express in $(O, \vec{i}, \vec{j})$, can be transformed into $M' = {}^t(x', y')$, with respect to $(O', \vec{u}, \vec{n})$. Given a zero-mean symmetric window function w taking values in $[0,1]$ such that $w(0) = 1$ and a symmetric profile function p taking values in $[0,1]$ satisfying $p(x) > 0,\ \forall x$, the function $s_p^w \colon [0,1]^2 \to [0,1]$ defined by

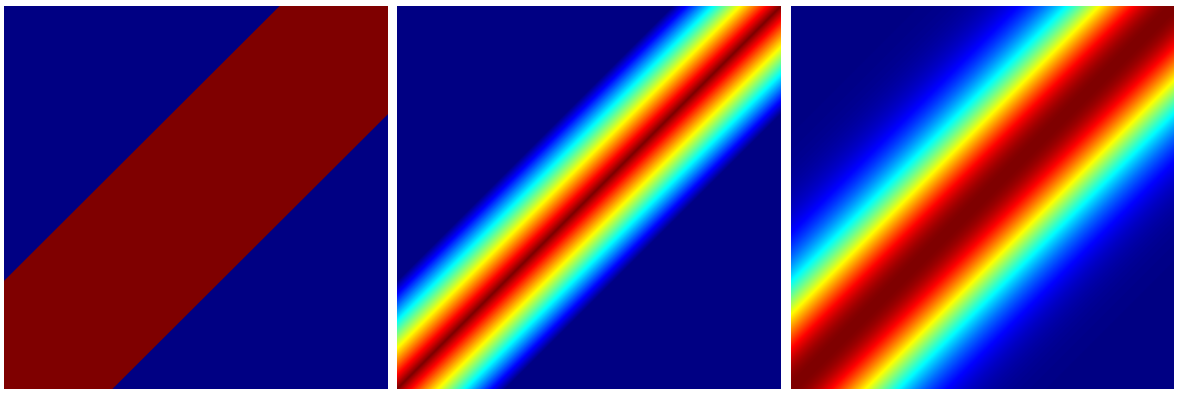
$$s_p^w(x,y) = w\left(\frac{y'}{p(x')}\right) \qquad (12)$$

is a measure of similarity between x and y w.r.t. axioms (9), (10) and (11). The proof being trivial, it is left to the reader. In (12), w controls the way x and y are considered similar with regard to their difference. Formally, it is a weighting function acting on the distance between M and Δ such that the farther M is from Δ, the smaller $s_p^w(x,y)$ is. Thus, choosing a window function w dropping quickly from 1 leads to a drastic similarity function s_p^w, *i.e* only close x and y values will be considered similar. Many symmetric window functions exist, some usual ones are reported in Table II. Fig. 2(b) presents the cuts of three s_p^w obtained with the three window functions w_U, w_T and w_G and whose isosurfaces are presented in Fig. 2(a). This example demonstrates how the behaviour of the similarity function s_p^w can be drastically modified according to w.

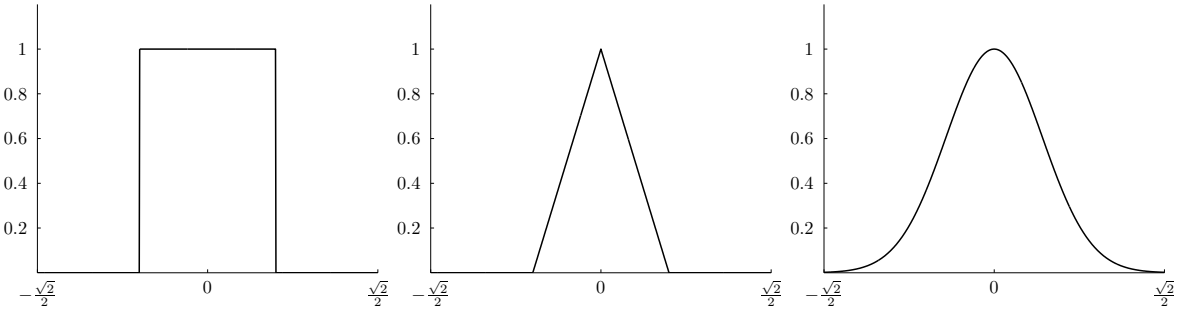
TABLE II
Usual window functions

Uniform	$w_U(x) = 1_{(x\leq 1)}$
Triangular	$w_T(x) = (1-\lvert x\rvert)1_{(x\leq 1)}$
Gaussian	$w_G(x) = \exp(-x^2)1_{(x\leq 1)}$
Epanechnikov	$w_E(x) = (1-x^2)1_{(x\leq 1)}$

In the same manner, the profile function p influences the similarity between x and y with respect to the distance between



(a) $w = w_U, w_T$ and w_G (from left to right) , $t = 0.2, r = 0, o$ is undefined



(b) Cut views of s_p^w plotted above along $x + y = 1$

Fig. 2. Isosurfaces and cut views of some s_p^w

M and O'. This allows to favour or not some specific ranges of values, according to the chosen *origin* parameter o. We propose to use the following p function:

$$p(x') = t + r\,x'^2 \tag{13}$$

where $t \in]0, \sqrt{2}]$ and $r \in \mathbb{R}_+$ are user defined parameters, called respectively the *thickness* and *curvature* parameters.

It is easy to show that with this particular profile function, O' has no influence whenever $r = 0$, so that no value for o is required.

As an example, Fig. 1 presents the isosurface of s_p^w with the following settings: $w = w_T$, a thickness $t = 0.1$, a curvature $r = 0.3$ and an origin $o = \frac{1}{2}$. One can observe that, for all M, the closer x and y are to $\frac{1}{2}$, the more selective $s_p^w(x, y)$ is, as expected. Fig. 3 also show examples of s_p^w functions using most of w functions of Table II with particular values for t, r and o, so that each row exhibits the role of each parameter. For instance, Fig. 3(a) shows the influence of t on the selectivity of s_p^w, according to its value (a small one, a middle one and the maximum one).

From this construction, we propose to define a new index measuring the concordance between two soft partitions U and V, called the *Normalized Soft Window-based similarity Rand Index* ($NSWRI$), by:

$$NSWRI(U, V) = \frac{1}{q} \sum_{k=2}^{n} \sum_{l=1}^{k-1} s_p^w(\phi_{U,kl}^{\top}, \phi_{V,kl}^{\top}) \tag{14}$$

where $\phi_{U,kl}^{\top}$ and $\phi_{V,kl}^{\top}$ are the terms of the normalized coincidence matrices Φ_U and Φ_V constructed according to (5).

Whatever the parameters used for the similarity function s_p^w, it is easy to show that this index reduces to the original crisp Rand index while comparing two crisp partitions. Moreover, like the $SERI$, it reaches its maximum value of 1 when $U \equiv V$, whatever their nature.

The set of parameters an user has to choose in order to compute $NSWRI(U, V)$ is $\{\top, w, t, r, o\}$. Since the range of values of each parameter is wide, we will only show some examples in the the following experimental results.

IV. Experimental results

A. Numerical experiments on fuzzy partitions.

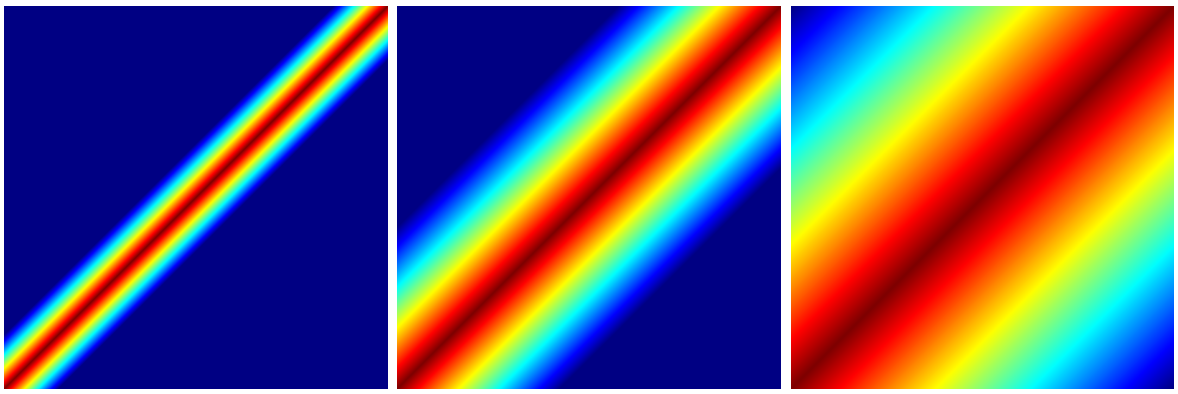
In this section, we propose to investigate the specificities and possibilities of this new index by mean of a simple set of synthetic partitions composed of one crisp partition $U_1 = \begin{pmatrix} 0 & 0 & 1 & 1 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix} \in \mathcal{M}_{h34}$ and eight fuzzy partitions in $\mathcal{M}_{f34}$:

$$U_2 = \begin{pmatrix} 0.05 & 0.10 & 0.85 & 0.95 \\ 0.00 & 0.90 & 0.15 & 0.00 \\ 0.95 & 0.00 & 0.00 & 0.05 \end{pmatrix}, U_3 = \begin{pmatrix} 0.10 & 0.10 & 0.80 & 0.90 \\ 0.00 & 0.80 & 0.20 & 0.00 \\ 0.90 & 0.10 & 0.00 & 0.10 \end{pmatrix},$$

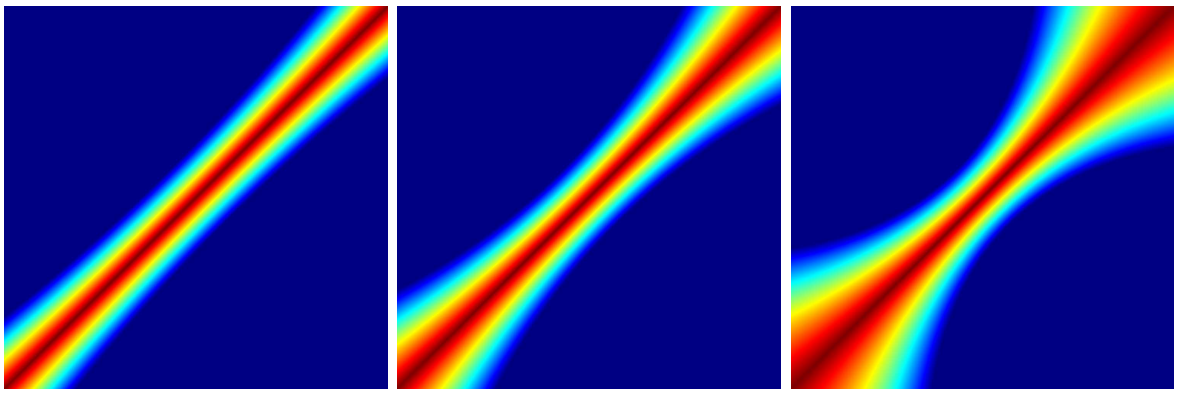
$$U_4 = \begin{pmatrix} 0.20 & 0.20 & 0.70 & 0.80 \\ 0.00 & 0.70 & 0.20 & 0.10 \\ 0.80 & 0.10 & 0.10 & 0.10 \end{pmatrix}, U_5 = \begin{pmatrix} 0.20 & 0.30 & 0.60 & 0.70 \\ 0.10 & 0.60 & 0.30 & 0.10 \\ 0.70 & 0.10 & 0.10 & 0.20 \end{pmatrix},$$

$$U_6 = \begin{pmatrix} 0.30 & 0.30 & 0.50 & 0.60 \\ 0.10 & 0.50 & 0.30 & 0.20 \\ 0.60 & 0.20 & 0.20 & 0.20 \end{pmatrix}, U_7 = \begin{pmatrix} 0.30 & 0.35 & 0.40 & 0.50 \\ 0.20 & 0.40 & 0.35 & 0.25 \\ 0.50 & 0.25 & 0.25 & 0.25 \end{pmatrix},$$

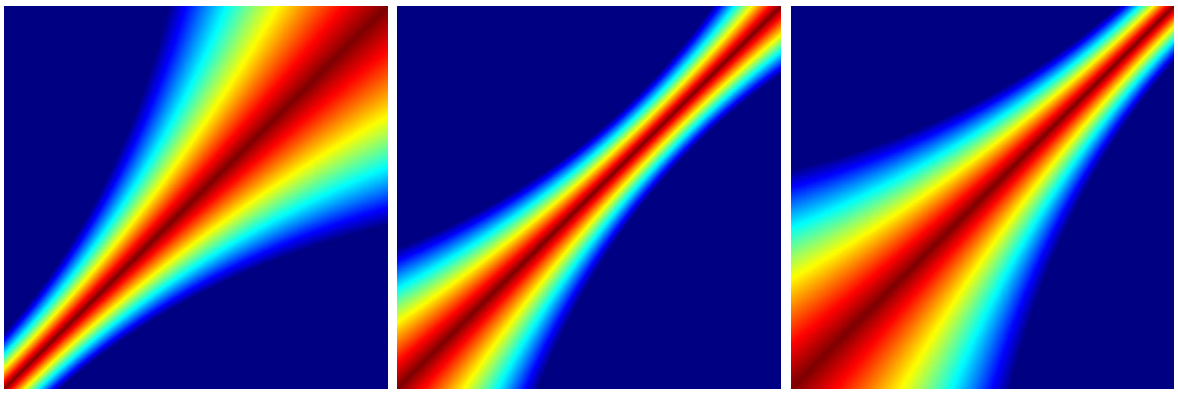
$$U_8 = \begin{pmatrix} 0.35 & 0.35 & 0.35 & 0.35 \\ 0.30 & 0.35 & 0.35 & 0.30 \\ 0.35 & 0.30 & 0.30 & 0.35 \end{pmatrix}, U_9 = \begin{pmatrix} 0.40 & 0.45 & 0.30 & 0.35 \\ 0.30 & 0.35 & 0.45 & 0.25 \\ 0.30 & 0.20 & 0.25 & 0.40 \end{pmatrix}.$$



(a) $w_T, t = 0.1, 0.3$ and $\frac{\sqrt{2}}{2}$ (from left to right) , $r = 0, o$ is undefined



(b) $w_T, t = 0.1, r = 0.1, 0.3$ and 0.8 (from left to right) , $o = 0.5$



(c) $w_T, t = 0.1, r = 0.3, o = 0, 0.7,$ and 1 (from left to right)

Fig. 3. Isosurfaces of some s_p^w

These partitions are chosen such that:

- $U_2, ..., U_7$ reduce to U_1 if hardened according to the maximal membership degree, while U_8 may not because of ties and U_9 does not
- $U_{\alpha+1}$ is fuzzier than U_α, $\forall \alpha \in \{1, ..., 7\}$ according to the *Partition Entropy* [1] (see table III), which indicates the amount of fuzziness in a given partition:

$$PE(U) = -\frac{1}{n} \sum_{i=1}^{c} \sum_{k=1}^{n} u_{ik} \log(u_{ik}) \qquad (15)$$

One can intuitively state that, according to their proximity with U_1, these partitions can thus be sorted decreasingly as $\{U_2, U_3, U_4, U_5, U_6, U_7, U_9, U_8\}$. Note that U_9 is considered closer to U_1 than U_8. Altought this may seems counterintuitive, it can be explained simply. Indeed, U_1 is fully determinist whereas U_8 presents, at the extreme opposite, complete uncer-

TABLE III
FUZZINESS OF PARTITIONS U_α, $\forall \alpha \in \{1, ..., 8\}$

	U_1	U_2	U_3	U_4	U_5	U_6	U_7	U_8
$PE(U)$	0	0.29	0.45	0.69	0.85	0.98	1.06	1.10

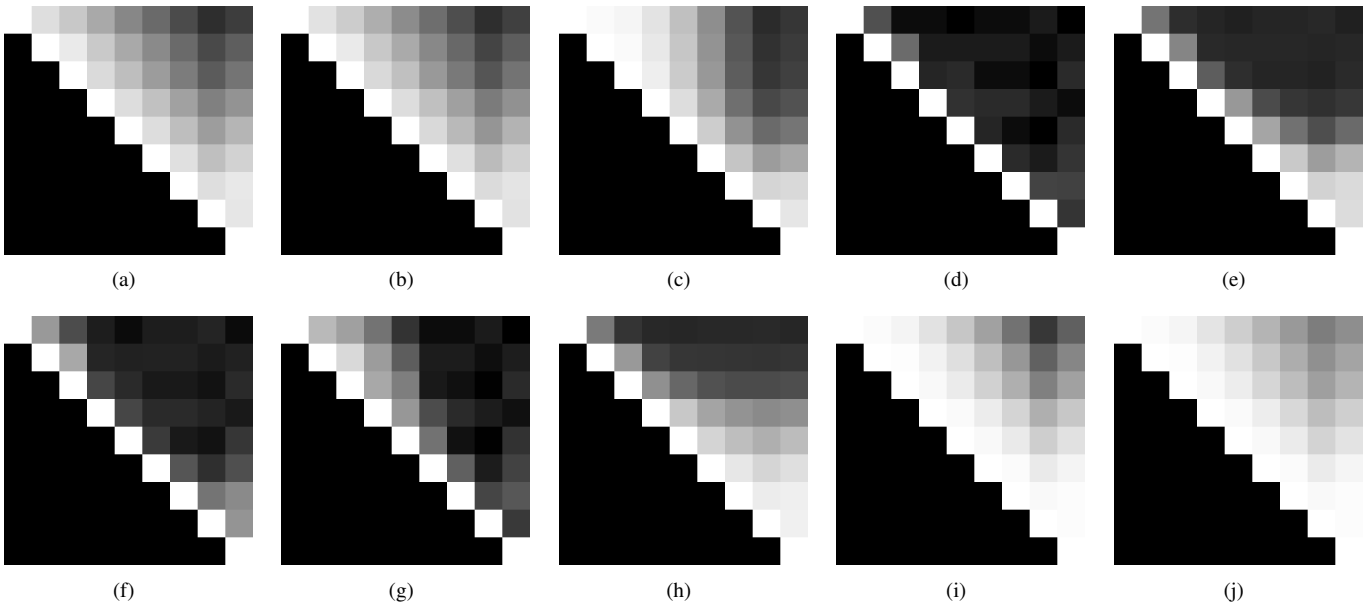


Fig. 4. Dissimilarity matrices crossing the nine partitions U_α with $SERI$ (a) and $NSWRI$ with different parameters (b)–(j) described in table IV

tainty. Thanks to a possible permutation of clusters, U_9 then shares more information in common with U_1 than U_8 does, as confirmed by the partition entropy $PE(U_9) = 1.07$.

So as to validate our proposal regarding to the intuitive proximities discussed above, nine dissimilarity matrices crossing all the pairs of partitions (U_i, U_j) with $NSWRI$ are computed for different values of each of the five parameters $\{\top, w, t, r, o\}$. These nine dissimilarity matrices are presented in Fig. 4 with an additional matrix computed with $SERI$ for comparison, presented in Fig. $4(a)$. The parameters used to compute the nine dissimilarity matrices (b)–(j) are reported in table IV. For each of them, partitions are ordered in rows and columns according to their index. The brighter a cell of a matrix is, the higher is the value of the index.

As one can directly see, the statemment made earlier about the relative proximities between the nine partitions mostly holds, according to the first row of each dissimilarity matrix, especially for (b), (c), (e), (h), (i) and (j) where $NSWRI$ is not to much drastic. While the statement does not hold, *i.e.* with (d), (f) and (g), it is interesting to note that $NSWRI$ almost provides a strong separation between the partitions, so that a threshold could be easily tuned to decide whether two partitions are similar or not. Moreover, other statements can be made while comparing some couples or triples of dissimilarity matrices:

- (a) and (b) clearly show that $NSWRI$ can be tuned to behave in the same way $SERI$ does.
- (b) and (c) demonstrate the influence of the t-norm. Indeed, by choosing a drastic t-norm such as $\top_{H_{100}}$, our proposal favour the less fuzzy partitions.
- the influence of the thickness parameter t is crucial as it enables to tune how drastic the index is, as shown by (b) and (d).
- (e), (f) and (g) show the influence of the chosen origin parameter o while the curvature r is not null: choosing o near 0 leads $NSWRI$ to favour extremely fuzzy partitions, while choosing o near 1 will lead $NSWRI$ to the opposite behaviour.
- (e) and (h) demonstrate the influence of the degree of curvature chosen for r on the previously described behaviour, *i.e.* a high value of r reinforce it.
- (b), (i) and (j) testify of the influence the window function w has on the selectivity and the range of response our proposal have. For instance, partitions U_α and $U_{\alpha+1}$ are considered closer by $NSWRI$ using w_E than using w_T.

All these remarks show that our $NSWRI$ is a really versatile tool for comparing partitions, that can be tuned to behave in many different ways.

TABLE IV
PARAMETERS USED TO COMPUTE $NSWRI$ IN THE EXPERIMENTATIONS DECRIBED BY FIG. 4

Dissimilarity matrix	$\top$	w	t	r	o
(b)	$\top_M$	w_T	$\frac{\sqrt{2}}{2}$	0	$\times$
(c)	$\top_{H_{100}}$	w_T	$\frac{\sqrt{2}}{2}$	0	$\times$
(d)	$\top_M$	w_T	0.1	0	$\times$
(e)	$\top_M$	w_T	0.1	0.3	0
(f)	$\top_M$	w_T	0.1	0.3	0.5

B. Numerical experiments on possibilistic partitions.

Consider the set composed of the crisp partition U_1 of the previous section and eight possibilistic $U^p_{\{2\ldots9\}}$ partitions defined from the previous fuzzy partitions $U_{\{2\ldots9\}} \in \mathcal{M}_{p34}$ such as $U^p_\alpha = \frac{U_\alpha}{2}$. As previously, the nine partitions are crossed

using $SERI$ and $NSWRI$ to compute two dissimilarity matrices presented in Fig. 5. The parameters used for the computation of $NSWRI$ are the same as those used for Fig. 4(b), see table IV.

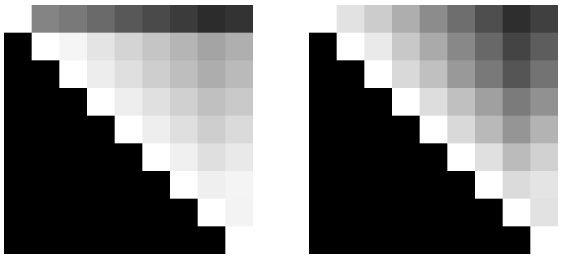

Fig. 5. Dissimilarity matrices crossing nine possibilistic partitions U_α^p, obtained with $SERI$ (left) and $NSWRI$ (right) with $\{\top_M, w_T, t = \frac{\sqrt{2}}{2}, r = 0\}$

One can observe that the $SERI$ makes a strong distinction between the crisp and the possibilistic partitions. At the opposite, results given here by $NSWRI$ strictly present no differences with the ones obtained with the previous set of fuzzy partitions U_α, as described in Fig. 4(b). This behaviour is the consequence of the normalization applied to the coincidence matrix of each partition. Moreover, this property holds for any set of parameters $\{\top, w, t, r, o\}$ while $\top \in \{\top_M, \top_P\}$ and barely holds with little differences with other t-norms, so that results obtained in previous section holds for possibilistic partitions. An interesting discussion is that no existing statement has already been made about the way possibilistic partitions must be compared to crisp or fuzzy ones, so that both $SERI$ and $NSWRI$ behaviour can be defended and used, depending on the application.

C. Comparing two fuzzy partitions provided by FCM.

We consider four well known datasets from the UCI Machine Learning Repository [14] presenting various characteristics in terms of: number n of samples, number p of features, true number $c^\star$ of classes/clusters and degree of overlap between clusters, as summarized in table V. For each dataset, the *Fuzzy C-Means algorithm* (FCM) [15] is run to produce a reference fuzzy partition R and a collection of 14 fuzzy c-partitions Q_c, $c \in 2, ..., 14$. Each partition Q_c is compared to R with different indices, namely $NSRI$, $SERI$ and our proposal $NSWRI$ with different parameters, provided the index requires some parametrization. For each index I, the computed value of $I(R, Q_c)$ is stored for each value of c. Fig. 6 presents some examples ofresulting curves. Each column is for a dataset, the first, second, third and fourth rows are respectively the results obtained by computing $NSWRI$ with $\{\top_P, w_T, 0.1, 0.1, 0\}$, $\{\top_P, w_T, 0.1, 0.8, 0\}$, $\{\top_P, w_T, 0.1, 0.1, 1\}$ and $\{\top_P, w_T, 0.1, 0.8, 1\}$. $NSRI$ is computed with $\top_P$ as well.

As expected, each index expresses its maximum value when c reaches the real number of classes $c^\star$, and they share the tendency to drop from this maximum toward an asymptotic value, different in each case and for each index and depending on the overlap of the dataset. $NSWRI$ does not always reach a value as large as the other two indices, but it presents a better dynamic and is thus more discriminant. One can observe that this behaviour is influenced by the choice of the origin parameter o. Indeed, the separation is emphasized in the whole set of examples when $o = 1$, backing the statements made in previous experiments, see section IV-A. Nevertheless, it seems that choosing a large value for r weakens the discriminant power of $NSWRI$, according to the results presented in each second and fourth row of Fig. 6.

TABLE V
REAL DATASETS AND THEIR CHARACTERISTICS.

dataset	n	p	$c^\star$	clusters property
Ionosphere	351	34	2	very strong overlap
Pima	768	9	2	strong overlap
Iris	150	4	3	slight overlap
Thyroid	215	5	3	slight overlap

V. CONCLUSION

In this article, we propose a new extension of the Rand index, meant to take benefits of two existing ones that belong to the class of conincidence-based comparison indices. These approaches lie respectively on fuzzy set-theoretic and similarity principles. It is shown that the former, although it is based on a direct extension of the crisp Rand index to the soft domain, presents some drawbacks because of the way the coincidence matrices are aggregated. These drawbacks are avoided by the latter, thanks to the use of a similarity measure. A new parametrized similarity measure is proposed to correct the drawbacks. It allows us to define a new versatile Rand index. Thanks to its flexibility, this index outperforms the existing ones as shown by numerous experimental results on both synthetic and real data. Moreover, by allowing to compare possibilistic partitions in a new way, the proposed concordance measure could become a privilegied tool for many practitioners.

***Abstract*—We propose a new relational clustering approach, called Fuzzy clustering with Learnable Cluster dependent Kernels (FLeCK), that learns multiple kernels while seeking compact clusters. A Gaussian kernel is learned with respect to each cluster. It reflects the relative density, size, and position of the cluster with respect to the other clusters. These kernels are learned by optimizing both the intra-cluster and the inter-cluster similarities. Moreover, FLeCK is formulated to work on relational data. This makes it applicable to data where objects cannot be represented by vectors or when clusters of similar objects cannot be represented efficiently by a single prototype. The experiments show that FLeCK outperforms several other algorithms. In particular, we show that when data include clusters with various inter and intra cluster distances, learning cluster dependent kernel is crucial in obtaining a good partition.**

***Index Terms*—Fuzzy clustering, kernel learning, Gaussian kernel.**

I. Introduction

Clustering consists of partitioning a data set into subsets, so that data in each subset share some common aspects. In other words, according to a defined distance measure, objects in the same cluster should be as similar as possible and objects in different clusters should be as dissimilar as possible. Clustering has been used in many applications related to understanding and exploring the structure of the data. In particular, fuzzy clustering techniques have been shown to be suitable to describe real situations with overlapping boundaries [1].

Typically, the set of objects to be clustered could be described in two ways: object based representation, and relational based representation. While for object data representation, each object is represented by a feature vector, for the relational representation only information of how two objects are related is available. Relational data representation is more general in the sense that it can be applied when only the degree of (dis)similarity between objects is available or when groups of similar objects cannot be represented efficiently by a single prototype.

Despite the large number of existing clustering methods, clustering remains a challenging task when the structure of the data does not correspond to easily separable categories, and when clusters vary in size, density and shape. Kernel based approaches [2], [3], [4] allow to adapt a specific similarity measure in order to make the problem easier. Gaussian kernel is the most common similarity function. Although good results were obtained using this kernel, it relies on the selection of a scale parameter. This selection is commonly done manually. Moreover, as it is a global parameter over the entire data, it may not be appropriate when the distributions of the different clusters in the feature space exhibit large variations. Thus, in the absence of apriori knowledge, the choice of a scaling parameter that can adapt to different clusters and discriminate between them is difficult. In such situations, the geometry of the data should be explored to learn local similarity measures by finding intrinsic properties, such as local dimensionality, and local parametrization.

In this work, we introduce a new fuzzy relational clustering technique. The proposed algorithm, called Fuzzy clustering with Learnable Cluster dependent Kernels (FLeCK), learns the underlying cluster dependent dissimilarity measure while finding compact clusters. The learned measure is a local dissimilarity based on the Gaussian kernel function defined with respect to each cluster. In particular, we propose to learn a scaling parameter σ_i with respect to each cluster i. This scaling parameter is designed to distinguish and separate the objects of cluster i from the rest of the data. We achieve this by considering one cluster at a time, and learning a scaling parameter that maximizes the intra-cluster similarity and minimizes the inter-cluster similarity.

The organization of the rest of this paper is as follows. In section 2, we highlight related clustering algorithms. In section 3, we present our algorithm. In section 4, we describe the experiments conducted to validate the proposed algorithm. Finally, section 5 contains the conclusions and potential future work.

II. Related works

In most applications categories are rarely well separated and boundaries are overlapping. Describing these real world situations by crisp sets does not allow the user to quantitatively distinguish between objects which are strongly associated with a particular category from those that have only a marginal association with multiple ones, particularly, along the overlap-

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

ping boundaries. Fuzzy clustering methods are good at dealing with these situations [5]. In fact, data elements can belong to more than one cluster with fuzzy membership degrees. These memberships indicate the strength of the association between that data element and a particular cluster. One of the most widely used fuzzy clustering algorithms is the Fuzzy C-Means (FCM) Algorithm [6] and its relational dual, Relational Fuzzy C-means algorithm (RFCM) [7].

Although FCM based approaches are quite efficient, they are not suitable for all types of data, and cannot handle clusters of different sizes and densities effectively [8]. Another major drawback of FCM based approaches is that they cannot separate clusters that are non-linearly separable in the input space. Two recent approaches have emerged for tackling such a problem. They allow mapping of the data into a new space in such a way that computing a linear partitioning in this feature space results in a nonlinear partitioning in the input space [2], [3], [4], [9]. These are mainly approaches based on kernel and spectral clustering.

Kernel methods allow the incorporation of a priori knowledge. This knowledge is implicit and is integrated in the learning process through the use of a kernel function. However, despite the existence of a large number of kernel clustering algorithm (e.g., kernel K-means [2], [10], kernel FCM [11], [12], [13], kernel SOM [3], [14] and kernel Neural Gas [4]), the choice of a good kernel function and the adaptation of its parameters to the data remains a challenging task. For instance, in the Kernelized Non-Euclidean Relational Fuzzy c-Means Algorithm (kNERF) [15], a relational Gaussian kernel is used with one global scaling parameter for all the data. The selection of the scaling parameter is discussed but there has been no attempt to devise methods to automatically select it. Moreover, a global scaling parameter may not be appropriate when clusters are of widely differing shapes, sizes, and densities.

Spectral clustering algorithm methods solve a similar problem as kernel methods, but use a different approach. Its theory arises from the graph cut concept [9]. As for kNERF, spectral clustering use the Gaussian similarity function in order to model the local neighborhood relationships between data points. Thus, it has the same challenging task of determining and adapting the scaling parameter to the data set.

The Gaussian similarity function, used in kernel and spectral clustering, is defined as

$$\mathbf{S}_{jk} = exp\left(-\frac{dist\left(\mathbf{x}_j, \mathbf{x}_k\right)}{\sigma^2}\right) \tag{1}$$

where $dist$ measures the dissimilarity between patterns and σ controls the rate of decay of S. The scaling parameter σ is commonly set manually.

Ng et al. [16] suggested selecting σ that provides the least distorted clusters by running the algorithm for different values of σ. However, the range of values to be tested still has to be set manually. Moreover, a global σ for mapping all the data may not provide a good clustering when the input data includes clusters with different local statistics.

In [17], the authors proposed to calculate a local scaling parameter σ_j for each data point $\mathbf{x}_j$ and defined the similarity between a pair of points as

$$\mathbf{S}_{jk} = exp\left(-\frac{dist\left(\mathbf{x}_j, \mathbf{x}_k\right)}{\sigma_j \sigma_k}\right) \tag{2}$$

The selection of the local scale σ_j is defined in [17] as the distance between point $\mathbf{x}_j$ and its P^{th} neighbor. Nevertheless, this approach is still dependent on the selection of the neighborhood parameter P which is fixed empirically for each data set. Moreover, if $\mathbf{x}_j$ is a noise point, adapting σ_j to this point will distort this fact.

To the best of our knowledge, no automatic way to select the optimal scaling parameter and adapt it to each cluster has been proposed even though the performance of Gaussian kernel based approaches is highly dependent on this parameter. In this paper, we propose a clustering algorithm, called Fuzzy clustering with Learnable Cluster dependent Kernels (FLeCK), that learns the underlying cluster dependent scaling parameters while finding compact clusters.

III. Fuzzy clustering with learnable cluster dependent kernels

Considering the Gaussian similarity function as defined in (1), the optimal choice of the scaling parameter is the one that allows to segregate and distinguish between the clusters. Thus, this scaling parameter has to ensure a high intra-cluster similarity and low inter-cluster similarity. A very large value of σ would minimize the intra-cluster similarity. However, this choice would also minimize the inter-cluster similarity and merge all the objects into a single cluster. One possible approach to avoid this trivial solution is to seek scaling parameters that minimize the intra-cluster similarities and maximize the intra-cluster similarities simultaneously.

Let $\{\mathbf{x}_1, \cdots, \mathbf{x}_N\}$ be a set of N data points and let $\mathbf{R} = [\mathbf{r_{jk}}]$ be a relational matrix where r_{jk} represent the degrees to which pairs of objects are similar. The FLeCK algorithm minimizes the intra-cluster similarity

$$\begin{aligned} J^{intra} &= \sum_{i=1}^{C}\sum_{j=1}^{N}\sum_{k=1}^{N}\beta_{jk}^{i}\left(1 - exp\left(-\frac{\mathbf{r}_{jk}}{\sigma_i}\right)\right) \\ &- \sum_{i=1}^{C}\frac{K}{\sigma_i} \end{aligned} \tag{3}$$

and maximizes the inter-cluster similarity

$$J^{inter} = \sum_{i=1}^{C}\sum_{j=1}^{N}\sum_{k=1}^{N}\alpha_{jk}^{i} exp\left(-\frac{\mathbf{r}_{jk}}{\sigma_i}\right) - \sum_{i=1}^{C}\frac{K}{\sigma_i} \tag{4}$$

In (3) and (4), C is the number of clusters. The constant K provides a way of specifying the relative importance of the regularization term compared to the sum of intra-cluster and inter-cluster distances. When K is zero, minimizing (3) with respect to σ_i gives the trivial solution of a very large σ_i that merges all points into a single cluster. Instead of treating K as a constant, we propose to determine the optimal K

by simultaneously minimizing the intra-cluster similarity and maximizing the inter-cluster similarity.

The term β^i_{jk} in (3) is the likelihood that two points $\mathbf{x}_j$ and $\mathbf{x}_k$ belong to the same cluster i and is defined as

$$\beta^i_{jk} = u^m_{ij} u^m_{ik} \tag{5}$$

where u_{ij} is the fuzzy membership of $\mathbf{x}_j$ in cluster i and satisfies the constraints

$$0 \leq u_{ij} \leq 1 \;\; and \;\; \sum_{i=1}^{C} u_{ij} = 1, \; for \; j \in \{1, \ldots N\}. \tag{6}$$

Similarly, the term α^i_{jk} in (4) refers to the likelihood that two points $\mathbf{x}_j$ and $\mathbf{x}_k$ do not belong to the same cluster i. It can also be defined using the fuzzy memberships of the two points using

$$\alpha^i_{jk} = u^m_{ij}\left(1 - u^m_{ik}\right) + u^m_{ik}\left(1 - u^m_{ij}\right). \tag{7}$$

In (5) and (7), $m \in (1, \infty)$ is a constant that determines the level of cluster fuzziness. A larger m results in fuzzier clusters. Typically, m is set to 2 [18].

The first term in (3) seeks clusters that have compact local relational distances

$$\mathbf{D}^i_{jk} = 1 - exp\left(-\frac{\mathbf{r}_{jk}}{\sigma_i}\right) \tag{8}$$

with respect to each cluster i. The scaling parameter, σ_i, controls the rate of decay of $\mathbf{D}^i_{jk}$. We should note here that our approach learns a cluster dependent σ_i in order to deal with the large variations between the distributions and the geometric characteristics of each cluster. The second term in (3) and (4) is a regularization term to avoid the trivial solution where all σ_i are infinitely large.

The proposed FLeCK algorithm attempts to optimize (3) and (4) by learning the C clusters, the scaling parameter, σ_i, of each cluster, and the membership values, u_{ij}, of each sample $\mathbf{x}_j$ in each cluster i.

In order to optimize (3) and (4) with respect to σ_i, we assume that σ_i's are independent from each others and reduce the optimization problem to C independent problems. That is, we convert the set of objective functions in (3) and (4) to the following C simpler set of functions

$$J^{intra}_i = \sum_{j=1}^{N}\sum_{k=1}^{N} \beta^i_{jk}\left(1 - exp\left(-\frac{\mathbf{r}_{jk}}{\sigma_i}\right)\right) - \frac{K}{\sigma_i}, \tag{9}$$

and

$$J^{inter}_i = \sum_{j=1}^{N}\sum_{k=1}^{N} \alpha^i_{jk} exp\left(-\frac{\mathbf{r}_{jk}}{\sigma_i}\right) - \frac{K}{\sigma_i} \tag{10}$$

for $i = 1, \ldots, C$. To obtain an update equation for the scaling parameters, we first set the derivative of J^{intra}_i with respect to σ_i to zero and solve for K. Then, we substitute the expression of K back in (10). Assuming that the values of σ_i do not change significantly from one iteration $(t-1)$ to the next one (t) and setting the derivative of J^{inter}_i to zero, we obtain

$$\sigma^{(t)}_i = \frac{Q^i_1}{Q^i_2} \tag{11}$$

where

$$Q^i_1 = \sum_{j=1}^{N}\sum_{k=1}^{N} \beta^i_{jk}\mathbf{r}^2_{jk} exp\left(-\frac{\mathbf{r}_{jk}}{\sigma^{(t-1)}_i}\right) \tag{12}$$

and

$$\begin{aligned} Q^i_2 &= \sum_{j=1}^{N}\sum_{k=1}^{N} \alpha^i_{jk}\mathbf{r}_{jk} exp\left(-\frac{\mathbf{r}_{jk}}{\sigma^{(t-1)}_i}\right) \\ &+ \sum_{j=1}^{N}\sum_{k=1}^{N} \beta^i_{jk}\mathbf{r}_{jk} exp\left(-\frac{\mathbf{r}_{jk}}{\sigma^{(t-1)}_i}\right) \end{aligned} \tag{13}$$

The expression of the scaling parameter defined by equation (11) depends on both the inter-cluster and the intra-cluster distances.

Optimization of (3) and (4) with respect to u_{ij} is not trivial and does not lead to a closed form expression. To keep the computation simple, we optimize only (3) with respect to u_{ij}. We achieve this by using the relational dual of the fuzzy C-means algorithm formulated by Hathaway et al. [7]. As it has been proved in [7], the Euclidean distance, $d^2_{ik} = \|\mathbf{x}_k - \mathbf{c}_i\|^2$, from feature $\mathbf{x}_k$ to the i^{th} cluster, $\mathbf{c}_i$, can be written in terms of the relational matrix $\mathbf{D}^i$ as

$$d^2_{ik} = \left(\mathbf{D}^i\mathbf{v}_i\right)_k - \frac{\mathbf{v}^t_i\mathbf{D}^i\mathbf{v}_i}{2}. \tag{14}$$

In (14), $\mathbf{v}_i$ is the membership vector of all N samples in cluster i defined by

$$\mathbf{v}_i = \frac{(u^m_{i1}, \ldots, u^m_{iN})^t}{\sum_{j=1}^{N} u^m_{ij}}. \tag{15}$$

Using Lagrange multiplier technique, it can be shown that optimization of (3) with respect to u_{ij}, subject to (6), yields the following membership update equation

$$u_{ij} = \frac{1}{\sum_{t=1}^{C}\left(d^2_{ij}/d^2_{tj}\right)^{\frac{1}{m-1}}}. \tag{16}$$

The resulting FLeCK algorithm is summarized below.

IV. Experimental Results

The performance of the proposed algorithm is illustrated and compared to kNERF [15] and Self tuning spectral [17]. We also illustrate the advantage of learning cluster dependent σ_i's compared to one global σ.

A. Synthetic data sets

To illustrate the ability of FLeCK to learn appropriate local scaling parameters and cluster the data simultaneously, we use it to categorize synthetic data sets. We use 2 data sets that include categories of different sizes and densities. We should mention here that for the purpose of visualizing the results, we use feature based and 2-dimensional data. Relational dissimilarity matrices are obtained by computing the Euclidean distance between these feature vectors. Results on real and high-dimensional data sets will be reported in the next section. Figure 1 displays the 2 synthetic data sets where each cluster is displayed with a different color.

For kNERF, and Self tuning spectral, we repeat the clustering with different parameters and report the best results. In particular, for Self tuning spectral, we tune the neighborhood parameter from 1 to 20 by an increment of 1. For kNERF, we tune the scaling parameter between 0.001 and 10 with a step of 0.01.

Figure 2 displays the clustering results of the three algorithms on data set 1. As shown in figure 2 (b), self tuning spectral was able to categorize it correctly after tuning the scaling parameter. Although, similar to spectral clustering kNERF is based on a non linear mapping of the input data, it was not able to categorize this data correctly (Fig. 2 (a)). This is due mainly to the fact that one global scaling parameter is not sufficient when the input data includes clusters with different local statistics. FLeCK and self tuning spectral provide local exponential mapping of the data and were able to partition this data correctly. The main difference between these approaches, as explained in section III, is that FLeCK learns the local scaling parameters and performs clustering simultaneously, while the self tuning spectral tunes the neighborhood within a user specified range to find local scaling parameters.

The scaling parameters learned by FLeCK reflect the relative position of each cluster with respect to the other clusters. For this data, cluster 1 and cluster 2 are close to each other, and cluster 3 is quite distant from both of them. Consequently, FLeCK learns a large scaling parameter $(\sigma_3 = 106.64)$ for

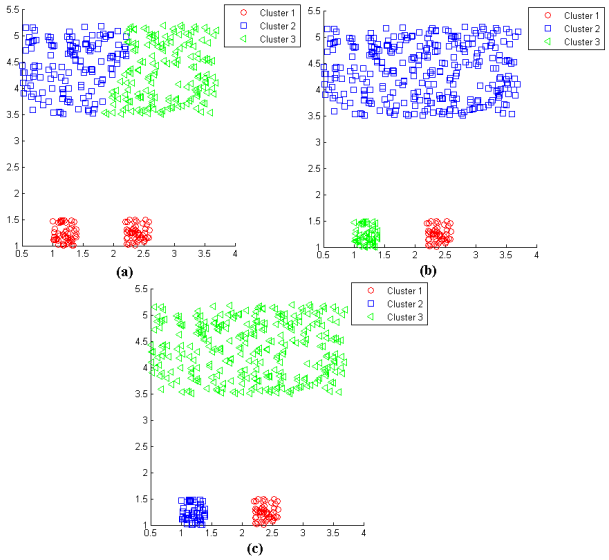

Fig. 2. Results of clustering the data in fig. 1 (a) using (a) kNERF, (b) Spectral, and (c) FLeCK

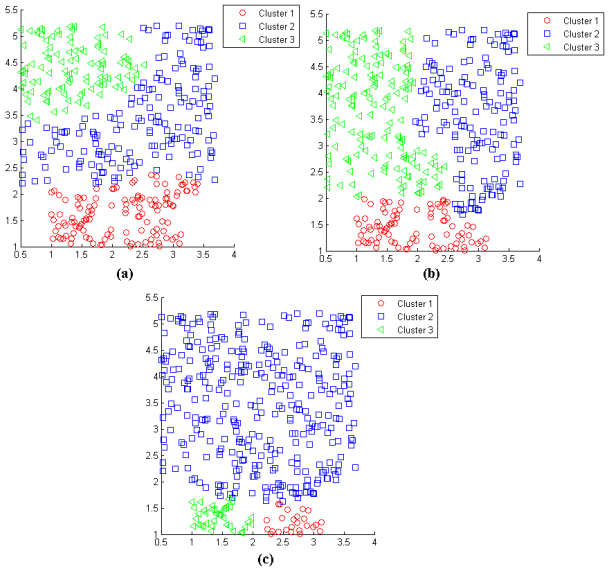

Fig. 3. Results of clustering the data in fig. 1 (b) using (a) kNERF, (b) Spectral, and (c) FLeCK

cluster 3. This large σ_3 allows points that are spatially dispersed to be grouped into one cluster without including points from the other clusters. On the other hand, FLeCK learns smaller σ_i's for the two small and dense clusters $(\sigma_1 = 24.94 \; and \; \sigma_2 = 30.17)$. These small σ_1 and σ_2 prevent points that are not spatially very close from being assigned to these clusters.

The second data set, shown in figure 1 (b), contains two clusters that have the same shape, density, and size, and a third cluster that is larger. The clustering results of the three algorithms on this data are shown in figure 3. As it can be seen, only FLeCK was able to partition this data correctly. This was possible due to the learned scaling parameters for each cluster.

TABLE I
NUMBER OF SAMPLES FORM EACH CATEGORY

Category	0	1	2	3	4	5	6	7	8	9
No. of samples	128	131	107	122	108	119	114	117	109	111

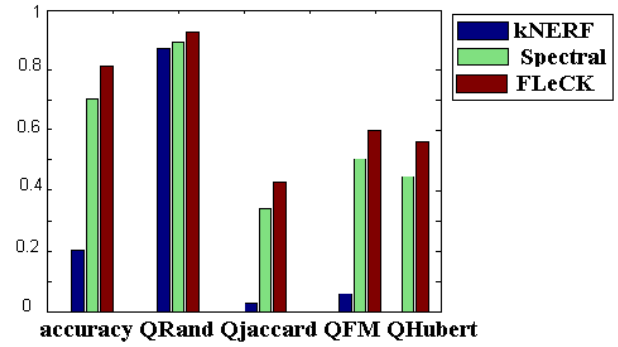

Fig. 4. Performance measures obtained on Handwritten Digits Data set using kNERF, Spectral and FLeCK clustering approaches.

For instance, cluster 2 has the smallest scaling parameter ($\sigma_2 = 0.0007$). This reflects the fact that points within this cluster are dispersed and some of them are closer to cluster 1 and cluster 3 than other points within this cluster. This small σ_2 ensures that cluster 2 does not include points from the other clusters. FLeCK learns a relatively bigger scaling parameters for cluster 1 and cluster 3 ($\sigma_1 = 12.21$ *and* $\sigma_3 = 11.3$). In fact, these two scaling parameters can be relatively larger (to maximize the intra-cluster similarity) without including points from the other cluster.

Besides giving a better clustering results than kNERF and self tuning spectral, FLeCK has two more main advantages over these two algorithms. First, it does not require the specification of the scaling parameter or the neighborhood parameter. Instead, it learns a cluster dependent scaling parameter in a completely unsupervised manner. Second, the learned scaling parameters provide a better description of the data and can be explored in subsequent learning steps.

B. Real data set

To illustrate the ability of FLeCK to learn local kernels and to cluster relational data derived from real and high dimensional data, we use it to categorize the Handwritten Digits database. We use a subset of 1166 handwritten digits from the Pen-Based Recognition of Handwritten Digits collection [19] available at the UCI Machine Learning data set. The handwritten samples were collected using a pressure sensitive tablet that sends the x and y coordinates of the pen at fixed time intervals. The raw data is processed so that each digit is represented by 8 (x,y) coordinates resulting in a 16-D feature vector. Table I displays the number of samples form each category.

We compare our clustering results to those obtained using the kNERF [15], and self tuning spectral clustering [17]. To quantify the performance of the different clustering algorithms and compare them, we assume that the ground truth is known,

TABLE II
KNERF CLUSTERING RESULTS ON THE HANDWRITTEN DIGIT DATA

and we evaluate the performance of the algorithms by using the accuracy, Rand statistics, *QRand*, Jaccard coefficient, *Qjaccard*, Folkes-Mallows index, *QFM*, and Hubert index, *QHubert*, [20]. All these measures provide larger values when the two partitions are more similar.

For all algorithms, we use the Euclidean distance and we fix the number of clusters to 16. For the fuzzy algorithms, we fix the fuzzifier m to 1.1. For Self tuning spectral, we tune the

neighborhood parameter from 1 to 20 by an increment of 1. For kNERF, we tune the scaling parameter between 0.01 and 100 with a step of 0.1. Since we should not use the ground truth to select the optimal parameter, for each algorithm, we select the parameter that gives the minimum intra-cluster similarity.

Figure 4 compares the performance of the three considered algorithms. As it can be seen, FLeCK outperforms the other methods with respect to all five measures. Although, kNERF and self tuning spectral use a similar Gaussian kernel, they were not able to cluster this data properly. This is due to their sensitivity to the choice of the scaling parameter.

As it can be seen from table II, kNERF has succeeded to segregate only the digit "3" (cluster 3). In fact, almost all the other elements of the data set are gathered in a big cluster (cluster 16) and the remaining clusters are empty. This is due to the fact that one global σ for mapping all the data can not provide the correct partition when the input data includes clusters with different local statistics.

The self tuning spectral did relatively better than kNERF because it uses a local scaling parameter that is defined as the distance between $\mathbf{x}_j$ and its P^{th} neighbor. However, as it can be seen from table III, it still creates one big cluster that contains 300 elements from categories '0', '6', '8' and '9'. Moreover, although category '1' was split in five clusters (cluster 1, 6, 12, 14, and 16), it was not well segregated in clusters 1 and 14. This may be due to the fact that adapting σ to each sample can distort the structure of the data.

FLeCK on the other hand, was able to partition the data better than kNERF and Self tuning spectral. Referring to the FLeCK clustering results shown in table IV, some digits have been categorized using more than one cluster (clusters 0, 4, 5 and 8). This is due to the different writing styles. For instance, digit '4' has been categorized using two clusters (cluster 11 and 16). Figure 5 displays the top 10 representatives of these two clusters (corresponding to the highest memberships). We can notice that each cluster contains one style of writing the digit '4'. On the other hand, FLeCK categorized other digits using one cluster (clusters 1, 2, 3, 6, 7, and 9). These are categories

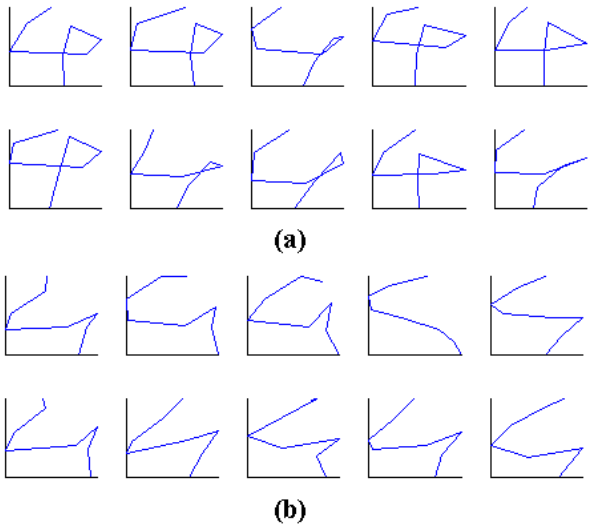

Fig. 5. The top 10 representatives of (a) cluster 11 and (b) cluster 16.

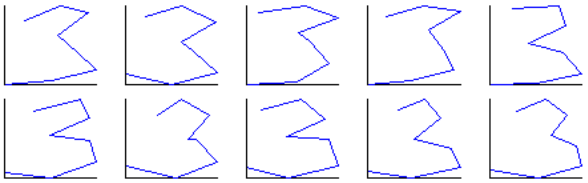

Fig. 6. The top 10 representatives of cluster 9.

with more consistent writing style. Figure 6 displays the top 10 representatives of one such cluster representing digit 3.

FLeCK learned a scaling parameter for each cluster. These parameters are reported in table V. For instance, cluster 4 is the smallest cluster and contains only 9 digits. These digits form the densest region in the feature space (small sum of intra cluster similarity) and are relatively close to other digits categories (small sum of inter cluster distances). Consequently, FLeCK learns a small scaling parameter ($\sigma_4 = 3.4$) for this cluster. This Small σ prevent digits that are spatially close but not within the dense region, from being assigned to this clusters.

On the other hand, FLeCK leaned a relatively larger scaling parameter for cluster 9 ($\sigma_9 = 50.65$) representing the digit 3. This is due to the fact that this cluster includes a large number of samples with large intra-cluster distances (without being split into small clusters).

V. CONCLUSIONS

We have proposed an approach that performs relational fuzzy clustering and local kernel learning. The learned kernel is based on a Gaussian function with a cluster dependent scaling parameter. The proposed approach minimizes both the inter-cluster dissimilarity and the intra-cluster dissimilarity to learn a scaling parameter with respect to each cluster. This allows FLeCK to adapt the distance to the characteristics of each cluster. FLeCK is formulated to work on pairwise relational

data. This makes it applicable when data is available only in relational form and when similar objects cannot be represented efficiently by a single prototype.

Using synthetic and real data sets, we have shown that our approach outperforms kNERF and self tuning spectral. In particular, we have shown that when data include clusters with various inter and intra cluster distances, learning cluster dependent scaling parameters is crucial in obtaining a good partition.

Currently, FLeCK uses fuzzy memberships that are constrained to sum to one. This type of membership does not discriminate between typical points that are close to multiple clusters and noise points. Consequently, FLeCK is not robust to noise and outliers. One way to overcome this limitation is to replace the fuzzy memberships with possibilistic memberships [21]. We are currently investigating this alternative.

***Abstract*—This paper mainly suggests a new type of interval time series: interval autoregressive (IAR) model. Firstly we state why we should introduce the interval time series models. Then we give necessary definitions about random intervals and interval time series. Thirdly, we introduce some methods of efficiency evaluation for forecasting of interval time series. And then we discuss parameter estimation and forecasting in IAR model, in which the methods of parameter estimation are based on the evaluation forecasting for interval data. Furthermore, we give the simulation results and apply it to real data from Shanghai Stock Index, which is to illustrate our modeling methodology. This model makes it possible for decision makers to forecast the best and worst possible situations based on interval-valued observations.**

Keywords: Interval time series; IAR model; parameter estimation; forecasting of stock price

I. Introduction

It is well-known that traditional time series models play an important role in many application areas. For instance, Box-Jenkins provided autoregressive integrated moving average (ARIMA) time series model in [4], which has been applied in engineering, economics, foreign current exchange, data analysis of stock markets, etc. In those traditional times series models, authors assumed that that the future values of a time series have a determined function relationship with current, past values and white noises. However, there are a great deal of economic problems that can not be explained and handled by these models since the actions of individuals in investment are affected not only by the random factors in financial market but also by the mental factors of investors. Therefore, interval-valued time series emerges quite naturally in some situations, which indicates uncertainty and variability.

Song and Chissom [11]-[13] believed in that fuzzy numbers would be better to describ the mental factors. So they introduced the concepts of fuzzy time series, and they assumed that the model parameters were fuzzy numbers. Tseng *et. al.* [15] built a fuzzy ARIMA model and gave the methods of parameter estimation and forecasting, and applied it to the foreign current exchange market.

The sample data usually are one-dimensional or multidimensional numbers in traditional time series analysis. However, in practice, the sample data sometimes are intervals in economics. For example, when the economists are surveyed to predict the economic increasing rate, they tend to give the answers like "5% to 7%", "5.2% to 6.7%" and so on . So we get the interval-valued sample data. Therefore, it is necessary to build the models of interval time series. The interval time series models show up the information in the form of a series of interval-valued data and make predictions based on the interval-valued data. Furthermore, such models also provide the upper boundary and lower boundary of possible selections for decision-makers or investors.

Hsu and Wu did a preliminary study on interval time series, and gave three evaluation criteria of forecasting efficiency for interval time series in [7], [8], that is, mean square error of interval (MSEI), mean relative interval error (MRIE), mean ratio of symmetric difference. Based on their works, we develop a new interval time series model in this paper ,which is called interval autoregressive (IAR) model .

This paper is organized as follows. Some definitions of random interval and interval time series are given in Section 2, especially interval autoregressive model is formulated and proposed. In Section 3, the methods of efficiency evaluation of forecasting for interval time series are presented. Methods of parameter estimation in IAR model are given in Section 4. In Section 5 and Section 6, simulation result and real data analysis are given respectively, which illustrate our modeling methodology.

II. Random Intervals and Interval Time Series

Random interval, as well as its operations, is the foundation in terms of analyzing the interval time series. Therefore, before the discussions of interval time series, we give some definitions of random interval and its operations.

Assume that $(\Omega, \mathcal{A}, P)$ is a probability space, $\mathbb{R}$ is the set of all real numbers.

Definition 2.1 The interval $X = [a, b]$ is called a random interval, if a, b: $\Omega \to \mathbb{R}$ are real-valued random variables with $a(\omega) \leq b(\omega)$ for all $\omega \in \Omega$. Then $c = (a + b)/2$ is called the center of the random interval X, $r = (b - a)/2$ is called the radius of the random interval X, and X is also denoted as $X = (c; r)$.

Let $X = [a, b] = (c; r)$ be a random interval, the interval length of X is $2r = b - a$, and denoted as $\|X\| = 2r$.

Remark 2.2 Actually the above concept of a random interval is the special case of that of a set-valued random variable (or a random set, or a multifunction in literature). Readers may refer to [2], [3], [6], [10], [16]. It was defined in a general way as follows.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Let $\mathfrak{X}$ be a separable Banach space with its dual space $\mathfrak{X}^*$. A set-valued mapping X from Ω to the family of all nonempty closed subsets of $\mathfrak{X}$ is called a set-valued random variable if, for each open subset O of $\mathfrak{X}$,

$$X^{-1}(O) = \{\omega \in \Omega : X(\omega) \cap O \neq \emptyset\} \in \mathcal{A}.$$

If X takes compact convex subsets of $\mathfrak{X}$, then that X is a set-valued random variable is equivalent to that, for any $x^* \in \mathfrak{X}^*$, its support function

$$s(x^*, X(\omega)) = \sup\{\langle x^*, x\rangle : x \in X(\omega)\}$$

is a real-valued random variable.

So it is obvious that, if we limit $\mathfrak{X} = \mathbb{R}$, X takes compact convex set values in $\mathbb{R}$, then the concept of a random interval above is consistent with that of a set-valued random variable.

Definition 2.3 Let $X_1 = [a_1, b_1] = (c_1; r_1)$, $X_2 = [a_2, b_2] = (c_2; r_2)$ be two random intervals. The interval addition, scalar multiplication and interval subtraction are defined as

(i) interval addition:

$$X_1 \oplus X_2 = (c_1; r_1) \oplus (c_2; r_2) = (c_1 + c_2; r_1 + r_2);$$

(ii) scalar multiplication:

$$k \cdot X_1 = kX_1 = k(c_1; r_1) = (kc_1; |k|r_1), \forall k \in \mathbb{R};$$

(iii) interval subtraction:

$$X_1 \ominus X_2 = X_1 \oplus (-X_2) = (c_1 - c_2; r_1 + r_2).$$

Remark 2.4 (1) Note that above definitions of interval addition, scalar multiplication are the special case of the definitions of addition and scalar multiplication of set-valued random variables in a separable Banach space.

(2) Let $\mathbf{K}_{kc}(\mathbb{R})$ be the set of all finite intervals of $\mathbb{R}$. We define interval addition and scalar multiplication on $\mathbf{K}_{kc}(\mathbb{R})$ as above definition. But we have to notice that $(\mathbf{K}_{kc}(\mathbb{R}), \oplus, \cdot)$ is not a linear space! This is because for any $[a, b]$ with $a < b$, $[a, b] \oplus (-[a, b]) \neq \{0\}$. Thus, above interval interval subtraction operator is not inverse operator of interval addition.

In the set theory, set difference $A \setminus B$ is defined by $A \setminus B = \{x : x \in A \text{ and } x \notin B\}$. While we use this definition of the set difference on the family of closed intervals, the difference of two closed intervals is a half-closed interval. Since we want it to be a closed set, we have to revise the definition of interval difference as follows.

Definition 2.5 Let $X_1 = [a_1, b_1] = (c_1; r_1)$, $X_2 = [a_2, b_2] = (c_2; r_2)$ be two random intervals, then the interval difference $X_1 - X_2$ is defined by

$$X_1 - X_2 = \mathrm{cl}(X_1 \bigcap X_2^c),$$

where $\mathrm{cl}(A)$ means the closure of the set A.

If $a_1 \leq a_2 \leq b_1 \leq b_2$, then $X_1 - X_2 = [a_1, b_1] - [a_2, b_2] = [a_1, a_2]$ by the above definition.

Definition 2.6 Let $X_1 = [a_1; b_1] = (c_1; r_1)$, $X_2 = [a_2; b_2] = (c_2; r_2)$ be two random intervals, then the symmetric difference is defined by $X_1 \triangle X_2 = (X_1 - X_2) \bigcup (X_2 - X_1)$.

If $a_1 \leq a_2 \leq b_1 \leq b_2$, then by the above definition, $X_1 \triangle X_2 = (X_1 - X_2) \bigcup (X_2 - X_1) = [a_1, a_2] \bigcup [b_1, b_2]$.

Definition 2.7 Let $X = (c; r)$, c and r are two real-valued random variables, then $X = (c; r)$ is called a generalized random interval.

Obviously, if r is positive, $X = (c; r)$ is a random interval defined in Definition 2.1. Similarly, we may define the addition and scalar multiplication for generalized random interval as we do in definition 2.3.

Definition 2.8 The expectation of the random interval $X = [a, b] = (c; r)$ is defined by

$$E[X] = [E(a), E(b)],$$

where $E(a), E(b)$ are the expectations of real-valued random variables a and b respectively.

Obviously, we have $E[X] = (E(c); E(r))$. If $X_i = [a_i, b_i]$, $i = 1, 2$, then $E[X_1 \oplus X_2] = E[X_1] \oplus E[X_2]$, $E[kX_1] = kE[X_1]$, for any $k \in \mathbb{R}$.

Remark 2.9 (1) The expectation of a random interval above is consistent with Aumann integral of a compact convex set-valued random variable in $\mathbb{R}$ (cf. [3], [10]). Hence, we may obtain the same properties of the expectations of random intervals as that of Aumann integrals.

(2) In [2] and [10], authors defined the concepts of the distribution of a set-valued random variable, independence of a sequence of set-valued random variables. Here we used them to the random interval case and we omit them. By the Chapter 3 in [10], we know that, if two random intervals $X_1 = [a_1, b_1] = (c_1; r_1)$ and $X_2 = [a_2, b_2] = (c_2; r_2)$ are independent, so are a_1 and a_2, b_1 and b_2, c_1 and c_2, r_1 and r_2 respectively.

Assume that a simple random sample $X_i = [a_i, b_i]$, $i = 1, 2, \cdots, n$, is taken from a random interval $X = [a, b]$, i.e. $X_1, X_2, \cdots, X_n$ are independent and identically distributed with X. Let

$$\overline{X} = \frac{1}{n}[X_1 \oplus X_2 \oplus \cdots \oplus X_n]$$

denote the random sample average. By using the strong law of large numbers of set-valued random variables (cf. [2] and [10]), we may estimate the expectation $E[X]$ of random interval X by using the random sample average

$$\overline{X} = \Big[\frac{1}{n}\sum_{i=1}^{n} a_i, \frac{1}{n}\sum_{i=1}^{n} b_i\Big].$$

It is obvious that $\overline{X}$ is an unbiased estimator of $E[X]$.

Now we introduce the definition of interval autoregressive model (IAR).

Definition 2.10 An interval time series is a sequence of random intervals, $X_t = [a_t, b_t] = (c_t; r_t), \ \ t = 1, 2, 3, \cdots$, denoted by $\{X_t\} = \{X_t = [a_t, b_t] = (c_t; r_t) : \ t = 1, 2, 3, \cdots\}$.

Assume that $\widetilde{\varepsilon}_t = (c_{\varepsilon_t}; r_{\varepsilon_t}),\ \ t = 1, 2, \cdots$ is a generalized random interval (r_{ε_t} may be negative), c_{ε_t} and r_{ε_t} are independent white noise processes $WN(0, \sigma_c^2)$ and $WN(0, \sigma_r^2)$ respectively, then the p-order equation

$$X_t = a_1 X_{t-1} + a_2 X_{t-2} + \cdots + a_p X_{t-p} + \widetilde{\varepsilon}_t, t \in \mathbb{Z}$$

is called a p-order interval autoregressive model, denoted as IAR(p), where $a_1, a_2, \cdots a_p$ ($a_p \neq 0$) are called autoregressive coefficients of the IAR(p) model.

III. Efficiency Evaluation of Forecasting with Interval Time Series

A. The Mean Square Error of Interval Time Series

Let $X_t = [a_t, b_t] = (c_t; r_t)$, $t = 1, 2, \cdots$, be an interval time series, and $\hat{X}_t = [\hat{a}_t, \hat{b}_t] = (\hat{c}_t; \hat{r}_t)$, $t = 1, 2, \cdots$, be the forecast interval with respect to $X_t = [a_t, b_t] = (c_t; r_t)$. In the analysis and forecasting of interval time series, we may meet four forecasting situations:

(1) If $\hat{a}_t \leq a_t \leq b_t \leq \hat{b}_t$, then the forecast interval is too wide, and denoted by FIW;

(2) If $a_t \leq \hat{a}_t \leq \hat{b}_t \leq b_t$, then the forecast interval is too narrow, and denoted by FIN;

(3) If $a_t \leq \hat{a}_t \leq b_t \leq \hat{b}_t$, then the forecast interval inclines to the right, and denoted by FIR;

(4) If $\hat{a}_t \leq a_t \leq \hat{b}_t \leq b_t$, then the forecast interval inclines to the left, and denoted by FIL.

In the classical time series models, we use the distance between actual value and forecast value to describe the efficiency of prediction. In the interval time series models, what we are concerned about are not only the forecasting of interval length, but also the location disparity between the predicted interval and the actual interval. Therefore, it is necessary to define new criteria for analyzing of interval time series forecasting.

Assume that $X_t = (c_t; r_t)$, $t = 1, 2, \cdots$, is an interval time series, $\hat{X}_t = (\hat{c}_t; \hat{r}_t)$, $t = 1, 2, \cdots$, is the forecasting interval series of X_t, mean square error of interval is given in the following.

Definition 3.1 The mean squared error of interval position (MSEP) is given by

$$MSEP = \frac{1}{s}\sum_{t=1}^{s}(c_{n+t} - \hat{c}_{n+t})^2,$$

and the mean squared error of interval length (MSEL) is defined as

$$MSEL = \frac{1}{s}\sum_{t=1}^{s}(r_{n+t} - \hat{r}_{n+t})^2,$$

where n denotes the current time, and s is the number of the preceding intervals.

Definition 3.2 The error between the forecast interval $\{\hat{X}_t = (\hat{c}_t; \hat{r}_t)\}$ and the actual interval $\{X_t = (c_t; r_t)\}$ consists of two parts: the position error and the length error. The mean square error of interval time series (MESI) is given by

$$\begin{aligned} MSEI &= MSEP + MSEL \\ &= \frac{1}{s}\sum_{t=1}^{s}(c_{n+t} - \hat{c}_{n+t})^2 + \frac{1}{s}\sum_{t=1}^{s}(r_{n+t} - \hat{r}_{n+t})^2, \end{aligned}$$

where n denotes the current time, and s is the number of the preceding intervals.

In practice, different people may have different standards in terms of the prediction of interval time series due to different situation of problems. One important case, we take into account, is that mean squared error of interval with respect to position and mean squared error of interval with respect to length should pose different influence to the total error. Thus we define a generalized mean squared error of interval time series as follows.

Definition 3.3 The generalized mean squared error of interval (GMSEI) between the forecast interval $\{\hat{X}_t = (\hat{c}_t; \hat{r}_t)\}$ and the actual interval $X_t = (c_t; r_t)$ of a time series is

$$\begin{aligned} GMSEI &= f(MSEP) + g(MSEL) \\ &= f\Big(\frac{1}{s}\sum_{t=1}^{s}(c_{n+t} - \hat{c}_{n+t})^2\Big) \\ &\quad + g\Big(\frac{1}{s}\sum_{t=1}^{s}(r_{n+t} - \hat{r}_{n+t})^2\Big), \end{aligned}$$

where f and g are strictly increasing functions with $f(0) = 0$, $g(0) = 0$, n is the current time and s is the number of the preceding intervals.

For instance, if we let $f(x) = e^x - 1, g(x) = x, \forall x \geq 0$, that is

$$GMSEI = \exp(MSEP) - 1 + MSEL.$$

Under this evaluation criteria of forecasting error, we believe that the $MSEP$ is more significant than $MSEI$ in terms of contribution to the total error.

B. Other Evaluation Criteria

Symmetric difference between the actual interval and the forecast interval shows their non-intersecting parts. The smaller the length of their symmetric difference is, the more the forecast interval covers the actual interval. By virtue of this character of symmetric difference, we offer another method of the efficiency evaluation for the interval time series forecasting, i.e. mean ratio of symmetric difference.

Definition 3.4 Let $\{X_t = (c_t; r_t), t = 1, 2, \cdots, s\}$, be an interval time series, and $\{\hat{X}_t = (\hat{c}_t; \hat{r}_t), t = 1, 2, \cdots, s\}$, be the forecast interval time series. Then the mean ratio of symmetric difference, denoted by MRSD, is defined as

$$MRSD = \frac{1}{s}\sum_{t=1}^{s}\frac{\|X_{n+t} \triangle \hat{X}_{n+t}\|}{\|X_{n+t}\|}.$$

Definition 3.5 [The efficiency of MRSD] Let $\{X_t = (c_t; r_t)\}$ be an interval time series, and the forecast interval

time series $\{\hat{X}_{1t} = (\hat{c}_{1t}; \hat{r}_{1t})\}$ and $\{\hat{X}_{2t} = (\hat{c}_{2t}; \hat{r}_{2t})\}$ are obtained by two different forecast methods. If the MRSD of $\{\hat{X}_{1t}\}$ (denoted as $MRSD_1$) is smaller than that of $\{\hat{X}_{2t}\}$ (denoted as $MRSD_2$), i.e. $MRSD_1 < MRSD_2$, we say the forecast interval $\{\hat{X}_{1t}\}$ is more efficient than the forecast interval $\{\hat{X}_{2t}\}$.

Hsu and Wu [7] also referred to another evaluation criterion, called mean relative interval error (MRIE). Roughly speaking, we believe that a forecast result is better if the center of this forecast interval is closer to the center of the actual interval, and the intersection of their intervals is larger. The definition of mean relative interval error is as follows.

Definition 3.6 Let $\varepsilon_t = \frac{|c_t - \hat{c}_t|}{r_t + \hat{r}_t}$ be the relative error between the forecast interval $\hat{X}_t$ and the actual interval X_t, the mean relative interval error (MRIE) is given by

$$MRIE = \frac{1}{s} \sum_{t=1}^{s} \frac{|c_t - \hat{c}_t|}{r_t + \hat{r}_t}.$$

In practical use, we may be confronted with the case that the importance of FIR errors and FIL errors are different. With respect to how to treat this case, we shall discuss it in future works since the page limitation of this paper.

IV. Parameter Estimation in IAR Model

In this section, we will estimate the order p, autoregressive coefficients $a_1, a_2, \cdots, a_p$ and the variances of white noises σ_c^2, σ_r^2 in IAR(p) model

$$X_t = a_1 X_{t-1} + a_2 X_{t-2} + \cdots + a_p X_{t-p} + \tilde{\varepsilon}_t, \quad t = 1, 2, \cdots$$

through the observation data $x_1, x_2, \cdots, x_N$.

A. Methods of coefficient estimation

Firstly, we assume that the order p is known. Now we will choose an evaluation criterion of prediction efficiency. Without loss of generality, we take mean square error of interval (MSEI) as an example here, if other evaluation criteria are taken, a similar conclusion can be derived.

The basic idea of parameter estimation here is similar to the least squares estimation in the classic statistics.

Now we use the linear combination of $x_{j-1}, x_{j-2}, \cdots, x_{j-p}$ with coefficients $a_1, a_2, \cdots, a_p$, i.e. $a_1 x_{j-1} + a_2 x_{j-2} + \cdots + a_p x_{j-p}$, to predict x_j, the reasonable estimators of $a_1, a_2, \cdots, a_p$ should minimize the square error

$$\begin{aligned} & S(a_1, a_2, \cdots, a_p) \\ = & \sum_{j=p+1}^{N} [c_j - (a_1 c_{j-1} + a_2 c_{j-2} + \cdots + a_p c_{j-p})]^2 \\ & + \sum_{j=p+1}^{N} [r_j - (|a_1| r_{j-1} + |a_2| r_{j-2} + \cdots + |a_p| r_{j-p})]^2. \end{aligned}$$

Thus, we take the values $\hat{a}_1, \hat{a}_2, \cdots, \hat{a}_p$ which minimize the $S(a_1, a_2, \cdots, a_p)$ as the estimators of autoregressive coefficients. And the estimators of the variances of the white noises, $c_{\varepsilon_t}, c_{\varepsilon_t}$ are

$$\widehat{\sigma_c^2} = \frac{1}{N-p} \sum_{j=p+1}^{N} [c_j - (\hat{a}_1 c_{j-1} + \hat{a}_2 c_{j-2} + \cdots + \hat{a}_p c_{j-p})]^2,$$

$$\widehat{\sigma_r^2} = \frac{1}{N-p} \sum_{j=p+1}^{N} [r_j - (|\hat{a}_1| r_{j-1} + |\hat{a}_2| r_{j-2} + \cdots + |\hat{a}_p| r_{j-p})]^2.$$

B. Order Selection

Parameter estimation in IAR model described above is based on that the order p is known. But order p is usually unknown when we cope with some practical problems. Therefore, order p should be estimated.

In terms of order selection problem in traditional single-valued time series models, one of the most applicable criteria is Akaike information criterion (AIC), which was given by Akaike in 1973 [1]. Here we use an interval version of AIC to select an order p. We assume order $p \leq P_0$, where $P_0 \in \mathbb{N}$. The AIC statistics, defined as

$$\begin{aligned} AIC(k) &= \ln \frac{S(\hat{a}_1, \hat{a}_2, \cdots, \hat{a}_p)}{N-k} + \frac{4k}{N} \\ &= \ln \left(\widehat{\sigma_c^2} + \widehat{\sigma_r^2} \right) + \frac{4k}{N}, \end{aligned}$$

where $k = 0, 1, \cdots, P_0$. We select the value of p as the order in our model which minimizes $AIC(k)$.

C. Diagnostic Checking

Typically, the goodness of fit of a statistical model to a set of data is judged by comparing the observed values with the corresponding predicted values obtained from the fitted model. If the fitted model is appropriate, the residuals should behave in a manner that is consistent with the model.

By the interval observation data $x_1, x_2, \cdots, x_N$, if now we have the estimation $\hat{p}$ and $(\hat{a}_1, \hat{a}_2 \cdots, \hat{a}_p)$ of the order p and the autoregressive coefficient $a_1, a_2, \cdots, a_p$ of IAR model

$$X_t = a_1 X_{t-1} + a_2 X_{t-2} + \cdots + a_p X_{t-p} + \tilde{\varepsilon}_t, \quad t = 1, 2, \cdots,$$

the residuals are defined as follows

$$\hat{\varepsilon}_{ct} = c_t - \sum_{j=1}^{p} \hat{a}_j c_{t-j}, \quad t = \hat{p}+1, \hat{p}+2, \cdots, N,$$

$$\hat{\varepsilon}_{rt} = r_t - \sum_{j=1}^{p} \hat{a}_j r_{t-j}, \quad t = \hat{p}+1, \hat{p}+2, \cdots, N.$$

If we can check that $\{\hat{\varepsilon}_{ct}\}$ and $\{\hat{\varepsilon}_{rt}\}$ are white noise processes, i.e. $\{\hat{\varepsilon}_{ct}\} \sim WN(0, \widehat{\sigma_c^2})$, $\{\hat{\varepsilon}_{rt}\} \sim WN(0, \widehat{\sigma_r^2})$, then the assertion that the above model is the true process in terms of generating $x_1, x_2, \cdots, x_N$ is acceptable.

V. SIMULATIONS

In this section, we conduct simulation experiments to illustrate the methodology of parameter estimation in IAR model. We indicate the mean square error of interval ($MSEI$) as the evaluation criterion in this section.

Our simulated data is generated from the IAR model

$$X_t = a_1 X_{t-1} + a_2 X_{t-2} + \tilde{\varepsilon}_t, \quad t = 3, 4, \cdots, n$$

(the order is p=2), where $\tilde{\varepsilon}_t = (c_{\varepsilon_t}; r_{\varepsilon_t}),\ t = 3, 4, \cdots, n$ is a generalized random interval, $c_{\varepsilon_t}, r_{\varepsilon_t}$ are independent normal white noise processes $WN(0, \sigma_c^2)$, $WN(0, \sigma_r^2)$, and let $a_1 = 0.85, a_2 = 0.152, \sigma_c = \sigma_r = 0.1$. Fix $X_1 = (10; 1), X_2 = (10.1; 0.9)$, then we can compute

$$\begin{aligned} X_t &= a_1 X_{t-1} + a_2 X_{t-2} + \tilde{\varepsilon}_t \\ &= 0.85 X_{t-1} + 0.152 X_{t-2} + \tilde{\varepsilon}_t, \quad t = 3, 4, \cdots, n, \end{aligned}$$

where $\tilde{\varepsilon}_t = (c_{\varepsilon_t}; r_{\varepsilon_t})$ is the generalized random intervals and $c_{\varepsilon_t}, r_{\varepsilon_t}$ are generated by normal random variables $N(0, \sigma_c^2) = N(0, 0.1^2)$, $N(0, \sigma_r^2) = N(0, 0.1^2)$ respectively.

Take the sample size n to be 50, Fig.1. shows a simulated orbit generated by the above IAR model.

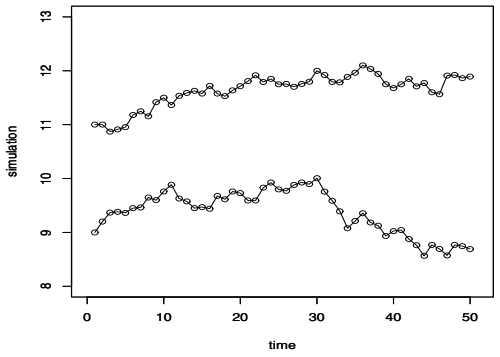

Fig.1.

We use the method introduced in Section 4.1 to estimate the autoregressive coefficient.

Now we simulate $\{X_t\}$ 500 times. Then we obtain 500 different estimators $\hat{a}_1, \hat{a}_2$ of autoregressive coefficients a_1, a_2. The mean values of this 500 different estimators are 0.847818 and 0.1541758 (the actual values are 0.85 and 0.152). Also, we get 500 estimators $\hat{\sigma}_c, \hat{\sigma}_r$ of standard deviation of white noise σ_c, σ_r, their mean value are 0.0989, 0.0989 (the actual values are 0.1, 0.1).

Again, we simulate $\{X_t\}$ 1000 times. Then we get 1000 different estimators $\hat{a}_1, \hat{a}_2$ of autoregressive coefficients a_1, a_2. The mean values of this 1000 different estimators are 0.8494906 and 0.1524187 (the actual values are 0.85 and 0.152). Also, we get 1000 estimators $\hat{\sigma}_c, \hat{\sigma}_r$ of standard deviation of white noise σ_c, σ_r, their mean value is 0.0991782, 0.0991782 (the actual values are 0.1, 0.1).

Such results show that the method of parameter estimation in Section 4.1 is fairly good.

VI. EMPIRICAL STUDY

In this section, we use an example to illustrate the parameter estimation and forecasting technique in IAR model.

While using the traditional time series models to forecast the stock price, we usually take the closing prices as the analyzing data. Then the information of fluctuations of stock price during each day is not able to be utilized. And the forecast value is also single-valued, so the information provided to the decision makers is also lack of flexibility. In the following, we will take the highest and the lowest daily price as the upper and lower boundary of the interval respectively, and the forecast will also be the interval-valued.

Here we collect data of the highest and lowest daily price of the Shanghai Stock Index from April 1 to June 17 in the year of 2009 (53 trading days in all). See Fig.2.

To select the order, $p = 2$, using the method described in Section 4.1, we obtain the estimated values of autoregressive coefficients, which are $\hat{a}_1 = 1.033, \hat{a}_2 = -0.03$.

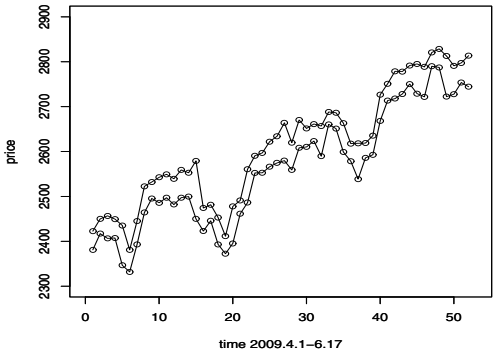

Fig.2.

Then check the residuals

$$\hat{\varepsilon}_{ct} = c_t - \sum_{j=1}^{2} \hat{a}_j c_{t-j}, \quad t = 3, 4, \cdots, 52,$$

$$\hat{\varepsilon}_{rt} = r_t - \sum_{j=1}^{2} \hat{a}_j r_{t-j}, \quad t = 3, 4, \cdots, 52,$$

by the method introduced in Section 4.3, $\{\hat{\varepsilon}_{ct}\}$ and $\{\hat{\varepsilon}_{rt}\}$ are white noise processes.

Now we can forecast the stock prices. We use the linear combination of the stock prices of the preceding two trade days X_{t-1}, X_{t-2} with coefficients which are the autoregressive coefficients $\hat{a}_1, \hat{a}_2$:

$$\begin{aligned} \widetilde{X_t} &= \hat{a}_1 X_{t-1} + \hat{a}_2 X_{t-2} \\ &= 1.033 X_{t-1} - 0.03 X_{t-2}, \quad t = 53, 54, \cdots \end{aligned}$$

as the forecast interval series.

We compare the forecast interval with the actual interval of the latter ten trading days.

The forecast intervals of latter ten trading days are
[2752.169,2822.535], [2821.281,2865.241],
[2856.997,2896.092], [2893.885,2933.112],

[2849.159,2950.418], [2890.083,2931.713],
[2918.681,2956.444], [2919.119,2946.144],
[2927.386,2987.030], [2963.269,3006.872].

The actual intervals of the latter ten trading days are
[2810.85,2855.42], [2847.36,2886.50],
[2884.13,2923.24], [2841.90,2941.06],
[2880.29,2923.47], [2909.09,2946.90],
[2910.35,2937.61], [2918.39,2976.92],
[2953.36,2997.27], [2947.69,3009.71].

The mean square error of interval (MSEI) of this ten-day forecasting is 729.2548. As is shown in Fig.3., the red lines depict the forecast interval series while the black lines describe the actual interval series.

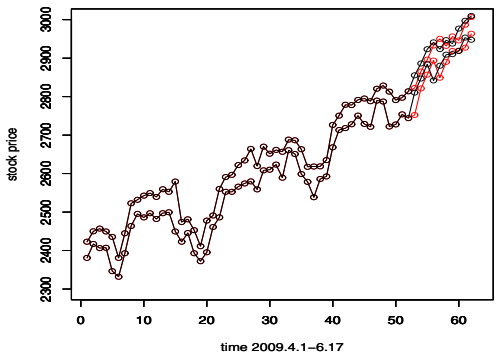

Fig.3.

VII. Conclusions

In this paper, based on the concepts of interval time series and efficiency evaluation of forecasting for interval time series, we suggest a new type of interval time series (IAR model), and present the methods of parameter estimation and forecasting in this model. Furthermore, we apply it to forecast the Shanghai Stock Index.

Both the examples regarding simulated data and real data show that the methods of parameter estimation are pretty good, which is based on the efficiency evaluation of forecasting for interval-valued data. The evaluation criterion we chosen is $MSEI$, and the parameter estimation based on other evaluation criteria can also be derived.

One advantage of the IAR model is that it is possible for decision makers to know the best and worst possible situations, and it requires fewer amount of observations than traditional time series models.

***Abstract*—Fuzzy C-Means Clustering, FCM, is an iterative algorithm whose aim is to find the center or centroid of data clusters that minimize an assigned dissimilarity function. The degree of being in a certain cluster can be defined in terms of the distance to the cluster-centroid. The domain knowledge is used to formulate an appropriate measure. However the Euclidean distance is considered as a general measure for such value. The calculation of the Euclidean distance doesn't take into consideration the degree of relevance of each feature to the classification model. In this paper, scoring methods like ChiMerge and Mutual information are used in the FCM model to improve the calculation of the Euclidean distance. Experimental results demonstrate the better performances of the improved FCM on UCI benchmark data sets rather than the ordinary FCM, where the ordinary FCM uses in classification either all features or the most important features while the improved FCM uses all the features but the Euclidean Distance will be calculated according to the relevance degree of each feature.**

***Index Terms*—Fuzzy C-Means; Feature selection; ChiMerge.**

I. Introduction

Fuzzy C-Mean (FCM) is a model of data clustering which allows one piece of data to belong to two or more clusters. It is based on minimization of an objective or dissimilarity function [1], [2]. With Fuzzy C-Means, the centroid of a cluster is computed as being the mean of all points, weighted by their degree of belonging to the cluster. The degree of being in a certain cluster is related to the inverse of the distance to the cluster. For high dimensional data, a popular measure is used for calculating the distance which is the Minkowski metric [3], Euclidean distance is a special case of such equation. The calculation of the Euclidean distance ignore the degree of relevance of each feature to the classification problem and treats all the features equally. On the other hand, high number of features may contain irrelevant or redundant features to the classification [4]. To handle this curse of dimensionality problem, feature reductions methods are used. The number of features are reduced to the minimum value either by selecting the best features or extracting a lower number of feature from the higher ones. Consequently, applying the classifier on the resulted and reduced features should show a better performance. Classifiers could use the ChiMerge and the Mutual Information (MI) methods as feature selection methods in the pre-processing step of the Classification system design procedure [5]. Chi-square testing χ^2 is a well-known discrete data hypothesis testing method from statistics, for continuous data sets, the ChiMerge method can automatically select a proper χ^2 values and determining the intervals of numeric attributes [6]. On the other hand MI indicates the strong informative relationships among the attributes. In this paper, the ChiMerge or MI methods are applied to evaluate the worth of each attribute by computing the value of the chi-squared statistic with respect to the class. The resulted value is scaled to the range or interval between 0 and 1 and will be defined as ranks. Previously, the result from the feature selection methods are either 0 or 1 and used in the classifier, but here we put into account all features but with different ranks. Then these ranks are used in the calculation of the Euclidean distance used in the Fuzzy C-Mean model. The new factor is that the features with less chi-square χ^2 or MI values will have a less influence on the classification procedure rather than being removed completely and rather than using the total set of feature. According to the results this modification generates a better classification performance. Also the results in the case of using ChiMerge and MI methods are compared and it shows that ChiMerge has a better results.

The rest of this paper is organized as follows. Section II discusses the related work. Section III explains the Fuzzy C-Mean clustering model. Section IV explain the calculation of the distance to the cluster center. Section V shows the feature evaluation method used in details which are the ChiMerge and Mutual information methods. section VI shows how the chi-Square values will be used in the Fuzzy C-Mean classification. Results and comparisons with other classifiers are illustrated in section VII. Conclusion and future work is discussed in section VIII.

II. Related Work

Most of the improvements in the Fuzzy C-Mean models are applied on the selection the most relevant or informative features. The benefits of feature selection [7] includes a lot of aspects like facilitating data visualization and data understanding, reducing the measurement and storage requirements, providing faster and more cost-effective classifiers, and defying the curse of dimensionality to

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

improve prediction performance. A paper like in [8] has an addition is that the fuzzy feature clustering and feature selection are based on the interdependence among features using chi-square methods. Other feature selection methods like in [9] has improved the MI formula for feature ranking which is used for feature selection in the pattern classification task. The problem of the current work in this area is that it stresses on the improvement of the feature selection methods, while ignores the use of the feature ranks of the selected features in the classification models. A similar study has been applied in [10] that propose an approach to feature-weight learning which is based on the gradient-desent technique. This method suffers from the high complexity due to the feature-weight learning which depends on the convergence of iterations in the traditional convergence technique. Also this method has a pre-assumption that the distribution of data is uniform which is not the case in real life data-sets.

III. Fuzzy C-Mean clustering

The discreteness of each cluster makes the C-Means analytically and algorithmically intractable. Partitioning the data set in a fuzzy manner avoid this problem. The FCM clustering treats each cluster as a fuzzy set and each feature vector is assigned to multiple clusters with some degree of certainty measured by the membership function [11]. The FCM optimizes the following objective function

$$J^m = \sum_{j:1..K} \sum_{i:1..N} \mu_{ji}^m * d_{ij} \tag{1}$$

Where: K is the number of clusters,
N is the number of objects,
m is the fuzziness controller which reduce the influence of small membership values, m is greater than 1,
d_{ij} represents the Euclidean distance between the object i of value x_i and the centroid of cluster j of value c_j which is represented by the following equation:

$$d_{ij} = \|x_i - c_j\| \tag{2}$$

and μ_{ji} denotes the membership of object i in cluster j; the values of μ_{ji} are initialized randomly such that the following condition is valid:

$$\sum_{j:1..K} \mu_{ji}^m = 1, i = 1, .., N \tag{3}$$

and c_j is the centroid of cluster j which it is calculated as follows:

$$c_j = \frac{\sum_{i:1..N} \mu_{ji}^m * x_i}{\sum_{i:1..N} \mu_{ji}^m} \tag{4}$$

After calculating the objective function J^m by equation (1), the value of μ_{ji} is updated by the following equation

$$\mu_{ji}^m = \frac{1}{\sum_{j:1..K} \frac{d_{ij}}{d_{ik}}} \tag{5}$$

The calculation of the J^m is repeated iteratively until the difference between the current J^m and the previous one is smaller than a certain threshold value ε such that:

$$J_{current}^m - J_{last}^m < \varepsilon \tag{6}$$

The correctness of equation (6) indicates the conversion of the objective function.

IV. Distance calculation to clusters center

A popular measure used for calculating the distance between any object and the cluster center, is the Minkowski metric. This measure is required for high dimensional data and it is calculated as follows:

$$d_p(x_i, x_j) = (\sum_{k=1..D} \mid x_{ik} - x_{jk} \mid^p)^{\frac{1}{p}} \tag{7}$$

Where x_i and x_j are two objects in the input data set. D is the dimensionality of the input data set, i.e. number of attributes. p is a parameter that represents the type of Minkowski measure. The Euclidean distance [12] is a special case of this measure, where in this case, p = 1, while Manhattan metric is the case where p = 2. However, there are no general theoretical guidelines for selecting a measure for any given application.

V. Feature Evaluation Methods

The selected feature evaluation techniques used in this paper are ChiMerge and Mutual Information approaches, which are considered as the most reliable methods for feature selection purpose with no significant difference between them [13].

A. ChiMerge feature evaluation

One of the most popular feature selection methods is the chi-Square χ^2 method, which measures the lack of independence between each attribute A and the target class c. ChiMerge or Chi2-Square is a χ^2-based discretization method [14]. It uses the χ^2 statistic to discretize numeric attributes repeatedly until some inconsistencies are found in the data that achieves feature selection via discretization. The χ^2 value is calculated for each continuous attribute as follows: Initially, each distinct value of a numeric attribute A is considered to be one interval. The values,intervals, of attribute A are sorted and the χ^2 is applied for every pair of adjacent intervals as follows:

$$\chi^2 = \sum_{i:1..2} \sum_{j:1..k} \frac{(A_{ij} - E_{ij})^2}{E_{ij}} \tag{8}$$

Where:
A_{ij} is the number of values in the ith interval and jth class,
R_{ij} is the number of values in the jth class = $\sum_{j:1..k} A_{ij}$,
C_{ij} is the number of values in the ith interval = $\sum_{i:1..2} A_{ij}$,
N is the total number of values = $\sum_{i:1..2} R_{ij}$,
and E_{ij} is the expected frequency of A_{ij} = $\frac{R_{ij} * C_{ij}}{N}$

Adjacent intervals with the least χ^2 values are merged together, because low χ^2 values for a pair indicates similar

class distributions. This merging process proceeds recursively until all χ^2 values of all pairs exceeds a parameter $signlevel$ (initially 0.5). Then repeat the previous steps with a decreasing $signlevel$ until an inconsistency rate is exceeded, where two patterns are the same but classified into different categories.

B. Mutual Information feature evaluation

The mutual information MI (also called cross entropy or information gain) is a widely used information theoretic measure for the stochastic dependency of discrete random variables. The mutual information $I(A;C)$ between values of feature A and the set of classes C can be considered as a measure of the amount of knowledge on C provided by A (or conversely on the amount of knowledge on A provided by C). In other words $I(A;C)$ measures the interdependence between A and C where it can be computed as follows:

$$I(A;C) = H(C) - H(C|A) \tag{9}$$

The entropy $H(C)$ measures the degree of uncertainty entailed by the set of classes C , and can be computed as

$$H(C) = -\sum_{c \in C} p(c) \log p(c) \tag{10}$$

where $p(c)$ is the probability density function (PDF) of c. The conditional entropy $H(C|X)$ measures the degree of uncertainty entailed by the set of classes C given the set of feature values X , and can be computed as

$$H(C|A) = \sum_{c \in C} \int_{a \in A} p(a,c) \log \frac{p(a|c)p(c)}{p(a)} dx \tag{11}$$

The integration in the expression above signifies that the feature space is continuous.

VI. Classification using the improved Fuzzy C-Mean model

By iteratively updating the cluster centers and the membership grades for each data point, FCM iteratively moves the cluster centers to the right location within a data set. But increasing the number of features may lead to ambiguity in training so that it would not even converge. The usual solution for this problem is to eliminant the features using the feature reduction methods, like applying feature selection of the most important and relevant features. After feature selection is applied, the data will be ready for training and testing by the classifier selected. The problem of this procedure is that not all features, even the selected features, are as important as each other to the classifier. On the other hand, in the calculations of the distance each object to the centroid in the Fuzzy C-Mean classifier model, all the attributes are used in the calculation in the same way.

In order to solve this problem, this paper uses a ranking procedure like the chi2-square method to give a percentage of importance to each feature. The results from the chiMerge method, χ^2 values, are processed such that these values range from 0 to 1 and the sum of all values are 1. Then uses the percentage that corresponds to each feature in the calculation of the Euclidean distance. Such that this percentage will be multiplied by the difference between the values of each object and the centroid corresponding to this attribute. So equation (7) will be adjusted to be as follows:

$$d_p(x_i, c_j) = (\sum_{k=1..D} r_k * \mid x_{ik} - c_{jk} \mid^p)^{\frac{1}{p}} \tag{12}$$

Where r_k represents the rank of attribute k, x_i represents the object i and c_j represents the centroid of class j.

The calculation of the rank values r_k will be as follows:

First, the values that are resulted from the feature selection methods are saved, in our paper these values are the χ^2 values. Then, the degree of importance of each feature is calculated according to the sorting of χ^2 values in an increasing order. The formula of the degree of importance will be in the form:

$$d_k = \frac{D - o_k}{\sum_{k=1..D} o_k} \tag{13}$$

Where o_k represents the order of the attribute from the chi-square method, for example, if o_k=1, this means that the attribute k is the best attribute, while if o_k= D, it means that attribute k is the worst attribute.

Then the χ^2 value of each feature k multiplied by d_k is divided by the sum of χ^2 values of all feature, and the result is assigned to the rank value r_k. So, r_k will be calculated as shown in the following formula (14):

$$r_k = \frac{\chi_k^2 * d_k}{\sum_{k=1..D} \chi_k^2} \tag{14}$$

In the case when the data set produces all χ^2 values have zero value, so formula (14) should be replaced by following formula (13). As shown in figure (1), the input from the training data set is evaluated by the chiMerge method then the χ^2 values are adjusted as in formula (14), and this input is introduced to Fuzzy C-Mean model for training. The evaluation from the chi2-square method will be used in the calculation of the distance to the centroid. When the termination condition is reached; either by convergence or elapsed number of iterations, the calculated centroids and the adjusted χ^2 values will be used in the testing of the classifier.

This improvement could be applied using the Mutual information method, such that the information gain resulted in equation (9) or the MI value for each attribute will be used in formula (14) as follows:

$$r_k = \frac{MI_k * d_k}{\sum_{k=1..D} \chi_k^2} \tag{15}$$

where MI_k value represents the mutual information between feature k and the set of target classes. The complete steps of the enhanced FCM model is shown in figure (1), in the steps of the model, scaling of the input data is important as it showed a better results in case of the scaled data than unscaled one.

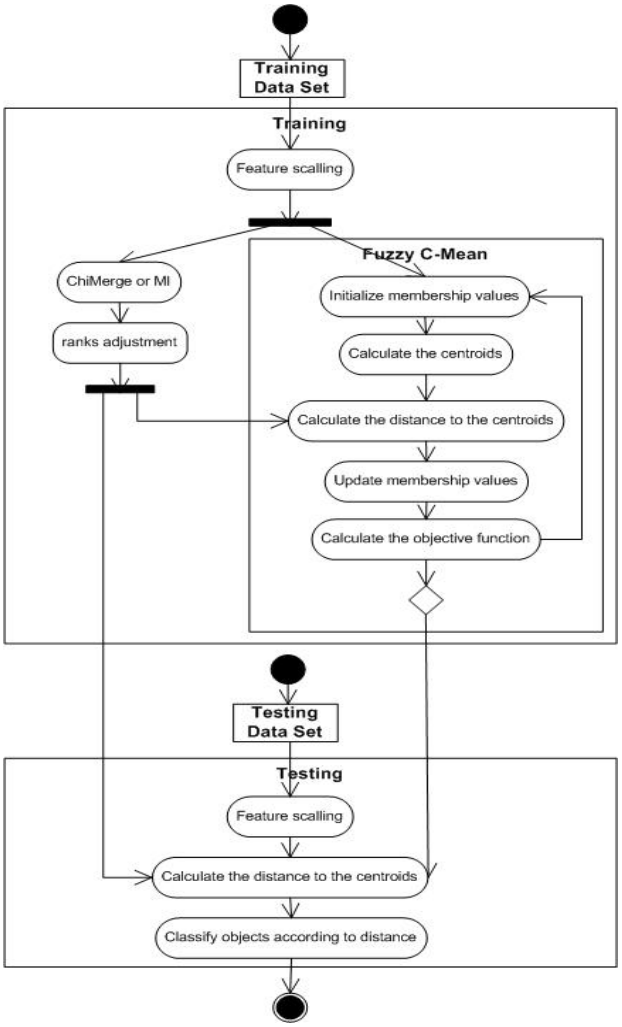

Fig. 1. Improved Fuzzy C-Mean model

VII. Experimental results and discussions

The proposed improvement is applied on two data sets and compared to the case when all features are used. Also it is compared to the case when only the important features are used in classification, in order to perform this, the test is applied on the first important feature only, then the first two important features, and so on until all feature are used in classification test. On the other hand the FCM with the proposed improvement is compared to other classifiers.

A. Data sets used in classification

This proposed enhancement is applied on two different data sets to ensure its capability and competency among other classifiers. These data sets are obtained from UCI machine learning repository [15]. Which are the pima-indians-diabetes data set of 536 objects and 8 features, and the Yeast data set of 600 objects and 8 features. 90% of the input data used for training while the rest of 10% is used for testing.

B. Classifiers used in the comparison analysis

The model is tested against other different classification techniques like Bayesian network, Support Vector Machine, Multilayered Neural Network and Decision table.

C. Classification results

1) Performance Measure: The classification effectiveness of the improved model is calculated in terms of $precision$ and $recall$ [16] which are defined as follows:

$$precision = \frac{a}{a+b}, a+b>0 \tag{16}$$

$$recall = \frac{a}{a+c}, a+c>0 \tag{17}$$

Where a counts the assigned and correct cases, b counts the assigned and incorrect cases, c counts the not assigned but incorrect cases and d counts the not assigned and correct cases. To evaluate the performance across categories, $F-measure$ is averaged. There are two kinds of averaged values, namely, micro average and macro average. The micro value is the average of the two values, $precision$ and $recall$, of all classes, while the macro average is the average of all micro values, this average represents the $F-measure$. Table (I) shows the Macro averaged $F-measure$ of the improved model when applying the ranking values in the improvement shown in equation (10). The results in the case of pima-indians-diabets and yeast data sets are compared to the FCM model without the improvement.

TABLE I
The $F-Measure$ results comparison

Data Set Used	IndianDiabets	Yeast
$F-Measure$ of FCM	0.796	0.601
$F-Measure$ of Improved FCM Ranking:ChiMerge	0.833	0.642
$F-Measure$ of Improved FCM Ranking:MI	0.833	0.627

2) Applying feature selection before classification: The following table (II) shows the results when perform the classification using the Fuzzy C-Mean after feature selection. The first row shows the result when only the first feature is used in classification, then the second row shows the results when the first two features are selected, and so on until all the features are used. The last row shows the results appear from the improved FCM model shown in table (I).

3) Comparison to the other classifiers: Table (III) shows the results of other classifiers in comparison to the enhanced FCM model where it appears to have best results.

D. Results analysis

Pima-indians-diabetes is continuous multi-variate features data set. So Fuzzy C-Mean model shows a better results

TABLE II
FCM CLASSIFICATION RESULTS OF THE PIMA-INDIANS-DIABETES (PID) DATA SET AND THE YEAST DATA SET

features used	$F-Measure$ of PID	$F-Measure$ of yeast
1 feature selected	0.740	0.500
2 features selected	0.777	0.600
3 features selected	0.777	0.600
4 features selected	0.777	0.533
5 features selected	0.796	0.533
6 features selected	0.796	0.533
7 features selected	0.796	0.516
8 features selected	0.777	0.566
Ranking features Improved FCM	0.833	0.642

TABLE III
COMPARISON BETWEEN DIFFERENT CLASSIFICATION MODELS ACCORDING TO ERROR PERCENTAGES AND RUNNING TIME IN SECONDS AND THE IMPROVED FCM MODEL (I-FCM)

Classifier	pima-indians-diabetes Classification $F-Measure$
I-FCM	0.814
Multilayer Perceptron	0.776
IB1	0692
BFTree	0.759
Decision Table	0.763
Naïve Bayes	0.746
Bayes Network	0.761
LibSVM	0.527

of 0.777 than other classifiers. As Decision trees and Decision tables tend to perform better when dealing with discrete/categorical features, while Bayes belief models like Bayesian Network (BN) and Naïve Bayesian Network due to the "independence assumption". Moreover, if feature selection is applied before the Fuzzy C-Mean classifier, the maximum classification performance appeared is 0.796 for five selected features. When applying the improvement on the Fuzzy C-Mean model, the classification results is raised more to 0.833. Also the enhancement in the classification performance from the Fuzzy C-Mean to the improved Fuzzy C-Mean model appears to be raised from 0.60 to 0.642 when being applied on the Yeast data set. Chi-Merge ranks leads to a better classification performance than that of Mutual information method due to the better discretization algorithm embedded in the Chi-Merge method. This proves that not all of the selected features have the same importance as each other. In the case of pima-indians-diabetes and yeast data sets, the chi-square method produces different values for each attributes and only few attributes have zero values, formula (14) will be applied without changes. In cases where all features are ordered with different importance but all have the zero rank values, r_k values could be replaced by d_k values.

VIII. CONCLUSIONS

This paper introduces a new application of the feature selection method in the classification model. It uses the ranks of each feature resulted from feature evaluation methods like ChiMerge and Mutual Information in the calculations of the Euclidian distance as a main parameter in the Fuzzy C-Mean model. This introduced modification in the Fuzzy C-Mean model enhanced the performance of the Fuzzy C-Mean model. The modified FCM has been applied on real life data sets including pima-indians-diabetes and yeast data sets, and it provides the best classification accuracy. The reason of these results is that even the selected features from the feature reduction methods have no equal relevance or contribution to the classifier, so if the degree of relevance in each classifier is taken into consideration, a better results can appear.

***Abstract*—Clustering is one of the most useful methods for understanding similarity among data. However, most conventional clustering methods do not pay sufficient attention to the geometric properties of data. Geometric algebra (GA) is a generalization of complex numbers and quaternions able to describe spatial objects and the relations between them. This paper uses conformal GA (CGA), which is a part of GA, to transform a vector in a real vector space into a vector in a CGA space and presents a proposed new clustering method using conformal vectors. In particular, this paper shows that the proposed method was able to extract the geometric clusters which could not be detected by conventional methods.**

***Index Terms*—conformal geometric algebra, hyper-sphere, inner product, distance, clustering.**

I. Introduction

Because nowadays enormous amounts of data are available in various fields, data mining, which analyzes data to reveal interesting information, becomes increasingly necessary. Clustering is an important technique in data mining. Methods of clustering [1] iteratively minimize an objective function based on a distance measure to label each individual data point. To take the geometric structure of data into consideration, [2] adopted a distance measure based on straight lines, and [3] adopted a distance measure based on spherical shells. The straight line measure and the spherical shell measure are applicable to datasets which have clusters generated respectively by translational motion and by rotational motion in m-dimensional space. But so far, a distance measure which detects a mixture of clusters generated by either translational or rotational motions has not been proposed. Furthermore, the spherical shell measure cannot detect a cluster around a spherical shell with dimension less than m. For example, it cannot express a data distribution around a circle in three-dimensional space because it optimizes an objective function based on distance from a three-dimensional spherical shell. This paper proposes a clustering method which can detect clusters with either translational or rotational relations. The proposed method can also detect clusters around spheres and planes of any dimension less than m because they are well expressed as elements of conformal geometric algebra.

In this study, we use geometric algebra (GA), which can describe spatial vectors and the higher-order subspace relations between them [4],[5],[6]. There are already many successful examples of its use in image processing, signal processing, color image processing, and multi-dimensional time-series signal processing with complex numbers or quaternions, which are low-dimensional GAs [7],[8],[9],[10],[11],[12],[13]. In addition, GA-valued neural network learning methods for learning input–output relationships [14] and the feature extraction based on GA [15] are well studied. This paper uses the vectors in conformal GA (CGA) [16] space, which is a part of GA to propose a new approach of approximation and a new clustering method for geometric data. A vector in CGA is called a conformal vector, and it can express both m-dimensional spheres and planes (infinite radius spheres). A conformal bivector, called a 2-blade in CGA, expresses the intersection of two m-dimensional elements, and thus it is able to express an $m-1$-dimensional sphere or plane. Likewise, a k-blade in CGA expresses an $m-k$-dimensional element. A conformal vector can also express a point as a sphere with zero radius.

In this paper, data vectors in the original space are first translated into conformal vectors expressing the data points. Then, the conformal vectors expressing the cluster centers are optimized using a distance measure on the cluster center conformal vectors and the data points. This optimization problem is solvable as an eigen-value decomposition using the Lagrange multiplier formulation. Each eigen-value is proportional to the sum of distances from an m-dimensional element expressed by the corresponding eigen conformal vectors to each of the data points. The sum of k eigen-values can be considered to be the sum of the distances from the intersection of k elements to the data points. The k eigen conformal vectors corresponding to the smallest k eigen-values can detect a cluster which is distributed over an $m-k$-dimensional spherical or planar surface.

A characteristic of the proposed method is that it is able to detect a cluster distributed over a sphere, plane, or intersection of some combination of the three, for example, a straight line or arc. Section II describes our proposal to approximate geometric data as conformal vectors and shows an algorithm of the proposed clustering method. Section III demonstrates the effectiveness of the proposed method through two experiments. One experiment estimates the probability density distribution of geometric data, and the other is a clustering experiment. The results of the first experiment demonstrate that the proposed method can approximate 2 express geometric data precisely.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

The results of the second experiment demonstrate that the kernel alignment [17] between the true labels and the labels detected by clustering using the proposed method is better than those from using conventional methods.

II. Proposed Method

A. Conformal Geometric Algebra and Estimation of Hyperspheres (-planes) from Geometric Data Sets

CGA is a special part of GA, which is also called Clifford algebras. GA defines the signature of $p+q$ orthonormal basis vectors $\mathcal{O} = \{\mathbf{e}_1, \ldots, \mathbf{e}_p, \mathbf{e}_{p+1}, \ldots, \mathbf{e}_{p+q}\}$, $\{\mathbf{e}_i\}$, such that $\mathbf{e}_i^2 = +1, \forall i \in \{1, \ldots, p\}$ and $\mathbf{e}_i^2 = -1, \forall i \in \{p+1, \ldots, p+q\}$. This paper denotes the geometric algebra determined from $\mathcal{O}$ by $\mathcal{G}_{p,q}$. For example, the geometric algebra determined from the m-dimensional real vector space $\mathbf{R}^m$ is denoted by $\mathcal{G}_{n,0}$.

A CGA space is extended from the real vector space $\mathbf{R}^m$ by adding 2 orthonormal basis vectors. Thus, a CGA space is determined by $m+2$ basis vectors $\{\mathbf{e}_1, \ldots, \mathbf{e}_m, \mathbf{e}_+, \mathbf{e}_-\}$, where $\mathbf{e}_+$ and $\mathbf{e}_-$ are defined so that

$$\begin{aligned} \mathbf{e}_+^2 = \mathbf{e}_+ \cdot \mathbf{e}_+ &= 1, \\ \mathbf{e}_-^2 = \mathbf{e}_- \cdot \mathbf{e}_- &= -1, \\ \mathbf{e}_+ \cdot \mathbf{e}_- = \mathbf{e}_+ \cdot \mathbf{e}_i = \mathbf{e}_- \cdot \mathbf{e}_i &= 0, \forall i \in \{1, \ldots, m\}. \end{aligned} \quad (1)$$

Therefore, a CGA space can be expressed by $\mathcal{G}_{m+1,1}$. This paper then defines the converted basis vectors $\mathbf{e}_0$ and $\mathbf{e}_\infty$ as

$$\mathbf{e}_0 = \frac{1}{2}(\mathbf{e}_- - \mathbf{e}_+), \mathbf{e}_\infty = (\mathbf{e}_- + \mathbf{e}_+). \quad (2)$$

From Eq. (1) and Eq. (2), we get

$$\begin{aligned} \mathbf{e}_0 \cdot \mathbf{e}_0 = \mathbf{e}_\infty \cdot \mathbf{e}_\infty &= 0, \\ \mathbf{e}_0 \cdot \mathbf{e}_\infty = \mathbf{e}_\infty \cdot \mathbf{e}_0 &= -1, \\ \mathbf{e}_0 \cdot \mathbf{e}_i = \mathbf{e}_\infty \cdot \mathbf{e}_i &= 0, \forall i \in \{1, \ldots, m\}. \end{aligned} \quad (3)$$

We also make use of a transform based upon that proposed by Hestenes[16]. The real vector $\mathbf{x} = \sum_i^m x_i \mathbf{e}_i \in \mathbf{R}^m$ is extended to a point $P \in \mathcal{G}_{m+1,1}$ according to the equation

$$P = \mathbf{x} + \frac{1}{2}\|\mathbf{x}\|^2 \mathbf{e}_\infty + \mathbf{e}_0. \quad (4)$$

Note that the inner product of P with itself, $P \cdot P$, is 0. Then, a sphere is represented as a conformal vector

$$\begin{aligned} S &= P - \frac{1}{2} r^2 \mathbf{e}_\infty \\ &= \mathbf{x} + \frac{1}{2}\{\|\mathbf{x}\|^2 - r^2\}\mathbf{e}_\infty + \mathbf{e}_0, \end{aligned} \quad (5)$$

where the sphere has center $\mathbf{x}$ and radius r in real space $\mathbf{R}^m$. The inner product $S \cdot Q$ is 0 for any point Q on the surface of the sphere. From Eqs. 4 and 5, we can see that a point is naturally expressed as a sphere with radius $r = 0$ in CGA space $\mathcal{G}_{m+1,1}$.

CGA also expresses a plane as a conformal vector:

$$L = \mathbf{n} + d\mathbf{e}_\infty, \quad (6)$$

where $\mathbf{n}$ is the normal vector, and d is a scalar coefficient of the plane $\mathbf{n} \cdot \mathbf{x} + d = 0$ in real space $\mathbf{R}^m$. The inner product $L \cdot Q$ is 0 for any point Q in the plane.

A conformal vector S in $\mathcal{G}_{n+1,1}$ is generally written in the following form:

$$S = \mathbf{s} + s_\infty \mathbf{e}_\infty + s_0 \mathbf{e}_0. \quad (7)$$

$\mathbf{s} = \sum_i^m s_i \mathbf{e}_i$ is a vector in the real vector space $\mathbf{R}^m$. s_∞ and s_0 are the scalar coefficients of the basis vectors $\mathbf{e}_\infty$ and $\mathbf{e}_0$.

In this paper, we use that the inner product between a point P and a conformal vector S in CGA space is proportional to the distance between them. From Eqs. (3), (4), and (7), the inner product of P and S is

$$\begin{aligned} d(P,S) &\propto P \cdot S \\ &= \left(\mathbf{x} + \frac{1}{2}\|\mathbf{x}\|^2 \mathbf{e}_\infty + \mathbf{e}_0\right) \cdot (\mathbf{s} + s_\infty \mathbf{e}_\infty + s_0 \mathbf{e}_0) \\ &= \mathbf{x} \cdot \mathbf{s} - s_\infty - \frac{1}{2}\|\mathbf{x}\|^2 s_0. \end{aligned} \quad (8)$$

When $d(P,S) = 0$, we get

$$\begin{aligned} & \mathbf{x} \cdot \mathbf{s} - s_\infty - \frac{1}{2}\|\mathbf{x}\|^2 s_0 = 0 \\ \Leftrightarrow & \begin{cases} \mathbf{x} \cdot \mathbf{s} - s_\infty = 0 & (s_0 = 0), \\ \|\mathbf{x} - \frac{1}{s_0}\mathbf{s}\|^2 = \frac{\|\mathbf{s}\|^2 - 2 s_\infty s_0}{s_0^2} & (s_0 \neq 0). \end{cases} \end{aligned} \quad (9)$$

Eq. (9) shows that when $d(P,S) = 0$, the point P lies on the hyper-plane or hyper-sphere expressed in CGA space as conformal vector S. Herein, we use this characteristic to approximate geometric data having rotational or the translational relations and propose a new approach for clustering.

Given a set of vectors $\mathcal{X} = \{\mathbf{x}_k = \sum_i^m x_{k;i} \mathbf{e}_i \in \mathbf{R}^m, k = 1, \ldots, n\}$, the proposed method transforms each m-dimensional vector to a point in CGA space using Eq. (4) to yield the set $\mathcal{P} = \{P_k = \mathbf{x}_k + \frac{1}{2}\|\mathbf{x}_k\|^2 \mathbf{e}_\infty + \mathbf{e}_0, k = 1, \ldots, n\}$ in $\mathcal{G}_{m+1,1}$. Then, the proposed method approximates the set of points $\mathcal{P}$ using a vector $S = \mathbf{s} + s_\infty \mathbf{e}_\infty + s_0 \mathbf{e}_0$ in $\mathcal{G}_{m+1,1}$, which is estimated using least squares. The error function E is defined as

$$\begin{aligned} E &= \sum_{k=1}^n d^2(P_k, S) \\ &= \sum_{k=1}^n \left(\mathbf{x}_k \cdot \mathbf{s} - s_\infty - \frac{1}{2}\|\mathbf{x}_k\|^2 s_0\right)^2. \end{aligned} \quad (10)$$

Eq. 9 can be solved by modifying the equation while preserving the equality, such as by multiplying both sides by a scalar value. Therefore, $\mathbf{s}$ can be restricted to $\|\mathbf{s}\|^2 = 1$. In this case, the optimization problem becomes

$$\min \sum_{k=1}^n \left(\mathbf{x}_k \cdot \mathbf{s} - s_\infty - \frac{1}{2}\|\mathbf{x}_k\|^2 s_0\right)^2 \quad (11)$$

subject to

$$\|\mathbf{s}\|^2 = 1. \quad (12)$$

Therefore, we might be tempted to express the previous problem by means of a non-negative Lagrange multiplier λ as the minimization of

$$L = \frac{1}{n}\sum_{k=1}^{n}\left(\mathbf{x}_k \cdot \mathbf{s} - s_\infty - \frac{1}{2}\|\mathbf{x}_k\|^2 s_0\right)^2 - \lambda\left(\|\mathbf{s}\|^2 - 1\right). \quad (13)$$

The critical values of L occur when its gradient is zero. The partial derivatives are

$$\frac{\partial L}{\partial \mathbf{s}} = \frac{2}{n}\sum_{k=1}^{n}\left(\mathbf{x}_k \cdot \mathbf{s} - s_\infty - \frac{1}{2}\|\mathbf{x}_k\|^2 s_0\right)\mathbf{x}_k - 2\lambda\mathbf{s} = 0, \quad (14)$$

$$\frac{\partial L}{\partial s_\infty} = -\frac{2}{n}\sum_{k=1}^{n}\left(\mathbf{x}_k \cdot \mathbf{s} - s_\infty - \frac{1}{2}\|\mathbf{x}_k\|^2 s_0\right) = 0, \quad (15)$$

$$\frac{\partial L}{\partial s_0} = -\frac{1}{n}\sum_{k=1}^{n}\left(\mathbf{x}_k \cdot \mathbf{s} - s_\infty - \frac{1}{2}\|\mathbf{x}_k\|^2 s_0\right)\|\mathbf{x}_k\|^2 = 0. \quad (16)$$

From Eqs. (15) and (16),

$$s_\infty = \mathbf{f}_\infty \cdot \mathbf{s}, \quad (17)$$

$$\frac{1}{2}s_0 = \mathbf{f}_0 \cdot \mathbf{s}, \quad (18)$$

where

$$\mathbf{f}_\infty = \frac{-\sum_{k=1}^{n}\|\mathbf{x}_k\|^4\sum_{k=1}^{n}\mathbf{x}_k + \sum_{k=1}^{n}\|\mathbf{x}_k\|^2\sum_{k=1}^{n}\|\mathbf{x}_k\|^2\mathbf{x}_k}{\sum_{k=1}^{n}\|\mathbf{x}_k\|^2\sum_{k=1}^{n}\|\mathbf{x}_k\|^2 - \sum_{k=1}^{n}\|\mathbf{x}_k\|^4\sum_{k=1}^{n}1}, \quad (19)$$

$$\mathbf{f}_0 = \frac{\sum_{k=1}^{n}\|\mathbf{x}_k\|^2\sum_{k=1}^{n}\mathbf{x}_k - \sum_{k=1}^{n}1\sum_{k=1}^{n}\|\mathbf{x}_k\|^2\mathbf{x}_k}{\sum_{k=1}^{n}\|\mathbf{x}_k\|^2\sum_{k=1}^{n}\|\mathbf{x}_k\|^2 - \sum_{k=1}^{n}\|\mathbf{x}_k\|^4\sum_{k=1}^{n}1}. \quad (20)$$

More simply, we define the equation

$$\mathbf{f}(\mathbf{x}) = \mathbf{x} - \mathbf{f}_\infty - \|\mathbf{x}\|^2\mathbf{f}_0 \in \mathbf{R}^m. \quad (21)$$

Then, Eq. (13) can be rewritten as

$$L = \mathbf{s}^T\mathbf{A}\mathbf{s} - \lambda\left(\|\mathbf{s}\|^2 - 1\right), \quad (22)$$

where

$$\mathbf{A} = \frac{1}{n}\sum_{k=1}^{n}\mathbf{f}(\mathbf{x}_k)\,\mathbf{f}^T(\mathbf{x}_k). \quad (23)$$

Therefore, the optimization problem is solved by the eigen decomposition

$$\mathbf{A}\mathbf{s} = \lambda\mathbf{s}. \quad (24)$$

An eigen vector $\mathbf{s}$ is an eigen conformal vector defining the hyper-sphere (-plane) $S = \mathbf{s} + s_\infty\mathbf{e}_\infty + s_0\mathbf{e}_0$, and the eigen-value λ is the variance, i.e., the sum of the squared distances between P_k and S. The estimated hyper-sphere or -plane will exactly fit the data set if the eigen-value λ is 0. Because there are m eigen-values when the original data space is m-dimensional, we can find m solutions of hyper-spheres (or planes). Thus, we can also detect the $m-k$-dimensional hyper-spheres (or planes) using the k eigen conformal vectors corresponding to the smallest k eigen-values. For example, in the case of three-dimensional data, we can detect a circle which is a intersection between two spheres having the smallest eigen-values. Furthermore, by also using the sphere with the largest eigen-value, we can detect a cluster of data with an arc, i.e., part of a circle. So, the proposed method is expected to improve clustering performance.

B. Geometric Clustering Method

This paper proposes a new clustering method based on the proposed approximation for data with both the mixture of rotational and translational relationships. For each cluster $\mathcal{X}_c = \{\mathbf{x}_k = \sum_i^m x_{k;i}\mathbf{e}_i \in \mathbf{R}^m \mid y_k = c, k \in \{1,\ldots,n\}\}$, the proposed method uses Eqs. (17), (18), and (24) to estimate the m pairs of hyper-spheres (-planes) $S_{c,l} = \mathbf{s}_{c,l} + s_{\infty c,l}\mathbf{e}_\infty + s_{0c,l}\mathbf{e}_0, l \in \{1,\ldots,m\}$ and eigen-values $\lambda_{c,l}$, where the eigen-values are the variances based on the distance $d(P, S_{c,l})$ between a point $P = \mathbf{x} + \frac{1}{2}\|\mathbf{x}\|^2\mathbf{e}_\infty + \mathbf{e}_0, \mathbf{x} \in \mathcal{X}_c$ and the hyper-sphere (-plane) $S_{c,l}$. Herein, we assume that the variance based on $d(P, S_{c,l})$ follows a Gaussian distribution. Then the density function is

$$p(\mathbf{x} \mid \lambda_{c,l}) = \frac{1}{\sqrt{2\pi\lambda_{c,l}}}\exp\left(-\frac{d^2(P, S_{c,l})}{2\lambda_{c,l}}\right). \quad (25)$$

Next, we assume that the variances corresponding to the eigenvalues are mutually statistically independent. Under these assumptions, the posterior probability density function for $\mathbf{x}$ given the cluster $y = c$ can be defined as

$$p(\mathbf{x} \mid c) = \prod_l^m p(\mathbf{x} \mid \lambda_{c,l}). \quad (26)$$

Then the following shows an algorithm of the proposed method using Eq. (26).

- Step1 Choose the number of clusters, C.
- Step2 Randomly assign label $y_k \in \{1,\ldots,C\}$ for each data point k.
- Step3 Estimate the posterior probability density function $p(\mathbf{x} \mid c)$ for all clusters $\mathcal{X}_c = \{\mathbf{x}_k \mid y_k = c\}$.
- Step4 Update the data label by $y_k = \arg\max_c p(\mathbf{x} \mid c)\,P(c)$, where $P(c) = \frac{|\mathcal{X}_c|}{n}$ is the prior distribution of cluster $\mathcal{X}_c$, and $|\mathcal{X}_c|$ is the number of data in cluster $\mathcal{X}_c$.
- Step5 Repeat the two previous steps until the algorithm has converged.

III. Experiments and Discussion

A. Estimation of Probability Density Function for Geometric Data Set

This subsection focuses on estimation of the probability density function for three kinds of two-dimensional geometric data: a circle, a line, and an arc. Tables I, II, and III show

the generating parameters and the parameters of the estimated conformal vectors. α and ϵ are random variables following the uniform distribution. x and y are the coordinates of the generated data. λ, $\mathbf{s}$, s_∞, and s_0 are the parameters which are estimated by the proposed method. $r = \sqrt{\frac{\|\mathbf{s}\|^2 - 2s_\infty s_0}{s_0^2}}$ is a radius calculated from the estimated parameters.

TABLE I
GENERATING AND ESTIMATED PARAMETERS FOR THE CIRCLE.

Generating Parameters				
α	uniform distribution on $[-\pi; \pi]$			
ϵ	uniform distribution on $[-0.5, -0.5]$			
x	$5 + (3.5 + \epsilon)\sin\alpha$			
y	$5 + (3.5 + \epsilon)\cos\alpha$			
Estimated Parameters				
λ	$\mathbf{s}$	s_∞	s_0	r
0.017	-0.71, -0.70	-2.70	-0.14	3.61
6.626	0.70, -0.71	0.12	-0.02	46.69

TABLE II
GENERATING AND ESTIMATED PARAMETERS FOR THE LINE.

Generating Parameters				
α	uniform distribution on $[1.5, 8.5]$			
ϵ	uniform distribution on $[-0.5, -0.5]$			
x	α			
y	$\alpha + \epsilon$			
Estimated Parameters				
λ	$\mathbf{s}$	s_∞	s_0	r
0.038	-0.75, 0.66	-0.17	-0.01	83.40
0.283	-0.66, -0.75	-3.07	-0.14	2.98

TABLE III
GENERATING AND ESTIMATED PARAMETERS FOR THE ARC.

Generating Parameters				
α	uniform distribution on $[-\frac{\pi}{3}; \frac{\pi}{3}]$			
ϵ	uniform distribution on $[-0.5, -0.5]$			
x	$5 + (3.5 + \epsilon)\sin\alpha$			
y	$5 + (3.5 + \epsilon)\cos\alpha$			
Estimated Parameters				
λ	$\mathbf{s}$	s_∞	s_0	r
0.013	-0.78, -0.63	-3.18	-0.13	2.85
0.399	0.63, -0.78	3.37	-0.04	28.77

Table I shows that the circle data is approximated by a circle with radius $r_{circle} = 3.61$ when the smallest eigen-value equals 0.017. The approximated circle is very similar to the circle of the generating parameters. Table II shows that the line data is approximated by a circle with a large radius ($r_{line} = 83.40$) when the smallest eigen-value equals 0.038. Thus, it is easy to see that the parameters which are estimated using the proposed method shown in Table II are reasonable if one considers a line as a circle with infinite radius. Table III shows the generating and estimated parameters for the arc data. As shown, the radius $r_{arc} = 2.85$ of the estimated circle is smaller than the generating radius $\hat{r}_{arc} = 3.5$. This shows that the radius of the estimated circle with smallest eigen-value in the case of arc data is different from the case of circle or line data. Thus, the proposed method is expected to be able to express arc data using a combination of all the estimated circles.

Next, we will use Eq. (26) to estimate the probability density function for geometric data. Fig. 1 shows the data distribution and the estimation results of the probability density function using the proposed method. Figs. 1(a), (b), and (c) show the data distributions for the circle, line, and arc data generated using the parameter values listed in Tables I, II, and III, respectively. Fig. 1(d), (e), and (f) show the estimated probability densities corresponding respectively to the data shown in Figs. 1(a), (b), and (c) using the proposed method. The results shown in Fig. 1 demonstrate that the proposed method can estimate the probability density for an arc, not just circles and lines. For a general m-dimensional vector space, it is easy to understand that the proposed method can estimate exactly the probability density for the hyper-sphere, -plane, and -arc.

B. Clustering Experiment

This subsection uses 2 kinds of triangular pyramid data for an experiment of clustering. Table IV shows the coordinate of vertexes of triangular pyramids which was used in this experiment. For each triangular pyramid $i \in \{1, 2\}$, we have a set of vectors $\xi_i = \{\mathbf{p}_{ij} = (\mathbf{p}_{ij,x}, \mathbf{p}_{ij,y}, \mathbf{p}_{ij,z}) \in \mathbf{R}^3; j = 1, 2, 3, 4\}$. We generated a data set $D = \{f(\xi_i, \Sigma)\}\}$ that randomly rotated each triangular pyramid 250 times, where Σ is a random rotation matrix. For each rotated triangular pyramids, we have a feature vector $f(\xi_i) = [\mathbf{p}_{i1}\Sigma, \ldots, \mathbf{p}_{i1}\Sigma] \in \mathbf{R}^{12}$ made by arranging 4 groups of 3 coordinates of each vector in a row. This experiment compares k-means[1], hard C Spherical Shells (HCSS) [3] and proposed clustering algorithm. In this paper, we choose true cluster number $C = 2$ for all algorithms.

TABLE IV
COORDINATE OF VERTEXES OF TRIANGULAR PYRAMIDS.

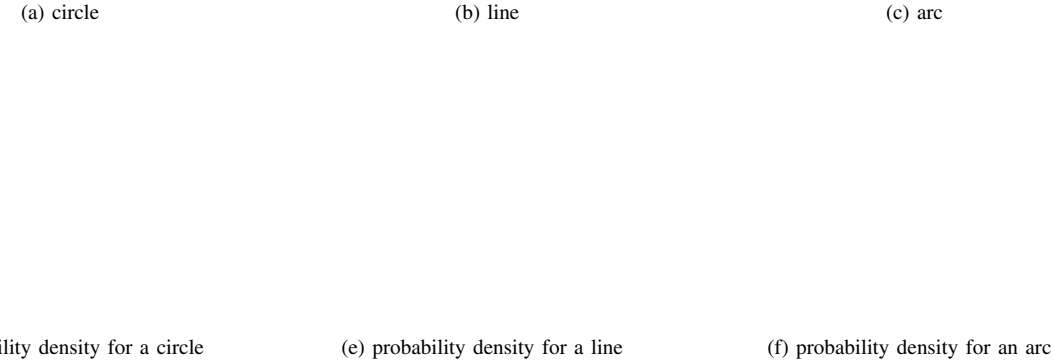
	Triangular pyramid 1			Triangular pyramid 2		
	x	y	z	x	y	z
$\mathbf{p}_1$	0	1	1	1	0	0
$\mathbf{p}_2$	1	0	1	0	1	0
$\mathbf{p}_3$	1	1	0	0	0	1
$\mathbf{p}_4$	0	0	0	-1	-1	-1

Because the results depend on the randomly assigned initial labels in most clustering methods, this experiment is performed using five different random sets of initial labels for each clustering method. The following kernel alignment function is used to evaluate the performance of the clustering results:

$$A(Y_t, Y_e) = \frac{\sum_{k,l} y_{kl;t} y_{kl;e}}{\sqrt{\sum_{k,l} y_{kl;t}^2} \sqrt{\sum_{k,l} y_{kl;e}^2}} \in [0, 1], \tag{27}$$

where $Y_t = [y_{kl;t}]$ and $Y_e = [y_{kl;e}]$ are symmetric matrices with n rows and n columns corresponding respectively to the generating data labels and the estimated data labels. y_{kl} indicates whether labels are different between instance k and instance l, and is defined by

$$y_{kl} = \begin{cases} 1 & (y_k = y_l), \\ 0 & (y_k \neq y_l). \end{cases} \tag{28}$$



(a) circle (b) line (c) arc

(d) probability density for a circle (e) probability density for a line (f) probability density for an arc

Fig. 1. Estimated probability densities for the (a) circle, (b) line, and (c) arc.

Table V shows the average of the kernel alignment when using k-means, HCSS, and the proposed method. As shown in Table V, the kernel alignment when using the proposed method was better than when using k-means or HCSS.

TABLE V
AVERAGE ALIGNMENTS OF K-MEANS, HCSS, AND THE PROPOSED METHOD.

Method	Average alignment
k-mean	0.50053
HSSC	0.50082
CGA	1.00000

The clustering based on k-means uses the center of each cluster as representative, and so it is not able to cluster geometric data based on hyper-spheres. HCSS can cluster the data based on hyper-spheres. But in this experiment, the vectors made by rotating from two triangular pyramids have a norm $\|f(\xi_i)\|_2 = \sum_j \|\mathbf{p}_{ij}\|^2 = 6, \forall i \in \{1,2\}$. So, these vectors lie on the same hyper-sphere in 12-dimensional space. Therefore, the clustering result of HCSS was not good. Unlike k-means and HCSS, the proposed method can detect clusters around spheres of any dimension less than 12 because they are well expressed as elements of conformal geometric algebra. Together, the results of this experiment verifies that the clustering results using the proposed method are better than those using these conventional methods.

IV. CONCLUSION

This paper proposed a new approach of approximating geometric data, including that based on hyper-spheres or hyper-plane using CGA. The proposed method used a Lagrange function and eigen decomposition to find eigen conformal vectors for constructing the approximation. In m-dimensional space, the proposed method could find m solutions of hyper-spheres (-planes) and m eigen-values. The method expresses various data distributions, such as those based on hyper-spheres (-planes), circles (lines), or arcs, by using probability density functions based on the Gaussian function for the distance defined by CGA. Then, this paper proposed a new clustering method using the proposed approximation. The results of the first experiment showed that the proposed method was able to express exactly geometric data based on circles, lines, or arcs. The results of the second experiment showed that the kernel alignment based on the clustering results using the proposed method was better than those of clustering using conventional methods.

***Abstract*—Previously studied fuzzy bipolar conditions of type "and if possible" are made of a mandatory condition c and an optional condition w. They allow expressing complex preferences of a conjunctive nature. We define in this paper, a new kind of fuzzy bipolar conditions of the form "or else" which express complex preferences of a disjunctive nature. We show that the "or else" form can be used as a negation operator of the "and if possible" form and vice versa. We also show that these both forms are compatible and, therefore, fuzzy bipolar conditions of both types can be used together in the same bipolar query.**

***Keywords*—Flexible querying, bipolar conditions, negation of bipolar conditions, fuzzy sets theory.**

I. Introduction

Flexible querying allows expressing preferences in user queries, which are addressed to regular databases and deliver a set of ranked answers from the most to the least preferred. In this context, the fuzzy sets theory [10] provide a general framework for the expression and the interpretation of queries involving preferences modelled by fuzzy predicates (or conditions). It is also possible to consider fuzzy bipolar conditions to model complex preferences [4], [5]. In this context, a bipolar condition is made of two components: a constraint and a wish. More precisely, for the expression of user preferences, we rely on fuzzy bipolar conditions in which the constraint and the wish are defined by fuzzy sets. We define then a bipolar query as a query that involves bipolar conditions.

Several interpretations have been introduced for the evaluation of queries involving fuzzy bipolar conditions of type "and if possible" (see [4], [5], [9], [11], [12]). The algebraic operators (selection, projection, join, union, intersection) have also been extended to fuzzy bipolar conditions [7], [2] of type "and if possible". It is therefore possible to express the usual query statements over relational bipolar relations, but in order to build a bipolar relational algebra, it stills to define a global operator for the negation of bipolar conditions. Several operators have been proposed in the literature but none of them fits in well with the framework of flexible querying.

We introduce in this paper a new kind of fuzzy bipolar conditions noted "or else", which expresses fuzzy bipolar conditions of a disjunctive nature. Its definition and properties allow us to define a negation operator of fuzzy bipolar conditions of the form "and if possible".

We show that each of these forms of bipolarity expresses a negation form of one another. These forms of bipolarity are also compatible in the sense that it is possible to mix in the same bipolar queries an "and if possible" fuzzy bipolar condition with an "or else" fuzzy bipolar condition.

The remainder of this paper is organized as follows. In section II, a short reminder about fuzzy bipolar conditions of type "and if possible" is introduced. In section III, we sum up different negation operators of fuzzy bipolar conditions of the form "and if possible", which have been proposed. Section IV is dedicated to our contribution; we introduce, firstly, the definition of fuzzy bipolar conditions of type "or else" and we show, secondly, that such fuzzy bipolar conditions can be used to define a negation operator for fuzzy bipolar conditions of type "and if possible". In section V, we show that these forms of fuzzy bipolar conditions are mutually compatible and can be used together in the same bipolar query. Section VI recalls our contribution and draws some lines for future works.

II. Fuzzy Bipolar Conditions

A bipolar condition is an association of a negative condition (negative pole) and positive condition (positive pole). In this paper, a bipolar condition is made of two conditions defined on the same universe: i) a constraint c, which describes the set of acceptable elements, ii) a wish w which defines the set of desired or wished elements. The negation of c is the set of rejected elements since it describes non-acceptable elements. Since it is not coherent to wish a rejected element, the following property of coherence holds: $w \subseteq c$.

In addition, condition c is mandatory since an element which does not satisfy c is rejected; $\neg c$ is then considered as the negative pole of the bipolar condition. Condition w is optional because its non-satisfaction does not automatically mean the rejection; w is then considered as the positive pole of the bipolar condition. In this paper, a bipolar condition is noted (c,w) and means, *"to satisfy c and if possible to satisfy w"* [4], [5].

If c and w are boolean conditions, the satisfaction with respect to (c,w) is an ordered pair from $\{0,1\}^2$. When querying a database with such a condition, tuples satisfying the constraint and the wish are returned in priority to the user. If such answers do not exist, tuples satisfying only the constraint are delivered.

If c and w are fuzzy conditions (defined on the universe U), the property of coherence becomes: $\forall u \in U, \mu_w(u) \leq \mu_c(u)$.

The satisfaction with respect to (c,w) is an ordered pair of degrees from the unit interval $[0,1]^2$. Each element u from U is then attached with a pair of grades $(\mu_c(u), \mu_w(u))$ that

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

expresses the degrees of its satisfaction respectively to the constraint and the wish.

When querying a relation R with a fuzzy bipolar condition, each tuple t from R is then attached with a pair of grades $(\mu_c(t), \mu_w(t))$ that expresses the degrees of its satisfaction respectively to the constraint c and the wish w (and a so-called fuzzy bipolar relation is obtained). A tuple t is then denoted $(\mu_c, \mu_w)/t$. Any tuple u such that $\mu_c(u) = 0$ does not belong to the fuzzy bipolar relation.

In such a context, tuples cannot be ranked from the most preferred to the least preferred using an aggregation of μ_c and μ_w because the constraint and the wish are not commensurable. However, they can be ranked using the lexicographical order: t_1 is preferred to t_2 if and only if:

$\mu_c(t_1) > \mu_c(t_2)$ or $(\mu_c(t_1) = \mu_c(t_2) \wedge \mu_w(t_1) > \mu_w(t_2))$,
which is noted $(\mu_c(t_1), \mu_w(t_1)) > (\mu_c(t_2), \mu_w(t_2))$.
In this case, the satisfaction with respect to the constraint is firstly used to discriminate among answers (the constraint being mandatory). The satisfactions with respect to the wish being optional, they can only be used to discriminate among answers having the same evaluation with respect to the constraint. A total order is then obtained on μ_c and μ_w (with $(1,1)$ as the greatest element and $(0,0)$ as the least element).

Based on the lexicographical order, the *lmin* and *lmax* operators [6], [2] are introduced in order to define the conjunction (resp. intersection) and the disjunction (resp. union) of bipolar conditions (resp. relations). They are respectively defined as follows:

$$\begin{array}{rcl} ([0,1]\times[0,1])^2 & \rightarrow & [0,1]\times[0,1] \\ ((\mu,\eta),(\mu',\eta')) & \mapsto & lmin((\mu,\eta),(\mu',\eta')) = \\ & & \begin{cases} (\mu,\eta) & if\ \mu < \mu' \vee (\mu = \mu' \wedge \eta < \eta'), \\ (\mu',\eta') & else. \end{cases} \end{array} \quad (1)$$

$$\begin{array}{rcl} ([0,1]\times[0,1])^2 & \rightarrow & [0,1]\times[0,1] \\ ((\mu,\eta),(\mu',\eta')) & \mapsto & lmax((\mu,\eta),(\mu',\eta')) = \\ & & \begin{cases} (\mu,\eta) & if\ \mu > \mu' \vee (\mu = \mu' \wedge \eta > \eta'), \\ (\mu',\eta') & else. \end{cases} \end{array} \quad (2)$$

The *lmin* (resp. *lmax*) operator is commutative, associative, idempotent and monotonic. The pair of grades $(1,1)$ is the neutral (resp. absorbing) element of the operator *lmin* (resp. *lmax*) and the pair $(0,0)$ is the absorbing (resp. neutral) element of the operator *lmin* (resp. *lmax*).

Remark 1: Fuzzy bipolar conditions generalize fuzzy conditions since a fuzzy condition C can be rewritten (C,C) to express *"to satisfy C and if possible to satisfy C"*. As a consequence, a fuzzy relation R is a particular case of a fuzzy bipolar relation such that $\forall t \in R, \mu_R(t) = \mu_c(t) = \mu_w(t)$. Therefore, it is easy to demonstrate that the *lmin* (resp. *lmax*) generalizes the triangular norm *min* (resp. the triangular co-norm *max*).

More formally, bipolar conditions of the form "C and if possible W" can be defined with the following properties:

1) $\neg C$ corresponds to the rejection (C denotes acceptable elements),
2) W corresponds to the optimal values,
3) The acceptability condition C is more important than the optimality (the condition W),
4) The set of optimal values is included in the set of acceptable values ($W \subseteq C$).

Remark 2: The property 3 means that the non-rejection (or the acceptability) is more important than the optimality, therefore, the lexicographical order can be used to rank between elements.

III. The negation of Fuzzy Bipolar Conditions

Many works have been carried out to define a negation operator of fuzzy bipolar conditions.

To be consistent, any negation operator must verify the following properties, which have been introduced in [1]:

Let (C',W') denotes the negation of a fuzzy bipolar condition (C,W).

a) Property 1. Order reversing: The negation operator must deliver tuples in reverse order in which they are delivered by the condition (C,W):

$$\begin{array}{r} \forall t_1,t_2, (\mu_C(t_1),\mu_W(t_1)) < (\mu_C(t_2),\mu_W(t_2)) \Leftrightarrow \\ (\mu_{C'}(t_2),\mu_{W'}(t_2)) < (\mu_C(t_1),\mu_W(t_1)). \end{array} \quad (3)$$

b) Property 2. Consistency condition: The negation operator must deliver a consistency bipolar condition, which means: $\forall t, \mu_{W'}(t) \leq \mu_{C'}(t)$.

This property means that the negation of a bipolar condition of the form "and if possible" must also be a bipolar condition.

c) Property 3. Involutivity: The negation operator must be an involutive operator, it means that: $\neg(\neg(C,W)) = (C,W)$.

Several negation operators have been proposed in the literature. Some of them are summarized in what follows.

A. The Negation Operator Inspired by Twofold Fuzzy Sets

This negation operator is proposed in [3]. In this context, the negation of the wish corresponds to the constraint and the negation of the constraint defines the wish of the obtained condition. More formally, let (C,W) be a bipolar condition, its negation is: $\neg(C,W) = (\neg W, \neg C)$.

This kind of negation is not intuitive and does not satisfy the property of order reversing as it is shown in the following example 1.

Example 1: Let (C,W) be a bipolar condition and R a relational table containing tuples t_1 and t_2 such that: $(\mu_C(t_1),\mu_W(t_1)) = (0.8,0)$ and $(\mu_C(t_2),\mu_W(t_1)) = (0.6,0.6)$, we obtain $t_1 > t_2$.

The negation of (C,W) delivers the following result: $(\mu_{C'}(t_1),\mu_{W'}(t_1)) = (1,0.2)$ and $(\mu_{C'}(t_2),\mu_{W'}(t_2)) = (0.4,0.4)$, we obtain, then $t_1 > t_2$. □

B. The Negation Operator Based on the Product and the Division

This operator has been proposed in [1]. It is defined as follows: $\neg(C,W) = (C',W')$, where:

$$\mu_{C'} = 1 - \mu_C, \tag{4}$$

and

$$\mu_{W'} = \begin{cases} (1-\mu_C) * (1 - \frac{\mu_W}{\mu_C}) & if\ \mu_C \neq 0, \\ 1 & else. \end{cases} \tag{5}$$

This operator is not involutive; indeed:
$\neg(\neg(1, b \neq 0)) = \neg(0,0) = (1,1) \neq (1, b \neq 0)$.

In order to make this operator involutive, it is necessary to accept ordered pairs of grades of the form $(0, b > 0)$ and to define the negation as follows:

$$\mu_{C'} = 1 - \mu_C \tag{6}$$

$$\mu_{W'} = \begin{cases} 1 - \mu_W & if\ \mu_C = \{0,1\}, \\ (1-\mu_C) * (1 - \frac{\mu_W}{\mu_C}) & else. \end{cases} \tag{7}$$

The above properties 1, 2 and 3 hold only if the following conditions are satisfied:

- do not substitute (C,W) by $(C, C \wedge W)$ when $\mu_C = 0$,
- substitute (C,W) by $(C, W \wedge (C \vee (\neg C \Rightarrow_{RG} true)))$, where $\Rightarrow_{RG}$ is the Rescher-Gaines fuzzy implication,
- do not discard from the bipolar relation, tuples which have an ordered pair of grades of the form $(0, b \neq 0)$.

Despite the satisfaction of properties $1, 2$ and 3 under above conditions, the following drawbacks are pointed out:

- this operator does not express a natural negation form from the user point of view,
- its implementation is difficult and complex,
- the three added conditions can be seen as an infringement to properties of fuzzy bipolar conditions.

C. The Negation Operator of the Form $(\neg C, false)$

This operator is proposed in [2] and it is defined as follows:

$$\neg(C,W) = (\neg C, false) \tag{8}$$

This operator means that if tuples satisfying the constraint are discarded, then the wish becomes meaningless.

This form of negation is not involutive:
$\neg(\neg(C,W)) = \neg(\neg C, false) = (C, false) \neq (C,W)$.

D. The Negation Operator of the Form $(\neg C, \neg W)$

This operator is proposed in [7], [6]. The negation operator in this approach is defined as follows: $\neg(C,W) = (\neg C, \neg W)$.

This operator does not satisfy the consistency condition because $\neg W \nsubseteq \neg C$. The obtained operator is no more bipolar and can leads to non-consistent queries as in the following example 2.

Example 2: The negation of *"Train tickets which cost less than* 100 *\$ and if possible less than* 75 *\$"* is defined in this context as *"Train tickets which cost more than* 100 *\$ and if possible more than* 75 *\$"*.

This query is not consistent because the set of tickets which cost more than 75 \$ in not included in the set of tickets which cost more than 100 \$, but rather the opposite. □

IV. Fuzzy bipolar conditions of the form "or else"

We introduce in this section a new kind of fuzzy bipolar conditions. They are of the form "or else". We, firstly, provide a formal definition for such bipolar conditions; then, we study semantic relationships and similarities between "or else" and "and if possible" fuzzy bipolar conditions. Finally, we show that these two forms can be used in a negation context to define a global negation operator for fuzzy bipolar conditions.

A. Definition

A bipolar condition of the form "E, or else F" is made of two parts: (i) a positive pole corresponding to the condition E, which expresses perfect values and (ii) a negative pole corresponding to the condition F that expresses acceptable values (any element does not satisfy F is discarded).

We define bipolar conditions of the form "E, or else F", denoted $[E,F]$, with the following properties:

1) $\neg F$ corresponds to the rejection (F denotes acceptable elements),
2) E corresponds to the optimal values,
3) The optimality condition E is more important than the acceptability condition F,
4) The set of optimal values is included in the set of acceptable values ($E \subseteq F$): $\forall x, \mu_E(x) \leq \mu_F(x)$.

The ordered pair of grades, denoted $[\mu_E(x), \mu_F(x)]$, expresses the satisfaction of an element x to the condition "E, or else F".

Since the satisfaction with respect to the optimality E is more important than the satisfaction with respect to the acceptability F, the lexicographical order can be used to rank between elements. Indeed, if an element x satisfies completely the optimal condition E then it gets a pair of grades $[1,1]$ because $\forall x, \mu_E(x) \leq \mu_F(x)$, and by definition, the lexicographical order shows that this element is optimal. If the satisfaction to the optimal condition E of an element x_1 is better than the satisfaction to the same condition by another element x_2, then x_1 is more preferred than x_2.

Finally, if both x_1 and x_2 have the same satisfaction to the optimal condition E, for want of anything better, the condition F is used to distinguish between them.

Remark 3: It is worth noticing that a fuzzy condition C can be expressed "C or else C" within the framework of bipolar conditions of the form "or else". This generalization of fuzzy conditions expresses that perfect and acceptable values are the same.

As is the case of fuzzy conditions of the form "and if possible", the *lmin* (resp. *lmax*) operator applied on bipolar conditions of the form "or else" defines an extended triangular norm (resp. co-norm).

B. Relationships Between "or else" and "and if possible" Fuzzy Bipolar Conditions

Let "E, or else F" and "C, and if possible W" be two fuzzy bipolar conditions. The former is denoted $[E,F]$, with $\forall x, \mu_E(x) \leq \mu_F(x)$ and the latter is denoted (C,W), with $\forall x, \mu_W(x) \leq \mu_C(x)$.

TABLE I
EXAMPLE OF THE BEHAVIOR OF THE (C,W) FORMALISM.

	$\mu_C(x_i)$	$\mu_W(x_i)$
t_1	1	1
t_2	0.8	0.2
t_3	0.7	0.5
t_4	0.4	0.3

TABLE II
EXAMPLE OF THE BEHAVIOR OF THE $[W,C]$ FORMALISM.

	$\mu_W(x_i)$	$\mu_C(x_i)$
t_1	1	1
t_3	0.5	0.7
t_4	0.3	0.4
t_2	0.2	0.8

We notice strong similarities between these two formalisms, since in both cases we have:

- C and F express the acceptable values (or a non rejected values),
- $\neg C$ and $\neg F$ correspond to the discarded values,
- W and E express the perfect or optimal values,
- the set of perfect values is included in the set of acceptable values.

Moreover, these two conditions generalize fuzzy conditions in the same way: a fuzzy condition C is expressed (C,C) or $[C,C]$.

Since W (resp. C) plays the same role as E (resp. F), it is interesting to study the behavior of (C,W) and $[W,C]$. First of all, we notice that in the boolean case, both formalisms have the same meaning, as shown in the example 3.

Example 3: Let x,y and z be three elements attached respectively to the following pair of grades: $(1,1),(1,0)$ and $(0,0)$ with respect to conditions C and W.

The lexicographical order delivers the same order in both situations (C,W) and $[W,C]$: $x > y > z$. □

However, when C and W are fuzzy conditions, the two formalisms do not express the same semantic because the lexicographical order does not deliver the same order.

Tables I and II show that tuples t_1,t_2,t_3 and t_4 are not sorted according to the same order, depending on whether the formalism (C,W) or $[W,C]$ is used.

The basic difference between these two formalisms is the fact that the formalism "C, and if possible W" gives more importance to the non rejected elements (that means the satisfaction with respect to the condition of acceptance C is privileged), whereas the formalism "E, or else F" gives more importance to the optimal elements (i.e. the satisfaction with respect to the optimal condition E is privileged).

In this context, a fuzzy bipolar condition of the form (C,W) can be defined as a pair of fuzzy conditions, which define a set of optimal values (W) and a set of acceptable values (C) under the consideration that the non-rejection is more important than the optimality; and a fuzzy bipolar condition of the form $[E,F]$ is defined as a pair of fuzzy conditions, which define a set of optimal values (E) and a set of acceptable values (F) under the consideration that the optimality is more important than the non-rejection.

TABLE III
EXAMPLE OF TUPLES ATTACHED WITH THEIR ORDERED PAIRS OF GRADES W.R.T THE FUZZY BIPOLAR CONDITION $(Young, Young \wedge WellPaid)$.

#Employee	$\mu_{Young}(\#Employee)$	$\mu_{Young}(\#Employee) \wedge \mu_{WellPaid}(\#Employee)$
10	1	1
11	0.75	0.56
12	0.6	0.36
13	0.5	0.25

C. The Negation Context

In this subsection, we show that the negation of the fuzzy bipolar condition (C,W) is the fuzzy bipolar condition $[\neg C,\neg W]$ and, reciprocally, the negation of the fuzzy bipolar condition $[E,F]$ is the fuzzy bipolar condition $(\neg E,\neg F)$.

1) Negation of (C,W): We recall that a bipolar condition (C,W) is defined by the following properties:

1) $\neg C$ corresponds to the rejection (C denotes acceptable elements),
2) W corresponds to the optimal values,
3) The acceptability condition C is more important than the optimality condition W.

In addition, the set of optimal values is included in the set of acceptable values ($W \subseteq C$).

If we express these properties in the context of a negation $\neg(C,W)$, we obtain:

1) $\neg C$ corresponds to the optimal values (C contains rejected and acceptable elements),
2) W corresponds to the rejected values ($\neg W$ denotes acceptable elements),
3) The optimality condition $\neg C$ is more important than the acceptability condition $\neg W$.

In addition, since $W \subseteq C$, we have $\neg C \subseteq \neg W$.

Therefore, we obtain a fuzzy bipolar condition which fits within the definition of the "or else" fuzzy bipolar conditions and we denote it by $[\neg C,\neg W]$. That means:

$$\neg(C,W) = [\neg C,\neg W]. \quad (9)$$

It is important to notice that in (C,W), the importance is put on C and the concept attached to C stills the most important for $\neg(C,W)$. As an example, when considering *"young and if possible young and well-paid employees"*, the importance is put on the *age* (young). In its negation, the *age* stills the most important aspect to consider.

Example 4: Let $(Young, Young \wedge WellPaid)$ be a fuzzy bipolar condition of type "and if possible" which defines *young and if possible young and well-paid employees*. Let table III be a set of returned tuples from a relational table. The negation of the fuzzy bipolar condition $(Young, Young \wedge WellPaid)$ is defined as $[notYoung, not(Young \wedge WellPaid)]$, which corresponds to *employees which are not young, or else are not (young and well-paid)*. We notice that concepts used to define the fuzzy bipolar condition $(Young, Young \wedge$

TABLE IV
EXAMPLE OF TUPLES ATTACHED WITH THEIR ORDERED PAIRS OF GRADES W.R.T THE FUZZY BIPOLAR CONDITION $[notYoung, not(Young \wedge WellPaid)]$.

#Employee	$\mu_{notYoung}(\#Employee)$	$\mu_{not(Young\ and\ WellPaid)}(\#Employee)$
13	0.5	0.75
12	0.4	0.64
11	0.25	0.44

WellPaid) are the same ones used to express its negation $[notYoung, not(Young \wedge WellPaid)]$. More precisely, the concept *age* is used to define the most important fuzzy condition in both fuzzy bipolar condition $(Young, Young \wedge WellPaid)$ and $[notYoung, not(Young \wedge WellPaid)]$.

The obtained ordered pairs of degrees for the fuzzy bipolar condition $[notYoung, not(Young \wedge WellPaid)]$ are summed up in the table IV. The tuple #10 is completely discarded. □

2) Negation of $[E,F]$*:* We recall that a fuzzy bipolar condition $[E,F]$ is defined by the following properties:

- $\neg F$ corresponds to the rejection (F denotes the acceptable elements),
- E corresponds to the optimal values,
- The optimality condition E is more important than the acceptability.

In addition, the set of optimal values is included in the set of acceptable values ($E \subseteq F$).

If we express these properties in the context of a negation, we obtain:

- $\neg F$ corresponds to the optimal values,
- E corresponds to the rejected values ($\neg E$ denotes the acceptable elements),
- The acceptability condition $\neg E$ is the more important condition.

In addition, since $E \subseteq F$, we have $\neg F \subseteq \neg E$. This property states that, in the context of negation of a fuzzy bipolar condition of the form $[E,F]$, the set of optimal values is included in the set of acceptable values.

Therefore, we obtain a fuzzy bipolar condition, which fits within the definition of the "and if possible" fuzzy bipolar conditions and we denote it by $(\neg E, \neg F)$. That means:

$$\neg[E,F] = (\neg E, \neg F). \tag{10}$$

As for bipolar conditions of type "and if possible", we notice that in $[E,F]$, the importance is put on E and the concept attached to E stills the most important for $\neg[E,F]$.

This form of negation is involutive and reverses the lexicographical order (either for $\neg(E,F)$ or $\neg[E,F]$).

Proof: Reversing of the lexicographical order.

The proof is based on the following properties:

$$(x_1,y_1) > (x_2,y_2) \Rightarrow (1-x_1, 1-y_1) < (1-x_2, 1-y_2).$$

Let $[E,F]$ or (E,F) be a fuzzy bipolar condition. A tuple t_i is preferred to t_j means that:

$(\mu_E(t_i), \mu_F(t_i)) > (\mu_E(t_j), \mu_F(t_j))$,
or $[\mu_E(t_i), \mu_F(t_i)] > [\mu_E(t_j), \mu_F(t_j)]$

From the definition of the lexicographical order, we get:

(t_i is preferred to t_j) $\Leftrightarrow \mu_E(t_i) > \mu_E(t_j)$ or
$(\mu_E(t_i) = \mu_E(t_j)$ and $\mu_E(t_i) > \mu_F(t_j))$
$\Leftrightarrow (1-\mu_E(t_i) < 1-\mu_E(t_j))$ or $((1-\mu_E(t_i) = 1-\mu_E(t_j))$
and $(1-\mu_E(t_i) < 1-\mu_F(t_j)))$

$\Leftrightarrow t_j$ is preferred to t_i for $(\neg E, \neg F)$ or $[\neg E, \neg F]$, with $(\neg E, \neg F) = \neg[E,F]$ and $[\neg E, \neg F] = \neg(E,F)$. The order is then reversed for the negation. ■

Proof: Involutivity.

$\neg(\neg(C,W)) = \neg[\neg C, \neg W] = (\neg\neg C, \neg\neg W) = (C,W)$ and $\neg(\neg[E,F]) = \neg(\neg E, \neg F) = [\neg\neg E, \neg\neg F] = [E,F]$. ■

V. MUTUAL COMPATIBILITY OF "AND IF POSSIBLE" AND "OR ELSE" FUZZY BIPOLAR CONDITIONS

It is possible to express fuzzy bipolar conditions of both forms "and if possible" and "or else" together in the same bipolar query. This means that it is possible to use *lmin* and *lmax* operators to compare and to handle ordered pairs of scores of these types of fuzzy bipolar conditions. This is due to the fact that both of them are semantically equivalent in the sense that they are defined similarly. Indeed, fuzzy bipolar conditions of types "and if possible" and "or else" consist of two parts: a first part which corresponds to the most important concept (the concept attached to C for the fuzzy bipolar condition (C,W) and the concept attached to E or the fuzzy bipolar condition $[E,F]$) and a second part which corresponds to the least important concept of the bipolar condition. Therefore, in order to rank between tuples, the first choice is made on the condition which corresponds to the most important concept in the fuzzy bipolar condition, and the second choice is made on the condition which corresponds to the least important concept of the same fuzzy bipolar condition. We show in the following example a bipolar query in which both forms of fuzzy bipolar conditions are used, and its returned tuples with their attached ordered pairs of degrees.

Example 5: Let R be a relational table about *journeys* from *Paris* to *Brest* (see table V), delivered from a multimodal transport information system.

One can express a bipolar query about preferred journeys in the following terms:

"Find journeys from Paris to Brest which are ***(fast, and if possible fast and cheap)****, or journeys with* ***(an early departure and a late arrival, or else an early departure)"****.*

In the above query, the preferred journeys are those which have a short duration and cost as low as possible, or journeys in which the user takes the time to travel, which correspond to journeys having an early departure and a late arrival, otherwise journeys which have an early departure.

Based on the fuzzy predicates *fast*, *cheap*, *early* and *late*, we define from the relation R the following bipolar relations $Journey_{(Fast, Fast \wedge Cheap)}$ (see table VI), which corresponds to fast *and if possible* cheap journeys, and $Journey_{[Early \wedge Late, Early]}$ (see table VII), which corresponds journeys having an early departure and a late arrival *or else* an early departure. Tuples of these relations are ranked from the most satisfactory to the least satisfactory with regard to fuzzy bipolar conditions $(Fast, Fast \wedge Cheap)$ and $[Early \wedge Late, Early]$ respectively.

TABLE V
EXAMPLE OF EXTENSION OF THE RELATION R.

#Journey	Duration	Departure	Mode	Cost	...
10	2h	11h30 am	Plane	60	...
11	2h45	11h am	Plane	150	...
12	2h30	8h30 am	Plan	260	...
13	3h10	8h am	Train	80	...
14	3h30	10h am	Train	80	...
15	4h10	7h30 am	Train	90	...
16	5h15	7h15 am	Bus	85	...

TABLE VI
THE FUZZY BIPOLAR RELATION $Journey_{(Fast,Fast \wedge Cheap)}$.

#Journey	$\mu_{Fast}(\#Journey)$	$\mu_{Fast \wedge Cheap}(\#Journey)$
10	1	1
11	0.80	0.64
12	0.80	0.25
13	0.60	0.36
14	0.40	0.36
15	0.40	0.16
16	0.25	0.25

The ordered pair of grades of satisfaction, with regard to the combination of the fuzzy bipolar conditions $(Fast, Fast \wedge Cheap)$ and $[Early \wedge Late, Early]$, attached to each tuple is obtained by the application of the $lmax$ operator on each tuple of both fuzzy bipolar relations as follows:

- #journey = 10: $lmax((1,1),[0.25,0.6]) = (1,1)$,
- #journey = 11: $lmax((0.8,0.64),[0.25,0.5]) = (0.8,0.64)$,
- #journey = 12: $lmax((0.8,0.25),[0.3,1]) = (0.8,0.25)$,
- #journey = 13: $lmax((0.6,0.36),[0.6,1]) = [0.6,1]$,
- #journey = 14: $lmax((0.4,0.36),[0.6,0.7]) = [0.6,0.7]$,
- #journey = 15: $lmax((0.4,0.16),[0.8,1]) = [0.8,1]$,
- #journey = 16: $lmax((0.25,0.25),[1,1]) = [1,1]$,

We notice that journeys are delivered depending on the grade of satisfaction w.r.t the most important fuzzy condition: *fast* for the fuzzy bipolar condition $(Fast, Fast \wedge Cheap)$ and *early* for the fuzzy bipolar condition $[Early \wedge Late, Early]$. In the case where the two most important conditions have the same satisfaction, the distinction is made on the least important conditions.

The maximum ordered pair of degrees is attached to tuples #10 and #16, because the corresponding fuzzy bipolar condition is completely satisfied (both are fully satisfactory and not distinguishable).

In the case of tuples #11, #12, #14, #15, the returned ordered pair of grades corresponds to the ordered pair in which the satisfaction w.r.t the most important fuzzy condition in both used fuzzy bipolar conditions is the highest.

TABLE VII
THE FUZZY BIPOLAR RELATION $Journey_{[Early \wedge Late, Early]}$.

#Journey	$\mu_{Early \wedge Late}(\#Journey)$	$\mu_{Early}(\#Journey)$
16	1	1
15	0.80	1
13	0.60	1
14	0.60	0.70
12	0.30	1
10	0.25	0.60
11	0.25	0.50

In the case of tuple #13, the satisfaction is the same with regard to the most important fuzzy condition in both fuzzy bipolar conditions; therefore, the least important condition is used to determine which ordered pair of degrees to attach to the resulting tuple.

Finally, journeys are delivered in the following order: $(1,1)$/#10, $[1,1]$/#16, $[0.8,1]$/#15, $(0.8,0.64)$/#11, $(0.8,0.25)$/#12, $[0.6,1]$/#13, $[0.6,0.7]$/#14.

VI. CONCLUSION AND FUTURE WORKS

A new kind of fuzzy bipolar conditions is introduced in this paper. These conditions are of the form "or else" and allow users to express complex preferences of a disjunctive nature in their queries. We showed that this form of fuzzy bipolar conditions are compatible with fuzzy bipolar conditions of the form "and if possible" in the sense that (i) each one can be used as the negation form of the other and that (ii) it is possible to combine them in the same query and to handle them using the lexicographical order based operator *lmin* and *lmax*.

As future work, we aim at studying this form of negation within the scope of a bipolar relational language and at integrating it into the bipolar SQLf language, which is an extension of the SQLf language to fuzzy bipolar conditions.

***Abstract*—A fuzzy optimization model based tolerance approach is proposed to handle timetable rescheduling in high speed railway during speed restriction period. As the limited speed and headway time are not crisp figures in practice especially when some natural hazards happen or some equipment failure, tolerance approach is introduced with the fuzzy membership functions of the original objective and soft constraints to find an new optimal objective with little slack of constraints. The original objective is treated in the same manner as the soft constraints, so the model is symmetric. The proposed fuzzy rescheduling model is simulated on the busiest part of a high speed railway line in China. The entire case study shows the significance of fuzzy optimization in case of speed restriction. The results shed light on how we could choose a better limited speed and headway time, so that the number of seriously impacted trains can be reduce greatly with little cost and risk.**

Keywords- timetable rescheduling; fuzzy optimization; tolerance approach

I. INTRODUCTION

At present, China is extensively developing the infrastructure of high speed railway. The target is to cover its major economic areas with a high speed railway network, which consists of four horizontal and four vertical lines [1], in the following several years. The network scale is much larger than any existing ones in the world. Train timetable rescheduling is a focal point to improve the operation mode with the characteristics of high train speed, high train frequency and mixed train speed (HHM), which is of great theoretical and practical significance for safety and efficiency operation of China high speed railway network.

In China, train rescheduling is mostly manual developed by the operator with the suport of computer in the existing line or the high speed railway, which is depends on human experience to dominate only one line or some section in one line with fixed three hours period. In future China will establish five comprehensive operation centers of the railway network, each of which will dominate several lines that total length over thousands of kilometers [2]. The scale of rescheduling object is far larger and the relationship between lines is far more complex than the existing situation, so the inefficient manually rescheduling, which seriously affect the use of the ability of high-speed rail and bring risk to railway safety, cannot support the advanced operation command mode.

Over the years, the research on the train operation automatic adjustment has been paid great attention and many different algorithms for optimal rescheduling have been put forward. The integer programming, such as branch and bound, linear programming and other traditional optimization method [3] are usually used for the simple transportation organization mode (only high speed or medium speed train running). In China, there are usually mixed high-speed and medium-speed trains running in one line, so there are great differences on the variable size, type of constraints and target values in the actual situation of the Chinese high-speed railway, and these methods cannot be directly applied to the train rescheduling problems in China.

Since the railway network is extensively developed and transportation organization mode is more complex in recent years, many heuristic methods of artificial intelligence, like DEDS-based simulation method [4], expert system [5], tabu search [6, 7], and some computational intelligence methods [8-14], like genetic algorithm, particle swarm optimization algorithm, are used to solve the large-scale combinatorial optimization problem by many scholars.

To some extent, these mathematical model and optimization algorithm have given a feasible solution for train operation automatic adjustment problem; actually there are many uncertainties of decision variables, parameters, constraints and goals for high speed railway timetable rescheduling optimization. For example, the running time at a section and the dwell time at a station of the train, which are typical uncertain variables, are easily impacted by railway and equipment status, technological level of crew and weather condition [15, 16]. So these methods that only consider the crisp parameters cannot adapt to the actual operation environment of high-speed railway under the great influence of uncertainty, and it can not achieve the purpose of automatic rescheduling, even play the role of decision support in practical applications. Therefore, the uncertainty character of high-speed

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

train operation automatic adjustment model should be considered in substance.

II. TIMETABLE RESCHEDULING PROBLEM

The aim of train rescheduling is to get a new timetable that adjustes the train movements to be consistent with the planned schedule as much as possible under some interference. The follow model focuses on minimizing the total delay as well as the number of seriously impacted trains.

A. Input Data

The numerical inputs are described as follows:

$inis_p$, $inie_p$: Initial start and end time of interval p according to original timetable.

z_p : The minimum size of interval p. If p is the possession of a station, d_p stands for the minimum dwell time of the train associated with p. Otherwise, it stands for the minimum running time of the train.

f_k : The minimum separation time of two intervals on station k, i.e. end time of an interval – start time of the subsequent interval.

hw_k : The headway of section k, i.e. start time of an interval – start time of the subsequent interval.

c_i^{delay} : The cost per time unit delay for train i.

w_i : Delay tolerance for train i.

W_i : Weight for objective i;

$$h_p = \begin{cases} 1, \ if \ \text{interval} \ p \ is \ a \ planned \ stop, \\ where \ p \in Itv \\ 0, otherwise \end{cases}$$

M : A very big integer, e.g. 100000.

TABLE I. SETS DEFINED FOR MODELING

Set Name	Description	Size	Index of set
Trn	All the trains.	T	i
Seg	All the segments.	S	k
$Stn \subseteq Seg$	All the stations.	N	--
$Sec \subseteq Seg$	All the sections.	S-N	--
Itv	All the intervals where an interval is the possession of a segment by a train with specified start and end time.	--	p
$Itv_i \subseteq Itv$	The ordered set of intervals for train i according to the original timetable.	--	--
$Itv_i^{stn} \subseteq Itv_i$	The ordered set of intervals associated with stopping at stations for trains i.	--	--
$Itv_k \subseteq Itv$	The ordered set of intervals for segment k according to the original timetable.	--	--
Trk_k	All the tracks of station k	L_k	l

Remarks: For the ease of understanding, we use p as the index for every interval-related set (i.e. Itv , Itv_i , Itv_i^{stn} and Itv_k). In each of the interval-related sets, p+1 indicates the first subsequent interval of p, and $\tilde{p}$ indicates all the subsequent intervals of p.

Some sets are defined in TABLE I for modeling. Note that the segment between two stations is called "section", while the station segment is called "station" for short.

B. Decision variables

s_p , e_p : Start time and end time of interval p.

d_p : Delay of interval p, which is defined as the difference between the departure time after adjustment and the planned departure time in the original timetable.

$$b_i = \begin{cases} 1, \ if \ train \ i \ reaches \ its \ final \ considered \ stop \\ with \ a \ delay \ larger \ than \ w_i, where \ i \in Trn \\ 0, otherwise \end{cases}$$

$$\eta_{pl} = \begin{cases} 1, \ if \ \text{interval} \ p \ uses \ track \ l, where \ p \in Itv_k, \\ l \in Trk_k \ and \ k \in Stn \\ 0, otherwise \end{cases}$$

$$\alpha_{p\tilde{p}} = \begin{cases} 1, \ if \ \text{interval} \ p \ occurs \ before \ \tilde{p} \ as \ in \ the \\ initial \ timetable, where \ p, \tilde{p} \in Itv_k, k \in Seg \\ 0, otherwise \end{cases}$$

$$\beta_{p\tilde{p}} = \begin{cases} 1, \ if \ \text{interval} \ p \ is \ changed \ to \ occur \ after \ \tilde{p}, \\ where \ p, \tilde{p} \in Itv_k, k \in Seg \\ 0, otherwise \end{cases}$$

C. Objective functions

i) To minimize the delay cost:

$$\text{Minimize} \sum_{i \in Trn} \left(c_i^{delay} \cdot \sum_{p \in Itv_i^{stn}} d_p \right) \quad (1)$$

ii) To minimize the number of trains exceeding delay tolerance:

$$\text{Minimize} \sum_{i \in Trn} b_i \quad (2)$$

$$S = W_1 \sum_{i \in Trn} \left(c_i^{delay} \cdot \sum_{p \in Itv_i^{stn}} d_p \right) + W_2 \sum_{i \in Trn} b_i \quad (3)$$

D. Constraints

i) Interval restrictions

$$e_p - s_p \geq z_p, \ p \in Itv \quad (4)$$

The real departure time cannot be earlier than the original departure time:

$$e_p \geq inie_p, \ p \in Itv \ \text{and} \ h_p = 1 \quad (5)$$

$$e_p - inie_p = d_p, \ p \in Itv \quad (6)$$

ii) Track restrictions

$$\sum_{l \in Trk_k} \eta_{pl} = 1,\ p \in Itv_k \text{ and } k \in Stn \tag{7}$$

iii) Connectivity restrictions

$$e_p = s_{p+1},\ p \in Itv_i,\ p \neq last(Itv_i) \text{ and } i \in Trn \tag{8}$$

For each station, if two intervals use the same track, at least one of α and β is forced to be 1:

$$\eta_{pl} + \eta_{\tilde{p}l} - 1 \leq \alpha_{p\tilde{p}} + \beta_{p\tilde{p}},\quad p, \tilde{p} \in Itv_k,\ p < \tilde{p},\ l \in Trk_k \text{ and } k \in Stn \tag{9}$$

One train can enter a station after the preceding train, which uses the same track, leaves it:

$$s_{\tilde{p}} - e_p \geq f_k \alpha_{p\tilde{p}} - M\left(1 - \alpha_{p\tilde{p}}\right),\quad p, \tilde{p} \in Itv_k \text{ and } k \in Stn \tag{10}$$

$$s_p - e_{\tilde{p}} \geq f_k \beta_{p\tilde{p}} - M\left(1 - \beta_{p\tilde{p}}\right),\quad p, \tilde{p} \in Itv_k \text{ and } k \in Stn \tag{11}$$

For each section, at least one of α and β is forced to be 1 because there is only one track:

$$\alpha_{p\tilde{p}} + \beta_{p\tilde{p}} = 1,\ p, \tilde{p} \in Itv_k \text{ and } k \in Sec \tag{12}$$

Headways for each section:

$$s_{\tilde{p}} - s_p \geq hw_k \alpha_{p\tilde{p}} - M\left(1 - \alpha_{p\tilde{p}}\right),\ p, \tilde{p} \in Itv_k \text{ and } k \in Sec \tag{13}$$

$$s_p - s_{\tilde{p}} \geq hw_k \beta_{p\tilde{p}} - M\left(1 - \beta_{p\tilde{p}}\right),\ p, \tilde{p} \in Itv_k \text{ and } k \in Sec \tag{14}$$

iv) Auxiliary restrictions

$$d_{last(Itv_i)} - w_i \leq Mb_i \tag{15}$$

In practice, some constraints of the model are not satisfied strictly because of the inexact operation time. Two kinds of constraints are changed as below:

i) Interval restrictions

z_p stands for the minimum running time or the minimum dwell time of the train associated with p. Both of them may be impacted by some weather and human factors. The running time of the train at a section is formed by pure running time at the section and addition time for departure and arrival at a station, which is easily impacted by railway and equipment status, technological level of crew and weather condition. Since the average running speed of the train usually changes within a certain range, especailly in speed restriction under some emergency, it is very important to find a safety and reasonable average speed that far below the limited speed to improve the optimization result greatly. Furthermore, many factors, like the train type, on and off time of passengers, preparation time for drivers and crew and station technology operation of the train may increase the uncertainty of the dwell time of the train at a station. So there should be a tolerance for z_p, and the constraint is changed as below:

$$g_1 = e_p - s_p \gtrsim z_p,\ p \in Itv \tag{16}$$

ii) Headway restrictions

The headway time for each station is decided by the number of receiving-departure track, the operation time of turnout and holding time of the track, which is also an uncertainty constraint due to the factors of equipment status and human technological level. So there should be a tolerance for f_k. The headway constraint for each station is changed as below:

$$g_2 = s_{\tilde{p}} - e_p \gtrsim f_k \alpha_{p\tilde{p}} - M\left(1 - \alpha_{p\tilde{p}}\right),\quad p, \tilde{p} \in Itv_k \text{ and } k \in Stn \tag{17}$$

$$g_3 = s_p - e_{\tilde{p}} \gtrsim f_k \beta_{p\tilde{p}} - M\left(1 - \beta_{p\tilde{p}}\right),\quad p, \tilde{p} \in Itv_k \text{ and } k \in Stn \tag{18}$$

The headway time for each section is decided by the number and length of the block between two tracking trains and the speeds of the trains, which ranges from 2.4 minutes to 3 minutes according to [17]. The headway constraint for each section is changed as below:

$$g_4 = s_{\tilde{p}} - s_p \gtrsim hw_k \alpha_{p\tilde{p}} - M\left(1 - \alpha_{p\tilde{p}}\right),\ p, \tilde{p} \in Itv_k \text{ and } k \in Sec \tag{19}$$

$$g_5 = s_p - s_{\tilde{p}} \gtrsim hw_k \beta_{p\tilde{p}} - M\left(1 - \beta_{p\tilde{p}}\right),\ p, \tilde{p} \in Itv_k \text{ and } k \in Sec \tag{20}$$

For this condition, the model above turns meaningless in the sense of mathematical viewpoints. To construct a reasonable mathematical model under the uncertain environment, the tolerance approach based timetable rescheduling model will be introduced in the next section.

III. FUZZY OPTIMIZATION MODEL BASED TIMETABLE RESCHEDULING

In the paper, we use the fuzzy optimization based tolerance approach to solve the uncertainty program, some necessary backgrounds and notions of the approach are reviewed.

A. Fuzzy optimization based tolerance approach

Tolerances are indicated in any technical process, that is the admissible limit of variation around the object value and the deviations allowed from the specified parameters.

A general model of a fuzzy linear programming problem (FLP-programming) is presented by the following system.

$$\text{Minimize } \tilde{C}_1 x_1 \oplus \tilde{C}_2 x_2 \oplus \cdots \oplus \tilde{C}_n x_n \tag{21}$$

$$\text{Subject to } \tilde{A}_{i,1} x_1 \oplus \tilde{A}_{i,2} x_2 \oplus \cdots \oplus \tilde{A}_{i,n} x_n \gtrsim \tilde{B}_i,\quad i = 1, \cdots m \tag{22}$$

$\tilde{A}_{i,j}, \tilde{B}_i, \tilde{C}_j$ ($i = 1, \cdots, m$; $j = 1, \cdots, n$) are fuzzy set in R. The symbol $\oplus$ represents the extended addition. Each real number a can be modeled as a fuzzy number.

$$\tilde{A} = \{(x, f_A(x)); x \in R\}$$
$$with \quad f_A(x) = \begin{cases} 1 & x = a \\ 0 & x \neq a \end{cases} \tag{23}$$

Here we only discuss the special case where the objective function is crisp and some constraints have the soft form and the rest constrains are crisp.

$$\text{Minimize } z(x) = c_1 x_1 + c_2 x_2 + \cdots + c_n x_n \tag{24}$$

Subject to

$$g_i(x) = a_{i,1}x_1 + a_{i,2}x_2 + \cdots + a_{i,n}x_n \gtrsim \tilde{B}_i, \quad i = 1, \cdots, m_1 \tag{25}$$

$$a_{i,1}x_1 + a_{i,2}x_2 + \cdots + a_{i,n}x_n \geq b_i, \quad i = m_1 + 1, \cdots, m \tag{26}$$

$$x_1, \cdots, x_n \geq 0$$

The m_1 soft constraints (25) may be described more precisely by the fuzzy set with the support $[b_i - d_i, b_i]$, and d_i is the tolerance according to b_i. Moreover the membership function $g_i(x)$ can be specified as the follow function.

$$\mu(g_i) = \begin{cases} 0, & g_i \leq b_i - d_i \\ \dfrac{g_i - (b_i - d_i)}{d_i}, & b_i - d_i < g_i \leq b_i, \\ i = 1, \cdots, m_1 & \\ 1, & b_i \leq g_i \end{cases} \tag{27}$$

Directly assigns a measure of the satisfaction of the i-th constraint to the solution $X = (x_1, x_2, \cdots x_n)$.

For the objective function $z(x)$, there is a fuzzy set $\tilde{Z} = \{(z, \mu_Z(z)) \mid z \in R\}$ Let

$$X_L = \{x \in R \mid a_{i1}x_1 + a_{i2}x_2 + \cdots a_{in}x_n \geq b_i - d_i, \forall i = 1, 2, \cdots, m_1 \quad and \quad a_{i1}x_1 + a_{i2}x_2 + \cdots a_{in}x_n \geq b_i, \forall i = m_1 + 1, \cdots m\} \tag{28}$$

$$X_U = \{x \in R \mid a_{i1}x_1 + a_{i2}x_2 + \cdots a_{in}x_n \geq b_i, \forall i = 1, 2, \cdots, m\} \tag{29}$$

$$\overline{z} = \underset{x \in X_U}{Min}\, z(x) \tag{30}$$

and

$$\underline{z} = \underset{x \in X_L}{Min}\, z(x) \tag{31}$$

So the membership function $\mu_Z(z)$ of $\tilde{Z}$ is given by

$$\mu_z(z) = \begin{cases} 0, & \overline{z} \leq z \\ 1 - \dfrac{z - \underline{z}}{\overline{z} - \underline{z}}, & \underline{z} < z \leq \overline{z} \\ 1, & z \leq \underline{z} \end{cases} \tag{32}$$

In order to determine a compromise solution, it is usually assumed in the literature that the total satisfaction of a decision maker may be described by

$$\lambda(x) = \min(\mu_Z(x), \mu_1(x), \cdots \mu_{m_1}(x)) \tag{33}$$

We treat the objective in the same manner as the soft constraints, so this is a symmetric model.

The optimization system is clearly equivalent to

$$\text{Maximize } \lambda \tag{34}$$

$$\text{Subject to } \mu_Z(x) \geq \lambda \tag{35}$$

$$\mu_i(x) \geq \lambda, \quad i = 1, \cdots m_1 \tag{36}$$

$$x \in X, \ \lambda \in [0,1]$$

Using linear membership functions or piecewise linear, concave membership function, the system can easily be solved by well-known algorithms.

B. Fuzzy optimization model based tolerance approach to timetable rescheduling

In the rescheduling model mentioned above, three additional inputs are involved to describe the tolerances of minimum running time or dwell time, headway time for section and station respectively. An additional decision variable λ is involved to describe the fuzzy number for the objective and constraints. All the additional parameters are list as below:

c_{z_p} : Tolerance of z_p

c_{f_k} : Tolerance of f_k

c_{hw_k} : Tolerance of hw_k

λ : Decision variable for the fuzzy number

s^0 : The objective value of the original model according to z_p, f_k, hw_k.

s^* : The objective value of the original model according to $z_p - c_{z_p}$, $f_k - c_{f_k}$, $hw_k - c_{hw_k}$.

So fuzzy membership function of objective is given by

$$\mu_0 = \begin{cases} 1, & S < s^* \\ 1 - \dfrac{S - s^*}{s^0 - s^*}, & s^* \leq S \leq s^0 \\ 0, & S > s^0 \end{cases} \tag{37}$$

Fig. 1 shows the objective fuzzy membership function.

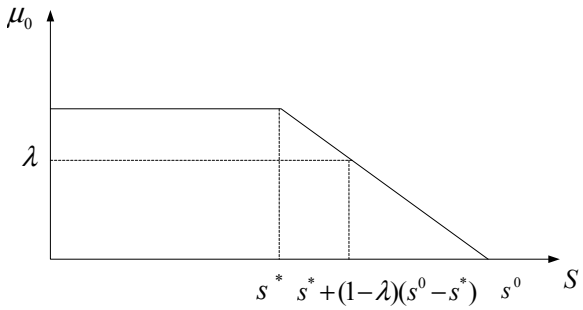

Figure 1. The objective fuzzy membership functione

Fuzzy membership function of run time constraint is given by

$$\mu_1=\begin{cases}1, & g_1>z_p\\ 1-\dfrac{z_p-g_1}{c_{z_p}}, & z_p-c_{z_p}\le g_1\le z_p\\ 0, & g_1<z_p-c_{z_p}\end{cases} \tag{38}$$

Fig. 2 shows the fuzzy membership function of run time constraint.

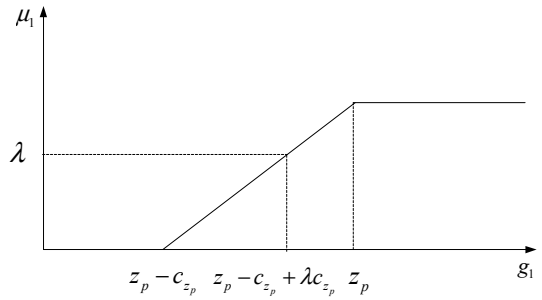

Figure 2. The run time constraint fuzzy membership function

Fuzzy membership functions of headway time constraints and their graphics are similar to figure 2.

$$\mu_2=\begin{cases}1, & g_2>f_k\\ 1-\dfrac{f_k-g_2}{c_{f_k}}, & f_k-c_{f_k}\le g_2\le f_k\\ 0, & g_2<f_k-c_{f_k}\end{cases} \tag{39}$$

$$\mu_3=\begin{cases}1, & g_3>f_k\\ 1-\dfrac{f_k-g_3}{c_{f_k}}, & f_k-c_{f_k}\le g_3\le f_k\\ 0, & g_3<f_k-c_{f_k}\end{cases} \tag{40}$$

$$\mu_4=\begin{cases}1, & g_4>hw_k\\ 1-\dfrac{hw_k-g_4}{c_{hw_k}}, & hw_k-c_{hw_k}\le g_4\le hw_k\\ 0, & g_4<hw_k-c_{hw_k}\end{cases} \tag{41}$$

$$\mu_5=\begin{cases}1, & g_5>hw_k\\ 1-\dfrac{hw_k-g_5}{c_{hw_k}}, & hw_k-c_{hw_k}\le g_5\le hw_k\\ 0, & g_5<hw_k-c_{hw_k}\end{cases} \tag{42}$$

So the model is changed as follow:

C. Objective functions

i) To maximize the fuzzy number:

Maximize λ (43)

D. Constraints

i) Objective restrictions

$$W_1\sum_{i\in Trn}\left(c_i^{delay}\cdot\sum_{p\in Itv_i^{stn}}d_p\right)+W_2\sum_{i\in Trn}b_i \le s^*+(1-\lambda)(s^0-s^*) \tag{44}$$

ii) Interval restrictions

$$e_p-s_p\ge z_p+(\lambda-1)c_{z_p},\ p\in Itv \tag{45}$$

The real departure time cannot be earlier than the original departure time:

$$e_p\ge inie_p,\ p\in Itv \text{ and } h_p=1 \tag{46}$$

$$e_p-inie_p=d_p,\ p\in Itv \tag{47}$$

iii) Track restrictions

$$\sum_{l\in Trk_k}\eta_{pl}=1,\ p\in Itv_k \text{ and } k\in Stn \tag{48}$$

iv) Connectivity restrictions

$$e_p=s_{p+1},\ p\in Itv_i,\ p\ne last(Itv_i) \text{ and } i\in Trn \tag{49}$$

For each station, if two intervals use the same track, at least one of α and β is forced to be 1:

$$\eta_{pl}+\eta_{\tilde{p}l}-1\le\alpha_{p\tilde{p}}+\beta_{p\tilde{p}},\quad p,\tilde{p}\in Itv_k,\ p<\tilde{p},\ l\in Trk_k \text{ and } k\in Stn \tag{50}$$

One train can enter a station after the preceding train, which uses the same track, leaves it:

$$s_{\tilde{p}}-e_p\ge(f_k+(\lambda-1)c_{f_k})\alpha_{p\tilde{p}}-M\left(1-\alpha_{p\tilde{p}}\right),\quad p,\tilde{p}\in Itv_k \text{ and } k\in Stn \tag{51}$$

$$s_p-e_{\tilde{p}}\ge(f_k+(\lambda-1)c_{f_k})\beta_{p\tilde{p}}-M\left(1-\beta_{p\tilde{p}}\right),\quad p,\tilde{p}\in Itv_k \text{ and } k\in Stn \tag{52}$$

For each section, at least one of α and β is forced to be 1 because there is only one track:

$$\alpha_{p\tilde{p}} + \beta_{p\tilde{p}} = 1,\ p, \tilde{p} \in Itv_k \text{ and } k \in Sec \quad (53)$$

Headways for each section:

$$s_{\tilde{p}} - s_p \geq (hw_k + (\lambda - 1)c_{hw_k})\alpha_{p\tilde{p}} - M\left(1 - \alpha_{p\tilde{p}}\right),$$
$$p, \tilde{p} \in Itv_k \text{ and } k \in Sec \quad (54)$$

$$s_p - s_{\tilde{p}} \geq (hw_k + (\lambda - 1)c_{hw_k})\beta_{p\tilde{p}} - M\left(1 - \beta_{p\tilde{p}}\right),$$
$$p, \tilde{p} \in Itv_k \text{ and } k \in Sec \quad (55)$$

v) Auxiliary restrictions

$$d_{last(Itv_i)} - w_i \leq Mb_i \quad (56)$$

Since M is a very integer, the headway time constraints can be changed as below:

$$s_{\tilde{p}} - e_p \geq f_k + (\lambda - 1)c_{f_k} - M\left(1 - \alpha_{p\tilde{p}}\right) \quad (57)$$

$$s_p - e_{\tilde{p}} \geq f_k + (\lambda - 1)c_{f_k} - M\left(1 - \beta_{p\tilde{p}}\right) \quad (58)$$

$$s_{\tilde{p}} - s_p \geq hw_k + (\lambda - 1)c_{hw_k} - M\left(1 - \alpha_{p\tilde{p}}\right) \quad (59)$$

$$s_p - s_{\tilde{p}} \geq hw_k + (\lambda - 1)c_{hw_k} - M\left(1 - \beta_{p\tilde{p}}\right) \quad (60)$$

IV. CASE STUDY

This model is simulated on the busiest part of Jing-Hu high speed line, between Nanjing (Ning for short) and Shanghai (Hu for short). In the rest of this paper, "Hu-Ning Part" is used to represent this part of the Jing-Hu high speed line. Since Jing-Hu high speed line is double-track, we only consider the direction from Ning to Hu without loss of generality. All the models are solved by IBM ILOG CPLEX 12.2.

There are seven stations on the Hu-Ning Part, thereby 6 sections, whose lengths are 65110m, 61050m, 56400m, 26810m, 31350m and 43570m. Its daily service starts at 6:30am and ends at 11:30pm. As currently planned, there are 52 trains (14 high speed trains and 38 medium speed trains) from Jing-Hu line and 8 medium speed trains from Riverside line that go from Ning to Hu by the Hu-Ning part. The trains from Jing-Hu line are called self-line trains, while those from Riverside line are called cross-line trains. As in reality, self-line trains have higher priority than cross-line trains. As for self-line trains, the high speed trains have higher priority than the quasi-high speed trains. We did two studies as follows.

A. speed restriction in all section

When some natural hazards happened, like heavy storm and strong wind, railway will be greatly affected in a large area. In the simulation, we assume there is a speed restriction in all sections and the average limited speed ranges from 170km/h to 150km/h; the headway is set from 3 minutes to 2.5 minutes and the minimum separation time on track possession in each station is set to 1min.

First we use the original model to solve the problem, and get the follow results. When we set the speed as 150km/h and headway time as 3 minutes, the solution value is 2580587; there are 54 trains late for 30 minutes and 6 trains late for one hour; and the total delay time is 3052.95 minutes. When the speed is 170km/h and headway time is 2.5 minutes, the Solution value is 1481413; there are 55 trains late for 30 minutes and no train late for one hour; and the total delay time is 2248.45 minutes. Although the latter result is very exciting, it is a significant risk to take the speed of 170km/h, as the highest speed must brings the high operation cost and may arouse some new delays. Then we using the above results as the inputs of the fuzzy model the paper described before and get the follow results. The fuzzy member λ is 0.689117, which means the average speed is 156km/h and headway time is 2.8445 minutes; there are 60 trains late for 30 minutes, no train late for one hour; and the total delay time is 2799.4 minutes. We can see that the fuzzy optimization result improved greatly with little slack of constraints that means little risk and operation cost. Fig. 3 is the rescheduling timetable by fuzzy model. The gray lines mean the initial timetable and blue lines mean the rescheduling timetable.

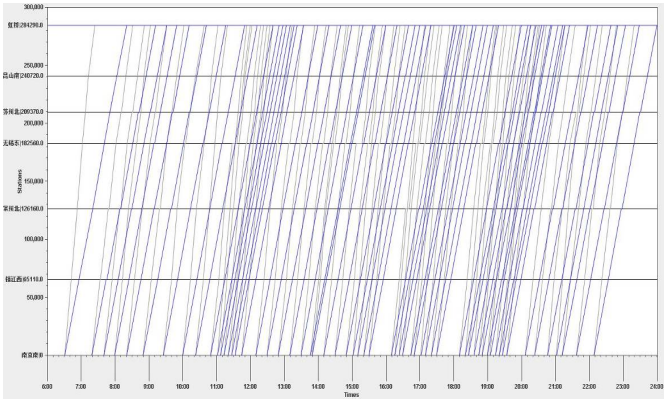

Figure 3. Rescheduling timetable with limited speed in all sections

B. speed restriction in one section

Sometimes equipment failure, like train signal failure, happens in some but not all the sections. In the simulation, we assume there is a speed restriction in first section and the limited speed ranges from 60km/h to 50km/h; the headway is also set from 3 minutes to 2.5 minutes; and the minimum separation time on track possession in each station is 1min.

First we use the original model to solve the problem and get the follow result. When the speed is 50km/h and headway time is 3 minutes, the solution value is 4040593; there are 52 trains late for 30 minutes and 8 trains late for one hour, and the total delay time is 3109.95 minutes. When the speed is 60km/h and headway time is 2.5 minutes, the solution value is 2518709; there are 56 trains late for 30 minutes and no train late for one hour, and the total delay time is 2328.45 minutes. Then we get the follow result using the fuzzy model the paper described before. The fuzzy member λ is 0.70606, which means the average speed is 53km/h and headway time is 2.85303 minutes; there are 60 trains late for 30 minutes, no train late for one hour, the total delay time is 2766.4 minutes. We can see that the optimization result also improved greatly with little slack of constraints. Fig. 4 is the rescheduling timetable with speed restriction in the first section.

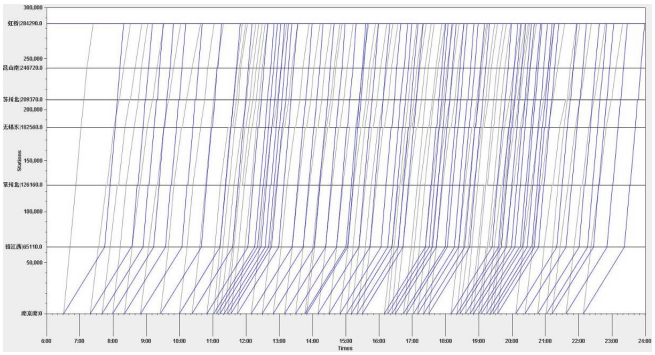

Figure 4. Rescheduling timetable with speed restriction in first section

These simulations are realized on the computer with Intel Core 2 Duo CPU E7500 and 2G Memory. Calculation time for the original model is about 4 seconds and it is less than 20 seconds for the fuzzy model.

V. CONCLUSION AND FUTURE WORK

This paper presents a fuzzy optimization model based tolerance approach for train rescheduling in speed restriction, which deal with the train running time at sections, train dwell time at stations, the headway time at sections and station as the fuzzy parameters. The simulation on Jing-Hu high speed line reveals that the fuzzy optimization result improved greatly with little slack of constraints, which means we can get a new timetable with fewer total delay time as well as the number of seriously impacted trains in safety and lower limited speed and enough headway time .

There remain many interesting areas to explore around membership functions of fuzzy parameters, which may be piecewise linear or more complex form in practice. In addition, there are also some stochastic factors in the timetable rescheduling problem. The more accurate the membership function is, the better result the uncertain optimization model gets. Our ultimate goal is to develop a real-time rescheduling system to significantly improve operation management and scheduling efficiency in the future.

***Abstract*—On-line first-order backpropagation (BP) has been widely employed for optimizing a multi-layer neural network and a fuzzy neural network. When BP is applied to a TSK fuzzy system, the interpretability of fuzzy rules may be lost. We describe a simple and effective remedy for the loss by casting the posed optimization problem into a general Bolza-type optimal-control mold so as to include stage costs on top of the terminal cost; this is what we called the (on-line) hidden-node teaching. Our on-line learning scheme turns out to be useful not only in optimizing a large model, a so-called CANFIS neuro-fuzzy modular network, but also in enhancing its generalization capacity. The fundamental concept is that each (local) expert network is supervised individually by hidden-node teaching for minimizing a stage cost while all local-expert modules are encouraged to cooperate in reducing the terminal cost simultaneously. Furthermore, we show how to construct a CANFIS modular network in order to alleviate the so-called curse of dimensionality that frequently hampers the design of fuzzy systems. In simulation, our concepts have been demonstrated in the letter recognition benchmark problem as well as in small regression and XOR-classification tasks.**

Keywords–CANFIS modular networks; hidden-node teaching.

I. Introduction

Consider a typical single-output fuzzy model with a given set of M fuzzy "if-then" rules; its final output y may be produced as

$$y = \sum_{p=1}^{M} w_p h_p, \tag{1}$$

where h_p, each of *then*-part outputs, is weighted by w_p, the firing strength of rule p, which is determined by *if*-part of fuzzy membership functions (MFs). When each h_p is expressed as a *linear* system, as shown next, the preceding fuzzy model is a well-known TSK (Takagi-Sugeno-Kang) fuzzy system:

$$h_p = \theta_{0,p} + \sum_{i=1}^{S} x_i \theta_{i,p}, \tag{2}$$

where S is the dimension of the input vector $\mathbf{x}$, and $\theta_{i,p}$ (with bias $\theta_{0,p}$) are the linear parameters. Since TSK was developed in 1980s [22], [21], it has enjoyed great popularity in diverse contexts, probably due to its simple linear then-part structure.

Our motivating example is a simple data fitting (regression) task described for Fig.1 on p.118 in [22], a task described for the original Takagi-Sugeno fuzzy system. In our interpretation, linear then-parts are given as h_p in the form of Equation (2), where $p = 1, 2$, for the following two fuzzy rules: (Rule 1) if input x is "small," then use linear h_1, and (Rule 2) if input x is "large," then use linear h_2. Those two fuzzy rules cooperate in producing final responses; this is what we call *complementary learning*. When we attack the posed regression task in conjunction with the "standard" on-line first-order backpropagation (BP), a problem often arises that h_p, the *then*-part of Rule p, may deviate from the data distribution beyond our expectation (hence, the loss of interpretability); Figure 1 shows such a situation. In the original Takagi-Sugeno fuzzy system [22], given *if*-part MF setups, RLSE (recursive least-squares estimation), implemented by the well-known Sherman-Morrison inverse formula, is applied in "batch" mode to optimizing *then*-part *linear* parameters. (The same method is used in ANFIS hybrid-learning.) Such a batch-mode RLSE-based approach may yield more interpretable then-part results than on-line first-order BP, but its batch-mode use of the Sherman-Morrison formula is not recommendable (see [8], [7]). More important, direct RLSE is not applicable to "nonlinear" then-part that can overcome the so-called curse of dimensionality when S, the dimension of inputs, is large. Later in Sec.III-B, we demonstrate our approach to the letter recognition benchmark problem ($S = 16$).

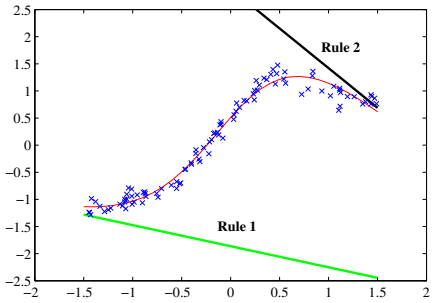

Fig. 1. An after-learning result obtained by "standard" on-line first-order BP on a TSK fuzzy system with two rules in a regression task that involves 100 data (marked by "×"), adapted from p.118 in [22]. The *then*-part linear rule's output deviates significantly from the data distribution in an unexpected manner.

In what follows, we describe a Bolza-type optimal-control formulation that can resolve the preceding problem indicated in Figure 1. We then discuss how to mitigate the curse of dimensionality, which becomes a serious obstacle in the design of fuzzy systems when the number of inputs increases. Throughout this paper, we highlight CANFIS (Co-Active Neuro-Fuzzy Inference System) [5], for its systematic design methodology offers a useful and consistent framework for describing representative adaptive-network models; such as

an aforementioned TSK, MLP (multilayer perceptron), RBFN (radial basis function network), and modular networks. In all numerical tests that follow, the bell-shaped Gaussian MF is used for the if-part of each fuzzy rule, and its center and width parameters are fine-tuned during the learning phase.

II. On-line CANFIS hidden-node learning

The first-order backpropagation (BP) is a simplified form of the Kelley-Bryson optimal-control gradient procedure (see [6] and references therein); it is originally contrived to attack a general Bolza-type optimal-control problem. We explain how such a general problem formulation inspires an elaborate neuro-fuzzy learning algorithm.

A. The Bolza-type optimal-control formulation

We describe an N-stage (discrete-time) optimal-control problem of Bolza in the framework of N-layer MLP-learning, where stage s (i.e., layer s) has P_s states (or nodes), and stage 1 corresponds to the first (nominal) input layer. The objective function J below includes an intermediate *stage cost* L^s at the hidden layer s as well as the *terminal cost* E at layer N (last stage):

$$J(\boldsymbol{\theta}) = \sum_{s=2}^{N-1} L^s(\mathbf{y}^s, \boldsymbol{\theta}^s) + E(\mathbf{y}^N), \quad (\text{with } \mathbf{y}^1 \text{ given}) \tag{3}$$

where $E(.)$, the terminal cost at stage N, depends only on terminal *state* vector $\mathbf{y}^N$ of length P_N (per datum), and $L^s(.,.)$, the cost at stage s, depends on both the P_s-dimensional *state* vector $\mathbf{y}^s$ of "after-node" outputs and the n_s-dimensional *control* vector $\boldsymbol{\theta}^s$ of weight parameters (including thresholds); hence, the length $n_s \equiv (1+P_s)P_{s+1}$ in MLP-learning. Equation (3) may consist of squared residuals on each (training) datum d (for $d=1,...,D$) at each stage s, where each residual vector $\mathbf{r}_d^s$ (of length P_s) is evaluated as the difference between the node-output vector $\mathbf{y}_d^s$ and the target vector $\mathbf{t}_d^s$. In fact, it is often the case that the terminal cost is defined as the squared-error measure below:

$$\begin{aligned} E(\mathbf{y}^N) &= \frac{1}{2}\sum_{d=1}^{D}\sum_{k=1}^{P_N}(y_{k,d}^N - t_{k,d}^N)^2 \\ &= \frac{1}{2}\sum_{d=1}^{D}\|\mathbf{y}_d^N - \mathbf{t}_d^N\|_2^2 = \frac{1}{2}\sum_{d=1}^{D}\mathbf{r}_d^{N\top}\mathbf{r}_d^N. \end{aligned} \tag{4}$$

Likewise, the stage cost $L^s(.,.)$ $(1<s<N)$ can be defined as

$$\begin{aligned} L^s(\mathbf{y}^s, \boldsymbol{\theta}^s) &= \frac{1}{2}\sum_{d=1}^{D}\sum_{k=1}^{P_s}(y_{k,d}^s - t_{k,d}^s)^2 + \frac{1}{2}\sum_{j=1}^{n_s}\left(\theta_j^s\right)^2 \\ &= \frac{1}{2}\sum_{d=1}^{D}\mathbf{r}_d^{s\top}\mathbf{r}_d^s + \frac{1}{2}\boldsymbol{\theta}^{s\top}\boldsymbol{\theta}^s, \end{aligned} \tag{5}$$

where the last quantity is a so-called weight-decay term for penalizing large weights in modulus, and $\mathbf{r}_d^s$ is the P_s-length vector of hidden residuals on datum d evaluated at intermediate layer s $(1 < s < N)$. The introduction of such a stage

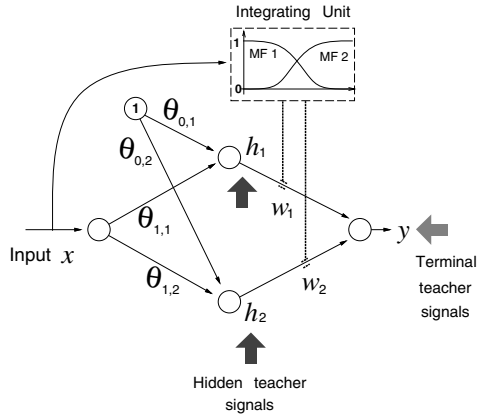

Fig. 2. A 1-2-1 MLP representation of CANFIS with two linear rules, in which two terminal weights, w_1 and w_2, are the firing strengths of corresponding two rules, Rule 1 and Rule 2, respectively, obtainable from the fuzzy membership functions. The posed network is equivalent to a TSK fuzzy system (see p.377 [5]). For hidden-node teaching, teacher signals are presented to the hidden layer as well as to the terminal output layer. In this model, each of two local-expert is a linear perceptron; expanding each of them to an MLP leads to a CANFIS modular network (see Figure 4).

cost $L^s(.,.)$ at intermediate stages (i.e., at *hidden layers*; $1<s<N$) is what we call *hidden-node teaching* [6], [9], [13]. For MLP-type node dynamics at layer s, $\mathbf{y}^s \equiv \mathbf{f}(\mathbf{x}^s, \boldsymbol{\theta}^s)$, we define two types of *node sensitivities*: (1) after-node sensitivity: $\boldsymbol{\xi}^s \equiv \frac{\partial J}{\partial \mathbf{y}^s}$ and (2) before-node sensitivity: $\boldsymbol{\delta}^s \equiv \frac{\partial J}{\partial \mathbf{x}^s}$; the former is used (as state sensitivity) in optimal control, whereas the latter is well-known for a generalized delta rule in the neural-network literature (e.g., see [6], [13]). Then, the Kelley-Bryson optimal-control gradient formula (on datum d with subscript d suppressed) is given by

$$\underbrace{\boldsymbol{\xi}^s}_{P_s\times 1} = \boldsymbol{\Theta}_{\text{void}}^{s^T}\boldsymbol{\delta}^{s+1} + (\mathbf{y}^s - \mathbf{t}^s), \tag{6}$$

where $\boldsymbol{\Theta}_{\text{void}}^s$ denotes a $P_{s+1}\times P_s$ matrix of parameters at stage s excluding "threshold" parameters (if any at stage s). By the above formula, the node sensitivities are propagated backwards in a layer-by-layer (i.e., stagewise) fashion.

B. CANFIS with linear rules
