where equalities (2), (3), and (4) follow from axioms ax_1, ax_2, and ax_3, respectively. Additionally, ax_3 implies that $Y_1^{\mathcal{I}}(\delta) \neq 1$ since otherwise $Y_1^{\mathcal{I}}(\delta)$ must also be 0. It then holds that

$$C^{\mathcal{I}}(\delta) + D^{\mathcal{I}}(\delta) = S^{\mathcal{I}}(\delta).$$

We can thus introduce the concept constructor $\boxplus$ to denote this addition without extending the expressivity of the logic. Notice however that the TBox having the axioms ax_1 to ax_3 is only satisfiable by models where $C^{\mathcal{I}}(\delta) + D^{\mathcal{I}}(\delta) \leq 1$ for all $\delta \in \Delta^{\mathcal{I}}$. One must keep this in mind when using this constructor to avoid making the ontology inconsistent. Given $C^{\mathcal{I}}(\delta)$ and $D^{\mathcal{I}}(\delta)$, there is exactly one value for $X_1^{\mathcal{I}}(\delta)$ and $Y_1^{\mathcal{I}}(\delta)$ that will satisfy the three axioms above. Then, describing the valuation of the concepts C and D suffices for knowing also the valuation of the auxiliar concepts X_1, Y_1.

Notation. *Let* C, D *be two concepts, then* $C \boxplus D$ *is also a concept, with the semantics* $(C \boxplus D)^{\mathcal{I}}(\delta) = C^{\mathcal{I}}(\delta) + D^{\mathcal{I}}(\delta)$.

Let $\mathcal{P} = (v_1, \ldots, v_m, w_1, \ldots, w_m)$ be an instance of the PCP. We will construct an ontology $\mathcal{O}_{\mathcal{P}}$ whose models represent a search tree for a solution for $\mathcal{P}$. More precisely, every model of $\mathcal{O}_{\mathcal{P}}$ will contain one node δ for each possible sequence of indices $i_1, \ldots, i_k$, such that the interpretations of two concept names A and B in δ encode the words $v_{i_1} \cdots v_{i_k}$ and $w_{i_1} \cdots w_{i_k}$, respectively. Then $\mathcal{P}$ has a solution iff for every model $\mathcal{I}$ of $\mathcal{O}_{\mathcal{P}}$ there is a δ such that $A^{\mathcal{I}}(\delta)$ and $B^{\mathcal{I}}(\delta)$ encode the same word.

Let $\Sigma = \{1, \ldots, s\}$ be the alphabet over which $\mathcal{P}$ is defined. We will encode words in Σ^* using numbers from the interval $[0, 1]$ in base $s+1$. For technical reasons that will become

clear later, the concepts A and B will encode words in a slightly different way. For every sequence of indices $i_1, \dots, i_k$, there will be a node δ such that $A^{\mathcal{I}}(\delta) = 0.1v_{i_1} \cdots v_{i_k}$ and $B^{\mathcal{I}}(\delta) = 0.0w_{i_1} \cdots w_{i_k}$ (see Figure 1).

If there is a node δ encoding the words v and w, then we want to ensure the existence of a node γ that encodes their concatenation with the i-th pair; i.e., vv_i and ww_i. To do this, we define, for every $i, 1 \leq i \leq m$, the TBox $\mathcal{T}^i_{\mathcal{P}}$ as follows:

$$\begin{aligned}\mathcal{T}^i_{\mathcal{P}} :=& \{\langle \exists r_i.\top = 1\rangle, \langle V_i = 0.0v_i\rangle, \langle W_i = 0.0w_i\rangle, \\ & \left\langle L_{v_i} = (s+1)^{-|v_i|}\right\rangle, \left\langle L_{w_i} = (s+1)^{-|w_i|}\right\rangle, \\ & \left\langle A \boxplus (V_i \sqcap L_A) \overset{r_i}{\rightsquigarrow} A\right\rangle, \left\langle L_A \sqcap L_{v_i} \overset{r_i}{\rightsquigarrow} L_A\right\rangle, \qquad (5) \\ & \left\langle B \boxplus (W_i \sqcap L_B) \overset{r_i}{\rightsquigarrow} B\right\rangle, \left\langle L_B \sqcap L_{w_i} \overset{r_i}{\rightsquigarrow} L_B\right\rangle\}. \qquad (6)\end{aligned}$$

Let $\mathcal{I}$ be a witnessed model of $\mathcal{T}^i_{\mathcal{P}}$ and $\delta \in \Delta^{\mathcal{I}}$ such that $A^{\mathcal{I}}(\delta) = 0.1v$ and $B^{\mathcal{I}}(\delta) = 0.0w$ for some words $v, w \in \Sigma^*$. Assume additionally that $L^{\mathcal{I}}_A(\delta) = (s+1)^{-|v|}$ and $L^{\mathcal{I}}_B(\delta) = (s+1)^{-|w|}$; that is, L_A, L_B yield information about the length of the words encoded by A and B in δ. From the first axiom we know that $(\exists r_i.\top)^{\mathcal{I}}(\delta) = 1$, and since $\mathcal{I}$ is witnessed, there must exist $\gamma \in \Delta^{\mathcal{I}}$ such that $r^{\mathcal{I}}_i(\delta, \gamma) = 1$. The axioms in line (5) ensure that

$$\begin{aligned}A^{\mathcal{I}}(\gamma) &= (A \boxplus (V_i \sqcap L_A))^{\mathcal{I}}(\delta) \\ &= A^{\mathcal{I}}(\delta) + (V_i^{\mathcal{I}}(\delta) \cdot L^{\mathcal{I}}_A(\delta)) \\ &= 0.1v + (0.0v_i \cdot (s+1)^{-|v|}) = 0.1vv_i \\ L^{\mathcal{I}}_A(\gamma) &= (L_A \sqcap L_{v_i})^{\mathcal{I}}(\delta) \\ &= (s+1)^{-|v|} \cdot (s+1)^{-|v_i|} = (s+1)^{-|vv_i|}\end{aligned}$$

and the axioms in (6) analogously entail

$$\begin{aligned}B^{\mathcal{I}}(\gamma) &= 0.0ww_i \\ L^{\mathcal{I}}_B(\gamma) &= (s+1)^{-|ww_i|}.\end{aligned}$$

Thus, the interpretation of A, B at node γ encodes the words vv_i, ww_i, and the concepts L_A, L_B yield information on the lengths of these words.

As we have seen, we can use the TBox $\mathcal{T}^i_{\mathcal{P}}$ to ensure that the concatenation of some words with the i-th pair of $\mathcal{P}$ will be encoded in every model. The following ABox $\mathcal{A}_{\mathcal{P}}$ introduces the root of the search tree, where A and B both encode the empty word, which obviously has lenght 0.

$$\begin{aligned}\mathcal{A}_{\mathcal{P}} := \{ &\langle a : A = 0.1\rangle, \langle a : B = 0\rangle, \\ &\langle a : L_A = 1\rangle, \langle a : L_B = 1\rangle\}\end{aligned}$$

Notice that every finite sequence of indices $i_1, \dots, i_k$, with $1 \leq i_j \leq m$ can be seen as a word $\nu \in \{1, \dots, m\}^*$. For a word $\nu = i_1 i_2 \cdots i_k \in \{1, \dots, m\}^*$, let v_ν and w_ν represent the words $v_{i_1} \cdots v_{i_k}, w_{i_1} \cdots w_{i_k} \in \{1, \dots, s\}^*$, respectively. We define the tree-like interpretation $\mathcal{I}_{\mathcal{P}} := (\Delta^{\mathcal{I}_{\mathcal{P}}}, \cdot^{\mathcal{I}_{\mathcal{P}}})$, where

- $\Delta^{\mathcal{I}_{\mathcal{P}}} = \{1, \dots, m\}^*$,
- $a^{\mathcal{I}_{\mathcal{P}}} = \varepsilon$,
- $A^{\mathcal{I}_{\mathcal{P}}}(\nu) = 0.1v_\nu$, $B^{\mathcal{I}_{\mathcal{P}}}(\nu) = 0.0w_\nu$,
- $L^{\mathcal{I}_{\mathcal{P}}}_A(\nu) = (s+1)^{-|v_\nu|}$, $L^{\mathcal{I}_{\mathcal{P}}}_B(\nu) = (s+1)^{-|w_\nu|}$, and

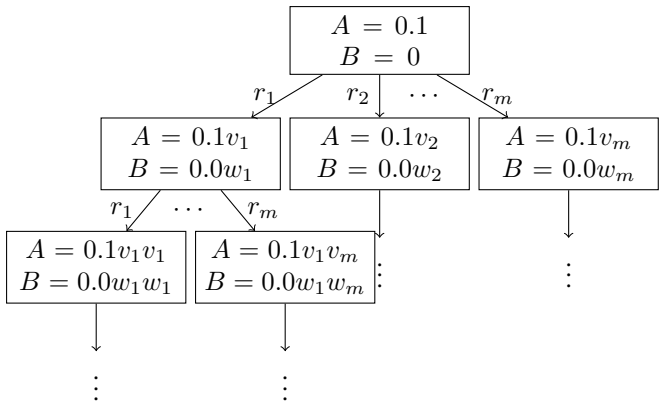

Fig. 1. The tree-shaped interpretation $\mathcal{I}_{\mathcal{P}}$.

for all $i, 1 \leq i \leq m$

- $r^{\mathcal{I}_{\mathcal{P}}}_i(\nu, \nu i) = 1$ and $r^{\mathcal{I}_{\mathcal{P}}}_i(\nu, \nu') = 0$ if $\nu' \neq \nu i$,
- $V^{\mathcal{I}_{\mathcal{P}}}_i(\nu) = 0.0v_i$, $W^{\mathcal{I}_{\mathcal{P}}}_i(\nu) = 0.0w_i$, $L^{\mathcal{I}_{\mathcal{P}}}_{v_i}(\nu) = (s+1)^{-|v_i|}$, and $L^{\mathcal{I}_{\mathcal{P}}}_{w_i}(\nu) = (s+1)^{-|w_i|}$.

The main idea underlying this interpretation is depicted in Figure 1. It is easy to see that this interpretation is a model of the ontology $\mathcal{O}_{\mathcal{P}} := (\mathcal{A}_{\mathcal{P}}, \bigcup_{i=1}^n \mathcal{T}^i_{\mathcal{P}})$.

Lemma 6. *$\mathcal{I}_{\mathcal{P}}$ is a model of $\mathcal{O}_{\mathcal{P}}$.*

More interesting, however, is that every witnessed model of $\mathcal{O}_{\mathcal{P}}$ must "include" $\mathcal{I}_{\mathcal{P}}$, as stated by the following lemma.

Lemma 7. *Let $\mathcal{I}$ be a witnessed model of $\mathcal{O}_{\mathcal{P}}$. Then there exists a function $f : \Delta^{\mathcal{I}_{\mathcal{P}}} \to \Delta^{\mathcal{I}}$ such that $C^{\mathcal{I}_{\mathcal{P}}}(\nu) = C^{\mathcal{I}}(f(\nu))$ holds for every concept name C occurring in $\mathcal{O}_{\mathcal{P}}$ and every $\nu \in \Delta^{\mathcal{I}_{\mathcal{P}}}$.*

Proof: We first remark that every model of $\mathcal{O}_{\mathcal{P}}$ must interpret the concept names V_i, W_i, L_{v_i}, and L_{w_i} with the same constant function defined by the TBox; e.g. $V^{\mathcal{I}}_i(\delta) = 0.0v_i$ for every model $\mathcal{I}$ and $\delta \in \Delta^{\mathcal{I}}$. Thus, the interpretation function of any model is fully determined by the interpretation of the concept names A, B, L_A, L_B.

We build the function f inductively on the length of ν. First, since $\mathcal{I}$ is a model of $\mathcal{A}_{\mathcal{P}}$, there must be a $\delta \in \Delta^{\mathcal{I}}$ such that $a^{\mathcal{I}} = \delta$. We fix $f(\varepsilon) := \delta$, and verify that

$$\begin{aligned}A^{\mathcal{I}}(\delta) = 0.1 &= A^{\mathcal{I}_{\mathcal{P}}}(\varepsilon) \\ B^{\mathcal{I}}(\delta) = 0 &= B^{\mathcal{I}_{\mathcal{P}}}(\varepsilon) \\ L^{\mathcal{I}}_A(\delta) = L^{\mathcal{I}}_B(\delta) = 1 &= L^{\mathcal{I}_{\mathcal{P}}}_A(\varepsilon) = L^{\mathcal{I}_{\mathcal{P}}}_B(\varepsilon).\end{aligned}$$

Let now ν be such that $f(\nu)$ has been defined. Then by induction we assume $A^{\mathcal{I}}(f(\nu)) = 0.1v_\nu$, $B^{\mathcal{I}}(f(\nu)) = 0.0w_\nu$, and L_A, L_B represent the lengths of these words. Since $\mathcal{I}$ is a witnessed model, for every $i, 1 \leq i \leq m$ there must exist a $\gamma \in \Delta^{\mathcal{I}}$ with $r^{\mathcal{I}}_i(f(\nu), \gamma) = 1$, $A^{\mathcal{I}}(\gamma) = 0.1v_\nu v_i$, $B^{\mathcal{I}}(\gamma) = 0.0w_\nu w_i$, and L_A, L_B encode the respective lengths. We set $f(\nu i) := \gamma$, which as we have seen satisfies the required property. ∎

From this lemma it follows that, if the PCP $\mathcal{P}$ has a solution

ν for some $\nu \in \{1,\dots,m\}^+$, then every witnessed model $\mathcal{I}$ must contain a node $\delta = f(\nu)$ such that $A^{\mathcal{I}}(\delta) = 0.1 + B^{\mathcal{I}}(\delta)$; that is, where A and B encode the same word. Thus, to decide whether $\mathcal{P}$ has a solution, we will search for a node δ such that $((\neg A) \boxplus B)^{\mathcal{I}}(\delta) = 1 - 0.1 = s/(s+1)$. Conversely, if every witnessed model contains such a node, then in particular $\mathcal{I}_{\mathcal{P}}$ has such a node, and thus $\mathcal{P}$ has a solution.

We now show how to detect whether a node where A and B encode the same non-empty word exists in every interpretation $\mathcal{I}$. To do this, we will introduce *flag* concepts that are interpreted as 1 whenever a given condition is satisfied. Let C, D be two concepts and $q \in [0,1]$. The axiom

$$\langle \neg F \sqsubseteq \neg F \sqcap \neg F \geq 1 - q \rangle$$

restricts every model $\mathcal{I}$ to satisfy, for every $\delta \in \Delta^{\mathcal{I}}$

$$((\neg F)^{\mathcal{I}}(\delta))^2 \geq (\neg F)^{\mathcal{I}}(\delta) \cdot (1-q);$$

that is, for every $\delta \in \Delta^{\mathcal{I}}$, it holds that either $(\neg F)^{\mathcal{I}}(\delta) = 0$ or $(\neg F)^{\mathcal{I}}(\delta) \geq 1 - q$. If we add the axiom $\langle C \sqsubseteq F \geq 1 \rangle$, then it follows that $C^{\mathcal{I}}(\delta) \leq F^{\mathcal{I}}(\delta)$, and hence, $F^{\mathcal{I}}(\delta) = 1$ if $C^{\mathcal{I}}(\delta) > q$. We will denote this concept F as $\mathbb{F}_{[C>q]}$. In addition, if we have the axioms

$$\langle \neg F \sqsubseteq \neg F \sqcap \neg F > q \rangle, \langle \neg F \sqsubseteq C \geq 1 \rangle$$

then it follows that for every $\delta \in \Delta^{\mathcal{I}}$, $F^{\mathcal{I}}(\delta) < 1 - q$ or $F^{\mathcal{I}}(\delta) = 1$, and that $1 - C^{\mathcal{I}}(\delta) \leq F^{\mathcal{I}}(\delta)$, and hence $F^{\mathcal{I}}(\delta) = 1$ if $C^{\mathcal{I}}(\delta) \leq q$. Such concept F will be denoted as $\mathbb{F}_{[C\leq q]}$.[4] In a similar way, we can define flags $\mathbb{F}_{[C<q]}$ and $\mathbb{F}_{[C\geq q]}$. Finally, the flag $\mathbb{F}_{[C=q]}$ is defined by $\langle \mathbb{F}_{[C=q]} \equiv \mathbb{F}_{[C\leq q]} \sqcap \mathbb{F}_{[C\geq q]} \rangle$.

Notation. *For a concept C and $q \in [0,1]$, the expression $\mathbb{F}_{[C\bowtie q]}$, where $\bowtie$ is one of $>, <, \geq, \leq, =$, denotes a concept such that for every model $\mathcal{I}$ and $\delta \in \Delta^{\mathcal{I}}$, $\mathbb{F}^{\mathcal{I}}_{[C\bowtie q]}(\delta) = 1$ if $C^{\mathcal{I}}(\delta) \bowtie q$.*

Using these flags, we can detect whether A and B encode the same word, that is $((\neg A) \boxplus B)^{\mathcal{I}}(\delta) = s/(s+1)$, by checking whether the flag $\mathbb{F}_{[(\neg A)\boxplus B = s/(s+1)]}$ is interpreted as 1, and test that this word is not the empty word using the flag $\mathbb{F}_{[A\sqcup B>0.1]}$. Notice, additionally, that $A^{\mathcal{I}_{\mathcal{P}}}(\delta) \geq B^{\mathcal{I}_{\mathcal{P}}}(\delta)$ for all δ, and thus the concept $(\neg A) \boxplus B$ is well-defined; that is, the axioms that are used to encode it are satisfied by $\mathcal{I}_{\mathcal{P}}$.

Thus, for a node δ, if $A^{\mathcal{I}}(\delta)$ and $B^{\mathcal{I}}(\delta)$ encode the same non-empty word, then

$$(\mathbb{F}_{[(\neg A)\boxplus B = s/(s+1)]} \sqcap \mathbb{F}_{[A\sqcup B>0.1]})^{\mathcal{I}}(\delta) = 1.$$

We now define the ontology $\mathcal{O}'_{\mathcal{P}} := (\mathcal{A}_{\mathcal{P}}, \mathcal{T}_{\mathcal{P}})$ where

$$\mathcal{T}_{\mathcal{P}} := \bigcup_{i=1}^{m} \mathcal{T}^i_{\mathcal{P}} \ \cup \ \{\top \sqsubseteq \neg(\mathbb{F}_{[(\neg A)\boxplus B = s/(s+1)]} \sqcap \mathbb{F}_{[A\sqcup B>0.1]}) > 0\}.$$

Theorem 8. *The instance $\mathcal{P}$ of the PCP has a solution iff the ontology $\mathcal{O}'_{\mathcal{P}}$ is not witnessed consistent.*

[4]Notice that this is the first instance of a strict axiom used in our construction so far.

Proof: Assume first that $\mathcal{P}$ has a solution $i_1, \dots, i_k$ and let $\nu = i_1 i_2 \cdots i_k \in \{1,\dots,m\}^*$ and $u = v_\nu = w_\nu$. Suppose there is a witnessed model $\mathcal{I}$ of $\mathcal{O}'_{\mathcal{P}}$. Since $\mathcal{O}_{\mathcal{P}} \subseteq \mathcal{O}'_{\mathcal{P}}$, $\mathcal{I}$ must also be a model of $\mathcal{O}_{\mathcal{P}}$. From Lemma 7 it follows that there is a node $\delta \in \Delta^{\mathcal{I}}$ such that

$$A^{\mathcal{I}}(\delta) = A^{\mathcal{I}_{\mathcal{P}}}(\nu) = 0.1u,$$
$$B^{\mathcal{I}}(\delta) = B^{\mathcal{I}_{\mathcal{P}}}(\nu) = 0.0u,$$

We thus have $((\neg A) \boxplus B)^{\mathcal{I}}(\delta) = s/(s+1)$ and hence $\mathbb{F}_{[(\neg A)\boxplus B = s/(s+1)]} = 1$. Additionally, since u is not the empty word, it follows that $(A \sqcup B)^{\mathcal{I}}(\delta) > 0.1$ and thus $\mathbb{F}_{[A\sqcup B>0.1]} = 1$. But this violates the last axiom in $\mathcal{T}_{\mathcal{P}}$, and hence $\mathcal{I}$ cannot be a model of $\mathcal{O}'_{\mathcal{P}}$.

To show the converse, we will extend $\mathcal{I}_{\mathcal{P}}$ to interpret the three flag concepts $\mathbb{F}_{[(\neg A)\boxplus B\geq s/(s+1)]}$, $\mathbb{F}_{[(\neg A)\boxplus B\leq s/(s+1)]}$, and $\mathbb{F}_{[A\sqcup B>0.1]}$ as follows for every $\delta \in \Delta^{\mathcal{I}_{\mathcal{P}}}$:

$$\mathbb{F}^{\mathcal{I}_{\mathcal{P}}}_{[C\bowtie q]}(\delta) = \begin{cases} 1 & \text{if } C^{\mathcal{I}_{\mathcal{P}}}(\delta) \bowtie q \\ C^{\mathcal{I}_{\mathcal{P}}}(\delta) & \text{otherwise} \end{cases}$$

if $\bowtie$ is either $\geq$ or $>$, and

$$\mathbb{F}^{\mathcal{I}_{\mathcal{P}}}_{[C\leq q]}(\delta) = \begin{cases} 1 & \text{if } C^{\mathcal{I}_{\mathcal{P}}}(\delta) \leq q \\ 1 - C^{\mathcal{I}_{\mathcal{P}}}(\delta) & \text{otherwise.} \end{cases}$$

It is easy to see that this valuation satisfies the two axioms that define each flag concept.

Additionally, every element $\nu \in \Delta^{\mathcal{I}_{\mathcal{P}}}$ has exactly one r_i-sucessor for every $i, 1 \leq i \leq m$, i.e. there is exactly one element $\nu' \in \Delta^{\mathcal{I}_{\mathcal{P}}}$ such that $r_i^{\mathcal{I}_{\mathcal{P}}}(\nu, \nu') > 0$. Thus, the interpretation $\mathcal{I}_{\mathcal{P}}$ trivially satisfies the two conditions of witnessed models.

Suppose now that $\mathcal{O}'_{\mathcal{P}}$ is not witnessed consistent. Then $\mathcal{I}_{\mathcal{P}}$ is not a model of $\mathcal{O}'_{\mathcal{P}}$. Since it is a model of $\mathcal{O}_{\mathcal{P}}$ and satisfies the axioms defining each of the three flag concepts, it must violate the last axiom added to $\mathcal{T}_{\mathcal{P}}$. Thus, there is a node $\nu \in \Delta^{\mathcal{I}_{\mathcal{P}}}$ such that $\mathbb{F}^{\mathcal{I}_{\mathcal{P}}}_{[(\neg A)\boxplus B = s/(s+1)]}(\nu) = 1$ and $\mathbb{F}^{\mathcal{I}_{\mathcal{P}}}_{[A\sqcup B>0.1]}(\nu) = 1$. By our interpretation of these flag concepts, it then follows that $1 - A^{\mathcal{I}_{\mathcal{P}}}(\nu) + B^{\mathcal{I}_{\mathcal{P}}}(\nu) = s/(s+1)$, or equivalently, $A^{\mathcal{I}_{\mathcal{P}}}(\nu) = 0.1 + B^{\mathcal{I}_{\mathcal{P}}}(\nu)$ which means that $A^{\mathcal{I}_{\mathcal{P}}}(\nu)$ and $B^{\mathcal{I}_{\mathcal{P}}}(\nu)$ encode the same word. From the second flag, it follows that they both encode a non-empty word. But then, this same ν must be a solution of $\mathcal{P}$, which finishes the proof. ∎

IV. Conclusions

We have shown that the algorithm from [10] is incorrect, and given an undecidability result for a small extension of fuzzy $\mathcal{ALC}$ with product t-norm and involutive negation. Our results do not show that the logic used in [10] is undecidable since we (i) added expressivity by means of the strict axioms, and (ii) used a weaker notion of witnessed models, which we believe to be more closely related to the idea of concept inclusions in DL. As future work, we will analyse the decidability status of consistency (witnessed consistency, strongly witnessed consistency) for the logic considered in [10], [11] with general concept inclusions. On the one hand, this involves

trying to correct the algorithm from [10] by introducing a more sophisticated blocking condition. On the other hand, we will also try to modify our undecidability proof such that it does not use strict inclusion axioms, or such that it can also deal with pure consistency or strongly witnessed consistency.

Another area for future work includes studying the impact of concept inclusion axioms when reasoning w.r.t. other t-norm based semantics, in particular with the Łukasiewicz t-norm. We will also analyse the applicability of other reasoning techniques to fuzzy DLs. It is important to notice that under the product t-norm semantics, the models of an ontology may, in general, require infinitely many different interpretation values. Hence, the methods for transforming fuzzy DL ontologies into crisp DL ontologies [19], [20], [21] cannot be applied in this setting.

Fuzzy Concept Lattice Construction

A Basis for Building Fuzzy Ontologies

***Abstract*— Fuzzy concept lattices are being used as the basis for creating fuzzy ontologies. Fuzzy formal contexts serve as the starting point for which a variety of proposed methods have been used to create fuzzy concept lattices from them. This paper reviews two of these methods: the one-sided threshold approach and the fuzzy closure operator approach and presents the first comparison between these two approaches. Some simple examples are used and then bioinformatics data, specifically several gene annotation data files. The results show that the fuzzy closure approach produces huge numbers of concepts as compared to the threshold approach, and the extents produced by the threshold approach are a subset of the extents produced by the fuzzy closure approach.**

Keywords-Fuzzy concept lattices; threshold method; fuzzy closure method; fuzzy ontologies; fuzzy formal concept analysis

I. INTRODUCTION

Ontologies have become accepted as the main knowledge representation method for making domain knowledge available on the web. Ontologies typically are specified in a machine-readable format and represent domain knowledge by defining concepts, attributes of the concepts and relationships between the concepts with the taxonomic is-a relationship creating the ontology structure. More formal ontology languages such as OWL [1] also allow axioms to be specified in the definition of the ontology. Ontologies facilitate the use of web resources and knowledge sharing by web applications.

One of the bottlenecks in the use of ontologies, however, is the time and effort to create them. Much research has been undertaken to automate as much as possible the building of ontologies [2]. More recently formal concept analysis (FCA) is being used to aid in constructing ontologies [3][4]. FCA was developed in the early 1980's [5] and has grown into a widely used tool for knowledge discovery [6]. FCA is an unsupervised learning method to cluster data to create concepts where a formal concept has two components, the instance objects which are its extent, and the attributes describing the objects, which are its intent.

Since real-world knowledge can be vague or uncertain, researchers have focused on integrating fuzzy logic into the modeling of domain knowledge and the result is the definition of fuzzy ontologies [7]. A natural extension to the use of FCA for creating ontologies is the use of fuzzy formal concept analysis (FFCA) to build fuzzy ontologies. In crisp FCA, the association of an attribute with an object is either complete or not at all. In FFCA an attribute may only be partially associated with an object, i.e., an attribute has a degree of association or membership when used to describe the object. The fuzzy formal context is typically specified by a matrix with a set of objects for its rows and a set of attributes or properties for its columns as shown in Fig. 1. It is basically a formal context where the relation R between the objects and the attributes is a fuzzy binary relation; that is, instead of a crisp 0 or 1 degree, the degree is taken from the interval [0, 1] and indicates that the object x_i possesses the attribute y_j to the specified degree.

	y_1	y_2	y_3	y_4	y_5
x_1	1	0.5	0.5	1	1
x_2	1	1	1	1	0.5
x_3	0	0	0.5	0.5	1

Fig. 1. A fuzzy formal context [11].

Numerous researchers have developed approaches for creating fuzzy concept lattices that are then used to develop fuzzy ontologies [8] [9] [10]. These approaches use an α-cut on the fuzzy formal context to first convert to a crisp formal context and then use standard FCA to both create the formal concepts and the structure of the concept lattice. The fuzziness is introduced back into concept lattice using several fuzzy operators on the fuzzy formal context. This method is referred to as the one-sided α-cut thresholding approach to fuzzy concept lattice creation. Recently a new approach to creating a fuzzy concept lattice that works directly on the fuzzy formal context has been introduced [11]. It is uses a fuzzy closure operator to calculate all fixpoints in a finite set over a finite chain of truth degrees. These fixpoints are the fuzzy formal concepts. The partial order on the set of all fixpoints is also determined to create the structure of the fuzzy concept lattice.

This paper extends the work in [12] and presents a more detailed comparison of these two approaches. Both algorithms have been implemented in Java and various test cases have been used to compare their results, first using a simple example and then using a gene annotation data set with three different protein families. Currently, these two different approaches have not been directly compared. For the most part, the fuzzy

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

closure approach has simply been used on experimentally generated fuzzy formal contexts with a focus on its practical performance [11]. The threshold approach has been experimented with to examine its usefulness for creating fuzzy concept lattices as a foundation for developing fuzzy ontologies [10]. The focus in this present paper is examining the differences in the interpretation of the two approaches and actually applying them to the same real world fuzzy formal context based on gene annotation data which plays an important role in bioinformatics research. Section 2 describes the one-sided α-cut threshold approach to fuzzy concept lattice creation. Section 3 describes the fuzzy closure approach. Both of these sections use the simple fuzzy formal context shown in Fig. 1 to illustrate the two different approaches. Section 4 outlines the experimental data used to compare the two approaches. The results of these experiments are analyzed in section 5. Section 6 summarizes the research and outlines plans to further experiment with these two approaches.

II. ONE-SIDED THRESHOLD APPROACH

A fuzzy formal context is basically a formal context where the relation between the objects and the attributes is a fuzzy binary relation R between a set of objects X and a set of attributes Y as illustrated in Fig. 1. For example, object x_1 possesses attribute y_3 to degree 0.5, i.e., $R(x_1,y_3)= 0.5$. The fuzzy formal context is viewed as a set of fuzzy sets where each fuzzy set describes either an object or an attribute, i.e., the side that is selected or given preference. If the object is given preference, then an object $x_i \in X$ in a fuzzy formal context K with attribute set Y is represented by a fuzzy set $\Phi(x_i)$ as $\{ R(x_i,y_1)/y_1, R(x_i,y_2)/y_2, ..., R(x_i,y_n)/y_n \}$ where $R(x_i,y_j)$ is the degree to which object x_i possesses attribute y_j. For example, the row for object x_3 specifies its fuzzy set description over the attributes, $\{0.5/y_3, 0.5/y_4, 1.0/y_5\}$. An attribute can also be represented as a fuzzy set over the objects, i.e., the column for attribute y_3 specifies its fuzzy set description over the objects, $\{0.5/x_1, 0.5/x_2, 1.0/x_3\}$. With this view, algorithms for creating the fuzzy formal concepts that include the extent and intent, the concept lattice structure, and the strength of the links from a parent concept to its children concepts have been developed.

In [10], the threshold approach is used to generate fuzzy ontologies from fuzzy formal context by taking α-cuts on the fuzzy formal context where the object is given preference. Then a fuzzy formal concept is defined by specifying an α value, also referred to as a confidence threshold. For $A \subseteq X$, then the crisp definition simply is modified to require $R(x,y) \geq \alpha$ instead of $R(x,y) = 1$ as given:

$$A' = \{y \in Y \mid \forall x \in A, R(x,y) \geq \alpha\} \quad (1)$$

and similarly, $B \subseteq Y$

$$B' = \{x \in X \mid \forall y \in B, R(x,y) \geq \alpha\} \quad (2)$$

The threshold α restricts the fuzzy concept lattice generation since it eliminates from the original fuzzy formal context all (x, y) pairs whose degree is less than the threshold and basically converts the fuzzy formal context into a crisp context for all those remaining pairs. This method then simply uses standard FCA to create the concepts and the concept lattice structure, but no fuzziness exists in the extent or intent at that point. The crisp formal concept must be transformed into a fuzzy formal concept.

The fuzzy formal concept of a fuzzy formal context K with a confidence threshold α is a pair (A_f, B), where $A'=B$ and $B'=A$ and each $x \in A$ has a membership degree defined as

$$A_f(x) = \min_{y \in B} R(x,y). \quad (3)$$

If B is the empty set, then $A_f(x) = 1$ for every x. A is the extent and B is the intent of the fuzzy formal concept. If attributes are given preference then the formula becomes

$$B_f(x) = \min_{x \in A} R(x,y). \quad (4)$$

The term fuzzy concept is used in the remainder of the paper as an abbreviation for fuzzy formal concept. Note that when the object is given preference, the extent of the fuzzy concept is a fuzzy set. The membership degree belonging to the object in the fuzzy extent is interpreted as the degree to which the object belongs to the fuzzy concept and specifies the minimum degree to which the object possesses all the attributes in the intent. The partial ordering of fuzzy concepts ≤ is defined such that $(A1_f, B1) \leq (A2_f, B2)$ if and only if $A1_f \subseteq A2_f$ and equivalently $B2 \subseteq B1$. This approach creates a set of fuzzy concepts and a fuzzy concept lattice based on the ≤ ordering.

Although the fuzzy concept lattice can be created from the fuzzy concepts and the ordering, the subsumption or ordering relation does not provide a degree of similarity or strength between the parent fuzzy concept and the child fuzzy concept. Thus a measure of fuzzy concept similarity between concepts $c1 = (A1, B1)$ and $c2 = (A2, B2)$ is defined using the Jaccard fuzzy set similarity measure between two fuzzy sets as

$$E(c1,c2) = \frac{|A1_f \cap A2_f|}{|A1_f \cup A2_f|}. \quad (5)$$

This approach has been used in recent papers focusing on fuzzy ontology generation [8]-[10]. If the attribute set is given preference, then the intents are fuzzy sets and the A sets would be replaced with corresponding B sets in (5).

For the fuzzy formal context in Fig. 1 and selecting the object side with a threshold of the minimum degree in the fuzzy formal context, i.e., 0.5, produces the following two concepts labeled 0 and 1 followed by the intent set and the extent set of each one:

0: $[0.5/x_1, 0.5/x_2, 0.5/x_3]$; $[y_3, y_4, y_5]$
1: $[0.5/x_1, 0.5/x_2]$; $[y_1, y_2, y_3, y_4, y_5]$

Since the minimum membership degree in the fuzzy formal context is selected as the threshold, any nonzero membership degree indicates that the object possess the attribute. The top concept 0 shows all objects in X possess attributes y_3, y_4 and y_5 to some degree, but the minimum degree of possession over all attributes in the intent of concept 0 is 0.5 for each of the objects. The bottom concept 1 shows that all attributes are possessed by both objects x_1 and x_2.

Again, the minimum degree of possession over all attributes in the intent of concept 1 is 0.5 for both x_1 and x_2. Concept 0 has concept 1 as its child with a link strength of 0.667 between them.

Using a threshold of 1.0 greatly changes the results. Only pairs of objects and attributes which have a 1.0 membership degree in the fuzzy formal context are considered. The following concepts are produced:

0: [1.0/ x_1, 1.0/x_2, 1.0/x_3]; []
1: [1.0/ x_1, 1.0/ x_2]; [y_1, y_4]
2: [1.0/ x_2]; [y_1, y_2, y_3, y_4]
3: [1.0/x_1, /1.0/x_3]; [y_5]
4: [1.0/ x_1]; [y_1, y_4, y_5]
5: []; [y_1, y_2, y_3, y_4, y_5]

The top concept 0 in the lattice shows that not a single attribute is possessed by all objects at the 1.0 degree. Concept 5, the bottom concept of the lattice, shows that not a single object possesses all attributes to degree 1.0. Concept 1 which is a child of concept 0 with a link strength of 0.667 shows that object x_1 and x_2 possess both attributes y_1 and y_4. Concept 3 which is also a child of concept 0 with a link strength of 0.667 shows that objects x_1 and x_3 possess attribute y_5. Concept 2 which is a child of concept 1 with a link strength of 0.5 shows that object x_2 possesses the attributes y_1, y_2, y_3, and y_4. Finally concept 4 which is a child of concept 1 with a link strength of 0.5 and a child of concept 3 with a link strength of 0.5 shows object x_1 possesses attributes y_1, y_4, and y_5. Concept 5 as the bottom concept is a child of both concepts 2 and 4 but with a link strength of 0.0 since its extent is empty and the intersection of it with the extents of concepts 2 and 4 is empty.

III. FUZZY CLOSURE APPROACH

The threshold approach can give preference to either the objects or the attributes. In its fuzzy concepts, a fuzzy extent exists if the objects are given preference, or a fuzzy intent exists if the attributes are given preference. In the fuzzy closure approach, however, the fuzzy concepts contain both fuzzy extents and fuzzy intents since it looks at the complete fuzzy formal context without giving preference to either objects or attributes. It also differs from the threshold approach in that it does not convert the fuzzy formal context into a crisp formal context in order to create the initial formal concepts and concept lattice structure. It also does not propose a link strength between fuzzy concepts although the fuzzy similarity measure given in (5) could be used between the intent fuzzy sets, the extent fuzzy sets or both to determine a link strength between a parent and child concept. A detailed description of the fuzzy closure approach and its algorithm can be found in [11] and an explanation and insights into the workings of the algorithm are provided in [12]. Here a summary and discussion of the important points of this approach are presented.

The fuzzy closure approach requires that the $R(x,y)$ values in the fuzzy formal context be taken from a complete residuated lattice L in the real unit interval [0,1], well-known in fuzzy logic [13]. L is assumed to be finite and linearly ordered. The lattice structure requires the two operations of fuzzy conjunction $\otimes$ and a residuum $\rightarrow$, a special kind of fuzzy implication operator defined as

$$a \rightarrow b = max\{c \text{ in } L \mid a \otimes c \leq b\}.$$

A residuum satisfies an adjointness condition: $a \otimes b \leq c$ iff $a \leq b \rightarrow c$. With the operations $\otimes$ and $\rightarrow$, L forms a complete residuated lattice. In [11], the example uses the Lukasiewiz operators

$$\begin{aligned} a \otimes b &= \max(0, a + b - 1) \\ a \rightarrow b &= \min(1 - a + b, 1) \end{aligned} \quad . \tag{5}$$

The set of all fuzzy sets using L in a universe X is denoted by L^X where a fuzzy set A means a mapping $A: X \rightarrow L$ assigning to any $x \in X$ a truth degree $A(x) \in L$ to which x belongs to A. Given the fuzzy formal context $<X, Y, R>$ where X is the set of objects, Y is the set of attributes, and R is the fuzzy binary relation, for fuzzy sets $A \in L^X$ and $B \in L^Y$, , fuzzy sets $A\uparrow \in L^Y$ and $B\downarrow \in L^X$ are defined as

$$\begin{aligned} A\uparrow &= min_{x \in X} (A(x) \rightarrow R(x,y)) \\ B\downarrow &= min_{y \in Y} (B(y) \rightarrow R(x,y)) \end{aligned} \tag{6}$$

The interpretation of $A\uparrow(y)$ based on fuzzy logic is that the membership degree of y in $A\uparrow$ specifies the truth degree that the attribute y is possessed by all objects in the fuzzy set A. Similarly, the membership degree of x in $B\downarrow$ specifies the truth degree that the object x possesses all attributes in the fuzzy set B. $<A, B>$ is a fuzzy formal concept in the fuzzy concept lattice if $A\uparrow = B$ and $B\downarrow = A$. Denote $\mathbf{B}$ <X, Y, R> = $\{<A, B> \mid A\uparrow = B, B\downarrow = A\}$ as the set of all fuzzy concepts for the fuzzy formal context $<X, Y, R>$.

The conceptual hierarchy is modeled by the relation $\leq$ defined on $\boldsymbol{B}$ $<X, Y, R>$ by $<A_1, B_1> \leq <A_2, B_2>$ if and only if $A_1 \subseteq A_2$ (or, equivalently $B_1 \supseteq B_2$). The set $\boldsymbol{B}$<X, Y, R> under the relation $\leq$ is a fuzzy concept lattice. Since fuzzy concepts are simply the fixpoints of a particular fuzzy closure operator [14], computing all fuzzy concepts reduces to computing all fixpoints of a fuzzy closure operator.

A fuzzy closure operator C on a universe X is a mapping $C: L^X \rightarrow L^X$ such that the following three conditions are satisfied: $A \subseteq C(A)$ (extensivity), $A \subseteq B$ implies $C(A) \subseteq C(B)$ (monotony), and $C(A) = C(C(A))$ (idempotency). If $A=C(A)$, then A is called a fixpoint of C. The set of all fixed points of C is denoted by $fix(C)$, such that $fix(C) = \{A \in L^X \mid A=C(A)\}$. Given a formal context $<X, Y, I>$, the compound mapping $\uparrow\downarrow: L^X \rightarrow L^X$ is a fuzzy closure operator in X and $\downarrow\uparrow: L^Y \rightarrow L^Y$ is a fuzzy closure operator in Y. The fixpoints of $\uparrow\downarrow$ and the fixpoints of $\downarrow\uparrow$ are just the extents and intents respectively of the fuzzy formal concepts of $<X, Y, I>$.

A brute-force method to determine all the fixpoints would be to simply generate all $A \in L^X$ and then output those where $A = C(A)$. This method has exponential time complexity and, therefore, is of no use. The research in [11] presents an algorithm to compute a fuzzy concept lattice, i.e., all the fixpoints of a fuzzy closure operator as well as the structure of the fuzzy concept lattice. It is based on extending the NEXTNEIGHBOR algorithm [15] which computes crisp concept lattices.

This recursive algorithm begins by calculating the fuzzy closure ↓↑ on the empty attribute set to produce the first intent B_0 of the fuzzy concept lattice. B_0 is the intent of the top concept $(B_0\downarrow, B_0)$ in the fuzzy concept lattice. The algorithm proceeds by generating from B_0 (GenerateFrom procedure) the intents of its set of upper neighbors (Neighbors procedure), i.e., the intents of the fuzzy concepts that are subconcepts of the fuzzy concept $(B_0\downarrow, B_0)$. A neighbor generated for fuzzy concept $(B_0\downarrow, B_0)$ has an intent that is a superset of B_0 and an extent that is a subset of the extent of $B_0\downarrow$, where the standard definition of inclusion on fuzzy sets is used, i.e., $F_1 \subseteq F_2$ if $\forall x \in X, \mu_{F_1}(x) \leq \mu_{F_2}(x)$. Each of these neighbors is then linked to $(B_0\downarrow, B_0)$. The generated intents of the neighbors not already in the set of intents for $\boldsymbol{B}$<X, Y, R> are then added to the set. Each intent added to the set of intents is then input to the GenerateFrom procedure to generate its neighbors. This process repeats recursively up to the intent consisting of *Y*, the complete attribute set, which is the greatest fixpoint of *C*.

The challenging part is finding the upper neighbor intents for a given input intent *B*. The *upper neighbor* $D \in fix(C)$ w.r.t *C*, written as $B \prec^C D$, is established if $B \in fix(C)$ such that *i)* $B \subset D$ *ii)* there is no $D' \in fix(C)$ such that $B \subset D' \subset D$. The Neighbors procedure relies on several lemmas and theorems proven in [11] that show each upper neighbor intent is in fact produced by some $y \in Y$. Two orderings are required by the Neighbors procedure: the ordered membership degrees in $L = \{a_1, a_2, \ldots a_k\}$ such that $0 = a_1 < a_2 < \ldots < a_k = 1$ and a fixed ordering of attributes from $Y = \{y_1, y_2, \ldots y_n\}$ and $y_i < y_j$ if $i < j$. The Neighbors procedure systematically proceeds through this fixed ordering checking each y_i that does not already have a membership degree of 1.0 in *B* as a possible generator of an upper neighbor of *B*. It does this by first modifying *B* to produce *B'*. Assume $B(y_i) = a_j$, then *B'* becomes $B \cup \{a_{j+1}/y_i\}$, that is, the membership degree of y_i in *B'* becomes the next membership degree in the ordering that is greater than the membership of y_i in *B*. Then the potential upper neighbor *D* which must be a fixpoint of *C* is calculated as $D = C(B')$. The problem, however, is that there might exist $D' \in fix(C)$ such that $B \subset D' \subset D$. The algorithm uses the fixed ordering of the attributes *Y* to make sure that the calculated *D* is selected as an upper neighbor of *B* only if no other *D'* exists.

The fuzzy formal context in Fig. 1 with $L = \{0, 0.5, 1.0\}$ and the implication operator → given in (5) was used to verify our implementation of the fuzzy closure operator approach to creating fuzzy concept lattices. The results produced are identical to those provided in [11]

0: [1.0/x1, 1.0/x2, 1.0/x3]; [0.5/y3, 0.5/y4, 0.5/y5]
1: [1.0/x1, 1.0/x2, 0.5/x3]; [0.5/y1, 0.5/y2, 0.5/y3, 1.0/y4, 0.5/y5]
2: [1.0/x1, 0.5/x2, 1.0/x3]; [0.5/y3, 0.5/y4, 1.0/y5]
3: [1.0/x1, 1.0/x2]; [1.0/y1, 0.5/y2, 0.5/y3, 1.0/y4, 0.5/y5]
4: [0.5/x1, 1.0/x2, 0.5/x3]; [0.5/y1, 0.5/y2, 1.0/y3, 1.0/y4, 0.5/y5]
5: [1.0/x1, 0.5/x2, 0.5/x3]; [0.5/y1, 0.5/y2, 0.5/y3, 1.0/y4, 1.0/y5]
6: [0.5/x1, 1.0/x2]; [1.0/y1, 1.0/y2, 1.0/y3, 1.0/y4, 0.5/y5]
7: [1.0/x1, 0.5/x2]; [1.0/y1, 0.5/y2, 0.5/y3, 1.0/y4, 1.0/y5]
8: [0.5/x1, 0.5/x2]; [1.0/y1, 1.0/y2, 1.0/y3, 1.0/y4, 1.0/y5]
9: [0.5/x1, 0.5/x2, 0.5/x3]; [0.5/y1, 0.5/y2, 1.0/y3, 1.0/y4, 1.0/y5]

The concept lattice hierarchy produced by our implementation shows the first the concept number followed by concept numbers of its children and agrees with that given in [11]:

0: 1; 2;
1: 3; 4; 5;
2: 5;
3: 6; 7;
4: 6; 9;
5: 7; 9;
6: 8;
7: 8;
8:
9: 8;

The results from the threshold approach for 0.5 threshold with object preference produced two very simple fuzzy concepts; whereas the fuzzy closure approach produces a more complex concept lattice with 10 fuzzy concepts where both the extents and intents are fuzzy sets. Notice that (3) used to produce the fuzzy extent in the threshold approach is basically using $B\downarrow$ given in (6); however, since the threshold approach assumes a membership degree of 1 for all attributes in the intents, $B\downarrow$ in (6) simply becomes $(1\text{-}1+ R(x,y))$ or simply $R(x,y)$ with the → operation given in (5). Notice that the results of the threshold approach with a 0.5 value produce a top concept 0 that is similar to the top concept 0 of the fuzzy closure approach. Both have the same objects in the extent and the same attributes in the intent. A major difference is that in threshold approach with object preference, an object is described as a fuzzy set over attributes; therefore, an object's membership degree in the extent of the fuzzy concept indicates the minimum degree to which the object possesses all of the attributes in the intent. For the fuzzy closure approach the top concept 0 has an extent where each object fully belongs. Here performing ↑ on this extent produces the corresponding fuzzy intent. Each attribute's membership degree indicates the truth degree that the attribute is shared by all objects in the extent. This truth degree is affected by how strongly the objects themselves belong to the fuzzy extent.

Similarly, the bottom concept 1 for the threshold approach agrees with the bottom concept 8 for the fuzzy closure approach with respect to the objects in the extent and the attributes in the intent. However, in this case the membership degrees also match. As pointed out in the fuzzy closure algorithm the greatest fixpoint of *C* is the set *Y* which is the intent of the bottom concept. All membership degrees are 1.0 so that performing $B\downarrow$ on this intent of Y simply reduces to using (3) with the Lukasiewicz implication operator in (5).

Notice that when the threshold is 1.0, the results for the top and bottom concepts are quite different from that of the fuzzy closure approach. This difference is to be expected since the threshold approach ignores all entries in the fuzzy formal context that do not meet the threshold value while the fuzzy closure approach uses all the non-zero entries.

IV. EXPERIMENTAL TEST CASES

In [11], the experiments that were run using the fuzzy closure approach focused on its practical performance in terms of the algorithm's running time as influenced by characteristics of the formal context such as the size and distribution of the truth degrees. The formal contexts used in these performance experiments were not real world data but randomly generated. Another characteristic considered in the performance evaluation is the number of truth degrees in L. The performance of the fuzzy closure approach is compared to that of a fuzzy extension to the NEXTCLOSURE presented in [16]. The results of these experiments showed that the algorithm in [16] performs best when only the fuzzy concepts need to be computed. The fuzzy closure approach, however, performs considerably better when the structure of the fuzzy concept lattice is also needed.

In [10] the experiment using the threshold approach has as its objective to determine the usefulness of the fuzzy concept lattice as a foundation for developing a fuzzy ontology and how to represent the fuzzy ontology using OWL. There is no comparison of other algorithms for creating fuzzy concept lattices. The experiments described in this present paper differs from the previous ones done separately with these two approaches since the objective is to compare the resulting fuzzy concepts and fuzzy concept lattices produced by these two different approaches. The following discusses the various test cases used in the experiments.

A. Olympic Data

The first test case is the formal context developed using Olympic data for several athletes and is taken from [11]. It was selected since it could be used as another verification test case for the software implementation of the fuzzy closure approach algorithm and provides a smaller fuzzy formal context for comparing the two approaches. It also provides a more complex formal context than the x objects and y attributes formal context and a larger L set with L = {0.0, 0.25, 0.5, 0.75, 1.0}. Here the five objects represent athletes and the ten attributes are Olympic events. The fill ratio, the fraction of non-zero degrees in the fuzzy formal context, is 100%. The membership degree can be interpreted as an indication of how well the athlete performs in the event.

	100m	long Jump	shot Put	high Jump	400m	110m Hurdl	discus Throw	pole Vault	Javekin Throw	1500m
Sebrle	0.5	1	1	1	0.75	1	0.75	0.75	1	0.75
Clay	1	1	0.75	0.75	0.5	1	0.75	0.5	1	0.5
Karpov	1	1	0.75	0.75	1	1	1	0.25	0.25	0.75
Macey	0.5	0.5	0.75	1	0.75	0.5	0.75	0.25	0.5	1
Warners	0.75	0.75	0.5	0.5	0.75	1	0.25	0.5	0.25	0.75

Figure 2. Olympic data [11].

B. Gene Annotation Data

A gene can be annotated with concepts from the Gene Ontology (GO) [17]. An evidence code is provided with an annotation, for example, Traceable Author Statement (TAS). The evidence code is translated into a degree of evidence strength between a GO concept and a gene product. In the following, the evidence codes are translated into membership degrees as done in [18]. Traceable Author Statement (TAS) is 1.0. Inferred from Sequence Similarity (ISS) is 0.8. Inferred from Electronic Annotation (IEA) is 0.6. Non-traceable Author Statement (NAS) is 0.4. Not Documented (ND) and Not Recorded (NR) were modified from 0.1 to 0.2 since the fuzzy closure operator approach requires that the set of membership degrees in L must form a closed lattice, i.e., they must be closed on the implication operator so that L= {0, 0.2, 0.4. 0.6, 0.8, 1.0} for all the annotation data test cases.

A fuzzy formal context can be created from an annotation data file with the genes as the objects, the GO terms as the attributes. The numeric evidence codes are interpreted as the degree to which a gene is annotated by a GO concept. For the experiments, the gene annotation data file GPD 194 data set [18] is used. It contains 194 human gene products (proteins). Here genes are classified into three families: collagen, myotubularin, and receptor precursor.

For the collagen annotation data shown in Fig. 3, there are 13 genes annotated by 23 GO terms. The fill-ratio is 20%.

Figure 4. Fuzzy formal context for the Myotubularin Family.

For the receptor precursor annotation, there are 7 genes annotated by 35 GO terms with a fill-ratio of 33%. This data set is not shown due to space limitations. In the combined gene annotation data, all three families, collagen, myotubularin and receptor, are considered as a single test. It contains 27 (13+7+7) genes as objects and 63 GO terms

(23+14+35 – 9 common terms) as attributes with a fill ratio of 10%. Due to the large size of this combined fuzzy formal context, it is not provided here. The rows are simply the union of all three sets of genes in each of the families and its columns are simply the union of all GO terms in the above three previous tables.

V. Analysis of the Experimental Results

The fuzzy closure approach uses the complete fuzzy formal context; thus, the results for the threshold approach are only given using the minimum membership degree in each of the fuzzy formal contexts in section IV. Other threshold values instead of the minimum degreet alters the fuzzy formal context from the one used by the fuzzy closure approach so that an unbiased comparison is not possible.

A. Olympic Data

The membership degrees in L can be interpreted as 0.0 does not performs in the event, 0.25 performs but not very well, 0.5 performs average in this event, 0.75 performs well in the event, and 1.0 performs exceptionally well in the event.

Threshold Approach: With $\alpha \geq 0.25$, only one concept which is both the top and bottom concept is produced :

0: [0.5/Sebrle, 0.5/Clay, 0.25/Karpov, 0.25/Macey, 0.25/Warners];
[100m, longJump, shotPut, highJump, 400m, 110mHurdl, discusThrow, poleVault, javekinThrow, 1500m]

The extent of concept 0 indicates that for this fuzzy formal context all of the objects possess all of the attributes to at least a degree value of 0.25. This result is expected since the fill ratio is 100%. The membership degrees in the extent, however, indicate for each object (athlete) the minimum degree of possession across all the attributes (events) in the intent. For example, the athlete Sebrle performs at least fair in all the events (his minimum degree in any event is 0.5). An examination of the formal context for the Olympic data confirms that indeed the 100m event has 0.5 degree, i.e., his weakest Olympic event.

Fuzzy Closure Approach: The Lukasiewicz implication operator produces 128 concepts. Fig. 5 provides a summary of this result since providing the complete listing of the concepts and the concept hierarchy would requires too much space. The complete results on this data set were verified by requesting from the authors of [11] their fuzzy concept lattice results since these were not provided in their original paper. An exact match existed with their produced fuzzy concepts and fuzzy concept lattice hierarchy.

Notice that the results of the threshold approach with a 0.25 value produce a top concept 0 that is similar to the top concept 0 of the fuzzy closure approach as seen for the simple fuzzy formal context in Fig. 1. For the threshold approach, the membership degree of the object in the extent of the fuzzy concept indicates the minimum degree to which the athlete performs in all the events in the intent. For the fuzzy closure

Detail	Concept Id	Concepts
Top Concept	0	**0:** [1.0/Sebrle, 1.0/Clay, 1.0/Karpov, 1.0/Macey, 1.0/Warners]; [0.5/100m, 0.5/longJump, 0.5/shotPut, 0.5/highJump, 0.5/400m, 0.5/110mHurdl, 0.25/discusThrow, 0.25/poleVault, 0.25/javekinThrow, 0.5/1500m]
Children of top concept	1, 2, 3	**1:** [1.0/Sebrle, 1.0/Clay, 1.0/Karpov, 0.75/Macey, 1.0/Warners]; [0.5/100m, 0.75/longJump, 0.5/shotPut, 0.5/highJump, 0.5/400m, 0.75/110mHurdl, 0.25/discusThrow, 0.25/poleVault, 0.25/javekinThrow, 0.5/1500m] **2:** [1.0/Sebrle, 1.0/Clay, 1.0/Karpov, 1.0/Macey, 0.75/Warners]; [0.5/100m, 0.5/longJump, 0.75/shotPut, 0.75/highJump, 0.5/400m, 0.5/110mHurdl, 0.5/discusThrow, 0.25/poleVault, 0.25/javekinThrow, 0.5/1500m] **3:** [1.0/Sebrle, 0.75/Clay, 1.0/Karpov, 1.0/Macey, 1.0/Warners]; [0.5/100m, 0.5/longJump, 0.5/shotPut, 0.5/highJump, 0.75/400m, 0.5/110mHurdl, 0.25/discusThrow, 0.25/poleVault, 0.25/javekinThrow, 0.75/1500m]
Bottom concept	31	31: [0.5/Sebrle, 0.5/Clay, 0.25/Karpov, 0.25/Macey, 0.25/Warners]; [1.0/100m, 1.0/longJump, 1.0/shotPut, 1.0/highJump, 1.0/400m, 1.0/110mHurdl, 1.0/discusThrow, 1.0/poleVault, 1.0/javekinThrow, 1.0/1500m]
Parents of Bottom Concept	30, 35, 55	30: [0.5/Sebrle, 0.5/Clay, 0.25/Karpov, 0.5/Macey, 0.25/Warners]; [1.0/100m, 1.0/longJump, 1.0/shotPut, 1.0/highJump, 1.0/400m, 1.0/110mHurdl, 1.0/discusThrow, 0.75/poleVault, 1.0/javekinThrow, 1.0/1500m] 35: [0.5/Sebrle, 0.5/Clay, 0.25/Karpov, 0.25/Macey, 0.5/Warners]; [1.0/100m, 1.0/longJump, 1.0/shotPut, 1.0/highJump, 1.0/400m, 1.0/110mHurdl, 0.75/discusThrow, 1.0/poleVault, 0.75/javekinThrow, 1.0/1500m] 55: [0.75/Sebrle, 0.5/Clay, 0.25/Karpov, 0.25/Macey, 0.25/Warners]; [0.75/100m, 1.0/longJump, 1.0/shotPut, 1.0/highJump, 1.0/400m, 1.0/110mHurdl, 1.0/discusThrow, 1.0/poleVault, 1.0/javekinThrow, 1.0/1500m]

Figure 5. Olympic Data Summary for Fuzzy Closure Approach.

approach the top concept 0 has an extent where each athlete fully belongs to the extent. Here performing $\uparrow$ on this extent produces the corresponding fuzzy intent. Each event's membership degree in the intent indicates the truth degree that the event is shared by all athletes in the extent.

Similarly, the bottom concept 0 (also the same as the top) for the threshold approach agrees with the bottom concept 31 for the fuzzy closure approach with respect to the athletes in the extent and the events in the intent. However, in this case the membership degrees also match as seen for the simple fuzzy formal context given in Fig. 1. As pointed out in the fuzzy closure algorithm the greatest fixpoint of C is the set Y which is the intent of the bottom concept, i.e. all events. All membership degrees for the events are 1.0 so that performing $B\downarrow$ on this intent Y simply reduces to using (3) with the Lukasiewicz implication operator in (5).

Fig. 5 also shows the children fuzzy concepts of the top concept 0, that is fuzzy concepts 1, 2, and 3 and the parent fuzzy concepts of the bottom concept 31, that is, fuzzy concepts 30, 35, and 55. For the children of the top concept, notice that each child has one or more athletes in the extent whose memberships is decreased by 0.25 from the extent of

the top concept and one or more events in the intent that are increased by 0.25 from the intent of the top concept. For example, fuzzy concept 3 has Clay's membership decreased by 0.25 in the fuzzy extent and has the 400m and the 1500 memberships increased by 0.25 in the fuzzy intent. For the parents of the bottom concept, each parent has one or more athletes in the extent whose memberships is increased by 0.25 and one or more events in the intent that are decreased by 0.25. For example, fuzzy concept 30 has Macy's membership increased by 0.25 in the fuzzy extent and has the pole vault membership decreased by 0.25 in the fuzzy intent. From this example, one can see that the fuzzy closure operator approach generates a vast number of fuzzy concepts, many of which are very close or similar to already existing fuzzy concepts.

B. Gene Annotation Data

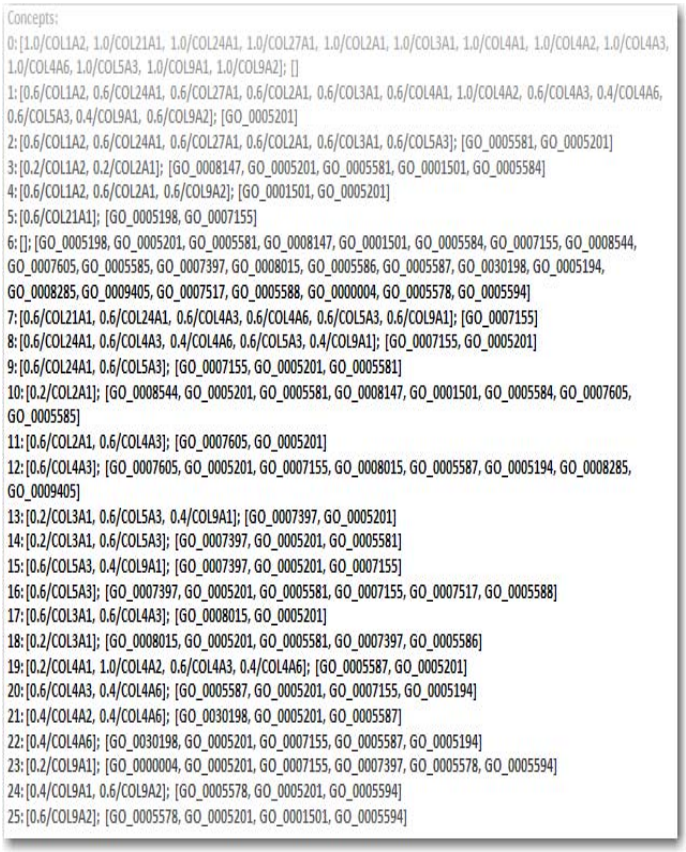
For all analysis, $\alpha \geq 0.2$ threshold is used. To illustrate and explain the similarities between the two approaches the collagen data set is selected. Fig. 6 shows the concepts produced for this data set. The concept lattice hierarchy is not shown due to space limitations but is described here. The top concept 0 has child concept 1 whose extent shows that almost all genes (one is missing) can be described by GO_0005201 with at least the minimum evidence code of 0.2. The extent of concept 7, the other child concept of the top concept 0, shows six genes can all be described by GO_0007155. The bottom concept 6 has several parent concepts 5, 10, 12, 16, 18, 22, 23, and 25, each having one gene described by a set of several GO terms. Concepts 10 and 12 have the largest intents with 12 GO terms; the single gene in their extents is described by the greatest number of GO terms at the minimum evidence code or better.

Since 1160 concepts are produced using the fuzzy closure approach, the results are not presented, but the similarities between the two approaches are discussed. For the collagen data set fuzzy closure top concept 0 has an empty intent and an extent with every gene having a 1.0 membership degree. Similarly, the bottom concept has an empty extent and an intent with every GO term having a 1.0 membership degree. No GO term is shared by all genes and no gene is shared by all GO terms. This result is similar to that of the threshold approach.

The two children of the top concept are concepts 1 and 2 and given below.

1: [1.0/COL1A2, 0.8/COL21A1, 1.0/COL24A1, 1.0/COL27A1, 1.0/COL2A1, 1.0/COL3A1, 1.0/COL4A1, 1.0/COL4A2, 1.0/COL4A3, 1.0/COL4A6, 1.0/COL5A3, 1.0/COL9A1, 1.0/COL9A2]; [0.2/GO_0005201]
2: [0.8/COL1A2, 1.0/COL21A1, 1.0/COL24A1, 0.8/COL27A1, 0.8/COL2A1, 0.8/COL3A1, 0.8/COL4A1, 0.8/COL4A2, 1.0/COL4A3, 1.0/COL4A6, 1.0/COL5A3, 1.0/COL9A1, 0.8/COL9A2]; [0.2/GO_0007155]

They have the same two GO terms found for the two children concepts of the top concept in the threshold approach, concepts 1 and 7; however, they disagree in the membership degrees with a 0.2 membership for both GO_0005201 and GO_0007155. This degree represents the truth degree that the specified GO term is possessed by all genes in its respective intent. The genes in the extents differ between the two approaches. For the threshold concept 1, the missing gene is COL21A1. In Fig. 3, one can see that this gene is not annotated by this GO term GO_0005201. Looking at concept 1 in the fuzzy closure approach, one sees that COL21A has a 0.8 membership degree. Similarly, for threshold concept 7, there are 7 missing genes in the extent that can be found with a 0.8 membership degree in the extent of concept 2 for the fuzzy closure approach. A similar analysis occurs for all the other gene data sets when comparing the threshold approach to the fuzzy closure approach. The top and bottom concepts agree with respect to the genes in the extent and the GO terms in the intent. They may have different membership degrees.



Concepts:
0: [1.0/COL1A2, 1.0/COL21A1, 1.0/COL24A1, 1.0/COL27A1, 1.0/COL2A1, 1.0/COL3A1, 1.0/COL4A1, 1.0/COL4A2, 1.0/COL4A3, 1.0/COL4A6, 1.0/COL5A3, 1.0/COL9A1, 1.0/COL9A2]; []

Figure 6. Collagen data threshold approach with $\alpha \geq 0.2$.

Fig. 7 compares the approaches. Column 1 gives the test data set. Columns 2 and 3 gives the number of concepts produced by the respective approaches. Column 4 gives the number of α-cut concepts exactly matching a fuzzy closure concept. For this column, the extent of the α-cut concept must agree with that of the fuzzy closure concept both with respect to the set of objects and their membership degrees. The intent of the α-cut concept, however, only has to agree with the set of attributes in the intent of the fuzzy closure concept since the α-cut intents assume degree of 1.0 for each attribute. Column 5 gives the number of concepts from the fuzzy closure approach that match an α-cut concept ignoring the membership degrees. Column 6 gives the number of concepts in the threshold approach having exactly the same extent including matching degrees. Column 7 gives the number of extents from the fuzzy closure approach that match to an α-cut extent, ignoring the membership degrees.

Column 8 gives the number of intents from the fuzzy closure approach that match to an α-cut intent, ignoring the membership degrees.

Test Cases	# concepts		#concepts exact matches	# concepts matches	# extent exact matches	# extent matches	# intent matches
	Alpha-cut	Fuzzy Closure					
x-object, y-attribute	2(0.5)	10	1	6	2	10	10
Olympic	1(0.25)	128	1	128	1	128	128
Collagen	26(0.2	1160	2	12	26	1160	1160
Myotubularin	13(0.2)	470	1	5	13	470	470
Receptor	17(0.2)	913	1	19	17	913	913
Combined gene	62(0.2)	3495	4	30	62	3495	3495

Figure 7. Summary comparing threshold to fuzzy closure approach.

Both column 3 and 7 have identical values. That is, each extent produced by threshold approach maps exactly to an extent in one of the concepts produced by the fuzzy closure approach. The conclusion is that extents produced by the threshold approach are a subset of the extents produced by the fuzzy closure approach. Secondly, the numbers in column 7 and column 8 are identical to that of column 3. Ignoring degrees, the extents produced by the closure approach result in the same set of extents produced by the threshold approach. A large number of extents produced by the closure approach are identical in the set of objects they contain. For example, for the 1160 extents of the collagen data, 26 sets of objects are unique and repeatedly used with varying membership degrees and similarly, for the intents of the collagen data. These test cases show that the fuzzy closure operator approach generates a vast number of fuzzy concepts, many of which are very close or similar to already existing fuzzy concepts within the lattice. Threshold approach using the smallest membership degree in the fuzzy formal context as the α-cut value is much simpler and produces all the extent sets and intent sets of the fuzzy closure approach ignoring membership degrees. The fuzzy closure approach provides additional information with respect to the intents membership degrees. Examining such large fuzzy concept lattices to uncover information hidden in the fuzzy formal context, would be very challenging.

VI. Conclusions and Future Work

The threshold approach and the fuzzy closure approach to creating fuzzy concept lattices from a fuzzy formal context have been implemented and verified using examples provided in [11]. GO annotation data files have also been used to experiment on larger fuzzy formal contexts. The two approaches have been compared using these data sets. The fuzzy closure approach produces an explosion in the number of fuzzy concepts compared to the threshold approach. The extents produced by the threshold approach are a subset of those produced by the fuzzy closure approach. Currently, the recommended factor analysis method [11] is being implemented to identify the significant fuzzy concepts from a fuzzy formal context. Different implication operators are currently being tested for the closure operator to compare the differences in the resulting lattices. Future plans are to apply this software to other real world application data to validate and enhance its usability.

***Abstract*—The Internet becomes an enormous source of information containing billions of documents. Users deal with an overwhelming number of alternatives, and continuously make decisions anytime they want to obtain meaningful information.**

The paper describes an approach for a simple yet effective selection of the most suitable information that fits user's needs. The novelty of the approach is twofold: the concept of lexicographical-like preferences used for a multi-criteria decision-making with elements of fuzziness and OWA operator; a simple fuzzy number based mechanism for estimating user's degrees of acceptance of criterion satisfaction. The lexicographic preferences allow for mimicking user's attitude that some criteria should be satisfied before other criteria are considered. The acceptance of criterion satisfaction levels are defined with a single threshold that represents a boundary value between acceptable and unacceptable values of attributes of alternatives.

The paper includes results of a simple case study preformed on a prototype of a web selection system built using the proposed approach.

Keywords-component; multi-criteria decision-making, fuzziness, lexicographic preferences, degrees of acceptance, satisfaction levels, OWA operator

I. INTRODUCTION

The Internet is a multi-user, multi-source information repository with billions of documents and millions of users. In order to transform the Web into a user-friendly environment where everyone can easily and precisely find suitable things there is a need for tools and systems that support users in coping with constant inflow of information and selection of the most suitable things they are looking for, e.g., books, hotels, or movies. In many cases, users' search is limited to a few or several alternatives – more extensive search leads to more time spent on browsing the web.

Up to date, a variety of systems – called recommender systems – supporting users in their selection activities have been proposed. The most popular ones apply the concept of collaboration filtering. This selection mechanism provides suggestions to the user based on selections made by users that are similar in their selecting/purchasing patterns with the user under consideration. These types of systems work pretty well for simple items. However, in more complex situations – more sophisticated requirements and more complicated items – these systems are not very effective. In order to address that issue, knowledge-based systems has been proposed. They use knowledge about a user. The suggestions they provide are derived using different decision making mechanisms based on users' direct input [1]. They build users' models and apply aggregation techniques, examples of some of them can be found in [2] and [3]. In many cases, these are complex and computationally intense approaches.

In this paper, we present a new approach of making suitable selection among all alternatives obtained from the web. The process takes into consideration multiple requirements that could be associated with different levels of importance. Additionally, the process of evaluating alternatives requires minimal input from the user representing user's estimation of usability of a given alternative.

The novelty of the proposed method is based on the application of a very simple yet effective method of ranking user's criteria. It uses the idea of a lexicographical (hierarchical) ordering. This ordering combined with a basic fuzzy operation is used for calculating values of weights required for an OWA-based aggregation of degrees of acceptance of criteria satisfaction levels. Our intention is to mimic the human method of making selections when some criteria dominate other criteria. In such case, levels of satisfaction of higher ranked criteria have influence on the ability of lower ranked criteria to contribute to the final decision. This influence is controlled by a t-norm operation.

As mentioned above, the presented approach for supporting selection processes relies on just a few pieces of information about the user. The user needs to identify her criteria of interest, provide ranking of those criteria, and give a basic information – in a form of single values – required for construction of fuzzy numbers representing user's levels of acceptance of criteria satisfaction levels.

This novel approach has been used to build a prototype system called *Personal Evaluation Tool* (*PET*).

II. SELECTION AND DECISION-MAKING PROCESS

A. Systems Supporting Human Activities on the Web

It is quite common to use the web for finding information, buying different items, making travel arrangements, and looking for different sorts of entertainment. A process of

finding suitable items translates into a process of identifying the best-fitted alternative among a set of responses the web provides as the result of user's request. In a nutshell, the purpose of systems performing such duties – called recommender systems – [4] is quite simple: they suppose to find an alternative – a product, a service, or a piece of information – that fits user's interests. Such systems can be applied in a variety of activities, from online shopping to service selection.

There are multiple ways how the most suitable item or service response can be recognized. It can be done based on 1) finding similarities between users based on ratings of different alternatives/items provided by them using so called collaborative filtering systems [5], or 2) identifying similarities between alternatives and products that users have already bought, used, or liked – content-based recommender systems [6]. Some of the most popular similarity measures used for recommendation purposes are cosine similarity, naive Bayesian (NB) classifier, and Pearson correlation. Research activities in the area of recommender systems have led to many different variations of both types of those systems.

A need for more tuned and personalized recommendations have resulted in a new set of selection techniques focusing on matching user's needs and preferences to a set of available alternatives [1]. Systems that consider user's information – such as their preferences and satisfaction levels, belong to the category of knowledge-based recommender systems [7]. Those systems can learn a profile of user's interests implicitly based on attributes of alternatives rated by a user in the past [6], or explicitly gaining this information from a user [8].

A successful selection of the most suitable alternative depends on modeling of user's preferences. The preferences represent user's expectations and requirements set against the most desirable alternative, i.e., the alternative that satisfies user's demands to the highest degree. In the case of constructing a user's model (preferences and needs) a number of techniques have been investigated: a causality-driven user's model representing more domain-relevant aspects of the selection process [3], incomplete preference relations [9], question-based dialogue [10], dialogue-wise techniques based on a finite state model [11], and cross recommender mediation [12] to name a few.

B. Multi-criteria Decision Making in Web Applications

The problem of identifying the most suitable alternative in the presence of user's needs is also addressed by algorithms and techniques originated in the domain of multi-criteria decision-making. The topic of finding a best alternative has already drawn a lot of attention for many years [13]. In a nutshell, a selection process of multi-criteria decision-making consists of evaluating each alternative based on multiple measures, comparing obtained evaluations, and selecting an alternative with the best (usually the highest) evaluation value.

Elicitation of preferences is not a trivial process and may cause problems in obtaining a true reflection of user's needs. In some decision-making approaches, a user provides preferences inspecting directly all possible alternatives. Other techniques, such as verbal decision analysis and its variations, have been proposed. Once user's preferences are known, a multi-criteria decision-making system has to induce a final selection. Many approaches identifying a final selection, such as the ones based on the concepts of Utility Theory, Analytic Hierarchy, and outranking approach, assume that a user provides preferences without any imprecision.

Another representation of user's needs is a set of criteria. Criteria represent principles by which a user would judge alternatives. A user specifies criteria as "constrains" imposed on the values of alternative attributes (an alternative is treated as a set of attributes. The values assigned to attributes constitute an "instance" of alternative). Based on comparison of a single criterion with an attribute value, a criterion evaluation value is generated. That value reflects how well a given criterion is satisfied by a given alternative. This process is performed for each criterion-attribute pair. A single alternative "generates" a number of criterion evaluation values (one for each criterion). These values have to be combined to obtain a final evaluation value of alternative. This step is called an aggregation of evaluation results. A number of possible aggregation operators can be applied here. Some of most popular ones are [2]:

- ordered weighted aggregation (OWA) operator [14];
- quasi-arithmetic means (different variations such as: quasi-linear means, weighted root-power mean, weighted harmonic mean, and weighted arithmetic mean);
- weighted median, and Sugeno interval.

Most of the above methods require weights. However, a process of identifying values of weights for aggregation calculations is not easy. Techniques dedicated to elicitation of weights involve asking a decision maker to answer simple questions about relative importance of criteria, analyzing these responses, and estimating 'true' weights. The weights used for OWA, and quasi-arithmetic means are calculated using criteria and regular non-decreasing quantifiers. For weighted median and Sugeno interval, weight values are obtained via a "try and error" approach process of satisfying user's criteria.

C. Lexicographical Rules

As mentioned above, once a given alternative is evaluated against each criterion, the results are aggregated and a single value representing goodness of this alternative is obtained. These processes are built based on diverse multi-criteria decision-making approaches suitable for aggregating multiple values [15]. The very captivating issue here is to perform such aggregation in a human-like way [16].

Mimicking a human decision-making process has been a subject of research activities for many years. One of the most popular techniques that fits a description of a human-like method and is applied for aggregation purposes are lexicographical rules [17, 18].

The lexicographical-based comparison of two alternatives is straightforward: it relays on a simple idea of comparing alternatives using one criterion at a time. The criteria are sorted based on their priorities, and a comparison sequence starts with a criterion of the highest priority. The choice between two alternatives A1 and A2 is made if the first criterion can identify a better alternative, if not, the second

criterion is used, and so on. If none criterion can do it, a random selection is applied. The method has been already applied in a number of different applications required simple, yet human-like decision making processes [19, 20].

The "popularity" of lexicographical decision-making rules has been also confirmed by studies in different application areas: for brand quality allocation, for estimating vales of rural landscape attributes, or for management decision-making in petroleum refinery industry for distribution of oil to the various depots in a form of lexicographic goal programming (LGP) model.

D. OWA and Linguistic Quantifiers

Aggregation of different pieces of information is a common aspect of any system that has to infer a single outcome from multiple facts. A very interesting class of aggression operators is called Ordered Weighted Averaging (OWA) [21]. In the simplest possible statement, this operator is a weighted sum over ordered pieces of information. In a formal representation, the operator, defined on the unit interval I and having dimension n, is a mapping $F_W : I^n \to I$ such that:

$$F_W(a_1,\ldots,a_n) = \sum_{j=1}^{n}(w_j \cdot b_j) \quad (1)$$

where b_j is the jth largest of all arguments $a_1, a_2, \ldots, a_n$, and w_j is a weight such that w_j is in [0,1] and $\sum_{j=1}^{n} w_j = 1$.

In the mid-nineties, Yager showed that a linguistic quantifier could be used to obtain weights associated with an OWA aggregation. He has introduced parameterized families of the Regular Increasing Monotone (RIM) quantifiers [22]. These quantifiers are able to guide aggregation procedures by verbally expressed concepts in a description independent dimension. A RIM quantifier is a fuzzy subset Q over $I=[0,1]$ in which for any proportion $r \in I$, $Q(r)$ indicates the degree to which r satisfies the concept indicated by the quantifier Q [22]. A fuzzy subset Q represents a RIM quantifier if: $Q(0)=0$, $Q(1)=1$, and *if* $r1 > r2$ *then* $Q(r1)>Q(r2)$.

Assuming a RIM quantifier, we can associate with Q an OWA weights such that for $j=1$ to n,

$$w_j = Q(\frac{j}{n}) - Q(\frac{j-1}{n}) \quad (2)$$

where n is a number of pieces of information to be aggregated. Using this expression the values of weights can be obtained directly from the expression representing the quantifier.

For example, let us take a look at the parameterized family $Q(r) = r^p$, where $p \in [0,\infty)$. Here if $p=0$, $w_1=1$ and $w_j=0$ for $j \neq 1$, we obtain the *existential (MAX)* quantifier, which makes the OWA operator F closer to an "or" operator; when $p \to \infty$, $w_n=1$ and $w_j=0$ for $j \neq n$, we have the quantifier *ALL (MIN)*, which makes the OWA operator F closer to an "and" operator; and when $p=1$ we have $Q(r)=r$, $w_j=1/n$ and we deal with the quantifier *SOME*.

The OWA aggregation has been used in multiple different applications including web-based information retrieval [23].

III. Fuzzy-based Selection Process: Human-Centric Aspects

There is a genuine need for tools and systems that are capable of supporting individual users in their unique way of exploring and utilizing information and services available on the Web. These systems should be able to mimic human selection processes in finding a single alternative that "fits" users' needs when multiple alternatives are available.

The most important challenges encountered by those systems are the abilities to perform multi-criteria decision-making that replicates user's selection behavior, and to elicit user's criterion satisfaction and acceptance levels in an easy and simple way.

In real life, selections performed by people can be quite complex. They can involve decisive factors influencing evaluation of each alternative. Alternatives can be evaluated using multiple criteria, and different strategies can be used to identify the most suitable alternatives. A truly human-friendly system has to deal with multi-criteria evaluation of alternatives, and be able to handle criteria with differing importance levels. We will look at features of such a human-friendly system from the following aspects: importance of criteria, acceptance of criterion satisfaction levels, and aggregation procedure.

A. Criteria Ranking

It is clear that utilization of multiple criteria does not mean that all criteria are equally important. Some of them can be critical, while some of them can represent requirements that are not essential – kind of 'good to have" requirements. As discussed in [14] user's behavior can be summarized in the following way: if the higher priority criteria are not satisfied it is irrelevant if lower priority criteria are satisfied or not. That attitude can be also observed in many other situations related to Internet activities. Thus a user needs a certain degree of satisfaction to their higher priority criteria before allowing some compensation by lower priority criteria.

Such approach for evaluating alternatives can be implemented when a user provides a ranking of his/her criteria. This ranking defines an ordering in which evaluations are aggregated, and how evaluation values of different criteria contribute to the evaluation value of a given alternative [14].

B. Acceptance (Process) Levels

A ranking list of available alternatives should reflect the user's degree of acceptance of these alternatives. An acceptance level for each alternative is estimated based on how well this alternative satisfies user's criteria, i.e., what is the acceptance level associated with each criterion, and how these levels can be aggregated. In order to evaluate an alternative based on a criterion, the user has to identify how different values of alternative's attribute related to this criterion satisfy his/her needs. In other words, the user has to provide some information allowing us to estimate up to what degree he/she is able to accept a particular value of an attribute. This information is applied to construct fuzzy numbers that are used for this estimation process.

An important objective of the proposed approach is to keep the process of elicitation of information required for determination of criterion acceptance levels as simple as possible. Since it is much easier for humans to provide values of directly observable attributes as opposed to introspective satisfaction levels of criteria, we have tried as much as possible to make use of values of attributes to determine the alternative's level of acceptance. The user provides only single threshold values for attributes associated with criteria. Once those thresholds are known, the system is able to generate acceptance levels directly from the values of attributes associated with given criteria.

In the approach proposed, the user is informed about minimum and maximum values of an attribute, and has to specify a threshold value within this range. It is explained to the user that the threshold is the attribute value at which he/she feels the full acceptance begins to deteriorate. More specifically, for a criterion whose acceptance level increases with bigger values of the attribute value its threshold can be described as "the smallest value of the attribute" which gives full acceptance (Fig. 1(a)). For those, such as cost, in which acceptance decreases with bigger values of the attribute value the threshold can be explained as "the biggest value of the attribute" which gives the full acceptance (Fig. 1(b)). In Fig. 1 we illustrate constructed fuzzy numbers used to transform attribute values into criterion acceptance levels. This figure represents two plots of criterion acceptance degrees – we will call them acceptance fuzzy numbers. As it can be seen, the acceptance levels below the threshold (Fig. 1(a)) are equal to *max_level* (usually 1.0), while the values above the threshold are monotonically decreasing. The decrease represents user's changes in criterion acceptance degree when the values of attribute become larger than the threshold. The maximum attribute value is associated with a small, non-zero value – *min_level*. Equivalently the same concept is applied when the desired attribute values should be larger – closer to the maximum (Fig. 1(b)). More sophisticated fuzzy numbers can be used if we are willing elicit more introspective information from a user.

C. Lexicographical-based Aggregation Method: Concept

The process of evaluating or scoring a single alternative based on a set of criteria depends on combining the following pieces of information:

- degrees of acceptance of individual criteria;
- weights reflecting priorities assigned to criteria.

One of the simplest ways of aggregating multiple pieces of information in order to obtain a single score representing the acceptance level of an alternative is a weighted sum. The formula is:

$$Score = \sum_{i=1}^{no_of_attributes} criterion_weight_i * acceptance(attribute_i) \quad (3)$$

Each component of the sum is a product of an acceptance level that is the result of application of an acceptance fuzzy number to an i-th $attribute_i$ and a weight associated with the equivalent criterion i – $criterion_weight_i$. The weights have to be determined for each criterion. They should denote user's preferences and his/her objectives regarding contribution of acceptance levels of individual criteria to the overall score.

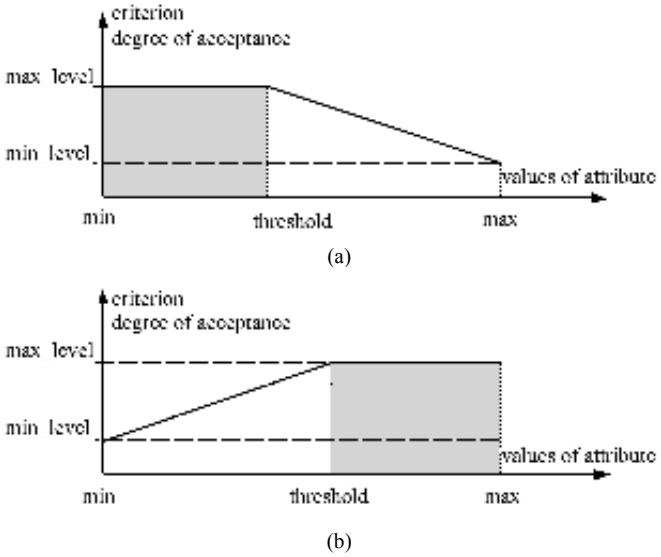

Fig. 1. Graphical representation of fuzzy numbers representing degree of acceptance for two scenarios: decreasing acceptance with increasing attribute value (a), and increasing acceptance with increasing attribute value (b).

The weights can be assigned in a universal way so they can be used in determining the scores for different alternatives. However, this universal assignment of weights independent of consideration of the alternative being evaluated is not always right. It is possible that if the highest criterion is not fully satisfied, high acceptance levels of low priority criteria can bring the *score* to the level that is higher then the *score* of another alternative satisfying the highest priority criterion but not satisfying low priority criteria. In such a case, a selection mechanism would indicate an alternative with low satisfaction of highest priority criteria as a winner.

Here we shall use a procedure, proposed in [14], for determining the criterion weights that avoids this problem. The weights are calculated via a unique combination of the criteria ranking and criterion acceptance levels. This leads to a schema that is very similar to lexicographic preferences. The criteria weights for a given alternative are calculated based on to the following formula where the term $acceptance(attribute_k)$ represents the level of acceptance of the *k-th* criteria for the alternative being scored

$$criterion_weight_i = \prod_{k=1}^{i-1} acceptance(attribute_k) \quad (4)$$

for $i=2, \ldots, n$, where n is a number of criteria, while **T** is a t-norm. It can be observed that the weight of i criterion depends on the acceptance levels obtained for all $i-1$ criteria that have a higher priority than i attribute (The indexing of criteria is equivalent to a hierarchy of criteria). For $i=1$ (the first criterion of the highest priority), its *criterion_weight* is equal to 1.0. Such approach prevents cases where lower priority

criteria can contribute to the overall evaluation value so much that this alternative is more "attractive" than an alternative with higher acceptance of high priority criteria but lower acceptance of low priority criteria.

The degree of contribution of the higher priority criteria on the weight of lower priority criteria is "controlled" by the type of applied t-norm (4). For the product t-norm, the weight of the attribute *i* is a product of acceptance levels of all criteria that have higher priority levels. It means that each criterion of lower priority has lower or the same weight comparing with the weights of criteria of higher priority. For the min t-norm, the weight value is equal to the smallest acceptance level among all i-1 criteria. It means that the weights of all criteria with priorities lower then the criterion with the lowest acceptance have the same weight and potentially the same contribution to the overall score.

Please note that the criteria weights in this approach will be different for each alternative as they have different acceptance levels for the criteria.

IV. Lexicographic-based Aggregation in Multi-Criteria Decision-Making

The proposed method for determining an alternative's aggregated score can be used in situation in which there are ties between criteria with respect to their level of importance. This induces a grouping of criteria. In this case, there are several groups of criteria, and each group has different priority, while all criteria from the same group have the same priority.

Let us assume that there are *g* different groups (levels) of criteria. The criteria C_{11}, C_{12}, ..., C_{1i}, ..., C_{1n_1} belong to the group of the most important criteria, C_{21}, C_{22}, ..., C_{2i}, ..., C_{2n_2} belong to the second most important group, and C_{g1}, C_{g2}, ..., C_{gi}, ..., C_{gn_g} to the least important group *g*. In total, there are $n=n_1+n_2+\ldots+n_g$ criteria. In this case, the attributes of an alternative x_k are indexed in the following way: $x_{k,(11)}$, $x_{k,(12)}$, ..., $x_{k,(1i)}$, ..., $x_{m,(1n1)}$, ..., $x_{k,(21)}$, $x_{k,(22)}$, ..., $x_{k,(2i)}$, ..., $x_{m,(2n2)}$, ..., $x_{k,(g1)}$, $x_{k,(g2)}$, ..., $x_{k,(gi)}$, ..., $x_{m,(gng)}$ (the indexes in the brackets represents indexes of attributes, and they are equal to the indexes of equivalent criteria).

Let $C_{ij}(x_{k,(ij)})$ represents a value of criteria C_{ij} for an attribute *j* in the group priority *i* of an alternative x_k. In the case of priority groups the aggregation process obeys the following formula:

$$Score(x_k) = \sum_{i=1}^{g} \sum_{j=1}^{n_i} w_{ij} C_{ij}(x_{k(ij)}) \tag{5}$$

The values of weights w_{ij} are obtained using the following procedure. Let S_i represents an acceptance value obtained for an alternative x_k based on the criteria from a priority group *i*. S_i can be calculated using the OWA operator. In such case:

$$S_i(x_k) = OWA\{C_{i1}(x_{k,(i1)}), C_{i2}(x_{k,(i2)}), \ldots, C_{in_i}(x_{k,(in_i)})\} \tag{6}$$

Different linguistic quantifiers can be combined with OWA (Section II.D). The quantifiers can represent different ways of user's needs imposed on the group criteria. One of them is *ALL* – all criteria in the group should be satisfied, and *SOME* – some criteria have to be satisfied in order to treat the criteria group as satisfied. Those quantifiers represent different "personalities" of users – *ALL* represents users more demanding and strict in their requirements, and *SOME* represents users who are willing to "forget" that all criteria in a group should be satisfied.

The values of S_i are calculated for each group and are directly used in calculations of pre-weights (7). The pre-weights for all criteria that belong to the same group are the same. In this case we talk about group pre-weights instead of individual criteria pre-weights.

$$\begin{aligned}
&u_{11} = u_{12} = u_{13} = \ldots = u_{1n_1} = 1 \\
&u_{21} = u_{22} = u_{23} = \ldots = u_{2n_2} = S_1(x_k) \\
&u_{31} = u_{32} = u_{33} = \ldots = u_{3n_3} = \prod_{i=1}^{2} S_i(x_k) \\
&\ldots \\
&u_{g1} = u_{g2} = u_{g3} = \ldots = u_{gn_g} = \prod_{p=1}^{g} S_p(x_k)
\end{aligned} \tag{7}$$

To ensure that an alternative with a full acceptance of all criteria obtains an overall score of 1.0, the values of the weights are obtained by dividing the pre-weights by the total number of criteria. Here, the total number of criteria is:

$$T = \sum_{i=1}^{g} n_i$$

and then

$$w_{ij} = \frac{u_{ij}}{T}. \tag{8}$$

Assuming that

$$\begin{aligned}
&w_{11} = w_{12} = w_{13} = \ldots = w_{1n_1} = w_1 \\
&w_{21} = w_{22} = w_{23} = \ldots = w_{2n_2} = w_2 \\
&w_{31} = w_{32} = w_{33} = \ldots = w_{3n_3} = w_3 \\
&\ldots \\
&w_{g1} = w_{g2} = w_{g3} = \ldots = w_{gn_g} = w_g
\end{aligned}$$

a new form of the equation (5) is:

$$Score(x_k) = \sum_{i=1}^{g} w_i \sum_{j=1}^{n_i} C_{ij}(x_{k(ij)}) \tag{9}$$

V. A Simple Web-based PET Architecture

The proposed lexicographical-based approach supporting user's selections process is a pivotal element of a *Personal Evaluation Tool* (*PET*). The *PET* is a simple web-based system that allows its users to input information about priorities of criteria and values of parameters needed for defining satisfaction level functions. As the result, the *PET* provides users with ranked – based on data entered by users – alternatives. The architecture of the *PET* is presented in Fig. 2. The *PET* consists of three execution components:

Web Interaction Unit: It is a simple unit that initiates a service processing activity based on a query provided by the user. Based on this query – received from the Browser-based User Interaction Unit – the unit performs a simple keyword-based web search. The result of that search – a set of responses matching the query keywords – is provided to the Selection Unit. Each response represents an alternative that is compared against users preferences and levels of acceptance.

Selection Unit: It is a "brain" of the *PET*. This is the place where each alternative is evaluated using acceptance fuzzy numbers. This process is a full implementation of the approach described in Section IV.

Browser-based User Interaction Unit: In order to utilize the presented priority-based approach, a web-based user interface has been developed. It allows a user to rank criteria, and enter her information about different criteria satisfaction levels.

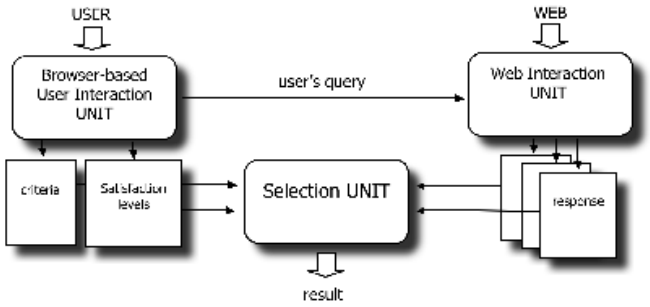

Fig. 2. Architecture of the Web-based *Personal Evaluation Tool* (*PET*)

The web-based interface has been developed for Hotel Reservation. The following criteria are identified:

- *room price*;
- *location* (here, we assume the distance from a hotel to the downtown);
- *access* (central reservation or not);
- *security* (personal safe, peephole, door chain);
- *services* (airport shuttle, room service, high speed internet, fax, photocopying, laundry/dry cleaning, lounge, bar);
- *tangibles* (family room, minibar, Jacuzzi, parking);
- *facilities* (printer, swimming pool).

The user has to provide information regarding ranking and satisfaction levels for all criteria. Once, the user selects the Hotel Reservation service, he/she ranks all criteria. We allow the user to identify more than one criterion at the same level of importance. Only relevance of positions is taken into consideration.

For acceptance levels, a user navigates to the page that allows for entering pieces of necessary information. For the criteria: *room price* and *location* – the user is provided with sliders that can be moved to positions representing the border (threshold) between a full acceptance and decreasing acceptance level. For example, for the *room price* – the user is satisfied with the price up to $140 (the level of acceptance for any price below the threshold of $140 is 1.0), any *room price* above that value means a decreased acceptance level. For location acceptance, a distance up to 2 km is okay for the user, any larger distance means lower level of acceptance – the value of acceptance reaches 0.1 for the distance of 5 km.

There are also few "radio button" entries that allow the user to select choices related to *access, security, services*, *tangibles* and *facilities*. Several sub-criteria are defined for each of them. The options provided to the user are "should have" and "don't care". In this case the values of acceptance are binary – it equals *one* if an alternative hotel has that feature, or *zero* if it does not.

VI. Case Study

A. Overview

The proposed lexicographical-based approach for effective selection of the most suitable alternative in the context of a web search process is validated, as well as compared with another method. The validation process is performed via comparison of the results obtained from the prototype *PET* with a realistic human selection process. The comparison of *PET*'s results with another method is focused on finding similarities and differences between *PET*'s selections and selections provided by a simple lexicographic-based approach "*Take-The-Best*" (*TTB*).

Take-the-Best

Our motivation for selecting another lexicographical-based method, called *Take-the-Best*, is based on a simple fact that it works surprisingly well when compared to statistical benchmarks [24]. The method uses a very strict and simple lexicographical rule. Once alternatives are evaluated against each criterion they are being pair-wise compared. The choice between two alternatives A and B is made if the first criterion can identify a better alternative, if not, the second criterion is used, and so on. If none criterion can do it, a random selection is applied. This means that once we have knowledge about priorities of criteria we sort them and perform comparison using sorted criteria on one at a time basis.

Normalized Distance-based Performance Measure (NDPM)

NDPM was proposed by Yao [24]. He developed *NDPM* theoretically, using an approach from decision and measurement theory. *NDPM* can be used to compare two different weakly ordered rankings.

$$NDPM = \frac{2P^c + P^o}{2P^t} \tag{10}$$

P^c is the number of contradictory preference relations between the system ranking and the user ranking. A contradictory preference relation happens when the system says that item A will be preferred to item B, and the user ranking says the opposite. P^o is the number of compatible preference relations, where the user rates item A higher than item B, but the system ranking has item A and item B at equal preference levels. P^t is the total number of "preferred" relationships in the user's ranking (i.e. pairs of items rated by the user for which one is rated higher than the other). This metric is comparable among different datasets (it is normalized), because the numerator represents the distance, and the denominator represents the worst possible distance.

Let us assume that we have a user's ranking of items: *Ia, Ib, Ic, Id, If*. For five items the value of P^t is ten – there are ten different pairs of items. The value of *NDPM* is 0.0 when the ranking is compared with another identical ranking. If both rankings differ in one pair the value of *NDPM* is equal to 0.1, two different pairs lead to 0.2. If there are ten differences – it means that the other ranking is totally different: *If, Id, Ic, Ib, Ia* – the value of *NDPM* is 1.0.

B. Hotel Reservation Service

The case study illustrates a Hotel Reservation service. The experiment involves eleven users. The selection process for the most suitable hotel takes into accounts six different criteria: *room price*, *location* (we assumed that the point of interest for each user is a downtown, therefore the location represents a distance from a given hotel to the downtown), *access*, *security services*, *tangibles*, and *facilities*. Such criteria as *security*, *additional services, tangibles,* and *leisure facilities*, contain multiple sub-criteria.

The case study is performed with five different hotels. The detailed information about each hotel is presented in Table 1. Each of users has identified his/her priorities, and provided information needed for construction of acceptance fuzzy numbers. Following that, each user has ranked all five hotels based on all features (Table 1).

TABLE 1. HOTEL RESERVATION SERVICE ALTERNATIVES

		H1	H2	H3	H4	H5
Price (single room)		$249	$199	$129	$99	$159
Location (distance from downtown)		0.5km	2.3km	1.9km	3.5km	1.0km
Access	Central reservation	x	x	-	-	-
Security	Personal safe in room	x	-	-	-	x
	Peephole, door chain	-	-	x	x	x
Additional Services	Airport shuttle	x	x	-	-	-
	Room service	x	x	x	-	x
	High speed internet	x	x	x	-	-
	Fax, photocopying	x	x	-	-	x
	Laundry/dry cleaning	x	-	-	-	x
	Lounge/bar	x	x	x	x	x
Tangibles	Family room	-	-	-	-	x
	Minibar	x	x	x	-	x
	Jacuzzi	x	x	-	-	-
	Parking	-	x	-	x	-
Leisure Facilities	Children's leisure	-	-	-	-	x
	Swimming pool	x	x	-	-	-
	Golf course	x	-	-	-	-

The selection process based on the proposed lexicographical-based approach has a number of variations. Such elements as a t-norm or OWA linguistic quantifier should be determined. In the case of a t-norm our choice is the min t-norm. The reason for that is the close resemblance of the proposed approach with the min t-norm to the lexicographical one. Additional experiments about suitability of different types of t-norm have been left for later. For the selection of a linguistic quantifier required for determining the value of S_i (6) we investigate two quantifiers *ALL* and *SOME*. The results of this work are shown below.

PET vs. *Users (NDPM)*

Firstly, the evaluation of *PET* results is performed using *NDPM*. As it has been indicated earlier, the ranking of five items leads to ten different preferences pairs. In this case the value of *NDPM* of 0.1 means that the rankings differ in one preference pair. The *NDPM* values calculated for a pair of rankings – one ranking given by the user, and the other offered by *PET* based on priorities and criteria entered by this user – for all eleven users and two linguistic quantifiers ALL and SOME are shown in Table 2. On average the value of *NDPM* is 0.3 meaning that on average the *PET's* rankings have three pairs of preferences different from the rankings provided by the users. The smallest difference between the *PET* and the user rankings is observed for the **user_#5** for *ALL* and the **user_#1** and **user_#3** for *SOME*. In the case of **user_#5** the contradictory pair has been observed for positions 3 and 4 – the user's rank of hotels is: **H5**, **H3**, **H4**, **H1**, **H2** (from the most to the least suitable), while the *PET's* ranking is: **H5**, **H3**, **H1**, **H4**, **H2**. The biggest difference is observed for the **user_#7** (for both *ALL* and *SOME*) – in this case, there are six contradictory preferences. The user's ranking is: **H5**, **H3**, **H2**, **H1**, **H4**, while *PET's* is: **H1**, **H2**, **H5**, **H3**, **H4**. A short discussion with the user has led to the conclusion that the user is not consistent – the preferences and criteria (s)he has entered to the *PET* system are different then those (s)he has used to make the selection. As we can observe, there is a small difference – on average – between results for quantifiers *ALL* and *SOME*.

TABLE 2. *NDPM* VALUES FOR RECOMMENDATIONS OBTAINED FROM *PET* WHEN COMPARED WITH RANKINGS PROVIDED BY THE USERS

	value of NDPM	
	OWA: ALL	OWA: SOME
user #1	0.25	**0.10**
user #2	**0.25**	0.30
user #3	0.15	**0.10**
user #4	0.20	0.20
user #5	**0.10**	0.20
user #6	0.30	0.30
user #7	0.60	0.60
user #8	0.30	0.30
user #9	0.55	**0.50**
user #10	**0.30**	0.50
user #11	0.25	**0.20**
average	**0.30**	**0.30**

PET vs. *TTB (1st recommendation)*

The *TTB* method (the simplest possible lexicographical-based selection technique) can only recommend a single hotel. Therefore, the analysis of results is done by comparison of the *PET's* 1st recommendation with the suggestion provided by *TTB*. The linguistic quantifier used here is *ALL* – this quantifier "is closer" to the original lexicographical approach. The results for *PET* and *TTB* are presented in Table 3. We can see that *TTB* is correct in four cases only. Looking at the first

position of the ranking provided by the *PET*, the *PET* is correct six times.

The *PET* prototype provides ranking of all hotel alternatives. Therefore, we also compare the top-2 and top-3 "suggestions" given by *PET* with the user's first choice. For the top-2, the *PET* finds the user's top choice for ten users (Table 3). For the top-3 recommended hotels, the *PET* system is able to identify the user's first choice for all eleven individuals.

TABLE 3. RESULTS FOR HOTEL RESERVATION SERVICE OBTAINED FROM *PET* AND *TTB* WHEN COMPARED TO THE USER'S FIRST CHOICE

	# of correct	# of incorrect
TTB – first recommendation	4	7
PET – first recommendation	6	5
PET – first two recommendations	10	1
PET – first three recommendations	11	0

VII. CONCLUSIONS

Increased popularity of the Internet triggered interest in development of methods and techniques supporting users' search for relevant information and services. One of the most challenging requirements is the ability to mimic human way of making selections and recommendations.

The paper proposes a novel technique for selecting the most suitable alternative based on multiple criteria. The technique combines information about ranking of criteria with criterion levels of satisfaction and acceptance. A new algorithm that calculates the evaluation value of each alternative has been proposed and described. The algorithm uses the principle of weighted aggregation – it dynamically calculates weights following the idea of lexicographic preferences combined with fuzzy operations – t-norms – and the OWA operator. The weights are recalculated for each alternative, and their values depend on location of a given criterion in criteria hierarchy and how well the satisfaction of criteria are acceptable for the user. The criteria acceptance levels are estimated using a newly proposed and simple process of constructing fuzzy numbers based on a single parameter representing a boundary value between acceptable and unacceptable values of criterion.

A simple system – called *PET* – has been developed based on the proposed technique. The case study has been preformed to assess usability of the proposed method. It indicated a good correlation of the rankings deduced by the *PET* prototype with the rankings provided by the users. An important conclusion of the performed comparison is a need for tracking changes in users' criteria – mismatches are the consequence of users' inconsistency in their preferences. More experiments are planed for investigations focused on different types of t-norms and linguistic quantifiers.

***Abstract*— In SOM learning, learning result depends on initial value of feature map and the location of the node or the distance between nodes on feature map is important factor to determine feature of individual data. For example, in data detection of hematopoietic tumors, given data is detected by location of the feature map. In this paper, we forcused on visual stability of SOM feature map, and we proposed new initialization method of SOM feature map. The purposes of proposed method are improvement of visual stability of SOM feature map, and utilization of generalization ability of SOM. By experiments, proposed method is visually stable than conventional method in the point of feature map location, and the computational complexity of proposed method is greatly reduced.**

Keywords-component; self-organizing map; feature maps; visual stability; improvement method;

I. INTRODUCTION

Kohonen's Self Organizing Map (SOM) involves neural networks, for which an algorithm learns the feature of input data through unsupervised, competitive neighborhood learning. The SOM is applied in many fields and has been widely studied [4-7]. Based on the conventional SOM learning algorithm, SOM learning is influenced by the sequence of learning data and the initial feature map. The location of the node or the distance between nodes on feature map is important factor to determine feature of individual data.

In conventional method, initial value of feature map has set at random, so a different mapping appears even by same input data. Consequently, it can be said that it lacks visual stability. For example, in data detection of hematopoietic tumors, given data is detected by location of the feature map. If given data are near to the area of physically unimpaired person then the data consider to normal, and if the data are near to the area of tumors then the data consider to abnormal. As well as this example, in many applications the judgment is made by a person depending on a location on the feature map.

If the learning results are visually unstable, maps must become different impressions in each learning, and maps of different impressions could be increased to the same data in different diagnosis.

To solve this visually unstable problem, there are steadies, that euclidean distance of learning data is pre-calculated and vector of feature map permute based on the result of pre-calclate. Because it is necessary to compare distance of all vectors, however, the computational complexity becomes very high, and a lot of time will be spent in analysis of learning data. As a result, generalization ability of SOM is not fully utilized. Moreover, the method focused on high speed leaning, so, there are not enough discussion about visual stability.

In this paper, we focused on visual stability of SOM feature map, and we proposed new initialization method.

II. SELF-ORGANIZING MAP

Kohonen's self-organizing map (SOM) [1] involves of neural networks, that learn the features of input data through unsupervised, competitive neighborhood learning. The SOM is mapping from high to low dimensional space, usually as a two-dimensional (2D) map. It provides a feature map that arranges similar classes nearer to one another to visualize high-dimensional information in a 2D feature map. Map representation makes it easier to understand relations between data. (Fig.1)

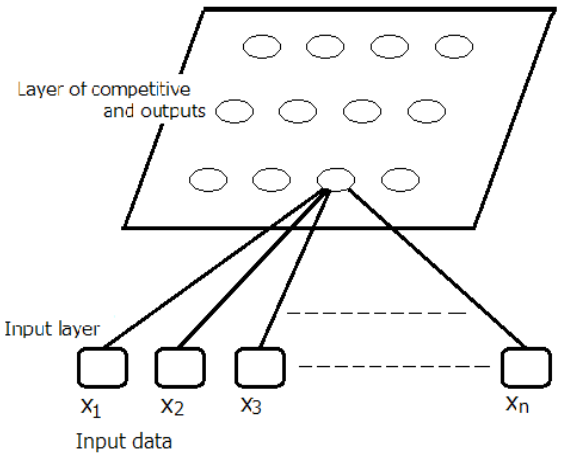

Figure 1. SOM overview

The SOM generally has two layers, an input layer and an output layer. Output layer nodes usually form a 2D grid and input layer nodes are fully connected with those at output layer nodes. Each connection has a connection weight, so all output layer nodes have patterns or vectors to be learned.

After learning, each node represents a group of individuals with similar features, the individual corresponding to the same node or to neighboring nodes. That is, the SOM configures output nodes into a topological representation of original data through a process called self-organization.

In learning process, when an input pattern or input vector is presented to the input layer as learning data, output layer nodes compete mutually for the right to be declared the winner. The winning node is the output layer node whose incoming connection weights are the closest to the input pattern in Euclidean distance. The connection weights of the winning node and its neighbor nodes are then adjusted, i.e., moved closer toward the input pattern.

As learning process progresses, the learning rate and the size of the neighbor area around the winning node decreases, so in an early stage of learning process, large numbers of output layer nodes are adjusted strongly and, in the final stage, the winning node alone is adjusted weakly.

III. Problem of Conventional Technology

A. Initial Value of Reference Vector

Vector of SOM's feature maps (reference vector) has been initializing by random number on conventional technology as described ahead. However, in learning process of SOM, simply initializing by random number has a big influence chiefly first learning. The example of possible problem in case of simply initializing it by random number is enumerated as follows.

First of all, there are large change of coordinates of winning node even if used same leaning data, because value of reference vector is selected by random number. In different learning, the location of winning node for the same leaning data is usually different, because initial vector is randomly set its values. The example is shown in figure 2.

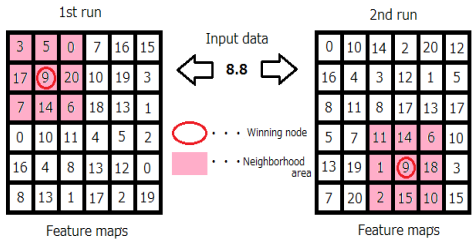

Figure 2. Difference of coordinates of winning node by random number

In the example, feature maps is 6×6, input data is 8.8, and neighborhood area is one surrounding space. Whenever winning node becomes completely random when value of reference vector is completely random like this. Vector surrounding winning node, i.e., vector in neighborhood area, also have random value, so, influence of learning is different in each leaning.

B. Data Pre-calculation Method

There are a method which initial value is calculated from input data. The method proposed by Mu-Chun Su [2] is enumerated as an example. (1) four vectors whose distance is the longest in input data are extracted. (2) it is allocated in the four corners of feature maps as weight. (3) data that is the furthest from both ends is allocated to opposite weight. (4) until all weights are assigned, this can be done clockwise repeatedly. As for the method of analyzing input data like this example and deciding initial value, the following problems are enumerated.

First of all, by this initialization method, learning data are analyzed their feature, so SOM leaning is used to miner adjustment. The purpose to use SOM is to analyze what kind of relations are exist in input data. The purpose might be lost by separately analyzing input data to decide initial value of reference vector.

Second, there is a problem that the computational complexity depends on the number of input data and number of dimensions. Therefore, a lot of procedures will be added before it learns by SOM.

Third, the method focused on high speed leaning, so, there are not enough discussion about visual stability.

C. Node Exchange Method

In the research of Miyoshi[3], they proposed initialization method that tried to utilize generalization ability of SOM. The method is to purpose at the speed-up study by improving the procedure of deciding initial value at random. This method relates input vector space to the position of feature maps in exchanging nodes of feature maps referring to learning data at initialization. The average moved distance of all nodes is shortened when this method is used, and the speed-up of the learning speed is confirmed.

In point of view that utilize generalization ability of SOM, this method has same purpose, however, the purpose to improve visual stability of output result is not discussed enough in the research.

IV. Proposed Method

The purposes of proposed method are (1) improvement of visual stability for output result, and (2) utilization of generalization ability of SOM. To achieve second purpose, renge of vector values are calculated from small number of learning data. And to achieve first pupose, reference vectors are sorted and allocated to give feature maps location tendency.

A. Range of Values

To reduce the complexity of learning, we try to limit the range of random values. To determine the range of values, randomly selected from a small number of learning data and approximate the maximum and minimum values for these data. Number of randomly selected data is determined by following formula:

$$n = \frac{N}{\left(\frac{E}{Z}\right)^2\left(\frac{N-1}{P(1-P)}\right)+1} \quad (1)$$

where, n is number of randomly selected data, N is a population, E is maximum error, Z is reliability coefficient, and P is population proportion. Using this formula, number of randomly selected data can be kept at a constant value.

Then the random numbers are provisionally allocated as initial value of reference vector. The advantage of this method is shown below. By this algorithm, it is possible to make the range of reference vector correspond to the range of learning data, and the calculation cost doesn't hang so much.

B. *Vector Sorting*

To give feature map location tendency, reference vector are sorted and allocated to feature map. First, the average of all dimentions value of each reference vector are calculated and, by using these averages as sorting key, reference vectors are sorted. Averages is caluclated by the following formula:

$$A = \left(m_{ij0} + m_{ij1} + m_{ij2} + \cdots + m_{ijk}\right)/k \quad (2)$$

where, A is average, m is reference vector, i is x axis of feature map, j is y axis of feature map, and k is value of dimention.

Then, vectors are allocated to feature map in sorting order. The image of sorting is shown in figure 3.

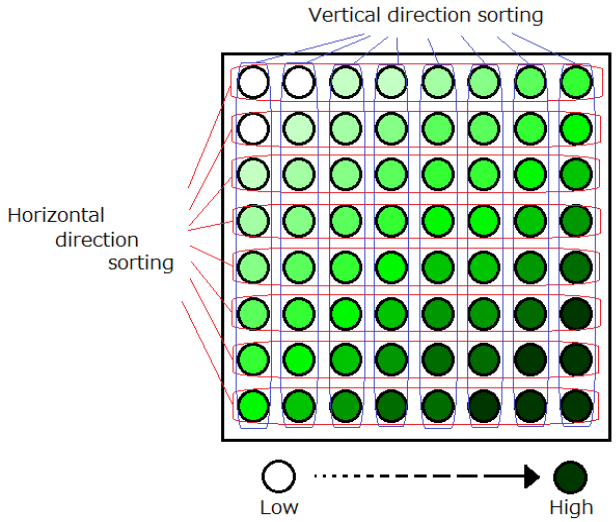

Figure 3. The image of sorting

As a result, the difference of winning node to same learning data is reduced. So, it is thought that output result is become steady.

C. *Algorithm of Feature Map Initialization*

Algorithm of Proposed Method is following.

- From the learning data, randomly select a value.
- From the selected value to determine the minimum and maximum values.
- random numbers are generated at the range of minimum and maximum values.
- Generated random number are temporarily assigned to the reference vector.
- To calculate the average value of the reference vectors.
- Based on the average, reference vector is done to quick sort in ascending order for the vertical direction feature map.
- Based on the average, reference vector is done to quick sort in ascending order for the horizontal direction feature map.
- Feature maps are made by this sorting, is initial value.

V. EXPERIMENTS FOR VISUAL STABILITY

To compare visual stability between conventional method and proposed method, we performed experiments. Conventional method is that of having initial value of reference vector by random numbers. The experiments are giving the same learning data to these two programs. In order to simplify the visual changes, bi-polarization data was used. The image of learning data is shown in figure 4.

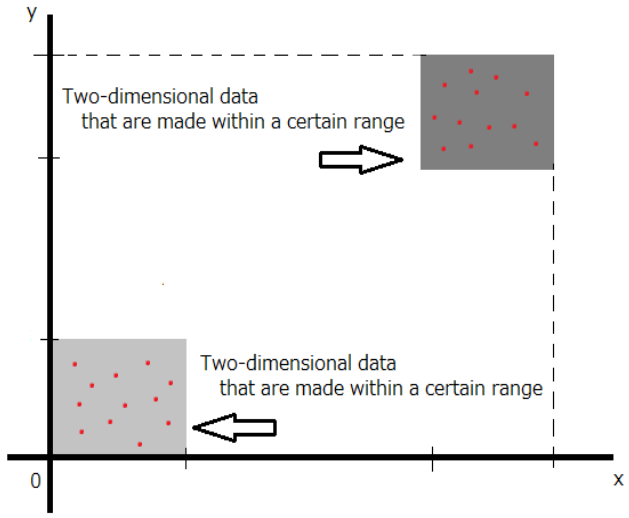

Figure 4. The image of learning data

Experiment parameters are followings. Learning data set is 3*200, feature maps size is 30*30 nodes, learning repetition is 4000 times, neighborhood area is 20 (it decreased from 20 to 1), and learning rate is 0.01*(neighborhood area size).

A. *Learning Results*

The experimental results is shown in figure 5. The left hand side are results of conventional method and, the right hand side are results of proposed method.

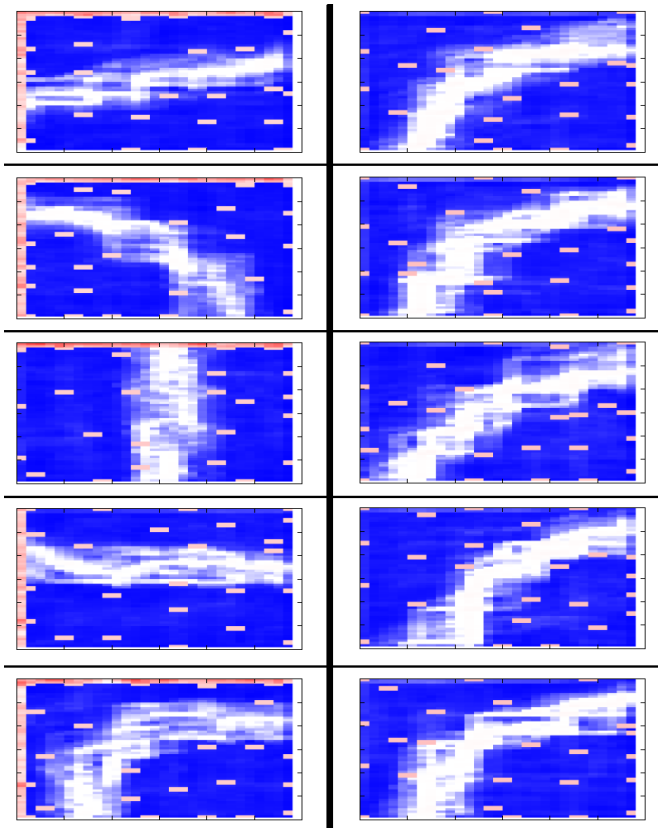

Figure 5. Output result of existing technology and proposal technique

According to the results of conventional method, visually different feature maps are generated at every single learning, even if leaning data is completely same. So, winning node of same input data is located in different part of each feature map. On the other hand, according to the results of proposed method, visually similar feature map are generated by same learning data. So, winning nodes of same input data are located in similar part of feature maps. The position of all input data showed similar tendency, typical winning nodes location are shows in figure 6.

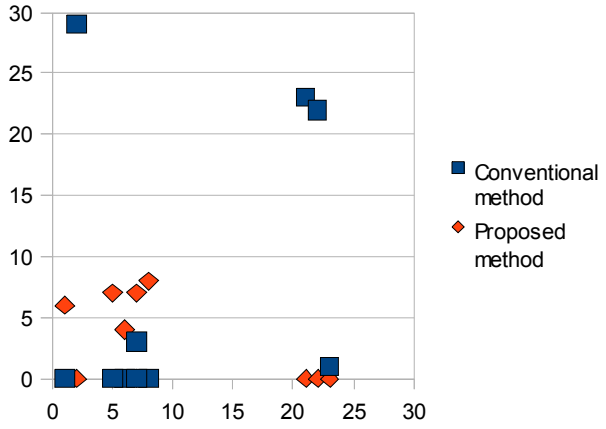

Figure 6. Feature map coordinates on a single input data

Figure 6 shows the location of winning nodes in five different feature maps for a single input data. X axis is x-coordinate and y axis is y-coordinate of feature map. According to Figure 6, winning node locations of conventional method are widely scattered even though input data is same. On the other hand, winning node locations of proposed method is almost unchanged corresponding to same input data.

The computational complexity of conventional method is estimated to $O(n!)$, and the one of proposed method is estimated to $O(n \log n)$. So, it can be said that the computational complexity of proposed method is greatly reduced.

VI. Conclusion

In this paper, we proposed new initialization method of SOM feature map. The purposes of proposed method are improvement of visual stability for output result, and utilization of generalization ability of SOM. The renge of reference vector values are calculated from maximum and minimum values approximated by randomly selected small number of learning data, and reference vectors are sorted and allocated to give location tendency in feature map.

By experiments, followings are revealed that, proposed method is visually stable than conventional method in the point of feature map location, the computational complexity of proposed method is greatly reduced.

As for further research, it is necessary to think about sorting method not related to number of dimensions. The average is sorting key in this time. However, sorting key to which stability of output result is kept even if the dimension increases is preferable. In addition, this study used a graph to show minutely the stability of the output information on input data. However, we need to think interface to output result more visually clear.

***Abstract*— We developed an idea support morphogenesis system that satisfies the designer's image and proposes the form with high mechanical rationality using a Genetic Algorithm. The image of an old system was input in two directions (X and Y). In the new system, the complex forms are created by the image input for three directions (X1, Y1, and Y2) or four directions (X1, X2, Y1, and Y2). The form is defined by control points of a spline curve. The form created by the image input is changed slightly by moving the control points. This system creates various forms by changing the moving quantities of control points and proposes Pareto solutions of "image" and "mechanical rationality." Based on the results, we analyze how the form is changed by differences in the moving quantities of control points.**

Keywords-component; Morphogenesis , Large-span roof , Evolutionary Computation , Designer's image

I. RESEARCH BACKGROUND

The performance of computers has been improving over time, and various system optimizations have been developed by evolutionary computing. [1].

In morphogenesis, there have been many studies of mechanical optimization for structural forms, but there have been few studies of morphogenesis taking into consideration the designer's esthetic sensibility and image. We developed an idea support morphogenesis system that satisfies the form design requirements and proposed the design with a high mechanical rationality using a genetic algorithm (GA). [2] [3].

However, the form design proposed by existing research is limited because of its symmetric form, and the proposed design does not provide a guarantee of satisfying the designer's form requirements.

To resolve these problems and to develop a more effective system, the following improvements were made in this study:

1) Enable the input of an asymmetric form design.
2) Propose Pareto solutions to a two-purpose optimization problem of "image satisfaction" and "equivalent stress," and develop a system by which the designer can specify the final form.
3) Obtain design knowledge related to morphological changes necessary to improve mechanical rationality.

II. OUTLINE OF THE EXISTING SYSTEM

The existing system is composed of an image input system and a rational valuation system.

In the image input system, the designer inputs his image by setting certain control points, and the system displays his image in 3D form.

In the rational valuation system, the control points input by the designer using the image input system are moved slightly, and mechanically excellent roof forms are generated using the GA. The GA can solve this optimization problem easily because genetic loci can easily express the amounts of change in the control points.

In particular, the control points of a spline curve expressing the form are moved slightly along the vertical direction using the 15 patterns listed in Table 1, thus, generating a new form. FEM analysis is performed for this new form, and the fitness of the GA is calculated as the mean value of the analyzed equivalent stresses for each element.

The GA is repeated until the specified generations by the designer and the form with minimum equivalent stress is proposed. The results of these analyses for a similar model of Ogunityoumin-taiikukan are shown in Fig. 1.

TABLE 1 Gene locus for changing pattern for the control points

0	0	0	0	−0.7 × α(m)	1	0	0	0	0.7 × α(m)
0	0	0	1	−0.6 × α(m)	1	0	0	1	0.6 × α(m)
0	0	1	0	−0.5 × α(m)	1	0	1	0	0.5 × α(m)
0	0	1	1	−0.4 × α(m)	1	0	1	1	0.4 × α(m)

0	1	1	0	−0.1 × α(m)	1	1	1	0	0.1 × α(m)
0	1	1	1	0m	1	1	1	1	0m

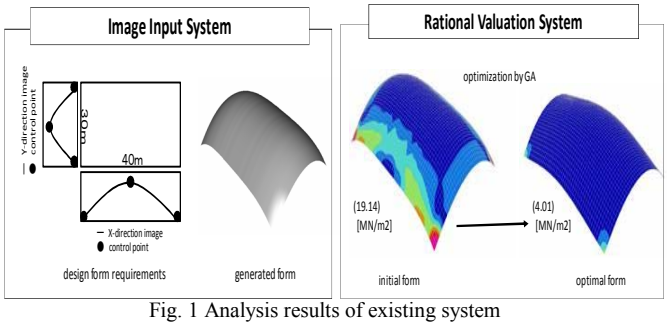

Fig. 1 Analysis results of existing system

III. OUTLINE OF THE NEW SYSTEM

In the existing system, the confronted two facades among the four outer facades are assumed to be the same facade. The designer inputs his image from two directions (X and Y). So, the existing system can create only symmetrical forms.

However, because the designer's proposed form may be asymmetric, the new system was improved to allow creation of asymmetric and complex forms by image input from three facades. The control point variation coefficient α is a variable that shows the amount of movement from the initial image.

In the existing system, the rational valuation system was implemented for the designated control point variation coefficient α by the designer. However, in this method, the obtained optimum solution is limited within that range. It is difficult to specify the control point variation coefficient α, and better optimum solutions may exist outside the designated α. Therefore, we developed a new system in which the rational valuation system was implemented using many control point variation coefficients without using the specified control point variation coefficient by the designer, and supposed the mechanically optimum form for each control point variation coefficient as the Pareto optimal solution of [Change of image] and [Equivalent stress].

The form that satisfies the requirements of both "image satisfaction" and "equivalent stress" is selected by the designer from all elite forms as the final form. The flow chart of the new system is shown in Fig. 2.

IV. APPLICATION EXAMPLE

To obtain design knowledge regarding the morphological changes in each control point variation coefficient, we created model-1, which has curvatures in one direction, and model-2, which has curvatures in two directions, using the image input system. The control points of these models were applied to the rational valuation system by 14 patterns of each control point variation coefficient α from 0.5 to 5.0, with an interval of 0.25. However, the control points of edges were not applied and were not moved. The planar shapes of both model-1 and model-2 are 40 m in the X direction and 30 m in the Y direction.

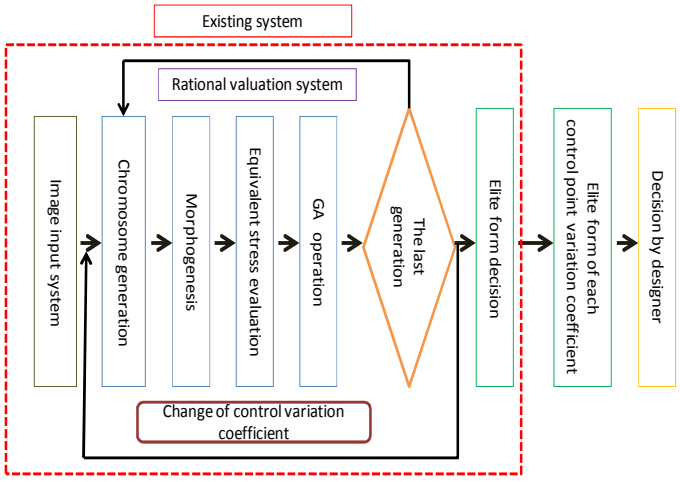

Fig. 2 Flow chart of new system

A. Outline of model-1

The characteristics of model-1 are as follows:

- Roof thickness of 0.15 m, load of 0.0036 MN/m^2 (only self-weight), modulus of elasticity of 20600 N/mm^2, and Poisson's ratio of 0.16.
- The parameters of the GA are as follows: The number of individuals is 40, the last generation is 50, the intersection method is a multi-point intersection method, the intersection rate is 100%, and the mutation rate is 5%.
- This model has three control points in the Y1 direction, three control points in the X direction, and five control points in the Y2 direction (Fig. 3).
- The edges are not moved because they are support points. The control points other than the edges are moved.
- This model has a single curvature in the X and Y1 directions, and multiple curvatures in the Y2 direction.
- The fitness of the GA is equal to the equivalent stress, which is calculated on the basis of the Mises yield criterion.

B. Execution results of model-1

Figure 4 shows the relationship between the control point variation coefficient α and the equivalent stress obtained from the analytical results. Figure 5 shows the elite forms of each control point variation coefficient. Figure 6 shows the relationship between the vertical coordinate values of the control points and the control point variation coefficient α.

The following points should be considered:

1) The equivalent stress converges when α exceeds 3.5 (Fig. 4), and the vertical coordinates of the control points (No. 8, 9, and 10 in the Y2 direction) with multiple curvatures become almost equal. This shows that mechanical rationality tends to increase when a curved surface with multiple curvatures is transformed to a curved surface with a single curvature.
2) Control point No. 2 in the Y1 direction and control point No. 5 in the X direction, each of which has a single curvature, tended to move in the direction in which the rise ratio increased.

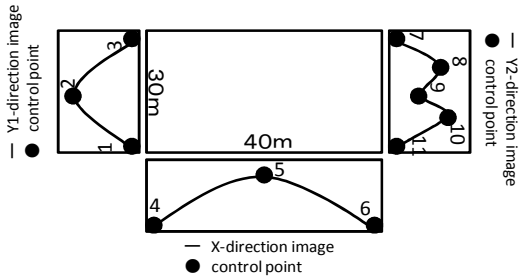

Fig. 3 Control points of model-1

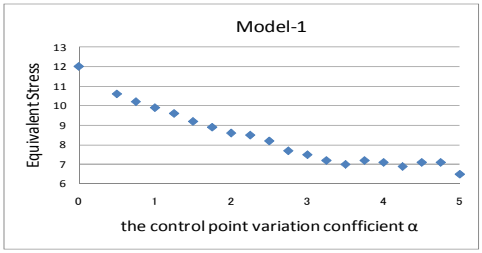

Fig. 4 Relation of equivalent stress and the control point variation coefficient α

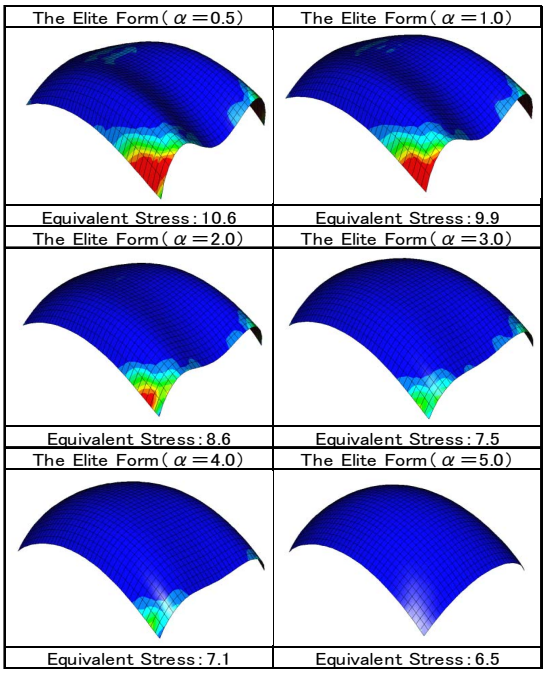

Fig. 5 Elite forms per the control point variation coefficient α

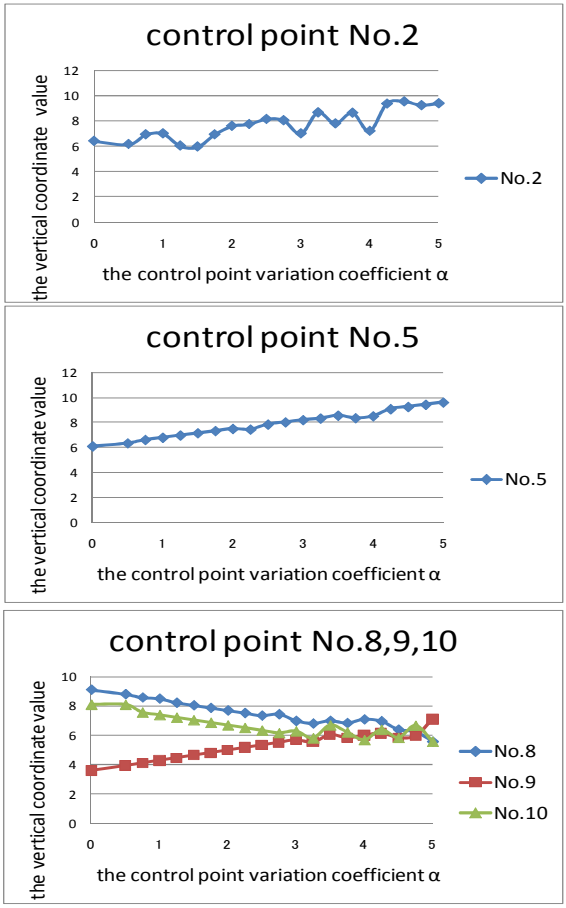

Fig. 6 Relation of the vertical coordinates of control points and the control point variation coefficient α

C. *Outline of model-2*

The characteristics of model-2 are as follows:

- Roof thickness of 0.15 m, load of 0.0036 MN/m^2 (only self-weight), modulus of elasticity of 20600 N/mm^2, and Poisson's ratio of 0.16.
- The parameters of the GA are as follows: The number of individuals is 40, the last generation is 50, the intersection method is a multi-point intersection method, the intersection rate is 100%, and the mutation rate is 5% (Fig. 7).
- This model has three control points in the Y1 direction, five control points in the X direction, and five control points in the Y2 direction.
- The edges are not moved because they are support points. The control points other than the edges are moved.
- This model has a single curvature in the X direction and multiple curvatures in the Y1 and Y2 directions.
- The fitness of the GA is equal to the equivalent stress, which is calculated on the basis of the Mises yield criterion.

D. *Execution results of model-2*

Figure 8 shows the relationship between the control point variation coefficient α and the equivalent stress obtained from the analytical results. Figure 9 shows the elite forms of each control point variation coefficient. Figure 10 shows the relationship between the vertical coordinate values of the control points and the control point variation coefficient α.

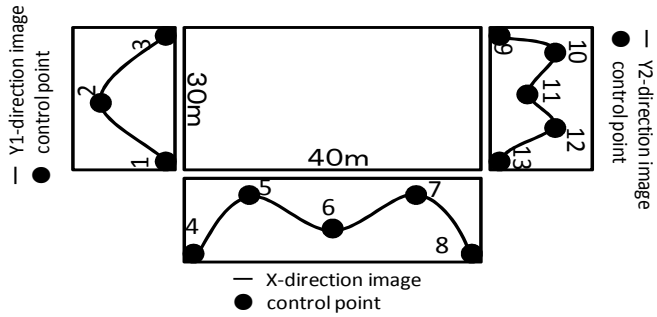

Fig. 7 Control points of model-2

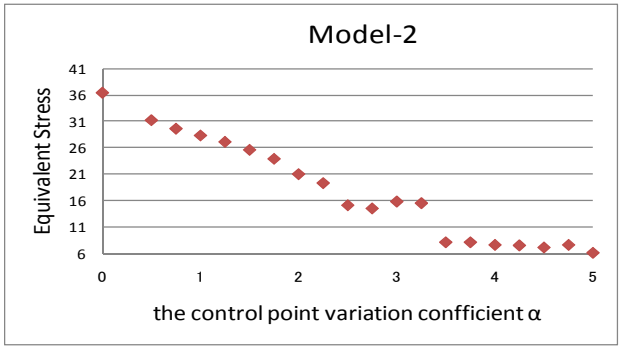

Fig. 8 Relation of equivalent stress and the control point variation coefficient α

1) In the case of model 2, the equivalent stress converges into two stages. The first convergence occurs when the control point variation coefficient α exceeds 2.5, and the vertical coordinates of the control points (No. 5, 6, and 7 in the X direction) with multiple curvatures become almost equal. That is, convergence occurs when a surface with multiple curvatures transforms to a surface with a single curvature.
2) The second convergence occurs when the control point variation coefficient α exceeds 3.5, and the vertical coordinates of the control points (No. 10, 11, and 12 in the Y2 direction) with multiple curvatures become almost equal. That is, convergence occurs when a surface with multiple curvatures transforms to a surface with a single curvature. Control point No. 2 in the Y1 direction, which has a single curvature, tends to move in the direction in which the rise ratio increases.

V. CONCLUSIONS

The following conclusions can be drawn from this study:

1) The equivalent stress decreases with an increase in the control point variation coefficient; however, the difference in the form image from the initial form increases. Thus, there is a trade-off between "image satisfaction" and "equivalent stress."
2) It becomes possible for the designer to select the form with both high image and mechanical rationality by proposing several elite forms for each control point variation coefficient.
3) From the execution results of model-1 and model-2, it is clear that mechanical rationality increases when a surface with multiple curvatures transforms to a surface with a single curvature.

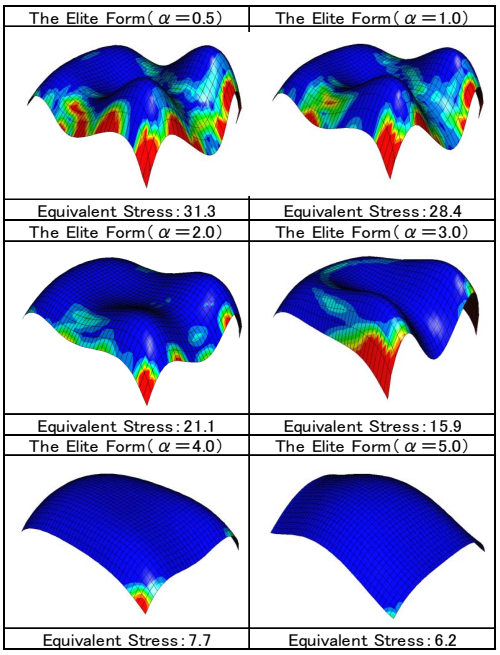

Fig. 9 Elite forms per the control point variation coefficient α

VI. FUTURE TASKS

We intend to improve the proposed design in the following manner:

1) Input the image from four directions
2) Diversify the planar shape
3) Diversify the fitness function

***Abstract*—In this paper we focus on a multiobjective two-level 0-1 programming problem in which the decision maker at the upper level has an objective function and the decision maker at the lower level has multiple objective functions. We assume that there is not coordination between the decision maker at the upper level and the decision maker at the lower level. The decision maker at the upper level must take account of multiple rational responses of the decision maker at the lower level in the problem. We examine two kinds of situations based on anticipation of the decision maker at the upper level; an optimistic anticipation and a pessimistic anticipation. We show mathematical programming problems for obtaining the Stackelberg solutions based on two kinds of anticipation and propose computational methods using genetic algorithms for obtaining the Stackelberg solutions. In order to demonstrate feasibility and effectiveness of the proposed computational methods through genetic algorithms, we plan to conduct numerical experiments.**

I. Introduction

In this paper, we deal with a multiobjective two-level 0-1 programming problem in which there is not coordination between the decision maker at the upper level (leader) and the decision maker at the lower level (follower). Each decision maker knows completely the objective functions and constraints of the opponent and self. For traditional two-level programming problems, the leader first specifies a decision and then the follower specifies a decision so as to optimize the objective with full knowledge of the decision of the leader. According to the rule, the leader also specifies the decision so as to optimize the objective function. We call the solution defined as the above mentioned procedure the Stackelberg solution [37].

It is often assumed that a set of rational responses $R(\boldsymbol{x})$ of the follower is a singleton in conventional two-level 0-1 programming problems. In multiobjective environments, however, the assumption is not realistic and consequently the leader takes into consideration multiple responses or an infinite number of responses of the followers with respect to the decision specified by the leader. In this paper we provide a prescriptive approach to the multiobjective two-level 0-1 programming problem from a viewpoint of the leader. We assume that the leader has some subjective anticipation or belief. Such anticipation or belief can be considered in two cases: (i) the leader anticipates that the follower will take a decision desirable for the leader (optimistic anticipation); (ii) the leader anticipates that the follower will take a decision undesirable for the leader (pessimistic anticipation).

On the other hand, genetic algorithms (GAs) [19] have received a great deal of attention regarding their potential as optimization techniques for solving discrete optimization problems or other hard optimization problems. Although GAs were not much known at the beginning, after the publication of Goldberg's book [17], many researchers in various fields have recently attracted much attention to GAs as a methodology for optimization, adaptation and learning [21], [34].

In order to solve multiobjective optimization problems, various types of GAs are proposed by many researchers [20], [16], [43], [11], [42], [9], [13], [41]. As an early GA application, Shaffer [36] proposes vector evaluated genetic algorithms (VEGA). VEGA performs independent selection cycles according to each objective. Then the whole population is thoroughly shuffled to apply a crossover operator and a mutation operator. Afterward, multiobjective genetic algorithms (MOGAs) are proposed by C. M. Fonseca *et al.* [15] and a non-dominated sorting genetic algorithm (NSGA) based on the non-dominated sorting procedure [17] are proposed by Srinivas *et al.* [38]. Also, Tamaki *et al.* [39] propose to preserve solution non-dominated in the current population. Then, K. Deb *et al.* [10] propose a non-dominated sorting genetic algorithm II (NSGA-II) for solving some problems of NSGA and show the effectiveness of the proposed method by performing numerical experiments.

As an overview of research dealing with two-level programming problems that include discrete variables, Bard *et al.* develope algorithms based on the branch-and-bound techniques for obtaining Stackelberg solutions to two-level 0-1 programming problems [6] and two-level mixed integer programming problems [5]. Wen *et al.* [40] propose an exact computational method and a heuristic method for obtaining a Stackelberg solution to two-level mixed 0-1 programming problems with 0-1 decision variables of the leader and continuous decision variables of the follower. Anandalingam *et al.* [3] propose a computational method using GAs for deriving a Stackelberg solution for two-level linear programming problems. Niwa *et al.* [27], [28] propose computational methods through GAs

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

with double string proposed by Sakawa *et al.* [34] so as to derive a Stackelberg solution for 0-1 programming problems related to two-level decentralized systems. Also, Niwa *et al.* propose computational methods that implement sharing [23] and cluster analysis [30] methods so as to improve the computational accuracy of the Stakelberg solution. Moreover, Niwa *et al.* propose a computational method through parallel genetic algorithms (single-population master-slave GAs) for obtaining a Stackelberg solution to two-level 0-1 programming problems [31] and develope computational methods using distributed genetic algorithms so as to solve two-level 0-1programming problems [26] and decentralized two-level 0-1 programming problems [25]. Specifically, in these computational methods, parallel genetic algorithms and distributed genetic algorithms are introduced with respect to the upper level GA, which handles decision variables for the upper level decision maker. Use of these methods allows for the derivation of approximate Stackelberg solutions with high precision and in a short time.

For the multiobjective two-level linear programming problems, Nishizaki *et al.* [22] propose solution concepts with the leader anticipation and develop computational methods based on the idea of the k th best method proposed by Bialas *et al.* [7] and a computational method by using branch-and-bound technique proposed by Bard *et al.* [4]. Niwa *et al.* develop computational methods through the vector evaluated genetic algorithms for obtaining Stackelberg solutions to multiobjective two-level 0-1 programming problems [29] and multiobjective two-level integer programming problems [24].

In this paper, therefore, we focus on a multiobjective two-level 0-1 programming problem and propose two types of computational methods for obtaining the Stackelberg solution. Specifically, in order to reduce computational time, we consider parallelization of a genetic algorithm handling the decision of the leader and adopt a distributed genetic algorithm as the genetic algorithm. Also, we consider parallelization of the genetic algorithm handling the decision of the follower. Moreover, a first type of proposed computational method adopts the vector evaluated genetic algorithms [36], [39] for deriving multiple rational responses of the follower. A second type of proposed computational method introduces NSGA-II [10] so as to derive multiple rational responses of the follower. In order to demonstrate the effectiveness and the feasibility of the proposed computational methods, we plan to conduct numerical experiments.

II. Multiobjective two-level 0-1 programming problem

In this paper, we consider a multiobjective two-level programming problem in which the leader has an objective function and the follower has multiple objective functions and decision variables of the leader and the follower are 0-1 variables. A multiobjective two-level 0-1 programming problem for obtaining a Stackelberg solution is represented as

$$\left.\begin{array}{ll} \underset{\boldsymbol{x}}{\text{minimize}} & \boldsymbol{z}_1(\boldsymbol{x},\boldsymbol{y}) = \boldsymbol{c}_1\boldsymbol{x} + \boldsymbol{d}_1\boldsymbol{y} \\ \text{where } \boldsymbol{y} \text{ solves} & \\ \underset{\boldsymbol{y}}{\text{minimize}} & \boldsymbol{z}_{21}(\boldsymbol{x},\boldsymbol{y}) = \boldsymbol{c}_{21}\boldsymbol{x} + \boldsymbol{d}_{21}\boldsymbol{y} \\ & \cdots \\ \underset{\boldsymbol{y}}{\text{minimize}} & \boldsymbol{z}_{2k_2}(\boldsymbol{x},\boldsymbol{y}) = \boldsymbol{c}_{2k_2}\boldsymbol{x} + \boldsymbol{d}_{2k_2}\boldsymbol{y} \\ \text{subject to} & A\boldsymbol{x} + B\boldsymbol{y} \leq \boldsymbol{b} \\ & x_i \in \{0,1\}, i = 1, ..., n_1 \\ & y_j \in \{0,1\}, j = 1, ..., n_2, \end{array}\right\} \quad (1)$$

where $\boldsymbol{c}_1$, $\boldsymbol{c}_{2k}, k = 1, \ldots, k_2$ are n_1-dimensional constant row vectors; $\boldsymbol{d}_1$, $\boldsymbol{d}_{2k}, k = 1, \ldots, k_2$ are n_2-dimensional constant row vectors, respectively. $\boldsymbol{b}$ is an m-dimensional constant column vector; A is an $m \times n_1$ constant matrix; B is an $m \times n_2$ constant matrix; these coefficients are assumed to be integer constants; $z_1(\boldsymbol{x},\boldsymbol{y})$ is the leader's objective function; $z_{2k}(\boldsymbol{x},\boldsymbol{y}), k = 1, \ldots, k_2$ are the follower's objective functions; $\boldsymbol{x}$ and $\boldsymbol{y}$ are the leader's and the follower's 0-1 decision variables, respectively.

For conventional two-level 0-1 programming problems, the leader first makes a decision and then the follower specifies a decision in order to optimize the objective function of the follower with full knowledge of the decision of the leader. According to the rule, the leader also determines a decision so as to optimize the objective function of self. We call the solution defined as the above mentioned procedure the Stackelberg solution. In this case, it is often assumed that the set of rational responses $R(\boldsymbol{x})$ for each of all the possible decisions $\boldsymbol{x}$ of the leader is a singleton. However, in multiobjective environment, the above assumption becomes meaningless and hence the leader takes into consideration multiple responses or an infinite number of responses of the follower with respect to the decision specified by the leader. It seems reasonable to suppose that at least the set of rational responses $R(\boldsymbol{x})$ is imposed is the Pareto optimality.

Therefore, we introduce the following set of Pareto optimal responses $P(\boldsymbol{x})$ as a substitute for the set of rational responses $R(\boldsymbol{x})$.

$$\begin{aligned} P(\boldsymbol{x})=\{\boldsymbol{y} \in S(\boldsymbol{x}) \mid & \text{ there does not exist another } \boldsymbol{y}' \in S(\boldsymbol{x}) \\ & \text{such that } z_{2k}(\boldsymbol{x},\boldsymbol{y}') \leq z_{2k}(\boldsymbol{x},\boldsymbol{y}), \forall k, k = 1, \ldots, k_2 \\ & \text{and } z_{2\ell}(\boldsymbol{x},\boldsymbol{y}') \neq z_{2\ell}(\boldsymbol{x},\boldsymbol{y}) \text{ for at least one } \ell.\}, \end{aligned} \quad (2)$$

where $S(\boldsymbol{x}) = \{\boldsymbol{y} \mid B\boldsymbol{y} \leq \boldsymbol{b} - A\boldsymbol{x},\ y_j \in \{0,1\}, j = 1, ..., n_2\}$.

For a decision $\boldsymbol{x}$ determined by the leader, the leader can presume only that a response $\boldsymbol{y}$ of the follower with respect to $\boldsymbol{x}$ belongs to the set of Pareto optimal responses $P(\boldsymbol{x})$.

As done in a conventional two-level 0-1 programming problem, the leader first has specified a decision $\boldsymbol{x}$ and then the follower takes a decision $\boldsymbol{y}$ which belongs to the set of Pareto optimal responses $P(\boldsymbol{x})$. However, the leader does not know which a response is chosen from the set of Pareto optimal responses by the follower. Then we can provide reasonable decisions of the leader in accordance with some subjective anticipation or belief if a prescriptive approach should be employed. Such anticipation or belief can be considered in two cases: i) a case where the leader anticipates that the follower

will take a decision desirable for the leader (the optimistic anticipation); ii) a case where the leader anticipates that the follower will take a decision undesirable for the leader (the pessimistic anticipation). When the leader does not know the preference of the follower, the leader would make a decision by consulting outcomes yielded from the optimistic anticipation and the pessimistic anticipation. We show multiobjective two-level 0-1 programming problems based on the optimistic anticipation and the pessimistic anticipation.

A. Optimistic Stackelberg solution

After the leader has chosen a decision $\hat{\boldsymbol{x}}$, the follower makes a decision $\boldsymbol{y}$ with full knowledge of the decision $\hat{\boldsymbol{x}}$ of the leader by solving the multiobjective 0-1 programming problem:

$$\left.\begin{array}{ll} \underset{\boldsymbol{y}}{\text{minimize}} & z_{21}(\hat{\boldsymbol{x}}, \boldsymbol{y}) = \boldsymbol{d}_{21}\boldsymbol{y} + \boldsymbol{c}_{21}\hat{\boldsymbol{x}} \\ & \cdots\cdots\cdots\cdots\cdots\cdots \\ \underset{\boldsymbol{y}}{\text{minimize}} & z_{2k_2}(\hat{\boldsymbol{x}}, \boldsymbol{y}) = \boldsymbol{d}_{2k_2}\boldsymbol{y} + \boldsymbol{c}_{2k_2}\hat{\boldsymbol{x}} \\ \text{subject to} & B\boldsymbol{y} \leq \boldsymbol{b} - A\hat{\boldsymbol{x}} \\ & y_j \in \{0,1\}, j = 1, ..., n_2. \end{array}\right\} \quad (3)$$

Let $P(\hat{\boldsymbol{x}})$ denote the set of Pareto optimal responses (solutions) of the multiobjective integer programming problem (3).

Hereafter, we call a Stackelberg solution based on the optimistic anticipation the optimistic Stackelberg solution simply. The optimistic Stackelberg solution is an optimal solution to the following problem (4).

$$\left.\begin{array}{ll} \min\limits_{\boldsymbol{x}} \min\limits_{\boldsymbol{y}} & \boldsymbol{z}_1(\boldsymbol{x}) = \boldsymbol{c}_1\boldsymbol{x} + \boldsymbol{d}_1\boldsymbol{y} \\ \text{subject to} & \boldsymbol{y} \in P(\boldsymbol{x}) \\ & A\boldsymbol{x} + B\boldsymbol{y} \leq \boldsymbol{b} \\ & x_i \in \{0,1\}, i = 1, ..., n_1 \end{array}\right\} \quad (4)$$

Problem (4) expresses a situation where the leader chooses a decision $\boldsymbol{x}$ so as to minimize the leader's objective function on the assumption that, for the given $\boldsymbol{x}$ of the leader, the follower takes a decision $\boldsymbol{y}$ in the set of Pareto optimal responses $P(\boldsymbol{x})$ such that the leader's objective function is minimized.

B. Pessimistic Stackelberg solution

Suppose that the leader makes a decision $\boldsymbol{x}$ and anticipates that the follower chooses a decision undesirable for the leader in the set of Pareto optimal responses $P(\boldsymbol{x})$. We call a Stackelberg solution based on the pessimistic anticipation the pessimistic Stackelberg solution. The pessimistic Stackelberg solution can be obtained by solving the problem

$$\left.\begin{array}{ll} \min\limits_{\boldsymbol{x}} \max\limits_{\boldsymbol{y}} & \boldsymbol{z}_1(\boldsymbol{x}) = \boldsymbol{c}_1\boldsymbol{x} + \boldsymbol{d}_1\boldsymbol{y} \\ \text{subject to} & \boldsymbol{y} \in P(\boldsymbol{x}) \\ & A\boldsymbol{x} + B\boldsymbol{y} \leq \boldsymbol{b} \\ & x_i \in \{0,1\}, i = 1, ..., n_1. \end{array}\right\} \quad (5)$$

This problem can be solved by an algorithm similar to the algorithm for the optimistic Stackelberg solutions.

III. Computational Methods through Genetic Algorithms

In this paper, we propose computational methods through genetic algorithms for obtaining Stackelberg solutions based on the optimistic anticipation and the pessimistic anticipation to multiobjective two-level 0-1 programming problems. The proposed computational methods are described as follows.

We propose two types of computational methods using GAs for obtaining Stackelberg solutions to the problem (4) and (5). The proposed computational methods use the double string [32] which composed of the substring corresponding to the decision of the leader, and the substring corresponding to the decision of the follower. In order to solve the problem (4) and (5), the decisions of the leader and the follower are handled by performing genetic operators on each substring. Specifically, in order to reduce computational time, we consider parallelization of a genetic algorithm handling the decision of the leader and adopt a destributed genetic algorithm as the genetic algorithm. Also, we consider parallelization of the genetic algorithm handling the decision of the follower. The above-mentioned parallelization approaches are improvements common to two types of the proposed computational methods. Moreover, a first type of the proposed computational method adopts VEGA [36], [39] for deriving multiple rational responses of the follower. Also, a second type of proposed computational method introduces NSGA-II [10] so as to derive multiple rational responses of the follower.

In the following sections III-A, III-B, III-C, III-D, we show common operators or procedures used for the proposed computational methods. In section III-E, we describe a reproduction operator used for each computational method in detail. Finally, we show algorithms used in the computational methods after improvement in section III-F.

A. Coding and decoding

For solving 0-1 programming problems using genetic algorithms, an individual is usually represented by a binary 0-1 string [18], [17], [21]. However, this representation may weaken the ability of genetic algorithms since an individual whose phenotype is feasible is scarcely generated under this representation.

For multidimensional 0-1 knapsack problems, Sakawa *et al.* [32] propose a double string representation and a decoding algorithm for eliminating infeasible solutions. In this paper, a double string which is composed of the substring corresponding to the decision of the leader, $\boldsymbol{x}$, and the substring corresponding to the decision of the follower, $\boldsymbol{y}$, as shown in Fig.1 is used so as to derive only feasible solutions.

The decisions of the leader and the follower are handled by applying genetic operators on each substring. We call the genetic algorithm operating to the decision $\boldsymbol{x}$ of the leader the upper level GA, and the genetic algorithm operating to the decision $\boldsymbol{y}$ of the follower the lower level GA.

$s_{i_x(m)} \in \{0,1\}, i_x(m) \in \{1, \ldots, n_1\}$, and for $m \neq m'$ it is assumed that $i_x(m) \neq i_x(m')$. Similarly, $s_{i_y(m)} \in \{0,1\}, i_y(m) \in \{1, \ldots, n_2\}$, and for $m \neq m'$ it is assumed

← Individual for $\boldsymbol{x}$ →			← Individual for $\boldsymbol{y}$ →		
$i_x(1)$	$\cdots$	$i_x(n_1)$	$i_y(1)$	$\cdots$	$i_y(n_2)$
$S_{i_x(1)}$	$\cdots$	$S_{i_x(n_1)}$	$S_{i_y(1)}$	$\cdots$	$S_{i_y(n_2)}$

Fig. 1. Double string

that $i_y(m) \neq i_y(m')$. Also, in the double string, $i_x(m)$, $i_y(m)$ and $s_{i_x(m)}$, $s_{i_y(m)}$ express indexes of the elements of each solution vector respectively, and their values.

Also, a decoding algorithm proposed by the Niwa *et al.* [27] is also applied to the upper level GA and the lower level GA so as to generate only feasible solutions.

B. Crossover and mutation

If a one-point or multi-point crossover operator is applied to individuals represented by double strings then there is a possibility that infeasible individuals may be generated because the indexes occurring in the offspring, $i_x(m)$, $i_x(m')$, $m \neq m'$ or $i_y(m)$, $i_y(m')$, $m \neq m'$, may have the same number. When solving the traveling salesman problem or the scheduling problem through GAs, this kind of violation occurs. One possible approach to circumvent such violation, a crossover method called partially matched crossover (PMX) is useful [18]. In this paper, a modified version of PMX is used in order to handle the double string proposed by Sakawa *et al.* [34]. Also, when determining whether or not to apply the crossover operator, the prespecified probability p_c is used. Its value is set in advance.

A mutation operator is thought to fulfill the role of local random search in genetic algorithms. In this paper, for the lower string of a double string, mutation of bit-reverse type is adopted. For the upper string of a double string, an inversion is used. When applying the mutation operator to individuals, it is first determined whether or not the mutation operator will be applied to an individual according to the prespecified probability p_m. In the case that mutation is applied, it is then determined whether to apply an inversion or mutation of bit-reverse type according to the prespecified probability M_{Pum}.

C. Application of parallel genetic algorithms

It is possible to divide the operations without a reproduction operator included in genetic algorithms, and to solve those operations simultaneously using multiple processors. However, in a reproduction operator, an evaluation value (ex. objective function value) for each individual is calculated, and fitness values for individuals are computed by using the evaluation values. Because it is necessary to divide this process in a reproduction operator, direct application of parallel processing is difficult. Research related to the parallelization of GAs started with improvements to such barriers to the implementation of parallelization, and a variety of types of models have been proposed and their effectiveness noted by numerous researchers. In general, parallel genetic algorithms are classified broadly into four types: 1) Single-population master-slave GAs, 2) Multiple-population GAs, 3) Fine-grained GAs, and 4) Hierarchical hybrids [8]. Single-population master-slave GAs have a single population. The master performs a selection operator a crossover operator and a mutation operator. Slaves only evaluate the fitness of the individuals. Multiple-population GAs or multiple-deme GAs consist of several subpopulations that exchange individuals every so often. This exchange of individuals is called migration. The subpopulations are assigned to multiple processors. A reproduction operator, a crossover operator and a mutation operator are performed on each subpopulation. These models are also known as distributed GAs or island parallel GAs. Fine-grained GAs consist of a single spatially-distributed population. Each processor has a very small number of individuals. Ideally, an individual is assigned to one processor and all individuals are evaluated simultaneously. Selection and mating are applied to a small neighborhood around each individual. The neighborhoods overlap, so that eventually the good characters of a superior individual can spread to the whole population. Hierarchical hybrids combine multiple-population GAs with single-population master-slave GAs or fine-grained GAs.

The single-population master-slave GAs executes parallel processing by not dividing the population, and using multiple processors only for the evaluation of individuals [1], [14]. This model may be used in a situation which spends too much time calculating the fitness of each individual. By adopting this model, calculated load may be able to distribute. Another characteristic is that it also implements a simpler algorithm than the other three models, and because there are no changes to the population due to parallelization, there will be no effects on the search for a solution.

A computational method proposed by Niwa *et al.* [31] adopts the single-population master-slave GAs as the upper level GA. In the computational method, a master only executes a reproduction operator and slaves evaluate the fitness of the individuals and performs a crossover operator and a mutation operator. Also, the computational method divides operations of the lower level GA and assigns them across multiple processors. By assigning calculations of fitness for individuals, a crossover operator and a mutation operator to multiple processors, calculation times are reduced. We call the computational method the computational method using master-slave GAs (MGA).

Moreover, Niwa *et al.* proposed computational methods through multiple-population GAs (distributed GAs) in order to solve a two-level 0-1 programming problem [26] and a decentralized two-level 0-1 programming problem [25]. We call these computational methods the computational methods using distributed GAs (DGA). In order to verify the effectiveness of DGA, numerical experiments are carried out. From the results, DGA is superior to MGA and the existing computational method through GAs [27], both from a standpoint of solution precision and required computational time.

In this paper, therefore, we employ computational methods thorough distributed GAs so as to reduce calculation times and obtain good approximate Stackelberg solutions.

D. Lower level GA avoidance procedures

We introduce a storage region shown in Fig. 2.

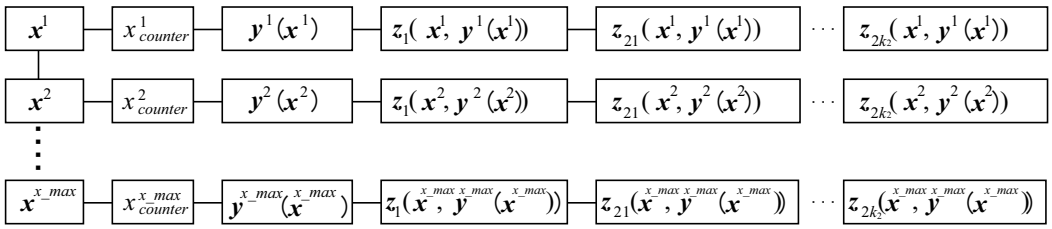

Fig. 2. Storage for saving $\boldsymbol{x}$ and $\boldsymbol{y}(\boldsymbol{x})$

Here, $\boldsymbol{x}^i, i = 1, \ldots, x_max$ indicate the values of $\boldsymbol{x}$ already handled as individuals by the upper level GA, and $\boldsymbol{y}^i(\boldsymbol{x}^i), i = 1, \ldots, x_max$ indicate the Pareto optimal responses associated with $\boldsymbol{x}^i$ obtained by the lower level GA. $x^i_{counter} \in \{1, 2, \ldots, y_max\}, i = 1, \ldots, x_max$ indicate the number of times that the lower level GA was used to find the Pareto optimal response $\boldsymbol{y}^i(\boldsymbol{x}^i)$ for $\boldsymbol{x}^i$. x_max indicates the maximum number of stored decisions $\boldsymbol{x}$, and y_max indicates the maximum number of times that the lower level GA can be repeatedly used to find the Pareto optimal response $\boldsymbol{y}^i(\boldsymbol{x}^i)$ for $\boldsymbol{x}^i$. $z_1(\boldsymbol{x}^i, \boldsymbol{y}^i(\boldsymbol{x}^i))$ is the value of the leader's objective function for $\boldsymbol{x}^i$ and $\boldsymbol{y}^i(\boldsymbol{x}^i)$. $z_{21}(\boldsymbol{x}^i, \boldsymbol{y}^i(\boldsymbol{x}^i))$, ..., $z_{2k_2}(\boldsymbol{x}^i, \boldsymbol{y}^i(\boldsymbol{x}^i))$ are the values of the follower's objective functions for $\boldsymbol{x}^i$ and $\boldsymbol{y}^i(\boldsymbol{x}^i)$. By using the following algorithm, the number of applications of the lower level GA is reduced, and unnecessary calculation times eliminated.

Storage of Pareto optimal response $y(x)$ and lower level GA avoidance procedures

Step 1 If an individual $\bar{\boldsymbol{x}}$ of the upper level GA exists in $\boldsymbol{x}^i$, proceed to Step 2. If such an individual does not exist, then check if the number of $\boldsymbol{x}^i$ has reached x_max, and if so continue on to Step 3. If not, proceed to Step 4.

Step 2 If $x^i_{counter}$ has reached y_max, then the saved $\boldsymbol{y}^i(\boldsymbol{x}^i)$ is returned to the upper level GA as the Pareto optimal response and the algorithm terminates. If not reached, proceed to Step 4.

Step 3 Select the worst value $z_1(\boldsymbol{x}^i, \boldsymbol{y}^i(\boldsymbol{x}^i))$ from the stored $\boldsymbol{x}^i$, and take that $\boldsymbol{x}^i$ value as $\boldsymbol{x}^k$. After applying the lower level GA and thus obtaining the Pareto optimal response $\boldsymbol{y}(\bar{\boldsymbol{x}})$ for $\bar{\boldsymbol{x}}$, if $z_1(\boldsymbol{x}^k, \boldsymbol{y}^k(\boldsymbol{x}^k)) \geq z_1(\bar{\boldsymbol{x}}, \boldsymbol{y}(\bar{\boldsymbol{x}}))$, save $\bar{\boldsymbol{x}}$, $\boldsymbol{y}(\bar{\boldsymbol{x}})$, $z_1(\bar{\boldsymbol{x}}, \boldsymbol{y}(\bar{\boldsymbol{x}}))$, $z_{21}(\bar{\boldsymbol{x}}, \boldsymbol{y}(\bar{\boldsymbol{x}})), \ldots, z_{2k_2}(\bar{\boldsymbol{x}}, \boldsymbol{y}(\bar{\boldsymbol{x}}))$ in the storage region $\boldsymbol{x}^k$, and terminate the algorithm.

Step 4 After obtaining the Pareto optimal response $\boldsymbol{y}(\bar{\boldsymbol{x}})$ for $\bar{\boldsymbol{x}}$ by applying the lower level GA, $\bar{\boldsymbol{x}}, \boldsymbol{y}(\bar{\boldsymbol{x}}), z_1(\bar{\boldsymbol{x}}, \boldsymbol{y}(\bar{\boldsymbol{x}})), z_{21}(\bar{\boldsymbol{x}}, \boldsymbol{y}(\bar{\boldsymbol{x}})), \ldots, z_{2k_2}(\bar{\boldsymbol{x}}, \boldsymbol{y}(\bar{\boldsymbol{x}}))$ are saved, and the algorithm is terminated.

E. Reproduction

We first describe the reproduction operator of the upper level GA. In the upper level GA, the value of $\boldsymbol{x}$ obtained by decoding individuals in the upper level GA and the follower's Pareto optimal responses $\boldsymbol{y}(\boldsymbol{x}) \in P(\boldsymbol{x})$ obtained by applying the lower level GA are substituted into the objective function of the leader $z_1(\boldsymbol{x}, \boldsymbol{y})$, and the value of the evaluation function for each individual is thus obtained. Next, the fitness value for each individual is calculated by applying linear scaling and adopting a clustering method. The individuals remaining in the next generation are determined by applying elitist expected value selection based on these fitness values.

Next, we describe the reproduction operator of the lower level GA. In the lower level GA, the value of $\boldsymbol{y}$ obtained by decoding individuals in the lower level GA, and the given values of the decision variables in the upper level GA, $\boldsymbol{x}$, are substituted into the follower's objective functions $z_{2k}(\boldsymbol{x}, \boldsymbol{y}), k = 1, \ldots, k_2$, and the value of the evaluation function for each individual is thus obtained. Then, in the first type of the proposed computational method, the reproduction operator of VEGA [36], [39] is adopted by using the value of the evaluation function for deriving multiple rational responses of the follower. Also, in the second type of the proposed computational method, the reproduction operator of NSGA-II [10]is applied by using the value of the evaluation function.

F. Algorithms for the proposed computational methods

Initially, an algorithm used in the first type of the proposed computational method after improvement can be summarized as follows. N_p denotes the number of processors.

Step 1 For each processor $q, q = 1, \ldots, N_p$, apply the upper level GA operations on Step1 through Step7. Generate N_u individuals at random to form the initial population. Set the generation index $t_{uq} := 0$ and determine the value of the maximal generation T_u.

Step 2 For each individual $\boldsymbol{x}$ in the upper level GA, determine whether or not to apply the operations of the lower level GA. If it is applied, then apply the lower level GA operations in Step 2-a through Step 2-c,

and obtain a Pareto optimal response $\boldsymbol{y}(\boldsymbol{x})$. If it is not applied, then a stored $\boldsymbol{y}(\boldsymbol{x})$ is taken as a Pareto optimal response, and proceed to Step 4.

Step a Randomly generate N_l lower level GA individuals $\boldsymbol{y}$, and take these as the initial population of the lower level GA. Set the generation index $t_l := 0$ and determine the value of the maximal generation T_l. Proceed to Step 2-b.

Step b By using $\boldsymbol{x}$ given as the upper level GA individual and $\boldsymbol{y}$ generated by the lower level GA, the follower's objective function values are calculated. As the reproduction operator, the parallel selection method is applied. Preserve non-dominated solutions in the population. Proceed to Step 2-c.

Step c If t_l has exceeded the maximal generation T_l, take the individual with the best fitness value as the optimal individual $\boldsymbol{y}(\boldsymbol{x})$, and proceed to Step 3. Otherwise, apply a crossover operator and a mutation operator to each lower level GA individual. Select individuals from the population at random, and exchange the individuals for the non-dominated solutions (individuals). Let $t_l = t_l + 1$, and proceed to Step 2-b.

Step 3 By using the follower's Pareto optimal response $\boldsymbol{y}(\boldsymbol{x})$ obtained by operation of the lower level GA and the individual $\boldsymbol{x}$ of the upper level GA, calculate objective function values for the leader and the follower. Perform the procedures required to save $\boldsymbol{x}$ and its Pareto optimal response $\boldsymbol{y}(\boldsymbol{x})$ to the storage region and proceed to Step 4.

Step 4 Calculate the leader's objective function value for each upper level GA individual $\boldsymbol{x}$, and after performing linear scaling, apply the clustering method to measure the level of convergence of the individuals. Depending upon the degree of convergence, calculate the fitness value of each individual. Proceed to Step 5.

Step 5 If t_{uq} has exceeded the maximal generation T_u, then terminate the algorithm. In that case, the individual obtained up to that generation with the best fitness value is taken as the optimal individual $(\boldsymbol{x}, \boldsymbol{y})$. Otherwise, proceed to Step 6.

Step 6 A reproduction operator is performed using the fitness values of each individual of the upper level GA. Apply a crossover operator and a mutation operator to each upper level GA individual, and proceed to Step7.

Step 7 If t_{uq} mod m_i (migration interval) = 0, after performing synchronization between the processors, apply migration. Return to Step 2 with $t_{uq} := t_{uq} + 1$.

Next, we show an algorithm used for the second type of the proposed computational method. Because the difference of two computational methods is only procedures to apply the lower level GA, an algorithm for the lower level GA is shown as follows.

Step a Set the generation index $t_l := 0$ and determine the value of the maximal generation T_l. Generate N_l lower level GA individuals $\boldsymbol{y}$ at random, and take these individuals as the initial population $P(t_l)$ of the lower level GA. Proceed to Step 2-b.

Step b If t_l has exceeded the maximal generation T_l, take the individual with the best fitness value as the optimal individual $\boldsymbol{y}(\boldsymbol{x})$, and proceed to Step 3. Otherwise, apply a crowded tournament selection operator, a crossover operator and a mutation operator to each lower level GA individual in $P(t_l)$ and form a population $Q(t_l)$ by use of these individuals.

Step c Let $R(t_l) = P(t_l) \cup Q(t_l)$. By using $\boldsymbol{x}$ given as an individual of the upper level GA and $\boldsymbol{y}$ given as an individual of the lower level GA in $R(t_l)$, the follower's objective function values are calculated. Based on these values, a non-dominated sorting is applied as a reproduction operator. Then, create the new population $P(t_l+1)$ of the next generation t_l+1. Let $t_l = t_l + 1$, and proceed to Step 2-b.

By using these coputational methods, it is possible to obtain the Stackelberg solutions to the problem (4) and (5).

IV. Conclusion

This paper has focused on a multiobjective two-level 0-1 programming problem in which there is not coordination between the decision maker at the upper level and the decision maker at the lower level. We have considered two kinds of situations based on anticipation of the decision maker at the upper level; an optimistic anticipation and a pessimistic anticipation. Mathematical programming problems for obtaining the Stackelberg solutions based on two kinds of anticipation have been shown and two types of computational methods for obtaining the Stackelberg solutions have been proposed. In order to demonstrate the effectiveness of the proposed methods, it is intended to conduct numerical experiments into both the solution precision and computation time, and thus compare the proposed computational methods with previous methods.

***Abstract*—By integrating the stabilizability condition, the orthogonal-functions approach (OFA), and the hybrid Taguchi-genetic algorithm (HTGA), an integrative method is presented in this paper to design the stable and quadratic-optimal static output feedback parallel-distributed-compensation (PDC) controller such that (i) the Takagi-Sugeno (TS) fuzzy-model-based control system can be stabilized, and (ii) a quadratic integral performance index for the TS-fuzzy-model-based control system can be minimized. In this paper, the stabilizability condition is proposed in terms of linear matrix inequalities (LMIs). A design example of stable and quadratic-optimal static output feedback PDC controller for a nonlinear inverted pendulum system controlled by a separately excited direct-current (DC) motor is given to demonstrate the applicability of the proposed new integrative approach.**

Keywords-static output feedback PDC controller; Takagi-Sugeno fuzzy model; orthogonal-functions approach; hybrid Taguchi-genetic algorithm; linear matrix inequalities

I. INTRODUCTION

Recently, it has been shown that the fuzzy-model-based representation proposed by Takagi and Sugeno [1], known as the TS fuzzy model, is a successful approach for dealing with the nonlinear control systems, and there are many successful applications of the TS-fuzzy-model-based approach to the nonlinear control systems [2].

Despite the success of applying the TS-fuzzy-model-based approach to the nonlinear control systems, it has become evident that many research issues remain to be addressed. In fact, in many cases it is very difficult, if not impossible, to obtain a full order output feedback controller of a nonlinear control system. This is due to the unaccessible measurement or the expensive measure. Therefore, recently, some researches [3]-[5] have proposed the linear-matrix-inequality-based (LMI-based) approach to design the static output feedback parallel-distributed-compensation (PDC) controllers for the TS-fuzzy-model-based control systems. Therefore, summing up the above statements and reasons, we can see that it is worth while to present an efficiently numerical optimization approach accompanied with the stabilizability condition to design the stable and quadratic-optimal static output feedback PDC controllers for the TS-fuzzy-model-based control systems, where the performance index subject to the constraint of stabilizability is considered to be directly minimized.

The purpose of this paper is to propose a numerical optimization method accompanied with the stabilizability condition to design the stable and quadratic-optimal static output feedback PDC controllers for the optimal control problem of the TS-fuzzy-model-based control systems by integrating the OFA, the hybrid Taguchi-genetic algorithm (HTGA) and the LMI technique, where the LMI technique is used to derive the stabilizability condition for ensuring that the closed-loop TS-fuzzy-model-based control systems can be stabilized. An illustrative example is also given in this paper to demonstrate the applicability of the proposed new integrative method.

II. PROBLEM STATEMENT

The TS-fuzzy-model-based control system for the nonlinear control system can be obtained as the following form:

$$\widetilde{R}^i: \text{IF } z_1(t) \text{ is } M_{i1} \text{ and } \ldots \text{ and } z_g(t) \text{ is } M_{ig},$$
$$\text{THEN } \begin{cases} \dot{x}(t) = A_i x(t) + B_i u(t), \\ y(t) = C_i x(t), \end{cases} \tag{1}$$

with the initial state vector $x(0)$, where $\widetilde{R}^i \ \ (i = 1, 2, \ldots, N)$ denotes the i-th implication, N is the number of fuzzy rules, $x(t) = [x_1(t), x_2(t), \ldots, x_n(t)]^{\mathrm{T}}$ denotes the n-dimensional state vector, $y(t) = [y_1(t), y_2(t), \ldots, y_r(t)]^{\mathrm{T}}$ denotes the r-dimensional output vector, $u(t) = [u_1(t), u_2(t), \ldots, u_p(t)]^{\mathrm{T}}$ denotes the p-dimensional input vector, $z_i(t) \ \ (i = 1, 2, \ldots, g)$ are the premise variables, A_i, B_i and $C_i \ \ (i = 1, 2, \ldots, N)$ are, respectively, the $n \times n$, $n \times p$ and $r \times n$ consequent constant matrices, and M_{ij} $(i = 1, 2, \ldots, N$ and $j = 1, 2, \ldots, g)$ are the fuzzy sets.

The resulting TS-fuzzy-model-based dynamic system inferred from (1) is represented as

$$\dot{x}(t) = \sum_{i=1}^{N} h_i(z(t))(A_i x(t) + B_i u(t)), \tag{2a}$$

$$y(t)=\sum_{i=1}^{N}h_i(z(t))C_i x(t), \tag{2b}$$

in which $z(t)=[z_1(t), z_2(t),\ldots, z_g(t)]^{\mathrm{T}}$ denotes the g-dimensional premise vector, $h_i(z(t))=w_i(z(t))\Big/\sum_{i=1}^{N}w_i(z(t))$, $w_i(z(t))=\prod_{j=1}^{g}M_{ij}(z_j(t))$, and $M_{ij}(z_j(t))$ are the grades of membership of $z_j(t)$ in the fuzzy sets M_{ij} $(i=1, 2,\ldots, N$ and $j=1, 2,\ldots, g)$. It can be seen that, for all t, $h_i(z(t))\ge 0$ and $\sum_{i=1}^{N}h_i(z(t))=1$.

The given dynamic system can be stabilized by the following static output feedback PDC controller:

$$\begin{aligned}u(t)&=-\sum_{i=1}^{N}h_i(z(t))F_i y(t)\\&=-\sum_{i=1}^{N}\sum_{j=1}^{N}h_i(z(t))h_j(z(t))F_i C_j x(t),\end{aligned} \tag{3}$$

where F_i $(i=1, 2,\ldots, N)$ denote the $p\times r$ local static output feedback gain matrices.

By substituting (3) into (2a), we can get the closed-loop TS-fuzzy-model-based dynamic system as

$$\dot{x}(t)=\sum_{i=1}^{N}\sum_{j=1}^{N}\sum_{k=1}^{N}h_i(z(t))h_j(z(t))h_k(z(t))(A_i-B_iF_jC_k)x(t). \tag{4}$$

In what follows, we present an LMI-based stabilizability criterion to analyze whether the closed-loop TS-fuzzy-model-based dynamic system in (4) can be stabilized by the static output feedback PDC controller or not, where the local static output feedback gain matrices F_j have been specified in advance.

Theorem:

The closed-loop TS-fuzzy-model-based dynamic system in (4) is stable, if, for the specified local static output feedback gains matrices F_j $(j=1, 2,\ldots, N)$ in (3), there exist a symmetric positive definite matrix P and the symmetric positive semidefinite matrices Q_k $(k=1, 2,\ldots, N)$ such that the following LMIs are simultaneously satisfied:

$$G_{kii}^{\mathrm{T}}P+PG_{kii}+(\bar{s}-1)Q_k<0, \tag{5a}$$

and

$$\left(\frac{G_{kij}+G_{kji}}{2}\right)^{\mathrm{T}}P+P\left(\frac{G_{kij}+G_{kji}}{2}\right)-Q_k\le 0, \tag{5b}$$

where $G_{ijk}=A_i-B_iF_jC_k$, $i<j$, $\bar{s}>1$, and $i, j, k=1, 2,\ldots, N$.

Proof: Here we omit it due to space limitation.

The problem considered in this paper is how to specify the local static output feedback gain matrices F_i $(i=1, 2,\ldots, N)$ of the static output feedback PDC controller in (3) such that the constraint of LMI-based stabilizability condition in (5) for the closed-loop TS-fuzzy-model-based dynamic system in (4) can be satisfied, and such that the optimal control performance for the TS-fuzzy-model-based dynamic system in (2) can be achieved by minimizing the following quadratic integral performance index:

$$\begin{aligned}J&=\int_0^{qt_f}\left[y^{\mathrm{T}}(t)Qy(t)+u^{\mathrm{T}}(t)Ru(t)\right]dt\\&=\sum_{k=0}^{q-1}\int_{kt_f}^{(k+1)t_f}\left[y^{\mathrm{T}}(t)Qy(t)+u^{\mathrm{T}}(t)Ru(t)\right]dt,\end{aligned} \tag{6}$$

where t_f denotes a small time interval which is chosen for the independent variable t, q is a positive integer specified by the designer, Q is a symmetric positive-semidefinite matrix, and R is a symmetric positive-definite matrix.

III. Stable and Quadratic-Optimal Static Output Feedback PDC Controllers Design

Here, consider the time interval $kt_f\le t\le(k+1)t_f$, where t_f is chosen for the independent variable t, and let us define

$$t=kt_f+\eta, \tag{7}$$

and

$$x_k=x(kt_f), \tag{8}$$

in which $k=0, 1, 2,\ldots, q-1$, and $0\le\eta\le t_f$.

The state vector $x(t)$, within $kt_f\le t\le(k+1)t_f$, can be approximated by the truncated orthogonal-functions (OF) representation as

$$x(t)=\sum_{s=0}^{m-1}x_s^{(k)}T_s(t)=\tilde{x}^{(k)}T(t), \tag{9}$$

where m is the number of terms required for the OF, $T(t)=[T_0(t), T_1(t),\ldots, T_{m-1}(t)]^{\mathrm{T}}$ denotes the $m\times 1$ OF basis vector, $T_i(t)$ $(i=0, 1,\ldots, m-1)$ denote the OF, $x_s^{(k)}$ $(s=0, 1,\ldots, m-1)$ are the $n\times 1$ coefficient vector, and $\tilde{x}^{(k)}=[x_0^{(k)}, x_1^{(k)},\ldots, x_{m-1}^{(k)}]$ is the $n\times m$ coefficient matrix of $x(t)$.

Substituting (3) and the truncated OF representation of $x(t)$ in (9) into the quadratic integral performance index in (6), the quadratic integral performance index J becomes the following algebraic form:

$$\begin{aligned}J=\sum_{k=0}^{q-1}\mathrm{trace}\Bigg[&W(\tilde{x}^{(k)})^{\mathrm{T}}\Bigg(\sum_{i=1}^{N}\sum_{j=1}^{N}\sum_{l=1}^{N}\sum_{o=1}^{N}h_i(z_k)h_j(z_k)h_l(z_k)h_o(z_k)\\&C_i^{\mathrm{T}}(Q+F_j^{\mathrm{T}}RF_l)C_o(\tilde{x}^{(k)})\Bigg)\Bigg],\end{aligned} \tag{10}$$

where the constant matrix W is the product-integration-matrix of two OF basis vectors [6].

Since, before the consequent output can be inferred within the small time interval $kt_f\le t\le(k+1)t_f$, the degree of fulfillment of the antecedent must be computed in advance, so, as the works given by Ho and Chou [7], we can let the value of $h_i(z(t))$, within $kt_f\le t\le(k+1)t_f$, be $h_i(z(kt_f))$. Then, integrating (2a) from $t=kt_f$ to $t=t$ within $kt_f\le t\le(k+1)t_f$, we obtain

$$x(t)-x(kt_f)=\sum_{i=1}^{N}h_i(z_k)\left[A_i\int_{kt_f}^{t}x(t)dt+B_i\int_{kt_f}^{t}u(t)dt\right], \quad (11)$$

where $h_i(z_k)=h_i(z(kt_f))$ and $k=0,\ 1,\ 2,\ldots,\ q-1$.

Using the following integral property of the OF:

$$\int_{kt_f}^{t}T(t)dt=HT(t), \quad (12)$$

and applying (3), (8) and (9), equation (11) can be cast into the form

$$\begin{aligned}&\tilde{x}^{(k)}-[x_k,\ 0,\ 0,\ldots,\ 0]\\&=\sum_{i=1}^{N}\sum_{j=1}^{N}\sum_{l=1}^{N}h_i(z_k)h_j(z_k)h_l(z_k)(A_i-B_iF_jC_l)\tilde{x}^{(k)}H,\end{aligned} \quad (13)$$

in which H is the operational matrix of integration for the OF [7].

Equation (13) can be rewritten as

$$\tilde{x}^{(k)}-\sum_{i=1}^{N}\sum_{j=1}^{N}\sum_{l=1}^{N}h_i(z_k)h_j(z_k)h_l(z_k)(A_i-B_iF_jC_l)\tilde{x}^{(k)}H=\tilde{Q}^{(k)}, \quad (14)$$

where $\tilde{Q}^{(k)}=[x_k,\ 0,\ 0,\ldots,\ 0]$ is an $n\times m$ matrix.

Making use of the Kronecker product, the explicit form for the coefficient matrix $\tilde{x}^{(k)}$ comes directly from (14) as

$$\begin{aligned}\hat{x}^{(k)}=\Bigg[I_{mn}-\sum_{i=1}^{N}\sum_{j=1}^{N}\sum_{l=1}^{N}h_i(z_k)h_j(z_k)h_l(z_k)\\(H^{\mathrm{T}}\otimes(A_i-B_iF_jC_l))\Bigg]^{-1}\hat{Q}^{(k)},\end{aligned} \quad (15)$$

where I_{mn} denotes the $mn\times mn$ identity matrix, $\hat{x}^{(k)}=\left[x_0^{(k)\mathrm{T}},\ x_1^{(k)\mathrm{T}},\ldots,\ x_{m-1}^{(k)\mathrm{T}}\right]^{\mathrm{T}}$, $\hat{Q}^{(k)}=[x_k^{\mathrm{T}},\ 0^{\mathrm{T}},\ 0^{\mathrm{T}},\ldots,\ 0^{\mathrm{T}}]^{\mathrm{T}}$, and $\otimes$ denotes the Kronecker product [8]. This implies that $\tilde{x}^{(k)}$ can be obtained from (15).

The value of the performance index of algebraic form in (10) is actually dependent on the set of local static output feedback gain matrices $\{F_1, F_2,\ldots, F_N\}$, which means

$$J=G(f_{111},\ f_{112},\ldots,\ f_{Npr}), \quad (16)$$

where f_{ijk} $(i=1,2,\ldots,N,\quad j=1,2,\ldots,p$ and $k=1,2,\ldots,r)$ denote the elements of the local static output feedback gain matrices F_i. This is equivalent to the static constrained-optimization problem in the following:

$$\text{minimize } J=G(f_{111},\ f_{112},\ldots,\ f_{Npr}) \quad (17)$$

subject to $|f_{ijk}|\le C_{ijk}$, and subject to the constraint that there exist a symmetric positive definite matrix P and the symmetric positive semidefinite matrices Q_k $(k=1,2,\ldots,N)$ to make the LMIs in (5) hold, for $i=1,2,\ldots,N,\quad j=1,2,\ldots,p$ and $k=1,2,\ldots,r$, where C_{ijk} are the positive real numbers given from the practical consideration, respectively. Then, the HTGA [9] can be employed to search for the optimal solution of the static constrained-optimization problem in (17).

IV. Illustrative Example

A nonlinear inverted pendulum system controlled by a separately excited direct-current (DC) motor [10] is considered in this example as

$$\begin{bmatrix}\dot{x}_1(t)\\\dot{x}_2(t)\\\dot{x}_3(t)\end{bmatrix}=\begin{bmatrix}x_2(t)\\K_1\sin x_1(t)+K_2x_3(t)\\K_3x_2(t)+K_4x_3(t)\end{bmatrix}+\begin{bmatrix}0\\0\\K_5\end{bmatrix}u(t), \quad (18)$$

where $x_1(t)\in[-\pi,\pi]$ is the angle of the pendulum, $x_2(t)=\dot{x}_1(t)$ is the angular velocity, $x_3(t)$ is the current of the motor, $u(t)$ denotes the control input voltage, $K_1=9.8$ $(1/\sec^2)$, $K_2=1$ $(1/\mathrm{A}\cdot\sec^2)$, $K_3=-10$ $(\mathrm{V}\cdot\sec/\mathrm{rad}\cdot\mathrm{mH})$, $K_4=-10$ (Ω/mH), and $K_5=10$ $(1/\mathrm{mH})$. The TS-fuzzy-model-based dynamic system for (18) can be obtained as following:

$$\tilde{R}^1:\ \text{IF } z_1(t) \text{ is } M_{11},\ \text{THEN } \begin{cases}\dot{x}(t)=A_1x(t)+B_1u(t),\\y(t)=C_1x(t),\end{cases} \quad (19a)$$

$$\tilde{R}^2:\ \text{IF } z_1(t) \text{ is } M_{21},\ \text{THEN } \begin{cases}\dot{x}(t)=A_2x(t)+B_2u(t),\\y(t)=C_2x(t),\end{cases} \quad (19b)$$

where

$z_1(t)=\sin x_1(t)/x_1(t)$, $x(t)=[x_1(t),\ x_2(t),\ x_3(t)]^{\mathrm{T}}$,

$x(0)=[\pi/6,\ 0,\ 0]^{\mathrm{T}}$, $x_1(t)\in[-\pi,\pi]$, $A_1(t)=\begin{bmatrix}0&1&0\\9.8&0&1\\0&-10&-10\end{bmatrix}$,

$A_2(t)=\begin{bmatrix}0&1&0\\0&0&1\\0&-10&-10\end{bmatrix}$, $B_1(t)=B_2(t)=[0,\ 0,\ 10]^{\mathrm{T}}$,

$C_1=C_2=\begin{bmatrix}1&0&0\\0&1&0\end{bmatrix}$ denote the feedback of the angle and angular velocity of the pendulum, simultaneously, $M_{11}(z_1(t))=\begin{cases}z_1(t), & x_1(t)\ne 0,\\1, & \text{otherwise},\end{cases}$ and $M_{21}(z_1(t))=1-M_{11}(z_1(t))$.

The quadratic integral performance index is

$$\begin{aligned}J&=\int_0^5[y^{\mathrm{T}}(t)Qy(t)+u^{\mathrm{T}}(t)Ru(t)]dt\\&=\sum_{k=0}^{q-1}\int_{kt_f}^{(k+1)t_f}[y^{\mathrm{T}}(t)Qy(t)+u^{\mathrm{T}}(t)Ru(t)]dt,\end{aligned} \quad (20)$$

where $q=500$, $t_f=0.01$, $Q=\mathrm{diag}\{1,\ 1\}$ and $R=1$.

By using the proposed integrative approach and the LMI toolbox [11], we can obtain a symmetric positive definite matrix P and the symmetric positive semidefinite matrix Q_1 and Q_2, respectively, as

$$P=\begin{bmatrix}167.7466&7.3397&0.7956\\7.3397&6.4890&0.1333\\0.7956&0.1333&0.0294\end{bmatrix},$$

$$Q_1=\begin{bmatrix}6.6895&0.5061&0.5553\\0.5061&12.5640&0.2238\\0.5553&0.2238&0.0690\end{bmatrix}$$

and

$$Q_2 = \begin{bmatrix} 59.2127 & 18.7103 & 0.5746 \\ 18.7103 & 13.1713 & 0.0558 \\ 0.5746 & 0.0558 & 0.0463 \end{bmatrix}.$$

The responses of the angle of the pendulum $x_1(t)$, and the angular velocity $x_2(t)$ for a nonlinear inverted pendulum system controlled by a separately excited DC motor system with the designed stable and quadratic-optimal static output feedback PDC controller obtained by using the proposed integrative approach are, respectively, shown in Figures 1 and 2. It can be seen that the proposed approach can have the satisfactory control results.

V. CONCLUSIONS

Based on the OFA, an algorithm has been presented in this paper for solving the TS-fuzzy-model-based feedback dynamic equations. Then, the presented algebraic algorithm is integrated with the HTGA to design the stable and quadratic-optimal static output feedback PDC controllers of the TS-fuzzy-model-based control systems such that the control objective of directly minimizing a quadratic integral performance index subject to the constraint of LMI-based stabilizability condition can be achieved, where the quadratic integral performance index is also converted into the algebraic form by using the OFA. The illustrative example regarding the nonlinear inverted pendulum system controlled by a separately excited DC motor has shown that the proposed approach is effective for designing the stable and quadratic optimal static output feedback PDC controllers of the TS-fuzzy-model-based control systems.

***Abstract*—This paper considers multiobjective linear programming problems where each coefficient of the objective functions is expressed by a random fuzzy variable. A new decision making model is proposed in order to maximize both of possibility and probability with respect to the objective function values. An interactive algorithm is constructed to obtain a satisficing solution for a decision maker from among a set of Pareto optimal solutions.**

***Index Terms*—random fuzzy variable; multiobjective programming; interactive algorithm; possibility measure; probability maximization**

I. Introduction

In the real-world, we are often faced with decision making problems under uncertainty. Recently, many researchers focus on mathematical programming problems including not only randomness but fuzziness. One of mathematical concepts dealing with both fuzziness and randomness is a *fuzzy random variable* [1], [2], and its applications are discussed [3], [4], [5], [6], [7], [8].

On the other hand, very recently, a random fuzzy variable [11] draws attention as a new tool for decision making under uncertainty. For example, parameters such as mean and variance of random variables may not be estimated as constants. In this case, random variables with fuzzy mean are expressed as random fuzzy variables.

Some studies focus on applications of random fuzzy variable [9], [10], [11], [12], [13]. These previous studies discussed a single objective case. However, when considering the real-world decision making situation that there are several conflicting objective functions, it needs to tackle a multiobjective case under random fuzzy environments. Therefore, this article develops a new multiobjective random fuzzy programming model which obtains a satisficing solution from among a Pareto optimal solution for a decision maker.

II. Random fuzzy variable

In the framework of stochastic programming [14], [15], [16], it is implicitly assumed that the uncertain parameter which well represents the stochastic factor of real systems can be definitely expressed as a single random variable. However, from the expert's experimental point of view, the experts may think of a collection of random variables to be appropriate to express stochastic factors rather than only a single random variables. In this case, reflecting the expert's conviction degree that each of random variables properly represents the stochastic factor, it would be quite reasonable to assign the different degrees of possibility to each of random variables. For handling such an uncertain parameter, a random fuzzy variable was defined by [11] as a function from a possibility space to a collection of random variables, which is considered to be an extended concept of fuzzy variable [17]. Considering that the fuzzy variables can be viewed as another way of dealing with the imprecision which was originally represented by fuzzy sets, the random fuzzy variable can be defined as an extension of fuzzy sets using the concept of membership function, instead of fuzzy variables. In this paper, we define the random fuzzy variables along the fusion line of membership functions and random variables.

Definition 1 (Random fuzzy variable) *Let Γ be a collection of random variables. Then, a random fuzzy variable $\tilde{\bar{C}}$ is defined by its membership function*

$$\mu_{\tilde{\bar{C}}} : \Gamma \to [0, 1]. \tag{1}$$

In Definition 1, the membership function $\mu_{\tilde{\bar{C}}}$ assigns each random variable $\bar{\gamma} \in \Gamma$ to a real number $\mu_{\tilde{\bar{C}}}(\bar{\gamma})$. It should be noted here that if Γ is defined as $\mathbb{R}$, then (1) becomes equivalent to the membership function of an ordinary fuzzy set. In this sense, a random fuzzy variable can be regarded as

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

an extended concept of fuzzy sets. On the other hand, if Γ is defined as a singleton $\Gamma = \{\bar{\gamma}\}$ and $\mu_{\bar{\tilde{C}}}(\bar{\gamma}) = 1$, then the corresponding random fuzzy variable $\bar{\tilde{C}}$ can be viewed as an ordinary random variable.

When taking account of the imprecise nature of the realized values of random variables, it would be appropriate to employ the concept of fuzzy random variables. However, it should be emphasized here that if mean and/or variance of random variables are specified by the expert as a set of real values or fuzzy sets, such uncertain parameters can be represented by not fuzzy random variables but random fuzzy variables.

As a simple example of random fuzzy variables, we consider a Gaussian random variable whose mean value is not definitely specified as a constant. For example, when some random parameter $\bar{\gamma}$ is represented by the Gaussian random variable $N(s_i, 10^2)$ where the expert identifies a set $\{s_1, s_2, s_3\}$ of possible mean values as $(s_1, s_2, s_3) = (90, 100, 110)$, if the membership function $\mu_{\bar{\tilde{C}}}$ is defined by

$$\mu_{\bar{\tilde{C}}}(\bar{\gamma}) = \begin{cases} 0.5 & \text{if } \bar{\gamma} \sim N(90, 10^2) \\ 0.7 & \text{if } \bar{\gamma} \sim N(100, 10^2) \\ 0.3 & \text{if } \bar{\gamma} \sim N(110, 10^2) \\ 0 & \text{otherwise,} \end{cases}$$

then $\bar{\tilde{C}}$ is a random fuzzy variable. More generally, when the mean values are expressed as fuzzy sets or fuzzy numbers, the corresponding random variable with the fuzzy mean is represented by a random fuzzy variable, as will be discussed in the following sections.

III. Problem formulation

Most of the real-world decision making problems usually involve multiple, noncommensurable, and conflicting objectives which should be considered simultaneously. In this paper, we consider the following multiobjective programming problem in which random fuzzy variables are involved in the objective functions:

$$\left.\begin{array}{ll} \text{minimize} & \bar{\tilde{\boldsymbol{C}}}_1\boldsymbol{x} \\ & \cdots \\ \text{minimize} & \bar{\tilde{\boldsymbol{C}}}_k\boldsymbol{x} \\ \text{subject to} & A\boldsymbol{x} \le \boldsymbol{b},\ \boldsymbol{x} \ge \boldsymbol{0}, \end{array}\right\} \tag{2}$$

where $\boldsymbol{x}$ is an n-dimensional decision variable column vector, A is an $m \times n$ matrix, $\boldsymbol{b}$ is an $m \times 1$ constant column vector, and $\bar{\tilde{\boldsymbol{C}}}_l = (\bar{\tilde{C}}_{l1}, \ldots, \bar{\tilde{C}}_{ln})$ is a random fuzzy variable coefficient vector. Here, assume that $\bar{\tilde{C}}_{lj}$ is a Gaussian random variable whose mean value is a fuzzy number $\tilde{M}_{lj}$ characterized by the membership function

$$\mu_{\tilde{M}_{lj}}(\tau) = \begin{cases} L\left(\dfrac{m_{lj} - \tau}{\alpha_{lj}}\right) & \text{if } m_{lj} \ge \tau \\ R\left(\dfrac{\tau - m_{lj}}{\beta_{lj}}\right) & \text{if } m_{lj} < \tau, \end{cases} \tag{3}$$

where L and R are nonincreasing continuous functions from $[0, \infty)$ to $[0, 1]$.

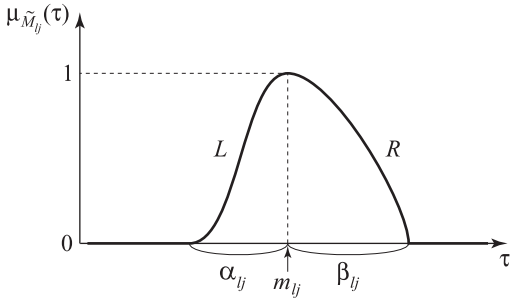

Fig. 1. Membership function $\mu_{\tilde{M}_{lj}}$.

Let Γ be a collection of all possible Gaussian random variables $N(s, \sigma^2)$ where $s \in (-\infty, \infty)$ and $\sigma^2 \in (0, \infty)$. Then, the membership function of $\bar{\tilde{C}}_{lj}$ is expressed as

$$\mu_{\bar{\tilde{C}}_{lj}}(\bar{\gamma}_{lj}) = \{\mu_{\tilde{M}_{lj}}(s_{lj}) | \bar{\gamma}_{lj} \sim N(s_{lj}, \sigma_{lj}^2)\},\ \forall \bar{\gamma}_{lj} \in \Gamma. \tag{4}$$

Using the Zadeh's extension principle, each objective function $\bar{\tilde{\boldsymbol{C}}}_l\boldsymbol{x}$ is expressed as a single random fuzzy variable characterized by the membership function

$$\mu_{\bar{\tilde{\boldsymbol{C}}}_l\boldsymbol{x}}(\bar{u}_l) \triangleq \sup_{\bar{\boldsymbol{\gamma}}_l} \left\{ \min_{1 \le j \le n} \mu_{\bar{\tilde{C}}_{lj}}(\bar{\gamma}_{lj}) \;\middle|\; \bar{u}_l = \sum_{j=1}^{n} \bar{\gamma}_{lj} x_j \right\},\ \forall \bar{u}_l \in \Gamma, \tag{5}$$

where $\bar{\boldsymbol{\gamma}}_l = (\bar{\gamma}_1, \ldots, \bar{\gamma}_n)$.

By substituting (4) into (5), the membership function of a random fuzzy variable corresponding to the objective function $\bar{\tilde{\boldsymbol{C}}}_l\boldsymbol{x}$ in (2) is rewritten as

$$\begin{aligned} & \mu_{\bar{\tilde{\boldsymbol{C}}}_l\boldsymbol{x}}(\bar{u}_l) \\ = & \sup_{\boldsymbol{s}_l} \left\{ \min_{1 \le j \le n} \mu_{\tilde{M}_{lj}}(s_{lj}) \;\middle|\; \bar{u}_l \sim N\Big(\sum_{j=1}^{n} s_{lj} x_j, \sum_{j=1}^{n} \sigma_{lj}^2 x_j^2 \Big) \right\}, \end{aligned} \tag{6}$$

where $\boldsymbol{s}_l = (s_{l1}, \ldots, s_{ln})$.

IV. Possibility-based probability model

Assuming that the DM concerns about the probability that each of the objective function values $\bar{\tilde{\boldsymbol{C}}}_l\boldsymbol{x}$ is smaller than or equal to a certain target values f_l, $l = 1, \ldots, k$, we introduce the probability $P\left(\omega \;\middle|\; \tilde{\boldsymbol{C}}_l(\omega)\boldsymbol{x} \le f_l\right)$ which is expressed as a fuzzy set $\tilde{P}_l$ with the membership function

$$\mu_{\tilde{P}_l}(p_l) = \sup_{\bar{u}_l} \left\{ \mu_{\bar{\tilde{\boldsymbol{C}}}_l\boldsymbol{x}}(\bar{u}_l) \;\middle|\; p_l = P\left(\omega \mid u_l(\omega) \le f_l\right) \right\}, \tag{7}$$

where f_l, $l = 1, \ldots, k$ are specified by the DM as constants. In order to consider the imprecise nature of the DM's judgments for the probability with respect to the lth objective function, we introduce the fuzzy goal $\tilde{G}_l$ with the nondecreasing continuous membership function $\mu_{\tilde{G}_l}$.

Recalling that the membership function $\mu_{\tilde{P}_l}(p_l)$ can be viewed as a possibility distribution on the basis of the concept of possibility measure [18], [19], the degree of possibility that

the fuzzy goal $\tilde{G}_l$ for the probability $\tilde{P}_l$ is satisfied is expressed by

$$\Pi_{\tilde{P}_l}(\tilde{G}_l) \triangleq \sup_{p_l} \min\{\mu_{\tilde{P}_l}(p_l),\ \mu_{\tilde{G}_l}(p_l)\}. \tag{8}$$

Then, we consider the possibility-based probability model for multiobjective random fuzzy programming problems formulated as

$$\left.\begin{array}{ll} \text{maximize} & \Pi_{\tilde{P}_1}(\tilde{G}_1) \\ & \cdots\cdots \\ \text{maximize} & \Pi_{\tilde{P}_k}(\tilde{G}_k) \\ \text{subject to} & A\boldsymbol{x} \le \boldsymbol{b},\ \boldsymbol{x} \ge \boldsymbol{0} \end{array}\right\} \tag{9}$$

or equivalently

$$\left.\begin{array}{ll} \text{maximize} & h_1 \\ & \vdots \\ \text{maximize} & h_k \\ \text{subject to} & \Pi_{\tilde{P}_l}(\tilde{G}_l) \ge h_l,\ 0 \le h_l \le 1,\ l = 1, \ldots, k \\ & A\boldsymbol{x} \le \boldsymbol{b},\ \boldsymbol{x} \ge \boldsymbol{0}. \end{array}\right\} \tag{10}$$

It should be noted here that (10) is regarded as a multiobjective decision making problem, and that there rarely exists a complete optimal solution that simultaneously optimizes all the objective functions. In this case, it is reasonable to find a Pareto optimal solution or a non-dominated solution.

V. Interactive satisficing method

By introducing an aggregation function $f_D(\boldsymbol{x}, \boldsymbol{h})$ for the k objective functions in (10), where $\boldsymbol{h} = (h_1, \ldots, h_k)$, the multiobjective programming problem (10) can be generally rewritten as

$$\left.\begin{array}{ll} \text{maximize} & f_D(\boldsymbol{x}, \boldsymbol{h}) \\ \text{subject to} & (\boldsymbol{x}, \boldsymbol{h}) \in X, \end{array}\right\} \tag{11}$$

where X is a feasible solution of (10).

The most crucial problem in (11) is probably the identification of an appropriate aggregation function which well represents the DM's preference. If $f_D(\boldsymbol{x}, \boldsymbol{h})$ can be explicitly identified, then (11) can be reduced to a standard mathematical programming problem, and the corresponding optimal solution is regarded as a Pareto optimal solution which is most desirable for the decision maker. However, the success in identifying such an aggregation function rarely happens, and then as an alternative way, it is recommended for the DM to examine multiple possible solutions in the set of Pareto optimal solutions through an interactive solution procedure to find a satisficing solution to (11).

In such an interactive satisficing method, to generate a candidate for a satisficing solution which is also Pareto optimal, the DM is asked to specify the aspiration levels of achievement for all the objective function values, called the reference levels.

For the DM's reference levels $\hat{h}_l$, $l = 1, \ldots, k$, the corresponding Pareto optimal solution, which is the nearest to the vector of the given reference levels in the minimax sense or better than it if the reference levels are attainable, is obtained by solving the minimax problem

$$\left.\begin{array}{ll} \text{minimize} & \max\limits_{l=1,\ldots,k} \left\{\hat{h}_l - h_l\right\} \\ \text{subject to} & \Pi_{\tilde{P}_l}(\tilde{G}_l) \ge h_l,\ l = 1, \ldots, k \\ & A\boldsymbol{x} \le \boldsymbol{b},\ \boldsymbol{x} \ge \boldsymbol{0}. \end{array}\right\} \tag{12}$$

Here, it should be stressed that if an optimal solution $(\boldsymbol{x}^*, \boldsymbol{h}^*)$ to (12) is not unique, then Pareto optimality of $\boldsymbol{x}^*$ is not guaranteed, and just weak Pareto optimality is assured. To obtain a Pareto optimal solution in a strict sense, we consider the augmented minimax problem

$$\left.\begin{array}{ll} \text{minimize} & \max\limits_{l=1,\ldots,k} \left\{\hat{h}_l - h_l + \rho \sum\limits_{l=1}^{k} (\hat{h}_l - h_l)\right\} \\ \text{subject to} & \Pi_{\tilde{P}_l}(\tilde{G}_l) \ge h_l,\ l = 1, \ldots, k \\ & A\boldsymbol{x} \le \boldsymbol{b},\ \boldsymbol{x} \ge \boldsymbol{0}, \end{array}\right\} \tag{13}$$

where ρ is a sufficiently small positive number.

From (8), the constraint $\Pi_{\tilde{P}_l}(\tilde{G}_l) \ge h_l$ in (13) is equivalently replaced by the condition that there exists a p_l such that $\mu_{\tilde{P}_l}(p_l) \ge h_l$ and $\mu_{\tilde{G}_l}(p_l) \ge h_l$, namely,

$$\sup_{\boldsymbol{s}_l} \min_{1 \le j \le n} \left\{ \mu_{\tilde{M}_{lj}}(s_{lj}) \;\middle|\; p_l = P\left(\omega \mid u_l(\omega) \le f_l\right), \right. \\ \left. \bar{u}_l \sim N\Big(\sum_{j=1}^{n} s_{lj} x_j, \sum_{j=1}^{n} \sigma_{lj}^2 x_j^2 \Big) \right\} \ge h_l \tag{14}$$

and $p_l \ge \mu^{\star}_{\tilde{G}_l}(h_l)$, where $\mu^{\star}_{\tilde{G}_l}(h_l)$ is a pseudo inverse function defined as $\mu^{\star}_{\tilde{G}_l}(h_l) = \sup\{p_l \mid \mu_{\tilde{G}_l}(p_l) \ge h_l\}$. This implies that there exists a vector $(p_l, \boldsymbol{s}_l, \bar{u}_l)$ such that

$$\min_{1 \le j \le n} \mu_{\tilde{M}_{lj}}(s_{lj}) \ge h_l,\ \bar{u}_l \sim N\left(\sum_{j=1}^{n} s_{lj} x_j, \sum_{j=1}^{n} \sigma_{lj}^2 x_j^2 \right), \\ p_l = P\left(\omega \mid u_l(\omega) \le f\right),\ p_l \ge \mu^{\star}_{\tilde{G}_l}(h_l),$$

which can be equivalently transformed into the condition that there exists a vector $(\boldsymbol{s}_l, \bar{u}_l)$ such that

$$\left.\begin{array}{l} \mu_{\tilde{M}_{lj}}(s_{lj}) \ge h_l,\ j = 1, \ldots, n, \\ \bar{u}_l \sim N\left(\sum\limits_{j=1}^{n} s_{lj} x_j, \sum\limits_{j=1}^{n} \sigma_{lj}^2 x_j^2 \right), \\ P\left(\omega \mid u_l(\omega) \le f_l\right) \ge \mu^{\star}_{\tilde{G}_l}(h_l). \end{array}\right\} \tag{15}$$

In view of (3), it follows that

$$\mu_{\tilde{M}_{lj}}(s_{lj}) \ge h_l \Leftrightarrow s_{lj} \in [m_{lj} - L^{\star}(h_l)\alpha_{lj},\ m_{lj} + R^{\star}(h_l)\beta_{lj}],$$

where $L^{\star}(h_l)$ and $R^{\star}(h_l)$ are pseudo inverse functions defined as $L^{\star}(h_l) = \sup\{t \mid L(t) \ge h_l\}$ and $R^{\star}(h_l) = \sup\{t \mid R(t) \ge h_l\}$. Hence, (15) is rewritten as the equivalent condition that there exists a $\bar{u}$ such that

$$P\left(\omega \mid u_l(\omega) \le f_l\right) \ge \mu^{\star}_{\tilde{G}}(h_l), \\ \bar{u}_l \sim N\left(\sum_{j=1}^{n} \{m_{lj} - L^{\star}(h_l)\alpha_{lj}\} x_j, \sum_{j=1}^{n} \sigma_{lj}^2 x_j^2 \right).$$

Since $P(\omega \mid u_l(\omega) \leq f_l)$ is transformed into

$$P\left(\omega \;\middle|\; \frac{u_l(\omega) - \sum_{j=1}^{n}\{m_{lj} - L^\star(h_l)\alpha_{lj}\}x_j}{\sqrt{\sum_{j=1}^{n}\sigma_{lj}^2 x_j^2}} \leq \frac{f_l - \sum_{j=1}^{n}\{m_{lj} - L^\star(h_l)\alpha_{lj}\}x_j}{\sqrt{\sum_{j=1}^{n}\sigma_{lj}^2 x_j^2}}\right),$$

in consideration of

$$\frac{\bar{u}_l - \sum_{j=1}^{n}\{m_{lj} - L^\star(h_l)\alpha_{lj}\}x_j}{\sqrt{\sum_{j=1}^{n}\sigma_{lj}^2 x_j^2}} \sim N(0,1),$$

(16) is equivalently transformed as

$$\Phi\left(\frac{f_l - \sum_{j=1}^{n}\{m_{lj} - L^\star(h_l)\alpha_{lj}\}x_j}{\sqrt{\sum_{j=1}^{n}\sigma_{lj}^2 x_j^2}}\right) \geq \mu_{\tilde{G}_l}^\star(h_l), \qquad (16)$$

where Φ is a probability distribution function of the standard Gaussian random variable $N(0,1)$.

From the monotone increasingness of Φ, (16) is rewritten as

$$\sum_{j=1}^{n}\{m_j - L^\star(h_l)\alpha_{lj}\}x_j + \Phi^{-1}(\mu_{\tilde{G}_l}^\star(h_l))\sqrt{\sum_{j=1}^{n}\sigma_{lj}^2 x_j^2} \leq f, \qquad (17)$$

where Φ^{-1} is the inverse function of Φ.

From (14)$-$(17), it holds that

$$\Pi_{\tilde{P}_l}(\tilde{G}_l) \geq h \Leftrightarrow \sum_{j=1}^{n}\{m_{lj} - L^\star(h_l)\alpha_{lj}\}x_j + \Phi^{-1}(\mu_{\tilde{G}_l}^\star(h_l))\sqrt{\sum_{j=1}^{n}\sigma_{lj}^2 x_j^2} \leq f. \qquad (18)$$

Consequently, (13) is rewritten as

$$\left.\begin{array}{ll} \text{minimize} & \max\limits_{l=1,\ldots,k}\left\{\hat{h}_l - h_l + \rho\sum\limits_{l=1}^{k}(\hat{h}_l - h_l)\right\} \\ \text{subject to} & \sum\limits_{j=1}^{n}\{m_{lj} - L^\star(h_l)\alpha_{lj}\}x_j \\ & \quad + \Phi^{-1}(\mu_{\tilde{G}_l}^\star(h_l))\sqrt{\sum\limits_{j=1}^{n}\sigma_{lj}^2 x_j^2} \leq f_l,\ l = 1,\ldots,k \\ & A\boldsymbol{x} \leq \boldsymbol{b},\ \boldsymbol{x} \geq \boldsymbol{0}. \end{array}\right\} \qquad (19)$$

Observing that (19) is a nonconvex nonlinear programming problem, we can employ genetic algorithms such as GENOCOPIII [20] or the revised GENOCOPIII [21] in order to obtain an approximate solution.

Now we are ready to construct an interactive algorithm for deriving the satisficing solution for the DM from among the Pareto optimal solution set.

Interactive satisficing method for the possibility-based probability model

Step 1: Ask the DM to specify the membership functions $\mu_{\tilde{G}_l}$ and the target values f_l, $l = 1,\ldots,k$.

Step 2: Set the initial reference possibility levels at 1s, which can be viewed as the ideal values, i.e., $\hat{h}_l = 1,\ l = 1,\ldots,k$.

Step 3: For the current reference possibility levels $\hat{h}_l$, $l = 1,\ldots,k$, solve the augmented minimax problem (19).

Step 4: The DM is supplied with the corresponding Pareto optimal solution $\boldsymbol{x}^*$. If the DM is satisfied with the current objective function values $h_l^*,\ l = 1,\ldots,k$, then stop. Otherwise, ask the DM to update the reference possibility levels $\hat{h}_l,\ l = 1,\ldots,k$ by considering the current values of objective functions $h_l,\ l = 1,\ldots,k$, and return to step 3.

It should be noted for the DM that any improvement of one objective function value can be achieved only at the expense of at least one of the other objective function values for the fixed target values $f_l,\ l = 1,\ldots,k$.

VI. Conclusions

In this paper, we have considered multiobjective programming problems in which the coefficients of the objective functions are random fuzzy variables. Incorporating the concept of possibility measure into the stochastic programming models, we have proposed a possibility-based probability model for random fuzzy programming problems. It has been shown that the formulated problem based on the proposed model can be transformed into deterministic nonlinear programming problem. In order to obtain a satisficing solution for a decision maker from among a Pareto optimal solution set, we have constructed an interactive satisficing algorithm.

In the future, we will consider more general problems in which random fuzzy variables are involved not only in the objective function but also in the constraints. Furthermore,

extensions of the proposed models to integer problems will be discussed elsewhere.

***Abstract*—Born primarily as means to model knowledge, ontologies have successfully been exploited to enable knowledge exchange among people, organizations and software agents. However, because of strong subjectivity of ontology modeling, a matching process is necessary in order to lead ontologies into mutual agreement and obtain the relative alignment, i.e., the set of correspondences among them. The aim of this paper is to propose a memetic algorithm to perform an automatic matching process capable of computing a suboptimal alignment between two ontologies. To achieve this aim, the ontology alignment problem has been formulated as a minimum optimization problem characterized by an objective function depending on a fuzzy similarity. As shown in the performed experiments, the memetic approach results more suitable for ontology alignment problem than other evolutionary techniques such as genetic algorithms.**

***Index Terms*—Memetic Algorithms, Ontology Alignment, Optimization.**

I. Introduction

Nowadays, ontologies are recognized to be the most appropriate means to support information sharing and reuse in all modern knowledge based systems. They have been successfully exploited in many research areas such as artificial intelligence (AI), information retrieval (IR), database theory, and most recently, World Wide Web (in particular for Semantic Web), e-Commerce and e-Learning. According to [1], an ontology is an explicit specification of a conceptualization, i.e., the objects, concepts, and other entities that are presumed to exist in some area of interest and the relationships that hold them[2]. Unfortunately, the variety of ways that a domain can be conceptualized (by considering different concepts, constraints and properties) results in the creation of different ontologies with contradicting or overlapping parts[3]. Therefore, a so called *mapping process* is necessary in order to reconcile heterogeneous ontologies and allow system interoperability. The recent researches about ontologies are heavily focused in the development of several automatic reconciliation processes to overcome this heterogeneity. One of the principal techniques is the so-called *matching process* which consists in detecting correspondences among existing ontologies in order to make them consistent. Different from other mapping methods such as *integration* and *merging* which return a single ontology, the matching process keeps separate the original ontologies and generates in output an *alignment*, i.e., the set of correspondences among them. In order to perform a matching process and to find an appropriate alignment between two ontologies, a lot of techniques[4][5][6] based on different theories have been exploited. The main aim of this paper is to propose an innovative method to perform an automatic matching process based on the so-called *memetic algorithms*, i.e, optimization hybrid methods which combine evolutionary algorithms with local search techniques [7]. In order to solve the ontology alignment problem through a memetic approach, a formulation of the alignment problem as a minimization problem has been provided by defining an appropriate objective function based on a fuzzy similarity measure able to quantify the matching level between ontologies entities.

In the experimental results section, our proposal is compared with genetic algorithms in order to show, in the ontology alignment problem context, the more suitability and efficiency of the memetic approach than other evolutionary techniques. The evaluation of the algorithms is executed through a statistical analysis, and precisely, by means of the well-known Wilcoxon's signed rank test[8]. The used benchmarks are provided by the Ontology Alignment Evaluation Initiative (OAEI) 2009 [9].

II. The Ontology Alignment Problem

In this section, a set of formal definitions concerning to matching process are given. According to [10], a matching process consists of generating an alignment (A') from a pair of ontologies (o and o') given in input. So, before formally defining the matching process, the conventional definitions of ontology and alignment are provided.

Definition 1 (Ontology): An ontology O is a triple

$$O = (C, P, I)$$

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

where C is the set of *classes*, P the set of *properties* and I the set of *individuals*.

Definition 2 (Alignment): An alignment is a set of so-called *mapping elements*. A mapping element is a 5-uple: $\langle id, e, e', n, R\rangle$ where

- id is a unique identifier of the given mapping element;
- e and e' are the entities (e.g., tables, XML elements, properties, classes) of the first and the second ontology respectively;
- n is a confidence measure in some mathematical structure (typically in the [0,1] range) holding for the correspondence between the entities e and e';
- R is a relation (e.g., equivalence ($=$); more general ($\sqsupseteq$); disjointness ($\perp$); overlapping ($\sqcap$)) holding between the entities e and e'.

In order to compute a mapping element, a matching process uses a *similarity measure* which determines the closeness between the entities e and e' in the range $[0, 1]$ where 0 stands for complete inequality and 1 for complete equality. A lot of kinds of similarity measures exist in literature. In particular, there are techniques which rely on vector representations of ontologies and use distances measures between these vectors and other approaches which consider an ontology as a set of entities and so depend on the techniques used for establishing the distance among ontology entities. A comparison between similarity distances is provided in [11].

In order to perform a matching process two input ontologies o and o' are needed, but also other optional inputs can be specified: a partial alignment A which is to be completed by the process to obtain A'; some parameters such as weights and thresholds and some external resources such as lexicons and databases. Therefore, the matching or alignment process can be formally defined as follows:

Definition 3 (Matching process): The matching process can be seen as a function ϕ which, from a pair of ontologies o and o' to align, an input alignment A, a set of parameters p, a set oracles and resources r, returns a new alignment A' between these ontologies:

$$A' = \phi(o, o', A, p, r).$$

In order to evaluate the quality of the output alignment A' provided by a matching process, typically conformance measures derived from the information retrieval field [12] are exploited. These methods require the employment of a *reference alignment* R. The most commonly used conformance measures are *precision*, *recall* and *f-measure* which represents a combination of the first ones. Formally:

Definition 4 (Precision): Given a reference alignment R, the precision of an alignment A is given by

$$Pr(A, R) = \frac{|R \cap A|}{|A|}.$$

Definition 5 (Recall): Given a reference alignment R, the recall of an alignment A is given by

$$Rec(A, R) = \frac{|R \cap A|}{|R|}.$$

Definition 6 (F-measure): Given a reference alignment R and a number α between 0 and 1, the F-measure of an alignment A is given by

$$M_\alpha = \frac{Pr(A, R) \cdot Rec(A, R)}{(1 - \alpha) \cdot Pr(A, R) + \alpha \cdot Rec(A, R)}.$$

If $\alpha = 1$, then the F-measure is equal to precision and if $\alpha = 0$, the F-measure is equal to recall. In between, the higher α, the more importance is given to precision with regard to recall. Very often, the value $\alpha = 0.5$ is used, i.e.,

$$M = \frac{2 \times Pr(A, R) \times Rec(A, R)}{Pr(A, R) + Rec(A, R)},$$

the harmonic mean of precision and recall.

In order to perform a matching process and to find an appropriate alignment between two ontologies, a lot of techniques based on different theories have been exploited. All methods can be classified as *instance-based* and *schema-based*: in order to perform a matching process, the former use all entities of an ontology including the individuals, the latter use only entities as classes and properties. A furthermore classification based on the kinds of inputs is possible among schema-based methods obtaining the following three categories: *terminological*, *structure* and *semantics* methods. A complete discussion can be found in [13]. Only recently, also evolutive methods such as machine learning and genetic algorithms have been exploited to solve the alignment problem[14][15][16].

Taking a cue from these new researches, our work proposes to detect correspondences between two ontologies by means of a memetic algorithm which performs a schema-based matching process taking in input two ontologies (leaving out the other input parameters) and considering a string distance based similarity measure.

III. Ontology Alignment as Optimization Problem

In this section, a formal definition of the ontology alignment problem is given by reformulating it as a minimization problem based an objective function that uses a fuzzy similarity in order measure the correspondence between ontology entities.

Beside the general scheme presented in the section II, the alignment process can be opportunely restricted in order to deliver a particular kind of alignment useful for a particular kind of applications. In particular, in our approach, the ontology alignment problem is depending upon the following features:

- a simplified definition of mapping element, renamed *correspondence* (see definition 7), which implies the equality as the relation R;
- cardinality $n : 1$ (many-to-one), i.e., an entity of the first ontology can be associated with an only entity of the second one, whereas, an entity of the second ontology can be associated also with more entities of the first one.

Definition 7 (Correspondence): For two ontologies O_1 and O_2, a correspondence is defined as:

$$c = (e_i, e_j)$$

where e_i is the i^{th} entity of ontology O_1 whereas e_j is the j^{th} entity of ontology O_2 and the implied relation is the equality with a confidence measure in $[0, 1]$.

Basing on these features, the formal definition of the ontology alignment problem taken into account in this work can be provided.

Definition 8 (Alignment): An alignment A between two ontology O_1 and O_2 is the set:

$$A = \{c_k = (e_i, e_j) | e_i \in O_1 \text{ with } i = 0, \ldots, h_1 - 1, \\ e_j \in O_2 \text{ with } j \in \{0, \ldots, h_2 - 1\} \text{ and} \\ k = 1, 2, \ldots, h_1\}$$

where $h_1 = |O_1|$ and $h_2 = |O_2|$.

In order to formulate the considered alignment problem as optimization problem, it is necessary to introduce the concept of the *evaluation of a correspondence*. The evaluation is performed by a method whose aim is to determine the goodness of a correspondence to achieve an optimal alignment. In general, the evaluation method is a function $f : A \rightarrow \mathbb{R}$ which associates a real value to each correspondence in A. In our work, a *fuzzy similarity* between the name labels of the entities composing a correspondence is chosen to realize the evaluation method. Precisely, the goodness of a correspondence is evaluated through a fuzzy relation between entity names computed by means of the well-known *levenshtein string distance* [17]. Formally, by considering s_1 and s_2 the name labels of the entities involved in the correspondence $c \in A$, the exploited evaluation method is given by the formula:

$$f(c) = \mu(s_1, s_2)$$

where $\mu : S \times S \rightarrow [0, 1]$ (S is the set of all entities names) is a membership function defined as follows:

$$\mu(s_1, s_2) = \frac{lev(s_1, s_2)}{N}$$

where

- $lev(s_1, s_2)$ is the levenshtein distance between the two strings s_1 and s_2, i.e, the minimum number of edits needed to transform the string s_1 into s_2, with the allowable edit operations being insertion, deletion, or substitution of a single character;
- $N = max(N_1, N_2)$ with N_1 and N_2, respectively, the lengths of the strings s_1 and s_2.

Finally, the alignment problem can be formulated as an optimization problem.

Definition 9 (Alignment problem): The alignment problem can be defined as the tuple (O_1, O_2, A_{set}, F) where:

- O_1 and O_2 are the ontologies to align:
- A_{set} is the set of all possible alignments between O_1 and O_2;
- $F : A \rightarrow \mathbb{R}$ is the objective function defined in the following way:

$$F(A) = \sum_{i=1}^{|A|} f(c_i) \text{ with } c_i \in A \quad (1)$$

In other words, it is possible to calculate the evaluation value of a specific alignment A by considering the sum of fuzzy evaluations of its correspondences. Since the correspondence evaluation function f is a distance measure between the correspondence entity names, the lower are $F(A)$ values and the alignment A is nearer to optimal one, so our aim is to minimize $F(A)$ values. Therefore, the considered alignment problem is a minimum optimization problem.

IV. Our proposal for the alignment problem: Memetic Algorithms

This paper aims of presenting a novel technique to solve the ontology alignment problem by exploiting an emergent hybrid method named Memetic Algorithms (MAs). The MAs are population-based search methods which combine evolutionary algorithms with local search (LS) methods. The name is inspired by Richard Dawkins concept of a *meme*, which represents a unit of cultural evolution that can exhibit local refinement [18]. Indeed, the MAs have the capability of realizing local search processes within the successive generations characterizing global search methods in order to refine population individuals.

In this section, a memetic algorithm which extends a genetic algorithm with the Stochastic Hill Climbing search is presented. Initially, the two components (the genetic algorithm and the Hill Climbing search) to be combined to realize our proposal are separately described. Then, their merging to perform an automatic matching process is discussed.

A. The First Component: a Genetic Algorithm

Our proposal is to realize a memetic algorithm as extension of a precise category of evolutionary methods, the genetic algorithms. For this reason, in this section the fundamental evolutive concepts and the genetic algorithm which will be extended to solve the considered alignment problem are given.

The interest in genetic algorithms began as early as the 1970s when Holland [19] first proposed them as search methods inspired by the mechanisms of evolutionary processes in nature. In particular, genetic algorithms are based on Darwinian principle of the natural selection which leads to the survival of the only fittest individuals. More in detail, in nature, evolution manifests itself as a succession of changes in species' features determined by genetic reproduction. The individual features, represented by chromosomes (formed in turn by genes), determine the survival capacity of individuals. Indeed, only fittest individuals capable of adapting to the changing environment survive and reproduce. Therefore, the evolution process is derived from the joint action of natural selection and the recombination of genetic material that occurs during reproduction and that generates diversity in the *gene pool* [20].

Genetic algorithms try to solve an optimization (or search) problem by manipulating a *population* of potential solutions and by reproducing the natural evolution process. Specifically, they operate on encoded representations of the solutions, called *chromosomes*, that equivalent to the representations of individual features in nature. The algorithm evolution starts from

a population of randomly generated individuals and consists in successive *generations*. In each generation, as in nature, a *selection process* provides the mechanism for selecting better solutions to survive. Each solution is evaluated by means a *fitness function* that reflects how good it is, compared with other solutions in the population. The higher is the fitness value of an individual and higher are its chances of surviving. Recombination of genetic material in genetic algorithms is simulated through two operators: *crossover* that exchanges portions between two randomly selected chromosomes and *mutation* that causes random alteration of the chromosome genes. The algorithm evolution terminates when specified conditions such as the maximum number of generations are reached. The general genetic algorithm structure is shown in the figure IV-A.

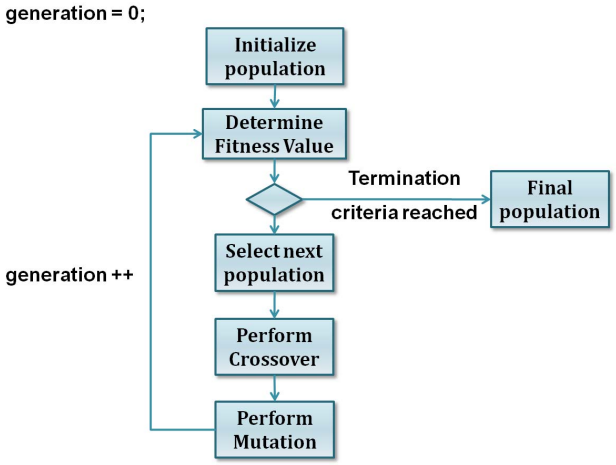

Fig. 1. The typical steps of a genetic algorithm.

In order to customize the building of the starting genetic algorithm for the considered alignment problem, it is necessary to define the chromosome structure in order to represent the solution of our problem, i.e, an alignment, and a fitness function which allows the evaluation of the considered solutions.

In particular, with regard to fitness function, simply it is to minimize the described function F (see eq.1), whereas, the proposed chromosome structure requires a more detailed description.

By remembering the definitions 7 and 8 and considering that each ontology entity is enumerated from 0 to $n+m+k-1$ where m, n, k are, respectively, the cardinalities of the sets C, P, I which compose an ontology, a chromosome representing an alignment A is a integer vector where each cell represents a correspondence between an entity of the first ontology and any entity of the second one. More in detail, by considering that the i^{th} vector cell contains the integer j, the cell represents the correspondence (e_i, e_j). The vector length is the same of the cardinality of alignment A, i.e., the number of the entities of the first ontology. Formally:

Definition 10 (Alignment Chromosome): A chromosome S representing an alignment A between two ontology O_1 and O_2 is the set:

$$S = \{(e_0, e_{j_0}), (e_1, e_{j_1}), (e_2, e_{j_2}), \ldots, (e_h, e_{j_h})\}$$

where $h = |O_1| - 1$ and $j_l \in \{0, 1, 2, \ldots, |O_2| - 1\}$ with $l = 0, 1, 2, \ldots, h$.

Therefore, the chromosome dimension depends on alignment problem instance.

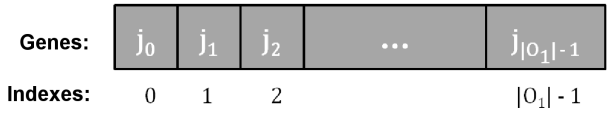

Fig. 2. The general structure of an alignment chromosome: each gene represents the correspondence (e_i, e_{j_i}) where $i = 0, 1, 2, \ldots, |O_1| - 1$ and $j_i \in 0, 1, 2, \ldots, |O_2| - 1$

In order to complete the initial genetic algorithm, the description of termination criteria has to be given. In details, our proposal is to consider a combined termination criterion which stops the genetic algorithm if the maximum number of iterations or the alignment f-measure value (definition 6) is achieved.

Once defined the alignment chromosome, the fitness function and the termination criteria, the genetic algorithm (shown in the table I) could be run in order to solve the described alignment problem.

B. The Second Component: the Hill Climbing Search

The local search strategies such as steepest-descent, conjugate-gradient and linear approximation methods perform iterative search for optimum solution in the *neighborhood* of a candidate. Starting from a single candidate solution, these methods use *local* information to decide which neighbor they should move to next [21]. In each iteration, typically, a mutation operator is applied in order to improve current candidate. The process ends when there are not changes which improve current solution or after a specific number of iterations.

In particular, the Hill Climbing algorithm is a local search iterative method which starts with an arbitrary solution to the problem at issue. During iterations, the algorithm attempts to find a better solution by incrementally changing a single component of the current one. If the change improves the current solution, then the new one becomes the current one. The search is repeated until no further improvements can be found or after a maximum number of iterations. There are several variants of Hill Climbing search depending on how the next solution is tried. For example, the *Simple Hill Climbing algorithm* chooses the first closer node to solution, whereas the *Steepest Ascent Hill Climbing search* compares all successors and then selects the closest.

Our proposal is to use the stochastic version of Hill Climbing search which represents a trade-off between the previous mentioned variants in terms of efficiency and efficacy. The Stochastic Hill Climbing algorithm, presented in the table II, selects a neighbor at random, and then decides whether to move to that neighbor or to examine another by considering the amount of improvement.

TABLE I
LISTING OF THE GENETIC ALGOTIRTHM.

Input: entity name string sets S_1 and S_2 of two ontologies O_1 and O_2 to align; the number of the entities n_1 and n_2 of the ontologies; parameters of GA (size of the population pop_size, crossover rate p_c, mutation rate p_m), temination criteria (maximum number of iterations max_iter and desidered f-measure value $f_{measure}$).

Output: the best optimized alignment (represented by the final best chromosome) between the ontologies O_1 and O_2.

$gen \leftarrow 0$;
$pop \leftarrow$ generatePopulation(pop_size); // Generate randomly an initial population pop of pop_size chromosomes
evaluateFitness(pop); // Evaluate fitness value for each chromosome
$best_chromosome \leftarrow$ getBestChromosome(pop); // Select the best chromosome of the current population
$quality \leftarrow$ evaluateAlignment($best_chromosome$); // $quality$ contains the f-measure value for the current best chromosome
while ($gen \leq max_iter$ AND $quality \leq f_{measure}$) **do**
  executeCrossover(pop, p_c); // Crossover chromosomes according to a crossover rate p_c to add new chromosomes to population pop
  executeMutation(pop, p_m); // Mutate chromosomes with a mutation probability p_m to add new chromosomes to population pop
  evaluateFitness(pop); // Evaluate fitness value for new chromosomes
  executeSelection(pop, pop_size); // Select pop_size chromosomes to generate next new population pop
  $best_chromosome \leftarrow$ getBestChromosome(pop); // Select the best chromosome of the current population
  preserveBestChromosome(pop, $best_chromosome$); // Preserve the best chromosome of the current population: Elitist Strategy
  $gen \leftarrow gen + 1$; // Increment number of iterations
  $quality \leftarrow$ evaluateAlignment($best_chromosome$); // $quality$ contains the f-measure value for the current best chromosome
end while
return $best_chromosome$;

TABLE II
LISTING OF THE STOCHASTIC HILL CLIMBING ALGORITHM.

Input: an alignment chromosome $align_solution$ representing the initial solution, the maximum number of iterations max_iter.

Output: the alignment chromosome sol which represents the solution optimized by means of local search.

$sol \leftarrow align_solution$;
$iter \leftarrow 0$;
while ($iter < max_iter$) **do**
  $new_sol \leftarrow$ getRandomNeighbor(sol);
  if (evaluate(new_sol) $<$ evaluate(sol)) **then**
    $sol \leftarrow new_sol$;
    $iter \leftarrow 0$;
  end if
end while
return sol;

C. Our Memetic Algorithm to Solve the Alignment Problem

In spite of their known efficiency, all local search approaches suffer from the same drawback: they tend to get stuck in local optima. Instead, thanks to their capability of exploring and exploiting promising regions of search space, the genetic algorithms have the strong benefit not to prone to stalling at local optima. However, they can take to relatively long time to locate the exact local optimum in a region of convergence (and may sometimes not to find the optimum with sufficient precision) [21]. For this reason, the idea to create an hybrid method that combines the genetic algorithms with the local search methods, i.e, the MAs.

The MAs, representing the marriage between global search and local improvement, have the complementary advantages of EAs (generality, robustness and global search efficiency) and local search methods (rapid convergence toward local minima). In the figure IV-C the typical structure of MAs which, in literature, are known also as hybrid EAs (e.g., [22]), genetic local searchers (e.g.,), Lamarckian GAs (e.g., [23]), Baldwinian GAs (e.g.,[24]), etc., is presented.

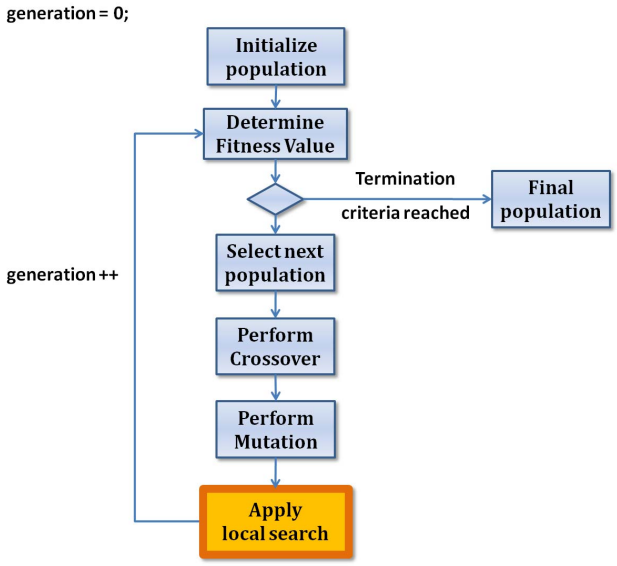

Fig. 3. The general structure of a memetic algorithm

In order to design a *competent* [25] MA a lot of issues must be addressed over the two principal components. Perhaps the foremost of these issues may be stated as [26]: *What is the best tradeoff between local search and the global search provided by evolution?*. This issue leads naturally to questions such as the following:

- *Local search frequency*: How often should local search be applied within the evolutionary cycle?
- *Order respect to genetic operators*: When should local search be applied?

- *Individual selection mechanism*: Which individuals in the population should be improved by local search?
- *Local search intensity*: How much computational effort should be allocated to each local search?

Therefore, in order to complete the design of a memetic algorithm for ontology alignment problem, the aforementioned issues must be considered. Our proposal is to build a memetic algorithm which has the following features:

- *Local search frequency = 1*, i.e., the local search is applied within each evolutionary cycle;
- *Order respect to genetic operators = after*, i.e., local refinement is executed after crossover and mutation operators;
- *Individual selection mechanism = only the best*, i.e., only the best chromosome of population is improved by the local search process;
- *Local search intensity = equal to n local search iterations*, i.e., each local search process ends after running n iterations.

Finally, the whole proposed memetic algorithm is presented in the table III.

V. Experimental results

In this section, an experimentation is led in order to investigate the performances of the proposed memetic algorithm and show the suitability of memetic approach in the ontology alignment context. To achieve this aim, the proposed algorithm is compared with the genetic algorithm shown in the table I.

In our experimentation, the matching process involves ontologies charactering the well-known benchmarks provided by the OAEI 2009. Table IV shows a brief description about the features of the used benchmarks.

TABLE IV
Benchmarks descriptions

Identifier	Description
101	Strictly identical ontologies
103	A regular ontology and other with a language generalization
104	A regular ontology and other with a language restriction
204	Ontologies with different naming conventions
221	A regular ontology and other with no specialisation
224	Identical ontologies without instances
225	Identical ontologies without restrictions

The evaluation of the algorithms is realized by means of a non-parametric statistical procedure for performing pairwise comparisons named Wilcoxon's signed rank test.

A. Characteristics of Experimentation

In this section, a description of the features of the performed experiments is reported.

In particular, the experiments are carried out as follows:

- The memetic and genetic algorithm are run 20 times for each selected benchmark;
- Each run stops when the computed alignment is characterized by a f-measure value equal to 0.8 or after executing 100000 iterations;
- The averages of number of fitness evaluations for each benchmark and for both algorithms are computed and shown in the table V.

The used parameters are the following ones:

- The GA parameters for both algorithms are:
  - population size = 20 chromosomes;
  - crossover rate = 0.8;
  - mutation rate = 0.02.
- The local search parameters are:
  - maximum number of iterations = 50.

Finally, the platform characteristics where the algorithms were run are:

- Processor: Intel Core 2 Duo;
- CPU Speed: 1.83 GHz;
- RAM Capacity: 2GB.

TABLE V
Samples for the Wilcoxon's test: the sigle AE stands for *average of the number of fitness evaluations over the executed 20 runs*

Identifier	Memetic AE	Genetic AE
101	12.120,70	36.287,45
103	11.524,00	33.735,70
104	12.234,85	35.798,70
204	28.558,50	97.602,90
221	11.652,15	34.569,15
224	13.202,50	35.168,30
225	11.532,40	35.167,05

B. Experimentation: Wilcoxon's test

As described in [27], the Wilcoxon's test is a non-parametric procedure employed in a hypothesis testing situation involving a design with two samples. It is a pairwise test used for answering this question: do two samples represent two different populations? Therefore, it can be employed to detect significant differences between the behavior of two algorithms and so it is suitable for our experimentation: showing that the memetic approach is better than genetic one for solving ontology alignment problem.

In order to compute the Wilcoxon's test, two samples related to the two compared algorithms have to be chosen. In our experimentation, the performance of algorithms depends on the executed number of fitness evaluations n_E: the smaller the value n_E and better is the algorithm at issue. For this reason, the two considered samples are represented by the data shown in the table V, i.e, the obtained averages of the number of fitness evaluations related to the two compared algorithms.

In general, a hypothesis testing as the Wilcoxon's test is a procedure in which sample data are employed to evaluate a hypothesis. In details, in order to evaluate the research hypothesis, i.e., the statement of what a researcher predicts,

TABLE III
LISTING OF THE MEMETIC ALGOTIRTHM.

Input: entity name string sets S_1 and S_2 of two ontologies O_1 and O_2 to align; the number of the entities n_1 and n_2 of the ontologies; GA parameters (size of the population pop_size, crossover rate p_c, mutation rate p_m), temination criteria (maximum number of iterations max_iter and desidered f-measure value $f_{measure}$); local search parameters (maximum number of iterations max_local_iter).

Output: the best optimized alignment (represented by the final best chromosome) between the ontologies O_1 and O_2.

$gen \leftarrow 0$;
$pop \leftarrow$ generatePopulation(pop_size); // Generate randomly an initial population pop of pop_size chromosomes
evaluateFitness(pop); // Evaluate fitness value for each chromosome
$best_chromosome \leftarrow$ getBestChromosome(pop); // Select the best chromosome of the current population
$quality \leftarrow$ evaluateAlignment($best_chromosome$); // $quality$ contains the f-measure value for the current best chromosome
while ($gen \leq max_iter$ AND $quality \leq f_{measure}$) **do**
  executeCrossover(pop, p_c); // Crossover chromosomes according to a crossover rate p_c to add new chromosomes to population pop
  executeMutation(pop, p_m); // Mutate chromosomes with a mutation probability p_m to add new chromosomes to population pop
  evaluateFitness(pop); // Evaluate fitness value for new chromosomes
  executeSelection(pop, pop_size); // Select pop_size chromosomes to generate next new population pop
  $best_chromosome \leftarrow$ getBestChromosome(pop); // Select the best chromosome of the current population
  preserveBestChromosome(pop, $best_chromosome$); // Preserve the best chromosome of the current population: Elitist Strategy
  $local_chr \leftarrow$ **executeHillClimbingSearch**($best_chromosome$, max_local_iter); // Execute the local search process on the best chromosome
  replaceWorstChromosome(pop, $local_chr$); // Select the worst chromosome and replace it with that obtained by the local search process
  $gen \leftarrow gen + 1$; // Increment number of iterations
  $quality \leftarrow$ evaluateAlignment($local_chr$); // $quality$ contains the f-measure value for the current best chromosome
end while
return $best_chromosome$;

two statistical hypotheses are needed: the so called *null hypothesis* (H_0) and the so called *alternative hypothesis* (H_1). In our experimentation, the null hypothesis states no difference between algorithms, i.e $H_0 : \theta_D = 0$, indicating that in the underlying populations represented by the two samples related to compared algorithms, the median of the difference scores equals zero. On the other side, a directional alternative hypothesis $H_1 : \theta_D < 0$ is chosen to indicate a difference between the memetic algorithm and the genetic one and specifically the superiority of the first one on the second one. Since the statement of our research hypothesis predicts the presence of a difference between algorithms which are being studied, and in particular, the superiority of memetic one, as result of our experimentation, the null hypothesis is expected to be rejected in favor of the alternative one.

The Wilcoxon's test is usually included in well-known statistical software packages such as SPSS, SAS and R. In particular, our experiment is performed by means of R tool by using the *wilcox* command in this way:

$$wilcox.text(x, y, \text{paired='TRUE', alternative='less'})$$

where x and y are two vectors which contain the averages of numbers of fitness evaluations, respectively, of the memetic and genetic algorithms.

However, before running the Wilcoxon's test, the used level of significance α for the performed experiment has to be decided. In particular, for our experimentation, a level of significance $\alpha = 0.05$ was chosen.

In the figure V-B, the R output for the executed Wilcoxon's test is shown. The computed p-value is 0.007813. Since the output of experimentation results in a p-value $< \alpha$, our experiment rejects the null hypothesis and affirms the superiority of memetic method over genetic approach in the context of the ontology alignment problem.

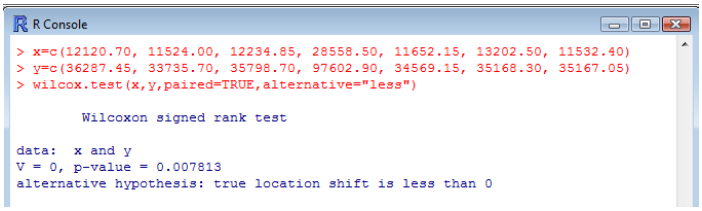

Fig. 4. The result of Wilcoxon's test

VI. CONCLUSIONS

The main aim of this paper is to apply the memetic approach to solve the ontology alignment problem. Memetic algorithms are an emergent optimization technique which combines evolutionary and local search methods. Therefore, in order to exploit a memetic algorithm capable of realizing a so-called matching process between two ontologies, it has been necessary to formulate the ontology alignment problem as a minimum optimization problem and to describe an appropriate objective function defined by means of a fuzzy similarity between the ontology entities. In order to prove the more suitability of the memetic proposal than other evolutionary techniques, an experimentation has been led by comparing the proposed memetic algorithm with the extended genetic one. The performed Wilcoxon's signed rank test shows the higher performances provided by the designed memetic approach.

***Abstract*—In this paper, the genetic fuzzy markup language (GFML) is presented to describe the knowledge base and rule base of the diet domain, including ingredients and the contained servings of six food categories of some common food. The domain experts first define the nutrient facts of the common food to construct the fuzzy food ontology. Meanwhile, the involved Taiwanese students of National University of Tainan (NUTN) record their daily meals for a constant period of time. Then, based on the built fuzzy food ontology, a GFML-based learning mechanism combining the genetic learning mechanism with the fuzzy markup language (FML) is carried out to infer the possibility of dietary healthy level for one-day meals. From the experimental results, it is known that the proposed GFML-based learning mechanism is workable for the diet-domain healthcare applications.**

Keywords: Fuzzy Ontology; Fuzzy Markup Language; Genetic Learning; Dietary Healthy Level Assessment

I. INTRODUCTION

A balanced diet must contain correctly proportioned carbohydarte, protein, fat, vitamins, mineral salts, and fiber because each nutrient plays an important role in supporting humans' everyday physical activities. However, what is a balanced diet? According to [1], eating a balanced diet means choosing a wide variety of foods and drinks from all the food groups. It also means eating certain things in moderation. The goal of the balanced diet is to take in nutrients you need for health at the recommended levels. And, how to begin a balanced diet is also a difficult problem for most of the people. At the present day, the desirable eating habits cannot be obtained easily since our lifestyle is getting diversified. To meet this requirement, some approaches intergrating the fuzzy inference mechanism and ontology have been proposed to support the diet assessment for the past few years. For example, Lee *et al.* proposed a type-2 fuzzy ontology to apply to the personal diabetic-diet recommendation [2] and diet assessment [3], [4].

Ontolgoies have become ubiquitous in information systems. As ontology development becomes increasingly widespread and collaborative, developers are creating ontologies using different tools and languages [6]. For example, Zouaq and Nkambou [7] presented the knowledge puzzle onotlogy learning tool to extract concept maps from text and export them into a domain ontology. Hisham and Nguyen [8] proposed a new ontology-structure-based technique for measuring the semantic similarity in single ontology and across multiple ontolgoies in the biomedical domain within the frameswork of Unified Medical Language System (UMLS). Ontology also has been extensively studied in many research fields, including the news summariation, multi-agent systems, webservice, natural language processing, medical science, computer game, and e-commerce platforms. For instance, Lee *et al.* proposed a fuzzy ontology to apply to news summarization [9] and diabetes decision support [5]. Chou *et al.* [10] focused on developing an ontology structure of elements for Web-based disaster management systems to assist developers and evaluators of Web sites in such domains.A fuzzy markup language (FML) implementation is based on the employment of tags able to model different parts of the fuzzy controller in a taxonomic way. It can be not only considered a standalone language used to model the fuzzy controllers, but also can effectively describe the knowledge base and rule base of the fuzzy logic system; therefore, the previous studies employed it to incorporate with the fuzzy inference mechanism [3], [4], [11], [12]. There are many FML-based apptications, such as Acompra et al. [19] proposed an Interoperable and adaptive fuzzy services for ambient intelligence application Lee er al. [3] [4] applied FML to diet assessment.

The genetic algorithm (GA) has been applied to to various research topics[13]. For example, Lee *et al.* proposed a genetic-based fuzzy image filter and its application to image processing [14] and meeting scheduling decision support system [15]. Khoo and Suganthan [16] presented a GA-based optimization procedure for structural pattern recognition in a model-based recognition system. The GFML-based fuzzy learning mechanism combined GA with FML is proposed and applied to the diet domain in this paepr. Based on the proposed food ontology, the devolped approach is able to show the involved people the healthy level of the eaten food to make them not only enjoy the delicous food but also eat healthily.

The remainder of this paper is structured as follows. The Taiwanes and Japanese fuzzy food ontologies are introduced in Section II. The GFML and the GFML-based learning mechanism are presented in Section III. The GFML-based learning mechanism on the diet application is introduced in Section IV. Experimental results are shown in Section V. Finally, some conclusions are given in Section VI.

II. FUZZY FOOD ONTOLOGY

It has been widely pointed out that classical ontology is not

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

sufficient to deal with imprecise and vague knowledge for some real-world applications [2]. On the other hand, fuzzy ontology can effectively help to handle and process uncertain data and knowledge [2], [17]. The fuzzy ontology is an extension of the domain ontology that is more suitable to describe the domain knowledge for solving the uncertainty reasoning problems [2]. In this paper, the Taiwanese fuzzy food ontology is constructed to describe the fuzzy concepts and fuzzy relations for some common Taiwanese food. The proposed *fuzzy ontology* is an extended version of our previous research works [2], [9].

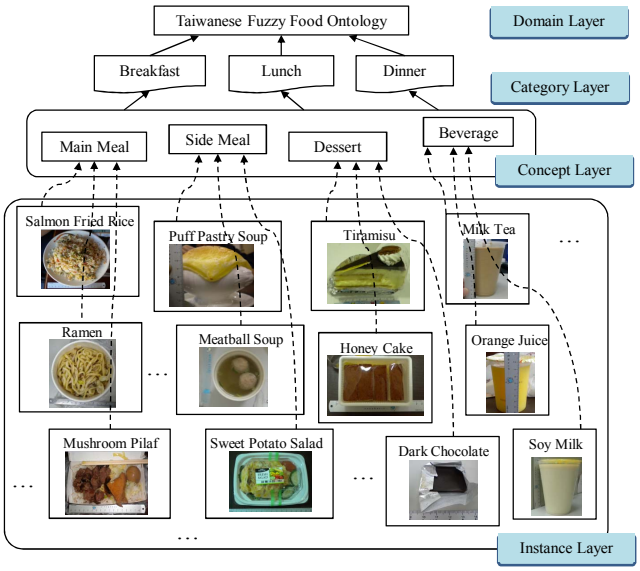

Fig. 1. Taiwanese fuzzy food ontology

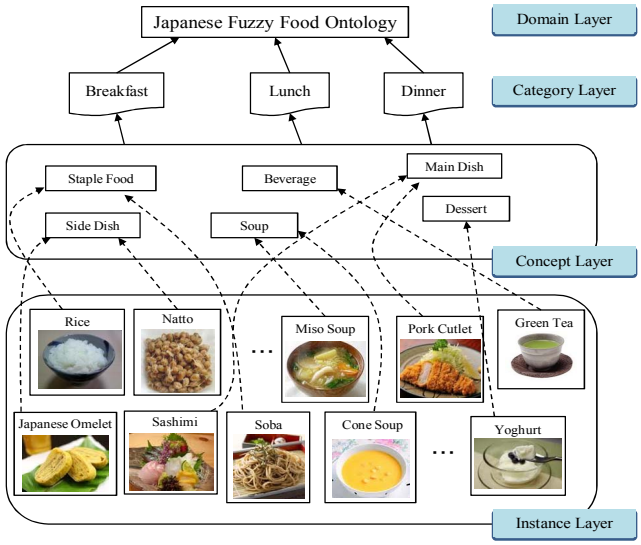

Fig. 2. Japanese fuzzy food ontology [18]

Figs. 1 and 2 show the four-layer fuzzy food ontology for Taiwanese food and Japanese food, respectively. The fuzzy food ontology is composed four layers, including (1) *Domain Layer*: This layer represents the domain name of the ontology. (2) *Category Layer*: In this layer, it comprises various categories defined by domain experts. In this paper, the category in Figs. 1 and 2 is divided into three meals, *Breakfast*, *Lunch*, and *Dinner* to simplify the ontology's structure. (3) *Concept layer*: This layer describes some components of the category layer. For Taiwanese fuzzy food ontology, there are concepts such as *Main Meal*, *Side Meal*, *Dessert*, and *Beverage*. On the other hand, for the Japanese food, some concepts like *Staple Food*, *Main Dish*, *Side Dish*, *Soup*, *Beverage*, and *Dessert* make up of this layer. (4) *Instance layer*: This layer consists of lots of instances of each concept in the *concept layer* [18].

There is a relationship between one concept and a lot of instances. For example, ramen is one kind of main meal for the Taiwanese food so Fig. 1 shows a relationship between Instance *Ramen* and concept *Main Meal*. Similarity, miso soup is one kind of soup for the Japanese food so there is a relationship between Instance *Miso Soup* and concept *Soup* in Fig. 2. In addition to showing the relationship among the food, the predefined fuzzy ontology also contains the nutritional information of each food, such as how many grams of carbohydrates, protein, and fat per portion and how many servings of six food groups per portion are contained. In this way, the proposed approach can evaluate how much healthy people's one-day meals are based on the fuzzy food ontology and people's basic personal profile such as height, weight, age, and everyday physical activity.

III. GENETIC FUZZY MARKUP LANGUAGE

In this paper, the genetic learning mechanism is embedded into the fuzzy markup language, and this novel approach is named the genetic fuzzy markup language learning mechanism. The details of the GFML-based learning mechanism like how to encode one GFML ontology into one chromosome and what is the mutation restriction will be introduced in this section.

A. Chromosome Representation of GFML

An example of how to encode the FML ontology into the chromosome is given in this sub-section. The FML ontology is encoded into one chromosome with a lot of genes. The genes on each chromosome are composed of three parts, including the rule-based part, knowledge-based part, and fuzzy-hedged part. The rule-based genes are a collection of the weight of the fuzzy rules. For example, there are four fuzzy rules listed in Table I. The genes of the chromosome about the rule-based part is {*1 0 0 1*}.

TABLE I. EXAMPLE ABOUT RULE-BASED GENES

```
<RuleBase type="mamdani" activationMethod="MIN" andMethod="MIN"
orMethod="MAX" name="RuleBase1">
    + <Rule connector="and" operator="MIN" weight="1" name="Rule1">
    + <Rule connector="and" operator="MIN" weight="0" name="Rule2">
    + <Rule connector="and" operator="MIN" weight="0" name="Rule3">
    + <Rule connector="and" operator="MIN" weight="1" name="Rule4">
</RuleBase>
```

The type about the knowledge-based genes is a hash table. The key and the value of this hash table are composed of the fuzzy variables' names and the objects with the fuzzy terms of their own fuzzy variables, respectively. The object could be a *TriangularShape*, *TrapezoidShape*, …, and so on. Take the Table II for an example. The genes about the knowledge-based part contain a dictionary entry, including the key is *CPURate*

and this key's value is {*<TriangularShape Param1="0" Param2="0" Param3="50" /><TriangularShape Param1="25" Param2="50" Param3="75" /><TriangularShape Param1="50" Param2="100" Param3="100" />*}. The fuzzy-hedged genes are also described as a hash table whose key is the fuzzy variable names, and the value of the key is represented by the fuzzy terms' hedge of the fuzzy variables. The value of the hedge (δ) is calculated by Eq. (1). For example, the key and the value of the fuzzy-hedged genes listed in Table III are *MemoryRate* and {*11111*}, respectively.

TABLE II. EXAMPLE ABOUT KNOWLEDGE-BASED GENES

```

B. GFML-based Learning Mechanism

The flowchart of GFML-based learning mechanism, shown in Fig. 3, operates as follows.

- **Part 1: Parameter Initialization**
- Initialize all of the necessary parameters including (1) crossover probability $p_{crossover}$, (2) mutation probability $p_{mutation}$, (3) generation number $N_{generation}$, (4) maximum evaluation number $N_{generation_max}$, (5) minimum fitness value $fitness_{minimum}$, (6) size of population of chromosomes $S_{population}$, and (7) maximum size of population of chromosomes $S_{population_max}$.
- **Part 2: Genetic Population Initialization**
- Encode before-learned FML ontology into one chromosome, herein, the FML ontology stores all of the information of the knowledge base and rule base of the FML-based inference mechanism.
- Mutate the generated chromosome based on the mutation probability.
- Decode the after-mutated chromosome into the GFML ontology, herein, the GFML ontology stores all of the information of the knowledge base and rule base of the GFML-based inference mechanism.
- Input the training data to execute the GFML-based inference mechanism to obtain the inferred results.
- Input the desired output, and then execute the fitness function to calculate the fitness value of the after-mutated chromosome, that is, compute the sum of the difference value between the inferred results and desired output of the training data.
- Repeat Part 2 until the size of the population reaches the maximum size of the population.

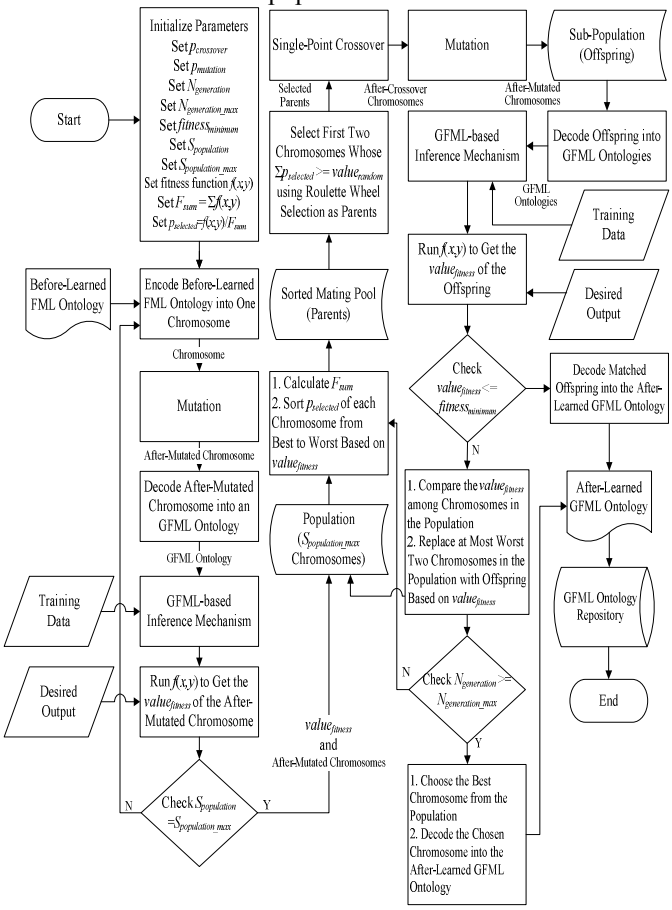

Fig. 3. GFML-based learning mechanism flowchart

- **Part 3: Genetic Evolution**
- Calculate the sum of the fitness value of all chromosomes in the population.
- Sort the selected probability of all chromosomes in the population from the best to the worst one based on each chromosome's fitness value.

- Based on the roulette wheel selection, choose the first two chromosomes whose sum of the selected probability is over the random created value as parents.
- Based on the crossover probability, make the single-crossover for the selected parents to generate the after-crossover chromosomes.
- Based on the mutation probability, mutate the after-crossover chromosomes to generate the offspring.
- Put the generated offspring into the sub-population.
- Decode the offspring into the GFML ontolgoies.
- Input the training data to execute the GFML-based inference mechanism to obtain the inferred results.
- Input the desired output, and then execute the fitness function to calculate the fitness value of the after-mutated chromosomes.
- Check if the fitness value of any one of offspring is less than the minimum fitness value.
- If it is positive, then decode the matched offspring into the after-learned GFML ontology, store it into the GFML ontology repository, and finally terminate the GFML-based learning mechanism.
- If it is negative, then compare the fitness value of all chromosomes in the population and replace at most worst two chromosomes in the population with the offspring.
- Check if the generation number is over the maximum generation number.
- If it is positive, then choose the best chromosome from the population, decode the chosen chromosome into the after-learned GFML ontology, store it into the GFML ontology repository, and eventually terminate the GFML-based learning mechanism.
- If it is negative, repeat Part 3 until the generation number reaches the maximum generation number or the minimum fitness value is matched.

C. *Mutation Restriction*

In this sub-section, the mutation restriction about the knowledge-based genes is introduced by Table IV. The membership functions of the fuzzy variables *Low* and *High* are depicted by Fig. 4.

TABLE IV. EXAMPLE ABOUT KNOWLEDGE-BSED GENES' MUTATION

```
<KnowledgeBase>
    <FuzzyVariable domainleft="Domain Left" domainright=" Domain Right"
    name="SampleFML " scale="%" type="input">
        <FuzzyTerm name="Low" hedge="Normal">
            <TriangularShape Param1="A" Param2="B" Param3="C" />
        </FuzzyTerm>
        <FuzzyTerm name="High" hedge="Normal">
            <TriangularShape Param1="A'" Param2="B'" Param3="C'" />
        </FuzzyTerm>
    </FuzzyVariable>
</KnowledgeBase>
```

The key of the knowledge-based genes is *SampleFML*, and the value of this key is {*<TriangularShape Param1="A" Param2="B" Param3="C" /><TriangularShape Param1=" A′ " Param2=" B′ " Param3=" C′ " />*}. The genes' mutation restriction of the knowledge-based part is to randomly select the values of parameters in order within a reasonable range. For example, the mutation value of *A* is a random value between *Domain Left* and *B*, and then the mutation value of *B* is a random value between the mutation-generated *A* and *A′*. Likely, the other parameters also are mutated in the same way as parameters *A* and *B*. After the mutation, the new genes about the knowledge-based part with the new parameters are obtained and correctly decoded it into the GFML ontology.

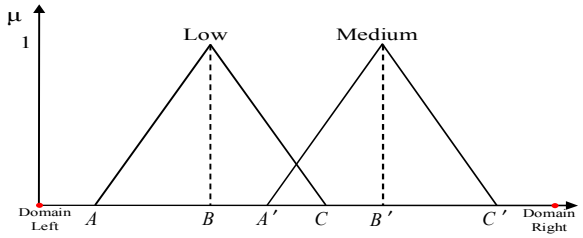

Fig. 4. Membership functions of the fuzzy variables Low and High

IV. GFML-BASED LEARNING MECHANISM ON DIET APPLICATION

A. *Structure*

The proposed diet healthy assessment system was introduced in previous work [3], [18]. Fig. 5 shows an overview of the GFML-based diet application and its procedures are as follows: (1) Nutrition facts of some popular food are gathered from the Internet, convenient stores, or fast food stores. (2) Domain experts, like dieticians, verify and define the detailed nutrient facts for each food item. (3) The fuzzy food ontology is constructed via the provided GFML editor. (4) The involved subjects record and input the daily eaten meals through the constructed platform. (5) The healthy-level evaluation of the eaten food is carried out by the GFML-based learning mechanism based on each subject's personal information and built fuzzy food ontology. Then, the output is stored into the dietary healthy level repository. (6) Finally, the involved subjects get the feedback and evaluated results from the domain experts via the provided interface.

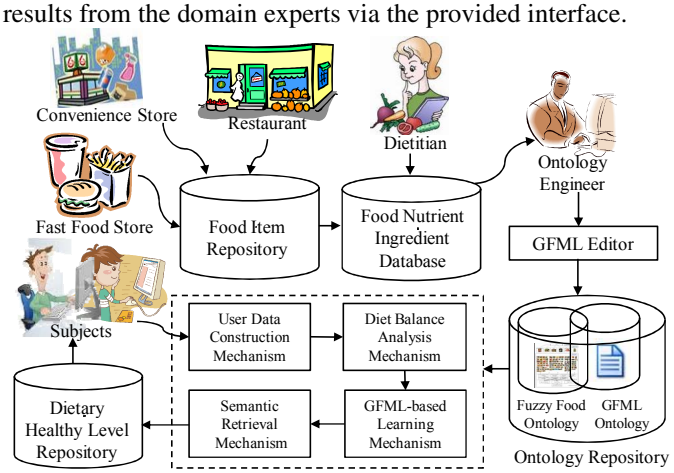

Fig. 5. Structure of the GFML-based diet application

B. *Considered Factors for Dietary Healthy Level*

Based on the collected meal records and the pre-defined fuzzy food ontology, everyday meals' Percentage of Calories from Carbohydrate (*PCC*), Percentage of Calories from Protein (*PCP*), Percentage of Calories from Fat (*PCF*), the Percentage of Caloric Ratio (*PCR*), and Food Group Balance (*FGB*) are acquired. The detailed information about these five fuzzy variables is described as followings.

In order to support one-day energy, it is necessary to consume the enough calories via the everyday diet. However, the main source of the calories is decided by the fact how many grams of the carbohydrate, protein, and fat that the food contains. As a result, to eat healthily, it is necessary for people to consider the balance of these three main nutrients, namely the carbohydrate, protein, and fat, when consuming your one-day meals. For this reason, this paper sets *PCC*, *PCP*, and *PCF* to represent the percentage of calories from carbohydrate, protein, and fat, respectively. According to [1], it indicates that (1) the suggested percentages of the daily intake for carbohydrate, protein, and fat are 55%~65%, 10%~20%, and 25%~35%, respectively, and (2) the contained calories for each gram of the carbohydrate, protein, and fat is 4kcal, 4kcal, and 9kcal, respectively. Based on the above-mentioned discussions, the *PCC*, *PCP*, and *PCF* are calculated by Eqs. (2), (3), and (4), respectively.

$$PCC(\%) = \frac{\text{Contained Grams of Carbohydrate} \times 4}{\text{Total Consumed Carloies}} \times 100\% \quad (2)$$

$$PCP(\%) = \frac{\text{Contained Grams of Protein} \times 4}{\text{Total Consumed Carloies}} \times 100\% \quad (3)$$

$$PCF(\%) = \frac{\text{Contained Grams of Fat} \times 9}{\text{Total Consumed Carloies}} \times 100\% \quad (4)$$

Besides considering the balance of the three main nutrients, the ratio of actual calories people consume to the planned caloric intake set by nutritionists is also an important factor to affect the healthy diet, especially for the fat and the slim. According to the involved domain experts' opinions, the one-day actually consuming calories for common people should be between 90% and 110% of the planned calories set by the dieticians. The domain experts set a planned goal for each person according to individual's height, weight, and daily physical activities. Based on the planned goal and the actual acquiring energies, the value of *PCR* is obtained by Eq. (5).

$$PCR(\%) = \frac{\text{Actual Consuming Calories}}{\text{Planned Consuming Calories}} \times 100\% \quad (5)$$

The balance of six food groups, including grains & starches, vegetables, fruits, milk, meats & proteins, and fats, is the most important factor to decide how much healthy level the eaten meals are. This is because the lack of some beneficial nutrients for our bodies such as fiber cannot be known if we only consider the balanced intake of carbohydrate, protein, and fat. So, in addition to planning the daily calories, the dieticians also plan one-day unique consuming servings of each food group for each person. Moreover, the contained quantity of sugar also affects the balance of intake-in food. Owing to the present-day living style, most people purchase the processed food as their usual meals from the shopping mall. However, unfortunately, the processed food frequently contains much more sugar than the natural food, and it is harmful for our bodies if too much sugar is eaten by people. The suggested percentage of daily sugar's intake is less than 10% of the planned caloric intake each day. The value of *FGB* is calculated by Eq. (6). With the retrieved information, including the values of *PCC*, *PCP*, *PCF*, *PCR*, and *FGB*, from the collected one-day meals, the dietary healthy level (*DHL*) is obtained after implementing the proposed approach.

$$FGB = BL_{Grains\&Starches} + BL_{Vegetables} + BL_{Fruits} + BL_{Milk} + BL_{Meats\&Proteins} + BL_{Fats} - CL_{Sugar} \quad (6)$$

where (1) $BL_{Grains\&Starches}$, $BL_{Vegetables}$, BL_{Fruits}, BL_{Milk}, $BL_{Meats\&Proteins}$, and BL_{Fats} represent the balanced level of the food groups grains & starches, vegetables, fruits, milk, meats & proteins, and fats, respectively. The higher the value is, the healthier the meals are; (2) CL_{Sugar} denotes the contained level of sugar for the meals. The lower the value is, the healthier the meals are; and (3) *FGB* value lies in the interval [0, 6].

C. GFML-based Inference Mechanism

In order to make the proposed system much more suitable to apply to the particular diet application, so the GFML is proposed in the paper. The GFML ontology is composed of the knowledge base and the rule base. Therefore, the GFML-based inference mechanism cannot be carried out until the GFML ontology is defined. Based on the above-discussed descriptions, the shapes and parameters of each factor's membership function are decided. Next is to design the rule base consisting of the 243 fuzzy rules. The involved dieticians regard that the *FGB* plays the most important role on the dietary healthy level. But, the *FCR* is as important as the *FGB* when people those who people are losing weight or gaining weight are neglected. As for *PCC*, *PCP*, and *PCF*, generally speaking, these three factors are equally important, but the dietary healthy level will be affected much when the *PCF* is not within the balanced range. Eventually, the fuzzy relation ratio of *PCC*:*PCP*:*PCF*:*PCR*:*FGB* (1:1:2:3:3) is determined by the involved domain experts.

Take one fuzzy rule for an example. Assume there is one fuzzy rule, and the if-part is "IF *PCC* is *Medium* AND *PCP* is *Medium* AND *PCF* is *Medium* AND *PCR* is *Medium* AND *FGB* is *Medium*." Computed by Eq. (7), this fuzzy rule's score (*S*) can be obtained according to Table V.

$$S = \frac{1\times 2 + 1\times 2 + 2\times 2 + 3\times 2 + 3\times 1}{1+1+2+3+3} = 1.7 \quad (7)$$

TABLE V. THE FUZZY RELATION OF EACH INPUT FUZZY VARIABLE

No	Fuzzy Variable	Fuzzy Relation	Fuzzy Term (Score)		
1	PCC	1	Low (1)	Medium (2)	High (1)
2	PCP	1	Low (1)	Medium (2)	High (1)
3	PCF	2	Low (1)	Medium (2)	High (0)
4	PCR	3	Low (1)	Medium (2)	High (1)
5	FGB	3	Low (0)	Medium (1)	High (2)

After the normalization, the normalized rule score (S_N) is acquired by Eq. (8), where the S_{min} and S_{max} are the minimum and maximum rule scores, respectively. Based on the normalized rule score, the then-part of the fuzzy rule could be determined by Table VI. Finally, the completed fuzzy rule is represented as "IF *PCC* is *Medium* AND *PCP* is *Medium* AND *PCF* is *Medium* AND *PCR* is *Medium* AND *FGB* is *Medium* THEN *DHL* is *VeryHigh*." The dietary healthy level is then inferred by carrying out the proposed method to indicate how much healthy, namely very high, high, medium, low, or very low, the eaten meals are. The before-learned membership functions of the fuzzy variables *PCC*, *PCP*, *PCF*, *PCR*, *FGB*, and *DHL* are illustrated in Fig. 6 and the partial before-learned fuzzy rules are shown in Table VII.

$$S_N = \frac{S - S_{min}}{S_{max} - S_{min}} = 0.83 \quad (8)$$

TABLE VI. S_N RANGE OF THE OUTPUT FUZZY VARIABLE

Fuzzy Term	VeryLow	Low	Medium	High	VeryHigh

V. EXPERIMENTAL RESULTS

In this section, some experimental results are given. The proposed GFML-based learning mechanism is implemented with the C# programming language. The research performance presented in this paper is a research project involving with the National University of Tainan (NUTN) and National Cheng Kung Hospital in Taiwan. With the support of the involved domain experts, the proposed method is applied to the diet domain. There are seven students involved in this research project. The involved students of NUTN are responsible for routinely recording their meals and three involved domain experts evaluate the proposed method performance. For the involved students, the meal records are collected through Monday to Friday for one month so that the total collected records are 140. Table VIII shows the partial before-learned FML ontology for the diet application in this paper.

In order to implement the genetic learning mechanism based on GFML, one-student 20 records are used as the training data listed in Table IX, and the rest of six-student 120 records are the testing data. In Table IX, the columns DHL_{DO} and DHL_{GFML} represent the desired output from the dieticians and the inferred results from the proposed method, respectively. In this paper, the values of the $N_{generation_max}$, $p_{crossover}$, $p_{mutation}$, $fitness_{minimum}$, and $S_{population}$ are 1000, 0.9, 0.1, 0, and 100, respectively. Fig. 7 shows the after-learned membership functions for fuzzy variables *PCC*, *PCP*, *PCF*, *FCR*, *FGB*, and *DHL*.

The mean square error (*MSE*) is utilized to evaluate the performance of the proposed method in this paper. The *MSE* is calculated by Eq. (9) and the lower *MSE* is, the better the performance is. Fig. 8 shows the distribution of the number when MSE_{GFML} is less than or equal to MSE_{GFML}, *Count* ($MSE_{GFML} \le MSE_{FML}$), and the number when MSE_{GFML} is bigger than MSE_{FML}, *Count* ($MSE_{GFML} > MSE_{FML}$), for the training data and the testing data. Fig. 8 indicates that the performance of the proposed approach is better than the FML-based inference mechanism for the training data. On the other hand, for the testing data, the FML-based inference mechanism is superior to the GFML-based inference mechanism. In addition, we also need to further use more number of training and testing subjects to demonstrate the performance of the proposed system in the future.

$$MSE = \frac{1}{n}\sum_{i=1}^{n} e_i^2, e_i = Y_i - \hat{Y}_i \tag{9}$$

where, Y_i represents the inferred results via the FML-based inference mechanism (DHL_{FML}) or the GFML-based learning mechanism (DHL_{GFML}), $\hat{Y}_i$ denotes the desired output recommended from the dieticians (DHL_{DO}), and n is the number of the meal records.

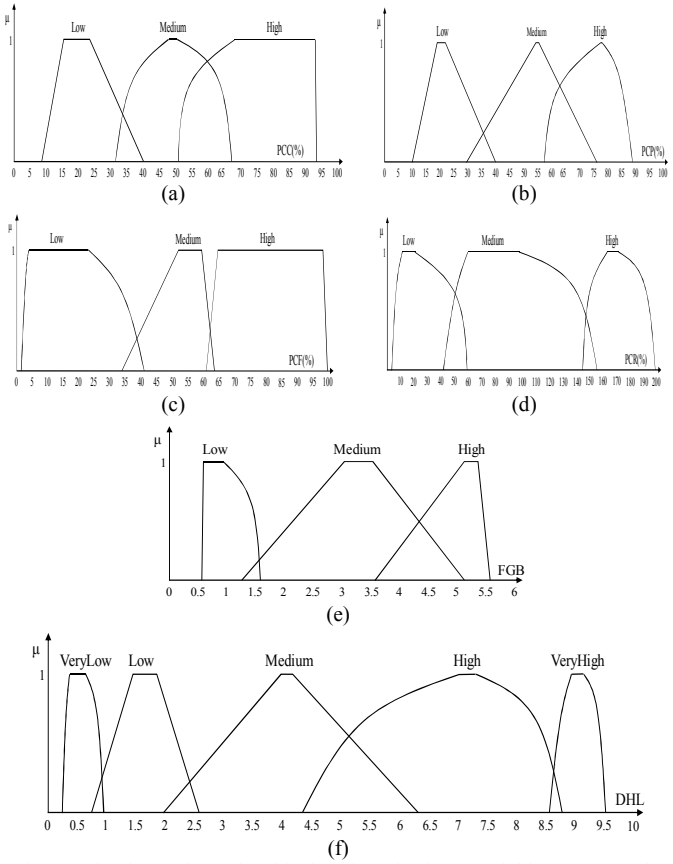

Fig. 7. After-learned membership functions for fuzzy variables (a) *PCC*, (b) *PCP*, (c) *PCF*, (d) *PCR*, (e) *FGB*, and (f) *DHL*

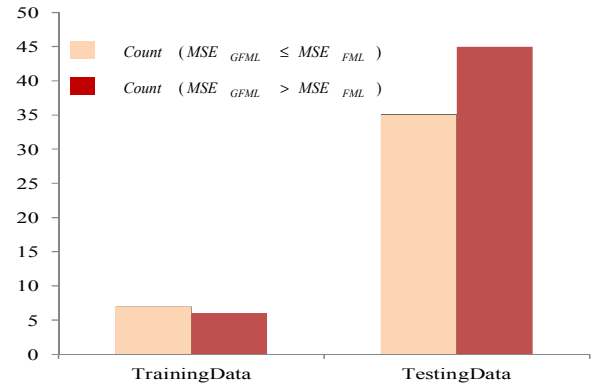

Fig. 8. Distribution for the training data and testing data

VI. CONCLUSIONS

The GFML-based learning mechanism combined the FML with the genetic learning mechanism is presented and applied

to the diet domain to infer the dietary healthy level of one-day eaten food. The effectiveness of the proposed method is verified by comparing with the results of dieticians' assessment. However, some noises such as the gray-marked records in Table IX are generated after executing the GFML-based learning mechanism; therefore, in the future, creating more training data and making some comparisons with other combinations of training and testing subjects are necessary to further improve the performance of the proposed method. Additionally, it is also feasible to introduce the proposed approach to other countries' diet in the future.

ACKNOWLEDGMENT

The authors would like to thank the National Science Council of Taiwan for financially supporting this international cooperation research project under the grant NSC98-2221-E-024-009-MY3, NSC 99-2622-E-024-003-CC3, and NSC 99-2911-I-024-004. The authors also would like to thank the involved students for their joining this research project.

***Abstract*—The Knowledge Mobilization project (KNOWMOBILE) has been a joint effort by Institute for Advanced Management Systems Research, Åbo Akademi University and VTT Technical Research Centre of Finland. Its goal was to better "mobilize" knowledge stored in heterogeneous databases for users with various backgrounds, geographical locations and situations. The working hypothesis of the project was that fuzzy mathematics combined with domain-specific data models, in other words, fuzzy ontologies, would help manage the uncertainty in finding information that matches the users needs. In this way, KNOWMOBILE places itself in the domain of knowledge management. In this paper we describe an industrial demonstration of fuzzy ontologies in information retrieval in the paper industry where problem solving reports are annotated with keywords and then stored in a database for later use. Furthermore, using Bellmann-Zadeh's principle to fuzzy decision-making we will show a method for identifying keyword dependencies in the keyword taxonomic tree.**

***Keywords*—Fuzzy ontology; keyword ontology; fuzzy coverage**

I. Introduction

Fuzzy ontologies have been proposed as a solution for addressing semantic meaning in an uncertain and inconsistent world. Since many concepts that are needed for intelligent systems lack well defined boundaries, or precisely defined criteria of membership, we need fuzzy logic to deal with notions of vagueness and imprecision. As with fuzzy logic, reasoning is approximate rather than precise. The aim is to avoid the theoretic pitfalls of monolithic ontologies, facilitate interoperability between different and independent ontologies [1], and provide flexible information retrieval capabilities [2]–[5]. In the KNOWMOBILE project, we developed a concept of a tool for searching plant knowledge with a search engine based on a fuzzy ontology. The usage scenario for the tool was that a process expert, dealing with a problem in the process chemistry of a paper machine, wishes to find past problem solving cases of a similar setting in order to find possible solutions to a current issue. This setting is a universal one: pieces of knowledge, called "nuggets", are written and stored by companies on different domains in the form of incident reports.

In the KNOWMOBILE project we have focused on the chemistry of the "wet end" in order to limit the work effort needed to construct the domain ontology and concentrate on a subject on which domain expertise and actual data were available. Nuggets are documents than can contain all kinds of raw data or multimedia extracted from different information systems. An expert author annotates the nuggets with suitable keywords, and it is these keywords that the search is then based on. In addition to providing exact results to queries, the tool uses a fuzzy domain ontology to extend the query to related keywords (see Figure 1). As a result, the search results include nuggets that may not necessary deal with exactly the same process equipment, variable, function or chemical, but nuggets that may still provide valuable insight to solving the problem at hand. The terms defined in the ontology should be familiar to the users of the system, e.g. for plant operators, process developers and chemical suppliers. On the other hand, the terminology should be based on sound principles of conceptual modeling and ontology development. Furthermore, the goal should be to have common concepts and plant models with equipment manufacturers and engineering contractors that provide the initial information and often participate in modifications and upgrade projects. This creates a link to the ongoing development of engineering data models for various industrial areas. Fuzzy keyword ontologies should thus make use of relevant product and plant modeling standards and more general upper ontologies. The key research question of the KNOWMOBILE project is [6]: How to build fuzzy ontologies for the process industry domain to enhance knowledge retrieval?

II. Fuzzy ontology for process industry

Our demonstration works with both engineering and operational knowledge of an industrial plant and we used the following taxonomic system,

- Top layer: general concepts (based on international standards).
- Middle layer: vocabulary defined and shared by business partners to share knowledge of, e.g. the type and structure of process equipment. This layer extends the top layer with domain-specific keywords.
- Bottom layer: custom, company-specific concepts, e.g. specific products and component types, or even individual process plants.

The system of keywords represents concepts, properties, relationships, axioms, and reasoning schemes relevant for the

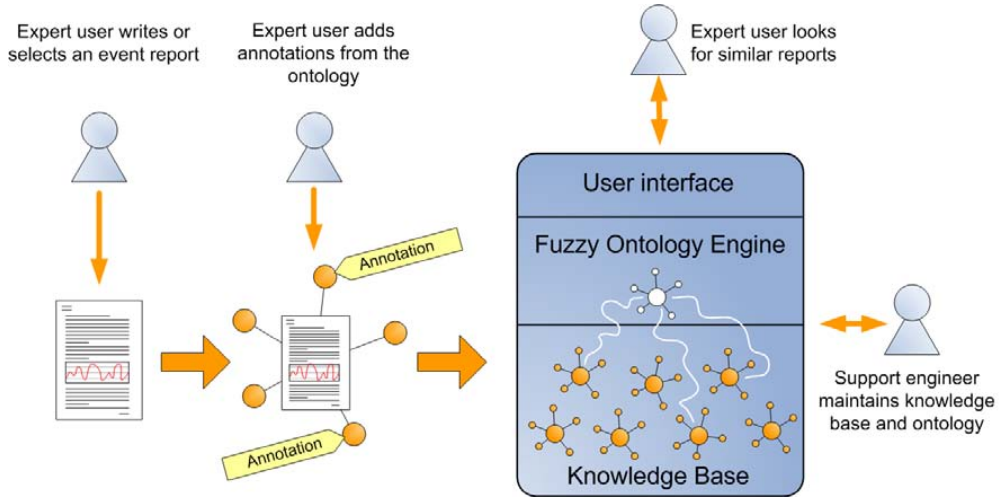

Fig. 1. System concept - a knowledge base of event reports [6].

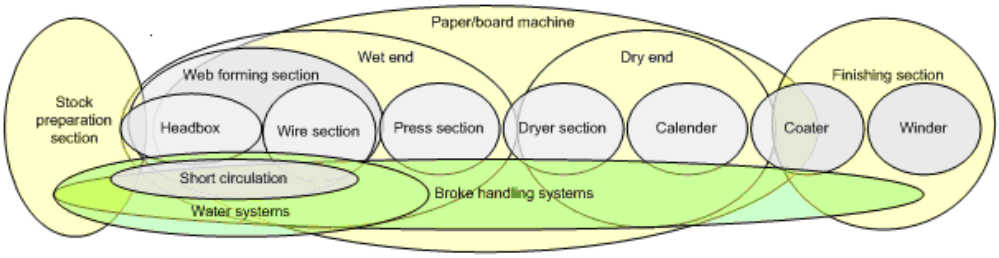

Fig. 2. System example - a fuzzy decomposition of a paper making line. [6].

application area. On the basis of various upper ontologies and industrial data models we identified that the following keyword categories are needed to characterize event reports:

- Systems: types of real-world components of a process plant, e.g. machines, buildings, software and people. (see Figure 2)
- Functions: phenomena and activities carried out at an industrial plant.
- Variables: properties and state variables of various entities, e.g. temperature.
- Events: types of interesting periods of plant life described in event reports, e.g. test runs or equipment failures.
- Materials: raw materials, products, consumables etc. handled in a process plant.

Our basic approach to conceptualize our application is shown in the informal Unified Modeling Language (UML) class diagram below (Figure 3).

Event reports describe events that are related to various entities of a process plant, e.g. to equipment, processing functions and materials. Nothing is assumed about the internal structure of event reports. Instead, they are characterized by an expert with keywords selected from a fuzzy ontology. The expert can select the keywords from five categories: event,

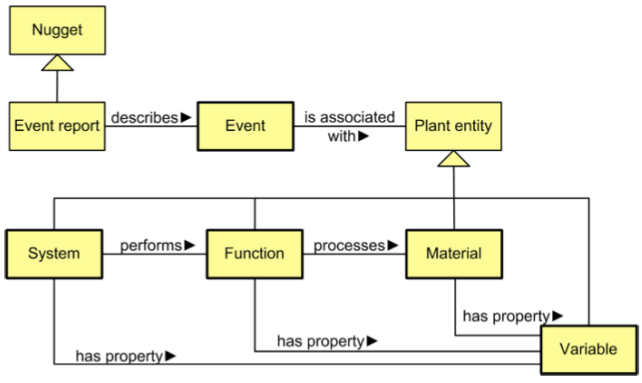

Fig. 3. Overall domain concepts [6].

system, function, material and variable. All keywords represent an entity type and can have subtypes and smaller parts. In the KNOWMOBILE demonstration tool keywords are used to characterize event reports and other nuggets stored in a database.

Classification (is-a) and decomposition (part-of) can be found in most ontologies and data models. They are important in the industrial context as well. So, the keywords in each cat-

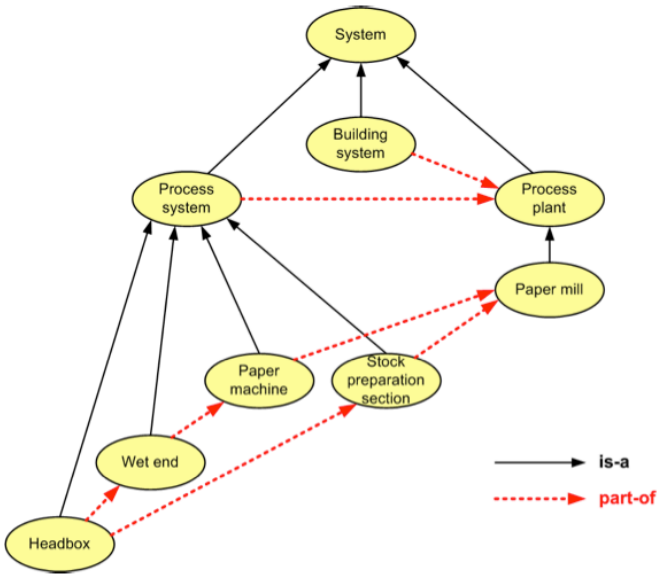

Fig. 4. Simplified event classification matrix [7].

egory are linked by is-a and part-of relationships as illustrated in Figure 4. Furthermore, the ontology should model functional and other kinds of dependencies between keywords in various keyword categories. As an example, systems can be or are used for some purposes, i.e. they play various roles in carrying out one or more functions. This creates a link between the keywords ”wire section (a part of paper machine)” and ”formation (a quality measure of the produced paper)”. Modeling classifications, decompositions and various dependencies leads to a situation where we have a taxonomy tree for each keyword category and a set of part-of relationships trees describing the decomposition to various domain entities (Figure 5). In addition, there are dependency relationships linking keywords to each other.

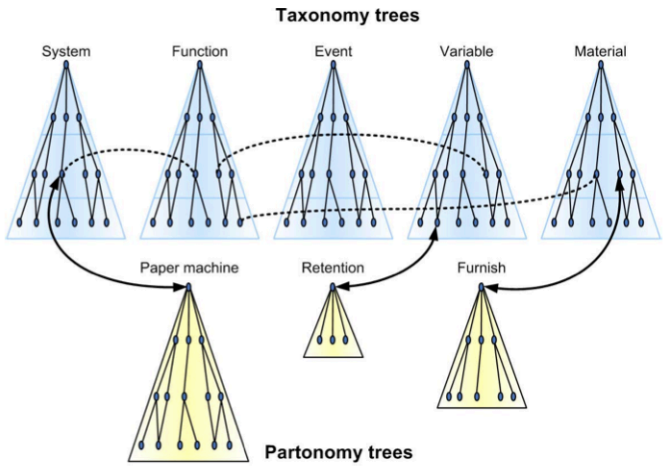

Fig. 5. The fuzzy ontology defines classification, decomposition and miscellaneous dependency relationships between keywords [7].

III. The keyword ontology

For developing a software tool the ontology should be expressed and stored in a more formal way. The basic approach for representing a fuzzy ontology is illustrated in Figure 6 with a combination of UML class and instance diagrams.

From all kinds of nuggets, the demonstration only looks at event reports that usually describe problematic situations. Each report, like the specific instance ”Report #1” in the diagram, is related to types of systems, plant functions, events, etc. Only the reference ”Report #1” to the keyword ”Holes” is shown in Figure 6 . As indicated by the ”instance of” associations, all keywords seen by the users are individuals, .i.e. instances of a subclass of ”Keyword category”. Fuzzy dependencies between keyword instances are described by a few fundamental relationship types like is-a (specialization), part-of and, as an option, instantiation. In the first version we focus on ”specializations”, i.e. fuzzy classification of keywords. The degree of overlapping (or inclusion) of the sets represented by the keywords is described by linguistic labels, i.e. natural language words like ”moderate” or ”significant”. So, the instance named ”Specialization #1” in Figure 6 tells us that ”Holes” is ”to a large extent” understood as a subclass of ”Quality problem but only represents a minor part of its scope”. In addition, the keyword ”Holes” may also specialize other problem types. In the KNOWMOBILE project we have modelled dependencies with one single dependency relationship. For simplicity it is symmetric and has a strength value between zero (independence) and one (full dependence).

IV. A Minimax Approach to Assess Keyword Dependencies

Now we show a method for approximating keyword dependencies in the keyword ontology. This method uses Bellman-Zadeh’s principle to fuzzy decision making [8]. An event type fuzzy taxonomy is shown in Figure 7. For example, consider the second column of event classification matrix ”Problem”. All ”Technical problems” are ”Problems” and they represent around 80% of all possible problems. That is ”Technical problem” covers ”Problem” with degree 0.8. Similarly, ”Human errors” are ”Problems ” and they represent around 30% of all possible problems. That is ”Human error” covers ”Problem” with degree 0.3. Following Bordogna and Pasi ([9], page 804) we will assume that if A and B are two keywords in the keyword taxonomic tree then

$$\text{coverage}(A, B) = \text{fuzzy inclusion}(A, B). \quad (1)$$

For example, ”System fault = {Device fault, Design flaw}” that is, ”System fault” is a union of these two events. Furthermore, ”Function failure = {Design flaw, Drift, Oscillation}” that is ”Function failure” is the union of these three events. ”Design flaw” covers ”System fault” with degree 0.6 and at the same time ”Design flaw” covers ”Function failure” with degree 0.4 (see Figure 7). Moreover, ”System fault” and ”Function failure” do not have any more component in common. We compute the degree of dependency between ”System fault”

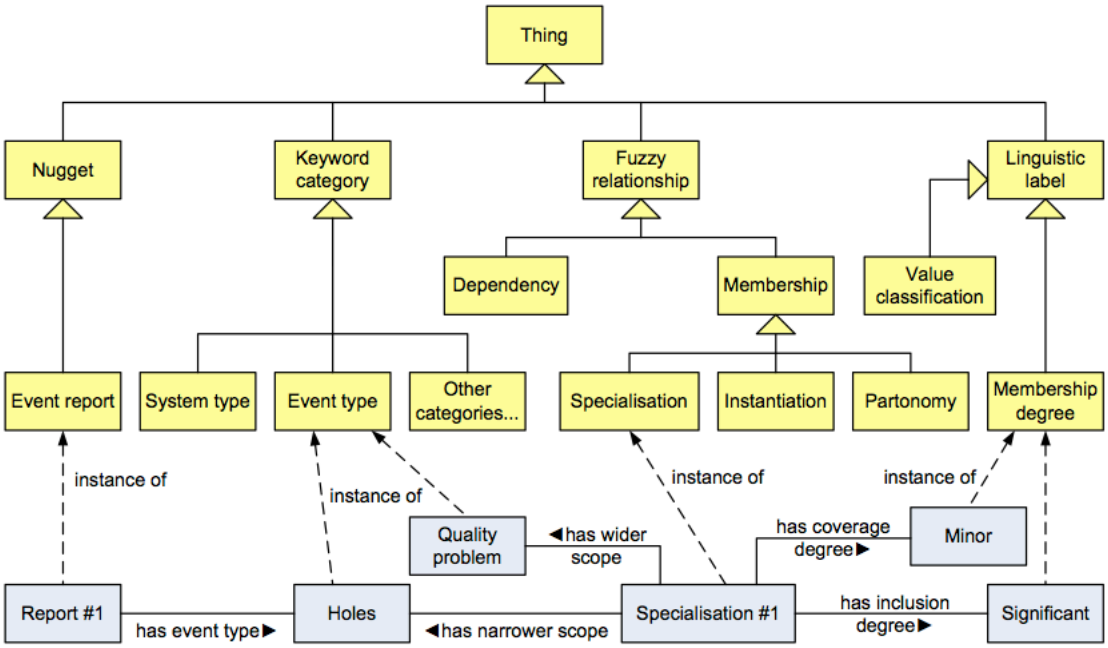

Fig. 6. Representing fuzzy keyword ontology with object classes and their instances [7].

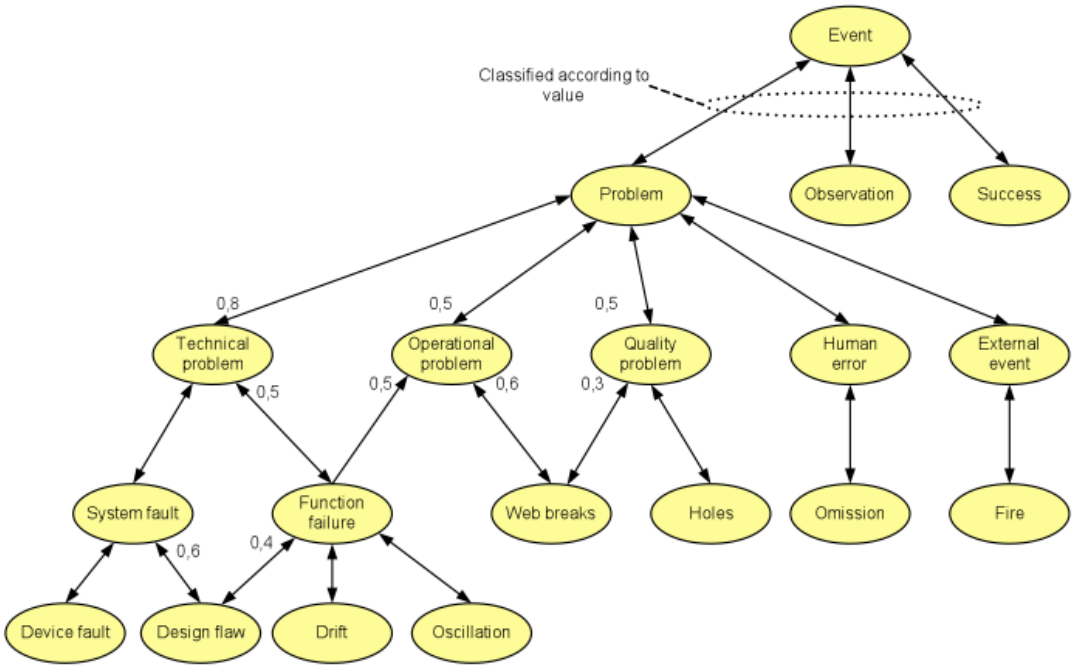

Fig. 7. A fragment of the event type fuzzy taxonomy [7].

(SF) and "Function failure" (FF) as their joint coverage by "Design flaw" (DF)

$$\text{dependency}(SF, FF) = \min\{\text{coverage}(DF, SF), \text{coverage}(DF, FF)\},$$

that is,

$$\text{dependency}(SF, FF) = \min\{0.6, 0.4\} = 0.4 \quad (2)$$

It is easy to see in Figure 7 that keywords "Function failure" and "Fire" are independent since they do not have any component in common. In this case we have,

$$\text{dependency}(\text{"Function failure"}, \text{"Fire"}) = 0. \quad (3)$$

Zero means independence, one means full dependence, and values between zero and one denote intermediate degrees of dependency between keywords. It can happen that two keywords have more than one joint component. Then we apply Bellman-Zadeh's principle (max-min approach) to fuzzy decision making to measure their dependency. For example, suppose that "System fault" and "Function failure" wrere to have two joint components, where the first one is "Design flaw" and the second one "Fluctuation" that has a coverage values 0.7 and 0.5, respectively. Then we measure the degree of dependency between "System fault" and "Function failure" according to Bellman-Zadeh's principle to fuzzy decision making as

$$\begin{aligned}\text{dependency}\{SF, FF\} &= \max\{\min\{0.6, 0.4\}, \min\{0.7, 0.5\}\} \\ &= \max\{0.4, 0.5\} = 0.5.\end{aligned}$$

Supposing that all the coverage degrees are given by experts. Then we can summarize our algorithm as follows: *Compute the degrees of dependency between keywords on the immediate upper level using the max-min approach. Then repeat this procedure until the top layer.* For example, consider keywords "Technical problem" (TP) and "Operational problem" (OP). Then we find (Figure 7),

$$\text{dependency}\{TP, OP\} = \min\{\text{coverage}(FF, TP), \text{coverage}(FF, OP)\} = 0.5.$$

One can further improve this model by introducing degrees of inclusion and coverage between concepts as suggested by Holi and Hyvönen [10], and Holi [11].

V. Demo architecture and implementation

The component-based demo architecture has been implemented by VTT Technical Research Centre of Finland, using the Protégé ontology editor to maintain the fuzzy ontology in OWL format (as shown in Figure 8). The GUI component (Graphical User Interface) guides the user in specifying the information query, and presents the results. Tools for browsing and evaluating the fuzzy reasoner component directly were also provided. A database adapter is used to access report data, which in this case was stored locally in XML files. Similarly, an ontology adapter is used to provide access to the fuzzy ontology, in this case stored in OWL files.

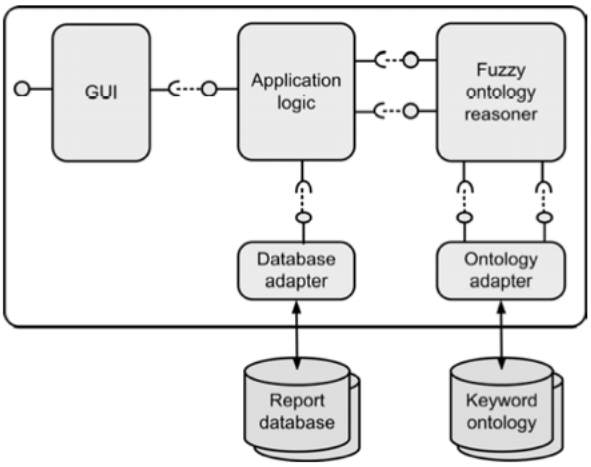

Fig. 8. Component-based demo application architecture [7].

The adapters help hide the different interfaces and protocols of different data sources (e.g. SQL, HTTP) and provide transparent access via an agreed interface. The fuzzy ontology reasoner component is used to process ontology-based information. Its main function in the demo is to extend a list of query keywords to a list of their closest neighbors in terms of fuzzy ontology relationships. For maintenance and evaluation purposes, the component interface also provides methods for directly accessing the ontology concepts and relationships. Finally, the application logic component binds all the functionality together by taking the query, using the reasoner component to extend it, passing the extended query to the report database and then combining and ordering the results for the GUI. The fuzzy ontology with fuzzy concepts, relations, and instances was defined using Protégé version 3.4. The developed ontology was exported for the reasoning software as a standard OWL file. Protégé is a widely used tool for developing ontologies. As such it provides some advantages, for example a forms-based interface for editing the basic classes and adding the individual keywords, reports, as well as their relationships. Protégé does not have a built-in support for modeling uncertainties, however in late 2010 Straccia [12] introduced new plug-in, called SoftFacts, which is an ontology mediated top-k information retrieval system over relational databases.

VI. Summary

We have examined the possible use of fuzzy ontologies in the retrieval of stored reports of industrial plant knowledge. Since no well-established definitions or mature tools exist, we have adopted a practical approach - defining those constructs that we deemed necessary in order to adequately capture domain semantics, and implementing a demonstration application in which to test those constructs against actual industrial data. The demo has been evaluated with the help of industry experts. Although the extended query tool seems to be promising, there has been a great deal of worry about the amount of

work needed for maintaining the fuzzy ontology relationship weights.

Abstract— **Disease prediction has become important in a variety of applications such as health insurance, tailored health communication and public health. Disease prediction is usually performed using publically available datasets such as HCUP, NHANES or MDS that were initially designed for health reporting or health cost evaluation but not for disease prediction. In these datasets, medical diagnoses are traditionally arranged in "diagnose-related groups" (DRGs). In this paper we compare the disease prediction based on crisp DRG features with the results obtained employing a new set of features that consist of the fuzzy membership of patient diagnoses in the DRG groups. The fuzzy membership features were computed using an ICD-9 ontological similarity approach. The prediction results obtained on a subset of 9,000 patients from the 2005 HCUP data representing three diseases (diabetes, atherosclerosis and hypertension) using two classifiers (random forest and SVM trained on 21,000 samples) show significant (about 10%) improvement as measured by the area under the ROC curve (AROC).**

Keywords-component; disease prediction; ICD-9 similarity measure; ontological features; random forest; SVM.

I. INTRODUCTION

Disease prediction is employed in different domains such as risk management, tailored health communication and public health. Risk management plays an important role in health insurance industry, mainly in the underwriting process. Health insurers use a process called underwriting in order to classify the applicant as standard or substandard, based on which they compute the policy rate and the premiums individuals have to pay [1].

Another domain where disease prediction may be applied is tailored health communication. For example, we can target specific medical educational materials and news to a subgroup within the general population that has a high predicted risk for a given disease. Cohen et al [2] discussed how tailored health communication for cancer patients can motivate cancer prevention and early detection. Disease risk prediction along with tailored health communication represents an effective preventive medicine method that may lead in the long-run to a reduction in the cost of medical care.

The reporting requirements of various US governmental agencies such as Center for Disease Control (CDC), Agency for Health Care Quality (AHRQ) and US Department of Health and Human Services Center for Medicare Services (CMS) have created huge public datasets that, we believe, are not utilized to their full potential. For example, CDC (www.cdc.gov) makes available National Health and Nutrition Examination Survey (NHANES) data. Using NHANES data, Yu et al. [3] predicts diabetes risk using an SVM classifier. CMS (www.cms.gov) uses the Medicare and Medicaid claims to create the minimum dataset (MDS). Herbert et al. [4] uses MDS data to identify people with diabetes. In this paper we use the National Inpatient Sample (NIS) data created by AHRQ (www.ahrq.gov) Healthcare Utilization Project (HCUP), to predict the risk for three diseases: diabetes, atherosclerosis and hypertension. To compute the disease risk we use a new set of ICD-9 features based on ontological similarity between the ICD-9 diagnoses contained in a DRG and the ICD-9 diagnoses of the patient. We compare this approach with the prediction of the same diseases described in [5].

The remainder of this article is structured thusly: in Section II we describe the ICD-9 medical taxonomy together with the similarity measure used in the feature extraction process. In Section III we describe the proposed ontological feature extraction algorithm together with a brief description of the classifiers employed, in Section IV we show some results obtained on a subset of 2005 HCUP patient dataset and in Section V we provide some conclusions and ideas for future research.

II. ICD-9 MEDICAL TAXONOMY AND SIMILARITY MEASURE

International classification of diseases-version 9 (ICD-9) is a diagnose coding system [6] used in hospitals for data retrieval and billing purposes. Every code represents a disease, condition, symptom, or cause of death. However, from our point of view ICD-9 represents an ontology, i.e. a controlled vocabulary overlaid with a "is-a" term hierarchy. The controlled vocabulary allows for detection of synonymy when two diagnoses are compared. The hierarchy (tree) structure allows for assessing the semantic similarity between diagnoses. A snippet of the ICD-9 tree is shown in Fig. 1.

This work has been supported in part by a UM Research Board grant.

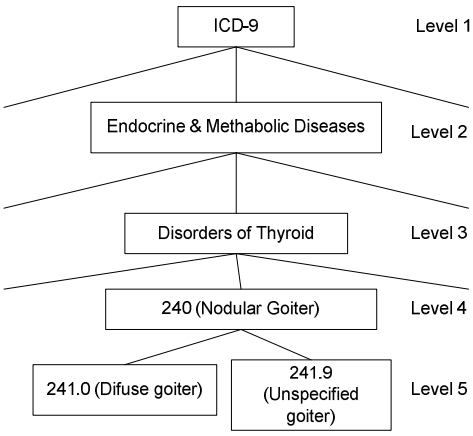

Figure 1. Partial view of the ICD-9 hierarchy

From Fig. 1 we see that diagnoses 241.0 and 241.9 are semantically related although they are syntactically (string-wise) different. Unfortunately, the ICD-9 hierarchy has only 5 levels. This will have an impact on the granularity of the term similarity as many pairs of terms will have the same similarity coefficient. However, even with this low granularity the impact on prediction performance is significant.

In our view, the hierarchical structure of the ICD-9 ontology represents the knowledge of the medical field as viewed by the domain experts (physicians). The key of our approach is to use the domain knowledge (hierarchy) in computing patient similarities. Given two patients described by a sequence of ICD-9 diagnoses, T_{ij}, we first consider the problem of computing the association (seen as fuzzy membership), $s(T_1, T_2)$, between two terms (diagnoses) T_1 and T_2.

There are many algorithms for defining term similarity in a taxonomy (see Chapter 2 in [7]). One way of computing term similarity is to assign each term T_i weights based on its importance, IMP, within the ontology. As a consequence, two patients are more similar if they both have the same rare (in the database) disease (say cystic fibrosis) than if they both have flu. The term importance can be computed (see Chapter 2 in [7]) using path-based, depth-based, density-based, information content-based approaches. In this work we use a depth-based approach. The importance IMP, of a term in the ICD-9 taxonomy is computed as IC=1-1/n where n = {1, 2, 3, 4, 5} is the level of the term within the hierarchy. For example, the IMP of diagnosis code 241 (Goiter, level 4) is IMP(241) = 1-1/n = 1-1/4 = 0.75. For consistency, we consider IMP(level 5) = 1. Now, returning to the problem from the beginning of this paragraph, the similarity of two diagnosis terms, $s(T_1, T_2)$, is defined as:

$$s(T_1, T_2)=IMP(NCA(T_1, T_2)). \quad (1)$$

where NCA="nearest common ancestor" of the two terms in the ontology.

In Fig. 1, the nearest common ancestor (NCA) of 241.0 and 241.9 is 241, and so, the similarity between the two diagnoses is s(241.0, 214.9)=IMP(241)=0.75. This is clearly the simplest approach and it is only used here for illustrative purposes.

For two sets of ICD-9 terms, $P_1 = \{T_{11}, \ldots, T_{1n}\}$ and $P_2=\{T_{21}, \ldots, T_{2m}\}$ we can define a variety of similarities (see Chapter 2 in [7] for details). In this paper we consider the following simple formula:

$$s(P_1, P_2)=\max_{ij}\{s(T_{1i}, T_{2j})\}. \quad (2)$$

III. STUDY METHODOLOGY

To better understand the feature extraction process we first describe the 2005 HCUP dataset used in this paper (denoted henceforth HCUP2005).

A. The HCUP2005 dataset

The Nationwide Inpatient Sample (NIS) is a database of hospital inpatient admissions that dates back to 1988 and it is used to identify, track, and analyze national trends in health care utilization, access, charges, quality, and outcomes. The NIS database is developed by the Healthcare Utilization Project (HCUP) and sponsored by the AHRQ. This database is publicly available and does not contain any patient identifiers. The database contains discharge level information on all inpatients from a 20% stratified sample of hospitals across the United States, representing approximately 90% of all US hospitals [8]. HCUP data from the year 2005, denoted as HCUP2005, will be used in this paper.

The data set contains 7,995,048 hospital stays and 126 clinical and nonclinical data elements for each hospital stay. Nonclinical elements include patient demographics, hospital identification, admission date, zip code, calendar year, total charges and length of stay. Clinical elements include procedures, procedure categories, diagnosis codes and diagnosis categories. Every record contains a vector of 15 ICD-9 diagnosis codes. In addition, every record contains a vector of 15 diagnosis category codes (DRGs). The diagnosis categorization is performed using the Clinical Classification Software (CCS) developed by HCUP. There are numerous ICD-9 codes, over 14,000, in HCUP; CCS collapsed these codes into a smaller number of clinically meaningful DRGs. There are 259 diagnosis categories in the HCUP2005 dataset, every category is denoted by a value in the range 1-259. Demographics such as age, race and sex are also included in our data set and used predicting the three medical conditions.

The prevalence in the HCUP2005 dataset of three diseases used in this paper (hypertension, diabetes mellitus and coronary atherosclerosis) is given in table I below. As we see from table I, some diseases like testis cancer might not have a sufficient number of samples for training a classifier even on such a large dataset.

TABLE I. THE PREVALENCE OF FOUR DISEASES IN THE HCUP2005 DATASET

Disease	Prevalence
Hypertension	29.1%
Diabetes mellitus, no complications	12%
Coronary Atherosclerosis	27.65%
Testis Cancer	0.046%

B. ICD-9 based Ontological Features

To predict a disease, we extract from HCUP2005 a random set of N patients, N/2 with the disease and N/2 without it. For each patient, P_i with i = {1, … , N}, we used from HCUP2005 the following variables: age, race, sex, 15 ICD-9 codes ($P_{i,ICD9}$) and 15 diagnosis categories ($P_{i,DRG}$). As mentioned before, there are 259 DRGs, DRG_j with j = {1, …, 259}, and every group contains a set of ICD-9 codes, DRG_j = {$ICD9_{j1}$, …, $ICD9_{jk}$}. In [5] we represented each patient P_i using a feature vector $\mathbf{x}_i^{crisp} \in R^P$, with P=262 dimensions. Features 1-259 (DRG related) were computed as:

$$x_{ip}^{crisp} = \begin{cases} 1 & P_{i,ICD9} \cap DRG_p \neq \varnothing \\ 0 & P_{i,ICD9} \cap DRG_p = \varnothing \end{cases} \quad (3)$$

Essentially, since the DRGs were computed for us, the feature vector had an 1 in position p if DRG_p was contained in the diagnoses set of patient i, $P_{i,DRG}$. As a result, each feature vector contained at most 15 ones (the number of DRGs stored per patient) which was a rather sparse representation. The last 3 features (index 260, 261, 262) were sex, age and race, respectively.

In this paper we propose to compute the 259 diagnose related features using a fuzzy membership in each DRG_j, i.e. a value between 0 and 1 that represents the similarity between a diagnose and DRG_j. The proposed features will be calculated as:

$$x_{ip} = s(P_{i,ICD9}, DRG_p), p \in \{1, \ldots, 259\}, \quad (4)$$

where the above similarity, s, is computed using formula (2). Features with index 260, 261 and 262 are similar to the ones we used in [5], i.e. age, race and sex.

Example 1

Consider a patient with the following set of diagnoses P={682.6, 486, 453.42, 493.92,41.11,250.00,782.3,278.01}. The crisp [5] and the fuzzy (ontological) features (index 1-259) related to this patient are shown in Fig. 2.

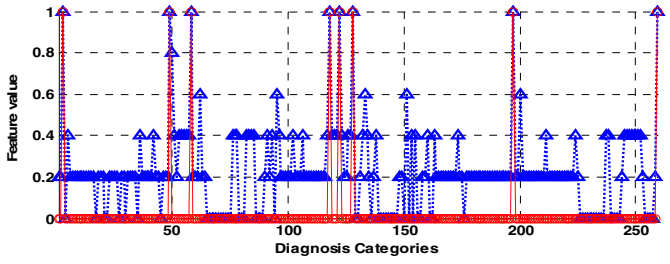

Figure 2. The crisp (red) and fuzzy ontological (blue) features for patient P from example 1.

We note that the ontological features coincide with the crisp ones for DRGs that contain one of the ICD-9 codes from the diagnoses set (in number of 8). An example is DRG index 49 ("diabetes mellitus without complications") that contains the ICD-9 code 250.00 ("Diabetes mellitus without complication type II or unspecified type not stated as uncontrolled"). However, there are other indices where the ontological features have a high value. Take for example DRG index 50 ("diabetes mellitus with complications") that contains among others the ICD-9 code 250.03 ("Diabetes mellitus without complication type I uncontrolled"). Since P does not contain code 250.0, $x_{50}^{crisp} = 0$. However, since s(250.00, 250.03) = 0.8, the related ontological feature is greater than zero, i.e. $x_{50} = 0.8$. Aside from the fact that by using the relations from the ICD-9 taxonomy we provide a better representation of the diagnoses set, we also account for the uncertainty of the coding process itself (known to be somewhat unreliable).

C. Classifiers used

In this paper we present experiments performed with two classifiers, random forests (RF) [9] and support vector machines (SVM) [10].

RF is an ensemble learner, a method that generates many classifiers and aggregates their results. RF adds a layer of randomness to bagging by building large collection of de-correlated trees. RF will create multiple CART-like trees, each trained on a bootstrap sample of the original training data and searches across a randomly selected subset of input variables to determine the split. Each tree in RF will cast a vote for some input x, then the output of the classifier is determined by majority voting of the trees. Since the focus of this paper is on features rather than on classifiers themselves, we refer the reader to [9] and [10] for more details on RF and SVM.

We performed the classification using R, which is an open source statistical software. We used R *randomForest* and *SVM* (e1071) packages. The parameters to the RF were as follows: number of trees (ntree) was set to 500. Overall, the number of trees didn't seem to influence the classification results. The number of variables randomly sampled as candidates at each split (mtry) is equal to the square root of the number of features. Since in our case we have 262 features, mtry was consequently set to 16.

For SVM we used a linear kernel, termination criterion (tolerance) was set to 0.001, epsilon for the insensitive-loss function was 0.1 and the regularization term (cost) was 1.

D. Experiments

We tested both classifiers, RF and SVM, with N=10,000 patients extracted from HCUP2005, N_d=5,000 that had the disease and N_n=5,000 that didn't. Out of the 10,000 samples, 7,000 were used for training and 3,000 for testing. Obviously, we excluded the target disease from the diagnosis set of the N_d patients that had it. We performed the same experiment for three diseases (first 3 lines in table I): hypertension, diabetes mellitus and arteriosclerosis. The results obtained are showed in the next section.

IV. Results

The classification results, area under the curve (AROC) and receiver operating characteristic (ROC) curve, for diabetes are shown in table II and Fig. 3.

TABLE II. AROC RESULTS FOR DIABETES PREDICTION

	Crisp Features	Fuzzy Features
RF	0.9524	0.9996
SVM	0.8567	0.981

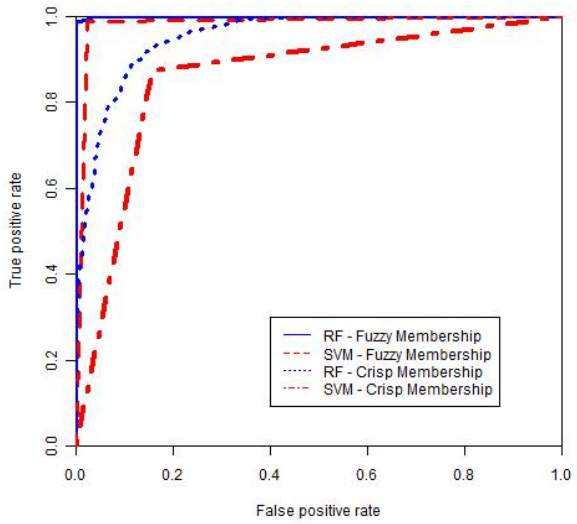

Figure 3. ROC curves for diabetes prediction obtained with random forest (blue) and SVM (red).

The AROC improvement was smaller for RF than for SVM, since RF had already a good prediction performance dues to its builtin feature selection property.

The results obtained for atheoriosclerosis prediction are shown in table III and Fig. 4.

TABLE III. AROC RESULTS FOR ARTHERIOSCLEROSIS PREDICTION

	Crisp Features	Fuzzy Features
RF	0.9647	0.9995
SVM	0.8833	0.9737

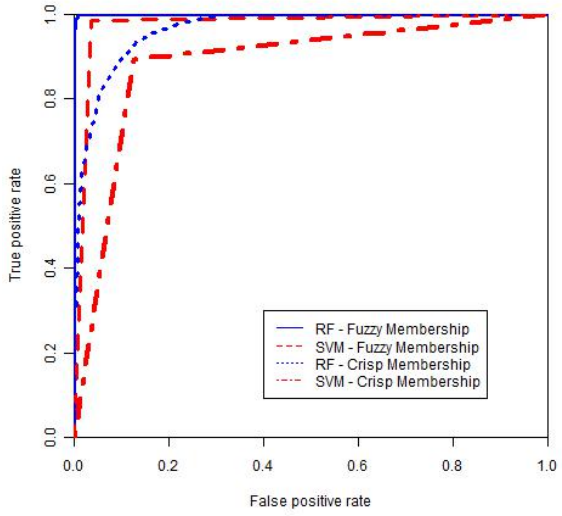

Figure 4. ROC curves for aterioscleroses prediction obtained using random forest (blue) and SVM (red)

For the atherioscelrosis prediction, too, we obtained a significant performance improvement (3-9%) when fuzzy features are used.

The results obtained for hypertension prediction are shown in table IV and Fig. 5. Again, a notable AROC improvement (5-13%) is obtained by using the fuzzy features instead of the crisp ones.

TABLE IV. AROC RESULTS FOR HYPERTENSION PREDICTION

	Crisp Features	Fuzzy Features
RF	0.9454	0.9991
SVM	0.8537	0.989

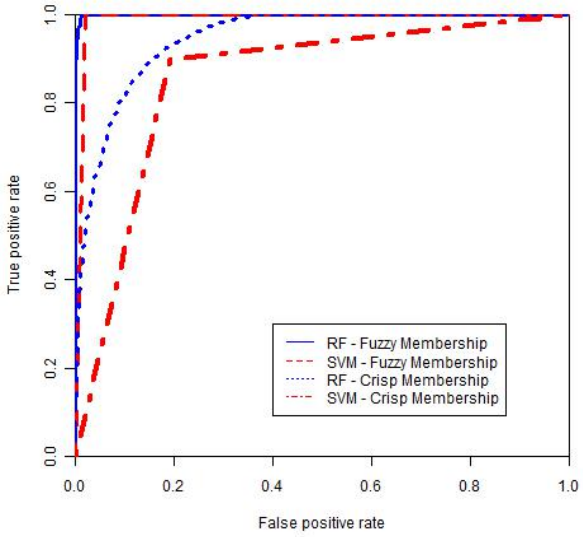

Figure 5. ROC curves for hypertension prediction obtained using random forest (blue) and SVM (red)

V. CONCLUSIONS

In this paper we presented a method for disease predicting using large public medical datasets. Disease prediction is important in a variety of applications such as health insurance, tailored health communication and public health. The presented method is based on employing ICD-9 diagnostic groups (DRGs) and demographics variables in conjunction with classification algorithms, such as SVM and RF. As opposed to using a crisp DRG membership for the ICD-9 codes, we introduced a novel fuzzy membership computed based on ICD-9 ontological similarity. The results presented on three different diseases and two classifiers show that the fuzzy features lead to an important improvement (between 3 and 13%) in prediction performance. The improvement is due to the fact that the fuzzy features capture the relationships between the DRG groups in the process of feature extraction.

In the near future, we plan to extend our approach to all 259 disease categories present in the HCUP dataset.

***Abstract*—Successful performance of software, and indeed Enterprise Resource Planning (ERP), depends on proper system maintenance. For this reason, firms should follow a maintenance process that drives the ERP system toward success. However, in general terms, ERP maintenance managers do not know what conditions they should target to successfully maintain their ERP systems. Moreover, numerous risks threaten ERP maintenance, but they are normally dealt trusting on experience. To address this requirement, we have built a FCM-based tool that helps ERP teams to simulate the impact of risks on ERP maintenance.**

Keywords: Simulation; Software maintenance; ERP; Fuzzy Cognitive Maps; Risks Simulation

I. INTRODUCTION

Enterprise Resource Planning (ERP) is one the most common and critical systems implemented by firms around the world. These systems allow the modeling, automation and integration of company business processes, grouping all data into a single database and providing relevant and updated information for decision-making and control.

Many firms have implemented ERP packages to fully integrate, standardize and coordinate their processes. These systems are more or less customized to fit them to the adopting company through the implementation process. But when the ERP is operative, practitioners undergo changes in the system. These modifications are carried out to correct or prevent failures, migrate the ERP to new releases and align the application regarding the specific business requirements or ERP users' expectations.

If the company does not properly maintain the ERP system, failures will arise, performance will decrease and the expected benefits will not be obtained [1]. This may even lead to early retirement of the ERP application. Hence, ERP maintenance becomes a key process in the post-implementation stage.

Given the significant risks inherent in ERP maintenance and the serious consequences that may follow, it is necessary to manage all risks properly. However, research on this particular issue remains inadequate. Previous studies neither indicate which conditions must be satisfied to support successful ERP maintenance, nor identify the risks that may threaten maintenance.

Accordingly, we assess the effects of risks on the success of ERP maintenance through a systematic approach similar to that proposed elsewhere. With this in mind, we identify risks to ERP maintenance success. Finally, we built a Fuzzy Cognitive Map to model risk effects on ERP maintenance success and simulate distinct scenarios.

Section 2 presents a literature review of theoretical background about ERP maintenance and risk. Section 3 presents the fundamentals of Fuzzy Cognitive Maps. Moreover, this section presents key aspects of the tool. Section 4 describes the process for building a Fuzzy Cognitive Map to model risk in ERP maintenance. Section 5 studies the results of the FCM simulation and the risks impacts on ERP maintenance. For this purpose, we define two scenarios and simulate them using the Fuzzy Cognitive Map. Finally, Section 6 offers the conclusions.

II. BACKGROUND

A. Enterprise Resource Planning

Enterprise Resource Planning (ERP) is one the most adopted enterprise systems. An ERP is a large commercial off-the-shelf configurable application that integrates the core enterprise business functions.

An ERP can be defined as a single software system to support the complete integration of information from all functional areas of a company by means of a single database that is accessible through a unified interface and channel of communication.

The ERP life cycle begins when top management decides to install the software. Following this decision, numerous tasks are carried out to implement the system. However, the ERP life cycle is not finished as soon as the application is operative and the ERP implementation stage has been concluded. At that moment, ERP enters into the post-implementation stage, which continues until its retirement.

B. ERP maintenance

ERP adopters have to perpetually maintain their ERPs until the end of its life span. However, frequent ERP modifications cause high risks and costs, which impact on software performance [2]. In such a case, the daily activity of the firm

Sponsors: Spanish Ministry of Science and Innovation and Andalusian Regional Government

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

would be hindered. Hence, ERP maintenance is considered a critical process, which needs to be managed carefully.

ERP maintenance can be defined as the process addressed to identify and perform changes required for improving or maintaining system performance through the ERP post-implementation stage. The maintenance team implements each maintenance request by means of projects.

In the literature, various papers propose models to support ERP maintenance [3], [4]. Despite this, models aware of risk have not been developed. For this reason, the aim of our research was to develop a formal model for managing ERP maintenance risks.

C. Risks within ERP maintenance

ERP system maintenance is a large-scale, unstructured and highly complex undertaking [5]. In some cases, it even requires the use of unfamiliar technologies and tools. Hence many controllable and uncontrollable risks can affect its outcome.

A risk is an event characterized by uncertainty because it may or may not occur. If this risk turns into a real problem, it may cause dangerous failures. In such case, the project performance and the maintained ERP will be seriously damaged. Therefore, risk management becomes a crucial process to ensure ERP success.

A proper risks management helps practitioners to be aware of the real situation of the project, their problematic aspects and potential causes existing of ERP project failure. They will thus resolve more efficiently the threats' projects. Otherwise, improper risks management lead the carrying out of evitable error and the appearance of potential problems, which make the achievement ERP maintenance project outcomes difficult. Therefore, active risks management is key to reach ERP maintenance projects success.

In this way, the literature provides numerous methods, checklists, analytical frameworks, risk assessment tools and risk response strategies to help project managers to handle risk factors more effectively [6]. These studies mainly focus on classic software projects. However, different risks affect ERP project success, because classic software projects and ERP projects are not similar [3]. This has encouraged the appearance of ERP project risk studies in the literature. However, these studies focus on the implementation stage.

Various research efforts have identified risk in the context of ERP projects. Sumner [7] identified, described and categorized the risk factors associated with ERP implementation. Moreover, Sumner also marked which risks are unique in ERP projects. Huang et al. combined a multi-criteria methodology and the Delphi method to identify and prioritize risks [8]. By contrast, post-implementation stage risk research is scarce in the literature.

III. FUZZY COGNITIVE MAPS

FCMs describe a cognitive map model with two significant characteristics. First, causal relation-ships between nodes have different intensities represented by fuzzy numbers. A fuzzy number is a quantity whose value is uncertain, rather than exact. It can be thought of as a function whose domain is usually the interval between 0 and 1 (or -1 and 1), inclusive. Each numerical value in the interval represents the degree of membership in a fuzzy set, where 0 is non-membership and 1 represents full membership. The second characteristic is that the system is dynamic – it evolves with time. The system involves feedback, and a change in a concept node may affect other concept nodes, which in turn can impact the node initiating the change. Feedback plays a prominent role in FCMs by propagating causal influences along complicated pathways.

Moreover, FCMs provide an intuitive, yet precise, way of expressing concepts and reasoning about them at their natural level of abstraction. By transforming decision modeling into causal graphs, decision makers with no technical background can understand all of the components in a given situation. In addition, with an FCM, it is possible to identify and consider the most relevant factor that seems to affect the expected target variable. For these reasons, we think that FCMs are a worthy tool.

A. FCM fundamentals

A FCM is a digraph composed of nodes and edges. The nodes (x_i) are the most relevant dynamic variables or factors describing a target real-world dynamic system. These may represent concepts such as costs, diseases, medication, investment, or marketing strategy, to name a few. For any context, the nodes are a set of entities that are relevant to the domain of study.

Relationships between nodes are represented by directed edges. An edge linking two nodes can model the influence of the causal variable on the effect variable [9]. In addition, edges also indicate the type of connection, incorporating either a plus (+) or a minus (-) sign. A positive relationship between two factors indicates that an increase or decrease in a causal variable causes the effect variable(s) to change in the same direction. When the relationship is negative, the change in the effect variable is in the opposite direction (i.e., an increase in the cause variable causes a decrease in the effect variable).

Because FCMs are hybrid methods that mix fuzzy logic and neural networks [10], each cause is assessed by its intensity, $w_{ij} \in [-1,+1]$, where i is the pre-synaptic (causal) node and j is the post-synaptic (effect) node one.

FCMs are dynamic systems involving feedback whereby change in a node may affect other nodes, which in turn can affect the node initiating the change. The analysis begins with the design of the initial vector state (C^0), which represents the initial value of each variable or concept (node). The initial vector state with n nodes is denoted as:

$$C^0 = \begin{pmatrix} C_1^0 & C_2^0 & \cdots & C_n^0 \end{pmatrix} \quad (1)$$

The new values of the nodes are computed in an iterative vector-matrix multiplication process with an activation function, which is used to monotonically map the node value into a normalized range [0,1]. The sigmoid is the most common function [11] when the concept (node) value maps onto the range [0,1].

B. FCM dynamics

The vector state C_i^{t+1} at the instant $t+1$ would be computed as:

$$C_i^{t+1} = f\left(\sum_{\substack{i=1 \\ i\neq j}}^{n} C_i^t \cdot w_{ij}\right) \tag{2}$$

where $f(x)$ is the transformation function.

The state changes along the process. Usually, two kinds of transformation functions are used in FCM dynamics. The first one is the unipolar sigmoid:

$$f(x) = \frac{1}{1+e^{-\lambda \cdot x}} \tag{3}$$

The second is the hyperbolic tangent:

$$f(x) = \tanh(x) = \frac{e^{\lambda \cdot x} - e^{-\lambda \cdot x}}{e^{\lambda \cdot x} + e^{-\lambda \cdot x}} \tag{4}$$

Both functions use λ as a constant for function slope (degree of fuzzification). The FCM designer has to specify the lambda value. For large values of lambda (e.g., $\lambda \geq 10$) the sigmoid approximates a discrete function that maps its results to interval (0,1); for smaller values of lambda (e.g., $\lambda \leq 1$) the sigmoid approximates a linear function; while values of lambda closer to 5 provide a good degree of fuzzification in the [0,1] interval [11].

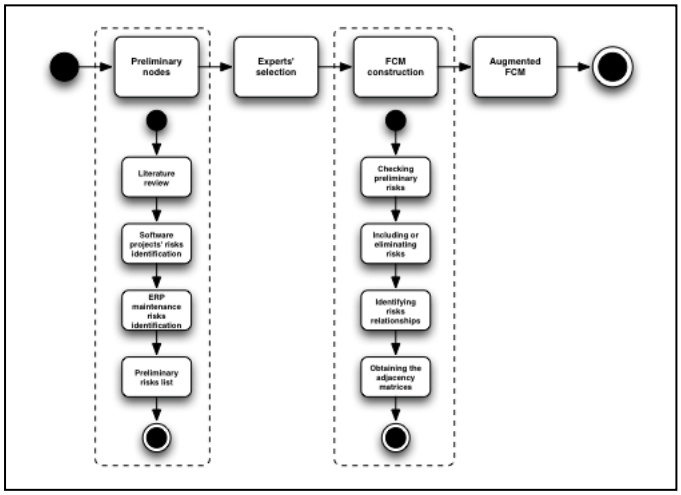

Figure 1. FCM construction process

The FCM inference process finishes when stability is reached. The final vector state shows the effect of the change in the value of each node on the FCM. After the inference process, the FCM reaches one of three states following a number of iterations. It settles down to a fixed pattern of node values, the so-called hidden pattern or fixed-point attractor.

Alternatively, the state can continue cycling between several fixed states, known as a limit cycle. With a continuous function, a third possibility is a chaotic attractor. This occurs when, instead of stabilizing, the FCM continues to produce different results (state vector values) for each cycle. In this case, the technique fails to offer a useful outcome for risk analysis.

IV. FCM CONSTRUCTION

The aim of this study was to create a FCM to simulate the risks' impact on ERP maintenance. We carried out the steps indicated in Figure 1 to build the FCM model. Firstly, we identified the preliminary nodes to help the experts create their FCMs. To do so, we performed a broader literature review on software projects risks and ERP projects. We thus achieved an initial large risks list. But, the initial list does not solely gather ERP maintenance risks.

So, we carefully analyzed the initial list to identify ERP maintenance risks. Subsequently, those risks affecting ERP maintenance were renamed, while the other risks were eliminated. In this way, we obtained the preliminary risks nodes of FCM.

The following activity consisted of selecting experts who were willing to participate in our research. In no case, did we select the experts because they were easily accessible. The main selection criterion considered was profound knowledge in the ERP maintenance and absence of conflicts of interest. A total of 10 leading experts decided to take part with us in this study. These experts belong to different professional scales. Moreover, they had participated or participate in the maintenance of ERP solutions supplied by different vendors. Therefore, we achieved the making up of a heterogeneous group of experts.

Thirdly, each expert individually built an FCM. To help them, we sent the list of preliminary risks nodes, which were only indicative. So, they checked them and eliminated those risks nodes, which do not affect ERP maintenance. Moreover, those experts, who concluded that we had not identified all ERP maintenance risks, added the non-identified risk(s) node(s) to the initial list. Subsequently, the experts state the relationship between the nodes. They also pointed out the risks impacts on ERP performance. We thus achieved one adjacency matrix for each expert.

We finally constructed the augmented matrix (A^*) adding the adjacency matrix of each one of them [10]. The elements' aggregation depend on if there are or are not common nodes. The experts' adjacency matrix had common nodes. So, the elements (w_{ij}^*) in the augmented matrix are computed by [12]:

$$w_{ij}^* = \frac{\Sigma_{k=1}^{n} A_k}{n} = \frac{\Sigma_{k=1}^{n} w_{ij}^k}{n} \tag{5}$$

n being the number of FCMs added, one per expert. The A^* obtained is the following:

$$A^* = \begin{bmatrix} 0 & .06 & 0 & 0 & .07 & 0 & 0 & 0 & .12 & .04 & 0 & 0 & -.05 \\ 0 & 0 & 0 & 0 & 0 & .03 & 0 & 0 & 0 & 0 & .01 & 0 & -.108 \\ 0 & 0 & 0 & .255 & .325 & .185 & .05 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & .15 & 0 & .105 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & .04 & 0 & .625 & 0 & .17 & 0 & 0 & 0 & 0 & -.018 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & .06 & 0 & 0 & 0 & 0 & -.109 \\ 0 & 0 & 0 & 0 & 0 & .23 & 0 & .08 & 0 & 0 & 0 & 0 & -.038 \\ 0 & 0 & 0 & 0 & 0 & .11 & 0 & 0 & 0 & 0 & .08 & 0 & -.029 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -.025 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -.032 \\ 0 & .14 & 0 & 0 & 0 & .28 & .315 & .035 & 0 & .02 & .02 & 0 & -.134 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \quad (6)$$

Figure 2 shows the FCM obtained, representing how existing risks in the implementation of maintenance request impacted on ERP performance.

V. FCM SIMULATION

Firstly, we defined what-if scenarios at the instant $t=0$. In other words, the values of all variables of the FCM are represented in an $1\times n$ initial state vector C^0.

We formulate several questions as following: which risks will impact the strongest on ERP performance during the system maintenance: risks derived from external or internal agents or both at the same time? How will these impacts on the rest of the risks? To answer the previous questions, we created three Scenarios and simulated them:

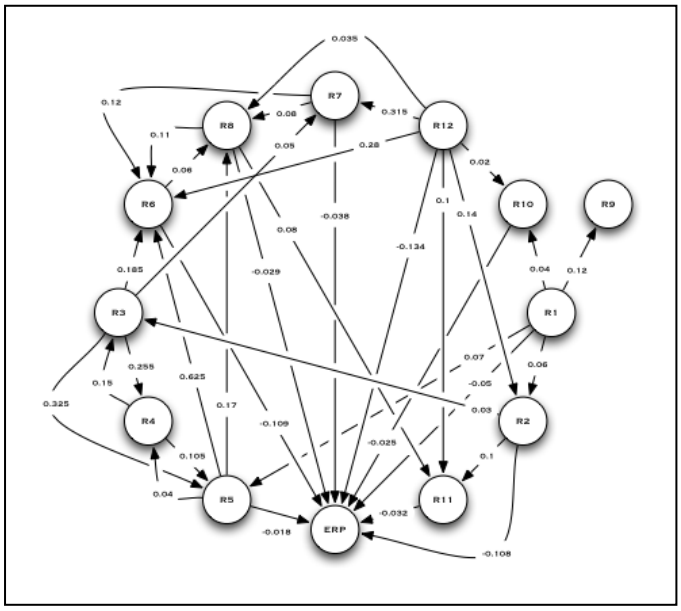

Figure 2. FCM-based ERP maintenance risks model

In Scenario 1 ($C^0_{S_1}$), we activated the risk derived from the external agents. In Scenario 2 ($C^0_{S_2}$), we activated risks derived from the internal agents.

$$C^0_{S1} = (0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 1 \quad 0) \quad (7)$$

$$C^0_{S2} = (0 \quad 0 \quad 1 \quad 1 \quad 1 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0) \quad (8)$$

Subsequently, we simulated these Scenarios computing A^* and $C^0_{S_i}$. Specifically, Scenarios were transformed using hyperbolic tangent function (4). We select this activation function (7) because the values of the nodes can fall within the range [-1, 1], 5 being the value assigned to λ.

The simulation finishes when the vector state reaches the stability (at a fixed point or limit cycle) or a chaotic behavior. In this research, both scenarios reached the stability. Table 1 presents the results obtained simulating each Scenario.

TABLE 1. Scenarios simulation results

Node	Description	Scenario 1	Scenario 2
R1	Continuous organizational changes	0	0
R2	Requirements incomplete and/or unclear	0.023556521	0
R3	Instability in maintenance team members	0	0.50123746
R4	Lack group spirit and attitude in maintenance team members	0	0.575731388
R5	Inadequate mix of team skills	0	0.637508649
R6	Quality of original programming	0.255256472	0.830216721
R7	Methodology and maintenance process are not defined	0.030705553	0.327804561
R8	Maintenance tasks are excessively hard	0.226292501	0.641248801
R9	Project milestones cannot be defined	0	0
R10	Use of inadequate technology for system testing	0.012737097	0
R11	Wrongly-fit system with pre-existing applications	0.229341662	0.442749349
R12	Lack active participation by external parties	0.005477003	0
ERP		**-0.308378881**	**-0.619552233**

The findings of Scenario 1 show that the impact of the unsuitable involvement of external agents in the project was positive and varied from null to low on the rest of the risks. The quality of the original programming (R6) and fit software with pre-existing applications (R11) were the ones highest affected by R12, both technical risks. The intensity of influence of R12 on ERP performance was higher than on the risks. This specifically was negative and slightly moderate. Therefore, R12 directly affected ERP performance instead of indirectly, that is, by means of other risks.

The results of the simulation of Scenario 2 show that the effect of risks derived from internal agents in the project was also positive. However, in this simulation, the effects on ERP maintenance risks were higher by far. In fact, the intensity of impacts was usually high. The intensities of impacts were from

2 to 6 times higher in Scenario 2 with respect to Scenario 1. Specifically, the influence of R3, R4 and R5 on other risks was from null to strong. As well as Scenario 1, R6 was the highest impacted risk. But the intensity of impact of risks activated in Scenario 2 was three times greater than the risk activated in Scenario 1.

The intensity of influence of risks activated in Scenario 2 on ERP performance was two times greater than the risk activated in Scenario 1. This was negative and slightly strong. R3, R4 and R5 impact directly less on ERP performance than on some other risks. Therefore, risks derived from internal agents directly and indirectly affect ERP performance.

VI. CONCLUSIONS

ERP maintenance is necessary to maintain or improve the usability and system performance. With this in mind, risky and complex maintenance projects follow one another continuously through the ERP life span.

However, numerous risks can arise during the implementation of maintenance requests. To prevent these risks negatively affecting system performance, practitioners have to manage them properly. But, in many cases, they deal these risks with intuitively and inefficiently.

In order to avoid this, this research aims at supporting practitioners work managing ERP maintenance risks. To do so, we decided to create an FCM. This identifies ERP maintenance risks as well as the existing connections between them. In addition, at any time the practitioner can easily modify the model, adding or eliminating further variables and/or relationships, to faithfully represent the phenomena.

The dynamic analysis of the FCM will help practitioners to take more efficient measures to minimize ERP maintenance risks. Static analysis specifically indicates which risks have more influence on other risks or impact stronger on ERP performance.

In contrast, the dynamic analysis of the FCM allows ERP practitioners to predict the effects of risks activated in the implementation of maintenance requests on ERP performance over time.

The result of dynamic analysis reveals that the risks derived from team maintenance have strongest impact on ERP performance. Hence, in order to achieve successful ERP maintenance, managers should create teams made up of highly qualified professionals in ERP technology, reduce the instability in maintenance team members, as well as improving the motivation and training of the members of maintenance teams.

Looking to the future, it is necessary to undertake further research on the existing risks in ERP maintenance. To manage such risks most effectively, managers should know which risks are most important to ERP maintenance success. Therefore, research that answers this question is required. The development of techniques to forecast the risks appearance within ERP maintenance projects is also very worthwhile.

***Abstract*—Fuzzy Cognitive Maps (FCM) is a popular technique for describing dynamic systems. A FCM for a dynamic system is a signed graph consisted of relevant concepts and causal relationships/weights between the concepts in the system. With suitable weights defined by experts in the related areas, the inference of the FCM can provide meaningful modeling of the system. Thus correctness of the weights is crucial to the success of a FCM system. Normally the weights are set by experts in the related areas. Considering the possible inefficiency and subjectivity of experts when judging the weights, it is an appealing idea to generate weights automatically according to the samples obtained through observation of the system. Some training algorithms were proposed. However, to our best knowledge, few learning algorithm has been reported to generate weight matrix based on sample sequences with continuous values. In this paper, we introduce a new learning algorithm to train the weights of FCM. In the proposed algorithm, the weights are updated by gradient descent on a squared Bellman residual, which is an accepted method in machine learning. The experiment results show that given sufficient training samples, the correct weights can be approximated by the algorithm. The algorithm proposes a new way for FCM research and applications.**

Keywords- Fuzzy cognitive maps

I. INTRODUCTION

Fuzzy Cognitive Maps (FCMs) was introduced [1] as an extension of cognitive maps proposed by political scientist Robert Axelrod [2]. A cognitive map is *signed digraph*, in which nodes are variable concepts and edges represent causal connections between the concepts. The positive or negative sign on a directed edge between two concepts indicates whether the change of the first concept causally increases or decreases the second concept. A matrix consisted of the signs of the edges is used to represent the cognitive map. In the matrix, a positive edge is shown as 1, a negative edge as -1 and 0 for unrelated concepts. Kosko proposed to apply fuzzy logic technique to represent the causal relationships between concepts. Fuzzy causal algebra was proposed to infer how a concept will influence another concept. Then Kosko proposed Bidirectional Associative Memories in neural networks [3]. This provides a theoretical base for simple FCM inference algorithm which is widely used in current FCM researches and applications. FCM inference is a qualitative approach for a dynamic system, where the gross behaviors of a system can be observed quickly and without the services of an operations research expert [4].

Since proposed, FCM has been researched and applied in many areas. The original application of FCM shown by Kosko was to predict political status changes [1]. Later the application of FCM was extended to simulation of virtual worlds. In [5], FCMs are designed for a virtual sea world. The behaviors of dolphin, fish and shark are predicted based on their behavior FCMs. For example, a FCM for the control of a dolphin consists of concepts such as 'Hunger', 'Food Search', 'Chase food' and so on. Through FCM inference, the status changes of the dolphin from an initial status can be observed. The status of the dolphin will finally reach a stable status or repeat for a cycle of limited statuses. The examples show that FCM output states can guide a cartoon of the virtual world. Besides the applications in virtual worlds, FCM technique is applied to solve real-world problems. For example, FCM applications are used in intelligent intrusion detection system [6], the system to control the valves based on the tank height and the gravity of the liquid in the tank [7], the brain tumor characterization system [8], the web surveillance system [9], and so on. FCM shows high efficiency and accuracy in these systems.

In these systems, it is very important to assign suitable weights to the causal relationships between concepts. In the early FCMs designed by Dickerson and Kosko [5], the weights take value as 1, -1 or 0. It is a rather easy job to assign weights by judging the positive, negative or neutral influences from one concept to another. However, in a real system where weights will take continuous values as suggested in [10], assignment of the weights is dependent on experts' personal knowledge and subjective judgments, which might not always be precise. So it is very appealing if the weights can be generated automatically. Some automatic algorithms have been proposed. We summarize them in the section of related work. No learning algorithm has been proposed to train FCM based on samples with continuous values. In this paper, we propose a gradient residual method to train the weights with some given sample sequences of a dynamic system. The algorithm updates the weights by gradients of squared

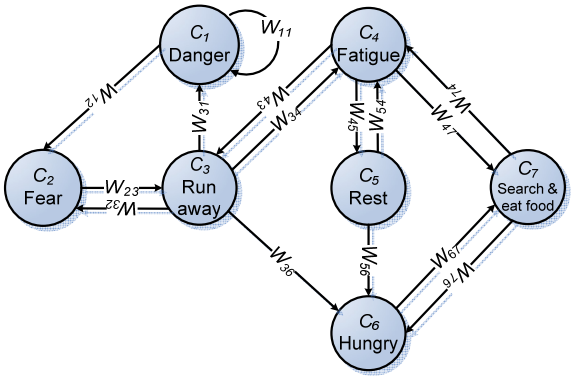

Figure 1. Example of a FCM.

Bellman residual. Experimental results show that the algorithm is very effective if sufficient sample sequences are given.

The rest of the paper is organized as following. We first give a brief illustration of FCM in Section II. Then the gradient algorithm to train FCM weights is explained in Section III and experimental results are shown in Section IV. Other FCM training methods are discussed in related work in Section V. Finally, a conclusion is given.

II. FUZZY COGNITIVE MAP

A. Definition

As introduced in last section, FCM is a directed graph which depicts a dynamic system. The nodes represent the concepts in the system. Weight on an edge between two nodes shows how much a concept will affect the next concept. The weight matrix can be shown as:

$$W = \begin{bmatrix} W_{11} & W_{12} & \dots & W_{1n} \\ W_{21} & W_{22} & \dots & W_{2n} \\ \dots & \dots & \dots & \dots \\ W_{n1} & W_{n2} & \dots & W_{nn} \end{bmatrix}$$

where, n is the number of concepts in the FCM.

An example FCM is shown in Figure 1. The FCM consists of seven concepts, which represent the status of a system to control an animal's behaviors. The possible relationships between the concepts are identified and shown in the figure.

In general, a weight W_{ij} takes values in the fuzzy causal interval [-1, 1]. A positive value means that the increase (decrease) of concept C_i will increase (decrease) the value of concept C_j. A negative value indicates the value of C_j will change in an opposite direction with C_i. A zero value means that C_i will not affect C_j. Only none-zero weights are shown in Figure 1. For example, we can say that the value of "Hungry" has no effect on "Rest". However, the value of "Hungry" will affect how the animal decides to "Search & eat food".

At a time t, the status vector of the FCM system is represented as $C^{(t)}=(C_1^{(t)}, C_2^{(t)}, \dots, C_n^{(t)})$. The initial status vector of FCM is shown as $C^{(0)}$. The status of a concept C_i in a time t can be calculated by summing the influences from last time. The equation is shown as:

$$C_i^{(t)} = f\left(\sum_{j=1}^{n} (C_j^{(t-1)} * W_{ji}) \right) \quad (1)$$

where, f is the threshold function.

Normally Sigmoid function is used as threshold function for FCM with continuous concept values. It is shown as:

$$f(x) = \left(1 + e^{-\lambda x}\right)^{-1} \quad (2)$$

where, λ is a parameter deciding the width of the sigmoid function. In this paper, λ takes default value 1.

The initial values of FCM concepts are obtained through measuring the concepts in the real system. Then the inference is performed by continuously calculating the status using the equations (1) and (2). The calculation does not stop until the model reaches a limit cycle or exhibits a chaotic change. The outputs of the FCM inference show how the system will change from the initial status.

Take the FCM example shown in Figure 1. A weight matrix W is decided by the experts in the domain of animal research and shown in Table I. Now we assume that the system starts from an initial status vector, $C^{(0)}$=(0.6, 0.3, 0.3, 0.6, 0.7, 0.7, 0.7). For example, the fuzzy value for concept "Fear" is 0.3, which means that the animal is in a status of being a little vigilant. The values of concepts at each step of FCM interaction can be calculated by using equation (1) and (2). The outputs are shown in Table II. It can be seen that the FCM

7	.557	.539	.487	.643	.647	.483	.677
8	.557	.539	.487	.643	.647	.483	.677

calculation converges at step 8. This means that without disturbs the animal will exhibit same behaviors after step 7.

B. *Generate FCM for a System*

A big question of FCM application is how to generate the weight matrix as shown in Table I. The normal method to construct a FCM relies heavily on a group of experts of the system. Each expert evaluates a causal relationship with a different fuzzy value depending on his personal experiences. Then the fuzzy rules are composited and de-composited to generate a fuzzy value which stands for the relationship [8]. It is obvious that the correctness of the weight matrix depends on the experts' personal experience and subjective judgments.

An alternative method is to automatically learn the weight matrix from the model of the dynamic system, which can be observed. Thus it is very attractive if the weight matrix could be generated from observed sample sequences as shown in Table II. Several learning algorithms have been introduced as summarized in Section V. In the next section, we will introduce our training algorithm to generate matrix from sample sequences.

III. GRADIENT FCM TRAINING ALGORITHM

A. *Problem Definition*

The training objective is to generate weight matrix of FCM based on sample sequences. An illustration of the training system is shown in Figure 2.

An initial weight matrix is input to the training algorithm as shown by arrow 1 in Figure 2. The original weights can be designed to show the basic positive or negative relationships between the concepts. However, there is no demand that the original weight W_{ij} must correctly indicate the causal positive or negative relationship from C_i to C_j. A value which is closer to the correct weight will save the training effort. 0 is assigned to W_{ij} if C_i has no influence to C_j. As we will show in the following algorithm, we must be very careful to set 0 as initial value for a weight because a weight with value 0 will not be updated by the training algorithm. If unsure, a random value other than 0 is suggested to be assigned to W_{ij}.

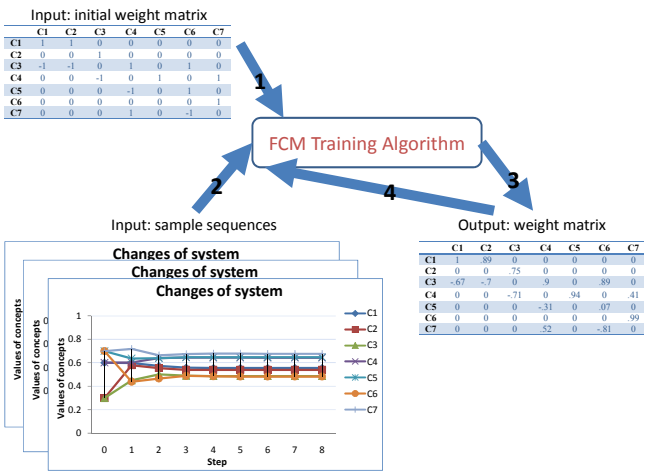

Figure 2. FCM training system.

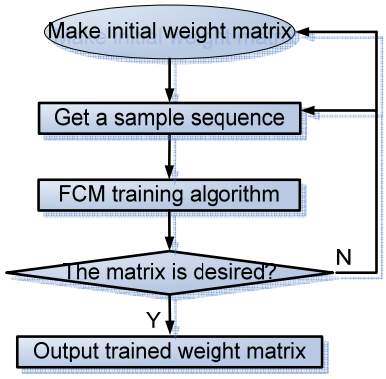

Figure 3. FCM training procedure.

Then some sample sequences are input as indicated by arrow 2 in Figure 2. The FCM training algorithm will train the initial matrix with the first sample sequence. After the training algorithm converges, a resulting weight matrix is output as shown by arrow 3 in Figure 2. The user needs to judge whether the output matrix meets the expectation. If not, the output matrix will be input into the training algorithm for next training as shown with arrow 4 in Figure 2. To be clear, an illustration about this procedure is shown in Figure 3.

Here it must be pointed out that human interference is still very important in the training system. System experts are needed to decide whether the output matrix is reasonable. As we will show later, the gradient training algorithm may be trapped in local minima or return a solution which is not desired. In these cases, a new initial weight matrix may be needed. However, it can be seen that in our training system the experts' jobs to observe system dynamics, make initial weight matrix, and judge whether the output matrix is desirable are easier, which are more objective than the jobs in traditional system to directly figure out the weight values [8]. In fact, as we will discuss in Section V, all other kinds of FCM learning algorithm also need human interference to judge whether their output weight matrix are suitable.

In the following, we will focus on the FCM training algorithm. Assume that a sample sequence is defined as: $\{S^{(0)}, S^{(1)}, \ldots, S^{(m)}\}$, where m is the number of steps in the sample sequence. Each status vector is defined as $S^{(t)}=(S_1^{(t)}, S_2^{(t)}, \ldots, S_n^{(t)})$, where n is the number of concepts. The training algorithm needs to update the initial weight matrix to get a new matrix such that with the output matrix, the FCM inference will be matching the sample sequence. We set $C^{(0)}$ as $S^{(0)}$. Thus the objective is to update each weight, which affects $C_i^{(t)}$, to decrease the difference between the calculated $C_i^{(t)}$ and the expected value $S_i^{(t)}$. The idea of residual algorithm used for function approximation system in machine learning can be exploited. We will first give a simple introduction about the residual algorithm. Then our gradient FCM training algorithm will be explained.

B. *Residual Algorithm*

Residual algorithm [11] is designed to modulate the weights of neural network which is used for approximating the expected values/rewards in machine learning. In a learning algorithm, Q is a value function to calculate the reward if an

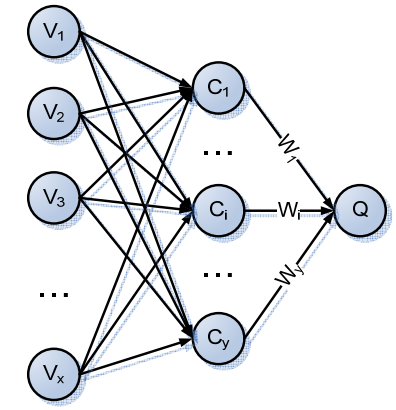

Figure 4. Function approximation system.

action is executed in a state. The objective of residual algorithm is to modulate the parameters in the Q function to make the function better approximate the expected reward.

The mean squared Bellman residual is defined as:

$$E = \frac{1}{|\Sigma|} * \Sigma (R + \gamma * v_{new} - Q)^2 \quad (3)$$

where, R is the immediate reward after an action is executed, γ represents the discount rate of future rewards, v_{new} is the value function for the successor state, Q is the current value function of the current state.

A simple illustration can be seen in Figure 4. Given an input vector $<V_1, V_2, \ldots, V_x>$, the neural network will output a value. In machine learning, the input variables represent the status and possible actions. The output represents the reward after executing the actions in the status. The residual algorithm will update the weights $<W_1, W_2, \ldots, W_y>$ to make the output value approximate to the expected value, correct reward. For this example, $E = (R - Q)^2$.

During training, the weights can be updated by performing gradient descent on the mean squared Bellman residual:

$$\Delta W_i = -\alpha * \frac{\partial E}{\partial W_i} \quad (4)$$

where, α is the learning rate.

The gradient residual algorithm guarantees to converge to a minimum, which is sometimes local. Although some mechanisms were proposed to avoid local minimum in gradient learning [12], no algorithm has been able to perfectly solve the problem. To solve this problem is not the intention of this paper. The algorithm proposed in this paper is just an application of the gradient method. In our training system, experts' judgment is needed to decide whether a final solution is suitable. If not, a new training will begin until an acceptable solution is found.

In the following, we will apply the idea of residual algorithm to the problem of FCM training.

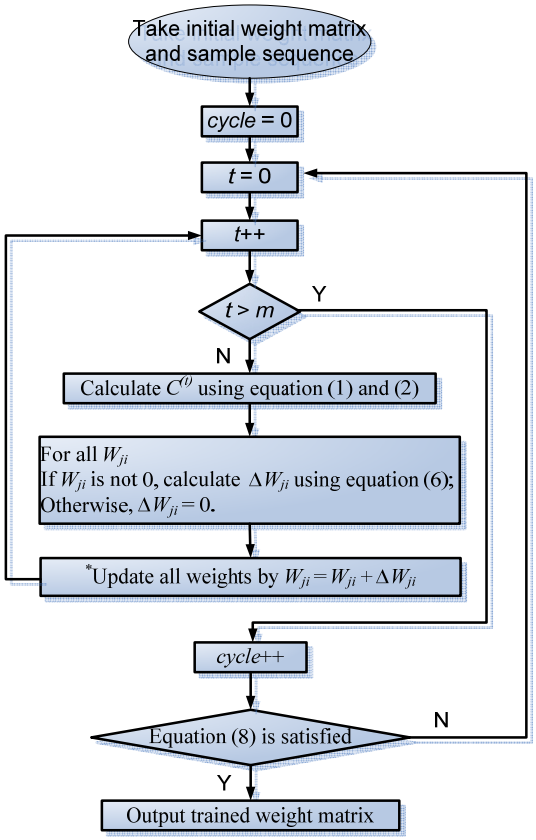

Figure 5. Residual training algorithm.

C. Gradient Algorithm for FCM Training

In FCM training, for each step t, the squared Bellman residual for a concept C_i is defined as:

$$E_i^{(t)} = \left(C_i^{(t)} - S_i^{(t)}\right)^2 \quad (5)$$

where, $C_i^{(t)}$ is the value of concept calculated by using equations (1) and (2) with the input value of $S^{(t-1)}$.

According to the residual algorithm, the update for W_{ji}, which affects $C_i^{(t)}$, is defined as:

$$\Delta W_{ji} = -\eta * \left[C_i^{(t)} - S_i^{(t)}\right] * \frac{\partial C_i^{(t)}}{\partial W_{ji}} \quad (6)$$

where, η is the learning rate.

With the equations (1) and (2), the gradient is calculated by:

$$\frac{\partial C_i^{(t)}}{\partial W_{ji}} = \frac{e^{-\lambda * \sum_{k=1}^{n} \left(W_{ki} * S_k^{(t-1)}\right)} * \lambda * S_j^{(t-1)}}{\left[1 + e^{-\lambda * \sum_{k=1}^{n} \left(W_{ki} * S_k^{(t-1)}\right)}\right]^2} \quad (7)$$

The weights will be updated at each step and the updated weight matrix will be used in next step.

The training algorithm is shown in Figure 5. Variable *cycle* is used to count how many cycles the FCM is trained. It is noticed that a standard is needed to judge whether the training converges. In this paper, a standard equation is designed as:

$$\sum_{i=1}^{n}\sum_{j=1}^{n}\left|\sum_{t=1}^{m}\Delta W_{ij}^{(t)}\right| < threshold \qquad (8)$$

where, the *threshold* value is used to decide whether the sum of changes of weights has been small enough.

It should be pointed out that if W_{ji} is updated to 0 from a non-zero value during the training, a very small value should be assigned to W_{ji}, instead of 0. This will ensure that W_{ji} is updated in future. This also means that if a user is not sure about a weight, a small value other than 0 should be used in the initial weight matrix.

Different training samples may produce different output matrices. However, all the output matrices should be able to satisfy the criteria in Equation (8) when being used to approximate the specific training samples. When more training samples are used to refine the output matrix, the final matrix to satisfy all the training samples will be produced.

We will show the experiment results of this algorithm in next section.

IV. EXPERIMENT

We realized the above training algorithm using Visual J#. The program is run on a desktop PC with Intel(R) Core(TM)2 Quad CPU Q9400 @ 2.66GHz, 3.37GB of RAM. The program is single thread and just one core of the CPU is utilized. To show the result of the training algorithm, the FCM system shown in Figure 1 is used as an example. We designed 3 experiments with different initial weight matrix.

TABLE IV. THE OUTPUT WEIGHT MATRIX *W*.

	C_1	C_2	C_3	C_4	C_5	C_6	C_7
C_1	.999	.881	0	0	0	0	0
C_2	0	0	.752	0	0	0	0
C_3	-.671	-.687	0	.859	0	.909	0
C_4	0	0	-.71	0	.94	0	.411
C_5	0	0	0	-.581	0	.311	0
C_6	0	0	0	0	0	0	.99
C_7	0	0	0	.806	0	-1.052	0

A. Experiment 1

In the first case, the initial weight matrix is made based on the causal relationships between the identified seven concepts. A positive relationship is assigned a weight, 1. A negative relationship is assigned a weight, -1. Otherwise, 0 is assigned. The initial weight matrix we created is shown in Table III. The sample values shown in Table II was used as the first training sample sequence.

Using parameters η as 0.1 and *threshold* as 0.00001, the training algorithm converges after 90,938 cycles in 2.39 seconds. The output matrix is shown in Table IV. We can see that the output matrix is quite close to the original matrix shown in Table I except the weights associated with C_4 and C_6. The matrix in Table IV is returned instead of the matrix in Table I because the training algorithm stops at a local minimum before the global optimal solution is found.

The values of concepts through FCM interaction are calculated using the output matrix in Table IV and shown in Table V. Although with the differences in the weights associated with C_4 and C_6, the calculated values are still very close to the original input sample sequence in Table II.

Compared to Table I, it is obvious that the output matrix in Table IV is not desired. Then we train the output matrix in Table IV with a new sample sequence as shown in Table VI. With the new training sample sequence, the learning algorithm converges in 7,289 cycles in 0.15625 seconds. The output matrix is shown in Table VII. This new output matrix is close to the matrix shown in Table I with negligible differences.

By this example, we can see that given sufficient training samples, the gradient learning algorithm is able to generate weight matrix for FCM system very precisely.

B. Experiment 2

In the second experiment, we will show how the initial input weight matrix will affect the learning. Like Experiment 1, the sequence in Table II is used as the first training sample. A new initial weight matrix is designed by setting all causal relationships in Table III as -1.

This time the learning algorithm converges in 54,787 cycles in 1.46875 seconds. The output matrix is shown in Table VIII. It is noticed that this output matrix is different from the matrix in Table IV.

The FCM inference results using this output weight matrix are very close to the original training sequence in Table II. Using this output weight matrix in Table VIII and the second training sample sequence in Table VI, the training algorithm converges after 7,333 cycles in 0.140625 seconds. The output weight matrix is shown in Table IX. The resultant output weight matrix is very close to the original weight matrix in Table I.

It is shown in Tables VII and IX the first weight of the output matrices is 1.001, which exceeds the range for weights, [-1, 1]. In these cases, the upper bound 1 is used to replace

C. *Experiment 3*

In this time, we assign random values to the initial weights. The initial weight matrix is shown in Table X.

We use the first sample sequence to train the weight matrix. The training algorithm converges after 26,730 cycles in 0.71875 seconds. The output matrix is shown in Table XI. We could see that this matrix is very close to the matrix shown in Table I.

More experiments with different initial weight matrixes which are randomly assigned are not shown. In these experiments, the gradient algorithm is also able to generate solution weight matrixes successfully.

V. RELATED WORKS

The idea to automatically generate weights matrix for FCM has been researched by many researchers. The proposed algorithms mostly fall into two groups, Hebbian learning algorithm and evolutionary algorithm.

Hebbian learning algorithm was first applied in training FCM by Kosko [13]. Before that, Kosko proposed a temporal associative memories (TAMs) algorithm [14]. TAMs can store only a few patterns. Then Kosko proposed to use the Differential Hebbian Law (DHL) to encode the usual binary changes in concepts. The experiment result in [5] shows that the algorithm was quite good at generating FCM weights to replicate the usual binary changes. Then an extension of DHL, Balanced Differential Learning (BDL) algorithm, was proposed in [15]. The new algorithm considered more factors while deciding how to update weights. Experiment results show that this algorithm is better to learn patterns. These two algorithms aim to learn the binary changes of concepts. Two more

extensions of DHL were also proposed to learn the weights of systems with continuous values [7], active hebbian learning (AHL) algorithm and nonlinear hebbian learning (NHL) algorithm. Different to other algorithms, the inputs of AHL and NHL are desirable regions of output concepts. These two algorithms need many user interferences to ensure that proper weights are trained. To the best of our knowledge, no learning algorithm which generates weight matrices based on sample sequences with continuous values has been reported.

Evolutionary algorithm is another frequently used algorithm when learning FCM weights matrix. The general idea is to search the weights matrix which can best replicate the training samples [16]. Red-coded genetic algorithms (RCGA) adds a floating-point extension to basic genetic algorithm, which makes genetic algorithm more effective for training weights with continuous values [17]. Another improvement of genetic algorithm can be seen in [18]. Tabu search method was applied to avoid local optima in genetic algorithms. The comparison results show that Tabu search is faster and can find solutions with better fitness than traditional genetic algorithms. Particle swarm optimization (PSO) is another kind of evolutionary algorithm which comes from swarm intelligence algorithms [19]. Besides these, simulated annealing method for training FCM is proposed recently [20]. Simulated annealing makes a serial of moves from an initial solution before it finds solution or is frozen in local optima. Evolutionary algorithm is an applicable way to find good weight matrix for FCM. However, like in our algorithm, human interference is needed to judge whether an output matrix meets the expectation.

VI. CONCLUSION

In this paper, we propose a gradient residual training algorithm for generating weights of FCM. The algorithm updates weights by trying to decrease the squared Bellman residual. The equations to update the weights and the training system are demonstrated. Then the experiments using the algorithm are shown. The results show that with sufficient training samples, the learning algorithm can generate output weight matrix which is very close to the desired matrix. It is an efficient algorithm for generating FCM weight matrix of a dynamic system given the change models of the system. The observations of system models are normally easier than to estimate the possible influences between the concepts. Thus the algorithm proposes a new direction for FCM research and applications. In future, more experiments will be performed in real applications to test the training system.

The example FCM in this paper contains seven concepts. The number of time steps is thus short (e.g. 8 steps). Some large FCMs with many concepts may generate infinite steps. The residual algorithm works quite well with such cases in our other experiments. In these experiments, the algorithm works well even for a FCM with 80 concepts. Due to the page limit, we cannot display many large matrices. Another point is that in the training, not all steps before convergence are required to train a weight matrix. The benefit of providing more steps is to generate matrix closer to the original matrix. More experiments and comparative analysis of residual algorithm and the GA algorithm by Stach [21] will be reported soon.

Causal Modeling Approximations In The Medical Domain

Lawrence J. Mazlack
Applied Computational Intelligence Laboratory
University of Cincinnati
mazlack@uc.edu

***Abstract*---Studies in the health sciences often seek to discover cause-effect relationships among observed variables of interest, for example: treatments, exposures, preconditions, and outcomes. Consequently, causal modeling and causal discovery are central to medical science. In order to algorithmically consider causal relations, the relations must be placed into a representation that supports manipulation and discovery. Knowledge of at least some causal effects is inherently imprecise or approximate. The most widespread causal representation is directed acyclic graphs (DAGs). However, DAGs are limited in what they can represent. Another graph methodology, fuzzy cognitive maps (FCMs) hold promise as a model that overcomes some of the difficulties found in other approaches. This paper considers causality and suggests fuzzy cognitive maps as a useful causal representation methodology.**

Keywords-causal, modeling, cognitive map

I. Introduction

Causal knowledge makes up much of what we know and want to know in science [1]. Causal modeling and causal discovery are central to medical science as recognition of cause-effect can lead to robust treatments. Causality is a *relation,* relating *causes* to *effects* [2]. Experimental studies, such as randomized controlled trials, often provide the trust worthiest results for establishing causal relationships. However, human experimental studies, while potentially informative, may not be: safe, ethical, logistically feasible, or financially worthwhile. Alternatively, observational data is often available in the form of medical records; this data can be analyzed to attempt to recognize causal relationships. Sometimes, there is insufficient data to draw precise results; or, the available data is imprecise, incomplete, or contradictory; this leads to the need to accommodate imprecision in a casual model.

The target of many studies in the health sciences is the discovery of cause-effect relationships among recorded variables of interest, for example: treatments, exposures, preconditions, and outcomes [3]. Yet, until recently, the dominant methodology in health science research has been statistical analysis. Statistical analysis of recorded data can provide information about correlations (or associations), but not necessarily information about causal relationships. For example, the correlation between a patient's *coughing* and *fever* may be high. But, this does not necessarily indicate a causal relationship; i.e., someone's *cough* is *caused* by their *fever* (or the other way around). A high correlation does not indicate causality. All that a high correlation tells us is that, for some reason, certain items often occur at the same time.

Causal relationships can be described as having varying strengths; i.e., we can say that they are *always true, often, sometimes true, rarely true, etc*. Zadeh [4] calls approximating natural language terms: *linguistic variables*. Linguistic imprecision can be best manipulated and represented using *fuzzy arithmetic* which is based on *fuzzy sets* [5].

Statistical analysis of observational data can provide information about correlations, but not necessarily information about causal relationships. For example,

> In a grocery store, the correlation between customer purchases of bread and the purchases of milk may be high and may be a frequently occurring data pair (association).

This does not necessarily indicate a causal relationship; i.e.,

> Someone's purchase of bread is caused by their purchase of milk (or the other way around).

Sometimes, high medical attribute correlations have led to questionable causal statements. For example,

> A Prussian army physician, Hans Reiter, observed a syndrome (called Reiter's syndrome) that often occurred where the patient also had syphilis. He concluded that Reiter's syndrome was caused by syphilis.

This causal connection description has found its way into many medical textbooks. Unfortunately for this causal connection statement, the incidence of syphilis was high in most armies of that time and almost any disorder, including the common cold, could have been similarly causally connected (by a high correlation) to syphilis. (In the Prussian army, the incidence of Reiter's syndrome was lower than the incidence of either syphilis or common colds.)

Similarly, some years ago,

> Epidemiologists found that women taking hormone therapy replacement therapy (HRT) had fewer heart attacks [6]. However follow on controlled studies showed that HRT caused more heart attacks. It turned out that women taking HRT in the epidemiologic study were from higher socio-economic classes, so they ate and exercised better. Economic class caused both HRT and fewer heart attacks.

Networks (graphs) of causes and effects can be constructed; i.e.,

$$(\alpha \rightarrow \beta,\gamma), (\beta \rightarrow \delta), (\gamma \rightarrow \varphi), (\beta \cap \delta \rightarrow \lambda)$$

The question is: How to best represent a causal network if the following characteristics are to be part of it: direction, strength, imprecision, network (graph) structure?

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

When trying to *precisely* reason about causality, complete knowledge of all of the relevant events and circumstances is needed. As complete knowledge may not be possible, imprecise causal reasoning is needed.

A. An Association Does Not, By Itself, Mean Causality

Associations or correlations do not *necessarily* describe causality. Sometimes, the association might be causal; for example, if

Someone eats salty peanuts, then drinks beer.

or

Someone drinks beer, then becomes inebriated.

there may be a degree of a causal relationship. On the other hand, if

A rooster grows, then the sun rises.

or

Someone wears a 'lucky' shirt, then wins a lottery.

there may not be a causal relationship. Recognizing true causal relationships greatly enhances the decision value of data analysis.

The naïve use of simple associations may lead to errors. Errors might occur; either if causality is recognized where there is no causality; or if the direction of the causal relationship is wrong [7] [8]. For example, if

A study of past customers shows that 94% are sick.

- Is it the following rule?

Our customers are sick, so they buy from us.

- Is it the following complementary rule?

If people use our products, they are likely to become sick.

When making a decision, it is not enough to know that

People both buy our products and are sick.

what is needed is knowledge of what causes what; and, to what degree is something a causal effect of another thing.

B. Granularity

Causality is often granular. This is true both with commonsense reasoning as well as for more formal mathematical and scientific approaches. At a very fine-grained level, the physical world itself may be granular [9]. Commonsense perceptions of causality are often large-grained while the underlying causal structures may be fine-grained.

Larger-grained causal objects are often more imprecise than some of the components that are collected into the larger-grained object. Some components of a larger-grained causal object may be precisely known, while others maybe be somewhat imprecise, and others unknown. The larger the grain, the greater is the likelihood that there might be missing or unknown components.

How to best evaluate the impreciseness of a larger-grained causal object when the impreciseness of the underlying cascade of components is not clear; perhaps, some form of Type-II fuzzy [10] manipulation might be helpful.

C. Reasoning

Commonsense understanding of the world tells us that we have to deal with imprecision, uncertainty and imperfect knowledge. This is also the case with scientific knowledge of the world. A difficulty is striking a good balance between precise formalism and commonsense imprecise reality.

Causal relationships exist in the commonsense world; for example:

When a glass is pushed off a table and breaks on the floor

it might be said that

Being pushed from the table *caused* the glass to break.

Although,

Being pushed from a table is not a ***certain*** *cause* of breakage; sometimes the glass bounces and no break occurs; or, someone catches the glass before it hits the floor.

Counterfactually, usually (but not always),

Not falling to the floor prevents breakage.

Sometimes,

A glass breaks when an errant object hits it, even though it does not fall from the table.

Positive causal relationships can be described as: *if* α *then* β (or, $\alpha \rightarrow \beta$). For example:

When an automobile driver fails to stop at a red light and there is an accident; it can be said that the failure to stop was the accident's *cause*.

However, negating the causal factor does not mean that the effect does not happen; sometimes effects can be *overdetermined.* For example:

An automobile that did not fail to stop at a red light can still be involved in an accident; another car can hit it because the other car swerved and hit it while the car was stopped.

Similarly, negating a causal description often does not work. This is often because an effect can be overdetermined. Also, negative statements are weaker than positive statements as the negative statements can become *overextended.* For example, it cannot be said that $\neg\alpha \rightarrow \neg\beta$, for example:

Failing to stop at a red light is not a ***certain*** *cause* of an accident occurring; sometimes no accident at all occurs. (There may be no other cars; the other cars brake in time; etc.)

Negative causal relationships are less sure as negative statements are easily overextended; but negative causal relationships are often stated; for example, it is often said that:

Not walking under a ladder prevents bad luck.

Or, usually (but not always), as before

Stopping for a red light avoids an accident.

Perhaps, complete knowledge of all possible factors might lead to a crisp understanding of whether an effect will occur. However, it is unlikely that all possible factors can be known for most situations, as the knowledge of at least some causal effects is imprecise for both positive and negative descriptions. Consequently, causal reasoning models must accommodate inherent ambiguity [13].

When trying to precisely reason about causality, complete knowledge of all of the relevant events and circumstances is needed. In commonsense, every day reasoning, approaches are used that do not require complete knowledge. Often, a *satisficing* [14] paradigm is acceptable.

II. Granularity And Complexes

When events happen, there are usually other related events. The entire collection of events can be called a complex. A "mechanism" [15] or a "causal complex" [16] [17] is a collection of events whose occurrence or non-occurrence results in a consequent event happening.

Each complex, taken as a whole, often can be reduced to a granule if the grain size is increased. Alternatively, larger complexes often can be decomposed into smaller complexes; going from large grained to small grained. For example, when describing starting an automobile, A large-grained to small-grained, nested causal view could start with

> When an automobile's ignition switch is turned on, this *causes* the engine to start.

But, it would not happen if a large system of other conditions were not in place.

> There has to be available fuel. The battery has to be good. The switch has to be connected to the battery so electricity can flow through it. The wiring has to connect the switch to the starter and ignition system (spark plugs, etc.). The engine has to be in good working order; and so forth.

Turning the ignition switch on is one action in a complex of conditions required to start the engine. One of the events might be used to represent the collection of equal grain sized events; or, a higher-level granule might be specified with the understanding that it will invoke a set of finer-grained events.

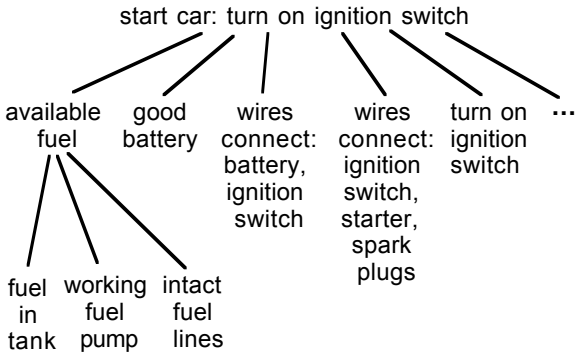

Figure 1. Nested causal complex.

In nested complex granules, the largest-grained event is the sole causal element: *Turn on the ignition switch*. The complex's other elements represent finer-grains. These elements in turn could be broken down into still finer-grains; for example: "available fuel" can be broken down into:

> fuel in tank, working fuel pump, intact fuel lines, ...

Sometimes, it is enough to know what happens at a large-grained level; at other times it is necessary to know the fined grained result. For example, if

> Bill believes that turning the ignition key of his automobile *causes* the automobile to start.

It is enough if

> Bill engages an automobile mechanic when his automobile does not start when he turns the key on.

However,

> The automobile mechanic needs to know a finer-grained view of an automobile's causal complex than does Robin.

Instead of being concerned with all of the fined grained detail, a better approach may be to incorporate granulation using rough sets [18] and/or fuzzy sets to soften the need for preciseness.

In causal reasoning, commonsense reasoning may recognize that a complex collection of elements can be involved causally in a particular effect, even if the precise elements of the complex are unknown. It may not be known what events are in the complex; or, what constraints and laws the complex is subject to. Sometimes, the details underlying an event are known, sometimes not. For example:

> A traffic jam might be observed in mid-town Manhattan. A reasonable supposition might be made that the jam was caused by a complex collection of elements. It might be possible to conjecture what were some of the causes; but, it is unlikely to be able to precisely know what were the complete set of actual causes.

Causal complexes may be described using nested granularity. A complex may have several larger-grained elements. In turn, each of the larger-grained elements may be made up of a complex of more fine-grained elements. Recursively, in turn, these elements may be made up still finer-grained elements. In general, people are more successful in applying commonsense reasoning to a few large-grain sized events than to many fine-grained elements.

When using large-grained commonsense reasoning, people do not always need to know the extent of the underling complexity.

> Somebody waiting for a dinner companion in mid-town Manhattan who observed a traffic jam might presume that they might be late because their taxi would most likely be delayed. Only the imprecise large-grained knowledge of the traffic jam would be needed; knowing the more precise finer-grained details of the jam are not be needed.

Not needing to know fine grained detail is also true for situations not involving commonsense reasoning; i.e.:

> When designing an electric circuit, designers are rarely concerned with the precise properties of the materials used; instead, they are concerned with the devices functional capabilities and take the device as a larger-grained object.

Hobbs [16] uses first order logic to describe his causal complexes. Pearl [19] develops probabilistic causal networks of directed graphs (DAGs). The causal complexes explicitly considered separately by Hobbs and Pearl have a required structure that may be overly restrictive for commonsense causal understanding:

- If *all* of the events in the causal complex appropriately happen, then the effect will occur
- There is nothing in the causal complex that is irrelevant to the effect

These requirements are probably too precise and extensive to be realized in a commonsense world. Sometimes, only some of the events need to happen. For example,

> Someone may be able to save more money:
> • If their taxes are lowered or
> • If they earn more money.

Either may lead to greater savings. However,

Neither may result in increased savings if they also have to pay a large divorce settlement.

If all of the events happen, the effect may happen. If some events happen, the effect may still happen. In the commonsense world, we rarely know whether all of the events are in a complex are necessary. For example,

A man may want to attract the attention of a woman. He may do a large number of things (e.g., hair, clothes, learn to dance, etc.). If he does attract the woman, he may never know which things were relevant and which were not

An example of restructuring a causal graph by increasing the grain size can be seen in Figures 2a,b. In Figure 2a, the idea is that solid, middle-sized, spherical things all roll are replaced with the concept class representation "ball" of Figure 2b. However, the price of collapsing the variables is a decrease in precision.

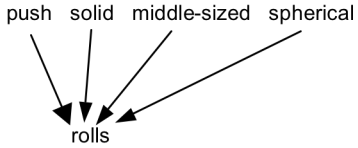

Figure 2a. Variables (solid, middle-sized, spherical) with common effect. [20]

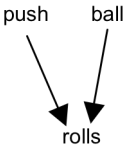

Figure 2b. Variables with a common effect (solid, middle-sized, spherical) collapsed into the concept "ball." [20]

An issue is how to distinguish between what is in a complex and what is not. Another issue is how to distinguish between the things that deserve to be called "causes" and those that do not. Hobbs [16] suggests that a consideration of causal complexes can be divided into:

- Distinguishing what events are in a causal complex from those outside of it. [21] [22] [15] [11] [19]
- Within a causal complex, recognizing the events that should be identified as causes from those that are not. [23] [24]

A major question concerning complexes is: To what extent can we increase the causal grain size and still have useful causal information? Conversely, can we start with a large-grained causal event and then derive the finer-grained structure? Can we measure and/or control the imprecision involved in changing grain size? If we start with a large-grained structure and resolve it, will our computational complexity burdens be reduced?

III. Directed Causal Graph Elements

The idea of "positive" causation ($\alpha \rightarrow \beta$) is at the commonsense causal reasoning core. Often, a positive causal relationship is represented as a network of nodes and branches with causal direction shown by an arrow.

Figure 3. Diagram indicating that α is causally dependent on β.

A. Directed Acyclic Graphs (DAGs)

Various graph based Bayesian based methods have been suggested to describe causality. Probably the best known is the class of methods based on Directed Acyclic Graphs (DAGs). The most fully developed approach is Pearl [19]. Silverstein [25] [26] followed a similar approach. From the commonsense causal reasoning view, the various directed graph methods have similar liabilities, specifically:

A.1 *Liability:* Discrete or continuous data must be reduced to Boolean values. This is an early technique that was and is used in data mining when analyzing market basket data. However, it is essentially flawed. Quantities do matter; some data co-occurrences are conditioned on there being a sufficiency of a co-occurring attribute. Also, some relationships may be non-linear based on quantity [8].

A.2. *Liability:* There can be no missing data. This is at variance with day-to-day experience. There is often missing data of some sort. Data collection is rarely fully representative and complete. Incremental data is often acquired that is at variance with previously acquired data. A methodology that is not brittle in the face of incompleteness is needed.

A.3. *Liability:* Causal relationships are not cyclic, either directly or indirectly (through another attribute). This is at variance with our commonsense understanding of the world. Within cyclic dependencies, there are several variants.

A.3.1 Cycles with time lag: There are many commonsense examples where cycles with a time lag are needed.

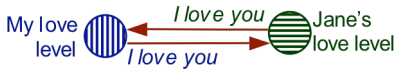

Figure 4. Positive feedback cycle: I tell Jane that I love her. Then, she tells me that she loves me. Then, I tell Jane that I love her more than before. Then, she … and so forth and so forth. Clearly, the cyclic reinforcement would be substantial.

Some cycles can be reasonably collapsed, some cannot be.

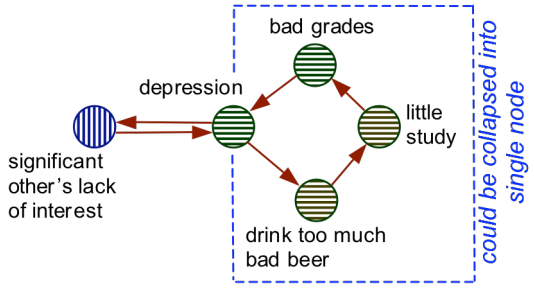

Figure 5. Cyclic relationship that can be collapsed while retaining meaning.

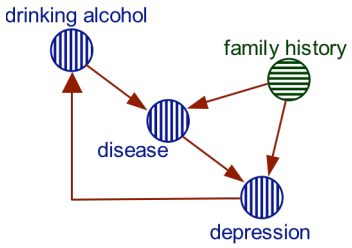

Figure 6. Cyclic relationship that cannot be easily collapsed while retaining meaning.

A.3.2 Concurrent cycles. Another form of a cycle is *joint mutual dependency.* It is possible that there might be mutual dependencies [13]; i.e., $\alpha \rightarrow \beta$ as well as $\beta \rightarrow a$. It seems to be possible that they do so with different strengths. They can be described as shown in the following figure where $S_{i,j}$ represents the strength of the causal relationship from i to j .

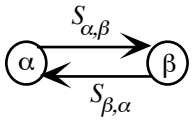

Figure 7. Cyclic relationship: Mutual unequal dependency. [13]

A.3.2.1 Different causal strengths for the same activity, occurring at the same time. Some argue that causality should be completely asymmetric and if it appears that items have mutual influences it is because there is another cause that causes both. A problem with this is that it can lead to eventual regression to a first cause. Whether this is true or not, it is not useful for commonsense understanding and representation. In contrast, Simon [15] and Shoham [27] identify cases where causality is simultaneous.

Mutual causal influences are also our commonsense experience. For example, in the preceding figure, α could be *short men* and β could be *tall women*. If $S_{\alpha,\beta}$ meant the strength of desire for a social meeting, it might be that $S_{\alpha,\beta} > S_{\beta,\alpha}$.

A.3.2.2 Different causal strengths for symmetric activities, occurring at different times. It would seem that if there were causal relationships in market basket data, there would often be imbalanced dependencies. For example, if

A customer first buys strawberries, there may be a reasonably good chance that they will then buy whipped cream.

Conversely, if

They first buys whipped cream, the subsequent purchase of strawberries may be less likely.

A.4 *Liability:* Markov Stationary Condition holds: Probabilities are time independent (DAG requirement). This does not correspond to our commonsense understanding of the world. When one event is dependent on two causal events, if one causal event happens much earlier (or later) than the other event, there may well be a different result. For example, if the goal is to have a successful dinner party, the catered food should be delivered before the guests arrive.

A.5 *Liability:* The Markov Memoryless Condition holds (DAG requirement). The *Markov Condition* is defined as: Let A be a node in a causal Bayesian network, and let B be any node that is not a descendant of A in the network. Then the Markov (Markoff) condition holds if A and B are independent, conditioned on the parents of A. The intuition of this condition is: If A and B are dependent, then B must either be (a possibly indirect) cause of A or (possibly indirectly) caused by A. In the second case, B is a descendant of A, while in the first B is an ancestor of A and has no effect on A once A's immediate parents are fixed. This makes sense in the example shown in the following figure.

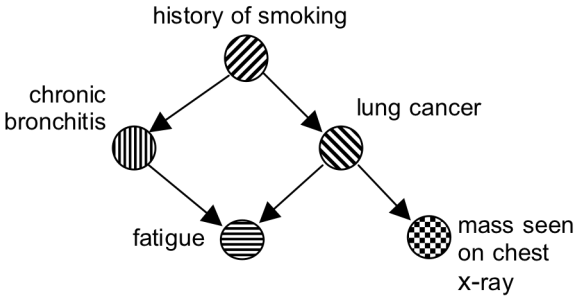

Figure 8. Memoryless Markov condition holds

However, not all commonsense perceptions of causality work this way. Often, we believe that history matters as in the example shown in the following figure.

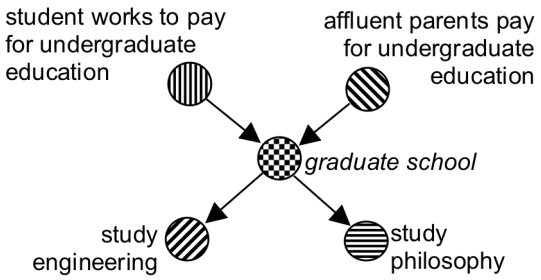

Figure 9. Causality where memory play a part. Memoryless Markov condition does not hold.

B. Markov Models

One possible way of describing the causal relationships is with first order Markov Models. They treat a system as a series of states with specific, constant rate transitions between them. At all times, the system is in exactly one state. (Transitions are considered to be instantaneous.) The only information available is the current state, the allowed transitions, and the probability of these transitions. This means that the system is totally characterized by its current state. None of the past states or transitions have any effect on the transitions out of the current state.

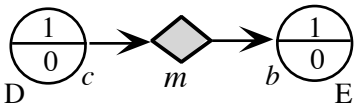

Figure 10. Random Markov model: c = P(D), m = the possibility/probability that when D is present, the causal mechanism brings about E, b = the probability that some other (unspecified) causal mechanism brings about E.

Describing the relationships between the nodes can be complex. One possibility is an extension of the random Markov model, shown in the following figure.

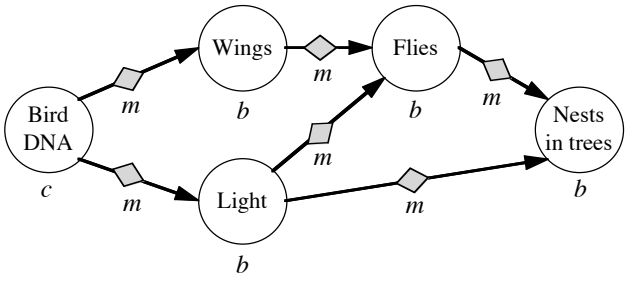

Figure 11. Markov model applied to a "bird" example [28]

Perhaps, fuzzy sets and fuzzy Markov algorithms in particular might be a good way of approaching causality represented by Markov models. Cheok [29] shows how the probabilities in the classic Markov model may be extended to fuzzy possibilities. The generalized hidden Markov Model can be defined with the same type of model parameters, but with a different mathematical basis than the classic one. Fuzzy logic replaces probability theory and this leads to a new definition of the model variables. The structure in terms of states and observations remains the same.

There has been a fair amount of work in fuzzy Markov models [30] [31] [32]. A fair amount of the work has a control theory or medical diagnostic orientation. Whether it can be extended to representing causality is to be seen. While Markov models are intuitively appealing, they have some of the cyclic representational problems as do DAGs. Consequently, they may not be a good solution.

IV. Fuzzy Cognitive Maps

A potentially useful form for representing causal structures that overcomes some of the deficiencies of directed acyclic graphs or similar representations is Fuzzy Cognitive Maps (FCMs). They bring their own liabilities in that how to autonomously form FCMs through data mining is unresolved.

Fuzzy Cognitive Maps are fuzzy structures that resemble neural networks. They have powerful and far-reaching consequences as a mathematical tool for modeling complex systems. At first, Axelord [33] used cognitive maps as a formal way of representing social scientific knowledge and modeling decision making in social and political systems [34]. Then, Kosko enhanced cognitive maps considering fuzzy values for them [35] [36] [37] [38].

Indeterminacy and unpredictability of life affect causal descriptions almost as much as the determined factors. It is a major handicap in mathematical modeling if we are only able to give precise values for known concepts and relationships between concepts, thereby presenting onto ourselves a skewed view. Fuzzy theory can offer more choices. Mendel [10] and Kandasamy [39] have introducing indeterminacy into Fuzzy theory; Mendel uses Type-2 Fuzzy Logic while Kandasamy uses Neutrosophic structures.

A FCM describes the behavior of a system in terms of concepts; each concept represents a state or a characteristic of the system. A FCM illustrates the system by a graph showing cause and effect between concepts. FCMs model the world as a collection of classes and causal relations between classes. FCMs are fuzzy signed directed graphs with feedback. The directed edge *Wij* from causal concept *Ci* to concept *Cj* measures how much *Ci* causes *Cj*. The time varying concept function *Ci(t)* measures the non-negative occurrence of some fuzzy event.

A Fuzzy Cognitive Map consists of nodes that represent concepts and arcs (edges) between concepts [40]. Each concept represents a characteristic of the system; in general it stands for events, actions, goals, values, trends of the system. A number Ai that represents its value characterizes each concept and it results from the transformation of the value of the system's variable, for which this concept stands, in the interval [-1,1]. The graph's edges are the casual influences between the concepts.

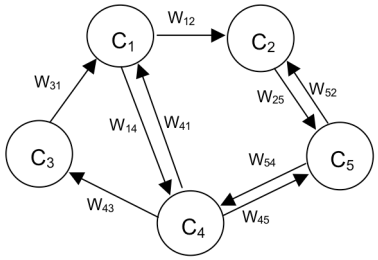

Figure 12. Example of a simple Fuzzy Cognitive Map

The edges *Wij* takes values in the fuzzy causal interval [–1, 1]. The weights of the arcs between concept *Ci* and concept *Cj* could be positive ($Wij > 0$) which means that an increase in the value of concept *Ci* leads to the increase of the value of concept *Cj* , and a decrease in the value of concept *Ci* leads to the decrease of the value of concept *Cj* . Or there is negative causality ($Wij < 0$) which means that an increase in the value of concept *Ci* leads to the decrease of the value of concept *Cj* and vice versa. $Wij = 0$ indicates no causality.

State vectors $\boldsymbol{C}$ are repeatedly passed through the FCM connection matrix $\boldsymbol{W}$, thresholding or non-linearly transforming the result after each pass. The limit cycle or fixed-point inference summarizes the joint effects of all the interacting fuzzy knowledge.

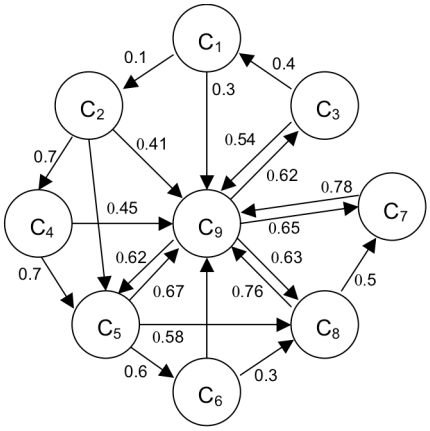

Figure 13. A urinary bladder tumor grading model [41]

The previous figure shows how a medical FCM application; where C_n, $n=1…8$ represent histological features using five positive linguistic variables depending on the characteristics of each particular concept. C_9 represents the target, tumor grade. The concepts are:

C_1: Cell distribution: Even, clustered
C_2: Cell size: Uniform, pleomorphic
C_3: Cell number: Numerous, variable
C_4: Cytoplasm: Homogeneous, variable
C_5: Nuclei: Uniform, irregular, very irregular, bizarre
C_6: Nucleoi: Inconspicuous, evident, prominent
C_7: Neocrosis: Inconspicuous, frequent
C_8: Mitoses: Absent-rate, occasional, numerous
C_9: Degree of tumor grade

The value of a node reflects the degree to which the concept is active in the system at a particular time. This value is a function of the sum of all incoming edges multiplied and the value of the originating concept at the immediately preceding state. The threshold function applied to the weighted sums can be fuzzy in nature. Concept values are expressed on a normalized range denoting a degree of activation rather than an exact quantitative value.

The mathematical model consists of $1 \times n$ state vector $\boldsymbol{A}$ that includes the values of the n concepts and a $n \times n$ weight matrix $\boldsymbol{W}$ that gathers the weights W_{ij} of the interconnections between the n concepts of the FCM. The matrix $\boldsymbol{W}$ has n rows and n columns where n equals the total number of distinct concepts of the FCM and the matrix diagonal is zero since it is assumed that no concept causes itself. The value of each concept is influenced by the values of the connected weighted concepts and by its previous value. The value A_i for each concept C_i is calculated by:

$$A_i f\left(\sum_{\substack{j=1 \\ j\neq 1}}^{n} A_j W_{ji}\right) + A_i^{old}$$

where Ai is the activation level of concept Ci at time t+1, Aj is the activation level of concept Cj at time t+1, Aj is the activation level of concept Ci at time t, and Wji is the weight of the interconnection between Cj and Ci, and f is a threshold function.

$$A_{new} = f\left(A_{old} \circ W\right) + A_{old}$$

The new state vector $\boldsymbol{A}_{new}$ is computed by multiplying the previous state vector $\boldsymbol{A}_{old}$ by the weight matrix $\boldsymbol{W}$. The new vector shows the effect of the change in the value of one concept in the entire Fuzzy Cognitive Map.

The simplest FCMs act as asymmetrical networks of threshold or continuous concepts and converge to an equilibrium point or limit cycles. FCMs have nonlinear structure of their concepts and differ in their global feedback dynamics [42] [38].

There are several unsupervised learning algorithms that might be used to reach convergence, or at least convergence within an acceptable tolerance [43] [44] [45] [46] [47] [48] [49]; the algorithms can be comparatively analyzed [50]; however, neither particular methods or a comparative analysis of the methods are within the scope of this paper. The FCM system model takes the initial values of the concepts from the real system and is free to interact. The interaction happens because of change in the value of one or more concepts [51]. The interaction continues until the model:

- Reaches equilibrium at a fixed point, with the output concept values stabilizing.
- Exhibits limit cycle behavior, with the concept values falling in a loop.
- Exhibits chaotic behavior in a non-deterministic way.

Causal feedback loops can occur in FCMs. FCM feedback allows causal adaptation. FCM feedback forces the abandonment of classic graph search, forward and backward chaining. Instead, the FCM is a dynamical system and take its equilibrium behavior as a forward-evolved inference. A FCM has the ability to specify a complex model, shows linear or non-linear relations and allows causal propagation [52].

The development of a FCM often occurs within a group context. Experts can pool or fuse their knowledge by adding the underlying FCM causal matrices [43]. The obvious advantage is that a causal relationship can be described in stages. If some form of data min-ing is discovering the causal relation-ships, it could be a highly desirable incremental method. Another claimed advantage [34] is that combining incomplete, conflicting opinions of different experts may cancel out the effect of oversight, ignorance and prejudice; although this would seem to require a fairly large number of overlapping relationships so a useful average relationship would be developed.

V. Epilogue

The target of many studies in the health sciences is the discovery of cause-effect relationships among observed variables of interest, for example: treatments, exposures, preconditions, and outcomes. Causal modeling and causal discovery are central to medical science. In order to algorithmically consider causal relations, the relationships must be placed into a representation that supports manipulation. An algorithmic way of handling causal imprecision is needed. There are several needs of a causal model. The needs are:

- Represent causal direction
- Represent degree of causal effect
- Represent causal imprecision
- Accommodate changes in grain size
- Describe complexes
- Support cycle models of all times
- Be time varying
- Not be restricted by Markov conditions

The most widespread causal representation is directed acyclic graphs (DAGs). However, DAGs are severely limited in what they can represent. This paper considered the needs of commonsense causality and suggested Fuzzy Cognitive Maps as an alternative to DAGs. Fuzzy Cognitive Maps appear to be a good approximation of complex casual complexes. They appear to be a comprehensive representation. Their primary difficulty lies with establishing their initial values.

***Abstract*—In this research, focusing on two-level linear programming problems involving fuzzy random variables, we propose a new decision making model through possibility measures. Taking into account vagueness of judgments of decision makers for each objective function, fuzzy goals are introduced. Noting that the degree of the possibility fluctuates stochastically, we propose a probability maximization model in stochastic programming. Through probability maximization, the transformed stochastic two-level programming problem can be reduced to a deterministic one. Interactive fuzzy programming to derive a satisfactory solution for the decision maker at the upper level in consideration of the cooperative relation between decision makers is presented.**

***Index Terms*—two-level programming; possibility; probability maximization; interactive fuzzy decision making**

I. Introduction

In the real world, the coefficients of objectives or constraints in problems are rather uncertain than constant. In order to deal with such uncertainty, stochastic programming [3] and fuzzy programming [21] were considered. They are useful tools for the decision making under a stochastic environment or a fuzzy environment, respectively. Most studies in respect to mathematical programming take account of either fuzziness or randomness. However, in practice, decision makers are faced with the situations where both fuzziness and randomness exist. In the case where some expert estimates coefficients of objective functions or constraints with uncertainty, they do not always represent the coefficients as random variables or fuzzy sets but as the values including both fuzziness and randomness. In such a case, it is important to realize that simultaneous considerations of both fuzziness and randomness would be required. A fuzzy random variable [7] is one of the mathematical concepts dealing with fuzziness and randomness simultaneously. Let us consider the situation that a profit per unit crop acreage is dependent on weathers, i. e., fine, cloudy, rain, etc., which are considered as scenarios that occur randomly. When a realized profit under each scenario is estimated as a fuzzy set or fuzzy number, it turns out that the profit is expressed by a fuzzy random variable. Studies on linear programming problems with fuzzy random variable coefficients, called fuzzy random linear programming problems, were initiated by Wang and Qiao [19], Qiao, Zhang and Wang [11] as seeking the probability distribution of the optimal solution and optimal value. A brief survey of major fuzzy stochastic programming models was found in the paper by Luhandjula [9].

Meanwhile, we often encounter situations where there are two or more decision makers in an organization with a hierarchical structure, and they make decisions in turn or at the same time so as to optimize their objective functions. In particular, consider a case where there are two decision makers; one of the decision makers first makes a decision, and then the other who knows the decision of the opponent makes a decision. Such a situation is formulated as a two-level programming problem [13]. In the context of two-level programming, the decision maker at the upper level first specifies a strategy, and then the decision maker at the lower level specifies a strategy so as to optimize the objective with full knowledge of the action of the decision maker at the upper level. In conventional multi-level mathematical programming models employing the solution concept of Stackelberg equilibrium, it is assumed that there is no communication among decision makers, or they do not make any binding agreement even if there exists such communication [1], [16], [17]. Compared with this, for decision making problems in such as decentralized large firms with divisional independence, it is quite natural to suppose that there exists communication and some cooperative relationship among the decision makers [13].

Assuming that the decision makers essentially cooperate with each other, Sakawa et al. [14], [15] have proposed interactive fuzzy programming for two-level or multi-level linear programming problems to obtain satisfactory solution for decision makers by eliminating the fuzzy goals for the decision variables.

Under these circumstances, in this research, assuming coop-

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

erative behavior of the decision makers, we consider solution methods for decision making problems in hierarchical organizations under fuzzy random environments. To deal with the formulated two-level linear programming problems involving fuzzy random variables, possibility measures are introduced and a stochastic two-level linear programming problem is defined for guaranteeing the degree of realization of the problem. Taking into account vagueness of judgments of decision makers, fuzzy goals are introduced and the stochastic two-level linear programming problem is transformed into the problem to maximize the satisfaction degree for each fuzzy goal. Following probability maximization, the transformed stochastic two-level programming problem can be reduced to a deterministic one. Interactive fuzzy programming to obtain a satisfactory solution for the decision maker at the upper level in consideration of the cooperative relation between decision makers is presented. It is shown that all of the problems to be solved in the proposed interactive fuzzy programming can be easily solved by the simplex method or the combined use of the bisection method and the simplex method.

II. Fuzzy random two-level linear programming problem

Fuzzy random variables, first introduced by Kwakernaak [7], have been defined in various ways [7], [10], [6], [8]. For example, as a special case of fuzzy random variables given by Kwakernaak, Kruse and Meyer [6] defined a fuzzy random variable as follows.

Definition 1 (Fuzzy random variable): Let (Ω, B, P) be a probability space, $F(\mathcal{R})$ the set of fuzzy numbers with compact supports and X a measurable mapping $\Omega \to F(\mathcal{R})$. Then X is a fuzzy random variable if and only if given $\omega \in \Omega$, $X_\alpha(\omega)$ is a random interval for any $\alpha \in (0, 1]$, where $X_\alpha(\omega)$ is an α-level set of the fuzzy set $X(\omega)$.

Although there exist some minor differences in several definitions of fuzzy random variables, fuzzy random variables are considered to be random variables whose observed values are fuzzy sets.

In this paper, we deal with two-level linear programming problems involving fuzzy random variable coefficients in objective functions formulated as:

$$\left.\begin{array}{ll} \underset{\text{for DM1}}{\text{minimize}} & z_1(\boldsymbol{x}_1, \boldsymbol{x}_2) = \tilde{\tilde{\boldsymbol{C}}}_{11}\boldsymbol{x}_1 + \tilde{\tilde{\boldsymbol{C}}}_{12}\boldsymbol{x}_2 \\ \underset{\text{for DM2}}{\text{minimize}} & z_2(\boldsymbol{x}_1, \boldsymbol{x}_2) = \tilde{\tilde{\boldsymbol{C}}}_{21}\boldsymbol{x}_1 + \tilde{\tilde{\boldsymbol{C}}}_{22}\boldsymbol{x}_2 \\ \text{subject to} & A_1\boldsymbol{x}_1 + A_2\boldsymbol{x}_2 \le \boldsymbol{b} \\ & \boldsymbol{x}_1 \ge \boldsymbol{0},\ \boldsymbol{x}_2 \ge \boldsymbol{0} \end{array}\right\} \quad (1)$$

where $\boldsymbol{x}_1$ is an n_1 dimensional decision variable column vector for the DM at the upper level (DM1), $\boldsymbol{x}_2$ is an n_2 dimensional decision variable column vector for the DM at the lower level (DM2), $z_1(\boldsymbol{x}_1, \boldsymbol{x}_2)$ is the objective function for DM1 and $z_2(\boldsymbol{x}_1, \boldsymbol{x}_2)$ is the objective function for DM2.

It should be emphasized here that randomness and fuzziness of the coefficients are denoted by the "dash above" and "wave above" i.e., " ¯ " and " ˜ ", respectively. In this formulation, $\boldsymbol{x}_1$ is an n_1 dimensional decision variable column vector for the DM at the upper level (DM1), $\boldsymbol{x}_2$ is an n_2 dimensional decision variable column vector for the DM at the lower level (DM2), $z_1(\boldsymbol{x}_1, \boldsymbol{x}_2)$ is the objective function for DM1 and $z_2(\boldsymbol{x}_1, \boldsymbol{x}_2)$ is the objective function for DM2. In (1), $\tilde{\tilde{\boldsymbol{C}}}_{lj}$, $l = 1, 2$, $j = 1, 2$ are vectors whose elements $\tilde{\tilde{C}}_{ljk}$, $k = 1, 2, \ldots, n_j$ are fuzzy random variables characterized by the following membership function:

$$\mu_{\tilde{\tilde{C}}_{ljk}}(\tau) = \begin{cases} L\left(\dfrac{\bar{d}_{ljk} - \tau}{\beta_{ljk}}\right) & , \quad \text{if } \tau \le \bar{d}_{ljk} \\ R\left(\dfrac{\tau - \bar{d}_{ljk}}{\gamma_{ljk}}\right) & , \quad \text{otherwise} \end{cases}$$

where $L : [0, \infty) \to [0, 1]$ is a monotone decreasing function defined as $L(t) = \max\{0, \lambda(t)\}$ and $R : [0, \infty) \to [0, 1]$ is also a monotone decreasing function defined as $R(t) = \max\{0, \rho(t)\}$. Here, $\lambda(t)$ and $\rho(t)$ are monotone decreasing functions which satisfy $\lambda(0) = 1$ and $\rho(0) = 1$, respectively. Furthermore, parameters $\bar{d}_{ljk}$, β_{ljk} and γ_{ljk} represent a mean value, the left spread and the right spread of $\tilde{\tilde{C}}_{ljk}$, respectively. In this paper, parameters $\bar{d}_{ljk}$ are random variables defined as $\bar{d}_{ljk} = d^1_{ljk} + \bar{t}_l d^2_{ljk}$, using random variables $\bar{t}_l$ with mean M_l, $l = 1, 2$. This definition of random variables is one of the simplest randomization modeling of coefficients using dilation and translation of random variables, as discussed by Stancu-Minasian [18] and Katagiri et al. [5].

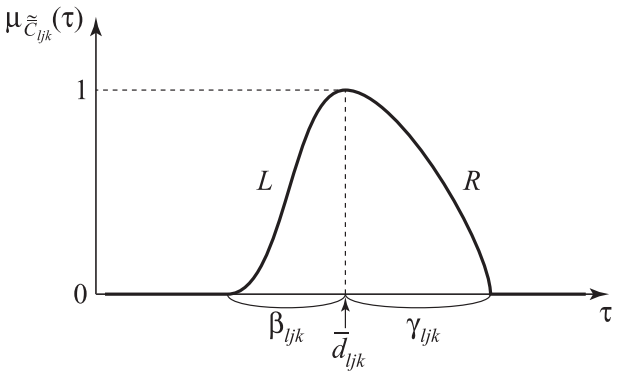

Fig. 1. An example of the membership function $\mu_{\tilde{\tilde{C}}_{ljk}}(\cdot)$ of a fuzzy random variable $\tilde{\tilde{C}}_{ljk}$.

Fig. 1 illustrates an example of the membership function of a fuzzy random variable $\tilde{\tilde{C}}_{ljk}$.

Fuzzy random two-level linear programming problems formulated as (1) are often seen in actual decision making situations. For example, consider a supply chain planning [12] where the distribution center (DM1) and the production part (DM2) hope to minimize the distribution cost and the production cost respectively. Since coefficients of these objective functions are often affected by the economic conditions varying at random, they can be regarded as random variables. In addition, since observed values of them are often ambiguous and estimated by fuzzy numbers, they are expressed by fuzzy random variables. Then, the supply chain planning problem

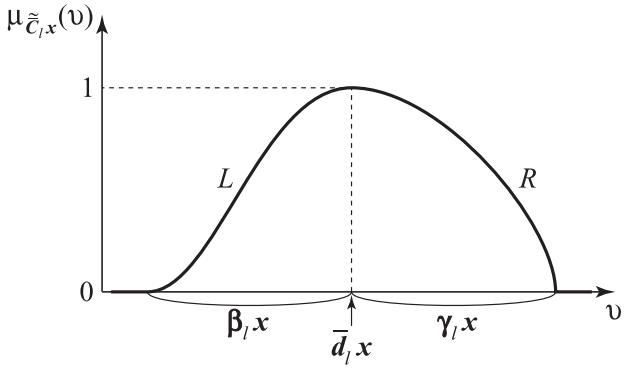

Fig. 2. An example of the membership function $\mu_{\tilde{\tilde{\boldsymbol{C}}}_l \boldsymbol{x}}(\cdot)$ of the objective function of DMl.

can be formulated as a two-level linear programming problem involving fuzzy random variable coefficients like (1).

Since each coefficient $\tilde{\tilde{C}}_{ljk}$ is a fuzzy random variable defined as a random variable whose observed values are L-R fuzzy numbers, each objective function $\tilde{\tilde{\boldsymbol{C}}}_l \boldsymbol{x} = \tilde{\tilde{\boldsymbol{C}}}_{l1} \boldsymbol{x}_1 + \tilde{\tilde{\boldsymbol{C}}}_{l2} \boldsymbol{x}_2$ is also a fuzzy random variable whose observed values are fuzzy numbers characterized by the following membership function.

$$\mu_{\tilde{\tilde{\boldsymbol{C}}}_l \boldsymbol{x}}(\upsilon) = \begin{cases} L\left(\dfrac{\bar{\boldsymbol{d}}_l \boldsymbol{x} - \upsilon}{\boldsymbol{\beta}_l \boldsymbol{x}}\right) & , \quad \text{if } \upsilon \leq \bar{\boldsymbol{d}}_l \boldsymbol{x} \\ R\left(\dfrac{\upsilon - \bar{\boldsymbol{d}}_l \boldsymbol{x}}{\boldsymbol{\gamma}_l \boldsymbol{x}}\right) & , \quad \text{otherwise} \end{cases}$$

An example of the membership function of the objective function of DMl is shown in Fig. 2.

III. Probability Maximization Model through Possibility Measures

Problem (1) is not a well-defined problem due to both fuzziness and randomness of the coefficients, and it cannot be minimized in the sense of deterministic mathematical programming. Therefore, it is necessary to interpret the problem from some point of view and to transform the problem into the deterministic equivalent one. Katagiri and Ishii [4] proposed a fuzzy random programming model using a possibility measure [20] for a linear programming problem where the right-hand side of a constraint is a fuzzy random variable. In this research, assuming that the decision makers are interested in the probability that each objective function attains a goal value rather than the expectation or variance of each membership function, we consider the case where the decision maker prefers to maximize the degree of possibility that the objective function value satisfies the fuzzy goal.

A. Fuzzy goal

A fuzzy goal for the objective is characterized by the following linear membership function:

$$\mu_{\tilde{G}_l}(y) = \begin{cases} 1 & (y < g_l^1) \\ g_l(y) & (g_l^1 \leq y \leq g_l^0) \\ 0 & (y > g_l^0) \end{cases}$$

where $g_l(y)$ is a monotone decreasing function.

B. Possibility and stochastic programming approach

Using the concept of a possibility measure, we define a degree of possibility that the objective function value $\tilde{\tilde{Y}}$ satisfies a fuzzy goal $\tilde{G}$ by

$$\Pi_{\tilde{\tilde{Y}}_l}(\tilde{G}_l) = \sup_y \min\{\mu_{\tilde{\tilde{Y}}_l}(y), \mu_{\tilde{G}_l}(y)\}$$

where Π denotes a possibility measure. Then, if the decision maker prefers to maximize the degree of possibility, problem (1) is reformulated as

$$\left.\begin{array}{ll} \underset{\text{for DM1}}{\text{maximize}} & \Pi_{\tilde{\tilde{\boldsymbol{C}}}_1 \boldsymbol{x}}(\tilde{G}_1) \\ \underset{\text{for DM2}}{\text{maximize}} & \Pi_{\tilde{\tilde{\boldsymbol{C}}}_2 \boldsymbol{x}}(\tilde{G}_2) \\ \text{subject to} & A_1 \boldsymbol{x}_1 + A_2 \boldsymbol{x}_2 \leq \boldsymbol{b} \\ & \boldsymbol{x}_1 \geq \boldsymbol{0},\ \boldsymbol{x}_2 \geq \boldsymbol{0} \end{array}\right\}. \tag{2}$$

The degree of possibility is expressed as the crossing point of two membership functions.

Since $\Pi_{\tilde{\tilde{\boldsymbol{C}}}_l \boldsymbol{x}}(\tilde{G}_l), l = 1, 2$ varies randomly due to the randomness of $\bar{c}_j$, problem (2) can be regarded as a stochastic linear programming problem. In stochastic programming, there are some major models [3]: an expectation optimization model, a variance minimization model and a probability maximization model.

In this research, we focus on the probability maximization model, which is to maximize the probability that the profit is greater than or equal to a certain permissible level and formulate the following problem:

$$\left.\begin{array}{ll} \underset{\text{for DM1}}{\text{maximize}} & \Pr[\Pi_{\tilde{\tilde{\boldsymbol{C}}}_1 \boldsymbol{x}}(\tilde{G}_1) \geq h_1] \\ \underset{\text{for DM2}}{\text{maximize}} & \Pr[\Pi_{\tilde{\tilde{\boldsymbol{C}}}_2 \boldsymbol{x}}(\tilde{G}_2) \geq h_2] \\ \text{subject to} & A_1 \boldsymbol{x}_1 + A_2 \boldsymbol{x}_2 \leq \boldsymbol{b} \\ & \boldsymbol{x}_1 \geq \boldsymbol{0},\ \boldsymbol{x}_2 \geq \boldsymbol{0} \end{array}\right\} \tag{3}$$

where $\Pr[\cdot]$ denotes probability and h_l is a goal value, called a permissible level, for the membership function $\mu_l(\cdot)$.

Since $\mu_l(\cdot), l = 1, 2$ are monotone decreasing, (3) can be rewritten as:

$$\left.\begin{array}{ll} \underset{\text{for DM1}}{\text{maximize}} & \Pr[\Pi_{\tilde{\tilde{\boldsymbol{C}}}_1 \boldsymbol{x}}(\tilde{G}_1) \leq \mu^*_{\tilde{G}_1}(h_1)] \\ \underset{\text{for DM2}}{\text{maximize}} & \Pr[\Pi_{\tilde{\tilde{\boldsymbol{C}}}_2 \boldsymbol{x}}(\tilde{G}_2) \leq \mu^*_{\tilde{G}_2}(h_2)] \\ \text{subject to} & A_1 \boldsymbol{x}_1 + A_2 \boldsymbol{x}_2 \leq \boldsymbol{b} \\ & \boldsymbol{x}_1 \geq \boldsymbol{0},\ \boldsymbol{x}_2 \geq \boldsymbol{0} \end{array}\right\} \tag{4}$$

where $\mu^*_{\tilde{G}_l}(\cdot)$ is a pseudo-inverse function of $\mu_{\tilde{G}_l}(\cdot)$ defined by $\mu^*_{\tilde{G}_l}(h_l) = \sup\{r | \mu_{\tilde{G}_l}(r) \geq h_l\}$ for $h_l \in (0, 1]$.

Let $L^*(\cdot)$ be a pseudo-inverse function of $L(\cdot)$ defined by $L^*(h_l) = \sup\{r | L(r) \geq h_l, r \geq 0\}$ Then the left side of the first and second constraint in (4) can be expressed as:

$$\Pr[\Pi_{\tilde{\tilde{\boldsymbol{C}}}_l \boldsymbol{x}}(\tilde{G}_l) \leq \mu^*_{\tilde{G}_l}(h_l)] = \Pr[\{\bar{\boldsymbol{d}}_l - L^*(h_l)\bar{\boldsymbol{\beta}}_l\}\boldsymbol{x} \leq \mu^*_{\tilde{G}_l}(h_l)].$$

From the assumption, $\bar{\boldsymbol{d}}_l$ is a random variable vector defined as $\bar{\boldsymbol{d}}_l = \boldsymbol{d}_l^1 + \bar{t}_l \cdot \boldsymbol{d}_l^2$ using a random variable $\bar{t}_l$ with mean M_l.

Provided that $\boldsymbol{d}_l^2\boldsymbol{x} > 0$, $l = 1, 2$,

$$
\begin{aligned}
&\Pr[\Pi_{\tilde{\boldsymbol{C}}_l\boldsymbol{x}}(\tilde{G}_l) \geq h_l] \\
&= \Pr[\{\bar{\boldsymbol{d}}_l - L^*(h_l)\bar{\boldsymbol{\beta}}_l\}\boldsymbol{x} \leq \mu^*_{\tilde{G}_l}(h_l)] \\
&= \Pr[\{(\boldsymbol{d}_l^1 + \bar{t}_l\boldsymbol{d}_l^2) - L^*(h_l)(\boldsymbol{\beta}_l^1 + \bar{t}_l\boldsymbol{\beta}_l^2)\}\boldsymbol{x} \leq \mu^*_{\tilde{G}_l}(h_l)] \\
&= \Pr\left[\bar{t}_l \leq \frac{\{L^*(h_l)\boldsymbol{\beta}_l^1 - \boldsymbol{d}_l^1\}\boldsymbol{x} + \mu^*_{\tilde{G}_l}(h_l)}{\{\boldsymbol{d}_l^2 - L^*(h_l)\boldsymbol{\beta}_l^2\}\boldsymbol{x}}\right] \\
&= T_l\left(\frac{\{L^*(h_l)\boldsymbol{\beta}_l^1 - \boldsymbol{d}_l^1\}\boldsymbol{x} + \mu^*_{\tilde{G}_l}(h_l)}{\{\boldsymbol{d}_l^2 - L^*(h_l)\boldsymbol{\beta}_l^2\}\boldsymbol{x}}\right) \\
&= T_l\left(\frac{\displaystyle\sum_{j=1}^{2}\sum_{k=1}^{n_j} L^*(h_l)\{\beta_{ljk}^1 - d_{ljk}^1\}x_{jk} + \mu^*_{\tilde{G}_l}(h_l)}{\displaystyle\sum_{j=1}^{2}\sum_{k=1}^{n_j}\{d_{ljk}^2 - L^*(h_l)\beta_{ljk}^2\}x_{jk}}\right)
\end{aligned}
$$

where $T_l(\cdot)$ is a probability distribution of $\bar{t}_l$ for DMl.

In this way, (4) can be transformed int the following problem:

$$
\left.
\begin{array}{ll}
\underset{\text{for DM1}}{\text{maximize}} & p_1(\boldsymbol{x}_1, \boldsymbol{x}_2) = \\
& T_1\left(\dfrac{\displaystyle\sum_{j=1}^{2}\sum_{k=1}^{n_j} L^*(h_1)\{\beta_{1jk}^1 - d_{1jk}^1\}x_{jk} + \mu^*_{\tilde{G}_1}(h_1)}{\displaystyle\sum_{j=1}^{2}\sum_{k=1}^{n_j}\{d_{1jk}^2 - L^*(h_1)\beta_{1jk}^2\}x_{jk}}\right) \\
\underset{\text{for DM2}}{\text{maximize}} & p_2(\boldsymbol{x}_1, \boldsymbol{x}_2) = \\
& T_2\left(\dfrac{\displaystyle\sum_{j=1}^{2}\sum_{k=1}^{n_j} L^*(h_2)\{\beta_{2jk}^1 - d_{2jk}^1\}x_{jk} + \mu^*_{\tilde{G}_2}(h_2)}{\displaystyle\sum_{j=1}^{2}\sum_{k=1}^{n_j}\{d_{2jk}^2 - L^*(h_2)\beta_{2jk}^2\}x_{jk}}\right) \\
\text{subject to} & A_1\boldsymbol{x}_1 + A_2\boldsymbol{x}_2 \leq \boldsymbol{b} \\
& \boldsymbol{x}_1 \geq \boldsymbol{0},\ \boldsymbol{x}_2 \geq \boldsymbol{0}
\end{array}
\right\}. \tag{5}
$$

IV. Interactive fuzzy programming

Observing the transformed problem (5) is a deterministic two-level programming problem, we can now construct the interactive algorithm to derive a satisfactory solution for the decision maker at the upper level in consideration of the cooperative relationships between DM1 and DM2.

Interactive fuzzy programming

Step 1: In order to calculate the individual minimum of $\mathrm{E}\{z_l(\boldsymbol{x}_1, \boldsymbol{x}_2)\}$, solve the following problems:

$$
\left.
\begin{array}{ll}
\text{minimize} & \mathrm{E}\{z_l(\boldsymbol{x}_1, \boldsymbol{x}_2)\} = \left(\boldsymbol{d}_l^1 + m_l \cdot \boldsymbol{d}_l^2\right)\boldsymbol{x} \\
\text{subject to} & A_1\boldsymbol{x}_1 + A_2\boldsymbol{x}_2 \leq \boldsymbol{b} \\
& \boldsymbol{x}_1 \geq \boldsymbol{0},\ \boldsymbol{x}_2 \geq \boldsymbol{0}
\end{array}
\right\}, \quad l = 1, 2. \tag{6}
$$

Let $\boldsymbol{x}^l_{\min}$ and $z^E_{l,\min}$ be optimal solutions to (6) and minimal objective function values to (6), respectively. Observing that (6) are linear programming problems, they can be easily solved by some linear programming technique like the simplex method.

Step 2: Ask DMs to specify the membership functions $\mu_l(\cdot)$, $l = 1, 2$ by considering the obtained values of $z^E_{l,\min}$, $l = 1, 2$.

Step 3: Ask DM1 to determine the permissible range $[\Delta_{\min}, \Delta_{\max}]$ and the initial value of permissible levels h_l, $l = 1, 2$.

Step 4: For the specified values of h_l, $l = 1, 2$, the following maximin problem is solved:

$$
\left.
\begin{array}{ll}
\underset{l\,=\,1,\,2}{\text{maximize}} & \min\left\{T_l\left(\dfrac{L^*(h_l)\{\boldsymbol{\beta}_l^1 - \boldsymbol{d}_l^1\}\boldsymbol{x} + \mu^*_{\tilde{G}_l}(h_l)}{\{\boldsymbol{d}_l^2 - L^*(h_l)\boldsymbol{\beta}_l^2\}\boldsymbol{x}}\right\}\right) \\
\text{subject to} & A_1\boldsymbol{x}_1 + A_2\boldsymbol{x}_2 \leq \boldsymbol{b} \\
& \boldsymbol{x}_1 \geq \boldsymbol{0},\ \boldsymbol{x}_2 \geq \boldsymbol{0}
\end{array}
\right\}. \tag{7}
$$

In view of (5), this problem is rewritten as:

$$
\left.
\begin{array}{ll}
& \text{maximize } v \\
& \text{subject to} \\
& T_1\left(\dfrac{(-\boldsymbol{d}_1^1 + L^*(h_1)\boldsymbol{\beta}_1)\boldsymbol{x} + \mu^*_{\tilde{G}_1}(h_1)}{(\boldsymbol{d}_1^2 - L^*(h_1)\beta_1^2)\boldsymbol{x}}\right) \geq \mu_1^*(v) \\
& T_2\left(\dfrac{(-\boldsymbol{d}_2^1 + L^*(h_2)\boldsymbol{\beta}_2)\boldsymbol{x} + \mu^*_{\tilde{G}_2}(h_2)}{(\boldsymbol{d}_2^2 - L^*(h_2)\beta_2^2)\boldsymbol{x}}\right) \geq \mu_2^*(v) \\
& A_1\boldsymbol{x}_1 + A_2\boldsymbol{x}_2 \leq \boldsymbol{b} \\
& \boldsymbol{x}_1 \geq \boldsymbol{0},\ \boldsymbol{x}_2 \geq \boldsymbol{0}
\end{array}
\right\} \tag{8}
$$

equivalently,

$$
\left.
\begin{array}{ll}
& \text{maximize } v \\
& \text{subject to} \\
& \dfrac{(-\boldsymbol{d}_1^1 + L^*(h_1)\boldsymbol{\beta}_1)\boldsymbol{x} + \mu_1^*(h_1)}{(\boldsymbol{d}_1^2 - L^*(h_1)\beta_1^2)\boldsymbol{x}} \geq T_1^*(\mu_1^*(v)) \\
& \dfrac{(-\boldsymbol{d}_2^1 + L^*(h_2)\boldsymbol{\beta}_2)\boldsymbol{x} + \mu_2^*(h_2)}{(\boldsymbol{d}_2^2 - L^*(h_2)\beta_2^2)\boldsymbol{x}} \geq T_2^*(\mu_2^*(v)) \\
& A_1\boldsymbol{x}_1 + A_2\boldsymbol{x}_2 \leq \boldsymbol{b} \\
& \boldsymbol{x}_1 \geq \boldsymbol{0},\ \boldsymbol{x}_2 \geq \boldsymbol{0}
\end{array}
\right\} \tag{9}
$$

where $T_l^*(\cdot)$ is a pseudo-inverse function of $T_l(\cdot)$. Obtaining the optimal value of v to this problem is equivalent to finding the maximum of v so that the set of feasible solutions to (9) is not empty. Although this problem is a nonlinear programming problem, we can easily find the maximum of v by the following algorithm based on the bisection method and the simplex method since the constraints of (9) are linear if v is fixed.

The combined use of the bisection method and the simplex method

4-1 Set $l := 0$ and $v := 0$. Test whether the set of feasible solutions to (9) for $v = 0$ is empty or not using the phase one of the simplex method. If it is empty, DMs must reassess

membership functions, α or h_l. Otherwise, let $v_{\text{feasible}} := v$ and go to 4-2

4-2 Set $v := 1$. Test whether the set of feasible solutions to (9) for $v = 1$ is empty or not using the phase one of the simplex method. If it is not empty, $v = 1$ is the optimal value v^* to (9) and the algorithm is terminated. Otherwise, the maximum of v so that the set of feasible solutions to (9) is not empty exists between 0 and 1. Let $v_{\text{infeasible}} := v$ and go to 4-3.

4-3 Set $v := (v_{\text{feasible}} + v_{\text{infeasible}})/2$, $l := l + 1$ and go to 4-4.

4-4 Test whether the set of feasible solutions to (9) for v determined in 4-3 is empty or not using the phase one of the simplex method. Observe that the sensitivity analysis technique can be applied for this test. If it is not empty and $(1/2)^l \leq \varepsilon$, the current value of v is regarded as the optimal value v^* to (9) and the algorithm is terminated. If it is not empty and $(1/2)^l > \varepsilon$, let $v_{\text{feasible}} := v$ and return to 4-3. On the other hand, if it is empty, let $v_{\text{infeasible}} := v$ and return to 4-3.

Then, for the obtained optimal value v^*, we can determine the corresponding optimal value $\boldsymbol{x}^*$ by solving the following linear fractional programming problem:

$$\left.\begin{array}{ll} \text{maximize} & p_1(\boldsymbol{x}_1, \boldsymbol{x}_2) \\ \text{subject to} & p_2(\boldsymbol{x}_1, \boldsymbol{x}_2) \geq \mu_2^*(v^*) \\ & A_1\boldsymbol{x}_1 + A_2\boldsymbol{x}_2 \leq \boldsymbol{b} \\ & \boldsymbol{x}_1 \geq \boldsymbol{0},\ \boldsymbol{x}_2 \geq \boldsymbol{0} \end{array}\right\} \tag{10}$$

It should be noted here that linear fractional programming problems can be reduced to equivalent linear programming problems through the variable transformation method by Charnes and Cooper [2]. Therefore, we can obtain an optimal solution to (10) by some linear programming technique.

Step 5: The DM1 is supplied with the current values of $\mu_1(p_1(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*))$ and $\mu_2(p_2(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*))$ for the optimal solution $\boldsymbol{x}^*$ calculated in step 4. If DM1 is satisfied with the current membership function values, the interaction process is terminated. If DM1 is not satisfied and desires to update h_l, $l = 1, 2$, ask DM1 to update h_l and return to step 4. Otherwise, ask DM1 to specify the minimal satisfactory level $\hat{\delta}$ for $\mu_1(p_1(\boldsymbol{x}_1, \boldsymbol{x}_2))$ and the permissible range $[\Delta_{\min}, \Delta_{\max}]$ of the ratio of membership functions $\Delta = \mu_2(p_2(\boldsymbol{x}_1, \boldsymbol{x}_2))/\mu_1(p_1(\boldsymbol{x}_1, \boldsymbol{x}_2))$.
Observe that the larger the minimal satisfactory level is assessed, the smaller the DM2's satisfactory degree becomes. Consequently, in order to take account of the overall satisfactory balance between both decision makers, DM1 needs to compromise with DM2 on DM1's own minimal satisfactory level. To do so, the permissible range of the ratio of the satisfactory degree of DM2 to that of DM1 is helpful.

Step 6: For the specified value of $\hat{\delta}$, solve the following problem to maximize the membership function $\mu_2(p_2(\boldsymbol{x}_1, \boldsymbol{x}_2))$ of DM2 considering the constraint that the membership function $\mu_1(p_1(\boldsymbol{x}_1, \boldsymbol{x}_2))$ of DM1 must be greater than or equal to $\hat{\delta}$.

$$\left.\begin{array}{ll} \text{maximize} & \mu_2(p_2(\boldsymbol{x}_1, \boldsymbol{x}_2)) \\ \text{subject to} & \mu_1(p_1(\boldsymbol{x}_1, \boldsymbol{x}_2)) \geq \hat{\delta} \\ & A_1\boldsymbol{x}_1 + A_2\boldsymbol{x}_2 \leq \boldsymbol{b} \\ & \boldsymbol{x}_1 \geq \boldsymbol{0},\ \boldsymbol{x}_2 \geq \boldsymbol{0} \end{array}\right\} \tag{11}$$

This problem can be rewritten as:

$$\left.\begin{array}{ll} \text{maximize} & p_2(\boldsymbol{x}_1, \boldsymbol{x}_2) \\ \text{subject to} & p_1(\boldsymbol{x}_1, \boldsymbol{x}_2) \geq \mu_1^*(\hat{\delta}) \\ & A_1\boldsymbol{x}_1 + A_2\boldsymbol{x}_2 \leq \boldsymbol{b} \\ & \boldsymbol{x}_1 \geq \boldsymbol{0},\ \boldsymbol{x}_2 \geq \boldsymbol{0} \end{array}\right\} \tag{12}$$

Observing that problem (12) is a linear fractional programming problem, it can be easily solved by some linear programming technique through the variable transformation method by Charnes and Cooper [2] like (10). For the optimal solution $\boldsymbol{x}^*$ to (11), calculate $p_1(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$, $p_2(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$ and Δ.

Step 7: DM1 is supplied with the current values of $p_1(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$, $p_2(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$ and Δ calculated in step 6. If $\Delta \in [\Delta_{\min}, \Delta_{\max}]$ and DM1 is satisfied with the current membership function values for the optimal solution $\boldsymbol{x}^*$, the interaction process is terminated. Otherwise, ask DM1 to update the permissible level h_l, $l = 1, 2$ or the minimal satisfactory level $\hat{\delta}$, and return to step 6.

In the proposed algorithm, $\Delta_{\min}$ and $\Delta_{\max}$ are usually set to be less than 1 since $p_1(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$ should be greater than $p_2(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$ because of the priority of DM1. In Step 6, if $\Delta < \Delta_{\min}$, i.e., $p_1(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$ is much greater than $p_2(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$, DM1 will decrease $\hat{\delta}$ to improve $p_2(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$ and increase Δ. Conversely, if $\Delta_{\max} < \Delta$, i.e., $p_1(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$ is slightly greater or less than $p_2(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$, DM1 will increase $\hat{\delta}$ to improve $p_1(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$ and decrease Δ. On the other hand, if DM1 decreases (increases) h_l, $l = 1, 2$, both $p_1(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$ and $p_2(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$ would increase (decrease). With this observation, it can be expected that desirable values of $p_1(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$, $p_1(\boldsymbol{x}_1^*, \boldsymbol{x}_2^*)$ and Δ will be obtained through a series of update procedures of $\hat{\delta}$, h_l, $l = 1, 2$ with DM1.

V. Conclusion

In this research, assuming cooperative behavior of the decision makers, interactive decision making methods in hierarchical organizations under fuzzy random environments were considered. For the formulated fuzzy random two-level linear programming problems, possibility measures were introduced and a stochastic two-level linear programming problem was defined for guaranteeing the degree of realization of the problem. Considering the vague natures of decision makers' judgments, fuzzy goals were introduced and the stochastic

two-level linear programming problem was transformed into the problem to maximize the satisfaction degree for each fuzzy goal. Through the possibility maximization model, the transformed stochastic two-level programming problem was reduced to a deterministic one. Interactive fuzzy programming to obtain a satisfactory solution for the decision maker at the upper level in consideration of the cooperative relation between decision makers was presented. In near future, we will report the result of the application of the proposed method to a numerical example to derive a satisfactory solution.

***Abstract*—This paper presents a decentralized adaptive approximation design to achieve attitude tracking control for decentralized formation flying in presence of control input saturation, model uncertainties, external disturbances and reaction wheel faults. A nonsingular fast terminal sliding mode control is designed for finite time distributed cooperative attitude synchronization. In the proposed control scheme, a fuzzy logic system (FLS) is introduced to approximate unknown individual satellite attitude dynamics on-line due to the actuators fault. In order to achieve the capability of fault management without the involvement of ground station operators, the proposed control laws do not requite an explicit fault detection and isolation mechanism. In the attitude control system of each satellite four reaction wheels are placed in a pyramid configuration, numerical simulation results including actuator dynamics and initial conditions' uncertainties show that the proposed strategy with FLS can compensate for the fault and the system continues to operate satisfactorily with wheel voltage or wheel speed faults and the closed loop distributed tracking control system is stochastically stable. Several simulation examples compared with the existing decentralized fault tolerant contoller are presented for illustrating the effectiveness of the proposed fault tolerant control methodology.**

Keywords: Fuzzy Logic System; Fast Terminal Sliding Mode Control; Decentralized Fault Tolerant Control

I. INTRODUCTION

Decentralized multi-agent cooperative control, including consensus, formation control and flocking has been studied extensively. The benefits such as scalability, robustness and easy maintenance can be obtained by embodying decentralized cooperative control [1]. The motivation of decentralized controller is to avoid the complete redesign of the control system when new subsystems are added and also guarantee the stability of the whole system. One limitation of those above approaches is that they did not provide finite-time control of a group of spacecraft, which could provide faster formation rearrangement capability during attitude coordination. In the reference [2], it is proved that nonsingular fast terminal sliding mode control can get rid of the singularity problem completely. Neural networks and fuzzy logic systems have been proposed as the tools to be capable of approximating any well defined functions over a compact set to arbitrary accuracy [3][4]. The fuzzy logic system is a very powerful technique in the discipline of systems with large uncertainties and strong nonlinearities. Therefore, a nonsingular terminal sliding mode control with fuzzy logic system is proposed in this paper as a fault-tolerant control strategy. Inspired by the work in [2] and [5], a nonsingular fast terminal fuzzy sliding mode control (NFFTSMC) is proposed for distributed cooperative attitude synchronization and precise 3-axis attitude tracking control of picosatellites in the presence of control input saturation, model uncertainties, and external disturbances. Also, the existing attitude synchronization or coordination literature addresses important issues relating to attitude control of multiple spacecraft, such as adapting the control system to modeling uncertainties, robust capability to attenuate external disturbances, communication delay, and actuator saturation constraint accommodation. Most traditional attitude fault-tolerant control reconfiguration techniques rely on failure detection and isolation. Reconfigurable attitude control system design for spacecraft based on FDI approaches and system redesign is fairly complex and depends strongly on the efficacy of the fault detection algorithm. Also, explicit failure identification and system redesign may require substantial on-board computational resources that works against the prevailing cost reduction measures undertaken by most commercial and military satellite markets. The problem of fault tolerance for attitude synchronization systems is still an open problem and there are a lot of theoretical challenges. An alternative approach to reconfigurable ACS design is based on adaptive or approximation control theory where the controller parameters are constantly updated based on adaptive or other estimates of the altered dynamics after failure. Neural network for adaptive approximation has been successfully applied to the design of nonlinear fault tolerant controllers [6]. In this paper, a fault-tolerant control strategy using adaptive nonsingular fast terminal fuzzy sliding mode control is proposed for multiple picosatellite attitude synchronization which is represented by quaternion. In order to achieving the capability of fault management without involvement of ground station operators, the proposed control laws do not require an explicit fault detection and isolation mechanism. Therefore, failure time instants, patterns, and values of actuator failures are unknown to the designer. When a reaction wheel failure or fault occurs, the control signals are autonomously redistributed to the remaining healthy wheels using an adaptive gain that is updated on-line based on the attitude tracking error. Each satellite with four reaction wheels is in a pyramid configuration. The numerical simulation results and a predicted theoretical

framework show that the proposed strategy can compensate for faults, the system continues to operate satisfactorily with initial conditions' uncertainites or wheel speeds faults, and the closed loop distributed tracking control system is stochastically stable.

A. Satellite With Four Reaction Wheels Attitude Dynamics and Kinematics Model

The individual satellites in the formation are modeled as rigid bodies [7]. The proposed system consists of four *rigid body satellites* in a circular orbit around the Earth. An *Earth centered inertial* (ECI) frame, denoted by Ł$-_{X_I Y_I Z_I}$, has its origin located at the center of the Earth, with Z_I-axis passing through the celestial North pole, X_I-axis directed towards the vernal equinox, and Y_I-axis completes the right-handed triad. Next, we define a local vertical local horizontal (LVLH) orbital reference frame $\pounds-_{x_o y_o z_o}$ fixed at the center of the satellite with the x_o-axis along the direction of motion, the y_o-axis opposite to the direction of the angular velocity (normal to the orbit plane), and the z_o-axis pointing towards the Earth. The nodal line represents the reference line in orbit for the measurement of the true anomaly (eccentric orbit) or reference angle θ (circular orbit). The corresponding principal body-fixed coordinate axes of the satellite are denoted by $\jmath - xyz$ with its origin located at the center of mass of the satellite. The notation [8] used for representing the relative velocity vector, $\mathbf{v}$, of frame $\pounds$ relative to frame Ł, expressed in the coordinates of $\jmath$ is: $\mathbf{v}_{LI}^{B}$. The cross-product of vectors $a \times b$ is defined as $[a^{\times}]b$ where $[a^{\times}]$ is a skew-symmetric operator.

Consider the i'th rigid satellite with a 4-wheel cluster installed to provide internal torques. The attitude dynamics of a rigid satellite controlled by reaction wheels can in general be described the following nonlinear differential equation [9]:

$$J_i \dot{\omega}_{iBI}^{B} = -\omega_{iBI}^{B} \times (J_{si}\omega_{iBI}^{B} + A_i J_{wi}\Omega_i) + A_i \tau_{rwi} + \tau_{ie} \quad (1)$$

The torques generated by the reaction wheels τ_{rwi} are given by

$$\tau_{rwi} = J_{wi}(\dot{\Omega}_i + A_i^T \dot{\omega}_{iBI}^{B}) \quad (2)$$

where ω_{iBI}^{B} is the angular velocity of the satellite relative to the inertial frame Ł, expressed in the $\jmath$ frame, and $\tau_{ie} \in \mathbb{R}^{3\times 1}$ represents the external torque acting on the system. A_i is the 3×4 matrix whose columns represent the influence of each reaction wheel on the angular acceleration of the satellite. We define a matrix $J_i = J_{si} - A_i J_{wi} A_i^T$, where $J_{si} \in \mathbb{R}^{3\times 3}$ is the moment of inertia of the satellite, including the wheels, and $J_{wi} \in R^{4\times 4} = \mathrm{diag}([J_{wi1}, J_{wi2}, J_{wi3}, J_{wi4}])$ denotes the axial moment of inertia of the reaction wheels. $\Omega_i \in \mathbb{R}^{4\times 1}$ denotes the axial angular velocity of the reaction wheels.

The external torques (τ_{ie}) are assumed to include gravity gradient torque (τ_{gi}) acting on the satellite. The gravity gradient torque is given by [10]

$$\tau_{ie} = 3\omega_0^2 [\hat{c}_3^{\times}] J_{si} \hat{c}_3, \qquad \hat{c}_3 = C_{iL}^{B}[0\ 0\ 1]^T \quad (3)$$

In this paper, we adopt the unit quaternion[7] to describe the attitude of the satellite. The unit quaternion $\bar{q}_i$ is defined by

$$\bar{q}_i = \begin{bmatrix} \bar{e}\sin(\Phi/2) \\ \cos(\Phi/2) \end{bmatrix} = \begin{bmatrix} q_{vi} \\ q_{4i} \end{bmatrix} \quad (4)$$

where Φ denotes the principal angle, and $\bar{e} = [e_1, e_2, e_3]^T$ denotes the principal axis associated with Euler's Theorem ($e_1^2 + e_2^2 + e_3^2 = 1$). $q_{4i} \in R$ and $q_{vi} \in \mathbb{R}^{3\times 1} = [q_{i1}, q_{i2}, q_{i3}]^T$ denote the Euler parameters that represent the orientation of the satellite body frame, $\jmath$, with respect to the orbital frame, $\pounds$, and satisfy the constraint $q_{vi}^T q_{vi} + q_{4i} = 1$. The nonlinear differential equations governing the kinematics of the satellite in terms of Euler parameters can be expressed as

$$\begin{bmatrix} \dot{q}_{vi} \\ \dot{q}_{4i} \end{bmatrix} = \frac{1}{2} \begin{bmatrix} q_{4i} I + [q_{vi}^{\times}] \\ -q_{vi}^T \end{bmatrix} \omega_{iBL}^{B} \quad (5)$$

where $I \in R^{3\times 3}$ represents the identity matrix, and $[q_{vi}^{\times}]$ denotes a skew-symmetric matrix which is given by

$$[q_{vi}^{\times}] = \begin{bmatrix} 0 & -q_{i3} & q_{i2} \\ q_{i3} & 0 & -q_{i1} \\ -q_{i2} & q_{i1} & 0 \end{bmatrix} \quad (6)$$

The angular velocity of the body-fixed reference frame, $\jmath$, with respect to the inertial frame, Ł, can be expressed as

$$\omega_{iBI}^{B} = \omega_{iBL}^{B} + \omega_{iLI}^{B} \quad (7)$$

The direction cosine matrix C_{iL}^{B} that describes the orientation of the satellite body-fixed frame, $\jmath$, with respect to the LVLH reference frame, $\pounds$ defined in terms of Euler parameters is given by

$$C_{iL}^{B} = (q_{4i}^2 - q_{vi}^T q_{vi})I + 2q_{vi}q_{vi}^T - 2q_{4i}[q_{vi}^{\times}] \quad (8)$$

The orbital angular velocity expressed in the $\jmath$ frame, ω_{iLI}^{B}, can be obtained by rotating the angular velocity in $\pounds$ using the transformation matrix C_{iL}^{B} as follows:

$$\omega_{iLI}^{B} = C_{iL}^{B} \begin{bmatrix} 0 & -\omega_{i0} & 0 \end{bmatrix}^T \quad (9)$$

where $\omega_{i0} = \dot{\theta}$ is the magnitude of orbital angular velocity of the LVLH frame. For a circular orbit, $\dot{\theta} = \sqrt{\mu_e / R_c^3}$, where μ represents the gravitational parameter of the Earth, and R_c defines the distance of the spacecraft measured from the center of the Earth.

Reaction wheels are widely used to perform precise satellites attitude maneuvers because they allow continuous and smooth control. They are capable of changing its internal angular momentum vector as each wheel spins about a body-fixed axis with variable spin speed [10]. Torques are produced on the satellites by accelerating or decelerating the reaction wheels. Let the torque demanded by the satellite be denoted as τ_{rwi}. The input voltage required to control the actuator dynamics of the reaction wheel can be shown as

$$e_{ai} = K_{bi}\Omega_i - R_{bi}K_{ti}^{-1}(A_i' \tau_{rwi}) \quad (10)$$

where $K_{ti} \in \mathbb{R}^{4\times 4} = \mathrm{diag}([k_{t1}, k_{t2}, k_{t3}, k_{t4}])$ is the motor torque constant. $K_{bi} \in \mathbb{R}^{4\times 4} = \mathrm{diag}([k_{b1}, k_{b2}, k_{b3}, k_{b4}])$ is the back-EMF constant, $R_{bi} \in \mathbb{R}^{4\times 4} = \mathrm{diag}([r_{b1}, r_{b2}, r_{b3}, r_{b4}])$ is the armature resistance, and we ignore the friction in the reaction wheels.

B. Station Keeping Attitude Tracking and Formation Keeping Attitude Tracking

In the case of tracking a desired rotational motion, the target attitude of the i'th satellite in the desired reference frame $\jmath_o$ with respect to the LVLH frame $\pounds$ is described by the orientation $(q_{dvi},\, q_{d4i}) \in \mathbb{R}^3 \times \mathbb{R}$ that satisfies the constraint $q_{dvi}^T q_{dvi} + q_{d4i}^2 = 1$. Let $\omega_{di} \in \mathbb{R}^3$ denote the angular velocity of $\jmath_o$ with respect to $\pounds$, expressed in the frame $\jmath_o$. To address the station-keeping attitude tracking problem, we define the quaternion absolute tracking error $(q_{ie},\, q_{i4e}) \in \mathbb{R}^3 \times \mathbb{R}$ as the relative orientation between the body-fixed frame $\jmath$ and the desired reference frame $\jmath_o$, which is computed as

$$\begin{aligned} q_{ie} &= q_{d4i} q_{vi} - q_{4i} q_{dvi} + [q_{vi}^{\times}] q_{dvi} \\ q_{i4e} &= q_{d4i} q_{4i} + q_{dvi}^T q_{vi} \end{aligned} \tag{11}$$

where $q_{ie}^T q_{ie} + q_{i4e}^2 = 1$. The corresponding rotation matrix $C_{ie} = C_i(q_{ie},\, q_{i4e}) \in SO(3)$ is given by

$$C_{ie} = (q_{i4e}^2 - q_{ie}^T q_{ie}) I + 2 q_{ie} q_{ie}^T - 2 q_{i4e} [q_{ie}^{\times}] \tag{12}$$

where $C_{ie}^T C_{ie} = 1$, $\|C_{ie}\| = 1$, $\det(C_{ie}) = 1$, and $\dot{C}_{ie} = -[\omega_{ie}^{\times}] C_{ie}$. Next, we define the absolute angular velocity tracking error $\omega_{ie} \in \mathbb{R}^3$ of $\jmath$ with respect to $\pounds$ as follows:

$$\omega_{ie} = \omega_{iBL}^B - C_{ie} \omega_{id} \tag{13}$$

From Eqs. (5), (11), and (13), the equations that govern the absolute attitude (station-keeping) error dynamics and kinematics are given by

$$\dot{q}_{ie} = \frac{1}{2} (q_{i4e} I + [q_{ie}^{\times}]) \omega_{ie} \tag{14}$$

$$\dot{q}_{i4e} = -\frac{1}{2} q_{ie}^T \omega_{ie} \tag{15}$$

Assumption 1: We assume that there exists known, finite constant, $c_1 > 0$ such that $\|q_{di}\|^2 + \|\dot{q}_{di}\|^2 + \|\ddot{q}_{di}\|^2 \le c_1$ for all $t \ge 0$.

We choose $\bar{q}_{ij}$ and ω_{ij} to represent the quaternion mapping of the i'th satellite body-fixed coordinate with respect to the j'th satellite body-fixed coordinate and the angular velocity of the i'th satellite with respect to the j'th satellite [11]

$$\bar{q}_{ij} = \left[{q_{ij}}^T q_4 \right]^T = \bar{q}_i \otimes \bar{q}_j^{-1} \tag{16}$$

$$q_{v_{ij}} = q_{v_i} - C_{ij} q_{v_j} \tag{17}$$

$$\omega_{ij} = \omega_i - C_{ij} \omega_j \tag{18}$$

where C_{ij} is the rotation matrix from the i'th body reference frame to the j'th body reference frame, which is a proper orthogonal matrix. $q_{v_{ij}}$ is defined as the formation flying attitude error.

$$C_{ij} = C_{ij}(\bar{q}_i \otimes \bar{q}_i^{-1}) = C_i(\bar{q}_i) C_j(\bar{q}_j)^T \tag{19}$$

According to Eq. (8),

$$C_i(\bar{q}_i) = ({q_{4i}}^2 - {q_{v_i}}^T q_{v_i}) I + 2 q_{v_i} {q_{v_i}}^T - 2 q_{4i} [{q_{v_i}}^{\times}] \tag{20}$$

The quaternion $(q_{v_{ij}})$ differential equations are obtained by the reference.

$$\dot{q_{v_{ij}}} = \frac{1}{2} (q_{ij_4} \omega_{ij} - \omega_{ij} \otimes q_{ij}) \tag{21}$$

C. Consensus Tracking

A weighted graph $G = (V, E, \bar{A})$ consists of a node set v, an edge set E and a weighted adjacency matrix $\bar{A}$. It is natural to describe the topology of the information flow between satellites in the formation by a graph. The weighted adjacency matrix $A = a_{ij} \in \mathbb{R}^{n \times n}$ is the weighted adjacency matrix of graph G with nonnegative elements. Node v_i represents the i'th satellite, and an edge in G is denoted by an unordered pair (ij). $ij \in E \Leftrightarrow ji \in E$. The adjacency element a_{ij} denotes the communication quality between the i'th satellite and the j'th satellite. It is assumed that $a_{ij} = a_{ji}$ and $\bar{A}$ is a symmetric matrix.

Let $D = diag(d_1, d_2, ..., d_n)$ be the degree matrix of G. The Laplacian matrix of L of the weighted graph G is defined by

$$L = D - \bar{A} \tag{22}$$

It is assumed that the multi-satellites formation flying studied in this paper has a connected graph topology G. The theorem [12] gives the existing results of the Laplacian matrix and graph theory.

Theorem 1: If $G = (V, E, \bar{A})$ is an undirected connected graph, then the graph Laplacian matrix L is a symmetric matrix with n real eigenvalues in an ascending order as:

$$0 = \lambda_1, \lambda_2 \le \lambda_3 ... \le \lambda_n \le 2 d_M \tag{23}$$

where $d_M = max_{1 \le i \le n} \{d_i\}$ is the maximum degree of a graph, and λ_2 is called the algebraic connectivity of a graph.

Let $a_{i1} \in \mathbb{R}^3$ and $a_{i2} \in \mathbb{R}^3$ be the consensus attitude error including the station-keeping and formation-keeping errors of the i'th satellite in the formation, which are defined as:

$$a_{i1} = k_p \sum_{j=1, i \ne j}^{n} a_{ij} q_{v_{ij}} + k_i q_{ie} \tag{24}$$

$$a_{i2} = k_p \sum_{j=1, i \ne j}^{n} a_{ij} \dot{q_{v_{ij}}} + k_i \dot{q_{ie}} \tag{25}$$

where $i = 1, 2, ..., n$. a_{ij} is the element of the weighted adjacency matrix A. k_p and k_i are positive constants determined by the controller designer, respectively.

The consensus error is used to evaluate the motion synchronization performance. Eqs. (24), (25) have to be written as follows:

$$a_{i1} = k_p \sum_{j=1}^{n} l_{ij} q_{j_e} + k_i q_{ie} \tag{26}$$

$$a_{i2} = k_p \sum_{j=1}^{n} l_{ij} \dot{q_{j_e}} + k_i \dot{q_{ie}} \tag{27}$$

Define $A_1 = ({a_{11}}^T, {a_{21}}^T, ..., {a_{n1}}^T)$, $A_2 = ({a_{12}}^T, {a_{22}}^T, ..., {a_{n2}}^T)$, $E_1 = ({qe_{11}}^T, {qe_{21}}^T, ..., {qe_{n1}}^T)$, $E_2 = ({\dot{q}e_{11}}^T, {\dot{q}e_{21}}^T, ..., {\dot{q}e_{n1}}^T)$, and $K = diag(k_1, k_2, ..., k_n)$. The Eqs. (26), (27) can be expressed in terms of the aforementioned quantities as follows:

$$A_1 = (k_p L \otimes I_3 + K \otimes I_3)E_1 \tag{28}$$

$$A_2 = (k_p L \otimes I_3 + K \otimes I_3)E_2 \tag{29}$$

Lemma 1: The matrix $M_1 = (k_p L \otimes I_3 + K \otimes I_3)$ is symmetric and positive definite.

$$\lambda_m \|x\|^2 \leq x^T((k_p L \otimes I_3 + K \otimes I_3))x \leq \lambda_M \|x\|^2, \forall x \in \mathbb{R}^{mn} \tag{30}$$

where $\lambda_m = min_{1 \leq i \leq n}(k_i)$ and $\lambda_M = k_p \lambda_n + max_{1 \leq i \leq n}(k_i)$ are positive constants.

The objective of control design becomes to design appropriate control input that guarantees the convergence of both the station-keeping q_{ie} and formation-keeping q_{vij} tracking error and consensus synchronization error a_{i1} and a_{i2}, even in the presence of unknown constant parameters,periodic disturbances, and actuator faults. In short, one needs to achieve $q_{ie}, q_{vij} \to 0$ and $a_{i1} \to 0$ as $t \to \infty$.

D. Finite Time Stability

The finite time convergence means that the system will converge on the sliding surface. On the sliding surface, the system is totally determined by a reduced-order system determined by the designer. Without the finite time convergence, the system moves in a vicinity of the sliding surface, where the system may converge slowly or even may not converge, determined by the sliding surface, the whole system dynamics including disturbances and uncertainties. Besides, with the finite time convergence, the matched disturbances and/or uncertainties can be rejected completely.

Lemma 2: [13] Assume there is a continuous positive definite function $V(t)$ satisfying the following differential inequality:

$$\dot{V} \leq -\gamma_1 V^{\bar{\rho}} \quad \forall t \geq t_0, V(t_0) \geq 0, \tag{31}$$

where $\gamma_1 > 0$ and $0 < \bar{\rho} < 1$ are positive constants. Then, for any given t_0, $V(t)$ satisfies the following inequality:

$$V^{1-\bar{\rho}}(t) \leq V^{1-\bar{\rho}}(t_0) - \gamma_1(1-\bar{\rho})(t-t_0), t_0 \leq t \leq t_1 \tag{32}$$

and $V(t) \equiv 0, \forall t \geq t_1$ with $t_1 = t_0 + \frac{V^{1-\bar{\rho}}(t)}{\gamma_1(1-\bar{\rho})}$.

E. Fuzzy Logic System

Fuzzy logic system is a collection of IF-THEN fuzzy rules as:

$$R^k: \quad IF \quad x_1 \quad is \quad A_1^k, \quad and, \quad \cdots, \quad x_n \quad is \quad A_n^k, \quad THEN \quad y \quad is \quad B^k. \tag{33}$$

The output of the fuzzy system (using singleton fuzzification, product inference and center average defuzzification) can be written as

$$y_{out} = \frac{\sum_{l=1}^{P} \theta_F^l(X) \prod_{i=1}^{N} \mu_{Ai^l(x_i)}^l}{\sum_{l=1}^{P} \prod_{i=1}^{N} \mu_{Ai^l(x_i)}^l} = \theta^T \xi \tag{34}$$

where P is the total fuzzy rules number. The membership functions $\mu_{A1^l(x_1)}, ..., \mu_{An^N(x_n)}$ (N is the number of membership functions) are Gaussian functions, ξ is fuzzy basis function $\left(\xi^l(x) = \frac{\prod_{i=1}^{N} \mu_{Ai^l(x_i)}}{\sum_{l=1}^{P} \prod_{i=1}^{N} \mu_{Ai^l(x_i)}}\right)$. In this paper, $N = 7$. Therefore, the membership functions can be chosen as linguistic terms Negative Big (NB), Negative Medium (NM), Negative Small (NS), Zero (ZE), Positive Small (PS), Positive Medium (PM) and Positive Big (PB), that are assigned to the inputs (x_1 to x_n) and the output ($\hat{F}$).

Therefore, the continuous nonlinear function $F_i(x)$ of each satellite can be approximated by the fuzzy logic system [14].

$$\hat{F}_i(x) = {\theta_i}^T \xi_i(x) \tag{35}$$

where ξ_F is the vector of the fuzzy basis function and is supposed to be fixed, while the parameters $\theta_{F_i}^T$ are the variable which will be designed by adaptive laws. It is assumed that there exists an optimal fuzzy logic system to learn the nonlinear terms $F_i(x)$ such that

$$F_i(x) - \hat{F}_i^*(x) = \varepsilon \tag{36}$$

where ε is the approximation error and is bounded. Approximation errors can be reduced by increasing the number of fuzzy rules.

In order to decrease the fuzzy rules, we use the nonsingular fast terminal sliding surface S instead of the state x for the adaptive parameters. Then, the adaptive parameters θ_F are updated by the following adaptive laws:

$$\dot{\theta}_i = \alpha_i M_2 \sigma_2 p/q \dot{A}_1^{p/q-1} S \xi_i \tag{37}$$

$$\xi_i(s_i) = \frac{\prod_{i=1}^{N} \mu_{Ai^l(s_i)}}{\sum_{l=1}^{P} \prod_{i=1}^{N} \mu_{Ai^l(s_i)}} \tag{38}$$

where α_i is a positive constant.

In order to guarantee that the estimated Fuzzy Logic System parameters remain within some known bounded sets, the smooth projection is considered in this paper. Let θ_i be the estimation of the optimal weight matrix θ_i^*, and define a smooth projection of θ_i as:

$$\pi_i(\theta_i) = \theta_{i\pi} = \pi_{i,jk}(\theta_{i,jk}), j = 1, 2, ..., m, k = 1, 2, ..., N_1 \tag{39}$$

Each projection operator $\pi_{i,jk}$ is a real-value smooth nondecreasing function defined by

$$\pi_{i,jk}(\theta_{i,jk}) = \theta_{i,jk} \tag{40}$$

Define $\tilde{\theta}_i = {\theta_i}^* - \theta_i$, $\tilde{\theta}_{i\pi} = {\theta_i}^* - \theta_{i\pi}$, and

$$V_{\theta_i} = \frac{1}{\delta_i} \sum_{j=1}^{m} \sum_{k=1}^{N_1} \int_0^{\tilde{\theta}_i} ({\theta^*}_{i,jk} - \pi_{i,jk}({\theta^*}_{i,jk} - \omega_{i,jk}) d\omega_{i,jk} \tag{41}$$

where, V_{θ_i} is positive definite with respect to $\tilde{\theta}_{i,jk}$ for $\theta_{i,jk}^* \in [\theta_{imin}, \theta_{imax}]$. Furthermore,

$$\dot{V}_{\theta_i} = -\frac{1}{\delta_i} \sum_{j=1}^{m} \sum_{k=1}^{N_1} \tilde{\theta}_{i\pi,jk} \dot{\theta}_{i,jk}^*, i = 1, 2, ..., n \tag{42}$$

Assumption 2: ε is bounded such that $\|\varepsilon_i\| \leq \varepsilon_{Mi} (i = 1, 2, ..., n)$, where ε_{Mi} is a positive constant.

Assumption 3: The optimal weight matrix $\theta_i^*(i=1,2,...,n)$ lies in a known bounded set ϱ_{Wi} defined by

$$\theta_i^* \in \varrho_{Wi} = \left\{\theta_i^* : \theta_{imin}^* \leq \theta_{i,jk}^* \leq \theta_{imin}^*\right\} \tag{43}$$

where θ_{imin}^* and θ_{imax}^* are known constants, respectively.

F. Mathematical Model for Controller Design

To employ the proposed control design methodology described in this paper, we need to construct a model to represent the nonlinear equations Eq. (1).

Denoting $p = 2[q_{4i}I + (q_{vi}^{\times})]^{-1}$, after taking the time derivative of Eq. (5), we obtain the following expression of ω_{iBL}^{B}:

$$\dot{\omega_i}_{BL}^{B} = \dot{p}\dot{q}_{vi} + p\ddot{q}_{vi} \tag{44}$$

where $T = [q_{4i}I + (q_{vi})^{\times}]^{-1}$.

Making use of Eq. (5) and Eq. (44), the quaternion equation can be written as:

$$\ddot{q}_{vi} = 2(T^{-1})^{T}(\dot{\omega_i}_{BI}^{B} - \dot{\omega_i}_{LI}^{B}) - 4(T^{-1})^{T}(\dot{T}^{-1})\dot{q}_{vi} \tag{45}$$

Since T is a skew-symmetric matrix, we derive $\dot{T}^{-1} = -T^{-1}\dot{T}T^{-1}$.

Substituting the Eqs. (1) and (9) into the Eq. (45), we obtain:

$$\begin{aligned}\ddot{q}_{vi} = 2(T^{-1})^{T}[{J_i}^{-1}(-\omega_{iBI}^{B} \times (J_{si}\omega_{iBI}^{B} + A_i J_{wi}\Omega_i) \\ + A_i\tau_{rwi} + \tau_{ie}) - \dot{\omega_i}_{LI}^{B}] - 4(T^{-1})^{T}(\dot{T}^{-1})\dot{q}_{vi}\end{aligned} \tag{46}$$

Using $\dot{C_L^B} = -[{\omega_{BL}^{B}}^{\times}]C_L^B$, we have:

$$\dot{\omega_i}_{LI}^{B} = -\omega_{iLI}^{B} \times \omega_{iLI}^{B} \tag{47}$$

The dynamics equation with actuator fault can be written as:

$$\ddot{q}_{vi} = f_i(q_{ie}, \dot{q}_{ie}) + (\tau_i + \Delta\tau_i) + \nu_i \tag{48}$$

A dynamic model of the satellite's relative attitude tracking with multiplicative reaction wheel faults (e.g. reduced control torque) is represented by a diagonal matrix E.

$$\begin{aligned}f_i(q_{ie}, \dot{q}_{ie}) = 2(T^{-1})^{T}[{J_i}^{-1}(-\omega_{iBI}^{B} \times (J_{si}\omega_{iBI}^{B} + A_i J_{wi}\Omega_i)] \\ - 4(T^{-1})^{T}(\dot{T}^{-1})\dot{q}_{vi} + 2(T^{-1})^{T}{J_i}^{-1}\omega_{iLI}^{B} \times \omega_{iLI}^{B}\end{aligned} \tag{49}$$

$$\tau_i = E[2(T^{-1})^{T}{J_i}^{-1}A_i\tau_{rwi}] \tag{50}$$

$$\nu_i = 2(T^{-1})^{T}{J_i}^{-1}\tau_{ie} \tag{51}$$

Assumption 4: The disturbance ν_i is bounded such that $\|\nu_i\| \leq \nu_{Mi}(i=1,2,...,n)$, where ν_{Mi} is a positive constant.

Assumption 5: The fault $\Delta\tau_i$ is bounded such that $\|\Delta\tau_i\| \leq \Delta\tau_{iMi}(i=1,2,...,n)$, where τ_{iMi} is a positive constant.

II. Design of Nonsingular Fast Fuzzy Terminal Sliding Mode Control

In this section we present the theoretical basis for developing NFFTSMC control algorithms for the four rigid body satellites attitude consensus tracking. The controller is decentralized as each controller does not require the decision from the other controllers. For each satellite, the NFFTSMC control overall design can be divided into two main steps. Step 1 involves the construction of a sliding surface containing absolute attitude and relative attitude tracking errors to ensure that once the system is restricted to the sliding surface, the satellite can be expected to be in the desired trajectory. Step 2 entails the derivation of parameter adaptation laws and fuzzy logic feedback control gains that can drive the relative state trajectory to the sliding surface, and maintain it in the manifold.

A. Nonsingular Fast Terminal Sliding Mode

The nonsingular fast terminal sliding mode can be defined by the following nonlinear differential equation:

$$s = x + \sigma_1 sign(x) + \sigma_2 \dot{x}^{\frac{p}{q}} \tag{52}$$

where $x \in \mathbb{R}$ and σ_1, σ_2 are positive constants. The positive odd integers p, q are chosen such that $1 < q/p < 2$.

We define the fast terminal sliding mode $s_i \in \mathbb{R}^m$ for the i'th satellite in the formation as:

$$s_i = a_{i2} + \beta_i a_{i1} = \Lambda_i + \beta_i \tag{53}$$

$$\begin{aligned}\Lambda_i(a_{i1}) &= a_{i1} + \sigma_{i1} sign(a_{i1}) \\ \beta_i(a_{i2}) &= \sigma_{i2} a_{i2}^{\frac{p}{q}}\end{aligned} \tag{54}$$

where $i = 1,2,...,n$. $\Lambda_i(a_{i1})$ and $\beta_i(a_{i2}) \in \mathbb{R}^m$. σ_{i1} and σ_{i2} are positive constants for the designer.

Defining $\beta = ({\beta_1}^{T}, {\beta_2}^{T}, ..., {\beta_n}^{T})^{T}$ and $s = ({s_1}^{T}, {s_2}^{T}, ..., {s_n}^{T})^{T}$, we have

$$s = \Lambda + \beta \tag{55}$$

The time derivative of the sliding mode Eq. (55) is given by

$$\dot{s} = \bar{\Lambda} + \bar{\beta} \tag{56}$$

B. Nonsingular Fast Fuzzy Terminal Sliding Mode Controller Design

The controller design for the i'th satellite in the formation is now given by

$$\tau_{rwi} = \bar{\tau}_i = \ddot{q}_d - K_{i1}s_i - K_{i2}{s_i}^{\rho} - \frac{q}{p\sigma_2}a_{i2}^{2-p/q} - \theta_i^T\xi_i - \varphi_i \tag{57}$$

where K_{i1} and K_{i2} are designed parameters.

with φ_i defined by [15]

$$\varphi_i \equiv \kappa_i tanh(\frac{3K_u\kappa_i s_i}{\epsilon}) \tag{58}$$

The controller consists three components: the nonlinear compensator $\ddot{q}_d$ is applied to compensate for the desired satellite dynamics, motivated by the fact that the attitude of each satellite in the formation reaches the desired trajectory of the formation, then station-keeping errors and formation-keeping errors will be zero. The nonlinear feedback $K_{i1}s_i + K_{i2}{s_i}^{\rho} + \frac{q}{p\sigma_2}a_{i2}^{2-p/q}$ is used to drive the satellite attitude to the sliding surface in finite time. The robust term $\varphi_i + \theta_i^T\xi_i$ is used to counteract the external disturbance and unknown system uncertainties due to the actuator faults. κ_i is a positive constant

satisfying $\varphi_i \geq d_{Mi}$. ϵ is a positive scalar. K_{i1} and K_{i2} are positive definite, diagonal and constant matrices. ρ is p/q. The proposed controller can provide finite time stability in both the reaching phase and the sliding phase, which is guaranteed by the Lyapunov theory described in the next subsection.

C. Stability Analysis

Theorem 2: Consider the system Eq. (48) and Assumption $1 \sim 5$, the nonsingular fast fuzzy terminal sliding control laws defined by Eqs. (57-58), with adaptive control laws given by Eq. (37) guarantees the state of the system starting from any initial point will move toward the switching surface and reach the sliding surface $s = 0$ in a finite time. Furthermore, the aggregated attitude tracking errors $a_{i1,j}$ and $a_{i2,j}$ ($i = 1, 2, ..., n$,j=1,2,3) will converge to the regions in finite time, respectively, and the station-keeping attitude tracking errors will converge to the regions in finite time, respectively.

Proof of Theorem 2: The dynamics equations for the absolute errors of the i'th satellite can be written as:

$$q_{ie} = e_{1i} \quad \dot{q}_{ie} = e_{2i} \tag{59}$$

$$\dot{e}_{i1} = e_{i2} \quad \dot{e}_{i2} = -\ddot{x}_{id} + f_i(q_{ie}, \dot{q}_{ie}) + \tau_i + \Delta\tau_i + \nu_i \tag{60}$$

Define $E_1 = ({e_{11}}^T, {e_{21}}^T, ..., {e_{n1}}^T)$, $E_2 = ({e_{12}}^T, {e_{22}}^T, ..., {e_{n2}}^T)$, $Q_d = (\ddot{q}_1^T, \ddot{q}_2^T, ..., \ddot{q}_n^T)$, $F = ({f_1}^T, {f_2}^T, ..., {f_n}^T)$, $\bar{\tau} = (\bar{\tau}_1^T, \bar{\tau}_2^T, ..., \bar{\tau}_n^T)$, $\Delta\tau = ({\Delta\tau_{i1}}^T, {\Delta\tau_{i2}}^T, ..., {\Delta\tau_{in}}^T)$ and $\nu = (\bar{\nu}_1^T, \bar{\nu}_2^T, ..., \bar{\nu}_n^T)$. The Eqs. (59) can be expressed in terms of the aforementioned quantities as follows:

$$\begin{aligned} \dot{E}_1 &= E_2 \\ \dot{E}_2 &= -Q_d + F + \tau + \Delta\tau + \nu \end{aligned} \tag{61}$$

Denote $M_1 = (k_p L + K) \otimes I_3$. Eqs. (28) and (29) can be expressed in terms of the aforementioned quantities as follows:

$$\begin{aligned} A_1 &= M_1 E_1 \\ A_2 &= M_1 E_2 \end{aligned} \tag{62}$$

The dynamics equations for A_1 and A_2 are defined as:

$$\begin{aligned} \dot{A}_1 &= A_2 \\ M_2 \dot{A}_2 &= -Q_d + F + \tau + \Delta\tau + \nu \end{aligned} \tag{63}$$

respectively, where $M_2 = M_1^{-1}$.

Using Eqs. (56) and (63), we obtained

$$\begin{aligned} M_2 \dot{s} &= M_2 \bar{\Lambda} + M_2 \bar{\beta} = M_2 \dot{A}_1 \\ &+ M_2 \sigma_2 p/q \dot{A}_1^{p/q-1} (-Q_d + F + \tau + \Delta\tau + \nu) \end{aligned} \tag{64}$$

Using the approximation property of Fuzzy Logic Systems, the unknown function $f_i (i = 1, 2, ..., n)$ can be approximated over the compact set Ω_d by Eqs. (35) and (37). Substituting the control law Eq. (57) into the error dynamics Eq. (64) yields the following dynamic equation for sliding surface s.

$$\begin{aligned} M_2 \dot{s} &= M_2 \bar{\Lambda} + M_2 \bar{\beta} \\ &= M_2 \dot{A}_1 + M_2 \sigma_2 p/q \dot{A}_1^{p/q-1} (-Q_d + F - F_d + F_d \\ &- \theta^T \xi - K_1 s - K_2 s^\rho \frac{q}{p\sigma_2} \dot{A}_1^{2-p/q} - \varphi + \nu + \Delta\tau) \\ &= M_2 \sigma_2 p/q \dot{A}_1^{p/q-1} (\varsigma + \tilde{\theta}^T \xi - K_1 s - K_2 s^\rho \\ &- \varphi + \nu + \varepsilon + \Delta\tau) \end{aligned} \tag{65}$$

where $\varsigma = -Q_d + F - F_d$ and $K_1 = ({K_{11}}^T, {K_{21}}^T, ..., {K_{n1}}^T)$, $K_2 = ({K_{12}}^T, {K_{22}}^T, ..., {K_{n2}}^T)$, $\varphi = ({\varphi_1}^T, {\varphi_2}^T, ..., {\varphi_n}^T)$, $\varepsilon = ({\varepsilon_1}^T, {\varepsilon_2}^T, ..., {\varepsilon_n}^T)$, $\theta^* = diag({\theta_1^*}^T, {\theta_2^*}^T, ..., {\theta_n^*}^T))$, $\theta = diag({\theta_{1\pi}}^T, {\theta_{2\pi}}^T, ..., {\theta_{n\pi}}^T))$, $\theta_\pi^* = \theta^* - \theta_\pi$, and $\xi = ({\xi_1}^T, {\xi_2}^T, ..., {\xi_n}^T)$.

Consider the following Lyapunov function candidate

$$V = \frac{1}{2} s^T M_2 s + \sum_{i=1}^{n} V_{\theta_i} \tag{66}$$

Thus, the time derivative of V is obtained as

$$\dot{V} = s^T M_2 \dot{s} + \sum_{i=1}^{n} \dot{V}_{\theta_i} \tag{67}$$

Due to the fact that

$$s^T M_2 \sigma_2 p/q \dot{A}_1^{p/q-1} \tilde{\theta}^T \xi - \frac{1}{\delta_i} \sum_{j=1}^{m} \sum_{k=1}^{N_1} \tilde{\theta}_{F_{i\pi,jk}} \dot{\theta}_{i,jk}^* = 0 \tag{68}$$

Substituting the Eqs. (42) and (65) to the Eq. (67), we obtain:

$$\begin{aligned} \dot{V} &= M_2 \sigma_2 p/q \dot{A}_1^{p/q-1} (s^T \varsigma + s^T \tilde{\theta}^T \xi - s^T K_1 s - s^T K_2 s^\rho - s^T \varphi \\ &+ s^T (\nu + \varepsilon + \Delta\tau) - \frac{1}{\delta_i} \sum_{j=1}^{m} \sum_{k=1}^{N_1} \tilde{\theta}_{F_{i\pi,jk}} \dot{\theta}_{i,jk}^*) \\ &= M_2 \sigma_2 p/q \dot{A}_1^{p/q-1} (s^T \varsigma - s^T K_1 s - s^T K_2 s^\rho - s^T \varphi \\ &+ s^T (\nu + \varepsilon + \Delta\tau)) \end{aligned} \tag{69}$$

Using the following inequalities

$$0 \leq -s^T \varphi + s^T (\nu + \varepsilon + \Delta\tau) \leq n\epsilon \tag{70}$$

$$0 \leq s^T \varsigma \leq c_5 s^T s + \frac{{\varsigma^2}_M}{4c_5} \tag{71}$$

where c_5 is a positive constant satisfying $c_5 < \lambda_{min}(K_1)$ with $\lambda_{min}(K_1)$ being the minimum eigenvalue of the matrix K_1, Eq. (69) becomes

$$\begin{aligned} \dot{V} &\leq M_2 \sigma_2 p/q \dot{A}_1^{p/q-1} (-(\lambda_{min}(K_1) - c_5) s^T s + c_4 - s^T K_2 s^\rho) \\ &\leq -M_2 \sigma_2 p/q \dot{A}_1^{p/q-1} |s|^2 \end{aligned} \tag{72}$$

where $c_4 = n\epsilon + \frac{\varsigma_M^2}{4c_5}$ is a positive constant.

$$
\begin{aligned}
-s^T K_2 s^\rho &\le -\lambda_{min}(K_2) \sum_{i=1}^{n}\sum_{j=1}^{m} s_{ij}^{\rho+1} \\
&\le -\lambda_{min}(K_2) \left(\frac{2}{\lambda_{max}}\right)^{(\rho+1)/2} \left(\sum_{i=1}^{n}\sum_{j=1}^{m} \frac{\lambda_{max}}{2} s_{ij}^2\right)^{(\rho+1)/2} \\
&\le -\lambda_{min}(K_2) \left(\frac{2}{\lambda_{max}}\right)^{(\rho+1)/2} \left(0.5 s^T M_2 s\right)^{(\rho+1)/2} \\
&= -\gamma_2 V^{\rho+1}/2
\end{aligned} \tag{73}
$$

where $\gamma_2 = \lambda_{min}(K_2)(2/\lambda_{max}(M_2))^{(\rho+1)/2}$. The Eq. (72) can be expressed as:

$$
\dot{V} \le -\gamma_1 V - \gamma_2 V^{(\rho+1)/2} + c_4 \tag{74}
$$

where $\gamma_1 = 2(\lambda_{min}(K_1) - c_5)/\lambda_{max}(M_2)$.

Then Eq. (74) can be written as the following two forms:

$$
\dot{V} \le -\gamma_1 V - (\gamma_2 - \frac{c_4}{V^{(\rho+1)/2}}) V^{(\rho+1)/2} \tag{75}
$$

From Eq. (75), if $\gamma_1 - c_4/V > 0$, then the finite-time stability is still guaranteed. According to the reference [16], the sliding surface s will reach the region $\|s\| \le \Delta$ in finite time, which means $s_{ij} \le \Delta \quad i = 1, 2, .., n, j = 1, 2, ..., m, i.e..$ All signals in the closed-loop system are uniformly ultimately bounded.

III. Results and Discussion

To study the effectiveness and performance of the proposed controller, the detailed response is numerically simulated using the set of governing system equations of motion Eq. (48) in conjunction with the control laws Eqs. (57-58).

The information exchange among satellite is represented by a graph with the weighted adjacency matrix $\bar{A}$ defined by

$$
\bar{A} = \begin{bmatrix} 0 & 0.5 & 0 & 0 \\ 0.5 & 0 & 0.6 & 0 \\ 0 & 0.6 & 0 & 0.7 \\ 0 & 0 & 0.7 & 0 \end{bmatrix}
$$

Seven Gaussian membership functions are defined for each variable $\tilde{A}_i, i = 1, 2, \cdots, 7$ as:

$$
\begin{aligned}
\mu_{\tilde{A}_1}(s_i) &= \frac{1}{1 + \exp(5(s_i + 0.9 \times a))}, \\
\mu_{\tilde{A}_2}(s_i) &= \exp\left(-\left(\frac{s_i + 0.6 \times a}{b}\right)^2\right), \\
\mu_{\tilde{A}_3}(s_i) &= \exp\left(-\left(\frac{s_i + 0.3 \times a}{b}\right)^2\right), \\
\mu_{\tilde{A}_4}(s_i) &= \exp\left(-\left(\frac{s_i}{b}\right)^2\right), \\
\mu_{\tilde{A}_5}(s_i) &= \exp\left(-\left(\frac{s_i - 0.3 \times a}{b}\right)^2\right), \\
\mu_{\tilde{A}_6}(s_i) &= \exp\left(-\left(\frac{s_i - 0.6 \times a}{b}\right)^2\right), \\
\mu_{\tilde{A}_7}(s_i) &= \frac{1}{1 + \exp(5(s_i - 0.9 \times a))}
\end{aligned} \tag{76}
$$

where a and b are different constant numbers designed according to s_i. In this paper, $a = b = 1$.

In this section, we present the simulation results for the following case I: Desired Attitude Trajectory is $q_d = [0, 0.05cos(0.02t), 0.05sin(0.02t)]^T$. For reaction wheel pyramid configuration, with desired trajectory q_d, after $t = 50s$, the wheels of satellites $three$ and $four$ only supply 40% and 50% of the designed speed. After $t = 70s$ another fault of satellite one occurs: three wheels of satellite one only supply 70% of their design speed and the second wheel's input voltage is zero. There is no fault within satellite two.

To compare the control performances of the nonsingular fast fuzzy terminal sliding control laws defined by Eqs. (57-58), a nonsingular fast terminal sliding mode controller $\hat{\tau}_{rwi}$ is designed in Eq.77 as following:

$$
\hat{\tau}_{rwi} = \ddot{q}_d - K_{i1} s_i - K_{i2} s_i^\rho - \frac{q}{p\sigma_2} a_{i2}^{2-p/q} - \varphi_i \tag{77}
$$

Figs. 1 shows the station-keeping attitude tracking errors by using quaternion $e_i (i = 1, 2, 3, 4)$, respectively. The formation-keeping attitude error case is given in Fig. 2. It is found that the proposed controller can still drive the station-keeping attitude tracking errors and formation-keeping to the neighborhood around zero in finite time even when the faults happened. Therefore, the proposed controller can still provide finite-time control for a group of satellite under actuation faults as in the previous case. Without the Fuzzy Logic System, the station keeping and formation keeping tracking errors can not drive the system back to the neighborhood around zero in finite time.

IV. Conclusions

The primary contribution of this paper is the development and analysis of a decentralized, attitude-coordinated control law that provides finite-time stability and convergence of attitude synchronization. The simulation results clearly establish

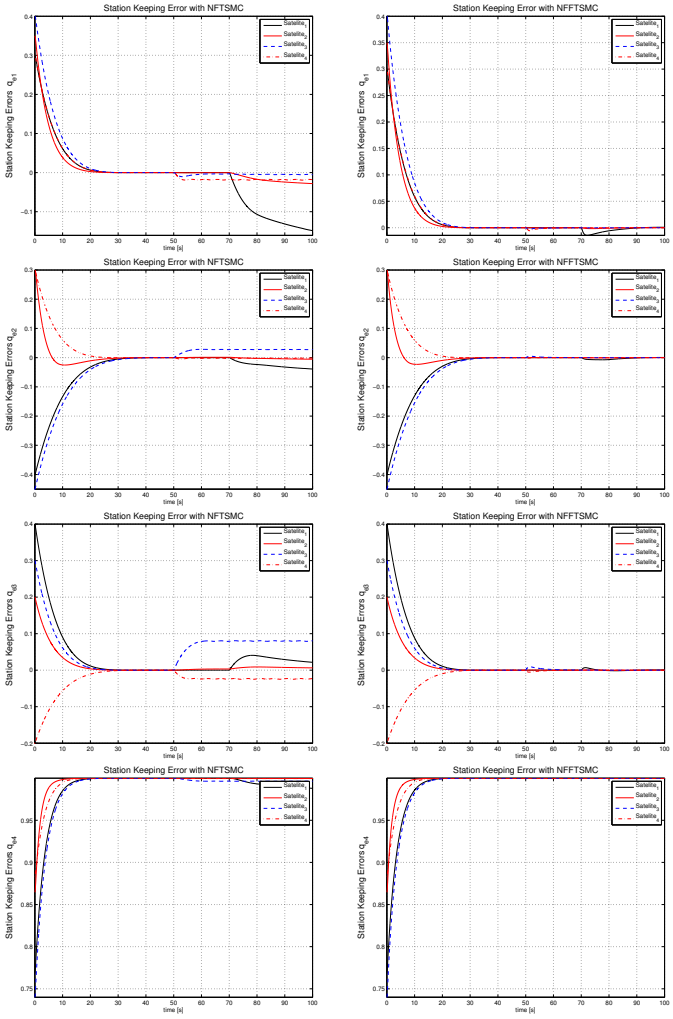

Fig. 1. Station-keeping Tracking Errors using Quaternion Simulation Result without Fuzzy Logic System and with Fuzzy Logic System

the robustness of the proposed adaptive control methodologies using nonsingular fast terminal sliding mode and fuzzy logic systems in tracking the attitude of formation flying satellites in the presence of actuator faults and time-varying disturbances.

***Abstract*—In this paper, we propose a T-S fuzzy model based controller for the H-type gantry stage. The synchronized error, which is caused by mismatch quality and friction, is an important control problem for the H-type gantry stage. Utilizing a Lagrangian equation, all states can be formulated as a state equation. Furthermore, the T-S fuzzy model based controller is designed to reduce velocity error, and the position error can also be obtained through internal transformation. Moreover, by utilizing additional transformations, the stabilization problem can be transformed into a linear matrix inequalities (LMIs) problem. Finally, numerical simulation and experimental results are illustrated to demonstrate that the control scheme can effectively reduce synchronized error and tracking error of a gantry stage.**

Keywords: gantry stage; T-S fuzzy model; Lagrangian equation; Linear Matrix Inequalities (LMIs);

I. INTRODUCTION

With the growth of industrial technology, motion systems with high speed and high precision have attracted increasing study and applications. As a coordinate system, the H-type gantry stage is widely applied in many fields, such as microelectronics, aerospace, solar cells, and flat panel manufacturing and inspection. Two motors of the stage are mounted on parallel slides that simultaneously push the third axis and motor, and a load can be installed on the third axis for applying in different systems. But motion of the load will affect behavior of the two parallel motors on the base, reducing precision and harming the machine's structure. Therefore, control of the synchronous error in the gantry configuration has become a challenge due to the increasing demands for high-speed and high-accuracy manufacturing and inspection.

Generally, the control problem of a gantry stage can be concluded as cascade control and parallel control. Cascade control contains two parallel axes, a master axis and a slave axis. For this control structure, control commands were sent to the master axis, and the response of master axis becomes a new command for slave axis. But the disadvantage of this structure is that it will cause state and input delays. For this reason, most studies adopt parallel control, which is a biaxial structure, can be independently designed, and can give same command simultaneously. Koren proposed cross-coupled biaxial computer control in 1980 [1], and variable-gain cross-coupling controller in 1991 [2]. Other studies utilize the optimum concept to decouple the structure [3-4]. In addition, other cross-coupled controllers have been investigated in parallel control structures [5]. However, these studies all discuss similar control structures. Teo first proposed a Lagrangian model to analyze the H-type gantry stage [6-7].

Fuzzy control technique has been widely used in many physical and engineering systems, especially for systems with incomplete plant information. In addition, fuzzy control has been widely applied to controller designs for nonlinear systems [8-14]. In most of these papers, a so-called Takagi-Sugeno (T-S) fuzzy model is adopted to approximate a nonlinear system, and then a fuzzy controller is designed via the parallel distributed compensation (PDC) scheme to stabilize the T-S fuzzy model. By examining, problems of stability and stabilization, LMI techniques have been adopted to find solutions for the T-S fuzzy model based control system.

In this paper, we propose a novel control scheme based on the Lagrangian model [6-7] and present a systematic design procedure to analyze this model. First we design a T-S fuzzy model based controller for velocity error. Secondly, through

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

state internal transformations, we obtain the controller gains of the velocity error and position error. Furthermore, by utilizing the structure, controller gains can be obtained through the LMIs and the velocity error and position error can be reduced. The main contributions of this paper include: i) first use of a T-S fuzzy model based control scheme for the H-type gantry stage, ii) propose a transformation method to transform the velocity error gains into position error gains, and iii) formulation all of stability and stabilization conditions into an LMI form.

This paper is organized as follows. In Section II, we discuss the development of dynamic Lagrangian model of gantry stage. In section III, the T-S fuzzy model based scheme is designed for this physical model utilizing the Lyapunov direct method, and stability/stabilization conditions are proposed to guarantee the system is asymptotic stable. Numerical simulation and experimental results are illustrated in Section IV. Finally, conclusions are given in Section V.

II. DYNAMIC MODELING OF GANTRY SYSTEM

A. Description of a gantry stage

A typical gantry mechanism and the corresponding coordinates are shown in Fig. 1. It can be considered as a three-degree-of-freedom servo mechanism. Two servo motors in y axis, considered in this paper are PMLSMs, carry a gantry on which a slider in x axis holding the inspection tool is mounted. Two motors on the y axis yield displacement d_{y_1} and d_{y_2} respectively. These two displacements will be equal when the two servo motors move synchronously, that implies $d_{y_1} = d_{y2}$. But in practice, their movements will be different due to the different dynamics exhibited in the two servo motors and the time-varying loading presented by translation of the slider along the gantry. The central point C of the gantry is thus constrained to move along the central dashed line with one degree of freedom. Due to the deviation between d_{y_1} and d_{y_2}, the gantry may also rotate about the center C, and the rotated angle is indicated as θ.

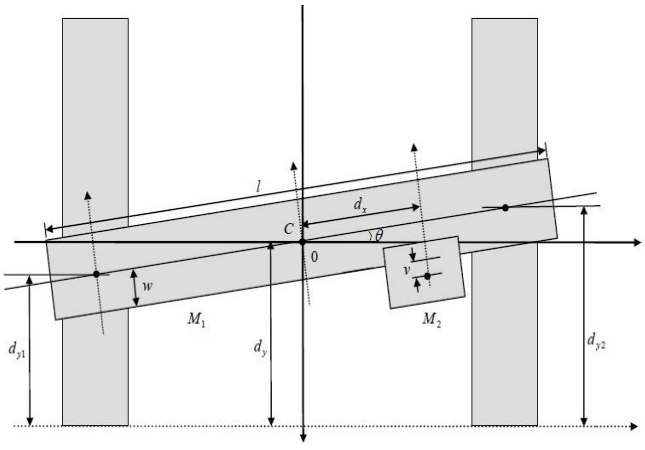

Figure 1. Three-degree-of-freedom scheme.

B. Lagrangian-based three-degree-of-freedom dynamic model

Let M_1 and M_2 denote the mass of the gantry and the slider, respectively; l and $2w$ denote the length and width of the gantry, respectively; and I_{M_1} and I_{M_2} denote the moment of inertia of the gantry and of the slider corresponding to the cntrer point C, respectively.

$$I_{M_1} = \frac{M_1}{12}\left(l^2 + (2w)^2\right) \tag{1}$$

$$I_{M_2} = M_2\left(d_x{}^2 + (w+v)^2\right) \tag{2}$$

Then the positions corresponding to the center of gravity of M_1 and M_2, $\mathbf{p}_{M_1}$ and $\mathbf{p}_{M_2}$ are represented as

$$\mathbf{p}_{M_1} = \begin{bmatrix} 0 \\ d_y \end{bmatrix} \tag{3}$$

$$\mathbf{p}_{M_2} = \begin{bmatrix} d_y - (w+v)\cos\theta + d_x \sin\theta \\ d_x \cos\theta + (w+v)\sin\theta \end{bmatrix} \tag{4}$$

where $d_y = d_{y1} + \left(d_{y2} - d_{y1}\right)/2$. The velocities corresponding, $\mathbf{v}_{M_1}$ and $\mathbf{v}_{M_2}$, to the center of gravity of M_1 and M_2 are represented as

$$\mathbf{v}_{M_1} = \begin{bmatrix} 0 \\ \dot{d}_y \end{bmatrix} \tag{5}$$

$$\mathbf{v}_{M_2} = \begin{bmatrix} \dot{d}_y + (w+v)\dot{\theta}\sin\theta + \dot{d}_x \sin\theta + d_x\dot{\theta}\cos\theta \\ \dot{d}_x \cos\theta - d_x\dot{\theta}\sin\theta + (w+v)\dot{\theta}\cos\theta \end{bmatrix} \tag{6}$$

Then the translational and rotational kinetic energy of the gantry and slider are shown as

$$K_{M_1} = \frac{1}{2}M_1 \mathbf{v}_{M_1}{}^T \mathbf{v}_{M_1} + \frac{1}{2}I_1\dot{\theta}^2 \tag{7}$$

$$K_{M_2} = \frac{1}{2}M_2 \mathbf{v}_{M_2}{}^T \mathbf{v}_{M_2} + \frac{1}{2}I_2\dot{\theta}^2 \tag{8}$$

Thus the total kinetic energy may be computed as

$$K = K_{M_1} + K_{M_2}$$

$$= \frac{1}{2}M_1 \mathbf{v}_{M_1}{}^T \mathbf{v}_{M_1} + \frac{1}{2}M_2 \mathbf{v}_{M_2}{}^T \mathbf{v}_{M_2} + \frac{1}{2}\left(I_1 + I_2\right)\dot{\theta}^2$$

$$= \frac{1}{2}\left(M_1 + M_2\right)\dot{d}_y{}^2 + \frac{1}{2}\left(I_1 + I_2 + M_2 d_x^2 + M_2(w+v)^2\right)\dot{\theta}^2$$

$$+\frac{1}{2}M_2\dot{d}_x^2+\dot{d}_y\dot{\theta}M_2\left[(w+v)\sin\theta+d_x\cos\theta\right]$$

$$+\dot{d}_y\dot{d}_xM_2\sin\theta+\dot{\theta}\dot{d}_xM_2(w+v) \tag{9}$$

which can be further written as

$$K=\frac{1}{2}\dot{\mathbf{X}}^T\mathbf{D}\dot{\mathbf{X}} \tag{10}$$

where $\mathbf{X}=\begin{bmatrix}d_y & \theta & d_x\end{bmatrix}^T$ and $\mathbf{D}$ is the inertia matrix given by

$$\mathbf{D}=\begin{bmatrix} M_1+M_2 & M_2(w+v)\sin\theta+M_2d_x\cos\theta & M_2\sin\theta \\ I_1+I_2+M_2d_x^2+M_2(w+v)^2 & M_2(w+v) & \\ M_2(w+v) & M_2 & \end{bmatrix} \tag{11}$$

The government equation of the gantry mechanism can be derived from the Lagrange equation

$$\frac{d}{dt}\left[\frac{\partial L}{\partial\dot{\mathbf{X}}}\right]-\frac{\partial L}{\partial\mathbf{X}}=\mathbf{F}+\mathbf{U} \tag{12}$$

where $L=K-V$, in which K is the summation of kinetic energy, V is potential energy and $\mathbf{U}$ is the driven force provided by motor and $\mathbf{F}$ is the friction force. Next, derive the elements of the Coriolis and centrifugal matrix $\mathbf{C}$ from

$$C_{ij}=\sum_{k=1}^{3}\left(c_{ijk}\dot{q}_k\right) \tag{13}$$

where d_{ij} represents the element in the i th row and j th column of the inertia matrix $\mathbf{D}$. Substituting the inertia equations I_1 and I_2 into (11) and computing (13), the matrix $\mathbf{C}$ can be obtained as

$$\mathbf{C}=M_2\begin{bmatrix} 0 & -d_x\dot{\theta}\sin\theta+d\dot{\theta}\cos\theta+\dot{d}_x\cos\theta & \dot{\theta}\cos\theta \\ \left(-d_x\sin\theta+d\cos\theta\right)\dot{d}_y+2d_x\dot{d}_x & 2d_x\dot{\theta}+\dot{d}_y\cos\theta & \\ 2d_x\dot{\theta}+\dot{d}_y\cos\theta & 0 & \end{bmatrix} \tag{14}$$

Finally, the dynamic model of the gantry position stage can be represtented as

$$\mathbf{D}\ddot{\mathbf{X}}+\mathbf{C}\dot{\mathbf{X}}=\mathbf{E}(\mathbf{U}-\mathbf{F}) \tag{15}$$

where

$$\mathbf{E}=\begin{bmatrix} 1 & 1 & 0 \\ l\cos\theta & -l\cos\theta & 0 \\ 0 & 0 & 1 \end{bmatrix} \tag{16}$$

$$\mathbf{F}=\begin{bmatrix}F_{y1}, & F_{y2}, & F_x\end{bmatrix}^T \tag{17}$$

$$\mathbf{U}=\begin{bmatrix}u_{y1}, & u_{y2}, & u_x\end{bmatrix}^T \tag{18}$$

F_{y1}, F_{y2} and F_x are the frictional forces, and u_{y1}, u_{y2} and u_x are the generated mechanical forces along d_{y1}, d_{y2} and d_x respectively. The frictional forces are described as LuGre Model

$$\frac{dz}{dt}=v-\sigma_0\frac{|v|}{g(v)}z \tag{19}$$

$$F_i=\sigma_0z+\sigma_1\frac{dz}{dt},\quad i=y1,y2,x \tag{20}$$

The LuGre model proposed by C. Canudas de Wit [15], can capture most of the known frictional behaviors and is suitable for control systems. Here z is the average bending displacement of virtual bristles between the interface of two bodies, $g(v)$ is a positive function of velocity, and where σ_0 and σ_1 are the stiffness and damping coefficients of average behavior of bristles.

III. T-S FUZZY MODEL BASED CONTROLLER DESIGN

In this study, a controller based on the T-S fuzzy model, used to enhance the approximate ability of nonlinear system, is proposed to control the gantry position stage. Further rewrite the state equation (15) as

$$\ddot{\mathbf{X}}(t)=\mathbf{A}\dot{\mathbf{X}}(t)+\mathbf{B}\mathbf{U}(t) \tag{21}$$

where $\mathbf{A}=-\mathbf{D}^{-1}\mathbf{C}$ and $\mathbf{B}=\mathbf{D}^{-1}\mathbf{E}$. We propose a novel control scheme based on the T-S fuzzy model, as shown in Fig. 2, to simultaneously achieve two control objectives: 1) position and velocity control of the gantry and slider, and 2) minimization of the synchronous position and velocity errors.

According to T-S fuzzy modeling method, the following equation can be obtained

$$\ddot{\mathbf{X}}(t)=\sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2}h_iw_jp_k(z(t))(\mathbf{A}_{ijk}\dot{\mathbf{X}}(t)+\mathbf{B}_{ijk}\mathbf{U}(t)) \tag{22}$$

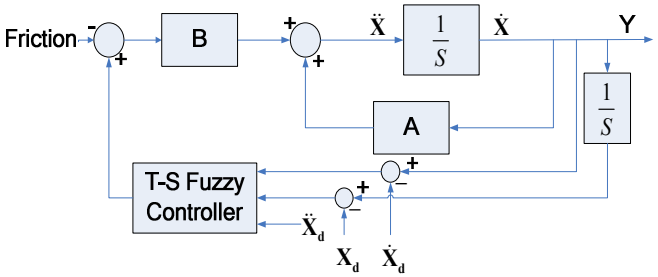

Figure 2. T-S fuzzy model based control scheme.

where $h_i w_j p_k(z(t)) = h_i(z(t)) w_j(z(t)) p_k(z(t))$. Two fuzzy rules of $\dot{d}_y(t)$, $\dot{\theta}(t)$ and $\dot{d}_x(t)$ are adopted in this study. The boundary of $\dot{d}_y(t)$ and $\dot{d}_x(t)$ are chosen as the maximum speed of servo motor which is about $\pm 0.5 m/s$, and the boundary of $\dot{\theta}(t)$ is chosen as $\pm 0.1 rad/s$, shown in Table. I and Fig. 3.

A. T-S fuzzy model based controller design

In general, the velocity tracking controller can be designed based on a T-S fuzzy model. That implies the objective is required to satisfy $[\dot{\mathbf{X}}(t) - \dot{\mathbf{X}}_\mathbf{d}(t)] \to 0$ as $t \to \infty$, where $\dot{\mathbf{X}}(t) = \begin{bmatrix} \dot{d}_y & \dot{\theta} & \dot{d}_x \end{bmatrix}^T$ and $\dot{\mathbf{X}}_\mathbf{d}(t)$ represent the velocity response and desired velocity command, respectively. Hence, the acceleration tracking error can be derived as

$$\begin{aligned}
\ddot{\tilde{\mathbf{X}}}(t) &= \ddot{\mathbf{X}}(t) - \ddot{\mathbf{X}}_\mathbf{d}(t) \\
&= \sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} h_i w_j p_k(z(t))(\mathbf{A}_{ijk}\dot{\mathbf{X}}(t) + \mathbf{B}_{ijk}\mathbf{U}(t)) - \ddot{\mathbf{X}}_d(t) \\
&= \sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} h_i w_j p_k(z(t))\mathbf{A}_{ijk}\dot{\mathbf{X}}(t) \\
&\quad - \sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} h_i w_j p_k(z(t))\mathbf{A}_{ijk}\dot{\mathbf{X}}_\mathbf{d}(t) \\
&\quad + \sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} h_i w_j p_k(z(t))\mathbf{B}_{ijk}\mathbf{U}(t) \\
&\quad + \sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} h_i w_j p_k(z(t))\mathbf{A}_{ijk}\dot{\mathbf{X}}_\mathbf{d}(t) - \ddot{\mathbf{X}}_\mathbf{d}(t)
\end{aligned} \tag{23}$$

Furthermore, we design a reference control effort $\boldsymbol{\tau}(t)$ and it must be satisfied

$$\sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} h_i w_j p_k(z(t))\mathbf{B}_{ijk}\boldsymbol{\tau}(t)$$

$$= \sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} h_i w_j p_k(z(t))\mathbf{B}_{ijk}\mathbf{U}(t)$$

$$+ \sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} h_i w_j p_k(z(t))\mathbf{A}_{ijk}\dot{\mathbf{X}}_\mathbf{d}(t) - \ddot{\mathbf{X}}_\mathbf{d}(t) \tag{24}$$

Substituting (24) into (23), the following equation can be obtained

$$\ddot{\tilde{\mathbf{X}}}(t) = \sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} h_i w_j p_k(z(t))\mathbf{A}_{ijk}\dot{\tilde{\mathbf{X}}}(t)$$

$$+ \sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} h_i w_j p_k(z(t))\mathbf{B}_{ijk}\boldsymbol{\tau}(t) \tag{25}$$

According to each rule of $h_i(z(t))$, $w_j(z(t))$ and $p_k(z(t))$, the new controller is designed as

$$\boldsymbol{\tau}(t) = -\mathbf{k}_{ijk}\dot{\tilde{\mathbf{X}}}(t) \tag{26}$$

Substituting (26) into (25), the closed loop form can be rewritten as

$$\ddot{\tilde{\mathbf{X}}}(t) = \sum_{i=1}^{2}\sum_{l=1}^{2}\sum_{j=1}^{2}\sum_{m=1}^{2}\sum_{k=1}^{2}\sum_{n=1}^{2} h_i w_j p_k(z(t)) h_l w_m p_n(z(t))(\mathbf{A}_{ijk} - \mathbf{B}_{ijk}\mathbf{k}_{lmn})\dot{\tilde{\mathbf{X}}}(t) \tag{27}$$

Let

$$\alpha(t) = \sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} h_i w_j p_k(z(t))\mathbf{A}_{ijk}$$

$$\beta(t) = \sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} h_i w_j p_k(z(t))\mathbf{B}_{ijk}$$

The relationship between actual and reference control efforts can be obtained from (24) as

$$\beta(t)(\mathbf{U}(t) - \boldsymbol{\tau}(t)) = -\alpha(t)\dot{\mathbf{X}}_\mathbf{d}(t) + \ddot{\mathbf{X}}_\mathbf{d}(t) \tag{28}$$

Then, substituting (28) into (25), the control effort $\mathbf{U}(t)$ in the controller can be obtained as

$$\mathbf{U}(t) = -\sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} h_i w_j p_k(z(t))\mathbf{k}_{ijk}\dot{\tilde{\mathbf{X}}}(t)$$

$$+ \beta^{-1}(t)(\ddot{\mathbf{X}}_\mathbf{d}(t) - \alpha(t)\dot{\mathbf{X}}_\mathbf{d}(t)) \tag{29}$$

TABLE I. FUZZY IF-THEN RULE

Rule		If	Then
$\dot{d}_y(t)$	$i=1$	$\dot{d}_y(t) \approx 0.5$	$h_1(z(t))=1, h_2(z(t))=0$
	$i=2$	$\dot{d}_y(t) \approx -0.5$	$h_1(z(t))=0, h_2(z(t))=1$
$\dot{\theta}(t)$	$j=1$	$\dot{\theta}(t) \approx 0.1$	$w_1(z(t))=1, w_2(z(t))=0$
	$j=2$	$\dot{\theta}(t) \approx -0.1$	$w_1(z(t))=0, w_2(z(t))=1$
$\dot{d}_x(t)$	$k=1$	$\dot{d}_x(t) \approx 0.5$	$p_1(z(t))=1, p_2(z(t))=0$
	$k=2$	$\dot{d}_x(t) \approx -0.5$	$p_1(z(t))=0, p_2(z(t))=1$

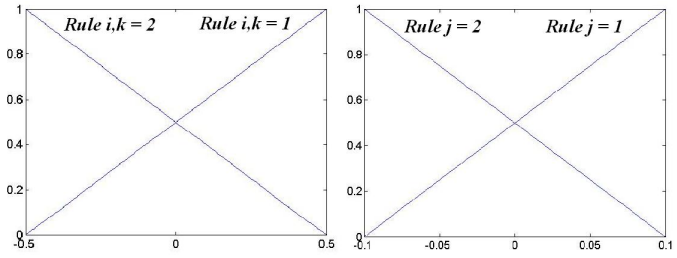

Figure 3. Membership function of rule i, j, k

B. T-S fuzzy model based controller with internal transformation

In the previous section, the controller is designed for velocity error, but real applications always demand high-precision position control. To design a new control gain of position error, first divide $\mathbf{k}_{ijk}$ into $\mathbf{k}_{ijk}^1$ and $\mathbf{k}_{ijk}^2$ as

$$\mathbf{k}_{ijk} = \mathbf{k}_{ijk}^1 + \mathbf{k}_{ijk}^2 \tag{30}$$

To obtain the information of $\tilde{\mathbf{X}}(t)$, design a new feedback controller $\mathbf{U}_{ijk}^2(t)$ to satisfy

$$\dot{\tilde{\mathbf{X}}}(t) = \mathbf{k}_{ijk}^{2\,-1}(\tilde{\mathbf{X}}(t) + \mathbf{U}_{ijk}^2(t)) \tag{31}$$

where $\mathbf{U}_{ijk}^2(t)$ is designed as (32), and the closed loop form can be obtained as (33)

$$\mathbf{U}_{ijk}^2(t) = -\mathbf{h}_{ijk}\tilde{\mathbf{X}}(t) \tag{32}$$

$$\dot{\tilde{\mathbf{X}}}(t) = \mathbf{k}_{ijk}^{2\,-1}(\mathbf{I} - \mathbf{h}_{ijk})\tilde{\mathbf{X}}(t) \tag{33}$$

Substituting (33) into (29), $\mathbf{U}(t)$ can be rewritten as

$$\mathbf{U}(t) = -\sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} h_i w_j p_k(z(t))(\mathbf{k}_{ijk}^1 \dot{\tilde{\mathbf{X}}}(t) + (\mathbf{I} - \mathbf{h}_{ijk})\tilde{\mathbf{X}}(t))$$

$$+\beta^{-1}(t)(\ddot{\mathbf{X}}_{\mathbf{d}}(t) - \alpha(t)\dot{\mathbf{X}}_{\mathbf{d}}(t)) \tag{34}$$

The T-S fuzzy model based controller with our proposed internal transformation is shown in Fig. 4.

C. Lyapunov stability analysis

The augmented matrix of velocity and position tracking errors is given by

$$\mathbf{\Phi}^T(t) = [\dot{\tilde{\mathbf{X}}}^T(t) \quad \tilde{\mathbf{X}}^T(t)]^T \tag{35}$$

After internal transformation, the following equation will be satisfied.

$$\dot{\mathbf{\Phi}}(t) = \boldsymbol{\gamma}\mathbf{\Phi}(t) \tag{36}$$

where

$$\boldsymbol{\gamma} = \begin{bmatrix} \alpha(t) - \beta(t)\mathbf{k}_{ijk} & 0 \\ 0 & \sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} h_i w_j p_k(z(t))(\mathbf{k}_{ijk}^{2\,-1}(\mathbf{I} - \mathbf{h}_{ijk})) \end{bmatrix} \tag{37}$$

The Lyapunov function can be represented as $V(\mathbf{\Phi}(t)) = \mathbf{\Phi}^T(t)\mathbf{P}\mathbf{\Phi}(t)$, where $\mathbf{P}$ is chosen a positive matrix, and the differential of the Lyapunov function can be represented as

$$\dot{V}(\mathbf{\Phi}(t)) = \dot{\mathbf{\Phi}}^T(t)\mathbf{P}\mathbf{\Phi}(t) + \mathbf{\Phi}^T(t)\mathbf{P}\dot{\mathbf{\Phi}}(t)$$

$$= \mathbf{\Phi}^T(t)\boldsymbol{\gamma}^T\mathbf{P}\mathbf{\Phi}(t) + \mathbf{\Phi}^T(t)\mathbf{P}\boldsymbol{\gamma}\mathbf{\Phi}(t)$$

$$= \mathbf{\Phi}^T(t)(\boldsymbol{\gamma}^T\mathbf{P} + \mathbf{P}\boldsymbol{\gamma})\mathbf{\Phi}(t) \tag{38}$$

From (37), $\mathbf{A} - \mathbf{B}\mathbf{k}_{ijk}$ and $\mathbf{k}_{ijk}^{2\,-1}(\mathbf{I} - \mathbf{h}_{ijk})$ can be separately designed by the separation theorem. In addition, the choice of $\mathbf{k}_{ijk}^2$ must guarantee that $\mathbf{k}_{ijk}^{2\,-1}$ exists. Then we can obtain positive definite matrix $\mathbf{P_1}, \mathbf{P_2}$ and feedback gains $\mathbf{k}_{ijk}, \mathbf{h}_{ijk}$ by using iteration method to solve linear matrix inequalities (LMIs). Therefore, the condition of $\dot{V}(\mathbf{\Phi}(t)) < 0$ can be obtained because $\boldsymbol{\gamma}$ is negative definite, which implies the system will be asymptotic stable.

IV. SIMULATION AND EXPERIMENTAL RESULTS

A. Simulation Results

To verify the effectiveness of the proposed T-S fuzzy model based controller, the PID control which using three PID controllers for each independent axis is proposed in this study to compare the control performance. For the PID controller, time-domain tuning design is used to find the parameters, and MATLAB simulation is used for two cases. The measurement parameters of gantry system are selected as follows: M_1 =2.88kg, M_2 =0.5kg, l =0.5m, w =0.0285m, and the LuGre friction parameters are $\sigma_0 = 230.087$,

$\sigma_1 = 35.835$, $F_c = 0.72$, $F_s = 2.15$, $v_s = 0.005$. The high speed sine command (position, velocity) is depicted in Fig. 5.

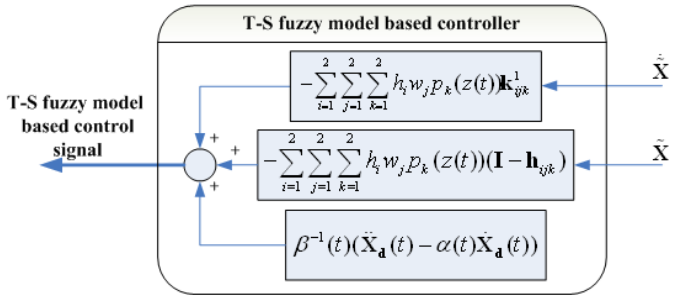

Figure 4. T-S fuzzy model based controller with control internal transformation.

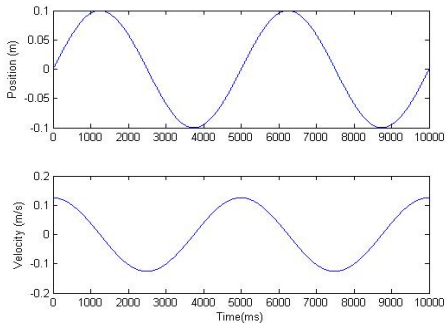

Figure 5. Desired high speed sine command.

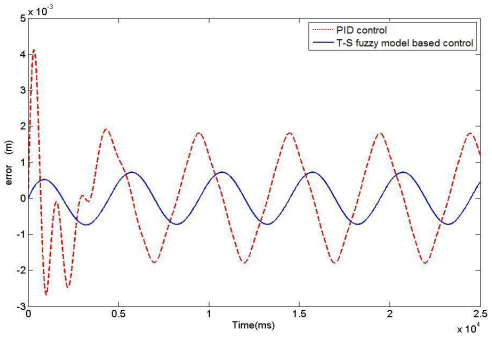

Figure 6. Tracking error of d_y (m).

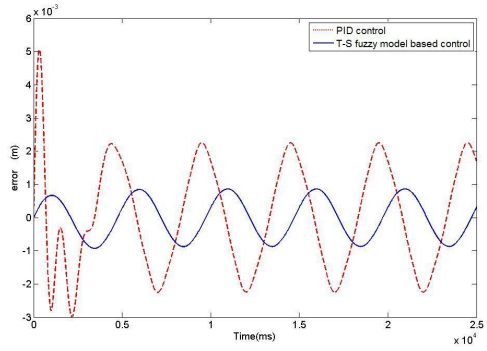

Figure 7. Tracking error of d_x (m).

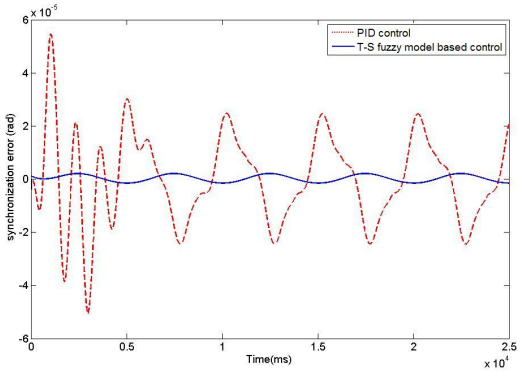

Figure 8. Synchronized error (rad).

TABLE II. SIMULATION RESULTS

Performance index \ Control system		PID control	T-S fuzzy model based control
Tracking error of d_y (m)	*Max*	0.0041	0.000742
	IAE	27.4033	11.1556
Tracking error of d_x (m)	*Max*	0.0051	0.000929
	IAE	35.3768	13.5032
synchronized error (rad)	*Max*	5.47×10^{-5}	3.79×10^{-6}
	IAE	0.3389	0.0282

The simulation results showing the error responses of d_y , d_x are depicted in Fig. 6 and Fig. 7, while the synchronized error(θ) is shown in Fig. 8. The high speed sine command initially rises fast, usually bringing with it a large error. From Fig. 6 and Fig. 7, the T-S fuzzy model based control outperforms the PID control, especially at the beginning. So when the velocity changes quickly, the proposed approach quickly yields significantly improved performance over PID control.

Fig. 8 shows that the proposed control algorithm provides cross-coupled control signal from state θ , which can dramatically reduce the synchronized error, better than PID independence control. Furthermore, the E_{Max} and E_{IAE} from the Table. II illustrate that the proposed control algorithm can minimize the tracking error and synchronized error.

B. Experimental Results

The block diagram of the DSP-based computer-controlled gantry position stage is shown in Fig. 9. A TMS320VC33 floating-point DSP is the core of the control computer. In addition, the control computer includes multi-channels of analog-to-digital converters (ADCs), digital-to-analog converters (DACs), parallel input/output (PIO) and encoder interface. The resolution of the linear scales for the PMLSM is $1\mu m$. Furthermore, the proposed control algorithms are

realized in the DSP using the "C" and "Assembly" languages. All the programs are developed under a Windows environment in a PC and then downloaded to the Flash ROM of the DSP.

The methodology proposed for the implementation of the real-time T-S fuzzy model based control system consists of a main program and one interrupt service routine (ISR). In the main program, parameters and input/output initialization are set first. Next, the interrupt interval for the ISR is set. After enabling the interrupt, the ISR with 1ms sampling rate is used for the encoder interface and DACs. The ISR first reads the positions of the three PMLSMs of the gantry position stage from the encoders and the velocities of the three PMLSMs of the gantry position stage are derived from the positions. Then the ISR calculates the tracking errors and generates the control Efforts $\mathbf{U}(t)$, according to the proposed control algorithms. Finally, the calculated commands are sent to the x-axis, $y1$-axis and $y2$-axis motor servo drives via three DACs. Photos of the experimental setup, including the gantry position stage, PMLSM drives and DSP-based control computer are shown in Fig. 10. Moreover, the field-oriented control mechanism is implemented in the PMLSM drives.

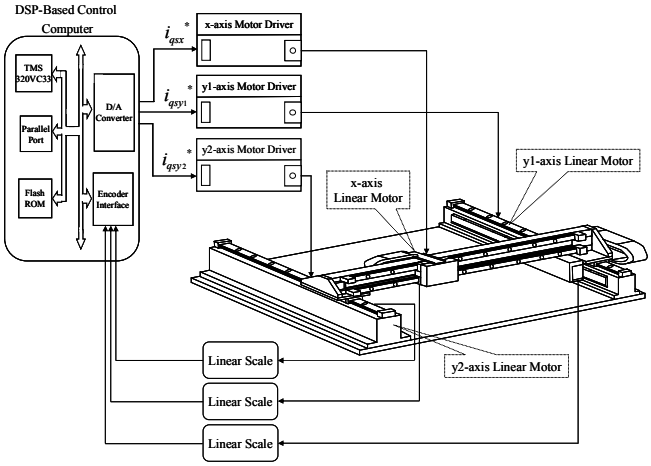

Figure 9. DSP-based computer-controlled gantry stage.

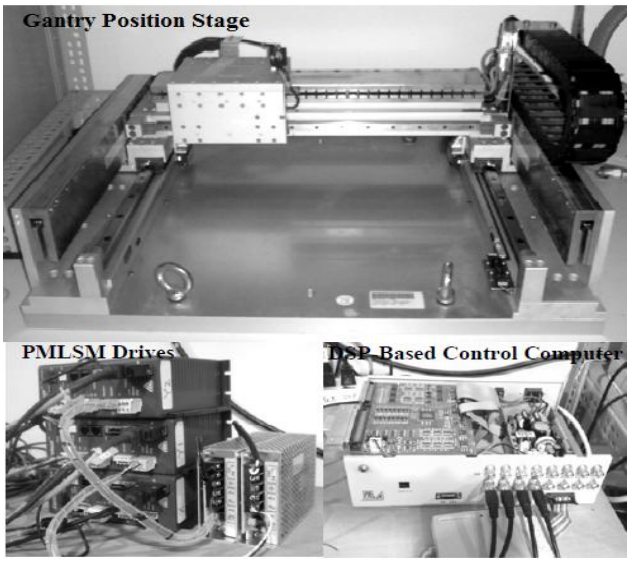

Figure 10. Experimental setup.

For PID-controlled implementation, where system identification is necessary, the closed velocity loop was excited by 1 volt step input as a test input and its output was recorded with a data acquisition system. From the experimental data, the approximate model parameters were obtained assuming the first order approximation as follows

$$G_i(s) = \frac{K_i}{\tau_i s + 1} (i = d_{y_1}, d_{y_2}, d_x) \tag{39}$$

The system Identification Toolbox in MATLAB can solve the parameters in (39), obtaining three transfer functions. Based on time-domain tuning design, the independent PID controllers are tuned as $K_{Py1} = 36.724$, $K_{Py2} = 35.883$, $K_{Px} = 33.671$, $K_{Iy1} = 1.386$, $K_{Iy2} = 1.353$, $K_{Ix} = 1$, $K_{Dy1} = 0.173$, $K_{Dy2} = 0.169$, $K_{Dx} = 0.125$.

Trajectory commands of the software simulation are used and the results are shown in Figs. 11–13. Fig. 11 and Fig. 12 are similar to the software simulations results, in steady state, performance of the T-S fuzzy model based controller is nearly the same as the PID controller, but it can effectively reduce the tracking error when the velocity is changing quickly. The E_{Max} and E_{IAE} from Table. III show that the T-S fuzzy model based controller is effective than the PID controller, especially in E_{Max}. In addition, Fig. 13 shows that the T-S fuzzy model based controller is able to minimize the synchronized error, whereas the PID controllers were only able to track individual trajectories independently. Table. III also shows the E_{Max} and E_{IAE} of synchronized error are reduced to 42.7% and 81.6 % respectively when using T-S fuzzy model based control.

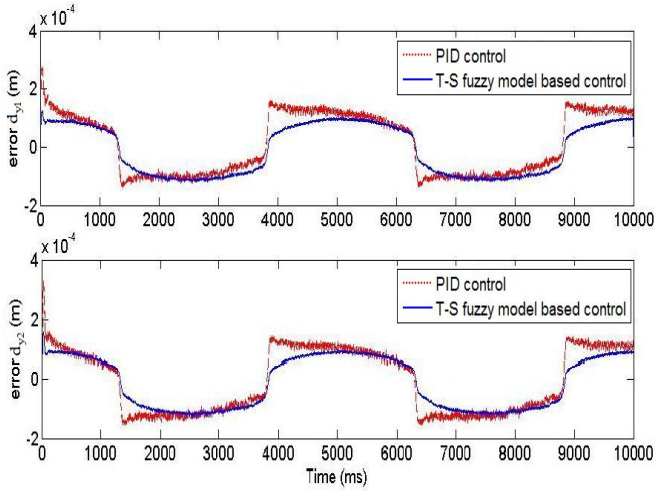

Figure 11. Tracking error of d_{y_1} , d_{y_2} respectively (m).

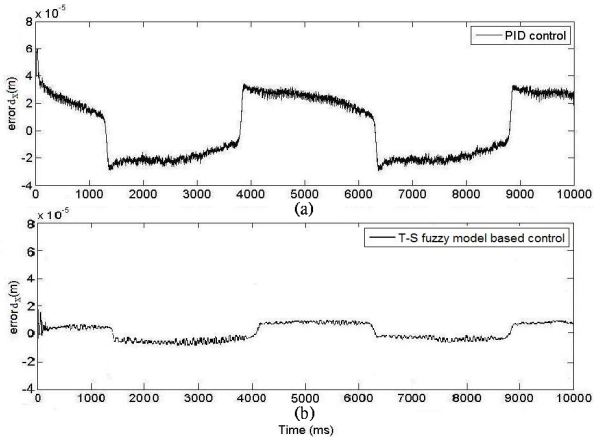

Figure 12. Tracking error of d_X using (a) PID control and (b)T-S fuzzy model based control.

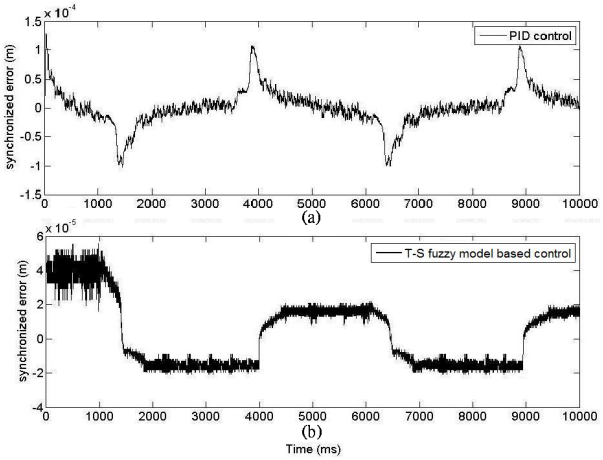

Figure 13. Synchronized error (m). Using (a) PID control, (b)T-S fuzzy model based control.

TABLE III. EXPERIMENTAL RESULTS

V. CONCLUTION

In this paper, we propose a T-S fuzzy model based controller for a gantry stage. Utilizing the Lagrangian equation, all states can be formulated as a state equation. Then a novel T-S fuzzy model based control scheme is proposed to achieve two control objectives together: 1) position and velocity control of the gantry and slider, and 2) minimization of the synchronous position and velocity errors. The simulation and experimental results show that this control system can dramatically decrease both the tracking error and synchronized error.

***Abstract*—In this paper, a novel observer-based adaptive fuzzy-neural network (FNN) control scheme for robotic systems is proposed for tracking performance and to suppress the effects caused by uncertainties, and disturbances. A PSO-SA based adaptive FNN system is used to approximate an unknown system from the manipulation of the model following tracking errors. The proposed scheme uses an observer, which allows for identifying the state of an unknown state in the system, simultaneously. It is shown that the proposed control scheme can guarantee the better tracking performance and suppress internal uncertainties or external disturbance. Simulations are given to show the validity and confirm the performance of the proposed scheme.**

I. INTRODUCTION

Recently, adaptive fuzzy control methods have been proposed to deal with nonlinear systems [1-5]. Based on the universal approximation theorem [1], adaptive fuzzy control schemes have been developed for a class of nonlinear uncertain systems [2]. In above schemes, the stability of the closed-loop system is established according to Lyapunov's theory. In order to process approximation errors and external disturbances, these adaptive fuzzy controllers are added by a robust compensator. However, in such schemes are based on the assumption that the states of the systems are measured directly.

Hence, the design of the observer for an uncertain nonlinear system is a very important issue. Direct and indirect adaptive fuzzy control schemes have been developed based on state or error observers [6-9]. In [8,10], the authors developed indirect and direct adaptive fuzzy controllers based on an observer for a class of single-input single-output (SISO) and multi-input multi-output (MIMO) nonlinear systems, respectively. In above schemes, the adaptive fuzzy control scheme can ensure the stability of the closed-loop system and achieve a prescribed tracking performance. However, most of adaptive fuzzy control scheme are usually operated based on human knowledge. Thus, they pose additional difficulties to the stabilization control design and, especially, the tracking control design. In order to overcome shortcomings in the design of a controller, various methods have been developed in the last decades. In this, a successful scheme is fuzzy logic control with tuning capability in neural weights. Recently, adaptive FNN control has attracted increasing attention, essentially because it can provide a powerful learning technique for complex unknown plants to perform complex tasks in highly nonlinear dynamical environments. Furthermore, it can make available information from repetitive adjustment of the system with better performance than those of adaptive fuzzy schemes with constant rules [11,12]. However, mathematical expressions of FNN must be derived for each network layer of a network topology, and it is very difficult to find the optimum solution. In order to overcome these drawbacks, the particle swarm optimization (PSO) based method is proposed.

Particle swarm optimization (PSO) is a relatively novel evolutionary algorithm that may be used to find optimal or near optimal solutions in multi-dimensional search spaces [13]. However, for the basic PSO algorithm, all particles are prone to be trapped in the local minimum of the later phase of convergence. The optimal value found is thus often a local minimum instead of a global minimum. To overcome the shortcomings of the basic PSO algorithm, we use a method which combines the PSO algorithm (PSO) with the simulated annealing (SA) algorithm.

The rest of this paper is organized as follows. In Section 2, the system description and the design of the FNN system are presented. The adaptive FNN controller based on PSO-SA and combined with observer is described in Section 3. Numerical simulations are given and the results show that the designed observers and controllers are feasible and valid in Section 4. Finally, conclusions are given in Section 5.

II. Problem Statement and Preliminaries

Consider the dynamical equation of an n -link robotic manipulator with external disturbances .The class of uncertain nonlinear systems to be studied in this paper is described by the following set of time-varying differential equations:

$$\mathbf{M}(q)\ddot{q} + c(q,\dot{q}) + g(q) + \tau_d(q,\dot{q}) + \tau_c(q,\dot{q}) = u\,, \qquad (1)$$

where $\mathbf{M}(q) \in \mathbf{R}^{n\times n}$ is the bounded positive definite inertia matrix; $c(q,\dot{q}) \in \boldsymbol{R}^n$ is the vector expressing centrifugal and Coriolis effects; $g(q)$ is the vector representing gravitational torques; $\tau_c(q,\dot{q}) \in R^n$, $\tau_d(q,\dot{q}) \in R^n$ are the vectors which represent the dynamic effects as nonlinear frictions, and bounded torque disturbances.

$u \in R^n$ is the vector of joint torques; $q \in R^n$ the vector of joint positions; $\dot{q} \in R^n$ the vector of joint velocities; and $\ddot{q} \in R^n$ is the vector of joint accelerations. Here $\boldsymbol{x} = [x_1, \cdots, x_n]^T \in R^n$, is the state vector which is assumed to be unavailable for measurement, the robot model (1) can be rewritten as:

$$\dot{x} = Ax + B\left[F(q,\dot{q}) + G(q)u + \Delta d(q,\dot{q})\right]\,, \qquad (2)$$

where

$F(q,\dot{q}) = \left[f_1(q,\dot{q}), \cdots, f_n(q,\dot{q})\right]^T$, $G(q) = \left[G_1(q), \cdots, G_n(q)\right]$, $G_i(q) = \left[g_{1i}(q), \cdots, g_{ni}(q)\right]^T$, $A = diag\left[A_1, \cdots, A_n\right]$, $B = diag\left[B_1, \cdots, B_n\right]$, $\Delta d(q,\dot{q}) = \left[\Delta d_1(q,\dot{q}), \cdots, \Delta d_n(q,\dot{q})\right]^T$.

The following assumption is made for the controller design:

Assumption 2.1. [14] The matrix $G(q)$, as previously defined, is nonsingular, i.e., $G^{-1}(q)$ exists, and bounded for all $q \in U$, where $U \in R^n$ is a compact set.

Based on Assumption 2.1, if $F(q,\dot{q})$ and $G(q)$ are exact known, with $G^{-1}(q) \neq 0$ and based on the equivalent approach, then the control law can be represented as belows:

$$u = G^{-1}(q)[-F(q,\dot{q}) + y_d^{(n)} - K_c e(t) + u_a(t)]\,, \qquad (3)$$

where K_c is a control gain vector and u_a is designed for compensating the approximation errors and the eliminate disturbance.

Control Objectives:

The tracking control problem can be stated as: for given bounded reference trajectories, the control input torques such as the robot's states follow the reference trajectories, with all involved signals in the closed loop remaining bounded.

Let $y_{1d}, \cdots, y_{nd}$ be the given bounded desired output signal that contains finite derivatives up to the n th order. The tracking errors of the system are found at:

$$\begin{aligned}\dot{e}_{in_i}(t) &= y_i^{(n_i)}(t) - y_{id}^{(n_i)}(t) \\ &= f_i(q,\dot{q}) + \sum_{j=1}^{n} g_{ij}(q)u_j - y_{id}^{(n)}(t) + \Delta d_i(q,\dot{q})\,, \end{aligned} \qquad (4)$$

where $i = 1, \cdots, n$. After some simple manipulations, we can obtain the error equation:

$$\dot{e}(t) = Ae(t) + B\left[F(q,\dot{q}) + G(q)u - y_d^{(n)}(t) + \Delta D(q,\dot{q})\right], \quad (5)$$

where $e = \left[e_1, \cdots, e_p\right]^T$, $\Delta D = \left[\Delta d_1, \cdots, \Delta d_n\right]^T$.

A. Fuzzy-neural network structure

The fuzzy rule base consists of a collection of fuzzy IF-THEN rules:

$R^{(l)}$: If x_1 is F_1^l and x_2 is F_2^l ... and x_n is F_n^l , $l = 1, 2, ..., n$.

then y_s is G_s^l , $s = 1, 2, ..., p$, (6)

where $x = \left[x_1, \cdots, x_n\right]^T$ is the fuzzy system input; y is the fuzzy system output; and F_n^l and G_s^l are fuzzy sets. The output of the fuzzy logic system can then be expressed as:

$$y_s = \theta_s^T \xi(x)\,, \; s = 1, \cdots, p\,, \qquad (7)$$

where $\theta_s^T = \left[\theta_s^1, \cdots, \theta_s^N\right]$, with each variable θ_s^l being the point at which the fuzzy membership function of G_s^l achieves the maximum value; and $\xi(x) = \left[\xi_1(x), \cdots, \xi_n(x)\right]^T$ with each variable ξ_l being the fuzzy basis function defined as:

$$\xi_l(x) = \prod_{i=1}^{n} \mu_{F_i^l}(x_i) \Big/ \sum_{l=1}^{N} \left(\prod_{i=1}^{n} \mu_{F_i^l}(x_i)\right), \qquad (8)$$

where $\mu_{F_i^l}(x_i)$ is the membership function of the fuzzy set.

The inputs are then fed into the fuzzy-neural network (FNN) shown in Figure 1. The outputs (layer IV) of the fuzzy-neural system are expressed as in (9). The fuzzy system based on the neural networks can then be established [15]. The approximator has four layers. At layer I, input nodes represent vector $x^T = \left[x_1, \cdots, x_n\right]$, while at layer II, they represent the values of the membership function. Each node in layer II performs a membership function value. At layer III, nodes are the values of the fuzzy basis vector ξ , with each node performing a fuzzy rule. The links between layer III and layer IV are fully connected by the weighting factors, i.e., the adjusted parameters $\theta^T = \left[\theta_1^T, \cdots, \theta_p^T\right]$. At layer IV, the outputs represent the values of the output y .

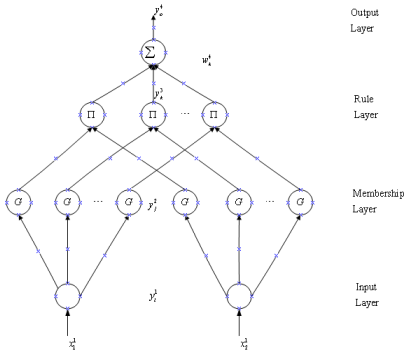

Figure 1. Structure is of a fuzzy-neural network.

Denote $\theta^T = diag\left[\theta_1^T, \cdots, \theta_p^T\right]$ and $\Phi(x) = diag\left[\xi(x), \cdots, \xi(x)\right]$. The FNN can be designed as:

$$y = \theta^T \Phi(x), \tag{9}$$

Let the nonlinear functions approximated by FNN be rewritten as:

$$\hat{F}((q,\dot{q})\big|\theta_f) = \theta_f^T \xi_f(x), \tag{10}$$

$$\hat{G}(q,\big|\theta_g) = \theta_g^T \xi_g(x). \tag{11}$$

III. Controller Design

In this section, we aim to design an observer-based adaptive fuzzy-neural network controller with PSO-SA for the robot system..

A. Basic PSO Algorithm

The concept of the PSO is the mathematical modeling and simulation of the food searching activities of a flock of birds. In multi-dimensional space, each particle moves toward the optimal point by changing its position according to a velocity. The cognitive component models the memory of the bird about its previous best position. The social component models the memory of the bird about the best position among the particles [16,17]. The mathematical model for PSO can be written ass:

$$\begin{aligned} V_i(k+1) &= V_i(k) + c_1 \cdot rand_1(\cdot) \times \left(Pbest_i - X_i(k)\right) \\ &\quad + c_2 \cdot rand_2(\cdot) \times \left(Gbest_n - X_i(k)\right) \\ X_i(k+1) &= X_i(k) + V_i(k+1),\ i = 1, \cdots, N_{swarm}, \end{aligned} \tag{12}$$

where V_i is the velocity of particle i; X_i represents the position of particle i; $Pbest_i$ and $Gbest_n$ are the best historical position of particle i and the best historical position of the neighbor of particle i, respectively; while $rand_1(\cdot)$ and $rand_2(\cdot)$ are random numbers between 0 and 1, constants c_1 and c_2 are the weighting factors of the stochastic acceleration terms, which pull each particle towards $Pbest_i$ and $Gbest_n$. Usually $Gbest_n$ is often replaced by $Gbest_g$, which is the global best position with an objective value. However, the method has the drawback of being easily trapped in the local minima; therefore, the following intelligence algorithm was proposed to overcome this shortcoming.

B. Simulated Annealing

The SA algorithm is introduced to prevent particles from becoming trapped in a local minimum and to increase the diversity of the particle swarm. Kirkpatrick [18] applied it to combinatorial optimization including the traveling salesman problem (TSP).

As mentioned before, in PSO, $Gbest_g$ is an element of the set of all $Pbest_i$, which can be regarded as a set of local optima. Thus, we modify the selection of $Gbest_g$ to overcome premature convergence. In particular, we employ the jumping mechanism of the SA for the selection of $Gbest_n$ instead of $Gbest_g$. $Pbest_i$ has better quality should have a larger probability of being selected. Borrowing the mechanism of the SA, all other $Pbest_i$ can be regarded as special solutions worse than $Gbest_g$. Meanwhile, we can set $e^{-(F_{F_i} - F_{F_g})/t}$ as the fitness value of each $Pbest_i$ to replace $Gbest_g$ at a certain temperature t. The largest fitness belongs to $Gbest_g$ and equals 1, with other fitness values within the interval $(0,1]$. Thus, the probability of selecting $Pbest_i$ as $Gbest_g$ can be calculated as follows:

$$\left(e^{-(F_{F_i} - F_{F_g})/t}\right) \Big/ \sum_{j=1}^{N_{swarm}} e^{-(F_{F_i} - F_{F_g})/t}, \tag{13}$$

Then, roulette wheel selection can be applied to randomly determine which $Pbest_i$ to select as $Gbest_g$.

C. Optimization of FNN with PSO-SA

For the FNN controller that has 3 membership functions (15 fuzzy sets) and 25 rules, there are a total of 60 parameters to be adjusted. Now the particles are manipulated as follows:

$$P_i = \left[{}^i\sigma_{11}\ {}^ic_{11}, \cdots, {}^i\sigma_{55}\ {}^ic_{55}\right],\ i = 1,2,3 \tag{14}$$

where parameters σ and c represent the center and deviation of the Gaussian membership functions, respectively.

The strategies of the PSO-SA are described as:

Step1: Let $k = 0$, and randomly initialize $X_i(0)$ and $V_i(0)$, $i = 1, \cdots, N_{swarm}$. Then, evaluate objective value F_i for all particles.

Step2: Initialize $Pbest_i$ with a copy of $X_i(0)$; initialize $Gbest_g$ with a copy of the best $Pbest_i$; and initialize the temperature $t(0) = t_0$.

Step3: Repeat until the stopping criterion is satisfied.

Calculate the fitness:

$$\text{Fitness}_i = \exp\left[-(F_{p_i} - F_{p_g})/t(k)\right], \quad (15)$$

$$\text{where} \quad F_p = \frac{1}{N_{swarm}} \sum_{i=1}^{N_{swarm}} \sqrt{e^2(i)} \ . \quad (16)$$

Step4: For every particle i, apply roulette wheel selection from the set of all $Pbest_i$, and then update V_i and X_i via the following equations.

$$V_i(k+1) = \chi \times \{V_i(k) + c_1 \cdot rand_1(\cdot) \times (Pbest_i - X_i(k)) + c_2 \cdot rand_2(\cdot) \times (Gbest_n - X_i(k))\}$$

$$X_i(k+1) = X_i(k) + V_i(k+1) \ , \quad (17)$$

where χ is called a constriction coefficient.

$$\chi = \frac{2}{\left|2 - C - \sqrt{C^2 - 4C}\right|} \ , C = c_1 + c_2 \ , \quad (18)$$

Step5: Evaluate the new objective value F_i for all particles, and then update $Pbest_i$ and $Gbest_g$ (including position values and objective values).

Step6: Set the annealing temperature to obtain $t(k+1)$, and let $k = k+1$.

Step7: The solution is then $Gbest_g$.

The biggest probability is selected as the fitness value of all $Pbest_i$ solutions as $Gbest_g$.

Remark 1. The initial temperature t_0 affects the performance of the PSO-SA. In these, the initial temperature can be written as:

$$t_0 = -F_{p_g} / \ln(0.8) \ . \quad (19)$$

D. Observer-Based Adaptive Fuzzy-Neural Robust Controller Design

Generally, an unknown numerical can be described as follows:

$$\hat{F}((q,\dot{q})|\theta_f) = \theta_f^T \xi_f(x) \ . \quad (20)$$

$$\hat{G}(q|\theta_g) = \theta_g^T \xi_g(x) \ . \quad (21)$$

$$\hat{g}_d((q,\dot{q})|\theta_{g_d}) = \theta_{g_d}^T \xi_{g_d}(x) \ . \quad (22)$$

The following technical assumption is necessary for the proof of the main statement.

Assumption 3.1: $\|\Delta D(x)\| \le g_d(x)$, (23)

where $g_d(x)$ is the unknown positive smooth continuous function.

In short, the control law (3) can be rewritten as:

$$u = \hat{G}^{-1}(q|\theta_g)[-\hat{F}((q,\dot{q})|\theta_f) + y_d^{(n)} - K_c e(t) + u_a(t)] \ , \quad (24)$$

where K_c is the control gain vector, and u_a is designed for compensating the approximation errors and the uncertainty.

Where

$$u_a = -\hat{w}_c - \frac{B_c^T P \tilde{e}_c}{\left\|\tilde{e}_c^T P_1 B_c\right\|}(\hat{g}_d(q,\dot{q})|\theta_{g_d}) - \frac{B_c^T P \tilde{e}_c}{\left\|\tilde{e}_c^T P_1 B_c\right\|^2}\left[\hat{e}^T P_2 K_o \tilde{e}_1\right]. \quad (25)$$

Furthermore, the parameter update laws are chosen as follows:

$$\dot{\theta}_f = \gamma_f \xi_f(\hat{x}) \tilde{e}_c^T P_1 B_c \ , \quad (26)$$

$$\dot{\theta}_g = \gamma_g \xi_g(\hat{x}) u \tilde{e}_c^T P_1 B_c \ , \quad (27)$$

$$\dot{\theta}_{g_d} = \gamma_{g_d} \left\|\tilde{e}_c^T P_1 B_c\right\| \xi_{g_d}(\hat{x}) \ , \quad (28)$$

$$\dot{\hat{w}}_c = \gamma_c \tilde{e}_c^T P_1 B_c \ , \quad (29)$$

where $\gamma_f > 0$, $\gamma_g > 0$, $\gamma_{g_d} > 0$, and $\gamma_c > 0$ are positive adaptive gains to be determined.

In order to constrain the parameters θ_f , θ_g , and θ_{gd} within the sets M_f , M_g , and M_{gd} , respectively, the proposed adaptive laws (26)-(28) can be modified as follows:

$$\dot{\theta}_f = \begin{cases} \gamma_f \xi_f(\hat{x}) \tilde{e}_c^T P_1 B_c, \ if \ \left(\|\theta_f\| \le M_f \right) \\ \qquad or \left(\begin{array}{l} \|\theta_f\| = M_f \\ and \ \tilde{e}_c^T P_1 B_c \theta_1^T \xi_f(\hat{x}) \le 0 \end{array} \right) \\ P\left\{\gamma_f \xi_f(\hat{x}) \tilde{e}_c^T P_1 B_c\right\}, if \ \left(\begin{array}{l} \|\theta_f\| = M_f \\ and \ \tilde{e}_c^T P_1 B_c \theta_1^T \xi_f(\hat{x}) > 0 \end{array} \right) \end{cases} , \quad (30)$$

where

$$P\left\{\gamma_f \xi_f(\hat{x}) \tilde{e}_c^T P_1 B_c\right\} = \gamma_f \xi_f(\hat{x}) \tilde{e}_c^T P_1 B_c - \gamma_f \frac{\theta_f \theta_f^T}{\|\theta_f\|} \xi_f(\hat{x}) \tilde{e}_c^T P_1 B_c \ .$$

$$\dot{\theta}_g = \begin{cases} \gamma_g \xi_g(\hat{x}) u \tilde{e}_c^T P_1 B_c, \ if \ \left(\|\theta_g\| \le M_g \right) \\ \qquad or \left(\begin{array}{l} \|\theta_g\| = M_g \\ and \ \tilde{e}_c^T P_1 B_c \theta_2^T \xi_g(\hat{x}) u \le 0 \end{array} \right) \\ P\left\{\gamma_g \xi_g(\hat{x}) u \tilde{e}_c^T P_1 B_c\right\}, if \ \left(\begin{array}{l} \|\theta_g\| = M_g \\ and \ \tilde{e}_c^T P_1 B_c \theta_g^T \xi_g(\hat{x}) u > 0 \end{array} \right) \end{cases} , \quad (31)$$

where

$$P\left\{\gamma_g \xi_g(\hat{x}) u \tilde{e}_c^T P_1 B_c\right\} = \gamma_g \xi_g(\hat{x}) u \tilde{e}_c^T P_1 B_c - \gamma_g \frac{\theta_g \theta_g^T}{\left\|\theta_g\right\|} \xi_g(\hat{x}) u \tilde{e}_c^T P_1 B_c$$

.

$$\dot{\theta}_{g_d} = \begin{cases} \gamma_{g_d} \left\|\tilde{e}_c^T P_1 B_c\right\| \xi_{g_d}(\hat{x}), \ if \ \left(\left\|\theta_{g_d}\right\| \le M_{\theta g_d}\right) \\ \qquad or \begin{pmatrix} \left\|\theta_{g_d}\right\| = M_{\theta_{g_d}} \\ and \ \left\|\tilde{e}_c^T P_1 B_c\right\| . \theta_{g_d}^T \xi_{g_d}(\hat{x}) \le 0 \end{pmatrix} \\ P\left\{\left\|\tilde{e}_c^T P_1 B_c\right\| \gamma_{g_d} \xi_{g_d}(\hat{x})\right\}, if \ \begin{pmatrix} \left\|\theta_{g_d}\right\| = M_{\theta_{g_d}} \\ and \ \left\|\tilde{e}_c^T P_1 B_c\right\| \theta_{g_d}^T \xi_{g_d}(\hat{x}) u > 0 \end{pmatrix} \end{cases}, \quad (32)$$

where

$$P\left\{\gamma_{g_d} \xi_{g_d}(\hat{x}) \tilde{e}_c^T P_1 B_c\right\} = \gamma_{g_d} \xi_{g_d}(\hat{x}) \left\|\tilde{e}_c^T P_1 B_c\right\| - \gamma_{g_d} \frac{\theta_{g_d} \theta_{g_d}^T}{\left\|\theta_{g_d}\right\|} \xi_{g_d}(\hat{x}) \left\|\tilde{e}_c^T P_1 B_c\right\| .$$

In this, the control input can be arranged as:

$$u = \hat{G}^{-1}(q|\theta_g)[-\hat{F}((q,\dot{q})|\theta_f) + y_d^{(n)} - K_c \hat{e}(t) + u_a(t)] . \quad (33)$$

By (6), (33) can be arranged:

$$\dot{e}(t) = Ae(t) - BK_c \hat{e}(t) + B\{F((q,\dot{q})) - \hat{F}((q,\dot{q})|\theta_f) + [G(q) - \hat{G}(q|\theta_g)]u(t) + u_a(t) + \Delta D((q,\dot{q}))\} . \quad (34)$$

The output tracking error vector is redefined as follows:

$$\dot{\hat{e}}(t) = (A - BK_c)\hat{e}(t) + K_o(e_q(t) - \hat{e}_q(t)) , \quad (35)$$

where K_o is the observer gain vector.

Define the observation error vector as:

$$\tilde{e}(t) = e(t) - \hat{e}(t) , \quad (36)$$

In short, one can obtain:

$$\dot{\tilde{e}} = (A - K_0 C)\tilde{e} + B\{[F(q,\dot{q}) - \hat{F}((q,\dot{q})|\theta_f)] + [G(q) - \hat{G}(q|\theta_g)]u(t) + u_a(t) + \Delta D((q,\dot{q}))]\} , \quad (37)$$

Define the optimal parameter vectors θ_f^*, θ_g^*, and $\theta_{g_d}^*$ as:

$$\theta_f^* = \arg \min_{\theta_f \in \Omega_f} \left\{ \sup_{x \in U_x, \hat{x} \in U_{\hat{x}}} \left| F(q,\dot{q}) - \hat{F}((q,\dot{q})|\theta_f) \right| \right\} , \quad (38)$$

$$\theta_g^* = \arg \min_{\theta_g \in \Omega_g} \left\{ \sup_{x \in U_x, \hat{x} \in U_{\hat{x}}} \left| G(q) - \hat{G}(q|\theta_g) \right| \right\} , \quad (39)$$

$$\theta_{g_d}^* = \arg \min_{\theta_{gd} \in \Omega_{g_d}} \left\{ \sup_{x \in U_x, \hat{x} \in U_{\hat{x}}} \left| g_d((q,\dot{q})) - \hat{g}_d((q,\dot{q})|\theta_{g_d}) \right| \right\} , \quad (40)$$

where $\tilde{\theta}_f = \theta_f^* - \theta_f$, $\tilde{\theta}_g = \theta_g^* - \theta_g$, and $\tilde{\theta}_{g_d} = \theta_{g_d}^* - \theta_{g_d}$ are parameter estimation errors.

The errors can be defined as:

$$w = F(q,\dot{q}) - \hat{F}((q,\dot{q})|\theta_f^*) + \left(G(q) - \hat{G}(q|\theta_g^*)\right)u + g_d(q,\dot{q}) - \hat{g}_d((q,\dot{q})|\theta_{g_d}^*) . \quad (41)$$

The linear transfer function $H(s)$ is realized using standard techniques by $H(s) = C\left(sI - \left(A - K_o C\right)\right)^{-1} B$, and it used SPR-Lyapunov design approach, and after some simple manipulations, we can obtain the equation:

$$\tilde{e}_q(t) = H(s)L(s)\left[L(s)^{-1}\tilde{\theta}_f^T \xi_f(\hat{x}) + L(s)^{-1}\tilde{\theta}_g^T \xi_g(\hat{x})u(t) + L(s)^{-1}\left(w + u_a(t) + \Delta D(q,\dot{q})\right)\right] , \quad (42)$$

where $L(s) = \left[L_1(s), \cdots, L_n(s)\right]$ and $L_i(s) = s^{m_i} + b_{i1}s^{m_i - 1} + \cdots + b_{im_i}$, $(m_i = n_i - 1)$, $i = 1, 2, \cdots, p$.

Hence, the state-space realization can be rewritten as follows:

$$\dot{\tilde{e}}_c = \left(A - K_0 C\right)\tilde{e}_c + B_c[\tilde{\theta}_f^T \xi_{cf}(\hat{x}) + \tilde{\theta}_g^T \xi_{cg}(\hat{x})u(t) + w_c + u_{ca}(t) + \Delta D_c(q,\dot{q})] , \quad (43)$$

where $B_c = diag\left[B_{c1}, \cdots, B_{cp}\right]$, $B_{ci} = diag\left[1, b_{i1}, \cdots, b_{im_i}\right]$, $\xi_{cf}(\hat{x}) = L(s)^{-1}\xi_f(\hat{x})$, $w_c = L(s)^{-1}w$, $\Delta D_c(q,\dot{q}) = L(s)^{-1}\Delta D(q,\dot{q})$, and $\xi_{cg}(\hat{x}) = L(s)^{-1}\xi_g(\hat{x})$.

Lemma 3.1 [14] Assuming that X and Y are vectors or matrices with corresponding dimensions, the following equation holds:

$$X^T X + Y^T Y \ge 2X^T Y . \quad (44)$$

Theorem 3.1: *For the given positive definite matrices $\boldsymbol{Q}_1$ and $\boldsymbol{Q}_2$, the augmented control system (2) containing the observer (35) is asymptotically stabilized via the controller (24) if there exist symmetric positive definite matrices $\boldsymbol{P}_1$ and $\boldsymbol{P}_2$ such that the following Lyapunov equations are satisfied.*

$$\left(A - K_o C\right)^T \boldsymbol{P}_1 + \boldsymbol{P}_1 \left(A - K_o C\right) \le -\boldsymbol{Q}_1 ,$$
$$\left(A - BK_c\right)^T \boldsymbol{P}_2 + \boldsymbol{P}_2 \left(A - BK_c\right) \le -\boldsymbol{Q}_2 . \quad (45)$$

Proof of Theorem 3.1

Consider the Lyapunov function as:

$$V = \frac{1}{2}\tilde{e}_c^T \boldsymbol{P}_1 \tilde{e}_c + \frac{1}{2}\hat{e}^T \boldsymbol{P}_2 \hat{e} + \frac{1}{2\gamma_f} tr\left(\tilde{\theta}_f^T \tilde{\theta}_f\right) + \frac{1}{2\gamma_g} tr(\tilde{\theta}_g^T \tilde{\theta}_g)$$

$$+ \frac{1}{2\gamma_c}(\tilde{w}^T \tilde{w}) + \frac{1}{2\gamma_{g_d}} tr(\tilde{\theta}_{g_d}^T \tilde{\theta}_{g_d}), \qquad (46)$$

Then, the time derivative of the Lyapunov (46) is:

$$\dot{V} = \frac{1}{2}\dot{\tilde{e}}^T \boldsymbol{P}_1 \tilde{e} + \frac{1}{2}\tilde{e}^T \boldsymbol{P}_1 \dot{\tilde{e}} + \frac{1}{2}\dot{\hat{e}}^T \boldsymbol{P}_2 \hat{e} + \frac{1}{2}\hat{e}^T \boldsymbol{P}_2 \dot{\hat{e}} - \frac{1}{\gamma_f} tr\left(\tilde{\theta}_f^T \dot{\hat{\theta}}_f\right)$$

$$- \frac{1}{\gamma_g} tr(\tilde{\theta}_g^T \dot{\hat{\theta}}_g) - \frac{1}{\gamma_{g_d}} tr(\tilde{\theta}_{g_d}^T \dot{\hat{\theta}}_{g_d}) - \frac{1}{\gamma_c}(\tilde{w}^T \dot{\hat{w}}). \quad (47)$$

After some simple manipulations, we can obtain as:

$$\dot{V} \le \frac{1}{2}\tilde{e}_c^T \left[(A - K_o C)^T \boldsymbol{P}_1 + \boldsymbol{P}_1 (A - K_o C)\right]\tilde{e}_c + \frac{1}{2}\hat{e}^T \left[(A - BK_c)^T \boldsymbol{P}_2 \right.$$
$$\left. + \boldsymbol{P}_2 (A - BK_c)\right]\hat{e} + \tilde{e}_c^T \boldsymbol{P}_1 B_c u_a + \tilde{e}_c^T \boldsymbol{P}_1 B_c \tilde{\theta}_f^T \xi_f(\hat{x})$$
$$+ \tilde{e}_c^T \boldsymbol{P}_1 B_c \tilde{\theta}_g^T \xi_g(\hat{x}) u + \tilde{e}_c^T \boldsymbol{P}_1 B_c (\tilde{w} + \hat{w}) + \left\|\tilde{e}_c^T \boldsymbol{P}_1 B_c\right\| \cdot \left\|\Delta D_f\right\|$$
$$+ \hat{e}^T \boldsymbol{P}_2 K_o \tilde{e}_1 - \frac{1}{\gamma_f} tr\left(\tilde{\theta}_f^T \dot{\theta}_f\right) - \frac{1}{\gamma_g} tr(\tilde{\theta}_g^T \dot{\theta}_g) - \frac{1}{\gamma_c}(\tilde{w}^T \dot{\hat{w}})$$
$$- \frac{1}{\gamma_{g_d}} tr(\tilde{\theta}_{g_d}^T \dot{\theta}_{g_d}). \qquad (48)$$

By using Lemma 3.1 and Assumption 2.1-3.1, we further have:

$$\dot{V} \le \frac{1}{2}\tilde{e}_c^T \left[(A - K_o C)^T \boldsymbol{P}_1 + \boldsymbol{P}_1 (A - K_o C)\right]\tilde{e}_c + \frac{1}{2}\hat{e}^T \left[(A - BK_c)^T \boldsymbol{P}_2 \right.$$
$$\left. + \boldsymbol{P}_2 (A - BK_c)\right]\hat{e} + \tilde{e}_c^T \boldsymbol{P}_1 B_c u_a + \tilde{e}_c^T \boldsymbol{P}_1 B_c \tilde{\theta}_f^T \xi_f(\hat{x})$$
$$+ \tilde{e}_c^T \boldsymbol{P}_1 B_c \tilde{\theta}_g^T \xi_g(\hat{x}) u + \tilde{e}_c^T P_1 B_c (\tilde{w} + \hat{w}) + \left\|\tilde{e}_c^T \boldsymbol{P}_1 B_c\right\|$$
$$\times \hat{g}_d((q, \dot{q})\big|\theta_{g_d}) + \left\|\tilde{e}_c^T \boldsymbol{P}_1 B_c\right\| \cdot \tilde{\theta}_{g_d}^T \xi_{g_d}(\hat{x}) + \hat{e}^T \boldsymbol{P}_2 K_o \tilde{e}_1$$
$$- \frac{1}{\gamma_f} tr\left(\tilde{\theta}_f^T \dot{\theta}_f\right) - \frac{1}{\gamma_g} tr(\tilde{\theta}_g^T \dot{\theta}_g) - \frac{1}{\gamma_c}(\tilde{w}^T \dot{\hat{w}})$$
$$- \frac{1}{\gamma_{g_d}} tr(\tilde{\theta}_{g_d}^T \dot{\theta}_{g_d}). \qquad (49)$$

Then, (49) can be written as:

$$\dot{V} \le \frac{1}{2}\tilde{e}_c^T \left[(A - K_o C)^T \boldsymbol{P}_1 + \boldsymbol{P}_1 (A - K_o C)\right]\tilde{e}_c + \frac{1}{2}\hat{e}^T \left[(A - BK_c)^T \boldsymbol{P}_2 \right.$$
$$\left. + \boldsymbol{P}_2 (A - BK_c)\right]\hat{e}. \qquad (50)$$

Finally:

$$\dot{V} \le -\frac{1}{2}\tilde{e}_c^T Q_1 \tilde{e}_c - \frac{1}{2}\hat{e}^T Q_2 \hat{e}.$$

IV. SIMULATION

This section presents the simulation results of the proposed observer-based adaptive fuzzy-neural network robust controller with PSO-SA for robot systems to illustrate that the stability for the closed-loop system. In order to demonstrate the effectiveness of the proposed approach, we apply it to a two-link plane robot system.

Example*:*

$$\mathbf{M}(q)\ddot{q} + c(q, \dot{q})\dot{q} + g(q) + \tau_d(q, \dot{q}) + \tau_c(q, \dot{q}) = u, \qquad (51)$$

where

$$\mathbf{M} = \begin{bmatrix} (m_1 + m_2)l_1^2 & m_2 l_1 l_2 (s_1 s_2 + c_1 c_2) \\ m_2 l_1 l_2 (s_1 s_2 + c_1 c_2) & m_2 l_2^2 \end{bmatrix},$$

$$c = \begin{bmatrix} -m_2 l_1 l_2 (c_1 s_2 - s_1 c_2)\dot{q}_2^2 \\ -m_2 l_1 l_2 (c_1 s_2 - s_1 c_2)\dot{q}_1^2 \end{bmatrix},\ g = \begin{bmatrix} -g(m_1 + m_2)s_1 l_1 \\ -g m_2 l_2 s_2 \end{bmatrix}.$$

In the simulation, the parameters are chosen as:

$c_1 = \cos(q_1)$, $c_2 = \cos(q_2)$, $s_1 = \sin(q_1)$, and $s_2 = \sin(q_2)$ .The robot physical parameters are: $l_1 = l_2 = 1\text{m}$, $m_1 = m_2 = 1\text{kg}$, $g = 9.8\,\text{m}/s^2$.

$$\Delta d(q, \dot{q}) = \begin{bmatrix} \sin(2q_1) + 2sign(\dot{q}_1) \\ \sin(q_2) + sign(\dot{q}_2) \end{bmatrix}.$$

The design algorithm is as follows:

Step1: Let parameters for PSO-SA at $c_1 = 1$, $c_2 = 1$, and $N_{swarm} = 100$.

Step2: Specify a positive definite $\boldsymbol{Q}_1 = diag[1,1,1,1]$, and $\boldsymbol{Q}_2 = diag[1,1,1,1]$ $\gamma_f = \gamma_g = 0.1$, $\gamma_{g_d} = 0.1$, $r_c = 0.01$,

Step3: Specify the design parameters $K_c = \begin{bmatrix} 4 & 4 & 0 & 0 \\ 0 & 0 & 4 & 4 \end{bmatrix}$,

$$K_o = \begin{bmatrix} 90 & 185 & 0 & 0 \\ 0 & 0 & 90 & 185 \end{bmatrix}^T.$$

Step4: The membership functions of the fuzzy controller are given by:

$$\mu_{F_i^1}(x_i) = 1/1 + \exp(5 \times (x_i + 2)),$$

$$\mu_{F_i^2}(x_i) = \exp[-(x_i + 1)^2],$$

$$\mu_{F_i^3}(x_i) = \exp[-x_i^2],$$

$$\mu_{F_i^4}(x_i) = \exp[-(x_i - 1)^2],$$

$$\mu_{F_i^5}(x_i) = 1/1 + \exp(5 \times (x_i - 2)).$$

Step5: Obtain the control law.

The initial conditions are $\boldsymbol{x}(0)=[2,2,2,2]^T$, $\boldsymbol{\theta}_f(0)=0$, $\boldsymbol{\theta}_g(0)=0.2$, and $\boldsymbol{\theta}_{g_d}(0)=0$. The initial membership functions for u are depicted as Figure 2 and Figure 3. Then, Figure 4 and Figure 5 show membership functions of u after self-adjustment with PSO-SA for u_1 and u_2 . In order to compare the stabilization and tracking performance of the proposed controller with that of a conventional observer-based fuzzy adaptive robust controller, we consider the example [19]. Figures 6-9 show the response of the system under the traditional control law and the proposed method for the same initial conditions. It is clear that the proposed controllers can stabilize the nonlinear system and show faster tracking responses than traditional control law.

V. CONCLUSION

An observer-based adaptive FNN controller design was proposed for robot systems. The main contributions of this paper are as follows: Firstly, a robust term is introduced to eliminate disturbance and the controller doesn't require a priori knowledge of the sign of the control coefficient. Secondly, PSO-SA is used to self-adjust membership function for the sub-optimal solution. Thirdly, the PSO-SA based adaptive FNN controller can generate a reduction in the dependence on expert knowledge, while the stabilization condition of the closed-loop was proposed using the Lyapunov theorem. Finally, stability conditions can be efficiently checked using dedicated optimization software.

***Abstract*—This paper aims at to realize the solar cell charged systems of 120W PV module with the dsPIC30F4011 control chip. All of the control schemes are written and accomplished with the C language. In the power converter, a single-ended primary inductance converter (SEPIC) is adopted which has the features including the buck-boost operating mode, no polarity inversion, low input current pulsation, and wide input voltage range, so, it is very suitable for the conversion of solar cell. In order to obtain the high efficient solar cell energy conversion, a fuzzy maximum power point tracking (MPPT) control is activated if the solarization is insufficient. The fuzzy controller is to maintain a charged current so as that the battery voltage can reach to desired value. The effectiveness of the proposed methods is demonstrated with the experimental results.**

I. INTRODUCTION

Solar energy from the sun is fruitful without environmental pollution. It does not consume the earth's resources and cause global warming. A solar panel is a device comprised of a number of solar cells connected series/parallel units which are used to convert solar energy into electricity. Solar panels have been used more and more each day. As the solar panel has been constructed, the only need is sunlight to create energy. The economic value of the solar panel is a popular choice to battle the rising cost of electricity. The solar energy technology has been developed for many years, but it is utilized today more than ever. One main reason for its rising usage is its renewable capability. The sun will always provide the Earth with more energy continuously than human being can consume.

The output voltage, current, and power of the solar panel are highly nonlinear and closely related to effects, such as: the sunlight intensity, working temperature, aging of components, and types of optical materials. The solar panels have their own inherent unique working curve with a corresponding maximum power point only, namely, the optimal working point of solar panels, therefore, to fully utilize solar energy, we need to enable the design of appropriate control algorithms in a variety of different working environments to obtain the maximum power from solar panels. This control method is called the maximum power tracking method. Maximum power point tracking methods are discussed in many literatures with different tracking ways to obtain the overall efficiency; so, we need to select the appropriate maximum power tracking method according to the actual environmental conditions. To select the maximum power tracking methods, one must understand the characteristics of solar panels, such as, output power, temperature, sunlight intensity, and the relationship between the loads. It is almost impossible to utilize all the available solar energy in varying load and atmospheric conditions with an uncontrolled system; so, there are several maximum power point extraction solutions via different type DC–DC converters presented in the literature [1-9]. The perturbation and observation method is the most often used algorithm which is based on periodically changing the operating point and observing the resultant change in power. Although, it is well established algorithm, some confusions and instabilities may occur when the irradiation and/or load changes rapidly and randomly. In this paper a fuzzy method is adopted for MPPT, The fuzzy MPPT method is simple and easy to be implemented which is based on the relationship that exists between the PV panel current and voltage. The charged system is implemented with the single-ended primary inductance converter (SEPIC). The SEPIC converter is very effective to charge a battery by PV panel, because the battery voltage could be higher or lower than the PV module voltage, and also the buck boost feature of the SEPIC widens the applicable PV voltage and thus increases the adopted PV module flexibility. Single-ended primary-inductor converter (SEPIC) is a type of DC-DC converter that allows its output voltage to be greater than or less than its input voltage; the output of the SEPIC is controlled by the duty cycle of the control transistor. Figure 1 shows the circuit diagram of the SEPIC converter with two inductors.

There are several advantages by using SEPIC in the charging system of PV module. For instance, the buck-boost

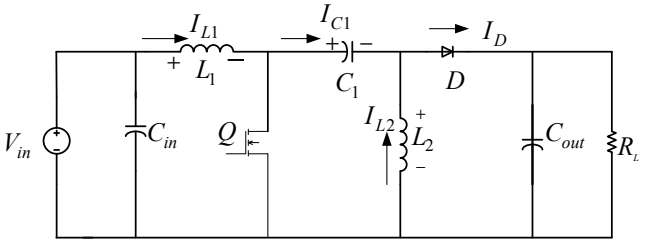

Figure 1. The SEPIC converter diagram

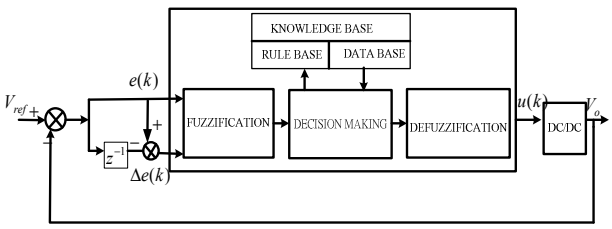

Figure 2. Block diagram of the FLC for DC–DC converters

converter operating voltage can be used to increasing the PV cells voltage range, and SEPIC converter output voltage does not reverse polarity problem. SEPIC converter inductively coupled inductor technology can be used to reduce the size of inductor. The input circuit has inductor can reduce the input current ripple and thus increase the precision of the maximum power point tracking [10, 11].

The fuzzy logic control (FLC) has been successfully applied to many control problems that the conventional one has difficulties to deal with when the controlled systems are complex, not well defined and/or model-free and can be controlled by a skilled human operator with the knowledge of their underlying dynamics. There are many papers pointed a way for an effective utilization of fuzzy control for both practical situations [14-23]. The block diagram of the FLC for DC–DC converters is shown in Figure 2. The fuzzy logic controller can be divided into four part: fuzzification is the input variable partition into suitable fuzzy sets; knowledge base includes fuzzy rule base and data base, they contain knowledge of the control rules and linguistic labels; decision making is inferring control action from rule base; defuzzification is the conversion from the inferred fuzzy value to real control crisp value [13].

The main work of this paper is to integrate fuzzy methodology and SEPIC DC-DC converter so as to realize a charged system of 120W PV module. The control chip is adopted dsPIC30F4011 in the circuit, and all of the control actions are written and completed with the software C program. In the DC-DC power converter, a single-ended primary inductance converter (SEPIC) is adopted. The SEPIC has the features of the buck-boost operating mode, no polarity inversion, low input current pulsation, and wide input voltage range, it is very suitable for the conversion of solar cell. In order to obtain the highest efficient solar cell energy, a fuzzy maximum power point tracking (MPPT) control is adopted, in the hope of reaching steady charging. Three stages of charging process are taken in this work. While the battery voltage is not full and the solarization is insufficient such that available power of the PV module is not enough to produce the charged current between 0.1C and 0.01C to battery, then fuzzy maximum power point tracking (MPPT) control is activated. As the battery voltage is not full, the solarization is sufficient, and the available peak power of the PV module is enough to produce 0.1C charged current to battery, then, 0.1C charged current is set as command and a fuzzy controller is taken to maintain 0.1C charged current of battery. No matter what the solarization is sufficient or not, once the battery voltage reaches a predefined value, the current command will be shifted to 0.01C, then, the fuzzy controller is activated to maintain a litter charged current so as the battery voltage can reach the desired value. The effectiveness of the proposed methods will be demonstrated by the experimental results.

TABLE I. SPECIFICATIONS AND PARAMETERS OF THE SEPIC.

Input voltage range	Charge voltage range	Input current range
5-40V	12V-14.4V	0.1-10A
Charge current range	Switching frequency	Output power range
0.1A-10A	100 kHZ	1W-120W
Coupled Inductor	Switch components	Coupling capacitor
63 mh	IRFP048NI	490uf/150V
Output diode	Duty cycle range	I/O filter capacitor
B20100 (20A/100V)	10%-70%	4700uF 53V

This paper is organized as follows. In Section II, the circuit characteristics of the SEPIC are described. The fuzzy maximum power point tracking and fuzzy control strategy is addressed in Section III. The experimental results are given in Section IV. Finally, the conclusions are drawn in Section V.

II. SEPIC CIRCUIT CHARACTERISTICS

Roberto *et al* [12] presented a simple method to properly choose the better DC-DC converter to be applied as MPPT in photovoltaic systems, as a function of the radiation, temperature operation range, and load connected at the photovoltaic module. The theory shows that buck and boost converters, although widely used on the literature, might not be the better option to work as MPPT, once they have tracking problems under different radiation and temperature combinations. Before to evaluate parameters of each component, there are some assumptions should be made first: (a) SEPIC operating in continuous conduction mode (CCM); (b) Circuit is at the steady state; (c) All semiconductor components are at ideal case; (d) The energy storage element is not considered. The parameters are listed in Table I.

Referring to the equivalent circuit of SEPIC converter at ON and OFF states as shown in Figure 3 and 4, respectively, when Q turns ON, the energy is stored in the inductor L1. At this time the inductor voltage equals to input voltage, and the energy stored in capacitor C1 will be transferred to inductor L2. The load is supplied by capacitor C2. Similarly, when Q turns OFF, the energy stored in inductor L1 is transferred to C1. The energy stored in L2 is transferred to C2 through D1 and supplying the energy to load. Figure 5 shows the corresponding switching waveforms of the SEPIC converter [23].

The relationship of SEPIC output and input voltage conversion in the static state can be expressed as

$$\frac{V_{in}}{V_{out}} = \frac{D}{1-D} \tag{1}$$

where V_{in} and V_{out} are the input and output voltage, respectively, and D is the duty cycle. Considering the diode forward bias voltage with the input maximum value, the maximum duty cycle $D_{\max}$ can be expressed as follow

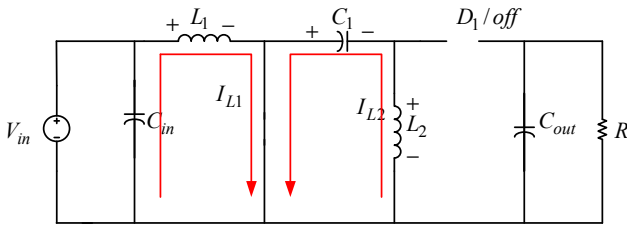

Figure 3. SW on

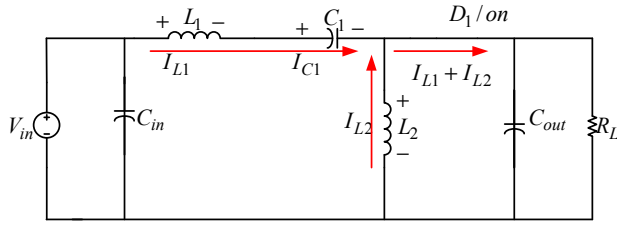

Figure 4. SW off

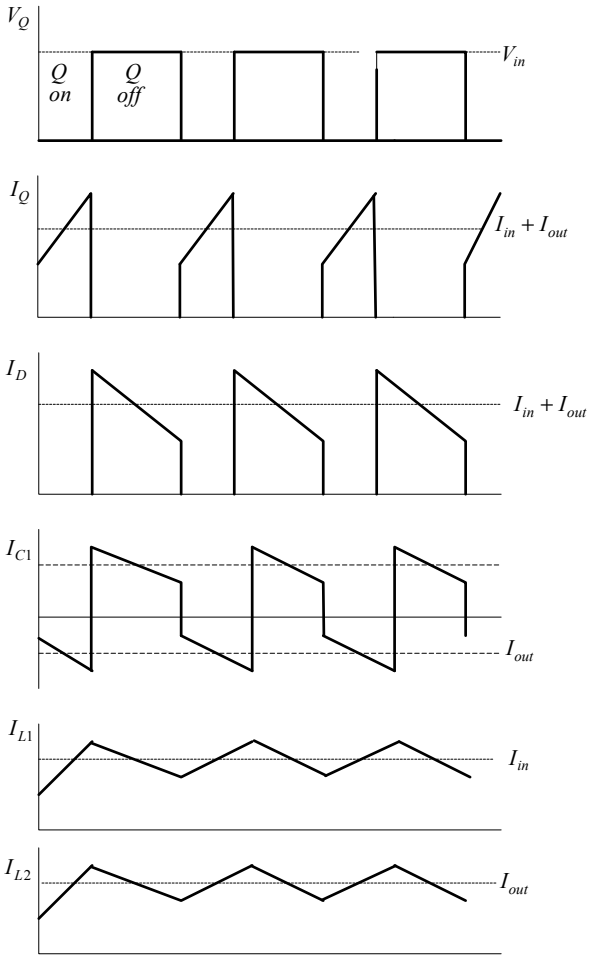

Figure 5. SEPIC Converter Switching Waveforms

$$D_{\max} = \frac{V_{out} + V_D}{V_{in(\max)} + V_{out} + V_D} \tag{2}$$

where V_D is the diode voltage. Because inductor L1 is in the input, the inductor peak to peak ripple current for the maximum input current of 40% is selected, so the L1 inductor ripple current is:

$$\Delta L_1 = I_{in} \times 40\% = \frac{I_{out}}{V_{in(\min)}} \times 40\% \tag{3}$$

Operating under the CCM, L1 must be equal to L2, the inductor value can be calculated as:

$$L_1 = L_2 \tag{4}$$

In order to ensure that the inductor saturation does not occur, the peak inductor current to be met is as follows

$$I_{L1(peak)} = \frac{V_{out} I_{out}}{V_{in(\min)}} \times (1 + \frac{40\%}{2}) \tag{5}$$

$$I_{L2(peak)} = I_{out} \times (1 + \frac{40\%}{2}) \tag{6}$$

where the inductor L1 and L2 are winded on the same core and the inductance value is half of L, then

$$L_1 = L_2 = \frac{L}{2} = D_{\max} \times \frac{V_{in(\min)}}{2 \times \Delta I_{L1} \times f_{SW}} \tag{7}$$

where f_{SW} is the switching frequency. According to the switching modes shown in Figure 3 and 4, the switch maximum voltage stress and the switch maximum current stress can be obtained, and then, the selected MOSFET switch specification will be as (8) and (9).

$$I_{SW} = I_{L1(peak)} + I_{L2(peak)} \tag{8}$$

$$V_{SW} = V_{out(\max)} + V_{in(\max)} \tag{9}$$

In the SEPIC converter circuit, the output diode D1 should withstand the reverse bias and peak output voltage.

$$V_{D(\max)} = V_{out(\max)} + V_{in(\max)} \tag{10}$$

At a fixed switching frequency and maximum duty cycle, the SEPIC coupling capacitor voltage must be greater than the maximum input voltage. The voltage ripple can be determined by the coupling capacitor, so the peak ripple voltage can approach to the input voltage as

$$\Delta V_C = \frac{I_{out} \times D_{\max}}{C_S \times f_{SW}} \times 40\% \tag{11}$$

where C is the battery capacitance. The battery capacity, adopted at the experiment, is 12V45AH with the maximum charging current limit set to 0.1C, When the battery voltage reaches to 14.4V, the minimum charge current command will be activated, and then the floating charge current command is shifted to 0.01C. Table I is SEPIC power converter implementation specifications and parameters list.

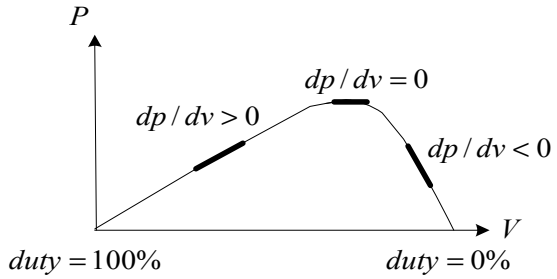

Figure 6. The PV panel power and voltage curve

III. FUZZY MAXIMUM POWER POINT TRACKING AND FUZZY CONTROL STRATEGY

In general, there are many different implementation methods for solar power systems to achieve maximum power point tracking control. One of the most popular methods used is P&O one which can be easy to be implemented, but, there are some disadvantages, for example: power will oscillates near the maximum point resulting to reduce energy efficiency of solar panels. Here, we use the fuzzy controller method for MPPT instead of the simple P&O one [1-3]. The fuzzy controller not only can reduce the time required to track the MPPT but also can reduce the fluctuation of power output. A simple fuzzy maximum power tracking control law is proposed here only with three fuzzy if-then control rules to complete the maximum power tracking work.

From PV panel power and voltage curve in Figure 6, one can see that the slope of PV curve can be partition into three parts, i.e. slope of $\Delta p/\Delta v > 0$, slope of $\Delta p/\Delta v = 0$, and slope of $\Delta p/\Delta v < 0$. Therefore; according to the slope of PV located in which part, the rate of increase of $\Delta u(k)$ is selected as one of the P, Z, or N, which denote positive, zero, and negative, respectively. The input of the proposed fuzzy logic controller is the slope $\Delta p/\Delta v$ and the output is rate change in duty ratio $\Delta u(k)$. The slope of $\Delta p/\Delta v$ is fuzzified into three partitions with triangular membership function labeled with P, Z, and N as shown in Figure 7(a). Similarly, the rate of increase of $\Delta u(k)$ is also fuzzified into three partitions with triangular membership function labeled with P, Z, and N as shown in Figure 7(b).

Thus; the fuzzy maximum power tracking control rules are given by

If $\Delta p/\Delta v$ is P Then Δu is N

If $\Delta p/\Delta v$ is Z Then Δu is Z

If $\Delta p/\Delta v$ is N Then Δu is P

The rate of increase of Δp and Δu are defined as follows:

$$\Delta p = p(k) - p(k-1) \tag{12}$$

$$\Delta v = v(k) - v(k-1) \tag{13}$$

The final control output is given by

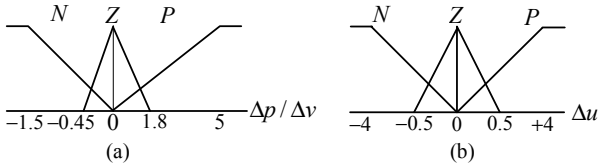

Figure 7. The membership functions of $\Delta p/\Delta v$ and Δu

$$u(k) = u(k-1) + \Delta u(k) \tag{14}$$

The actual control command $u(k)$ which is used to control the duty ratio of the switching pulse is calculated by the center weighted average defuzzification method, *i.e.*,

$$\Delta u = \frac{\sum_{i=1}^{3} w_i C_{R_i}}{\sum_{i=1}^{3} w_i} \tag{15}$$

where w_i is the antecedent part's membership function value of the *i*th-rule, C_{Ri} is the center of Consequent parts of the *i*th-rule.

When the charged current command is shifted to 0.1C or 0,01C, the fuzzy controller is activated to maintain the charged current reach to desired command value. In this situation, for precision control goal, the input variable $e(k)$, $\Delta e(k)$ and output variable $\Delta u(k)$ are fuzzified into seven fuzzy sets which are labeled as negative big (NB), negative medium (NM), negative small (NS), zero (ZE), positive small (PS), positive medium (PM), positive big (PB). The fuzzy sets used in input and output are triangular membership functions as shown in Figure 8 and Figure 9, respectively. The error e and difference of error Δe are defined as

$$e = I_{ref} - I_{BAT} \tag{16}$$

$$\Delta e(k) = e(k) - e(k-1) \tag{17}$$

where I_{ref} is the reference charged current of battery, which

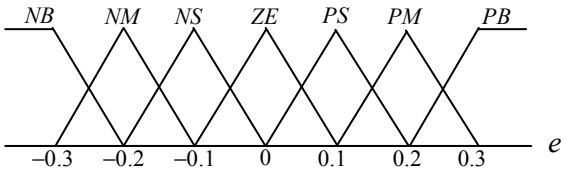

Figure 8. The the membership function of e

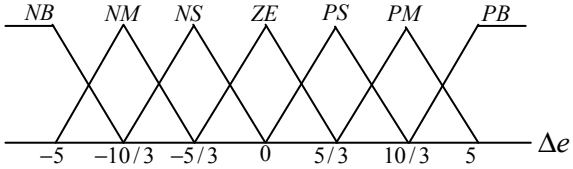

Figure 9. The the membership function of Δe

depended on how sufficiency is the solarization such that PV panel can provide either 0.1C or 0.01C current command. To simplify the design scheme of the fuzzy control, the discourse of universe of $e(k)$ is taken the same value for both 0.1C and 0.01C. and also as $\Delta e(k)$. The crisp output of the duty ratio of the switching pulse is calculated by the center weighted average defuzzification method that the same as (15). The output of the FLC is changed in duty ratio $\Delta u(k)$. The duty cycle $u(k)$ at the k*th* sampling time is defined as

$$u(k) = u(k-1) + \Delta u(k) \tag{18}$$

Then, it is sent through the PWM to DC–DC converter to generate desired switching action. The control rule must be designed in order that input variable $e(k)$ has to always be zero. The rule table of the FLC is listed in Table 2.

IV. EXPERIMENTS AND RESULTS

A. *Halogen irradiation experiments:*

The completed digital charged system circuit board is shown as Figure 10. Because of the sunlight is lack in winter, so that the experiment environment is emulated by using four 500W halogen lamps to irradiate the 120W solar cell instead. The wavelength between halogen lamp and sunlight is different, so the power generated by using halogen lamps is smaller than that from sunlight. In Figure 11, the red graph is the record for the fuzzy MPPT method, the blue curve graph is

the record of solar cell power versus voltage data.

The battery charged voltage (red) and charge current (blue) are shown in Figure 12. When the battery voltage is close to the setpoint voltage 14.3V, then controller reduce the charge current command limit to 0.01C to float charge state to keep the battery maintain full voltage state, and ultimately battery voltage will maintain at the setpoint value 14.3V.

B. solar irradiation experiments: Cloudy 12:35

At this condition, the sun illumination is 714W/m2 and the solar cells temperature is 60 degrees, Figure 13 is the maximum power point tracking record graph. At this time, because the sun illumination not enough to make controller to set the charge current command limit to 0.1C, therefore; controller is set to MPPT charge mode, Figure 14 is the solar cell V-I curve.

Due to insufficient light in the morning and afternoon, he battery voltage is less than 14.3, the controller is set to MPPT charge mode automatically, and therefore maximum power tracking is activated. Figure 15 is the Maximum power tracking record plots in a long period of time.

V. CONCLUSIONS

This paper have completed SEPIC converter circuit board and implemented the fuzzy control strategy. In order to obtain the high efficient solar cell energy conversion, a FMPPT control is activated if the solarization is insufficient. The fuzzy controller has been successfully to maintain a charged current so as that the battery voltage can reach to desired value, 0.1C charged current command and 0.01C floating charged current command. Three cases of the experimental results show that the circuit design and the proposed charge strategy are effective and feasible.

***Abstract*—In this paper, we propose two kinds of fuzzy approaches to obtain a satisfactory solution for multiobjective stochastic linear programming problems, in which the criteria of probability maximization and fractile optimization are considered simultaneously. In the first approach, a probability maximization model is applied to multiobjective stochastic linear programming problems, where the decision maker is required to specify not permissible objective levels but the corresponding membership functions which represent fuzzy goals for permissible objective levels. By adopting the fuzzy decision to integrate both the membership functions for permissible objective levels and the ones for the probability functions, a probability maximization model is transformed to the maxmin problem without permissible objective levels as parameters. Similarly, in the second approach, a fractile optimization model is applied to multiobjective stochastic linear programming problems, where the decision maker is required to specify not permissible probability levels but the corresponding membership functions which represent fuzzy goals for permissible probability levels. By adopting the fuzzy decision to integrate both the membership functions for permissible probability levels and the ones for the objective functions, a fractile optimization model is transformed to the maxmin problem without permissible probability levels as parameters. It is shown that such two fuzzy approaches are same.**

Keywords- multiobjective stochastic linear programming; probability maximization; fractile optimization; fuzzy decision

I. INTRODUCTION

In the real world decision making situations, we often have to make a decision under uncertainty. In order to deal with decision problems involving uncertainty, stochastic programming approaches and fuzzy programming approaches have been developed. In stochastic programming approaches, two stage problems [3] and chance constrained programming models [1] have been investigated in various ways, and they were extended to multiobjective stochastic programming problems [7],[10]. In fuzzy programming approaches, various types of fuzzy programming problems have been formulated and investigated [5],[6],[12]. As a natural extension, multiobjective fuzzy programming technique first proposed by Zimmermann [11], and many methods have been proposed [8],[12].

Recently, in order to deal with probabilistic uncertainty and fuzzy one simultaneously, the hybrid approaches of stochastic programming and fuzzy programming have been proposed [4]. Especially, Sakawa et al. [9] proposed an interactive fuzzy satisficing method for multiobjective linear programming problem with random variable coefficients. In their method, a probability maximization model was adopted to transform stochastic programming problems into well-defined mathematical programming ones. When adopting a probability maximization model, it is required in advance that the decision maker specifies permissible levels for objective functions (called permissible objective levels) in his/her subjective manner. However, it seems to be very difficult to specify such values in advance, because there exist conflicts among permissible objective levels and the corresponding distribution function values. This means that the less values of permissible objective levels for minimization problems results in the less values of the corresponding distribution function. On the other hand, when a fractile optimization model is adopted, it is required in advance that the decision maker specifies permissible levels for the probability levels (called permissible probability levels) in his/her subjective manner. Similar to a probability maximization model, there exist conflicts among permissible probability levels and the corresponding objective function values. This means that the larger values of permissible probability levels results in the larger values of the corresponding objective function for minimization problems.

In this paper, we propose two kinds of fuzzy approaches to obtain a satisfactory solution for multiobjective stochastic linear programming problems, in which the criteria of probability maximization and fractile optimization are considered simultaneously. In section II, in order to deal with a probability maximization model and a fractile optimization model for multiobjective stochastic linear programming problems, P-Pareto optimal solution concept and F-Pareto optimal solution concept are defined respectively. The relationships between them are investigated. In section III, a probability maximization model is applied to multiobjective stochastic linear programming problems, where the decision maker is required to specify the membership functions which represent fuzzy goals for permissible objective levels. By adopting the fuzzy decision [8],[12] to integrate both the membership functions for permissible objective levels and the ones for the probability functions, a probability maximization model is transformed

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

to the maxmin problem without permissible objective levels as parameters. In section IV, a fractile optimization model is applied to multiobjective stochastic linear programming problems, where the decision maker is required to specify the membership functions which represent fuzzy goals for permissible probability levels. By adopting the fuzzy decision [8],[12] to integrate both the membership functions for permissible probability levels and the ones for the objective functions, a fractile optimization model is transformed to the maxmin problem without permissible probability levels as parameters. It is shown that two types of maxmin problems based on a probability maximization model and a fractile optimization model are same. In section V, an illustrative numerical example, which is formulated by Sakawa et al. [9], for multiobjective stochastic linear programming problems demonstrates the feasibility of the proposed approach.

II. Two Formulations for Multiobjective Stochastic Linear Programming Problems Through a Probability Maximization Model and a Fractile Optimization Model

In this section, we focus on multiobjective linear programming problem involving random variable coefficients in objective functions and the right-hand side of constraints, which is called multiobjective stochastic linear programming problem (MOSLP). MOSLP can be formally formulated as follows.

[MOSLP]

$$\min_{\boldsymbol{x}\geq\boldsymbol{0}} \boldsymbol{z}(\boldsymbol{x},\omega) = (z_1(\boldsymbol{x},\omega),\cdots,z_k(\boldsymbol{x},\omega)) \tag{1}$$

subject to

$$A\boldsymbol{x} \leq \boldsymbol{b}(\omega) \tag{2}$$

where $\boldsymbol{x} = (x_1, x_2, \cdots, x_n)^T$ is an n dimensional decision variable column vector,

$$z_i(\boldsymbol{x},\omega) = \boldsymbol{c}_i(\omega)\boldsymbol{x} + \alpha_i(\omega), i = 1,\cdots,k, \tag{3}$$

are multiobjective functions involving random variable coefficients, $\boldsymbol{c}_i(\omega)$ is a n dimensional random variable row vector expressed by $\boldsymbol{c}_i(\omega) = \boldsymbol{c}_i^1 + t_i(\omega)\boldsymbol{c}_i^2$ where $t_i(\omega)$ is a random variable and $\alpha_i(\omega)$ is a random variable row vector expressed by $\alpha_i(\omega) = \alpha_i^1 + t_i(\omega)\alpha_i^2$. A is an $(m\times n)$ coefficient matrix, $\boldsymbol{b}(\omega) = (b_1(\omega),\cdots,b_m(\omega))^T$ is an m dimensional column vector, whose elements $b_j(\omega), j = 1,\cdots,m$ are random variables independent each other. Let us denote distribution functions of random variables $t_i(\omega)$ and $b_j(\omega)$ as follows.

$$T_i(r) \stackrel{\text{def}}{=} \Pr(t_i(\omega) < r), i = 1,\cdots,k \tag{4}$$

$$F_j(r) \stackrel{\text{def}}{=} \Pr(b_j(\omega) < r), j = 1,\cdots,m \tag{5}$$

It is assumed that distribution functions $T_i(\cdot), i = 1,\cdots,k$ and $F_j(\cdot), j = 1,\cdots,m$ are strictly increasing and continuous.

Since MOSLP contains random variable coefficients in objective functions and the right-hand side of constraints, mathematical programming techniques can not be directly applied. In order to deal with MOSLP, we interpret the constraints (2) as chance constrained conditions [1], which mean that the j-th constraint of (2) is required to be satisfied with a certain probability β_j (called a constraint probability level) and over.

$$X(\boldsymbol{\beta}) = \{\boldsymbol{x} \geq \boldsymbol{0} \mid \Pr(\boldsymbol{a}_j\boldsymbol{x} \leq b_j(\omega)) \geq \beta_j, j = 1,\cdots,m\} \tag{6}$$

where $\boldsymbol{a}_j$ is the j-th row vector of A. Using a distribution function $F_j(r)$, the j-th constraint in (6) can be rewritten as follows.

$$\begin{aligned} & \Pr(\boldsymbol{a}_j\boldsymbol{x} \leq b_j(\omega)) \geq \beta_j, \\ \Leftrightarrow\ & 1 - F_j(\boldsymbol{a}_j\boldsymbol{x}) \geq \beta_j, \\ \Leftrightarrow\ & F_j(\boldsymbol{a}_j\boldsymbol{x}) \leq 1 - \beta_j, \\ \Leftrightarrow\ & \boldsymbol{a}_j\boldsymbol{x} \leq F_j^{-1}(1-\beta_j) \end{aligned}$$

where $F_j^{-1}(\cdot)$ means a pseudo-inverse function corresponding to $F_j(\cdot)$ defined by $F_j^{-1}(h) = \inf\{y \mid F_j(y) \geq h\}$.

Under the above chance constrained conditions (6), if we adopt a probability maximization model for the objective functions in MOSLP, we can substitute the minimization of the objective functions $z_i(\boldsymbol{x},\omega) = \boldsymbol{c}_i(\omega)\boldsymbol{x} + \alpha_i(\omega), i = 1,\cdots,k$ for the maximization of the probability that each objective functions $z_i(\boldsymbol{x},\omega)$ is less than or equal to a certain permissible level $\bar{f}_i$ (called a permissible objective level). Such a probability function can be defined as follows.

$$p_i(\boldsymbol{x},\bar{f}_i) \stackrel{\text{def}}{=} \Pr(z_i(\boldsymbol{x},\omega) \leq \bar{f}_i), i = 1,\cdots,k \tag{7}$$

where

$$\bar{\boldsymbol{f}} = (\bar{f}_1,\cdots,\bar{f}_k). \tag{8}$$

is a k-dimensional vector of permissible objective levels which are specified by the decision maker in his/her subjective manner. Then, MOSLP can be converted as the following form.

[MOP1($\bar{\boldsymbol{f}},\boldsymbol{\beta}$)]

$$\max_{\boldsymbol{x}\in X(\boldsymbol{\beta})} (p_1(\boldsymbol{x},\bar{f}_1),\cdots,p_k(\boldsymbol{x},\bar{f}_k)) \tag{9}$$

In MOP1($\bar{\boldsymbol{f}},\boldsymbol{\beta}$), assuming that $\boldsymbol{c}_i^2\boldsymbol{x} + \alpha_i^2 > 0, i = 1,\cdots,k$ for any $\boldsymbol{x} \in X(\boldsymbol{\beta})$, we can rewrite the objective function $p_i(\boldsymbol{x},\bar{f}_i)$ as follows.

$$\begin{aligned} p_i(\boldsymbol{x},\bar{f}_i) &= \Pr(z_i(\boldsymbol{x},\omega) \leq \bar{f}_i) \\ &= \Pr(\boldsymbol{c}_i(\omega)\boldsymbol{x} + \alpha_i(\omega) \leq \bar{f}_i) \\ &= \Pr((\boldsymbol{c}_{r\ell}^1 + t_{r\ell}(\omega)\boldsymbol{c}_{r\ell}^2)\boldsymbol{x} \\ &\quad +(\alpha_{r\ell}^1 + t_{r\ell}(\omega)\alpha_{r\ell}^2) \leq f_{r\ell}) \\ &= \Pr\left(t_i(\omega) \leq \frac{\bar{f}_i - (\boldsymbol{c}_i^1\boldsymbol{x} + \alpha_i^1)}{\boldsymbol{c}_i^2\boldsymbol{x} + \alpha_i^2}\right) \\ &= T_i\left(\frac{\bar{f}_i - (\boldsymbol{c}_i^1\boldsymbol{x} + \alpha_i^1)}{\boldsymbol{c}_i^2\boldsymbol{x} + \alpha_i^2}\right) \end{aligned}$$

In order to deal with MOP1($\bar{\boldsymbol{f}},\beta$), we introduce a P-Pareto optimal solution concept as follows.

Definition 1.

$\boldsymbol{x}^* \in X(\boldsymbol{\beta})$ is said to be a P-Pareto optimal solution to MOP1($\bar{\boldsymbol{f}},\boldsymbol{\beta}$), if and only if there does not exist another $\boldsymbol{x} \in X(\boldsymbol{\beta})$ such that $p_i(\boldsymbol{x},\bar{f}_i) \geq p_i(\boldsymbol{x}^*,\bar{f}_i)$, $i = 1,\cdots,k$, with strict inequality holding for at least one i.

On the other hand, if we adopt a fractile optimization model for the objective functions in MOSLP under the chance constrained conditions (6), we can convert MOSLP to the following multiobjective programming problem.

[MOP2($\bar{\boldsymbol{p}}, \boldsymbol{\beta}$)]

$$\min_{\boldsymbol{x} \in X(\boldsymbol{\beta}), \bar{f}_i, i=1,\cdots,k} (\bar{f}_1, \cdots, \bar{f}_k) \tag{10}$$

subject to

$$p_i(\boldsymbol{x}, \bar{f}_i) \geq \bar{p}_i, i = 1, \cdots, k \tag{11}$$

where

$$\bar{\boldsymbol{p}} = (\bar{p}_1, \cdots, \bar{p}_k) \tag{12}$$

is a k-dimensional vector of permissible probability levels which are specified by the decision maker in his/her subjective manner.

In MOP2($\bar{\boldsymbol{p}}, \beta$), since a distribution function $T_i(\cdot)$ is continuous and strictly increasing and continuous, the constraints (11) can be transformed to the following form.

$$\begin{aligned} \bar{p}_i &\leq p_i(\boldsymbol{x}, \bar{f}_i) = T_i\left(\frac{\bar{f}_i - (\boldsymbol{c}_i^1 \boldsymbol{x} + \alpha_i^1)}{\boldsymbol{c}_i^2 \boldsymbol{x} + \alpha_i^2}\right) \\ \Leftrightarrow \bar{f}_i &\geq T_i^{-1}(\bar{p}_i) \cdot (\boldsymbol{c}_i^2 \boldsymbol{x} + \alpha_i^2) + (\boldsymbol{c}_i^1 \boldsymbol{x} + \alpha_i^1) \end{aligned} \tag{13}$$

Let us define the right-hand side of the inequality (13) as follows.

$$f_i(\boldsymbol{x}, \bar{p}_i) \stackrel{\text{def}}{=} T_i^{-1}(\bar{p}_i) \cdot (\boldsymbol{c}_i^2 \boldsymbol{x} + \alpha_i^2) + (\boldsymbol{c}_i^1 \boldsymbol{x} + \alpha_i^1) \tag{14}$$

Then, MOP2($\bar{\boldsymbol{p}}, \boldsymbol{\beta}$) can be equivalently reduced to the following simple form, where $\bar{f}_i, i = 1, \cdots, k$ are disappeared.

[MOP3($\bar{\boldsymbol{p}}, \boldsymbol{\beta}$)]

$$\min_{\boldsymbol{x} \in X(\boldsymbol{\beta})} (f_1(\boldsymbol{x}, \bar{p}_1), \cdots, f_k(\boldsymbol{x}, \bar{p}_k)) \tag{15}$$

In order to deal with MOP3($\bar{\boldsymbol{p}}, \boldsymbol{\beta}$), we introduce an F-Pareto optimal solution concept as follows.

Definition 2.

$\boldsymbol{x}^* \in X(\boldsymbol{\beta})$ is said to be an F-Pareto optimal solution to MOP3($\bar{\boldsymbol{p}}, \boldsymbol{\beta}$), if and only if there does not exist another $\boldsymbol{x} \in X(\boldsymbol{\beta})$ such that $f_i(\boldsymbol{x}, \bar{p}_i) \leq f_i(\boldsymbol{x}^*, \bar{p}_i),\ i = 1, \cdots, k$, with strict inequality holding for at least one i.

The relationships between a P-Pareto optimal solution to MOP1($\bar{\boldsymbol{f}}, \boldsymbol{\beta}$) and an F-Pareto optimal solution to MOP3($\bar{\boldsymbol{p}}, \boldsymbol{\beta}$) can be characterized by the following theorem.

Theorem 1.

(1) If $\boldsymbol{x}^* \in X(\boldsymbol{\beta})$ is a P-Pareto optimal solution to MOP1($\bar{\boldsymbol{f}}, \boldsymbol{\beta}$) for some given permissible objective levels $\bar{\boldsymbol{f}}$, then, there exist some permissible probability levels $\bar{\boldsymbol{p}}$ such that $\boldsymbol{x}^* \in X(\boldsymbol{\beta})$ is an F-Pareto optimal solution to MOP3($\bar{\boldsymbol{p}}, \boldsymbol{\beta}$).

(2) If $\boldsymbol{x}^* \in X(\boldsymbol{\beta})$ is an F-Pareto optimal solution to MOP3($\bar{\boldsymbol{p}}, \boldsymbol{\beta}$) for some given permissible probability levels $\bar{\boldsymbol{p}}$, then, there exist some permissible objective levels $\bar{\boldsymbol{f}}$ such that $\boldsymbol{x}^* \in X(\boldsymbol{\beta})$ is a P-Pareto optimal solution to MOP1($\bar{\boldsymbol{f}}, \boldsymbol{\beta}$).

(Proof)

(1) Assume that $\boldsymbol{x}^* \in X(\boldsymbol{\beta})$ is a P-Pareto optimal solution to MOP1($\bar{\boldsymbol{f}}, \boldsymbol{\beta}$) for some given permissible objective levels $\bar{\boldsymbol{f}}$. Then, from Definition 1, there does not exist $\boldsymbol{x} \in X(\boldsymbol{\beta})$ such that

$$\begin{aligned} & p_i(\boldsymbol{x}, \bar{f}_i) \geq p_i(\boldsymbol{x}^*, \bar{f}_i) \\ \Leftrightarrow\ & T_i\left(\frac{\bar{f}_i - (\boldsymbol{c}_i^1 \boldsymbol{x} + \alpha_i^1)}{\boldsymbol{c}_i^2 \boldsymbol{x} + \alpha_i^2}\right) \geq T_i\left(\frac{\bar{f}_i - (\boldsymbol{c}_i^1 \boldsymbol{x}^* + \alpha_i^1)}{\boldsymbol{c}_i^2 \boldsymbol{x}^* + \alpha_i^2}\right) \\ & i = 1, \cdots, k \end{aligned} \tag{16}$$

with strict inequality holding for at least one i. For the left-hand side of the inequality (16), let us set as :

$$\bar{p}_i = T_i\left(\frac{\bar{f}_i - (\boldsymbol{c}_i^1 \boldsymbol{x}^* + \alpha_i^1)}{\boldsymbol{c}_i^2 \boldsymbol{x}^* + \alpha_i^2}\right). \tag{17}$$

Then, because of the definition (14) and $\boldsymbol{c}_i^2 \boldsymbol{x} + \alpha_i^2 > 0$, the inequality (16) can be transformed as follows.

$$\begin{aligned} & T_i\left(\frac{\bar{f}_i - (\boldsymbol{c}_i^1 \boldsymbol{x} + \alpha_i^1)}{\boldsymbol{c}_i^2 \boldsymbol{x} + \alpha_i^2}\right) \geq \bar{p}_i \\ \Leftrightarrow\ & \bar{f}_i - (\boldsymbol{c}_i^1 \boldsymbol{x} + \alpha_i^1) \geq T_i^{-1}(\bar{p}_i) \cdot (\boldsymbol{c}_i^2 \boldsymbol{x} + \alpha_i^2) \\ \Leftrightarrow\ & \bar{f}_i \geq f_i(\boldsymbol{x}, \bar{p}_i) \end{aligned} \tag{18}$$

On the other hand, from the relationship (17), it immediately holds that

$$\begin{aligned} \bar{f}_i &= T_i^{-1}(\bar{p}_i) \cdot (\boldsymbol{c}_i^2 \boldsymbol{x}^* + \alpha_i^2) + (\boldsymbol{c}_i^1 \boldsymbol{x}^* + \alpha_i^1) \\ &= f_i(\boldsymbol{x}^*, \bar{p}_i). \end{aligned}$$

This means that there does not exist $\boldsymbol{x} \in X(\boldsymbol{\beta})$ such that $f_i(\boldsymbol{x}, \bar{p}_i) \leq f_i(\boldsymbol{x}^*, \bar{p}_i),\ i = 1, \cdots, k$ with strict inequality holding for at least one i. Therefore, $\boldsymbol{x}^* \in X(\boldsymbol{\beta})$ is an F-Pareto optimal solution to MOP3($\bar{\boldsymbol{p}}, \boldsymbol{\beta}$).

(2) The proof is same to (1).

Sakawa et al.[9] formulated multiobjective linear programming problems with random variable coefficients in objective functions through a probability maximization model. In their approach, assuming that the decision maker has a fuzzy goal for each distribution function $p_i(\boldsymbol{x}, \bar{f}_i)$, the satisfactory solution is derived from among M-Pareto optimal solution set by updating the reference membership levels in membership space. However, in a probability maximization model, the permissible objective levels $\bar{f}_i, i = 1, \cdots, k$ for the original objective functions $z_i(\boldsymbol{x}, \omega), i = 1, \cdots, k$ must be specified in advance by the decision. The less values for the permissible objective levels $\bar{f}_i, i = 1, \cdots, k$ in MOP1($\bar{\boldsymbol{f}}, \boldsymbol{\beta}$) will give the less values for the corresponding distribution functions $p_i(\boldsymbol{x}, \bar{f}_i), i = 1, \cdots, k$. As a result, if the decision maker specifies the less values for the permissible objective levels $\bar{f}_i, i = 1, \cdots, k$, he/she may not be able to accept any candidate of the satisfactory solution, because the corresponding values of the distribution functions $p_i(\boldsymbol{x}, \bar{f}_i), i = 1, \cdots, k$ will become close to zero.

On the other hand, instead of a probability maximization model, let us consider the case where a fractile optimization model is adopted to formulate multiobjective linear programming problems with random variable coefficients in objective functions. In such a model, the permissible probability levels $\bar{p}_i, i = 1, \cdots, k$ must be specified by the decision maker in advance. The larger values for the permissible probability

levels $\bar{p}_i, i = 1, \cdots, k$ will give the larger values for the objective functions $f_i(\boldsymbol{x}, \bar{p}_i), i = 1, \cdots, k$ for minimization problems. As a result, similar to the case where a probability maximization model is adopted, if the decision maker specifies the larger values for the permissible probability levels $\bar{p}_i, i = 1, \cdots, k$, he/she may not be able to accept any candidate of the satisfactory solution, because the corresponding values of the objective functions $f_i(\boldsymbol{x}, \bar{p}_i), i = 1, \cdots, k$ will become the larger values.

In the next section, we assume that, the decision maker has fuzzy goals for not only each distribution function $p_i(\boldsymbol{x}, \bar{f}_i)$ but also each permissible objective levels $\bar{f}_i$ for MOSLP through a probability maximization model. After eliciting the membership functions for such fuzzy goals, we propose a fuzzy approach for MOSLP through a probability maximization model. to obtain the satisfactory solution.

III. A Fuzzy Approach for Multiobjective Stochastic Linear Programming Problems Through a Probability Maximization Model

In this section, we propose a fuzzy approach to MOP1($\bar{\boldsymbol{f}}, \boldsymbol{\beta}$) where MOSLP is formulated through a probability maximization model. In order to deal with MOP1($\bar{\boldsymbol{f}}, \boldsymbol{\beta}$), the decision maker must specify his/her permissible objective levels $\bar{\boldsymbol{f}}$ in advance. However, in general, the decision maker seems to prefer not only the larger value of the distribution function $p_i(\boldsymbol{x}, \bar{f}_i)$ but also the less value of permissible objective level $\bar{f}_i$. Since these values conflict with each other, the less values of permissible objective level $\bar{f}_i$ results in the less value of probability function $p_i(\boldsymbol{x}, \bar{f}_i)$. From such a point of view, we consider the following multiobjective programming problem which can be regarded as a natural extension of MOP1($\bar{\boldsymbol{f}}, \boldsymbol{\beta}$).

[MOP4($\boldsymbol{\beta}$)]

$$\max_{\boldsymbol{x} \in X(\boldsymbol{\beta}), \bar{f}_i, i=1,\cdots,k} \big(p_1(\boldsymbol{x}, \bar{f}_1), \cdots, p_k(\boldsymbol{x}, \bar{f}_k), -\bar{f}_1, \cdots, -\bar{f}_k\big) \tag{19}$$

It should be noted in MOP4($\boldsymbol{\beta}$) that the permissible objective levels $\bar{f}_i, i = 1, \cdots, k$ are not the fixed values but the decision variables.

Considering the imprecise nature of the decision maker's judgment, it is natural to assume that the decision maker have fuzzy goals for each objective function in MOP4($\boldsymbol{\beta}$). In this section, we assume that such fuzzy goals can be quantified by eliciting the corresponding membership functions. Let us denote a membership function of a probability function $p_i(\boldsymbol{x}, \bar{f}_i)$ as $\mu_{p_i}(p_i(\boldsymbol{x}, \bar{f}_i))$, and a membership function of a permissible objective level $\bar{f}_i$ as $\mu_{\bar{f}_i}(\bar{f}_i)$ respectively. Then, MOP4($\boldsymbol{\beta}$) can be transformed as the following multiobjective programming problem.

[MOP5($\boldsymbol{\beta}$)]

$$\max_{\boldsymbol{x} \in X(\boldsymbol{\beta}), \bar{f}_i, i=1,\cdots,k} \big(\mu_{p_1}(p_1(\boldsymbol{x}, \bar{f}_1)), \cdots, \mu_{p_k}(p_k(\boldsymbol{x}, \bar{f}_k)), \mu_{\bar{f}_1}(\bar{f}_1), \cdots, \mu_{\bar{f}_k}(\bar{f}_k)\big) \tag{20}$$

Throughout this section, we make the following assumptions.

Assumption 1.
$\mu_{\bar{f}_i}(\bar{f}_i), i = 1, \cdots, k$ are strictly decreasing and continuous with respect to $\bar{f}_i$.

Assumption 2.
$\mu_{p_i}(p_i(\boldsymbol{x}, \bar{f}_i)), i = 1, \cdots, k$ are strictly increasing and continuous with respect to $p_i(\boldsymbol{x}, \bar{f}_i)$.

For example, we can define the membership functions $\mu_{\bar{f}_i}(\bar{f}_i)$, $\mu_{p_i}(p_i(\boldsymbol{x}, \bar{f}_i)), i = 1, \cdots, k$ as follows. Considering the individual minimum and maximum of $E(z_i(\boldsymbol{x}, \omega))$:

$$\min_{\boldsymbol{x} \in X(\boldsymbol{\beta})} \; / \; \max_{\boldsymbol{x} \in X(\boldsymbol{\beta})} E(z_i(\boldsymbol{x}, \omega)), i = 1, \cdots, k,$$

the decision maker subjectively specifies a sufficiently satisfactory maximum value $f_{i\min}$ and an acceptable maximum value $f_{i\max}$. Then, the domain of $\mu_{\bar{f}_i}(\bar{f}_i)$ can be set as:

$$F_i = [f_{i\min}, f_{i\max}]. \tag{21}$$

According to Assumption 1, the decision maker can define his/her membership function $\mu_{\bar{f}_i}(\bar{f}_i)$ on the domain F_i. Corresponding to the domain F_i, let us denote the domain of $\mu_{p_i}(p_i(\boldsymbol{x}, f_i))$ as:

$$P_i(F_i) = [p_{i\min}, p_{i\max}]. \tag{22}$$

where $p_{i\min}$ is an acceptable minimum value and $p_{i\max}$ is a sufficiently satisfactory minimum value. $p_{i\max}$ can be obtained by solving the following problem.

$$p_{i\max} = \max_{\boldsymbol{x} \in X(\boldsymbol{\beta})} p_i(\boldsymbol{x}, f_{i\max}) \tag{23}$$

It should be noted here that the above problem is equivalent to the following linear fractional programming problem [2] because a distribution function $T_i(\cdot)$ is strictly increasing and continuous.

$$\max_{\boldsymbol{x} \in X(\boldsymbol{\beta})} \left(\frac{f_{i\max} - (\boldsymbol{c}_i^1 \boldsymbol{x} + \alpha_i^1)}{\boldsymbol{c}_i^2 \boldsymbol{x} + \alpha_i^2} \right) \tag{24}$$

On the other hand, in order to obtain $p_{i\min}$, we first solve $\max_{\boldsymbol{x} \in X(\boldsymbol{\beta})} p_i(\boldsymbol{x}, f_{i\min})$, and denote the corresponding optimal solution as $\boldsymbol{x}_i$. Using the optimal solutions $\boldsymbol{x}_i, i = 1, \cdots, k$, $p_{i\min}$ can be obtained as follows.

$$p_{i\min} = \min_{\ell=1,\cdots,k, \ell \neq i} p_i(\boldsymbol{x}_\ell, f_{i\min}) \tag{25}$$

According to Assumption 2, the decision maker can define his/her membership function $\mu_{p_i}(p_i(\boldsymbol{x}, \bar{f}_i))$ on the domain $P_i(F_i)$.

Then, if the decision maker adopts the fuzzy decision [8],[12] as an aggregation operator for MOP5($\boldsymbol{\beta}$), the satisfactory solution is obtained by solving the following maxmin problem.

[MAXMIN1]

$$\max_{\boldsymbol{x} \in X(\boldsymbol{\beta}), \bar{f}_i \in F_i, i=1,\cdots,k, \lambda \in [0,1]} \lambda \tag{26}$$

subject to

$$\mu_{p_i}(p_i(\boldsymbol{x}, \bar{f}_i)) \geq \lambda, i = 1, \cdots, k \tag{27}$$

$$\mu_{\bar{f}_i}(\bar{f}_i) \geq \lambda, i = 1, \cdots, k \tag{28}$$

Because of Assumption 2 and $\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2>0$, the constraints (27) can be transformed as:

$$\begin{aligned}
&\mu_{p_i}(p_i(\boldsymbol{x},\bar{f}_i))\geq\lambda,\\
\Leftrightarrow\quad & p_i(\boldsymbol{x},\bar{f}_i)\geq\mu_{p_i}^{-1}(\lambda),\\
\Leftrightarrow\quad & T_i\left(\frac{\bar{f}_i-(\boldsymbol{c}_i^1\boldsymbol{x}+\alpha_i^1)}{\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2}\right)\geq\mu_{p_i}^{-1}(\lambda),\\
\Leftrightarrow\quad & \bar{f}_i-(\boldsymbol{c}_i^1\boldsymbol{x}+\alpha_i^1)\geq T_i^{-1}(\mu_{p_i}^{-1}(\lambda))\cdot(\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2),
\end{aligned}\tag{29}$$

where $\mu_{p_i}^{-1}(\cdot)$ is a pseudo-inverse function. From the constraints (28) and Assumption 1, it holds that $\bar{f}_i\leq\mu_{\bar{f}_i}^{-1}(\lambda)$. Therefore, the constraint (29) can be reduced to the following inequality where a permissible objective level $\bar{f}_i$ is disappeared.

$$\mu_{\bar{f}_i}^{-1}(\lambda)-(\boldsymbol{c}_i^1\boldsymbol{x}+\alpha_i^1)\geq T_i^{-1}(\mu_{p_i}^{-1}(\lambda))\cdot(\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2)\tag{30}$$

Then, MAXMIN1 is equivalently transformed into the following problem.

[MAXMIN2]

$$\max_{\boldsymbol{x}\in X(\boldsymbol{\beta}),\lambda\in[0,1]}\ \lambda\tag{31}$$

subject to

$$\begin{aligned}
\mu_{\bar{f}_i}^{-1}(\lambda)-(\boldsymbol{c}_i^1\boldsymbol{x}+\alpha_i^1)\quad\geq\quad & T_i^{-1}(\mu_{p_i}^{-1}(\lambda))\cdot(\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2),\\
& i=1,\cdots,k
\end{aligned}\tag{32}$$

It should be noted here that the constraints (32) can be reduced to a set of linear inequalities for some fixed value $\lambda\in[0,1]$. This means that an optimal solution $(\boldsymbol{x}^*,\lambda^*)$ of MAXMIN2 is obtained by combined use of the bisection method with respect to λ and the first-phase of the two-phase simplex method of linear programming.

The relationships between the optimal solution $(\boldsymbol{x}^*,\lambda^*)$ of MAXMIN2, P-Pareto optimal solutions to MOP1$(\bar{\boldsymbol{f}},\boldsymbol{\beta})$, and F-Pareto optimal solutions to MOP3$(\bar{\boldsymbol{p}},\boldsymbol{\beta})$ can be characterized by the following theorem.

Theorem 2.

(1) If $(\boldsymbol{x}^*,\lambda^*)$ is a unique optimal solution of MAXMIN2, then $\boldsymbol{x}^*\in X(\boldsymbol{\beta})$ is a P-Pareto optimal solution to MOP1$(\bar{\boldsymbol{f}}^*,\boldsymbol{\beta})$, where $\bar{\boldsymbol{f}}^*=(\bar{f}_1^*,\cdots,\bar{f}_k^*)=(\mu_{\bar{f}_1}^{-1}(\lambda^*),\cdots,\mu_{\bar{f}_k}^{-1}(\lambda^*))$.

(2) If $(\boldsymbol{x}^*,\lambda^*)$ is a unique optimal solution of MAXMIN2, then $\boldsymbol{x}^*\in X(\boldsymbol{\beta})$ is an F-Pareto optimal solution to MOP3$(\bar{\boldsymbol{p}}^*,\boldsymbol{\beta})$, where $\bar{\boldsymbol{p}}^*=(\bar{p}_1^*,\cdots,\bar{p}_k^*)=(\mu_{p_1}^{-1}(\lambda^*),\cdots,\mu_{p_k}^{-1}(\lambda^*))$.

(Proof)

(1) Let $(\boldsymbol{x}^*,\lambda^*)$ be a unique optimal solution of MAXMIN2. Since an optimal solution $(\boldsymbol{x}^*,\lambda^*)$ satisfies the constraints (32), it holds that

$$\begin{aligned}
&\mu_{\bar{f}_i}^{-1}(\lambda^*)-(\boldsymbol{c}_i^1\boldsymbol{x}^*+\alpha_i^1)\\
&\geq T_i^{-1}(\mu_{p_i}^{-1}(\lambda^*))\cdot(\boldsymbol{c}_i^2\boldsymbol{x}^*+\alpha_i^2),\\
\Leftrightarrow\quad & T_i\left(\frac{\mu_{\bar{f}_i}^{-1}(\lambda^*)-(\boldsymbol{c}_i^1\boldsymbol{x}^*+\alpha_i^1)}{\boldsymbol{c}_i^2\boldsymbol{x}^*+\alpha_i^2}\right)=p_i(\boldsymbol{x}^*,\mu_{\bar{f}_i}^{-1}(\lambda^*))\\
&\geq\mu_{p_i}^{-1}(\lambda^*),i=1,\cdots,k.
\end{aligned}$$

Assume that $\boldsymbol{x}^*\in X(\beta)$ is not a P-Pareto optimal solution to MOP1$(\bar{\boldsymbol{f}}^*,\boldsymbol{\beta})$, where $\bar{\boldsymbol{f}}^*=(\mu_{\bar{f}_1}^{-1}(\lambda^*),\cdots,\mu_{\bar{f}_k}^{-1}(\lambda^*))$, then there exists $\boldsymbol{x}\in X(\boldsymbol{\beta})$ such that

$$\begin{aligned}
&p_i(\boldsymbol{x},\mu_{\bar{f}_i}^{-1}(\lambda^*))\geq p_i(\boldsymbol{x}^*,\mu_{\bar{f}_i}^{-1}(\lambda^*))\geq\mu_{p_i}^{-1}(\lambda^*),\\
&i=1,\cdots,k.
\end{aligned}$$

This means that there exists $\boldsymbol{x}\in X(\boldsymbol{\beta})$ such that

$$\begin{aligned}
\mu_{\bar{f}_i}^{-1}(\lambda^*)-(\boldsymbol{c}_i^1\boldsymbol{x}+\alpha_i^1)\quad\geq\quad & T_i^{-1}(\mu_{p_i}^{-1}(\lambda^*))\cdot(\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2),\\
& i=1,\cdots,k,
\end{aligned}$$

which contradicts the fact that $(\boldsymbol{x}^*,\lambda^*)$ is a unique optimal solution of MAXMIN2.

(2) Assume that $\boldsymbol{x}^*\in X(\boldsymbol{\beta})$ is not an F-Pareto optimal solution to MOP3$(\bar{\boldsymbol{p}}^*,\boldsymbol{\beta})$, where $\bar{p}_i^*=\mu_{p_i}^{-1}(\lambda^*),i=1,\cdots,k$. Then, because of (14), there exists $\boldsymbol{x}\in X(\boldsymbol{\beta})$ such that

$$\begin{aligned}
&f_i(\boldsymbol{x},\bar{p}_i^*)\leq f_i(\boldsymbol{x}^*,\bar{p}_i^*)\\
\Leftrightarrow\quad & T_i^{-1}(\bar{p}_i^*)\cdot(\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2)+(\boldsymbol{c}_i^1\boldsymbol{x}+\alpha_i^1)\\
\leq\quad & T_i^{-1}(\bar{p}_i^*)\cdot(\boldsymbol{c}_i^2\boldsymbol{x}^*+\alpha_i^2)+(\boldsymbol{c}_i^1\boldsymbol{x}^*+\alpha_i^1)\stackrel{\text{def}}{=}\bar{f}_i^*\\
\Leftrightarrow\quad & \bar{f}_i^*-(\boldsymbol{c}_i^1\boldsymbol{x}+\alpha_i^1)\geq T_i^{-1}(\bar{p}_i^*)\cdot(\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2)\\
\Leftrightarrow\quad & \bar{f}_i^*-(\boldsymbol{c}_i^1\boldsymbol{x}+\alpha_i^1)\geq T_i^{-1}(\mu_{p_i}^{-1}(\lambda^*))\cdot(\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2)
\end{aligned}$$

On the other hand, since $(\boldsymbol{x}^*,\lambda^*)$ is an optimal solution of MAXMIN2, from (32), it holds that

$$\mu_{\bar{f}_i}^{-1}(\lambda^*)-(\boldsymbol{c}_i^1\boldsymbol{x}^*+\alpha_i^1)\geq T_i^{-1}(\mu_{p_i}^{-1}(\lambda^*))\cdot(\boldsymbol{c}_i^2\boldsymbol{x}^*+\alpha_i^2).$$

This means that

$$\begin{aligned}
\mu_{\bar{f}_i}^{-1}(\lambda^*)\quad\geq\quad & (\boldsymbol{c}_i^1\boldsymbol{x}^*+\alpha_i^1)+T_i^{-1}(\mu_{p_i}^{-1}(\lambda^*))\cdot(\boldsymbol{c}_i^2\boldsymbol{x}^*+\alpha_i^2)\\
=\quad & \bar{f}_i^*.
\end{aligned}$$

Therefore, it holds that

$$\begin{aligned}
\mu_{\bar{f}_i}^{-1}(\lambda^*)-(\boldsymbol{c}_i^1\boldsymbol{x}+\alpha_i^1)\quad\geq\quad & T_i^{-1}(\mu_{p_i}^{-1}(\lambda^*))\cdot(\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2),\\
& i=1,\cdots,k,
\end{aligned}$$

which contradicts the fact that $(\boldsymbol{x}^*,\lambda^*)$ is a unique optimal solution of MAXMIN2.

IV. A Fuzzy Approach for Multiobjective Stochastic Linear Programming Problems Through a Fractile Optimization Model

In this section, we propose a fuzzy approach to MOP3$(\bar{\boldsymbol{p}},\boldsymbol{\beta})$ where MOSLP is formulated through a fractile optimization model, and show that the corresponding formulation is same to MAXMIN2. In order to deal with MOP3$(\bar{\boldsymbol{p}},\boldsymbol{\beta})$, the decision maker must specify permissible probability levels $\bar{\boldsymbol{p}}$ in advance. However, in general, the decision maker seems to prefer not only the less value of the objective function $f_i(\boldsymbol{x},\bar{p}_i)$ of MOP3$(\bar{\boldsymbol{p}},\boldsymbol{\beta})$ but also the larger value of the permissible probability level $\bar{p}_i$. Since these values conflict with each other, the larger value of the permissible probability level $\bar{p}_i$ results in the larger value of the objective function $f_i(\boldsymbol{x},\bar{p}_i)$ of MOP3$(\bar{\boldsymbol{p}},\boldsymbol{\beta})$. From such a point of view, we consider the following multiobjective programming problem which can be regarded as a natural extension of MOP3$(\bar{\boldsymbol{p}},\boldsymbol{\beta})$.

[MOP6($\boldsymbol{\beta}$)]

$$\min_{\boldsymbol{x}\in X(\boldsymbol{\beta}),\bar{p}_i,i=1,\cdots,k} (f_1(\boldsymbol{x},\bar{p}_1),\cdots,f_k(\boldsymbol{x},\bar{p}_k),-\bar{p}_1,\cdots,-\bar{p}_k) \tag{33}$$

It should be noted in MOP6($\boldsymbol{\beta}$) that permissible probability levels $\bar{p}_i, i=1,\cdots,k$ are not the fixed values but the decision variables.

Considering the imprecise nature of the decision maker's judgment, we assume that the decision maker has fuzzy goals for each objective function in MOP6($\boldsymbol{\beta}$). Such fuzzy goals can be quantified by eliciting the corresponding membership functions. Let us denote a membership function of an objective function $f_i(\boldsymbol{x},\bar{p}_i)$ as $\mu_{f_i}(f_i(\boldsymbol{x},\bar{p}_i))$, and a membership function of a permissible probability level $\bar{p}_i$ as $\mu_{\bar{p}_i}(\bar{p}_i)$ respectively. Then, MOP6($\boldsymbol{\beta}$) can be transformed as the following multiobjective programming problem.

[MOP7($\boldsymbol{\beta}$)]

$$\max_{\boldsymbol{x}\in X(\boldsymbol{\beta}),\bar{p}_i,i=1,\cdots,k} (\mu_{f_1}(f_1(\boldsymbol{x},\bar{p}_1)),\cdots,\mu_{f_k}(f_k(\boldsymbol{x},\bar{p}_k)), \mu_{\bar{p}_1}(\bar{p}_1),\cdots,\mu_{\bar{p}_k}(\bar{p}_k)) \tag{34}$$

Throughout this section, we make the following assumptions.

Assumption 3.

$\mu_{\bar{p}_i}(\bar{p}_i), i=1,\cdots,k$ are strictly increasing and continuous with respect to $\bar{p}_i$.

Assumption 4.

$\mu_{f_i}(f_i(\boldsymbol{x},\bar{p}_i)), i=1,\cdots,k$ are strictly decreasing and continuous with respect to $f_i(\boldsymbol{x},\bar{p}_i)$.

For example, we can define the membership functions $\mu_{\bar{p}_i}(\bar{p}_i)$, $\mu_{f_i}(f_i(\boldsymbol{x},\bar{p}_i))$ as follows. At first, the decision maker specifies permissible probability intervals in his/her subjective manner,

$$P_i = [p_{i\min}, p_{i\max}], i=1,\cdots,k, \tag{35}$$

where $p_{i\min}$ is an acceptable minimum value and $p_{i\max}$ is a sufficiently satisfactory minimum value. According to Assumption 3, the decision maker can define his/her membership function $\mu_{\bar{p}_i}(\bar{p}_i)$ on the domain P_i. Corresponding to the domain P_i, Let us denote the domain of $\mu_{f_i}(f_i(\boldsymbol{x},\bar{p}_i))$ as:

$$F_i(P_i) = [f_{i\min}, f_{i\max}], \tag{36}$$

where $f_{i\min}$ is a sufficiently satisfactory maximum value and $f_{i\max}$ is an acceptable maximum value. $f_{i\min}$ can be obtained by solving the following linear programming problem.

$$f_{i\min} = \min_{\boldsymbol{x}\in X(\boldsymbol{\beta})} f_i(\boldsymbol{x}, p_{i\min}) \tag{37}$$

In order to obtain $f_{i\max}$, we first solve the following k linear programming problems.

$$\min_{\boldsymbol{x}\in X(\boldsymbol{\beta})} f_i(\boldsymbol{x}, p_{i\max}), i=1,\cdots,k \tag{38}$$

Let $\boldsymbol{x}_i, i=1,\cdots,k$ be the above optimal solution. Using the optimal solutions $\boldsymbol{x}_i, i=1,\cdots,k$, $f_{i\max}$ can be obtained as follows.

$$f_{i\max} = \max_{\ell=1,\cdots,k,\ell\neq i} f_i(\boldsymbol{x}_\ell, p_{i\max}) \tag{39}$$

According to Assumption 4, the decision maker can define his/her membership function $\mu_{f_i}(f_i(\boldsymbol{x},\bar{p}_i))$ on the domain $F_i(P_i)$.

Then, if the decision maker adopts the fuzzy decision [8],[12] as an aggregation operator for MOP7($\boldsymbol{\beta}$), the satisfactory solution is obtained by solving the following maxmin problem.

[MAXMIN3]

$$\max_{\boldsymbol{x}\in X(\boldsymbol{\beta}),\bar{p}_i\in P_i,i=1,\cdots,k,\lambda\in[0,1]} \lambda \tag{40}$$

subject to

$$\mu_{f_i}(f_i(\boldsymbol{x},\bar{p}_i)) \geq \lambda, i=1,\cdots,k \tag{41}$$

$$\mu_{\bar{p}_i}(\bar{p}_i) \geq \lambda, i=1,\cdots,k \tag{42}$$

Because of Assumption 4 and $\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2 > 0$, the constraints (41) can be transformed as:

$$\begin{aligned} & \mu_{f_i}(f_i(\boldsymbol{x},\bar{p}_i)) \geq \lambda, \\ \Leftrightarrow\ & f_i(\boldsymbol{x},\bar{p}_i) \leq \mu_{f_i}^{-1}(\lambda), \\ \Leftrightarrow\ & T_i^{-1}(\bar{p}_i)\cdot(\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2)+(\boldsymbol{c}_i^1\boldsymbol{x}+\alpha_i^1) \leq \mu_{f_i}^{-1}(\lambda), \\ \Leftrightarrow\ & \bar{p}_i \leq T_i\left(\frac{\mu_{f_i}^{-1}(\lambda)-(\boldsymbol{c}_i^1\boldsymbol{x}+\alpha_i^1)}{\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2}\right) \end{aligned} \tag{43}$$

where $\mu_{f_i}^{-1}(\cdot)$ is a pseudo-inverse function. From the constraints (42) and Assumption 3, it holds that $\bar{p}_i \geq \mu_{\bar{p}_i}^{-1}(\lambda)$. Therefore, the constraint (43) can be reduced to the following inequality where a permissible probability level $\bar{p}_i$ is disappeared.

$$\begin{aligned} & \mu_{\bar{p}_i}^{-1}(\lambda) \leq T_i\left(\frac{\mu_{f_i}^{-1}(\lambda)-(\boldsymbol{c}_i^1\boldsymbol{x}+\alpha_i^1)}{\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2}\right) \\ \Leftrightarrow\ & \mu_{f_i}^{-1}(\lambda)-(\boldsymbol{c}_i^1\boldsymbol{x}+\alpha_i^1) \\ & \geq T_i^{-1}(\mu_{\bar{p}_i}^{-1}(\lambda))\cdot(\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2) \end{aligned} \tag{44}$$

Then, MAXMIN3 is equivalently transformed into the following problem.

[MAXMIN4]

$$\max_{\boldsymbol{x}\in X(\boldsymbol{\beta}),\lambda\in[0,1]} \lambda \tag{45}$$

subject to

$$\mu_{f_i}^{-1}(\lambda)-(\boldsymbol{c}_i^1\boldsymbol{x}+\alpha_i^1) \geq T_i^{-1}(\mu_{\bar{p}_i}^{-1}(\lambda))\cdot(\boldsymbol{c}_i^2\boldsymbol{x}+\alpha_i^2), \quad i=1,\cdots,k \tag{46}$$

It should be noted here that MAXMIN4 is equivalent to MAXMIN2, and the constraints (46) can be reduced to a set of linear inequalities for some fixed value $\lambda\in[0,1]$. This means that an optimal solution $(\boldsymbol{x}^*,\lambda^*)$ of MAXMIN4 is obtained by combined use of the bisection method with respect to λ and the first-phase of the two-phase simplex method of linear programming.

The relationship between the optimal solution $(\boldsymbol{x}^*,\lambda^*)$ of MAXMIN4, P-Pareto optimal solutions to MOP1($\bar{\boldsymbol{f}},\boldsymbol{\beta}$), and F-Pareto optimal solutions to MOP3($\bar{\boldsymbol{p}},\boldsymbol{\beta}$) can be characterized by the following theorem.

Theorem 3.
(1) If $(\boldsymbol{x}^*, \lambda^*)$ is a unique optimal solution of MAXMIN4, then $\boldsymbol{x}^* \in X(\boldsymbol{\beta})$ is a P-Pareto optimal solution to MOP1($\bar{\boldsymbol{f}}^*, \boldsymbol{\beta}$), where $\bar{\boldsymbol{f}}^* = (\bar{f}_1^*, \cdots, \bar{f}_k^*) = (\mu_{f_1}^{-1}(\lambda^*), \cdots, \mu_{f_k}^{-1}(\lambda^*))$.
(2) If $(\boldsymbol{x}^*, \lambda^*)$ is a unique optimal solution of MAXMIN4, then $\boldsymbol{x}^* \in X(\boldsymbol{\beta})$ is an F-Pareto optimal solution to MOP3($\bar{\boldsymbol{p}}^*, \boldsymbol{\beta}$), where $\bar{\boldsymbol{p}}^* = (\bar{p}_1^*, \cdots, \bar{p}_k^*)$ = $(\mu_{\bar{p}_1}^{-1}(\lambda^*), \cdots, \mu_{\bar{p}_k}^{-1}(\lambda^*))$.
(Proof)
(1) Let $(\boldsymbol{x}^*, \lambda^*)$ be a unique optimal solution of MAXMIN4. Since an optimal solution $(\boldsymbol{x}^*, \lambda^*)$ satisfies the constraints (46), it holds that

$$\begin{aligned} & \mu_{f_i}^{-1}(\lambda^*) - (\boldsymbol{c}_i^1 \boldsymbol{x}^* + \alpha_i^1) \\ & \geq T_i^{-1}(\mu_{\bar{p}_i}^{-1}(\lambda^*)) \cdot (\boldsymbol{c}_i^2 \boldsymbol{x}^* + \alpha_i^2), \\ \Leftrightarrow \quad & T_i\left(\frac{\mu_{f_i}^{-1}(\lambda^*) - (\boldsymbol{c}_i^1 \boldsymbol{x}^* + \alpha_i^1)}{\boldsymbol{c}_i^2 \boldsymbol{x}^* + \alpha_i^2}\right) = p_i(\boldsymbol{x}^*, \mu_{f_i}^{-1}(\lambda^*)) \\ & \geq \mu_{\bar{p}_i}^{-1}(\lambda^*), i = 1, \cdots, k. \end{aligned}$$

Assume that $\boldsymbol{x}^* \in X(\beta)$ is not a P-Pareto optimal solution to MOP1($\bar{\boldsymbol{f}}^*, \boldsymbol{\beta}$), where $\bar{\boldsymbol{f}}^* = (\mu_{f_1}^{-1}(\lambda^*), \cdots, \mu_{f_k}^{-1}(\lambda^*))$. Then there exists $\boldsymbol{x} \in X(\boldsymbol{\beta})$ such that

$$\begin{aligned} & p_i(\boldsymbol{x}, \mu_{f_i}^{-1}(\lambda^*)) \geq p_i(\boldsymbol{x}^*, \mu_{f_i}^{-1}(\lambda^*)) \geq \mu_{\bar{p}_i}^{-1}(\lambda^*), \\ & i = 1, \cdots, k. \end{aligned}$$

This means that there exists $\boldsymbol{x} \in X(\boldsymbol{\beta})$ such that

$$\begin{aligned} \mu_{f_i}^{-1}(\lambda^*) - (\boldsymbol{c}_i^1 \boldsymbol{x} + \alpha_i^1) \quad \geq \quad & T_i^{-1}(\mu_{\bar{p}_i}^{-1}(\lambda^*)) \cdot (\boldsymbol{c}_i^2 \boldsymbol{x} + \alpha_i^2), \\ & i = 1, \cdots, k, \end{aligned}$$

which contradicts the fact that $(\boldsymbol{x}^*, \lambda^*)$ is a unique optimal solution of MAXMIN4.
(2) Assume that $\boldsymbol{x}^* \in X(\boldsymbol{\beta})$ is not an F-Pareto optimal solution to MOP3($\bar{\boldsymbol{p}}^*, \boldsymbol{\beta}$), where $\bar{p}_i^* = \mu_{\bar{p}_i}^{-1}(\lambda^*), i = 1, \cdots, k$. Then, because of (14), there exists $\boldsymbol{x} \in X(\boldsymbol{\beta})$ such that

$$\begin{aligned} & f_i(\boldsymbol{x}, \bar{p}_i^*) \leq f_i(\boldsymbol{x}^*, \bar{p}_i^*) \\ \Leftrightarrow \quad & T_i^{-1}(\bar{p}_i^*) \cdot (\boldsymbol{c}_i^2 \boldsymbol{x} + \alpha_i^2) + (\boldsymbol{c}_i^1 \boldsymbol{x} + \alpha_i^1) \\ \leq \quad & T_i^{-1}(\bar{p}_i^*) \cdot (\boldsymbol{c}_i^2 \boldsymbol{x}^* + \alpha_i^2) + (\boldsymbol{c}_i^1 \boldsymbol{x}^* + \alpha_i^1) \stackrel{\text{def}}{=} \bar{f}_i^* \\ \Leftrightarrow \quad & \bar{f}_i^* - (\boldsymbol{c}_i^1 \boldsymbol{x} + \alpha_i^1) \geq T_i^{-1}(\bar{p}_i^*) \cdot (\boldsymbol{c}_i^2 \boldsymbol{x} + \alpha_i^2) \\ \Leftrightarrow \quad & \bar{f}_i^* - (\boldsymbol{c}_i^1 \boldsymbol{x} + \alpha_i^1) \geq T_i^{-1}(\mu_{\bar{p}_i}^{-1}(\lambda^*)) \cdot (\boldsymbol{c}_i^2 \boldsymbol{x} + \alpha_i^2) \end{aligned}$$

On the other hand, since $(\boldsymbol{x}^*, \lambda^*)$ is an optimal solution of MAXMIN4, from (46), it holds that

$$\mu_{f_i}^{-1}(\lambda^*) - (\boldsymbol{c}_i^1 \boldsymbol{x}^* + \alpha_i^1) \geq T_i^{-1}(\mu_{\bar{p}_i}^{-1}(\lambda^*)) \cdot (\boldsymbol{c}_i^2 \boldsymbol{x}^* + \alpha_i^2).$$

This means that

$$\begin{aligned} \mu_{f_i}^{-1}(\lambda^*) \quad \geq \quad & (\boldsymbol{c}_i^1 \boldsymbol{x}^* + \alpha_i^1) + T_i^{-1}(\mu_{\bar{p}_i}^{-1}(\lambda^*)) \cdot (\boldsymbol{c}_i^2 \boldsymbol{x}^* + \alpha_i^2) \\ = \quad & \bar{f}_i^*. \end{aligned}$$

Therefore, it holds that

$$\begin{aligned} \mu_{f_i}^{-1}(\lambda^*) - (\boldsymbol{c}_i^1 \boldsymbol{x} + \alpha_i^1) \quad \geq \quad & T_i^{-1}(\mu_{\bar{p}_i}^{-1}(\lambda^*)) \cdot (\boldsymbol{c}_i^2 \boldsymbol{x} + \alpha_i^2), \\ & i = 1, \cdots, k, \end{aligned}$$

which contradicts the fact that $(\boldsymbol{x}^*, \lambda^*)$ is a unique optimal solution of MAXMIN4.

TABLE I
CONSTANT COEFFICIENTS OF OBJECTIVE FUNCTIONS AND CONSTRAINTS

$\boldsymbol{x}$	x_1	x_2	x_3	x_4	x_5	x_6	x_7	x_8	x_9	x_{10}

V. A NUMERICAL EXAMPLE

We consider the following three-objective linear programming problems involving random variable coefficients, which is formulated by Sakawa et al. [9], to demonstrate the feasibility of our proposed fuzzy approach.
[MOSLP]

$$\min \ (\boldsymbol{c}_1^1 + t_1(\omega)\boldsymbol{c}_1^2)\boldsymbol{x} + (\alpha_1^1 + t_1(\omega)\alpha_1^2)$$

$$\min \ (\boldsymbol{c}_2^1 + t_2(\omega)\boldsymbol{c}_2^2)\boldsymbol{x} + (\alpha_2^1 + t_2(\omega)\alpha_2^2)$$

$$\min \ (\boldsymbol{c}_3^1 + t_3(\omega)\boldsymbol{c}_3^2)\boldsymbol{x} + (\alpha_3^1 + t_3(\omega)\alpha_3^2)$$

subject to $\boldsymbol{a}_i \boldsymbol{x} \leq b_i(\omega), i = 1, \cdots, 7, \boldsymbol{x} \geq \boldsymbol{0}$

where $\boldsymbol{x} = (x_1, x_2, \cdots, x_{10})^T$ is a ten-dimensional decision column vector, $\boldsymbol{a}_i, i = 1, \cdots, 7, c_1^1, c_1^2, c_2^1, c_2^2, c_3^1, c_3^2$ are ten-dimensional coefficient row vectors (Table 1), and $\alpha_1^1 = -18, \alpha_1^2 = 5, \alpha_2^1 = -27, \alpha_2^2 = 6, \alpha_3^1 = -10, \alpha_3^2 = 4$. $t_i(\omega), i = 1, \cdots, 3$, $b_j(\omega), j = 1, \cdots, 7$ are Gaussian random variables defined as follows.

$$\begin{aligned} & t_1(\omega) \sim \mathrm{N}(4, 2^2), && t_2(\omega) \sim \mathrm{N}(3, 3^2), \\ & t_3(\omega) \sim \mathrm{N}(3, 2^2), && b_1(\omega) \sim \mathrm{N}(164, 30^2), \\ & b_2(\omega) \sim \mathrm{N}(-190, 20^2), && b_3(\omega) \sim \mathrm{N}(-184, 15^2), \\ & b_4(\omega) \sim \mathrm{N}(99, 22^2), && b_5(\omega) \sim \mathrm{N}(-150, 17^2), \\ & b_6(\omega) \sim \mathrm{N}(154, 35^2), && b_7(\omega) \sim \mathrm{N}(142, 42^2). \end{aligned}$$

Let us assume that the hypothetical decision maker sets constraint probability levels as $\boldsymbol{\beta} = (\beta_1, \cdots, \beta_7) = (0.85, 0.95, 0.8, 0.9, 0.85, 0.8, 0.9)$ for the constraints in MOSLP, which are same values to the numerical example [9]. Since, in the numerical example [9], a probability maximization model is adopted to formulate MOSLP, we adopt MAXMIN2 for MOSLP in order to compare our proposed fuzzy approach with the results of Sakawa et al.[9].

Let us set the membership functions $\mu_{p_i}(p_i(\boldsymbol{x}, \bar{f}_i))$ for distribution functions $p_i(\boldsymbol{x}, \bar{f}_i)$, $i = 1, 2, 3$ as follows, which

are same to [9].

$$\mu_{p_1}(p_1(\boldsymbol{x}, \bar{f}_1)) = \frac{p_1(\boldsymbol{x}, \bar{f}_1) - 0.502}{(0.88 - 0.502)}$$
$$\mu_{p_2}(p_2(\boldsymbol{x}, \bar{f}_2)) = \frac{p_2(\boldsymbol{x}, \bar{f}_2) - 0.06}{(0.783 - 0.06)}$$
$$\mu_{p_3}(p_3(\boldsymbol{x}, \bar{f}_3)) = \frac{p_3(\boldsymbol{x}, \bar{f}_3) - 0.446}{(0.664 - 0.446)}$$

In the numerical example [9], as permissible objective levels for a probability maximization model, $\bar{\boldsymbol{f}} = (\bar{f}_1, \bar{f}_2, \bar{f}_3) = (2150, 450, -950)$ are adopted. Corresponding to these values, we assume that the hypothetical decision maker sets his/her membership functions $\mu_{\bar{f}_i}(\bar{f}_i)$ for permissible objective levels $\bar{f}_i$, $i = 1, 2, 3$ as follows.

$$\mu_{\bar{f}_1}(\bar{f}_1) = \frac{3000 - \bar{f}_1}{(3000 - 2150)}$$
$$\mu_{\bar{f}_2}(\bar{f}_2) = \frac{1000 - \bar{f}_2}{(1000 - 450)}$$
$$\mu_{\bar{f}_3}(\bar{f}_3) = \frac{-900 - \bar{f}_3}{((-900) - (-950))}$$

For these membership functions, MAXMIN2 is solved by combined use of the bisection method with respect to λ and the first-phase of the two-phase simplex method of linear programming. The optimal solution $(\boldsymbol{x}^*, \lambda^*)$ is obtained at $\lambda^* = 0.826714$. The corresponding membership function values are obtained as $\mu_{\bar{f}_i}(\bar{f}_i^*) = \mu_{p_i}(p_i(\boldsymbol{x}^*, \bar{f}_i^*)) = 0.826714, i = 1, 2, 3$, where

$$\bar{f}_i^* = (\boldsymbol{c}_i^1 \boldsymbol{x}^* + \alpha_i^1) + T_i^{-1}(\mu_{p_i}^{-1}(\lambda^*)) \cdot (\boldsymbol{c}_i^2 \boldsymbol{x}^* + \alpha_i^2),$$
$$p_i(\boldsymbol{x}^*, \bar{f}_i^*) = T_i \left(\frac{\bar{f}_i^* - (\boldsymbol{c}_i^1 \boldsymbol{x}^* + \alpha_i^1)}{\boldsymbol{c}_i^2 \boldsymbol{x}^* + \alpha_i^2} \right).$$

In Table 2, not only the optimal values $\bar{f}_i^*, p_i(\boldsymbol{x}^*, \bar{f}_i^*)$, $i = 1, 2, 3$ of MAXMIN2 but also the results of Sakawa et al. (especially, $p_i(\boldsymbol{x}^*, \bar{f}_i)$ for the fixed values of permissible objective levels $(\bar{f}_1, \bar{f}_2, \bar{f}_3) = (2150, 450, -950)$ at the first interaction of Table 3 [9]) are shown. From Table 2, it can be understood that, at the optimal solution of MAXMIN2, the distribution function $p_i(\boldsymbol{x}^*, \bar{f}_i^*)$ is improved at the expense of the permissible objective level in comparison with the results of Sakawa et al. [9]. From this result, it is expected that the proper balance between the distribution function $p_i(\boldsymbol{x}, \bar{f}_i)$ and the permissible objective level $\bar{f}_i$ in a probability maximization model will be attained at the optimal solution of MAXMIN2. Similarly, it is also expected that the proper balance between the objective function $f_i(\boldsymbol{x}, \bar{p}_i)$ and the permissible probability level $\bar{p}_i$ in a fractile optimization model will be attained at the optimal solution of MAXMIN4.

TABLE II
THE OPTIMAL SOLUTIONS OF MAXMIN2 AND THE FIRST INTERACTION IN TABLE 3 [9]

	MAXMIN2	The first interaction in Table 3 [9]
$\bar{f}_1^*$	2297.29	2150.0
$\bar{f}_2^*$	545.308	450.0
$\bar{f}_3^*$	-941.336	-950.0
$p_1(\boldsymbol{x}^*, \bar{f}_1^*)$	0.814498	0.719
$p_2(\boldsymbol{x}^*, \bar{f}_2^*)$	0.657714	0.474
$p_3(\boldsymbol{x}^*, \bar{f}_3^*)$	0.626224	0.571

VI. CONCLUSION

In this paper, two fuzzy approaches to multiobjective stochastic linear programming problems through a probability maximization model and a fractile optimization model are proposed. MAXMIN2 is formulated for multiobjective stochastic linear programming problems through a probability maximization model to obtain a satisfactory solution of the decision maker. Similarly, MAXMIN4 is formulated for multiobjective stochastic linear programming problems through a fractile optimization model to obtain a satisfactory solution of the decision maker. Both problems can be easily solved by linear programming technique and, at the optimal solution, it is expected that a proper balance between permissible objective levels and the corresponding distribution function values or permissible probability levels and the corresponding objective function values is attained. It has been also shown that such two problems are same. Although a probability maximization model or a fractile optimization model is one of the most efficient tool to transform stochastic programming problems into well-defined mathematical programming ones, appropriate permissible levels are not known for the decision maker in advance. In order to overcome such a difficulty, we have proposed fuzzy approaches for multiobjective stochastic linear programming problems.

***Abstract*—Hierarchical Document Signature (HDS) has been successfully applied in document computing to find similarity between different pieces of text [1], [2], [3]; for example sentence-sentence similarity, sentence-phrase similarity. HDS is application specific, it is dependent on different features at different levels. This paper hence presents a comprehensive study of enhancement of the performance of HDS to find semantic sentence similarity by tuning some of its significant features. The experimental results support this and show the optimal conditions at which HDS performs similarly to humans.**

***Keywords*- Fuzzy signature, Hierarchical Document Signature, sentence similarity, word similarity**

I. Introduction

It is important to abstract information available to form humanly accessible structures. The way people think and talk is hierarchical with limited information presented in any one sentence, and that information is always linked together to further information. As such, Hierarchical Document Signature (HDS) is a significant way to represent sentences when finding their similarity.

Sentences are considered to be the same if they share the same or similar meaning. There are different methods to find sentence similarities [4], [5], and [6], and HDS is one of them. Manna et al., have discussed two different HDS models in [1], [3]. In this paper we focus on the model described in [3] where similarities between sentence pairs are computed using semantic information from the source text.

The following sections briefly describe HDS, and different experiments at word and sentence level to show optimal parameters for the enhancement of performance of HDS for computing sentence similarity.

II. Brief Description of HDS

Hierarchical Document Signature (HDS) [1], [3] is a special form of Fuzzy Signature (FS) [7] meant for document analysis. In this case, the natural hierarchy of a document is maintained through the structure of HDS; document level to sentence level, sentence level to word level. HDS, like fuzzy signatures, can describe, compare and classify objects with complex structure and interdependent features. The hierarchical organization of HDS expresses the structural complexity of a problem. The local preference relations among the hierarchies and sub-branches of a document signature can be used to approximate the global preference relation of a decision problem.

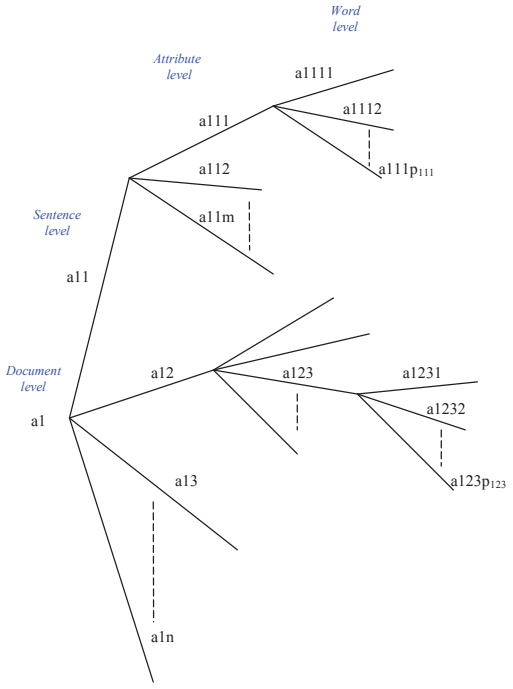

Fig. 1. Generic illustration of Hierarchical Document Signature

In fig.1, $a1$ represents a document at *document level*. A document is now segmented into n sentences, which we denote by $a11$ to $a1n$. This is the *sentence level* of the signature we developed. Next is the *attribute level*, which basically classifies the words of the sentences into their corresponding major *parts of speech*, namely *noun*, *verb*, *adjective* and *adverb*. So, for each sentence, we have m different attributes, which is fixed for each document signature. In general m is a integer, but it is constant with specific application for the ease of comparison. Now each attribute of each sentence has words, and this level is called *word level*. There can be any number of words in each attribute (POS). Here, p_{111} is the maximum number of words for attribute $a111$.

HDS can be used for computing semantic similarity of contexts. Its levels can vary depending on applications where it is used. In this case, parts of speech (POS) is a level

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

which deals with the semantic information of the sentences of a document. The aggregations at different level contribute to the final similarity value. It uses Fuzzy Word Similarity (FWS) [8] at the word level to deal with the similarity or relatedness of a word pair; which then propagates to the next higher level using appropriate aggregations and continues till it reaches the document level. In this application, sentence-sentence similarity is computed.

III. Word level Scenario

The performance of HDS is mainly dependent on the word level. The similarity computed at this level is aggregated and propagated to the next higher level; thus it is essential to tune different features to achieve good performance. This word pair similarity used is known as Fuzzy Word Similarity (FWS) which was introduced in [8]. Choice of proper membership function, similarity threshold as well as the input similarity measures are different essential factors which can affect the results of FWS. So the following experiments will deal with each of these separately with proper illustrations.

a) Input Similarity Measures for FWS: As explained in [8], FWS requires two different types of similarity measures to compute PGMeasure; path based measures and gloss based measures. For path based, Lin's [9] as well as Jiang and Conrath's [10] are both experimented on. These effects can be seen in tables IV to XXVIII with different datasets in different conditions.

b) Impact of membership functions: Three sets of membership functions are shown in the table I. The membership functions are tuned based on repeated experiments and expert comments. In [8] it is seen that triangular membership functions performed better than trapezoidal at the output. But when it is further tuned, it is noticed that the trapezoidal membership functions can also be used at the output and it also gives reasonably good results. The corresponding results can be seen in tables IV to XXVIII.

TABLE I
Co-ordinates of different membership functions of fuzzy sets used here

Set I	INPUT Low_trapez	(0, 1)	(0.3, 1)	(0.4, 0)	-
	INPUT Medium_trapez	(0.3, 0)	(0.4, 1)	(0.6, 1)	(0.7, 0)
	INPUT High_trapez	(0.6, 0)	(0.8, 1)	(1, 1)	-
	OUTPUT Low_trapez	(0, 1)	(0.3, 1)	(0.4, 0)	-
	OUTPUT Medium_trapez	(0.3, 0)	(0.4, 1)	(0.6, 1)	(0.7, 0)
	OUTPUT High_trapez	(0.6, 0)	(0.8, 1)	(1, 1)	-
Set II	INPUT Low_trapez	(0, 1)	(0.3, 1)	(0.4, 0)	-
	INPUT Medium_trapez	(0.3, 0)	(0.4, 1)	(0.6, 1)	(0.7, 0)
	INPUT High_trapez	(0.6, 0)	(0.8, 1)	(1, 1)	-
	OUTPUT Low_tri	(0, 0)	(0.3, 1)	(0.6, 0)	-
	OUTPUT Medium_tri	(0.3, 0)	(0.55, 1)	(0.8, 0)	-
	OUTPUT High_tri	(0.6, 0)	(0.8, 1)	(1, 0)	-
Set III	INPUT Low_trapez	(0, 1)	(0.2, 1)	(0.3, 0)	-
	INPUT Medium_trapez	(0.2, 0)	(0.3, 1)	(0.4, 1)	(0.5, 0)
	INPUT High_trapez	(0.4, 0)	(0.5, 1)	(1, 1)	-
	OUTPUT Low_trapez	(0, 1)	(0.1, 1)	(0.3, 0)	-
	OUTPUT Medium_trapez	(0.1, 0)	(0.3, 1)	(0.5, 1)	(0.7, 0)
	OUTPUT High_trapez	(0.5, 0)	(0.7,1)	(1, 1)	-

c) Fuzzy rule-bases: In fuzzy system, there are different rule extraction methods as seen in [11] besides expert knowledge, where the rules are decided manually based on expert's understanding about the similarity measures. These rules have been used to compute FWS between a word pair.

Rule 1: If path is L AND gloss is L THEN output is L.
Rule 2: If path is L AND gloss is M THEN output is L.
Rule 3: If path is L AND gloss is H THEN output is M.
Rule 4: If path is M AND gloss is L THEN output is L.
Rule 5: If path is M AND gloss is M THEN output is M.
Rule 6: If path is M AND gloss is H THEN output is H.
Rule 7: If path is H AND gloss is L THEN output is M.
Rule 8: If path is H AND gloss is M THEN output is H.
Rule 9: If path is H AND gloss is H THEN output is H.

d) Impact of thresholds at word level: Similarity thresholds also affect the performance of HDS. Normally, for similarity computations, similarity value of 0.5 [12] is considered. But due to fuzzy approximations which initiate at word level, a new threshold of 0.4 is also experimented with and seen to be more suitable for this application.

IV. Experiments at Word Level

A. Evaluation metrics at word level

In this sub-section, evaluation of three different word similarity approaches (*path measure*, *gloss overlap* and *PGMeasure*) are presented. This has been taken directly from [8]. Unlike [12], the following metrics are defined at *word level* instead of sentence level. These are *Recall*, *Precision*, *F-measure*, *Rejection*, *Accuracy*, and *f1*. **Recall** is a proportion of correctly predicted similar word pairs compared to all similar word pairs. **Precision** is a proportion of correctly predicted similar word pairs compared to all predicted similar word pairs. **F-Measure (F1)** is a uniform harmonic mean of precision and recall. **Rejection** is a proportion of correctly predicted dissimilar word pairs compared to all dissimilar word pairs. **Accuracy** is a proportion of all correctly predicted word pairs compared to all word pairs. Lastly, **f1** is defined as a uniform harmonic mean of rejection and recall. In this work, *accuracy*, *rejection* and *f1* metrics are included in addition to the standard precision-recall based metrics as it presents another aspect of the performance based on the tradeoff between true positive and true negative judgments.

B. Evaluation process

Two words are considered to be similar if they reach certain threshold value. A scoring threshold for similar pairs is defined at 0.5 [12]. But in this case, threshold of 0.4 is also evaluated because of fuzzy approximations used in formulating PGMeasure (FWS). Thus for each kind of input and output fuzzy sets shown in table. I, results with both the thresholds are shown for each method; which will clearly explain why 0.4 has been preferred over 0.5 for word similarity computation using FWS.

C. Datasets

Results on two datasets are shown. One is data from Test of English as a Foreign Language (ESL) and the other from [13] which is called Rubenstein data in this paper. The dataset is prepared by human assessors and then experimented on.

1) ESL dataset: There is no standard benchmark dataset for computing word similarity. Generally people have evaluated their word similarities [14], [15] using some kind of multiple choice questions and their answers in TOEFL (Test of English as a Foreign Language) or ESL[1](English as a second language) or any other linguistic exams. Thus, for this work, a dataset is prepared from ESL mock exams. Like [16], the experiment is not restricted to verbs, rather all four main parts of speech are covered which have been encountered in the multiple choice questions (MCQ) in ESL. Each practice exams had several questions; with 4 choices. Out of these four, one gives you the exact match. Like Microsoft Research paraphrase corpus, [17] binary judgements are assigned to the word pair similarity instead of sentence similarity as mentioned in the dataset. For the correct choices, based on ESL answer set, 1 is assigned as relevancy score of the word pair similarity, for the rest of the incorrect answers, 0 is assigned. Antonyms are chosen deliberately for the incorrect choices (out of 3 incorrect choices) except for the questions which had some other options. Linguistically, it is difficult to determine any crisp boundary for word similarity. The binary scores are assigned as a benchmark. It is also found that for some words, which returned 'incorrect choice' in ESL test set, has some degree of similarity linguistically, might not be very relevant to the context of the question being asked. So, for these words, there are false negatives. Respective parts of speech are also assigned for the word pairs. Here, in table. II a snapshot of the dataset generated from ESL multiple choice questions is shown.

TABLE II
SNAPSHOT OF DATASET GENERATED FROM ESL MULTIPLE CHOICE QUESTIONS

Relevance	word_1	word_2	POS
1	balmy	warm	adjective
0	balmy	cold	adjective
1	pored	examined	verb
0	pored	memorized	verb
1	intersection	crossing	noun
0	intersection	ending	noun
1	repugnant	disgusting	adjective
0	repugnant	delightful	adjective
1	diligence	dedication	noun
0	diligence	ease	noun
0	widespread	limited	adjective
1	harsh	extreme	adjective
0	harsh	pleasant	adjective
1	touched	began	verb
...			

a) Comparison of different senses of word pairs using different methods: Table. III is a snapshot of the results obtained at word sense level. In some words, gloss overlap is 0, which signifies that semantically they do not share any information, but due to their taxonomical location in WordNet, they have some information in common. The PGMeasure combines these kinds of information which can be seen from this table. The tuning of membership functions can definitely provide more refined similarity values for the word pairs.

It is known that each word can have many synsets. So when similarity between two words are computed, similarity between all their combinations of synsets are computed using both gloss overlap and path measure. Maximum similarity between the synsets contribute to the word pairs' final similarity. This is used in the tables for comparison with PGMeasure.

TABLE III
WORD SIMILARITY RESULTS AT SENSE LEVEL: A SNAPSHOT OF RESULTS

(w_i#s_k,w_j#s_l)	P	G	PG
(enquiry#1,investigation#1)	0.05	0.25	0.30
(enquiry#1,investigation#2)	0.09	0.0	0.30
(enquiry#2,investigation#1)	0.48	0.0	0.30
....			
(enquiry#1,interview#1)	0.46	0.2	0.30
(enquiry#1,interview#2)	0.06	0.0	0.30
...			
(outlets#1,stores#2)	0.06	0.0	0.30
...			

b) ESL experiment results with similarity threshold = 0.5: Tables IV to XV show the comparisons of path, gloss and PGMeasure using ESL dataset with the membership functions shown in table. I at similarity threshold at 0.5 and 0.4 respectively. In this case, to measure *path measure* of two given words, maximum similarity score of the synset pairs are taken to represent the overall similarity of a word pair. Likewise for the other two measures. The effects of variation in performance due to different membership functions used, threshold, as well as different path based measures are also shown. Initially the experiments were done using Set I and Set II of table. I; where the combination of Lin's similarity score as path measure with triangular membership function for the output fuzzy set has given better performance in terms of the evaluation metrics. Inspite of 'Center Of Gravity' approximation of the trapezoidal membership functions, it is seen in that if the values of the membership functions are tuned further, then it gives very sensible results. Thus the experiments are redone using set III of table. I and the results are presented.

PGMeasure	0.2	1.0	0.33	0.61	1.0	0.33

TABLE IX
COMPARISON OF DIFFERENT WORD SIMILARITY MEASURES USING LIN'S PATH MEASURE AS ONE OF THE INPUTS IN FIS WITH THE MEMBERSHIP FUNCTIONS OF SET III, THRESHOLD = 0.5, ESL DATASET

Methods	recall	precision	F1	accuracy	rejection	f1
Path	0.44	0.61	0.51	0.59	0.73	0.55
Gloss	0.36	1.0	0.53	0.69	1.0	0.53
PGMeasure	0.28	0.78	0.41	0.61	0.92	0.43

Tables IV to IX illustrate the results with threshold = 0.5. For all cases, performance of PGMeasure is higher when Lin's measure is used as one of the inputs to FIS. At 0.5 threshold using Set I and II, PGMeasure performed as expected using Lin's method as a path measure. The recall is lowered but the precision and rejection has increased showing that the method could properly identify predicted similar and dissimilar word pairs using set III.

c) ESL experiment results with similarity threshold = 0.4: Tables X to XV illustrate the evaluation results with threshold of 0.4. Like the previous cases, here too using Lin's path measure as input to FIS has shown better performance than Jiang and Conrath's. With further tuning of membership functions in Set III of table. I, the recall score has improved to a greater extent. Now if the same methods are compared at threshold 0.4 and 0.5, as per expert's comments, the similarities at 0.4 level by PGMeasure are more accurate.

Using Jiang and Conrath's similarity measure as one of the inputs of FIS, the precision and rejection for all the three sets of membership functions are higher for PGMeasure than Lin's when used in FIS; but recall is lower. Recall and accuracy increased using set III of membership functions showing overall improvement with slight reduction in precision.

TABLE X

2) Rubenstein dataset: Similar evaluation is done with data collected from Rubenstein's paper [13]. Words pairs are assigned a score rated by human assessors. If table. XVI is noticed, the relevance scores assigned by humans are unnormalized. But normalization is required for evaluation. So, the values are normalized by,

$$x_i^{norm} = \frac{x_i - min_X}{max_X - min_X},\ i \in [1, |X|] \tag{1}$$

where X is a set of word pairs.

TABLE XIII

a) Rubenstein experiment results with similarity threshold = 0.5: Now, tables XVII to XXII present evaluation result with Rubenstein's data at similarity threshold of 0.5. Like ESL's results, here too Lin's method gives better performance than Jiang and Conrath. But in this case Set III are not as good as Set I and II at this threshold.

Set I and II showed better evaluation metrics for set I and set II, but not for set III at this threshold for this dataset.

b) Rubenstein experiment results with similarity threshold = 0.4: Tables XXIII to XXVIII show performance of different similarity measures 0.4 threshold. Like the other cases illustrated so far, Lin's method for each of these sets perform better. But Set III's performance is best here and can be seen in table. XXVIII.

Now, at threshold of 0.4, using set I and set II of table. I, the evaluation metrics are little lower than 0.5. Set III has given better recall and more practical evaluation scores at 0.4 with this dataset like ESL.

V. SIMILARITY COMPUTATION WITH HDS

A document is modularized into sentences, and then the words of the sentences are grouped based on their POS. Using fuzzy word similarity measure (PGMeasure) similarity between two words are calculated and assigned them as the similarity score for each word in a sentences with respective POS. Then aggregations are applied at each level to get final similarity between a sentence pair. The similarity value of 0 shows the sentences are not at all related and 1 means they are identical. But practically due to fuzzy approximations at word level, the value of 1 can not be reached even if all the words are identical.

This experimental setup is taken directly from [3] with variations in the features. So, in this paper, we only mention them.

A. Evaluation Metrics at Sentence Level

Similar evaluation settings are set here as in IV-A but at sentence level. The similarities computed are evaluated with respect to the benchmark similarities provided by humans in the dataset used. The same metrics are used here as used by [12] which are namely *recall*, *precision*, *F1*, *accuracy*, *rejection*, and *f1* respectively.

The definitions are re-defined at sentence level. **Recall** is a proportion of correctly predicted similar sentences compared to all similar sentences. **Precision** is a proportion of correctly predicted similar sentences compared to all predicted similar sentences. **F1** is a uniform harmonic mean of precision and recall. **Rejection** is a proportion of correctly predicted dissimilar sentences compared to all dissimilar sentences. **Accuracy** is a proportion of all correctly predicted sentences compared to all sentences. Lastly, we define **f1** as a uniform harmonic mean of rejection and recall. A scoring threshold for positive pairs is defined at 0.4 is used unlike [12], where it was 0.5.

This has to be done due to fuzzy membership tuning at the word level.

Other than HDS, *cosine similarity*[2] is used for comparison of results; it is basically a vector space model and works on only 'bag of words' concept.

With similar reasoning as word level, in this case the experiments are done at similarity threshold of 0.4. It is also shown that set II and III of the membership functions work better for this application than set I. So we focus on experiments with these two only.

B. Dataset - The Microsoft Paraphrase Corpus

In 2005, Microsoft researchers Dolan, Brocket, and Quirck [17] published the first paraphrase corpus containing 5801 pairs of sentences with 3900 tagged as "semantically equivalent" or true paraphrases. Sentences were obtained from massive parallel news sources and tagged by 3 human raters according to guidelines described in [17]. This corpus will be referred to below as the MSRPC.

At the word level computation of HDS, membership functions mentioned in Set II and III of table. I are used by FWS. As shown in the word similarity evaluations, similarity threshold of 0.4 is used for all the evaluation in this chapter as well. Tables XXIX and XXX are based on Set II membership functions.

TABLE XXIX
EVALUATION METRIC OF SENTENCE SIMILARITY WITH 500 SENTENCE PAIRS OF MSRPC TEST DATASET

Methods	recall	precision	F1	accuracy	rejection	f1
CosineSim	1	0.68	0.81	0.68	0	0
HDS	0.88	0.71	0.79	0.68	0.24	0.38

TABLE XXX
EVALUATION METRIC OF SENTENCE SIMILARITY WITH WHOLE MSRPC TEST DATASET

Methods	recall	precision	F1	accuracy	rejection	f1
CosineSim	1	0.66	0.80	0.66	0	0
HDS	0.87	0.69	0.77	0.65	0.24	0.37

In table. XXX, it is seen that HDS has higher precision than cosine similarity. But there is minor drop in performance due to wrongly tagged words by the parser used. This is detected when the tagging was checked manually. There is slight rejection of 0.1 in the similarity findings. In the dataset, the humans assigned either 1 or 0 for similar or dissimilar sentences. But this is not very appropriate because similarity measurements when done by humans, can have certain level of uncertainty, which can be captured using fuzzy methods. This is actually done by HDS and the snapshot is shown in table. XXXI.

[2]http://www10.org/cdrom/papers/519/node12.html

TABLE XXXI
SNAPSHOT OF RESULTS WITH MSRPC

Sent1ID	Sent2ID	HumanScore	CosineSim	HDS Sim
3354381	3354396	0	1.0	0.37
1390995	1391183	1	0.99	0.5
2201401	2201285	0	1.0	0.55
...	...	...	...	...

c) Effect of tuning membership functions at word level computation: The HDS structure explained here is dependent on the features of the word level. The semantic similarity between words are computed by PGMeasure as discussed in [8]. The similarity values depend on the tuning of membership functions at this word level. The better the membership functions chosen, the more the results will be similar to human approximations. Here a new set (Set III of table. I) of membership functions are used and the HDS is again run on MSRP corpus and the results are observed in tables XXXII and XXXIII.

TABLE XXXII
EVALUATION METRIC OF SENTENCE SIMILARITY WITH 500 SENTENCE PAIRS OF MSRPC TEST DATASET

Methods	recall	precision	F1	accuracy	rejection	f1
CosineSim	1.0	0.68	0.81	0.68	0	0
HDS	1.0	0.69	0.82	0.70	0.05	0.10

TABLE XXXIII
EVALUATION METRIC OF SENTENCE SIMILARITY WITH WHOLE MSRPC TEST DATASET

Methods	recall	precision	F1	accuracy	rejection	f1
CosineSim	1.0	0.66	0.80	0.66	0	0
HDS	0.99	0.67	0.80	0.67	0.03	0.06

From tables XXXII and XXXIII, it is clearly noticed that the recall and precision have improved over the previous cases.

C. Effect of different Parts of Speech on HDS performance

Similarity of words are determined based on context. It is rather difficult to say which words are similar without a context. But if they belong to same parts of speech then it can be assumed that the contextual appearance of the words will also be similar if not exactly the same. Since HDS uses the word level similarity to propagate to the sentence level, it is essential to identify these words based on their proper parts of speech; as it is known that the same word in different parts of speech may have different meaning. Thus it is necessary to formulate a method which disambiguates the interpretational uncertainties and delivers more contextually appropriate word similarity - taking into account different measures, such as - graph based measures and glosses of the contextual senses. Hierarchical Document Signature (HDS) is hence chosen. It organizes a sentence into a hierarchical structure that helps to compare two or more sentences based on their part-of-speech

(POS) using fuzzy aggregation. As such, its result is effected by the result of POS tagging directly.

Now another experiment is conducted to see the effect of different POS taggers on HDS. Normally, for the previous evaluations, Stanford POS tagger is used. But it is seen that there are many instances when Stanford POS tagger produces errors and lead to wrongly tagged words. As HDS is dependent on POS, so proper tagging is required. Here, four different taggers 'hunpos' [18], 'opennlp' [19], 'crftag' [20], and 'lingpipe' [21] are used and sentence similarity is recomputed with different taggers using 500 MSRP data and the results are shown in fig. 2. It reflects that the performance of HDS can be improved using a better tagging algorithm.

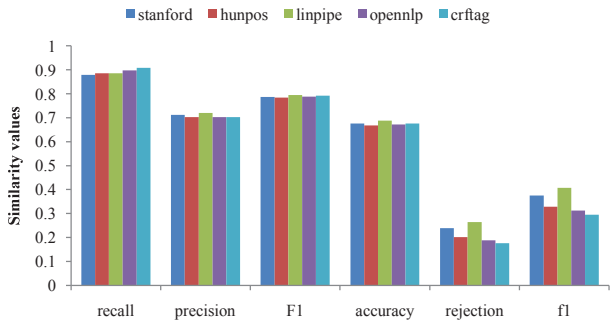

Fig. 2. Comparison of performance evaluation with varying POS taggers

VI. Conclusion

This paper discusses a detailed study of different features for improving the performance of the Hierarchical Document Signature. It is seen that proper tuning of features like fuzzy membership functions, similarity thresholds, input fuzzy sets and even a better choice of POS tagger improve HDS' performance. As future work, the main aim will be to tune the features automatically based on the nature of the dataset.

***Abstract*— In this study, sliding adaptive fuzzy control (SAFC) is proposed to chaos control for a class of time-delayed chaotic systems. An adaptation law based on Gradient Descent (GD) method is utilized to determine the parameters of fuzzy controller. The first derivation of Lyapunov function is considered as the cost function which must be minimized, so the stability of proposed method is guaranteed with Lyapunov stability theory. Moreover, the changes of parameters and delay time are investigated. Simulation results show that the proposed method is appropriate to chaos control and it is robust with respect to changes of parameters. Also it is illustrated that the performance of proposed method is better than the performance of sliding mode controller.**

Keywords: Chaos control, Sliding mode control, Adaptive fuzzy Control , Time-delayed chaotic systems

I. INTRODUCTION

Chaos is the long and finite aperiodic behavior in deterministic systems which are extremely sensitive to initial conditions [1, 2]. This phenomenon has occurred in many fields such as physical, chemical, biological process and secure communications [3, 4]. Chaos is often undesirable or unwanted, so the chaos control is required to attain the system with the regular behavior. However, sometimes it is useful as in mixing and coding process [5, 6]. Since Ott, Grebogi and Yorke proposed the OGY method in 1990 [7], chaos control has been one of the interesting topics for researchers. Many various control methods have been studied to chaos control such as fuzzy [5, 6], sliding mode control (SMC) [8, 9], delayed feedback [10], and radial basis function (RBF) sliding mode controller [11].

Since Mackey and Glass observed the oscillation and chaos in physiological systems by first order differential delay equations in 1977 [12], time-delayed chaotic systems have attracted many interests. After that, many time-delayed chaotic systems were found with one state variable, such Ikeda model simplified the model of a laser with optical feedback. Logistic model is the other one which describes the model of population increasing in an unchangeable environment. One of the important researches studied the behavior of these systems is presented in [13]. In 2004, Ikeda model and bifurcation phenomenon are restudied in [14]. Logistic model is studied in [15]. The bifurcation phenomenon in Logistic model is investigated with considering the different delay in [16].

Time-delayed chaotic systems introduce infinite dimension, so chaos control in these systems is more complicated than in the chaotic systems with finite dimension. Many studies have been done on chaos control in these systems, for example, the occasional proportional feedback [17], and the delayed feedback controller (DFC) [18]. Hybrid control including SMC and delayed feedback controller is designed to stabilize unstable periodic orbits (UPO's) and unstable fixed points (UFP's) [19]. An observer-based approach to control of time-delay chaotic systems via Takagi – Sugeno fuzzy model is studied in [20].

In this study, an adaptive fuzzy controller is applied to stabilize UPO's and UFP's .The input of this controller is a sliding surface. The basic idea of this method is minimizing the first derivation of Lyapunov function, so that the stability is achieved. Notice that, to stabilize UPO's, sliding adaptive fuzzy control (SAFC) based delayed feedback is proposed in this paper. Also, the effect of model parameters and time delay are investigated with considering different values of them. The SAFC is implemented on Mackey-Glass and Logistic models.

This paper is organized as follows: in section 2, the model of time-delayed chaotic systems and its properties are described. The structure of proposed controller constitutes section 3. Stability analysis is studied in section 4. Simulation results and conclusion are given in section 5 and 6, respectively.

II. MODEL OF SYSTEM

A class of time-delayed systems is considered as follows:

$$\dot{x}(t) = -ax(t) + f_b(x(t-\tau)) + u(t) \tag{1}$$

where, $x, u \in R$ are the state variable and control input, respectively. a, b, τ are the system parameters , $\tau \succ 0$. Time-delayed system in (1) can show chaotic behavior when the nonlinear function $f_b(.)$ satisfies the following conditions [21, 22]:

$(i) f_b(0) = 0;$

$(ii) \forall x \quad x f_b(x) \geq 0;$

$(iii) \exists x_{eq} \succ 0 \quad f_b(x_{eq}) = x_{eq};$

$(iiii) \exists r \in (0, x_{eq}) : \forall x \quad f_b(x) \leq f_b(r) = M \quad , M \succ 0.$

Some time-delayed chaotic systems satisfied above conditions are Mackey-Glass, Ikeda and Logistic models. These models are given as

Mackey-Glass Model [12, 21]

$$f_b(z) = \frac{bz}{1 + |z|^C} \quad (C \succ 1) \tag{2}$$

Ikeda model [13, 21, 23]

$$f_b(z) = \begin{cases} b\sin(z) & |z| \leq \pi \\ 0 & otherwise \end{cases} \tag{3}$$

Logistic model [22]

$$f_b(z) = \begin{cases} bz(1-z) & 0 \leq z \leq 1 \\ 0 & otherwise \end{cases} \tag{4}$$

In this paper, Mackey-Glass and Logistic models are studied.

III. DESIGN OF CONTROLLER

In this section, sliding adaptive fuzzy control is designed to chaos control in time-delayed chaotic systems. Gradient Descent (GD) is applied to train the parameters of fuzzy controller. In this method, minimizing the first derivation of Lyapunov function is considered, so that the stability is achieved. This derivation is applied as a cost function to determine unknown parameters to design of controller. Based on the Lyapunov theorem, the sliding surface reaching condition is $s\dot{s} \prec 0$.

Sliding surface is defined as follows:

$$s(t) = e(t) = \begin{cases} x(t) - x_{eq} & ; to\ stabilize\ UFP's \\ x(t) - \alpha x(t-T) & ; to\ stabilize\ UPO's \end{cases} \tag{5}$$

where $0 \prec \alpha \prec 1$. If $\alpha = 1$, then a stable periodic solution is obtained and if $\alpha \prec 1$, the origin will be stabilized. Notice that to stabilize UPO's, it is assumed that $x^*(t)$ is considered as the desired UPO with $x^*(t+T) = \alpha x^*(t)$ .The fuzzy system used in this study has product inference engine, singleton fuzzifier, center average defuzzifier, and Gaussian membership function. So, the fuzzy system is given as

$$u_1 = \frac{\sum_{l=1}^{E} y^l \left[\prod_{i=1}^{n} \exp(-(\frac{s - c_i^l}{\sigma})^2) \right]}{\sum_{l=1}^{E} \left[\prod_{i=1}^{n} \exp(-(\frac{s - c_i^l}{\sigma})^2) \right]} = \hat{Y}^T \phi \tag{6}$$

where $\hat{Y} = [y^1, ..., y^n]^T$, E is fixed, y^l , c_i^l and σ are free parameters. $s \in R^n$ is the input of the fuzzy system, and $u_1 \in R$ is the output of the fuzzy system. y^l is the center of fuzzy set. Parameters c_i^l and σ are centers and radius of basis function, respectively. In this paper, c_i^l and σ are chosen arbitrarily. Since this fuzzy system is considered with one input, n is equal to 1. To design the controller, the parameter y^l must be determined based on the reaching condition, $s\dot{s} < 0$. Thus, the GD method is applied to determine it as follows:

$$\dot{y}^l = -\gamma \frac{\partial s(t)\dot{s}(t)}{\partial y^l(t)} \tag{7}$$

Equation (7) can be rewritten as

$$\dot{y}^l = -\gamma \frac{\partial s(t)\dot{s}(t)}{\partial y^l(t)} = -\gamma \frac{\partial s(t)\dot{s}(t)}{\partial u(t)} \frac{\partial u(t)}{\partial y^l(t)} \tag{8}$$

Let us to define

$$u = u_1 + u_2 \tag{9}$$

where $u_2 = -f_b(x(t-\tau))$, so the non-linear term is cancelled. Then

$$\begin{aligned}\dot{y}^l &= -\gamma \frac{\partial s(t)\dot{s}(t)}{\partial y^l(t)} = -\gamma \frac{\partial s(t)\dot{s}(t)}{\partial u(t)} \frac{\partial u(t)}{\partial y^l(t)} \\ &= -\gamma \frac{\partial s(t)\dot{s}(t)}{\partial u_1(t)} \frac{\partial u_1(t)}{\partial y^l(t)} \\ &= -\gamma s(t) \frac{\exp(-(\frac{s-c^l}{\sigma})^2)}{\sum_{l=1}^{E} \exp(-(\frac{s-c^l}{\sigma})^2)} = -\gamma s(t)\phi_l(s)\end{aligned} \tag{10}$$

where γ is the learning rate parameter. Finally, y^l can be on-line adjusted as it was shown in (10). The SAFC will be compared with SMC described as

$$u(t) = -k_1 sat(\frac{x(t) - x_{eq}}{k_2}) \tag{11}$$

where x_{eq} is the desired fixed point and k_1, k_2 are the controller parameters. This controller has been used in [19]. Since (1) shows chaotic behavior, many unstable periodic orbits exist in its attractor. The SAFC based delayed feedback can be useful to stabilize UPO's with desired period. The SAFC based delayed feedback is described as

$$u(t) = \alpha u(t-T) + u_1 + u_2 \tag{12}$$

Notice that $x^*(t+T) = \alpha x^*(t)$, and $x^*(t)$ is considered as the desired UPO.

IV. STABILITY ANALYSIS

Lyapunov stability analysis is applied to prove the stability of UFP's and UPO's. From the theory of sliding mode control, a perfect control law is obtained as

$$u_{eq} = \begin{cases} \dot{x}(t) + ax(t) + \dot{s}(t) + \lambda s(t) & ; for\ UFP's \\ -\alpha u(t-T) + \dot{x}(t) & \\ \quad + ax(t) + \dot{s}(t) + \lambda s(t) & ; for\ UPO's \end{cases} \tag{13}$$

where s is presented in (5).
First, to analyze the stability, (9) is substituted in (1):

$$\dot{x}(t) = \begin{cases} -ax(t) + u_1(t) & ; for\ UFP's \\ -ax(t) + \alpha u(t-T) + u_1(t) & ; for\ UPO's \end{cases} \tag{14}$$

if u_1 is substituted with u_{eq} then $\dot{s}(t) + \lambda s(t) = 0$. Since λ is a positive constant parameter, the sliding surface variable s will converge to zero, gradually. So, e will converge to zero. From (13) and (14):

$$\dot{s}(t) = -\lambda s(t) + (u_{eq}(t) - u_1(t)) \tag{15}$$

Theorem ([24]). *Suppose that the input universe of discourse U is a compact set in R^n. Then, for any given real continuous function $g(z)$ on U and arbitrary $\xi \succ 0$, there exists a fuzzy system $F(z)$ in the form of (10) such that*

$$\sup_{z \in U} \left\| g(z) - F(z) \right\| \le \xi$$

That is, the fuzzy systems with product inference engine, singleton fuzzifier, center average defuzzifier, and Gaussian membership functions are universal approximators.

Therefore, the control law u_1 can be obtained via the optimal weighting vector $\overline{Y}$ of the fuzzy system. The designed control is applied to estimate the u_{eq}. This approximation can be achieved with the error which is smaller than ξ.

$$\max \left| \overline{u}(x, \overline{Y}) - u_{eq}(x) \right| \prec \xi$$

where $\overline{u}(x, \overline{Y}) = \sum_{l=1}^{E} \overline{y}^l \phi_l = \overline{Y}^T \phi$ and $u_{eq}(x) = \overline{Y}^T \phi + \xi$.

Define $\widetilde{Y} = \overline{Y} - \hat{Y}$ as the weighting error, and then (15) can be rewritten as

$$\dot{s}(t) = -\lambda s(t) + (\widetilde{Y}^T \phi + \xi) \tag{16}$$

Notice that $\overline{Y}$ and $\hat{Y}$ are the optimal and estimated values of Y, respectively.
Define the Lyapunov function as follows:

$$V(s, \widetilde{Y}) = \frac{1}{2} s^2 + \frac{1}{2\gamma} \widetilde{Y}^T \widetilde{Y} \tag{17}$$

The first derivation of (17) with respect to time is obtained as

$$\dot{V} = s\dot{s} + \frac{1}{\gamma} \widetilde{Y}^T \dot{\widetilde{Y}} \tag{18}$$

Substituting (10), (16) in to (18), then

$$\dot{V} = s(-\lambda s + \tilde{Y}^T \phi + \xi) + \frac{1}{\gamma}\tilde{Y}^T(-\gamma s \phi) = -\lambda s^2 + s\xi \quad (19)$$

Thus

$$\dot{V} \le |s|(-\lambda|s| + \xi) \quad (20)$$

So, if $|s| \ge \xi/\lambda$, then $\dot{V} \le 0$ which means that this Lyapunov function will decrease gradually. It can be concluded that the error of state variable will converge into a boundary layer ξ/λ around $e = s = 0$ in the phase plane. Hence, it can be resulted that the SAFC is stable and the error of state variable will converge into a small value.

V. SIMULATION RESULTS

A. Implementation with constant values of a, b, τ

In this section, the behavior of two considered models with $\tau = 10$, $a = 1$, $b = 2$ (for Mackey-Glass model), $b = 4$ (for Logistic model), $C = 10$ and $x(0) = 0.1$ is studied. For Mackey-Glass and Logistic models, UFP's other than the origin are $\pm 10\sqrt{\frac{b-a}{a}} = \pm 1$ and $\frac{b-a}{b} = 0.75$, respectively. Fig. 1 shows the phase plane of the uncontrolled system.

The SAFC and the SAFC based delayed feedback are applied to stabilize the UFP'S and UPO's, respectively. The parameters of SMC are $k_1 = 3, k_2 = 0.1$ and the reason of these choices has been described in [19]. System responses are shown in Fig. 2. As it is shown in Fig. 3 the control effort of SAFC is less than the control effort of SMC and the control signal of SAFC is smoother than the control signal of SMC. Notice that the speed of SAFC and SMC is controllable. The SAFC speed is improved with a proportional gain. Also, the speed of response with SMC becomes better if k_1 is chosen larger than 3 or k_2 is chosen smaller than 0.1. Notice that if k_1 is chosen larger than 3, the control signal will become larger. In this mode, system may be damaged, and if k_2 is chosen smaller than 0.1, the control effort will become more that it is not desired. Furthermore, it is assumed that $|s(t)| \le k_2$ is $s(t)$'s domain of attraction, so very small value of k_2 is not desired. In summary, with comparing the response speeds and control efforts of SAFC and SMC, it is obtained that the performance of SAFC is better than the performance of SMC. To show the effect of small value of k_2, its value is changed to 0.0001. Fig. 3 shows that in this case, the control effort becomes more, although the speed of response becomes better.

To stabilize UPO's, it is assumed that $\alpha = 1, T = 13$. The results obtained after using SAFC based delayed feedback at $t = 100$ are shown in Fig. 5. As it is shown in this figure, the period of the response is exactly the same as it has been desired.

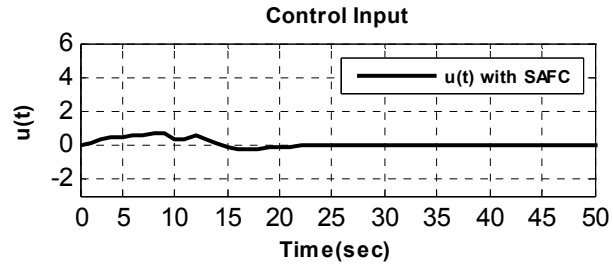
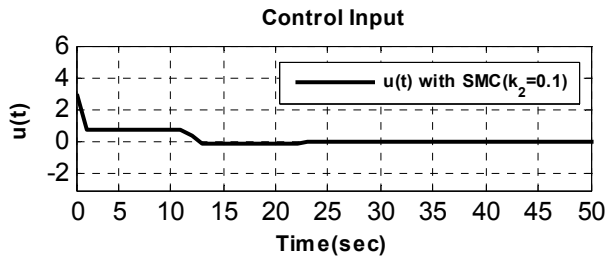
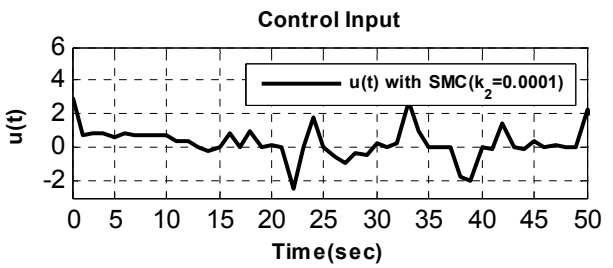
(a)







(b)

Figure 5. Response of (a) Mackey-Glass , (b) Logistic model to SAFC based delayed feedback with $T = 13, \alpha = 1$. The control force was applied at $t = 100$.

For better comparison, the performance of two considered controllers is compared with the following criteria:

1. Mean square error after 10τ (MSE).
2. Output error variance after 10τ (EV).
3. Output error settling time. It is the time at which $|e| < 0.1$ (EST).
4. Control signal variance after 10τ (CV).
5. Maximum of absolute value of control signal (MAC) after 0.1τ .

As we know, the less the MSE and EV, the better control is achieved. The less the EST, the sooner is the convergence. Moreover, less control effort (CV) and lower magnitude of the control signals (MAC) is desired in real-time control applications. The results of these comparisons for Mackey-Glass and Logistic models are given in Table 1, 2 respectively.

TABLE I. COMPARISONS BETWEEN DIFFERENT METHODS OF CHAOS CONTROL FOR MACKEY-GLASS MODEL

Criterion	Control Method		
	SAFC	***SMC*** ($k_2 = 0.1$)	***SMC*** ($k_2 = 1e-4$)
MSE	0	8.1690e-008	7.2888e-10
EV	0	7.9303e-008	7.3373e-10
EST(sec)	11	2	2
CV	0	7.1373e-005	0.6604
MAC	0.9784	0.9818	2.8349

TABLE II. COMPARISONS BETWEEN DIFFERENT METHODS OF CHAOS CONTROL FOR LOGISTIC MODEL

Criterion	Control Method		
	SAFC	***SMC*** ($k_2 = 0.1$)	***SMC*** ($k_2 = 1e-4$)
MSE	0	2.6254e-008	5.8916e-010
EV	0	2.4969e-008	5.7386e-010
EST(sec)	10	2	2
CV	4.415e-031	2.2472e-005	0.5165
MAC	0.6936	0.7350	2.7129

These results show that SAFC is better than SMC in all cases except EST.

B. Synchronization of two nonidentical systems with known parameter Implementation with differences in values of a, b, τ s

To study the effect of parameters changing, the parameters of Mackey-Glass and Logistic models are changed to $a = 6, b = 8$ at $t = 400$, so new UFP of Mackey-Glass and Logistic model are 0.89595 and 0.25, respectively and the time delay is changed to $\tau = 105$ at $t = 70$. Figs. 6, 7, 8 Show that the SAFC acts as well as when the parameters are not changed and SMC performance becomes worse when τ is changed to 105 at $t = 70$.

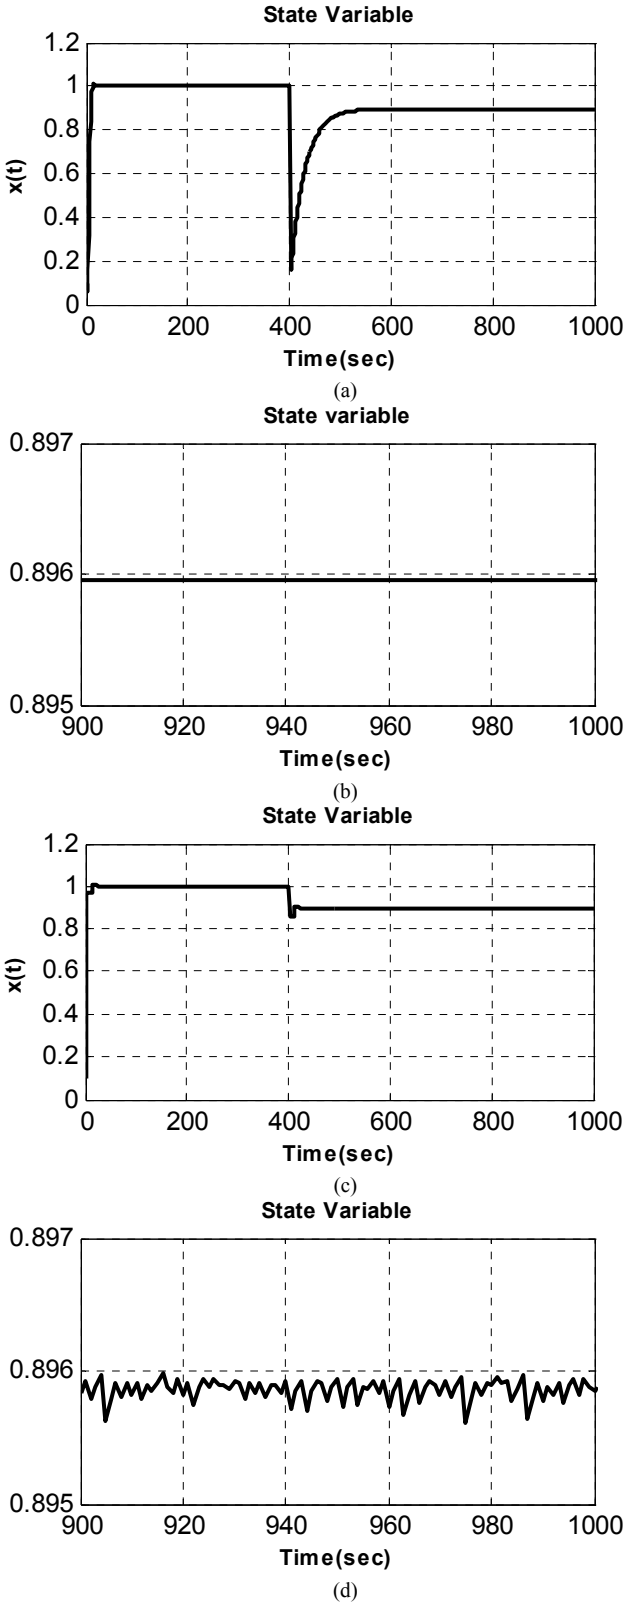

Figure 6. System response of Mackey-Glass model to (a, b) SAFC, (c, d) SMC when the parameters a, b are changed at $t = 400$.

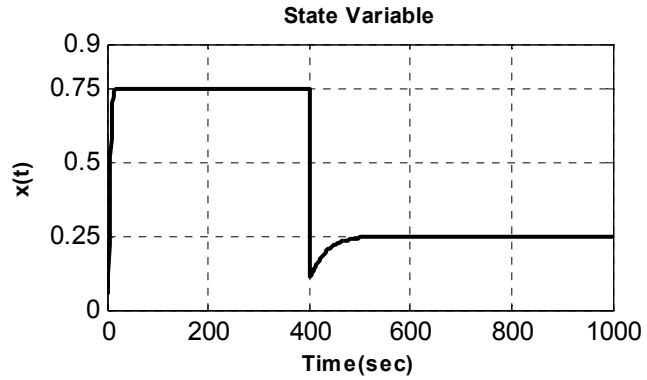
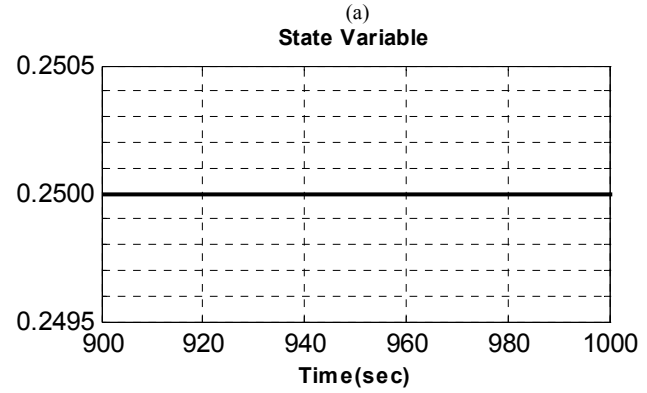
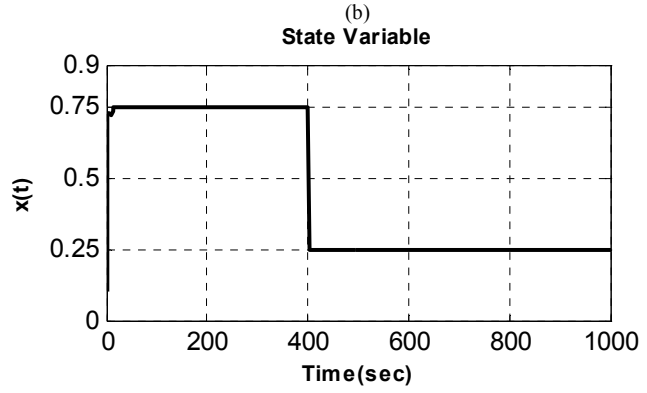


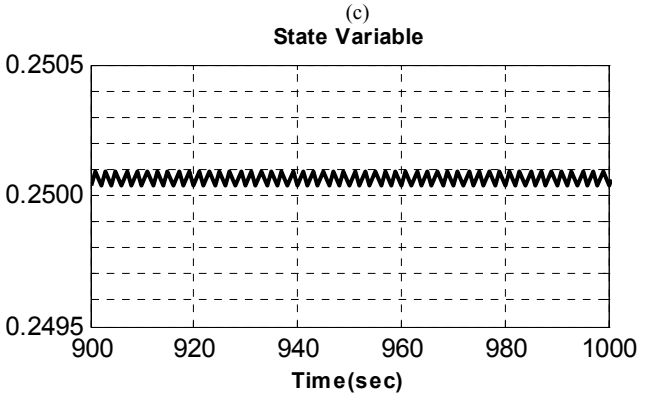
(a)



(b)

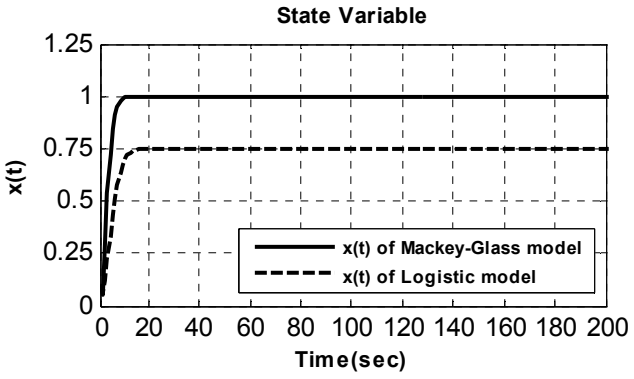


(c)

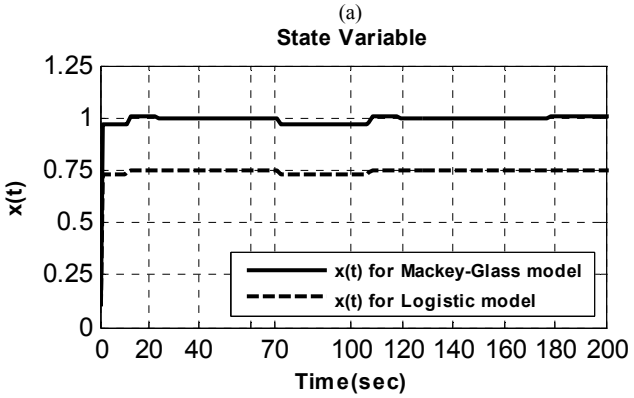


(d)

Figure 7. System response of Logistic model to (a, b) SAFC, (c, d) SMC when the parameters a, b are changed at $t = 400$.



(a)



(b)

Figure 8. . System response of Mackey-Glass and Logistic model to (a) SAFC, (b) SMC when the parameter τ is changed at $t = 70$.

In summary, the SAFC performance is better than SMC performance in the cases considered in this section.

VI. CONCLUSION

In this paper, the behavior of two time-delayed chaotic systems is studied; Mackey-Glass and Logistic models. The sliding adaptive fuzzy controller and the sliding adaptive fuzzy controller based delayed feedback are applied to stabilize UFP's and UPO's respectively. Also, the SAFC has been compared with SMC applied to stabilize UFP's. The simulation results show that the SAFC is robust with respect to offline and online changes of parameters. Finally, it is concluded that SAFC is effective to chaos control in time-delayed chaotic systems and its performance is better than the SMC performance in many cases considered in this paper.

***Abstract*—Microarray experiments usually generate data sets with multiple missing value due to several reasons. In the paper a robust method has been proposed to estimate the missing value of microarray experimental data. Missing values are imputed using fuzzy similarity measure by identifying the genes having similar characteristics to that of the gene with missing values. In this approach, biological knowledge of the gene is extracted using fuzzy relation and based on that knowledge, missing value is predicted and optimized. The estimation accuracy of the proposed method is compared with the existing K-nearest neighbour (KNN) based missing value imputing method. The result demonstrates that the proposed method outperforms the KNN based method.**

***Index Terms*—Microarray gene expression, missing value, fuzzy similarity, biological knowledge**

I. Introduction

Microarray technology, a high throughput technology [1] evaluates the expression of thousands of genes simultaneously [2]. A microarray experiment typically assesses a large number of DNA sequences (genes, cDNA clones, or expressed sequence tags) under multiple conditions. These conditions may be a time series during a biological process or a collection of different tissue samples (e.g., normal versus cancerous tissues). Data obtained from a microarray experiment is represented by a real-valued gene expression matrix, where the rows form the expression patterns of genes, columns represent expression profiles of the samples and each cell is the measured expression level of gene samples.

Usually, data from microarray experiments contain missing value due to different reasons including dust or scratches on the slide, error in experiments, image corruption and insufficient resolution. Typically 1-50% of data are missing [3], affecting up to 95% of the genes. Missing value is a predominant problem for the analysis of microarray data, which needs attention in order to obtain accurate results from microarray data analysis [2], [4]. Therefore, as a preprocessing step missing value estimation is essential. Existing algorithms require a full dataset for statistical analysis of microarray data [4] because the underlying statistical methodology is based on balanced datasets. There are many approaches to deal with missing value, including:

a) Repeating the experiment [5]
b) Ignoring objects containing missing value [6]
c) Estimating the missing value

The first approach is expensive and time consuming while the second approach usually lost too much useful information and may bias the results if the remaining cases don't represent the entire sample properly. The third approach can be subdivided into two groups. The missing value estimation methods of the first group substitute the missing values by a global constant such as 'zero' [6] or by the average of the available gene expression values [7] resulting distortion in relationships among the variables. Correlation structure is considered in the second group in two steps. At first, genes similar to the gene with missing value(s) are identified and then the missing values are predicted with the help of the observed values of the identified genes. The widely used weighted *K*-nearest neighbor imputation (KNN impute) procedure [8] reconstructs the missing values using a weighted average of *K* most similar genes [9]. These methods have better performance though the estimation ability largely depends on the selection of *K* parameter. There is no theoretical way to determine the value of *K* appropriately but to specify by the user. In cluster-based algorithms [10], [11] determination of missing values have been proposed where number of cluster either predetermined or the user have to specify that. Moreover, since the accuracy of the clustering algorithms depends on number of clusters, its selection becomes very crucial. The limitation of the existing methods is due to the fact that the estimation is based solely on the gene expression data ignoring biological information, which is inherent in the gene dataset.

Fig. 1 shows three genes g_1, g_2, and g_3 on seventeen experimental conditions c_j for j = 1,..., 17 where the y-axis shows the expression level of a gene g_i on a particular condition c_j, plotted along x axis. Based on a distance function g_1 and g_2 are clustered together. However, from the biological viewpoint, it is more appropriate to cluster g_1 and g_3 because g_1 and g_3 exhibit similar tendency along a subset of conditions. It is therefore, concluded [12]-[14] that strong correlations may

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

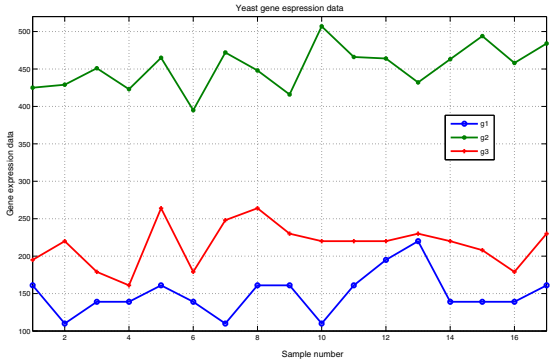

Fig. 1. Three genes with seventeen experimental conditions.

exist among a set of genes, even if their spatial localities are far apart from each other. Pattern-based and tendency-based biclustering algorithms were proposed [15] to overcome the conventional constraints of spatial proximity and able to discover clusters in all subspaces by pattern/tendency similarities. However, a pattern-based model is only capable of identifying positive correlated genes if and only if some linear transformation relationships such as shifting [14], [16], [17] and scaling [18] exist among their expression levels. The mechanism of gene regulation is complicated and becomes oversimplified if one assumes that only linear relationships exist in coregulated gene profiles [19]. Order Preserving Cluster (OP-CLUSTER) [12] and Tendency Preserving cluster (TP-CLUSTER) [13] are tendency based clustering algorithms adopt a model for efficient discovery of genes. Here, the gene expression levels synchronously rise and fall in a subspace while at the same time do not impose any particular magnitude transformation relationships among the genes. However, recent research work [19], [20] provides a greater diversity of correlations among coregulated genes such as genes with a negative pattern or inverted behavior, where existing pattern-based and tendency-based algorithms lost their significance.

In the paper, a robust method has been proposed to estimate the missing value of microarray experimental data by considering both positive and negative correlated genes. Missing values are imputed by identifying the genes which have similar characteristics to that of the gene with missing value, determined by soft class membership value using fuzzy similarity measure. The paper briefly addresses the approaches for finding related genes followed by the discussions of necessities for finding co-relational gene, with support from real examples.

The rest of the paper is organized as follows. The proposed method is described in section II. Experimental results are presented in section III. Concluding remarks and suggestions for future work are given in section IV.

II. Methodology

Clustering is an unsupervised learning technique that aims at partitioning a given set of objects into subgroups or clusters based on the similarity of objects. It has been observed that each gene may be involved in more than one biological activity, therefore, hard clustering which assign each gene to a single cluster fails to express the total characteristics of the genes [21]. In the paper, first gene expression dataset is normalized and then clustered using fuzzy c means clustering algorithm [22] that measures similarity between genes. The belongingness of a single gene into multiple clusters is determined with varied degree of membership value obtained using clustering analysis. The proposed method determines the functional similarity between the genes inherent in the sample values in order to acquire more biologically interpretable clusters.

A. Pattern Similarity Matching (PSM) Algorithm

Few terminologies are defined below for understanding the proposed PSM algorithm.

Normalized gene expression ($NGE_{(i,j)}$): Difference between the j^{th} sample value of each i^{th} gene_expression and mean of the sample values of the corresponding gene_mean represent zero mean normalize gene expression, defined in (1). The available sample values of genes are normalized and the gene expression matrix is reconstructed with the new gene expression data (*Normalized gene expression*). This represent zero mean relational activity level of that gene for the sample.

$$NGE_{(i,j)} = gene_expression_{(i,j)} - gene_mean_{(i,j)} \quad (1)$$

Activation level ($Al_{(i)}$): Distribution of gene expression data in two-dimension space reveals the fact that several genes are highly active compare to others. Initialize the activation level of each gene to zero. Increase the activation level of gene i by one when its present sample, say j having higher value than its previous sample, as defined in (2).

$$Al_{(i)} = Al_{(i)} + 1 \quad if \quad NGE_{(i,j)} > NGE_{(i,j-1)} \quad (2)$$

Depending on the activity of gene i, its class membership value $Mfl_{(i)}$ is evaluated using the concept of fuzzy similarity measure, defined in (3) that represent its degree of belongingness in a particular class.

$$Mfl_{(i)} = \frac{Al_{(i)}}{gs} \quad (3)$$

where gs is the number of samples in gene i without any missing value.

Missing gene list(*misg*): The list contains genes having one or more missing sample value.

Not A Number (*NaN*): Not a Number (*NaN*)[23] represents fractional sample value of a gene. *NaN*'s are represented by a bit pattern with an exponent of all 1s with non-zero fraction value.

Gene expression data represents the logarithmic value of gene's protein production under a particular time interval. Generally, each gene expression data is distinct, so normalization

is required to find out the similar active genes. The normalized value of a particular sample is basically information about the gene's protein production, typically the zero mean, depicted in (1). The PSM algorithm calculates similarity of the genes based on their class membership value(*M fl*) as given in equation (3). If a set of genes (i = 1 ... n) have similar activity level of protein production with a gene having missing value (l) then a particular sample position among the similar genes is selected using (4) to impute the missing value at k^{th} sample position of l^{th} gene.

$$Optv = min_{(\forall i, \forall j)}(|gene_expression(i,j) - gene_expression(i,k)|) \quad (4)$$

Optv is the difference between the sample value at missing position k with other sample positions of the respective gene belonging to the same cluster. Minimum difference occurs say, at sample position *s* of a particular gene. Now the sample value at position *s* of the missing gene (l) is used to impute the missing value at position *k*.

Missing gene expression value can be estimated from k^{th} sample position of missing gene *l*.

B. Procedure:

Input: Microarray gene expression data, with some genes' (object) sample (attribute) value missing.

Output: Microarray gene expression data, with some artificial data impute.

Step1: *mean_gene*:= mean*(gene_array)*

Step2: *misg*:=find_missing_gene(*gene*)

Step3: for all *i gene* in *gene_array* do

for all *j sample* of the *gene* do

$NGE_{(i,j)}$:= $gene_array_{(i,j)}$- $mean_gene_{(i)}$

if ($NGE_{(i,(j-1))} > NGE_{(i,j)}$) then

$Al_{(i)} := Al_{(i)}$ + 1

end if

end j^{th} loop

$Mfl_{(i)}$:=$\frac{Al_{(i)}}{gs}$

end i^{th} loop

Step4: for all *l gene* having missing value in *misg* do
$smi_Mfl_{(l)}$:= fuzzy similar gene ($Mfl_{(l)}$)

miss:= find missing sample*(gene_array(misg(l)))*

for i^{th} gene in $smi_Mfl_{(l)}$ do

for all *k* missing sample in *miss* do

for all *j* sample in $smi_Mfl_{(l,i)}$
without *NaN* gene expression for that sample in l^{th} and i^{th} both gene

$Optv := |gene_array_{(smi_Mfl_{((l,i),j))}} - gene_array_{(smi_Mfl_{((l,i),k))}}|$

if *Optv* is minimum then
selected_sample:=j^{th}

Step5:

$gene_array_{(misg(l),k)} := gene_array_{(misg(l),selected_sample)}$

The following example illustrates the above procedure and summarized in tables I, II, III, IV and V by considering twelve genes, each having six samples.

TABLE I
AFTER RANDOMLY DELETION OF DATA FROM ORIGINAL MICROARRAY GENE EXPRESSION MATRIX

Gene id	S_1	S_2	S_3	S_4	S_5	S_6
G_1	7.5	7.58	7.66	7.68	7.01	7.47
G_2	80.2	80.7	80.3	NaN	81	82
G_3	8	8.9	9	9.5	8	8.5
G_4	80	82	84	88	81	79
G_5	2.5	3	2.7	3.2	4	3.5
G_6	3	3	2.7	3.2	3.5	3.5
G_7	72.4	73	62	61	60	58
G_8	82.3	83	82.7	80.2	80	80.5
G_9	92.5	92	91.7	93.2	91	90.8
G_{10}	32	31.6	31.7	31.8	31	30
G_{11}	50	49	48	48.5	49	50
G_{12}	62	62.8	62.1	62.5	62.1	62

TABLE II
MEAN OF EACH GENE IN MICROARRAY GENE EXPRESSION MATRIX

Gene id	Mean
G_1	7.48
G_2	80.84

G_9	91.87
G_{10}	31.35
G_{11}	49.08
G_{12}	62.25

According to the PSM algorithm, *Optv* value (tableV) of all genes (tableI) that are similar to gene with missing value i.e. G_2 are calculated. The minimum value ($|G_1, S_4$ - $G_1, S_3|$ = 0.02) occurs at sample position 3. Now impute (G_2, S_4) using 80.3 from (G_2, S_3) to remove missing value in the original microarray gene expression matrix (table I) .

TABLE III
RECONSTRUCTION OF MICROARRAY GENE EXPRESSION MATRIX AFTER NORMALIZATION OF DATA

Gene id	S_1	S_2	S_3	S_4	S_5	S_6

G_9	1	0.167
G_{10}	2	0.33
G_{11}	2	0.33
G_{12}	2	0.33

The following example illustrates the above procedure with multiple missing values and summarized in tables VI, VII, VIII, IX, X and XI by considering fourteen genes, each having six samples.

Using (4) *Optv* value (tableX) of all genes (tableVI) that are similar to gene with missing value i.e. G_1 are calculated. Minimum value ($|G_3, S_4$ - $G_3, S_3|$ = 0.5) occurs at sample position 3, as given in table X. Now impute (G_1, S_4), which had missing value in the original microarray gene expression matrix (table VI) using 7.77 from (G_1, S_3). Similarly (G_2, S_3) is imputed from (G_2, S_2) considering similar gene G_4. It has been observed that G_3 with multiple missing value is similar to G_1 and minimum *Optv* value is attained in (G_1, S_6) from table XI. But (G_3, S_6) is NaN, so search for next minimum *Optv* value, occurred at $(G_1, S_1)$and (G_3, S_5) is imputed using (G_3, S_1).

III. RESULTS AND COMPARISONS

A. Data set

In this paper, the performance of each method is evaluated using [24]. RNA was obtained from histologically normal bronchial epithelium of smokers during time of clinical bronchoscopy from relatively accessible airway tissue. Gene expression data from smokers with lung cancer was compared with samples of smokers without lung cancer.

B. Measurements for performance

The gene expression matrix obtained from the microarray experiment is modified by replacing all the rows containing missing values with randomly generated artificial missing

G_{14}	-0.25	0.55	-0.15	0.25	-0.15	-0.25

values. The performance is measured by Normalise Root Mean Square Error (NRMSE) evaluated for error detection of Y_{guess}, where Y_{guess} is estimated by the proposed algorithm and Y_{answer} is the original microarray gene expression value.

$$NRMSE = \frac{\sqrt{(mean[(Y_{guess} - Y_{answer})^2])}}{Var(Y_{answer})} \quad (5)$$

Where *Var(x)* returns the variance of matrix *x* and *mean(y)* mean of the *y* matrix.

In Figure 2 and 3 comparison of NRMSE value for GSE4115 and GDS2771 series data are shown by applying PSM and KNN algorithms, respectively. Estimated sample value based on PSM impute method is closer to experimental data. KNN impute method estimates zero value if the sample value at the same position of *k* nearest neighbor genes is missing. On the other hand, if every gene consists missing

value then KNN fails to impute any such missing value. However, the proposed PSM method able to impute 100% missing value in several passes varying with different rate of success. Keeping the missing percentage same with respect to microarray data, increase of number of missing value resulting rapid increase of NRMSE value in case of KNN while in case of PSM the rate is significantly less.

The PSM impute method shows comparable results with the previously developed methods in present research. The outstanding estimation ability of this impute method is partly due to the use of the most missing value information by incorporating fuzzy relation scheme. The results show that the estimating sample values obtained by the proposed PSM

impute method of gene expression data for different genes are less deviated with respect to the microarray data. KNN method depends on how far sample value of *K* number of genes are closed with the missing value ignoring the characteristic pattern of genes, which are might be different. But the PSM algorithm depends on the characteristic pattern, and here *K* varies depending on characteristics of genes. KNN impute method find out *K* nearest gene for each missing value from the remaining gene. Time complexity is high in KNN method due to large number of comparisons, whereas in PSM based impute method time complexity depends on number of unique active level. Therefore, application of PSM algorithm provides better result in less time than KNN impute method in microarray data set consisting of genes with sample values not very close to each other.

IV. Conclusion

The proposed PSM method demonstrates better results in comparisons with the existing method. Here biological knowledge has been exploited to determine similar genes for prediction of missing values unlike the previous works where distance measures were used for missing value prediction, ignoring the inherent knowledge of the genes.The missing value in a gene is predicted from the available value of the same gene, resulting least error in estimation of sample value. The optimized missing value thus provides near exact knowledge for important application. Moreover, time complexity of the PSM algorithm is much less compare to the KNN due to search of selective genes for imputing missing value.

Abstract: **This paper presented an investigation on fault detection of an active suspension system using interval fuzzy modeling. A well known nonlinear classical controller called back-stepping method is used to simulate dynamic response of a half-car suspension system. Confidence bands for the system input-outputs data is approximated using an interval fuzzy model. Then Fault detection has been done by the use of these confidence bands. Simulation results depict that the proposed fault detection is highly effective in evaluating the performance of an active suspension system.**

Keywords: Active Suspension System; Fault Detection; Interval Fuzzy modeling.

I. INTRODUCTION

The interval fuzzy model identification is a methodology for approximating the functions of a finite set of input and output measurements. This approach can also be used to compress information in the case of a nonlinear function family approximation to obtain the interval of parameters that results in a band containing the whole set of measurements [4-6]. Interval fuzzy model also has been used for detecting faults of nonlinear input-output systems with unstructured uncertainties or interval type parameters [7-9].

The residual signal formation and evaluating of it, is a very important part of a fault detection procedure. The major advantage of using interval fuzzy model is, easier generation of residual signal than other methods.

This study tries to use Interval fuzzy model for evaluating the performance of active suspension system. A suspension system is one of the important components of a vehicle which plays a crucial role in handling ride convenience and safety of a vehicle. There are three types of suspension: passive suspension, active suspension and semi-active suspension. An active suspension system is specified by employing some types of suspension force generation such as pneumatic, electromagnetic or hydraulic actuators. Interests are significantly growing on designing and controlling of active suspension systems for automotives in the past three decades. Most of the researches have been done till now, focused on designing a controller for a passive system to improve the driving characteristics of an automobile or simply changing passive systems to active ones. Just a few amounts of recent published papers have also chosen more complex models in order to more precise results, Such as the half-car model with four degree of freedom using various types of controllers as linear and fuzzy logic controllers and also the classical back stepping scheme. Complete modeling of active suspension systems using simulation tools and software has also been done. Identification of active suspension systems have been performed in many cases for specific purposes by the use of various approaches as a basis for controller design and for model based fault detection on a quarter-car model [2,6].

The paper is organized as follows. Firstly, the model of a half-car suspension system is introduced .Then a nonlinear back-stepping controller applied on it. Furthermore the interval fuzzy model of a half-car suspension system is presented after derivation of an interval fuzzy model. Finally residual formation with a fault-diagnostic scenario is described with some concluding remarks.

II. SUSPENSION MODEL, DYNAMICS AND SIMULATION

The model of a half-car suspension system is shown in Figure 1[6]. The model is excited by road surface bump.

The displacements of the sprung mass (car body) for front and rear bodies are given by

Front Body

$$Z_{sf} = Z - a\sin\theta \approx Z - a\theta \tag{1}$$

Rear Body

$$Z_{sr} = Z + b\sin\theta \approx Z + b\theta \tag{2}$$

where Z_{sf} is the front body displacement, Z_{sr} is the rear body displacement, a is the longitudinal distance between front axle and centre of gravity, b is the longitudinal distance between rear axle and centre of gravity, θ is the stroke angel and Z is the displacement of centre of gravity.

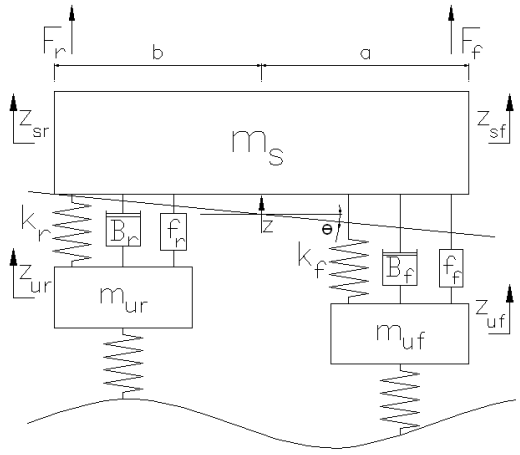

Figure 1: Half car active suspension system model

By applying Newton's second law, the equations of motion for front and rear bodies of the half-car suspension system model are as following

Front Body

$$m_s\ddot{Z}_{sf} = -K_f(Z_{sf} - Z_{uf}) - B_f(\dot{Z}_{sf} - \dot{Z}_{uf}) \\ -k_r(Z_{sr} - Z_{ur}) - B_r(\dot{Z}_{sr} - \dot{Z}_{ur}) + f_f + f_r - am_s\ddot{\theta} \quad (3)$$

Rear Body

$$m_s\ddot{Z}_{sr} = -K_f(Z_{sf} - Z_{uf}) - B_f(\dot{Z}_{sf} - \dot{Z}_{uf}) \\ -k_r(Z_{sr} - Z_{ur}) - B_r(\dot{Z}_{sr} - \dot{Z}_{ur}) + f_f + f_r + bm_s\ddot{\theta} \quad (4)$$

where f_f and f_r are the front and rear control input force, B_f and B_r are the front and rear damping coefficients, k_f and k_r are the front and rear spring coefficients and Z_{uf} and Z_{ur} are the front and rear wheel displacements, respectively.

Knowing that J_y is the centroidal moment of inertia of the car and using $J_y = m_s r^2_y$ where r_y is the radius of gyration and m_s is the mass of the car body, one can get the equation of motion for the angular stroke motion

$$\ddot{\theta} = \frac{1}{m_s r_y^2}\begin{bmatrix} aK_f(Z_{sf} - Z_{uf}) - bK_r(Z_{sr} - Z_{ur}) \\ + aB_f(\dot{Z}_{sf} - \dot{Z}_{uf}) - bB_r(\dot{Z}_{sr} - \dot{Z}_{ur}) \\ - af_f + bf \end{bmatrix} \quad (5)$$

The equations of motion for the front and rear unsprung masses (front and rear wheels) can be obtained again by applying Newton's second law as follows:

Front wheel

$$m_{uf}\ddot{Z}_{uf} = K_f(Z_{sf} - Z_{uf}) + B_f(\dot{Z}_{sf} - \dot{Z}_{uf}) \\ -K_{tf}(Z_{uf} - Z_{rf}) - f_f \quad (6)$$

Rear wheel

$$m_{ur}\ddot{Z}_{ur} = K_r(Z_{sr} - Z_{ur}) + B_r(\dot{Z}_{sr} - \dot{Z}_{ur}) \\ -K_{tr}(Z_{ur} - Z_{rr}) - f_r \quad (7)$$

The system state variables will be then set as $x_1 = Z_{sf}$ for the front sprung mass displacement, $x_2 = \dot{Z}_{sf}$ for the front sprung mass velocity, $x_3 = Z_{uf}$ for the front unsprung mass displacement, $x_4 = \dot{Z}_{uf}$ for the front unsprung mass velocity, $x_5 = Z_{sr}$ for the rear sprung mass displacement, $x_6 = \dot{Z}_{sr}$ for the rear sprung mass velocity, $x_7 = Z_{ur}$ for the rear unsprung mass displacement and $x_8 = \dot{Z}_{ur}$ for the rear unsprung mass velocity, respectively.

The state equations with these assigned state variables for the half-car suspension system are then given as follows

$$\dot{x}_1 = x_2$$

$$\dot{x}_2 = -\alpha K_f x_1 - \alpha B_f x_2 + \alpha K_f x_3 + \alpha B_f x_4 - \beta K_r x_5 - \beta B_r x_6 + \beta K_r x_7 + \beta B_r x_8 + \alpha f_f + \beta f_r$$

$$\dot{x}_3 = x_4$$

$$\dot{x}_4 = \frac{1}{m_{uf}}[K_f x_1 + B_f x_2 - (K_f + K_{tf})x_3 - B_f x_4 + K_{tf} z_{rf} - f_f]$$

$$\dot{x}_5 = x_6$$

$$\dot{x}_6 = -\beta K_f x_1 - \beta B_f x_2 + \beta K_f x_3 + \beta B_f x_4 - \gamma K_r x_5 - \gamma B_r x_6 + \gamma K_r x_7 + \gamma B_r x_8 + \beta f_f + \gamma f_r$$

$$\dot{x}_7 = x_8$$

$$\dot{x}_8 = \frac{1}{m_{ur}}[K_r x_5 + B_r x_6 - (K_r + K_{tr})x_7 - B_r x_8 + K_{tr} z_{rr} - f_r] \quad (8)$$

f_f And f_r are actuator inputs of the front and rear wheels which have been taken from an available back stepping control scheme [1].The equations for these two control laws have been given as

Front control law

$$f_f = \frac{1}{\alpha}[\beta k_r x_5 + \beta B_r x_6 - \beta k_r x_7 - \beta B_r x_8 \\ - z_1 - c_2 z_2 - \mu_2] + k_f x_1 + B_f x_2 - k_f x_3 - B_f x_4 \quad (9)$$

Rear control law

$$f_r = \frac{1}{\gamma}[\beta k_f x_1 + \beta B_f x_2 - \beta k_f x_3 - \beta B_f x_4 \\ - z_3 - c_4 z_4 - \mu_4] + k_r x_5 + B_r x_6 - k_r x_7 - B_r x_8 \quad (10)$$

where

$$\alpha=\frac{1}{m_s}+\frac{a^2}{J_y},\beta=\frac{1}{m_s}-\frac{ab}{J_y},\gamma=\frac{1}{m_s}+\frac{b^2}{J_y}$$

$z_1,z_2,z_3,z_4,\mu_2,\mu_4$ are nonlinear parameters and functions which are obtained through controller procedure design and certainly affect our simulations; But their equations have not been represented here again. Figure 2 illustrates the effect of controller on the front body mass displacement.

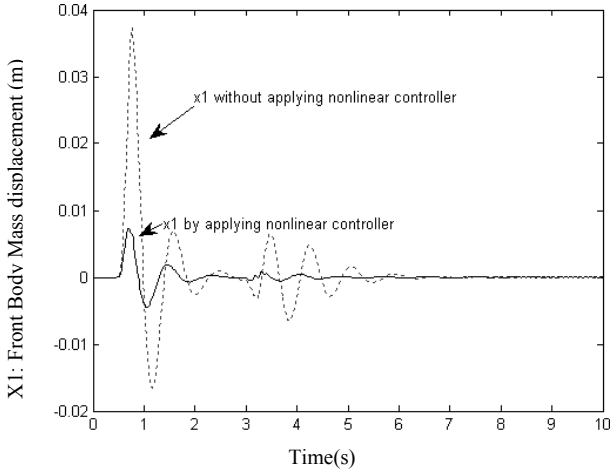

Figure 2: the effect of controller on the front body mass displacement

Z_{rf} And Z_{rr} are the road excitations that have been chosen as

$$z_{rf}(t)=\mu_r(1-rand(1)) \quad , 0.5\le t\le 0.75 \tag{11}$$

$$z_{rr}(t)=\mu_r(1-rand(1)) \quad , \quad 3\le t\le 3.25 \tag{12}$$

where μ_r is amplitude defining the bump height here set to $\mu_r=0.025$ for a bump height of 5cm. The parameters of the half-car model selected for this study are taken from [1].

III. MODELING AND FAULT DETECTION OF THE HALF-CAR MODEL WITH INTERVAL FUZZY MODEL

In this section after derivation of an interval fuzzy model interval fuzzy model of a half-car suspension system has been presented.

A. Derivation of an interval fuzzy model

A typical fuzzy TS-type model in affine form can be supposed as a set of rules.

$$R_j\text{: If } x_p=A_j \text{ , then y}=\theta_j^T x, \quad \text{j=1}\cdots\text{n} \tag{13}$$

The variable x_p=u is the model input and y is the model output and θ_j is a vector of fuzzy parameters, respectively. The consequent vector is denoted $x^T=[u,1]$. Unity is added to the vector for describing the output functions in affine form. Equation (13) can be rewritten as following.

$$y=\beta^T(x_p)\Theta x \tag{14}$$

$\beta^T(x_p)=[\beta_1(x_p),\beta_2(x_p),\cdots,\beta_m(x_p)]$ is a vector of normalized membership functions. Matrix of the coefficients for the whole set of rules is $\Theta^T=[\theta_1,\theta_2,\cdots,\theta_m]$.

Now, we want to find upper and lower boundary functions that satisfy following conditions for any arbitrary ε>0 and for each z=$[x_p\ x^T]^T$.

$$\bar{g}(\text{Z})\ge\text{Max g (z)}, \exists\, g\epsilon\mathcal{G}:\ \bar{g}(\text{z})<\text{g (z)}+\varepsilon \tag{15}$$

$$\underline{g}(\text{Z})\ge\text{Min g (z)}, \exists\, g\epsilon\mathcal{G}:\ \underline{g}(\text{z})>\text{g (z)}+\varepsilon \tag{16}$$

In the above equations, it has been let that C$\subset R^{n+2}$ is a compact set and $\mathcal{G}$= {g: C→R} is a class of nonlinear functions. Finding bounds in (15) and (16) requires masses data; therefore it is impossible to find exact bounds because only finite amount of data is available.

For solving this problem Stone-Weierstrass theorem has been used. This theorem says that, for any real continuous function g, on a compact set C$\subset R^d$ and arbitrary ε>0, there exist a fuzzy system f, such that [7-9]

$$sup|f(z_i)-g(z_i)|_{z_i\epsilon z}<\varepsilon \qquad \forall i \tag{17}$$

By Stone-Weierstrass extension theorem the following equations will be obtained.

$$0<\bar{f}(z_i)-g(z_i)<\varepsilon \quad \forall i \tag{18}$$

$$-\varepsilon<\underline{f}(z_i)-g(z_i)<0 \quad \forall i \tag{19}$$

The defined band should be as narrow as possible. The upper and the lower fuzzy functions can be found by solving the following optimization problems, respectively. Both problems can be known as linear programming problems.

$$min_{\underline{\Theta}}max_{z_i\epsilon z}\left|y_i-\underline{f}(z_i)\right| \ \ s.t \ \ y_i-\underline{f}(z_i)\ge 0 \tag{20}$$

$$min_{\overline{\Theta}}max_{z_i\epsilon z}\left|y_i-\overline{f}(z_i)\right| \ \ s.t \ \ y_i-\overline{f}(z_i)\ge 0 \tag{21}$$

$\underline{f}(z_i)=\beta^T(x_p)\underline{\Theta}x$ and $\overline{f}(z_i)=\beta^T(x_p)\overline{\Theta}x$ in (20), (21). Required data are obtained by sampling different functions from $\mathcal{G}$ with arbitrary values of z_i.

B. Interval fuzzy model of half-car suspension system

In this section interval fuzzy model has been used for identification and modeling of half car suspension system. As mentioned before, this method is used for functions of a finite set of input and output measurements or systems with interval parameters on the other hand there is a class of functions for description of one system.

It is assumed that parameters' uncertainty of the half-car suspension is 1%. On the other word it is assumed 1% perturbation of nominal value of parameters is acceptable. It's the key idea for using interval fuzzy model for identification of the purposed system. Therefore new model for active suspension system with uncertain parameter will be obtained.

This new model is used to produce the data set for identification of the interval fuzzy model. Responses of the system were studied by 80 different simulations. In each iteration the input signal remained fixed where as uncertain parameters' value changed. The input vector includes Z_{rf} and Z_{rr} . Training of the model has achieved by first 60 simulations and 20 iteration used for validation.

All of the eight state variables of the half-car suspension system have been identified with 8 multi input-Single output interval fuzzy models (INFUMO). Main system and its nonlinear controller consider as a single system. Thus the resultant system is nonlinear. The results of these identifications for two state variables are presented in figures 4 and 5.

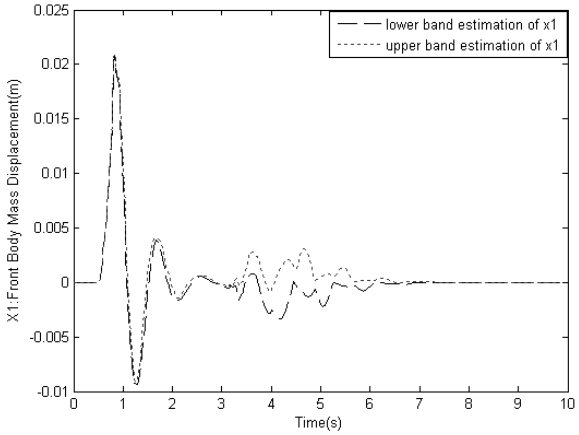

Figure 3: identification of the front body mass displacement with interval fuzzy model

Identified bounds have been used for fault detection of purposed system. Using resultant Interval fuzzy models residual signal could be obtained.

The benefit of this method is that confidence bands for output signals could be obtained easily, and these bands could be used for generating residual signal. The residual signal could be defined in the following way [7-9]:

$$if\ y_{out}<\hat{y}, re(y_{out}) = \frac{y_{out}-\hat{y}}{\underline{\hat{y}}-\hat{y}} \quad (22)$$

$$if\ y_{out}>\hat{y}, re(y_{out}) = \frac{y_{out}-\hat{y}}{\overline{\hat{y}}-\hat{y}} \quad (23)$$

$$\hat{y}=\frac{\overline{\hat{y}}+\underline{\hat{y}}}{2} \quad (24)$$

The residual signal in (22), (23) is zero when the output is equal to $\hat{y}$ and approaches the value 1 if the measurement output is close to one of the interval bounds.

C. Fault detection

Different fault detection methods have been applied to passive, semi-active, and active suspension systems till now. Fault detection of front and rear damper and springs were not possible in Karami et.al [6] model at all whereas it has been done in this research. As mentioned in the previous section, in this case study, it has been supposed that 1% perturbation of nominal parameters' values is acceptable.

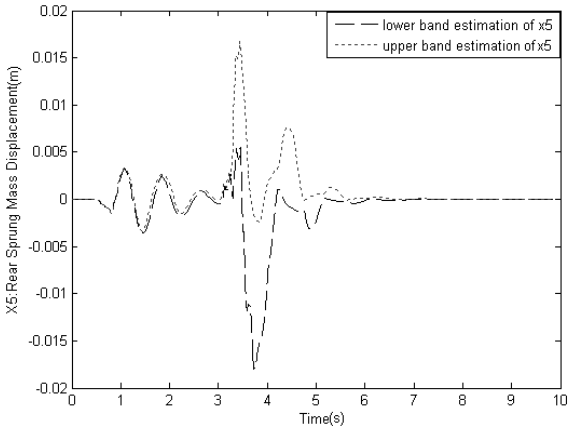

Figure 4: identification of the rear sprung mass displacement with interval fuzzy model

Figure 6 shows the fault detection scheme that has been used in this paper. Each of the state variables of the half-car suspension system assumed to be an output of the system.

In the previous section for each of the state variables an INFUMO has been found. Interval fuzzy models have been put in the parallel position with the main system.

It is possible to use only one INFUMO however eight INFUMOs are used for more accurate fault detection. Residual signals enter the alarm signal blocks, if the value of residual signals are more than unity output of the alarm signal blocks become one otherwise it will be zero.

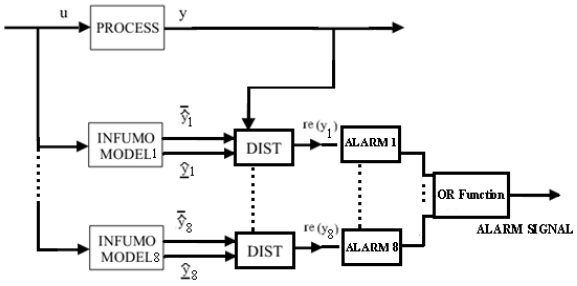

Figure 5: Fault detection using INFUMO model

The last alarm signal is logical OR of eight outputs of the alarm signal blocks. Therefore, if all outputs of system belong to the corresponding identified bounds the performance of the system is correct; otherwise a fault occurred in the system.

10% and 20% fault have been applied on different rear and front component of half-car suspension system. The time of simulation is ten seconds. Since faults have been applied on the system before starting simulation, the alarm signal value expected to be unity during whole time of simulation.

Results are shown in figs 6 to 11. Figure 6 shows an instance of residual signal and its corresponding alarm signal these signals are obtained when 20% fault occurred on the rear damper. Figs 7 to 11 are the main alarm signals that show the occurrence of fault in the different component of the half-car suspension system. Totally these figures reveal that

particularly for up to 20% applied fault, there is a good agreement with the expected result of the problem. Although for 20% fault better results have been obtained, this method can be used for detecting 10% fault that occurred on system's rear and front dampers and springs. The results have been briefly presented in the table 1.

Finally, 30% abrupt fault has been applied on sensor1 at t=4s. The result has been shown in fig11. This figure shows that by this method it is possible to detect the time of occurrence of fault.

TABLE I. RESULT OF FAULT DETECTION FOR DIFFERENT COMPONENT OF HALF-CAR SUSPENSION SYSTEM

Fault	B_r	B_f	K_r	K_f
20% fault	Well	Well	Well	Well
10% fault	Well	Well	Not bad	Not bad

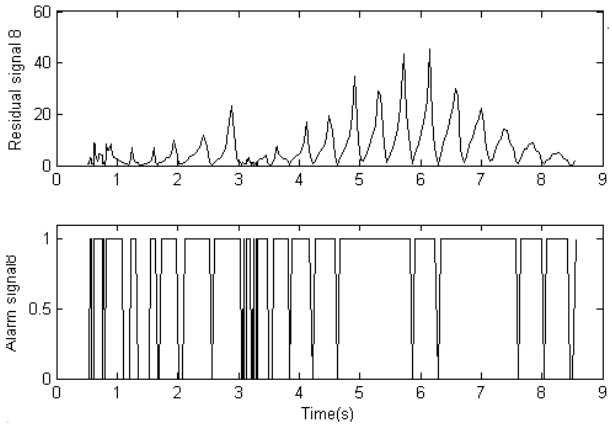

Figure 6: a. shows residual signal when 20% fault occurred on Br. b. shows alarm signal when 20% fault occurred on Br

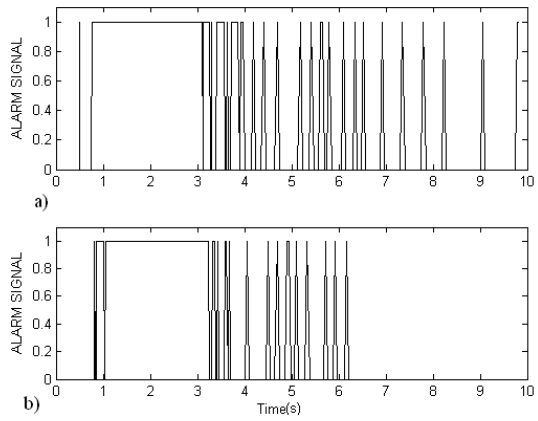

Figure 7: .a. shows alarm signal when 20% fault occurred on Kf. b. shows alarm signal when 10% fault occurred on Kf

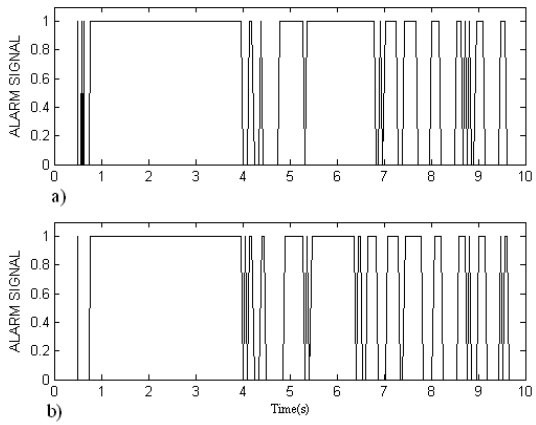

Figure 8: a. shows alarm signal when 20% fault occurred on Bf. b. shows alarm signal when 10% fault occurred on Bf

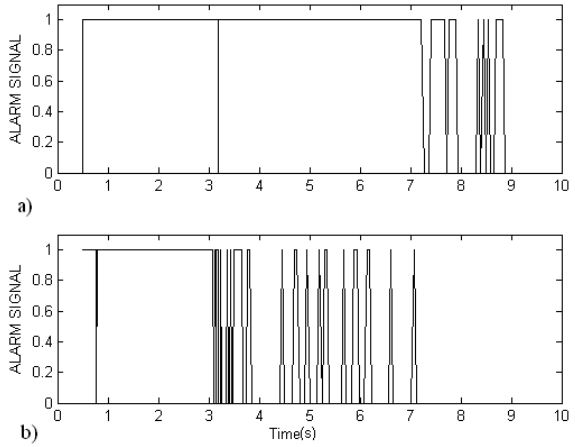

Figure 9: a. shows alarm signal when 20% fault occurred on Kr. b. shows alarm signal when 10% fault occurred on Kr

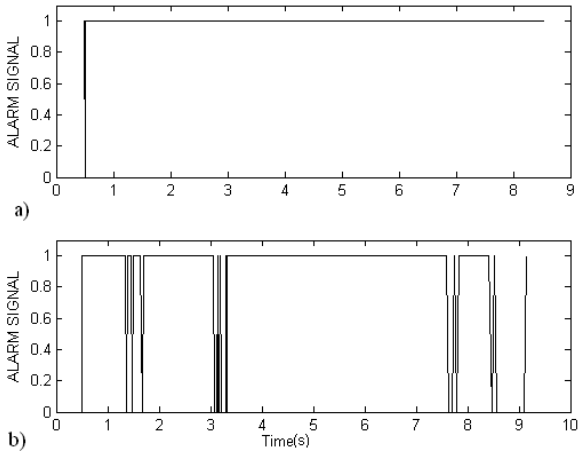

Figure 10: a. shows alarm signal when 20% fault occurred on Br. b: shows alarm signal when 10% fault occurred on Br

IV. CONCLUSION

An application of interval fuzzy model for fault detection of an active suspension system is introduced in this paper. Interval fuzzy model was applied for residual signal generation. Introduced approach has been employed in fault detection for a class of the processes with interval-type parameters or for a nonlinear system with uncertain parameters. In this paper uncertainty was added to the active suspension system. Therefore, the novelty of this paper is applying interval fuzzy model for fault detection of half-car suspension system that hasn't uncertain parameters.

Simulation results have shown that proposed method could be an effective tool for fault detection of active sustention system. This method was able to detect 20% fault very well and also it has good result for 10% fault. Furthermore this method can be used for on-line application too.

For more accurate fault detection, finding more narrow confidence bands for state variables is suggested. In this work it is assumed 1% uncertainty exists in the parameters value. If less uncertainty to be assumed for parameters value, more narrow bands can be obtained.

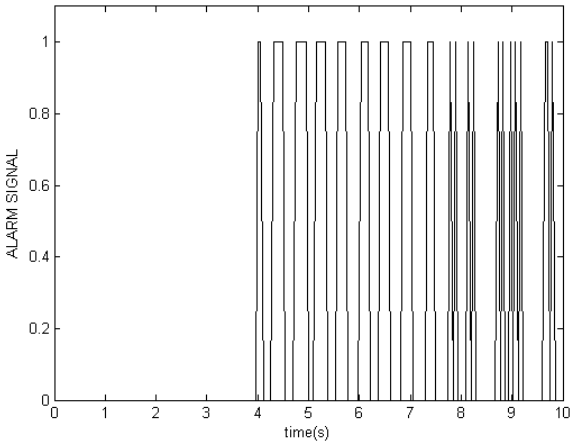

Figure 11: alarm signal when 30% fault occurred on sensor1 (output1) at t=4s

***Abstract*—Manifestation of a given emotion on facial expression is not always unique, as the facial attributes in different instances of similar emotional experiences may vary widely. When a number of facial attributes are used to recognize the emotion of a subject, the variation of individual attributes together makes the problem more complicated. This variation is the main source of uncertainty in the emotion recognition problem, which has been addressed here in two steps using type-2 fuzzy sets. First a type-2 fuzzy face-space is constructed with the background knowledge of facial features of different subjects for different emotions. Second, the emotion of the unknown subject is determined based on the consensus of the measured facial features with the fuzzy face-space. The face-space comprises both primary and secondary membership distributions. The primary membership distributions here have been constructed based on the highest frequency of occurrence of the individual attributes. Naturally, the membership values of an attribute at all except the point of highest frequency of occurrence suffer from inaccuracy, which has been taken care of by secondary memberships. An algorithm for the evaluation of the secondary membership distribution from its type-2 primary counterpart has been proposed. The uncertainty management policy adopted using general type-2 fuzzy set has a classification accuracy of 96.67% in comparison to 88.67% obtained by interval type-2 counterpart only.**

Keywords-Emotion Recognition, Facial feature extraction , Type-2 primary membership, Type-2 secondary membership

I. INTRODUCTION

Emotion recognition is currently gaining importance for its increasing scope of applications in human-computer interactive systems. Several modalities of emotion recognition, including facial expression, voice, gesture and posture have been studied in the literature. However, irrespective of the modality, emotion recognition comprises two fundamental steps involving feature extraction and classification [1]. Feature extraction refers to determining a set of features/attributes, preferably independent, which together represents a given emotional expression. Classification aims at mapping emotional features into one of several emotion classes.

Both feature extraction and classification are equally important to determine the performance of an emotion recognition system. Sometimes, a good classification algorithm cannot yield high classification accuracy for poorly selected features. Naturally, selection of good features is a pre-requisite for high classification accuracy. Several methods of emotion recognition from facial expression have been developed over the last three decades. The study undertaken so far aimed at improving the performance of emotion classification by either selecting suitable features [2], [3], [4], [5], [6], [7], [8], [9], or by identifying the right classifier [10], [11], [12], [13], [14], [15], [6], [16], [17].

Emotional features, on many occasions are subjective. For example, facial expression of a representative emotion varies greatly from person to person. Further, facial expression of a given subject experiencing similar instances of a given emotion looks different. Naturally, it is difficult to have a unique set of features for a given emotion, free from both intra- and inter-personal level variations. In this paper, we thus attempted to consider emotion recognition as a problem of *uncertainty management* with an aim to minimize the effect of intra- and inter-personal level variations in features on emotion classification.

Type-2 fuzzy set has the potential to handle both intra- and inter-personal level uncertainty [18], which usually is modeled by the primary and secondary membership distributions of each measurement variable obtained from different sources. This characteristic of type-2 fuzzy sets motivated us to employ it for emotion classification of an unknown person. The principle of type-2 fuzzy emotion classification comprises two fundamental steps. First a type-2 fuzzy face-space, containing primary and secondary membership distributions of facial features for different subjects carrying distinct emotions, is created. Next to determine the emotion of an unknown person, selective facial features of the person are extracted and encoded using type-2 fuzzy sets, and finally an approximate matching algorithm is invoked to compare the fuzzy encoded features with those in the fuzzy face-space. The classification of the given facial expression to one of several emotion classes is determined by a simple but robust fuzzy decision making algorithm. It is indeed

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

important to note here that the decision making process here considers taking support of individual emotion class to a given set of fuzzy measurements, and declaring the class with the *maximum support* as the winner.

Experiments reveal that the classification accuracy of emotion of an unknown person by the general type-2 fuzzy set based scheme is as high as 96%. When secondary memberships are ignored, and classification is performed with only interval type-2 fuzzy sets, the classification accuracy falls by a margin of 8%. The additional 8% classification accuracy obtained by general type-2 fuzzy set, however, has to pay a price for additional complexity of ($m \times n \times k$) multiplications, where m, n and k denote the number of features/subject, no. of subjects, and no. of emotion classes respectively.

The paper is divided into seven sections. In section II, we propose the principle of uncertainty management in fuzzy face-space for emotion recognition. Section III is concerned with the computation of fuzzy type-2 membership distributions. Section IV provides the main steps for emotion classification with a more emphasis on feature extraction. Experimental details are given in section V. Performance Analysis is given in section VI. Conclusions are listed in section VII.

II. Uncertainty Management In Fuzzy Face-Space For Emotion Recognition

This section provides a general overview of the proposed scheme for emotion recognition using type-2 fuzzy sets. Here, the emotion recognition problem is considered as uncertainty management in fuzzy space after encoding the measured facial attributes by type-2 fuzzy sets.

Let $F=\{f_1, f_2, \ldots, f_m\}$ be the set of m facial features. Let $\mu_A(f_i)$ be the primary membership in [0,1] of the feature f_i to be a member of set A, and $\mu(f_i, \mu_A(f_i))$ be the secondary membership of the measured variable f_i in [0,1]. If the measurement of a facial feature, f_i, is performed p times on the same subject experiencing the same emotion, and the measurements are quantized into q intervals of equal size, we can evaluate the frequency of occurrence of the measured variable f_i in q quantized intervals. The interval containing the highest frequency of occurrence then can be identified, and its centre, m_i, approximately represents the mode of the measurement variable f_i. The second moment, σ_i, around m_i is determined, and an exponential bell-shaped (Gaussian) membership function centered on m_i and with spread σ_i is used to represent the membership function of the random variable f_i. This function represents the membership of f_i to be CLOSE-TO the central value, m_i. It may be noted that a bell-shaped (Gaussian-like) membership curve would have a peak at the centre with a membership value one, indicating that membership at this point is the largest for an obvious reason of having the highest frequency of f_i at the centre.

On repetition of the above experiment for variable f_i on n subjects, each experiencing the same emotion, we obtain n such membership functions, each one for one individual subject. Naturally, the measurement variable f_i now has both intra- and inter-personal level uncertainty. The intra-personal level uncertainty occurs due to pre-assumption of the bell-shape (Gaussian distribution) of the membership function, and the inter-personal level uncertainty occurs due to multiplicity of the membership distribution for n subjects. Thus a new measurement for an unknown person can be encoded using all the n-membership curves, giving n possible membership values, thus giving rise to uncertainty in the fuzzy space.

The uncertainty involved in the present problem has been addressed here by two distinctive approaches, using: i) Interval Type-2 Fuzzy Set (IT2FS), and ii) General Type-2 Fuzzy Set (GT2FS). Naturally, the former approach is simple, but more error-prone as it ignores the intra-personal level uncertainty. The second approach is more robust, and is capable to take care of both the uncertainties. But it needs additional complexity as it involves more computation. Though both the approaches have many common steps, we briefly outline the first one for its simplicity, and then explain the latter without repeating the common steps further.

A. First Approach

Let $f_i^{/}$ be the measurement of the i-th feature for an unknown subject experiencing an emotion of class c. Now, by consulting the n known primary membership distributions for a given emotion, we obtain n primary membership values of the variable. Let they be $\mu^1_A(f_i^{/})$, $\mu^2_A(f_i^{/}),\ldots,$ $\mu^n_A(f_i^{/})$. Here, $\mu^k_A(f_i^{/})$ represents the degree of membership of a feature $f_i^{/}$ for the unknown subject in a fuzzy set A, interpreted using the known membership distribution of the same feature for the k-th subject.

We now determine the maximum and minimum of these n membership values, and thus obtain an interval $[\mu^{min}_A(f_i^{/}), \mu^{max}_A(f_i^{/})]$, representing the entire span of uncertainty of the measurement variable $f_i^{/}$ in the fuzzy space, induced by n subjects. If there exist m different facial features, then for each feature we would have such an interval, and consequently we obtain m such intervals given by

$$[\mu^{min}_A(f_1^{/}),\ \mu^{max}_A(f_1^{/})],\ [\mu^{min}_A(f_2^{/}),\ \mu^{max}_A(f_2^{/})],\ \ldots.,\ [\mu^{min}_A(f_m^{/}),\ \mu^{max}_A(f_m^{/})].$$

Since an emotion is characterized by all of these m features, to find the overall support of the m features (m measurements made for the unknown subject) to the emotion class c represented by the n primary memberships, we use the fuzzy meet operation to get the interval $S_{c\text{-}i} = [s_c^{min}, s_c^{max}]$, where

$$s_c^{min} = Min\{\mu^{min}_A(f_1^{/}), \mu^{min}_A(f_2^{/}), \ldots, \mu^{min}_A(f_m^{/})\},$$

and $$s_c^{max} = Min\{\mu^{max}_A(f_1^{/}), \mu^{max}_A(f_2^{/}), \ldots, \mu^{max}_A(f_m^{/})\}.$$

Thus we can say that the unknown subject is experiencing the emotion class c at least to the extent s_c^{min}, and at the most to the extent s_c^{max}.

To reduce the non-specificity associated with the interval $S_{c\text{-}i}$, different approaches can be taken. For example, the most conservative approach would be to use lower bound, while the most liberal view would to use the upper bound of the interval as the support for the class c. In absence of any additional information, a balanced approach would be to use center of the interval as the support for the class c by the n primary memberships to unknown subject. This idea is supported by Mendel [31] and Lee [32]. Thus, we compute the centre, S_c of the interval $S_{c\text{-}i}$,

$S_c = (s_c^{min} + s_c^{max})/2$.

Thus S_c is the degree of support that the unknown subject is in emotion class c.

Now to predict the emotion of a person from his facial expression, we determine S_c for each emotion class. Presuming that there exist k emotion classes, let us denote them by S_1, S_2,…., S_k for emotion class 1, 2,…, k, respectively. Since a given facial expression may convey different emotions with different degrees, we resolve the conflict by ranking the S_j for j = 1 to k, and thus determine the emotion class *l*, for which $S_l >= S_j$ for all j.

To make the algorithm robust, we consider association of fuzzy encoded measurements with emotion class by considering the weakest reliability of the joint occurrence of the fuzzy measurements, and identify the winning emotion class having this measure of reliability superseding the same of other emotion classes.

B. Second Approach

The second approach employs similar methodology like the first one to reduce inter-personal level uncertainty, but considers secondary memberships to reduce intra-personal level uncertainty as well. The main step in the second approach is to evaluate type-2 secondary membership values from the primary membership distributions. This, of course, is a difficult problem, and is discussed in detail in section III. The intra-personal level uncertainty in primary membership is reduced by correctly adjusting them with their secondary membership by the following transformation.

Let f_i' be the measurement of the i-th feature for an unknown subject. Now, by consulting the n primary membership functions for a given emotion, we obtain n primary membership values of the variable given by $\mu^1_A(f_i')$, $\mu^2_A(f_i')$,…, $\mu^n_A(f_i')$. Let the secondary membership values for each primary membership respectively be $\mu(f_i', \mu^1_A(f_i'))$, $\mu(f_i', \mu^2_A(f_i'))$,…, $\mu(f_i', \mu^n_A(f_i'))$. Since the secondary memberships denote the degree of accuracy of the primary memberships, the uncertainty in a primary membership distribution can be reduced by multiplying each primary membership value by its secondary membership. Thus the modified primary membership values are given by

$$^{mod}\mu^1_A(f_i') = \mu^1_A(f_i') \times \mu(f_i', \mu^1_A(f_i')),$$

$$^{mod}\mu^2_A(f_i') = \mu^2_A(f_i') \times \mu(f_i', \mu^2_A(f_i')), \ \ldots..,$$

$$^{mod}\mu^n_A(f_i') = \mu^n_A(f_i') \times \mu(f_i', \mu^n_A(f_i')),$$

where $^{mod}\mu^j_A(f_i')$ denotes the modified primary membership value for j-th subject. The rest of the procedure in approach 2 is similar to approach 1 with replacement of $\mu^j_A(f_i')$ by $^{mod}\mu^j_A(f_i')$ for all j = 1 to n.

III. FUZZY TYPE-2 MEMBERSHIP EVALUATION

This section provides an introduction to type-2 membership evaluation [20], [21], [22]. Classical fuzzy sets consider primary membership distribution $\mu_A(x)$ of a fuzzy linguistic variable *x*, in a fuzzy set A, where $x \in X$ and $A \subseteq X$. Usually $\mu_A(x)$ is defined by an expert in a specialized domain. However, it has been found that different experts assign different membership distribution for the variable *x*. Consider for example, a fuzzy linguistic variable age in universe AGE, where age belongs to 0 to 120 years. Let YOUNG be a fuzzy set in the universe AGE. Now, the membership distribution $\mu_{YOUNG}(age)$ can be assigned by different people in different forms. Considering a Gaussian type distribution, for $\mu_{YOUNG}(age)$, we note that the peak of the distribution may be fixed at 18, 20 or 22 years depending on the relative preference of the individual. Such membership distributions suffer from two distinct type of uncertainty. The first type of uncertainty, called the intra-personal level uncertainty, is due to approximate values of membership within a given distribution assigned by an expert. The inter-personal level uncertainty refers to relative variations among the membership distributions for a given value of age.

Although theoretically very sound, type-2 fuzzy set has limitedly been used over the last two decades because of the users' inadequate knowledge to correctly assign the secondary memberships. This paper, however, overcomes this problem by extracting type-2 membership distribution from its type-1 counterpart by an evolutionary algorithm. A brief outline to the construction of secondary membership distribution is given in this section.

Intuitively, when an expert assigns a grade of membership distribution, she is relatively more certain to determine the location of the peaks and the minima over the distribution, but may not have enough background to correctly assign the membership values in the rest. Presuming that the membership values at the peak and the minima are close to 1, we attempt to compute secondary memberships at the rest of the secondary distribution. The following assumptions are used to construct an objective function, which needs to be minimized to obtain the solution of the problem.

1. Let $x=x_p$ and $x=x_q$ be two successive optima (peak/minimum) on the primary membership distribution $\mu_A(x)$. Then at any point *x* lying between x_p and x_q, the secondary membership $\mu(x, \mu_A(x))$ will be smaller than both $\mu(x_p, \mu_A(x_p))$ and $\mu(x_q, \mu_A(x_q))$.

2. The fall-off in secondary membership at a point *x* away from a peak/minimum $\mu(x_p, \mu_A(x_p))$ is exponential, given by

$$\mu(x, \mu_A(x)) = \mu(x_p, \mu_A(x_p)).\ exp(-|(x- x_p|) \quad (1)$$

The secondary membership at any point *x* between two consecutive optima at $x=x_p$ and $x=x_q$ in the primary membership is selected from the range $[\alpha, \beta]$, where

$$\alpha = \mu(x_p, \mu_A(x_p)).\ exp(-|(x- x_p|) \quad (2)$$

$$\text{and } \beta = \mu(x_q, \mu_A(x_q)).\ exp(-|(x- x_q|) \quad (3)$$

3. The defuzzified signal obtained on averaging the primary membership distributions at all *x* from n sources, is equal to the defuzzified signal obtained from type-2 primary and secondary distributions. The logic behind this, though apparent, is briefly explained here. The inter-

personal level uncertainty involved in the averaged membership distribution is the minimum with respect to individual primary distribution, as the uncertainty is also averaged at a given value of x, and is thus reduced.

4. The secondary membership at two consecutive values of x separated by a small positive δ has a small difference. This is required to avoid sharp changes in the secondary grade.

Given the primary membership distributions from n sources be $\mu_{A1}(x)$, $\mu_{A2}(x)$,....., $\mu_{An}(x)$, then the average membership distribution which represents a special form of fuzzy aggregation is given by

$$\mu_A(x) = \frac{\sum_{i=1}^{n} \mu_{Ai}(x)}{n}, \forall x \tag{4}$$

i.e., at each position of $x=x_j$, the above membership aggregation is employed to evaluate a new composite membership profile $\mu_A(x)$.The defuzzified signal obtained by the centroidal method [23] from the averaged primary membership distribution is given by

$$\bar{\bar{x}} = \frac{\sum_{\forall x} x \mu_A(x)}{\sum_{\forall x} \mu_A(x)}. \tag{5}$$

Further, the type-2 centroidal defuzzified signal obtained from the i-th primary and secondary membership distributions is given by

$$\bar{x} = \frac{\sum_{\forall x} x \mu_{Ai}(x).\mu_{Ai}(x, \mu_{Ai}(x))}{\sum_{\forall x} \mu_{Ai}(x).\mu_{Ai}(x, \mu_{Ai}(x))} \tag{6}$$

Using assumptions 3 and 4, we construct a performance index J given by (7)

$$J = \left(\bar{x} - \bar{\bar{x}}\right)^2 + \sum_{x=x_1}^{x_{n-1}} \{\mu((x+\delta), \mu_A(x+\delta)) - \mu(x, \mu_A(x))\}^2 \tag{7}$$

The secondary membership evaluation problem, now, transforms to minimization of J by selecting $\mu(x, \mu_A(x))$ from a given range $[\alpha, \beta]$, where α and β are the secondary memberships at the two optima in secondary distribution around the point x. Expressions (2) and (3) are used to compute α and β for each x separately.

Any derivative-free optimization algorithm can be used to minimize J, and obtain $\mu(x, \mu_A(x))$ at each x except the optima on the secondary distribution. Differential Evolution (DE) is one such derivative-free optimization algorithm, which has fewer control parameters, and has outperformed the well-known binary coded Genetic Algorithm and Particle Swarm Optimization algorithms with respect to standard benchmark functions. Further, DE is simple and has only a few lines code, which motivated us to employ it for the above optimization problem. The details of DE are not given here for lack of space. Readers may have it from the standard literature [24]. The main steps of the secondary membership evaluation procedure are outlined below.

1. Obtain the averaged primary membership distribution $\mu_A(x)$ from the primary distributions $\mu_{Ai}(x)$ obtained from n sources, i.e., i=1 to n. Evaluate $\bar{\bar{x}}$, and also $\bar{x}$ for a selected primary membership distribution $\mu_{Ai}(x)$ using (5) and (6) respectively.

2. Find the optima on $\mu_{Aj}(x)$ for a given j. Let the set of x corresponding to the optima be S. Set the secondary membership $\mu(x, \mu_{Aj}(x))$ to 0.99(close to one) for all $x \in X$.

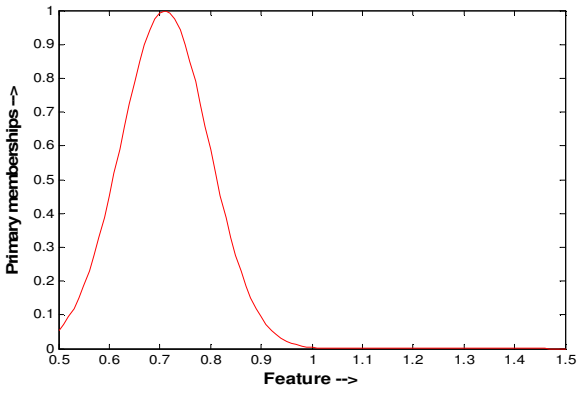
3. For each $x \in X$, where $x \notin S$, identify the optima closest around x from S. Let they be located at $x=x_p$ and $x=x_q$, where $x_p < x < x_q$. Determine α and β for each x, given by (2) and (3).

4. For each x, where $\mu(x, \mu_A(x))$ lies in $[\alpha,\beta]$, minimize J by DE.

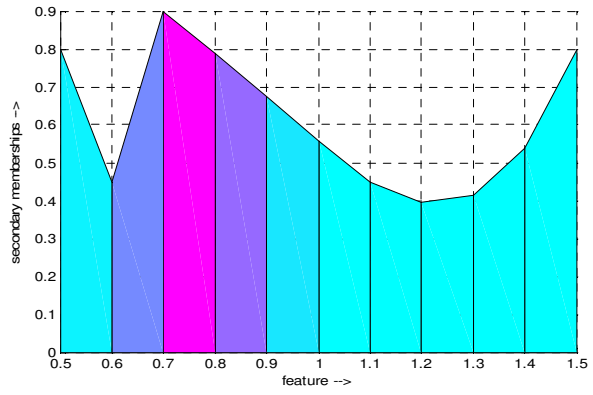
5. Obtain $\mu(x, \mu_A(x))$ for all x after the DE converges.

6. Repeat step 2 onwards for all j.

An illustrative plot of secondary membership distribution for a given primary is given in Fig. 1



(a)



(b)

Fig. 1.(a) Primary distribution (b) Secondary distribution from the primary .

IV. METHODOLOGY

In this section, we present the methodology of emotion recognition using the principles introduced in section II and III. We here consider 5 emotion classes, (i.e., k=5) including anger, fear, disgust, happiness and relaxation. We consider n=10 subjects to characterize the type-2 membership distributions. To study the performance of the proposed scheme, we consider 30 facial expressions taken from 6 unknown persons. Five facial features, (i.e., m=5) have been used here to design the type-2 fuzzy face-space. The whole process of emotion recognition of an unknown person from his/her facial expression is divided into six main steps, as outlined below.

1. Facial feature extraction,
2. Type-2 primary membership evaluation from n-curves, one for each known subject,
3. Type-2 secondary membership evaluation corresponding to n primary membership values,
4. Reducing intra-personal level uncertainty by re-defining primary membership as the product of primary and secondary membership,
5. Evaluation of interval S^j and finally S_c^j for k competitive emotion classes using modified primary memberships,
6. Determining the winning emotion class l by selecting S_c^l, where S_c^l is the largest among S_c^j for emotion class j.

The explanation of all the steps except step 1 has already been outlined in section II. So, we now give an overview to step 1 only.

In order to extract the facial features from emotionally expressive facial images, it is essential to list down the most important features of the face. From earlier research results [19], [17], it is evident that the most important regions for recognizing the emotion of a person are the eyes and lips. This motivated us to select the following features: Left Eye Opening (EO_L), Right Eye Opening (EO_R), Distance between the Lower Eyelid to Eyebrow for Left Eye (LEE_L), Distance between the Lower Eyelid to Eyebrow for Right Eye (LEE_R), and Maximum Mouth opening (MO) including lower and upper lips. Fig. 2 explains the above facial features on a selected facial image.

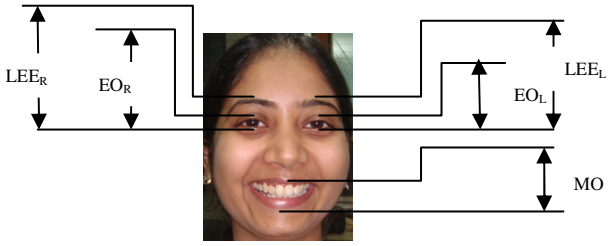


Fig. 2 Facial Features

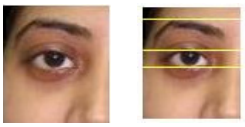
For extraction of any of the features mentioned above, the first step that needs to be carried out is to separate out the skin and the non-skin regions of the image.

Estimation of Eye features (EO_L , LEE_L, EO_R and LEE_R): To estimate the eye features, we first localize the eye region as shown in Fig. 3 (a). A look at Fig. 3 reveals that there is a sharp change in color while moving from the forehead region to the eyebrow region. Thus to detect the location of the eyebrow, we take the average intensity (in three primary color planes) over each row of the image from the top, and identify the row with a maximum dip in all the three planes. This row indicates the top of the eyebrow region (Fig.3b). Similarly, we detect the lower eyelid by identifying the row with a sharp dip in intensity in all the three planes, while scanning the face up from the bottommost row. The location of the top eyelid region is identified by scanning the face up from the marked lower eyelid until a dip in the three color planes are noted together.



(a) (b)

Fig. 3. (a) Localized Eye search region , (b) Detection of eye features

Estimation of Mouth Opening (MO): In order to estimate the MO, we first localize the mouth region as shown in Fig. 4(a). Then a conversion from rgb to lab color space is undertaken. The k-means clustering algorithm is applied next on this image to get three clusters. The three clusters are: skin cluster, lip cluster and teeth cluster. We select the lip cluster (Fig. 4(b)) to determine the mouth opening. To obtain mouth-opening, we take the average intensity of three primary pixel colors, and plot the row-average of such value contributed by each pixel against the row number (Fig. 4c). It is observed that the width of the zero-crossing zone in Fig. 4c provides a measure of mouth-opening.

V. EXPERIMENTAL DETAILS

The experiment is conducted in Jadavpur University with two sets of subjects: a) the first set of 10 subjects (n=10) is considered for designing the fuzzy face-space and, b) the other set of 30 facial expressions taken from 6 unknown subjects is considered to validate the result of the proposed emotion classification scheme. The experiment thus consists of two distinct phases as indicated in the next two sub-sections.

A. Creating the type-2 fuzzy face-space

Type-2 fuzzy face-space contains both primary and secondary membership distributions for each facial feature. Since we have 5 facial features and the experiment includes 5 distinct emotions of 10 subjects, we obtain 10×5×5=250 primary membership curves. These 250 membership curves are grouped into 25 heads, each containing 10 membership curves of ten subjects for a specific feature representing a given emotion. Fig. 5 gives an illustration of one such group of 10

membership distributions for the feature EO $_L$ for the emotion: disgust.

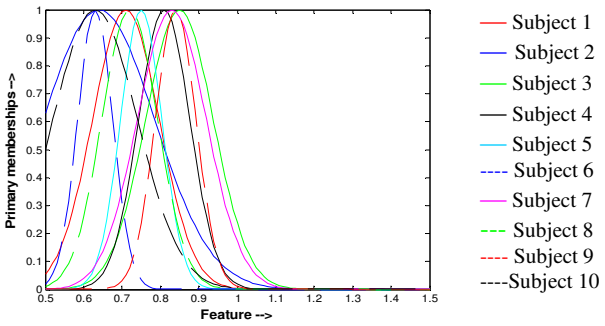

Fig. 5 Membership distributions for emotion disgust and feature EO_L

For each primary membership distribution, we have a corresponding secondary membership distribution. Thus we obtain 250 secondary membership distributions. Two illustrative type-2 secondary distributions for subject 1 and 2 for the feature EO_L for emotion disgust are given in Fig. 6. The axes in the figure represent feature (EO_L), primary and secondary membership values as indicated.

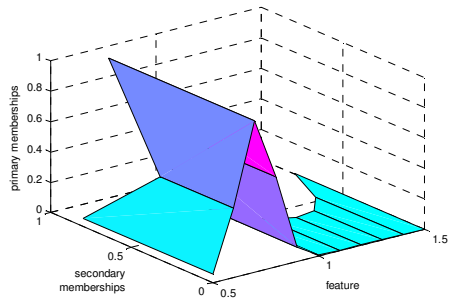

Fig. 6a Secondary Membership curve of Subject1

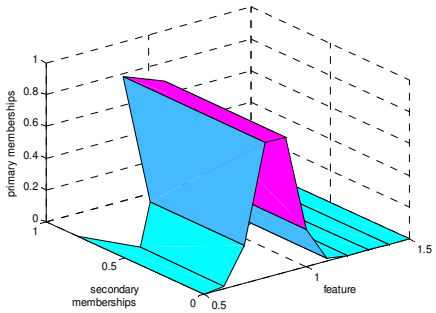

Fig. 6.b Secondary Membership curve of Subject2

B. *Emotion recognition of an unknown subject*

Suppose we want to recognize the correct emotion class of the facial image in fig. 7.

Fig. 7 Facial Image of an unknown subject

First, the facial features are extracted as mentioned in section IV. The extracted features are self-normalized by dividing individual feature obtained in a given emotional state by its value in the relaxed state. This nullifies the effect of the distance variation while image capturing. The extracted features for Fig.7 are enlisted in Table I.

TABLE I. EXTRACTED FEATURES OF FIG. 7

EO_L	EO_R	MO	LEE_L	LEE_R
0.636	0.6371	1.77	0.969	0.968

Now, for each facial feature, we consult 5 sets of 10 primary membership distributions as in Fig. 5, each corresponding to one distinct emotion of 10 subjects. Thus we obtain 10 primary membership values of that feature to fall in a given emotion class. Secondary memberships corresponding to a given feature and obtained primary membership are determined using curves like Fig. 6. Table II provides the summary of the primary and secondary memberships obtained for EO_L for the emotion disgust.

TABLE II. CALCULATED MEMBERSHIP VALUES FOR FEATURE :EO_L EMOTION: DISGUST

Feature	Primary Memberships (μ_{pri})	Secondary memberships (μ_{sec})	$\mu_{pri} \times \mu_{sec}$	Range after intersection
EO_L	0.1562	0.6371	0.0980	0.0056-0.8011
	0.6531	0.6039	0.3940	
	0.0983	0.5566	0.0545	
	0.9471	0.8460	0.8011	
	0.0983	0.5513	0.0540	
	0.2496	0.5961	0.1487	
	0.0100	0.5566	0.0056	
	0.9000	0.8513	0.7662	
	0.6241	0.8539	0.5290	
	0.5134	0.5724	0.2947	

In Table II, we computed the product of primary and secondary memberships, and then obtain the minimum and maximum of the product to determine its range, as indicated in the last column of Table II.

For each feature we obtain 5 Tables like Table II, each one for a given emotion. Thus for 5 features, we would have altogether 25 such tables. The range for each feature corresponding to individual emotions is given in Table III. Now, we obtain a new range with lower (upper) boundary equal to the intersection of the lower (upper) range boundaries for different features under a given emotion. This measure, enumerated in the last column of Table III, indicates an interval of fuzzy certainty about the joint occurrence of the features in a given facial expression representing a specific emotion class.

The center of the interval has minimum uncertainty, and so we compared them, and finally determine the winning emotion with the largest centre. It is clear from Table III that the centre value is maximum for emotion happiness. So, we regard the emotion portrayed in Fig. 7 as Happiness.

TABLE III. CALCULATED FEATURE RANGES AND CENTRE VALUE FOR EACH EMOTION

Emotion	Range of Features					Range S_c^j after Intersection (centre)
	EO_L	EO_R	MO	LEE_L	LEE_R	
Anger	0-0.199	0 - 0.239	0.439 -0.964	0.0034 - 0.8145	0.0027-0.7813	0-0.239 (0.1195)
Disgust	0.0056-0.8011	0.0021-0.798	0-0	0-0.39	0.0011-0.261	0-0 (0)
Fear	0 - .298	0-0.1751	0.004-0.912	0.024-0.673	0.077-0.715	0-0.1751 (0.0875)
Happiness	0 - 0.555	0.0011-0.604	0.673-0.975	0.1343-0.8151	0.3214-0.7213	0-0.555 (0.2775)
Relaxed	0 - 0.132	0-0.221	0-0	0.013-0.458	0.046-0.552	0-0 (0)

VI. PERFORMANCE ANALYSIS

We now analyze the performance of our method with 30 facial expressions, each representing a given emotion. The emotion conveyed in each image is analyzed, and the results are tabulated in the form of confusion matrix [14], [19], [25]. It may be noted that in section II, we introduced two methods for emotion recognition. The first method yields a confusion matrix given in Table IV, while the confusion matrix obtained by method 2 is given in Table V. It is clear from Table V that the relaxation and disgust emotion can be classified with 100 % high accuracy followed by happiness (96%). Fear and anger are often confusing, and thus classification accuracy is relatively low for both.

TABLE IV. CONFUSION MATRIX FOR TYPE-2 PRIMARY FUZZY FACE-SPACE WITH ENTRIES IN %

In/Out	Anger	Disgust	Happiness	Fear	Relaxed
Anger	83.33	0	10	16.66	0
Disgust	0	93.33	0	0	0
Happiness	3.33	3.33	86.66	3.33	0
Fear	13.33	0	3.33	80	0
Relaxed	0	3.33	0	0	100

TABLE V. CONFUSION MATRIX FOR TYPE-2 SECONDARY FUZZY FACE-SPACE WITH ENTRIES IN %

In/Out	Anger	Disgust	Happiness	Fear	Relaxed
Anger	93.33	0	3.33	6.66	0
Disgust	0	100	0	0	0
Happiness	0	0	96.66	0	0
Fear	6.66	0	0	93.33	0
Relaxed	0	0	0	0	100

A look at Table IV and V reveals that the percentage accuracy obtained in Table-V is better than the same in Table-IV. It may be recalled that Table-V employed both primary and secondary memberships (i.e., GT2FS), while Table-IV used only primary membership distributions for n-sources (i.e., IT2FS). This justifies the significance of GT2FS in emotion recognition. Average accuracy obtained by ranking the diagonal entries of Table IV and V are 88.66% and 96.67% respectively.

Table VI shows the comparison of our proposed emotion recognition scheme with other existing methods. It is clear from the Table that the proposed method has the highest classification accuracy with respect to the published results.

TABLE VI. COMPARISON OVER OTHER TECHNIQUES

Facial Emotion Recognition by	Success rate
Multi-Layer Perceptron(MLP) and Radial Basis Function Network (RBFN) [26][27]	73% for MLP, and 65% for RBFN
Fuzzy Neural Network and HMM [10]	Higher than 78%
Using Linear Support Vector Machine [17]	95%
(Type-1) Fuzzy Relational Approach [19]	88.2% for adult male and 92.2 for adult female
Bayesian classifier[28][29]	63% to 71%
Fuzzy Kernel Clustering and Support Vector Machines[30]	90%
Principal Component Analysis (PCA) [25]	Average classification accuracy is 100% on train data and 95.47% on cross validation data.
Our proposed method	**96.67%**

VII. CONCLUSION

The paper proposed a simple and time-efficient scheme for emotion recognition from a pre-constructed type-2 fuzzy face-space. Experiments reveal that the classification accuracy of emotion by considering GT2FS is as high as 96.67%. The accuracy falls off by 8% when the solution is obtained by using IT2FS formulation. The classical rule based method for emotion classification [19] depends largely on the relational matrix used to represent implication relations. In the present context, the emotion analysis is performed intentionally on the fuzzy encoded measurement space to make the system performance robust.

***Abstract*— An improvement is presented for the tunnel algorithm introduced in [17] for determining the minimum number of rules required by a fuzzy system for modeling and identification in the SISO case. The original tunnel algorithm can deal with only Mamdani type fuzzy systems, while the Testing Point algorithm proposed in this paper, can be used to construct Takagi-Sugeno type fuzzy systems with consequent parts of any order and has the potential to be further extended to the MISO case. Numerical examples are given to illustrate the idea and improvement.**

Keywords-Fuzzy modeling and identification; Takagi-Sugeno fuzzy systems; Rule reduction

I. INTRODUCTION

How to construct fuzzy systems using as less as possible rules with guaranteed performance is a difficult but important problem, which has attracted much attention over the fuzzy society [1], [3]-[15], [17], [19]-[24]. Among them, a so-called tunnel algorithm (TA) was proposed by [17], which can partition the input domain in a non-uniform manner according to the sampling data distribution and the approximation error tolerance, when dealing with the following problem in fuzzy modeling and identification.

Given a limited number of input-output data pairs or say samples $\{x_k, g(x_k)\}$, $k=1,2,\cdots,N$, of a single-input-single-output (SISO) system with an unknown analytical representation $g(x)$, it is expected to construct a fuzzy system $f(x)$ using M rules to approximate the unknown function $g(x)$, where M should be the minimum, and the approximation errors at each data point are less than a predefined error tolerance ε. From mathematical point of view, the task can be formulated as the following optimization problem:

$$\begin{aligned} &\text{minimize: } M, \\ &\text{subject to: } \max_{k=1,2,\ldots,n} \left| g(x_k) - f(x_k) \right| \le \varepsilon. \end{aligned} \tag{1}$$

The rest of this section briefly reviews the tunnel algorithm proposed in [17]. Restricted by the error tolerance ε, each sampling point $p_k = \{x_k, g(x_k)\}$, $k=1,2,\cdots,N$, as shown in Fig. 1, has its upper limit $p_k^+ = \{x_k, g(x_k)+\varepsilon\}$ and lower limit $p_k^- = \{x_k, g(x_k)-\varepsilon\}$. Connecting all the points p_k, p_k^+ and p_k^- respectively by lines in order along axis x, forms three piecewise lines PL, PL_ε^+ and PL_ε^-. PL_ε^- and PL_ε^+ are called the lower and upper boundaries of PL, respectively. *Tunnel* $P(\varepsilon)$ is the polygon area encircled by PL_ε^+ and PL_ε^-. The line segments $e = \overline{p_1^+ p_1^-}$ and $e' = \overline{p_N^+ p_N^-}$ are called the *edges* of the tunnel $P(\varepsilon)$.

Owing to the nice property of the Mamdani type fuzzy systems, the design problem can be reduced to finding as less as possible continuous line segments with guaranteed approximation accuracy. The key idea is to convert the optimization problem in (1) into an *edge-visibility* problem using the concepts and techniques from computational geometry. More specifically, "*a* is *visible* from *b*" means there exists a straight-line path connecting *a* and *b*, where *a* and *b* can be points, edges, polygons or any combination of them. If the edge $\overline{p_N^+ p_N^-}$ is invisible from $e = \overline{p_1^+ p_1^-}$, then the whole polygon $P(\varepsilon)$ can be divided into two parts: the *visible polygon* and the *invisible polygon*. The intersection of the boundaries of the visible and invisible polygons is called the *window* from the edge e in the polygon P.

The Tunnel Algorithm (TA)

The tunnel algorithm goes through five steps as follows.

Step 1: Initialization. Form the upper and lower boundaries PL_ε^+ and PL_ε^- for the given data set $\{x_k, g(x_k)\}, k=1,2,...,N$. The initial tunnel is $P_1 = P(\varepsilon)$. Set the edge $e_1 = \overline{p_1^+ p_1^-}$ and $i=1$.

Step 2: Searching.

WHILE $\overline{p_N^+ p_N^-}$ is not visible from e_i in polygon P_i DO

e_{i+1} = window from e_i to $\overline{p_N^+ p_N^-}$ in polygon P_i;

This work is supported in part by the Macau Science and Technology Development Fund under Grant FDCT/017/2007/A and the University of Macau Research Committee under Grant RG076/07-08S/WF/FST.

P_{i+1} = invisible polygon of e_i containing $\overline{p_N^+ p_N^-}$ in polygon P_i;

q_i = point of intersection of the line containing e_{i+1} and the edge e_i;

$i = i+1$.

Step 3: Output the searching results. $m = i+1$; find a point q_{m-1} on the edge e_i and a point q_m on the edge $\overline{p_N^+ p_N^-}$ that are visible from each other within the polygon P_{m-1}.

Step 4: Use the data at the points $q_l, l = 1,2,\cdots,m$, to compute the parameters $\{a_l, b_l\}$ of the line segments $\overline{q_l q_{l+1}}$, for $l = 1,2,\cdots,m-1$.

Step 5: Determine the minimum rule number and compute the parameters for the Mamdani type fuzzy system. According to Theorem 1 in [17], the number of fuzzy rule M equals m+1. The centers of M fuzzy sets in the IF part can be expressed as $A_l = x(q_l), l = 1,2,\cdots,M$. The corresponding centers of M fuzzy sets in the THEN part is $y_l = y(q_l), l = 1,2,\cdots,M$. With $x(q_l)$ and $y(q_l)$ standing for the coordinate values of point q_l, the l-th rule can be expressed as

$$R_l: \text{IF}(x \text{ is } A_l), \text{THEN}(y \text{ is } y_l). \quad (2)$$

The number of the rules extracted by the tunnel algorithm has been proved to be the minimum in [17].

Remark 1: The original tunnel algorithm gives an optimal solution to the problem (1) restricted inside the tunnel; however, this solution can be further improved. According to the optimization problem (1), the built fuzzy system is constrained to the accuracy requirement on the N output values observed at the input values $x_k, k = 1,2,\cdots,N$, and no more information other than these discrete points is available, thus no further restriction is necessary. Therefore, except at these N discrete points $x_k, k = 1,2,\cdots,N$, the upper and lower boundaries of the tunnel, need not to be considered as constraints for accuracy. Next section begins with a modification aiming at breaking the tunnel and the consequent limitation aforementioned, to improve the original algorithm for a better result.

II. Testing Point Algorithm

In this section, two examples in [17] are first revisited, to show the above-mentioned restriction due to the tunnel, and the modification is proposed to break the restriction. Then, in order to extend the algorithm for the design of Takagi-Sugeno (TS) type fuzzy system, an algebraic approach is proposed which can be used to construct TS type fuzzy system with any-order consequences.

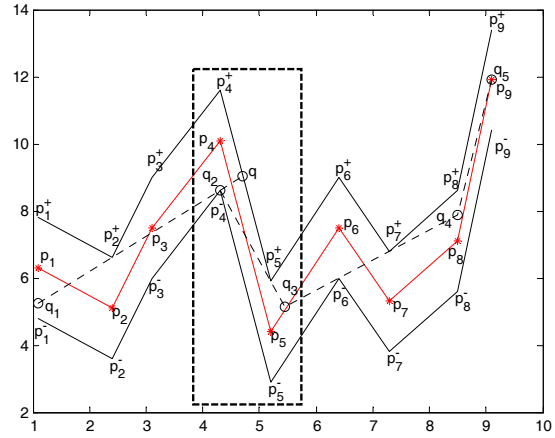

Fig. 1. Result of the tunnel algorithm. (red "*" : the available data points; dashed line: the output of the fuzzy system)

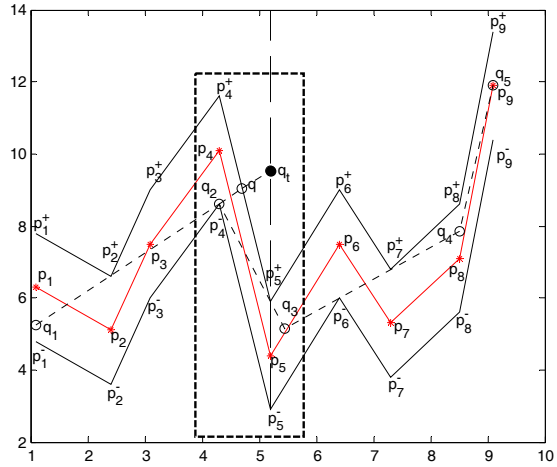

Fig. 2. Illustration of how to remove the restriction due to the tunnel.

Example 1 [17]: Construct a standard Mamdani type fuzzy system given the following nine pairs of input-output data:

$$\left\{\begin{matrix}(1.1,6.3),(2.4,5.1),(3.1,7.5),(4.3,10.1),(5.2,4.4)\\(6.4,7.5),(7.3,5.3),(8.5,7.1),(9.1,11.9)\end{matrix}\right\}.$$

The number of rules in the fuzzy system should be minimal, while the approximation error should be less than 1.5. The result of the tunnel algorithm is shown in Fig. 1.

The initial edge is the line segment $e = \overline{p_1^+ p_1^-}$. Because $\overline{p_N^+ p_N^-}$ is invisible, the whole polygon should be divided into two parts to form a window for the next search. Tunnel algorithm finds the line segment $\overline{p_4^- q}$ as the first window. Within the square area in Fig. 1, obviously the end point q of the window determined by the tunnel degrades the optimality. If the tunnel boundaries can be broken, the new constructed window will have a wider field of vision. This improved window begins with p_4^- and ends at the point intersected by $x = x_5$ (see Fig. 2 for details, where $\overline{p_4^- q_t}$ is the improved window). As stated in Remark 1, whether the output of the

fuzzy system goes through the line segments $\overline{p_4^+ p_4^-}$ and $\overline{p_5^+ p_5^-}$ is the only concern on accuracy, since what response in between the region (x_4, x_5) does not violate the accuracy tolerance. Example 1 shows the idea of the modification, its performance is to be elaborated through a comparison study in the next example.

Example 2 [17]: A standard Mamdani type fuzzy system is constructed to model an unknown plant described by the nonlinear function $g(x) = \cos\left(\left(e^x\right)^2\right)$. The modeling error tolerance is $\varepsilon = 0.05$. A set of input-output pairs of the plant are provided, in which the inputs x_k are evenly distributed in the interval $[0,2]$ with space 0.05. Fig. 3 shows the response of the final fuzzy system developed by the original tunnel algorithm while Fig. 4 shows the results from the improved tunnel algorithm. Red "*" represents the sampling data, boundaries of the tunnel are depicted by black lines, black circles are the *q's* with each of which one can conclude a fuzzy rule, and the output of the fuzzy system is drawn by dashed lines. The areas marked by blue dashed ellipses show the improvement owning to the proposed algorithm. In or near the marked areas, there may be a rule reduction due to the improvement through tunnel breaking. It is clear that in most of the areas the number of *q* points for rules in Fig. 4 is less than that in Fig. 3. In fact, the original tunnel algorithm extracts 25 fuzzy rules while the improved algorithm finally extracts only 19.

The above example shows a large improvement of the proposed algorithm in determining the minimum number of fuzzy rules. However, the algorithm is based on the computational geometry, which is not easy for further extension to high-order or high-dimension cases. In what follows, the strategy using visibility concepts from computational geometry will be reformulated and extended to the design of TS type fuzzy systems, which are much more widely used than Mamdani type fuzzy systems in real applications.

Compared with Mamdani type fuzzy systems, the major difference is that the consequent parts of a TS type fuzzy system are polynomial functions of its inputs. Consider the simplest case, where the *l-th* rule of a TS type fuzzy system is in the form of

$$R_l: \text{IF}\left(x \text{ is } A_l\right), \text{ THEN}\left(y = f_l(x)\right) \tag{3}$$

with linear consequent parts $f_l(x) = \beta_1^l x + \beta_2^l$, where β_1^l and β_2^l are constant coefficients.

Replacing the rule base (2) with (3) in the fuzzy system results in a first order TS type fuzzy system, which means the consequent part of each rule is a first order polynomial function of its inputs. If for simplicity the triangular membership functions are used, the mapping defined by this first order TS type fuzzy system becomes

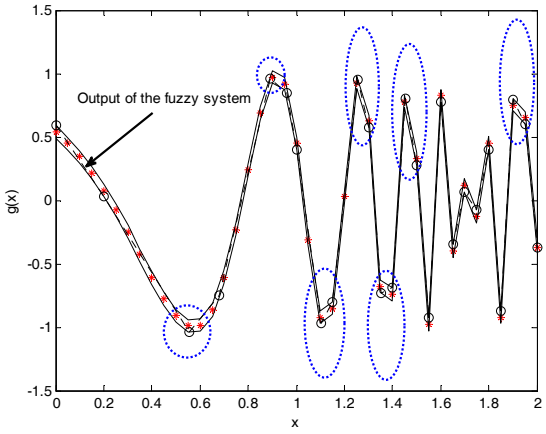

Fig. 3. Result by the tunnel algorithm in Example 2.

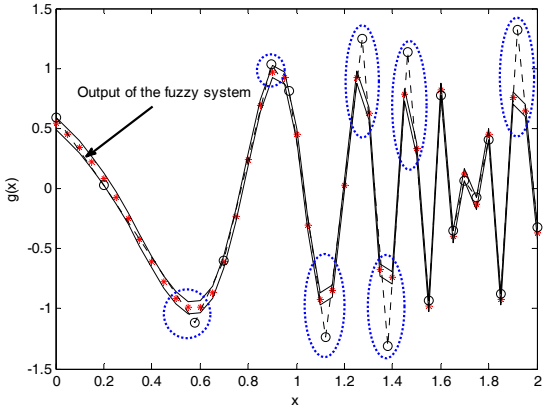

Fig. 4. Result by the improved tunnel algorithm in Example 2.

$$f(x) = \frac{\sum_{l=1}^{M}\left(f_l(x)\mu_{A_l}(x)\right)}{\sum_{l=1}^{M}\mu_{A_l}(x)}. \tag{4}$$

Theorem 1: The TS type fuzzy system in (4) draws piecewise parabolas, and the number of rules used in the fuzzy system is equal to the number of the segments plus one.

Proof: Because of the localization property of the triangular membership function, among all the membership values $\mu_{A_l}(x)$ for any x, at most two but at least one value will be nonzero while the others are zero. Therefore, the input domain can be decomposed as $D = D^1 \cup \cdots \cup D^{M-1}$, where $D = [x_{\min}, x_{\max}]$ and $D^l = [d_l, d_{l+1}], l = 1,2,\cdots,M-1$. For any $x \in D^l$, it is known that $\mu_{A_l}(x) + \mu_{A_{l+1}}(x) = 1$, so the fuzzy system (4) in D^l can be simplified as

$$\begin{aligned} f(x) &= \sum_{j=1}^{M} f_j(x)\mu_{A_j}(x) = \sum_{j=l}^{l+1} f_j(x)\mu_{A_j}(x) \\ &= \left(1 - \frac{x-d_l}{\Delta d_l}\right)\left(\beta_1^l x + \beta_2^l\right) + \frac{x-d_l}{\Delta d_l}\left(\beta_1^{l+1} x + \beta_2^{l+1}\right) \\ &= \frac{\beta_1^{l+1} - \beta_1^l}{\Delta d_l}x^2 + \frac{\beta_1^l d_{l+1} - \beta_1^{l+1} d_l + \beta_2^{l+1} - \beta_2^l}{\Delta d_l}x + \frac{\beta_2^l d_{l+1} - \beta_2^{l+1} d_l}{\Delta d_l} \end{aligned} \tag{5}$$

Therefore, the fuzzy system over the whole domain D consists of $M-1$ pieces of parabolas. This proves the theorem. □

The judging of visibility from geometry point of view for parabola curves is quite difficult. In the following, an algebraic approach is proposed to convert the edge-visibility problem into a Testing Point problem which can be easily extended to any order TS type fuzzy system. The following notations and theorems are necessary and straightforward.

Let the (n-1)-*th* order polynomial function be ($n \geq 2$)

$$p(x) = a_1 x^{n-1} + a_2 x^{n-2} + \cdots + a_{n-1} x + a_n , \quad (6)$$

where $a_i, i = 1, \cdots, n$, are the constant coefficients.

Theorem 2: To determine the coefficients of an (n-1) order ($n \geq 2$) polynomial curve characterized by $p(x)$, n distinct samples on this curve are required.

Proof: Substituting n distinct samples to the polynomial function gives n linear independent equations. Thus, the n coefficients $\{a_1, a_2, \cdots, a_n\}$ can be computed by solving the linear equations. This proves Theorem 2. □

Theorem 3: If a polynomial function $p(x)$ in (6) is specified by n distinct samples $(x_k, y_k'), k = 1, 2, \cdots, n$, then $y = p(x_{n+1})$ that $p(x)$ can generate at the point x_{n+1} can be written as a weighted linear combination of y_k', $k = 1, 2, \cdots, n$, i.e. $y = c_1 y_1^{'} + c_2 y_2^{'} + \cdots + c_n y_n^{'}$, where c_i, $i = 1, 2, \cdots, n$, are constants which are determined by the samples.

Proof: In view of linear dependency, the conclusion is apparent. The following deduces an exact expression of the linear combination. Substituting $(x_k, y_k'), k = 1, 2, \cdots, n$, to (6) results in n linear equations. Let $\mathbf{A} = [a_1, a_2, \cdots, a_n]^T$, $\mathbf{Y} = [y_1^{'}, y_2^{'}, \cdots, y_n^{'}]^T$ and $\mathbf{X} = \begin{bmatrix} x_1^{n-1} & x_1^{n-2} & \cdots & x_1 & 1 \\ x_2^{n-1} & x_2^{n-2} & \cdots & x_2 & 1 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ x_n^{n-1} & x_n^{n-2} & \cdots & x_n & 1 \end{bmatrix}$.

The linear equations can be written as

$$\mathbf{XA} = \mathbf{Y} , \quad (7)$$

and $\mathbf{X}$ can be treated as a Vandermonde matrix with $\det(\mathbf{X}) = \prod_{1 \leq i < j \leq n} (x_i - x_j)$.

Since the n samples are different, i.e. $x_i \neq x_j$ when $i \neq j$, $\det(\mathbf{X}) \neq 0$. Hence, $\mathbf{X}$ is invertible.

Denote $\mathbf{IX} = \mathbf{X}^{-1}$, then matrix $\mathbf{A}$ can be obtained from $\mathbf{A} = \mathbf{IX} * \mathbf{Y}$ and its *k-th* element ($k = 1, 2, \cdots, n$) can be expressed as

$$a_k = \mathbf{IX}(k,1) \cdot y_1' + \mathbf{IX}(k,2) \cdot y_2' + \cdots + \mathbf{IX}(k,n) \cdot y_n' . \quad (8)$$

Therefore,

$$y = p(x_{n+1}) = a_1 x_{n+1}^{n-1} + a_2 x_{n+1}^{n-2} + \cdots + a_{n-1} x_{n+1} + a_n . \quad (9)$$

Substituting (8) to (9) and performing simplification gives

$$y = c_1 y_1^{'} + c_2 y_2^{'} + \cdots + c_n y_n^{'} \quad (10)$$

where

$$c_k = \mathbf{IX}(1,k) \cdot x_{n+1}^{n-1} + \mathbf{IX}(2,k) \cdot x_{n+1}^{n-2} + \cdots + \mathbf{IX}(n-1,k) \cdot x_{n+1} + \mathbf{IX}(n,k), \quad k = 1, 2, \cdots, n$$

are constants. □

Following the edge-visibility strategy, notations (p and q) have the same meaning as the original tunnel algorithm, and the window e_k, $k \geq 2$ (e_1 is a line segment for initialization), which is a matrix consists with n different points, is the *k-th* polynomial curve found by the algorithm. Theorem 3 reveals the idea of the testing point algorithm. More specifically, equation (10) shows that the value $y = p(x_{n+1})$ at the point x_{n+1} is a weighted linear combination of y_k''s , $k = 1, 2, \cdots, n$, i.e. $y = c_1 y_1^{'} + c_2 y_2^{'} + \cdots + c_n y_n^{'}$ where $c_i, i = 1, 2, \cdots, n$ are constants already fixed by the n samples. When x_k is given and fixed, the only changeable values are the y_k''s which are constrained by the error bands as $y_k' \in [g(x_k) - \varepsilon, g(x_k) + \varepsilon]$. Each combination of the n y_k''s represents a normal polynomial curve, therefore all the combinations of y_k''s form a family of curves.

Definition 1: The data point $p_j = (x_j, g(x_j))$ is *reachable* by a curve family means that its range, in which this curve family and the line $x = x_j$ intersect, has a non-empty intersection with the tolerance band $[g(x_j) - \varepsilon, g(x_j) + \varepsilon]$.

The above range of the curve family can be derived directly from (10), as equation (10) is apparently continuous and its extreme points can be easily computed based on the signs of c_k's . For instance, if c_k's are all positive, the upper limit of the range $y_j^{\max}$ can be calculated when all the y_k''s are equal to their upper limits $g(x_k) + \varepsilon$ and the lower limit of the range $y_j^{\min}$ is calculated when all the y_k''s are equal to their lower limits $g(x_k) - \varepsilon$. Because of the continuity in (10), the range can be written as $[y_j^{\min}, y_j^{\max}]$ whose limits are determined by only the limits of its variables y_k''s . With the help of the above definitions, theorems and proofs, the following testing point algorithm is thus straightforward.

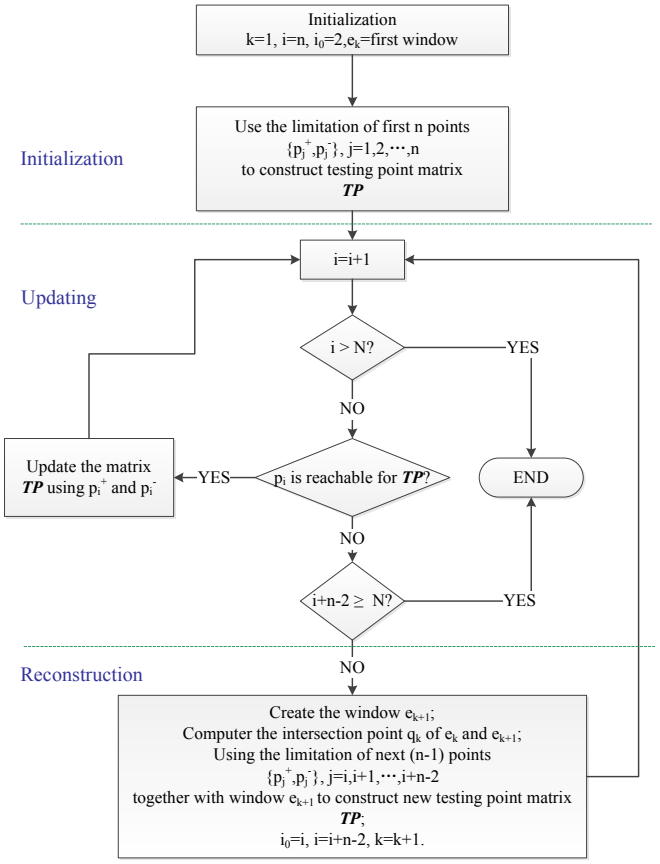

Fig. 5. Flowchart of the proposed testing point algorithm, where *TP*: the matrix stores the polynomials to be checked; *k*: the index of the created windows; *i*: the index of the sampling data; i_0: the index of the first sampling data to be checked from the current window; e_k: the *k-th* window.

The Testing Point Algorithm (TPA)

Step 1: Initialization. Set $k=1,\ i_0=2,\ i=n,\ e_k=\{p_1^+, p_1^-\}$, the array **isReachable** $=0^{N\times 1}$. Form the testing point matrix $\mathbf{TP}\in R^{2^n\times n}$ which consists with all the combinations of the upper and lower limits of the first *n* points shown below.

$$\mathbf{TP}=\begin{bmatrix} p_1^+ & p_2^+ & \cdots & p_n^+ \\ \vdots & \vdots & \vdots & \vdots \\ p_1^+ & p_2^- & \cdots & p_n^- \\ p_1^- & p_2^- & \cdots & p_n^- \end{bmatrix} \tag{11}$$

Step 2: Judging. $i=i+1$. If $i>N$, go to Step 5. Otherwise, determine whether the point p_i is reachable or not. If p_i is reachable, set **isReachable**$(i)=1$ and go to Step 3; otherwise, set **isReachable**$(i)=0$ and go to Step 4.

Step 3: Updating. Since p_i is reachable, use $\{p_i^-, p_i^+\}$ to update **TP** through the following procedure.

Replacing all the elements in a column in **TP** with p_i^+ creates a submatrix. Therfore, the replacement of the *n* columns leads to *n* submatrices. The same number of submatrix is obtained when using p_i^- for replacement. The updated $\mathbf{TP}_{updated}$ are constructed by combining all of the submatrices and the original **TP**. As several rows may be the same in the $\mathbf{TP}_{updated}$, it is necessary to remove the redundant rows from $\mathbf{TP}_{updated}$. Each row of $\mathbf{TP}_{updated}$ represents a normal polynomial curve, and all of the polynomial curves are checked one by one to see whether the points $p_{i_0}, p_{i_0+1},\cdots, p_i$ are all reachable from the selected polynomial curve. If not, the corresponding row in the $\mathbf{TP}_{updated}$ is removed. After this procedure, set $\mathbf{TP}=\mathbf{TP}_{updated}$ and finish the updating step.

Step 4: Reconstruction. This step handles the **TP** construction when the judging step finds immediately p_i not reachable. It needs (*n*-1) new points together with the window e_{k+1} to reconstruct the **TP** for testing on the next samples. If $i+n-2\geq N$ which means the remaining data points are just enough to form one polynomial function, go to Step 5 to finish. Otherwise, reconstruct the testing point matrix **TP**.

The reconstruction is very similar to Step 1. The difference is that the first point p_{fst} is the limit point from the area that the window e_{k+1} is able to cover, instead of the limit points of the line segment such as $\overline{p_1^- p_1^+}$.

Select the polynomial function e_{k+1} which is the closest one to the point p_i from **TP**. Theorem 3 shows that **TP** consists with several limit points. Pick the point p_{fst}^1 with the largest value in *x*-axis from e_{k+1}, then calculate the intersection point p_{fst}^{end} between e_{k+1} and the line $\overline{p_i^- p_i^+}$. The limit points of the reachable points **rP** from e_{k+1} in between the range $\left[p_{fst}^1, p_{fst}^{\text{end}}\right]$ are treated as the elements of p_{fst}. Then, the upper and lower limits of next (*n*-1) points together with p_{fst} are used to construct the new **TP** in the form of (11). There may be some illegal rows constructed from which the polynomial function violates the accuracy requirement. The **TP** is therefore checked, by testing whether the points in **rP** are all reachable from the polynomial under checking or e_{k+1}. If not reachable, the row is considered as illegal and thus removed. This constructs a new **TP** for the test on the next samples.

q_k can be calculated as the intersection between e_{k+1} and e_k. Set $i_0=i, i=i+n-2, k=k+1$.

Step 5: End. This is the ending process, where the last polynomial function e_{k+1} is found with its range $[q_k, q_{k+1}]$ for the fuzzy system.

If $i>N$ (jumped from Step 2), which means the last point p_N is reachable from the current **TP**, then find a representative one e_{k+1} from the **TP** which reaches p_N. A

typical choice is the one who is the closest to p_N. Then, calculate the q_k where e_k and e_{k+1} intersect. The final point q_{k+1} is the intersection between e_{k+1} and the line segment $\overline{p_N^- p_N^+}$.

If $i \le N$ (jumped from Step 4), which means the point p_i is not reachable but p_{i-1} is reachable from the current **TP** and the number of remaining un-judged sample points is equal or less than n, then we need to construct the e_{k+1} as $e_{k+1} = \{q_k, p_i, p_{i+1}, \cdots, p_N\}$ where q_k is the intersection between e_k and the line segment $\overline{p_{i-1}^- p_{i-1}^+}$. If the elements of e_{k+1} are not enough to determine a polynomial function, the designer can arbitrarily add some points into it (this will not affect the fuzzy rule number). A typical suggestion is to select the midpoints of line segments $\overline{p_{i+j} p_{i+j+1}}, j = 0,1,\cdots, N-i-1$.

Step 6: This step determines the minimum rule number and computes the parameters in the TS type fuzzy system. From the above five steps, q_j are used to store the partitions of the fuzzy sets and e_{j+1} to store the outputs in the range $x \in [q_j, q_{j+1}]$, $j = 1,2,\cdots,k$. For (n-1)-*th* order TS type fuzzy system, each e_{j+1} contains (n+1) points, while the response within this area is interacted by the two rules j and (j+1) each of which has n parameters. In total, there are 2n parameters to be computed. Obviously, when $2n > (n+1)$, i.e. $n \ge 2$, the solution is not unique. The reason is that the parameters $\{\beta_i^1\}, i = 1,2,\cdots,n$ of the first rule can be only evaluated through the first area $[q_1, q_2]$. Since the degree of freedom is more than the number of equations, the solution can only show a relationship between $\{\beta_*^1\}$ and $\{\beta_*^2\}$ (Subscript "*" represents an index in $[1,2,\cdots,n]$), the solution in $[q_2, q_3]$ gives a relationship between $\{\beta_*^2\}$ and $\{\beta_*^3\}$, and similarly in all areas $[q_j, q_{j+1}]$, $j = 1,2,\cdots,k$. The sets of parameters are nesty related: if one is specified, all of the rest can be determined uniquely. A suggested choice for simplicity is to let the first rule be

$$\text{IF}\left(x \text{ is } A_1\right), \text{ THEN}\left(y = y\left(q_1\right)\right), \tag{12}$$

and then all the parameters can be determined.

The flowchart of the proposed testing point algorithm for (n-1)-*th* order TS type fuzzy system is given in Fig. 5.

Remark 2: No matter what parameters of the final fuzzy system are determined through the above algorithm, the number of the rules can be guaranteed to be the minimum, which is of the most importance and the target of this research.

Remark 3: In most applications, TS type fuzzy systems with first order consequent parts are used, although less fuzzy rules may be needed if the order of the consequences is increased, because higher order interpolation may increase the computational complexity and cause the so-called Runge's phenomena (artificial oscillations with amplitude increasing with the degree of the interpolating polynomial) [17] which are not preferred. Nevertheless, in some special cases, to model highly nonlinear systems for instance, higher order TS type fuzzy system may be adopted, for which the solution to the design (based on maximal absolute error and minimum number of rules) is also provided by the proposed testing point algorithm.

III. Simulation Results

The testing point algorithm works for the (n-1)-*th* order TS type fuzzy system in modeling and identification. In the following, we just demonstrate the algorithm for modeling with the first order TS type fuzzy system, suggested by Remark 3.

Example 3 [17]: Consider the same problem in Example 2, the process to be modeled is characterized by $g(x) = \cos\left(\left(e^x\right)^2\right)$. Fig. 6 gives the final result and Fig. 7 shows the partitions of the input domain and the membership functions obtained from q_k's.

Eventually 12 fuzzy sets $\{A_1, A_2, \cdots, A_{12}\}$ are found centered at:

$$\begin{aligned}\{\alpha_1, \alpha_2, \cdots, \alpha_{12}\} = \{&0, 0.549, 0.876, 1.084, 1.237, 1.380,\\ &1.543, 1.650, 1.750, 1.850, 1.950, 2.000\}\end{aligned} \tag{13}$$

The l-th rule ($l = 1,2,\cdots,12$) of the first order TS type fuzzy system is in the form of

$$R_l\text{: IF}\left(x \text{ is } A_l\right), \text{THEN}\left(y \text{ is } \beta_1^l x + \beta_2^l\right), \tag{14}$$

where β_1^l and β_2^l are constants.

In the partitions $[\alpha_l, \alpha_{l+1}], l = 1,2,\cdots,k$, the output of the fuzzy system can be derived from (6), which can be re-written as

$$\begin{aligned} f_l(x) = &\frac{\beta_1^{l+1} - \beta_1^l}{\alpha_{l+1} - \alpha_l} x^2 \\ &+ \frac{\beta_1^l \alpha_{l+1} - \beta_1^{l+1} \alpha_l + \beta_2^{l+1} - \beta_2^l}{\alpha_{l+1} - \alpha_l} x + \frac{\beta_2^l \alpha_{l+1} - \beta_2^{l+1} \alpha_l}{\alpha_{l+1} - \alpha_l}. \end{aligned} \tag{15}$$

Substituting all the points stored in $e_{l+1}, l = 1,2,\cdots,11$ to (14) with corresponding l generates in total 12 linear equations. According to (12), let $\beta_1^1 = 0, \beta_2^1 = y\left(q_1\right)$. It is easy to solve the equations and finally obtain all the remaining parameters $\{\beta_1^l, \beta_2^l\}, l = 2,3,\cdots,12$. The 12 fuzzy rules can then be concluded as

$$R_1\text{: IF}\left(x \text{ is } A_1\right), \text{THEN}\left(y = 0 \cdot x + 0.5903\right)$$

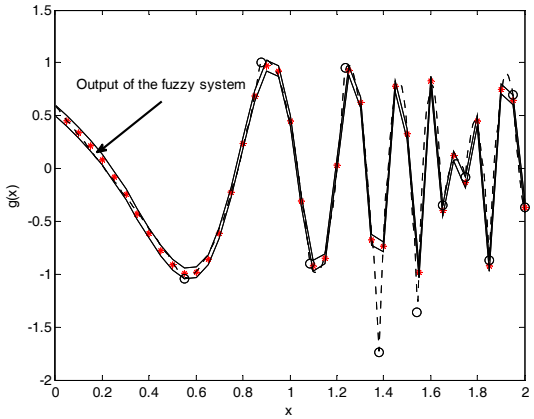

Fig. 6. First order TS type fuzzy system constructed in Example 3.

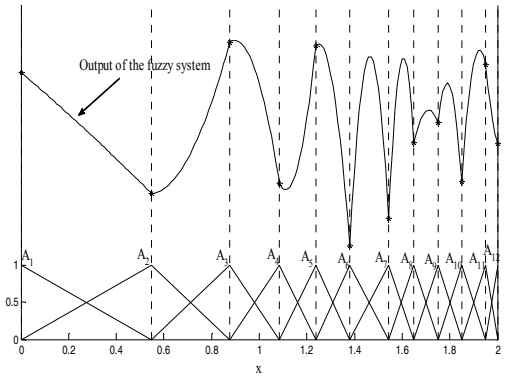

Fig. 7. The partitions of the input domain and the output of the fuzzy system in Example 3.

$$R_2\text{: IF}\left(x \text{ is } A_2\right), \text{THEN}\left(y = -0.2607x - 0.8981\right)$$

$$R_3\text{: IF}\left(x \text{ is } A_3\right), \text{THEN}\left(y = 5.5178x - 3.8344\right)$$

$$R_4\text{: IF}\left(x \text{ is } A_4\right), \text{THEN}\left(y = -5.8993x + 5.4988\right)$$

$$R_5\text{: IF}\left(x \text{ is } A_5\right), \text{THEN}\left(y = 12.7912x - 14.8718\right)$$

$$R_6\text{: IF}\left(x \text{ is } A_6\right), \text{THEN}\left(y = -10.0108x + 12.0781\right)$$

$$R_7\text{: IF}\left(x \text{ is } A_7\right), \text{THEN}\left(y = -67.8593x + 103.3699\right)$$

$$R_8\text{: IF}\left(x \text{ is } A_8\right), \text{THEN}\left(y = -128.1263x + 211.0606\right)$$

$$R_9\text{: IF}\left(x \text{ is } A_9\right), \text{THEN}\left(y = -139.3971x + 243.8665\right)$$

$$R_{10}\text{: IF}\left(x \text{ is } A_{10}\right), \text{THEN}\left(y = -174.5493x + 322.0426\right)$$

$$R_{11}\text{: IF}\left(x \text{ is } A_{11}\right), \text{THEN}\left(y = -206.1204x + 402.6349\right)$$

$$R_{12}\text{: IF}\left(x \text{ is } A_{12}\right), \text{THEN}\left(y = -195.4124x + 390.4542\right)$$

where $\{A_1, A_2, \cdots, A_{12}\}$ are shown in Fig. 7 with centers in (13). As shown in Fig. 6, for the training data, the maximal absolute error is less than $\varepsilon = 0.05$. Table 1 concludes the results from different algorithms for the same modeling problem and clearly shows the improvement of the proposed testing point algorithm.

Table 1: Numbers of Extracted Rules by Different Algorithms in Example 3

	Mamdani type Fuzzy System		TS type Fuzzy System
	Tunnel Algorithm	Testing Point Algorithm	Testing Point Algorithm
Number of Rules	25	19	12

IV. Concluding Remarks

An improved algorithm based on the geometric approach in [17] was proposed to build any order TS type fuzzy model with minimum number of rules and guaranteed approximation accuracy, from the input-output data of an unknown nonlinear system. Comparison study through numerical simulations demonstrates the effectiveness of the method.

This proposed testing point algorithm in its current format works only for SISO cases. Extension to higher dimension, i.e. MIMO (multiple-input-multiple-output) cases will greatly expand the applicability of the strategy and is a major concern for the future work.

***Abstract*— The Photovoltaic cells have P-V characteristics which indicate that there is only one point that produces a maximum output power. The point of the maximum power lies at the knee of the I-V curve. Tracking this point is a very important issue concerning the energy yield of the PV systems. One of the efficient tracking techniques is based on the Fuzzy agents which are able of fine tuning the cell operating voltage and current to keep the maximum possible output power. In this paper, a fuzzy agent with two input parameters enhanced by the fractional open circuit voltage technique will be used to track the MPP in a fast and accurate manner that is better than the traditional techniques. Assigning different weights for the two inputs of the fuzzy agent adapts the power response to achieve fast settling and accurate tracking of the cell maximum output power even under extreme variable atmospheric conditions in an efficient manner with better performance than conventional fuzzy MPPT technique.**

Keywords- Adaptive Fuzzy agent, Fractional Open circuit Voltage, Fuzzy Control, MPPT, Photovoltaic modules.

I. INTRODUCTION

Achieving the maximum possible output power from a PV module is an important aim in any PV system to compensate its initial cost. The task can be handled using a DC-DC converter with variable duty cycle D that is determined through a maximum power point tracker MPPT. The aim of the tracker is to vary the module operating current and voltage such that the maximum output power is achieved in a fast and accurate manner even under variable irradiance or temperature conditions. At the maximum power point, the power variation with respect to voltage variation or current variation is zero as will be seen. So, using this variation as an input signal to a fuzzy agent beside another input which is the variation of the first input helps the fuzzy agent to vary and fine tune the duty cycle of the DC-DC converter in a manner that keeps the maximum power transfer to the desired load even under large atmospheric variations. The usage of the fractional open circuit voltage is useful in reducing the searching and hence the settling times. The proposed technique has the advantage of fast settling and accurate tracking without steady state error.

II. MPPT TECHNIQUES

The I-V and P-V characteristics of the photovoltaic module under study are shown in fig. 1. The maximum power occurs at the knee of the I-V curve as shown in the same figure. The characteristics are for the module GUC09 of the commercial type *BP7185S-Saturn 7* series.

Many MPPT techniques were developed in the literature aiming at fast and accurate tracking. As in [1] and [2], some of them will be discussed.

A. Fractional Open-Circuit Voltage

This method uses the approximate ratio of the PV module maximum power point voltage V_{MPP} to the to its open circuit voltage V_{OC} which is nearly constant as a simple feed forward technique for tracking the maximum output power, as can be seen from (1).

$$V_{MPP} \approx K_1 \times V_{OC} \tag{1}$$

The factor K_1 has been reported to be between 0.71 and 0.78. Once the constant K_1 is calculated, V_{MPP} is computed by measuring V_{OC} periodically using pilot PV cells.

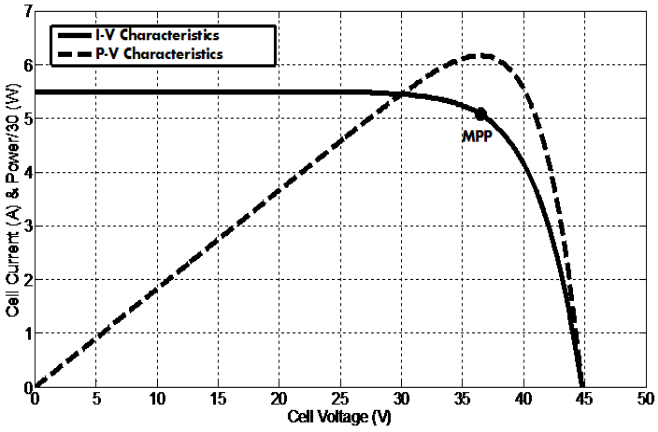

Fig. 1. I-V & P-V characteristics of a PV module

The problem is that the factor K_1 is temperature and irradiance dependent as was stated in [3] and hence the obtained results of such a technique are not accurate. Although the implementation of this method is simple and cheap, its tracking efficiency is relatively low due to the utilization of inaccurate values of the constant K_1 in the computation of V_{MPP}.

B. Fractional Short-Circuit Current

As in the fractional open circuit voltage, it was found also that the ratio between the maximum power point current and the short circuit current is also constant as in (2).

$$I_{MPP} = K_2 \times I_{SC} \tag{2}$$

Where I_{MPP} is the maximum power point current, I_{SC} is the short circuit current, and K_2 is the proportionality constant. According to [1], the constant K_2 ranges between 0.78 and 0.92 and depends on the PV module characteristics and the atmospheric conditions. The method depends on periodic measurements of the short circuit current as it is not fixed. The measurement of the short circuit current requires the usage of a pilot cell for periodic measurement. The method is then simple but needs a current sensor which is expensive and unreliable. The method can be either analog or digital. An atmospheric compensation for K_2 is proposed also in [4].

C. Perturb and Observe P&O

According to [5], the Perturb & Observe method operates by setting an initial operating voltage for the PV module and then a perturbation or voltage change is made and afterwards an observation for the power is made. If the perturbation (voltage change) is positive (increase) and a positive observation (power increase) is detected, the next perturbation will be positive and if a negative observation is detected, the next perturbation will be negative. While if the perturbation is negative (decrease) and a positive observation is detected, the next perturbation will be negative and if a negative observation is detected, the next perturbation will be positive. Of course this is done by sampling both the PV current and voltage. The tracker operates by periodically incrementing or decrementing the solar module voltage. Actually, the system oscillates about the MPP. Reducing the perturbation step size can minimize the oscillation. However, small step size slows down the MPPT. To solve this problem, a variable perturbation size that gets smaller towards the MPP should be used. However, the P&O method can fail under rapidly changing atmospheric conditions. Several research activities have been carried out to improve the traditional Hill-climbing and P&O methods.

D. Incremental Conductance

The method is based on the principle that the slope of the PV module power curve is zero at the maximum power point. In this method, the operating voltage is changed until dP/dV equals zero which occurs at the maximum power point as stated in [6]. Using fig.1, the ratio $\Delta P/\Delta V$ follows one of the cases described in (3). The incremental conductance method requires both voltage and current sensors in addition to a DSP or microcontroller. This method is a digital tracking method not an analog one and hence cost factor may be taken into consideration. The accuracy of this technique is good but it is usually better when combined with the P&O MPPT technique.

$$\begin{cases} \dfrac{\Delta P}{\Delta V} = 0, \textit{ at MPP} \\ \dfrac{\Delta P}{\Delta V} > 0, \textit{ left of MPP} \\ \dfrac{\Delta P}{\Delta V} < 0, \textit{ right of MPP} \end{cases} \tag{3}$$

III. PROPOSED MPPT TECHNIQUE

Using (3) and fig. 1, the parameter $\Delta P/\Delta V$ will be defined as the error signal E which should be equal to zero for best performance and it will be fed to a Fuzzy agent for the purpose of maximum power point tracking. At the maximum power point, the error signal equals zero and hence it is desired to keep the error signal at zero value in order to track the MPP. For fine tuning, the variation of the error signal ΔE is defined as a second input for the fuzzy agent. For simulation purposes, the PV model driven in [7] and [8] will be adapted to the available practical module and will be used. According to [1], the error E and its change ΔE can be defined by (4) and (5) respectively.

$$E(k) = \frac{P(k) - P(k-1)}{V(k) - V(k-1)} \tag{4}$$

$$\Delta E(k) = E(k) - E(k-1) \tag{5}$$

The fuzzy knowledge-base controller is one part of Fuzzy Logic Control which is composed of three main parts: fuzzification, inference engine, and defuzzification as in [9].

A. Fuzzification

Membership function values are assigned to the linguistic variables, using five fuzzy subsets: NB (negative big), NS (negative small), ZE (zero), PS (positive small), and PB (positive big). The partition of fuzzy subsets and the shape of membership functions, which can adapt shape up to appropriate system, are shown in fig. 2.

The choice of the member ship functions is based on the error signal variations with voltage as can be seen from fig. 3.

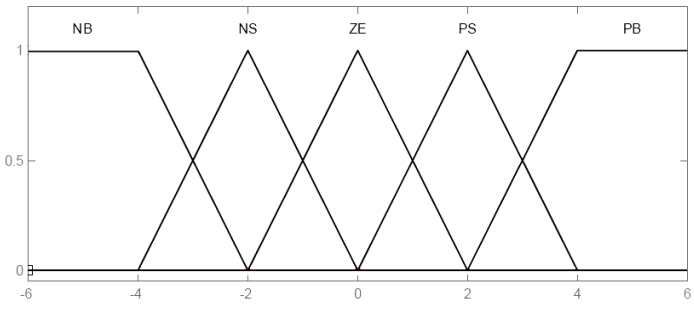

Fig. 2. Membership functions of E and ΔE

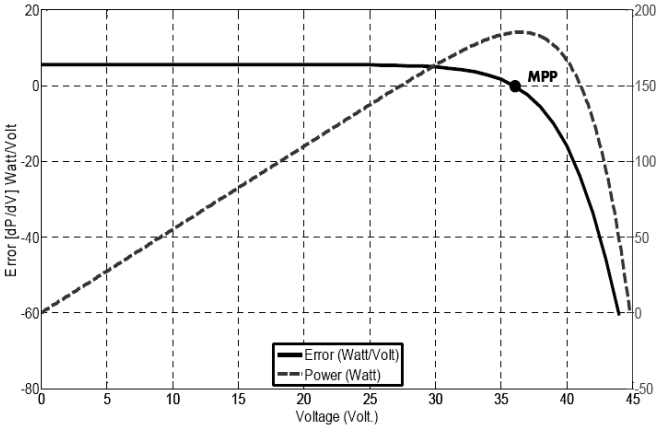

Fig. 3. Error Variations with the module voltage

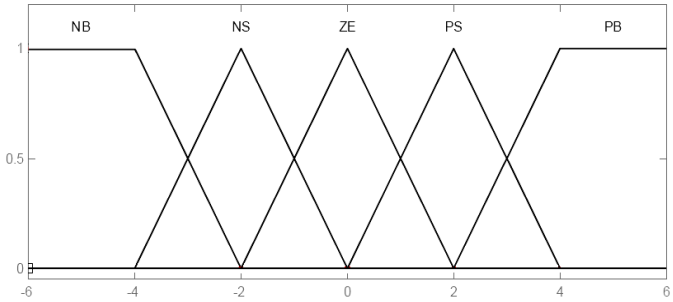

Fig. 4. Output Membership functions

The output (ΔV) membership functions are shown in fig. 4.

B. *Inference method*

As in [9], the composition operation is the method by which a control output is generated. Several composition methods such as Max–Min and Max-Dot have been proposed in the literature. The commonly used method, Max–Min, is used in this paper. The output membership function of each rule is given by the Min (minimum) operator and Max (maximum) operator. Table 1 shows the rule base of the FLC like some rules of [10]. The fuzzy rule base table depends basically on the error E variations with voltage change shown in fig. 3.
From fig. 3, it is clear that the error is positive constant till V=25 V and then it will be positive decaying till V=36 V (at MPP). After the MPP, the error is negative decaying. As long

TABLE I. FUZZY RULE TABLE

Error E	**Change of Error ΔE**				
	NB	***NS***	***ZE***	***PS***	***PB***
NB	NS	ZE	PB	PB	PB
NS	ZE	ZE	PS	PS	PS
ZE	PS	ZE	ZE	ZE	NS
PS	NS	NS	NS	ZE	ZE
PB	NB	NB	NB	ZE	PS

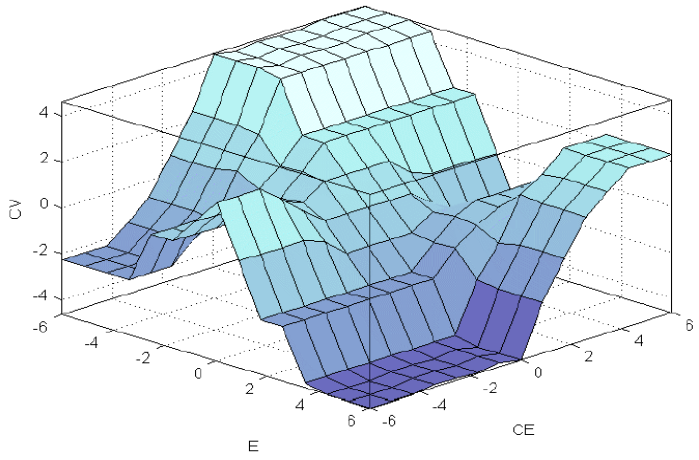

Fig. 5. Fuzzy Rule Surface

as the error is positive, the voltage should be increased and the rate of increase depends on the rate of change of the error signal ΔE which is used for fine tuning. When the error is negative, the voltage should be decreased and the rate of decrease depends on the fine tuning factor (ΔE).
The control rule surface is shown in fig. 5.

C. *Defuzzification*

The output of this fuzzy controller is a fuzzy subset of control. To get a non-fuzzy value of control, a defuzzfication stage is necessary. Defuzzification for this system can be performed by height method. The non fuzzy value of control output can be gained using a discrete time integrator simply and quickly because the output is the voltage change ΔV.

A simple block diagram representation of the whole PV and MPPT system is shown in fig. 6. The controller is a fuzzy agent adapted by the fractional open circuit voltage technique to reduce the settling or tracking time by giving an initial estimation for the operating voltage. The technique is applied to the BP7185S-Saturn 7 series with the electrical characteristics shown in Table 2 with 72 series PV cells.
If no fractional open circuit voltage is used as the traditional fuzzy techniques, the power response of the module will have a large settling time (62 m sec) as shown in fig. 7 and hence the use of the fractional open circuit voltage leads to a faster power response as shown in fig. 8. The time step in the graph is (m sec) and it may depend on the used data acquisition system.

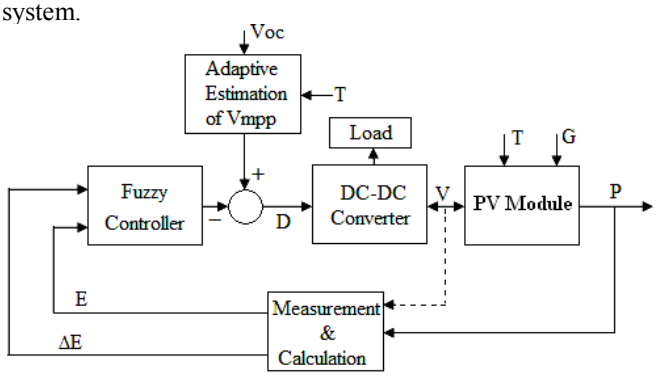

Fig. 6. PV MPPT System

TABLE II. ELECTRICAL CHARACTERISTICS OF BP7185S

Parameter	Value
Warranted minimum power	185 W
Voltage at MPP (V_{MPP})	36.5 V
Current at MPP (I_{MPP})	5.1 A
Open Circuit Voltage (V_{OC})	44.8 V
Short Circuit Current (I_{SC})	5.5 A
Temperature coefficient of V_{OC}	-(160±20)mV/K
Temperature coefficient of I_{SC}	(0.065±0.015)%/K
Temperature coefficient of P	-(0.5±0.05)%/K
NOCT (Air 20ºC; Sun 800W/m^2; wind 1m/s)	47±2 Cº
Maximum series fuse rating	15 A
Maximum System Voltage	1000 V (IEC 61215 rating)

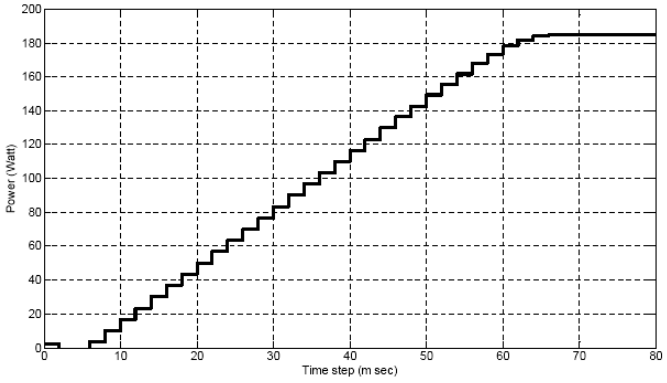

Fig. 7. Power response for no Fractional V_{OC}

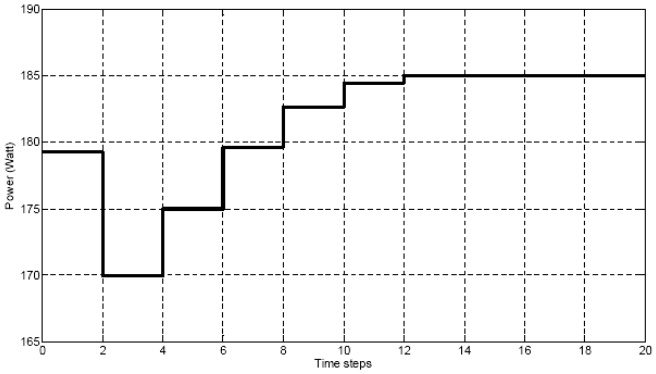

Fig. 8. Power response using Fractional V_{OC}

In fig. 8, there is no steady state error in the output power (which settles at 185 W) and the searching time is smaller than the traditional fuzzy method of fig. 7 by more than 50 m sec, which is a good improvement.

The fuzzy agent in turn controls the duty cycle of the DC-DC converter used for load matching in order to keep the operating point of the PV module at (V_{MPP}, I_{MPP}). For a load of 12 V DC as an example, the duty cycle will vary with time as shown in fig. 9 through a fuzzy agent adapted by fractional open circuit voltage.

Based on the adaptation idea developed in [11], another adaptation idea is to add different weights for the inputs of the fuzzy agent. The error signal should have the full weight while the fine tuning signal which is the change in the error signal

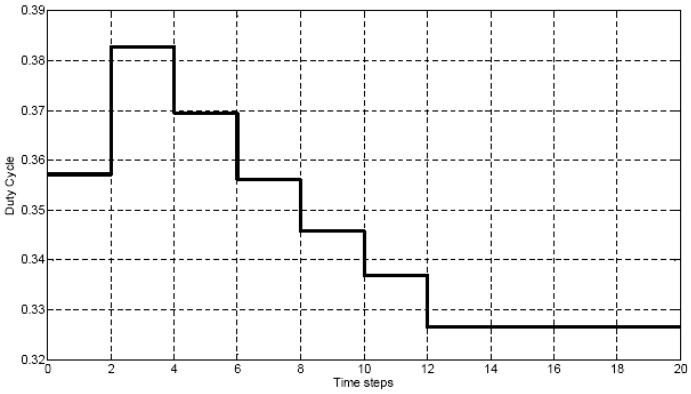

Fig. 9. Duty cycle variations using fractional V_{OC}

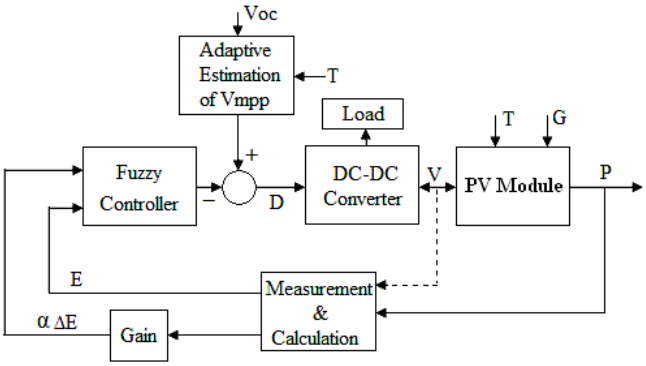

Fig. 10. Adaptive Fuzzy MPPT

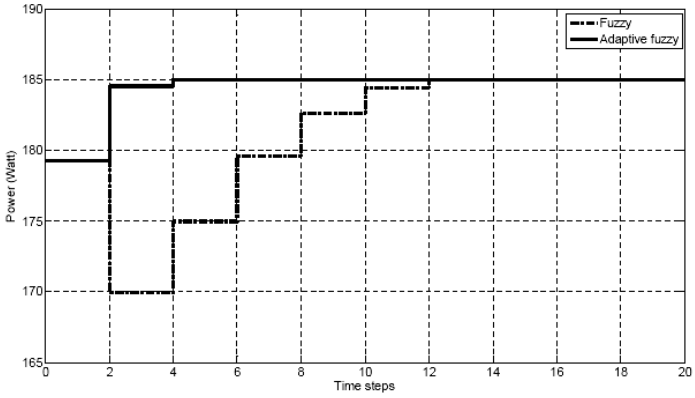

Fig. 11. Fuzzy vs. Adaptive fuzzy power response

may have a smaller weight compared to the error signal. The block diagram of the adaptive technique is shown in fig. 10.

The response of this case in comparison with the previous case is shown in fig. 11 knowing that both techniques use fractional open circuit voltage for initial estimation of V_{MPP}.

The proposed adaptive tracking technique shows a good response even under variable atmospheric conditions as can be seen in fig. 12.

Fig. 12 shows that the proposed technique is suitable for any atmospheric conditions such as variable module temperature or variable irradiance. The proposed technique has a better response under variable atmospheric conditions than the traditional MPPT technique driven in [12].

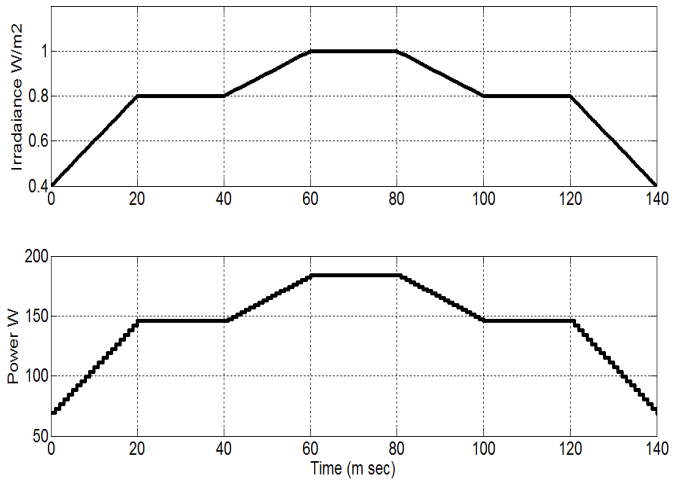

Fig. 12. Power response under variable irradiance

In the literature, the change in the converter duty cycle may be used as a third input for the fuzzy agent in order to improve the power response of the PV module but with more complexity. The tracking speed of the proposed technique is even better than the other traditional MPPT techniques like that in [2] which has a searching time of about 20 m sec.

A comparison between the traditional MPPT techniques and the newly adapted fuzzy technique based on [1] is given in table 3 where New fuzzy represents the developed technique.

TABLE III. COMPARISON BETWEEN MPPT TECHNIQUES

MPPT Technique	Module - dependent	True MPP	Tracking speed	Tracking accuracy	Atmospheric effect
Fractional V_{OC}	Yes	No	Medium	Low	High
Fractional I_{SC}	Yes	No	Medium	Low	High
P & O	No	Yes	Varies	Varies	High
Inc. Cond.	No	Yes	Varies	Varies	Low
Fuzzy	Yes	Yes	Fast	High	Low
New Fuzzy	Yes	Yes	Very Fast	Very High	Low

IV. CONCLUSION

The fuzzy agent with two input parameters, which are E= $\Delta P/\Delta V$ and its change ΔE, enhanced by an initial estimation for the MPP voltage V_{MPP} using the fractional open circuit voltage technique leads to a good power response. This technique achieves the maximum possible output power from the PV module (185 W) without any steady state error in a small searching time (10 m sec). The improvement achieved by the proposed technique compared to the traditional fuzzy technique appears in the small searching time of the MPP by reducing the searching time to 20% from its traditional value. The developed MPPT technique shows a good response even under variable atmospheric conditions depending on the temperature adaptation of the initial estimation of V_{MPP} and the closed loop advantage of the fuzzy control scheme. Adaptation of the fuzzy agent may be done by giving the fuzzy agent inputs different weights causing a smaller settling time (2 m sec) and high accuracy thus leading to a newly developed efficient technique. The proposed technique has the advantages of fast settling, accurate tracking, and simple implementation. Moreover, it is faster than the traditional MPPT techniques. Also, the technique is a closed loop control system which is able of avoiding aging effects of the PV module which is not available in feed forward MPPT systems.

eehsu@et4.thit.edu.tw

Abstract— **In this paper, a fuzzy inference digital image stabilization method is proposed to adaptively determine better motion compensation method through the selection of two different motion compensation methods. The experimental results show the good performance. It solves the problem of lag and overshoot of motion trajectory.**

Keywords- fuzzy inference; DIS; motion compensaton;

I. INTRODUCTION

Digital image stabilization (DIS) system is generally composed of two processing units. One is the motion estimation unit and the other is the motion compensation unit. The purpose of motion estimation unit is to estimation the reliable camera global movement. The motion compensation unit generates the compensation motion vector to obtain a smoother image sequence [1]-[5].

In the motion compensation of DIS, accumulated motion vector estimation and frame position smoothing (FPS) are the two popular approaches [6]. The accumulated motion vector estimation needs to compromise stabilization and intentional panning (constant motion) preservation since the panning condition causes a steady-state lag in the motion trajectory. The FPS accomplished the smooth reconstruction of an actual long-term camera motion by filtering out jitter components based on the concept of designing the filter with appropriated cut-off frequency. The disadvantage of FPS is that it does not guarantee the availability of the determined compensating motion vector when the specified-bound is restricted to preserve the effective image area in the DIS applications [8].

Fig. 1 shows the motion compensation schematics. The window of frame(t-1) is the previous compensated image. The compensating motion vector v is generated by the DIS according to the global motion vector between two consecutive images. The window of frame(t) is the picking window according to the compensating motion vector v to minimize the shaking effect. Compensating motion vector should be less than window shifting allowance for preservation of the whole image presented in the frame. How to generate motion compensation vector to achieve the optimal stabilization of shaking images within a specified compensation range (window shifting allowance) is a state of the art.

This work was supported by the National Science Council of Taiwan under the Grant NSC 99-2632-E-233-001-MY3.

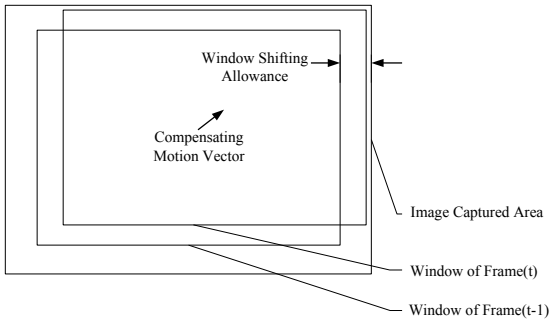

Fig. 1. Motion compensation schematics.

J. K. Paik proposed the accumulated motion vector method in 1992. The computation procedure is given by:[1]

$$CMV(t) = k(CMV(t-1)) + (\alpha GMV(t) + (1-\alpha)GMV(t-1)), \quad (1)$$

where t represents the frame number, $0 < k < 1$ and $0 \le \alpha \le 1$. The constant k is used for smooth panning. The constant α is used to filter out the unexpected noise effect. The increase in k causes the decrease in unwanted shaking effect but the increase in the value of CMV leads more allowance to compensate. It means that, in the definite allowance, it may not fully stabilize the image sequence by the CMV, especially in a high panning condition.

S. C. Hsu etc. proposed the CMV computation procedure to attack the drawback of tremendous lag during constant panning in 2005. This is presented by: [7]

$$\begin{aligned} CMV(t) &= \mathbf{k} \bullet CMV(t-1) + GMV(t) - \boldsymbol{\beta} \bullet CMV_I(t-1) \\ CMV_I(t) &= CMV_I(t-1) + CMV(t) \\ CMV(t) &= \frac{1}{2}\left(|CMV(t)+l| - |CMV(t)-l|\right) \end{aligned} \quad , \quad (2)$$

where $\begin{bmatrix} 0 \\ 0 \end{bmatrix} \le \mathbf{k}, \boldsymbol{\beta} \le \begin{bmatrix} 1 \\ 1 \end{bmatrix}$, $\bullet$ denotes array multiplication.

The objective of motion compensation is to achieve the optimal stabilization of shaking images within a specified compensation range (window shifting allowance). Eq. 1 can get a good result in a general case. But in the constant motion case, the undesired shaking effect cannot be eliminated by this method. The equation proposed in Eq. 2 can overcome this

drawback. The inner feedback-loop integrator was combined with a clipper function to reduce the steady-state lag for steady motion, as well as to keep the CMV operating in the appropriate range. Due to the characteristics of the integral, the overshoot will occur in certain back and forth low frequency image panning. Fig. 2 shows overshoot in low frequency back and forth image panning. The motion trajectory has obvious overshoot. This overshoot will reduce the effect of stabilization.

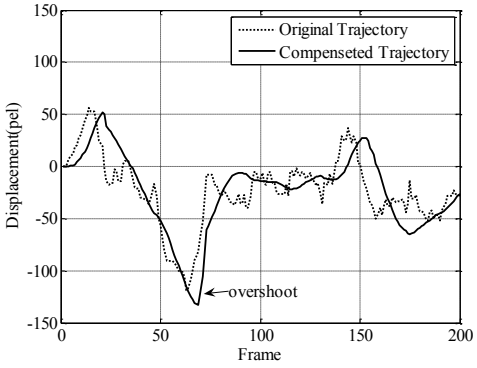

Fig. 2. Overshoot in low frequency back and forth image panning.

In this paper, two methods of motion compensation will combine through fuzzy inference to decide the optimal compensation method. In the next section, the architecture of fuzzy inference applied to DIS will be proposed. Section III shows the experimental results and section IV makes a discussion.

II. METHOD

A. Architecture of fuzzy inference

The typical architecture of a fuzzy logic decision system is comprised of four principal components: a fuzzifier, a fuzzy rule base, an inference engine, and a defuzzifier. The fuzzifier transforming crisp measured data into suitable linguistic values. The fuzzy rule base stores the empirical knowledge of the operation. The inference engine is the kernel of the decision system, and it has the capability of simulation human decision making by performing approximate reasoning to achieve a desired result based on the fuzzy rule base. The defuzzifier yields a nonfuzzy decision to perform the desired action [9][10].

In this paper, the design idea is to keep the merits of each motion compensation method, i.e. reduce compensated motion trajectory lag and overshoot, to improve the DIS in different conditions. Fig. 3. shows the architecture of fuzzy inference applied to digital image stabilization. The system architecture will focus on the motion compensation unit. The motion compensation unit includes two motion compensation methods, fuzzy inference system and motion compensation. Due to the differences of environments, conditions and shaking patterns of the captured images, the different motion compensation methods have individual merits separately. Fig. 4 shows the architecture of the fuzzy inference system. The pre-process block inputs global motion vector (GMV), compensating motion vector #1&#2 (CMV#1, CMV#2) are to transform into delta of short term smoothness index($\Delta SI(n)$) and delta of deviation(Δd) which are inputs of fuzzy inference. The fuzzy inference determines the weighted value to calculate the compensation vector. And then the block of image compensation uses the compensation vector to stabilize the image sequence.

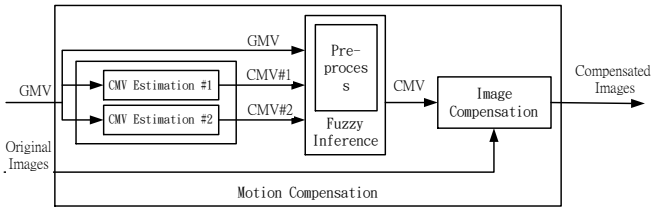

Fig. 3. The architecture of fuzzy inference applied to digital image stabilization

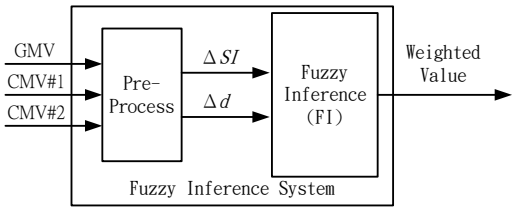

Fig. 4. The architecture of the fuzzy inference system

B. Pre-process

The main function of pre-process is to transform external signals into distinguished signals of fuzzy inference input. The major consideration is the smoothness index. To realize the effect of the compensation method in a short term period, the short term smoothness index $SI(n)$ is defined as

$$SI(n) = \frac{1}{p+1}\sum_{i=n-p}^{n}\Delta m(i) = \frac{1}{p+1}\sum_{i=n-p}^{n} m\times\left|GMV(i)-GMV(i-1)\right| \quad (3)$$

where n is the frame number, p is the short term frame amount. The delta of short term smoothness index($\Delta SI(n)$) can be expressed as

$$\Delta SI(n) = SI\#1(n) - SI\#2(n) \quad (4)$$

where $SI\#1(n)$ and $SI\#2(n)$ are short term smoothness indexes generated by Eq. 1 and 2 , respectively.

When $\Delta SI(n) < 0$, the motion trajectory compensated by CMV#1 is smoother than what was compensated by CMV#2 and vice versa. The secondary consideration is the deviation between the original and compensated motion trajectories. The deviation ($d(n)$) is defined as

$$d(n) = \left|MTraj_o(n) - MTraj_c(n)\right| \quad (5)$$

where $MTraj_o(n)$ is the original motion trajectory and $MTraj_c(n)$ is the compensated motion trajectory. The motion trajectories are define as

$$MTraj_o(t) = \sum_{i=1}^{t} GMV(i) \quad (6)$$

$$MTraj_o(t) = \sum_{i=1}^{t} GMV(i), \quad (7)$$

The large deviation between original and compensated motion trajectories will affect the image stabilization result. Therefore, the delta of deviation (Δd) is defined as a distinguished signal which is expressed as

$$\Delta d(n) = d\#1(n) - d\#2(n) \quad (8)$$

where $d\#1(n)$ and $d\#2(n)$ are deviations of motion trajectory compensated by CMV#1 and CMV#2. When $\Delta d(n) < 0$ means the deviations of motion trajectory compensated by CMV#1 is better than compensated by CMV#2 and vice versa.

C. Membership functions

Fig. 5 shows the Architecture of internal fuzzy inference. It contains a fuzzifier, a fuzzy rule base, an inference engine and a defuzzifier. The function of the fuzzifier is to transform crisp measured data $\Delta SI(n)$ and $\Delta d(n)$ into suitable linguistic values. The membership functions of these two signals are shown in Fig. 6. The linguistic descriptors are: large negative (FN), small negative (SN), zero (Z), small positive (SP), large positive (LP). Fuzzy rule base is characterized by a collection of fuzzy IF-THEN rules in which the preconditions and consequents involve linguistic variables. The collection of fuzzy inference rules characterizes the simple input-output relation of the system. The Eq. 9~19 are the statements of fuzzy rules:

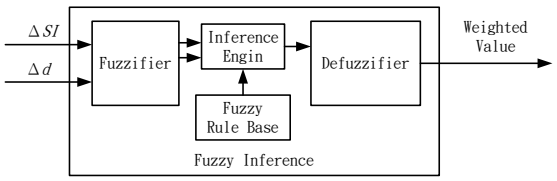

Fig. 5. Architecture of internal fuzzy inference.

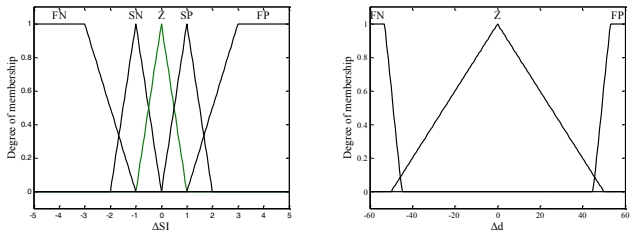

Fig. 6. Membership functions of inputs (a) $\Delta SI(n)$; (b) $\Delta d(n)$.

IF ΔSI is SN and Δd is FN THEN Output is L (9)
IF ΔSI is SN and Δd is Z THEN Output is L (10)
IF ΔSI is SN and Δd is FP THEN Output is M (11)
IF ΔSI is Z and Δd is FN THEN Output is L (12)
IF ΔSI is Z and Δd is Z THEN Output is M (13)
IF ΔSI is Z and Δd is FP THEN Output is S (14)
IF ΔSI is SP and Δd is FN THEN Output is M (15)
IF ΔSI is SP and Δd is Z THEN Output is S (16)
IF ΔSI is SP and Δd is FP THEN Output is S (17)
IF ΔSI is FN THEN Output is L (18)
IF ΔSI is FP THEN Output is S (19)

Mamdani's fuzzy implication method R_c , associated with the min operation, is used in the proposed inference system. The membership function of output signal is shown in Fig. 7. The linguistic descriptors are: large (L), Medium (M), small (S). The output represents the weighted value of motion compensation method#1. Because two methods are included in the system, the final motion compensation vector is calculated by:

$$\begin{aligned} CMV(n) = {} & k \times CMV(n-1) \\ & + y(n) \times (CMV\#1(n) - CMV\#1(n-1)) \\ & + (1 - y(n)) \times (CMV\#2(n) - CMV\#2(n-1)) \end{aligned} \quad (20)$$

where y(n) is the weighted value, $0 < k < 1$, $CMV\#1(n)$ and $CMV\#2(n)$ are the compensated vectors estimated by method #1 and #2.

Defuzzifier is a mapping from a space of fuzzy set defined over an output universe of discourse into a space of nonfuzzy set. The method of defuzzification used in the fuzzy inference system is the center of area (COA).

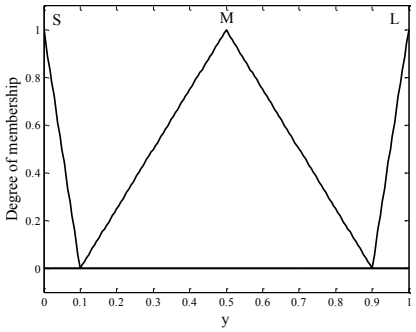

Fig. 7. Membership function of output.

III. EXPERIMENTAL RESULTS

In this section, the performance of proposed method in various conditions is demonstrated. To do this, GMVs estimated by three real video sequences that contain 200 frames are named GMV#1~3. To simplify the problem, one horizontal dimension is discussed and illustrated. The characteristics of GMVs are: GMV#1 contains constant speed movement and small fluctuation, GMV#2 contains constant speed movement and large fluctuation, GMV#3 contains only fluctuation without constant speed movement. The three sets of GMV observe the effects of image stabilization. The image size of the experiment is 640x480 pels. The clipper is bounded within ±53 pels. Parameters of MC#1 are set $k =$ and

$\alpha =$, MC#2 are set $k = 0.95$ and $\beta = 0.015$, the proposed method is set $k = 0.98$.

Fig. 8. shows the result of proposed method which uses a short term smoothness index to determine the better compensation method. The sequence n=1~200 corresponds to GMV#1, n=201~400 corresponds to GMV#2, and so on. In the first segment (n=1~200), the CMVs processed by MC#1 and MC#2 have almost the same $SI(n)$. Therefore, the fuzzy output is about 0.5. In the segment of n=250~400, the $SI(n)$ of MC#1 is higher; then the fuzzy output is close to 0. In other words, MC#2 has a better $SI(n)$ in this segment. In the segment of n=422~438, the $SI(n)$ of MC#2 has a spiked shape. Therefore, the fuzzy output approaches 1 and MC#1 is selected to compensate. Obviously, FIDIS is superior to MC#1, MC#2, respectively, for evaluating motion trajectory, the smoothness index or the short term smoothness index.

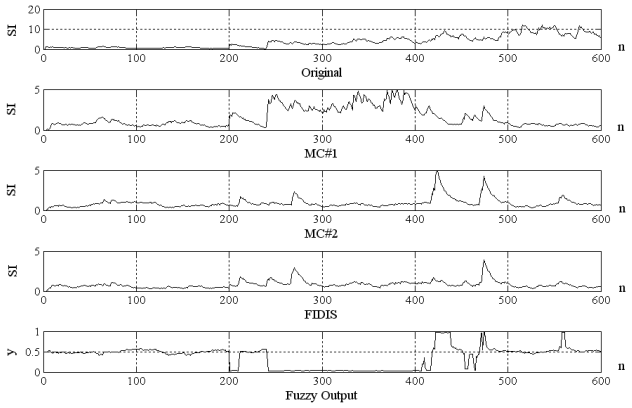

Fig. 8. Proposed method illustrated by short term smoothness $SI(n)$ and fuzzy output.

IV. DISCUSSION

The objective of motion compensation is to achieve the optimal stabilization of shaking images within a specified compensation range. The proposed method combines two motion compensation methods to adaptively determine a better method for motion compensation. It solves the problem of lag and overshoot of motion trajectory. The proposed method shows effective improvements in different conditions of image sequence through the evaluations of a smoothness index and motion trajectory.

ACKNOWLEDGMENT

The author would like to thank Chair Prof. C. T. Lin for providing the valuable opinions and part of resources to fulfill the whole research.

***Abstract*—Linear discriminant analysis (LDA) is a commonly used feature extraction (FE) method to resolve the Hughes phenomenon for classification. The Hughes phenomenon (also called the curse of dimensionality) is often encountered in classification when the dimensionality of the space grows and the size of the training set is fixed, especially in the small sampling size problem. Recent studies show that the spatial information can greatly improve the classification performance. Hence, for hyperspectral image classification, it is not only necessary to use the available spectral information but also to exploit the spatial information. In this paper, a semisupervised feature extraction method which is based on the scatter matrices of the fuzzy-type LDA and uses the semi-information is proposed. The experimental results on two hyperspectral images, the Washington DC Mall and the Indian Pine Site, show that the proposed method can yield a better classification performance than LDA in the small sampling size problem.**

Keywords--feature extraction; linear discriminate analysis

I. INTRODUCTION

Linear discriminant analysis (LDA) [4] is a commonly used feature extraction (FE) method to resolve the Hughes phenomenon (also called the curse of dimensionality) which means that when the dimension of the space grows and the size of the training set is fixed, the classification accuracy reach a maximum for a given size, then it decreases for the hyperspectral image classification. Recently, a fuzzy-type LDA (FLDA), an unsupervised version of linear discriminant analysis (UFLDA), based on the membership values is proposed [3]. The membership values of the scatter matrices in FLDA are obtained from the cluster result of fuzzy linear discriminant clustering (FLDC). Then the generalized eigenvectors form the transformation matrix to transform the samples in the space with lower dimensionality.

Moreover, the spatial information by considering semi-labels can greatly improve the accuracy of the hyperspectral image classification [1]-[2]. Using the semi-labels of the unknown samples can not only increase the training samples but also decrease the imprecise estimation of samples, which have very similar spectral properties, and have difficulty distinguishing the unlabeled patterns [1]-[2].

Therefore, in this study, we want to integrate the scatter matrices of FLDA and semi-information to develop spatial scatter matrices. The membership values of the scatter matrices of FLDA are determined by the posteriors of every pixel in the image from the previous classification results. After obtaining the within- and between-cluster scatter matrices based on the spatial information, combine with the scatter matrices of LDA to form semi-scatter matrices. Therefore, in this paper, a LDA based on semi-information (SLDA) is proposed. The experimental results on the Washington DC Mall image and the Indian Pine Site image data sets show that the proposed method can yield a better classification performance than LDA when sampling size is small.

The study is organized as followed. The LDA and its unsupervised version will be introduced in section II. Section III describes our proposed method, SLDA, and the experimental results are shown in Section IV. Finally, some conclusions are addressed in Section V.

II. LINEAR DISCRIMINANT ANALYSIS AND ITS UNSUPERISED VERSION

A. Linear Discriminant Analysis (LDA)

LDA [4] uses the mean vector and covariance matrix of each class, to formulate within-class, between-class, and mixture-class scatter matrices. Based on the Fisher criterion, the LDA method finds features such that the ratio of the between-class scatter to the average within-class scatter is maximized, in a lower dimensional space. By applying the concept of class scattering to class separation, the Fisher criterion, takes the large values from samples when they are well clustered around their mean within each class, and the

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

clusters of the different classes are well separated. The formula is stated as the following:

Suppose $H_i = \{x_1^{(i)},...,x_{N_i}^{(i)}\} \subset R^d$ were the set of samples in class i, N_i were the number of samples in class i, $i = 1,\ldots,L$, and $N = N_1 + \cdots + N_L$ were the number of all training samples. The between-class scatter matrix S_b^{LDA} and the within-class scatter matrix S_w^{LDA} would be defined as

$$S_b^{LDA} = \sum_{i=1}^{L} \frac{N_i}{N}(m_i - m)(m_i - m)^T \quad (1)$$

and

$$S_w^{LDA} = \sum_{i=1}^{L}\sum_{j=1}^{N_i} \frac{1}{N}\left(x_j^{(i)} - m_i\right)\left(x_j^{(i)} - m_i\right)^T \quad (2)$$

where m_i were the class mean defined by $m_i = \frac{1}{N_i}\sum_{j=1}^{N_i} x_j^{(i)}$ and $m = \frac{1}{N}\sum_{i=1}^{L}\sum_{j=1}^{N_i} x_j^{(i)}$ representing the total mean.

The optimal features are determined by optimizing the Fisher criterion given by $J_{LDA} = tr[(S_w^{LDA})^{-1} S_b^{LDA}]$. This is equivalent to solving the generalized eigenvalue problem, $S_b^{LDA} v_z = \lambda_z S_w^{LDA} v_z$, $z = 1,\ldots,d$ with $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_d$ where the extracted eigenvectors are used to form the transformation matrix of LDA, i.e., the transformation matrix from the original space to the reduced subspace is defined by: $A^{LDA} = [v_1, v_2, ..., v_p]$. The Fisher criterion J_{LDA} is able to detect the capacity of the separability for the transformed training samples.

B. Fuzzy-type Linear Discriminant Analysis (FLDA)

In the subsection, an unsupervised LDA, fuzzy-type LDA (FLDA), using the concept of membership values is described [3].Let X be a hyperspectral d-dimensional image of size $N \times z$ pixels, and $\{x_1,...,x_{N\times z}\} \subset R^d$ be all samples in the image. The between scatter matrix S_b^{FLDA} and the within scatter matrix S_w^{FLDA} as follows:

$$S_b^{FLDA} = \sum_{i=1}^{L} \frac{\sum_{t=1}^{N\times z} u_{it}}{N \times z}(m_i - m)(m_i - m)^T \quad (3)$$

and

$$S_w^{FLDA} = \sum_{i=1}^{L}\sum_{t=1}^{N\times z} \frac{u_{it}}{N \times z}(x_t - m_i)(x_t - m_i)^T \quad (4)$$

where u_{it} means the membership value of the sample x_t in class i,

$$m_i = \sum_{t=1}^{N\times z} \frac{u_{it}}{\sum_{k=1}^{N} u_{ik}} x_t$$

is the class mean, and $m = \frac{1}{N\times z}\sum_{t=1}^{N\times z} x_t$ represents the total mean.

The weight $\sum_{t=1}^{N\times z} u_{it}/(N\times z)$ indicates the influence of the samples in class i. If clustering results show that the number of samples in cluster i is larger than in cluster k, then

$$\sum_{t=1}^{N\times z} u_{it}/(N\times z) > \sum_{t=1}^{N\times z} u_{kj}/(N\times z),$$

i.e., the influence of m_i is larger than m_k in measuring the between separability. The weight $u_{it}/(N\times z)$ indicates the influence of the t-th sample in class i. If $u_{it}/(N\times z) > u_{kt}/(N\times z)$, then the k-th sample favors in class i. Hence, the corresponding weights in the within measure is larger.

Furthermore, it is easy to observe that the scatter matrices of LDA are special cases of the scatter matrices of FLDA [3], i.e., $u_{it} = 1$ and $u_{kt} = 0, k \neq i$ when x_t is the training sample in class i. In [3], the clustering performance of FLDA outperforms the clustering performance of principal component analysis (PCA) and independent component analysis (ICA).

III. A SPECTRAL AND SPATIAL FEATURE EXTRACTION METHOD

In this section, we propose a semi-information based LDA (SLDA) algorithm. The purpose of incorporating the semi-information in feature extraction is to increase the useable samples. In this study, the posteriori probabilities by applying the Gaussian classifier are used to form the weights in the scatter matrices of FLDA. Then the semi-information then can be both used to adjust the extracted direction, and the classification performance will be improved.

After applying the Gaussian classifier [4], the class-conditional probability density function of the unknown sample x_j is

$$p(x_j \mid i) = \frac{1}{(2\pi)^{d/2} \mid \Sigma_i \mid^{1/2}} \exp\left(-\frac{1}{2}(x_j - m_i)^T \Sigma_i^{-1}(x_j - m_i)\right)$$

where $m_i = \frac{1}{N_i}\sum_{\ell=1}^{N_i} x_\ell^{(i)}$ is the mean of class i,

$$\Sigma_i = \frac{1}{N_i}\sum_{\ell=1}^{N_i}(x_\ell^{(i)} - m_i)(x_\ell^{(i)} - m_i)^T$$

is the $d \times d$ covariance matrix, and $|\Sigma_i|$ denotes the determinant of Σ_i. Then x_j is distinguished to class i, if

$$p(x_j \mid i)p(i) \geq p(x_j \mid k)p(k)$$

for all $k \neq i$, where $p(i)$ is the priori probability of class i.

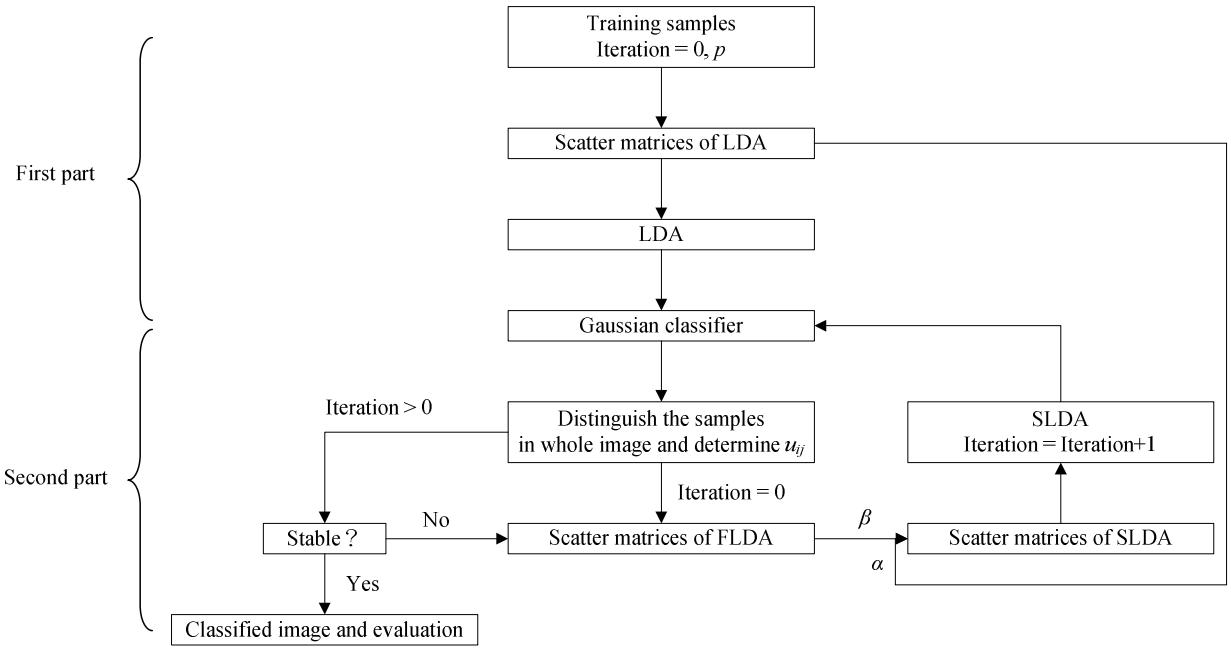

Figure 1. The framework of the proposed method, SLDA, which is based on semi-information.

In SLDA, the membership values of the semi-scatter matrices are defined as the posterior probabilities. According to the Bayes rule, the membership value u_{iq} of the unknown sample x_q, is defined as

$$u_{iq} = p(i \mid x_q) = \frac{p(x_q \mid i)p(i)}{\sum_{i=1}^{L} p(x_q \mid i)p(i)} .$$

for $i = 1, \ldots, L$, and $q = 1, \ldots, N \times z$.

The between scatter matrix S_b^{SLDA} and the within scatter matrix S_w^{SLDA} are defined as follows:

$$S_b^{SLDA} = \alpha S_b^{LDA} + \beta S_b^{FLDA} \tag{5}$$

and

$$S_w^{SLDA} = \alpha S_w^{LDA} + \beta S_w^{FLDA} \tag{6}$$

where α and β are two parameters to control the influences of the scatter matrices of LDA and semi-scatter matrices of FLDA. In this paper, the *k*-fold cross validation method is used to determined the proper parameters, α and β.

The features of SLDA can be obtained by solving the following generalized eigenvalue problem: $S_b^{SLDA} v_z = \lambda_z S_w^{SLDA} v$. The extracted eigenvectors form the transformation matrix of SLDA, i.e.,

$$A^{SLDA} = [v_1, v_2, ..., v_p].$$

One can find that if $\beta = 0$, then

$$A^{SLDA} = A^{LDA} .$$

TABLE I. THE ALGORITHM OF SLDA

Step 1:	Set the number of extracted features $p \le d$. Use the transformation A^{LDA} to project the samples in the image and obtain the semi-labels by the Gaussian classifier.
Step 2:	Compute u_{it} for every sample x_t in the whole image.
Step 3:	Compute S_b^{FLDA} and S_w^{FLDA}.
Step 4:	Compute S_b^{SLDA} and S_w^{SLDA} by multiplying the parameters α and β.
Step 5:	Solve the eignevalue problem $S_b^{SLDA} v_z = \lambda_z S_w^{SLDA} v_z$, $z = 1, \ldots, d$ with $\lambda_1 \ge \lambda_2 \ge \cdots \ge \lambda_d$.
Step 6:	The transformation function from the original space to the reduced subspace is defined by $A^{SLDA} = [v_1, v_2, \ldots, v_p]$.
Step 7:	Use the transformation A^{SLDA} to project the samples in the image and obtain the new semi-labels by the Gaussian classifier.
Step 8:	Repeat steps 2 and 7 until the iteration and the above iteration is below a certain tolerance value or it's no longer decreasing.

Fig. 1 is the framework of the proposed method, SLDA, which is based on semi-information. Given the training samples and determine the reduced dimensionality *p*. In the first part, the scatter matrices of LDA are computed and LDA is used for feature extraction. After applying the Gaussian classifier, the semi-labels and membership values can be obtained, and the scatter matrices of FLDA in the second part can be computed. By multiplying the parameters α and β, the scatter matrices of SLDA can be computed. After applying the SLDA and the Gaussian classifier, the new semi-labels and membership values can be obtained. If the change rate of semi-

labels is less than a threshold, then stop the iteration. Otherwise, continue the second part until the change rate of semi-labels is less than a threshold. The algorithm of SLDA is described in the Table I.

IV. Experimental Results

A. Experimental Data and Design

In this study, two real data sets are applied to evaluate the classification performances. They are the Indian Pine site (IPS): a mixed forest/agricultural site in Indiana [5] and the Washington, D.C. Mall hyperspectral image [5] as an urban site.

The IPS dataset was gathered by a sensor known as the Airborne Visible/Infrared Imaging Spectrometer (AVIRIS). This dataset was obtained from an aircraft flown at 65000ft. altitude and operated by the NASA/Jet Propulsion Laboratory, with a size of 145×145 pixels and has 220 spectral bands measuring approximately 20m across the ground. The grayscale IR image and ground truth of IPS are shown in Figs. 2 and 3, respectively. There are 9 different land-cover classes available in the original ground-truth. 9 categories, Corn – no till, Corn – min till, Grass / Pasture, Grass / Trees, Hay – windrowed, Soybean – no till, Soybean – min till, Soybean – clean till, Woods, would be used in our experiments.

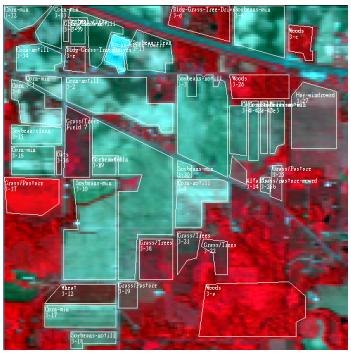

Figure 2. A portion of the Indian pine site image with a size of 145×145 pixels.

Figure 3. The ground truth of Indian pine site dataset.

The second data set, the Washington, D.C. Mall (DC) from an urban area, is a Hyperspectral Digital Imagery Collection Experiment (HYDICE) airborne hyperspectral data flightline over the Washington, DC Mall. Two hundred and ten bands were collected in the 0.4–2.4 μm region of the visible and infrared spectrum. Some water absorption channels are discarded, resulting in 191 channels. The dataset is available in the student CD-ROM of (Landgrebe, 2003). In our experiment, there are 7 classes, grass (class 1), tree (class 2), roof (class 3), water (class 4), road (class 5), trail (class 6), and shadow (class 7). The grayscale IR image of a portion of the image and the corresponding seven categories are shown in Fig. 4.

No.	Category
1	grass
2	tree
3	roof
4	water
5	road
6	trail
7	shadow

Figure 4. The false-color IR image of a portion of Washington, D.C. Mall image with a size of 205×307 pixels. There are seven categories, grass, tree, roof, water, road, trail, and shadow.

In the experiment, for investigating the influence of training sample size to the dimensionality, three distinct subsets, which N_i is the number of each class training samples, d is the number of dimension, and N is the number of total training samples. N_u=20 < N < d (case 1), N_u=40 < d < N (case 2), and d < N_u=300 < N (case 3), will be discussed in these two hyperspectral image data sets. For example, the Indian Pine site (IPS) dataset. In case 1, N_u = 20 < N =180 < d is a so called ill-posed classification situation, which means data dimensionality exceeds the total number of independent training samples in every class. In case 2, N_u = 40 < d < N is a so called poorly-posed classification situation, which means data dimensionality is greater than or comparable to the number of (independent) per-class representative training samples, but smaller than the total number of representative samples. In case 3, there are enough independent training samples. The MultiSpec [5] was used to select training and testing samples (100 testing samples per class) randomly in our experiments [6]-[8].

In the experiments, the classification performances by applying LDA and SLDA with the Gaussian classifier are compared. The grid search with k-fold cross validation is used to find the proper parameters α and β within a set $\{0, 0.1, 0.2, \ldots, 2\}$.

B. Results

In the experimental results, the classification accuracies in percentages for two different data sets are showed in Table II-IV. Because of LDA only can extract L–1 (number of classes minus one) features. For example, the Indian Pine site (IPS) dataset has 9 categories, so LDA only can extract 8 features. As result of `experiment we can know that the number of dimensionality with the classification accuracies has weak correlation. The classification performances by applying our proposed SLDA are higher than the classification performances by applying LDA in cases 1 and 2. However, in case 3 (Table IV), the accuracies by applying our proposed method are similar to that by applying LDA. Hence, in the small sample

size problem, the proposed method can yield a better classification performance than LDA.

Fig. 5-7 and 8-10 show the classification maps of the IPS and DC data sets by applying LDA and SLDA with the Gaussian classifier in three cases, respectively. From Fig. 5-6 and 8-9, i.e., case 1 and case 2, the proposed method SLDA can not only increase the classification performance but also decrease the imprecise estimation of samples, especially, "Woods," "Grass/trees," "Grass/pasture," "Soybeans-clean till," and "Hay-windowed" for IPS dataset, and all classes for DC dataset. Similarly, the classification maps are similar by applying LDA and SLDA for these two data sets except the "trail" in DC dataset. For this class ("trail"), SLDA outperforms LDA.

TABLE II. THE ACCURACY IN PERCENTAGES FOR TWO DIFFERENT DATA SETS IN CASE 1, N_U=20. THE NUMBER IN BRACKET IS THE REDUCED DIMENSIONALITY

FE	IPS	DC
LDA	55.89% (7)	47.71% (3)
SLDA	69.56% (8)	90.86% (4)

V. CONCLUSION

In this paper, a semi-information based LDA (SLDA) algorithm is proposed. The posteriors after applying the Gaussian classifier were used to determine the membership values of FLDA. Combining the scatter matrices of LDA and semi-scatter matrices of FLDA, the scatter matrices of SLDA are computed. According to the experiments on the Washington DC Mall image and the Indian Pine Site image data sets, SLDA can yield a better classification performance than LDA when sampling size is small.

ACKNOWLEDGMENT

The authors would like to thank Dr. Landgrebe for providing the Indian Pines site and The Washington DC Mall data sets. This work was supported in part by the National Science Council, Taiwan, under Grant NSC 98-2221-E-142-005.

Abstract—**Amid the rapid advance of technologies in recent years, people live at fast paces and suffer invisible pressures in family, at workplace as well as in school. Emotional undulation tends easily to lead to melancholy. Statistically, the number of bipolar disorder sufferers in the last three years was 40 times that in the past 10 years. What should be more attended to is that 90 percent of suicide cases involved a history of "depression" or "bipolar disorder". Currently, to assess the mental pressure on an individual, questionnaires or interviews are applied and determination is made by physician's personal experiences. The development of a more viable quantitative method for assessing individual psychological pressure would facilitate self-management of health. This paper thus aims to CCD-capture human face, measure user's physiological data using BtECG and determine his/her emotional status by using the fuzzy theory based on the analysis of human face, eyes and Heart Rate Variability. The features of measurements and the determination are also fed to database, which can serve as reference for doctors in consulting related psychological disorders in future.**

Keywords-component: Bipolar Disorder, Fuzzy Inference, Heart Rate Variability, BtECG, Emotion State

I. INTRODUCTION

Living at fast paces and in a hectic society, people today suffer invisible pressures in family, at workplace as well as in school. They find themselves disoriented from motional undulation and, additionally, are liable to be in an ill cycle of melancholy due to complex interpersonal competitions which arise when mental adaption or external support is not complete. As a result, working efficiency drops, more frustration and setbacks follow with the ill cycle, causing not only psychological problems but also physiological disorders.

The object of this paper is to develop an emotion recognition system by combining the analysis of Heart Rate Variability (HRV) and the recognition of facial expressions. As psychological disorders are relatively difficult to detect in normal conditions, it is hope to determine, as early as possible, the presence of these disorders by measurement of HRV and recognition of facial expressions. Or, otherwise, the abnormal emotions due to illness are hoped to be diagnosed as early as possible, in order to prevent tragedies. With the development of the system, not only is it possible to measure user's emotional status, but also can the measurements be saved in the database as future reference for doctors in case medical aid is sought.

II. DOCUMENTARY REVIEW AND EXPLORATION

Sufferers of psychological disorders like depression and bipolar disorder increase in recent years. According to statistics, the number of bipolar disorder sufferers in the last three years was 40 times that in the past 10 years. More importantly, 90 percent of suicide cases involved a history of "depression" or "bipolar disorder". According to data from the Suicide Prevention Center of Department of Health, averagely one person commits suicide in every two hours and two minutes. Last year 1,472,000 Taiwan residents "thought of" ending their lives, with 416,000 people "did attempt to end their lives", of whom 130,000 "attempted more than once". Depression occurring on children or teenagers generally differs from that on adults: children tend not to talk about their own symptoms or describe their moods using the terms like melancholy; but they are more likely to express it through behaviors. In contrast, the depression in the elderly is obscure partly because it is traditionally believed that the elderly are losing their mobility and look less lively such that they are often thought to be simply getting old by their offspring, with the potential symptoms of depression being ignored. Hence the development of emotion recognition system becomes necessary.

Reference is first made to Heart Rate Variability, HRV. Heart Rate Variability means the beat-to-beat variation in time within a certain period of sinus rhythm, i.e., the analysis of the magnitude and regularity of the variation in heart rate [1]. Unlike mean heart rate variance which is expressed in minute, the HRV analysis examines the nuance time variance in each cycle of heartbeat and its regularity. Because heart rate is subject to many effects like breathing, blood pressure, endocrine and emotion, it can be used to observe the interaction between autonomic nerve and sino-atrial node. As well as a tool to analyze the conditions of cardiovascular diseases, it is a valuable index in predicting sudden cardiac death and cardiac arrhythmia.

The common methods of HRV analysis include Time Domain Methods and Frequency Domain Methods [1].

1. Time Domain Methods:

This can be divided in statistic and diagram approaches. Overall, time domain methods use indices that depict the shapes of standard deviation of all normal to normal R-R intervals (SDNN), and the root mean square of successive

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

differences between adjacent normal cycles (RMSSD), quantitatively HRV RMSSD with broader shape indicates bigger HRV, and vice versa.

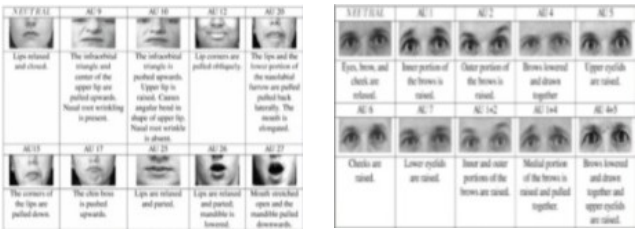
2. Frequency Domain Methods:

The common methods of transforming HRV curves into spectra include Fast Fourier Transform (FFT). Frequency domain methods make differences in the meaning of analytic results between long periods and short ones. With analyses of shorter periods (5min), it needs to control the well surrounding conditions so as to avoid that affecting autonomic nervous activities. With analyses of longer periods (24hr), as it is difficult to control the factors like smoking, drinking and emotional undulation, only the overall condition can be generally reflected. In their research, Akselrod discovered in 1981, that the power spectra of HRV features derived from ECG signals obtained by non-invasive measuring which have further been processed by Fourier transform can reflect the control of sympathetic and parasympathetic nervous systems on physiological mechanisms. By doing spectrum analysis on R-R interval, it is possible to observe three noticeable spectral peaks, which are high frequency (HF), low frequency (LF) and very-low frequency (VLF) and which are reflected in HRV. In 1996, the American Heart Association (AHA) set new criteria for the bandwidths of HRV, which are 0.15-0.4 Hz as HF bands, 0.04-0.15Hz as LF bands and 0.003-0.04Hz as VLF bands. The LF represents sympathetic nervous activity, HF for parasympathetic nervous activity and VLF for temperature regulation, Rennin-Agiotensin-Aldosterone System (RAA System) and part of parasympathetic nervous functions. HRV is controlled by autonomic nervous system (ANS), whereby to maintain the body balance, and the variance in heartbeat interval is affected by sympathetic and parasympathetic nervous systems; hence, the study of HRV can serve as an index for the autonomic nervous system [2].

HRV analysis, as a physiological index, began to catch doctors' attention in recent years. It has been used to monitor the regulation of human body by the autonomic nervous system, also served as a reference index in the death rate due to cardiovascular diseases. The commonly seen indices for death due to cardiovascular diseases are the LF rise of sympathetic and partly parasympathetic nervous regulations, and the HF decrease of parasympathetic nervous regulation. When the diagnosis is a likely coronary artery disease, it often further takes cardiac catheterization. Patients are often seen with emotions like anxiety and unease and become anxious or fearful for the dangers and side effects that may occur during the examination or the uncertainty of examination results, where they need appropriate caring guide to mitigate the anxiety. These emotions are potential pressures to patients of cardiovascular diseases. In anxiety, the rate of occurrence of sudden heart diseases also increases while the HRV is seen decreasing. Research showed that in patients of Myocardial Infarction, the emotions of anxiety and panic is associated with HRV decrease, and that both anxiety and melancholy decrease HRV and are related to the increase in risk of cardiovascular death in patients of coronary artery disease and irregular heartbeats. When Zen meditation is used to intervene in the measurement of characteristic anxiety scale and the changes of HRV analysis, the findings were that in sufferers of high-degree anxiety who underwent Zen meditation training and concentrated, the anxiety decreased the scores on the scale, the scores on characteristic anxiety scale were reversely related to slow alpha wave ($r=-0.482$, $p<0.05$)and positively related to HF index of HRV ($r=0.555$,$p<0.01$), but were not significantly related to LF and LF/HF ratio ($r=0.305$,$p<0.17$). It was reported that before cardiac catheterization, both contextual anxiety score and characteristic anxiety score in men were lower than in women, where the characteristic anxiety scale and HRV were significantly different in terms of gender ($t=-2.44$,$p<0.019$), while contextual anxiety scores were insignificant statistically. Also, in the gender differences in HRV analysis, it was seen that SDNN of HRV by time domain methods and HF and LF indices in women were all significantly greater than in men ($p<0.05$). Mental stress causes unstable emotions like negative one such as dysphoria, anger and discontentment, which affect the autonomic nervous system, stimulate the changes in sympathetic and parasympathetic nervous activities and are reflected in heart rate. In the research in short-period R-R interval and spectra analysis of cardiovascular systolic pressure, which explored the effects of psychological stress on autonomic nervous system and circulation system, the finding was that when concentrating, the subjects had higher-than-usual energy in the LF bands. That same study observed the correlations between skin temperature, vascular changes and sympathetic nervous activities using the indices of HRV, changes in skin temperature and vasomotor nervous activities of peripheral vessels, in the condition of mental stress and biofeedback. It was believed in that document that the degree of sympathetic nervous activities could serve as an index for durability to pressures. It was reported that under mental stress, HF energy dropped greatly and LF/HF noticeably rose and was significant statistically ($P<0.05$); when mental stress decreased, the LF/HF ratios lowered notably and was significant statistically ($P<0.05$). It is thus clear that when mental stress is strong, sympathetic nervous activities would increase by far, which can serve as an index for the assessment of the condition of mental stress, further to assist in clinic testing and diagnosis.

Now we talk about the recognition of facial emotions. Ekman and Friesen were the first to develop Facial Action Coding System (FACS), which defined 44 different Action Units (AU) by the principle that man pulls different facial muscles when making different expressions [3]. As Fig.1 shows, Fig.(a) is action units of upper face and some combinations of action units, and Fig.(b) action units of lower face. By combining certain action units, human facial expressions can be depicted. The FACS theory has been applied in most research to identify facial expressions. While applying it, a study made a difference in the capturing of facial features and the selection of recognition and sorting methods [4]. It divided the facial features in constant features and transient ones; the former were the changes in eyes and mouth and the latter were the wrinkle changes in between the

brows, cheeks and upper mouth edges. That study manually set the initial positions for these feature points, followed by tracking the changes of these points and then recognizing them with Artificial Neural Network [4]. Another study used Optical flow to track the movement of multiple feature points, which were set in a first image of a sequence of images. The characteristic vectors that were produced combining the feature point displacements in the first image and the last one were used to identify different action units and different facial expressions [5].



(a) (b)

Figure 1. Facial Action Units [5]

Feature capturing involves two aspects: the holistic approach and the local approach. The holistic approach is about first obtaining feature areas or feature points, whereby to detect deformation or movement, such as optical flow and characteristic tracking [6]. The local approach divides human face in several key blocks and then extracts characteristic information from them for determining the action [7].

This paper includes four chapters, first chapter is introduction, second is documentary review and exploration, the third is methodology and steps, we introduce hardware architecture and our methods, the fourth is experiment results, and the last is conclusions.

III. METHODOLOGY AND STEPS

Figure 2. Diagram of system framework

The development of emotion recognition system plays an important role in the research of psychological disorders and health care. This system will be discussed in separate sections: software and hardware. The hardware comprises an embedded system as the core, which works with Webcam to capture facial images and with Blue-tooth electrocardiograph (BtECG), to measure physiological signals. The software incorporates Webcam driver, Fuzzy Inference method, HRV analysis, facial detection and the techniques of eye and mouth state recognition.

In the system, the Webcam captures facial images; for reference values used to determine by the Fuzzy Inference method, thirteen features, as follows, are used: distance between eyeballs, number of changes in eyeball height, the extent to which the mouse opens, SDNN, Standard deviation of the averages of NN intervals in all 5-minute segments of the entire recording (SDANN), RMSSD, Number of pairs of adjacent NN intervals differing by more than 50 ms in the entire recording (NN50 count), NN50 count divided by the total number of all NN intervals (pNN50), Mean RR intervals (RRI-Mean), Standard deviation of differences between adjacent RR intervals (SDSD), Standard deviation of all normal to normal intervals index (SDNN index), VLF, LF, HF and analysis of LF/HF power. The job of embedded system is processing the measured HRV features and the imaged the Webcam sent, and detecting user's facial positions and identifying the state of the eyes and the mouth by facial detection and eye-and-mouth state identification. In this paper to combine the Fuzzy Inference method to distinguish the differences in degree of emotion based on the features of the eyes, the mouth and HRV. The system outputs the results of determination to a screen or informs relevant persons by texting. Elaboration will now be made on the software.

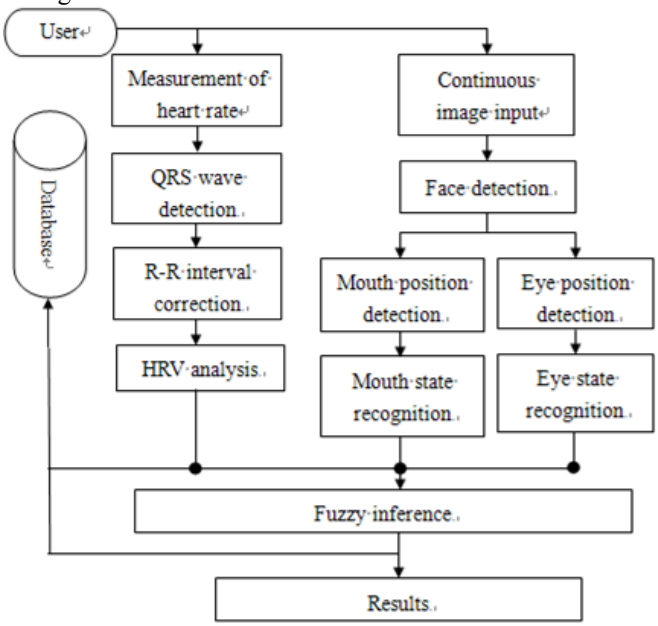


Figure 3. Flow chart for emotion recognition system

The flow chart of this paper is shown in Fig.3. To begin with, relevant data are downloaded to the embedded system via a USB device for use. That is followed by developing USB Webcam driver codes in the embedded system to enable the WINCE platform to drive Webcam to capture images, which will be saved in the embedded system. Again, this is followed by pre-process of the user's image, which aims to eliminate the influences of indoor light and noises in order to enhance the accuracy of capturing. A technique of graph identification is used to detect the state of the eyes and the mouth and then a BtECG is used to transmit physiological signals to the embedded system. The QRS-wave detection is employed to make correction to R-R interval before analyzing HRV by time domain methods and frequency domain methods with the features. When characteristic identification has been conducted, the fuzzy inference method is applied to combine the HRV features and the features on images, with their

degrees distinguished. Lastly, based on different degrees, the system analyzes and determines the user's emotional state.
In respect of above flow, the research method is divided in below steps:

A. Facial detection

(1) Preprocessing: the system employs an image pro-process, of which the object is to eliminate noise interference in the image and to adjust brightness as well as remove the noise.

(2) Skin region detection:

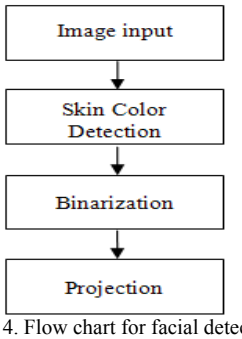

Figure 4. Flow chart for facial detection

Detection of facial and eye position is the first and important step of eye status recognition. There are many detection methods of facial position; but this paper employs facial complexion in detection. Also in this paper, the images having been processed by binarization are taken to locate the face after horizontal and vertical projection. The method of complexion detection uses the information on complexion to capture the face in an image, discerning it from the background. An image is transformed from the RGB space to the YC_bC_r space.

$$\begin{bmatrix} Y \\ C_b \\ C_r \end{bmatrix} = \begin{bmatrix} 0.299 & 0.587 & 0.114 \\ -0.1687 & -0.3312 & 0.5 \\ 0.5 & -0.4183 & 0.0816 \end{bmatrix} \begin{bmatrix} R \\ G \\ B \end{bmatrix} \quad (1)$$

$$60 < Y < 255 \quad (2)$$

$$25 < C_b < 0 \quad (3)$$

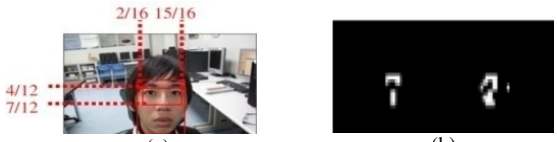
$$10 < C_r < 45 \quad (4)$$

As the complexion has a fixed zonal distribution in the YC_bC_r space, this paper sets the pixels that distribute in such zone as 1 and the values in this zone as 0. As the face occupies the largest one of a great number of blocks taken in the image by complexion, the method of projection is used to identify the complexion block of biggest area. The area is gradually closed by morphological operations algorithm, and the separate pixels are conjoined through expansion; further, the areas that are weakly connected are separated by erosion to obtain binary images.

B. The Detection of Feature Point Position

(1)Eye detection:

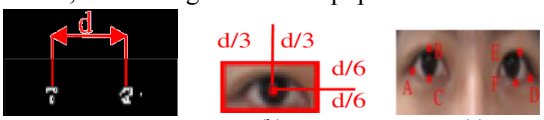
The length of human face is about 1.2 times of the width. According to the facial features proportion, when starting from the top of the face, the pupil will be at the 4/12 to 7/12 of the face length. Starting from the left of the face, the pupil will be at the 2/16 to 15/16 of the face width. We find the pupil in this area. Compared with the nearby area, the pupil is of darker color. Thus we use the dynamic method to find the critical value. First calculate the grayscale histogram of this area. Since the pixels of the pupil is within the 1% of the darkest area, we calculate from the grayscale of 0, accumulate to the 1% of the total pixels of this area and set the value of this pixel as the critical value. When the pixel value of the area is smaller than the critical value, set it as 1, otherwise set as 0, as shown in Fig. 5.



(a) (b)

Figure 5. (a)The approximate area of the eye (b)The result of the binarization of the dynamic critical value of the pupil area

Then we separate the eye area into right and left two sections. Raise the left pupil as an example, in the process of binarization of the pupil, it may also binarize the eyebrow and hair near the eye. This will affect our action of finding the position of the pupil. However, because the eyebrow and hair are above the pupil, our algorithm may search the first pixel of 1' in a bottom up way. And then use this pixel as starting point, which, together with two pixels on the left and right, and 5 pixels above will generate a 5*5 area. And then calculate the center of gravity of all the pixel value 1's pixels in this area. We find that this center of gravity is the position of the pupil. For the same reason, we can find the right pupil with the same method. And then use the distance(d) of the two pupils as in Fig. 6, follow the relationship of the human face features' proportion to generate the area of the eye. The eye area is at the place where the pupil is the center, go up and downwards 1/6 distance, left and rightwards 1/3 pupil distance area.



(a) (b) (c)

Figure 6. (a)Pupil distance d (b)the eye area detection result (c)the feature point of the outer corner of the eye.

After finding the eye area, we utilize the pixel center of gravity obtained by the above 5*5 area. As this pixel center of gravity is always inside the pupil area and the grayscale value is similar to that of the other pixels in the pupil, we use the Region Growing method to use the pixel center of gravity as seed to grow complete pupil area. In this way, we will know the coordinates of the uppermost pixel point and that of the bottommost pixel point.

When we find the top and bottom threshold of the pupil, we will find the outer corner of the eye to be the other feature point for identification. Use the top and bottom feature points as the upper and lower bounds along the y axis. Then use the pixel center of gravity as the starting point and seed along the

x axis. Similarly we use the Region Growing method along the outer corner of the eye orderly. When scanning the connecting zone of the pupil and the white of the eye, due to the fact that the white of the eye is not the pupil area, the grayscale may change greatly. Record this pixel point as the first point, then use the next pixel point, i.e. the pixel point inside the white of the eye as seed for processing. Similarly when scanning the connecting zone of the white of the eye and the skin; the grayscale may change greatly. Record this pixel point as the second point. Repeat these processing steps till the boundary of the eye area. Finally find the outermost point of the points we record. This is the feature point of the outer corner of the eye we need, as shown in Fig. 6(c).

(2) Mouth detection:

When acquiring the feature point of the mouth, we first use the facial features proportion to generate the approximate area of the mouth. The position of the mouth will be at the 7/10 to 9/10 face length and 2/6 to 5/6 face width area when starting from the top of the face, as shown in Fig. 7. As the color of the lip is redder than other skin, we use this information to obtain the feature point of the mouth. First convert the human face image from RGB color space to HSV color space. In this way we can separate the color and the brightness to avoid the influence from the outside light source. Then use (1) to transform the H (hue) value in the HSV color space. The equation is as follows:

$$f(h)=\begin{cases}1-\dfrac{(h-h_0)^2}{w^2}, & |h-h_0|\le w\\ 0 & |h-h_0|\ge w\end{cases} \qquad (5)$$

Where the h is the h value of the mouth area, h_0 is the offset value defined according to the hue. Here we set it as 1/3. The w is set as 0.60. This equation can be viewed as use the h_0 as center and use w to filter the area that can be accepted. Farther the distance between h value and h_0 of the mouth area, smaller the value will be. The value of f (h) is between 0 and 1. Then we amplify the f (h) value of the mouth area. Round off the f (h)*100 value into integer and amplify it 100 times to produce histogram as shown in Fig. 8. We found from the observation that when the value of f (h)*100 is between 50 and 100, there is a peak as the skin. There is a point on the left-hand side with a large slope. When the gradient is gentle, it is suitable to be the critical value to separate the mouth and the skin. Thus if the f (h)*100 value is smaller than this critical value, it is the mouth area. Set the pixel value as 1, otherwise set it as 0. Binarize the image as shown in Fig. 9.

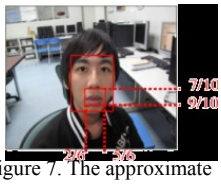


Figure 7. The approximate mouth area

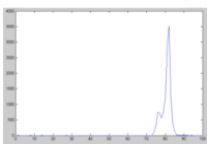

Figure 8. f (h)*100 histogram

Figure 9. Mouth area binarization result.

As the mouth has the horizontal edge direction tendency, we use the horizontal Sobel wave filter to generate the horizontal direction edge of the mouth area and do the binarization. Then search from left to right to find the point where the first mouth binarization and Sobel binarization pixel value both are 1. This is the feature point G. Search from right to left to find the point where the first mouth binarization and Sobel binarization pixel value both are 1. This is the feature point I. From the horizontal direction center point of the left and right feature points, 2 pixels on the right and left, there will be 5 horizontal pixels in total. Search top-down to find the point where the first in these five horizontal pixels, the mouth binarization and Sobel binarization pixel value both are 1. This is the feature point H. Search bottom- up to find the point where the first in these five horizontal pixels, the mouth binarization and Sobel binarization pixel value both are 1. This is the feature point J as shown in Fig. 11.

Figure 10. Mouth Sobel binarization result

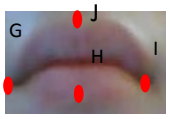

Figure 11. Mouth feature points

C. Heart Rate Variation Analysis

Regarding the studies of the periodicity of the heart beat, they mostly use the continuous R-R interval as the continuous period of the heart beat. The R wave of the electrocardiogram is the most commonly used in the heart rate variation analysis. By calculating the time interval between the RR, we get a series of numbers. The heart rate variation analysis usually excludes the Arrhythmia case. It focuses on the slight heart rate variation of the normal rhythm for study.

First, we stick the sticky thread on the user's left and right wrist, and then use the BtEEG to measure the physical signal of the user. The measuring time is 5 minutes. Transfer the physical signal to the mosaic system through the BtEEG. To reduce the interference of the heart rate variation result, we keep the environment quiet. In this paper we use the method proposed by Willis J. Tompkins to detect QRS wave. This method follows the frequency range of the signal to filter out the noise to get the QRS wave. We can find the position of the R wave through the QRS wave. Fig. 12 is the flow chart of using the Willis J. Tompkins' method detecting QRS wave.

- Band-pass integer filter: As the center frequency of QRS wave is about 17Hz, we use a low-pass filter (25Hz) and a high-pass filter (15Hz) to form a band-pass integer filter and keep the frequency between 15 and 25Hz. In this way, we can get a clearer QRS complex wave and reduce the T wave substantially.
- Differential: After the signal passes the band-pass integer filter, we can use differential to make features of QRS wave more high-lighted. After differential, we can easily distinguish the R wave.
- Square: In order to convert the signal into the positive and make high-frequency part of the QRS wave more obvious, we use square to make it stand out.
- The acquisition of R wave's position: We get the peak value of R wave by adjusting the threshold dynamically. However, someone's T wave is higher than his R wave or only slightly

lower than his R wave. We have to filter out T wave before catching R wave, and then search the peak value of R wave. In this way, we can find the next R wave and obtain the R-R interval.

However, R-R interval will change because of age or certain diseases of the user. Therefore, this program will use the above method to find the R-R interval, and modify it by using the methods proposed by [7]. The specific steps are as follows:

1. Expand the above R-R interval*0.6 to the left of R point and R-R interval * 0.3 to the right of R point. Repeat this step and select 20 heartbeats randomly.
2. Use the method of Signal averaging to make 20 heartbeats' electrocardiogram point at R point. After getting the cumulative average, we should calculate the related feature value for identification.

At present, there are two kinds of methods on analysis of heart rate variability, namely time domain analysis and frequency domain analysis. Time domain analysis is to record the statistical analysis result of R-R interval between two neighboring heart rates, while frequency domain analysis is to use the fast Fourier transform to convert the R-R interval from time domain into frequency domain for Power Spectral Density (PSD) analysis. This program will analyze time domain and frequency domain, and make time domain analysis through the following features

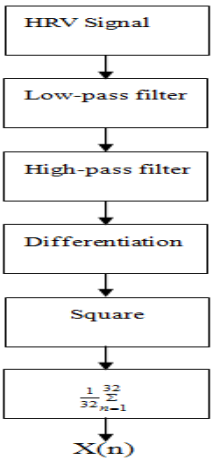

Figure 12. The flow chart of using Willis J. Tompkins' method to detect QRS wave[8].

1. SDNN: Standard deviation of Sinus rhythm, with the clinical significance to estimate the overall heart rate variability.
2. SDANN: Standard deviation of the interval average of all normal heartbeats every five minutes.
3. RMSSD: The square and the average square root of neighboring R-R interval difference.
4. NN50 count: The count of the time interval of each pair of neighboring normal heart rates that is more than 50 milliseconds.
5. pNN50: NN50 count divides all the normal heartbeat intervals in the ECG.
6. RRI-Mean: The average RR interval every 5 minutes.
7. SDSD: Standard deviation of differences between adjacent RR intervals.
8. SDNN index: Calculation of the standard deviation of normal heartbeat every 5 minutes and then get the average value.

This program adopts the above eight features to analyze time domain, and uses the Bluetooth ECG machine of Yang Yin Inc. to conduct a five-minute measurement of the user.

Frequency domain analysis:

We use the fast Fourier transform to convert the R-R interval from time domain into frequency domain and then display it in the way of Power Spectral Density (PSD). According to the size of the different frequency, Power Spectral is divided into total power, ultra-low frequency, low frequency, high frequency and low frequency vs. high frequency. This program will focus on analysis of ultra- low frequency, low frequency, high frequency and low frequency vs. high frequency.

D. Feature Identification

After getting the position of various features and the features of heart rate variability, we will make the feature acquisition calculation. This program touches upon the values of thirteen features, namely, the distance between eyeballs, the size of open mouth, times of eyeball height changes, SDNN, SDANN, RMSSD, NN50 count, pNN50, RRI-Mean, SDSD, SDNN index, ultra-low frequency, low frequency and high frequency vs. low frequency. As the above feature values will vary in different emotional states, the distance between eyeballs and times of eyeball height changes will vary with the emotion. We can analyze the distance between eyeballs through (2):

$$eyed = \frac{|B-C|}{d} \tag{6}$$

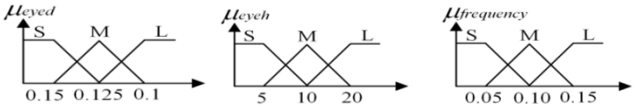
As is shown in Fig. 7 (c), $|B-C|$ is the vertical distance from B to C of the feature point in the right eye, while "d" is the distance between two pupils in Fig. 7(a). In different emotional states, two eyes do the same action, so we make judgment based on the right eye. We analyze the mouth openness through the Euler distance, which is the vertical distance from H to J in Fig. 11. Accordingly, there are also different conditions on heart rate variability, for example, when depressed, SDNN value will be lower than usual, and the high frequency energy will plummet. Low-frequency will increase remarkably when there is huge mental stress, and it will decrease significantly when the mental stress is decreased. This program will analyze four emotional states, normal, happy, sad and angry through Fuzzy Inference method. We will use the thirteen features to find out the attribution between the input and output variables. First, we will set up the semantic formula of fuzzy inference on input and output variables:

(1) The distance between eyeballs: If it is smaller than 0.125 cm , it is diagnosed as mild eye openness(S), from 0.1 to 0.15 cm as moderate eye openness (M), and higher than 0.125 cm as high eye openness (L), whose membership function is μ_{eyed}

(2)Times of the height change of eyeballs: If it is less than 10 times, it is small amount of change (S), 5 to 20 times is

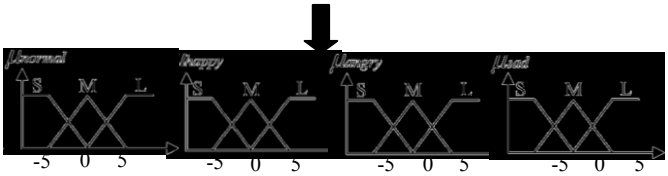
moderate changes (M), and more than 10 times is large amount of change (L), whose membership function is μ_{eyeh} (3)The frequency: if it is higher than 0.15, it is called high frequency, from 0.05 to 0.15 is called low frequency, and lower than 0.05 is called ultra-low frequency, whose membership function is $\mu_{frequenct}$ (4)SDNN: the attribution function is μ_{SDNN} (5)SDANN: the attribution function is μ_{SDANN} (6)RMSSD: the attribution function is μ_{RMSSD} (7)NN50 count: the attribution function is $\mu_{NN50count}$ (8)pNN50:the attribution function is μ_{pnn50} (9)RRI-Mean: the attribution function is $\mu_{RRI-Mean}$ (10)SDSD: the attribution function i μ_{SDSD} (11)SDNN index: the attribution function is $\mu_{SDNNINDEX}$ (12)Low frequency vs. high frequency: the attribution function is $\mu_{LF/HF}$ (13)The mouth openness: If the distance from H to J is less than 1.48 cm, it is slight openness (S), from 1 to 2.21 cm, it is moderate openness (M), and larger than 1.48 cm is large openness (L), whose attribution function is μ_{mouth} .

In the following construction of fuzzy rules, we can use semantic fuzzy rules obtained by the doctor or through learning, and finally get the fuzzy sets. Then we use Center of Gravity Method for defuzzification. We can also distinguish the four emotions into three levels, that is slight(S), moderate(M) and large(L). Fig. 13 is the attribution function of the above features and each kind of emotion.



(a) (b) (c)

(a) The attribution function of the distance between eyeballs. (b)The attribution function of times change of eyeball height. (c)The attribution function of the heart rate feature of HRV.



(d)Normal (e)Happy (f) Angry (g) Sad

Figure 13. The flow chart of emotional state inference.

E. The Output Result

Based on the input image and the features of heart rate variability, this program shows the emotional states of the current users by using inference results of Fuzzy Inference, that is, normal, happy, sad and angry. What's more, this program stores the image, features of heart rate variability and emotional states into the database, which can provide the reference for doctors in case of medical treatment in the future.

IV. EXPERIMENT RESULTS

The results of this paper, we propose an intelligent method to construct the emotion recognition system for testing and discussion its recognition rate. Herein, the CCD camera is QuickCam™ Pro 4000 of Logitech. The image resolution is 320×240, and the camera capture 30 images per second. Because the measured time is five minutes, we can capture 9000 images. Meanwhile, the paper uses embedded system for testing, and its operating system is Windows Embedded CE 6.0 R2, the RAM size is 1024MB. The distance from human face to CCD camera is 40cm~60cm, the speed of recognition spends about 0.4~0.6sec. In addition, the part of measuring heart rate, we use Bluetooth ECG device to do measurement, which is produced by yang yin co. The measuring environment is in the laboratory, and keeps quiet for five minutes measurement; we conducted heart rate and face test for 20persons.

Fig. 16 and 17 show the results of face detection; however, because of light and noises we still have mistakes in human face detection. Fig. 16 shows successful cases in human face detection and Fig. 17 shows failure detections. And the failure is resulted from skin's color range and lights.

Figure 14. Successful cases in human face detection

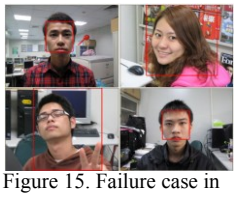


Figure 15. Failure case in human face detection

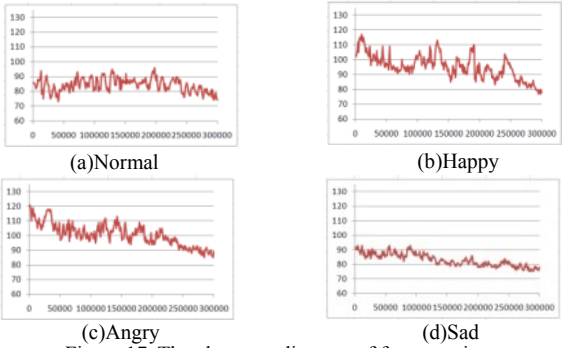
After detecting human face, we proceed to extract facial features. Fig. 18 shows the result of the extraction of feature points.

Figure 16 shows the result of the extraction of feature points.

Next, to extract the feature of heart rate, we extract 20 people's respectively extract 4 emotions electrocardiogram for each 20 persons, Fig. 19 show the electrocardiogram of (a)normal, (b)happy, (c) angry, (d) sad, respectively.



(a)Normal (b)Happy

(c)Angry (d)Sad

Figure 17. The electrocardiogram of four emotions

After obtaining above features, the paper use fuzzy inference method to judge emotion state. In fuzzy inference, we use 13 features, and divide them into three levels. They are slight(S), moderate (M) and large (L), respectively. The system is multi-input and single-output, and the emotion is divided into sad, angry, happy, normal, after deduction. We

also divided 4 emotions into three levels. Because there are 13 features in the system and infer a emotion state, total rules have 3^{14} rules, after reducing, the total rules remain 3^{10} rules. For instance:

R^1:if eyed is S, eyeh is S, frequency is M, SDNN is M, SDANN is S, RMSSD is S, NN50 count is S, pNN50 is S, RRI-Mean is S, SDSD is M, SDNN index is M, $\frac{LF}{HF}$ is S, mouth is S Then normal is S.

R^2:if eyed is M, eyeh is M, frequency is M, SDNN is M, SDANN is S, RMSSD is M, NN50 count is M, pNN50 is S, RRI-Mean is S, SDSD is M, SDNN index is M, $\frac{LF}{HF}$ is S, mouth is M Then happy is M.

R^3:if eyed is L, eyeh is L, frequency is L, SDNN is M, SDANN is L, RMSSD is M, NN50 count is L, pNN50 is L, RRI-Mean is S, SDSD is M, SDNN index is M, $\frac{LF}{HF}$ is M, mouth is M Then angry is M.

Table I shows the average successful rate of mouth and eyes detection is 82.03%.The success rate of our system is 84.31%.

Average successful rate 82.03%			

V. CONCLUSIONS

We provide an emotion recognition system by using eye's close/open condition, mouth close/open condition, physiological signals, and the method of Fuzzy Inference and apply emotion recognition system in the embedded system. This system is light, so has less spatial constraint. However, there are still parts required improvements in this emotion recognition system. For example, we hope natural light can be used to replace external light, so they obtained eyeball images will not so easily be influenced by reflection points and image capturing will be more accurate. Another solution is to find a webcam that has higher resolution and can filter some external image noises. However, problems regarding how to reduce dynamic distribution but with clear captures on the eyes or how to emphasize pupil's features should be dealt with by designing other appropriate image processing rules. In addition, we want to improve QRS detection in heart rate detection. In facial detection, the average successful rate is 82.03%, and the success rate of our system is 84.31%.

In the future, we expect that in the parts of human face detection, features capture and heart rate detection, we can process with better algorithm (for example, the color space of light's images and capturing more featured areas), establish a database to collect more reference materials.

***Abstract*—This paper proposes the design of fuzzy control of a bi-directional converter with variable inductance for dc microgrids. The nonlinear inductance model is developed and taken into consideration in the controller design of the bi-directional inverter to promote the performance. A novel fuzzy control strategy is proposed to increase the magnetizing voltage such that the current distortion is reduced. Simulated results demonstrated the effectiveness of the design.**

Keywords- Bi-directional converter, fuzzy control, dc microgrids

I. INTRODUCTION

Energy crisis inevitably brings nearer for the depletion of fossil. The greenhouse effect becomes more serious by the increased requirements for electric power. In recent years, renewable energy has received great attention due to the advantages of clean, no pollution and huge reserves. Many distributed generations such as photovoltaic cells, wind turbines and fuel cells have been linked with the utility grids [1]. However, the power quality of utility grids will be decreased by distributed generations [2]. To reduce conversion losses and supply high quality power, the dc microgrid is proposed in this paper.

Power electronic converters are one of the most important devices among the components of the microgrid [3]. In this paper, a bi-directional converter is designed to regulate the dc bus voltage for different types of energy sources and energy storage. The functions of the bi-directional inverter include grid connection mode and rectification mode. Fig. 1 shows the schema of the microgrid system.

The inductance is usually assumed to be a constant in the design of the inverter controller [4]. However, the inductance is a highly nonlinear function varied with the current. It is important to take the inductance variation into account when the operational principle of the bi-directional inverter is designed. In this paper, the methodology of nonlinear least squares is applied to build the nonlinear inductance model such that the performance of the bi-directional inverter is improved. Besides, the magnetizing voltage will be too low to track the reference current if the inductor is magnetized only with line voltage in rectification mode. A current hollow will appear near the zone of zero crossing no matter how the control duty ratio is filled. Thus, a novel fuzzy control strategy is proposed to increase the magnetizing voltage such that the current distortion is reduced.

Fuzzy theory is introduced by Zadeh in 1965 [5]. In artificial intelligence, fuzzy sets could be applied to control the plant. Based on fuzzy logic, a fuzzy controller converts a linguistic control strategy into an automatic control strategy, and fuzzy rules are constructed by expert experience or knowledge. The main feature [6] of fuzzy control is that the controller design doesn't rely on a mathematical model of a plant. The fuzzy inference system employing fuzzy if-then rules can control a plant using the human knowledge. Fuzzy controller has been widely used in industry for its easy realization and good robustness. Accordingly, the fuzzy logic is employed to design the PWM gain of the bi-directional inverter for dc microgrid.

The rest of this paper is organized as follows. Section 2 describes the model of the bi-directional inverter. Section 3 proposes the design of fuzzy controller. Section 4 shows simulation results with the presented scheme. Section 5 gives the conclusion.

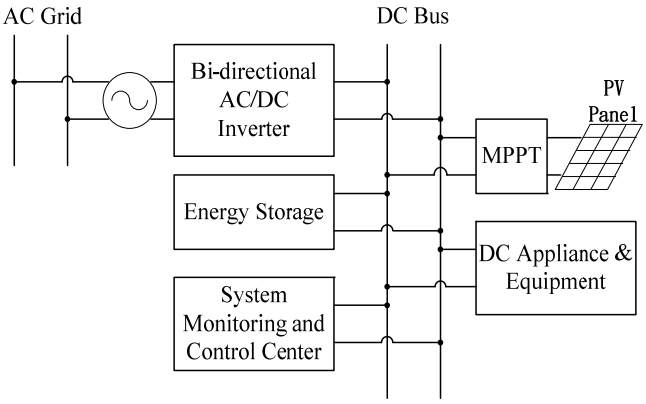

Fig. 1 The schema of the microgrid system

II. THE BI-DIRECTIONAL INVERTER

A. Circuit Configuration

Fig. 2 shows the proposed bi-directional inverter with a full-bridge configuration. The functions of the bi-directional

inverter include grid connection mode and rectification mode mode. The inverter senses inductor current i_L and uses the dc-link voltage v_{dc} and line voltage v_s in the single-chip microcontroller (dsPIC30F2023) to determine a control for operating the inverter stably.

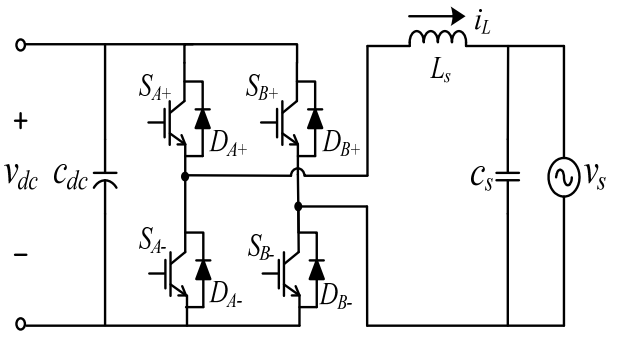

Fig. 2 The circuit configuration of the bi-directional inverter

B. Duty Ratio

In the grid connection mode, $\Delta i_L = \Delta i_{L(on)} + \Delta i_{L(off)}$

$$\Delta i_L = \frac{v_{dc} - |v_s|}{L} dT_s - \frac{|v_s|}{L}(1-d)T_s \tag{1}$$

where T_S is the period of the PWM. The duty ratio can be expressed as

$$d = \frac{\Delta i_L \cdot L}{v_{dc} \cdot T_s} + \frac{|v_s|}{v_{dc}} \tag{2}$$

In the rectification mode,

$$\Delta i_L = \frac{|v_s|}{L_s} dT_s - \frac{v_{dc} - |v_s|}{L_s}(1-d)T_s \tag{3}$$

The duty ratio can be expressed as

$$d = \frac{\Delta i_L \cdot L_s}{v_{dc} \cdot T_s} + \frac{v_{dc} - |v_s|}{v_{dc}} \tag{4}$$

C. Nonlinear Inductance Model

Let the nonlinear inductance model be

$$y = f(x) = ax^2 + bx + c \tag{5}$$

where y is the estimated value of inductance, x is the value of current. The sum of square error between the estimated and measured value of inductance will be

$$\sum \left[ax_i^2 + bx_i + c - y_i \right]^2 \tag{6}$$

where n is the total number of experimental date (x_i, y_i).

To minimize the sum of square error, taking the partial derivative to a, b and c, respectively gets

$$\begin{cases} \sum 2x_i^2 (ax_i^2 + bx_i + c - y_i) = 0 \\ \sum 2x_i (ax_i^2 + bx_i + c - y_i) = 0 \\ \sum 2(ax_i^2 + bx_i + c - y_i) = 0 \end{cases} \tag{7}$$

After substituting the experimental date (x_i, y_i) into the above equation, we can get a nonlinear inductance model to approximate the nonlinear mapping between the inductance and the current.

D. Refining Tracking Error

If the inductor L_s is magnetized by only turning on S_{A+} in the rectification mode, the magnetizing voltage v_s will be too low to track the reference current near the zero crossing. To refine the waveform of inductor current, a novel PWM strategy is developed as shown in Fig. 3. The magnetizing voltage should be increased to $v_L = v_{dc} + v_s$ by appropriately turning on S_{A+} and S_{B-}.

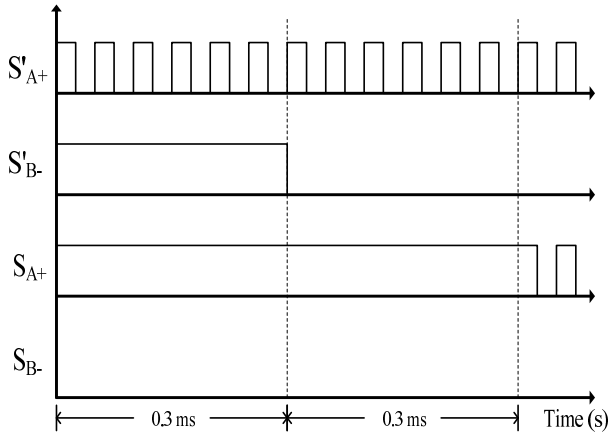

Fig. 3 Different switching sequence

III. Fuzzy Control

A. Fuzzification

The design procedure of fuzzy logic controller includes fuzzification, fuzzy rule base, fuzzy inference and defuzzification. In this paper, the linguistic variables are state error e, change in error Δe and fuzzy gain u. The Mamdani fuzzy inference system uses minimum and maximum for T-norm and T-conorm operators, respectively.

The fuzzy sets and the fuzzy rules are defined as follows. The linguistic variables of input e and Δe are defined as {N, Z, P}, where N means negative, Z means zero and P means positive. The linguistic variables of output u are defined as {SS, SM, SB, MS, MM, MB, BS, BM, BB}, where S means small, M means medium and B means big.

The universe of discourse of e is assigned to be [-1 1]. The universe of discourse of Δe is assigned to be [-1 1]. The membership functions of the fuzzy sets corresponding to variables e and Δe are shown in Fig. 4.

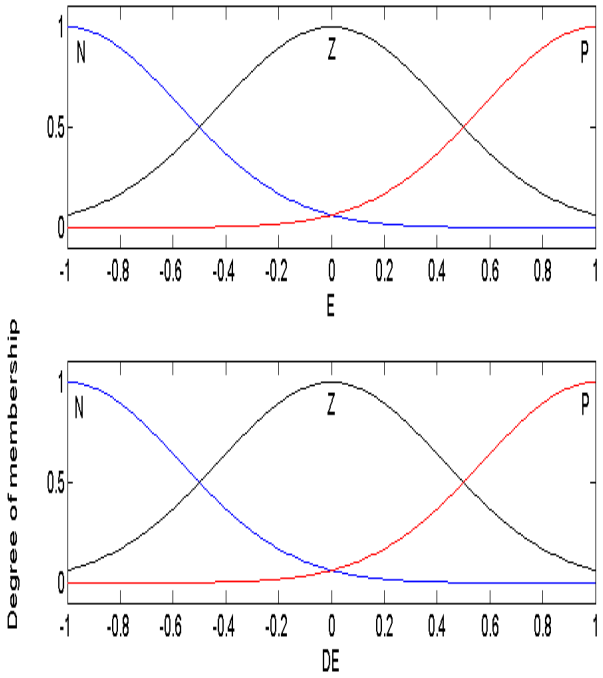

Fig. 4 Membership Functions

B. *Fuzzy Inference Engine*

The minimum inference engine is applied to design fuzzy inference mechanism in this study. With max-min composition, the consequence $\mu_{B'}(y)$ is

$$\mu_{B'}(y) = \max_{l=1}^{m}[\mu_{A_1^l}(x_1) \wedge \mu_{A_2^l}(x_2) \wedge \mu_{B^l}(y)] \tag{8}$$

where x_1, x_2 and y represent the fuzzy sets e, Δe and u, respectively; $\mu_{A_1^l}(x_1)$, $\mu_{A_2^l}(x_2)$ and $\mu_{B^l}(y)$ mean the membership functions of e, Δe and u, respectively; l is the index of membership functions for every fuzzy set; m is the number of triggered fuzzy rules.

C. *Fuzzy Rules*

According to the Mamdani inference method, fuzzy if-then rules are designed. By means of using three linguistic variables N, Z and P of each input variable, nine fuzzy rules are derived. These fuzzy inference rules are summarized in Table 1.

Table 1. Fuzzy inference rules

	e(t)			
		N	Z	P
Δe	N	BM	SM	MM
	Z	BS	SS	MB
	P	MS	SB	BB

D. *Defuzzification*

Defuzzification is used to extract a crisp value from a fuzzy set. There are a lot of methods for defuzzifying a fuzzy set. The center of gravity defuzzification is used in this paper

$$Y^* = \frac{\sum_{i=1}^{m} \mu_{B^i}(y_i) \cdot y_i}{\sum_{i=1}^{m} \mu_{B^i}(y_i)} \tag{9}$$

where Y^* is the crisp values of fuzzy gain u, i is the index of consequent rules.

IV. Simulation Results

Fig. 5(a) shows the shows the experimental data of measured inductance. After substituting these experimental date (x_i, y_i) into the equation (7), we can get the following nonlinear inductance model

$$L_S = 2.851 I_L^{\,2} - 244.6 I_L + 5604 \tag{10}$$

Fig. 5(b) shows the comparison between the nonlinear inductance model and the measured values. Obviously, the nonlinear model is very similar to the experimental data.

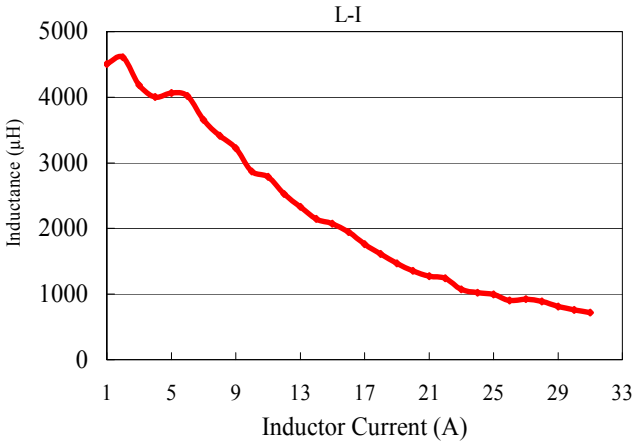

Fig. 5(a) Experimental data of inductance variation

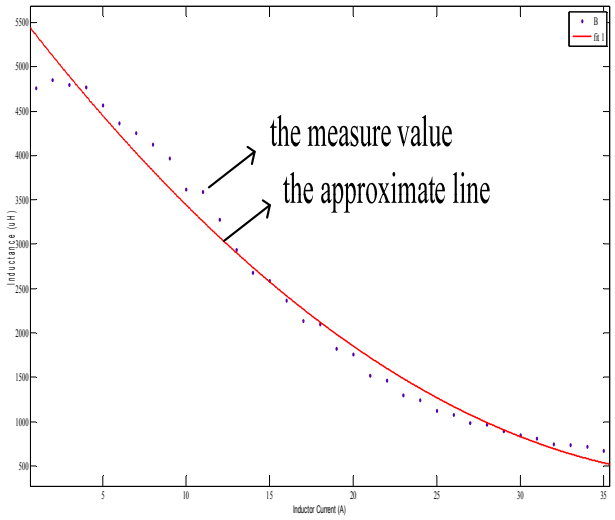

Fig. 5(b) The nonlinear model of inductance variation

Modeling and simulation are essential for developing controller programs. In this paper, the Matlab and Simulink software is utilized for modeling and simulating. Fig. 6(a) shows the simulation response without considering inductance variation in the grid connected mode. Fig. 6(b) shows the simulation response considering inductance variation in the grid connected mode. Apparently, the inductance current will have better waveform when the controller design takes the inductance variation into consideration. Fig. 7(a) shows the simulation response without considering inductance variation in the rectification mode. Fig. 7(b) shows the simulation response considering inductance variation in the rectification mode. Again, the inductance current will have more fluctuation if the controller design shorts of inductance variation consideration. Fig. 8(a) shows the simulation response of inductor current by turning on S_{A+} only. Fig. 8(b) shows the simulation response of inductor current by turning on S_{A+} and S_{B-}. The tracking error is significantly reduced between the reference current and the inductor current.

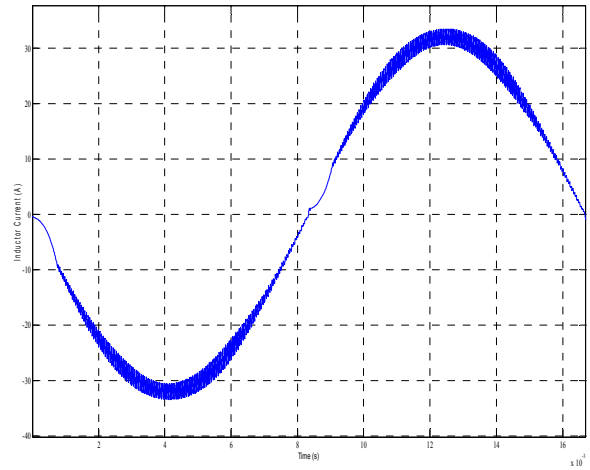

Fig. 7(b) Rectification mode with inductance variation

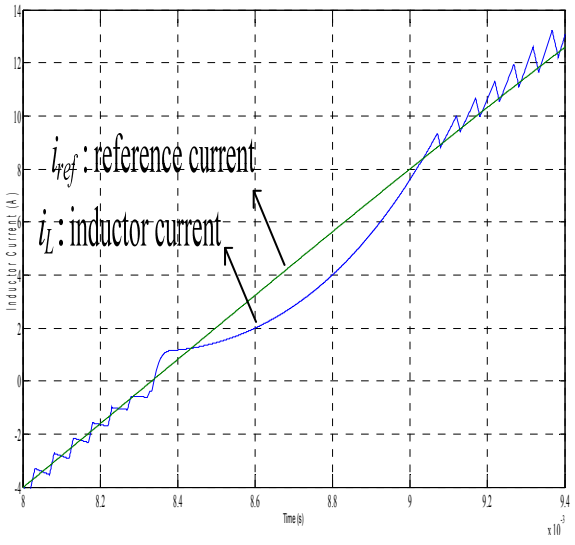

Fig. 8(a) Simulation response (S_{A+} on)

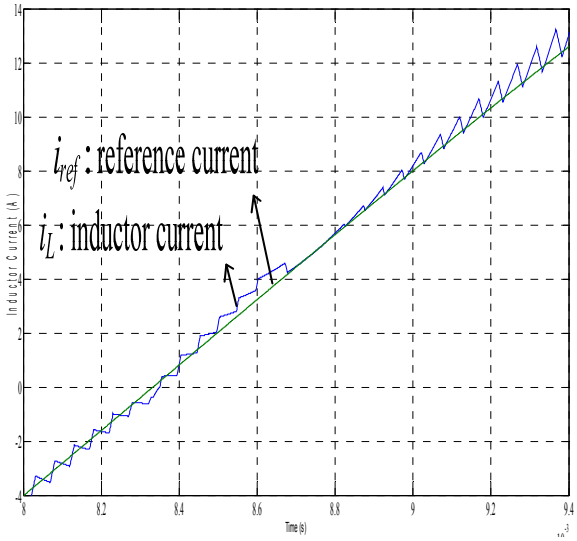

Fig. 8(b) Simulation response (S_{A+} and S_{B-} on)

V. Conclusion

We considered the dc bus voltage regulation problem of the bi-directional converter using fuzzy control strategy. Furthermore, to promote the regulation performance, a nonlinear inductance model between the current and the inductance mapping is established. Then, a novel fuzzy control strategy which takes account of inductance variation is proposed to increase the magnetizing voltage such that the current distortion is reduced. Last, the computer simulation shows that the fuzzy controller with inductance variation design is superior to the fuzzy controller without inductance variation design.

***Abstract*—In this paper, we constructed an intelligent robotic wheelchair equipped with automatic tracking function in barrier-free environment of campus; the system used video paint line detection as the basis of automatic tracking navigation; since the barrier-free environment of campus includes indoor and outdoor environment and the outdoor environment includes gentle slopes, sidewalk and etc, we proposed a paint line detection method, which showed color distribution and judgment of paint line using Gaussian mixture models; the input image completed paint line detection and parameters calculation with this method and then input them into the fuzzy logic controller of wheelchair and in this way, the tracking navigation control of wheelchair was performed; the system was actually tested on barrier-free paths in campus, including straight and curve barrier-free paths; the result showed that the system could make the wheelchair keep moving on the paint line correctly and the mean deviation was kept within ±10 cm, which proved the navigation of intelligent robotic wheelchair could be realized automatically and successfully on barrier-free paths in campus.**

Keywords-path lane following; gaussian mixture models; color spacec conversion; color segmentation; fuzzy control.

I. INTRODUCTION

In Taiwan, the percentage of population of the old aged above 65 to the total population increased from 10.4% in 2008 to 10.6% in 2009; it is estimated that the aging population will account for 20.04% of the total population in 2070[1, 2]; these figures show Taiwan has entered the aging society, therefore, there is an urgent need of the care for the aged. As more and more people are using wheel chairs in aging society, barrier-free space is built out in succession in many places; Chaoyang University of Technology has been always paying much attention to this issue, so a barrier-free space has been built in the campus; to apply the technology to the concept of holistic care [3], we introduced the intelligent robotic wheelchair in barrier-free environment in campus and created a intelligent robotic wheelchair equipped with automatic tracking navigation based on computer vision; the system captures images of barrier-free environment with a camera installed on the wheelchair and controls the automatic tracking navigation of robotic wheelchair in barrier-free environment in campus through real time detection of paint line and fuzzy control.

The automatic tracking navigation technology based on paint line detection of computer vision has been mentioned in many related researches [4-13]; generally, the common detection methods include comparison based on characteristics, colors, models, etc; to highlight positions, the distinct paint line was used as path guide in barrier-free environment, so we used color detection method in this paper. The simplest method for color detection is critical value method; range of critical value was set according to the distribution of color to be detected; when color fell into the range, it was deemed to be the color detected, otherwise it was not; furthermore, some scholars proposed the method using the single Gaussian function to show the distribution of specific color in space [14]; since the barrier-free environment of campus includes indoor and outdoor environment and there is shadow, tree shade and stain, etc in outdoors, which can not be shown by the single Gaussian function, we proposed to express the probability distribution of color of paint line with Gaussian mixture models which are composed of several Gaussian functions according to different weight values, thus it can show the probability distribution of color of paint line more correctly; the input image could complete the detection of color of paint line through Gaussian mixture models more accurately; moreover, color of paint line changed at any time with environment and external light source, so we updated Gaussian mixture models at real time with the updating algorithm of dynamic Gaussian mixture models to make the paint line detection of the system more stable and more suitable for various environments. After paint line detection, calculate the position and angle of paint line with Hough transform, input the result into the entry of fuzzy controller of wheelchair and control the difference between velocity of the right wheel and left wheel through fuzzy logic to control wheel chair direction and then complete the tracking navigation function of robotic wheelchair.

The other structures of the paper are described as below; Section II proposes system architecture; Section III introduces methods to detect paint line; Section IV introduces fuzzy system control of automatic lane following of robotic

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

wheelchair; the simulated experiment and the actual experimental results are shown in Section V; the last section is conclusion and discussion.

II. SYSTEM ARCHITECTURE

Fig.1 shows the system architecture of intelligent robotic wheelchair proposed by us, which includes image capture and correction, paint line detection, parameter calculation, graphical operation interface, fuzzy controller, etc. Image capture and correction read images into the system through camera and capture card and converting camera into space coordinates; as camera coordinates are different from space coordinates, the input images should be converted to aerial view through coordinate conversion; paint line detection and parameter calculation detect color of paint line through images and calculate angular separation between paint line position and wheelchair direction through Hough transform.

Fuzzy logic controller is responsible for controlling tracking navigation of wheelchair; it has two entries, which are angular separation between straight line of paint line and wheelchair direction; while the output controls the difference between velocities of two wheels directly, getting an angular velocity through changes of the difference between velocities of two wheels to make wheelchair be able to make a turn to proceed towards the correct direction; the last part is graphical operation interface; the system operation can be simplified through graphical operation interface to make the mobility-handicapped or senior citizen be able to operate the system by clicking.

We will elaborate on technologies of every part in Fig.1 in the following chapters.

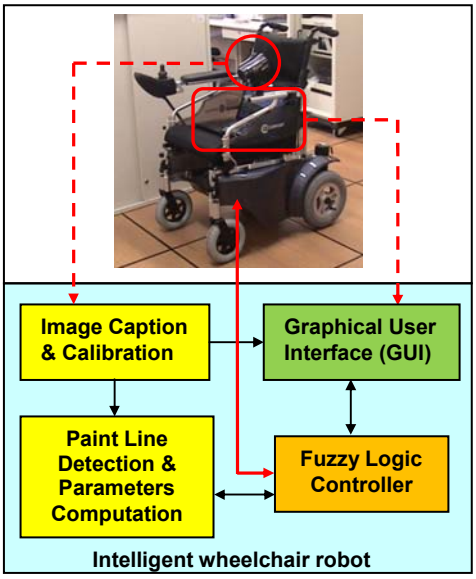

Figure 1. System architecture

III. PAINT LINE DETECTION

It was difficult to detect the position of paint line with color; since color of paint line was susceptible to light source, weather, stain, shadow and etc, we proposed a set of robust paint line detection method in this paper; this method learned the probability distribution of color of paint line using a Gaussian mixture model and the input image detected position of paint line of image through a Gaussian mixture model it had learnt before. Below is detailed description.

A. Color space conversion

To reduce the effect of light source on color detection, we used a and b in CIE-Lab color space as the basis of paint line detection; in this paper, we used BT-709 format conversion of ITU-R and employed D65 as reference white point; since RGB color space could not correspond to Lab color space directly, it must be converted to XYZ color space first and then converted to Lab color space; the conversion of RGB color space to XYZ color space can be expressed by the matrix operation equation (1) below:

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix} = \begin{bmatrix} 0.4124 & 0.3576 & 0.1805 \\ 0.2126 & 0.7152 & 0.0722 \\ 0.0193 & 0.1192 & 0.9505 \end{bmatrix} \begin{bmatrix} R \\ G \\ B \end{bmatrix}, \tag{1}$$

while the conversion of XYZ color space to Lab color space can be defined as the equation (2):

$$\begin{aligned} L &= 116 f\left(\frac{Y}{Y_n}\right) - 16, \\ a &= 500\left[f\left(\frac{X}{X_n}\right) - f\left(\frac{Y}{Y_n}\right)\right], \\ b &= 200\left[f\left(\frac{Y}{Y_n}\right) - f\left(\frac{Z}{Z_n}\right)\right], \\ f(t) &= \begin{cases} t^{\frac{1}{3}}, & t > 0.008856 \\ 7.787t + \frac{16}{116}, & t \le 0.008856 \end{cases}, \end{aligned} \tag{2}$$

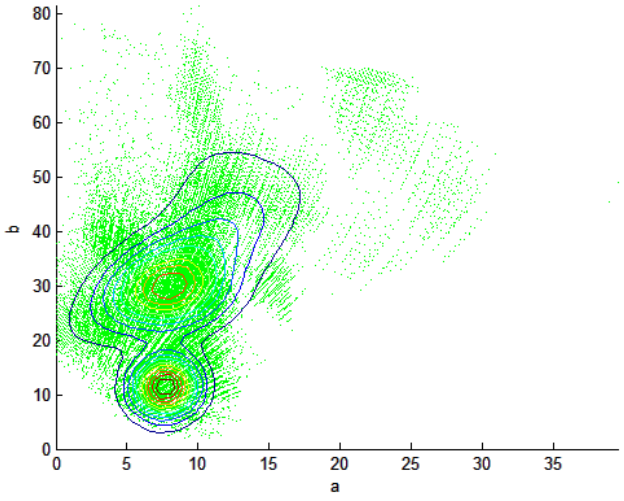

Figure 2. Distribution of a-b values of paint line color and the contour line of 5 Gaussian mixture models

where, $X_{n,}$=0.9504, Y_n=1 and Z_n=1.0883 are D65 reference white points. Fig.2 shows the distribution map of a-b values of paint line color, where every blue point represents the sampling value of every paint line color a-b. We collected a-b values of 1,250,000 paint line colors under many circumstances (indoors and outdoors; the latter includes rainy

days, sunny days, at dusk, daytime, etc); we can find from the figure that the distribution of *a-b* values of paint line color is irregular, so it can not be expressed by setting range of critical values or by the single Gaussian function and we used mixed model of Gaussian function to learn the probability distribution of *a-b* values of paint line color.

B. *The expression of paint line color by Gaussian mixture models*

Gaussian mixture model (GMM) refers to a mixed model composed of multiple Gaussian functions; because GMM can approach probability density distribution of any shape, it is very suitable for modeling the probability distribution of *a-b* values of paint line color; GMM can be represented by the weight sum of *K* Gaussian functions and the definition is shown as equation(3):

$$p(\mathbf{x}_i|\mathbf{\Theta}) = \sum_{k=1}^{K} p_k p(\mathbf{x}_i|\boldsymbol{\mu}_k, \boldsymbol{\Sigma}_k), k = 1, 2, ..., K, \quad (3)$$

where $\mathbf{x}_i \in R^2$, i = 1, 2, …, n, is input vector; n refers to number of samples input; $\mathbf{\Theta} = \{\boldsymbol{\mu}_1, \boldsymbol{\mu}_2, ..., \boldsymbol{\mu}_K | \boldsymbol{\Sigma}_1, \boldsymbol{\Sigma}_2, ..., \boldsymbol{\Sigma}_K\}$, where $\boldsymbol{\mu}_k$ and $\boldsymbol{\Sigma}_k$ refer to the mean value and covariance matrix of the kth Gaussian function separately; p_k, k = 1, 2, …, K, represents the weight value of component of every Gaussian function in Gaussian mixture models and every Gaussian function can be expressed as equation (4):

$$p(\mathbf{x}_i|\boldsymbol{\mu}_k, \boldsymbol{\Sigma}_k) = \frac{1}{\sqrt{(2\pi)^d |\boldsymbol{\Sigma}_k|}} \exp\left[-\frac{1}{2}(\mathbf{x}_i - \boldsymbol{\mu}_k)^T \boldsymbol{\Sigma}_k^{-1}(\mathbf{x}_i - \boldsymbol{\mu}_k)\right], \quad , k = 1, 2, ..., K, \quad (4)$$

where, $\boldsymbol{\mu}_k$ and $\boldsymbol{\Sigma}_k$ refer to the mean value and covariance matrix of the kth Gaussian function separately, therefore, there are K mean values and K covariance matrixes; $\mathbf{\Theta} = \{\boldsymbol{\mu}_1, \boldsymbol{\mu}_2, ..., \boldsymbol{\mu}_K | \boldsymbol{\Sigma}_1, \boldsymbol{\Sigma}_2, ..., \boldsymbol{\Sigma}_K\}$; the method used to train Gaussian mixture models is called EM algorithm which is a recursive algorithm including two procedures, namely, estimation procedure(*E*-procedure) and update procedure (*M*-procedure) separately; *E*-procedure refers to estimating the probability that every input sample belongs to individual Gaussian function based on the current parameters of Gaussian mixture models and its calculation is defined as:

$$\hat{p}(k|i) = p(y_i = k|\mathbf{x}_i, \boldsymbol{\theta}_k), \forall k, i, \quad (5)$$

where, k = 1, 2, …, K, K refers to the number of Gaussian functions used by GMM; i = 1, 2, …, n, n refers to the number of samples input, so $\hat{p}(k|i)$ stands for the probability that the input $\mathbf{x}_i$ *the kth* belongs to Gaussian function; $\boldsymbol{\theta}_k = \{\boldsymbol{\mu}_k, \boldsymbol{\Sigma}_k\}$, $\boldsymbol{\mu}_k$ and $\boldsymbol{\Sigma}_k$ refer to the mean value and covariance matrix of the kth Gaussian function separately; *M*-procedure updates all parameters with $\hat{p}(k|i)$ and its calculation is defined as below:

$$\hat{n}_k \leftarrow \sum_{i=1}^{n} \hat{p}(k|i), \forall k, \quad (6)$$

$$\hat{p}_k \leftarrow \frac{\hat{n}_k}{n}, \forall k, \quad (7)$$

$$\hat{\boldsymbol{\mu}}_k \leftarrow \frac{1}{\hat{n}_k} \sum_{i=1}^{n} \hat{p}(k|i)\mathbf{x}_i, \forall k, \quad (8)$$

$$\hat{\boldsymbol{\Sigma}}_k \leftarrow \frac{1}{\hat{n}_k} \sum_{i=1}^{n} \hat{p}(k|i)(\mathbf{x}_i - \hat{\boldsymbol{\mu}}_k)(\mathbf{x}_i - \hat{\boldsymbol{\mu}}_k)^T, \forall k, \quad (9)$$

Repeat *E*-procedure and *M*-procedure above until the convergence.

The contour line in Fig.2 shows Gaussian mixture model which uses 5 Gaussian functions to learn the result of probability distribution of *a-b* values of paint line color; it can be clearly seen from the figure that the probability distribution of two Gaussian functions is more distinct mainly because most *a-b* values of paint line color are converged in the range covered by the two Gaussian functions. After learning, Gaussian mixture models can be used to show the probability distribution of *a-b* values of paint line color, therefore, the *a-b* values of each pixel color of any input image can be substituted in Gaussian mixture models that has learnt in advance; after simple critical value judgment, the image result of paint line corresponding to input image can be obtained and its calculation definition is shown as below:

$$F(\mathbf{x}_i) = \begin{cases} 1, & p(\mathbf{x}_i|\mathbf{\Theta}) \geq Th1 \\ 0, & otherwise \end{cases}, \quad (10)$$

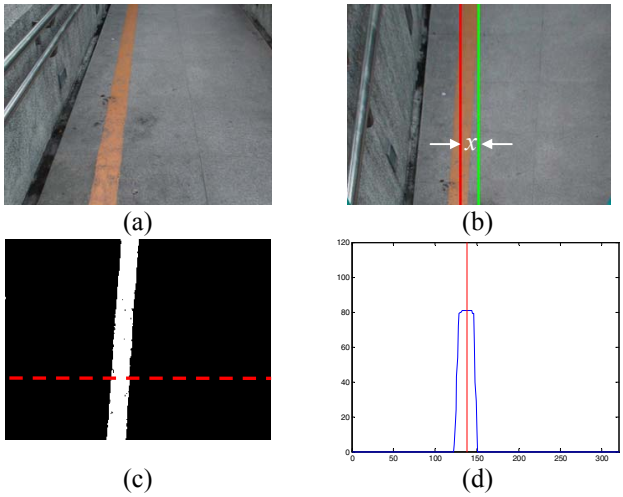

Figure 3. Example of paint line detection, (a) original input image, (b) aerial view of input image, (c) result of paint line detection, and (d) result of paint line position detection

where F represents the image result of paint line detection and $Th1$ is critical value 0.0005. Fig.3 is an example of paint line detection; Fig.3(a) is original input image; Fig.3(b) is the aerial view of input image after coordinate conversion; Fig.3(c) is result of paint line detection of the aerial view; the result shown in Fig.3(d) can be obtained by accumulating the 2/3

height of paint line image to its projection from the bottom to the horizontal axis; in Fig.3(d), we can find the mean value of the horizontal position corresponding to the maximum value, as shown by the red vertical full line in Fig.3(b) and (d), therefore, the width between the mean position to the imaging centre is defined as x(as pointed at by white arrow in Fig.3(b), where the green vertical line is the horizontal and center of image) and the variable quantity of x is defined as dx; these two values are used as two input parameters of fuzzy control system, which will be introduced in the following chapter.

IV. FUZZY CONTROL OF WHEELCHAIR

In this paper, we used fuzzy logic to control wheelchair for tracking navigation because the advantage of fuzzy control is that it can express the expert knowledge as system easily to make the system closer to human thinking and comply with the nonlinear system in real world better. Fig.4 shows the fuzzy control system architecture proposed by us; the architecture includes two input parameters x and dx, and one output parameter is angular acceleration of wheelchair; a_1 and a_2 in the figure stand for normalized coefficients of input parameters and normalize input parameters to values within [-1, 1]; a_3 represents the output value, which was changed from output parameter by [-1, 1] to corresponding motor control; Fig.5, 6 and 7 show triangular fuzzy membership function corresponding to input parameters x and dx, and angular acceleration of output, we use triangular membership functions, the main reason is simplify computation, and effective expression expert knowledge; each input parameter has 5 membership functions: {LE, LC, CE, RC, RI} and {LE', LC', CE', RC', RI'}, where LE means Left, LC means Left Center, CE means Center, RC means Right Center, RI means Right, each output parameter has 5 membership functions: {NM, NS, ZE, PS, PM}, where NM means Negative Medium, NS means Negative Small, ZE means Zero, PS means Positive Small, PM means Positive Medium, so there are 25 fuzzy rules in the rule base; table 1 lists membership functions of output corresponding to fuzzy rules; Fig.8 is the output fuzzy graph of fuzzy control system.

V. EXPERIMENTAL RESULT

In this paper, to verify the method proposed by us can complete paint line detection and automatic tracking navigation effectively, we conducted a simulated experiment and an actual test, which will be described below respectively.

A. Simulation test of wheelchair motion equation

To verify that the fuzzy control system can be applied to wheelchair control, we first use the equation of wheelchair motion to simulate the tracking control performance of wheelchair; Fig.9 is a schematic diagram of a robotic wheelchair which is driven mainly by two rear wheels; the two front wheels are steering auxiliary wheels which can support 360-degree steering and are used to stabilize wheelchair besides direction control; v stands for velocity of wheelchair and ϕ for the included angle between wheelchair and paint line; assume the right and left wheel velocities are defined as ω_l and ω_r and tyro radius of driving wheel of wheelchair is r, and then the velocity of the right and left wheels can be defined as:

$$v_l = r\omega_l \quad \text{and} \quad v_r = r\omega_r. \tag{11}$$

Since wheelchair velocity can be expressed as $v = (v_r + v_l)/2$, substitute the equation (11) into it and we can get:

$$v = \frac{r}{2}(\omega_r + \omega_l). \tag{12}$$

Finally, we can get the equation of wheelchair motion:

$$\dot{y} = v\cos(\phi), \dot{x} = v\sin(\phi), \text{and } \dot{\phi} = \omega, \tag{13}$$

where $\dot{y}$ and $\dot{x}$ refer to the variable quantity in the direction of x and y, and $\dot{\phi}$, the variable quantity of angle, is the angular velocity of wheelchair. Simulate the motion of wheelchair with the equation of wheelchair motion and fuzzy control and the result is shown in Fig.10, where the red block stands for wheelchair and the green arrow stands for the moving direction and the blue curve for the position of paint line; in this example, assume the initial position of wheelchair is 20 cm from the right of paint line and the wheelchair moves in parallel with the paint line; it is found after simulation of fuzzy control that the wheelchair approaches the paint line slowly and moves forward along the paint line indeed. Fig.11 shows x, the distance between wheelchair and paint line; Fig.12 shows the angle between wheelchair and paint line.

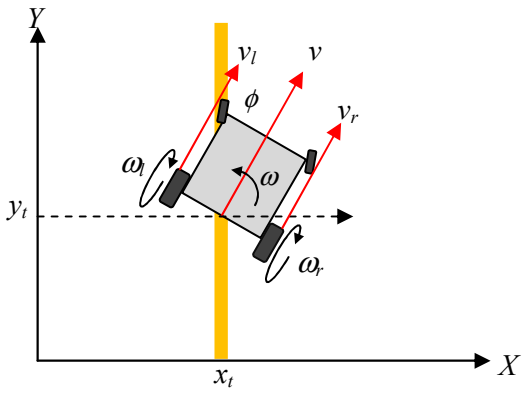

Figure 9. Motion model of wheelchair

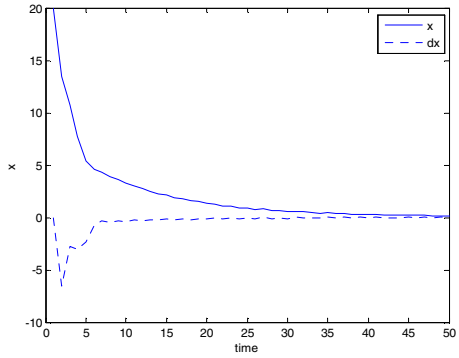

Figure 11. Result of navigation simulation at horizontal position

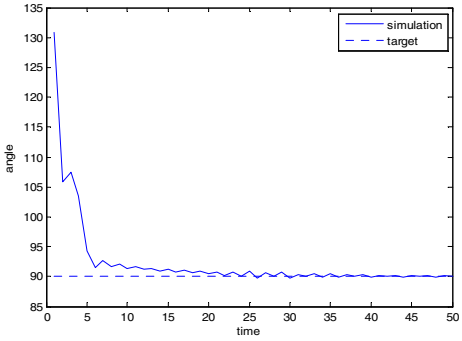

Figure 12. Result of navigation simulation at angle

B. *Field testing*

For this experiment, we divided it into two parts for description, namely, paint line detection and field test; for paint line detection, we performed it based on the effect of Gaussian functions of different numbers on Gaussian mixture models; we used GMM with best Gaussian function numbers to complete the field test. They will be discussed and described separately below:

First, perform test on paint line detection based on Gaussian functions of different numbers; we used images in different environment and under different light sources for tests; the results of paint line detection by GMMs with 1, 3, 5 and 10 Gaussian functions separately were used in the experiment(Fig. 15); it could be found from the experimental result that the result based on 1 Gaussian function was the worst; the result based on 3 Gaussian functions was much better than that of 1 Gaussian function; the result based on 5 and 10 Gaussian functions were improved, compared with that of 3 Gaussian functions under certain condition; there was little difference between detection results based on 5 and 10 Gaussian functions, therefore, we used GMM with 5 Gaussian functions for the subsequent tests.

Next test on environment of barrier-free path was performed; we experimented with a barrier-free space in campus, which included two paths which were a straight path of paint line as shown in Fig.13(a) and a quarter-turn curve path as shown in Fig.13(b) with the overall length of 40m; upon the start of the experiment, we pointed the camera on wheelchair at the position 20cm from the right of paint line and made it parallel to the paint line; the wheelchair advanced at about 5 km/h; because the camera was not completely against the pain line direction at first, it was obvious that the

wheelchair moved to the left after program execution in an attempt to make the camera pointing at the paint line; Fig.14 shows *x*, the distance between paint line and the horizontal center of image during experiment; it can be seen clearly from Fig.14(a) that the distance between paint line in image and the horizontal center of image was -20cm at first and it approached zero slowly, which took about 1second (10~15 frames/sec), and then the wheelchair moved forward along the paint line; Fig.14(b) shows the result of experiment in the quarter-turn curve path, from which we can find that the wheelchair entered the turn in 380 frame, when the distance between paint line in image and the median of image was significantly negative (as pointed by the first arrow in Fig.14(a)) and the wheelchair turned left; immediately the wheelchair approached paint line slowly(as pointed by the second arrow in Fig.14(b)); at last, *x*, the distance between paint line and the center of image, approached zero again and the wheelchair moved forward along the paint line continuously. Table 2 shows the performance of paint line detection and the *MSE* defines as following:

$$MSE = \frac{1}{N}\sum_{i=1}^{N} x_i^2, \tag{14}$$

where *N* is the number of frames.

VI. CONCLUSION AND FUTURE RESEARCH

In this paper, we constructed an intelligent robotic wheelchair equipped with automatic tracking navigation, which used video paint line detection and fuzzy logic control for automatic tracking navigation of wheelchair; for paint line color detection, we proposed a robust method to detect color of paint line, which is suitable for indoor and outdoor barrier-free path; in addition, for wheelchair control, we used fuzzy logic to complete the control system of robotic wheelchair and the system is actually tested in experiment of barrier-free path in campus, including straight and curve barrier-free paths; the result shows the system could make the wheelchair move along the paint line correctly and the mean deviation was kept within ±10cm. In future research, the robotic wheelchair will be equipped with ultrasonic range sensors all around to avoid colliding pedestrians or obstacles on barrier-free paths and we will build an intelligent robotic wheelchair with automatic obstacle-avoidance navigation, drawing on the ultrasonic sensor, besides completing automatic paint line detection tracking navigation.

ACKNOWLEDGMENT

For the results of this paper, we show our gratitude to the support from the Program Institute of National Science Council, the number is NSC-99-2632-E-324-001-MY3 and Ministry of Education technical colleges to establish a specialty model plan, the number is 0990045921n.

***Abstract*—With the advent of service-oriented computing, the issue of trust and Quality of Service (QoS) have become increasingly important. In service-oriented environments, when there are a few service providers providing the same service, a service client would be keen to know the trustworthiness of each service provider in the forthcoming transaction. The trust rating of a delivered service from a service provider can be predicted according to a set of advertised QoS data collected by the trust management authority. Although trust and QoS are qualitative by nature, most data sets represent trust and QoS in the ordinal form for the sake of simplicity.**

This paper introduces a new approach based on Fuzzy Linear Regression Analysis (FLRA) to extract qualitative information from quantitative data and so use the obtained qualitative information for better modeling of the data. For verification purposes, the proposed approach can be applied for the trust prediction in the forthcoming transaction based on a set of advertised QoS in service-oriented environments.

***Index Terms*—Fuzzy linear regression; Trust prediction; Quality of service;**

I. Introduction

In Service-Oriented Computing (SOC), a service is an autonomous and platform-independent computational entity, which can be described, published, discovered and dynamically assembled for developing massively distributed systems [1]. In fact, any piece of code or application component deployed on a system can be taken as a service [1], [2].

In SOC environments, QoS (Quality of Service) refers to various nonfunctional characteristics. These specified characteristics should be measurable and constitute a description of what a service can offer. The QoS of an IT service is often expressed in terms of capacity, latency, bandwidth, the number of service requests, and the number of incidents [3]. QoS is essential when a set of quality metrics have to be achieved during service provision [3]. In contrast, in SOC environments, the general quality of a delivered service can be represented by a trust rating given by a service client. As trust and QoS both focus on the quality of service, the trust rating of a service or service provider can be taken as a function of a set of advertised QoS values reflecting the quality of the service or the service provider, and the trust rating can be predicted by the trust management authority.

When a service client looks for a service from a large set of services offered by different service providers, in addition to functionality and QoS, reputation-based trust is also a key factor for service selection. It is also critical for the trust management authority to be responsible for maintaining the list of reputable and trustworthy services and service providers with their advertised QoS values, and providing them to clients as required [2].

Conceptually, trust is the measure taken by one party on the willingness and ability of another party to act in the interest of the former party in a certain situation [4]. If the trust value is in the range of [0,1], it can be taken as the subjective probability with which, one party expects that another party performs a given action [5].

The trust issue has been widely studied in many applications. In e-commerce environments, a trust management system can provide valuable information to buyers and prevent certain typical attacks [6], [7]. In Peer-to-Peer information-sharing networks, binary ratings work pretty well as a file is either the definitively correct version or not [8]. In SOC environments, an effective trust management system is critical to identify potential risks, provide objective trust results to clients and prevent malicious service providers from easily deceiving clients [9]. Different from P2P information-sharing networks or the eBay reputation management system, where a binary rating system is used [8], in SOC environments, trust data is usually captured in its ordinal form, such as *5-star*, *gold* and *high-class*, due to the abstraction or even the simplicity of representation. This abstraction makes the trust value more understandable for the end users and service clients, but it is not really suitable for any further inference. An intuitively appealing approach towards trust, which is qualitative by nature, is to not quantize the trust but to take the uncertainty which comes from vagueness into consideration in the level of inference [10]. In contrast, the quantization only takes place for representing the trust to the end users or service clients when it is deemed to become necessary [10].

As mentioned above, the trust rating, representing the subjective belief of a service client on the general quality of the delivered service, is both subjective and qualitative. However, by quantization both subjective and qualitative information in the trust data set would be overlooked. For example, two

978-1-4244-7316-8/11/$26.00 ©2011 Crown

services with the same trust level of *5-star* may not be necessarily the same for a specific purpose or the requirement of a service client. In fact, one service could be much more suitable than the other one, but, due to the quantization process, such kind of important information may be ignored in the service selection process.

This paper proposes a QoS based approach to trust prediction using Fuzzy Linear Regression Analysis (FLRA). This approach is built up with the ordinal trust data which can be extracted, so that the hidden fuzzy information can be taken into consideration where it has been overlooked in the original trust data set. The motivations of applying FLRA for predicting trust are summarized as follows.

- Capturing the hidden fuzziness: we want to capture the fuzziness overlooked in the ordinal trust data set due to the reasons such as abstraction. The other machine learning approaches such as neural networks, decision trees and support vector machines in their original form, do not take the fuzziness into consideration and only model the original trust data set.
- Having a transparent model: we want to seek for a transparent relationship between the delivered trust rating and the advertised QoS values where the underlying function is extractable. In industry, neural networks or any other approaches, which have the black-box nature, are not suitable for marketing purposes.
- More detailed information: we want to provide more information than only a few trust levels. For example, a web service is not necessarily either *platinum* or *gold*; it could be for instance *better than gold,* but *worse than platinum* - which can be represented by a fuzzy value.

FLRA is a powerful tool to model the relationships in situations where the attributes are inexact. FLRA is widely applied in economy, finance, marketing, social sciences, healthcare and other domains [11], [12], [13]. In addition, trust is also a widely studied and complex issue, including many uncertain factors [6]. Hence, with the fuzziness, fuzzy regression based on fuzzy set theory can deal with QoS based trust prediction in a reasonable manner. In this paper, we propose a method for the prediction of trust rating based on fuzzy linear regression for building up a mapping from a set of advertised QoS values to the trust rating of the corresponding delivered service of a service provider. Then, the service client can predict the trustworthiness of the service provider in the forthcoming transaction with its advertised QoS values.

This paper is organized as follows. In Section II, we review trust management, trust evaluation and uncertainty. Section IV presents our QoS based trust prediction method with fuzzy regression. Some experiments are presented in Section V for illustrating how our proposed method can predict trust with QoS values. Finally Section VI concludes our work.

A. Trust Evaluation in E-Commerce Environments

Trust is an important issue in e-commerce (EC) environments. At eBay [14], after each transaction, a buyer can give feedback with a rating of "positive", "neutral" or "negative" to the system according to the service quality of the seller. eBay calculates the feedback score $S = P - N$, where P is the number of positive ratings left by buyers and N is the number of negative ratings. Then the positive feedback rate $R = \frac{P}{P+N}$ (e.g., $R = 99.1\%$) is calculated and displayed on web pages. This is a simple trust management system providing valuable reputation information to buyers.

In [7], the Sporas system is introduced to evaluate the trust for EC applications based on the ratings of transactions over a recent time period. In this method, the ratings of later transactions are given higher weights as they are more important in trust evaluation. In [6], Wang *et al* propose an approach to evaluate the situational transaction trust, which binds the trust ratings of previous transactions with a new transaction. Since the situational trust includes service specific trust, service category trust, transaction amount category specific trust and price trust, it can deliver more accurate trust information to buyers and prevent some typical attacks.

B. Trust Evaluation in P2P Information Sharing Networks

The trust issue has been actively studied in Peer-to-Peer (P2P) information sharing networks as a client peer needs to know prior to download actions which serving peer can provide complete files. In [15], Damiani *et al* propose an approach for evaluating the reputation of peers through the use of the distributed polling algorithm and the *XRep* protocol before initiating any download action. This approach adopts a binary rating system and it is based on the Gnutella query broadcasting method. EigenTrust [16] adopts a binary rating system as well and aims to collect the local trust values of all peers to calculate the global trust value of a given peer.

Some other earlier studies also adopted the binary rating system. In [8], Xiong *et al* propose a *PeerTrust* model which has two main features. First, they introduce three basic trust parameters (i.e., the feedback that a peer receives from other peers, the total number of transactions that a peer performs, the credibility of the feedback sources) and two adaptive factors in computing trustworthiness of peers (i.e., transaction context factor and the community context factor). Second, they define some general trust metrics and formulas to aggregate these parameters into a final trust value.

C. Trust Evaluation in Service-Oriented Environments

In the literature, the issue of trust has also received much attention in the field of service-oriented computing (SOC). In [9], Vu *et al* present a model to evaluate the service trust by comparing the advertised service quality and the delivered service quality. If the advertised service quality is as good as the delivered service quality, the service is reputable.

The application of machine learning and soft-computing approaches for predicting the trust in service-oriented environments are suggested to be very successful in the literature. In [17], Wang *et al* propose several trust evaluation metrics and a formula for trust computation, with which a final trust value is computed. In addition, they propose a fuzzy logic based

approach for determining reputation ranks that particularly differentiate the service periods of new service providers and old (long-existing) ones. The aim is to provide incentives to new service providers and penalize those old service providers with poor service quality.

Other machine learning methods such as neural networks, decision trees, support vector machines and other classifiers are suggested and applied for predicting the ordinal trust rating based on the QoS data [18], [19].

D. Uncertainty

It is reported that the uncertainty in a system can be due to several reasons [20]:

- The high complexity of the environment, which necessitates the adaptation of abstraction (granulation of information) for generalization purposes [21].
- The influence of human subjective judgement in the decision process or the involvement of human-machine interactions [22], [23], [24].
- Partially available information [25], due to miss-recording or inaccurate measurements [26].

The trust terms in service-oriented environments come with uncertainty as they are derived from the *human subjective judgement* - one of the above reasons.

However, to the best of our knowledge, the application of FLRA for predicting the trust rating in service-oriented environments has only been studied in [13]. This approach applies FLRA to fit the ordinal data, however, it does not extract the fuzziness overlooked in the data set.

There are other approaches in different engineering applications where FLRA has been applied. However, a manual fuzzification of the data (by adding spreads) with some predefined variables estimated by experts is applied.

Therefore, there is a need to propose a novel fuzzy regression approach for QoS based trust prediction in service-oriented environments.

III. Fuzzy Regression Analysis

Regression analysis [27] is a statistical technique for modeling and investigating the relationship between two or more variables. For example, here regression analysis can be used to build up a model that represents the trust rating of the delivered service as a function of a set of advertised QoS values. Then this model can be used to predict the trust rating of the new delivered service with a new set of advertised QoS values.

A. Classical Regression Analysis

In the classical regression method, a set of parameters of an unknown function $f(x,\omega)$ can be estimated by making measurements of the function with uncertainty at any point x_i:

$$y_i = f(x_i,\omega) + \epsilon_i, \tag{1}$$

where the uncertain ϵ_i is independent of x and is distributed according to a known density $p_\omega(\epsilon)$. Based on the observed data sample $S = \{(x_i, y_i)|i = 1, 2, \ldots, n\}$, the likelihood is given by

$$P(S|\omega) = \sum_{i=1}^{n} \ln p_\omega(y_i - f(x_i,\omega)). \tag{2}$$

Assuming that uncertainty follows a normal distribution with the mean 0 and the variance δ, the likelihood is given by

$$P(S|\omega) = -\frac{1}{2\delta^2}\sum_{i=1}^{n}(y_i - f(x_i,\omega))^2 - n\ln(\sqrt{2\pi}\delta) \tag{3}$$

Maximizing the likelihood in Eq. (3) is equivalent to minimizing

$$E(\omega) = \frac{1}{n}\sum_{i=1}^{n}(y_i - f(x_i,\omega))^2, \tag{4}$$

which is in fact the same as the estimation by the method of least squares. Namely, the regression line is estimated so that the sum of squares of the deviations between the observations and the regression line is minimized.

Classical regression analysis [27] is a statistical technique for modeling and investigating the relationship for quantitative or homogeneous data. However, for qualitative heterogeneous data, an application of fuzzy regression analysis is more promising. In such systems, uncertainty arises usually not due to randomness but due to the phenomenon of fuzziness [20].

B. Fuzzy Regression Model Parameters

Prior to presenting the details of the fuzzy regression model, some definitions about the parameters of the model are introduced first in this section.

1) Membership Function: The fuzzy number mentioned in this paper is $\widetilde{A}(\alpha, C)$ with the following *membership function* [28],

$$\mu_{\widetilde{A}}(x) = \begin{cases} \begin{cases} 1 - \frac{|x-\alpha|}{C}, & |x-\alpha| \le C, \\ 0, & \text{otherwise}, \end{cases} & C > 0, \\ \begin{cases} 1, & x = \alpha, \\ 0, & \text{otherwise}, \end{cases} & C = 0. \end{cases} \tag{5}$$

According to Eq. (5), it is easy to prove that $\lambda\widetilde{A}$ is the fuzzy number $\widetilde{A}(\lambda\alpha, |\lambda|C)$ and $\widetilde{A}_1 + \widetilde{A}_2$ is the fuzzy number $\widetilde{A}(\alpha_1 + \alpha_2, C_1 + C_2)$. Therefore, if the following condition holds:

$$\widetilde{T}_i^* = \widetilde{A}_0 + q_{i1}\widetilde{A}_1 + \ldots + q_{in}\widetilde{A}_n, \tag{6}$$

then $\widetilde{T}_i^*$ is the fuzzy number

$$\widetilde{T}_i^*(\alpha_0 + \sum_{j=1}^{n} q_{ij}\alpha_j, C_0 + \sum_{j=1}^{n}|q_{ij}|C_j). \tag{7}$$

2) Goodness-of-fit:

Definition 1: Let A, B be the fuzzy sets in real space $\mathbf{R}$, then

$$h = \bigvee_{x\in\mathbf{R}} \{\mu_{\widetilde{A}}(x) \wedge \mu_{\widetilde{B}}(x)\} \tag{8}$$

is the *goodness-of-fit* from A to B.

In fact, the goodness-of-fit is defined as the inner product here. According to Definition 1, the goodness-of-fit from the fuzzy number $\widetilde{A}(\alpha_1, C_1)$ to the fuzzy number $\widetilde{B}(\alpha_2, C_2)$ is

$$h = \begin{cases} 1 - \frac{|\alpha_1 - \alpha_2|}{C_1 + C_2}, & |\alpha_1 - \alpha_2| \leq C_1 + C_2, \\ 0, & \text{otherwise.} \end{cases} \quad (9)$$

Hence, the goodness-of-fit h_i from $\widetilde{T}_i(T_i, e_i)$ to Eq. (7) $\widetilde{T}_i^*(\alpha_0 + \sum_{j=1}^n q_{ij}\alpha_j, C_0 + \sum_{j=1}^n |q_{ij}|C_j)$ is

$$h_i = \begin{cases} 1 - \frac{|T_i - (\alpha_0 + \sum_{j=1}^n q_{ij}\alpha_j)|}{C_0 + \sum_{j=1}^n |q_{ij}|C_j + e_i}, & |T_i - (\alpha_0 + \sum_{j=1}^n q_{ij}\alpha_j)| \\ & \leq C_0 + \sum_{j=1}^n |q_{ij}|C_j + e_i, \\ 0 & \text{otherwise.} \end{cases}$$

3) Fuzziness:

Definition 2: Let $A(\alpha, C)$ be a fuzzy number, then the *fuzziness* [28] of A is given as:

$$S_A = \frac{1}{2}C. \quad (10)$$

The fuzziness measures how fuzzy or vague the fuzzy set is or how clear it is not. According to Definition 2, the fuzziness of $\widetilde{T}_i^*$ in Eq. (6) is

$$S_{\widetilde{T}_i^*} = \frac{1}{2}(C_0 + \sum_{j=1}^{n} |q_{ij}|C_j). \quad (11)$$

C. Fuzzy Linear Regression Analysis (FLRA)

In the FLRA model, we are interested in finding a fuzzy function $\widetilde{y}$ in the form given below in Eq. (12) which fits a finite number of numeric input - fuzzy output data $\left((x_{1i}, x_{2i}, \cdots, x_{(n-1)i}, x_{ni}), \widetilde{y}_i^*\right)$ $i = 1, \cdots, k$ with a minimum uncertain [24].

$$\widetilde{y}_i = \quad (12)$$
$$\widetilde{A}_n x_{ni} + \widetilde{A}_{n-1} x_{(n-1)i} + \cdots + \widetilde{A}_j x_{ji} + \cdots + \widetilde{A}_1 x_{1i} + \widetilde{A}_0$$

In a more general situation, inputs and outputs are all treated as fuzzy numbers. In this case, we are looking for a function such as the one given by Eq. (13), to fit the fuzzy input and fuzzy output data $\left((\widetilde{x}_{1i}, \widetilde{x}_{2i}, \cdots, \widetilde{x}_{(n-1)i}, \widetilde{x}_{ni}), \widetilde{y}_i^*\right)$.

$$\widetilde{y}_i = \quad (13)$$
$$\widetilde{A}_n \widetilde{x}_{ni} + \widetilde{A}_{n-1} \widetilde{x}_{(n-1)i} + \cdots + \widetilde{A}_j \widetilde{x}_{ji} + \cdots + \widetilde{A}_1 \widetilde{x}_{1i} + \widetilde{A}_0$$

where in Eqs (12) and (13), $\widetilde{A}_j$ $(j = 0, \cdots, n)$ is the fuzzy coefficient (parameter) of the regression model. The parameters are optimized such that the differences between the observed outputs $\widetilde{y}_i^*$ and estimated ones $\widetilde{y}_i$ are as small as possible. All $\widetilde{y}_i$ $(i = 1, \cdots, k)$, $\widetilde{A}_j$ $(j = 0, \cdots, n)$ and $\widetilde{x}_{ji}$ are fuzzy numbers, and the operations used above are all treated as the multiplication and addition of fuzzy numbers.

The first FLR model, proposed by Tanaka *et al* [24], was based on the possibility theory and solved by Linear Programming (LP). Diamond [29] proposed a FR model based on the Least Square (LS) approach. According to the definition of the error, FR models are classified in two categories: probabilistic with LP, and LS approaches. In the former approach, the aim is to minimize the overall fuzziness by minimizing the total spread of the fuzzy coefficients while the estimated outputs and the observed ones are within a certain h-level of confidence [30]. The term h expresses the fitness between the estimated fuzzy outputs and the observed ones. On the other hand, in the LS-based model, a similarity measure between observed and estimated outputs, is used as the measurement for the fitness of the model.

In fuzzy mathematics, LP is a well-known technique used in probabilistic approaches to minimize the fuzziness of the coefficients. In the LP based approaches with additional observation data, two constraints are added to LP [20]. However, having extra constraints is not an issue in practice since the data sets for fuzzy regression are small and also, LP problems even with thousands of variables and constraints can be solved in a few seconds. The goal of LP based approaches is to cover the spreads of all the observations (up to an h-level). The goal of LS based approaches is to find a model which has the most similar estimated outputs to the observed ones based on the chosen similarity measure.

For example, here regression analysis can be used to build up a model that represents the trust rating of the delivered service as a function of a set of advertised QoS values. Then, this model can be used to predict the trust rating of the new delivered service with a new set of advertised QoS values in the forthcoming transaction.

IV. Trust Prediction Based on Fuzzy Regression

In this paper, we investigate the application of FLRA for the prediction of trust based on a set of advertised QoS values. The main goal in this paper is to predict the trust rating of a web-service, which could be represented by linguistic expressions such as platinum, gold, silver and bronze. So, a common approach is to seek the relationship between the independent attributes (the QoS attributes) and dependent attribute (the trust attribute). For doing so, a numeric form of the trust attribute is considered to construct the model - even if the QoS data comes with some imprecision or uncertainty. Hence, initially the linguistic expressions of trust are all considered to be ordinal data. Then, after they are quantized (defuzzified), classical approaches can be applied [10].

The critical issue here is that the quantization process causes some important information to be overlooked or neglected [20]. In environments with uncertain data, the best option is then to not defuzzify the data but to take the uncertainty in the data into consideration in the level of inference [10]. However, the final results could be defuzzified for the presentation purposes only if it becomes necessary [10].

A linear regression model in the form of

$$Y = a_0 + a_1 x_1 + \cdots + a_n x_n,$$

where n is the number of input variables, is applied for QoS based trust estimation for each web-service. However, we have

added an extra term to fuzzify the results. A triangular fuzzy value, like $\widetilde{B_i}$ which derives from

$$(\sum_{i=1}^{n} x_i) \cdot (b_1, b_2, b_3),$$

where $b_1 \leq b_2 \leq b_3$ is added to the above linear regression model given in Eq. (14).

$$\widetilde{Y_i} = a_0 + a_1 x_1 + \cdots + a_9 x_9 + \widetilde{B_i} \tag{14}$$

The coefficients $a_0, a_1, \cdots, a_n$ are estimated by statistical linear regression. The motivation of applying the model given in Eq. (14) is due to the fact that this model does not have the *spread increasing problem* - an issue which exists in the original models given in Eqs (12) and (13). A model with the spread increasing problem would increase the uncertainty of the trust of a service by an increase in the magnitude of the input QoS variables.

To derive the best values of the variables b_1, b_2 and b_3, tabu-harmony search is applied [20]. In order to measure the goodness of the individual models in tabu-harmony search, we need to count how many predictions of the model are correct. However, the models have a fuzzy estimation of the trust value which is hard to be compared with the actual trust values which are ordinal values. One way to tackle this issue is to defuzzify the estimation and then assign it to a class of trust which has the smallest distance to it. Basically by doing so, the fuzziness is taken into consideration for inference and the quantization process takes place only in the final stage for the sake of presentation [10].

In this paper, we have defined the same margin for all the classes by assigning a class for each estimation. For example, if the margin is 0.2, then in our example estimations will be in the bands of

$$(-\infty, 1.2],\ (1.2, 2.2],\ (2.2, 3.2],\ \text{and}\ (3.2, +\infty).$$

We introduce the variable b_4 to derive the best margin. Since the value of b_4 depends on the selection of b_1, b_2 and b_3, we optimize all the four variables in one phase.

In contrast to the other methods, with our method, the trust rating will be estimated in terms of a fuzzy number. In fact, trust is naturally an inexact concept. However, due to the abstraction, it is usually converted to a traditional classification problem and the fuzziness is overlooked.

V. Experiments

The most comprehensive data sets for web-services classification used by [19], [31], [32], include ten crisp independent attributes and one linguistic expression which represents the trust level of the web-service. To the best of our knowledge, in most studies in the literature, the trust terms (being platinum, gold, silver and bronze) are quantized to 1 to 4, respectively.

In the experiment, the web-services data set used for the simulation purposes is taken from [33]. The data set contains 365 real web service implementations extracted from the Web. These services were collected using the Web Service Crawler Engine (WSCE). The majority of the Web services were obtained from public sources on the Web including Universal Description, Discovery, and Integration (UDDI) registries, search engines, and service portals.[1] From the list of attributes given in Table I, we have excluded *WSRF* due to its high dominance [19].

The settings of experiments in this section are as follows.

- The introduced data set with the properties given in Table I is first normalized and then we perform 10-fold cross validation as used in [19].
- Tabu-harmony search with a population size of 100 for 2000 iterations is used.
- The migration and crossover fractions are set to 0.7 and 0.05, respectively.
- The lower and upper bounds of b_1, b_2, b_3 and b_4 are set to -1 and 1, respectively.

The comparison of the method and the results obtained from Support Vector Machines (SVM), decision tree and linear regression are given in Table II. We can observe the following results.

- The accuracy of the proposed method based on fuzzy linear regression is about 80%, which is superior to the other methods compared in this paper.
- The standard deviation is estimated to be 0.07, which reveals the robustness of the approach on different runs.
- Both the standard deviation and the performance of our proposed approach based on fuzzy linear regression is better than those of the one which applies the traditional linear regression.
- Moreover, as discussed earlier, our approach is able to regenerate the overlooked uncertainty in the trust of service and use it for inference.
- The standard deviations and the training performances of the other methods are not given in Table II, as they are not reported in [19].

As an example, we have estimated the trust ratings of two web services from the obtained model during training. The trust values are in the form of fuzzy triangular numbers as follows:

$$(1.5714, 3.4027, 4.1017),\ (1.9139, 3.8692, 4.6155).$$

Although after defuzzification both would be classified as *gold*, there are differences between them in terms of QoS. In fact, Figure 1 reveals that the second service is slightly better than the first one. Moreover, there is an uncertainty that the quality of both services depicted in Figure 1 might actually be silver, as the left spreads of both the fuzzy numbers are very wide.

As another example, we assume the trust of two web services given in Figure 2. In case of using traditional (exact) methods, it is deduced that service 2 is superior to service 1. However, as the left spread of service 2 goes all the way to the bronze quality, this may result in selecting service 1 over service 2.

VI. CONCLUSIONS

In this paper, we have proposed an approach based on fuzzy linear regression to extract the qualitative information which may have been overlooked in the original data set. The extracted qualitative data is then used for modeling the data. The proposed approach is applied for the trust prediction of the delivered web-services based on a set of advertised QoS values. The method not only provides more detailed information of trust but it also has promising results. Although in order to quantitatively compare the performance of the method, the results are defuzzified, one could use the fuzzy results as they provide more information.

For future work, one may consider having different weights for each of the QoS variables. By doing so the number of variables for optimization increases, but the obtained model will be more generalized.

***Abstract*—This paper presents an observer-based hybrid fuzzy cerebellar model articulation controller (CMAC) neural network control with a supervisory controller for a class of uncertain chaotic systems. This proposed control system is integrating sliding mode control (SMC) theory and CMAC neural network into fuzzy controller design. The total states of the chaotic system are not assumed to be available for measurement. A state observer is used to estimate unmeasured states of the systems. The supervised control is appended to assure that the fuzzy CMAC controller achieve a stable closed-loop system through Lyapunov stability theory. Finally, simulation results show that the effect of the approximation error on the tracking error can be attenuated efficiently by the proposed method.**

Keywords- CMAC; fuzzy control; chaotic systems; observer; sliding mode control;

I. INTRODUCTION

Many different aspects of chaotic dynamics have attracted considerable attention in laser physics, digital communication, chemical reaction analysis and design, biological systems, power converters, circuit systems [1]-[5], etc. An interesting and challenging problem in the field is the control of chaotic systems. However, the chaotic systems have complex and unpredictable dynamical behavior. Inevitably, the constructed model comprises unmodeled nonlinearity and uncertain disturbance that conventional control strategies based on the accurate mathematical models of the controlled systems are difficult to derive.

The cerebellar model articulation controller (CMAC), developed by Albus in the 1970s [6]-[7], is a nonfully connected perceptron-like associative memory network with overlapping receptive-fields. The contents of these memory locations are referred as weights, and the output of this network is a linear combination of these weights in the memory addressed by the activated inputs [8]. Compared with the general multiplayer neural network with back-propagation algorithm, the CMAC has been applied to a wide variety of complex dynamical systems because of its simple computation, fast learning property and good generalization capability [9]-[10]. In the meantime, sliding mode control (SMC), or variable structure control, has successfully been developed as a popular robust strategy to a wide variety of systems having uncertainties and invariance to unknown disturbance [11]-[12]. Integrating CMAC neural network and SMC into fuzzy controller design have acquired superior performance [13]. However, these control methods are based on the assumption that the system states are known or available for feedback. If system states are not available for measurement, the conventional adaptive laws would be difficult to be realized. To treat this problem, an observer needs to estimate the unmeasured states and the SPR-Lyapunov design approach has been used to design an adaptive scheme [14]-[15]. The goal of this paper is to design a hybrid observer-based fuzzy CMAC controller with supervisory control for a class of uncertain chaotic systems under the constraint that only the system output is available for measurement.

II. PROBLEM FORMULATION

Consider the *n*th-order nonlinear system described in the following form:

$$\begin{aligned} x^{(n)} &= f(\boldsymbol{x}) + bu + d \\ y &= x \end{aligned} \tag{1}$$

where $f(\boldsymbol{x})$ is unknown real continuous function, $u \in R$ and $y \in R$ are the control input and output of the system, respectively, b is a positive constant, and $\boldsymbol{x} = [x, \dot{x}, \cdots, x^{(n-1)}]^T = [x_1, x_2, \cdots, x_n]^T$ is the state vector of system, d is the external disturbance with the properties of standard smoothness and it is assumed to have an upper bound D_N.

Rewriting (1) in the following form

$$\begin{aligned} \dot{\boldsymbol{x}} &= A\boldsymbol{x} + B(f(\boldsymbol{x}) + bu + d) \\ y &= C^T \boldsymbol{x} \end{aligned} \tag{2}$$

where $A = \begin{bmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \vdots \\ 0 & 0 & 0 & \cdots & 0 \end{bmatrix}$, $B = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}$, $C = \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}$

The control objective is to design an observer-based fuzzy CMAC controller such that the system output y follows a given desired trajectory y_d. The desired trajectory vector $\boldsymbol{y}_d$, the output tracking error vector $\boldsymbol{e}$ and the estimation error vector $\hat{\boldsymbol{e}}$ are defined as, respectively,

$$\boldsymbol{y}_d = [y_d \;\; \dot{y}_d \;\; \ddot{y}_d \;\; \cdots \;\; y_d^{(n-1)}]^T, \tag{3}$$

$$\boldsymbol{e} = \boldsymbol{y}_d - \boldsymbol{x} = [e \;\; \dot{e} \;\; \cdots \;\; e^{(n-1)}]^T = [e_1 \;\; e_2 \;\; \cdots \;\; e_n]^T \tag{4}$$

$$\hat{\boldsymbol{e}} = \boldsymbol{y}_d - \hat{\boldsymbol{x}} = [e \;\; \dot{\hat{e}} \;\; \cdots \;\; \hat{e}^{(n-1)}]^T \tag{5}$$

where $\hat{\boldsymbol{x}}$ and $\hat{\boldsymbol{e}}$ denote the estimates of $\boldsymbol{x}$ and $\boldsymbol{e}$, respectively. Set the sliding surface as

$$S(\boldsymbol{e}) = \boldsymbol{\lambda}^T \boldsymbol{e} \tag{6}$$

where $\boldsymbol{\lambda} = [\lambda_1, \lambda_2, \cdots, \lambda_n]^T$ is chosen such that $\lambda_n = 1$ and the polynomial $h(p)$

$$h(p) = \lambda_n p^{(n-1)} + \lambda_{n-1} p^{(n-2)} + \cdots + \lambda_1 p \tag{7}$$

is strictly Hurwitz [16].

Since (7) satisfies Hurwitz stability criterion, maintaining system states on surface $S(\boldsymbol{e},t)$ for all $t > 0$ is equivalent to the tracking problem $y = y_d$. The tracking control problem can be formulated by keeping the error vector $\boldsymbol{e}$ on the sliding surface defined as follows:

$$\dot{S} = y_d^{(n)} - f(\boldsymbol{x}) - bu - d + \sum_{i=1}^{n-1} \lambda_i e^{(i)} \tag{8}$$

In the design of the sliding mode controller, an equivalent control is given first such that each state Lyapunov-like condition holds for system stability [12]:

$$\frac{1}{2}\frac{d}{dt}(S^2) \le -\eta|S|, \;\; \eta > 0 \tag{9}$$

Therefore the control problem is to obtain the optimal control input u^* that guarantees the sliding condition (9).

If function $f(\boldsymbol{x})$ is known and the system is free of external disturbance *d*, the control law can be designed as

$$u^* = b^{-1}[-f(\boldsymbol{x}) + y_d^{(n)} + K_c^T \boldsymbol{e} + \eta \,\mathrm{sgn}(S)] \tag{10}$$

where $K_c = [k_{c1}, k_{c2}, \cdots, k_{cn}]^T$ is the feedback gain vector, $\eta > 0$ and $\mathrm{sgn}(S)$ is defined as

$$\mathrm{sgn}(S) = \begin{cases} 1 & S > 0 \\ 0 & S = 0 \\ -1 & S < 0 \end{cases} \tag{11}$$

By plugging u^* into (8), we will have $\dot{S} = -\eta \,\mathrm{sgn}(S)$. Thus, the sliding condition (9) can be easily verified. However, $f(\boldsymbol{x})$ is unknown, the control law (10) cannot be implement, and not all system state x_i are available. Therefore, to overcome such problems, we will design an observer to estimate the state $\boldsymbol{x}$ and the fuzzy CMAC systems are utilized to approximate unknown functions.

III. Description of the Fuzzy CMAC System

The CMAC is a simple and fast associative memory type neural network that is proposed as a well-established computational model based on the cerebellum in humans [6]-[7]. Fig. 1 depicts the structure of a two-dimensional CMAC. Each input variable, I_1 and I_2, must be quantized and the problem space is divided into discrete regions (called an *element*) and 3 elements are accumulated as a block. For each input variable, three kinds of segmentation are used, the variable I_1 is divided into blocks *A*, *B* and *C*, and the variable I_2 is divided into blocks *a*, *b* and *c*. Then, the areas formed by blocks, referred to as *Aa*, *Ab*, *Ac*, *Ba*, *Bb*, *Bc*, *Ca*, *Cb* and *Cc* are the addresses or the locations that store data which are called receptive-fields (or hypercubes). When each block is shifted by a small interval, different blocks will be obtained. For instance, blocks *D*, *E* and *F* in the second row for I_1 and *d*, *e* and *f* in the second column for I_2 are possible shifted regions. Then, *Dd*, *De*, *Df*, *Ed*, *Ee*, *Ef*, *Fd*, *Fe* and *Ff* are new hypercubes from the shifted regions. Similarly, hypercubes *Gg*, *Gh*, *Gi*, *Hg*, *Hh*, *Hi*, *Ig*, *Ih* and *Ii* are defined in the third layer. No hypercube is formed by the combination of different layers. Each activated element in each layer becomes a firing element, thus, the weight of each block can be obtained.

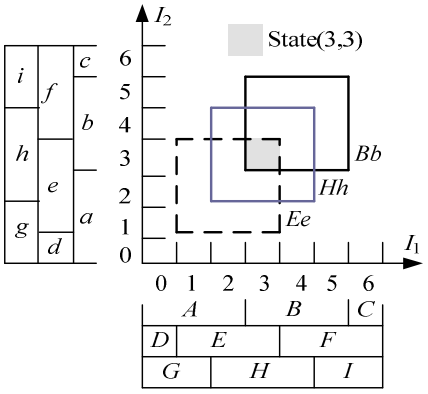

Figure 1. Block division of a 2-D CMAC.

CMAC uses a set of indices as an address in accordance with the current state to extract the stored data. Assume that N_n is the number of hypercubes; this is the same as the memory size in the case. Using the CMAC technique, a stored data y_i can be mathematically expressed as

$$y_i = \boldsymbol{a}_i \boldsymbol{w} = \sum_{j=1}^{N_n} a_{ij} w_j \tag{12}$$

where $\boldsymbol{w}$ indicates the column vector of memory contents and $\boldsymbol{a}_i$ is a memory element selection row vector that has N_e ones. Each hypercube is associated to an " arbitrary but deterministic" physical memory address. In Fig. 1, there are 27 hypercubes used to distinguish 49 different states in the 2-D CMAC. For example, let the hypercubes *Bb*, *Ee*, and *Hh* be addressed by the state $(v_1, v_2) = (3,3)$. Since each state addresses exactly N_n hypercubes, only these three hypercubes are set to 1, and the others are set to 0. Note that after the way of block division (see Fig. 1) is determined, the vector $\boldsymbol{a}_i$ for a specific quantized state is fixed.

A fuzzy CMAC controller system can be controlled by the following linguistic rules

$$R^{(j)}: \text{IF } x_1 \text{ is } F_1^j \text{ and} \cdots \text{and } x_n \text{ is } F_n^j, \text{ THEN } \hat{f} = \boldsymbol{a}_j \boldsymbol{w}_I \tag{13}$$

and

$$R^{(k)}: \text{IF } x_1 \text{ is } F_1^k \text{ and} \cdots \text{and } x_n \text{ is } F_n^k, \text{ THEN } u_D = \boldsymbol{a}_k \boldsymbol{w}_D \tag{14}$$

where $\hat{f}$ is the approximation of f, $\boldsymbol{a}_j$ and $\boldsymbol{a}_k$ are the memory element selection row vectors, $\boldsymbol{w}_I$ and $\boldsymbol{w}_D$ are the weighting column vectors of the CMAC. The FCMAC system with center-average defuzzifier, product inference and singleton fuzzifier is defined as [16]

$$\hat{f} = \sum_{l=1}^{N} \boldsymbol{a}_j \boldsymbol{w}_I \mu^l(\boldsymbol{x}) \Big/ \sum_{l=1}^{N} \mu^l(\boldsymbol{x}) = (\boldsymbol{A}_I \boldsymbol{w}_I)^T \boldsymbol{\Phi}(\boldsymbol{x}) \tag{15}$$

$$u_D = \sum_{k=1}^{N} \boldsymbol{a}_k \boldsymbol{w}_D \mu^l(\boldsymbol{x}) \Big/ \sum_{j=1}^{N} \mu^l(\boldsymbol{x}) = (\boldsymbol{A}_D \boldsymbol{w}_D)^T \boldsymbol{\Phi}(\boldsymbol{x}) \tag{16}$$

where $\mu^l(\boldsymbol{x}) = \prod_{i=1}^{n} \mu_{F_i^l}(x_i)$ is the matching degree of the lth, N is the number of the total IF-THEN rules,, $\boldsymbol{A}_I$ and $\boldsymbol{A}_d$ are matrix constituted from the memory element selection vector $\boldsymbol{a}_j$ and $\boldsymbol{a}_k$, respectively, and $\boldsymbol{\Phi} = (\phi_1, \phi_2, \cdots, \phi_N)^T$ is a column vector whose proper dimension depends on the number of fuzzy rules with ϕ_j is defined as

$$\phi_j(\boldsymbol{x}) = \left(\prod_{i=1}^{n} \mu_{F_i^j}(x_i) \right) \Big/ \sum_{l=1}^{N} \left(\prod_{i=1}^{n} \mu_{F_i^j}(x_i) \right) \tag{17}$$

IV. STATE OBSERVER SCHEME

In the previous section, due to assumption that the state vector $\boldsymbol{x}$ is immeasurable, $f(\boldsymbol{x})$ are unavailable, by replacing the function $f(\boldsymbol{x})$, system state $\boldsymbol{x}$, error vector $\boldsymbol{e}$ and sliding surface S in (10) with their estimates $\hat{f}(\hat{\boldsymbol{x}})$, $\hat{\boldsymbol{x}}$, $\hat{\boldsymbol{e}}$ and $\hat{S}(\hat{\boldsymbol{e}})$. Since the fuzzy CMAC systems have the property such that they can approximate any continuous functions on a compact set, utilize fuzzy CMAC systems $\hat{f}(\hat{\boldsymbol{x}})$ be of the form

$$\hat{f}(\hat{\boldsymbol{x}}) = \boldsymbol{w}_I^T \boldsymbol{A}_I^T \boldsymbol{\Phi}(\hat{\boldsymbol{x}}) \tag{18}$$

where $\boldsymbol{\Phi}(\hat{\boldsymbol{x}}) = [\phi_1(\hat{\boldsymbol{x}}), \cdots, \phi_N(\hat{\boldsymbol{x}})]^T$. An indirect controller is comprised of a fuzzy CMAC based certainty equivalent controller and is given by

$$u_I = b^{-1}[-\hat{f}(\hat{\boldsymbol{x}}) + y_d^{(n)} + K_c^T \hat{\boldsymbol{e}} + \eta \operatorname{sgn}(\hat{S})] \tag{19}$$

where $\hat{S} = \boldsymbol{\lambda}^T \hat{\boldsymbol{e}}$. The direct fuzzy CMAC controller is chosen as

$$u_D = \boldsymbol{w}_D^T \boldsymbol{A}_D^T \boldsymbol{\Phi}(\hat{\boldsymbol{x}}) \tag{20}$$

where u_D is the fuzzy CMAC system to directly approximate the control law (10). Thus, the resulting control law is

$$u = u_H + u_s = \alpha u_I + (1-\alpha) u_D + u_s \tag{21}$$

where $u_H = \alpha u_I + (1-\alpha) u_D$ is the hybrid fuzzy CMAC controller, u_I is the indirect fuzzy CMAC controller as (19), u_D is the direct fuzzy CMAC controller as (20), u_s is utilized to compensate the modeling error and external disturbance, and $\alpha \in [0,1]$. Substituting (21) into (2), after some manipulation, one has

$$\begin{aligned} \dot{\boldsymbol{e}} &= A\boldsymbol{e} - BK_c^T \hat{\boldsymbol{e}} + B[\alpha(\hat{f}(\hat{\boldsymbol{x}}) - f(\boldsymbol{x})) \\ &\quad - (1-\alpha) b(u_D(\hat{\boldsymbol{x}}) - u^*(\boldsymbol{x}))] - B[bu_s + \eta \operatorname{sgn}(\hat{S}) + d] \\ e_1 &= C^T \boldsymbol{e} \end{aligned} \tag{22}$$

where $u^*(\boldsymbol{x}) = b^{-1}[-f(\boldsymbol{x}) + y_d^{(n)} + K_c^T \hat{\boldsymbol{e}} + \eta \operatorname{sgn}(\hat{S})]$. Thus, the tracking problem has been converted to the regulation problem of designing a sate observer for estimating the state vector $\boldsymbol{e}$ in (22).

Design the following observer to estimate the error vector $\boldsymbol{e}$ in (22)

$$\begin{aligned} \dot{\hat{\boldsymbol{e}}} &= A\hat{\boldsymbol{e}} - B[K_c^T \hat{\boldsymbol{e}} + \eta \operatorname{sgn}(\hat{S})] + K_o(e_1 - \hat{e}_1) \\ \hat{e}_1 &= C^T \hat{\boldsymbol{e}} \end{aligned} \tag{23}$$

where $K_o = [k_{o1}, k_{o2}, \cdots, k_{on}]^T$ is the observer gain vector, which is selected such that the characteristic polynomial of $A - K_o C^T$ is strictly Hurwitz because (C, A) is observable. Define the observation errors $\tilde{\boldsymbol{e}} = \boldsymbol{e} - \hat{\boldsymbol{e}}$ and $\tilde{e}_1 = e_1 - \hat{e}_1$. Subtracting (23) from (22) yields

$$\begin{aligned} \dot{\tilde{\boldsymbol{e}}} &= (A - K_o C^T)\tilde{\boldsymbol{e}} + B[\alpha(\hat{f}(\hat{\boldsymbol{x}}) - f(\boldsymbol{x})) \\ &\quad - (1-\alpha) b(u_D(\hat{\boldsymbol{x}}) - u^*(\boldsymbol{x})) - bu_s - d] \\ \tilde{e}_1 &= C^T \tilde{\boldsymbol{e}} \end{aligned} \tag{24}$$

Since (C, A) is observable, there exist a positive-definite symmetric matrix P which satisfies the Lyapunov equation

$$\begin{aligned} &(A - BK_o^T)^T P + P(A - BK_o^T) = -Q \\ &PB = C \end{aligned} \tag{25}$$

where Q is a given positive-definite matrix.

V. ADAPTIVE LAW AND STABILITY ANALYSIS

This section is to use fuzzy CMAC system to approximate the nonlinear functions $f(\boldsymbol{x})$, $u_D(\boldsymbol{x})$ and derive the adaptive laws to adjust the weighting factors of the fuzzy CMAC system for the purpose of forcing the estimation error $\tilde{\boldsymbol{e}}$ to converge to zero.

First, replace the estimation $\hat{f}(\hat{\boldsymbol{x}})$ of the indirect control effort and the direct control effort $u_D(\hat{\boldsymbol{x}})$ in specific fuzzy CMAC systems as (13) and (14), i.e.

$$\hat{f}(\hat{\boldsymbol{x}}) = \hat{f}(\hat{\boldsymbol{x}} \mid \boldsymbol{w}_I) = \boldsymbol{w}_I^T \boldsymbol{A}_I^T \boldsymbol{\Phi}(\hat{\boldsymbol{x}}) \tag{26}$$

$$u_D(\hat{\boldsymbol{x}}) = u_D(\hat{\boldsymbol{x}} \mid \boldsymbol{w}_D) = \boldsymbol{w}_D^T \boldsymbol{A}_D^T \boldsymbol{\Phi}(\hat{\boldsymbol{x}}) \tag{27}$$

Suppose there exists constant optimal parameter vectors $\boldsymbol{w}_I^*$, $\boldsymbol{w}_D^*$

$$\boldsymbol{w}_I^* = \arg \min_{\boldsymbol{w}_I \in \Omega_f} \left[\sup_{\boldsymbol{x} \in U_1, \hat{\boldsymbol{x}} \in U_2} \left| f(\boldsymbol{x}) - \hat{f}(\hat{\boldsymbol{x}} \mid \boldsymbol{w}_I) \right| \right] \tag{28}$$

$$\boldsymbol{w}_D^* = \arg \min_{\boldsymbol{w}_D \in \Omega_D} \left[\sup_{\boldsymbol{x} \in U_1, \hat{\boldsymbol{x}} \in U_2} \left| u^*(\boldsymbol{x}) - u_D(\hat{\boldsymbol{x}} \mid \boldsymbol{w}_D) \right| \right] \tag{29}$$

where $\boldsymbol{x}$, $\hat{\boldsymbol{x}}$, $\boldsymbol{w}_I$ and $\boldsymbol{w}_D$ belong to compact sets U_1, U_2, Ω_f and Ω_D, respectively, which are defined as $U_1 = \{\boldsymbol{x} \in R^n : \|\boldsymbol{x}\| \le M_1\}$, $U_2 = \{\hat{\boldsymbol{x}} \in R^n : \|\hat{\boldsymbol{x}}\| \le M_2\}$, $\Omega_f = \{\boldsymbol{w}_I \in R^N : \|\boldsymbol{w}_I\| \le M_f\}$ and $\Omega_D = \{\boldsymbol{\theta}_D \in R^N : \|\boldsymbol{\theta}_D\| \le M_D\}$, where M_1, M_2, M_f and M_D are the designed parameters. Let the minimum approximation error be defined as

$$w = \alpha[\hat{f}(\hat{\boldsymbol{x}} \mid \boldsymbol{w}_I^*) - f(\boldsymbol{x})] - (1-\alpha)b[(u_D(\hat{\boldsymbol{x}} \mid \boldsymbol{w}_D^*) - u^*(\boldsymbol{x})] \quad (30)$$

Applying (28) and (29), the error dynamics (24) of the observation can be formulated as

$$\begin{aligned} \dot{\tilde{\boldsymbol{e}}} &= (A - K_o C^T)\tilde{\boldsymbol{e}} + B[\alpha \tilde{\boldsymbol{w}}_I^T \boldsymbol{A}_I^T \boldsymbol{\Phi}(\hat{\boldsymbol{x}}) \\ &\quad - (1-\alpha)b\tilde{\boldsymbol{w}}_D^T \boldsymbol{A}_D^T \boldsymbol{\Phi}(\hat{\boldsymbol{x}}) + w - bu_s - d] \\ \tilde{e}_1 &= C^T \tilde{\boldsymbol{e}} \end{aligned} \quad (31)$$

where $\tilde{\boldsymbol{w}}_I = \boldsymbol{w}_I - \boldsymbol{w}_I^*$, $\tilde{\boldsymbol{w}}_D = \boldsymbol{w}_D - \boldsymbol{w}_D^*$.

Assumption 1. We can choose K_c to guarantee $\boldsymbol{x} \approx \hat{\boldsymbol{x}}$. The bound function $f^U(\boldsymbol{x})$ is known such that

$$|f(\boldsymbol{x})| \le f^U(\boldsymbol{x}) \approx f^U(\hat{\boldsymbol{x}}) < \infty,$$

Considering the error dynamical equation (24), let the Lyapunov function candidate be

$$V_{\tilde{e}} = \frac{1}{2}\tilde{\boldsymbol{e}}^T P \tilde{\boldsymbol{e}} \quad (32)$$

Differentiating (32) with respect to time yields

$$\begin{aligned} \dot{V}_{\tilde{e}} &= \frac{1}{2}\dot{\tilde{\boldsymbol{e}}}^T P\tilde{\boldsymbol{e}} + \frac{1}{2}\tilde{\boldsymbol{e}}^T P\dot{\tilde{\boldsymbol{e}}} \\ &= \frac{1}{2}\tilde{\boldsymbol{e}}^T\{(A - K_o C^T)^T P + P(A - K_o C^T)\}\tilde{\boldsymbol{e}} + \tilde{\boldsymbol{e}}^T PB[\alpha(\hat{f}(\hat{\boldsymbol{x}}) \\ &\quad - f(\boldsymbol{x})) - (1-\alpha)b(u_D(\hat{\boldsymbol{x}}) - u^*(\boldsymbol{x})) - bu_s - d] \\ &\le -\frac{1}{2}\tilde{\boldsymbol{e}}^T Q\tilde{\boldsymbol{e}} - \tilde{\boldsymbol{e}}^T PBbu_s + \|\tilde{\boldsymbol{e}}^T PB\|(|\hat{f}(\hat{\boldsymbol{x}})| + |f(\boldsymbol{x})| + \\ &\quad |y_d^{(n)} + K_c^T \hat{\boldsymbol{e}}| + |bu_D(\hat{\boldsymbol{x}})| + \eta + |d|) \end{aligned} \quad (33)$$

Based on Assumption 1 and by observing (33), the supervisory control u_s is chosen as

$$\begin{aligned} u_s = I^* \operatorname{sgn}(\tilde{\boldsymbol{e}}^T PB)b^{-1}(&|\hat{f}(\hat{\boldsymbol{x}})| + f^U + |y_d^{(n)} + K_c^T \hat{\boldsymbol{e}}| \\ &+ |bu_D(\hat{\boldsymbol{x}})| + \eta + D_N) \end{aligned} \quad (34)$$

where $\hat{f}(\hat{\boldsymbol{x}})$ and $\hat{u}_D(\hat{\boldsymbol{x}})$ can be obtained from the output of the fuzzy CMAC system, sgn( ) is a sign function, I^* is defined as

$$I^* = \begin{cases} 1 & V_{\tilde{e}} > \overline{V} \\ 0 & V_{\tilde{e}} \le \overline{V} \end{cases} \quad (35)$$

where $\overline{V}$ is a pre-specific constant by designer. Consider the case $V_{\tilde{e}} > \overline{V}$, substituting (34) into (33) yields

$$\begin{aligned} \dot{V}_{\tilde{e}} &\le -\frac{1}{2}\tilde{\boldsymbol{e}}^T Q\tilde{\boldsymbol{e}} + |\tilde{\boldsymbol{e}}^T PB| \cdot [(|\hat{f}(\hat{\boldsymbol{x}})| + |f(\boldsymbol{x})| \\ &\quad + |y_d^{(n)} + K_c^T \hat{\boldsymbol{e}}| + |bu_D(\hat{\boldsymbol{x}})| + \eta + |d|) \\ &\quad - (|\hat{f}(\hat{\boldsymbol{x}})| + f^U + |y_d^{(n)} + K_c^T \hat{\boldsymbol{e}}| + |bu_D(\hat{\boldsymbol{x}})| + \eta + D_N)] \\ &\le -\frac{1}{2}\tilde{\boldsymbol{e}}^T Q\tilde{\boldsymbol{e}} \le 0 \end{aligned} \quad (36)$$

Theorem 1: Consider the nonlinear system (1) with control law (19), (21) and (34), $\hat{f}(\hat{\boldsymbol{x}} \mid \boldsymbol{w}_I)$ and $u_D(\hat{\boldsymbol{x}} \mid \boldsymbol{w}_D)$ are given by (26) and (27), and the parameter adaptation law are chosen as

$$\dot{\boldsymbol{\theta}}_f = -r_1 \tilde{\boldsymbol{e}}^T PB\boldsymbol{A}_I^T \boldsymbol{\Phi}(\hat{\boldsymbol{x}}) \quad (37)$$

$$\dot{\boldsymbol{\theta}}_D = r_2 b\boldsymbol{e}^T PB\boldsymbol{A}_D^T \boldsymbol{\Phi}(\hat{\boldsymbol{x}}) \quad (38)$$

where $r_1 > 0$ and $r_2 > 0$ are positive adaptive gain constants to be designed. If Assumption 1 is satisfied, the proposed control scheme can ensures that all the closed-loop signals are bounded, and the tracking errors converge to zero.

Proof:

Choose the Lyapunov-like function candidate as

$$V = \frac{1}{2}\tilde{\boldsymbol{e}}^T P\tilde{\boldsymbol{e}} + \frac{\alpha}{2r_1}\tilde{\boldsymbol{w}}_I^T \tilde{\boldsymbol{w}}_I + \frac{1-\alpha}{2r_2}\tilde{\boldsymbol{w}}_D^T \tilde{\boldsymbol{w}}_D \quad (39)$$

with $P = P^T > 0$. Taking the time derivative of V yields

$$\dot{V} = \frac{1}{2}(\dot{\tilde{\boldsymbol{e}}}^T P\tilde{\boldsymbol{e}} + \tilde{\boldsymbol{e}}^T P\dot{\tilde{\boldsymbol{e}}}) + \frac{\alpha}{r_1}\tilde{\boldsymbol{w}}_I^T \dot{\tilde{\boldsymbol{w}}}_I + \frac{1-\alpha}{r_2}\tilde{\boldsymbol{w}}_D^T \dot{\tilde{\boldsymbol{w}}}_D \quad (40)$$

Substituting (24) into (40) and the fact $\dot{\tilde{\boldsymbol{w}}}_I = \dot{\boldsymbol{w}}_I$, $\dot{\tilde{\boldsymbol{w}}}_D = \dot{\boldsymbol{w}}_D$, the above equation becomes

$$\begin{aligned} \dot{V} &= \frac{1}{2}[\tilde{\boldsymbol{e}}^T (A - K_o C^T)^T P\tilde{\boldsymbol{e}} + \tilde{\boldsymbol{e}}^T P(A - K_o C^T)\tilde{\boldsymbol{e}}] \\ &\quad + \tilde{\boldsymbol{e}}^T PB(w - bu_s - d) + \frac{\alpha}{r_1}\tilde{\boldsymbol{w}}_I^T (r_1 \tilde{\boldsymbol{e}}^T PB\boldsymbol{A}_I^T \boldsymbol{\Phi}(\hat{\boldsymbol{x}}) + \dot{\boldsymbol{w}}_I) \\ &\quad - \frac{1-\alpha}{r_2}\tilde{\boldsymbol{w}}_D^T (r_2 b\boldsymbol{e}^T PB\boldsymbol{A}_D^T \boldsymbol{\Phi}(\hat{\boldsymbol{x}}) - \dot{\boldsymbol{w}}_D) \end{aligned} \quad (41)$$

Using parameter adaptation law (37)-(38) and (25), and the definition of u_s in (34), then (41) can be formulated as

$$\dot{V} = -\frac{1}{2}\tilde{\boldsymbol{e}}^T Q\tilde{\boldsymbol{e}} + \tilde{\boldsymbol{e}}^T PB(w - bu_s - d) \le -\frac{1}{2}\tilde{\boldsymbol{e}}^T Q\tilde{\boldsymbol{e}} \le 0 \quad (42)$$

This means that the inequality $\dot{V}_i < 0$ is obtained and the whole closed-loop system is stable.

VI. SIMULATION RESULTS

Chaotic system is a nonlinear deterministic system that displays complex, noisy-like and unpredictable dynamical behavior. To illustrate the performance and efficiency of the proposed fuzzy CMAC control system, it is applied to control a Duffing forced oscillation system [16]. The oscillation system has chaotic phenomena if the control input equals zero. The dynamic equation of a Duffing forced oscillation system can be described as follows:

$$\begin{bmatrix}\dot{x}_1\\ \dot{x}_2\end{bmatrix}=\begin{bmatrix}0 & 1\\ 0 & 0\end{bmatrix}\begin{bmatrix}x_1\\ x_2\end{bmatrix}+\begin{bmatrix}0\\ 1\end{bmatrix}(f+bu+d),$$
$$y=\begin{bmatrix}1 & 0\end{bmatrix}\begin{bmatrix}x_1\\ x_2\end{bmatrix}. \tag{43}$$

where $f(x_1,x_2)=-0.1x_2-x_1^3+12\cos(t)$, y is the system output, u is the applied force (the control input) and d is the external disturbance. Also the external disturbance $d(t)$ is assumed to be a square wave with an amplitude ±1 and a period of 2π.

The control objective is to maintain the output x_1 of the system to track the desired trajectory $y_d=\sin(t)$ under the constraint that only the system output is available for measurement. In the implementation, the fuzzy sets of states $\hat{x}_1$ and $\hat{x}_2$ are defined as {*NB, NM, NS, ZE, PS, PM, PB*} and their membership functions are

$\mu_{NB}(\hat{x}_i)=1/(1+\exp(5(\hat{x}_i+3))$, $\mu_{NM}(\hat{x}_i)=\exp(-((\hat{x}_i+2)^2)$,
$\mu_{NS}(\hat{x}_i)=\exp(-(\hat{x}_i+1)^2)$, $\mu_{ZE}(\hat{x}_i)=\exp(-(\hat{x}_i)^2)$,
$\mu_{PS}(\hat{x}_i)=\exp(-(\hat{x}_i-1)^2)$, $\mu_{PM}(\hat{x}_i)=\exp((\hat{x}_i-2)^2)$,
$\mu_{PB}(\hat{x}_i)=1/(1+\exp(-5(\hat{x}_i-3)^2)$.

Select the positive matrices $Q=Diag[10\ 10]$ and choose the feedback and observer gain vector as $K_c^T=[30,50]$ and $K_o^T=[60,140]$. The sliding surface is selected as $\hat{S}=\Lambda^T\tilde{\boldsymbol{e}}$, where $\Lambda=[5,1]^{\mathrm{T}}$. The initial states are chosen as $\boldsymbol{x}(0)=[0.2,0.2]^T$, $\hat{\boldsymbol{x}}(0)=[1.5,1.5]^T$ and let adaptation gains as $r_1=r_2=100$. Consider three cases of prescribed adaptation levels $\alpha=1$, 0, 0.5, respectively, the simulation results are shown in Fig. 2 to Fig. 4. The simulation results show that the tracking error has been attenuated efficiently. Thus the proposed adaptive control scheme can control the system to follow the desired trajectory and achieve desired performance.

VII. SIMULATION RESULTS

The goal of this work is the development and implementation of a hybrid fuzzy CMAC control based sliding mode control for the robust trajectory tracking of uncertain chaotic systems. This design obtains robustness in the sense that the self-tuning mechanism can automatically adapt the fuzzy CMAC controller by using a learning algorithm and the global asymptotic stability of the algorithm is established via Lyapunov stability criterion. The simulation presented in the Duffing forced oscillation system control indicates that the proposed approach is capable of achieving a good trajectory following performance without the knowledge of plant parameters. Although only the Duffing forced oscillation system has been studied in this paper, the proposed control scheme can also be used to address the other class of chaotic systems.

***Abstract*—We propose a fully automatic plaque boundary extraction system for an intravascular ultrasound (IVUS) image aiming at practical use in clinic. The IVUS image, which is commonly used for a diagnosis of acute coronary syndromes (ACS) in the field of cardiology, has coarse-grained texture due to heavy speckle noise. A medical doctor's interpretation of the IVUS image is disturbed frequently by the heavy speckle noise. In the proposed system, the heavy speckle noise is reduced firstly by using an anisotropic diffusion filter. Secondarily, the plaque boundary is extracted by using the Takagi-Sugeno (T-S) type fuzzy inference with a weighted separability measure and some heuristic rules. Extraction of plaque boundary is achieved fully automatically. The proposed system substantially reduces the workload of medical doctors. The effectiveness of the proposed system has been verified by the experiments using the real IVUS images.**

***Index Terms*—Acute coronary syndromes, IVUS image, plaque boundary extraction, fuzzy inference.**

I. Introduction

Intravascular ultrasound (IVUS) method [1], [2] is a real-time computed tomographic imaging method for the visualization of coronary atherosclerotic plaque. It provides thousands of cross-sectional images of a coronary artery in vivo, and is employed especially for a diagnosis of the acute coronary syndromes (ACS) caused by a rupture of vulnerable plaque [3], [4]. For quantitative assessment of plaque [5], precise boundary extraction of plaque is strongly required in the interpretation of the tomographic images produced by the IVUS method. In particular, the inner and outer boundaries of the plaque and the cross-sectional area of the plaque are to be extracted and evaluated precisely in order to monitor the effect of medical treatment.

Frequently, medical doctors manually trace the boundaries of the plaque and then evaluate the area of that plaque for many IVUS images. After that, the volume of the plaque is estimated by integrating the extracted area. However, the boundary extraction task of plaque is tough and time-consuming for a medical doctor. This is not only because a large number of the IVUS images must be processed, but also because recognizing the boundaries of plaque is very hard due to a heavy blood speckle noise. A computer-aided full-automatic precise boundary extraction of plaque is thus strongly desired.

So far, in the representative boundary extraction methods [6], *e.g.*, curve interpolation method such as spline interpolation is used, where seed points are given manually by a medical doctor. Those methods and tools can reduce somewhat the workload of the tracing task on a medical doctor. However, the accuracy of the plaque boundary extraction by the curve interpolation is considerably affected by the number of the seed points and/or the positions of those points.

On the other hand, the methods based on automatic search algorithms, *e.g.*, an active contour (snake) model [7], genetic algorithm [8], and so on, have been proposed to date. However, those methods involve some iterative processes for optimizing evaluation function and take plenty of computing time. To meet with a demand for a practical use, a quick and fully automatic boundary extraction of plaque is definitely required.

In the past, to cope with this problem, the authors proposed some fundamental techniques for the plaque boundary extraction such as speckle noise reduction by using a modified anisotropic diffusion filter [9], [10] with a statistical discriminant measure (being called separability) [11], an automatic searching algorithm for the boundary extraction area based on some heuristic rules [12], boundary extraction method by using Takagi-Sugeno (T-S) type fuzzy inference [13], and so on. Then the authors furthermore advanced the method by employing an adaptive allocation rule of membership functions in the T-S fuzzy inference engine, and some of the performance of the proposed method has been presented in [14]. The fuzzy inference-based method realizes a fast, precise, robust, and automatic extraction of the boundary of plaque.

In this paper, we introduce an automatic boundary extraction system which combines all the above-mentioned fundamental techniques. The proposed system is implemented as

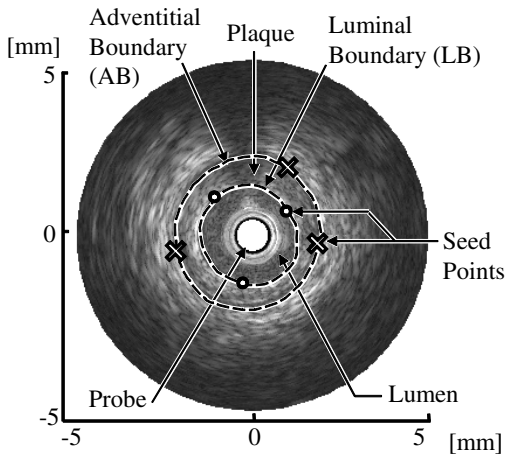

Fig. 2. An example of B-mode image obtained by the IVUS method. In the image, 4mm corresponds to 2,048 pixels.

a software with easy-to-use graphical user interface (GUI) aiming at the real practical use in clinic and at the research use.

In the proposed system, the plaque boundary extraction area is automatically searched and is found by an edge-preserved smoothing filter using anisotropic diffusion, weighted separability, the heuristic rules, and T-S type fuzzy inference. This system also has a semi-automatic boundary extraction function using the seed points allocated by the user, for the IVUS images with very complicated boundary of coronary plaque.

The validity and the effectiveness of the system are briefly reviewed by applying it to the practical problem of plaque boundary extraction in clinic. Finally, it is shown that a 3-dimensional image of the coronary plaque can be reconstructed.

II. Intravascular Ultrasound (IVUS) Method

Intravascular ultrasound (IVUS) method [1], [2] is one of the medical imaging techniques. It allows the application of ultrasound technology to observe from inside the blood vessels out through the surrounding blood column, visualizing the coronary plaque in vivo.

In the IVUS method, a specially designed thin catheter with the ultimately-miniaturized ultrasound probe attached to its distal end is used (see Fig. 1). To visualize the coronary arteries and plaques in vivo, angiographic techniques are used. A medical doctor steers the guidewire with very thin diameter from outside the body through angiography catheters into the coronary artery to be visualized. The ultrasound catheter tip is slid in over the guidewire and positioned, using angiography techniques so that the tip is at the farthest away position to be visualized. The guidewire is kept stationary and the ultrasound catheter tip is slid backwards, usually under motorized control.

The proximal end of the catheter is connected to a computerized ultrasound equipment. The ultrasound waves are emitted from the ultrasound probe, which are in the 40MHz range in this study, and the catheter also receives the reflected signal from the plaque tissue. It is sampled at 400 MHz and stored in the computerized ultrasound equipment.

An IVUS image is constructed of the amplitude information of the received radiofrequency (RF) signal. In order to visualize the inside of a coronary artery, the sampled RF signal is first transformed into an 8-bit luminal intensity signal by taking the absolute value of a signal, then by taking the envelope of a signal, and finally by taking its logarithmic value.

The luminal intensity signals in all radial directions are then formed to obtain a tomographic cross sectional image of a coronary artery as shown in Fig. 2. The IVUS image of Fig. 2 is called "B-mode image." A B-mode image displays a real time ultrasound cross-sectional image of a thin section of a blood vessel currently surrounding a catheter probe.

In this study, the B-mode image is constructed with 2,048 pixels in depth, and 256 lines in radial direction. Hence, the resolution of distance and angle are $1.95\mu m$/pixel and $1.41°$/line, respectively.

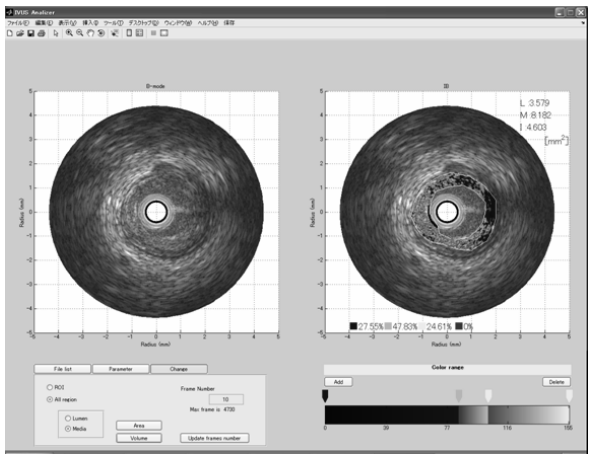
In the quantitative assessment of coronary plaque, the following two boundaries are extracted in the IVUS B-mode image as shown in Fig. 2. One is a luminal boundary (LB) between the lumen and the plaque, and the other is an adventitial boundary (AB) between the plaque and the vascular wall.

III. Proposed System

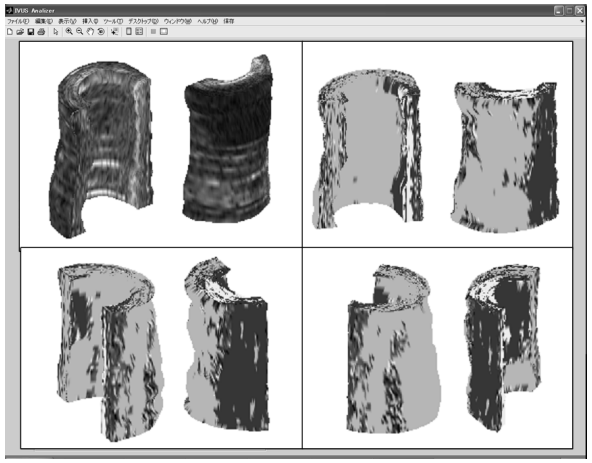
Figs. 3(a) and 3(b) show the overviews of the proposed diagnosis system. By applying a set of IVUS data obtained by IVUS instrument, the software extracts the boundaries of plaque by the full-automatic extraction algorithm and reconstructs the 3-D classified tissue structure of the plaque as shown in Fig. 3(b). In this section, we firstly describe the full-automatic search method for the area of boundary extraction without using any seed points and giving any initial boundary. Then semi-automatic (interactive) boundary extraction method, which is used for IVUS images with very complicated boundaries of plaque, is described.

A. Fully automatic plaque boundary extraction

In the present method, at first, an IVUS image is transformed from the polar coordinate system into the orthogonal coordinate system as shown in Fig. 4(a). Then the edge-preserved smoothing using anisotropic diffusion is performed



(a)



(b)

Fig. 3. Overview of the proposed diagnosis system. (a) Overview of main GUI. (b) 3-D viewing of the extracted plaque.

on the input image as shown in Fig. 4(b). An anisotropic diffusion filter is known as an effective edge-preserved smoothing method, and it is broadly used.

Then image processing using some heuristic rules are applied to find out the boundary extraction areas. Finally in the found areas, the objective boundaries are extracted by T-S type fuzzy inference with the weighted separability measure. The weighted separability is a modification of a separability measure with special consideration to an IVUS image.

1) Speckle Noise Reduction by Perona-Malik's anisotropic diffusion (PMD): The anisotropic diffusion filter proposed by Perona and Malik [9] is employed to realize an edge-preserved smoothing for an IVUS B-mode image. The discrete version of PMD is given as follows:

$$I_{\boldsymbol{s}}^{(n+1)} = I_{\boldsymbol{s}}^{(n)} + \frac{\lambda}{|\phi_{\boldsymbol{s}}|} \sum_{\boldsymbol{p}\in\phi_{\boldsymbol{s}}} g(\nabla I_{\boldsymbol{s},\boldsymbol{p}}^{(n)}) \cdot \nabla I_{\boldsymbol{s},\boldsymbol{p}}^{(n)}, \qquad (1)$$

where $\boldsymbol{s}$=(x, y) and $\boldsymbol{p}$ are the coordinates of the pixel of concern and its neighboring pixels, respectively. $I_s^{(n)}$ is an intensity at $\boldsymbol{s}$ with an iteration count n. $\phi_{\boldsymbol{s}}$ represents the four neighboring pixels in North, West, South and East diffusion

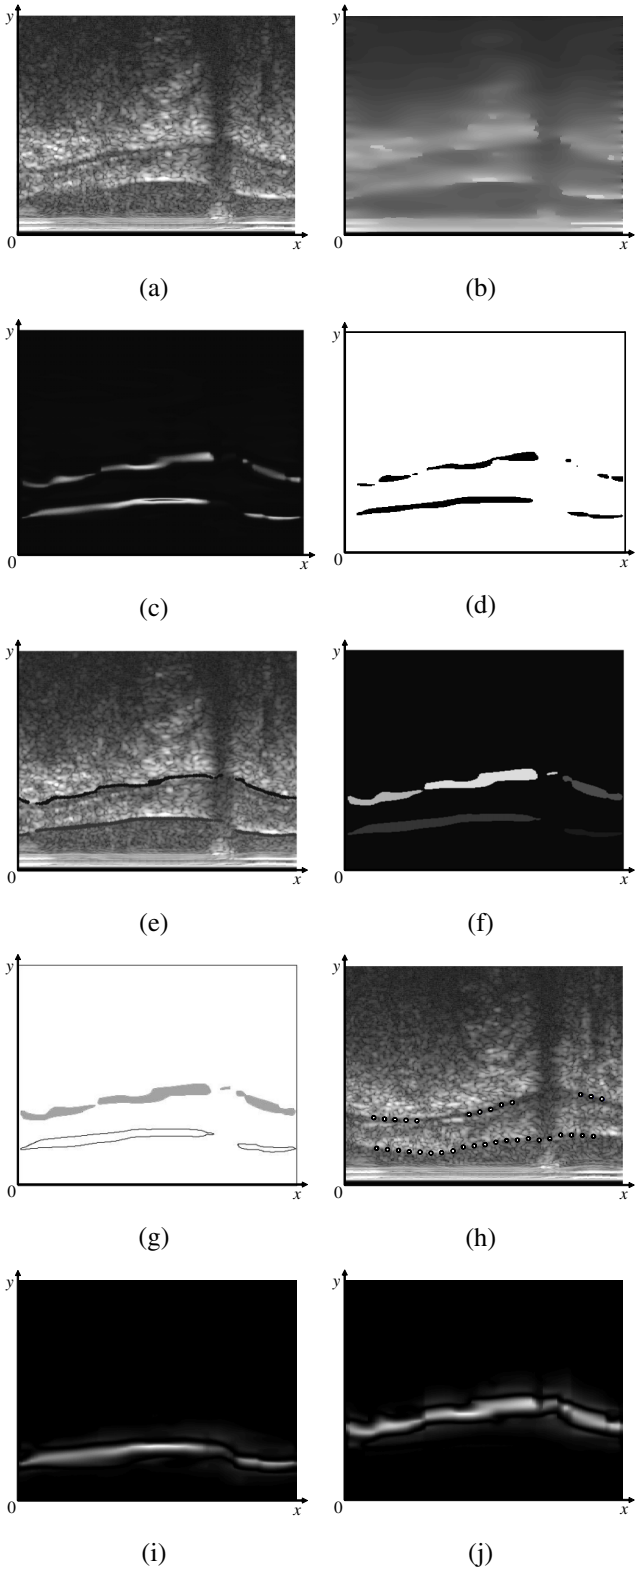


Fig. 4. Automatic placement of seed points and automatic partitioning of boundary extraction area. (a) Input image. (b) Edge-preserved and smoothed image by PMD. (j) The plaque boundary extraction area for adventitial boundary (AB).

directions. $|\phi_{\boldsymbol{s}}|$ is a number of the pixels in the neighborhood area, which is then $|\phi_{\boldsymbol{s}}|=4$ in this study. λ is a parameter. $g(\cdot)$ is called an edge stopping function. A monotonically decreasing function of the gradient of an image is usually adopted as $g(\cdot)$. The gradient of the image is calculated by:

$$\nabla I^{(n)}_{\boldsymbol{s},\boldsymbol{p}} = I^{(n)}_{\boldsymbol{p}} - I^{(n)}_{\boldsymbol{s}}. \tag{2}$$

In PMD, the edge stopping function is given by:

$$g(z) = \frac{1}{1+\left(\frac{z}{K}\right)^2}, \tag{3}$$

where K is a parameter which controls the strength of diffusion. $g(\cdot)$ takes large values at the regions where the intensity gradients are small. On the contrary, it takes small values at the regions where the intensity gradients are large.

By applying the PMD to an IVUS B-mode image as a pre-processing, the speckle patterns are reduced enough, and the edges corresponding to the luminal boundary and the adventitial boundary of plaque are preserved enough as shown in Fig. 4(b).

2) Detection of boundary extraction area by weighted separability measure: In order to distinguish the edge of plaque and that of the speckle pattern in an IVUS image, the proposed method employs a statistical discriminant measure of image separability [11]. Evaluation of image separability is very simple, and it has the following features:

i) Robust to noisy and blurred edge,
ii) Sensitive to an edge between different texture regions.

Separability is calculated by a linear discriminant analysis using the information of the two local regions. The separability $\eta_{\boldsymbol{s}}$ for the pixel $\boldsymbol{s}=(x,y)$ is calculated by:

$$\eta_{\boldsymbol{s}} = \frac{\sum_{k=1}^{k=L} \sigma^2_{bk}}{\sum_{k=1}^{k=L} \sigma^2_{Tk}}, \tag{4}$$

$$\sigma^2_{bk} = n_1(\bar{I}_{k1}-\bar{I}_k)^2 + n_2(\bar{I}_{k2}-\bar{I}_k)^2, \tag{5}$$

and

$$\sigma^2_{Tk} = \sum_{i=1}^{n_1+n_2} (I_{ki}-\bar{I}_k), \tag{6}$$

where $\bar{I}_{k1}$ and $\bar{I}_{k2}$ are the means of the intensities in the regions 1 and 2, respectively. $\bar{I}_k$ is the mean of the intensities in the combined two regions. n_1 and n_2 represent the numbers of the pixels in regions 1 and 2, respectively. $\eta_{\boldsymbol{s}}$ is $0 \le \eta_{\boldsymbol{s}} \le 1$, and it takes a large value when two regions are separated with each other in the meaning of separability.

The weighted separability, which is a modification of the original separability [11], detects the candidates of the inner (lower) and the outer (upper) boundaries of plaque by considering the following two conditions peculiar to an IVUS image. Those are: i) intensity in the outside area of a luminal boundary (LB) tends to be bigger than that in the inside area of LB; ii) intensity in the outside area of an adventitial boundary (AB) tends to be bigger than that in the inside area of AB.

The weighted separability for a pixel $\boldsymbol{s}=(i,j)$ is defined by:

$$\eta^w_{\boldsymbol{s}} = \eta_{\boldsymbol{s}} \cdot \left(\frac{\bar{I}_2(I_{Max}-\bar{I}_1)}{I_{Max}}\right)^2, \tag{7}$$

where I_{Max} is a maximum intensity on the whole IVUS image. $\bar{I}_1$ and $\bar{I}_2$ are the means of the intensities in the two discriminative regions 1 and 2, respectively [14].

Fig. 4(c) shows a discriminant image of Fig. 4(b) by using $\eta^w_{\boldsymbol{s}}$. Each pixel of the image represents the weighted separability $\eta^w_{\boldsymbol{s}}$. When $\eta^w_{\boldsymbol{s}}$ is large, high brightness is assigned to its corresponding pixel.

The weighted separability takes a large value around the regional edge of the IVUS image. That is, a chain of white pixels with high brightness can then be a candidate of a boundary of plaque.

Fig. 4(c) shows vividly the two candidates of plaque boundary. Furthermore, it is observed that the weighted separability in the area where the blood speckle noise exists (in the lumen area) is suppressed.

3) Automatic partitioning of boundary extraction area and placement of seed points by heuristic rules: Here, the candidates of boundaries of plaque shown in Fig. 4(c) are partitioned to the candidate for LB and that for AB. The following are the concrete processes of each step shown in Figs. 4(d)-(h).

Fig. 4(d) shows a binary image obtained by the threshold processing for the image of Fig. 4(c). Here, let the threshold value of the weighted separability be ζ. By changing the value of ζ from ζ_{low} to ζ_{high} at regular intervals, a binary image with each threshold value of ζ, such as Fig. 4(d), is obtained.

The points on the central line of each black-colored region of Fig. 4(d) are regarded as candidates of the seed points. The candidates are detected by line scanning in parallel to the x-axis. When two regions are detected by the line scanning, the centers of regions are regarded as the candidates. The candidates of the seed points for all the binary images are superimposed on Fig. 4(e).

The optimum threshold value of ζ has to be set to obtain the best binary image of Fig. 4(d) for detecting the final seed points. In this process, the binary images are evaluated by using the following score S:

$$G_1 = \begin{cases} \frac{1}{N_{r1}} \cdot n_r & 0 \le n_r < N_{r1} \\ -\frac{1}{N_{r2}-N_{r1}} \cdot n_r + \frac{N_{r2}}{N_{r2}-N_{r1}} & N_{r1} \le n_r < N_{r2} \\ 0 & N_{r2} \le n_r, \end{cases} \tag{8}$$

$$G_2 = \begin{cases} 0 & 0 \le n_p < N_{p1} \\ \frac{1}{N_{p2}-N_{p1}} \cdot n_p - \frac{N_{p1}}{N_{p2}-N_{p1}} & N_{p1} \le n_p < N_{p2} \\ -\frac{1}{N_{p3}-N_{p2}} \cdot n_p + \frac{N_{p3}}{N_{p3}-N_{p2}} & N_{p2} \le n_p < N_{p3} \\ 0 & N_{p3} \le n_p, \end{cases} \tag{9}$$

$$G_3 = \begin{cases} 0 & 0 \le l_r < L_{r1} \\ \frac{1}{L_{r2}-L_{r1}} \cdot l_r - \frac{L_{r1}}{L_{r2}-L_{r1}} & L_{r1} \le l_r < L_{r2} \\ -\frac{1}{L_{r3}-L_{r2}} \cdot l_r + \frac{L_{r3}}{L_{r3}-L_{r2}} & L_{r2} \le l_r < L_{r3} \\ 0 & L_{r3} \le l_r, \end{cases} \tag{10}$$

$$S = G_1 \cdot G_2 \cdot G_3, \tag{11}$$

where G_1, G_2 and G_3 are concerned with the membership functions for the number of regions n_r, the number of pixels n_p, and the total length of regions l_r, respectively.

The sets of parameters $\{N_{r1}, N_{r2}\}$, $\{N_{p1}, N_{p2}, N_{p3}\}$, $\{L_{r1}, L_{r2}, L_{r3}\}$ define the figure of each membership function. Those functions are empirically determined by analyzing hundreds of real IVUS images. The image with the maximum score of S is selected to obtain Fig. 4(f).

The color-coded regions in Fig. 4(f) are then classified either to the region for LB or that for AB as shown in Fig. 4(g) by majority decision by using the class information of the candidates of the seed points.

Finally, the points on the central line of each region of Fig. 4(g) are regarded as the final seed points to get Fig. 4(h). The selected seed points are linearly interpolated, and the boundary extraction areas are allocated around this linearly interpolated curve with weights of the following Gaussian kernel function:

$$f(y) = \exp(-\frac{(y - y(i))^2}{2\sigma^2}), \tag{12}$$

$$\sigma = (y_{out}(i) - y_{in}(i))/3, \tag{13}$$

where $y_{in}(i)$ and $y_{out}(i)$ are lines obtained by the interpolation for LB and AB, respectively. The allocated areas for the boundary extraction are shown in Fig. 4(i) and 4(j).

4) Plaque boundary extraction by T-S type fuzzy inference: By using the images obtained by the above-mentioned procedures shown in Figs. 4(i) and 4(j), the objective true boundaries of coronary plaque are extracted by T-S type fuzzy model [13] as shown in Figs. 5(a) and 5(b).

Concretely, the boundary is piecewise approximated by the polynomials in the orthogonal coordinates by a series of the following fuzzy if-then rules [15]:

$$\text{IF } x_i \text{ is } A_\ell \text{ THEN } f_\ell(x_i) = a_\ell x_i + b_\ell,$$

where A_ℓ is a fuzzy set with the membership function (MSF) μ_ℓ as shown in Fig. 5(b). Usually, four complementary triangular MSFs are uniformly allocated over the interval of concern. x_i corresponds to an angle index, and $f_\ell(x_i)$ is a linear function. The ℓ-th rule thus stands for a piecewise approximation of a plaque boundary by a linear function in the interval $[t_{\ell-1}, t_{\ell+1}]$. The inferred boundary $\hat{y}(x_i)$ is given by:

$$\hat{y}(x_i) = \mu_\ell(x_i) f_\ell(x_i) + \mu_{\ell+1}(x_i) f_{\ell+1}(x_i). \tag{14}$$

The optimum coefficients a_ℓ^* and b_ℓ^* of the ℓ-th fuzzy if-then rule are determined with use of the weighted least square method (WLSM) so as to minimize the following weighted error criterion:

$$E = \sum_{j=0}^{J-1} \sum_{i=0}^{I-1} \eta_{ij}^2 \{y_j - \hat{y}(x_i)\}^2, \tag{15}$$

where η_{ij} is a separability of pixel $\boldsymbol{s} = (i, j)$ [11].

In this method η_{ij} which lies in the specified boundary search area, *i.e.*, within the thin dotted lines in Fig. 5(a), are used as the weights of WLSM.

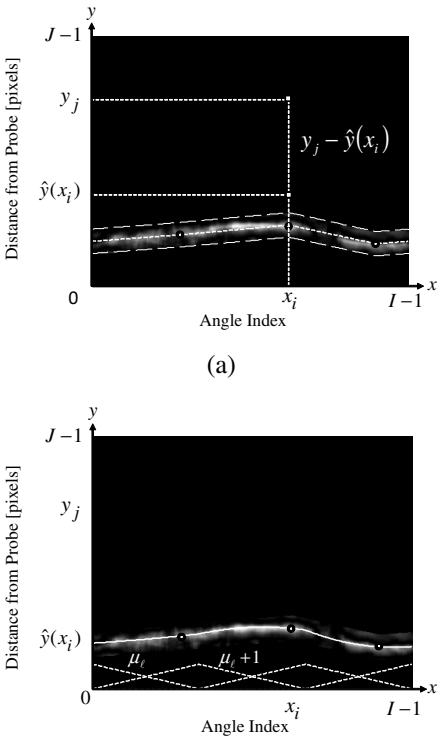

Fig. 5. Plaque boundary extraction scheme by the T-S type fuzzy inference. (a) A primitive boundary and a specified search area, which is within the two thin dotted lines. (b) The extracted luminal boundary (LB) by T-S type fuzzy inference.

B. Semi-automatic (interactive) plaque boundary extraction with adaptive allocation of membership functions

At first, Seed points are placed on the B-mode image by a medical doctor. The image is then transformed from the polar coordinates into the orthogonal coordinates.

The seed points are first linearly interpolated on the orthogonal coordinates to obtain a primitive boundary (the bold dotted line shown in Fig. 6. The true boundary is then searched by starting from this primitive boundary. The weighted separability is calculated for this image and the search area is restricted around this primitive boundary.

Let θ_n $(n = 1, \ldots, N)$ be a specified angle at the n-th seed point as shown in Fig. 6. If all θ_n are obtuse angles, four complementary triangular MSFs are uniformly allocated over the interval of concern. A plaque boundary is then extracted by

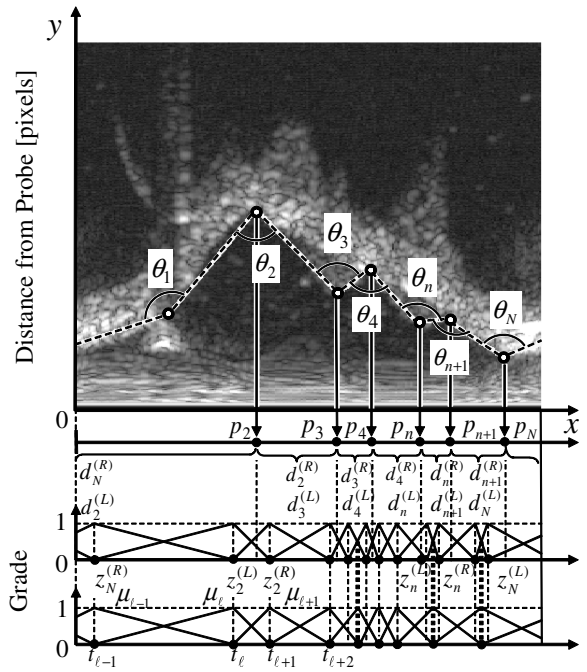

Fig. 6. Procedure of adaptive allocation of membership functions. Some θ_i angles look like to be obtuse, but they are acute. This is because of the length and width ratio of the Cartesian coordinates of the figure.

the T-S fuzzy model. In that case, a smooth plaque boundary is depicted along the obtuse seed points with a small number of MSFs.

In other cases, e.g., acute and obtuse angles coexist in the interval of concern, the following procedures are applied for the seed points with acute angles. The seed points with obtuse angles are left unprocessed.

i) Let p_n be an angle index of the n-th seed point, and $d_n^{(R)}$ and $d_n^{(L)}$ be the length between p_n and p_{n+1}, and between p_{n-1} and p_n, respectively. Note that the right-hand side edge and the left-hand side edge of the plaque boundary in Fig. 6 are linked.

ii) Two complementary and triangular MSFs are allocated on either side of each seed point. Let $z_n^{(R)}$ and $z_n^{(L)}$ be the tentative peak positions of the MSFs on the right-hand side and the left-hand side of p_n, which are given as:

$$\begin{cases} z_n^{(R)} = p_n + (1-\rho_n)[d_n^{(R)}/\{2+\beta(d_n^{(R)})\}] \\ z_n^{(L)} = p_n - (1-\rho_n)[d_n^{(L)}/\{2+\beta(d_n^{(L)})\}], \end{cases} \quad (16)$$

where ρ_n is a sharpness of the angle θ_n defined by:

$$\rho_n = \begin{cases} 1-\theta_n/T & \theta_n < T \\ 0 & \theta_n \geq T. \end{cases} \quad (17)$$

T is a constant value. The function $\beta(\cdot)$ compensates the peak position of $d_n^{(\cdot)}$ when it is extremely large, and is defined by:

$$\beta(d_n^{(\cdot)}) = 1/[1+\exp\{-a(d_n^{(\cdot)}-c)\}], \quad (18)$$

where a and c are parameters to fix the shape of $\beta(\cdot)$. Eq. (16) specifies that when θ_n is small, the MSFs are allocated close to the n-th seed point. This means that the MSFs around p_n are allocated densely, because when θ_n is small, the plaque boundary is complex. The MSFs' allocation map at the upper row in Fig. 6 is thus obtained.

iii) The tentatively allocated MSFs above are merged if the following three conditions are satisfied at the same time; (a) the seed point position p_n and the peak position of its right-hand side MSF $z_n^{(R)}$ are apart enough each other; (b) the seed point position p_{n+1} and the peak position of its left-hand side MSF $z_{n+1}^{(L)}$ are apart enough each other; (c) the positions of the peaks $z_n^{(R)}$ and $z_{n+1}^{(L)}$ are close each other. We now define the following criterion to reflect the above three merging conditions:

$$f_1 = 2\|p_n - z_n^{(R)}\|/d_n^{(R)}, \quad (19)$$

$$f_2 = 2\|p_{n+1} - z_{n+1}^{(L)}\|/d_n^{(R)}, \quad (20)$$

$$f_3 = \max(1 - 2\|z_n^{(R)} - z_{n+1}^{(L)}\|/d_n^{(R)}, 0), \quad (21)$$

$$S_{merge} = f_1 \cdot f_2 \cdot f_3. \quad (22)$$

If S_{merge} is greater than 0.5, the peaks $z_n^{(R)}$ and $z_{n+1}^{(L)}$ are merged. An example of merging is shown in the MSFs' allocation map at the bottom row of Fig. 6.

TABLE I
QUANTITATIVE EVALUATION FOR THE PLAQUE BOUNDARY EXTRACTION RESULTS.

(μm)

	Spline Function		Previous Method		Present Method	
	LB	AB	LB	AB	LB	AB
RMSE	14.5	16.9	36.5	52.1	37.5	63.2
SD	14.3	16.5	34.5	31.1	34.9	33.3

IV. EXPERIMENTAL RESULTS

In this section, experimental results of the full-automatic boundary extraction and of the semi-automatic boundary extraction are shown.

A. Fully automatic plaque boundary extraction

The proposed method is applied to real IVUS B-mode images. Extraction results are compared to those by spline function method and by our previous method. In those experiments, the threshold values of ζ_{Low} and ζ_{High} are set to be 0.1 and 0.2, respectively. The binary images are generated by changing ζ at 0.02 intervals. The other settings are the same as those in our previous paper [14].

The parameters of Eqs. (9)-(11) which define the figures of each membership function, are empirically set to be $\{N_{r1}, N_{r2}\} = \{4, 20\}$, $\{N_{p1}, N_{p2}, N_{p3}\} = \{5000, 15000, 25000\}$, $\{L_{r1}, L_{r2}, L_{r3}\} = \{256, 512, 640\}$.

Figs. 7(a)-7(d) show the plaque boundary extraction results for the IVUS image. The results show that the proposed

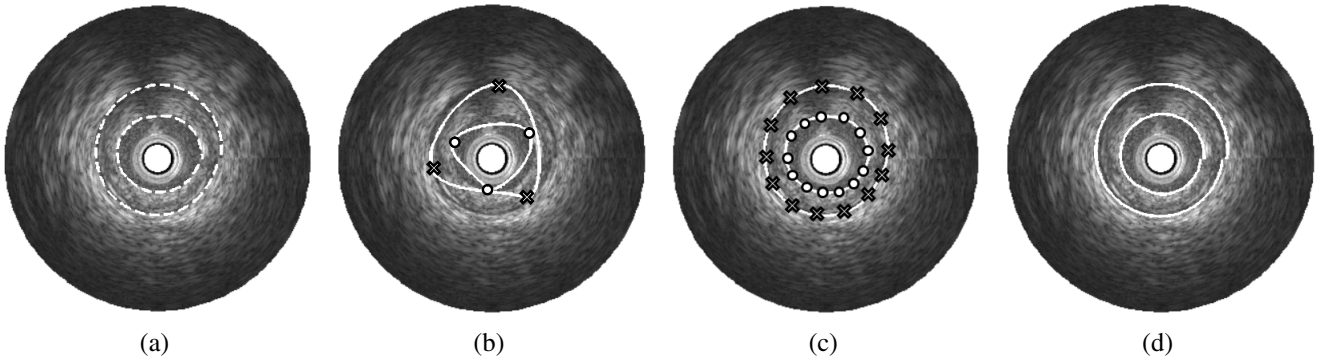

Fig. 7. Plaque boundary extraction results. ×: Given seed points for AB (Adventitial Boundary). ○: Given seed points for LB (Luminal Boundary). (a) B-mode image and objective true boundaries to be extracted. (b) Extracted boundaries by spline function method with a few seed points. (c) Extracted boundaries by spline function with many seed points. (d) Extracted boundaries by the proposed method without using any seed points (fully automatic boundary extraction).

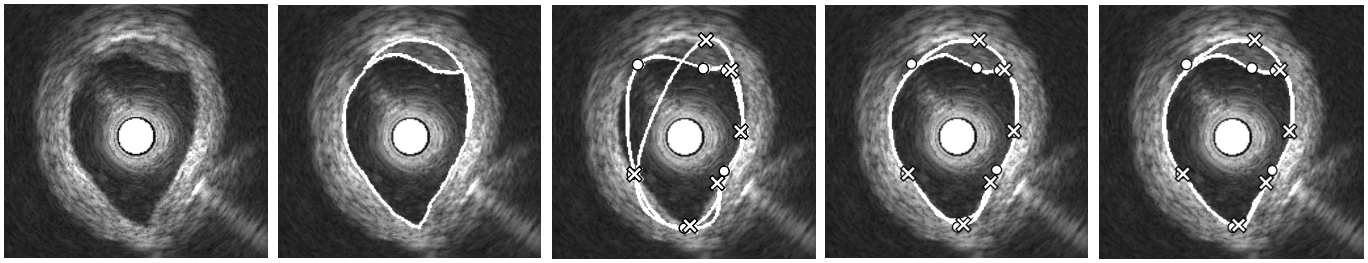

Fig. 8. Boundary extraction results. × : Given seed points for AB (Adventitial Boundary). ○: Given seed points for LB (Luminal Boundary). (a) B-mode image 4. (b) Objective true boundaries to be extracted. (c) Extracted boundaries by spline function method with a few seed points. (d) Extracted boundaries by the proposed method with the fixed membership functions uniformly allocated. (e) Extracted boundary by the proposed method with the membership functions adaptively allocated.

method works very well compared to the conventional methods, even if without using any seed points. Particularly, the spline function method requires many seed points though the accuracy of boundary extraction is good.

The root mean square errors (RMSEs) between the true boundary $y^*(x_i)$ and the extracted one $\hat{y}(x_i)$, and the standard deviations (SDs) calculated from 60 IVUS images are shown in Table I. The true boundary is calculated by a parametric spline-interpolation with a lot of seed points. It is observed that the proposed method, fully automatic, gives nearly equal extraction results to the previous method which uses some seed points given by a medical doctor.

With those results, the effectiveness of the proposed method has been verified.

B. Semi-automatic (interactive) plaque boundary extraction with user's assistance

The proposed method is applied to four IVUS B-mode images (Image 1 through Image 4). Extraction results are compared to those by the conventional method with fixed MSFs allocated at even intervals. In the experiments, the parameters in Eqs. (17) and (18) are empirically assigned to be T=45, a=0.05 and c=150.

The parameter T must be tuned by considering the figures of the boundaries of the objective IVUS images. In this experiment, T=45 is employed. On the other hand, the parameters a and c in Eq. (18) are not so sensitive for the extraction of plaque boundaries. This is because a function $\beta(\cdot)$ is used only for a compensation of a peak position of the MFS.

TABLE II
COMPARISON OF RMSES OF BOUNDARY EXTRACTION RESULTS UNDER THE SAME NUMBER OF MSFS.

(μm)

	Img. 1		Img. 2		Img. 3		Img. 4	
	LB	AB	LB	AB	LB	AB	LB	AB
No. of MSFs	4	3	10	4	12	9	9	6
Proposed Method	**33.2**	**27.3**	**44.5**	**46.4**	**30.6**	**34.5**	**72.7**	**29.4**
Fixed MSFs	**33.2**	43.3	49.3	68.3	38.0	41.9	89.9	78.8

Fig. 8 shows the boundary extraction results for Image 4, one of the four IVUS images employed for the experiments. The results show that the proposed method works very well compared to the conventional method with the fixed MSFs uniformly allocated.

The root mean square errors (RMSEs) between the objective boundary $y^*(x_i)$ and the extracted one $\hat{y}(x_i)$ are shown in Table II. The objective boundary is calculated by a parametric spline-interpolation using a lot of seed points given. It is observed that the proposed method gives better extraction results than the conventional methods with the fixed MSFs uniformly allocated. Table II shows the RMSEs of boundary extraction results in case of using the same number of MSFs in comparison with the method with the fixed MSFs and the

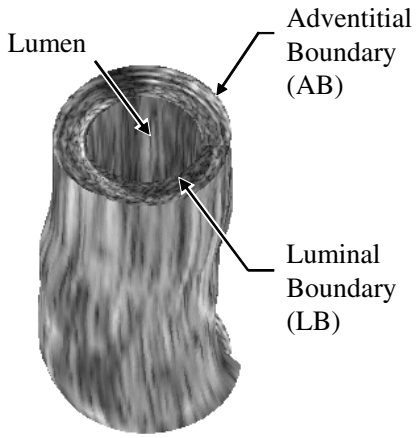

Fig. 9. 3-dimensional viewing of coronary plaque.

method with MSFs adaptively allocated (the proposed method). This implies that the position of each MSF is important for an accurate boundary extraction.

With those results the effectiveness of the proposed method has been verified.

C. 3-dimensional viewing of coronary plaque

Fig. 9 shows a 3-dimensional viewing of a coronary plaque which is reconstructed by interpolating the extracted boundary of 20 frames of B-mode image. By using the automatic plaque boundary extraction function of the proposed system, the 3-dimensional view is easily obtained. This 3-dimensional viewing is very useful and indispensable for analyzing the structure of coronary plaque. Particularly, the assessment of the objective response to therapeutic interventions by measuring the volume of plaque can be achieved by using this 3-D view of coronary plaque.

V. Conclusions

We have proposed fully automatic and semi-automatic plaque boundary extraction techniques for an IVUS image, and have implemented them as a software diagnosis system. In the present system, the plaque boundary extraction area is automatically found by using anisotropic diffusion, weighted separability, and some heuristic rules. T-S type fuzzy inference is used to extract the plaque boundary in that area.

The fully automatic present system has shown a nearly equal extraction performance to the previous method using seed points placed by a medical doctor, and thus the workload of a medical doctor is substantially reduced. After the boundary extraction, the proposed system can produce the 3-D view of coronary plaque which can be used for assessment of objective response to therapeutic interventions.

Future works are automatic adjustment of parameters and further speed up of each calculation process.

***Abstract*—In this paper we propose an effective method to design a Single-Input Single-Output (SISO) Unnormalized Interval Type-2 Takagi-Sugeno-Kang (TSK) Fuzzy Logic System (UIT2FLS) for noisy regression problems based on multi-source knowledge which includes here the information from sample data and the prior knowledge of bounded range, symmetry and monotonicity. The sufficient conditions are given which ensure that the prior knowledge can be embedded into the UIT2FLS, and then the UIT2FLS is designed so that the target function can be approached as accurately as possible via constrained least squares algorithm. The performance of the UIT2FLS is verified through comparisons with unnormalized type-1 Fuzzy Logic Systems (FLSs) and normalized interval type-2 FLSs under three different noisy circumstances. Simulation results verify the correctness of the sufficient conditions, and demonstrate that the UIT2FLS has the best overall performance.**

Keywords – interval type-2 fuzzy logic system; constrained least squares algorithm; prior knowledge

I. INTRODUCTION

In the past decades, there had been many excellent studies on the theory and application of type-2 FLSs [1] – [5]. Type-2 FLSs are extensions of type-1 FLSs, and more complex than type-1 FLSs due to using type-2 fuzzy sets in the antecedent and the consequent part of fuzzy rules. Interval Type-2 Fuzzy Logic Systems (IT2FLSs), a special case of type-2 FLSs, have obvious advantages for handling different sources of uncertainties, such as noisy data.

Although interval type-2 FLSs provide a powerful framework to represent and handle the uncertainties, the problem of how to design interval type-2 FLSs is still a heavily researched issue, especially when sample data are insufficient and noisy. In order to overcome the problem, we can utilize some prior knowledge of plants or systems, such as bounded range, symmetry, monotonicity, etc., to compensate the insufficiency of the information from sample data or to make the data invalid which are out of accord with the known prior knowledge. Recently, many researchers have incorporated prior knowledge into neural networks [6], type-1 FLSs [7] – [10] and normalized IT2FLSs [11], [12]. Lindskog [7] proposed a fuzzy model structure to ensure monotonic gain characteristics in identified models. In [8], Won gave sufficient conditions of monotonicity for normalized type-1 TSK fuzzy systems. In [11], [12], Li and Yi gave sufficient conditions to ensure that the prior knowledge of bounded range, symmetry and monotonicity can be incorporated into normalized IT2FLSs.

Unnormalized type-1 TSK FLSs are employed by K.Tanaka [13], and then Liang combined unnormalized TSK fuzzy systems with type-2 fuzzy logic in [4]. Unnormalizing the output of a TSK FLS can provide fast inference, reduce computational complexity, and may achieve the same performance as the normalized TSK in some specific applications [13]. At present, there are a few studies in the literature that incorporate prior knowledge. In [14], Wang and Yi gave the sufficient conditions to ensure that the prior knowledge of monotonicity and convexity can be integrated into UIT2FLSs, but did not present the method of designing an UIT2FLS. In this paper, we propose an effective method to design an UIT2FLS based on multi-source knowledge, and demonstrate the advantages of UIT2FLSs over type-1 FLSs and normalized IT2FLSs in simulation.

II. SISO ZEROTH-ORDER UIT2FLS

Consider an SISO zeroth-order type-2 FLS whose fuzzy rule base consists of M fuzzy rules. The ith rule R^i is denoted as

$$R^i: \text{ IF } x \text{ is } \widetilde{A}^i, \text{ THEN } Y^i = [\underline{w}^i, \overline{w}^i], \tag{1}$$

where $i = 1, 2, \ldots, M$; x is an input variable; $\widetilde{A}^i$s are the antecedent IT2FSs which can be completely depicted by the lower and the upper membership functions - $\underline{\mu}_{\widetilde{A}^i}(x)$ and $\overline{\mu}_{\widetilde{A}^i}(x)$, which are the trapezoidal membership functions formulated by (4) and (5) shown in Fig. 1, or the quadratic polynomial membership functions formulated by (6) and (7) shown in Fig. 2. The firing set F^i of rule R^i is an interval type-1 set, i.e., $F^i = [\underline{f}^i(x), \overline{f}^i(x)]$, in which $\underline{f}^i(x) = \underline{\mu}_{\widetilde{A}^i}(x)$ and $\overline{f}^i(x) = \overline{\mu}_{\widetilde{A}^i}(x)$.

Definition 2.1: If the computation method of the SISO zeroth-order type-2 FLS described by (1) follows that

$$\widehat{y}(x) = \int_{y^1 \in Y^1} \cdots \int_{y^M \in Y^M} \int_{f^1 \in F^1} \cdots \int_{f^M \in F^M} \frac{1}{\sum_{i=1}^{M} f^i y^i}, \tag{2}$$

then we refer to the fuzzy system as UIT2FLS.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

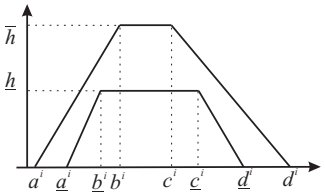

Fig. 1. Interval type-2 trapezoidal membership function.

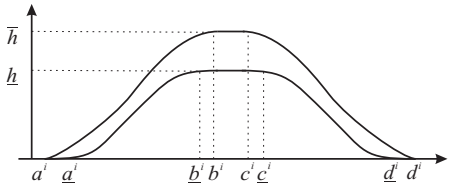

Fig. 2. Interval type-2 polynomial trapezoidal membership function.

According to Theorem 13-2 in [1], the final output $\widehat{y}(x)$ of the UIT2FLS is inferred as

$$\widehat{y}(x) = \frac{1}{2}\sum_{i=1}^{M}(\underline{f}^i(x)\underline{w}^i + \overline{f}^i(x)\overline{w}^i). \tag{3}$$

$$\underline{\mu}_{\widetilde{A}^i}(x) = \begin{cases} 0 & x < \underline{a}^i, \\ \underline{h}(\frac{x-\underline{a}^i}{\underline{b}^i-\underline{a}^i}) & \underline{a}^i \le x < \underline{b}^i, \\ \underline{h} & \underline{b}^i \le x < \underline{c}^i, \\ \underline{h}(\frac{\underline{d}^i-x}{\underline{d}^i-\underline{c}^i}) & \underline{c}^i \le x < \underline{d}^i, \\ 0 & x \ge \underline{d}^i. \end{cases} \tag{4}$$

$$\overline{\mu}_{\widetilde{A}^i}(x) = \begin{cases} 0 & x < a^i, \\ \overline{h}(\frac{x-a^i}{b^i-a^i}) & a^i \le x < b^i, \\ \overline{h} & b^i \le x < c^i, \\ \overline{h}(\frac{d^i-x}{d^i-c^i}) & c^i \le x < d^i, \\ 0 & x \ge d^i. \end{cases} \tag{5}$$

$$\underline{\mu}_{\widetilde{A}^i}(x) = \begin{cases} 0 & x < \underline{a}^i, \\ 2\underline{h}(\frac{x-\underline{a}^i}{\underline{b}^i-\underline{a}^i})^2 & \underline{a}^i \le x < \frac{\underline{a}^i+\underline{b}^i}{2}, \\ \underline{h} - 2\underline{h}(\frac{\underline{b}^i-x}{\underline{b}^i-\underline{a}^i})^2 & \frac{\underline{a}^i+\underline{b}^i}{2} \le x < \underline{b}^i, \\ \underline{h} & \underline{b}^i \le x < \underline{c}^i, \\ \underline{h} - 2\underline{h}(\frac{x-\underline{c}^i}{\underline{d}^i-\underline{c}^i})^2 & \underline{c}^i \le x < \frac{\underline{c}^i+\underline{d}^i}{2}, \\ 2\underline{h}(\frac{\underline{d}^i-x}{\underline{d}^i-\underline{c}^i})^2 & \frac{\underline{c}^i+\underline{d}^i}{2} \le x < \underline{d}^i, \\ 0 & x \ge \underline{d}^i. \end{cases} \tag{6}$$

$$\overline{\mu}_{\widetilde{A}^i}(x) = \begin{cases} 0 & x < a^i, \\ 2\overline{h}(\frac{x-a^i}{b^i-a^i})^2 & a^i \le x < \frac{a^i+b^i}{2}, \\ \overline{h} - 2\overline{h}(\frac{b^i-x}{b^i-a^i})^2 & \frac{a^i+b^i}{2} \le x < b^i, \\ \overline{h} & b^i \le x < c^i, \\ \overline{h} - 2\overline{h}(\frac{x-c^i}{d^i-c^i})^2 & c^i \le x < \frac{c^i+d^i}{2}, \\ 2\overline{h}(\frac{d^i-x}{d^i-c^i})^2 & \frac{c^i+d^i}{2} \le x < d^i, \\ 0 & x \ge d^i. \end{cases} \tag{7}$$

where $a^i \le \underline{a}^i$, $\underline{b}^i \le b^i$, $c^i \le \underline{c}^i$, $\underline{d}^i \le d^i$, $b^i \le m^i \le c^i$, and $\underline{\mu}_{\widetilde{A}^i}(x) \le \overline{\mu}_{\widetilde{A}^i}(x)$.

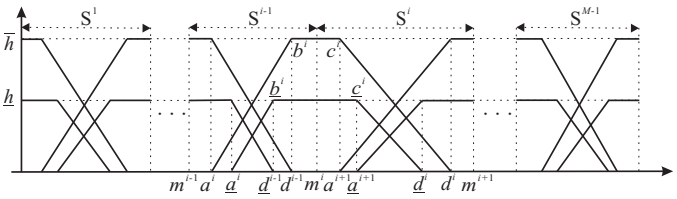

Fig. 3. Interval type-2 fuzzy partition of trapezoidal membership function.

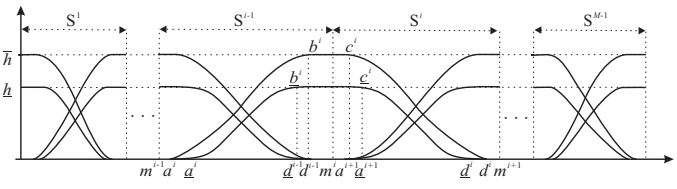

Fig. 4. Interval type-2 fuzzy partition of polynomial trapezoidal membership function.

III. Constraint conditions of Prior Knowledge

In this section, we will give some sufficient conditions to ensure that some prior knowledge can be integrated into an UIT2FLS. We will consider the prior knowledge of bounded range, symmetry and monotonicity.

A. Prior Knowledge of Bounded Range

For the prior knowledge of bounded range, we have the following results for an SISO zeroth-order UIT2FLS.

Theorem 3.1: Assume that the input domain $U = [\underline{u}, \overline{u}]$ is partitioned by M IT2FSs $\widetilde{A}^1, \widetilde{A}^2, \ldots, \widetilde{A}^M$ shown in Fig. 3 or Fig. 4. Then, the output $\widehat{y}(x)$ of the UIT2FLS is bounded on $[\underline{b}, \overline{b}]$, if the following conditions are satisfied:

1) No more than two fuzzy rules are fired.
2) Inequalities (8) and (9) hold.

$$\begin{aligned} &\frac{1}{2}\Big(\min_{p=1,\ldots,M-1}\{\underline{v}^p_{min}\}\min_{i=1,2,\ldots,M}\{\underline{w}^i\} \\ &+\min_{p=1,\ldots,M-1}\{\overline{v}^p_{min}\}\min_{i=1,2,\ldots,M}\{\overline{w}^i\}\Big) \ge \underline{b}, \end{aligned} \tag{8}$$

$$\begin{aligned} &\frac{1}{2}\Big(\max_{p=1,\ldots,M-1}\{\underline{v}^p_{max}\}\max_{i=1,2,\ldots,M}\{\underline{w}^i\} \\ &+\max_{p=1,\ldots,M-1}\{\overline{v}^p_{max}\}\max_{i=1,2,\ldots,M}\{\overline{w}^i\}\Big) \le \overline{b}, \end{aligned} \tag{9}$$

where

$$\begin{aligned} \underline{v}^p_{max} &= \sup\{\underline{\mu}_{\widetilde{A}^p}(x) + \underline{\mu}_{\widetilde{A}^{p+1}}(x) : x \in S^p\}, \\ \underline{v}^p_{min} &= \inf\{\underline{\mu}_{\widetilde{A}^p}(x) + \underline{\mu}_{\widetilde{A}^{p+1}}(x) : x \in S^p\}, \\ \overline{v}^p_{max} &= \sup\{\overline{\mu}_{\widetilde{A}^p}(x) + \overline{\mu}_{\widetilde{A}^{p+1}}(x) : x \in S^p\}, \\ \overline{v}^p_{min} &= \inf\{\overline{\mu}_{\widetilde{A}^p}(x) + \overline{\mu}_{\widetilde{A}^{p+1}}(x) : x \in S^p\}, \\ S^p &= [m^p, m^{p+1}] \quad (p = 1, 2, \ldots, M-1). \end{aligned}$$

Proof: Suppose that no more than two fuzzy IT2FSs are fired, and the ordinal numbers of the two fired rules are p and $p+1$.

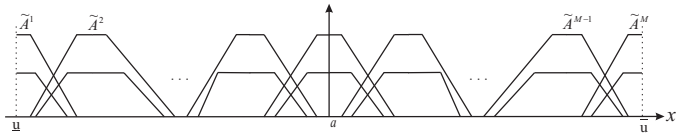

Fig. 5. Interval type-2 fuzzy partition symmetrically around a with trapezoidal membership functions.

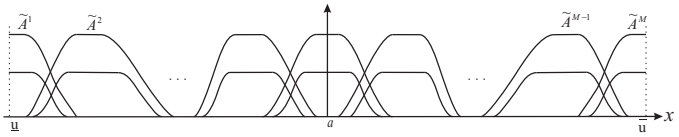

Fig. 6. Interval type-2 fuzzy partition symmetrically around a with quadratic polynomial membership functions.

Then, from (3), the final output can be rewritten as

$$\widehat{y}(x) = \frac{1}{2}\sum_{k=p}^{p+1}\big(\underline{\mu}_{\widetilde{A}^k}(x)\underline{w}^k + \overline{\mu}_{\widetilde{A}^k}(x)\overline{w}^k\big). \tag{10}$$

When x' is an input to the UIT2FLS, we get

$$\begin{aligned} y_l &= \sum\nolimits_{i=p}^{p+1}\underline{\mu}_{\widetilde{A}^i}(x')\underline{w}^i \\ &\geq \big(\underline{\mu}_{\widetilde{A}^p}(x') + \underline{\mu}_{\widetilde{A}^{p+1}}(x')\big)\min_{i=1,2,\ldots,M}\{\underline{w}^i\} \\ &\geq \underline{v}^p_{min}\min_{i=1,2,\ldots,M}\{\underline{w}^i\} \\ &\geq \min_{p=1,\ldots,M-1}\{\underline{v}^p_{min}\}\min_{i=1,2,\ldots,M}\{\underline{w}^i\}, \end{aligned} \tag{11}$$

and

$$\begin{aligned} y_l &= \sum\nolimits_{i=p}^{p+1}\underline{\mu}_{\widetilde{A}^i}(x')\underline{w}^i \\ &\leq \big(\underline{\mu}_{\widetilde{A}^p}(x') + \underline{\mu}_{\widetilde{A}^{p+1}}(x')\big)\max_{i=1,2,\ldots,M}\{\underline{w}^i\} \\ &\leq \underline{v}^p_{max}\max_{i=1,2,\ldots,M}\{\underline{w}^i\} \\ &\leq \max_{p=1,\ldots,M-1}\{\underline{v}^p_{max}\}\max_{i=1,2,\ldots,M}\{\underline{w}^i\}. \end{aligned} \tag{12}$$

In the similar way, we have

$$y_r \geq \min_{p=1,\ldots,M-1}\{\overline{v}^p_{min}\}\min_{i=1,2,\ldots,M}\{\overline{w}^i\} \tag{13}$$

and

$$y_r \leq \max_{p=1,\ldots,M-1}\{\overline{v}^p_{max}\}\max_{i=1,2,\ldots,M}\{\overline{w}^i\}, \tag{14}$$

From (11), (12), (13) and (14), it is obvious that

$$\begin{aligned} &\frac{1}{2}\Big(\min_{p=1,\ldots,M-1}\{\underline{v}^p_{min}\}\min_{i=1,2,\ldots,M}\{\underline{w}^i\} \\ &+ \min_{p=1,\ldots,M-1}\{\overline{v}^p_{min}\}\min_{i=1,2,\ldots,M}\{\overline{w}^i\}\Big) \\ &\leq \widehat{y}(x) \leq \frac{1}{2}\Big(\max_{p=1,\ldots,M-1}\{\underline{v}^p_{max}\}\max_{i=1,2,\ldots,M}\{\underline{w}^i\} \\ &+ \max_{p=1,\ldots,M-1}\{\overline{v}^p_{max}\}\max_{i=1,2,\ldots,M}\{\overline{w}^i\}\Big). \end{aligned} \tag{15}$$

As a result, if (8) and (9) hold, then $\underline{b} \leq \widehat{y}(x) \leq \overline{b}$.

Hence, the theorem holds. □

B. Prior Knowledge of Symmetry

For the prior knowledge of symmetry, we have the following results for an SISO zeroth-order UIT2FLS.

Theorem 3.2: An UIT2FLS is even symmetry around a, i.e. $\widehat{y}(x) = \widehat{y}(2a - x)$, if the following conditions are satisfied:

1) The input domain of $x \in [\underline{u}, \overline{u}]$ is partitioned symmetrically around a by IT2FSs $\widetilde{A}^1, \widetilde{A}^2, \ldots, \widetilde{A}^M$ shown in Fig. 5 or Fig. 6, where M is an odd number.
2) The consequent interval weights of the rules R^is satisfy that $[\underline{w}^i, \overline{w}^i] = [\underline{w}^{M+1-i}, \overline{w}^{M+1-i}]$ for $i = 1, 2, \ldots, \frac{M-1}{2}$.

Proof: when x' is an input, assume that t fuzzy IT2FSs can be fired, and the ordinal numbers of the fired rules are $i_1, i_2, \ldots, i_t$, here t is a positive integer.

As the fuzzy rule base is complete, and the input domain is partitioned symmetrically around a. Therefore, when $2a - x'$ is input to the UIT2FLS, the ordinal numbers of the fired rules is $M + 1 - i_1, M + 1 - i_2, \ldots, M + 1 - i_t$.

The conditions of Theorem 3.2 can also be stated as follows:

$$\underline{\mu}_{\widetilde{A}^{i_p}}(x') = \underline{\mu}_{\widetilde{A}^{M+1-i_p}}(2a - x'), \tag{16a}$$
$$\overline{\mu}_{\widetilde{A}^{i_p}}(x') = \overline{\mu}_{\widetilde{A}^{M+1-i_p}}(2a - x'), \tag{16b}$$

and

$$\underline{w}^{i_p} = \underline{w}^{M+1-i_p}, \tag{17a}$$
$$\overline{w}^{i_p} = \overline{w}^{M+1-i_p}, \tag{17b}$$

where $p = 1, 2, \ldots, t$.

Since

$$\underline{y}(x') = \sum\nolimits_{p=1}^{t}\underline{\mu}_{\widetilde{A}^{i_p}}(x')\underline{w}^{i_p}$$

and

$$\underline{y}(2a - x') = \sum\nolimits_{p=1}^{t}\underline{\mu}_{\widetilde{A}^{M+1-i_p}}(2a - x')\underline{w}^{M+1-i_p},$$

according to (16a) and (17a), we can derive that $\underline{y}(x') = \underline{y}(2a - x')$.

Similarly, according to (16b) and (17b), we can derive that

$$\overline{y}(x') = \overline{y}(2a - x').$$

Therefore,

$$\begin{aligned} y(x') &= \frac{1}{2}\big(\underline{y}(x') + \overline{y}(x')\big) \\ &= \frac{1}{2}\big(\underline{y}(2a - x') + \overline{y}(2a - x')\big) \\ &= y(2a - x') \end{aligned} \tag{18}$$

From (18), Theorem 3.2 holds. □

C. Prior Knowledge of Monotonicity

We consider the monotonicity of an SISO zeroth-order UIT2FLS. Firstly, the definition of SISO monotonic fuzzy systems is given as follows.

Definition 3.1: Let x be an input of a fuzzy system defined on $U = [a, b]$, where $U \subset \mathbb{R}$. And, $y = F(x)$ be the output of the fuzzy system in the set $V \subset \mathbb{R}$. Then, $F : U \mapsto V$ is said to be monotonically increasing if $a \leq x_1 \leq x_2 \leq b$ implies

$$F(x_1) \leq F(x_2). \tag{19}$$

If Inequality (19) is reversed, we obtain the definition of SISO monotonically decreasing fuzzy systems.

For the prior knowledge of monotonically increasing property, we have the following results for an SISO zeroth-order UIT2FLS.

Theorem 3.3: Assume that the fuzzy system is single-input single-output, and that the input domain $U = [\underline{u}, \overline{u}]$ which consists of $M-1$ intervals $S^i = [m^i, m^{i+1}]$ is partitioned by M IT2FSs $\widetilde{A}^1, \widetilde{A}^2, \ldots, \widetilde{A}^M$ shown in Fig. 3 or Fig. 4. Then, the UIT2FLS monotonically increases with respect to x, if the following conditions are satisfied:

1) No more than two fuzzy rules are fired, i.e. $a^1 = \underline{a}^1 = \underline{b}^1 = b^1 = m^1 = \underline{u}$, $m^M = c^M = \underline{c}^M = \underline{d}^M = d^M = \overline{u}$, $a^i \leq \underline{a}^i$, $\underline{b}^i \leq b^i$, $c^i \leq \underline{c}^i$, $\underline{d}^i \leq d^i$, $b^i \leq m^i \leq c^i$ for $2 \leq i \leq M-1$;
2) For any $x \in S^i$, $b^{i+1} = d^i$, $\underline{b}^{i+1} = \underline{d}^i$, $a^{i+1} = c^i$, $\underline{a}^{i+1} = \underline{c}^i$, so that $\overline{\mu}_{\widetilde{A}^i}(x) + \overline{\mu}_{\widetilde{A}^{i+1}}(x) = \overline{h}$, and $\underline{\mu}_{\widetilde{A}^i}(x) + \underline{\mu}_{\widetilde{A}^{i+1}}(x) = \underline{h}$ $(i = 1, 2, \ldots, M-1)$;
3) $\underline{w}^i \leq \underline{w}^{i+1}$ and $\overline{w}^i \leq \overline{w}^{i+1} (i = 1, 2, \ldots, M-1)$.

Proof: Assume that no more than two fuzzy IT2FSs can be fired, and the ordinal numbers of the fired rules are k and $k+1$.

Let

$$\underline{y}^k(x) = \sum\nolimits_{i=k}^{k+1} \underline{\mu}_{\widetilde{A}^i}(x)\underline{w}^i, \tag{20}$$

$$\overline{y}^k(x) = \sum\nolimits_{i=k}^{k+1} \overline{\mu}_{\widetilde{A}^i}(x)\overline{w}^i. \tag{21}$$

Hence, we have $\widehat{y}(x) = \frac{1}{2}\big(\underline{y}^k(x) + \overline{y}^k(x)\big)$.

1) When $x \in S^k$, $x' \in S^k$, $x' > x$, from the second condition of this theorem, (20) can be rewritten as

$$\begin{aligned}\underline{y}^k(x) &= \underline{\mu}_{\widetilde{A}^k}(x)\underline{w}^k + \underline{\mu}_{\widetilde{A}^{k+1}}(x)\underline{w}^{k+1} \\ &= (\underline{h} - \underline{\mu}_{\widetilde{A}^{k+1}}(x))\underline{w}^k + \underline{\mu}_{\widetilde{A}^{k+1}}(x)\underline{w}^{k+1} \\ &= \underline{h}\,\underline{w}^k + \underline{\mu}_{\widetilde{A}^{k+1}}(x)(\underline{w}^{k+1} - \underline{w}^k). \end{aligned} \tag{22}$$

Then, we get

$$\begin{aligned}&\underline{y}^k(x') - \underline{y}^k(x) = \\ &(\underline{\mu}_{\widetilde{A}^{k+1}}(x') - \underline{\mu}_{\widetilde{A}^{k+1}}(x))(\underline{w}^{k+1} - \underline{w}^k). \end{aligned} \tag{23}$$

Notice that $\underline{\mu}_{\widetilde{A}^{k+1}}(x)$ monotonically increases when $x \in S^k$, i.e.,

$$\underline{\mu}_{\widetilde{A}^{k+1}}(x') - \underline{\mu}_{\widetilde{A}^{k+1}}(x) \geq 0.$$

If the third condition of this theorem holds, we can deduce that

$$\underline{y}^k(x') - \underline{y}^k(x) \geq 0. \tag{24}$$

In the same way, we can also obtain that

$$\overline{y}^k(x') - \overline{y}^k(x) \geq 0. \tag{25}$$

According to (24) and (25), when $x \in S^k$, we can deduce that

$$\widehat{y}(x') \geq \widehat{y}(x) \tag{26}$$

2) When $x \in S^k$, $x' \in S^{k'}$, $k' > k$, and $k, k' = 1, 2, \ldots, M$, it is clear that $x' > x$ holds.
From Equations (20) and (21), when $x \in S^k$, we can see that

$$\begin{aligned}\underline{h}\,\underline{w}^k \leq \underline{y}^k(x) \leq \underline{h}\,\underline{w}^{k+1}, \\ \overline{h}\,\overline{w}^k \leq \overline{y}^k(x) \leq \overline{h}\,\overline{w}^{k+1}.\end{aligned}$$

With Condition 3) of this theorem holding, it follows that

$$\begin{aligned}\underline{y}^1(x^1) \leq \underline{y}^2(x^2) \leq \ldots \leq \underline{y}^M(x^M), \\ \overline{y}^1(x^1) \leq \overline{y}^2(x^2) \leq \ldots \leq \overline{y}^M(x^M),\end{aligned}$$

where $x^i \in S^i$, $i = 1, \ldots, M-1$. So, in this circumstances, we can deduce that

$$\widehat{y}(x') \geq \widehat{y}(x) \tag{27}$$

Therefore, from the discussion above, we can conclude that the theorem holds. □

Next, we give the sufficient conditions on the prior knowledge of monotonically decreasing property.

Theorem 3.4: Assume that the fuzzy system is single-input single-output, and that the input domain $U = [\underline{u}, \overline{u}]$ which consists of $M-1$ intervals $S^i = [m^i, m^{i+1}]$ is partitioned by M IT2FSs $\widetilde{A}^1, \widetilde{A}^2, \ldots, \widetilde{A}^M$ as shown in Fig. 3 or Fig. 4. Then, the UIT2FLS monotonically decreases with respect to x, if the following conditions are satisfied:

1) No more than two fuzzy rules are fired, i.e. $a^1 = \underline{a}^1 = \underline{b}^1 = b^1 = m^1 = \underline{u}$, $m^M = c^M = \underline{c}^M = \underline{d}^M = d^M = \overline{u}$, $a^i \leq \underline{a}^i$, $\underline{b}^i \leq b^i$, $c^i \leq \underline{c}^i$, $\underline{d}^i \leq d^i$, $b^i \leq m^i \leq c^i$ for $2 \leq i \leq M-1$;
2) For any $x \in S^i$, $b^{i+1} = d^i$, $\underline{b}^{i+1} = \underline{d}^i$, $a^{i+1} = c^i$, $\underline{a}^{i+1} = \underline{c}^i$, so that $\overline{\mu}_{\widetilde{A}^i}(x) + \overline{\mu}_{\widetilde{A}^{i+1}}(x) = \overline{h}$, and $\underline{\mu}_{\widetilde{A}^i}(x) + \underline{\mu}_{\widetilde{A}^{i+1}}(x) = \underline{h}$ $(i = 1, 2, \ldots, M-1)$;
3) $\underline{w}^i \geq \underline{w}^{i+1}$ and $\overline{w}^i \geq \overline{w}^{i+1} (i = 1, 2, \ldots, M-1)$.

Proof: The theorem can be proved in the similar way as Theorem 3.3. □

IV. Design of UIT2FLSs Using Multi-source Knowledge

Suppose that there exist r input-output data pairs (x_1, y_1), $\ldots$, (x_r, y_r). And our objective is that the parameters of the above-mentioned UIT2FLS can be optimized subject to the following training criteria (28) such that overall error measure E is minimal.

$$\min_{\boldsymbol{w}} E = \min_{\boldsymbol{w}} \sum_{k=1}^{r} \big(\widehat{y}(x_k) - y_k\big)^2. \tag{28}$$

Then, according to the objective, we design the UIT2FLS based on sample data and prior knowledge via constrained least squares algorithm.

A. Design of UIT2FLSs Using the Constrained Least Squares Algorithm

Firstly, we should determine whether the output of the UIT2FLS is linear with its consequent parameters.

Since (3) can be written as

$$\widehat{y}(x) = \boldsymbol{\phi}^{\mathrm{T}}(x)\boldsymbol{w}, \tag{29}$$

where

$$\begin{aligned}
\phi_i(x) &= \begin{cases} \frac{1}{2}\underline{\mu}_{\widetilde{A}^i}(x) & \text{if } i = 1, 2, \ldots, M, \\ \frac{1}{2}\overline{\mu}_{\widetilde{A}^i}(x) & \text{if } i = M+1, \ldots, 2M, \end{cases} \\
\boldsymbol{\phi}(x) &= [\phi_1(x), \phi_2(x), \ldots, \phi_{2M}(x)]^{\mathrm{T}}, \\
\boldsymbol{w} &= [\underline{w}^1, \ldots, \underline{w}^M, \overline{w}^1, \ldots, \overline{w}^M]^{\mathrm{T}},
\end{aligned}$$

we can deduce that the output of the UIT2FLS is linear with its consequent parameters. Then, the overall error measure E can be rewritten as the following form:

$$E = (\Phi\boldsymbol{w} - \boldsymbol{y})^{\mathrm{T}}(\Phi\boldsymbol{w} - \boldsymbol{y}), \tag{30}$$

where

$$\begin{aligned}
\boldsymbol{y} &= [y_1, y_2, \ldots, y_r], \\
\Phi &= \left[\boldsymbol{\phi}^{\mathrm{T}}(x_1), \boldsymbol{\phi}^{\mathrm{T}}(x_2), \ldots, \boldsymbol{\phi}^{\mathrm{T}}(x_r)\right]^{\mathrm{T}}.
\end{aligned}$$

Since the sample data should satisfy one or several kinds of prior knowledge such as bounded range, symmetry and monotonicity, we can use the sample data to train the consequent parameters of the UIT2FLS when the antecedent parameters are determined beforehand. From (30), according to our objective, the UIT2FLS design problem can be transformed into the following constrained least squares optimization problem (31). Therefore, we can solve (31) to design the UIT2FLS utilizing the multi-source knowledge which includes the information from both sample data and prior knowledge.

$$\begin{cases} \min\limits_{\boldsymbol{w}} (\Phi\boldsymbol{w} - \boldsymbol{y})^{\mathrm{T}}(\Phi\boldsymbol{w} - \boldsymbol{y}) \\ \text{subject to} \quad \boldsymbol{w} \in \Omega \end{cases}, \tag{31}$$

where Ω represents the constrained feasible parameter space.

Next, we will show that how to transform different kinds of prior knowledge description into the constraints of the consequent parameters of UIT2FLSs.

B. Constraints for Bounded Range

The constraints on the consequent interval weights of bounded UIT2FLSs in Theorem 3.1 can be expressed as

$$\begin{aligned}
\frac{1}{2}(\underline{v}_{min}\underline{w}^i + \overline{v}_{min}\overline{w}^i) &\geq \underline{b}, \\
\frac{1}{2}(\underline{v}_{max}\underline{w}^i + \overline{v}_{max}\overline{w}^i) &\leq \overline{b},
\end{aligned}$$

where

$$\begin{aligned}
\underline{v}_{min} &= \min_{p=1,\ldots,M-1}\{\underline{v}^p_{min}\}, \\
\overline{v}_{min} &= \min_{p=1,\ldots,M-1}\{\overline{v}^p_{min}\}, \\
\underline{v}_{max} &= \max_{p=1,\ldots,M-1}\{\underline{v}^p_{max}\}, \\
\overline{v}_{max} &= \max_{p=1,\ldots,M-1}\{\overline{v}^p_{max}\}, \\
i &= 1, 2, \ldots, M.
\end{aligned}$$

Therefore, there exist the $2M$ linear inequality constraints. It is convenient and brief to formulate these constraints as the following linear matrix inequality:

$$\begin{bmatrix} -\frac{1}{2}\underline{v}_{min}I_M & -\frac{1}{2}\overline{v}_{min}I_M \\ \frac{1}{2}\underline{v}_{max}I_M & \frac{1}{2}\underline{v}_{max}I_M \end{bmatrix}\boldsymbol{w} \leq \begin{bmatrix} -\underline{\boldsymbol{b}} \\ \overline{\boldsymbol{b}} \end{bmatrix}, \tag{32}$$

where I_M is the $M \times M$ identity matrix, $\underline{\boldsymbol{b}} = [\underline{b}, \ldots, \underline{b}]^{\mathrm{T}} \in \mathbb{R}^M$, and $\overline{\boldsymbol{b}} = [\overline{b}, \ldots, \overline{b}]^{\mathrm{T}} \in \mathbb{R}^M$.

C. Constraints for Symmetry

The constraints on the consequent parameters of symmetrical UIT2FLSs in Theorem 3.2 can be expressed as

$$\begin{aligned}
&\underline{w}^i - \underline{w}^{M+1-i} = 0, \\
&\overline{w}^i - \overline{w}^{M+1-i} = 0, \ (i = 1, \ldots, \tfrac{M-1}{2}) \\
&\underline{w}^j \leq \overline{w}^j, \ (j = 1, \ldots, M).
\end{aligned}$$

Hence, there exist $M-1$ equality and M inequality constraints for these parameters, and the matrix form of the constraints can be expressed as

$$\begin{bmatrix} I_{\frac{M-1}{2}} & \mathbf{0}_{\frac{M-1}{2}\times 1} & -I^{\mathrm{R}}_{\frac{M-1}{2}} & \mathbf{0}_{\frac{M-1}{2}} & \mathbf{0}_{\frac{M-1}{2}\times 1} & \mathbf{0}_{\frac{M-1}{2}} \\ \mathbf{0}_{\frac{M-1}{2}} & \mathbf{0}_{\frac{M-1}{2}\times 1} & \mathbf{0}_{\frac{M-1}{2}} & I_{\frac{M-1}{2}} & \mathbf{0}_{\frac{M-1}{2}\times 1} & -I^{\mathrm{R}}_{\frac{M-1}{2}} \end{bmatrix} \times \boldsymbol{w} = \mathbf{0}_{M-1\times 1}, \tag{33}$$

$$\begin{bmatrix} I_M & -I_M \end{bmatrix}\boldsymbol{w} \leq \mathbf{0}_{M\times 1}, \tag{34}$$

where I^{R}_M denotes the $M \times M$ matrix obtained by rotating I_M 90 degrees clockwise.

D. Constraints for Monotonicity

The constraints on the consequent parameters of monotonically increasing UIT2FLSs on U in Theorem 3.3 can be expressed as

$$\begin{aligned}
&\underline{w}^i - \underline{w}^{i+1} \leq 0, \\
&\overline{w}^i - \overline{w}^{i+1} \leq 0, \ (i = 1, 2, \ldots, M-1), \\
&\underline{w}^j - \overline{w}^j \leq 0, \ (j = 1, 2, \ldots, M).
\end{aligned}$$

Hence, there exist $3M - 2$ inequality constraints for these parameters, and the matrix form of the constraints can be expressed as

$$\begin{bmatrix} Y_{11} & \mathbf{0}_{(M-1)\times M} \\ \mathbf{0}_{(M-1)\times M} & Y_{22} \\ I_M & -I_M \end{bmatrix}\boldsymbol{w} \leq \mathbf{0}_{(3M-2)\times 1}, \tag{35}$$

where

$$Y_{11} = Y_{22} = \begin{bmatrix} 1 & -1 & 0 & \dots & 0 & 0 \\ 0 & 1 & -1 & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 1 & -1 \end{bmatrix} \in \mathbb{R}^{(M-1)\times M}.$$

In a similar way, based on Theorem 3.4, there exist $3M-2$ inequality constraints for the consequent parameters, and when UIT2FLSs monotonically decrease, the matrix form of the constraints can be expressed as

$$\begin{bmatrix} Z_{11} & \mathbf{0}_{(M-1)\times M} \\ \mathbf{0}_{(M-1)\times M} & Z_{22} \\ I_M & -I_M \end{bmatrix} \boldsymbol{w} \leq \mathbf{0}_{(3M-2)\times 1}, \qquad (36)$$

where $Z_{11} = Z_{22} = -Y_{11} \in \mathbb{R}^{(M-1)\times M}$.

Remarks: Assume there exists a function $y = f(x)$, which is monotonically decreasing when $x < 0$, and monotonically increasing when $x > 0$. If the input variable x is partitioned as shown in Fig. 5, then we can deal with the circumstances as follows:

$$\begin{bmatrix} ZY & \mathbf{0}_{(M-1)\times M} \\ \mathbf{0}_{(M-1)\times M} & ZY \\ I_M & -I_M \end{bmatrix} \boldsymbol{w} \leq \mathbf{0}_{(3M-2)\times 1}, \qquad (37)$$

where

$$ZY = \begin{bmatrix} Z_{11} & \mathbf{0}_{\frac{M-1}{2}\times\frac{M-1}{2}} \\ \mathbf{0}_{\frac{M-1}{2}\times\frac{M-1}{2}} & Y_{11} \end{bmatrix} \in \mathbb{R}^{(M-1)\times M}.$$

where $Z_{11}, Y_{11} \in \mathbb{R}^{\frac{M-1}{2}\times\frac{M+1}{2}}$, and M is odd number.

V. Simulation

In this section, we use a simulation example to illustrate the advantages based on multi-source knowledge, as above mentioned, when the output of a target function is corrupted by white noise.

Consider the following SISO nonlinear function

$$y = \left(\frac{x}{3}\right)^2 \tanh(|x|), \qquad (38)$$

where $x \in U = [-3, 3]$. It is obvious that the function is even symmetry with respect to $x = 0$, bounded on interval [0,1], monotonically decreases on interval [-3,0], and monotonically increases on interval [0,3].

We can create 500-training-data set $\mathfrak{D}$ whose elements $(x_i, \widetilde{y}_i)$ $(i = 1, \dots, 500)$ are generated by $\widetilde{y} = y + Noise$, where $Noise \in [-n_b, n_b]$ is the uniformly distributed additive noise. From Equation (38), we can obtain 500 input-output data pairs (x_i, y_i) $(i = 1, \dots, 500)$ which are the elements of test data set $\mathfrak{E}$. In this simulation, we test three different levels of noisy disturbance including $n_b = 20\%, 30\%, 40\%$. For each level of noisy disturbance, five cases are considered. In case k $(k = 1, \dots, 5)$, the elements of training data subset $\mathfrak{D}_k$ and test data subset $\mathfrak{E}_k$ are randomly chosen from $\mathfrak{D}$ and $\mathfrak{E}$, respectively. The numbers of the training data subset and the test data subset r_k are 25, 40, 60, 80, 100, and all the values of input variable x_i in $\mathfrak{D}_k$ and $\mathfrak{E}_k$ are different in each case k.

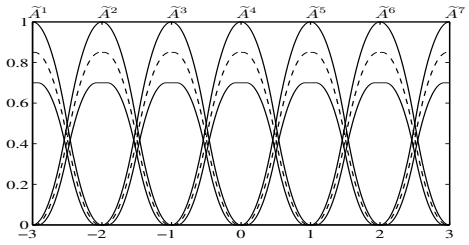

Fig. 7. Type-1 (dashed line) and type-2 (solid line) fuzzy partitions of the input domain.

In order to demonstrate the superiority of prior knowledge and type-2 FLSs, we use the following six FLSs to identify the target function: UIT2FLS with the monotonic, symmetric and bounded constraints (T2PFLS), UIT2FLS without the constraints (T2NPFLS), unnormalized type-1 FLS (UT1FLS) with the constraints (T1PFLS), UT1FLS without the constraints (T1NPFLS), normalized interval type-2 FLS (NT2FLS) with the constraints (NT2PFLS) and NT2FLS without the constraints (NT2NPFLS). For each FLS, we use seven membership functions equally distributed on input domain, and the fuzzy partitions which are shown in Fig. 7 satisfy the conditions on the parameters of the antecedent parts in Theorem 3.1 – 3.4.

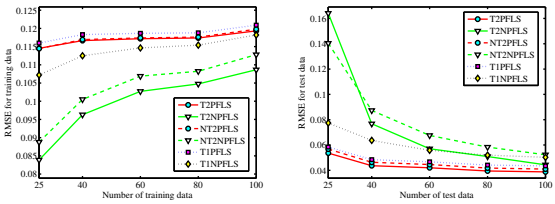
Based on the training data and the test data, we use the following two RMSE performance indices in case k,

$$ap_k = \left(\frac{1}{r_k}\sum_{i=1}^{r_k}\left(\widehat{y}(x_k) - \widetilde{y}_k\right)^2\right)^{\frac{1}{2}}, \qquad (39)$$

$$gp_k = \left(\frac{1}{r_k}\sum_{i=1}^{r_k}\left(\widehat{y}(x_k) - y_k\right)^2\right)^{\frac{1}{2}}, \qquad (40)$$

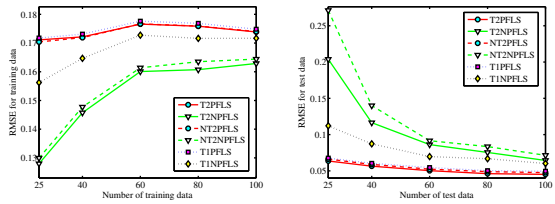
where ap_k can reflect the approximation performance of the fuzzy systems for the training data, and gp_k can reflect the generalization performance of the fuzzy systems for the test data. From (39) and (40), we know that the less both indices are, the better the corresponding performances are. Furthermore, in order to avoid particularity, we calculate the statistical indices of the approximation performance and the generalization performance, ap_{sk} and gp_{sk}, which are the arithmetic mean of the corresponding indices obtained from 50 runs.

As mentioned above, three different levels of noise and five cases for each level of noise are considered. The comparisons between the six FLSs are drawn with respect to the size of data subsets and the noise level for the statistical RMSEs of the approximation performance and the generalization performance, ap_{is} and gp_{is}, which are shown in Fig. 8, Fig. 9 and Fig. 10, respectively. When the training data subset is comprised of 25 sample data, and the noise distributes uniformly in $[-40\%, 40\%]$, we obtain one of the identification results shown in Fig. 11. We can note that the data shown in Fig. 11 are consistent with the corresponding data in Fig.10



(a) (b)

Fig. 8. Performance comparisons of six different FLSs when $n_b = 20\%$: (a) approximation performance (b) generalization performance.



(a) (b)

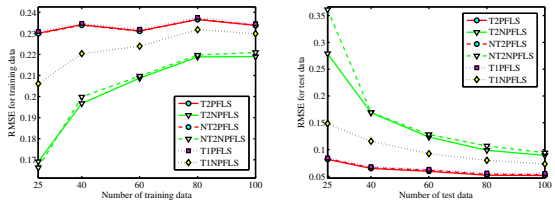
Fig. 9. Performance comparisons of six different FLSs when $n_b = 30\%$: (a) approximation performance (b) generalization performance.

on the whole.

From these figures, we can compare and analyze the approximation performances and the generalization performances in terms of both the size of the data subsets and the level of noise for the six FLSs as follows:

(1) About approximation performance, from Fig. 8(a), Fig. 9(a) and Fig. 10(a), we observe that the unnormalized interval type-2 FLS without the prior knowledge constraints (T2NPFLS) performs better than the other five FLSs listed in the descending order of approximation performance, in general, as follows: NT2NPFLS, T1NPFLS, T2PFLS, NT2PFLS and T1PFLS. Also, it is can be observed that the FLSs without the constraints have better approximation capabilities than the FLSs with the constraints, whose performance indices are almost the same apparently. There exist the following two reasons to explain this. For one thing, the consequent parameters of T2NPFLS, NT2NPFLS and T1NPFLS are not constrained by the prior knowledge, so the three FLSs have a larger degree of freedom than the counterpart of T2PFLS, NT2PFLS and T1PFLS. For another, type-2 FLSs have more parameters than type-1 FLSs. Thus interval type-2 FLSs without constraints have best approximation capabilities among the six FLSs. In terms of the size of a training data subset, note that the smaller the size of the subset is, the better the approximation performance is in each case. As the level of noise increases, the approximation performances deteriorate for the six FLSs in each case.

(2) About generalization performance, from Fig. 8(b), Fig. 9(b) and Fig. 10(b), we observe that the unnormalized interval type-2 FLS with the prior knowledge constraints (T2PFLS) outperforms the other five FLSs listed in the descending order of generalization performance, in general,



(a) (b)

Fig. 10. Performance comparisons of six different FLSs when $n_b = 40\%$: (a) approximation performance (b) generalization performance.

as follows: NT2PFLS, T1PFLS, T1NPFLS, T2NPFLS and NT2NPFLS. Also, it is can be observed that the FLSs with the constraints, whose performance indices are different slightly, have better generalization capabilities than the FLSs without the constraints. The reason for this is that the prior knowledge makes the FLSs with the constraints not be over-fitted to the target function so that their feasible parameters spaces are smaller than the counterpart of the FLSs without constraints. Thus, to some extent, T2PFLS, NT2PFLS and T1PFLS can overcome the effect of noise to approach better the original noise-free function. In terms of the size of a test data subset, note that the bigger the size of the subset is, the better the generalization performance is in each case. As the level of noise increases, the generalization performances deteriorate for the six FLSs in each case.

(3) About T2PFLS, NT2PFLS and T1PFLS, from Fig. 8 – Fig. 10, we observe that the performance curves of the three FLSs are in close proximity both for approximation capability and for generalization capability, and as the level of noise increases, they become closer. The following reasons can explain the fact. Since the consequent weights of the three kinds of FLSs are constrained identically, the performances of T2PFLS and NT2PFLS are almost the same as that of T1PFLS. However, the interval type-2 FLSs are formed by the linear combination of the two type-1 bounding FLSs [3]. This implies that type-2 FLSs have more parameters and more freedom degrees than type-1 FLSs. Thus, the approximation performances and the generalization performances of the two kinds of FLSs are better slightly than the counterpart of T1PFLS.

(4) From Fig. 8 – Fig. 10, we observe that unnormalized interval type-2 FLSs perform slightly better than normalized interval type-2 FLSs, and as the level of noise increases, the difference between the unnormalized T2FLSs and the normalized T2FLSs became smaller and smaller. On the other hand, since unnormalized T2FLSs do not need the operation of normalization, i.e., division operation, its elapsed time is less than that of normalized T2FLSs. Here, elapsed time of a type-2 FLS is defined as the time spent on computing the output $\widehat{y}(x)$ of the type-2 FLS for a data subset. Without loss of generality, in the simulation, we use arithmetic means of all the elapsed time obtained from 50 runs. For each case k of T2NPFLS and NT2NPFLS, the average values of the elapsed time are shown in Table I. From the table, we can know that if

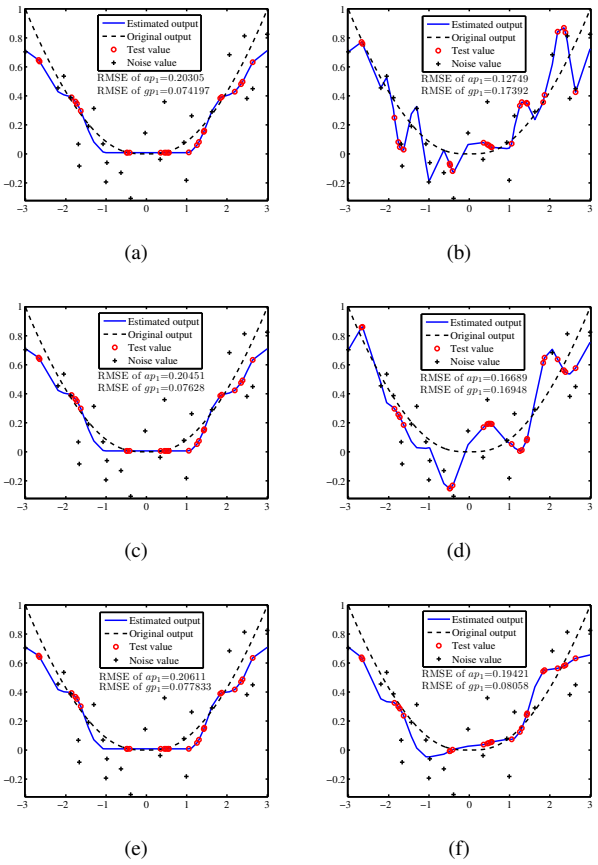


Fig. 11. one of identification results of the six FLSs when the $r_1 = 25$ and $n_b = 40\%$: (a) T2PFLS (b) T2NPFLS (c) NT2PFLS (d) NT2NPFLS (e) T1PFLS (f) T1NPFLS

TABLE I
ELAPSED TIME OF DIFFERENT SAMPLE NUMBER

FLS type	sample number 25	40	60	80	100
T2NPFLS	0.0052	0.0076	0.012	0.015	0.019
NT2NPFLS	0.0060	0.0088	0.013	0.017	0.021

we utilize UIT2FLS, we would save about 11% of the elapsed time of normalized IT2FLS.

In conclusion, based on multi-source knowledge, not only can the UIT2FLS obtain better performance than unnormalized type-1 FLSs on the whole, but also the UIT2FLS slightly outperform and need less computation time than normalized IT2FLSs.

VI. CONCLUSIONS

In this paper, we give some sufficient conditions on ensuring that the prior knowledge of bounded range, symmetry and monotonicity can be incorporated into UIT2FLSs. And then, we design an SISO zeroth-order UIT2FLS for noisy regression problems via constrained least squares algorithm. The simulation results have verified the validity of Theorem 3.1 – 3.4. The FLSs with prior knowledge description have better performances than the FLSs without prior knowledge description on the whole. In contrast with T1PFLS, T2PFLS have better overall performance for approximation capability and generalization capability. In contrast with NT2PFLS, T2PFLS can save more computation time, and have slightly better performance. Therefore, we can conclude that based on multi-source knowledge, the UIT2FLS performs best among all the six fuzzy logic systems.

***Abstract*—This paper tries to show some important properties of the single input rule modules (SIRMs) connected fuzzy inference systems (FIS), including both type-1 (T1) and interval type-2 (IT2) FISs. Three kinds of properties – continuity, monotonicity and robustness – are explored. First, conditions on the parameters are derived to ensure that the SIRMs connected FISs are continuous and monotonic. Then, a methodology for the robustness analysis of the SIRMs connected FISs are presented. At last, an example is given to show the correctness of the theorems on the continuity and monotonicity and to demonstrate the effectiveness of the proposed methodology for robustness analysis. These results can not only deepen our understanding of the SIRMs connected FISs, but also provide us guidelines for the design of the SIRMs connected FISs.**

Keywords — type-2 fuzzy; continuity; monotonicity; robustness analysis

I. Introduction

The single input rule modules (SIRMs) connected fuzzy inference system (FIS) is first proposed by J. Yi, et al. [1-3] to simplify the design process of the conventional type-1 (T1) FIS, and then studied by H. Seki, et al. [4, 5, 24]. Compared with the conventional FISs, the number of rules of the SIRMs connected FISs can be reduced greatly. And, this kind of FIS has been applied to many problems, such as the stabilization control of parallel-type double inverted pendulum systems [1], anti-swing and positioning control of overhead traveling crane [3], etc. Recently, we have extended the SIRMs connected T1 FISs to the interval type-2 (IT2) case [6]. Moreover, we have also utilized the SIRMs connected IT2 FISs to realize the stabilization control of the TORA system [7] and the inverted pendulum system [8].

However, little theoretical research has been conducted for the SIRMs connected FISs. To the best of the authors' knowledge, only two theoretical aspects of the SIRMs connected FISs have been explored. The first aspect is about the relationships between the SIRMs connected FISs and other types of FISs (e.g. Takagi-Sugeno FISs). Such issue has been explored by us [6] and Seki et al. [4, 5]. Recently, we have also studied another theoretical aspect – stability of the SIRMs connected FISs [9]. But, the theoretical research of the SIRMs connected FISs is still not profound enough. And, more properties of the SIRMs connected FISs should be derived to deepen our understanding of this kind of FIS.

Therefore, in this paper, we will study some new properties of the SIRMs connected FISs, such as continuity, monotonicity and robustness. First, we will derive parameter conditions to ensure the continuity and monotonicity of the SIRMs connected FISs. Then, we will present a methodology for the robustness analysis of the SIRMs connected FISs. At last, to show the correctness of the conditions for continuity and monotonicity and to demonstrate the effectiveness of the proposed methodology for robustness analysis, an example will be given. These results can help us to design more reasonable and robust SIRMs connected FISs.

The organization of this paper is as follows. In Section II, the SIRMs connected IT2 FIS is introduced briefly. In Section III, three properties – continuity, monotonicity and robustness – are explored. In Section IV, an example is given. At last, conclusions are drawn in Section V.

II. SIRMs Connected Fuzzy Inference System

As the SIRMs connected T1 FISs are special cases of the SIRMs connected IT2 FISs, in this paper, we will only consider the general case – the SIRMs connected IT2 FISs in detail. The presented results can be readily used for the SIRMs connected T1 FISs as well. In the following, we will give a brief introduction of the SIRMs connected IT2 FISs first.

A SIRMs connected IT2 FIS, which has n input variables x_1, x_2, ..., x_n, is composed of n IT2 SIRMs. The IT2 SIRM for the input variable x_i (IT2SIRM-i) can be expressed as [1-3, 6-9]

$$\text{IT2SIRM-}i: \quad \left\{ R_i^j: \quad x_i = \widetilde{A}_i^j \;\rightarrow\; y_i = \widetilde{C}_i^j \right\}_{j=1}^{M_i}, \qquad (1)$$

where $\widetilde{A}_i^j$s are IT2 fuzzy sets (FSs), $\widetilde{C}_i^j$s are interval weighting factors, and $\widetilde{C}_i^j = [\underline{c}_i^j, \overline{c}_i^j]$. IT2FSs $\widetilde{A}_i^j$s and interval weighting factors $[\underline{c}_i^j, \overline{c}_i^j]$s can be formed by blurring type-1 fuzzy sets A_i^js and crisp values c_i^js, respectively [10-16].

A IT2 SIRM can be seen as a single-input-single-output interval type-2 fuzzy logic system (IT2FLS) [10-16]. Therefore, the inference structure of the IT2 SIRM is the same as the inference structure of the IT2FLS, which consists of a fuzzifier, an inference engine, a rule base, a type-reducer and a defuzzifier [10-16].

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Once a crisp input x_i is applied to IT2SIRM-i, the firing strength of the jth rule can be expressed as

$$F_i^j(x_i) = \left[\underline{f}_i^j(x_i), \overline{f}_i^j(x_i)\right], \tag{2}$$

where

$$\underline{f}_i^j(x_i) = \underline{\mu}_{\widetilde{A}_i^j}(x_i), \quad \overline{f}_i^j(x_i) = \overline{\mu}_{\widetilde{A}_i^j}(x_i), \tag{3}$$

in which $\underline{\mu}(), \overline{\mu}()$ denote the grades of the lower membership functions (MFs) and upper MFs of IT2 FSs.

To generate a crisp output from IT2SIRM-i, different type-reduction and defuzzification methods can be used. Here, for the convenience of rigorous mathematical analysis, the following inference engine, which is an extension of the inference engine proposed in [16], is used:

$$y_i(x_i) = m_i \frac{\sum_{j=1}^{M_i} \underline{f}_i^j(x_i)\underline{c}_i^j}{\sum_{j=1}^{M_i} \underline{f}_i^j(x_i)} + n_i \frac{\sum_{j=1}^{M_i} \overline{f}_i^j(x_i)\overline{c}_i^j}{\sum_{j=1}^{M_i} \overline{f}_i^j(x_i)}, \tag{4}$$

where m_i and n_i, which satisfy that $m_i + n_i = 1$, are inference coefficient.

Once the fuzzy inference result $y_i(x_i)$ of IT2SIRM-i is already calculated, to express clearly the different role of each input varible on system performance, the output $y(\boldsymbol{x})$ of the SIRMs connected IT2 FIS will be computed as the summation of the products of the fuzzy inference result $y_i(x_i)$ and the importance degree w_i of the ith input varible x_i. In other words, the output $y(\boldsymbol{x})$ of the SIRMs connected IT2 FIS can be calculated as [6-9]

$$\begin{aligned} y(\boldsymbol{x}) &= \sum_{i=1}^{n} w_i y_i(x_i) \\ &= \sum_{i=1}^{n} w_i \left[m_i \frac{\sum_{j=1}^{M_i} \underline{f}_i^j(x_i)\underline{c}_i^j}{\sum_{j=1}^{M_i} \underline{f}_i^j(x_i)} + n_i \frac{\sum_{j=1}^{M_i} \overline{f}_i^j(x_i)\overline{c}_i^j}{\sum_{j=1}^{M_i} \overline{f}_i^j(x_i)} \right]. \end{aligned} \tag{5}$$

From (5), we can observe that the input-output mapping of the SIRMs connected FIS can be seen as a multi-variable function.

III. Properties of SIRMs Connected FISs

In this section, we will study the continuity, monotonicity and robustness of the SIRMs connected FISs. These properties always needs to be met in practical applications, e.g. the controller designed for the cart-pole system should be continuous, monotonic and robust. First, let us discuss the issue of continuity.

A. Continuity

As stated in [17], "*in many cases, continuous and smooth input-output mapping is desired for a FLS, because most physical systems are continuous*". Also in [17], the conditions have been derived to assure the continuity of the input-output mappings of IT2 FISs under six different type-reduction and defuzzification methods. From Section II, we can see that the type-reduction and defuzzification method adopted in the SIRMs is different from the six ones studied in [17], and the inference process of the SIRMs connected IT2 FISs differs from the inference process of conventional IT2 FISs. Hence, there is a need for us to study the continuity of the SIRMs connected FISs.

To begin, let us introduce the definition of continuity.

Definition 1 [17, 18]: A multi-variable function $f(\boldsymbol{x})$, where $\boldsymbol{x} = (x_1, ..., x_n) \in \mathbb{X}_1 \times \mathbb{X}_2 \times \cdots \times \mathbb{X}_n$, is continuous at $\boldsymbol{x}^* = (x_1^*, ..., x_n^*) \in \mathbb{X}_1 \times \mathbb{X}_2 \times \cdots \times \mathbb{X}_n$ if and only if it is defined at $\boldsymbol{x}^*$, and $\lim_{\boldsymbol{x} \to \boldsymbol{x}^*} f(\boldsymbol{x}) = f(\boldsymbol{x}^*)$. And $f(\boldsymbol{x})$ is said to be continuous if it is continuous at each point of the universe of discourse $\mathbb{X}_1 \times \mathbb{X}_2 \times \cdots \times \mathbb{X}_n$.

Definition 2 [17]: An IT2 FS A is continuous if and only if its lower MF $\underline{\mu}_{\widetilde{A}}(x)$ and upper MF $\overline{\mu}_{\widetilde{A}}(x)$ are continuous functions of x.

As T1 FSs are special cases of IT2 FSs, hence *Definition 2* is also valid for continuous T1 FSs. In this paper, all IT2 (T1) FSs used in the SIRMs connected IT2 (T1) FISs are supposed to be continuous IT2 (T1) FSs.

The following theorem and corollary show the conditions for the continuity of the SIRMs connected IT2 FISs and the SIRMs connected T1 FISs.

Theorem 1: The SIRMs connected IT2 FIS is continuous if and only if $\max_{j=1,2,...,M_i} \underline{\mu}_{\widetilde{A}_i^j}(x_i) > 0$ for $i = 1, 2, ..., n$, i.e., each point of $\mathbb{X}_i$ is covered by some lower MFs.

Proof: First, recall the following facts about continuous functions [17, 18]:

If both $f_1(\boldsymbol{x})$ and $f_2(\boldsymbol{x})$ are continuous, then,

a) for any constant k, the function $k \cdot f_1(\boldsymbol{x})$ is continuous;

b) the sum of finite continuous functions is also continuous;

c) $f_1(\boldsymbol{x})/f_2(\boldsymbol{x})$ is continuous if and only if $f_2(\boldsymbol{x}) \neq 0$.

Therefore, to prove that the input-output mapping of a SIRMs connected IT2 FIS is continuous, we just need to prove that $\frac{\sum_{j=1}^{M_i} \underline{f}_i^j(x_i)\underline{c}_i^j}{\sum_{j=1}^{M_i} \underline{f}_i^j(x_i)}$ and $\frac{\sum_{j=1}^{M_i} \overline{f}_i^j(x_i)\overline{c}_i^j}{\sum_{j=1}^{M_i} \overline{f}_i^j(x_i)}$ are continuous for $i = 1, 2, ..., n$.

Since all lower and upper MFs are continuous, so $\underline{f}_i^j(x_i)$ and $\overline{f}_i^j(x_i)$ $(j = 1, 2, ..., M_i)$ are continuous for the input variable x_i. Hence, from the above fact b), both $\sum_{j=1}^{M_i} \underline{f}_i^j(x_i)$ and $\sum_{j=1}^{M_i} \overline{f}_i^j(x_i)$ are continuous.

Then, from the above fact c), $\frac{\sum_{j=1}^{M_i} \underline{f}_i^j(x_i)\underline{c}_i^j}{\sum_{j=1}^{M_i} \underline{f}_i^j(x_i)}$ and $\frac{\sum_{j=1}^{M_i} \overline{f}_i^j(x_i)\overline{c}_i^j}{\sum_{j=1}^{M_i} \overline{f}_i^j(x_i)}$ are continuous if and only if $\sum_{j=1}^{M_i} \underline{f}_i^j(x_i) > 0$ and $\sum_{j=1}^{M_i} \overline{f}_i^j(x_i) > 0$. This implies that $\max_{j=1,2,...,M_i} \underline{\mu}_{\widetilde{A}_i^j}(x_i) > 0$.

From above discussions, we can conclude that the SIRMs connected IT2 FIS is continuous if and only if, for $i = 1, 2, ..., n$, $\max_{j=1,2,...,M_i} \underline{\mu}_{\widetilde{A}_i^j}(x_i) > 0$.

□

Corollary 1: The SIRMs connected T1 FIS is continuous if and only if $\max_{j=1,2,...,M_i} \mu_{\widetilde{A}_i^j}(x_i) > 0$ for $i = 1, 2, ..., n$, i.e., everywhere of the universe of discourse $\mathbb{X}_i$ is covered by some MFs.

In this subsection, conditions for the continuity of the SIRMs connected IT2 FISs and T1 FISs were derived. Such

results should be very useful in traditional control problems, where the input-output mappings of the designed controllers are usually required to be continuous.

B. Monotonicity

Many applications of fuzzy logic control requires monotonicity of the output with respect to inputs, e.g., in the cart-pole system, an appropriate controller for the cart-pole system needs to satisfy the monotonicity between the pole angle and the desired cart acceleration. Several papers have studied the monotonicity of traditional T1 FISs [19, 20] and traditional IT2 FISs [21-23]; however, only one paper has focused on the monotonicity of the SIRMs connected T1 FISs [24]. In the following, we will derive conditions to ensure the monotonicity between the inputs and outputs of the SIRMs connected IT2 FISs. As the SIRMs connected T1 FISs are the special SIRMs connected IT2 FISs, so our result is more general than that in [24].

To begin, let us give the definition of monotonicity.

Definition 2 [20]: A multi-variable function $f(\boldsymbol{x})$, where $\boldsymbol{x} = (x_1, ..., x_n) \in \mathbb{X}_1 \times \mathbb{X}_2 \times \cdots \times \mathbb{X}_n$, is said to be monotonically increasing with respect to (w.r.t) x_k if $\forall x_k^1 \leq x_k^2 \in \mathbb{X}_k$ implies that $f(x_1, ..., x_k^1, ..., x_n) \leq f(x_1, ..., x_k^2, ..., x_n)$ for all combinations of $(x_1, ..., x_{k-1}, x_{k+1}, ..., x_n)$.

In this study, we just take increasing monotonicity into account. Similar results can be obtained for decreasing monotonicity.

Theorem 2: The SIRMs connected IT2 FIS is monotonically increasing w.r.t x_k if the following conditions can be satisfied:

1): $\frac{\partial \underline{\mu}_{\widetilde{A}_k^i}(x_k)}{\partial x_k} \underline{\mu}_{\widetilde{A}_k^j}(x_k) \leq \frac{\partial \underline{\mu}_{\widetilde{A}_k^j}(x_k)}{\partial x_k} \underline{\mu}_{\widetilde{A}_k^i}(x_k)$ and $\frac{\partial \overline{\mu}_{\widetilde{A}_k^i}(x_k)}{\partial x_k} \cdot \overline{\mu}_{\widetilde{A}_k^j}(x_k) \leq \frac{\partial \overline{\mu}_{\widetilde{A}_k^j}(x_k)}{\partial x_k} \overline{\mu}_{\widetilde{A}_k^i}(x_k)$, where $1 \leq i \leq j \leq M_k$;

2): $\underline{c}_k^1 \leq \underline{c}_k^2 \leq ... \leq \underline{c}_k^{M_k}$ and $\overline{c}_k^1 \leq \overline{c}_k^2 \leq ... \leq \overline{c}_k^{M_k}$.

Proof: Denote that $\boldsymbol{x}^1 = (x_1, ..., x_k^1, ..., x_n)$ and $\boldsymbol{x}^2 = (x_1, ..., x_k^2, ..., x_n)$.

From (4) and (5), we can obtain that

$$\begin{aligned} y(\boldsymbol{x}^2) - y(\boldsymbol{x}^1) &= w_k[y_k(x_k^1) - y_k(x_k^2)] \\ &= w_k m_k \alpha_k + w_k n_k \beta_k. \end{aligned} \tag{6}$$

where $w_k > 0, 0 \leq m_k = 1 - n_k \leq 1$ and

$$\alpha_k = \frac{\sum_{j=1}^{M_k} \underline{f}_k^j(x_k^2)\underline{c}_k^j}{\sum_{j=1}^{M_k} \underline{f}_k^j(x_k^2)} - \frac{\sum_{j=1}^{M_k} \underline{f}_k^j(x_k^1)\underline{c}_k^j}{\sum_{j=1}^{M_k} \underline{f}_k^j(x_k^1)}, \tag{7}$$

$$\beta_k = \frac{\sum_{j=1}^{M_k} \overline{f}_k^j(x_k^2)\overline{c}_k^j}{\sum_{j=1}^{M_k} \overline{f}_k^j(x_k^2)} - \frac{\sum_{j=1}^{M_k} \overline{f}_k^j(x_k^1)\overline{c}_k^j}{\sum_{j=1}^{M_k} \overline{f}_k^j(x_k^1)}. \tag{8}$$

Therefore, to prove that the SIRMs connected IT2 FIS is monotonically increasing w.r.t x_k, we only need to prove that $\alpha_k \geq 0$ and $\beta_k \geq 0$.

Below, we will only prove that $\alpha_k \geq 0$.

Note that

$$\begin{aligned} \alpha_k &= \frac{\sum_{j=1}^{M_k} \underline{f}_k^j(x_k^2)\underline{c}_k^j}{\sum_{j=1}^{M_k} \underline{f}_k^j(x_k^2)} - \frac{\sum_{j=1}^{M_k} \underline{f}_k^j(x_k^1)\underline{c}_k^j}{\sum_{j=1}^{M_k} \underline{f}_k^j(x_k^1)} \\ &= \frac{\sum_{i=1}^{M_k}\sum_{j=1}^{M_k} \underline{f}_k^i(x_k^1)\underline{f}_k^j(x_k^2)\underline{c}_k^j - \sum_{i=1}^{M_k}\sum_{j=1}^{M_k} \underline{f}_k^i(x_k^1)\underline{f}_k^j(x_k^2)\underline{c}_k^i}{\sum_{j=1}^{M_k} \underline{f}_k^j(x_k^2) \sum_{i=1}^{M_k} \underline{f}_k^i(x_k^1)} \\ &= \frac{\sum_{i=1}^{M_k}\sum_{j=1}^{M_k} (\underline{c}_k^j - \underline{c}_k^i)\underline{f}_k^i(x_k^1)\underline{f}_k^j(x_k^2)}{\sum_{j=1}^{M_k} \underline{f}_k^j(x_k^2) \sum_{i=1}^{M_k} \underline{f}_k^i(x_k^1)} \\ &= \frac{\sum_{i=1}^{M_k-1}\sum_{j=i+1}^{M_k} (\underline{c}_k^j - \underline{c}_k^i)\left[\underline{f}_k^j(x_k^2)\underline{f}_k^i(x_k^1) - \underline{f}_k^i(x_k^2)\underline{f}_k^j(x_k^1)\right]}{\sum_{j=1}^{M_k} \underline{f}_k^j(x_k^2) \sum_{i=1}^{M_k} \underline{f}_k^i(x_k^1)}. \end{aligned} \tag{9}$$

Condition 2) implies that, if $j > i$, then

$$\underline{c}_k^j - \underline{c}_k^i \geq 0. \tag{10}$$

Condition 1) implies that $\frac{\partial}{\partial x_k}\left[\frac{\underline{\mu}_{\widetilde{A}_k^j}(x_k)}{\underline{\mu}_{\widetilde{A}_k^i}(x_k)}\right] \geq 0$, which means that $\frac{\underline{\mu}_{\widetilde{A}_k^j}(x_k)}{\underline{\mu}_{\widetilde{A}_k^i}(x_k)}$ is monotonically increasing w.r.t x_k.

Therefore,

$$\frac{\underline{\mu}_{\widetilde{A}_k^j}(x_k^2)}{\underline{\mu}_{\widetilde{A}_k^i}(x_k^2)} - \frac{\underline{\mu}_{\widetilde{A}_k^j}(x_k)}{\underline{\mu}_{\widetilde{A}_k^i}(x_k)} = \frac{\underline{f}_k^j(x_k^2)}{\underline{f}_k^i(x_k^2)} - \frac{\underline{f}_k^j(x_k^1)}{\underline{f}_k^i(x_k^1)} \geq 0, \tag{11}$$

which implies that

$$\underline{f}_k^j(x_k^2)\underline{f}_k^i(x_k^1) - \underline{f}_k^i(x_k^2)\underline{f}_k^j(x_k^1) \geq 0. \tag{12}$$

From (9), (10) and (12), we can conclude that $\alpha_k \geq 0$.

The result that $\beta_k \geq 0$ can be similarly proved.

In conclusion, this theorem holds.

□

In [20], Won et al. have derived parameter conditions of triangular, trapezoidal and Gaussian T1 MFs to satisfy that $\frac{\partial \underline{\mu}_{\widetilde{A}^i}(x)}{\partial x} \underline{\mu}_{\widetilde{A}^j}(x) \leq \frac{\partial \underline{\mu}_{\widetilde{A}^j}(x)}{\partial x} \underline{\mu}_{\widetilde{A}^i}(x)$, where $j \geq i$.

Similarly, parameter conditions of triangular, trapezoidal and Gaussian lower MFs and upper MFs of IT2 FSs can be derived to satisfy the first condition in *Theorem 2*. The related conclusions are listed in the following:

I): Suppose that the lower and upper MFs of IT2 FS $\widetilde{A}_k^t$ are triangular as depicted below

$$\underline{\mu}_{\widetilde{A}_k^t}(x_k) = \underline{\mu}_{\widetilde{A}_k^t}(x_k, \underline{a}_k^t, b_k^t, \underline{c}_k^t) = \begin{cases} \frac{x_k - \underline{a}_k^t}{b_k^t - \underline{a}_k^t}, & x_k \in (\underline{a}_k^t, b_k^t], \\ \frac{\underline{c}_k^t - x_k}{\underline{c}_k^t - b_k^t}, & x_k \in (b_k^t, \underline{c}_k^t], \\ 0, & else \end{cases} \tag{13}$$

$$\overline{\mu}_{\widetilde{A}_k^t}(x_k) = \overline{\mu}_{\widetilde{A}_k^t}(x_k, \overline{a}_k^t, b_k^t, \overline{c}_k^t) = \begin{cases} \frac{x_k - \overline{a}_k^t}{b_k^t - \overline{a}_k^t}, & x_k \in (\overline{a}_k^t, b_k^t], \\ \frac{\overline{c}_k^t - x_k}{\overline{c}_k^t - b_k^t}, & x_k \in (b_k^t, \overline{c}_k^t], \\ 0, & else \end{cases} \tag{14}$$

where $\overline{a}_k^t \leq \underline{a}_k^t \leq b_k^t \leq \underline{c}_k^t \leq \overline{c}_k^t$.

For triangular IT2 FSs, if $\underline{a}_k^i \leq \underline{a}_k^j$, $b_k^i \leq b_k^j$, $\underline{c}_k^i \leq \underline{c}_k^j$, $\overline{a}_k^i \leq \overline{a}_k^j$, and $\overline{c}_k^i \leq \overline{c}_k^j$, then the first condition in ***Theorem 2*** can be satisfied.

II): Suppose that the lower and upper MFs of IT2 FS $\widetilde{A}_k^t$ are trapezoidal as depicted below

$$\underline{\mu}_{\widetilde{A}_k^t}(x_k)=\underline{\mu}_{\widetilde{A}_k^t}(x_k,\underline{a}_k^t,\underline{b}_k^t,\underline{c}_k^t,\underline{d}_k^t)=\begin{cases}\frac{x_k-\underline{a}_k^t}{\underline{b}_k^t-\underline{a}_k^t}, & x_k\in(\underline{a}_k^t,\underline{b}_k^t],\\ 1, & x_k\in(\underline{b}_k^t,\underline{c}_k^t],\\ \frac{\underline{d}_k^t-x_k}{\underline{d}_k^t-\underline{c}_k^t}, & x_k\in(\underline{c}_k^t,\underline{d}_k^t],\\ 0, & else\end{cases} \tag{15}$$

$$\overline{\mu}_{\widetilde{A}_k^t}(x_k)=\overline{\mu}_{\widetilde{A}_k^t}(x_k,\overline{a}_k^t,\overline{b}_k^t,\overline{c}_k^t,\overline{d}_k^t)=\begin{cases}\frac{x_k-\overline{a}_k^t}{\overline{b}_k^t-\overline{a}_k^t}, & x_k\in(\overline{a}_k^t,\overline{b}_k^t],\\ 1, & x_k\in(\overline{b}_k^t,\overline{c}_k^t],\\ \frac{\overline{d}_k^t-x_k}{\overline{d}_k^t-\overline{c}_k^t}, & x_k\in(\overline{c}_k^t,\overline{d}_k^t],\\ 0, & else\end{cases} \tag{16}$$

where $\overline{a}_k^t\le\underline{a}_k^t$, $\overline{b}_k^t\le\underline{b}_k^t$, $\underline{c}_k^t\le\overline{c}_k^t$ and $\underline{d}_k^t\le\overline{d}_k^t$.

For trapezoidal IT2 FSs, if $\underline{a}_k^i\le\underline{a}_k^j$, $\underline{b}_k^i\le\underline{b}_k^j$, $\underline{c}_k^i\le\underline{c}_k^j$, $\underline{d}_k^i\le\underline{d}_k^j$, $\overline{a}_k^i\le\overline{a}_k^j$, $\overline{b}_k^i\le\overline{b}_k^j$, $\overline{c}_k^i\le\overline{c}_k^j$ and $\overline{d}_k^i\le\overline{d}_k^j$, then the first condition in ***Theorem 2*** can be satisfied.

III): Suppose that the lower and upper MFs of IT2 FS $\widetilde{A}_k^t$ are Gaussian as depicted below

$$\underline{\mu}_{\widetilde{A}_k^t}(x_k)=\underline{\mu}_{\widetilde{A}_k^t}(x_k,c_k^t,\underline{\delta}_k^t)=\exp\left(-\frac{1}{2}\frac{(x_k-c_k^t)^2}{{\underline{\delta}_k^t}^2}\right), \tag{17}$$

$$\overline{\mu}_{\widetilde{A}_k^t}(x_k)=\overline{\mu}_{\widetilde{A}_k^t}(x_k,c_k^t,\overline{\delta}_k^t)=\exp\left(-\frac{1}{2}\frac{(x_k-c_k^t)^2}{{\overline{\delta}_k^t}^2}\right), \tag{18}$$

where $0<\underline{\delta}_k^t\le\overline{\delta}_k^t$.

For Gaussian IT2 FSs, if $c_k^i\le c_k^j$, $\underline{\delta}_k^i=\underline{\delta}_k^j$ and $\overline{\delta}_k^i=\overline{\delta}_k^j$, then the first condition in ***Theorem 2*** can be satisfied.

When IT2 FSs become to T1 FSs, the SIRMs connected IT2 FIS become to the SIRMs connected T1 FIS, and the result in *Theorem 2* can be rewritten for the SIRMs connected T1 FIS as follows.

Corollary 2: The SIRMs connected T1 FIS is monotonically increasing w.r.t x_k if the following conditions can be satisfied:

1): $\frac{\partial\mu_{\widetilde{A}_k^i}(x_k)}{\partial x_k}\mu_{\widetilde{A}_k^j}(x_k)\le\frac{\partial\mu_{\widetilde{A}_k^j}(x_k)}{\partial x_k}\mu_{\widetilde{A}_k^i}(x_k)$, where $1\le i\le j\le M_k$;

2): $c_k^1\le c_k^2\le...\le c_k^{M_k}$.

In this subsection, parameter conditions were derived to ensure the monotonicity of the SIRMs connected FISs. These conditions can be easily satisfied in the design process of the SIRMs connected FISs. But we should notice that the above derived conditions are sufficient ones. It means that, if such conditions are not fulfilled, the SIRMs connected FIS may still be monotonic.

C. Robustness

Robustness is an interesting and important issue of FISs as discussed in [25]:

When a system is subjected to small deviations around the sampling points (operating points), it is essential to find the maximum tolerance of the system with respect to those perturbations, referred to herein as the systems robustness. Thus, in the context of modeling, robustness is a metric for measuring the impact of input deviations on the desired output.

In the following, we will first give the definition of the robustness of the SIRMs connected FISs as defined in [25], and then study how to compute the robustness of the SIRMs connected FISs.

Definition 3: the **robustness** of the SIRMs connected FIS at point $\boldsymbol{x}^*$ w.r.t x_k is defined as

$$R_k=\frac{\Delta_k}{\Delta y_d}, \tag{19}$$

where Δy_d is the given allowable output deviation, and Δ_k is the maximum allowable perturbation of the kth input variable at the sampling point $\boldsymbol{x}^*$ such that $|y(\boldsymbol{x}^*+\Delta\boldsymbol{x})-y(\boldsymbol{x}^*)|\le\Delta y_d$, i.e.

$$\Delta_k=\max\Big\{|\Delta x_k|\Big||y(\boldsymbol{x}^*+\Delta\boldsymbol{x})-y(\boldsymbol{x}^*)|\le\Delta y_d\Big\}.$$

Definition 4: the **robustness** of the SIRMs connected FIS at points $\{\boldsymbol{x}^{*1},\boldsymbol{x}^{*2},...,\boldsymbol{x}^{*L}\}$ w.r.t x_k is defined as

$$R_k=\frac{\min\limits_{j=1,2,...,L}\{\Delta_k^j\}}{\Delta y_d}, \tag{20}$$

where Δy_d is the given allowable output deviation, and Δ_k^j is the maximum allowable perturbation of the kth input variable at the sampling point $\boldsymbol{x}^{*j}$ such that $|y(\boldsymbol{x}^{*j}+\Delta\boldsymbol{x}^j)-y(\boldsymbol{x}^{*j})|\le\Delta y_d$, i.e.

$$\Delta_k^j=\max\Big\{|\Delta x_k^j|\Big||y(\boldsymbol{x}^{*j}+\Delta\boldsymbol{x}^j)-y(\boldsymbol{x}^{*j})|\le\Delta y_d\Big\}.$$

One thing deserves to be mentioned is that the definition of robustness is mathematically equivalent to the sub–additivity or output resolution properties studied in [26-29]. Such properties are proposed for the assessment problems.

Below, we will discuss how to compute the robustness of the SIRMs connected FISs.

First, let us derive the formula for the computation of $\Delta y(\boldsymbol{x}^*)=y(\boldsymbol{x}^*+\Delta\boldsymbol{x})-y(\boldsymbol{x}^*)$.

Note that

$$\begin{aligned}\Delta y(\boldsymbol{x}^*)&=y(\boldsymbol{x}^*+\Delta\boldsymbol{x})-y(\boldsymbol{x}^*)\\&=\sum_{i=1}^n w_i[y_i(x_i^*+\Delta x_i)-y_i(x_i^*)].\end{aligned} \tag{21}$$

Define

$$\Delta y_i(x_i^*)=y_i(x_i^*+\Delta x_i)-y_i(x_i^*). \tag{22}$$

It follows

$$\Delta y(\boldsymbol{x}^*)=\sum_{i=1}^n w_i\Delta y_i(x_i^*). \tag{23}$$

Assuming Δx_i is small and using a Taylor-series expansion, $y(x_i^*+\Delta x_i)$ can be expressed around x_i^* as

$$y_i(x_i^*+\Delta x_i)=y_i(x_i^*)+\left.\frac{\partial y_i(x_i)}{\partial x_i}\right|_{x_i=x_i^*}\Delta x_i+h.o.t, \tag{24}$$

where $h.o.t$ is short for higher order terms.

From (22) and (24), we obtain that

$$\Delta y_i(x_i^*) \simeq \left.\frac{\partial y_i(x_i)}{\partial x_i}\right|_{x_i=x_i^*} \cdot \Delta x_i. \tag{25}$$

From (4)

$$y_i(x_i) = m_i \underline{g}_i(x_i) + n_i \overline{g}_i(x_i). \tag{26}$$

where

$$\underline{g}_i(x_i) = \frac{\sum_{j=1}^{M_i} \underline{f}_i^j(x_i)\underline{c}_i^j}{\sum_{j=1}^{M_i} \underline{f}_i^j(x_i)}, \tag{27}$$

$$\overline{g}_i(x_i) = \frac{\sum_{j=1}^{M_i} \overline{f}_i^j(x_i)\overline{c}_i^j}{\sum_{j=1}^{M_i} \overline{f}_i^j(x_i)}. \tag{28}$$

It follows that

$$\frac{\partial y_i(x_i)}{\partial x_i} = m_i \frac{\partial \underline{g}_i(x_i)}{\partial x_i} + n_i \frac{\partial \overline{g}_i(x_i)}{\partial x_i}. \tag{29}$$

First, derive $\frac{\partial \underline{g}_i(x_i)}{\partial x_i}$ and $\frac{\partial \overline{g}_i(x_i)}{\partial x_i}$.

$$\begin{aligned}\frac{\partial \underline{g}_i(x_i)}{\partial x_i} &= \frac{\sum_{j=1}^{M_i}\sum_{s=1}^{M_i} \frac{\partial \underline{f}_i^j(x_i)}{\partial x_i} \cdot \underline{f}_i^s(x_i) \cdot [\underline{c}_i^j - \underline{c}_i^s]}{\left[\sum_{j=1}^{M_i} \underline{f}_i^j(x_i)\right]^2} \\ &= \frac{\sum_{j=1}^{M_i}\sum_{s=1}^{M_i} \frac{\partial \underline{\mu}_{\widetilde{A}_i^j}(x_i)}{\partial x_i} \cdot \underline{\mu}_{\widetilde{A}_i^s}(x_i) \cdot [\underline{c}_i^j - \underline{c}_i^s]}{\left[\sum_{j=1}^{M_i} \underline{\mu}_{\widetilde{A}_i^j}(x_i)\right]^2}, \end{aligned} \tag{30}$$

$$\begin{aligned}\frac{\partial \overline{g}_i(x_i)}{\partial x_i} &= \frac{\sum_{j=1}^{M_i}\sum_{s=1}^{M_i} \frac{\partial \overline{f}_i^j(x_i)}{\partial x_i} \cdot \overline{f}_i^s(x_i) \cdot [\overline{c}_i^j - \overline{c}_i^s]}{\left[\sum_{j=1}^{M_i} \overline{f}_i^j(x_i)\right]^2} \\ &= \frac{\sum_{j=1}^{M_i}\sum_{s=1}^{M_i} \frac{\partial \overline{\mu}_{\widetilde{A}_i^j}(x_i)}{\partial x_i} \cdot \overline{\mu}_{\widetilde{A}_i^s}(x_i) \cdot [\overline{c}_i^j - \overline{c}_i^s]}{\left[\sum_{j=1}^{M_i} \overline{\mu}_{\widetilde{A}_i^j}(x_i)\right]^2}. \end{aligned} \tag{31}$$

From (23) (25), and (29)-(31), we can conclude that, at the sampling point (operating point) $\boldsymbol{x}^*$,

$$\Delta y(\boldsymbol{x}^*) \simeq \sum_{i=1}^{n} w_i \eta_i(x_i^*) \Delta x_i, \tag{32}$$

where

$$\begin{aligned}\eta_i(x_i^*) = m_i &\frac{\sum_{j=1}^{M_i}\sum_{s=1}^{M_i} \frac{\partial \underline{\mu}_{\widetilde{A}_i^j}(x_i^*)}{\partial x_i} \cdot \underline{\mu}_{\widetilde{A}_i^s}(x_i^*) \cdot [\underline{c}_i^j - \underline{c}_i^s]}{\left[\sum_{j=1}^{M_i} \underline{\mu}_{\widetilde{A}_i^j}(x_i^*)\right]^2} \\ + n_i &\frac{\sum_{j=1}^{M_i}\sum_{s=1}^{M_i} \frac{\partial \overline{\mu}_{\widetilde{A}_i^j}(x_i^*)}{\partial x_i} \cdot \overline{\mu}_{\widetilde{A}_i^s}(x_i^*) \cdot [\overline{c}_i^j - \overline{c}_i^s]}{\left[\sum_{j=1}^{M_i} \overline{\mu}_{\widetilde{A}_i^j}(x_i^*)\right]^2}. \end{aligned} \tag{33}$$

For the T1 case, (33) can be rewritten as

$$\eta_i(x_i^*) = \frac{\sum_{j=1}^{M_i}\sum_{s=1}^{M_i} \frac{\partial \mu_{\widetilde{A}_i^j}(x_i^*)}{\partial x_i} \cdot \mu_{\widetilde{A}_i^s}(x_i^*) \cdot [c_i^j - c_i^s]}{\left[\sum_{j=1}^{M_i} \mu_{\widetilde{A}_i^j}(x_i^*)\right]^2}. \tag{34}$$

From Definition 3, to compute the robustness of the SIRMs connected IT2 FIS at point $\boldsymbol{x}^*$ w.r.t $x_1, x_2, ..., x_n$, we need to derive the maximum allowable perturbation $\Delta_1, \Delta_2, ..., \Delta_n$ at point $\boldsymbol{x}^*$, which can be computed as $(\Delta_1, \Delta_2, ..., \Delta_n) = \max\left\{\left(|\Delta x_1|, |\Delta x_2|, ..., |\Delta x_n|\right) \middle| \sum_{i=1}^{n} w_i \eta_i(x_i^*) \Delta x_i| \le \Delta y_d\right\}$

Therefore, $(\Delta_1, \Delta_2, ..., \Delta_n)$ can be obtained by solving the following optimization problem:

$$\begin{cases} maximize \quad \left(|\Delta x_1|, |\Delta x_2|, ..., |\Delta x_n|\right) \\ s.t. \left|w_1\eta_1(x_1^*)\Delta x_1 + \cdots + w_n\eta_n(x_n^*)\Delta x_n\right| \le \Delta y_d \end{cases} \tag{35}$$

From Definition 4, to compute the robustness of the SIRMs connected IT2 FIS at points $\{\boldsymbol{x}^{*1}, \boldsymbol{x}^{*2}, ..., \boldsymbol{x}^{*L}\}$ w.r.t $x_1, x_2, ..., x_n$, we just need to derive the maximum allowable perturbation $(\Delta_1^j, \Delta_2^j, ..., \Delta_n^j)$s at each point $\boldsymbol{x}^{j*}$ using the aforementioned optimization problem.

IV. Example

In this section, we will give an example to show the continuity and monotonicity of the SIRMs connected FISs. Also, the robustness of the SIRMs connected FISs will be computed in this example.

Consider the following SIRMs connected T1 and IT2 FISs:

SIRMs connected IT2 FIS

$$\text{IT2SIRM} - 1 = \begin{cases} x_1 = \widetilde{A}_1^1 \to y_1 = [8, 10] \\ x_1 = \widetilde{A}_1^2 \to y_1 = [14, 16] \\ x_1 = \widetilde{A}_1^3 \to y_1 = [20, 22] \end{cases}$$

$$\text{IT2SIRM} - 2 = \begin{cases} x_2 = \widetilde{A}_2^1 \to y_2 = [6, 10] \\ x_2 = \widetilde{A}_2^2 \to y_2 = [16, 20] \\ x_2 = \widetilde{A}_2^3 \to y_2 = [26, 30] \end{cases}$$

SIRMs connected T1 FIS

$$\text{T1SIRM} - 1 = \begin{cases} x_1 = \widetilde{A}_1^1 \to y_1 = 9 \\ x_1 = \widetilde{A}_1^2 \to y_1 = 15 \\ x_1 = \widetilde{A}_1^3 \to y_1 = 21 \end{cases}$$

$$\text{T1SIRM} - 2 = \begin{cases} x_2 = \widetilde{A}_2^1 \to y_2 = 8 \\ x_2 = \widetilde{A}_2^2 \to y_2 = 18 \\ x_2 = \widetilde{A}_2^3 \to y_2 = 28 \end{cases}$$

where the IT2 MFs and T1 MFs are shown in Fig. 1, and the importance degrees of IT2 (T1) SIRM-1 and IT2 (T1) SIRM-2 are 0.7 and 0.3, respectively. The coefficients used in the inference engine of the IT2 case are chosen as $m_1 = m_2 = 0.6$ and $n_1 = n_2 = 0.4$.

Fig. 2 shows the input-output mappings of the SIRMs connected T1 and IT2 FISs. We can observe from Fig. 2 that the corresponding input-output mappings are continuous and monotonically increasing. Such results are consistent with Theorem 1, Theorem 2 and their corollaries.

Now, let us compute the robustness of these two-input-one-output SIRMs connected FISs. To do so, we first need to solve the optimization problem below

$$\begin{cases} maximize \quad \left(|\Delta x_1|, |\Delta x_2|\right) \\ s.t. \quad \left|w_1\eta_1(x_1^*)\Delta x_1 + w_2\eta_2(x_2^*)\Delta x_2\right| \le \Delta y_d \end{cases} \tag{36}$$

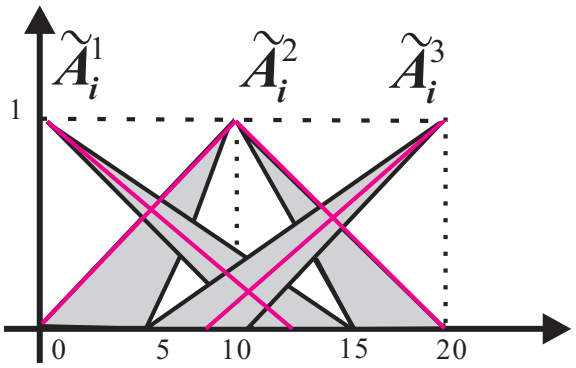

Fig. 1. IT2 MFs (grey areas) and T1 MFs (red lines)

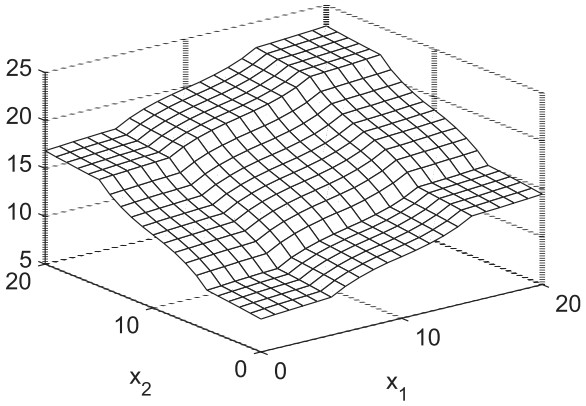
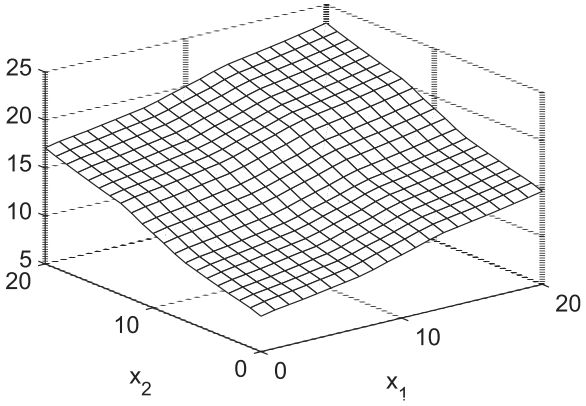


(a) SIRMs Connected IT2 FIS



(b) SIRMs Connected T1 FIS

Fig. 2. Input-output mappings of the SIRMs connected FISs

The result of this optimization problem can be obtained as (details are omitted)

$$\Delta_1 = \frac{\Delta y_d}{2w_1|\eta_1(x_1^*)|}, \tag{37}$$

$$\Delta_2 = \frac{\Delta y_d}{2w_2|\eta_2(x_2^*)|}. \tag{38}$$

Hence, the robustness of such SIRMs connected FISs at

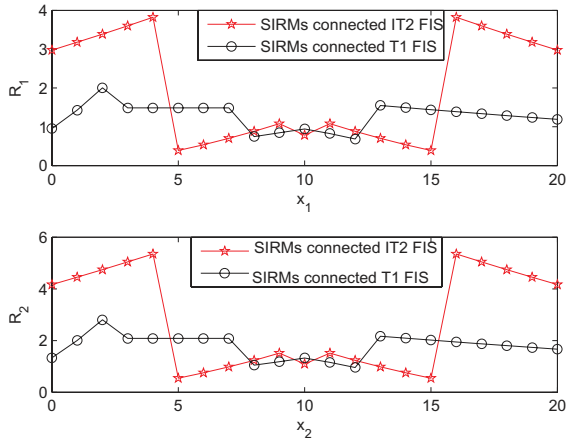


Fig. 3. Robustness indexes of the SIRMs connected FISs

point $\boldsymbol{x}^*$ w.r.t x_1, x_2 can be computed respectively as

$$R_1 = \frac{1}{2w_1|\eta_1(x_1^*)|}, \tag{39}$$

$$R_2 = \frac{1}{2w_2|\eta_2(x_2^*)|}. \tag{40}$$

It is easy to see that, in the two-input-one-output SIRMs connected FISs, R_1 and R_2 are only functions of the sampling points. Thus, the robustness R_i is constant for different desired output deviations.

The robustness of the SIRMs connected FISs at different sampling points w.r.t x_1, x_2 are shown in Fig. 3.

From Fig. 2 and Fig. 3, we can observe and conclude that:

1) The robustness of the SIRMs connected FISs w.r.t x_1, x_2 lies in the intervals $(0, 4]$ and $(0, 6]$, respectively. This means that, for the given allowable output deviation $\Delta y_d = 1$, the maximum allowable perturbation of the first and second input variables lies in $(0, 4]$ and $(0, 6]$ at different sampling points. This result is reasonable and also consistent with the input-output mappings.

2) The SIRMs connected IT2 FIS performs more robustly than the SIRMs connected T1 FIS when $x_1 \in [0, 4.5] \cup [15.5, 20]$ and $x_2 \in [0, 4.5] \cup [15.5, 20]$, although the input-output mapping of the SIRMs connected T1 FIS seems smoother than the IT2 one. The reason for this may be that the output of the SIRMs connected IT2 FIS changes more slowly in the neighbor of these sampling points.

3) For both SIRMs connected FISs, if their outputs change slowly in the neighbor of one sampling point, then the robustness at this point will be large. On the contrary, if the outputs change fast in the neighbor of one sampling point, then the robustness at this point will become small. This is also consistent with our intuition.

V. Conclusion

In this paper, new properties – continuity, monotonicity and robustness – of the SIRMs connected FISs, including both T1 and IT2 cases, are explored. Parameter conditions are derived to ensure the continuity and monotonicity of the

SIRMs connected FISs. These conditions can be easily satisfied in the design process of the SIRMs connected FISs. Also, a methodology for the robustness analysis of the SIRMs connected FISs is presented. The given example demonstrate that the proposed robustness analysis methodology is reasonable. However, how to design SIRMs connected FISs using the proposed methodology has not been studied. This will be one of our future research directions.

***Abstract*—In this paper, a novel digital controller is proposed for the nonlinear systems with packet loss using the intelligent digital redesign (IDR). For the fuzzy controller, the nonlinear system is represented by a Takagi–Sugeno (T–S) fuzzy model. The IDR technique is to convert a pre-designed analog controller into an equivalent digital controller. For this technique, the discretized models of the analog and digital closed-loop system are presented, respectively. The digital control gain is obtained to minimize the norm error between the state of the analog and digital closed-loop systems and stabilize the digital closed-loop system. Its sufficient conditions are derived in terms of linear matrix inequalities (LMIs). Finally, a numerical example is provided to verify the effectiveness of the proposed technique.**

***Index Terms*—intelligent digital redesign (IDR), Takagi–Sugeno (T–S) fuzzy model, packet loss, linear matrix inequality (LMI)**

I. Introduction

Networked control system (NCS) has been a very hot research topic over the past decade [1], [2], [3], [4], [5]. NCSs have attracted much attention because of their successful applications in modern complicated industry processes, e.g., aircraft and space shuttle, unclear power stations, high-performance automobiles, etc. Basically, NCS has wireless communication channels or networks between sensors, controllers, and actuators. Due to these structure, there are many problems, such as time delay, packet loss and so on. Also, the system is continuous, while the control law is discrete. For solving above problems, many studies were progressed. However, contrary to time delay and sampling study, there are not enough studies for packet loss problem. To solve the packet loss problem, it needs an stochastic approach.

Also, because of continuous system and discrete controller, the study for the digital control is essential for NCS. Among many digital control methods, a digital redesign (DR) is widely used as the predominant digital controller design technique [6], [7], [8]. It executes as a tool which converts an original analog controller into a new digital one maintaining the state-matching condition. However, there is a problem that the DR can be only used in linear systems.

In order to apply DR method in the nonlinear system, an intelligent digital redesign (IDR), which is merged with the fuzzy control scheme and the DR method, was proposed in [9]. Also, the robust IDR problem was studied for nonlinear systems with parametric uncertainties [10]. However, these papers dealt with the local state-matching without concerning the global one. The global approaches of the IDR problem were presented in [11], [12], [13], but they did not consider the packet loss problem of the nonlinear systems. The stochastic stability for the nonlinear systems with packet loss were proposed in [3], [4], [5]. But there were no studies about the IDR problem for the nonlinear systems with packet loss.

In this paper, we propose a novel digital controller design for the nonlinear systems which can be modelled by T–S fuzzy systems. For the digital controller design, we use the IDR approach which is to convert a pre-designed analong controller into an equivalent digital one. To develop the IDR technique, the discretized models of the analog and digital closed-loop system with the decentralized controller are presented, respectively. Based on discretized models, sufficient conditions are achieved for both the state-matching condition between analog and digital closed-loop systems and the stability of the digital closed-loop system. Its constructive conditions are presented in terms of linear matrix inequalities (LMIs). Finally, it shows the validity of the proposed ideas, techniques and procedures, through simple example.

This paper is organized as follows: Section 2 describes the discretized models of the T–S fuzzy systems. The stability and state-matching conditions are proposed with the LMI form in Section 3. In Section 4, simulation example is provided to demonstrate the design procedures. Finally, the conclusions are given in Section 5.

II. Preliminaries

Consider a T–S fuzzy system, in which the ith IF-THEN rule is represented by the following form:

$$R_i : \text{IF } z_1(t) \text{ is } \Gamma_{i1} \text{ and } \cdots \text{ and } z_p(t) \text{ is } \Gamma_{ip}$$
$$\text{THEN } \dot{x}(t) = A_i x(t) + B_i u(t) \quad (1)$$

where z_h, $h \in \mathcal{I}_p$ is the premise variable; $x \in \mathbb{R}^n$ and $u \in \mathbb{R}^m$ are the state and control input, respectively; Γ_{ih}, $(i,h) \in \mathcal{I}_r \times$

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

$\mathcal{I}_p$, is a fuzzy set for $z_h(t)$; A_i and B_i denote nominal system matrices with appropriate dimensions for the ith rule.

Using the center-average defuzzification, product inference, and singleton fuzzifier, the global dynamics is inferred as

$$\dot{x}(t) = \sum_{i=1}^{r} \mu_i(z(t))\Big(A_i x(t) + B_i u(t)\Big) \tag{2}$$

where

$$\mu_i(z(t)) = \omega_i(z(t)) \Big/ \sum_{i=1}^{r} \omega_i(z(t)),$$
$$\omega_i(z(t)) = \prod_{h=1}^{p} \Gamma_{ih}(z_h(t))$$

in which $\Gamma_{ih}(z_h(t))$ is the fuzzy membership grade of $z_h(t)$ in Γ_{ih}.

Suppose the pre-designed analog and the digital fuzzy controller (2).

$$u_c(t) = \sum_{i=1}^{r} \mu_i(z(t)) K_i^c x_c(t) \tag{3}$$

$$u_d(t) = u_d(kT) = \alpha(kT) \sum_{i=1}^{r} \mu_i(z(t)) K_i^d x_d(kT) \tag{4}$$

where K_i^c and K_i^d denote the analog and the digital control gains, the subscript 'c' and 'd' mean the analog control and the digital control, respectively, and $\alpha(kT)$ is a Bernoulli random process to determine the packet loss with the following assumption:

Assumption 1: Bernoulli random process $\alpha(kT)$ is an independent, identically distributed (iid) random sequence specified by the following law:

$$\begin{cases} \mathbf{Prob}\{\alpha(kT) = 1\} = \mathbb{E}\{\alpha(kT)\} = \tilde{\alpha} \\ \mathbf{Prob}\{\alpha(kT) = 0\} = 1 - \mathbb{E}\{\alpha(kT)\} = 1 - \tilde{\alpha} \end{cases}$$

Substituting (3) and (4) into (2), respectively, the closed-loop systems are written as

$$\dot{x}_c(t) = \sum_{i=1}^{r}\sum_{j=1}^{r} \mu_i(z(t))\mu_j(z(t))\big(A_i + B_i K_j^c\big)x(t) \tag{5}$$

$$\dot{x}_d(t) = \sum_{i=1}^{r}\sum_{j=1}^{r} \mu_i(z(t))\mu_j(z(kT)) \times \big(A_i x(t) + \alpha(kT) B_i K_j^d x(kT)\big) \tag{6}$$

To obtain the discretized systems of (5) and (6), we have introduced the following assumption.

Assumption 2: Assume that $\mu_i(z(t)) \approx \mu_i(z(kT))$ for $t \in [kT,\ kT+T)$. Consequently, the nonlinear matrix functions $\sum_{i=1}^{r} \mu_i(z(t))A_i$ and $\sum_{i=1}^{r} \mu_i(z(t))B_i$ can be represented by constant matrices $\sum_{i=1}^{r} \mu_i(z(kT))A_i$ and $\sum_{i=1}^{r} \mu_i(z(t))B_i$, respectively, over any interval $[kT,\ kT+T)$, $k \in \mathbb{Z}_{\geq 0}$.

Supposing the sampling period T, closed-loop fuzzy system (5) and (6) are approximately discretized as

$$x_c(kT+T) \approx \sum_{i=1}^{r}\sum_{j=1}^{r} \mu_i(z(kT))\mu_j(z(kT))\Phi_{ij} x_c(kT) \tag{7}$$

where

$$\Phi_{ij} = \exp\Big(\big(A_i + B_i K_j^c\big)T\Big)$$

$$x_d(kT+T) \approx \sum_{i=1}^{r}\sum_{j=1}^{r} \mu_i(z(kT))\mu_j(z(kT)) \times \Big(\big(G_i + \alpha(kT) H_i K_j^d\big)T\Big) x_d(kT) \tag{8}$$

where

$$G_i = \exp(A_i T),$$
$$H_i = (G_i - I)(A_i)^{-1} B_i.$$

The objective of this paper is to obtain the LMI for the digital fuzzy control gain K_i^d which minimize the state-matching error between $x_c(kT)$ and $x_d(kT)$ and stabilize the digital closed-loop system (6).

III. Main results

In order to proceed to main results, the following definition and lemmas will be needed throughout the proof.

Definition 1: The equilibrium point $x(t) = 0$ is said to be stochastically stable in the nonlinear system if, for any $\epsilon > 0$ there exists a $\delta = \delta(\epsilon) > 0$, such that

$$\|x(0)\| < \delta \Rightarrow E\{\|x(t)\|\} < \epsilon, \qquad \forall t \geq 0$$

Lemma 1 ([14]): If there exist a Lyapunov functional and a non-decreasing convex function $a(r)$ satisfying the following conditions:

$$\begin{cases} V(0) = 0 \\ a(\|x(t)\|) \leq V(x(t)) \\ E\{V(x(t+1))\} - E\{V(x(t))\} < 0 \end{cases}$$

then the equilibrium point $x(t) = 0$ of the fuzzy system (8) is stochastically stable.

Lemma 2 ([15]): Given any matrices Y and $P = P^T \succ 0$, we have

$$-Y^T P^{-1} Y \preceq P - Y^T - Y\ .$$

Lemma 3 ([16]): : For any real matrices X_i, Y_i for $1 \leq i \leq N$, and $S \succ 0$ with appropriate dimensions, we have

$$2\sum_{i=1}^{N}\sum_{j=1}^{N}\sum_{k=1}^{N}\sum_{l=1}^{N} h_i h_j h_k h_l X_{ij}^T S Y_{kl} \leq \sum_{i=1}^{N}\sum_{j=1}^{N} h_i h_j (X_{ij}^T S X_{ij} + Y_{ij}^T S Y_{ij})$$

where h_i $(1 \leq i \leq N)$ are defined as $h_i \geq 0$, $\sum_{i=1}^{N} h_i = 1$.

Lemma 4 ([17]): : For real matrices X and Y with appropriate dimensions, the following inequality is always satisfied.

$$X^T Y + Y^T X \leq \sigma X^T X + \frac{1}{\sigma} Y^T Y$$

where σ is a positive constant.

Proposition 1: In (6), there exists some constant $\delta > 0$ such that

$$\mathbb{E}\{\|x(t)\|\} \le \delta \mathbb{E}\{\|x(kT)\|\} \tag{9}$$

where

$$\begin{aligned}\delta =&(1+T\beta)e^{\alpha T},\\ \alpha =& \sup_{i\in\mathcal{I}_r}\|A_i\|,\\ \beta =& \sup_{(i,j)\in\mathcal{I}_r\times\mathcal{I}_r}\|B_iK_j^d\|\end{aligned}$$

for $t \in [kT, kT+T)$.

Proof: Integrating (6) from kT to t, $t \in [kT, kT+T)$ and taking the norm on both sides of the results yields

$$\begin{aligned}&\|x(t)\|\\ &\le \|x(kT)\| + \int_{kT}^{t}\left(\left\|\sum_{i=1}^{r}\mu_i(z(t))A_i\right\|\|x(\tau)\|\right.\\ &\quad\left.+\left\|\sum_{i=1}^{r}\sum_{j=1}^{r}\mu_i(z(t))\mu_j(z(kT))\alpha(kT)B_iK_j\right\|\|x(kT)\|\right)d\tau\\ &\le \sup_{(i,j)\in\mathcal{I}_r\times\mathcal{I}_r}\left\{\big(1+T\|B_iK_j^d\|\big)\|x(kT)\| + \int_{kT}^{t}\|A_i\|\|x(\tau)d\tau\right\}\end{aligned}$$

An application of the Grownwall-Bellman inequality to $\|x(t)\|$ constructs the inequality

$$\|x(t)\| \le \delta\|x(kT)\| \tag{10}$$

where

$$\delta = \sup_{(i,j)\in\mathcal{I}_r\times\mathcal{I}_r}\left\{\big(1+T\|B_iK_j^d\|\big)e^{\|A_i\|T}\right\}$$

is independent of k. Taking the expectation of (10), we can obtain the inequality (1). ■

Theorem 1: If there exist some symmetric and positive matrix Q and some matrix M_i, such that the following LMIs have optimal solutions, then, $x_d(kT)$ of (8) closely matches $x_c(kT)$ of (7), and origin of (8) is stochastically stable.

$$\underset{Q,M_i}{\text{minimize}} \quad \gamma \quad \text{subject to}$$

$$\begin{bmatrix}-\gamma Q & * & *\\ \Phi_{ij}Q - G_iQ - \tilde{\alpha}H_iM_j & -\gamma I & *\\ \sqrt{(1-\tilde{\alpha})\tilde{\alpha}}H_iM_j & 0 & -\gamma I\end{bmatrix} \prec 0 \tag{11}$$

$$\begin{bmatrix}-Q & * & *\\ G_iQ + \tilde{\alpha}H_iM_i & -Q & *\\ \sqrt{(1-\tilde{\alpha})\tilde{\alpha}}H_iM_j & 0 & -Q\end{bmatrix} \prec 0 \tag{12}$$

$$\begin{bmatrix}-4Q & * & *\\ G_iQ + G_jQ + \tilde{\alpha}H_iM_j + \tilde{\alpha}H_jM_i & -Q & *\\ \sqrt{(1-\tilde{\alpha})\tilde{\alpha}}(H_iM_j + H_jM_i) & 0 & -Q\end{bmatrix} \prec 0 \tag{13}$$

for $\forall\{(i,j) \in \mathcal{I}_r \times \mathcal{I}_r | 1 \le i \le j \le r\}$.

Proof: In order to closely match $x_d(kT)$ of (8) to $x_c(kT)$ of (7), consider the norm minimization problem in the following form:

$$\left\|\Phi_{ij}^k - (G_i + \alpha(kT)H_iK_j^d)\right\| \le \hat{\gamma} \tag{14}$$

for some $\hat{\gamma} > 0$. Using the norm property, the above inequality holds

$$\begin{aligned}&\Big(\Phi_{ij} - (G_i + \alpha(kT)H_iK_j^d)\Big)^T\Big(\Phi_{ij} - (G_i + \alpha(kT)H_iK_j^d)\Big)\\ &\prec \gamma^2 P\end{aligned} \tag{15}$$

where $\gamma > 0$ and $P^k = (P)^T \succ 0$ with $\hat{\gamma}I \prec \gamma^2 P$. Taking the expectation, inequality (15) results in

$$\begin{aligned}(15) \Rightarrow& E\Big\{\Big(\Phi_{ij} - (\Psi_{ij} + \hat{\alpha}(kT)H_i^kK_j^d)\Big)^T\\ &\times\Big(\Phi_{ij} - (\Psi_{ij} + \hat{\alpha}(kT)H_i^kK_j^d)\Big) - \gamma^2 P\Big\}\\ =&\big(\Phi_{ij} - \Psi_{ij}\big)^T\big(\Phi_{ij} - \Psi_{ij}\big) - \gamma^2 P\\ &+ (1-\tilde{\alpha})\tilde{\alpha}(K_j^d)^TH_i^TH_iK_j^d\end{aligned} \tag{16}$$

where

$$\begin{aligned}\Psi_{ij} &= G_i + \tilde{\alpha}H_iK_j^d,\\ \hat{\alpha}(kT) &= \alpha(kT) - \tilde{\alpha}.\end{aligned}$$

Taking the Schur complement and the congruence transformation with $\mathrm{diag}\{\gamma^{-1}P^{-1}, I, I\}$ and denoting $K_j^dQ = M_j$, inequality (15) yields (11).

Apart from the state-matching problem, for solving the stability problem, we choose the Lyapunov function candidate $V(x(kT))$ for (8) as follows:

$$V(x(kT)) = x_d^T(kT)Px_d(kT)$$

The rate of increase of $E\{V(x(kT))\}$ along (8) is then

$$\begin{aligned}&E\{V(kT+T)\} - E\{V(kT)\}\\ &\le E\Big\{\frac{1}{4}\sum_{i=1}^{r}\sum_{j=1}^{r}\mu_i(z(kT))\mu_j(z(kT))\\ &\quad\times\Big(\Big((\Psi_{ij}+\Psi_{ji} + \hat{\alpha}(kT)H_iK_j^d + \hat{\alpha}(kT)H_jK_i^d)x_d\Big)^T\\ &\quad\times P^k\Big((\Psi_{ij}+\Psi_{ji} + \hat{\alpha}(kT)H_iK_j^d + \hat{\alpha}(kT)H_jK_i^d)x_d\Big)\\ &\quad - 4x_d^TP^kx_d\Big)\Big\}\end{aligned} \tag{17}$$

Because of $\mathbb{E}\{\hat{\alpha}(kT)\} = 0$ and $\mathbb{E}\{\hat{\alpha}^2(kT)\} = (1-\tilde{\alpha})\tilde{\alpha}$, inequality (17) is rearranged as follows:

$$\begin{aligned}&E\{V(kT+T)\} - E\{V(kT)\}\\ &\le \frac{1}{4}\sum_{i=1}^{r}\sum_{j=1}^{r}\mu_i(z(kT))\mu_j(z(kT))\\ &\quad\times\Big(\Big((\Psi_{ij}+\Psi_{ji})x_d\Big)^TP\Big((\Psi_{ij}+\Psi_{ji})x_d\Big) - 4x_d^TP^kx_d\\ &\quad + (1-\tilde{\alpha})\tilde{\alpha}x_d^T\big(H_iK_j^d + H_jK_i^d\big)^TP\big(H_iK_j^d + H_jK_i^d\big)x_d\Big)\end{aligned} \tag{18}$$

Form (18), if the following inequalities hold for any $1 \le i < j \le r$, we know that the closed-loop system (6) is

stochastically stable by Definition 1 and Proposition 1.

$$\Psi_{ii}^T P \Psi_{ii} - P + (1-\tilde{\alpha})\alpha (K_j^d)^T H_i^T P H_i K_j^d \prec 0 \tag{19}$$

$$\left(\frac{\Psi_{ij}+\Psi_{ji}}{2}\right)^T P \left(\frac{\Psi_{ij}+\Psi_{ji}}{2}\right) - P + (1-\tilde{\alpha})\alpha \left(\frac{H_i K_j^d + H_j K_i^d}{2}\right)^T P \left(\frac{H_i K_j^d + H_j K_i^d}{2}\right) \prec 0 \tag{20}$$

Using Schur complement and congruence transformation with $\mathrm{diag}\{P^{-1}, I, I\}$ to (19) and (20), we can obtain the LMI conditions (12) and (13) in the Theorem 1. ■

Remark 1: The inequalities for the pair (k, m) such that $\mu_{ik}(x_i(t) \times \mu_{im}(x_i(t)) = 0$, do not need to be solved to determine global stability.

IV. Numerical Examples

In this section, an example is given to validate the proposed method. We consider the fuzzy system which is called the chaotic Lorenz system. The dynamic equations of the system are described by [18]

$$\begin{aligned}\dot{w}(t) &= -\sigma w(t) + \sigma y(t)\\ \dot{y}(t) &= r w(t) - y(t) - w(t) z(t)\\ \dot{z}(t) &= w(t) y(t) - b z(t)\end{aligned}$$

where $\sigma = 10$, $r = 28$ and $b = -\frac{8}{3}$.

Assuming $w(t) \in [M_1, M_2]$ and choosing $x(t) = \begin{bmatrix} x_1(t) & x_2(t) & x_3(t)\end{bmatrix}^T = \begin{bmatrix} w(t) & y(t) & z(t)\end{bmatrix}^T$, the T–S fuzzy system can be constructed as follows:

$$\dot{x}(t) = \sum_{i=1}^{2} \mu_i(x_1(t))\big(A_i x(t) + B_i u(t)\big)$$

where

$$A_1 = \begin{bmatrix} -\sigma & \sigma & 0\\ r & -1 & -M_1\\ 0 & M_1 & -b\end{bmatrix}$$

$$A_2 = \begin{bmatrix} -\sigma & \sigma & 0\\ r & -1 & -M_2\\ 0 & M_2 & -b\end{bmatrix}$$

$$B_1 = B_2 = \begin{bmatrix} 1 & 0 & 0\end{bmatrix}$$

for $i \in \mathcal{I}_r$. The membership functions are

$$\mu_1(x_1(t)) = \frac{-x_1(t) + M_2}{M_2 - M_1}$$

$$\mu_2(x_1(t)) = \frac{x_1(t) - M_1}{M_2 - M_1}$$

We assume $M_1 = -20$, $M_2 = 30$, the initial sate conditions $x(0) = [10, -10, -10]^T$, packet loss probability $\tilde{\alpha} = 0.8$ and a sampling time $T = 0.05$s.

By using Theorem 1 and solving the corresponding LMIs, we obtain the control gains:

$$K_1^d = \begin{bmatrix} -25.0411 & -15.8009 & -11.6152\end{bmatrix}$$

$$K_2^d = \begin{bmatrix} -23.4177 & -10.0505 & 15.5128\end{bmatrix}$$

Time responses for each subsystem are shown in Figs. 1, 2 and 3. As shown in these figures, we can observe that the controlled state variables by IDR method follow the controlled analog ones and converge to the origin. Thus we can know that the proposed IDR technique satisfies an asymptotic stability of digitally closed-loop fuzzy system and the state-matching requirement with the originally closed-loop system.

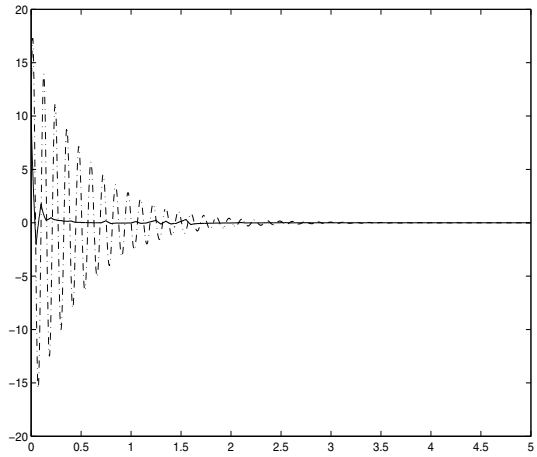

Fig. 1. The time responses x_1 of controlled system for $T = 0.2$s: analog (dash-dotted), proposed (solid).

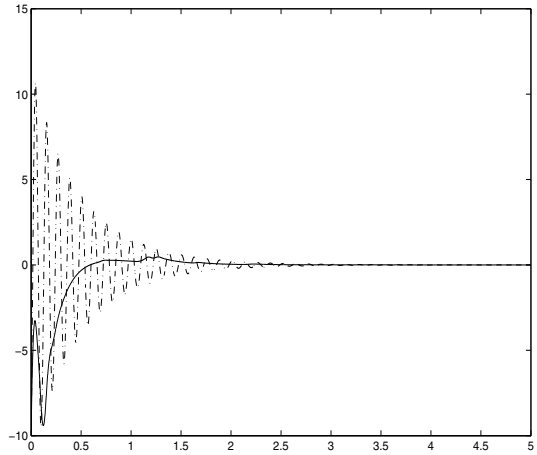

Fig. 2. The time responses x_2 of controlled system for $T = 0.2$s: analog (dash-dotted), proposed (solid).

V. Conclusion

This paper has established the IDR method for the fuzzy systems. Using the T–S fuzzy model, we has presented the analog and digital closed-loop fuzzy systems. For the IDR method, descritized models of each closed-loop systems are obtained. Based on the descritized systems, it was shown that the IDR technique can find the digital fuzzy gains to minimize the norm error between the state of analog system and digital system and stabilize the digital closed-loop system. Also, the sufficient design conditions were derived and formulated in the LMI format, and were therefore easily tractable by convex

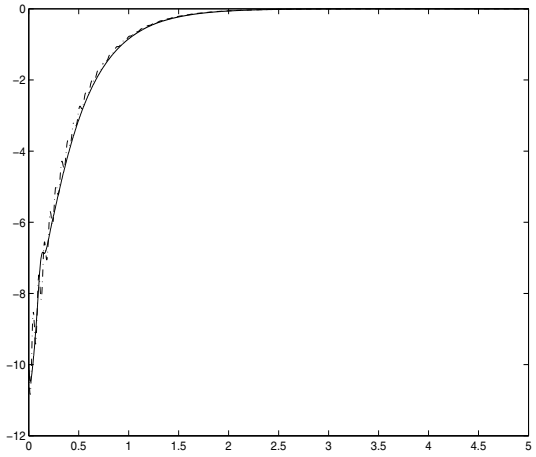

Fig. 3. The time responses x_3 of controlled system for $T = 0.2$s: analog (dash-dotted), proposed (solid).

optimization. Finally a simulation example has shown that the results of this paper are effective and valuable.

I. Introduction

The purpose of target tracking is an accurate state estimation of a moving object. Estimating as accurately as possible of the state of a dynamic system have been a very important topic. Among the various approaches proposed in this topic, the estimation processes a relative states between a moving platform and a target as well as estimation of the target states[1], [2], [3]. In most cases, whether the target states are described in inertial, spherical, or modified spherical coordinates in[5]. The model-based adaptive filtering method was presented in [7], [9], [10], [11] that consider the motion of a target by using multiple sub-filters. Almost all maneuvering target tracking methods are model based. Research continues on techniques and applications to the target tracking problem each of these approaches has its own drawbacks. And all are approximate from sense in discrete-time domain and some do not apply to the tracking problem[6], [7], [9], [10]. They assume that the target motion and its observation can be represented by some known mathematical models accurately[8]. The most of thesis used target motion and measurement model in continuous-time(CT) domain or discrete-time(DT) domain.

However, the target motion is more accurately modeled in CT domain. They should not depend on how and when samples are taken. And measurements are usually available only at discrete time instants. To design the target motion in DT domain, the discretisation of it is usually first required. The discretisation methods of the fuzzy system have been studied[12], [13]. This method is directly discretise the global dynamics of the fuzzy model. And Takagi-Sugeno(T-S) fuzzy model have the important advantage of its universal approximation.

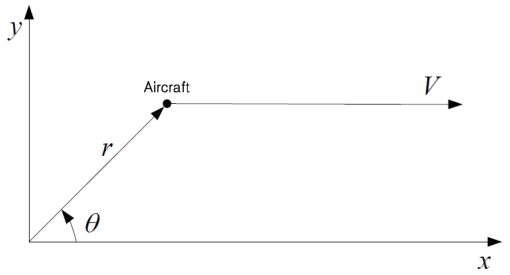

Fig. 1. Radar tracking geometry

In this paper, we concerned with the mixed-time fuzzy optimal estimator for the target tracking. We propose that take account of behavior for target motion in CT domain and system measurement in DT domain. The overall dynamic of system in CT is discretised by using T-S fuzzy models. Based on the fuzzy model, the fuzzy estimation is studied. Then the error state of the filtering process is mean square bounded. A basis dependent Lyapunov function approach is developed to design the fuzzy filter and a filter gain is minimized by using some linear matrix inequalities(LMIs) constraints. A numerical example is provided to demonstrate various aspects of theoretical results. This paper is organized as follows: Section 2 describes the conventional discretisation method of the continuous-time T-S fuzzy model. Section 3 describes the fuzzy filter design by using the discretizing system and measurement. In Section 4, a numerical example is provided to design the fuzzy filter. Finally, the conclusions are given in Section 5.

II. Preliminaries and problem description

We assume here that the target moves in a plane that is the two-dimensional radar tracking problem illustrated in Figure 1. In fact, the target motion is more accurately modeled in CT domain while observations are usually available only at DT instants. It is often more appropriate to use the following mixed-time models for most tracking problem.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

A. State and measurement models

The moving target[14] can be described as

$$\begin{aligned} r^2 &= x^2 + y^2 \\ 2r\dot{r} &= 2x\dot{x} + 2y\dot{y} \\ \dot{r} &= \frac{x}{r}\dot{x} + \frac{y}{r}\dot{y} \end{aligned} \tag{1}$$

where $x = rcos\theta$, $\dot{x} = V$, $\dot{y} = 0$, V is velocity, r is the radar measurement range and θ is azimuth, therefore

$$\dot{r} = Vcos\theta \tag{2}$$

Assume that the aircraft is not accelerating so that $\dot{V} = 0$. If r and θ do not change much during each scan of the radar(about 1-10s), we have $\ddot{r} \approx 0$ and $\ddot{\theta} \approx 0$.

Differentiating

$$\begin{aligned} \frac{d}{dt}\dot{r} &= \dot{V}cos\theta - V\dot{\theta}sin\theta \\ \frac{d}{dt}\theta &= -\left(\frac{\dot{V}r - V\dot{r}}{r^2}\right)sin\theta - \frac{V}{r}\dot{\theta}cos\theta \end{aligned} \tag{3}$$

We have the state equation as

$$\frac{d}{dt}\begin{bmatrix} r \\ \dot{r} \\ \theta \\ \dot{\theta} \end{bmatrix} = A\begin{bmatrix} r \\ \dot{r} \\ \theta \\ \dot{\theta} \end{bmatrix} + \begin{bmatrix} 0 \\ w_1(t) \\ 0 \\ w_2(t) \end{bmatrix} \tag{4}$$

where A is system matrix and $w_1(t), w_2(t)$ are random disturbances. From (4), we have the continuous-time state model.

$$\dot{X}(t) = AX(t) + BW(t) \tag{5}$$

$$y(k) = CX(k) + v(k) \tag{6}$$

where $X(t) = [r \quad \dot{r} \quad \theta \quad \dot{\theta}]^T$ denotes the state vector, $y(k)$ denotes measurement equation, A, B, C denote the system matrix, $W(t)$ is maneuver noise, $v(k)$ is measurement noise.

Remark 1: Measurements are available only at discrete-time instants because they are in fact from sensor. It is often more appropriate to use the following mixed-time models for most tracking problems.

The general solution to (5) excited by the initial state $X(t_0)$ is given by

$$\dot{X}(t) = \Phi(t, t_0) + \int_{t_0}^{t} \Phi(t, \tau)Bw(\tau)d\tau \tag{7}$$

where the state transition matrix $\Phi(t, t_0)$ satisfies $\Phi(t, t_0) = \Phi(t, t_1)\Phi(t_1, t_0)$ with initial condition $\Phi(t, t_0) = I$. The solution to (5) at $t = (k+1)T$ with $t_0 = kT$ is

$$\begin{aligned} X(kT+T) =& exp(AT)X(kT) \\ &+ \int_{kT}^{kT+T} exp(A(kT+T-\tau))BW(kT)d\tau \\ =& GX(kT) + HW(kT) \end{aligned} \tag{8}$$

where $G = exp(AT)$ and $H = (G - I)BA^{-1}$.

B. The discretizing the continuous-time T-S fuzzy model

The discretising the continuous-time T-S fuzzy model is to apply the discretisation method for system to the consequent parts of the fuzzy rules. The rule of the T-S fuzzy system is formulated in the following form

$$\begin{aligned} R_i &: \text{IF } z_1(t) \text{ is about } \Gamma_{i1} \text{ and } \cdots \text{ and } z_g(t) \text{ is about } \Gamma_{ig}, \\ &\text{THEN } \dot{X}(t) = A_iX(t) + B_iW(t) \end{aligned} \tag{9}$$

where $i \in \Re_g = \{1, 2, ..., g\}$, denotes the ith fuzzy rule; $z_h(t)$, $h \in \Re_p = \{1, 2, ..., p\}$, the hth premise variable; $\Gamma_{ih}, (i, h) \in \Re_q \times \Re_g$, the fuzzy set. If $z_h(t)$ for $t \in [kT, kT+T)$ is $z_h(kT)$, the rule of the corresponding discrete-time T-S fuzzy model is obtained as follows

$$\begin{aligned} R_i &: \text{IF } z_1(kT) \text{ is about } \Gamma_{i1} \text{ and } \cdots \text{ and } z_g(kT) \text{ is about } \Gamma_{ig}, \\ &\text{THEN } X(kT+T) = G_iX(kT) + H_iW(kT) \\ &\qquad y(kT) = C_iX(kT) + v(kT) \end{aligned} \tag{10}$$

where $G_i = exp(A_iT)$ and $H_i = (G_i - I)B_iA_i^{-1}$. Using the center-average defuzzification, product inference and singleton fuzzifier, the overall dynamics of this discrete-time T-S fuzzy model is described by

$$X(kT+T) = \sum_{i=1}^{g} \theta_i(z(kT))(G_iX(kT) + H_iW(kT)) \tag{11}$$

$$y(kT) = \sum_{i=1}^{g} \theta_i(z(kT))(C_iX(kT) + v(kT)) \tag{12}$$

where $\theta_i(z(kT)) = \frac{\mu_i(z(kT))}{\sum_{i=1}^{p}\mu_i(z(kT))}$,
$\mu_i(z(kT)) = \prod_j^q \Gamma_{ij}(z_j(kT))$ and $\Gamma_{ih}(z_h(kT))$ is the grade of membership of $z_h(kT)$ in Γ_{ih}.

Remark 2: In the target tracking, a target is usually treated as a point object a shape in tracking, The state is often approximated piecewise constant with $X(k) = X(t), t(k) \leq t < t(k+1)$ when discretizing a continuous time system. Note that $W(k) \neq W(t_k), X(k) \neq X(t_k)$.

We denote that

$$\begin{aligned} X(kT) &= G_{if}X(kT) + H_{if}W(kT) \\ y(kT) &= C_{if}X(kT) + v(kT) \end{aligned} \tag{13}$$

where

$$\begin{aligned} G_{if} &= \sum_{i=1}^{g} \theta_i(z(kT))G_i, \qquad H_{if} = \sum_{i=1}^{g} \theta_i(z(kT))H_i, \\ C_{if} &= \sum_{i=1}^{g} \theta_i(z(kT))C_i. \end{aligned} \tag{14}$$

In this paper, we use the discretizing fuzzy system for accurately model of the target motion. Because the target motion modeling is one of the first tasks for maneuvering target tracking.

III. T-S Fuzzy Model based Fuzzy Filter Design

This Section presents a fuzzy filter design method based on Lyapunov function. We present the proposed discretised version of the continuous-time T-S fuzzy system. The discretising fuzzy model is used to deal with the state estimation. Before proceeding, let us introduce the following lemma which will be essential for the proof of our main result.

Lemma 1: (Schur complement [4]) Given constant symmetric matrices N, O and L of appropriate dimensions, the following two inequalities are equivalent:

$$O > 0, \quad N + L^T O L < 0, \tag{15}$$

$$\begin{bmatrix} N & L^T \\ L & -O^{-1} \end{bmatrix} < 0 \quad \text{or} \quad \begin{bmatrix} -O^{-1} & L \\ L^T & N \end{bmatrix} < 0$$

The following fuzzy filter is proposed to deal with a state estimation.

Filter Rule R_j

IF $z_1(kT)$ is about Γ_{j1} and $\cdots$ and $z_g(kT)$ is about Γ_{jg},

THEN $\hat{X}(kT+T) = G_j\hat{X}(kT) + L_j(y(kT) - \hat{y}(kT))$ (16)

where $\hat{X}(kT)$ is an estimate of $X(kT)$, $G_j = exp(A_jT)$ and L_j is the filter parameter to be determined, $\hat{y}(kT) = \sum_{k=1}^{q}\theta(z(kT))C_k(kT)\hat{X}(kT)$ and L_j is the filter gain with jth filter rule. The defuzzified outputs are given by

$$\begin{aligned}\hat{X}(kT+T) =& \sum_{j=1}^{q}\theta_j(z(kT))\sum_{k=1}^{q}\theta(kT)(z(kT)) \\ & \times [G_j\hat{X}(kT) + L_j(y(kT) - \hat{y}(kT))] \\ =& \sum_{i=1}^{q}\theta_i(z(kT))\sum_{j=1}^{q}\theta_j(z(kT))\sum_{k=1}^{q}\theta_k(z(kT)) \\ & \{L_jC_iX(kT) + L_jv(kT) \\ & +(G_j - L_jC_k(kT))\hat{X}(kT)\Big\}\end{aligned} \tag{17}$$

For the notational convenience in the following discussions, we denote that

$$\begin{aligned}\hat{X}(kT+T) =& L_{jf}C_{if}X(kT) \\ & +(C_{jf} - L_{jf})\hat{X}(kT) + L_jv(kT)\end{aligned} \tag{18}$$

where

$$L_{jf} = \sum_{j=1}^{q}\theta_j(z(kT))L_j, \quad G_{jf} = \sum_{j=1}^{q}\theta_j(z(kT))G_j,$$
$$C_{kf} = \sum_{k=1}^{q}\theta_j(z(kT))C_k.$$

From (11) and (17), the augmented system can be expressed as

$$\eta(kT+T) = G_m\eta(kT) + B_md(kT+T) \tag{19}$$

where

$$\begin{aligned}\eta(kT+T) &:= \begin{bmatrix} X(kT+T) & \hat{X}(kT+T) \end{bmatrix}^T \\ d(kT+T) &:= \begin{bmatrix} W(kT+T) & \hat{v}(kT+T) \end{bmatrix}^T \\ G_m &:= \begin{bmatrix} G_{if} & 0 \\ L_{if}C_{if} & (C_{jf} - L_{jf}) \end{bmatrix} \\ B_m &:= \begin{bmatrix} H_{if} & 0 \\ 0 & L_{jf} \end{bmatrix}\end{aligned} \tag{20}$$

Before proceeding further, we define the estimation error as

$$\begin{aligned}e(kT+T) :=& X(kT+T) - \hat{X}(kT+T) \\ =& [I \ -I] \times \begin{bmatrix} X(k+T) \\ \hat{X}(kT+T) \end{bmatrix} \\ =& D_m\eta(kT).\end{aligned} \tag{21}$$

Then, the optimal fuzzy filter is concerned. We assume that the filter system is stochastically stable in the mean square with filter gain L_{jf} performance. The filter gain is to specify L_{jf} such that the following minimal problem is achieved in (22)

$$\min \sup_{d(kT)\in L_\infty} \frac{\|e(kT)\|_\infty}{\|d(kT)\|_\infty}. \tag{22}$$

However it is difficult to directly solve the minimax problem in (22). In this paper, the suboptimal approach via minimizing the upper bounded of the L_{jf} gain is obtained. The optimal L_{jf} gain fuzzy filter problem is the following minimax problem.

Theorem 1:

$$\begin{bmatrix} P & * & * & * \\ 0 & -\alpha^2 I & * & * \\ \left(\frac{G_{m_{ijk}}D_m + G_{m_{ikj}}D_m}{2}\right) & B_mD_m & P^{-1} & * \\ -D_m & 0 & 0 & I \end{bmatrix} \geq 0 \tag{23}$$

where P is symmetric positive-definite matrix and α is positive constant.

Proof: Using by the Tanaka disturbance rejection [15]; there exists a quadratic function $V(e(kT)) = e(kT)^TPe(kT)$, $P > 0$, and $\alpha \geq 0$, such that for all $t \in [kT, kT+T)$,

$$\begin{aligned}& V(e(kT)) = e^T(kT)Pe(kT), \\ & \triangle V(e(kT))_{\geq 0} + e^T(kT)e(kT) - \alpha^2 d^T(kT)d(kT) \leq 0 \\ & \xi(k) = [\eta(kT)^T \quad d(kT)^T],\end{aligned} \tag{24}$$

$$
\begin{aligned}
&\triangle V(e(kT)) \\
&= E\left\{V(e(kT+T))|\xi(k)\right\} - V(kT) \\
&= E\left\{(D_m\eta(kT+T))^T P(D_m\eta(kT+T))|\xi(kT)\right\} \\
&\quad - \eta^T(kT)D_m^T P D_m\eta(kT) \\
&= E\left\{[(G_m\eta(kT+T)+B_m d(kT+T)]^T D_m^T P\right. \\
&\quad \left.\times\, D_m[G_m\eta(kT+T)+B_m d(kT+T)]|\xi(kT)\right\} \\
&\quad - \eta^T(kT)D_m^T P D_m\eta(kT) \\
&= E\left\{\xi(kT)^T \begin{bmatrix} G_m^T D_m^T \\ B_m^T D_m^T \end{bmatrix} P \begin{bmatrix} D_m G_m & D_m B_m \end{bmatrix} \xi(kT)|\xi(kT)\right\} \\
&\quad - \eta^T(kT)D_m^T P D_m\eta(kT) \\
&= \xi(kT)^T \left(\begin{bmatrix} G_m^T D_m^T \\ B_m^T D_m^T \end{bmatrix} P \begin{bmatrix} D_m G_m & D_m B_m \end{bmatrix} \right) \xi(kT) \\
&\quad - \eta^T(kT)D_m^T P D_m\eta(kT). \qquad (25)
\end{aligned}
$$

Since $V(e(kT)) \geq 0$, this implies

$$
\frac{\|e(kT)\|}{\|d(kT)\|} \leq \alpha \qquad (26)
$$

and

$$
\begin{aligned}
&e^T(kT)e(kT) - \alpha^2 d^T(kT)d(kT) \\
&= \xi^T(kT) \begin{bmatrix} D_m^T D_m & 0 \\ 0 & -\alpha^2 I \end{bmatrix} \xi(kT). \qquad (27)
\end{aligned}
$$

Then we have

$$
\begin{aligned}
&\xi^T(kT) \left(\begin{bmatrix} G_m^T D_m^T \\ B_m^T D_m^T \end{bmatrix} P \begin{bmatrix} D_m G_m & D_m B_m \end{bmatrix} \right. \\
&\left. - \begin{bmatrix} D_m^T P D_m & 0 \\ 0 & \alpha^2 I \end{bmatrix} \right) \xi(kT) \leq 0. \qquad (28)
\end{aligned}
$$

Form the Schur complement [4], we obtain the LMIs condition;

$$
\begin{bmatrix} P & * & * & * \\ 0 & -\alpha^2 I & * & * \\ \left(\frac{G_{m_{ijk}} D_m + G_{m_{ikj}} D_m}{2}\right) & B_m D_m & P^{-1} & * \\ -D_m & 0 & 0 & I \end{bmatrix} \geq 0 \qquad (29)
$$

■

By multiplying both sides of (29) by block-diag$[X\ I\ I\ I]$, (23) is obtained, where $X = P^{-1}$, the subscript $\{i, j, k\}$ is fuzzy filter rule each. The proof is completed.

IV. Simulation

In this section, we demonstrate the results in Section 3 to discretise the continuous-time T-S system for the moving target like the Van der Pol oscillator. We first the dynamic state equations in CT are given by

$$
\begin{aligned}
\frac{d}{dt}x_1(t) &= x_2(t) \\
\frac{d}{dt}x_2(t) &= -x_1(t) + (1 - x_1^2(t))x_2(t) + w(t) \\
y(t) &= (1 + 0.25x_1(t)) + v(t) \qquad (30)
\end{aligned}
$$

The corresponding T-S fuzzy model of the system in (30) is expressed as follows:

$$
\begin{aligned}
R_1 &: \text{IF } x_1(t) \text{ is about } \Gamma_{11}, \\
&\quad \text{THEN } \dot{x}(t) = A_1 x(t) + B_1 w(t), \\
&\qquad y(t) = C_1 x(t) + v(t). \\
R_2 &: \text{IF } x_1(t) \text{ is about } \Gamma_{12}, \\
&\quad \text{THEN } \dot{x}(t) = A_2 x(t) + B_2 w(t), \\
&\qquad y(t) = C_2 x(t) + v(t). \qquad (31)
\end{aligned}
$$

where A_i, B_i, C_i are by the following as

$$
\begin{aligned}
&A_1 = \begin{bmatrix} 0 & 1 \\ -1 & 1-k^2 \end{bmatrix}, \quad A_2 = \begin{bmatrix} 0 & 1 \\ -1 & 1 \end{bmatrix}, \\
&C_1 = \begin{bmatrix} 1 + 0.2k^2 & 0 \end{bmatrix}, \quad C_2 = \begin{bmatrix} 1 & 0 \end{bmatrix}, \\
&B_i = \begin{bmatrix} 0 & 1 \end{bmatrix}^T, \qquad i = 1, 2, \qquad (32)
\end{aligned}
$$

and the membership function are

$$
\Gamma_{11} = x_1^2/k^2, \quad \Gamma_{12} = 1 - x_1^2/k^2 \qquad (33)
$$

where $k = 2.5$.

First, we simulate the continuous-time T-S fuzzy system. To obtain the corresponding discretised T-S fuzzy system for the sampling time $T = 0.01(s)$, Theorem 1 is applied. The discretised version of the continuous-time T-S fuzzy system is

$$
\begin{aligned}
R_1 &: \text{IF } x_1(kT) \text{ is about } \Gamma_{11} \\
&\quad \text{THEN } x(kT+T) = \Phi_1 x(kT) + B_1 w(kT) \\
&\qquad y(kT+T) = C_1 x(kT) + v(kT) \\
R_2 &: \text{IF } x_2(kT) \text{ is about } \Gamma_{12} \\
&\quad \text{THEN } x(kT+T) = \Phi_2 x(kT) + B_2 w(kT) \\
&\qquad y(kT+T) = C_2 x(kT) + v(kT) \qquad (34)
\end{aligned}
$$

By using Theorem 1 and solving the corresponding LMIs constraints, we obtain the filter gains L and P:

$$
\begin{aligned}
&P = \begin{bmatrix} 0.0277 & -0.0050 \\ -0.0050 & 0.0036 \end{bmatrix}, \\
&L_1 = \begin{bmatrix} 0.1496 \\ 1.3159 \end{bmatrix}, \quad L_2 = \begin{bmatrix} 0.2187 \\ 1.7408 \end{bmatrix}. \qquad (35)
\end{aligned}
$$

V. Conclusion

In this paper, we has been proposed for the mixed-time fuzzy optimal estimator design for the target tracking. The proposed method has taken account of behavior for target motion in CT domain and system measurement in DT domain. The overall dynamic system in DT domain has discretized by using T-S fuzzy models. Based on the fuzzy model, the fuzzy estimation has been studied. The error state of the filtering process have mean square bounded. In addition, a basis dependent Lyapunov function approach has developed to design the fuzzy filter and a filter gain has minimized by

using some LMIs constraints. A numerical example have been provided to demonstrate various aspects of theoretical results.

Abstract— **In this paper, generalized projective synchronization (GPS) of two time-delayed chaotic systems using sliding adaptive fuzzy control (SAFC) is investigated. The proposed method combines the advantages of the adaptive control, fuzzy systems and sliding mode control theory. Lyapunov stability theory is employed to guarantee the stability of error dynamics. Assuming that the parameters of the chaotic drive system are unknown, recursive least square (RLS) method is applied to estimate these unknown parameters. Simulation results show the validity and effectiveness of the proposed method for synchronization of two identical and nonidentical time-delayed chaotic systems.**

Keywords: Generalized Projective Synchronization, Time-Delayed Chaotic Systems, Adaptive Fuzzy Control

I. INTRODUCTION

Since Pecora and Carroll observed the synchronization of two identical chaotic systems under different initial conditions in 1990 [1], chaos synchronization has attracted many interests, especially in secure communication. Moreover, it has been widely explored in a variety of fields such as physical, chemical and ecological process [2]. In previous researches, different types of synchronization have been found in interacting chaotic systems, such as complete synchronization (CS) [1,3,4,5,6], projective synchronization (PS)[2], generalized synchronization (GS) [7,8,9,10], phase synchronization [11,12], anti-phase synchronization [13,14,15] and so on. In PS, the drive-response system synchronizes up to a constant scaling factor α . CS is a special case of PS at $\alpha = 1$, as well as anti-phase synchronization at $\alpha = -1$ [16].

Many various synchronization methods such as backstepping design [17], active control [18], nonlinear control [19], adaptive control [20] and adaptive fuzzy control [21] have been applied for chaos synchronization in low-dimensional systems such as Lorenz and Duffing systems [22]. Since low-dimensional chaotic signals can be easily detected, they are not suitable for applications such as secure communications [22]. But, because of the infinite-dimensional of time-delayed chaotic systems, they are safety for secure communications.

Since Mackey and Glass first observed chaos in time-delayed system [23], many researchers interested in time-delayed chaotic systems. After that, the synchronization of time-delayed chaotic systems is also investigated by many researchers.

A few works have been done on synchronization of time-delayed chaotic systems. The problem of CS [24,25] and GS [26] of time-delayed systems have been studied for some special models. PS has been proposed to synchronize identical Logistic delayed models [27]. Fuzzy delayed output feedback synchronization for time-delayed chaotic systems is studied, too [28]. Sliding mode controller is applied for projective synchronization of time-delayed systems in [29].

In this paper, sliding adaptive fuzzy control (SAFC) is proposed for generalized projective synchronization (GPS) of two identical and nonidentical time-delayed chaotic systems. Furthermore, synchronization of time-delayed chaotic systems with unknown parameters is studied. It is shown that the speed of synchronization is appropriate and the performance of the proposed controller is well when the response system designed with the estimated parameters of the drive system.

This paper is organized as follows: in section 2, the model of time-delayed chaotic systems and its properties are described. The structure of proposed controller constitutes section 3. Stability analysis is studied in section 4. Simulation

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

results and conclusion are given in section 5 and 6, respectively.

II. MODEL OF SYSTEM

A class of time-delayed systems is considered as follows:

$$\dot{x}(t) = -ax(t) + f_b(x(t-\tau)) + u(t) \tag{1}$$

where, $x, u \in R$ are the state variable and control input, respectively. a, b, τ are the system parameters , $\tau \succ 0$. Time-delayed system in (1) can show chaotic behavior when the nonlinear function $f_b(.)$ satisfies the following conditions [30,31]:

$(i) f_b(0) = 0;$

$(ii) \forall x \quad x f_b(x) \geq 0;$

$(iii) \exists x_{eq} \succ 0 \quad f_b(x_{eq}) = x_{eq};$

$(iiii) \exists r \in (0, x_{eq}) : \forall x \quad f_b(x) \leq f_b(r) = M \quad , M \succ 0.$

Some time-delayed chaotic systems satisfied above conditions are Mackey-Glass, Ikeda and Logistic models. These models are given as

Mackey-Glass Model [30]

$$f_b(z) = \frac{bz}{1 + |z|^C} \quad (C \succ 1) \tag{2}$$

Ikeda model [30]

$$f_b(z) = \begin{cases} b\sin(z) & |z| \leq \pi \\ 0 & otherwise \end{cases} \tag{3}$$

Logistic model [31]

$$f_b(z) = \begin{cases} bz(1-z) & 0 \leq z \leq 1 \\ 0 & otherwise \end{cases} \tag{4}$$

In this paper, Mackey-Glass and Logistic models are studied.

III. GENERALIZED PROJECTIVE SYNCHRONIZATION VIA SLIDING ADAPTIVE FUZZY CONTROL

In this section, SAFC is designed to chaos synchronization of time-delayed chaotic systems.

Now, the drive and response systems are considered as follows:

$$\text{Drive:} \quad \begin{cases} \dot{x}(t) = -ax(t) + f_b(x(t-\tau)) \\ x(t) = \varphi_1 \quad -\tau \leq t \leq 0 \end{cases} \tag{5}$$

$$\text{Response:} \quad \begin{cases} \dot{y}(t) = -ay(t) + g_\beta(y(t-\theta)) + u \\ y(t) = \varphi_2 \quad -\theta \leq t \leq 0 \end{cases} \tag{6}$$

where $f_b(.)$ and $g_\beta(.)$ have the properties described in section 2. a, b, β are systems parameters, and τ, θ are time delays. φ_1, φ_2 are initial values of drive and response systems, respectively. Notice that, if synchronization of two identical systems is considered, then $f = g$. Also f is not equal to g for synchronization of two nonidentical systems. For GPS, the synchronization error is defined as follows:

$$e = \alpha x - y \tag{7}$$

where α is the scaling factor of GPS, then

$$\dot{e} = -\alpha a x(t) + a y(t) - g_\beta(y(t-\theta)) + \alpha f_b(x(t-\tau)) - u \tag{8}$$

It is assumed that $f_b(.)$ and $g_\beta(.)$ are bounded and α is known. The control signal is defined as

$$u = u_1 + u_2 \tag{9}$$

Where u_2 is the output of fuzzy controller and u_1 is determined as follows

$$u_1 = -\alpha a x(t) + a y(t) - g_\beta(y(t-\theta)) + \alpha f_b(x(t-\tau)) \tag{10}$$

To design the proposed controller u_2, GD is applied to train the parameters of fuzzy controller. In the proposed method, minimizing the first derivation of Lyapunov function is considered, so that the stability is achieved. This derivation is applied as a cost function to determine unknown parameters utilized to design of the control system.

Sliding surface is defined as follows:

$$s = e = \alpha x - y \tag{11}$$

The fuzzy system used in this study has product inference engine, singleton fuzzifier, center average defuzzifier, and Gaussian membership function. So, the fuzzy system is given as

$$u_2 = \frac{\sum_{l=1}^{E} w^l \left[\prod_{i=1}^{n} \exp(-(\frac{s - c_i^l}{\sigma})^2) \right]}{\sum_{l=1}^{E} \left[\prod_{i=1}^{n} \exp(-(\frac{s - c_i^l}{\sigma})^2) \right]} = \hat{W}^T \phi \qquad (12)$$

where $\hat{W} = [w^1, ..., w^n]^T$, E is fixed, w^l, c_i^l and σ are free parameters. $s \in R^n$ is the input of the fuzzy system, and $u_2 \in R$ is the output of the fuzzy system. w^l is the center of fuzzy set. Parameters c_i^l and σ are centers and radius of basis function, respectively. In this paper, c_i^l and σ are chosen arbitrarily. Since this fuzzy system is considered with one input, n is equal to 1. To design the controller, the parameter w^l must be determined based on the reaching condition, $s\dot{s} < 0$. Thus, the GD method is applied to determine it as follows:

$$\dot{w}^l = -\gamma \frac{\partial s(t)\dot{s}(t)}{\partial w^l(t)} \qquad (13)$$

Equation (13) can be rewritten as

$$\begin{aligned} \dot{w}^l &= -\gamma \frac{\partial s(t)\dot{s}(t)}{\partial w^l(t)} = -\gamma \frac{\partial s(t)\dot{s}(t)}{\partial u(t)} \frac{\partial u(t)}{\partial w^l(t)} \\ &= -\gamma \frac{\partial s(t)\dot{s}(t)}{\partial u_2(t)} \frac{\partial u_2(t)}{\partial w^l(t)} \\ &= \gamma s(t) \frac{\exp(-(\frac{s - c^l}{\sigma})^2)}{\sum_{l=1}^{E} \exp(-(\frac{s - c^l}{\sigma})^2)} = \gamma s(t) \phi_l(s) \end{aligned} \qquad (14)$$

where γ is the learning rate parameter. Finally, w_i can be on-line adjusted as it is shown in (14).

Now, with defined control signal the synchronization is achieved. In the next section, the stability of the control system is investigated.

IV. STABILITY ANALYSIS

Lyapunov stability analysis is applied to prove the stability of error dynamics. From the theory of sliding mode control and (8), a perfect control law is obtained as

$$u_{eq} = -\dot{e} + \dot{s} + \lambda s \qquad (15)$$

where is presented in (11).

First, to analyze the stability, (9) and (10) are substituted in (8):

$$\dot{e} = -u_2 \qquad (16)$$

If u_2 is substituted with u_{eq} then $\dot{s}(t) + \lambda s(t) = 0$. Since λ is a positive constant parameter, the sliding surface variable s will converge to zero, gradually. So, will converge to zero. From (15) and (16):

$$\dot{s}(t) = -\lambda s(t) + (u_{eq} - u_2) \qquad (17)$$

Theorem [32]. *Suppose that the input universe of discourse U is a compact set in R^n. Then, for any given real continuous function $g(z)$ on U and arbitrary $\xi \succ 0$, there exists a fuzzy system $F(z)$ in the form of (10) such that*

$$\sup_{z \in U} \left\| g(z) - F(z) \right\| \le \xi$$

That is, the fuzzy systems with product inference engine, singleton fuzzifier, center average defuzzifier, and Gaussian membership functions are universal approximators.

Therefore, the control law u_2 can be btained via the optimal weighting vector $\overline{W}$ of the fuzzy system. The designed control is applied to estimate the u_{eq}. This approximation can be achieved with the error which is smaller than ξ

$$\max \left| \overline{u}(x, \overline{W}) - u_{eq}(x) \right| \prec \xi$$

where $\overline{u}(x, \overline{W}) = \sum_{k=1}^{n} \overline{w}_k \phi_k = \overline{W}^T \phi$ and $u_{eq}(x) = \overline{W}^T \phi + \xi$.

Define $\tilde{W} = \overline{W} - \hat{W}$ as the weighting error, and then (17) can be rewritten as

$$\dot{s}(t) = -\lambda s(t) + (\tilde{W}^T \phi + \xi) \qquad (18)$$

Notice that $\overline{W}$ and $\hat{W}$ are the optimal and estimated values of W, respectively.

Define the Lyapunov function as follows:

$$V(s, \tilde{W}) = \frac{1}{2} s^2 + \frac{1}{2\gamma} \tilde{W}^T \tilde{W} \qquad (19)$$

The first derivation of (19) with respect to time is obtained as

$$\dot{V} = s\dot{s} + \frac{1}{\gamma}\tilde{W}^T\dot{\tilde{W}} = s\dot{s} + \frac{1}{\gamma}\tilde{W}^T(-\dot{\hat{W}}) \quad (20)$$

Substituting (14) and (18) in to (20), then

$$\dot{V} = s(-\lambda s + \tilde{W}^T\phi + \xi) + \frac{1}{\gamma}\tilde{W}^T(-\gamma s\phi) = -\lambda s^2 + s\xi \quad (21)$$

Thus

$$\dot{V} \le |s|(-\lambda|s| + \xi) \quad (22)$$

So, if $|s| \ge \xi/\lambda$, then $\dot{V} \le 0$ which means that this Lyapunov function will decrease gradually. It can be concluded that the error of state variable will converge into a boundary layer ξ/λ around $e = s = 0$ in the phase plane.

Hence, the SAFC is stable and the error of state variable will converge into a small value.

V. SIMULATION RESULTS

A. Synchronization of two identical systems with known parameters

To synchronize two identical Mackey-Glass systems, the parameters of drive and response systems are chosen as $a = 1, b = 2, \varphi_1 = 0.1, \varphi_2 = 0.01, \tau = 10, \theta = 10$, and it is assumed that $\alpha = 0.5$ Fig. 1a,b shows the state trajectory of drive and response systems. Fig. 1c shows the phase plane $(\alpha x, y)$ and Fig. 1d shows the synchronization error.

B. Synchronization of two nonidentical systems with known parameters

In this section, Mackey-Glass and Logistic models are chosen as drive and response systems, respectively. The parameters of two considered systems are $a = 1, b = 2, \varphi_1 = 0.1, \quad \varphi_2 = 0.01, \tau = 20, \theta = 20$, and it is assumed that $\alpha = 0.5$. Fig. 2a,b shows the state trajectory of drive and response systems, Fig. 2c shows the phase plane $(\alpha x, y)$ and Fig. 2d shows the synchronization error.

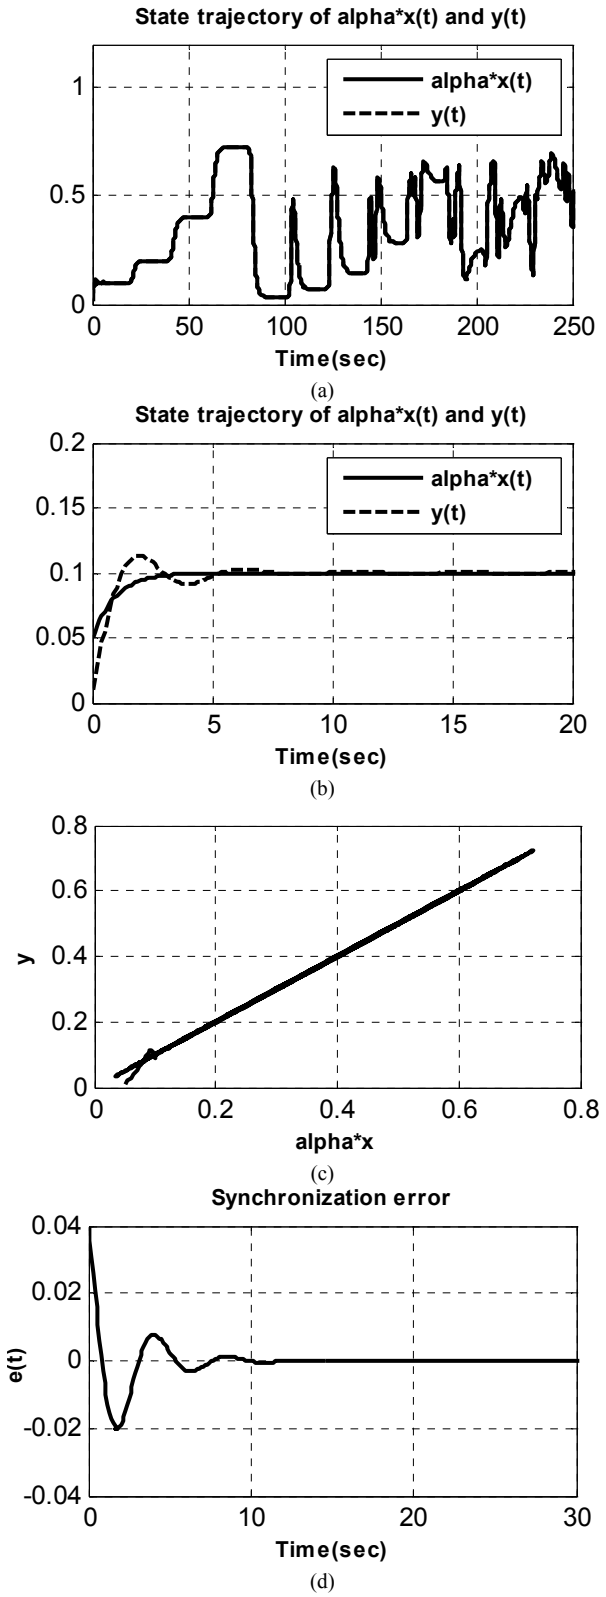

Figure 2. The state trajectory of Mackey-Glass and Logistic systems: (a, b) drive (Mackey-Glass) and response (Logistic) system; (c) the phase plane; (d) the synchronization error.

C. *Synchronization of two identical systems with unknown parameters*

In this section, synchronization is studied when the drive system has unknown parameters with known nonlinear part. To design a response system, the estimated parameters of the drive system is used. Mackey-Glass model is chosen as drive and response systems. The parameters of drive system are $a = 1, b = 2, \varphi_1 = 0.1, \tau = 10,$ and for response system, the parameters are considered as $\varphi_2 = 0.01, \theta = 10$ and it is assumed that $\alpha = 0.5$.

The recursive least square (RLS) method is applied to estimate $\hat{a}$, $\hat{b}$. Note that the estimated parameters affect the $s(t)$. The initial values of $\hat{a}, \hat{b}$ are considered as 0.1 and 0.5, respectively. Fig. 3a,b shows the state trajectory of drive and response systems, Fig. 3c shows the phase plane $(\alpha x, y)$, and Fig. 3d shows the synchronization error. The convergence of parameters $\hat{a}, \hat{b}$ to their actual values are shown in Figs. 5a and 5b.

In this section, the performance of SAFC for synchronization of delayed chaotic systems is compared with fuzzy model-based adaptive synchronization of time-delayed chaotic systems proposed in [22]. In this method, to design the fuzzy controller, the chaotic system is modeled by Takagi Sugeno fuzzy system considering the properties of the nonlinear part of the system [22].

Define $h_1(x)$ and $h_2(x)$ as

$$h_1(x) = \begin{cases} \dfrac{f(x)}{x} & x \neq 0 \\ 0 & x = 0 \end{cases} \tag{23}$$

$$h_2(x) = 1 - h_1(x) \tag{24}$$

The adaptation laws for $\hat{a}_i$ and $\hat{b}_i$ are chosen as

$$\dot{\hat{a}}_i = -\frac{h_i e(t) y(t)}{p_i} \tag{25}$$

$$\dot{\hat{b}}_i = \frac{h_i e(t) y(t-\tau)}{q_i} \tag{26}$$

where $p_i, q_i > 0$ (Vasegh and Johari Majd, 2009).

The parameters of Mackey-Glass model with the both controllers are assumed as it is considered in this section. Furthermore, we choose $p_i = q_i = 1/220, a_s = 10$ .The initial values of $\hat{a}, \hat{b}$ are chosen as 0.1 and 0.5, respectively. Simulation results are shown in Figs.4 and 5. From Figures.3,4 and 5, it is concluded that SAFC is better than the other considered method for chaos synchronization of two identical systems when the drive system has unknown parameters. The convergence of parameters with SAFC is faster and smoother than that with fuzzy model-based adaptive control. In summary, it is concluded that the speed of synchronization with the proposed method is better than that with fuzzy model-based adaptive control and it is an advantage of SAFC. Notice that the speed of synchronization with SAFC can be controlled and improved.

For better comparison, the performance of two considered controllers is compared with the following criteria:

1. Synchronization error variance after 10τ (EV).
2. Synchronization error settling time. It is the time at which $|e| < 0.005$ and e remains in this bound (EST).

As we know, the less the EV, the better synchronization is achieved. The less the EST, the sooner is the convergence. The results of these comparisons are given in Table 1.

It is resulted that SAFC performs better than fuzzy model-based adaptive control. Notice that the best performance of fuzzy model-based adaptive control was considered.

VI. CONCOLUSION

In this paper, an effective control method was used for synchronization of scalar time-delayed chaotic systems. Using the Lyapunov stability theory, a sliding mode controller based on the fuzzy system was applied for synchronization of two identical and nonidentical chaotic systems. When synchronization with unknown parameters was considered, the drive system had unknown parameters with known nonlinear part. To design a response system, the estimated parameters of the drive system was used. Numerical simulations for Mackey-Glass and Logistic models are provided to show the effectiveness and feasibility of the proposed controller. The convergence of parameters to their actual values with SAFC is faster than that with FMBAC. These results are obtained from comparisons of these two methods with two criteria which show the quality of the performance of the control system.

I. INTRODUCTION

Early studies indicate that effective knowledge management is positively associated with firm's value and operating performance [1, 2, 3]. Recent studies further suggest that individual level innovation may lead to knowledge management success in an organization (e.g. [4]). Extending from these findings, the purpose of this study is to expand the knowledge management literature by investigating how individual's professional ability affects the association between the effectiveness of knowledge management and firms' operating performance. More specifically, we examine the impact of new CIO's education on the association between the level of research and development expenses and firm's financial performance measurements.

By using OLS regression analysis on a sample of 103 firms that appointed new CIO from 2007 to 2008, we find that the positive relationship between the effectiveness of knowledge management and firm's operating performance is more prominent when the firm's new CIO has a PHD degree. Our study contributes to the knowledge management literature by providing empirical evidence that CIO's education facilitates the application of knowledge management. To our knowledge, this is the first study showing the CIO's education has influences on firms' knowledge and financial performance. Our study should therefore be of interest to researchers and academia since it provides evidence to suggest that education of the management plays a significant role in enhancing the knowledge management process and firm's financial performance.

The remainder of this paper is organized as follows. Section 2 discusses prior research and hypothesis development. Section 3 presents the research design. Section 4 describes the sample selection process. Section 5 presents the empirical results and Section 6 provides the conclusion and limitations.

II. PRIOR RESEARCH AND HYPOTHESIS DEVELOPMENT

A. Knowledge Management, Firm's Value and Operating Performance

Extant research shows that effective knowledge management has a positive effect on firm's value and financial performance. [1] examine the short-term impact of announcements of information technology based knowledge management efforts on firm value and find that firms' cumulative abnormal returns are positively associated with these knowledge management events. [2] investigates how knowledge management capability affects firm performance and suggests that the synergies created by the information technology relatedness and managerial knowledge resources increase the financial performance of the firm. [3] explore the introduction of knowledge management practices and find that these practices are able to improve firm's performance. In summary, firm's effective knowledge management is found to be associated with better financial performance.

B. Knowledge Management, CIO and Education

Prior research shows that hiring new managers with MBA degrees leads to short-term improvements in operating performance [5] and management change is an important factor of business performance [6]. Besides, education level is often employed as a measurement for intellectual capital in empirical research [7]. Knowledge management is largely driven by the information technology department, where CIO plays a critical role in the entire process. CIO is responsible to integrate firm's limited information technology resources as well as human capitals. In addition, CIO has to combine business operation and e-commerce for future knowledge formations, sharing and applications. Especially in today's global economy and complex business environment, the education level of CIO should be a suitable proxy for firm's ability of knowledge creation and innovation.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

[4] further suggest that individual's conceptual knowledge increases operational and contextual knowledge, and in turn improves operational knowledge. Since individual knowledge innovation is documented to help organizations to be more productive, CIO with better education should be more innovative in facilitating the effectiveness of knowledge management process and therefore enhances firm's financial performance.

C. Hypothesis Development

Since effective knowledge management has a positive effect on firm's performance, and better education of CIO is expected to strengthen this effect, we thus develop the following research hypothesis:

H: *The positive relationship between the effectiveness of knowledge management and firm's operating performance is more prominent when the firm's new CIO has a PHD degree.*

III. RESEARCH DESIGN

A. OLS Regression Test

We use a multivariate OLS regression model to test the impact of new CIO's education on the association between the effectiveness of knowledge management and firm's financial performance measurements. The effectiveness of knowledge management is measured by the level of research and development expenses in this study. The level of support for research and development activities has been documented as a major influencing factor (knowledge generation) of successful knowledge management process and infrastructure [8]. Additionally, [3] find that there is a positive relationship between the development of an innovative culture that encourages research and development projects and firm performance. Prior research also show that the level of research and development may decide the competitive advantage of firms in terms of higher quality, reduced cycle time and lowered costs [9]. In addition, a company invests lower research and development outlay than its competitors is more likely to lose its competitiveness of products and services which will shortly be reflected in its operating performance [10]. Further, [10] finds that firms experience a consistent five-year positive operating performance as well as positive stock returns following their research and development expenditures increase. Therefore, we expect that any new management occurring in IT firms will utilize IT advantages through promoting research and development use. In this study, we investigate whether new CIO with a PHD degree enhances individual level innovation in an organization and in turn strengthens the positive relationship between research and development projects and firm performance. Based on prior research, we also control for traditional variables related to firm's financial performance (e.g., [8, 10, 11]). We therefore use the following logistic regression model:

$$Performance = \alpha + \beta_1 NI/REV + \beta_2 RESTR + \beta_3 LEV + \beta_4 SQSEG + \beta_5 GROWTH + \beta_6 PHD + \beta_7 RD/REV + \beta_8 PHD*RD/REV + \varepsilon \quad (1)$$

Performance is measured by the following financial variables:
EPSDiluted = Diluted earnings per share[1];
EPSBasic = Basic earnings per share[2];
ROA = Returns on assets.

Control variables include:

NI/REV = Net income ratio measured by net income over total revenues;
RESTR = 1 if firm had restructuring, 0 otherwise;
LEV = Percentage of total debts over total assets;
SQSEG = Square root of the number of business segments reported on *Compustat*;
GROWTH = Sales growth (percent change in sales from prior year);
PHD = 1 if the new CIO has a PHD degree, else 0;
RD/REV = Ratio of research and development expense to total revenues;
*PHD*RD/REV* = Interaction of research and development activities and CIO's education.

We used several measures of financial performance to investigate our research question, resulting in three separate OLS regression models. We first control the company's profitability (NI/REV) which is expected to have positive influence on financial performance. Consistent with prior research, we use RESTR and LEV to proxy for firm's financial condition. Rapidly growing firms (GROWTH) and firms with diverse operations (SQSEG) which have higher business risks are also controlled. The positive effect of research and development expense on firm's performance is also controlled [3, 9, 10]. For our variable of interest, we expect CIO's better education may facilitate the effectiveness of research and development activities so the coefficient of PHD*RD/REV is positive.

IV. SAMPLE SELECTION PROCEDURES

We select our sample of 103 firms hiring new CIO reported in *AuditAnalytics* in the recent two years. The sample includes firms satisfying the following criteria: (1) the firm has CIO turnover data for 2007 and 2008 (2) the CIO's education data is presented, and (3) financial data are available on *Compustat*.

[1] This item represents basic earnings per share for common shares after allowing for the conversion of convertible senior stock and debt, and the exercise of warrants, options and agreements for issuance of common shares upon satisfaction of certain conditions.

[2] The basic earnings figures should be reported by the company (as outlined in Accounting Principles Board Opinion No. 15) after the effect of conversion of convertible preferred, convertible debentures and option and warrants that have been identified as common/ordinary stock (capital) equivalents and before extraordinary items.

Table 1 reports the sample distribution by industry. The 103 sample firms span several two-digit SIC codes, with the maximum number of firms being 30 (29.1%) in the computers industry.

< Insert Table 1 here >

V. Empirical Results

A. Descriptive Statistics

Table 2 reports the means, medians and standard deviations of the variables for our sample firms[3]. The means and medians of research and development level are 0.30 and 0.02, respectively.

< Insert Table 2 here >

In table 3, the descriptive data of research and development level is reported separately in two groups: CIO with a PHD degree and CIO without a PHD degree. The means and medians of research and development level in PHD group (non-PHD group) are 0.63 (0.28) and 0.11 (0.01), respectively. Table 3 also reports univariate tests of differences between the two groups using the parametric t-test and the Wilcoxon ranksum test. The median of research and development level is significantly higher in the PHD group than the non-PHD group ($p=0.01$, two-tailed). This is consistent with our expectation that CIO with a higher degree facilitates effective knowledge management applications.

< Insert Table 3 here >

B. Logistic Regression Results

Table 4 reports the OLS regression results for our three models. Model 1 measures financial performance using diluted earnings per share. Model 2 uses basic earnings per share, and Model 3 uses the returns on assets. All the three models are significant at $p < 0.01$ (two-tailed) and show satisfactory R-squares.

The interactive variable *PHD*RD/REV* is significantly positive at $p < 0.10$ (two-tailed) in all the three models. The variable *RD/REV* is also positively significant at conventional levels. The significantly positive coefficients indicate that the level of research and development benefits firm's financial performance and this relationship is further strengthened by the CIO's education level. This empirical result is consistent with our hypothesis.

Consistent with our expectations, NI/REV is significant and positive at $p < 0.01$ (two-tailed) in all the models. Besides, RESTR is negatively significant in model 1 and model 2 showing higher business risks may result in poorer financial outcomes.

< Insert Table 4 here >

VI. Conclusion and Limitations

In this paper, we examine how new CIO's education affects the association between knowledge management and firm's operating performance. Using OLS regression analysis, we find that the positive relationship between the effectiveness of knowledge management and firm's operating performance is more prominent when the firm's new CIO has a PHD degree. Our results therefore provide empirical evidence that CIO's education facilitates the application of knowledge management, which is never explored in prior studies.

Our study is subject to several limitations. First, while we control for factors we believe are associated with firm's financial performance in our models, there is still a possibility of omitted variables. Second, the power of our tests is subject to the small sample size of firms with available CIO and education data. Third, around one-third of our sample firms are in computer industry. The uneven distribution of numbers of company types may lead to sample selection bias. Future research could investigate if CIO education has similar effects on the other knowledge management proxies.

[3] In order to eliminate the outlier effects, we winsorize 5% for all control variables.

***Abstract*—In this paper, based on financial report analysis, a multi-criteria decision-making approach for supporting decision is presented. There are five companies are evaluated by proposed method. Fuzzy AHP (Analytic Hierarchy Process) is utilized to evaluate weights of criteria for selecting company and fuzzy TOPSIS (technique for order preference by similarity to ideal solution) is used to determine the most suitable alternative with respect to various considered criteria. A numerical example is also included to demonstrate the proposed approach.**

Keywords-FAHP, FTOPSIS, Financial report

I. INTRODUCTION

Decision-making problem is a problem that one has to face in life. MCDM (multi-criteria decision-making) problem is the process that chooses the best preferred solution from all considered possible alternatives under evaluation criteria. It has been proved significant to numerous fields such as management science, engineering, education, public administration and military issues. In convention, the ratings of alternatives and the weights of criteria are treated as crisp values when one makes decisions. In real world, however, the used data in MCDM problems are very often imprecise and vague. As one knows, linguistic statements are usually used to evaluate alternatives and criteria. Fuzzy set theory is frequently utilized to deal with uncertainity. Numerous researches have paid attention to fuzzy MCDM problems. Investment issue can be regarded as a FMCDM problem without doubt. Somebody will deposit their money to bank, buy a land, real estate, stock, currency or/and gold for example. In this paper, we focus on how to choose a good stock of company. In addition, financial report is used to analyze the company's performance.

A hybrid model that incorporates FAHP and FTOPSIS methods is employed to solve MCDM problems in a fuzzy environment. According to the proposal model, we have to perform three stages in that the objectives of alternative and criterion will be determined from the investors and practitioners. After that the evaluation will be made by the experts who have much experience in finance fields. We will build hierarchy model include the criteria and alternatives. In next stage, fuzzy AHP is used to determine the preference weights of alternative. Finally, the fuzzy TOPSIS is employed to find out the best alternative for achieving the aspired/desired levels based on the proposed company

II. LITERATURE REVIEW

In the empirical studies, one of the widely used methods is financial report analysis. Tozum (2009) carried out the measurement of performances by using ratio analysis and performance evaluation of bank. He emphasized that traditional ratio analyses were not sufficient to measure company performance and they should be evaluated in a multilateral way. Another important method used in the measurement of bank performance is data envelopment analysis (DEA). This method is used for measuring the efficiencies of bank's branches. Demir and Astarcioglu (2007) analyzed Turkish commercial banks' performance with DEA by considering their total commercials, interest income and expenses, non-interest income and expense. Ravi *et. al* (2008) suggested some models to estimate banks' financial performances. Mercan *et. al* (2003) examined the impact of ownership and growth of the bank on performance with the selected financial ratios in the period between 1989 and 1999. Thai and Kumar (2008) developed some models for the estimation of banks' financial performances by financial variables and they combined these models with the neural networks and statistical techniques. Beccalli (2007) examined the relation between bank performances and the investment in informatics.

There are so many financial ratios that may be evaluated a company. It makes a difficult problem to evaluate the alternatives. So, I have made a Questionnaire for evaluating the important financial ratios. The aim of this questionnaire reduces a number of financial ratios and support to calculate more easily. This questionnaire has sent to 4 experts who have many experiences in field of finance to get the evaluation opinion. Questionnaire will be fill in the blank to express the important level of each financial ratio based on the linguistic value is presented in table 3.1. After 4 questionnaires have been collected, we have calculated the average value of each ratio (according to Appendix 1). If any average value of each ratio is larger than 7 (very strongly important), they will be

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

selected. The result of this evaluation is selected 7 important financial ratios

TABLE I. THE IMPORTANT RATIOS

No.	Ratios	Sign	Criteria Direction	Measuring Units
1	Current ratios	S1	Max	Fraction
2	Debt ratio	S2	Min	Fraction
3	Equity/ Debt ratio	S3	Max	Fraction
4	Operation profit ratio	S4	Max	Percentage
5	Income before tax ratio	S5	Max	Percentage
6	Net income revenue	S6	Max	Percentage
7	Return on total assets	S7	Max	Percentage

III. RESEARCH METHOD

MCDM is a well-known method of decision making. It is a branch of a general class of operations research models, which deal with decision problems under the presence of a number of decision criteria. This part presents a Fuzzy MCDM model for criteria selection and evaluation. Fuzzy MCDM model are briefly reviewed combining the general Decision making process. Then Fuzzy sets, weighting method, FMCDM are presented

A. Fuzzy Set Theory

Linguistic expressions are usually used in daily life, and more or less represent some degree of uncertainly of human thought. The fuzzy set theory [1], proposed by Zadeh, is frequently used to treat uncertainity problems. Fuzzy number is a fuzzy subset of real number; they represent the expansion of the idea of a confidence interval. In this paper, we use triangle fuzzy number (TFN) to represent the importance weighting of criterion and rating of alternative. It can be represented by

$$\mu_A(x) = \begin{cases} \dfrac{(x-a)}{(b-a)}, a \le x \le b \\ \dfrac{(x-c)}{(b-c)}, b \le x \le c \\ 0, \ otherwise \end{cases} \quad (1)$$

Based on the characteristic of TFN and the extension definition proposed by Zadeh [1], given any two TFN and a positive real number *r*, some algebraic operation of TFN can be described as follow:

Addition of two TFN:

$$A_1 + A_2 = (a_1 + a_2, b_1 + b_2, c_1 + c_2) \quad (2)$$

Multiplication of two TFN

$$A_1 \otimes A_2 = (a_1 \times a_2, b_1 \times b_2, c_1 \times c_2) \quad (3)$$

Multiplication of any real number and a TFN:

$$r \otimes A_1 = (ra_1, ra_2, ra_3) \quad (4)$$

Subtraction of two TFNs:

$$A_1 - A_2 = (a_1 - c_2, b_2 - b_1, c_1 - a_2) \quad (5)$$

Division of two TFNs:

$$A_1 / A_2 = (a_1 / c_2, b_2 / b_1, c_1 / a_2) \quad (6)$$

Reciprocal of a TFN:

$$A_1^{-1} = (1/c_1, 1/b_1, 1/a_1) \quad (7)$$

Let two TFNs A_1 and A_2, then the vertex method is defined to calculate the distance between them [26]

$$d(\tilde{A}_1, \tilde{A}_2) = \sqrt{\frac{1}{3}[(a_1 - a_2)^2 + (b_1 - b_2)^2 + (c_1 - c_2)^2]} \quad (8)$$

B. Linguistic Variable

Linguistic variable represents crisp information in a form and precision appropriate for the problem. For example, to answer the question "How do you think about this clothe?" we can answer "it is "not bad" outside. So, "not bad" is linguistic variable. The computational technique is based on the following fuzzy numbers defined by Hsieh *et. al*. We have a table corresponding linguistic variable as follows.

TABLE II. FUZZY PREFERENCE USED IN THE STUDY

Fuzzy number	Linguistic variable	TFN	Reciprocal
$\tilde{9}$	Absolutely Important	(7,9,9)	(1/9,1/9,1/7)
$\tilde{7}$	Very strongly important	(5,7,9)	(1/9,1/7,1/5)
$\tilde{5}$	Essential important	(3,5,7)	(1/7,1/5,1/3)
$\tilde{3}$	Weakly important	(1,3,5)	(1/5,1/3,1)
$\tilde{1}$	Equally important	(1,1,3)	(1/3,1,1)
$\tilde{2},\tilde{4},\tilde{6},\tilde{8}$	Intermediate value between two adjacent judgments		

C. The AHP and Fuzzy AHP method

The AHP method, developed by Saaty (1980), addresses how to determine the relative importance of a set of activities in a multi-criteria decision problem its main characteristic is that it is based on pair-wise comparison judgments. However, the pure AHP model has some problems (Yang & Chen, 2004). They pointed out that the AHP method is mainly used in nearly crisp data applications, creates and deals with a very unbalanced scale of judgment, rather imprecise; and the subjective judgment, selection and preference of decision-makers have much influence on the AHP results. To overcome these problems, several researchers integrate fuzzy theory with AHP to improve the uncertainty.

Step 1: AHP uses several small problems to present a complex problem. Thus, the first ace decompose into a hierarchy with a goal at the top, criteria and sub-criteria at level and sub-level and decision alternative at the bottom of the hierarchy (Fig 3)

Step 2: Construct fuzzy pair-wise comparison matrices. Through expert questionnaires, each expert is asked to assign

linguistic terms by TFN (as shown in Table 2 and Fig. 2 to the pair-wise comparisons among all criteria in the dimensions of a hierarchy system

$$D = \begin{array}{c} \\ C_1 \\ C_2 \\ \vdots \\ C_i \\ \vdots \\ C_n \end{array} \begin{array}{c} \begin{array}{cccccc} C_1 & C_2 & \cdots & C_j & \cdots & C_m \end{array} \\ \begin{bmatrix} \tilde{a}_{11} & \tilde{a}_{12} & \cdots & \tilde{a}_{1j} & \cdots & \tilde{a}_{1m} \\ \tilde{a}_{21} & \tilde{a}_{22} & \cdots & \tilde{a}_{2j} & \cdots & \tilde{a}_{2m} \\ \vdots & \vdots & \cdots & \vdots & \cdots & \cdots \\ \tilde{a}_{i1} & \tilde{a}_{i2} & \cdots & \tilde{a}_{ij} & \cdots & \tilde{a}_{im} \\ \vdots & \vdots & \cdots & \vdots & \cdots & \cdots \\ \tilde{a}_{n1} & \tilde{a}_{n2} & \cdots & \tilde{a}_{nj} & \cdots & \tilde{a}_{nm} \end{bmatrix} \end{array}$$

The elements a_{ij} can be interpreted as the degree preference of ith criterion over jth criterion. The comparison matrix has to be normalized into the range of [0, 1] by Eq. (13)

$$\tilde{r}_{ij} = \frac{\tilde{a}_{ij}}{\sum_{i=1}^{n} \tilde{a}_{ij}} \quad (13)$$

$$R = \begin{bmatrix} r_{11} & r_{12} & \cdots & r_{1j} & \cdots & r_{1m} \\ r_{21} & r_{22} & \cdots & r_{2j} & \cdots & r_{2m} \\ \vdots & \vdots & \cdots & \vdots & \cdots & \cdots \\ r_{i1} & r_{i2} & \cdots & r_{ij} & \cdots & r_{im} \\ \vdots & \vdots & \cdots & \vdots & \cdots & \cdots \\ r_{n1} & r_{n2} & \cdots & r_{nj} & \cdots & r_{nm} \end{bmatrix}$$

Step 3: Examine the consistency of the fuzzy pair-wise comparison matrices like the AHP method

According to the research of Buckley (1985), it proves that if $A = [a_{ij}]$ is a positive reciprocal matrix then A^{-1} is a fuzzy positive reciprocal matrix. That is, if the result of the comparisons of $A = [a_{ij}]$ is consistent.

Step 4: in the next step, transform the real elements of matrix R into the fuzzy numbers

Step 5: before conducting all the calculation of vector of priorities, the comparison matrix D has to be normalized by Eq. (13)

Step 6: Compute the fuzzy geometric mean for each criterion.

The geometric technique is used to calculate the geometric mean of the fuzzy comparison values of criterion to each criterion, as shown in Eq. (20), where r_i is a fuzzy value of the pair-wise comparison of criterion *i* to criterion *n* (Buckley, 1985)

$$r_i = [r_{i1}, r_{i2}, \ldots r_{in}] \quad (14)$$

Step 7: compute the fuzzy weight by normalization. The fuzzy weight of the criterion can be derived as Eq. (15), where $\tilde{w}_i$ denoted as $\tilde{w}_i = (L_{w_i}, M_{w_i}, U_{w_i})$ by a TFN and $L_{w_i}, M_{w_i}, U_{w_i}$ represent a lower, middle, upper value of the fuzzy weight of the i-th criterion.

$$\tilde{w}_i = \tilde{r}_i \otimes (\tilde{r}_1 \oplus \tilde{r}_2 \oplus \ldots \tilde{r}_n)^{-1} \quad (15)$$

D. Fuzzy Topsis method

Topsis was developed by Hwang and Yoon (1980). Topsis method is based on choosing the best alternative, which has the shortest distance from the positive ideal-solution (PIS) and has the longest from the negative ideal-solution (NIS) for solving problem.In this study, the combination between Topsis and fuzzy number has been applied. The general step-by-step procedure using Fuzzy Topsis method is briefly listed as follow

Step 1: The Fuzzy MCDM can be concisely expressed in the matrix format as follow:

$$X = \begin{array}{c} \\ A_1 \\ A_2 \\ \vdots \\ A_i \\ \vdots \\ A_n \end{array} \begin{array}{c} \begin{array}{cccccc} C_1 & C_2 & \cdots & C_j & \cdots & C_m \end{array} \\ \begin{bmatrix} x_{11} & x_{12} & \cdots & x_{1j} & \cdots & x_{1m} \\ x_{21} & x_{22} & \cdots & x_{2j} & \cdots & x_{2m} \\ \vdots & \vdots & \cdots & \vdots & \cdots & \cdots \\ x_{i1} & x_{i2} & \cdots & x_{ij} & \cdots & x_{im} \\ \vdots & \vdots & \cdots & \vdots & \cdots & \cdots \\ x_{n1} & x_{n2} & \cdots & x_{nj} & \cdots & x_{nm} \end{bmatrix} \end{array}$$

$$\tilde{w} = (\tilde{w}_1, \tilde{w}_2, \ldots \tilde{w}_n)^t$$

If the expert's opinions are evaluated by *k*th persons, we will calculate the average value as the following Eq. (26)

$$x_{ij} = (1/k)(x_{ij}^1 + x_{ij}^2 + \ldots x_{ij}^k) \quad (26)$$

Where A_i denotes by the alternatives, i=1, 2…n; C_j denotes by the criteria, j=1, 2…m. The fuzzy linguistic rating x_{ij} is a fuzzy value indicating the performance rating of the alternative A_i with respect to each criterion C_j. If x_{ij} preserves the property that the range of normalized fuzzy number belong to [0, 1], there is no need for normalization. Decision matrix is normalized as following Eq. (19)

Step 2: calculated the weighted normalization fuzzy decision matrix by multiplying the normalized decision matrix by its association weighted. The weighted normalized value is $\tilde{v}_{ij}$ calculated by (26)

$$\tilde{v}_{ij} = \tilde{w}_i \times \tilde{r}_{ij} \quad (26)$$

$$\tilde{V} = [\tilde{v}_{ij}]_{nm} \quad (27)$$

Where *i*= 1, 2,….*n* and *j*= 1, 2, …*m*.

Step 3: calculate the distance of each alternative from A^* and A^- using the following equation:

$$D_j^* = \sum_j^m d(\tilde{v}_{ij}, \tilde{v}_i^*) \quad (28)$$

$$D_j^- = \sum_j^m d(\tilde{v}_{ij}, \tilde{v}_i^-) \quad (29)$$

where j= 1, 2, …m.

Step 4: Identify positive ideal A^* and negative ideal solution A^-. The fuzzy positive ideal and fuzzy negative ideal solution are shown in the following Equation.

$$A^* = \{\tilde{v}_1^*, \tilde{v}_2^*, \ldots \tilde{v}_i^*\} = \{(max_j\, v_{ij}\ i \in B), (min_j\, v_{ij}\ i \in C)\} \quad (30)$$

$$A^- = \{\tilde{v}_1^-, \tilde{v}_2^-, \ldots \tilde{v}_i^-\} = \{(min_j\, v_{ij}\ i \in B), (max_j\, v_{ij}\ i \in C)\} \quad (31)$$

where i= 1, 2,….i and j= 1, 2, …j.

Where ***B*** is associated with benefit criteria and C ***C*** is associated with cost criteria.

Step 5: calculate the relative closeness to the ideal solution

$$CC_j = \frac{D_j^-}{D_j^+ + D_j^-} \quad j\text{= 1, 2, …}m. \quad (32)$$

Step 6: Rank preference order. Rank alternatives according to CC_j in descending order.

IV. A NUMERICAL APPLICATION FROM THE TAIWAN STOCK EXCHANGE

In this research, we first base on the criteria and ratios of the financial statement to prepare a list of performance evaluation indicators, and then have a survey with the experts in related financial areas in Taiwan. A questionnaire is designed using the AHP and TOPSIS questionnaire format, the criteria and ratios of the financial statement and the selected companies are included. The results can provide some suggestions and orientation to investors in developing their investment strategies in the future.

For selecting operation system, four main criteria and seven sub-criteria are used in application. Regarding the evaluation of the firm's financial statement, three experts were invited to survey five alternatives. After the construction of hierarchy, the different priority weights of each criterion attribute and alternatives are calculated using the fuzzy AHP and Fuzzy TOPSIS approaches. The comparison of the importance or preference of one criterion, attribute or alternative over another can be done with the help of the survey questionnaire. The method of calculating priority weights of the difference decision alternatives is presented below.

We transfer the linguistic scales to the corresponding fuzzy numbers (as Appendix A). Computing the elements of synthetic pair-wise comparison matrix by using the geometric mean method suggested by Buckley (1985) that is:

$$\tilde{a}_{ij} = \left(\tilde{a}_{ij}^1 \otimes \tilde{a}_{ij}^2 \otimes \tilde{a}_{ij}^3\right)^{1/3} \tilde{a}_{12} = [(5,6,7) \otimes (6,7,8) \otimes (2,3,4)]^{1/3} = (3.91,5.01,6.07)$$

TABLE III. WEIGHT OF DIMENSIONS

No.	Criteria	Weights	BNP	Rank
S1	Current ratio	$(\mathbf{0.185, 0.284, 0.372})$	0.281	1
S2	Debt ratio	$(\mathbf{0.185, 0.234, 0.299})$	0.239	2
S3	Equity/Debt ratio	$(\mathbf{0.091, 0.123, 0.165})$	0.126	4
S4	Operation profit ratio	$(\mathbf{0.091, 0.122, 0.167})$	0.127	3
S5	Income before tax ratio	$(\mathbf{0.095, 0.115, 0.153})$	0.121	5
S6	Net income revenue	$(\mathbf{0.058, 0.072, 0.094})$	0.075	6
S7	Return on total asset ratio	$(\mathbf{0.054, 0.051, 0.068})$	0.058	7

It can be obtained the other matrix elements by the same computational procedure; therefore, the synthetic pair-wise comparison matrix of the five representatives will be constructed as follows matrix D

To apply the COA method to compare the BNP value of the fuzzy weights of each dimension: to take the BNP value of the weight of S1 (current ratio) as an example, the calculation process is as follows:

$$BNP_{S1} = \frac{[(U_{w1} - L_{w1}) + (M_{w1} - L_{w1})]}{3} + L_{w1} = \frac{[(0.372 - 0.185) + (0.284 - 0.185)]}{3} + 0.185 = 0.281$$

Then, the weights for the remaining dimensions can be found as shown in table 4. This table shows the relative weight of eight dimensions of the evaluation of the companies, which obtained by Fuzzy AHP method.

$$\begin{bmatrix} (1,1,1) & (3.91,5.01,6.07) & (4.64,5.65,6.65) & (2.88,4.12,5.24) & (1.49,1.82,2.19) & (0.79,1.17,1.55) & (1.10,1.44,1.82) \\ (0.25,0.20,0.26) & (1,1,1) & (3.78,4.82,5.85) & (5.19,6.21,7.23) & (1.67,1.69,2.08) & (1.91,1.71,1.98) & (4.31,5.31,6.32) \\ (0.26,0.18,0.22) & (0.28,0.21,0.26) & (1,1,1) & (2.62,3.83,4.93) & (0.83,1.49,2.08) & (1.14,1.33,1.59) & (2.62,3.63,4.64) \\ (0.150.24,0.35) & (0.24,0.16,0.19) & (0.30,0.26,0.38) & (1,1,1) & (3.91,5.01,6.07) & (3.63,4.72,5.77) & (2.88,4.12,5.24) \\ (0.48,0.55,0.67) & (0.48,0.59,0.75) & (0.48,0.67,1.00) & (0.31,0.20,0.26) & (1,1,1) & (6.21,7.23,8.24) & (2.88,2.00,2.38) \\ (0.61,0.85,1.26) & (0.51,0.58,0.69) & (0.63,0.75,0.94) & (0.26,0.21,0.28) & (0.22,0.14,0.16) & (1,1,1) & (1.82,2.11,2.43) \\ (0.87,0.69,0.91) & (0.29,0.19,0.23) & (0.37,0.28,0.38) & (0.35,0.24,0.35) & (0.42,0.50,0.60 & (0.85,0.47,0.55) & (1,1,1) \end{bmatrix}$$

In order to calculate the closeness coefficients of each of the alternatives. The values d_1^+ and d_1^- can be calculated as a follows:

$$\mathbf{d_1^+} = \sum\sqrt{[(\mathbf{0.074-1})^2+(\mathbf{0.170-1})^2+(\mathbf{0.289-1})^2]\frac{\mathbf{1}}{\mathbf{3}}}+\cdots$$

$$+\sqrt{[(\mathbf{0.021-1})^2+(\mathbf{0.030-1})^2+(\mathbf{0.055-1})^2]\frac{\mathbf{1}}{\mathbf{3}}}$$

$$=\mathbf{6.281}$$

$$\mathbf{d_1^-} = \sum\sqrt{[(\mathbf{0.074-0})^2+(\mathbf{0.170-0})^2+(\mathbf{0.289-0})^2]\frac{\mathbf{1}}{\mathbf{3}}}+\cdots$$

$$+\sqrt{[(\mathbf{0.021-0})^2+(\mathbf{0.030-0})^2+(\mathbf{0.055-0})^2]\frac{\mathbf{1}}{\mathbf{3}}}=\mathbf{0.799}$$

Once the distances from FPIS and FNIS are determined, the closeness coefficient can be obtained with (32). The index CC_1 of firstalternative is calculated as:

$$CC_1 = \frac{0.799}{0.799+6.281} = 0.113$$

The other results are shown in table 5.

TABLE IV. CLOSENESS COEFFICIENTS AMONG DIFFERENT COMPANIES

Company	d+	d-	Satisfaction of CC_1^-	Rank
China Steel	6.281	0.799	0.113	5
Cathay	6.277	0.805	0.114	4
TSMC	6.225	0.855	0.121	2
Acer	6.208	0.869	0.123	1
Asus	6.256	0.821	0.116	3

V. CONCLUSION

The result of this study can offer us the way to select the best company among the company group. It help the people to invest the best one based on analyzing the information from financial report and applying fuzzy MCDM method. The new point of this study is that the user only needs some basic knowledge of finance to construct the criteria hierarchy, and the necessary result will be obtained. This method used in the study can also be applied to other industries only the considered criteria may be different. For example, solvency ratios are very important with banks. However, they are less important than with manufacturing company. In the future, we will try to develop or use the fuzzy MCDM method to solve the decision problems.

***Abstract*—Antimalware applications represent one of the most important research topic in the area of information security threat. Indeed, most computer network issues have malwares as their underlying cause. As a consequence, enhanced systems for analyzing the behavior of malwares are needed in order to try to predict their malicious actions and minimize eventual computer damages. However, because the environments where malwares operate are characterized by high levels of imprecision and vagueness, the conventional data analysis tools lack to deal with these computer safety applications. This work tries to bridge this gap by integrating semantic technologies and computational intelligence methods, such as the Fuzzy Ontologies and Fuzzy Markup Language (FML), in order to propose an advanced semantic decision making system that, as shown by experimental results, achieves good performances in terms of malicious programs identification.**

Keywords-malware behavioural analysis; ontology; fuzzy ontology; fuzzy markup language

I. INTRODUCTION

In recent years, the rapid growth of information technology has strongly enhanced computer systems both in terms of computational and networking capabilities. However, these novel distributed computing scenarios, other than enabling the development of efficient computer applications, have raised important issues about the security and safety of the interconnected hardware systems. Indeed, computer threats, such as viruses and backdoor programs have created different economical and technological disasters all around the world. Internet fraud activities [1], users private data stealing, malwares damaging computer systems without the owner's informed consent [2], are only some examples of computer threats each day sabotage personal, academic and industrial computer equipments. As a consequence, enhanced systems for analyzing the behavior of malwares are needed in order to try to predict their malicious actions and minimize eventual computer damages [3]. However, because the environments where malwares operate are characterized by high levels of imprecision and vagueness, the conventional data analysis tools lack to deal with these computer safety applications. This work tries to bridge this gap by integrating different computational intelligence methods, such as the Fuzzy Ontologies [4] and Fuzzy Markup Language (FML) [5].

Ontologies are structural frameworks for modeling information by means of an explicit specification and a shared conceptualization [6]; they are mainly used as good knowledge representation and communication model for intelligent agents [4]. Nevertheless, in their conventional view, ontologies are not enough to deal with imprecise and vague knowledge. As a consequence, many researchers have explored the use of fuzzy ontologies, i.e., structural frameworks based on fuzzy logic used for modeling information characterized by high levels of imprecision and vagueness. For example, Lee *et al.* proposed a fuzzy ontology for designing an intelligent decision making system for summarization systems [4]; Quan *et al.* presented the automatic fuzzy ontology generation for semantic help desk support [7], and the automatic fuzzy ontology generation for semantic web [8]. Typically, the joint exploitation of Fuzzy Ontologies and FML is mainly used as support framework for designing intelligent fuzzy inference systems, one of the key topics in artificial and computational intelligence research [9].

The FML [10] is a novel computer language useful for modeling advanced fuzzy systems by means of a structural and taxonomic approach that improves fuzzy systems design from a twofold point of view: transparency and reliability (see section II.B). This paper presents an FML-based ontological agent for malware behavioral analysis. In particular, this agent uses a fuzzy ontology for modeling malware behavioral knowledge collected by domain experts and our homemade tool, Taiwan Malware Analysis Net (TWMAN) [1, 3]. An FML program is used in order to design an intelligent decision making system whose behavioral rules are used to detect viruses and malicious programs and, consequently, provide a better protection to computer equipments.

This paper contains five sections. Section II describes the literature survey about Web Ontology Language (OWL), FML and TWMAN. Section III describe the integration of a fuzzy ontology model and FML for modeling the knowledge about malware behaviors and propose an intelligent decision making system for detecting computer anomalies. Section IV discusses the experimental results of this study. Finally, some conclusive remarks are offered in Section V.

II. BASIC CONCEPTS AND BACKGROUND

Today, there is a growing interest in the development of systems based on knowledge representation by means of ontological approaches. Nevertheless, conventional ontology languages are not appropriate to deal with uncertainty [11],

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

vagueness or imprecision which strongly characterize the real world scenarios . It is not surprising that fuzzy set theory and fuzzy logic are handle these types of knowledge and, indeed, fuzzy ontologies are emerging as a useful methodology for knowledge representation in several semantic-oriented applications. In this paper, a decision making system for analyzing malware system behavior is implemented by integrating the following technologies: Web Ontology Language (OWL), Fuzzy Markup Language (FML) and Taiwan Malware Analysis Net (TWMAN) .

A. Web Ontology Language (OWL)

When a malware behavioral analysis tool owns the malwares source code at its disposal, the analysis step becomes quite simple. Indeed, understanding the malicious program is as simple as reading, interpreting and looking for code fragments that reveal key information on the attacker and the attack. However, our approach does not own malwares source codes to detect eventual viruses or similar programs, but it exploits an ontological view of malwares behavior in order to define a more general and efficient detection platform. In order to express the ontological knowledge about malware behavior, our proposal uses the OWL2 language, a standard tool for modeling knowledge in a semantic way. In particular, our framework uses OWL for describing an ontological model for malware behavioral (see Fig. 1) composed by the following information: *File Hash (FH)*, *Connect IP (CI)*, *Files Change (FC) and Similarity (SI)* (see section II.C) [1]. Precisely, File Hash is a malware information (computed by the *ssdeep* program [12]) useful to detect the presence of malwares on the system under protection by comparing the hash code of a suspicious file with a collection of malware hash codes previously gathered. Connect Ip allow us to count the number of TCP/IP connection opened by a given program and, as a consequence, to detect anomalous network behaviors; this information is computed by INetSim [13], a software suite for simulating common internet services for analyzing the network behavior of unknown malware samples; File change is a malware information used to evaluate the number of changes occurred in the file system due to some eventual malware actions; it is computed by the Advanced Intrusion Detection Environment (AIDE) [14]. The Similarity concept is a cumulative information used to evaluate the level of maliciousness of a program; it is computed starting from FH, CI and FC. However, even though OWL enables a suitable representation of malwares knowledge, it is not able to apply advanced inference mechanisms to derive additional imprecise and vague knowledge in the scenario of malwares detection. For this reason, we exploit FML, an innovative fuzzy inference language bridging the gap shown by other methodologies.

B. Fuzzy Markup Language (FML)

FML is a domain-specific language proposed by Acampora and Loia [10] whose main aim is to model fuzzy systems by directly dealing with fuzzy concepts, fuzzy rules and fuzzy inference engines [9]. In particular, it is used to model two well-known kind of fuzzy controllers: Mamdani and Takagi-Sugeno-Kang (TSK). This language is XML-based, so FML programs are coded through a collection of correlated semantic XML tags, following an opportune XML Schema, capable of modeling the different components of a fuzzy controller. Some samples of FML tag are [15]:

- <FUZZYCONTROL> that models a whole fuzzy system;
- <KNOWLEDGEBASE> and <RULEBASE> that represent the main components of a fuzzy system: the knowledge base and the rule base.

However, since an FML program realizes only a static view of a fuzzy system, the so-called eXtensible Stylesheet Language Translator (XSLT) is provided to change this static view to a computable version. Therefore, in short, FML is essentially composed by three layers [9]:

- XML in order to create a new markup language for fuzzy logic control;
- a XML Schema Document (XSD) as grammar to define the legal building blocks;
- a XSLT in order to convert a fuzzy controller description into a general-purpose computer language.

Differently from other similar approaches used to describe fuzzy controllers such as Fuzzy Control Language or MATLAB Fuzzy Inference System (FIS) developed by the Math Works, FML allows fuzzy designers to simply code their ideas on heterogeneous hardware by exploiting abstraction benefits offered by XML tools. Indeed, thanks to FML it is possible to design a fuzzy controller in human-readable and hardware independent way by avoiding additional work and development phases. The exploitation of FML is resulted in a new fuzzy control design philosophy named *transparent fuzzy controller* based on the integration among fuzzy systems, labeled tree theory, and XML methodology. Fig. 2 shows the tree structure of FML.

C. Taiwan Malware Analysis Net (TWMAN)

TWMAN is an open source (GPL v2) project based on a real OS environment such as the Joe Stewart's Truman [1, 3, 16]. TWMAN is an automated behavioral malware analysis environment to analyze the malware and a client-server architecture. The server works on Linux, while the client is Microsoft Windows, which use PXE-Boot in a real environment . In a Windows environment, malware usually attempts to execute or to install other applications in the Windows. It also includes the WinSock-functions, which can be able to communicate with TCP/IP-networks, such as the Internet or an intranet system. Some important efforts are made to interpret the Winsock calls. It must detect HTTP, FTP, SMTP and IRC connections and extracts the important data (i.e. FTP and IRC login information). It is interesting to know what the malware can create or how it can modify files on the disk. Windows NT/2000/2003/XP stores configuration data in a registry. It is a central repository for data configuration which is stored in a hierarchical manner. Systems, users, applications, and hardware in Windows allow the registry to store their configuration especially when a registry run key has been modified by some programs to make itself auto-start. The Advanced Intrusion Detection Environment (AIDE) against the disk image after the malware is run and compare it to the clean image that was uploaded to the client before the process and

take note if files were added, modified, or deleted during the malware run.

In order to test and verify, we have completed analyze 4840 malwares and generated report by TWMAN (Please see Table I). Our approach can get correct malware behavioral information, which can be expanded to solve more complex, practical problems and exploited to malware behavioral by agents to infer additional information and provide advanced services to end users.

III. FUZZY ONTOLOGICAL MODEL FOR TWMAN

This section is devoted to integrate OWL and FML in order to design a semantic methodology for improving malware behavioral analysis. In particular, in this section, we will describe how to use fuzzy ontologies to model the knowledge related to malware behaviors and how to merge these fuzzy ontologies with FML in order to design the proposed intelligent system. The main tools used to achieve the proposed result are: OWL by Protégé and VisualFML.

Description Logic and Fuzzy set theory are well-known formalisms for representing complex knowledge related to different application domains. According to the FML, which can create a data-oriented markup language features, and combine fuzzy logic, then create a vague abstraction of the fuzzy controller. Fig. 3 shows structure of FML-based malware behavioral analysis, so we can see two parts, namely the left part of the Knowledge Base and the right half of the rule base, and Table III shows the part of example FML code.

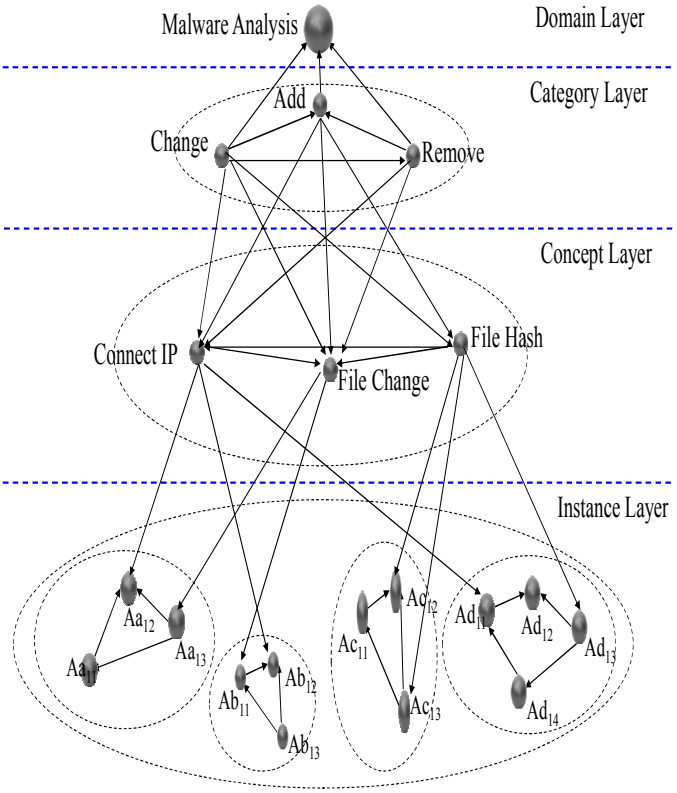

Figure 1. Structure of the malware behavioral ontology [1, 5].

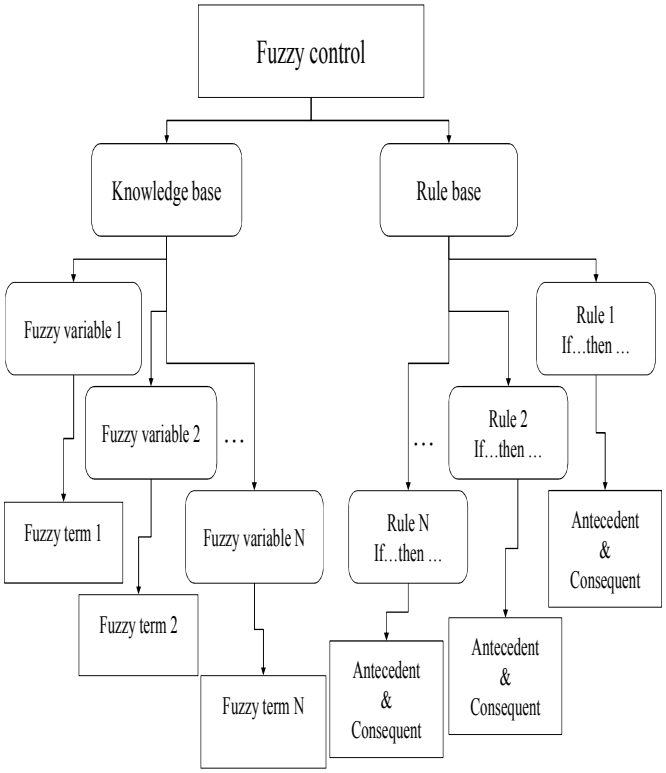

Figure 2. The tree structure of FML [10, 15].

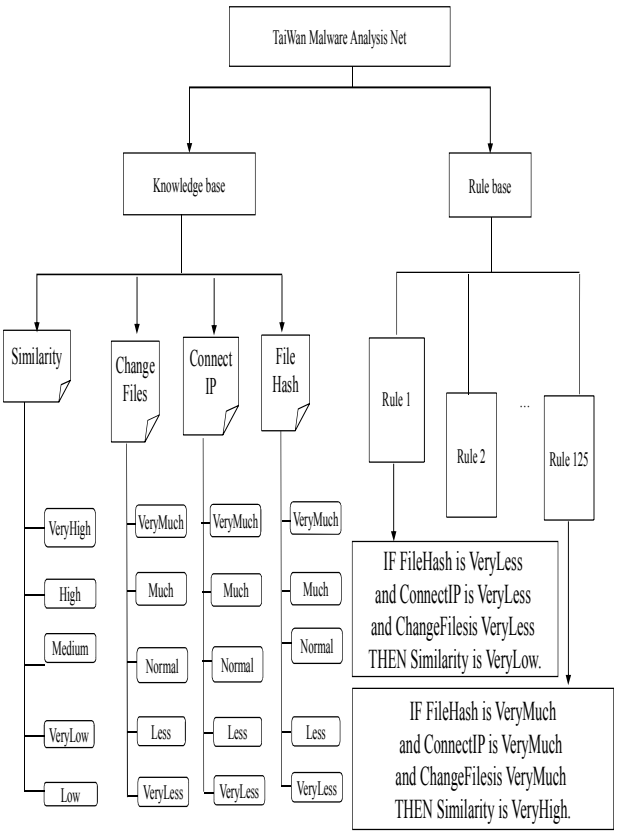

Figure 3. The structure of FML-based malware behavioral analysis.

A. OWL and FML Model

There are several knowledge representation language, DLs and Fuzzy DLs have existed, e.g., Semantic Web Rule Language (SWRL), Java Environment Expert Systems (Jess), FUZZYDL and DELOREAN. Which provide a shared vocabulary of an application domain. Indeed, OWL can describe the relation between concept with instance and inference new instance, but the limitation of the first one must integrate SWRL language and Jess in Protégé 3, and the second one have to integrate Fuzzy OWL in Protégé 4. Table II shows the part of example OWL code. Therefore, we will introduce FML to model malware behavioral knowledge, are the following ones.

FML parser was used to extract the knowledge from the FML-based definition. The input is FML-based definition of the fuzzy controller which denoted by CFML. The output is composed of a set of Fin={FileHashVeryLess, FileHashLess, FileHashNormal, FileHashMuch, FileHashVeryMuch, ConnectIPVeryLess, ConnectIPLess, ConnectIPNormal, ConnectIPMuch, ConnectIPVeryMuch FileChangeLess, FileChangeVeryLess, FileChangeNormal, FileChangeMuch, FileChangeVeryMuch}, a set of Fout={ SimilarityVeryLow, SimilarityLow, SimilarityMedium, SimilarityHigh, SimilarityVeryHigh } and fuzzy inference rules set FS={Rule1, Rule2,..,Rule125}.

VisualFML Tool is a development environment for fuzzy-inference-based systems developed by Acampora and Loia [4]. The environment has been completely programmed in Java, so it can be executed on any platform with JRE (Java Runtime Environment) installed. Its functionalities cover the different stages of the fuzzy system design process, from their initial description to the final implementation [4]. It is possible to import a *.fml* file to build a fuzzy controller, and also to export a system created by the tool in a .fml file. The main functionalities the tool provides are the following ones: Fuzzy system description: define the system creating linguistic variables and rules; Verification: monitor the system behavior showing outputs corresponding to different inserted inputs; Tuning: apply algorithms based on neural network; Synthesis: generate high-level languages descriptions. Fig. 4 shows the fuzzy input variable editor in VisualFML and Fig. 5 shows the conceptual framework for the fuzzy controller.

B. Fuzzy Inference Mechanism

In order to design the our proposal of malware behavioral analysis tool, the main fuzzy components composing the system have to be defined. Fig. 6 show the membership functions of the fuzzy variables: File Hash (FH), Connect IP (CI), File Change (FC), and Similarity (SI) respectively. Fig. 7 shows the fuzzy variable control surface viewer. Table IV lists the parameters of the membership functions. Table V lists part of the fuzzy rules, which are constructed by the domain experts. Starting from this initial information, the proposed decision making system will be able to take opportune decisions about the malicious program detection. Next section is devoted to introduce a case study where our intelligent framework has been tested and validated.

TABLE II. THE PART OF EXAMPLE OWL CODE.

IV. EXPERIMENTAL RESULTS

In order to evaluate the effectiveness of the proposed approach, we adopt 30 attendance records retrieved from the malware repository of National Center for High Performance and Computing (NCHC) as the experimental data in Table VI. Fig. 7 shows a three-dimensional graphical representation of the system behavior and results of fuzzy inference process, which the values of the different output variables for a given set of input values.

TABLE VII. VARIOUS PARAMETERS USED IN EQS. (1), (2) AND (3).

Actual results	Prediction results	
	YES	NO
YES	TP (true positive)	FN (false negative)
NO	FP (false positive)	TN (true negative)

$$Accuracy = (TN+TP)/(TP+TN+FP+FN) \times 100\% \quad (1)$$

$$Precision = TP/(TP+FP) \times 100\% \quad (2)$$

$$Recall = TP/(TP+FN) \times 100\% \quad (3)$$

The accuracy, precision and recall functions are shown by Eqs. (1), (2) and (3), respectively. The parameters of TP, FP, FN and TN are defined and listed in Table VII. The distribution of the accuracy, precision and recall are shown in Fig. 8.

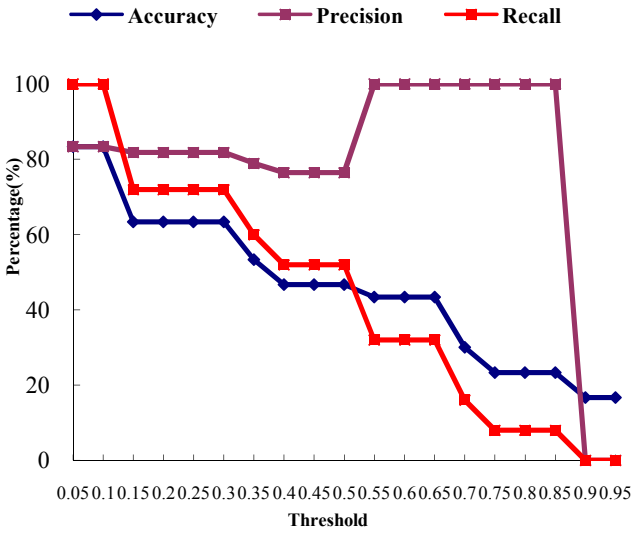

Figure 8. Results of the accuracy, precision and recall.

V. CONCLUSION

In this study, fuzzy ontology for malware behavioral analysis scheme based on FML has been presented. It is composed of a fuzzy inference and semantic decision-making mechanism to describe the changes of the registry key value, network connection and file to build the ontology and behavioral rules. The experimental results show that our approach will feasible and usable for malware behavioral analysis system. It can utilize them to determine the behaviors of virus or malicious program to provide better protection and services to end users.

In the future, there are more vague knowledge of OS platform with experimental data will be collected, and type-1 FML is not enough to deal with. Therefore, some upgradable technologies, like genetic algorithm and type-2 fuzzy set, will be update to be exercised for comparing with the current technology. We also compare the performance with other classification methods. In order to take prompt and appropriate measures, TWMAN can integrate with a human thinking semantic model. Therefore, we consider that TWMAN could be a powerful tool to improve the network safety.

ACKNOWLEDGMENT

The authors would like to thank the National Center for High Performance Center of Taiwan for financially supporting this open source research project. In addition, the authors would like to thank National Science Council of Taiwan for financially supporting this research under the Grant NSC 99-2923-E-024-003-MY3, NSC 98-2221-E-024-009-MY3, NSC 99-2911-I-024-004 and NSC 99-2218-E-492-006 .

***Abstract* - The launch of the digital era has made information security management a most significant and critical issue. However, perfect information security management requires certain factors for complete success. This study aims to collect Key Success Factors (KSFs) for information security management through literature review and design of a questionnaire survey. This comprises four major aspects: (1) External dimension, (2) Internal dimension, (3) Technology dimension, and (4) Execution dimension. Based on these, we proceed with categorization and analysis using Fuzzy Analytic Hierarchy Process (Fuzzy AHP or FAHP), which was applied to this study to overcome the seeming failure of general Analytical Hierarchy Process (AHP) in dealing with respondents' impersonal differences in paired comparison.**

The ordered ranking of objectives under each aspect is: system, human resource, security function, organization, performance, operation, market, and legislation. The results sifted from the FAHP approach suggest five top key success factors: "Training Plan", "MIS Staffing", "System Structure", "Regulation", and "Maintain Service".

***Keywords* - Information Security Management, Key Success Factors, Fuzzy Analytic Hierarchy Process**

I. INTRODUCTION

It has been recognized that due to the development of information and communication technology, most organizations now heavily rely on information systems to provide effective information for supporting operation and decision activities. This information is valuable and important capital for organizations. Porter and Millar stated that the complete information management keeps an enterprise competitive [1]. Information management also sustains an enterprise's competitive advantage [2], and contributes to its performance [3, 4]; Obviously, the key issue is how to manage information security systems to meet the requirements of all of organizations and achieve organization's goals [5]. Torres et al. also mentioned the importance of information security management to ensure an organization can take advantage of information management, with its criticality, openness and risk [6].

Gordon and Martin analyzed the role of information security based on the viewpoint of competition systems [7]. They regarded investment in information security to have extreme value, as it could help an organization occupy markets and upgrade competence. Organizations should make appropriate information security management policies in order to keep their information system safe [8, 9]. Information security management issues could be addressed through several dimensions and diverse means [10], but might be concluded to be the combination of information, technology, and people [11]. Another definition is that information security management is the detection and prevention of unauthorized actions from computer system users [12, 13]. There are many factors that will affect the organizational policies for information security management [14]. Austin et al. also pointed out that certain key items should be noted to implement information security management [15].

As discussed above, in order to realize the importance of information security management implementation through study, we use theories, key success factors (KSFs) and Fuzzy AHP. Identification of the KSFs of information security management implementation is a multiple-criteria decision making (MCDM) problem with many quantitative and qualitative attributes. We selected the analytic hierarchy process (AHP) method developed by Saaty [16], as it has been widely applied for affirming the issue of criteria importance [17]. However, conventional AHP uses pairwise comparisons at each level with respect to the importance of criteria for the goal, and judge by using a nine-degree scale. So there is a possibility that the application of Saaty's AHP might have some shortcomings [18].

In addition, respondent considerations on criteria priority and importance always contain ambiguity and multiplicity of meaning. It is also recognized that human assessment of qualitative attributes is always subjective and thus imprecise. Therefore, conventional AHP seems inadequate to explicitly capture the considerations of respondents. In order to model this uncertainty in human preference, fuzzy sets could be incorporated with pairwise comparison as an extension of AHP.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

This Fuzzy AHP was formerly proposed to solve the inevitable vagueness incident to AHP, and allows a more accurate description of the decision making process.

In this research, a fuzzy AHP approach is proposed to compensate for the vagueness and uncertainty of the attribute importance determination of respondents. This approach is used because the crisp pairwise comparison of conventional AHP seems too insufficient and imprecise in capturing the degree of importance of respondents' KSF evaluations. Our goal is to discover the KSFs of information security management implementation, and apply Fuzzy AHP to analyze them.

II. LITERATURE REVIEW

A. Key Success Factors (KSFs)

The perspective of KSFs was first proposed by Daniel [19], who stated that most successful organizations possess three to six fundamental elements. An organization that wants to succeed must focus and specialize on these essentialities. Most recently, the KSFs concept has been widely applied to management research. Many researchers apply it, especially in industrial analysis and strategy management where the concept of KSFs is interpreted and extended. This shows KSFs becoming explainable, durable, and consistent [20, 21, 22, 23, 24]

We concur with previous researchers who argued that KSFs are characters, criteria, or variables. If these factors are appropriately supported, maintained, and managed, they would be greatly beneficial to the success of organizations in certain industries [25]. KSFs would be a character, like price competence, and also a criterion, like capital structure or superior customer combination.

B. Fuzzy Analytic Hierarchy Process (FAHP)

The earliest research in fuzzy AHP was argued by van Laarhoven and Pedrycz [26], who compared fuzzy ratios described by triangular membership functions. In this research, Lootsma's logarithmic least square was used to derive local fuzzy priorities. Later, using geometric mean, Buckley determined fuzzy priorities of comparison ratios whose membership functions were trapezoidal [27]. Modifying van Laarhoven and Pedrycz's method, Boender et al. presented a more robust approach to the normalization of local priorities [28]. Taking the perspective, Chang [29] and Mikhailov [30] applied row mean method to obtain priorities for comparison ratios which were fuzzy triangular numbers.

All the aforementioned works compute fuzzy priorities based on arithmetic operations for fuzzy triangular (or trapezoidal) numbers. To be able to use fuzzy arithmetic operations, specific assumptions on the forms of membership functions are required. To date, there are only a limited number of membership-function forms that are computationally manageable. Moreover, the accuracy of the final ranking is inevitably weakened by the series of approximations required during the computation procedure. But the most important criticism on these works has to be their failure to address the issue of consistency.

The issue of consistency in fuzzy AHP was first tackled by Salo [31]. Departing from the fuzzy arithmetic approach, Salo derived fuzzy weights using an auxiliary programming formulation, which described relative fuzzy ratios as constraints on the membership values of local priorities. Expressing relative weights' feasible region in terms of linear inequalities was previously proposed by Arbel [32], and extended in Salo and Hämäläinen [33]. Requiring only quasi-concave and continuous fuzzy comparison ratios, Salo defined consistency in terms of the mean values of the fuzzy ratios (range of values with membership degree equal to one). Here, a fuzzy matrix was considered consistent if there were a set of crisp relative weights within the feasible region defined by the ranges of mean values. When the matrix was not consistent (no crisp weights existed), Salo proposed a simple heuristic which enlarged the feasible region and also guaranteed feasible weights.

After the above literature review, we found the fuzzy AHP method modified problems that might happen in the traditional AHP method, including imprecision, obscurity and disproportion of scales. Therefore, this research decided to use the fuzzy AHP method to study weights of the KSFs of information security management implementation. This is by using triangular fuzzy numbers, group integration, and fuzzy ranking to build fuzzy analytic hierarchy process.

III. FAHP RESEARCH APPROACH

The FAHP research approach for studying the KSFs of information security management is demonstrated in the following steps:

Step 1: Building the Hierarchy Model and Its Criteria

Based on literature review, we used KJ method to build the hierarchy model [34]. After revising both the hierarchy and descriptions of criteria, we finally developed a hierarchy KSFs model (refer to Figure 1). The first level is the goal, the KSFs of information security management. The second level is the four aspects of the KSFs. The third level is objectives which affect the success of information security management. The fourth level represents all involved and relevant criteria.

Step 2: Designing the Questionnaire

Using the hierarchy model built in Step 1, we adopt the concept of AHP to design the questionnaire as pairwise comparison of the relative importance of criteria, using a scale from 1 to 9, to form comparison matrices.

Based on the FAHP analysis, the variables were compared in pairs. The relative importance between two variables, from low to high, was mainly given five ranks: (1) for equally important, (3) for slightly important, (5) for very important, (7) for extremely important, and (9) for absolutely important. Ranks (2), (4), (6), and (8) in were also assigned between these ranks accordingly. In fuzzy sets, the interval value, instead of crisp value, was provided for filling in the questionnaires for the pairwise comparison.

Step 3: Building Fuzzy Converted Judgments $\tilde{M}_{ij}$ *Matrices*

We used the triangular membership function and cuts to convert the subjective judgments of the respondents to fuzzy judgments. We extracted the judgments of each criterion, objective and aspect, and use the triangular fuzzy number rules on Table I to convert.

Table Ⅰ. Triangular fuzzy numbers for the pairwise comparison scale

Linguistic Scale	Triangular fuzzy numbers
Equal Important	$\tilde{1}=(1,1,1)$
Between each ranks	$\tilde{2}=(1,2,3)$
Slightly Important	$\tilde{3}=(2,3,4)$
Between each ranks	$\tilde{4}=(3,4,5)$
Very Important	$\tilde{5}=(4,5,6)$
Between each ranks	$\tilde{6}=(5,6,7)$
Extremely important	$\tilde{7}=(6,7,8)$
Between each ranks	$\tilde{8}=(7,8,9)$
Absolutely important	$\tilde{9}=(8,9,10)$

We first formulated all initial individual fuzzy comparison matrices based on the triangular membership function, then used Microsoft Excel to calculate the fuzzy weight.

$$M=\left[\tilde{M}_{ij}\right]\ ;\quad \tilde{M}_{ij}=\left(L_{ij},M_{ij},R_{ij}\right)\ ;\quad \tilde{M}_{ij}=1\Big/\tilde{M}_{ji}\ ,\quad \forall i,j=1,2,\ldots,n \tag{1}$$

Step 4: Group Integration

We used the geometric approach of Buckley to integrate respondents' judgments into group fuzzy comparison matrices [27]. The formula is as follows:

$$\tilde{m}_{ij}=(1/N)\otimes(\tilde{m}_{ij}^{1}\oplus\tilde{m}_{ij}^{2}\oplus\ldots\oplus\tilde{m}_{ij}^{N}) \tag{2}$$

Step 5: Calculating Fuzzy Weights

We calculated fuzzy weights $\tilde{w}_i$ through the following formulas:

$$\tilde{Z}_i=\left(\tilde{a}_{i1}\otimes\tilde{a}_{i2}\otimes\ldots\otimes\tilde{a}_{in}\right)^{\frac{1}{n}},\forall i=1,2,\ldots,n \tag{3}$$

$$\tilde{w}_i=\tilde{Z}_i\otimes\left(\tilde{Z}_1\oplus\tilde{Z}_2\oplus\ldots\tilde{Z}_n\right)^{-1} \tag{4}$$

Step 6: Defuzzication

We took the algorithm developed by Teng & Tzeng to do defuzzication [54]. The equation of the weights of defuzzication, DF_{ij}, is as follows:

$$DF_{ij}=\left[\left(R_{ij}-L_{ij}\right)+\left(M_{ij}-L_{ij}\right)\right]/3+L_{ij} \tag{5}$$

Step 7: Normalization

The formula of normalization weights NW_i is as follows:

$$NW_i=DF_{ij}/\sum DF_{ij} \tag{6}$$

Step 8: Series of Hierarchical

Through the above steps, we got the weights NW_i of "i" aspect at level 2, and NW_{ij} of "j" objective at level 3 under certain level 2 aspect. NW_{ijk} is the weight of criterion "k" at level 4. If we want to get NW_k, the final weight of "k" criterion under level 1, the top goal of this research, we calculate per series of hierarchical using formula (7).

$$NW_K=NW_i\times NW_{ij}\times NW_{ijk} \tag{7}$$

With above illustration and calculus, we can get the weights to rank the priority of KSFs after series of hierarchical, achieving the goal of this research. This research mainly used Microsoft Excel to process data and analyze the questionnaire.

IV. EVALUATING HIERACHICAL STRUCTURE FOR KSFS

This research found the KSFs of information security management through literature review, then extracted and compiled the KSFs into 25 criteria, as Table Ⅱ illustrates. Next, we used KJ method to categorize these 25 criteria into 8 objectives, then conducted these 8 objectives into 4 aspects to fulfill the goal, the KSFs of information security management. The 4 aspects are: (1) External Dimension; (2) Internal Dimension, (3) Technology Dimension, and (4) Execution Dimension. KSFs could be inducted from the External and Internal Dimension of the organization, or the condition of the topic [22, 35, 36, 37]. A successful information security management results from the two dimensions Technology and Execution [38, 39, 40]. In this way, we completed the framework of the research hierarchy shown in Figure 1.

(Table Ⅱ. The criteria of KSFs and relative references)

(Figure 1. The hierarchy model of KSFs of information security management.)

V. DATA ANALYSIS

We released a total of 25 expertise questionnaires and collected results for all. Ten of the respondents are experts in the information security system industry, and the other 15 are information system managers in sizable companies. The following results were obtained through Fuzzy AHP analysis.

A. The Evaluation Results and the Analysis of the Measurement in Level 2

The level 2 aspects are: (1) External Dimension, (2) Internal Dimension, (3) Technology Dimension, and (4) Execution Dimension. The fuzzy weighted values and rankings are shown in Table Ⅲ.

Table Ⅲ. The fuzzy weights of the aspects

Aspects	Fuzzy weights	Ranking
External Dimension	0.12	4
Internal Dimension	0.21	3
Technology Dimension	0.38	1

Execution Dimension	0.29	2
CI=0.047 CR＝0.049		

Table Ⅲ states that the Technology Dimension is the most important aspect of the KSFs of information security management. The next in importance was the Execution Dimension. The Internal Dimension is the third most important factor, and the External Dimension is the last.

B. The Evaluation Results and the Analysis of the Measurement in Level 3

The level 3 objectives and their fuzzy weighted values and ranking are shown in Table Ⅳ.

Table Ⅳ. The fuzzy weights of the objectives

Level 2 Aspects	Level 3 Objectives	Fuzzy weights	Ranking	Tests
External Dimension	Legislation	0.46	2	CI=0.046 CR=0.080
	Market	0.54	1	
Internal Dimension	Organization	0.61	1	CI=0.049 CR=0.084
	Operation	0.39	2	
Technology Dimension	System	0.52	1	CI=0.034 CR=0.059
	Security Function	0.48	2	
Execution Dimension	Human Resource	0.65	1	CI=0.046 CR=0.079
	Performance	0.35	2	

C. The Evaluation Results and the Analysis of the Measurement in Level 4

The level 4 criteria and their fuzzy weighted values and ranking are shown in Table Ⅴ.

(Table Ⅴ. The fuzzy weights of the criteria)

D. The Weights of Series of Hierarchical

Using Tables 3, 4, and 5, we can calculate the weights after series of hierarchical to rank all criteria in the KSFs of information security management. This is shown in Table Ⅵ.

(Table Ⅵ. The weights after series of hierarchical)

Table 6 demonstrates the final results from using FAHP to rank the KSFs in order of importance, using the data on the 25 criteria received from respondents. The highest final weight is "Training Plan" under Human Resource, which accounts for about 8.1% and is therefore the most important factor. The second is "MIS Staffing", also under Human Resource, which accounts for 6.6%. The close relationship of these criteria to the "Human Resource" objective could obviously indicate that people are a critical aspect of information security management execution.

The third most important accounted for 6.2%, and is "System Structure" under System and the most important factor at Technology Dimension. However, since Technology Dimension is the most important aspect, its factors are comparatively unremarkable. The fourth most important factor, "Regulation", accounts for 5.5%. We understand that government policy has some affect on enterprises implementing information security management. The System's "Maintain Service" accounted for 5.3%, and is fifth in the ranking. It seems enterprises rely more on system suppliers' service.

VI. CONCLUSION

This research adopts Fuzzy AHP that ranks the KSFs of information security management per investigation of expert opinions in this field. By using the empirical analysis results, we verified the perspectives of previous research on factors affecting information security systems, and worked out systematic priority of these factors. The results can also be organized and interpreted to form suggestions to relevant people. This Fuzzy AHP approach makes this research capable of precisely disclosing the importance of factors and developing deep knowledge of them.

The research results of the KSFs of information security management analyze the 25 criteria listed previously in this paper, and suggest the more critical success factors for information security management. Although some weights are distributed averagely, we can still realize successful information security management through multi-aspect efforts to achieve the goal without neglecting anyone.

The "Technology Dimension" aspect conclusively takes the first position, and reveals that technology criteria all play considerably important roles in information security management. Although "Execution Dimension" does not rank as high as "Technology Dimension" in aspect comparison, its criteria under the Human Resource objective, "Training Plan" and "MIS Staffing", are the two most important criteria. This shows that reviewing KSFs from different levels may result in different answers, and this is evidently also pointed out by AHP analysis.

***Abstract*—In this paper, we propose a personalized approach for flexible querying of information systems. This approach consists in the combination of the reasoning capabilities of the fuzzy DLR-Lite ontology and the expressivity of the SQLf language. The interpretation of the gradual inclusion (subsumption) axioms of the ontology is based on the Gödel fuzzy implication. Its generalization to a tree of inclusions is also proposed. This tree and its property of propagation of degrees are the basic theoretical elements of our application, which consists in querying of a multimodal transport information system which is embedded in a mobile terminal characterized by limited storage and processing capabilities.**

***Keywords*—Ontology, flexible querying, personalization, fuzzy DLR-Lite, SQLf, fuzzy sets theory, multimodal transportation.**

I. Introduction

The personalization of flexible querying of information systems dedicated to multimodal transportation networks is addressed in this paper. We propose an approach which consists in the development of a fuzzy semantic layer in order to extend the functionalities of information systems to reasoning. This layer is made of reasoning functions which combine domain application data with ontology axioms. Ontologies are able (i) to model the domain knowledge, (ii) to unify its vocabulary, (iii) to reason with available knowledge and (iv) to deduce implicit data from explicit data.

The proposed approach is developed in the framework of flexible querying of information systems which allows the user to express preferences in his/her queries. In such a system, the delivered answers are ranked from the most to the least preferred. In this context, user preferences can be expressed by vague or fuzzy predicates such as *fast*, *expensive*, *near*, etc. which are defined by fuzzy sets [16]. From the querying point of view, the SQLf language [4], [3] is a suitable language to express query with preferences. It is an extension of the SQL language to fuzzy predicates (conditions) and provides more expressive SQL-like statements.

From the reasoning point of view, several fuzzy ontologies (based on description logics [1]) have been developed (see [2], [8], [9], [10], [11], [12]) in which theoretical aspects have been widely studied (the definition of fuzzy concepts and relations, the definition and the interpretation of fuzzy inclusion or subsumption axioms, the fuzzy extension of subsumption algorithms, etc.). However, these ontologies are not suitable to address querying issue. Indeed, ontologies save axioms, individuals and related data in text files which are not appropriate for the needs of real applications. Ontology-based querying systems are faced with a large amount of data to such extent that the combination of ontologies and databases become an absolute necessity. In addition, the developed ontology-based querying systems, such as [15], [5], [10], [13], are based on limited description logics in terms of expressivity. To overcome this limitation, databases are combined with ontologies to provide DBMS functionalities such as data persistence and query evaluation. Ontology axioms are then used in the query rewriting process to take into account the logical relationships between concepts.

In this context, we consider the Description Logic extended to *m*-ary Relations [5] denoted DLR-Lite. More precisely, we are interested in the fuzzy extension of the DLR-Lite, called fuzzy DLR-Lite [7], [14], [15], which is made of a reduced set of fuzzy operators and abstraction rules which are connected to databases through SQL statements.

In this paper, we aim to design a flexible querying system that combines a fuzzy DLR-Lite knowledge base with the SQLf language, so as to take profit from the expressivity of the SQLf language and the reasoning mechanisms of the fuzzy DLR-Lite. Firstly, we show the relevance of the Gödel fuzzy implication to the interpretation of gradual inclusion (subsumption) axioms of the fuzzy ontology. Then, we consider the enrichment of the fuzzy DLR-Lite knowledge base with the SQLf language. The resulting knowledge base is finally applied on a sample mobile application in the field of multimodal transportation. The developed application is embedded in a lightweight terminal in which the accessible data are limited to a subset of the knowledge base. This restriction is due to the limited storage and processing capabilities of such terminals.

The remainder of the paper is structured as follows. Section II introduces the fuzzy DLR-Lite knowledge base. In section III, the Gödel fuzzy implication is used to define an interpretation to the gradual inclusion axiom; its contrapositive is also used to define a restricted form of the negation operator. We also show in section III the way in which our interpretation is extended to a tree of gradual inclusion axioms and its degree propagation property. Section IV introduces briefly the SQLf language and points out the relevance of the enrichment of

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

the fuzzy DLR-Lite knowledge base with this language. Our sample application is described in section V. Section VI recalls our contributions and draws some lines for future works.

II. The Fuzzy DLR-Lite Ontology

In this section, we introduce some elements of both the fuzzy sets theory and the fuzzy DLR-Lite knowledge base.

A. The Fuzzy Sets Theory

The fuzzy sets theory is introduced by Zadeh [16] to express the gradual membership of an element to a set. Formally, a fuzzy set F is defined on a referential U by a membership function $\mu_F : U \mapsto [0,1]$ such that $\mu_F(x)$ denotes the membership grade of x in F.

In particular, $\mu_F(x) = 1$ denotes the full membership of x in F, $\mu_F(x) = 0$ expresses the absolute non-membership and when $0 < \mu_F(x) < 1$, it reflects a partial membership (the more $\mu_F(x)$ is close to 1, the more x is a member of F).

A fuzzy set generalizes a crisp set in which membership grades are in $\{0,1\}$. If a fuzzy set is a discrete set then it is denoted by $F = \{(x_1, \mu_F(x_1)), ..., (x_n, \mu_F(x_n))\}$, otherwise, it is characterized by its membership function.

The union $\cup$ and the intersection $\cap$ operators are defined with a couple of (t-norm, t-conorm) such as (min, max). Let F, G be two fuzzy sets; $\mu_{F\cup G}(x) = max(\mu_F(x), \mu_G(x))$, $\mu_{F\cap G}(x) = min(\mu_F(x), \mu_G(x))$ and the complement of F, noted F^c, is defined by $\mu_{F^c}(x) = 1 - \mu_F(x)$. The logical counterparts of $\cap$, $\cup$ and the complement are resp. $\wedge, \vee$ and $\neg$. Other operators are also defined such as fuzzy implications.

B. The Fuzzy DLR-Lite Knowledge Base

The fuzzy DLR-Lite knowledge base $\mathscr{K}$ consists of three components $(\mathscr{O}, \mathscr{F}, \mathscr{A})$ defined in what follows.

1) The Facts Component $\mathscr{F}$: It contains the extensions of relations made of tuples of the form $R(c_1, ..., c_n)[s]$, where R is an n-ary relation, $c_{i,i=1,...,n}$ are constants and $s \in]0,1]$ is a grade indicating in which extent the tuple $\langle c_1, ..., c_n \rangle$ is an instance of the relation R.

2) The Ontology Component $\mathscr{O}$: The ontology defines the concepts of the application domain by means of projection, intersection and inclusion axioms:

- *The gradual inclusion (subsumption) axiom* has the form $(R_1 \sqcap R_2 \sqcap ... \sqcap R_l \sqsubseteq R_r)[s]$, where $l \geq 1$ and all the involved relations are of the same arity and $s \in]0,1]$ is the truth degree of the axiom.
- *The projection axioms* allow to define new concepts and their attached facts by extracting one or more columns from other relations. Two kinds of projection axioms are defined in the ontology component: *the simple projection* and *the restricted projection*.
  The simple projection is of the form $\exists[i_1, ..., i_k]R$ that expresses the projection of the relation R on columns $i_1, ..., i_k$, and *the restricted projection* is of the form $\exists[i_1, ..., i_k]R.(Cond_1 \sqcap ... \sqcap Cond_h)$ which restricts the projection of $\exists[i_1, ..., i_k]R$ according to the boolean conditions $Cond_{j,j=1,...,h}$ of the form $([i]\theta v)$, where $[i]$ corresponds to a column number of the relation R, $\theta \in \{<, \leq, =, \neq, >, \geq\}$ and v is a value.

3) The Abstraction Component $\mathscr{A}$: It forms the set of statements that connect concepts and relations, defined in the ontology component, to physical relational tables defined in a database. Simple and complex abstraction statements are defined as follows:

- *Simple abstraction statement* has the form:
  $R_1 \longmapsto R_2(c_1[t_1], ..., c_n[t_n])[c_s]$ which states that the n-ary relation R_1 of the ontology component is mapped into the projection on columns $c_1, ..., c_n$ of the m-ary table R_2 $(n \leq m)$ each of which is of type t_i. The score of the delivered tuples is provided by the column c_s.
- *Complex abstraction statement* has the form:
  $R_1 \longmapsto (t_1, ..., t_n)[c_s].sql$ where R_1 is an n-ary relation of the ontology component and sql is an SQL query which returns the n-ary tuples $\langle t_1, ..., t_n \rangle$ ranked in decreasing order of their scores c_s.

C. Interpretation of the Ontology Axioms $\mathscr{O}$

An interpretation of the fuzzy DLR-Lite ontology, denoted $\mathscr{I} =< \Delta, \cdot^{\mathscr{I}} >$, consists of a finite interpretation domain Δ and of an interpretation function $\cdot^{\mathscr{I}}$ which associates for each relation R (of arity m) an interpretation $R^{\mathscr{I}} : \Delta^m \to [0,1]$ where $R^{\mathscr{I}}(c)$ denotes the grade of membership of the tuple c to the relation R.

It is worth noticing that the interpretation function $R^{\mathscr{I}}$ has the same meaning as the membership function μ_R as defined in the fuzzy sets theory. Therefore, both $R^{\mathscr{I}}(x)$ and $\mu_R(x)$ notations are identical.

For sake of clarity, we only introduce the interpretation of the gradual inclusion axiom; see [14] for more details about the interpretation of simple and restricted projection axioms.

The interpretation of the gradual inclusion axiom is defined as follows:

$$\mathscr{I} \models (R_1 \sqcap ... \sqcap R_l \sqsubseteq R_r)[n] \Leftrightarrow \forall c \in \Delta^m, n \otimes R_1^{\mathscr{I}}(c) \otimes ... \otimes R_l^{\mathscr{I}}(c) \leq R_r^{\mathscr{I}}(c), \quad (1)$$

where m is the arity of the relations $R_{i,i=1,...,m}$ and R_r and $\otimes$ is a t-norm.

The formula (1) states that if c is an instance of $R_{i,i=1,...,l}$ at the degree $s_i = R_i^{\mathscr{I}}(c)$ then c is an instance of R_r at the minimal degree $n \otimes s_1 \otimes ... \otimes s_l$.

D. The Query Language

A fuzzy DLR-Lite query consists in a conjunction query combined with a scoring function to rank answers. The query is of the following form:

$$\underbrace{q(x)[s]}_{head} \leftarrow \underbrace{\exists y R_1(z_1)[s_1], ..., R_l(z_l)[s_l],}_{body} \underbrace{OrderBy(s = f(s_1, ..., s_l))}_{scoring\ function},$$

where q is a k-ary relation, each R_i is a relation, x (resp. y) is a vector of distinguished (resp. non distinguished) variables, z_i is a tuple of constants or variables from x or y, f is a scoring

function which combines the scores $s_1,...,s_l$ and s is the degree of satisfaction of a tuple x to the query q.

Such a query is evaluated using the gradual inclusion axioms defined in the ontology component. Each query atom $(R_i(z_i)[s_i])$ appearing in the right-hand side of an inclusion axiom is substituted by its left-hand side. Each axiom substitution generates a new query which is added to a disjunctive query. Each subquery of the resulting disjunctive query is finally translated into an SQL query to be evaluated over the facts component.

Example 1. Let *Journey* be a relational table of journeys defined from a multimodal transportation system. We define the fuzzy relation *FastJourney* from the *Journey* relation and the following inclusion (subsumption) axiom:

$(FastJourney \sqsubseteq FavoriteJourney)[0.7]$,

which states that each *fast* journey is also a *favorite* journey at the minimal degree of 0.7.

Any query involving *favorite* journeys, such as:

$q(t)[s] \leftarrow FavoriteJourney(t), OrderBy(s)$

is rewritten, based on the above gradual inclusion axiom, in terms of *fast* journeys (the t-norm used is *min*) as follows:

$q'(t)[s] \leftarrow FastJourney(t)[s'], OrderBy(s = min(0.7, s'))$,

where $s' = fast^{\mathscr{I}}(t)$ is the grade which expresses in what extent the journey t is *fast*.

We obtain for each journey t a minimal grade of satisfaction to the query q equals to $min(0.7, fast^{\mathscr{I}}(t))$ since the interpretation of the gradual inclusion axiom means:

$\forall t, Favorite^{\mathscr{I}}(t) \geq min(0.7, fast^{\mathscr{I}}(t))$. ▪

III. The Gradual Inclusion Axiom and the Gödel Fuzzy Implication

In this section, we show that the interpretation of the gradual inclusion axioms of the fuzzy DLR-Lite ontology is based on the Gödel fuzzy implication. We also show the interest of its contrapositive for the definition of a restricted form of the negation operator. We finally generalize the Gödel fuzzy implication based interpretation to a tree of gradual inclusion axioms.

A. Gödel Fuzzy Implication Based Interpretation of the Gradual Inclusion (Subsumption) Axiom

Let $(A \sqsubseteq B)[\alpha]$ be a gradual inclusion axiom, denoted by $A \sqsubseteq^{\alpha} B$. It is interpreted in the framework of the fuzzy DLR-Lite [14] as follows:

$$\forall x \in \Delta, B^{\mathscr{I}}(x) \geq min(\alpha, A^{\mathscr{I}}(x)) \quad (2)$$

We can prove that this interpretation is based on a gradual inclusion defined by the Gödel fuzzy implication $(\mu_A(x) \Rightarrow_{G\ddot{o}} \mu_B(x) = 1 \ \ if \ \ \mu_A(x) \leq \mu_B(x); \mu_B(x), otherwise)$:

$$A \sqsubseteq^{\alpha}_{G\ddot{o}} B \Leftrightarrow min_x(\mu_A(x) \Rightarrow_{G\ddot{o}} \mu_B(x)) = \alpha \quad (3)$$

In the remainder of the paper, we use equally the notations $A \sqsubseteq^{\alpha} B$ and $A \sqsubseteq^{\alpha}_{G\ddot{o}} B$.

Proof: The Gödel fuzzy implication is an R-implication defined by:

$\mu_A(x) \Rightarrow_{G\ddot{o}} \mu_B(x) = \sup_{[0,1]}\{u | min(\mu_A(x), u) \leq \mu_B(x)\}$.
We denote $(\mu_A(x) \Rightarrow_{G\ddot{o}} \mu_B(x))$ by $I(\mu_A(x), \mu_B(x))$.
As $I(\mu_A(x), \mu_B(x))$ is a u value then:

$$\forall x, min(\mu_A(x), I(\mu_A(x), \mu_B(x))) \leq \mu_B(x) \quad (4)$$

having $\alpha = min_x(I(\mu_A(x), \mu_B(x)))$ then
$\forall x, \alpha \leq I(\mu_A(x), \mu_B(x)) \Rightarrow$
$\forall x, min(\mu_A(x), \alpha) \leq min(\mu_A(x), I(\mu_A(x), \mu_B(x)))$.
From the formula (4), we obtain: $\forall x, min(\mu_A(x), \alpha) \leq \mu_B(x)$. ■

This interpretation, based on the Gödel fuzzy implication, allows the definition of a minimal threshold of satisfaction to queries in which substitutions of the gradual inclusion axioms are performed.

In addition, the Gödel fuzzy implication provides effective means of computing the minimal grade of the gradual inclusion axioms (formula (1)).

B. The Gradual Inclusion Axiom and the Contrapositive of the Gödel Fuzzy Implication

The contrapositive of the Gödel fuzzy implication could be used to define a new type of fuzzy inclusion (subsumption) denoted $\sqsubseteq_{ContG}$:

$$A \sqsubseteq^{\beta}_{ContG} B \Leftrightarrow min_x(1 - \mu_B(x) \Rightarrow_{G\ddot{o}} 1 - \mu_A(x)) = \beta \quad (5)$$

The interpretation of this form of fuzzy inclusion axioms is deduced from the interpretation based on the Gödel fuzzy implication as follows:

$$A \sqsubseteq^{\beta}_{ContG} B \Rightarrow \forall x, \neg A^{\mathscr{I}}(x) \geq min(\beta, \neg B^{\mathscr{I}}(x)) \quad (6)$$

The proof of this interpretation is similar to the previous proof. This form of gradual inclusion axioms allows to express a restricted negation operator.

Example 2. Let $TouristJourney \sqsubseteq^{0.6}_{ContG} FavoriteJourney$ be a fuzzy inclusion (subsumption) axiom which means that the fuzzy set of *touristic* journeys is included in the fuzzy set of *favorite* journeys at the minimal degree of 0.6. In the case that the access is limited to *favorite* journeys, the system can answer queries about journeys which aren't *touristic*, based on the above fuzzy inclusion axiom, as follows:

$\neg TouristJourney(t) \geq min(1 - FavoriteJourney(t), 0.6)$ (formula (5)). ▪

Please notice that this negation is only applicable to relations involved in gradual inclusion axioms.

C. Interpretation of a Tree of Gradual Inclusion Axioms

The proposed interpretation of the gradual inclusion axiom is generalized in the case of a tree of inclusion axioms. This tree structure and its property of degree propagation are the basis of the developed application in section 5.

Without loss of generality, we restrict the tree structure to two levels of inclusion as depicted in Fig. 1a.

Such a tree structure means: $A \sqsubseteq^{\alpha}_{G\ddot{o}} B$ and $B \sqsubseteq^{\beta}_{G\ddot{o}} C$, where $\alpha, \beta \in]0,1]$.

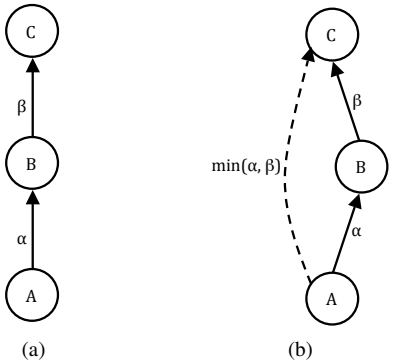

Fig. 1: A tree structure with two levels.

By applying the formula (2), we obtain:

$$\mu_B(x) \geq min(\mu_A(x), \alpha) \tag{7}$$

$$\mu_C(x) \geq min(\mu_B(x), \beta) \tag{8}$$

The propagation property allows the deduction of the grade of inclusion of the concept A in the concept C (see Fig. 1b).

Proof: From the formula (7), we deduce:

$$\mu_B(x) \geq min(\mu_A(x), \alpha) \Rightarrow$$
$$min(\beta, \mu_B(x)) \geq min(\beta, min(\mu_A(x), \alpha)) =$$
$$min(\alpha, \beta, \mu_A(x)) = min(min(\alpha, \beta), \mu_A(x)).$$

From $\begin{cases} min(\beta, \mu_B(x)) \geq min(min(\alpha, \beta), \mu_A(x)) \\ \mu_C(x) \geq min(\mu_B(x), \beta) \, (cf.\ formula\, 8) \end{cases}$

$$\Rightarrow \mu_C(x) \geq min(min(\alpha, \beta), \mu_A(x)).$$

■

This property of degree propagation can be generalized to a series of gradual inclusion axioms of the form:

$$A_1 \sqsubseteq_{G\ddot{o}}^{\alpha_1} A_2 \sqsubseteq_{G\ddot{o}}^{\alpha_2} \ldots \sqsubseteq_{G\ddot{o}}^{\alpha_{n-1}} A_n.$$

Effectively, transitive relationships of the form: $A_i \sqsubseteq_{G\ddot{o}}^{\alpha} A_j$, where $i < j$ can be interpreted as follows:

$\forall x : \mu_{A_j}(x) \geq min(\mu_{A_i}(x), \alpha)$,

where $\alpha = min(\alpha_i, \alpha_{i+1}, \ldots, \alpha_{j-1})$.

IV. The Enrichment of the Fuzzy DLR-Lite With the SQLf Language

The SQLf language [4], [3] is an extension of the SQL language to flexible querying by extending its statements to fuzzy conditions. An SQLf query delivers a fuzzy relation r which is a fuzzy set in which the grade of membership of tuple t to the relation r, denoted $\mu_r(t)$, expresses its level of satisfaction. The closer to 1 $\mu_r(t)$, the more t is preferred.

The SQLf language is based on the extension of the relational algebra operators to fuzzy conditions. The basic form of an SQLf query (fuzzy restriction) is as follows:

Select [distinct] *[n|t|n,t] attributes* ***From*** *relations*
Where *fuzzy_cond;*

The above query returns a set of ranked tuples with their grades of satisfaction, where n is a limitation of the size of the returned set and $t \in]0,1]$ is a minimal threshold of satisfaction.

Furthermore, the SQLf language allows more complex statements such as partitioning, fuzzy nesting, division involving fuzzy relations and queries based on fuzzy quantified propositions. These complex statements haven't any boolean counterpart [3].

The limitation of the fuzzy DLR-Lite lies in its inability to express complex preferences. This is due to the fact that abstraction statements, based on SQL queries, do not allow the user to define complex concepts such as *"journeys that satisfy almost all important criteria"*, which is based on a fuzzy quantified proposition.

In order to improve the expressiveness of the fuzzy DLR-Lite knowledge base, we propose the extension of the complex abstraction statements to the SQLf language. So that, it becomes possible to express preferences using complex SQLf statements. We redefine, then, the extended complex abstraction statements as follows:

$R_1 \mapsto (t_1, \ldots, t_k)[c_s].sqlf$, where R_1 is a concept from the ontology and *sqlf* is an SQLf query which delivers a fuzzy relation.

Example 3. The extended complex abstraction statements allow to define concepts and relations corresponding to complex preferences, such as *MyFastJourney* that corresponds to *"journeys having most of steps are fast"*, which is a fuzzy relation that can be defined by the following extended abstraction statement using an SQLf statement:

MyFastJourneys $\mapsto$ (int)$[c_s]$.(***Select*** *#Journey* ***From*** *Journey* ***Group By*** *#Journey* ***Having*** *most (#step) are fast(durLink)*); ▪

From the semantic point of view, our extension fits in well with the fuzzy DLR-Lite knowledge base and ensures backward compatibility, since the SQLf language covers the SQL language and the fuzzy sets theory is the common formal framework of interpretation of both SQLf queries and axioms of the fuzzy DLR-Lite, which is based on the Gödel fuzzy implication and the t-norm *min*.

V. Illustrative Example

In this section, a sample application is developed in the field of multimodal transportation, in order to show the interests of our approach, and to emphasize the benefit gained from the interpretation of the gradual inclusion axiom, using the Gödel fuzzy implication and the enrichment of the knowledge base with the SQLf language. The main features and the context of the application are described in following subsections.

A. The Context of the application

The considered application is developed in the context of mobile applications. The user terminal is a lightweight terminal which is limited in terms of main storage and processing capabilities. Therefore, the user terminal only embeds a subset of the knowledge base that consists of (i) fuzzy relations defined by the abstraction statements, (ii) fuzzy predicates and (iii) gradual inclusion axioms.

The user can query the embedded application with conjunctive queries which will be evaluated over the available data, based on the gradual inclusion axioms.

We assume that a user interface is provided to define membership functions corresponding to fuzzy concepts. The embedded system can deduce, from the gradual inclusion axioms, the minimal grade of inclusion of the already defined fuzzy concepts in the user-defined fuzzy concepts.

B. An Embedded Multimodal Transport Information System

We design a mobile application in the field of multimodal transportation. The conceptual data model of the system is consistent with the Transmodel standard [6]. Transmodel is an european standard defining a unified conceptual data model of multimodal transport networks which combine bus, tramway, trolley bus and underground networks. Transmodel provides operating data model for network management activities such as timetables, staff, fleet and rolling stock management, real time monitoring and user information circulation.

In practice, travelers are more interested in information about available networks, timetables and services. So, a subset of the database is enough, from the user point of view, to answer his/her queries which are generally about journeys.

For the sake of clarity, the knowledge base of our application is limited to one level of gradual inclusion enriched after that with a user defined fuzzy predicate.

We introduce below the 3 steps for the design of the embedded application: (i) data preprocessing, (ii) querying of the embedded system and (iii) the enrichment of the system.

1) Step 1. Data Preprocessing: Let the following relational tables be a subset of a database from a multimodal transport information system:

Network, Line, Station, Link and *LinkLine*.

We define the *Journey* relation as follows:

Journey (#journey, #link, departure, arrival, source, destination, duration, DepLink, ArrLink, modeLink, durLink, costLink, comfLink, waitLink).

It is assumed that journeys from source s to destination d are preprocessed.

Based on the SQLf queries, the following fuzzy relations are defined from the *Journey* relation:

1) *TouristJourney* $\mapsto$ [*#Journey*].***Select*** *#Journey* ***From*** *Journey* ***Group By*** *#Journey* ***Having*** *(most #Link are Touristic);*
2) *PleasantJourney* $\mapsto$ [*#Journey*].***Select*** *#Journey* ***From*** *Journey* ***Group By*** *#Journey* ***Having*** *(most #Link are Short(waitLink));*

The above extended complex abstraction statements state respectively that a *touristic* journey is a journey in which most of its steps (named link in the statements) cut across touristic sites and a *pleasant* journey is a journey in which the waiting time of most of its steps is *short*. Both *touristic* and *short* are fuzzy predicates.

The fuzzy predicate *MorningDeparture* is also defined by the membership function described in Fig. 2.

The following gradual inclusion axioms could be obtained by a processing using the formula (2) over the database:

- TouristJourney $\sqsubseteq^{0.7}_{G\ddot{o}}$ MorningDepartureJourney
- PleasantJourney $\sqsubseteq^{0.8}_{G\ddot{o}}$ MorningDepartureJourney

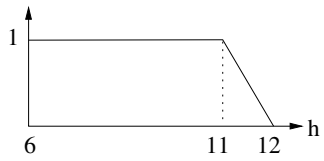

Fig. 2: The membership function of the fuzzy predicate *Morning*.

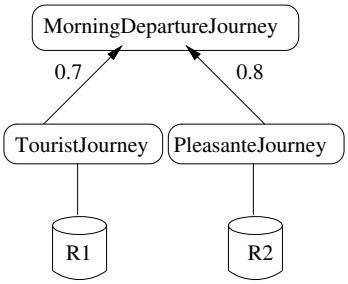

Fig. 3: The embedded concepts and data.

2) Step 2. Querying the Embedded System: The data embedded in the user terminal are illustrated in Fig. 3. The fuzzy relations $R_{i,i=1,2}(\#Journey)$ (in the sense of the SQLf language) are resulting from SQLf queries of the extended complex abstraction statements and mapped respectively to fuzzy concepts (relations in the sense of the fuzzy DLR-Lite) *TouristJourney* et *PleasantJourney*.

Due to the storage limitation of the user terminal, both the relations $R_{i,i=1,2}$ only contain the *#Journey* and the score columns. The membership function of the fuzzy predicate *MorningDeparture* is also embedded.

The user can query the system based on the embedded fuzzy predicates. The grade of satisfaction to both fuzzy conditions *Touristic* and *pleasant* are embedded within the relations $R_{i,i=1,2}$. About the fuzzy relation *MorningDepartureJourney*, a minimal grade of satisfaction can be obtained using the formula (2). For example:

$\forall t, \mu_{Morning}(t) \geq min(\mu_{Touristic}, 0.7) = min(\mu_{R_1}(t), 0.7)$,
and
$\forall t, \mu_{Morning}(t) \geq min(\mu_{Pleasant}(t), 0.8) = min(\mu_{R_2}(t), 0.8)$.
Finally, we can write:

$$\forall t, \mu_{Morning}(t) \geq max(min(\mu_{R_1}(t), 0.7), min(\mu_{R_2}(t), 0.8)).$$

3) Step 3. Enrichment of the Embedded System: The user can define his/her own fuzzy concepts to express his/her preferences. These concepts could be connected to the previously defined tree structure of concepts in order to personalize the embedded system. The query evaluation process is then made more accurate and close to user expectations.

Example 4. Through the fuzzy concept definition interface, the user can define *FavoriteDepartureJourney* as a fuzzy concept based on the favorite departure time (see Fig. 4). *FavoriteDepartureJourney* is then bound to *MorningDepartureJourney* fuzzy concept as follows:
$MorningDepartureJourney \sqsubseteq^{\alpha}_{G\ddot{o}} FavoriteDepartureJourney$.

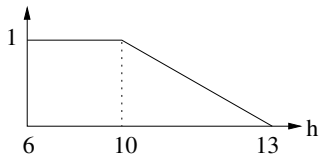

Fig. 4: The membership function of the fuzzy predicate *Favorite*.

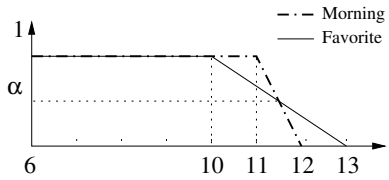

Fig. 5: Computation of the value of α.

The value of α in the above gradual inclusion axiom is $\alpha = min_t(\mu_{Morning}(t) \Rightarrow_{Gö} \mu_{Favorite}(t))$ and can be computed from the membership functions of both *Morning* and *Favorite* fuzzy predicates as depicted in Fig. 5.

Once the value of α is obtained ($\alpha = 0.5$ in this example), the embedded system, by applying the propagation property, deduces the grade of gradual inclusion links that bind the added concept to the existing ones as described in Fig. 6.

Any query which is about the fuzzy predicate *FavoriteDepartureJourney* is evaluated over the available data which covers *pleasant* and *touristic* journeys such that:

$\forall t, \mu_{Favorite}(t) \geq max(min(0.5, \mu_{R_1}(t)), min(0.5, \mu_{R_2}(t)))$. ▪

Remark. The deduction of the minimal grade of inclusion of a fuzzy concept in a user-defined fuzzy concept is based on both their respective membership function and the formula:

$$A \sqsubseteq^{\alpha}_{Gö} B \Leftrightarrow min_x(\mu_A(x) \Rightarrow_{Gö} \mu_B(x)) = \alpha.$$

This computation is only significant if the concept B generalizes the concept A (in the same way as concept hierarchies in ontologies) which means that $Support(A) \subseteq Support(B)$. Indeed, if $Support(A) \nsubseteq Support(B)$ then the grade of inclusion is equal to 0; which is in fact worthless.

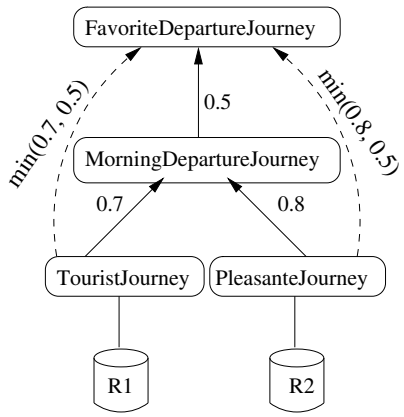

Fig. 6: Enrichment of the system.

VI. Conclusion and future works

The flexible querying approach developed in this paper is based on the combination of a fuzzy description logic (denoted fuzzy DLR-Lite) and the SQLf language that allows the expression of more complex fuzzy relations than those could be expressed by the SQL language. An interpretation of the gradual inclusion axiom based on the Gödel fuzzy implication is introduced. This interpretation provides a formal framework in which a restricted form of the negation operator is defined and a generalization to a tree of fuzzy relations is also proposed.

An implementation, based on algorithms for query evaluation introduced in [14], is in progress. It remains the development of an effective algorithm to compute the minimum grade of inclusion of fuzzy concepts added to the knowledge base. We also plan to extend the enrichment process to complex fuzzy predicates as those defined by division involving fuzzy relations.

***Abstract*- Translator Stylometry is a small but growing area of research in computational linguistics. Despite the research proliferation on the wider research field of authorship attribution using computational linguistics techniques, the translator stylometry problem is more challenging and there is no sufficient literature on the topic. Some authors even claimed that this problem does not have a solution; a claim we will challenge in this paper. We present an innovative set of translator stylometric features that can be used as signatures to detect and identify translators. The features are based on the concept of network motifs: small graph local substructures which have been used successfully in characterizing global network dynamics. The text is transformed into a network, where words become nodes and their adjacencies in a sentence are represented through links. Motifs of size 3 are then extracted from this network and their distribution is used as a signature for the corresponding translator.**

We then investigate the impact of sample size, method of normalization and imbalance dataset on classification accuracy. We also adopt the Fuzzy Lattice Reasoning Classifier (FLR) among others, where FLR achieved the best performance with a classification accuracy reaching the 70% mark.

Keywords-component; Translator Stylometry; Authorship Attributions; Network Motifs; Decision Tree Analysis; Fuzzy Classifier; Computational linguistics; Arabic-English Corpus.

I. INTRODUCTION

Identifying the author of a text is an important area of research in *"Computational Linguistics"* [1, 2]. There are many studies in *"Authorship Attributions"* [1-14]. These studies use the stylometric features of the authors to identify the original authors. These stylometric features include lexical, character, syntactic, semantic, and application-specific features [1-14].

On the one hand, the problem of authorship attributions is a difficult one and research challenges remain to exist in this area. On the other hand, the sub-problem of translator attributions is even harder and no solution for it exists so far.

Translation is a fascinating topic. While the original writer of a text had a specific mental picture in her mind and an intended message to be communicated through the text, a translator faces a different type of challenge. Successful translation necessitates that the translator needs to form the same mental picture as the original author of the text. Good translation does not stop at the level of mapping words, but extends to mapping meaning, mental pictures, imagination, and feelings. This is called the "loyalty" dilemma, where a wide discussion in the literature exists on the importance of maintaining the spirit of the original work.

If we compare author attributions to translator attributions, we find that the former is expected to have more signatures or discriminatory factors representing the choices made by the authors. Authors have many more degrees of freedom, where they can build their own identity as authors. Translators have less. Being constrained with the original text is a non-trivial limitation. This feature alone makes translator attributions a more difficult problem than author attributions. Nevertheless, we conjecture that translators attempt to have their own touch, signatures that can be used to detect who translated what. This is the hypothesis we hold in this paper.

The problem of how to identify translator stylometry is under-studied in the literature; probably because it is a harder problem. Some argue that translated work is considered as the original author's literature work rather than the translator's own work; however, no one can ignore the fact that translators are individuals [15]; they make personal choices which can affect the translation process. This is what we call "*Translator Stylometry*".

In this paper, we are going to introduce a new method that uses network motifs to identify the difference in translator's style. Our hypothesis is reformulated as "network motifs can be used to differentiate between different translators based on their own writing stylometrics". To test this hypothesis, we represent our datasets as networks. This is done by generating a word adjacency network for each piece of work by a translator in the dataset. To analyze and compare two networks, we can use their global statistical features; these include Shortest-path length, global centrality, clustering coefficient, etc.., or their structural design principles like the network motifs. Network motifs which are initially introduced by Ron Milo et al. [16] are patterns

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

(represented by small subgraphs) that are repeated in a real network more often than randomly generated networks.

Our method is an instance based approach, in which each sample generates its own network representing a single piece of work. After extracting the motifs, we use a classifier to classify the translated works. The accuracy of this classifier is used to test our hypothesis on a dataset comprising 30 chapters from the Holy Quran. We focus this paper on a text written in Arabic and translated into English.

II. BACKGROUND

A. Stylometry

The translator has to make many personal decisions while he is translating a piece of work. Examples of these decisions include the choice of words, discourse markers, modal verb selection, length of sentences, frames, and their own understanding of the original text.

In 2010, Winters discusses how a translator's attitude influences her translation [17]. He uses two German translations of the original novel "*The Beautiful and Damned*" (1922) written by F. Scott Fitzgerald. He shows that different translators' views affect the macro level of the novel, and how this from his point of view extended to influence the readers' attitude as well.

Xiumei uses relevance theory to explain the translator's style [18]. The findings demonstrated that, while the translator tries to balance between the original author's communicative intentions and the target reader's cognitive environment, she is still influenced by her own preferences and abilities; the outcome of all of that introduces her style.

The sample of papers reviewed above and others [17-19] demonstrate that studies in linguistics highlight that there are translator stylometric features existing in translated texts. However, the area of automatic identification and feature extraction of translator stylometric features has not seen an equivalent breed of research. The only attempt that we are aware of was in 2001 by Mikhailov and Villikka [15]. They tried to find *"stylistic fingerprints"* for translator by extracting three lexical features as: "Vocabulary richness", "Most frequent words" and "Favorite words". Their experiment was done on Russian fiction texts in addition to their Finnish translations. The lexical features that they used in the research failed to find stylistic fingerprints for different translators. Their conclusion was summed up in their title; that it is not possible to differentiate between translators. While this conclusion is inconsistent with traditional linguistic studies, it seems that it was sufficient to turn away researchers from this line of research over the last 10 years and since the publication of Mikhailov and Villikka paper in 2001.

B. Network analysis:

Newmann [20] defined a *Network* as "*a collection of points joined together in pairs by lines*"; these points are referred to as vertices or nodes and the lines are referred to as edges. Networks are everywhere; almost any system can be represented as a network. The traditional definition of a system is that it is a group of components interacting together for a purpose; this is a definition whereby network representation is paramount (components are nodes and interactions are through links). Many tools exist in the literature for analysing networks [21]. These tools vary from mathematical, computational, to statistical tools.

Network mining is the process whereby a problem is represented through networks and is searched to identify patterns. Examples of network mining problems include: link prediction, link type prediction, discovery of communities of interest, and discovery of infrequent or unusual patterns. Networks can be analyzed through measurements on the global and local level. Local measures attempt to capture from local constructs the global features of the network. A widely used local measure is network motifs. They are used to uncover network structural design principles [22]. Network motifs have been successfully used by different researchers in Biology [23, 24], Game theory [25], Electronic circuits [26], and Software [27].

C. Fuzzy classifier:

In our research, we are going to employ two fuzzy classifiers; the first one is *Unordered Fuzzy Rule Induction Algorithm* called FURIA [28], which is an extension to the well-known RIPPER algorithm [29] but using fuzzy rather than conventional rules. This algorithm is introduced in 2009 by Hühn and demonstrated promising results in some types of classification problems [28, 30].

The other fuzzy classifier is the Fuzzy Lattice Reasoning Classifier (FLR), which is initially introduced by Athanasiadis in 2003 [31] . This classifier uses the Fuzzy Lattices to create a Reasoning Environment. The rules are induced in a mathematical lattice data domain. FLR has the advantage that it can be incremental. It is also able to deal with missing data [32].

III. DATA

In our work, we are going to work on translation from Arabic to English. We choose the Arabic language as it is spoken by approximately 280 million native speakers [33]. It is also the official language for 26 countries[1]; it is the third most official language in the world after English and French. The Arabic language is gaining interest due to its socio-political importance. Millions of Muslims (both Arab and non-Arab) are studying the Arabic Language as the Holy Qur'an (the main religious text of Islam) is written in Arabic; also, all the Islamic terms are in Arabic. Therefore, the interpretation of the Arabic language has wider significance.

In our work, we are going to use "The Holy Qur'an" and the translation of its meaning as our corpus. The Holy Qur'an is a widely popular text as it is read on daily basis by Muslims. The total number of Muslims worldwide is more than 1.3 billions [34] but not all Muslims can read Arabic. Hence, there is a need to translate Qur'an meanings accurately that reflect and respect the original meaning. Despite the existence of many translations of this text, there is considerable dispute about the loss in the

1 As in World Atlas website http://www.worldatlas.com/ on 28th of January 2011

translation of Qur'an meanings due to the uniqueness of its textual characteristics. Another important consideration for the choice of this text was the expectation that given its religious significance, there would be minimal difference in the translations.

We obtained our corpus data from tanzil.net [2] website. This website introduces 14 different English translations for the meanings of Holy Qur'an. We choose two of them; the first one is by Muhammad Marmaduke Pickthall and the second one is by Abdullah Yusuf Ali. These two translations are among the few translations that have been assessed by Khaleel Mohammed in 2005 [35] as being among the most accurate translations.

IV. METHODOLOGY

A. Network formation

To establish the word-adjacency network from the dataset, we worked on Ayah (verse) level. Each word is represented by a node, and each ordered word adjacency is represented by edge going from the first occurring word to the following word. The frequency of two words adjacency is counted and represented by edges labels. The edges here represent an "occurring- before" binary relationship.

B. Features identification

Working on the lexical level, there are different features that can be extracted like word n-gram, vocabulary richness, word frequencies, and token-based [36]. We are trying to find the linkage between the words and how frequently they are used by different translators. We also attempt to extract the frequency of occurrence of patterns of ordered words –known in linguistics as 'lexical chunks'- in the text.

C. Motif extraction

The motifs are small subgraphs, usually 3, 4 or 5 nodes. For a subgraph with three connected nodes, we have only 13 distinguished possible subgraphs as shown in Fig. 1. While for four connected nodes, we have 199 distinguished possible subgraphs, and 9364 possible subgraphs for five nodes. This study uses 3-node motifs.

To illustrate how we can extract these 13 motifs, we give an example using a sample translation by "Yousif Ali"[2] for chapter 112 in the Holy Qura'n in Fig. 1. The sample text is "Say: He is Allah, the One and Only; (1) Allah, the Eternal, Absolute; (2) He begetteth not, nor is He begotten; (3) And there is none like unto Him. (4)".

For example, motif 7 (M7) represent the relationship between three nodes; two way relationship between the left and upper nodes, and one way relationship between the right and upper nodes. The first relationship is represented by the ordered appearance of words "is" and "He" in Aya (3), and the other direction where "He" before "is" in Aya (1). The second relationship is represented by the ordered appearance of words "nor" and "He" in Aya (3).

In motif 8 (M8), the first relationship that appeared in motif 7 is the same, while we has another two way relationship between the upper and right nodes, represented in Aya (3) where the word "He" appeared once before "not" and the second time after it.

We scanned the network for all of these possible subgraphs and counted each of them. All matches are counted, even if there are overlapping counts. We used ***MAVisto***[37] for pre-processing.

M1		Aya (1): "Say: **He** is **Allah**, **the** One and Only"	M2		Aya (1): "Say: **He** is **Allah**, the One and **Only**;"	M3		Aya (3): "**He begetteth not**, nor is **He** begotten;"	M4		Aya (1):"Say: He is **Allah**, the One **and Only**;"	M5		Aya(1): "Say: **He is Allah**, the One and Only". Aya(3): "He begetteth not, nor **is He** begotten;"	M6		Aya(2):" **Allah**, the **Eternal**, **Absolute**	M7		Aya(1): "Say: **He is** Allah, the One and Only" Aya(3): "He begetteth not, **nor is He** begotten;"	M8		Aya(1):" Say: **He is** Allah, the One and Only" Aya(3):" **He** begetteth **not**, nor **is He** begotten;"	M9		Aya(3):"He begetteth not, nor **is He** begotten;" Aya(1):"Say: **He** is Allah, the One **and** Only;" Aya(4):"**And** there **is** none like unto Him"	M10		Aya(3):" He begetteth not, nor **is He** begotten;" Aya(1):" Say: **He is** Allah, the One **and** Only;" Aya(4):" **And** there **is** none like unto Him"	M11		Aya(3): "He begetteth not, nor **is He** begotten;" Aya(1): " Say: **He is** Allah, the One **and** Only;" Aya(4): "**And** there **is** none like unto Him"	M12		Aya(3): "**He begetteth** not, nor **is He** begotten;" Aya(1): "Say: **He is** Allah, the One and Only;"	M13		Not applicable for this sample text	

Figure 1. All possible 3-nodes connected Subgraph

[2] ***Tanzil*** is a quranic project launched in early 2007 to produce a highly verified Unicode quran text to be used in quranic websites and applications. www.*tanzil.net*

D. Randomization:

To randomize the network, a random local rewiring algorithm is used. This algorithm keeps the degrees of the vertices constant. This is done by reshuffling the links: If A is connected to B (A->B), and C is connected to D (C->D).

Then, it makes a link from A to D and from C to B instead of the old links. But before applying the new links, it checks if these links already exist in the network. If so, this process is skipped and the algorithm attempts to find other links. This check is necessary to prevent having multiple links connecting the same vertices [38]. This process is repeated several times in excess of the total number of edges in the system to generate a randomized network [39]. We considered 500 randomized networks for each sample when conducting our experiments.

E. Significance test

To calculate Z-score, we need to calculate the average and standard deviation of occurrences of a motif in all randomized networks. The z-score is calculated as the difference between the frequency of this motif in the target network and the mean frequency of the generated randomized networks divided by the standard deviation of the frequency values for these randomized networks.

Since we are testing for confidence level %95, the z normal range is from -1.96 to +1.96. If the z-score is within this range, it is not significant. If it is outside this range, it is significant.

V. EXPERIMENTS

A. Research questions

The main question we attempt to answer in this paper is: Can we use network motifs to detect translator's style? The sub-questions of our research include:

- How can data normalization affect the bias of the sample?
- What is an appropriate sample size for detecting translator stylometry?
- How can class distribution balance/imbalance affect the results?

B. Expiremneal design

For all tests we used 30 parallel samples for two translators in addition to their original texts, so that we have 30 chapters from the Qur'an with their corresponding translations for two translators.

First: to address the normalization problem, we conduct 5 different tests considering the parameters as in Table 1: In the first test, we consider absolute values: The attributes of motifs represent f(xi) and f(yi). So, we have 13 attributes representing the 13 motifs and one attribute representing class label for 40 samples for training and 20 samples for testing considering class balance. The second test, using the same configuration of the first test but we tried to minimise the translator bias to her own writing; thus, we used the attributes of motifs to represent f(xi)/Σ(f(xi)) for the first translator, and f(yi)/Σ(f(yi)). In the third Test: The attributes of motifs represent f(xi)/f(zi) and f(yi)/f(zi). The conjecture behind this is to minimise the bias regarding the original text. While in the fourth test; we used the attributes of motifs to represent f(x)/(Σ(f (xi)* f(zi)) as a conjecture for minimising both the original text bias and translator bias. For tests 3 and 4, we need to divide by the frequency of Arabic motifs, which is sometimes zero, so we increment the number of motifs for Arabic text by 1. In the fifth test, we used 16 attributes which are the 13 motifs in addition to the number of nodes and edges and one attribute for class label.

Second: to address the sample size problem, we repeated the previous experiments with 10 sample chapters for each translator for training and 10 samples for testing, and compared these results to their corresponding results from the first experiment. The comparison is between an experiment with 10 samples as the training size and the other with 20 samples for the training size. In both cases, we maintained the test sample constant to have a fair comparison. The test size is 10 sample chapters, forming a total of 20 chapters covering both translators.

The third question was about class balance. To address such question we repeated the first experiment but considered randomizing the choice of the classes for training and testing purposes, and compared the results to the balanced experiment. Since we have 30 samples which introduce 60(30x2) instances, and we are considering an imbalance problem, we choose randomly 40 out of the 60 instances for training and the rest are used for testing.

C. Classifiers:

We used six different classifiers in our experiments to study which of them can produce more accurate results in our problem. These classifiers are:

1. FT: Functional Tree (FT) is a classifier that was introduced by João in 2004 [40]. This classifier uses decision tests based on a combination of attributes. FT is used with its default parameters using WEKA where the minimum number of instances at which a node is considered for splitting is set to 15, and the number of fixed LogitBoost iterations is set to 15 with no weight trimming.
2. NBTree**:** This decision tree uses Naive Bayes classifiers at the leaves. This hyperid classifier is firstly presented by Kohavi in 1996 [41].
3. Random Forest: This classifier generates a random number of decision trees that represent a forest to be used for classification[42].

TABLE 1 EXPERIMENTS PARAMETERS

$f(x_i)$	is the frequency of each motif in a sample i for the first translator
$\Sigma(f(x_i))$	is the summation of all frequencies of motifs in a sample i for the first translator
$F(y_i)$	is the frequency of each motif in a sample i for the second translator
$\Sigma(f(y_i))$	is the summation of all frequencies of motifs in a sample i for the second translator
$F(z_i)$	is the frequency of each motif in a sample i for the original Arabic text

We used this classifier with no constraints on the maximum depth of the trees and the number of attributes to be used, while the number of trees in limited to 10.

4. Random Tree: While constructing decision trees, a random number of attributes is chosen at each node to introduce a Random Tree classifier. We used the defaults parameters for this classifier which includes no backfitting or pruning.
5. FURIA: Fuzzy Unordered Rule Induction algorithm (FURIA) is discussed in detail in section II(C) of this paper; the parameters for applying this algorithm includes setting the minimum total weight of the instances in a rule to two, with two runs of an optimization procedure, and to use check for error rate that >= 0.5 for the stopping criterion.
6. FLR: Fuzzy Lattice Reasoning Classifier (FLR) is discussed earlier in section II(C) as well. The vigilance parameter value is set to 0.5 while running our experiments.
7. Multiclass Classifier: This classifier uses multi-class datasets with 2-class classifiers. In these experiments we used a logistic classifier. It applies error correcting output codes to increase the accuracy.

VI. Results and Analysis

Looking at Fig. 2; when we calculated the means of the 30 sample that we have for each translator, we found that the appearance of the motifs is different for each author. The second translator has the highest average for all motifs.

A. Paired T-test:

We applied paired t-test on the frequencies of motifs for each paired sample text, where the pair here represents two translations of the same original text. Two tail t-critical for alpha=0.05 and sample size of 30 is 2.04523.

Table 2 displays the t-calculated for each motif. All of them show that the differences between the frequencies for the two translators are significant.

B. Correlation between motifs:

We calculated the Pearson correlation coefficient between the motifs for each translator to find how often these motifs appeared concurrently, and then compared them to each other. We summarized the important differences in Table 3.

Since these motifs represent links between words in the text, and the correlation represents how often these motifs occur together, the difference between these correlations indicates difference in translator's style.

C. Experiment 1:

For Experiment 1; as Table 4 shows the best results are obtained using the functional tree classifier and multiclass classifier with test 5 which includes the number of nodes and edges with the motif frequency as inputs. The accuracy of these classifiers is 70%, which is the same accuracy of NBTree and FLR when applied to test 3, where the data is normalised against the original text bias.

D. Experiment 2:

For experiment 2, we test using smaller training sample size, which are 10 for each translator. We noticed that the results for the multiclass classifier are enhanced compared to the first experiment, while the functional tree accuracy decreased. The best accuracy obtained for this experiment remained at 70% as shown in

Table 5. This level of accuracy is obtained using Random Tree classifier and FLR classifier for test2 where the data is normalized against the translator bias. It is also obtained by the multiclass classifier with test5 which is the same result for this classifier in the first experiment.

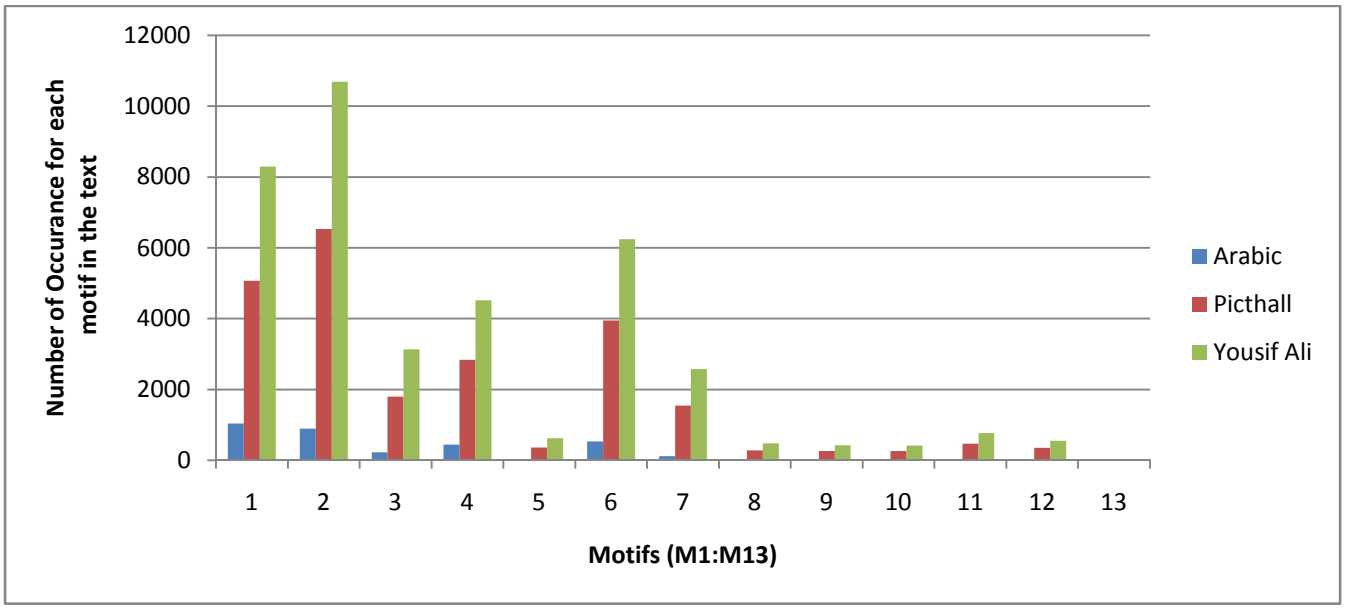

Figure 2. Comparison between the average of the 13 motifs for the Arabic, First English Translation, Second Translation

E. Experiment 3:

In the third experiment, we addressed the imbalance class problem. We used the 40 instances for training as 24 instances for the first translator "Pitchall" and 16 instances for the second translator "Yousif Ali". For testing, we used 20 instances, where 6 instances for "Pitchall" and 14 for "Yousif Ali". We noticed that most of the results were only 30% as shown in

Table 6 where the classifiers classified all the instances to belong to the first translator. The only classifier that gives acceptable results was FLR, where we got 70% accuracy for test 3 where data is normalized against the original text.

In general, the Random Forest classifier and FURIA consistently failed to detect the differences between translator's styles. On the other hand, the FLR classifier introduced acceptable results in the three experiments. Test 1 and test 4 failed to identify the translator's style, where in test 1 the data is not normalized, and in test 4 it is normalized against both the translator bias and the original text bias.

Both test 3 and test 5 introduced acceptable classifiers three times in the overall experiments. That indicates the importance of normalizing the data against its original text bias and the importance of including the number of nodes and edges into the attributes as it may help the classifier to normalize the data implicitly.

VII. CONCLUSION

Studying *"Translator Stylometry"* is a non-trivial task. While there has been research in linguistics and social sciences discussing the characteristics of each translator, this line of research is limited in computational linguistics. Contrary to previous findings that this problem does not have an automatic solution, this paper presented a first attempt to counteract this belief. We demonstrated that translators cannot disappear under the skin of the original authors; they have their own identities. Different translators represent the same idea in different ways. Although some existing authorship attributions couldn't capture these differences [15], this work shows that we can use social network analysis to differentiate between translators' styles. Detecting network motifs shows that each author is using certain patterns while writing. The proposed method introduces a classifier that can classify translated texts into their translators with accuracy of 70%. Fuzzy Lattice Reasoning Classifier (FLR) introduces the best results among seven tested classifiers. Normalising the data against its original text and the network size offers promising results. Further analysis is needed to explore this research area.

***Abstract*—A network intrusion detection system (NIDS) based on genetic-fuzzy association rules is presented in the paper, which mines rules in an incremental manner in order to meet the real-time requirement of a NIDS. More precisely, the proposed NIDS adopts the incremental mining of fuzzy association rules from network traffic, in which membership functions of fuzzy variables are optimized by a genetic algorithm. The proposed online system belongs to anomaly detection, not misuse detection. Some denial-of-service (DoS) attacks were experimented in this study to show the performance of the proposed NIDS. The results show that the proposed NIDS can detect DoS attacks in both effectiveness and efficiency.**

Keywords-Genetic-fuzzy association rules; incremental mining; membership functions; genetic algorithm; anomaly detection; denial-of-service (DoS) attacks

I. INTRODUCTION

Misuse detection, such as SNORT [1], aims to detect known attacks by characterizing the rules that govern these attacks. Thus, a rules update is most important and is frequently released by IDS vendors. However, the rapid emergence of new vulnerabilities and exploits makes misuse detection difficult to trust day after day. Anomaly detection is designed to capture any deviation from the profiles of normal behavior patterns. It is much more suitable than misuse detection for detecting unknown or novel attacks, but it has the potential to generate too many false positives. Many approaches have been proposed in previous literature concerning the design of anomaly NIDSs, such as neuro-fuzzy [2], support vector machine [3], decision tree [4], Bayesian Neural Networks [5], Naïve Nayes [6], genetic-fuzzy [7, 8], and fuzzy association rules [9, 10, 11, 12, 13, 14].

For a NIDS, effectiveness is usually measured by detection rate, false alarm rate, etc., and efficiency is measured by response time when an attack has occurred. This study focuses on how to create an anomaly NIDS, based on genetic optimized mining of fuzzy association rules, which can detect and react to a flooding attack in real-time. In contrast to traditional static mining for NIDS designs [9, 10, 11, 12, 13, 14], which can only be applied to offline NIDS, this system was designed based on an incremental mining approach, which enables the system to make a decision per time unit. In addition, a genetic algorithm was applied to help select the best membership functions for the fuzzy variables of mining. Consequently the performance of the proposed response system can be improved.

The remainder of this paper is organized as follows: Section 2 states fuzzy association rules and membership functions of a genetic algorithm; Section 3 introduces the genetically optimized incremental mining algorithm for fuzzy association rules; Section 4 describes the proposed NIDS by genetic-fuzzy association rules; Section 5 shows some experimental results; and Section 6 is the conclusions.

II. FUZZY ASSOCIATION RULES

Agrawal and Srikant proposed the well-known Apriori algorithm [15] in 1994 in which, given two thresholds of *mini_sup* and *mini_conf*, the algorithm will find all such rules as "$X \Rightarrow Y$" with *support* $\geq$ *mini_sup* and *confidence* $\geq$ *mini_conf*, where X and Y are subsets of the set of items, and $X \cap Y = \varnothing$. The rule $X \Rightarrow Y$ in the database D has *support* s if the percentage of records in D that contain $X \cup Y$ is s, and has *confidence* c if the ratio of the number of records in D that contain $X \cup Y$ to the number of records in D that contain X is c. Since the Apriori algorithm was designed for mining in databases with binary items, fuzzy association rules mining [16, 17, 18] has been one of the variations which has dealt with quantitative items.

While applying fuzzy association rules to an IDS (intrusion detection system) design, the term item, is replaced by the term feature, and thus, the term itemset is equivalent to the term feature-set, which is a set of features. Let $D = \{r_1, r_2, \ldots, r_n\}$ be the database and $I = \{x_1, x_2, \ldots, x_m\}$ represent all features appearing in D. The record r_i represents the ith m-tuple in D. Each quantitative feature x_k, $1 \leq k \leq m$, is associated with some fuzzy variables, say $v_1, v_2, \ldots, v_t$. Every fuzzy variable is represented by a membership function. For easy representation in the following, $MFx_i.v_j$, $1 \leq i \leq m$ and $1 \leq j \leq t$, is used to uniquely denote the jth membership function of feature x_i. In the mining of fuzzy association rules [18, 19], a fuzzy itemset consists of two parts: items and fuzzy variables, say $<X, U>$, where $X = (x_1, x_2, \ldots, x_k) \subset I$ is a collection of items (or features) and $U = (v_1, v_2, \ldots, v_k)$ is the collection of corresponding fuzzy variables to X in order. Suppose there are totally n records in the database. Then the support of $<X, U>$ is computed as:

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

$$\text{Sup}(\langle X, U\rangle) = \frac{\sum_{i=1}^{n}\prod_{j=1}^{k} MF_{x_j \cdot v_j}(r_i[x_j])}{n}, \quad (1)$$

where $r_i[x_j]$ denotes the value of feature x_j of the ith record. For example, suppose four features, *#packet*, *#SYN*, *#ACK*, and *#connection,* are of concern in a NIDS, and each feature has three fuzzy variables, say *low*, *medium* and *high*, then 4 × 3 = 12 membership functions are involved, i.e., $MF_{\#packet.low}$ denotes the low function of feature *#packet*, $MF_{\#ACK.high}$ denotes the high function of feature *#ACK*, etc. Suppose there are three records in the database, as shown in Table 1. Then the support of the fuzzy itemset <(*#packet*, *#SYN*, *#connection*), (*low*, *medium*, *low*)> is computed as ($MF_{\#packet.low}(3260)$ × $MF_{\#SYN.medium}(135)$ × $MF_{\#connection.low}(27)$ + $MF_{\#packet.low}(2170)$ × $MF_{\#SYN.medium}(75)$ × $MF_{\#connection.low}(65)$ + $MF_{\#packet.low}(6123)$ × $MF_{\#SYN.medium}(213)$ × $MF_{\#connection.low}(89)$) / 3.

TABLE I. RECORDS IN DATABASE, FOR AN EXAMPLE

#packet	*#SYN*	*#ACK*	*#connection*
3260	135	75	27
2170	75	43	65
6123	213	27	89

A fuzzy association rule has the form of "<*X*, *U*> ⇒ <*Y*, *V*>", where <*X*, *U*> and <*Y*, *V*> are two fuzzy itemsets and $X \cap Y = \varnothing$. Let $Z = X \oplus Y$ and $W = U \oplus V$, where ⊕ is the concatenation operation. The support of the fuzzy association rule "<*X*, *U*> ⇒ <*Y*, *V*>" is computed as Sup (<*Z*, *W*>), and the confidence of the rule is computed as Sup (<*Z*, *W*>) / Sup (<*X*, *U*>). For example, let us consider the following fuzzy association rule.

<(*#SYN*, *#ACK*), (*high*, *low*)> ⇒ <(*#connection*), (*medium*)>.

//if *#SYN* is high and *#ACK* is low, then *#connection* is medium

Its support is computed as Sup(<(*#SYN*, *#ACK*, *#connection*), (*high*, *low*, *medium*)>), and its confidence is computed as Sup(<(*#SYN*, *#ACK*, *#connection*), (*high*, *low*, *medium*)>) / Sup(<(*#SYN*, *#ACK*), (*high*, *low*)>).

III. FUZZY ASSOCIATION RULES THROUGH INCREMENTAL MINING WITH GENETIC OPTIMIZATION ON MEMBERSHIP FUNCTIONS

Two important keys need to be addressed for a successful NIDS based on fuzzy association rules. One is applying incremental mining, instead of static mining, to meet real-time demands. The other is a deliberate design for membership functions. We have proposed an incremental mining algorithm [20] to derive fuzzy association rules from network traffic. Based on the incremental mining algorithm, the paper further extends the algorithm to design an online detection system with genetic optimization in membership functions.

According to the proposed algorithm [20], packet information was collected to form one record every short time unit, and to mine out the newest rule set as the latest record was being gathered. Each current support value of a fuzzy itemset was kept in the memory for a time unit. As the next record was being gathered, the algorithm used the current support value to compute the next one, and then replaced it with the new one, as shown in the example below. Suppose the quantitative values of the four features, *#packet*, *#SYN*, *#ACK* and *#connection*, are measured for each time unit, and in sequence they are t_1 = (97, 310, 66, 311), t_2 = (215, 208, 75, 210), t_3 = (62, 710, 41, 88), …, t_i = (230, 86, 31, 720), …. For the fuzzy itemset <*X*, *U*> = <(*#packet*, *#SYN*, *#connection*), (*low*, *medium*, *low*)>, its support value *s* at t_1, t_2, t_3, …, t_i, …, is computed individually as:

s_{t1} = ($MF_{\#packet.low}(97)$ × $MF_{\#SYN.medium}(310)$ × $MF_{\#connection.low}(311)$) /1 → *tmp*;

s_{t2} = (*tmp* × 1 + ($MF_{\#packet.low}(215)$ × $MF_{\#SYN.medium}(208)$ × $MF_{\#connection.low}(210)$)) / 2 → *tmp*;

s_{t3} = (*tmp* × 2 + ($MF_{\#packet.low}(62)$ × $MF_{\#SYN.medium}(710)$ × $MF_{\#connection.low}(88)$)) / 3 → *tmp*;

…

s_{ti} = (*tmp* × (*i*-1) + ($MF_{\#packet.low}(230)$ × $MF_{\#SYN.medium}(86)$ × $MF_{\#connection.low}(720)$)) / *i* → *tmp*.

…

Since the contribution of previous records to the current support of a fuzzy itemset is ephemerally saved in the variable, i.e, *tmp*, the cost of mining time will not be prolonged as the aggregate records increase. The whole algorithm can be found in [20].

Membership functions design is important, and they usually have profound affects on the mined rules. This research adopts a genetic algorithm to select the best membership functions for the features applied in the proposed NIDS system. The membership functions applied in this paper are listed below, in which abs( ) is the absolute function, ^ is the power operation, and *a*, *b*, *c*, *d*, *e*, *f*, *g*, and *h* are the constants. The output value of a membership function falls in the interval of [0, 1]. Each feature has its own membership functions, i.e., with different constants from feature to feature. The goal of a genetic algorithm is to derive the most appropriate membership functions for every feature. As shown in Figure 1, for a feature, its membership functions before and after genetic evolution, are depicted by solid lines and dashed lines, respectively.

Fuzzy membership functions:

Low: $f(x) = 1 / (1 + \text{abs}((x - a) / b) \text{ ^ } c)$

Medium: $f(x) = 1 / (1 + \text{abs}((x - d) / e)^{\wedge} f)$

High: $f(x) = 1 / (1 + \exp(-g(x - h)))$

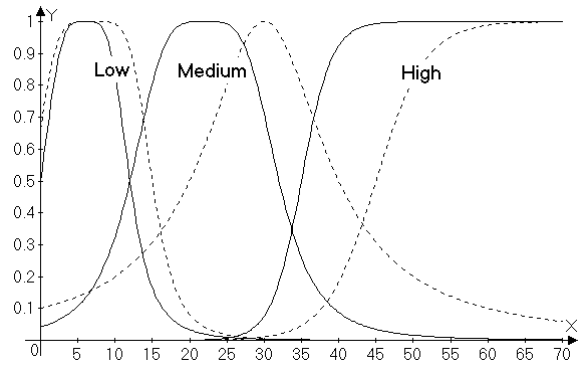

Figure 1 Fuzzy membership functions before and after genetic optimization

Suppose *n* features are considered in the NIDS design, then one chromosome in the genetic algorithm contains the *n* features' membership functions, as defined in Figure 2. The first chromosome in the experiment was constructed heuristically. An initial population, containing 30 chromosomes, was derived from the first chromosome by repeated application of the mutation process. In each generation, the fitness of each new chromosome was evaluated according to the performance of the proposed NIDS, using the fuzzy membership functions represented by the chromosome, i.e., the fitness function of the genetic algorithm was to maximize the overall accuracy in a given labeled dataset. A specified percentage of the chromosomes with high fitness were retained for the next generation. Then, parent chromosomes were repeatedly selected from the current generation, and new chromosomes were generated from these parents by crossover and mutation. One generation ended when the number of chromosomes for the next generation had reached the original population, i.e., 30 chromosomes. The evolution process was repeated for 250 generations.

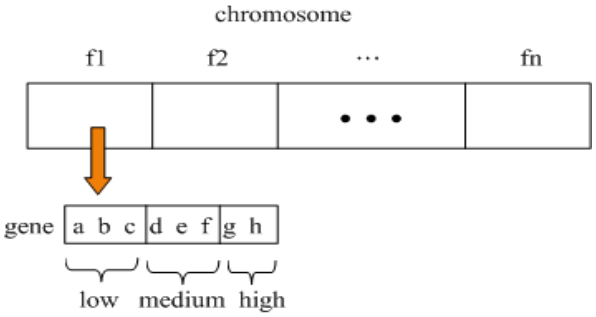

Figure 2 Gene and chromosome structures of evolution

IV. THE PROPOSED NIDS

The proposed system was designed for online detection and response to flooding attacks. A short time unit was defined, thus, the reaction of the system must be performed once every time unit. Two seconds defined one unit in this research, i.e., one record was generated regardless of the number of captured packets. In the training stage, attack-free network traffic information was collected at the rate of one record every two seconds, and the genetic optimized membership functions were derived in advance from a labeled dataset. The online response system consists of four modules. Module_A collected run-time network traffic information online, at the rate of one record every two seconds, and consistently sent the records to module_B. Module_B applied the genetically optimized incremental mining algorithm to generate the newest fuzzy rule set every two seconds. At the same time, module_C also performed the algorithm every 2 seconds on the attack-free data records, i.e., adding one new attack-free record every 2 seconds to the set of mined data records. The two newest rule sets from module_C and module_B were then sent to module_D for comparison, again, once every two seconds. If their similarity was below the threshold, an anomaly of network traffic could be found. Once an attack had been detected, three actions resulted: an alarm was inserted into the database, module_A was required to gather more detailed information about the attack and, finally, the filtering rule in the firewall could be changed dynamically. In the implementation, a round-robin strategy was applied on the attack-free records in module_C.

In this paper, the similarity between the two rule sets was defined as follows. Let $S1$ and $S2$ be two rule sets. The similarity between them was computed as:

$$sim(S_1, S_2) = \frac{SCORE1}{|S_1|} \times \frac{SCORE2}{|S_2|}, \quad (2)$$

where $|S_1|$, $|S_2|$ represent the number of rules in the sets, $SCORE1 = \sum_{\forall r \in S_1} score(r, S_2)$ and $SCORE2 = \sum_{\forall r \in S_2} score(r, S_1)$. For a single rule r with support s and confidence c and a rule set S, $score(r, S)$ was defined as:

If there is a rule $r' = r$ in S with support s' and confidence c', then $score(r, S) = 1 - \max(\frac{|c - c'|}{\max(c, c')}, \frac{|s - s'|}{\max(s, s')})$, else $score(r, S) = -\max(c, s)$. (3)

Two rules, r and r', are regarded as $r = r'$, if they have the same antecedents and consequents. Finally, let SCORE1 or SCORE2 be 0 if it was a negative value. In our system, for any fuzzy itemset, its support was computed by:

Current support = support due to the latest record * k + support due to all historical records * $(1 - k)$, where k is a constant between 0 and 1. (4)

V. SIMULATION RESULTS

In the experiments of this section, a commercial application named IP Traffic [21] was applied to produce background traffic which can generate any amount of TCP/UDP/ICMP packets by hardware limit. Two hosts running IP Traffic played sender and receiver, respectively, and the receiver in the LAN and the sender transmitting packets was deployed through the Internet. During the experiments of this study, the amount of network traffic remained from 0 to 80 Mbps through random connection and random flow size. One laptop launched flooding attacks against the victim located in the LAN through the Internet. Our system, deployed in the LAN, was coded by Microsoft Visual C++ - MFC and run on a laptop with Windows XP. A total of 1000 attack-free traffic records were derived from IP Traffic in advance and stored in the database, one at a time for every two seconds. As these records in the database were exhausted, they were cyclically reused.

TABLE II. 15-FEATURE LIST

IP:D.IP slots hit	TCP:checksum_error count
IP:MF_Flag count	IP:checksum_error count
TCP:S.IP+URG_Flag+URG data count	ARP:Size error count
IGMP:checksum_error count	TCP:URG_Flag+URG_data count
ARP:S.IP+ARP count	UDP:Same_length_interval count
IGMP:Length>1000 count	ICMP:Length>1000 count
TCP:Sequence_number==0 count	IP:(Total length>1400 || <40)&&TTL == 64 count
ICMP: Type error count	

All of the 15 features applied in this research are listed in Table 2, which were all derived from IP, TCP, UDP, ICMP, ARP, and IGMP headers. They were adopted to collect packet information and generate one record every two seconds. Some of the features were single condition, e.g., *D.IP slots hit*, and some were compound, e.g., *S.IP + ARP count*. The example, *D.IP slots hit*, for instance denoted how many slots of IP addresses were hit by network packets, according to their destination IP addresses. This study mapped a 32-bit IP address to one of 256 slots by its twice-folded IP address, i.e., mapping IP:x1.x2.x3.x4 to slot (x1⊕x2)⊕(x3⊕x4). The first three features in Table 2 before and after genetic optimization on membership functions are depicted in Figure3, Figure 4, and Figure 5, respectively. The before functions that were adopted in [20] are obtained by manually heuristic selections.

Figure 5 Fuzzy membership functions of the feature " TCP:S.IP+URG_Flag+URG data count " before and after genetic optimization

As all 15 features' membership functions after genetic optimization were used to replace that in the original NIDS system [20], the similarity degradation at DoS attacks are more apparent than ever had in [20], as shown in Figures 6-8 for Angryping Attack, ChinBomb Attack, and DeepThroat Attack, respectively. This represents that the modified NIDS, proposed in this paper, can be more precisely than its predecessor, because false positives can be reduced. The two red vertical lines in each figure denote the attack starting and ending time.

Three cases of k in Eq. (4), k = 0.2, k = 0.5, and k = 0.8, were considered separately in the experiments. Detail of the similarity in degradation from the *win32.fakeping* attack is illustrated in Figure 9. A *win32.fakeping* attack was remotely launched at the fifth time unit lasting for 10 time units of flooding; the attack was stopped at the fifteenth time unit. This system deployed in the LAN showed that the similarity began to degrade at the sixth time unit, even more so during the next ten units, and then started to upgrade at the sixteenth time unit. If the threshold of similarity is set to 0.5, the system, for the case of k = 0.2, would generate the first alarm at the seventh time unit (similarity value = 0.483554) and the last alarm at the twentieth time unit (similarity value = 0.478354). Ideally, the NIDS system in the LAN should show an alarm at the sixth time unit because an attack has occurred and to end the alarm at the sixteenth time unit because the attack has disappeared. Since historical data records are taken into consideration in the incremental design, it may be difficult for the similarity to immediately go down below the threshold as an attack occurs, and immediately go up above the threshold as the attack disappears. The smallest similarity value was 0.124654 for the case of k = 0.2 in Figure 9, occurred at the fifteenth time unit. It also can be concluded from Figure 9 that during the incremental mining the larger ratio of the latest record, i.e. k value, causes the system to become more susceptible. *Win32.fakeping* ceaselessly pings the victim machine with an abnormal size of payload.

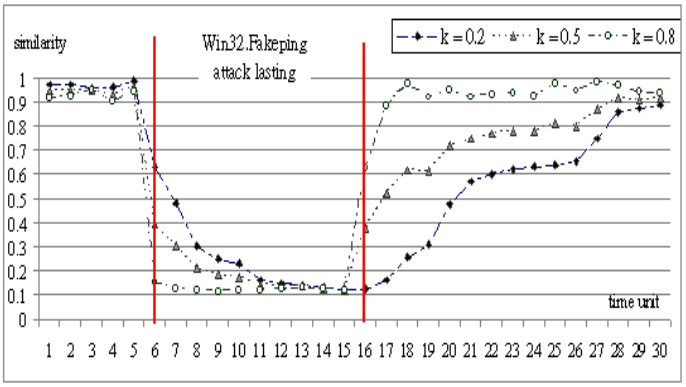

Figure 9 Similarity degradations while being Win32.Fakeping attacked

VI. CONCLUSION REMARKS

In the design, this proposed system has adopted incremental mining of fuzzy association rules, with genetic optimization on the membership functions. Experiments were conducted which demonstrated the effectiveness and efficiency of this intrusion detection system in detecting DoS attacks by an anomaly detection approach.

***Abstract*—Personalized web-based learning has become an important learning form in the 21st century. An earlier research result showed that a fuzzy knowledge extraction model can be established to extract personalized recommendation knowledge by discovering effective learning paths from an access database through an ant colony model. However, critical limitations arose when considering its applications in real world situations. In this paper, the aim is to improve the model by devising more efficient algorithms that requires a reasonable number of learners and training cycles to find satisfying good results. The key approaches to resolving the practical issues include revising the global update policy, an adaptive search policy and a segmented-goal training strategy. Based on simulation results, it is shown that these new ingredients added to the original knowledge extraction algorithm result in more efficient ones that can be applied in practical situations.**

Keywords- Web-based learning ;personalized recommendatio; learning style; fuzzy set theory; ant colony optimization

I. INTRODUCTION

As the explosion of information due to the Internet in modern age, it becomes more important and more difficult to retrieve information adapted to user preferences. Therefore, personalized recommendation systems are in need to provide proper recommendations based on users' requirements and preferences [10]. Recommendation systems also find their applications in the eLearning area, especially as personalized web-based learning has become an important learning paradigm in the 21st century. Since learning resources grow so abundant on the Internet that the problem of how to help learners get appropriate learning materials to fit their learning needs has become a popular research subject in the area of adaptive content delivery.

A challenging work of this research lies in how to discover recommendation knowledge efficiently from a huge access database of a web-based learning platform [1][2]. An earlier research of ours [6] showed that a fuzzy knowledge extraction model can be established to extract personalized recommendation knowledge by discovering effective learning paths from the access database through a novel approach that is inspired by the experience sharing mechanism of natural ants. This approach imitates the experience sharing mechanism of natural ants, which share the paths they have found leading to food by scattering pheromone along the paths. In this approach, learners play the role of ants, scattering trail marks in a proper way according to their learning performances along the learning paths characterized by appropriate learning contexts. These trail marks can then be used to discover effective learning paths for learners with specific learning styles and competency.

However, though the research results [6] revealed the theoretical potential of the proposed method in discovering effective learning paths for learners, critical limitations arose when considering its application in real world situations, such as the requirement of a large amount of learners and a long period of training cycles in order to discover good learning paths for learners. That requirement is impractical for large classes in life and the reasonable time for a course to accumulate good learning experiences should be as short as possible. Therefore, the aim of this research is to resolve the aforementioned issues by devising more efficient algorithms that basically run on the same ant colony model yet requiring only a reasonable number of learners and training cycles to find satisfactory good results.

II. LITERATURE REVIEW

In the context of personalized recommendation on the Internet, web usage mining has been used as a potential approach to fulfill the requirement of web personalization [4][11][12][13][14][15]. In some commercial applications, the problem is approached by building an anticipation model through analyzing the content of items that a user has purchased in the past or were in his personal preference list. Sometimes, the items can be those in the user's navigation history. However, this content-based approach has several shortcomings and critical issues, including that only a very shallow analysis of specific kinds of content (text documents, etc.) are available; users can receive only recommendations similar to their earlier experiences; and the sparseness problem of item rating information [16][17].

This research was supported by National Science Council of Taiwan under contract NSC 98-2221-E-130 -023

On the other hand, in the approach of collaborative filtering [10], items are recommended to a particular user when other similar users also prefer them. The definition of 'similarity' between users depends on applications. For example, it may be defined as users having similar ratings of items or users having similar navigation behavior. However, a pure collaborative filtering system also has several shortcomings and critical issues, including that the coverage of item ratings could be very sparse, hence yielding poor recommendation efficiency; it is difficult to provide services for users who have unusual tastes; and the user clustering and classification problems for users with changing and/or evolving preferences [18].

As far as learning on the web is concerned, the experiences that learners have left need to be further distinguished into good and bad ones in terms of learning effectiveness. Therefore, the aforementioned approaches to personalized recommendation have to be extended in some way so that they can distinguish good experiences from bad ones in terms of some performance measurement. Another fact that distinguishes recommendation systems for eLearning from other fields is that intrinsic characteristics of a learner, such as learning style and competency, need to be considered to deliver appropriate contents to his/her needs. From this view point, our approach can deal with the recommendation problem for personalized learning by considering all the special demands in a seamless way.

Finally, a research area that relates to this research is the development of a new paradigm for computational optimization algorithms, called ACO (Ant Colony Optimization) in computer science. The ant algorithm proposed by Dorigo (1996) [9] generated an artificial wisdom (heuristic) which was developed based on the behavior of nature ants to control the direction of finding good solutions to optimization problems. Computational threads, called artificial ants, are executed separately to find solutions based on their individual states. At each move of an artificial ant, the choice is made in a certain probabilistic distribution, which is determined by a proper combination of a priori information of the structure of good solutions and a posteriori information of the structure of previously found solutions. A posteriori information of the structure of previously found solutions is accumulated by the amount of "pheromone" spread over the moves of the solutions previously found. The better quality of a found solution is of, the more pheromone it will spread over its moves. In order to avoid the phenomena of "local optimization", evaporation of pheromone in a proper rate is allowed. It was also found that a global update of the pheromone amount along the moves of the best solution only is useful to speed the convergence of solutions.

Compared with the problem to be dealt with in this research, the problems to be solved by ACO algorithms are simpler in the sense that there is only one goal to be solved for all artificial ants, and the goal to be solved is independent of the internal states of the artificial ants during the search of solutions. In contrast, the problem addressed in this research considers different goals pursued by individuals with different and changing internal states. For example, a learner who is a beginner pursues a more achievable learning goal that is easier than the one pursued when s/he becomes an advanced learner.

III. THE ANT-COLONY MODEL

In the following, to facilitate a better understanding of the problem dealt with in this research, we first give a brief explanation about the term "learning experience". Learning experience is defined as the sequence of resource accesses, where resources refer to those in a web-based learning platform that are helpful for student learning, such as contents, assessments, learning activities and so on. Another term for learning experience we use interchangeably here is "learning path". Furthermore, "good" learning experiences refer to those that can help certain types of students (with specific learning styles and competency) to achieve significant improvement in learning performance. In other words, good learning experiences mean different for different types of learners. Finally, learning performance is assumed to be measurable by assessment tools such as those developed in [7]. Therefore, the "value" of a learning experience can be measured by the degree to which it can help students to improve their learning performance. Next, we present the main idea of our approach in the following sections.

In the context of web-based learning, learners learn through accessing online materials and doing self-assessments to evaluate their performance. Learners with different characteristics such as competency and learning styles may need different kinds of materials to meet their current learning needs. The problem here is how to provide appropriate recommendations for learners matching their individual characteristics so that they can learn to achieve optimal performance.

In this research, individual characteristics are described in terms of competency and learning styles. As for learning styles, categories developed by researchers can be a represented as a discrete symbolic set like $\{L_1, L_2, L_3, L_4\}$ for the Kolb styles [3]. Competency is represented as a numerical value, coding the level of a learner's proficiency in a certain concept of a specific domain. Furthermore, the competency level is divided into a fixed set of linguistic categories using fuzzy classifications. Without loss of generality, three linguistic categories of competency are used, that is, the "Novice", "Experienced" and "Master". For the limitation of the size of the paper, readers could refer to [19] for more details about fuzzy sets.

The problem is modeled as finding solution paths for different types of learners in a multiple-dimensional knowledge space consisting of nodes and edges, dictating the learning paths of learners with particular learning contexts, forming knowledge subspaces indexed by competency levels and learning styles. Specifically, each node in a knowledge subspace represents an online resource. An edge, labeled as *e*, linking from one node to another node represents the transition of the corresponding nodes caused by accessing a resource *e*. The knowledge space plays the role of recording, accumulating and sharing learning experiences with learner characteristics, including learner competency and learning styles, encoded appropriately.

For example, consider the knowledge subspaces illustrated in Figure 1, where a learner with learning style L_x and competency level *c* has the fuzzy competency levels

represented as $\mu_{Novice}(c) = 0.4$, $\mu_{Experienced}(c) = 0.8$, and $\mu_{Master}(c) = 0.2$. Suppose the learner is now in the knowledge node of $\{e\}$. When the learner accesses a resource f, it will lead him to the knowledge node of $\{f\}$. In this situation, the system will mark the learner's trail by adding an edge linking from $\{e\}$ to $\{f\}$ with a strength proportional to the learner's membership in the corresponding knowledge subspaces. After updating the trail marks in the knowledge subspaces, the learner's current state is relocated at the knowledge node of $\{f\}$. This event is called a "local" update of the trails in the knowledge subspaces.

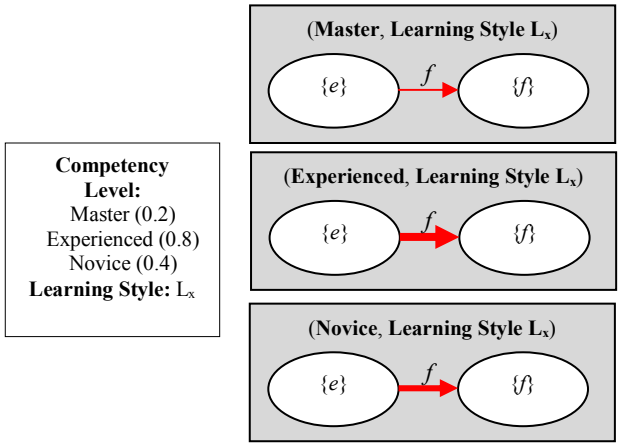

Figure 1. State transitions and local update in fuzzy knowledge subspaces.

Specifically, for a given learner x, the local update formula on the pheromone of an edge in a subspace S is given by (1):

Local update:

$$\tau = (1-\lambda)\tau + \lambda\Delta\tau$$
$$\Delta\tau = \mu_S(x) * \tau_0 \quad (1)$$

where τ is the current pheromone of an edge, λ is the evaporation parameter, $\triangle\tau$ is the change amount of pheromone, which is specified by $\mu_S(x)$ the user membership degree of the learner in the subspace S, and τ_0 is a fixed amount of pheromone.

On the other hand, Figure 2 shows how the trails in the knowledge subspaces are reinforced in the situation when changes of a learner's competency are affirmed through feedbacks obtained from either a self-assessment test or by a self-evaluation questionnaire. (It is assumed that learning styles are not changed during the learning course. Otherwise, the trail reinforcement also happens for changes of learning styles). Specifically, the edges of the path passed through in-between the change of learner states are updated in each knowledge subspace with an appropriate amount of trail marks dependent on the learner's membership in the corresponding knowledge subspaces. This is called a "global" update of the trails in the knowledge subspaces. The global update formula on the pheromone of a path in a subspace S is given by (2):

Global update:

$$\tau_{path} = (1-\rho)\tau_{path} + \Delta\tau_{path} \quad (2)$$

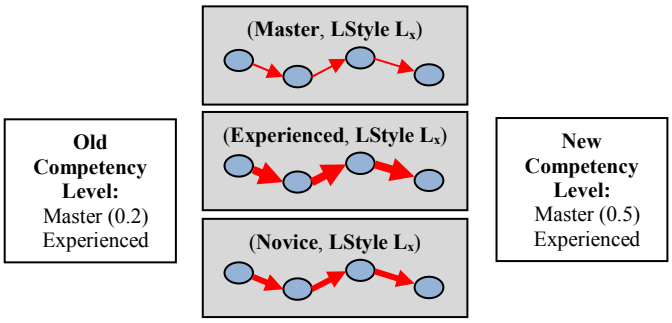

Figure 2. Learner state change and global update in fuzzy knowledge subspaces.

where τ_{path} is a set of pheromone values of the edges in a path, and ρ is the evaporation parameter, and $\triangle\tau_{path}$ is the change of pheromone values on the edges of the path, which is given by (3):

$$\Delta\tau_{path} = \mu_S(x) * \Delta D$$
$$\Delta D = effectiveness * \Delta Q \quad (3)$$

where $\triangle Q$ is a constant value, and $\triangle D$ increases when the learner's performance (effectiveness) in that session is better. The effectiveness of a learner's performance can be defined in a certain form dependent on applications. For example, the competency estimated by the assessment tool developed in [7] can be used to measure the learner's performance.

Now, as far as personalized recommendation is concerned, a knowledge subspace provides recommendations for a learner of certain characteristics by considering the membership degree to which s/he belong to it and the knowledge node that s/he is currently in. The transitions (resource) that leads out from the current node in each subspace are candidates for recommendation, and they are associated with a strength (amount of pheromone) that is computed as the product of the transition strength and the membership degree of the learner in the subspace. Different recommendation policies can be used in this phase. For example, recommendations can be given by selecting the top R-ranked transitions under the transition strength, where R is a number chosen by the system designer.

IV. The Revised Method

As shown in [6], the method has the theoretical potential in discovering effective learning paths for learners. Table I shows one of the results.

TABLE I. Number of Cycles Required for Different Effectiveness and Numbers of Learners [6]

Effectiveness	0.5	0.6	0.7	0.8	0.9
100 人	48	55	95	172	251
200 人	23	28	47	86	115
500 人	9	11	18	33	45
1000 人	5	6	10	17	33

However, critical limitations arose when considering its applications in real world situations. For example, for a large class of 100-200 students, it would take almost 300 training cycles to discover good learning paths for learners. Though increasing the number of students to 1000 might help, it is still impractical for real large classes in life, where the number of students is often limited by 200 to 300.

Three observations are worth mentioning from the research of [6]:

1. The more number of virtual ants involved, the sooner the network gets staged (the situation of being unable to improve paths easily).

2. Another fact is that during the searching of good paths, the memory of those good paths are apt to lost if more number of virtual ants are passing through them due to the local-update effect. This means that in certain situations, adding more virtual ants might cause the system to lose memory of its good paths due to the fading pheromone on the edges.

3. One last fact is that in situations of low global evaporation rates, newly found good paths are apt to hold the pheromones it had during global updates. That is, they temped to be dominated by their old states. In contrast, in situations of high global evaporation rates, newly found good paths are apt to be dominated by their current states.

The key approaches to resolving the practical issues will include (1) revising the ant exploration and global update policy, (2) adopting segmented-goal training strategy, and (3) adopting an adaptive randomness control policy, In the following, we describe the rationale behind each new approach to solving the practical issues of the problem.

A. Revise the ant exploration and global update policy

The original global update policy is to activate the global update mechanism once a virtual ant has produced its evaluation feedback. That is, the system updates the pheromone trail using all the solutions produced by the ant colony. As indicated in [8][9], it would be more effective if only the best solution found since the beginning of the computation is used to globally update the pheromone, since it avoids long convergence time by directly concentrate the search in a neighborhood of the best path found up to the current iteration of the algorithm.

B. Adopt segmented-goal training strategy

It was also observed in [6] that the length of the goal path also affect the convergence time of the algorithm. As the length increased, the convergence time also increased in an exponential way. To handle this problem, one possible way is to divide a learning session into more but a reasonable number of stages, with a sub goal specified in each stage.

C. Adopt an adaptive randomness control policy

In our previous work [6], the exploration policy is a two-fold decision. First, a random number in-between 0 and 1 is generated, and if it is larger than a threshold (say 0.1) the virtual ant would explore a visited neighboring node according to the accumulated probability distribution formed from the out-going edge weights of its current knowledge node. Otherwise, it will randomly choose an unvisited neighboring node. In other words, the decision about whether to explore a new edge or follow existing good (more weighted) edges is determined by a randomness control parameter, which was set to 0.1.

The original exploration policy in [6] may incur another problem when quality of the good paths is in good situations. In that circumstance, it should be better to deterministically follow the edges of the paths. On the other hand, when the quality of the good paths is poor, exploration of unvisited edges should be encouraged. Therefore, the new ant exploration policy is updated so that it will prefer choosing best nodes if the quality of the current best paths is good enough. To achieve this goal we adopt the "value" of the best-found solutions computed by (5) as an indicator of the system's solution quality.

V. DESIGN OF SIMULATION

To investigate whether the proposed method is useful for extracting effective recommendation knowledge, a simulation program was developed that simulates learners of different competency levels and learning styles exploring a web-based knowledge space consisted of material documents based on the aforementioned path finding model. In one simulation run, simulated learners explore the knowledge space by receiving system recommendations of documents or choose a document as they wish to explore. The decision about whether to explore a new edge (document) or follow existing edges (documents) is determined by a randomness control parameter, which can be fixed (say 0.1) or adaptive.

In the program, we predefined a set of "good" learning paths to be found for simulated learners of different competency levels and learning styles. The competency of a simulated learner gets an increment to a degree proportional to the similarity between its current learning path and the "hidden" good learning paths. The increment of competency will be fed back to the ant colony model according to the global update mechanism. In particular, the similarity between a learner's learning path and a "hidden" good learning path is calculated as follows [5]:

$$\text{Similarity}: S = S_1 + S_2 + \ldots + S_i + \ldots + S_n$$
$$\text{hidden good path}: X = X_1 X_2 \ldots X_j \ldots X_n$$
$$\text{user's path}: Y = Y_1 Y_2 \ldots . Y_i \ldots . Y_m$$
$$\text{for } i = 1, \ldots, n,$$
$$(1) \exists j, j = 1, \ldots, m, \text{such that } X_i = Y_j \text{ and } i = j \Rightarrow S_i = \frac{1}{n}$$
$$(2) \exists j, j = 1, \ldots, m, X_i = Y_j \text{ but } i \neq j \Rightarrow S_i = \frac{1}{n} * \frac{1}{|i - j|}$$
$$(3) \forall j, j = 1, \ldots, m, X_i \neq Y_j \Rightarrow S_i = 0$$

As a result, for a learner with a learning path of $Y = Y_1 Y_2 \ldots . Y_i \ldots . Y_m$, its effectiveness regarding to the hidden good path of $X=X_1X_2\ldots X_j\ldots X_n$, is defined as (5):

$$effctiveness(s, A) = \mu_A(s) \times Sim \quad (5)$$

where $\mu_A(s)$ is the degree that the learner belongs to the subspace of competency level of A.

The simulation program runs iteratively for a number of training cycles, and in each cycle a virtual learner can give a number of self-evaluation feedbacks as is given by (5) to the system. The effectiveness of one simulation run is defined as the best similarity between user learning paths and the "hidden" good paths.

VI. Results and Discussion

The simulations are run under different combinations of strategies and parameter settings. Specifically, the ant number can be 50, 100, and 200; and the GE (Global Evaporation) rate can be 0.01, 0.1 and 0.9; and the goal structure can be single-goal or segmented-goal; and the meta-control for search can be fixed or adaptive. The local evaporation rate is set to 0.01 for all simulations. All the simulations are run within 100 cycles and three times of intermediate feedbacks for each cycle. The size of the search space is determined by 30 resource items with the maximum length of the goal sequence set to 10.

Figure 3 shows the effectiveness of the algorithm under "fixed" randomness control and single-goal strategies with different number of ants (50, 100, 200) and GE settings (0.01, 0.1, 0.9); while Figure 4 shows the effectiveness of the algorithm under "adaptive" randomness control and segmented-goal strategies with the counter-parameter settings. From the figures, it can be seen that the algorithms get convergent quite fast, and as is common in ACO algorithms, the phenomena of "stagnation" appears in the algorithms. It also seems that different combinations of the ant number and GE settings have higher impacts on the effectiveness for algorithms under "adaptive" randomness control and segmented-goal strategies than those under "fixed" randomness control and single-goal strategies.

To further investigate the effect of the proposed strategies on the effectiveness of the algorithms, look at Figures 5-7. From Figure 5, it can be seen that under the fixed randomness control strategy, the algorithm equipped with segmented-goal strategy works comparable with the one equipped with the single-goal strategy.

From Figure 6, it can be seen that under the adaptive randomness control strategy, the new algorithm equipped with segmented-goal strategy outperforms the one equipped with the single-goal strategy in effectiveness.

From Figure 7, it can be seen that the new algorithm under the segmented-goal and adaptive randomness strategies has higher effectiveness than the one with the single-goal and fixed randomness strategies.

Furthermore, as shown in Table II and III, the new algorithm under the segmented-goal and adaptive randomness strategies requires few cycles than the one with the single-goal and fixed randomness strategies. And they are both much better than the original one reported in [6], as shown in Table I. As a result, the combinations of the new ingredients added to the original knowledge extraction algorithm can result in more efficient algorithms in the long run.

VII. Conclusion

In this paper, an improved ACO algorithm is devised to handle the problem of personalized recommendation for Web-based learning. It was verified through simulation that the segmented-goal training and meta-search control strategies proposed in this paper are useful for extracting personalized recommendation knowledge with a smaller amount of learners and training cycles. This makes our algorithm more suitable for practical situations. In the future, we will conduct experiments on real students to investigate its effectiveness in sharing good learning experiences among learners.

***Abstract*—Collaborative Filtering (CF) has been applied to many commercial systems successfully, such as IMDB, Netflix and son on. The basic idea of a CF system is to generate recommendations based on the experiences of past similar users. The users' option can be categorized into objective and subject information. The former was furnished by the common users and the later represents solicit opinions provided by experts (such as film critics). Both information types are valuable and important for the CF system. This study attempts to propose a novel collaborative filtering framework based on fuzzy set theory which integrates the subjective and objective information. The new methodology not only provides a comprehensive result but also solve the problems of traditional CF system, new user and new item. Finally, an experiment is performed, and the result indicates that the proposed methodology produces high-quality recommendations.**

Keywords- Data mining, recommender system, collaborative filtering, fuzzy set theory, objective evaluation, subjective evaluation

I. INTRODUCTION

E-commerce (EC) has been growing rapidly in the last decade. More and more items, however, result in an information overloading problem. In other words, consumers have to browse a huge of product lists to determine their final needs. In response to the above issue, an idea of the online product recommendation systems is proposed to assist customers for reducing these redundant information and offer advice to find suitable products for facilitating online decision-making [9, 15].

Generally, the study of recommender systems can be divided into three categories: (1) content based recommendation, (2) collaborative recommendation and (3) hybrid approaches [1]. Collaborative filtering (CF) is the most successful technologies among the above-mentioned systems and has been applied in many applications such as Amazon.com, Netflix, and MovieLens [8, 14, 15]. Basically, the idea of CF is to provide the users the recommendation based on their personal profile of previous rentals and the rentals of other similar customers. That is, the CF systems use historical data on user preferences or behavior to predict how new/old users will act.

The recommender system is the most useful way to help consumers to purchase products in an EC system. The information generated from the experiences of past similar users in a traditional recommender system is called the objective information. This kind of information does not include the influence of domain experts or opinion leaders on the customers' purchasing decision. Consider the following scenario: someone goes to see a movie on Saturday; he will check the film review from many difference ways, such as: Yahoo movie and IMDB. Because the influence of domain expert on consumers is self-evident, it will be better if the opinion from domain expert can be involved in the recommender system. Therefore, this research proposes a new integrated approach, which combines the subjective and objective information to generate recommendations for an active consumer. The subjective information solicits opinion from domain experts or option leaders [5, 12, 22]. The objective information clarifies the active user's preference based on the similar users' preference or the perdition from his past experience.

There are some common limitations in the traditional CF systems: (1) the new user, (2) new item and (3) sparsity problems [1]. They may cause the system to provide the lower quality recommendations. Therefore, this study attempts to propose a novel recommendation methodology which aggregates both the subjective and objective information to recommend items to address these limitations. In addition, if a user's preference to be provided in systems is not sufficient, the proposed method still can give recommendations from the subjective information.

Also noted herein, most previous methods are based on users' ratings which suffer from the effects of personal differences in scoring behavior. Generally, assessing users' preference by assigning precise values (rating) is difficult for users. Therefore, a fuzzy linguistic assessment (called fuzzy set theoretic method, FTM) is adopted in the proposed methodology. Linguistic assessment is based on words rather than numbers. This assessment can approach human perception, making it easier to evaluate qualitative problems [8, 20].

The proposed approach has the following two major advantages for recommender systems. First, the proposed algorithm aggregates the subjective and objective information to generate recommendations. The processing of opinion merged is more natural for the consumer decision process.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Second, we present a new idea by applying the fuzzy linguistic model. Use of linguistic terms to present human beings' mind is a better way to understand the users' preference.

This paper is organized in the following sections. First, this study will formally define the problem in Section 2 and propose the algorithms in Section 3. Then, we evaluate the effectiveness of the proposed methods in Section 4. Finally, conclusions and valuable discussions are stated in Section 5.

II. Related Work

In a recent survey of state-of-the-art recommender systems they can be classified into collaborative, content-based and hybrid approaches. The classification is dependent on how recommendations are made.

Collaborative filtering is widely used and is the preferred method for personal recommendation. Recommendations are made for items that people with similar tastes and preferences have liked in the past. Many systems, such as that of Amazon.com [13], Sarwar [14], Hofmann [11], and GroupLens [16], have adopted this technique.

CF algorithms can be divided into two main categories [1]: User-based and Item-based. The former combines the similar users' previous preferences to make rating predications. The later is to compute the similarity between items, and then selects the most similar one.

The basic purpose for the CF algorithm is to generate recommendations from the experiences of past similar users. Most CF-based algorithms recommend items for users based on the nearest-neighborhood method [7, 10, 11]. A typical nearest-neighborhood procedure can be separated into three steps. The first step is to determine a neighborhood for the active user or item through the similarity value, which is usually defined by the Pearson correlations. Then, a prediction is calculated from a weighted combination of selected neighbors' ratings for the active user or given item. Finally, a descending sorted list is made from these predications. Recommendations are generated by choosing the top N items on this list.

Yager gives a methodology for using fuzzy set methods to represent the content knowledge in a content-based recommender system[18]. He assumes the availability of a representation scheme for each object that allows the development of an appropriate tool to calculate the similarity relationship for the set of objects. A different approach is to use fuzzy values to represent the attributes of an item. The proposed recommendation strategies are purely content-based. Zenebe followed the concepts of Yager to propose a new approach which uses items features such as background data and user feedback as input [22].

III. Problem Statement and Definitions

A. Problem Description

Let $U = \{u_1, u_2, ..., u_m\}$ and $I = \{i_1, i_2, ..., i_n\}$ denote all users and the set of all distinct items, respectively. A preference function, $\mathrm{P}_{u_i}(i_p)$, represents user u_i's preference for the item i_p. The active user is defined as u_a and the domain expert can be a subjective user denoted us. The goal of this study is to propose new algorithms which aggregate both the subjective and the objective information to make prediction for unrated items. After having the predicted information, the top-N recommendations will be derived for the active user.

B. Problem Definitions

1) User's Preference Representation Using Fuzzy Set

As stated previously, it is nature for users to assess their preference function based on words rather than numbers [2, 4, 22]. The preference function can be defined by a linguistic term. The semantic meaning of each term can be quantified by fuzzy numbers.

The preference function illustrates user u_i's preference for the items i_p. The number of users is m and the number of items is n. The preference function $\mathrm{P}_{u_i}(i_p)$ is determined as follows:

$$P_{u_i}(i_p) = \langle q_{ip}^1, q_{ip}^2, q_{ip}^3, q_{ip}^4, q_{ip}^5 \rangle, \quad q_{ip}^k \in [0,1],\ 1 \le k \le 5,\ 1 \le i \le m,\ 1 \le p \le n \tag{1}$$

In Eq. (1), $\langle q_{ip}^k \rangle$ denotes 5-touples used for the user u_i preference degree on item i_p by mapping the linguistic terms listed in Table 1. As shown in Table 1, the linguistic terms "highly recommend", "very like", "like", "somewhat like", "no comment", "somewhat dislike", "dislike", "very dislike" and "hate" are used to represent the degree of user's preference in this study.

TABLE I. The mapping of linguistic terms and 5-touples.

Linguistic term	5-tuples
highly recommend very like	< 1, 0, 0, 0, 0> < 0.8, 0.2, 0, 0, 0 >
like somewhat like	< 0.3, 0.6, 0.1, 0, 0> < 0.1, 0.5, 0.4, 0, 0 >
no comment	< 0, 0.25, 0.5, 0.25, 0 >
somewhat dislike dislike	< 0, 0, 0.2, 0.6, 0.2 > < 0, 0, 0.1, 0.7, 0.2 >
very dislike hate NULL	< 0, 0, 0, 0.2, 0.8 > < 0, 0, 0, 0, 1 > <0, 0, 0, 0, 0 >

For example:

If user u_a likes item 1 very much, we may set $P_{u_a}(i_1)$ = "very like" = <0.8, 0.2, 0, 0, 0>. In other words, $P_{u_a}(i_2)$ will be NULL if user u_a does not provide rating for item 2.

2) Similarity Measure

The user's preference function is expressed by a fuzzy number. The Euclidean fuzzy near compactness is widely used to assess the distance of similarity between two fuzzy numbers. While the Euclidean near compactness is close to 1, the degree of similarity becomes higher.

The preference function of user u_i and u_j can be expressed as $P_{u_i}(i_p)=\langle q_{ip}^1, q_{ip}^2, q_{ip}^3, q_{ip}^4, q_{ip}^5\rangle$ and $P_{u_j}(i_p)=\langle q_{jp}^1, q_{jp}^2, q_{jp}^3, q_{jp}^4, q_{jp}^5\rangle$

The similarity $S_{u_i,u_j}(i_p)$ between u_i and u_j for the item i_p is defined as Eq. (2).

$$S_{u_i,u_j}(i_p)=1-\frac{1}{\sqrt{5}}\left(\sum_{k=1}^{5}\left(q_{ip}^k-q_{jp}^k\right)^2\right)^{1/2} \tag{2}$$

For example: if user u_a likes item 1 very much, we may set $P_{u_1}(i_1)$ = "very like" = <0.8, 0.2, 0, 0, 0>. In other words, $P_{u_2}(i_1)$ = "like" =< 0.3, 0.6, 0.1, 0, 0>

$$S_{u_1,u_2}(i_1)=1-\frac{1}{\sqrt{5}}\left(\sum_{j=1}^{5}(0.8-0.3)^2+(0.2-0.6)^2+(0-0.1)^2+(0)^2+(0)^2\right)^{1/2}=0.71$$

The average degree of similarity S(u_i , u_j) between u_i and u_j is defined as

$$S(u_i,u_j)=\frac{\sum_{q=1}^{|Z|}S_{u_i,u_j}(i_q)}{|Z|}, \tag{3}$$

where Z is the set of items for which users u_i and u_j provide ratings simultaneously and $|Z|$ is the number of items .

3) Generate The Prediction for Unrated Item

Once the neighbors are found, we can combine the preference value of neighbors to compute a prediction value on unrated items for the active user. The influence of different neighbor will not be equal. The following weight function denotes the influence of user u_j on the active user u_a It is expressed as:

$$w_{u_j,u_a}=\frac{S(u_j,u_a)}{\sum_{N}S(u_k,u_a)} \tag{4}$$

As shown Eq. (4), each neighbor should be weighted by the similarity value. The higher similarity value between a neighbor and the active user will cause the larger weight to account for the prediction value. Therefore, we can derive a weight vector W^a based on the normalized similarity from neighbors.

To generate the perdition for the active user's preference degree on item i_p, the process can be implemented through the composition matrix operation $W^a \circ E^a$. The matrix E^a, called evaluation matrix, contains the linguistic term of each neighbor's preference.

Let the number of neighbors be n. The prediction for the preference of u_a for item i_p is defined as follows:

$$\begin{aligned}Y^a &= W^a \circ E^a \\ &= \begin{bmatrix}w_1^a & \dots & w_n^a\end{bmatrix}\circ\begin{bmatrix}P_{u_k}(i_p)\\ .\\ .\\ .\\ P_{u_n}(i_p)\end{bmatrix} \\ &= \begin{bmatrix}w_1^a & \dots & w_n^a\end{bmatrix}\circ\begin{bmatrix}q_{kp}^1 & q_{kp}^2 & q_{kp}^3 & q_{kp}^4 & q_{kp}^5\\ . & . & . & & \\ q_{kn}^1 & q_{kn}^2 & q_{kn}^3 & q_{kn}^4 & q_{kn}^5\end{bmatrix} \\ &= \begin{bmatrix}y_1^a & \dots & y_n^a\end{bmatrix}\end{aligned} \tag{5}$$

Where $y_j^a=(w_j^a \bullet q_{kp}^j)\oplus\dots\oplus(w_n^a \bullet q_{kn}^j)$ and "$\bullet$", "$\oplus$" are defined as algebraic product (a $\bullet$ b = ab), bounded sum (a$\oplus$b = *min* {1, a + b}), respectively.

For example, Let the weight vector W be [0.36 0.33 0.31] and the preference matrix of item i_p be expressed as:

$$E=\begin{bmatrix}0.8 & 0.2 & 0 & 0 & 0\\ 0.6 & 0.3 & 0.1 & 0 & 0\\ 1 & 0 & 0 & 0 & 0\end{bmatrix}$$

Finally, user ua's preference for item i_p can be conducted

$$Y = W \circ E = \begin{bmatrix}0.36 & 0.33 & 0.31\end{bmatrix}\circ\begin{bmatrix}0.8 & 0.2 & 0 & 0 & 0\\ 0.6 & 0.3 & 0.1 & 0 & 0\\ 1 & 0 & 0 & 0 & 0\end{bmatrix}$$

= [0.796 0.171 0.033 0 0]

The proposed system will recommend item i_p for user u_a.

A defuzzification process is necessary in order to generate a ranked list of recommendations for the active user u_a. There are several defuzzification methods, such as center of gravity, center of sum, maximum method and so on. The most popular is the center of gravity method which can be defined as follows:

$$y^*=\frac{\sum_{i=1}^{5}y_i^a\times(5-i+1)}{\sum_{i=1}^{5}y_i^a} \tag{6}$$

If the defuzzification value y^* of the prediction for item i_p is larger than 4, the framework will put the item i_p into the recommendation list.

IV. SOLUTION FRAMEWORK

This section details the proposed algorithm which is similar in spirit to the classical memory-based CF approach. To model the users' perceptions of preference, the system defines nine linguistic terms shown in table 1 to represent the degrees of preference. Each user has his/her own perception of the approximate value of each linguistic term. The proposed framework is illustrated in Fig.1.

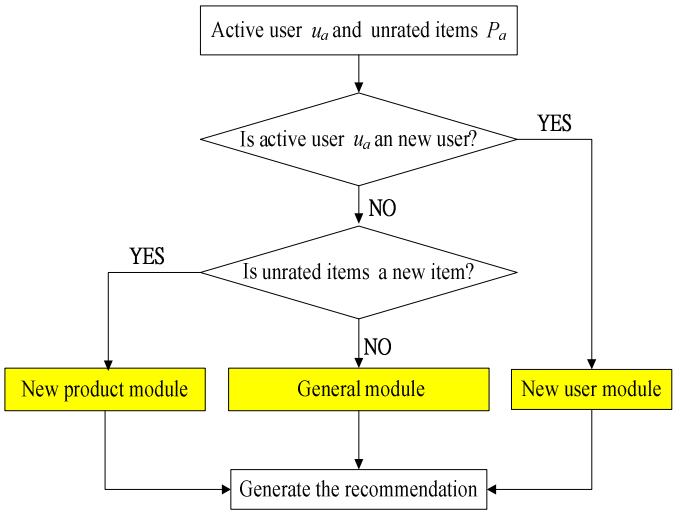

Figure 1 The flowchart of the proposed framework.

Fig. 1 shows the flowchart of the proposed framework. When the active user is an old user and the unrated item has been rated by other users, the framework will use the general module to make prediction. If the active user is an old user and the unrated item is new, the system will use the new item module. However, if the active user is a new user, the system will furnish the subjective information to make a prediction. We will explain each step in detail as follows.

A. New Product Module

New products are added regularly to recommender systems. When the new product launch, some domain experts will write the product review. For example, when a new movie launch, there are some film review written by famous film critic. To calculate the similarity between the active user and the subjective user, the result will demonstrate whether the active user like mainstream films. We compute the average similarity $S_{u_s,u_a}(i_q)$ between subjective user u_s and u_a for the item i_q based on Eqs. (2) and (3). Then the proposed algorithm will use Eqs. (4) and (5) to predict the value.

B. New User Modeule

For users that are new to the recommender system, information about their preferences is initially unknown. We can furnish the subjective user's information to the new user.

C. General Modeule

There are four steps in this module. The nearest-neighbor technique and user-based approach are applied to find the users similar to active user u_a. Neighborhood, *Neighbor* (u_a), is a set of users who are similar to u_a. The aggregated information from all neighbors' preference could be represented as the objective users' opinion. The proposed algorithm will make prediction based on the aggregation of objective and the subjective users' information.

Input:
Set of items: I, Set of users: U, Subjective user: u_s, Active user: u_a
Subjective users' preference, objective users' preference
Active user's preference, Set of unrated items for u_a: P_a
Output: Top N recommendations
Method:
// Subjective module
for each $u \in U$
Use Eq. (3) to compute average degree of similarity S(u, u_s)
According to the average similarity S(u, u_s), we rank all users into a rank list RL
// Objective module
Based on S(u_a, u_s) and choose $k+v$ nearest neighbors from RL to *Neighbors*
for each $u \in$ *Neighbors*
Use Eq. (3) to compute average degree of similarity S(u, u_a)
Select the best k nearest neighbors from *Neighbors* to *Neighbor* (u_a)
Use Eq. (4) to compute the weight of influence in *Neighbor* (u_a)
Construct a weight vector W^a
Call *Generate the predictions and recommendations procedure*

■ Subjective Procedure:

The subjective procedure is a preprocessing phase, a special procedure in the proposed algorithm. This job is usually performed offline and the results are stored in a database. Let the subjective user be denoted by u_s. When we input one user's preference data, the system automatically computes the average similarity between this user and subjective user using Eq. (3). We will generate a ranking list which contains all users, based on the average similarity between each user and the subjective user.

■ Objective Procedure:

(1) Creating Possible Neighborhoods for an Active User u_a

According to the similarity between the active user and the subjective user S(u_a, u_s), the system filters the nearest $k + v$ neighbors to a temporary buffer *Neighbors*. Eq. (3) will be used to compute the average degree of similarity of each user to the active user. Next, we choose the best k nearest neighbors to form *Neighbor* (u_a). We use Eq. (4) to compute each user's weight of influence in *Neighbor* (u_a) and then determine a weight vector W^a based on the normalized similarity of the neighbors.

(2) Compute the Influence for Each User in Neighbor (u_a)

Once the best k neighbors are found, we can aggregate the preference value of neighbors to compute a prediction value for unrated items for the active user. Evaluators may want to assign some level of importance when the top k users'

information is considered. The influence of different neighbors will not be equal. Therefore, we determine a weight vector W^a based on the normalized similarity of neighbors from Eq. (4). The evaluation matrix E^a contains a linguistic term for each neighbor's preference.

(3) Generate the Predictions and Recommendations Procedure

The process of generating a prediction for item i_p can be implemented through the composition matrix operation $W^a \circ E^a$. The result is a fuzzy vector giving user u_a preference for item i_p. The prediction for u_a's preference for item i_p is defined as

$$Y^a = W^a \circ E^a.$$

The prediction y^* is a fuzzy number which should lead to defuzzification by Eq. (6). After predicting all the unrated items, the top N recommendations, a set of ordered items with a higher predicted value is identified.

V. Experiment Evaluation

To evaluate the performance of the proposed model, we collected preference data about movies from IMDB. One hundred different movies from IMDB are collected for 618 users. Therefore, the dataset consisted of ratings from 618 users on 100 items. The subjective information is the film review from Yahoo! Movies. Four popular metrics are adopted to evaluate the effectiveness of recommendations in this study. Precision is defined as the ratio of relevant items selected to number items selected. It can be expressed as follow：

$$precision = \frac{\text{recommend items that are relevant}}{\text{total recommend items}} \tag{7}$$

Recall represents the probability that a relevant item will be selected. It can be expressed as follow：

$$recall = \frac{\text{relevant items that are recommended}}{\text{total known relevant items}} \tag{8}$$

F1 combines precision and recall into a single number. It can be expressed as follow：

$$F1 = \frac{2 \times precision \times recall}{(precision + recall)} \tag{9}$$

Mean absolute error (MAE) measures the average absolute deviation between a predicted rating and the true one. It can be expressed as follow：

$$E = \frac{\sum_{i=1}^{N} | p_i - r_i |}{N} \tag{10}$$

where N is the number of all items; p_i and r_i represent the predicted rating and the true rating, respectively.

In this experiment we evaluate the effect of neighbor size with the proposed algorithms. It is useful to select a subset of users to use in computing prediction instead of the entire user database. We compare the accuracy of the proposed algorithms based on two kinds of datasets, rich and sparse. The results are shown in Figs. 2, 3, 4. In these figure, the x-axis and y-axis represent the size of the neighborhood and the measures of accuracy, respectively. The size of the neighborhood will be 5, 10, 15, 20, 25 or 30. An examination of the results in these figures indicates that the best performance will be met when the size of the neighborhood is fifteen.

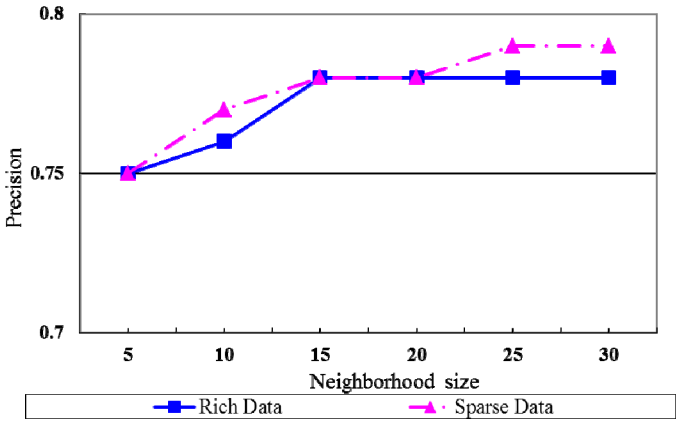

Figure 2 Precision for the proposed algorithms as neighborhood size grows.

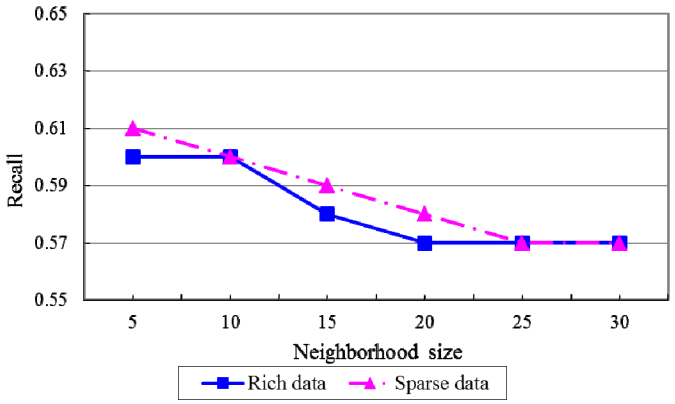

Figure 3 Recall for the proposed algorithms as neighborhood size grows.

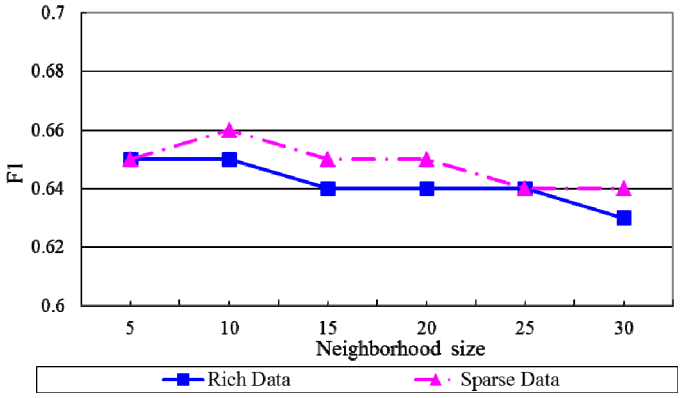

Fig. 4 F1 for the proposed algorithms as neighborhood size grows

There is no significant difference in the accuracy of the proposed algorithm between the sparse and rich dataset, as illustrated in Figs. 2, 3 and 4. When the users' preferences are insufficient (sparse dataset), most recommender systems suffer from neighbor forming bias so that those neighbors are not really similar to the active user. However, the accuracy of the proposed algorithm is not influenced by the sparsity problem. We also observe that the subjective module plays an important role. This is because the subjective user's information is always sufficient. The similarity between the subjective user and active user is always reliable.

VI. Conclusion

Traditional CF methods suffer from some limitations which are new user, new item and sparsity. This study proposes a novel CF framework based on fuzzy set theory. The proposed algorithm which combines the subjective and objective information can overcome the limitations. Experimental results show that the proposed method not only can provide reasonable recommendations as traditional CF methods, but also can solve the traditional limitations.

Abstract— **Our study investigates the generalization capability of fuzzy rule-based trading systems and conducted an empirical study on Taiwan's stock market during 1991/1/1-2010/12/31. The empirical conclusions are as follows (1) The investment performance in the training period is much better than that in the testing period, which exhibits over-learning. (2) The symmetry rules approach demonstrates that the pure price trend trading system is better than the pure volume trend trading system and hybrid price-volume trend trading system. The pure volume trend trading system is the poorest system. (3) The asymmetry rules approach demonstrates that the trading system optimized in one period may be performed poorer in another period. The pure price trend buy-rule combined with the pure volume trend sell-rule has good performance in 1991-2000 but acts poorly in 2001-2010.**

Keywords-fuzzy rule; market timing; stock market; moving average; over-learning

I. INTRODUCTION

The stock market is a high-risk market. The reason is that too many factors affect the stock prices, making them hard to predict. Nearly a dozen years, many artificial intelligence methods, such as artificial neural networks [1], genetic algorithms [2,3], and hybrid approach [4], have been applied to the stock price forecast and the buy-sell decision-making. These studies first attempt to establish a stock price forecast system, and then use the forecast system to develop the buy-sell decision system. Because of the unpredictability of the stock prices, the effect of such a study has its limitations [5-15].

Recently, some studies [16, 17] adopted new ways of thinking to directly construct the buy-sell decision system, instead of developing a stock price forecast system, and indicated that this strategy can effectively enhance investment performance. Although this thinking may seem unreasonable, but it is feasible if we consider it from the perspective of control theory. Just like most people can learn driving through practice, but very few people really understand vehicle dynamics. In other words, most people can't accurately predict the movement of the vehicle, but still capable of making decisions (control the steering wheel).

The fuzzy rule-based systems (FRBS) are decision-making systems combining the non-linear model of fuzzy rules and the stock trading simulation mechanism. FRBS use the strategy of optimization to skip the construction of stock price forecast system and directly develop the buy-sell decision system. The rationale is to employ the fuzzy rule-based system as the decision system. The technical indicators based on daily stock prices and trading volume are employed as the system inputs, and the buy-sell decision indicator as the system output. When these technical indicators trigger the fuzzy buy-rule, a buying decision is recommended; when these indicators trigger the fuzzy sell-rule, a selling decision is suggested. This study adjusted the parameters in these fuzzy rules to optimize the performance to produce the decision-making system. The steps of building FRBS are detailed as follows:

1. Build the fuzzy rule-based trading system

There are the buy-rule and the sell-rule in the system. Each rule has some adjustable parameters, such as membership function shape parameters, rule trigger thresholds, and weights of conditions.

2. Optimize the fuzzy rule-based trading system

Alter the adjustable parameters in the system to maximize the profits under the simulated environment of using the historical stock market data in the training period.

3. Evaluate the fuzzy rule-based trading system

Use the optimized adjustable parameters in the system, and evaluate the profits under the simulated environment in the testing periods.

4. Determine the best parameters

Choose the parameters that have the best performance during testing periods.

Because of the changing nature of stock markets, the decision-making system generated from the fuzzy rule-based approach can only be guaranteed for generating good profits in the training period, but it is not guaranteed to produce good profits in the future. The future performance of this original decision-making system is suspicious. Therefore, to objectively prove that the generated decision-making system has good performance in the future, the historical stock market data must

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

be divided into several parts, for example, four parts. Every time we use one of the parts as the "training period" and the others as the "testing periods" as shown in Fig. 1. In the second step of FRBS, several fuzzy rule-based systems are generated, according to the profits, in the training period. In step three of FRBS, the profits produced in the testing periods are used to evaluate which systems can be generalized to the testing periods. That is, if we can generate a system that not only has good performance in the training periods but also has good performance in the testing periods, then we can expect this system will generate good profits in the future.

Our study aims to examine whether FRBS have the generalization capability. Section 2 describes the rationale of fuzzy rule-based stock trading decision system. Section 3 examines the investment performance of FRBS in the testing periods. Section 4 contains concluding remarks.

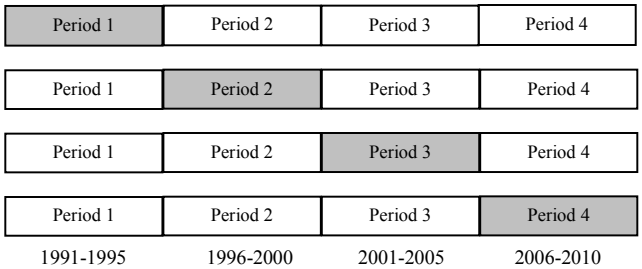

Figure 1. Cross-Evaluation Approach (the gray boxes represent the training periods, and the white ones are testing periods)

II. FUZZY RULE-BASED STOCK TRADING SYSTEM

A. *The calculation of technical indicators*

Although there are thousands of technical indicators can be used in the stock market, the moving averages of price and volume are essential. A moving average is calculated by adding the security's prices for the most recent N time periods and then divided by N. It smooths out a data series, making it easier to spot trends.

The Moving Average Indicator (MAI) and Moving Average Volume Indicator (MVI) are defined as follows

$$MAI_{m,n} = \frac{MA_m}{MA_n} \tag{1}$$

$$MVI_{m,n} = \frac{MV_m}{MV_n} \tag{2}$$

where MA_m and MA_n = *m*-day and *n*-day moving average of closing prices; MV_m and MV_n = *m*-day *n*-day moving average of trading volume. In this study, we adopted m=1 and n=50.

B. *The fuzzy rules*

There are two rules in the system

Buy-rule: IF MAI is big and MVI is big Then buy

Sell-rule: IF MAI is small and MVI is small Then sell

The membership functions are defined as follows

$$\mu(MAI\ is\ big) = \frac{1}{1+\exp(-MAI)} \tag{3}$$

$$\mu(MVI\ is\ big) = \frac{1}{1+\exp(-MVI)} \tag{4}$$

$$\mu(MAI\ is\ small) = 1-\mu(MAI\ is\ big) \tag{5}$$

$$\mu(MVI\ is\ small) = 1-\mu(MVI\ is\ big) \tag{6}$$

where

$$MAI = \frac{MAI_{m,n}-1}{k\cdot\sigma_{MAI}} \tag{7}$$

$$MVI = \frac{MVI_{m,n}-1}{k\cdot\sigma_{MVI}} \tag{8}$$

where σ_{MAI} and σ_{MVI} are the standard deviations of $MAI_{m,n}$ and $MVI_{m,n}$ in the recent n days, and k is the membership function shape parameter.

We use the weighted summation instead of minimization for the "and" operation; that is the fuzzy rules triggered based on the following rules

$$If\ w_{MAI-Buy}\cdot\mu(MAI\ is\ big)+w_{MVI-Buy}\cdot\mu(MVI\ is\ big) > \theta_{buy}\quad Then\ Buy \tag{9}$$

$$If\ w_{MAI-Sell}\cdot\mu(MAI\ is\ small)+w_{MVI-Sell}\cdot\mu(MVI\ is\ small) > \theta_{sell}\quad Then\ Sell \tag{10}$$

where θ_{buy} and θ_{sell} are the rule trigger thresholds, and we assumed

$$\theta_{sell} = \theta_{buy} = \theta \tag{11}$$

and $w_{MAI-Buy}$ and $w_{MVI-Buy}$ are the weights of conditions in the Buy-rule; $w_{MAI-Sell}$ and $w_{MVI-Sell}$ are the weights of conditions in the Sell-rule, , and we assume

$$w_{MVI-Buy} = 1 - w_{MAI-Buy} \tag{12}$$

$$w_{MVI-Sell} = 1 - w_{MAI-Sell} \tag{13}$$

The fuzzy rule response surfaces are shown in Fig. 2. When the k, membership function shape parameter, is close to 0, then the system is close to crisp system instead of fuzzy system. The weights of conditions control the slope direction of the response surface.

III. The Results of FRBS in Taiwan Stock Market

We use daily data of the Taiwan Stock Market Index (TAIEX) from 1 Jan 1991 to 31 Dec 2010 as shown in Figure 3. Totally 5297 individual data were collected. The data are divided into four parts by timing and are shown in Figure 1. This research considers the profit or loss in the training period and in the testing period.

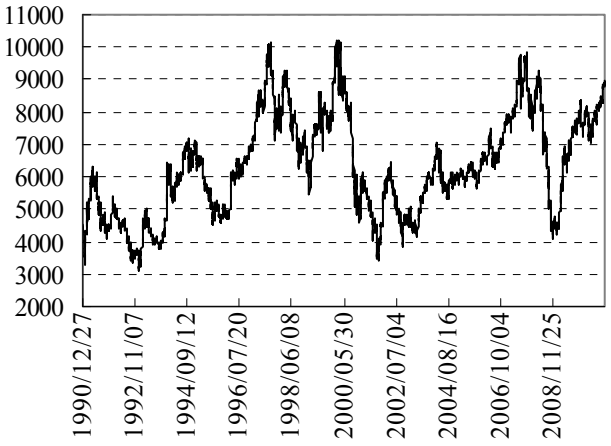

Figure 3. TAIEX (1991/1/1-2010/12/31)

Figure 3 exhibits the stock market fluctuating in the training and in the testing periods, which show the representativeness of the data. Every time we use one of the parts as the "training period" and the remaining ones as the "testing periods". Several fuzzy rule-based systems are produced based on the profits generated in the training period, and then the profits in the testing period are used to evaluate which systems can be generalized to the testing periods.

Because the objective of this study is to develop a decision-making system with high investment performance in Taiwan's stock market; therefore, the transaction costs refer to the practical stock transaction costs in Taiwan. These costs include transaction fees of purchasing accounting for 0.1425% of the buying price; the transaction fees and trading tax of selling account for 0.1425% and 0.3% of the selling price, respectively. The profits (annual return) of buy-and-hold strategy in the 4 parts are 4.0%, -1.7%, 6.7%, 6.5%, respectively.

A. The symmetry rules approach

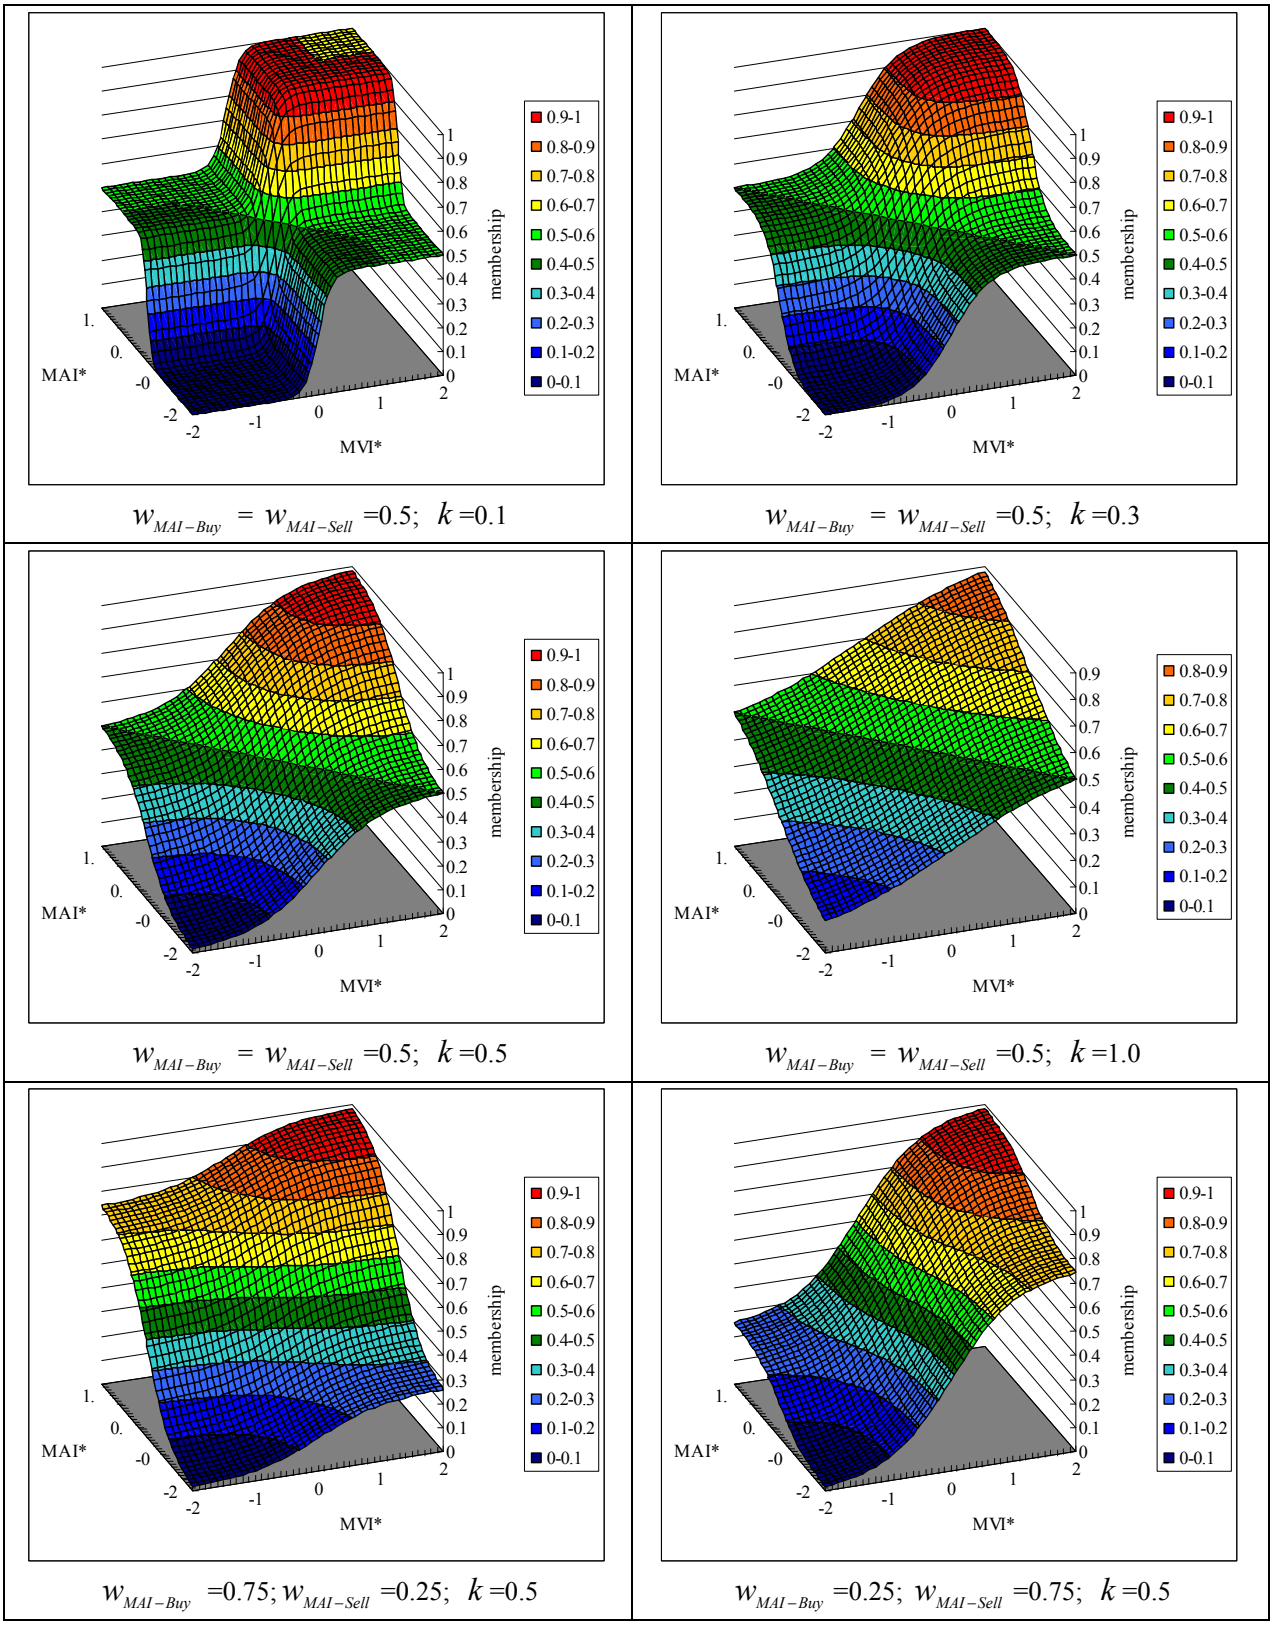
In this approach, we assume that the weights of conditions of the buy-rule and the sell-rule are the same.

$$w_{MAI-Buy} = w_{MAI-Sell} = w_{MAI} \tag{14}$$

We firstly use 0, 0.3, 0.5, 0.7, 1 for the w_{MAI}, and change the rest of adjustable parameters, the membership function shape parameters k (0.1, 0.2, …, 1) and rule trigger threshold θ (0.5, 0.55, …, 0.95), in the system to maximize the profits under the simulated environment of using the historical stock market data in the training period. To avoid the profit comes form few trades, we eliminated all the results whose number of trade is less than 60 times in the 20 years (60 times for buy and 60 times for sell). Then we use the optimized adjustable parameters in the system and evaluate the profits under the simulated environment in the testing periods. The results are shown in Table 1. In this table, we use the profit gain, the gap between the annual return of the system and the buy-and-hold strategy, to evaluate these systems.

To objectively prove that the generated decision-making system has good performance in the training period, we use the average profit gain produced in the testing periods to evaluate the system. Because we exclude the profit gain generated in the training periods, the average profit gain can objectively be used to evaluate the performance of the system. If we can generate a system that not only has good performance in the training periods, but also has good performance in all the testing periods, then we can expect this system will generate good profits in the future. We also use the standard deviation of profit gain to evaluate the stability of the system. Finally, we use the ratio of the average profit gain to the standard deviation of profit gain to measure the total performance for a specific weight. The results show that when the weight is varied (0, 0.3, 0.5, 0.7, and 1), the generated profit gains in the training periods are 8.0, 7.1, 7.0, 7.3, and 6.8, and the ratios are 2.14, 1.20, 1.51, 1.85, and 3.40, respectively. On the other hand, in the testing periods, when the weight is changed (0, 0.3, 0.5, 0.7, and 1), the produced profit gains are 3.0, 1.8, 2.6, 3.6, and 5.5, and the ratios are 0.74, 0.54, 0.56, 1.03, and 3.09, respectively. The investment performance in the training period is much better than that in the testing period, which exhibits over-learning.

The results show that 1.0 is the best weight of conditions. That is, the best fuzzy rule is the rule containing only the MAI conditions, and the MVI conditions are not included in the system. Figure 4-7 show its performance. The initial capital is 10000. All these four optimized fuzzy rule sets can obtain fairly high final cumulated capital.



$w_{MAI-Buy} = w_{MAI-Sell} = 0.5;\ k = 0.1$ | $w_{MAI-Buy} = w_{MAI-Sell} = 0.5;\ k = 0.3$

$w_{MAI-Buy} = w_{MAI-Sell} = 0.5;\ k = 0.5$ | $w_{MAI-Buy} = w_{MAI-Sell} = 0.5;\ k = 1.0$

$w_{MAI-Buy} = 0.75; w_{MAI-Sell} = 0.25;\ k = 0.5$ | $w_{MAI-Buy} = 0.25;\ w_{MAI-Sell} = 0.75;\ k = 0.5$

	4	0.85	0.1	6.4	4.7	1.1	**6.4**			
(1,1)	1	0.8	0.1	**8.7**	5.8	3.3	6.0	**6.8** 5.5	**2.0** 1.8	**3.40** 3.09
	2	0.7	0.2	8.2	**7.0**	4.0	4.5			
	3	0.7	0.2	8.2	7.0	**4.0**	4.5			
	4	0.6	0.3	6.4	5.4	2.7	**7.6**			

(The bold values are based on the training period; the rest of the values are based on the testing periods.)

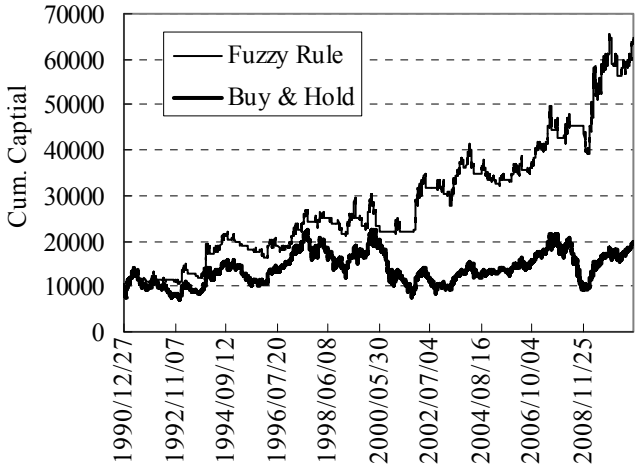

Figure 4. The cumulated capital employing the optimized fuzzy rule set with the weight pair (1,1) in the 1st period (1991-95).

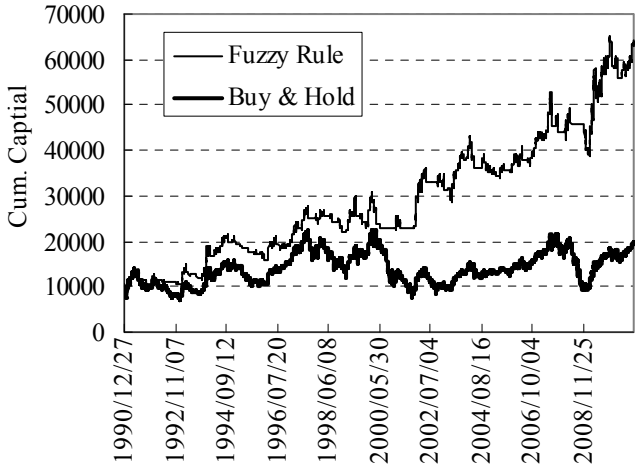

Figure 5. The cumulated capital employing the optimized fuzzy rule set with the weight pair (1,1) in the 2nd period (1996-00).

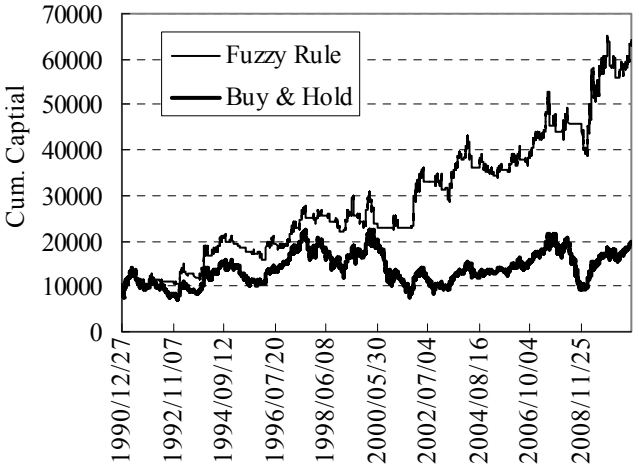

Figure 6. The cumulated capital employing the optimized fuzzy rule set with the weight pair (1,1) in the 3rd period (2001-05).

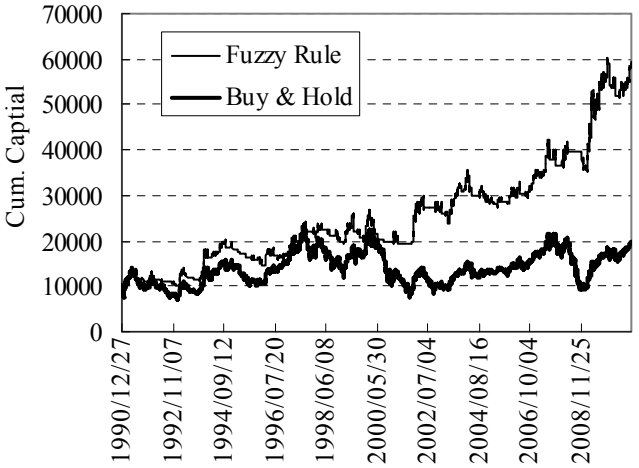

Figure 7. The cumulated capital employing the optimized fuzzy rule set with the weight pair (1,1) in the 4th period (2006-10).

B. The asymmetry rules approach

In this approach, we assume that the weights of conditions of the buy-rule and the sell-rule are different. We try the buy weight and the sell weight pair=(0,1) and (1,0). The results are shown in Table 2. Figure 8-11 show the cumulated capital employing the optimized fuzzy rule set with the weight pair (1, 0), which is the pure price trend buy-rule combined with the pure volume trend sell-rule, in the four different periods. Although these four optimized fuzzy rule sets can obtain rather high final cumulated capital, but he systems generated from the period 1 (1991-1995) and period 2 (1996-2000) have relatively poor performance in period 3 (2001-2005) and period 4 (2006-2010), which demonstrates that the optimized trade system produced from one period may be performed poorer in another period. We also use different weights such as 0, 0.05, 0.1, 0.15, 0.2,…, 1. Therefore, there are totally 21x21=441 weight pairs. The pair of (0.8, 1) has the highest ratio of the average profit gain to the standard deviation of profit gain. However, it also exhibits over-learning.

IV. CONCLUSION

Our study investigates the generalization capability of fuzzy rule-based trading systems and conducted an empirical study on Taiwan's stock market during 1991/1/1-2010/12/31. The empirical conclusions are as follows:

1. The investment performance in the training period is much better than that in the testing period, which exhibits over-learning.
2. The symmetry rules approach demonstrates that the pure price trend trading system performs better than the pure volume trend trading system and hybrid price-volume trend trading system. The pure volume trend trading system has the poorest performance.

TABLE 2. The Results of FRBS: Asymmetry Rules Approach

weight pair	Train Period	Opt. θ	Opt. k	Test period 1	2	3	4	Avg profit gain	Std of profit gain	Ratio
(0,1)	1	0.55	1	**7.2**	7.1	1.9	3.3	**5.9** 3.1	**2.7** 3.0	**2.18** 1.03
	2	0.95	0.1	3.2	**9.1**	-0.1	0.0			
	3	0.65	0.4	5.2	9.0	**3.2**	2.4			
	4	0.65	0.2	3.5	2.8	-1.5	**4.2**			
(1,0)	1	0.95	0.1	**13.3**	8.4	0.8	-2.7	**7.7** 4.7	**6.4** 5.0	**1.20** 0.95
	2	0.7	0.2	11.7	**13.1**	-0.3	0.2			
	3	0.7	0.1	6.2	10.9	**1.7**	2.6			
	4	0.7	0.1	6.2	10.9	1.7	**2.6**			
(0.8, 1)	1	0.8	0.1	**10.9**	6.7	1.5	4.7	**7.9** 5.6	**3.26** 2.7	**2.50** 2.04
	2	0.7	0.2	5.6	**9.7**	1.8	6.1			
	3	0.6	0.4	9.4	8.5	**3.7**	5.9			
	4	0.6	0.5	7.9	7.1	1.4	**7.4**			

(The bold values are based on the training period; the rest of the values are based on the testing periods)

3. The asymmetry rules approach demonstrates that the optimized trading system in one period might act poorer in another period. The pure price trend buy-rule combined with the pure volume trend sell-rule has fairly good performance in the period of 1991-2000, but has poor performance in 2001-2010.

The deterioration of the investment performance may be resulted from that the 5-year training period is not long enough to gather sufficient patterns to build general model; or maybe the 5-year testing period is too long and the stock market structure has been changed during the time, which also makes the developed trading system cannot be applied to the testing period. Apparently, it is not easy to use the current framework to overcome the problem of over-learning. Researchers have to solve this problem through different approaches.

***Abstract*—In this paper we present the preliminary results of application of Fuzzy Markup Language (FML) to suspect a non-common disease. Under non-common diseases we understand rare diseases. From the broad point of view this problem belongs to the computer-assisted decision support in medical diagnostics and can be supported by fuzzy logic controllers. We can use conventional methods to diagnose a rare disease if it can be exhibited by outstanding symptoms. For example, there are several search machines and data banks that allow to find a rare disease clearly exhibited by a patient's symptoms/signs. But it is very difficult to diagnose a rare disease if it masks as a common disease. Diagnostic of rare diseases is connected with lack, uncertainty and imprecision of knowledge, medical mistake and even medical failure. Additionally, very often a common disease is also established with some degree of belief, thus, the expressions such as "it is possible that a patient has a particular disease" rather often present in the daily medical practice. It is clear that if we would know the common diseases, then deviations from them can be considered as a sign of non-common diseases. In this paper we investigate such deviations with the help of FML. We show how FML mechanism can be adjusted to suspect a rare disease, and discuss the appropriateness of the available operators.**

***Index Terms*—Fuzzy Systems, Fuzzy Markup Language, Medical Diagnosis, Rare diseases.**

I. Introduction

In this paper we present the preliminary results of application of Fuzzy Markup Language (FML) to suspect a non-common disease. Under non-common diseases we understand rare diseases. A rare disease is any disease that affects a small percentage of the population. There is no single, widely accepted definition for rare diseases (RD)[1]. According to different definitions the prevalence of RD should be between $1/200000$ and $1/1000$, usually about $1/2000$. There are several thousand rare diseases. Their total number is quite significant: the 5-6% of population have some rare diseases[2].

From the broad point of view this problem belongs to the computer-assisted decision support in medical diagnostics and can be supported by fuzzy logic controllers. It is possible to diagnose a rare disease if it can be exhibited by outstanding symptoms. For example, there are several search machines and data banks that allow to find a rare disease clearly exhibited by a patient's symptoms/signs[3]. But it is very difficult to diagnose a rare disease if it masks as a common disease. Diagnostic of rare diseases is connected with lack, uncertainty and imprecision of knowledge, medical mistake and even medical failure. From another side, a common disease also is established with some degree of belief, so the expressions such as "it is possible that a patient has a particular disease" rather often present in the daily medical practice.

It is clear that if we would know the common diseases, then deviations from them can be considered as a sign of non-common diseases. If these deviations reach a certain level, a suspicious of a rare disease exists. Thus, a physician obtains a sign of "non-normality" of a case in hand. Then a search of a rare disease can be continued in the specific databases, cited above.

In our approach we use a methodology based on fuzzy logic, because the elements of the diagnostic process (symptoms, diagnoses, connections between both) and a diagnostic process itself are mostly described imprecisely and approximately. First, we define what we understand under common (normal) diseases and then consider possible deviations from them. Our description of common (normal) diseases is based on the terminology used in CADIAG-like systems [1], [2], [3], [4], [5], [6], [7], [8], [9], [10], [11], [12], whereas, we investigate the deviations from normal diseases with the help of FML [13], [14]. In the last years, FML (Fuzzy Markup Language) is emerging as one of the most efficient and useful language to define fuzzy control thanks to its capability of modeling Fuzzy Logic Controllers in a human-readable and hardware inde-

pendent way, i.e., the so-called Transparent Fuzzy Controllers (TFCs) [15]. We show how FML mechanism can be adjusted to suspect a rare disease, and discuss the appropriateness of the available operators.

In next Section we recall some necessary definition and denotations. In the Section III we present a brief FML description. The results of FML applications to suspect a rare disease on examples are reported in the Section IV. Section V concludes our work.

II. Preliminaries. Notions and denotations

We present a medical decision support mechanism based on the fuzzy approach generally as follows. Three components take part in the process: symptoms/signs of the patient to whom a diagnosis should be established, medical knowledge (written as "IF S THEN D", but formalized as fuzzy relations) available before the process starts and diagnosis that we are trying to find. A schema of the process is presented below.

Symptoms		Medical Knowledge	Diagnosis
$\Downarrow$			
Symptoms +		Medical Knowledge	= Diagnosis
$\Downarrow$		$\Downarrow$	$\Downarrow$
S_p	$\circ$	R_{SD}	$=D_p$

R_{SD} is a fuzzy relation between symptoms/signs and diseases is defined as

$$R_{SD} : \Sigma \times \Delta \to [0,1] \tag{1}$$

$$S_p : \Sigma \to [0,1] \tag{2}$$

$$D_p : \Delta \to [0,1] \tag{3}$$

where $\Sigma = \{s_1, \ldots, s_m\}$ is the crisp set of symptoms/signs, $\Pi = \{p_1, \ldots, p_r\}$ is the crisp set of patients, $\Delta = \{d_1, \ldots, d_n\}$ is the crisp set of diseases, each element of the fuzzy set S_p shows to which degree it is true, that a patient $p \in \Pi$ has symptom/sign s_i, or a degree of possibility of the presence of the symptom, or its severity; symbol D_p is used for the final diagnosis for a patient $p \in \Pi$ and each element of the fuzzy set D_p shows to which degree it is true, that a patient $p \in \Pi$ has a given disease d_j, or a degree of possibility with which we can attach each relevant diagnostic label to the patient [16]. R_{SD} can be of different types, it depends what information is available from experts or manuals. For example, R_{SD} can be considered as *confirmation* relation (R^c_{SD}), *occurrence* relation (R^o_{SD}), *exclusion* relation (R^e_{SD}) , *temporal* or *time of manifestation* relation (R^t_{SD}). R^c_{SD} shows the degree to which a symptom/sign confirms the presence of disease, R^o_{SD} shows the frequency of occurrence of symptom/sign with disease, R^e_{SD} indicates the degree in which the present symptom/sign (combination) excludes (or disconfirms) the disease, R^t_{SD} relation shows to which degree it is true that exhibition of a symptom leads to immediate manifestation of a disease (or a disease is manifested after some period of time).

	d_1	d_2	$\ldots$	d_n
s_1	$f(s_1\|d_1)$	$f(s_1\|d_2)$	$\ldots$	$f(s_1\|d_n)$
s_2	$f(s_2\|d_1)$	$f(s_2\|d_2)$	$\ldots$	$f(s_2\|d_n)$
$\vdots$	$\vdots$	$\vdots$	$f(s_i\|d_j)$	$\vdots$
s_m	$f(s_m\|d_1)$	$f(s_m\|d_2)$	$\ldots$	$f(s_m\|d_n)$

TABLE I: Numerical representation of symptom/sign - disease connections for R^o_{SD}

never,	very seldom,	seldom,
sometimes,	unspecified,	occasionally,
often,	very often,	always

TABLE II: Linguistic values

$R^o_{SD}(s_i, d_j)$ and $R^c_{SD}(s_i, d_j)$ can be derived from relative frequencies, i.e., numerically [5]:

$$R^o_{SD}(s_i, d_j) = f(s_i|d_j) \tag{4}$$

and

$$R^c_{SD}(s_i, d_j) = f(d_j|s_i) \tag{5}$$

where $f(s_i|d_j) = \frac{f(d_j \cap s_i)}{f(d_j)}$, $f(d_j|s_i) = \frac{f(d_j \cap s_i)}{f(s_i)}$; $f(s_i|d_j)$ is a conditional frequency of s_i given d_j, $f(d_j|s_i)$ is a conditional frequency of d_j given s_i, $f(d_j \cap s_i)$ is the absolute frequency of joint occurrence of d_j and s_i, $f(d_j)$ and $f(s_i)$ are absolute frequencies of d_j and s_i, correspondingly. We call this numerical interpretation.

An example of a numerical description is presented in the Table I.

A linguistic way opens a possibility to estimate relations R^o_{SD}, R^c_{SD}, R^e_{SD}, R^t_{SD} (linguistic variables) using fuzzy sets (values of linguistic variables), e.g., presented in the Table II.

The fuzzy sets (Table II) are defined as mappings from $[0,1]$ to $[0,1]$. An example of a linguistic description of symptom/sign - disease connection is presented in the Table III. Each linguistic value can be defined by an expert [17]. For example, an expert can define his own fuzzy set *often* and supports the interpretation with the following sentence: symptom/sign and disease meet each other often, if it happens in, approximately, 60%. Such way fuzzy relations of type II [16] are defined. An example of linguistic values from the scale (Table II) as triangular fuzzy sets is shown in the Table IV.

Another possibility to define linguistic values (simple one) is to assign to them an ordered set of numbers, e.g, from $[0,1]$ as shown in the Table V.

	d_1	d_2	$\ldots$	d_n
s_1	`often`	`always`	$\ldots$	`never`
s_2	`never`	`often`	$\ldots$	`always`

0.7	0.8	1.0

TABLE V: Representation of linguistic terms as numbers

In our work we use the scale (shown in Table II) to estimate the relationships of the symptoms/signs and diseases.

A $\max - \min$ composition of fuzzy relations [18], [19] or its generalised version t-conorm-t-norm composition can be used for medical diagnosing. Thus,

$$D_p = S_p \circ R_{SD} \tag{6}$$

is a composition of a fuzzy set and a fuzzy relation.

Moreover $\forall d_j \in \Delta$

$$D_p(d_j) = \vee_{s_i \in \Sigma} \wedge \{S_p(s_i); R_{SD}(s_i, d_j)\} \tag{7}$$

where $D_p : \Delta \to [0, 1]$ are inferred possible diagnoses for the patient $p \in \Pi$, $\vee$ is a t-conorm and $\wedge$ is a t-norm.

In general, the aggregation operators can be used in this inference mechanism [16].

Working with a decision-support system, a physician expects from a computer program a tip, a help, what diagnosis it can be for a patient at hand. In this way, the system should alarm if some things are outside of its normal functioning, i.e., if the case is neither confirmed nor possible, or has "strange" values. Thus, such behaviour of a system could be considered as a sign of a possible rare disease.

It is obvious that conclusions about the patient's diagnosis with a help of a computer program is made based on the information available, in particular, what initial information is contained in the knowledge base and what information about a patient at hand we have. It is possible to investigate how to suspect a rare disease under the presence of different initial information, in our denotation R^o_{SD}, R^c_{SD}, R^e_{SD} or R^t_{SD}. In the section IV we consider relation R^o_{SD} and simulate the inference process with FML. For this reason, a description of this novel language is provided in the following section.

III. Fuzzy Markup Language: A Description

Fuzzy Markup Language (FML) is a XML-based domain-specific language proposed by Acampora and Loia [13] whose main aim is to model fuzzy systems by directly dealing with fuzzy concepts, fuzzy rules and fuzzy inference engines [8]. In particular, it is used to model two well-known kind of fuzzy controllers: Mamdani and Takagi-Sugeno-Kang (TSK). FML programs are coded through a collection of correlated semantic tags capable of modeling different components of a controller by exploiting abstraction benefits offered by XML tools. Differently from other similar approaches used to describe fuzzy controllers such as Fuzzy Control Language (FCL) or MATLAB Fuzzy Inference System (FIS) developed by the Matworks, FML allows fuzzy designers to simply code their ideas on heterogeneous hardware without understanding details related to the different platforms. In short, thanks to FML it is possible to model a fuzzy controller in human-readable and hardware independent way. The exploitation of FML is resulted in a new fuzzy control design philosophy named *transparent fuzzy controller* [20] based on the integration among fuzzy systems, labeled tree theory [21], and XML methodology.

In the following, a brief description of the used FML tags is given. The root tag of FML program is <FuzzyController> which has two attributes: name and ip. The *name* attribute permits to specify the name of fuzzy controller and *ip* is used to define the location of controller in a computer network. The fuzzy knowledge base is defined by means of the tag <KnowledgeBase> which maintains the set of fuzzy concepts used to model the fuzzy system. In order to define a fuzzy concept, the following set of nested tags is used:

- <FuzzyVariable> defines the fuzzy concept;
- <FuzzyTerm> defines a linguistic term describing the fuzzy concept;
- a set of tags defining a shape of fuzzy sets related to fuzzy terms.

The attributes of <FuzzyVariable> tag are: name, scale, domainLeft, domainRight, type and, for only output concept, accumulation, defuzzifier and defaultValue. The *name* attribute defines the name of fuzzy concept; *scale* is employed to define the scale used to measure the fuzzy concept, *domainLeft* and *domainRight* are used to model the universe of discourse of fuzzy concept, i.e, the set of real values related to fuzzy concept; the position of fuzzy concept into rule (consequent part or antecedent part) is defined by *type* attribute (input/output); *accumulation* attribute defines the method of accumulation that is a method that permits the combination of results of a variable of each rule in a final result; *defuzzifier* attribute defines the method used to execute the conversion from a fuzzy set, obtained after aggregation process, into a numerical value to give it in output to system; *defaultValue* attribute defines a real value used only when no rule has fired for the variable at issue. <FuzzyTerm> uses two attributes: *name* used to identify the linguistic value associate with fuzzy concept and *complement*, a boolean attribute that defines, if it is true, it is necessary to consider the complement of membership function defined by given parameters. Fuzzy shape tags, used to complete the definition of fuzzy concept, are several, in our case of study, the triangular membership functions has been used through <TriangularShape> tag. Each shaping tag uses a set of attributes which defines the real outline of corresponding

fuzzy set. In particular, the <TriangularShape> tag uses three parameters. The rule base is modeled by <RuleBase> tag which defines a fuzzy rule set. The <RuleBase> tag uses five attributes: name, type, activationMethod, andMethod and orMethod. Obviously, the *name* attribute uniquely identifies the rule base. The *type* attribute permits to specify the kind of fuzzy controller (Mamdani or TSK) respect to the rule base at issue. The *activationMethod* attribute defines the method used to implication process; the *andMethod* and *orMethod* attribute define, respectively, the and and or algorithm to use by default. In order to define the single rule the <Rule> tag is used. The attributes used by the <Rule> tag are: name, connector, operator and weight. The *name* attribute permits to identify the rule; *connector* is used to define the logical operator used to connect the different clauses in antecedent part (and/or); *operator* defines the algorithm to use for chosen connector; *weight* defines the importance of rule during inference engine time. The definition of antecedent and consequent rule part is obtained by using <Antecedent> and <Consequent> tags. <Clause> tag is used to model the fuzzy clauses in antecedent and consequent part. This tag use the attribute *modifier* to describe a modification to term used in the clause. To complete the definition of fuzzy clause the nested <Variable> and <Term> tag have to be used.

The FML tags represent the set of lexemes used to build a fuzzy controller. However, in order to realize a well-formed XML-based language, an FML context-free grammar is necessary. The FML context-free grammar is modeled by XML file in the form of a XML Schema Document (XSD). Moreover, since an FML program realizes only a static view of a fuzzy system, the so-called eXtensible Stylesheet Language Translator (XSLT) is provided to change this static view to a computable version. In particular, the XSLT technology is used to convert a fuzzy controller description into a general-purpose computer language to be computed on several hardware platforms.

Finally, the FML is essentially composed by three layers:

- XML in order to create a new markup language for fuzzy logic control;
- a XML Schema Document in order to define the legal building blocks;
- extensible stylesheet language transformations (XSLT) in order to convert a fuzzy controller description into a specific programming language.

IV. FML IN SIMULATION

In this section, the simulation with FML of the inference process used to suspect a rare disease under the presence of the initial information R^o_{SD} is shown and discussed.

In particular, we illustrate the use of FML to suspect a rare disease by means of an example. Assume, that a knowledge base contains R^o_{SD} as, for example, in the Table VI and corresponding numerical form (due to the scale Table V) as singletons and/or triangular fuzzy sets. In this case $\Delta = \{d_1, d_2\}$, $\Sigma = \{s_1, s_2, \ldots, s_6\}$. We assume that a rare disease is not in the knowledge base, it means that it is not in Δ.

	Bronchitis	*Pneumonia*
wheezing	sometimes	occasionally

s_5	0.4	0.4
s_6	0.3	0.3

TABLE VII: Corresponding numerical descriptions for "normal" diseases (see Table VI)

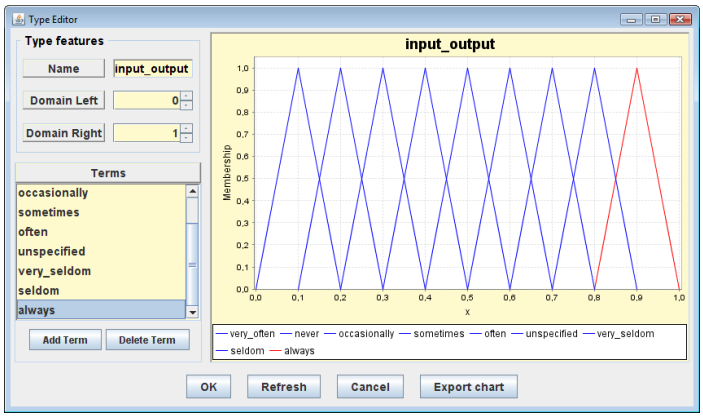

Fig. 1: Presentation of linguistic values from Table V in FML

We define nine linguistic values from Table IV as shown in Figure 1.

Thus, we use the same type of input and output variables in FML, in particular, triangular shape.

As input variables we consider 6 symptoms: wheezing, breathlessness, anosmia, fever, sinusitis, chronicotitis. As output variables we consider two diseases: Bronchitis and Pneumonia. Due to the Table VI we have constructed the following rule base (see Figure 2).

In the listing 1, a portion of the FML-based fuzzy controller to suspect a rare disease is presented.

As we speak about a rare disease, we consider how "far" is this case from the common representation.

In the Table VII we present corresponding singletons for linguistic values from Table VI for the explanation reason.

We can predefined an excluded diagnoses in the case if a symptom is fully present/absent with a corresponding full

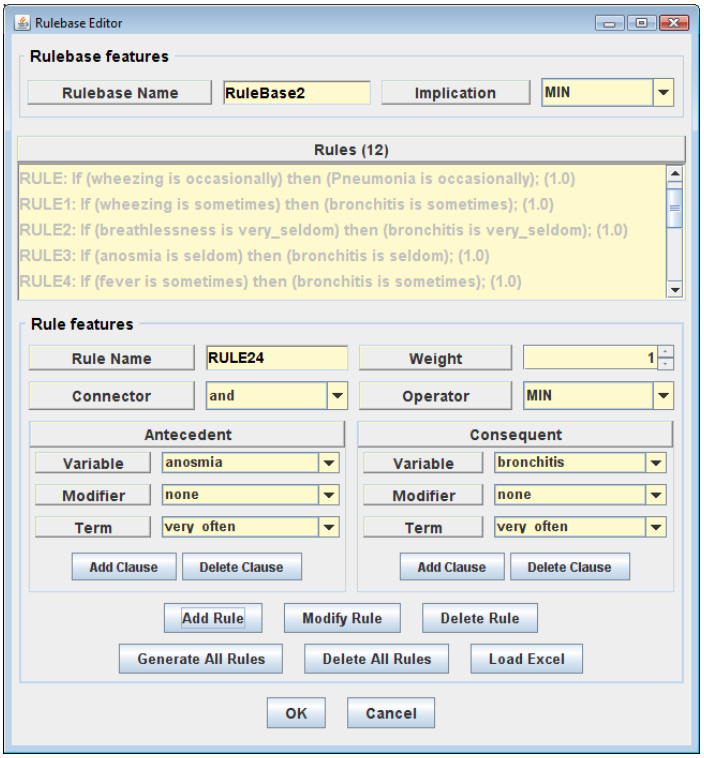

Fig. 2: 12 rules describing relation of six symptoms and two diseases in FML

occurrence/absent of occurrence. Simply speaking, at least one element of the Table VII should be 1 or 0 and at least one membership degree of fuzzy set S_p should be 1 or 0 as well. It means, that, to define such case, we need a crisp information. It is a clear situation, but is not always a case.

As we have already mentioned, the difficulty to suspect a rare disease is because of its symptomatic similarity to the "normal cases" and, of course, absence of the necessary information. If a physician has enough experience with a computer program, s/he usually has been working, and s/he mentions that the values for possible diagnoses are much below or much above the usual representation, it can be also the sign of alarm "a rare disease" for a physician.

We need to define appropriate operations and thresholds (that allow to detect a deviation from the "normal" case). If we take max-min composition of fuzzy relations (7), it restricts the maximum membership degree of possible diseases for a patient by values in Table VII. For example, if a patient at hand has

$$S_p^1 = \{(s_1, 0.4), (s_2, 0.2), (s_3, 0.3), (s_4, 0.4), (s_5, 0.4), (s_6, 0.2)\}$$

the possible diagnosis d_1 has the membership degree 0.4 (see (8)). If a patient at hand has

$$S_p^2 = \{(s_1, 1.0), (s_2, 1.0), (s_3, 0.2), (s_4, 0.3), (s_5, 0.2), (s_6, 0.2)\}$$

the possible diagnosis d_1 has the membership degree 0.4

.

$$D_p(d_1) = \max \left\{ \begin{array}{l} \min\{0.4, 0.4\}; \\ \min\{0.2, 0.2\}; \\ \min\{0.3, 0.3\}; \\ \min\{0.4, 0.4\}; \\ \min\{0.4, 0.4\}; \\ \min\{0.3, 0.3\}; \end{array} \right\} = 0.4 \qquad (8)$$

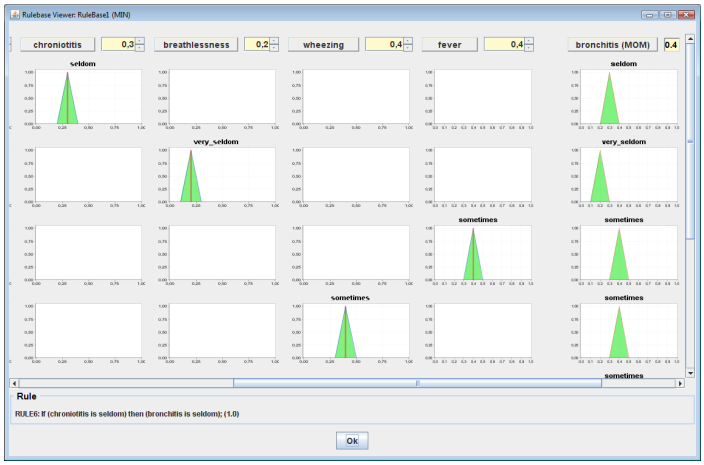

Fig. 3: Results of execution of FML under S_p^1 for d_1

This standard $\max - \min$ composition in our case guarantees that the degree of occurrence can be less than 0.4, but not more (see Figure 3, Table VIII). Using FML, the antecedent and consequent of a rule in the rule base should be defined as fuzzy sets. We, however, consider R_{SD} relation is a given one, we do not construct it from fuzzy sets described symptoms/signs and diseases. The omission of this step can be solved by assigning the same linguistic values to the antecedent variable and the consequent variable. In general, due to our approach to define deviations from "common" diseases as a sign of non-normality, and consequently, a suspicious of a rare disease, we need operators, that allow to estimate such deviation. For example, in controllers, realized in the FML, an input value and antecedent value are connected by 'min' operator, but if we need to know, how far is an input value from the antecedent value, we need a corresponding operator that estimates the distance between two fuzzy sets.

Let us continue to discuss our considerations on examples.

If we take the *absolute difference* (for two numbers a and b their *absolute difference* is defined as $|a - b|$) instead of min-operation (max-operation remains unchanged) we obtain more flexibility to detect deviations. For example, for S_p^1 the

S_p^3	0.40	0.26

TABLE IX: Possible degrees for "normal" diseases under $mean - absolute\ difference$ composition

membership degree of d_1 in this case is 0 and for S_p^2 we obtain 0.8. If instead of the max operator we take another aggregation operator, such as the *arithmetic mean* of deviations (the *arithmetic mean* of $a_1, a_2, \ldots, a_n$ is $\frac{a_1+a_2+\cdots+a_n}{n}$), for d_1 in the case of S_p^1 we obtain 0 as well and 0.23 in the case of S_p^2. We interpret 0 as a sign of most believable diagnosis, and every deviation from 0 points less believable diagnosis. The question is, as always in applications, how to detect a threshold, under (or above) which a suspicious of a rare disease arises. If we take $max - absolute\ difference$ composition of S_p and R_{SD} and a result is different from 0, the final value shows that at least one symptom/sign differs from the normal case, but does not say anything about the rest of symptoms. When a rare disease can be pointed by a representative symptom (i.e., such symptom which presence/absence is a sure sign of the non-normality of a diagnosis) $\max$- *absolute difference* is suitable.

The $mean - absolute\ difference$ composition of S_p and R_{SD} shows the mean value of all deviations. As it is often with rare diseases, they are described with the same symptoms/signs as "normal" diseases and only a certain deviation can point a rare disease, the application of $mean - absolute\ difference$ composition of S_p and R_{SD} seems to be reasonable. Notice, that in general, a $p - mean$, and/or other distance metrics can be considered.

$$S_p^3 = \{(s_1, 0.7), (s_2, 0.7), (s_3, 0.7), \\ (s_4, 0.7), (s_5, 0.8), (s_6, 0.7)\}$$

The possible degrees for d_1, d_2 under S_p^1, S_p^2, S_p^3 using $\max - \min$ composition are presented in the Table VIII.

The possible degrees for d_1, d_2 under S_p^1, S_p^2, S_p^3 using $mean - absolute\ difference$ composition are presented in the Table IX.

For this particular example 0.25 can be chosen as a threshold to point a suspicion of a rare disease, i.e., if all numbers in one string in the Table IX are above 0.25 a physician should think about "non-normality" of a possible diagnosis for a patient at hand. It means, that we found an approach to suspect a rare disease if the diagnoses from the initially defined list seems to be possible. The choice of a threshold remains on experts. There are many ways to formalise this procedure[22], [23], [24], which approach has to be used is a subject of a separate investigation.

Notice, that the difference between symptoms of a given patient and the predefined symptoms/signs picture of a disease may be also calculated as ratio $\frac{a}{b}$ and then also a mean value of these ratios may be calculated. In this case a value for a normal case will be 1.

So, we need an operation that will calculate a distance

between two fuzzy sets in the inference mechanism. It is a subject of our future applications.

It can be also argued that one number, as a threshold, does not reflect a flexibility in diagnostics. In forthcoming time we investigate interval- and fuzzy sets estimations of linguistic expressions for a rare disease diagnostic problem. In this paper our intend was to discuss the principal approach to diagnostics of rare diseases and show the first steps for its realisation with the help of FML.

V. Conclusions

The problem to suspect a rare disease (in particular, in pediatrics) with a help of computer - assisted system is an important problem and till now is not well investigated. This problem is connected with absence, insufficiency, uncertainty and imprecision of information and, therefore, belongs to the category of problems, that can be solved by fuzzy logic approaches.

Our main idea to suspect a rare disease is based on the assumption, that deviation from a "normal" disease is a sign to warn a rare disease. Thus, well acquaintance with normal diseases involves a recognition of a rare disease. We suppose, that a physician has already established a preliminary diagnosis for a patient, but s/he hesitates about its correctness. Then a physician, based on the patient's data, checks the deviations from the "normal" cases, and if these deviations reach certain level, a suspicion of a rare disease arises.

We test our approach on FML and preliminary results have shown that we are able successfully model the process of suspicious of a rare disease, but for flexibility we need additional operators, that allow to estimate a deviation of one fuzzy set from another. It is a subject of our recent collaborative work.

***Abstract*—In this paper, we propose a linguistic summarization procedure for describing long-term trends of change in human behavior. Our objective consists of defining methods that provide information to elders, caregivers, social workers or even family in an understandable language. We adapt a measure that we defined in previous work on soft cluster partition similarity for comparing behaviors that are adapted over time. From that measure, we are able to produce a time series that numerically describes change in behavior over time. In this article, the resulting time series is partitioned and linguistically summarized depending on a user's (caregiver, social worker, etc.) desired time resolution. Simulated resident behavior is used in order to explore a range of different scenarios and the response of the proposed linguistic summarization process is investigated.**

Keywords- comparing soft partitions, human behavior, anomaly detection, fuzzy linguistic summarization

I. INTRODUCTION

In recent years, successful aging has become one of the most important problems in our society. Life expectancy has improved, and along with it the resources required to maintain quality and style of life. Emerging applications combining *technology* and *medicine* provide one possible solution. Multiple large scale projects combine these subjects. One such project is the center for Eldercare and Rehabilitation Technology (CERT) [1] and the TigerPlace facility [2]. This effort is a large interdisciplinary collaboration between electrical and computer engineers, gerontological nurses, social workers, physical therapists and others at the University of Missouri. This group has installed multiple sensing technologies in the homes of elders. One goal of these technologies includes assisting residents with "aging in place" as independently as possible. Other projects include the MavHome project [3], iDorm [4], CASAS [5] and the Georgia Tech Aware Home [6]. In addition, in [7] eight other relevant projects in this field are summarized.

Important advantages of behavior analysis in the eldercare domain include: reducing dependency, enhancing personal comfort and safety and delaying the process of moving to a nursing home. Many projects are centered around Activities of Daily Living (ADL) [8]. From the set that focus on the ADL, we emphasize [9], an approach based on multiple behavioral hidden Markov models (MBHMM). The authors propose the creation of multiple HMMs for each variation of an action. The most important advantage of this proposal is that the system is able to determine which tasks are currently active, even if the user has not yet completed the activity.

A related fuzzy approach is [10]. In that work, the authors propose an AmI fuzzy computing system, which is a multilayer architecture to learn and model human behavior. They attempt to join the advantages of a multi-agent based framework with fuzzy control techniques to improve the recognition process and continuously enrich the knowledge about the user and environment.

The majority of existing efforts are focused on the detection of normal and abnormal behaviors at the moment the resident is performing them. In previous work [11], we introduced a method to identify changes in patterns of behavior over longer periods of time (days, weeks or months). Identification of changes in behavior over such time frames is significant in the regard that it can be used to help predict cognitive and/or functional decline that affects overall quality of life [12, 13, 14]. If significant change in human behavior can be recognized early, then caregivers can take action to help avoid or postpone catastrophic events. However, the information obtained is a numerical data set. In this article our objective consists of developing a method to produce linguistic information that is of greater use to users. Our approach is based on the concept of linguistic summarization. A linguistic data summary is a concise, human-consistent description of a (numerical) data set [15, 16, 17]. This process allows us to summarize a data time series by segmenting and describing long-terms trends of change in behavior.

In the existing literature, there are different approaches to deal with time series summarization. The application range is very assorted, but the business field stands out over the rest. In [18, 20] Kacprzyk and Wilbik deals with time series used for an analysis of the past performance of investment (mutual) funds and extracts summaries to help to make future investment decisions. Focusing on human activities, in [19] the authors propose a novel method for recognizing human

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

activity from linguistic summarizations of temporal fuzzy inference curves representing the states of a three-dimensional object called voxel person. However, the approach taken in this article is most similar to that of Kacprzyk et al. [20]. Primarily, they focus on stock market analysis and finance applications. They propose a way to summarize trends identified with straight line segments of a piecewise defined linear approximation of time series of change in long-term human behavior. They employ a set of features (attributes) to characterize the trends such as the slope of the line segment. They then use a linguistic quantifier driven aggregation of trends to perform the linguistic summary. In addition, they also study the description of duration and variability.

Herein, we introduce a method to obtain a natural language description about change in long-term adapted behavior. The user selects a time period amount (resolution) to summarize, e.g., day, week, month, etc. A resident history is partitioned according to this time window and we extract features to characterize the change. In particular, we look for decreasing, constant, or increasing change (similarity) in behavior. This makes it possible to monitor cases such as a degenerative disease or a rehabilitation process without the need to continuously bother an elder.

This paper is organized as follows. Section 2 is previous work, which is required in order to understand this article. Next, in section 3 we introduce the linguistic summarization process, specifying the parameters used and the structure of the sentences. Section 4 is experiments. We present simulated user behavior in order to demonstrate a wide range of different possible scenarios and the response of our proposed approach.

II. Related Work

A. Modeling Human Behavior

Modeling human behavior in eldercare is a field that studies computational techniques to represent and analyze human daily activities in order to provide people with services if required, but without loss of independence. In this article, our objective is to extract a linguistic description of trends in long-term change of human behavior. This approach depends on the choice of representation. Here, we focus on a computational framework investigated by our research team in unpublished [21, 22]. The choice of representation is a sequence of cascaded AND gates with an underlying probability distribution that characterizes temporal dependency requirements over a set of actions for the different ways in which a user can perform a behavior. The work in [21, 22] is summarized in this subsection.

An abnormal situation occurs when a person does not perform the behavior as expected, i.e., forgetting things, performing actions in a dangerous order, etc. Example 1 demonstrates the role of detecting abnormal situations in the context of the goals of this work.

Example 1: Suppose that every morning a resident wakes up, goes to the bathroom, takes his pajamas off, takes a shower, washes his face, gets dressed and returns to the bedroom. All of these actions could be embraced as a single behavior concept, "morning routine". However, suppose that for a period of time the person does not take a shower. This is considered as a change in the "morning routine" behavior. This abnormal situation needs to be identified and the behavior model needs to be updated accordingly.

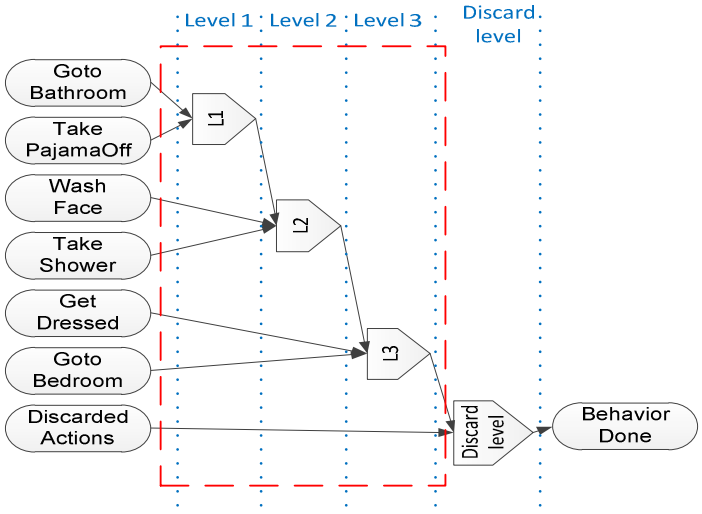

Fig.1. Morning routine behavior model (example 1).

In example 1, two important concepts are introduced, *action* and *behavior*. Informally, an action is the output of a sensor or a low-level algorithm interpreting sensor firings, e.g., the refrigerator door is closed, the front door is opened, a person is sitting on the couch, etc. Behavior is the set of actions and the order in which the actions need be performed. Formally, these concepts are characterized as follows.

Definition 1 (Human Action) [21, 22]: A human action h_i is a triple $h_i =< l_i, s_i, t_i >$, where l_i is a label used to identify the action, s_i is a sensor event and t_i is a time stamp in which the action occurs.

Definition 2 (Behavior) [21, 22]: A human behavior B_i is a quadruple $B_i =< H, R_i, C_i, \prec >$, where $H = \{h_1, h_2, \dots, h_n\}$ is a set of available human tasks, $R_i = \{r_1^i, r_2^i, \dots, r_{|R_i|}^i\} \subseteq H$ is the subset of available human tasks that are required to complete the behavior, and C_i is a set of temporal constraints between the tasks in R_i defined over a partial order relationship operator $\prec$. The partial order relationship $\prec$ defines the temporal dependency requirements over the actions of a behavior, and its formal definition is

$$r_a^i \prec r_b^i \leftrightarrow t_a \prec t_b. \quad (1)$$

Thus, a behavior is represented as a set of relevant actions, which maintain a specific order of performance between them. In [21, 22], we demonstrated that a behavior can be represented as a set of cascaded AND gates. An action in the system corresponds to an input of a specific AND gate. Each input is true if the action has been performed, or false if not. On the other hand, although all the tasks in the H set may be taken into consideration for a specific behavior, only those

actions that are included in the R set are really required for it. To handle this situation, we introduced a discard-level in which those actions that are irrelevant are assigned.

Besides relevant actions, this representation contains more knowledge about a specific behavior, such as the order relationship between diverse actions. As previously pointed out, a behavior is designed as a set of actions that maintains an order relationship between them. The level-representation for a behavior simulates the order relationship between the actions in such a way that those actions that are the input to an AND gate in Level_n have to be done previously to those that are the inputs to the following AND gate, in Level_{n+1}. Fig. 1 shows the sequence of AND gates obtained from example 1.

Nevertheless, a behavior does not have a single way to be performed. Hence, there may be several combinations of the same set of actions for a behavior, i.e., that some tasks may be performed in different levels of the structure without loss of meaning. For instance, in example 1, the action "wash face" could be performed either in level 2 or in the level 3 and be a legitimate Morning Routine. To deal with this disparity, in [21, 22] a probability matrix, $P(i,j)$, was computed, whose rows, $1 \le i \le |H|$, are actions, H set, and columns, $1 \le j \le |L|$, are available levels in the sequence of ANDs. Each element represents the probability of an action being performed in a particular level. Therefore, the behavior model represents, for each action, the most expected level for it being carried out. Next, keeping on with the prior example, an achievable matrix is presented below.

Continuation of example 1: Let us suppose that we want to study a "morning routine" behavior. In addition, let us suppose that we have the actions presented in example 1, plus the action "go to kitchen". Then, if the maximum number of levels was fixed to four, a possible P matrix to represent the model presented in fig. 1 could be

$$\begin{bmatrix} & L_1 & L_2 & L_3 & L_4 & L_5(discard\ level) \\ go\ to\ bathroom & 0.7 & 0.2 & 0 & 0 & 0 \\ take\ pajama\ off & 0.6 & 0.4 & 0 & 0 & 0 \\ take\ shower & 0.2 & 0.7 & 0.1 & 0 & 0 \\ wash\ face & 0 & 0.5 & 0.3 & 0 & 0.2 \\ get\ dressed & 0 & 0.2 & 0.6 & 0.2 & 0 \\ go\ to\ bedroom & 0 & 0.1 & 0.5 & 0.3 & 0.1 \\ go\ to\ kitchen & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

Among the advantages of our approach, the independence between the behavior representation and the method used to learn, recognize or adapt is the most important. This separation allows us to achieve better system modularization and to use a higher number of learning methods for the same activity model [21]. In [21, 22] we constructed a learning and recognition/adaptation process that will be used in this article to obtain the input to the process presented here. However, as this is not the focus of our article, we refer the reader to our previous work [11, 21, 22].

B. Comparing Soft Partitions

The next tool used in this investigation comes from the field of clustering. This method is used herein to compute the similarity between two behaviors according to how closely actions group into levels. Let $O = \{o_1, \ldots, o_n\}$ denote n objects. When each object in O is represented by a (column) vector x, the set $X = \{x_1, \ldots, x_n\} \subset \Re^p$ is an *object data representation* of O. When each object in $o_i \in O$ has a *physical label*, O is a set of *labeled data*; otherwise, O is unlabeled. Let integer c denote the number of groups, $1 < c < n$. Clustering in unlabeled data is the assignment of one of four types of labels to each object in O. After clustering, the label vectors of the objects are the columns of c-partitions of O, which are sets of (cn) values $\{ u_{ik} \}$ that can be conveniently arrayed as $(c \times n)$ matrices, $U = [u_{ik}]$. These labels can be crisp, probabilistic, fuzzy, or possibilistic.

When clustering produces more than one candidate for partitioning a finite set of objects O, there are two approaches to validation, i.e., selection of a "best" partition, and implicitly, a best value for c, the number of clusters in O. First, one could use an internal index, which evaluates each partition separately. Second, one could compare pairs of candidate partitions to each other, or to a reference partition that purports to represent the "true" cluster structure in the objects. In [23], we generalized many of the classical indices that have been used with outputs of crisp clustering algorithms so that they are applicable for candidate partitions of any type, i.e. crisp or soft, soft comprising the fuzzy, probabilistic and possibilistic cases. In particular, we concentrated on the Rand index and its modifications. We showed that our extension of the Rand index is $\boldsymbol{O}(n)$.

Let U and V be crisp partitions of O. Here, U and V need not possess the same number of clusters, i.e., r need not equal to c ($r \neq c$). The four classical combinations for pairs of objects from $O \times O$ in clusters of U and V are: (a) paired in U and V; (b) not paired in U nor in V; (c) paired in V but not in U; and (d) paired in U but not in V [24]. The comparison of U to V with a similarity measure s begins with the $r \times c$ contingency matrix $N = UV^T$ that contains counts of the number of occurrences of each of the four types over the $n(n-1)/2$ distinct, unordered pairs in $O \times O$. Entry n_{ij} is the number of objects common to subgroups U_i and V_j. The building blocks of many similarity measures for $s(U,V)$ are the four expressions (a)-(d) below. These four calculations count the number of occurrences amongst the $n(n-1)/2$ pairs of each of the four types of unordered pairs:

$$a = \frac{1}{2} \sum_{i=1}^{r} \sum_{j=1}^{c} n_{ij}(n_{ij} - 1); \quad (2)$$

$$d = \frac{1}{2} \left(n^2 + \sum_{i=1}^{r} \sum_{j=1}^{c} n_{ij}^2 - \left(\sum_{i=1}^{r} n_{i\bullet}^2 + \sum_{j=1}^{c} n_{\bullet j}^2 \right) \right); \quad (3)$$

$$b = \frac{1}{2} \left(\sum_{j=1}^{c} n_{\bullet j}^2 - \sum_{i=1}^{r} \sum_{j=1}^{c} n_{ij}^2 \right); \quad (4)$$

$$c = \frac{1}{2} \left(\sum_{i=1}^{r} n_{i\bullet}^2 - \sum_{i=1}^{r} \sum_{j=1}^{c} n_{ij}^2 \right). \quad (5)$$

where $n_{i\bullet}$ and $n_{\bullet j}$ referring respectively to the number of objects in classes U_i and V_j, using standard "dot" notation for row and column sums.

The sums $(a+d)$ and $(b+c)$ are usually interpreted, respectively, as (the total number of) *agreements* and *disagreements* between U and V. Anderson et al. [23] tabulate a (non-exhaustive) list of 14 coefficients that have been proposed for $s(U,V)$ based on functions of a, b, c and d; Sokal and Sneath list many others [25]. In addition, Anderson et al. also present a scaling value in the case of possibilistic labels. Here, we focus on the Rand, the classical form of which is

$$s_R(U,V) = (a+d)\,/\,(a+b+c+d). \quad (6)$$

The measure $s(U,V)$ can be used to address a variety of clustering problems [23]. For example, it can be used to compare a *clustering* to a reference partition that purports to represent the "true cluster structure", measure the effect of noise or missing data with respect to a specific clustering algorithm, study the convergence of a clustering algorithm at successive iterations, perform prediction (regression), as well as compare two different clustering algorithms.

C. Similarity measure for comparing human behavior

In [11], a similarity measure is introduced for comparing pairs of learned behavior and subsequently anomaly detection. Our new measure for analyzing long term human activity tends includes three different components: (1) comparing partitions, (2) subsethood of non-discarded actions, and the (3) similarity of partial order relations.

- *Comparing soft partitions*
  We determine the similarity between pairs of behaviors according to the strength of actions grouping into similar levels. Specifically, $s(U,V)$ is used, where U and V are behavior probability matrices acquired using the procedures described in subsection IIA, i.e. $U(i,j)$ is the probability that action i belongs to level j. In [11], we presented a scaling of $s(U,V)$ to produce a [0,1] value that is more appealing to human interpretation. The formula used to compare two different behaviors is

$$s_{cp}(U,V) = s(U,V)\,/\,maximum(\,s(U,U)\,,s(V,V)\,) \quad (7)$$

- *Subsethood of Non-Discarded Actions*
  This term is included to reduce the influence of the discarded level on $s_{cp}(U,V)$. This is because U and V generally share many actions in that level, independently of the represented behavior. First, the most likely level, $L_{i,max} = argmax_j\, P(i,j)$, for each action is found. Next, the crisp sets, $R_U \subseteq H_U$ and $R_V \subseteq H_V$, of actions in which $L_{i,max}$ does not equal the discard level is found. The matrix P contains evidence about the importance of actions to a behavior and the criteria of picking all actions that are not most likely in the discard level is feature selection. The subsethood measure of non-discarded actions over R_U and R_V is

$$s_{sub}(U,V) = |R_U \wedge R_V| \,/\, |R_U \vee R_V| \quad (8)$$

where $\wedge$ is intersection, $\vee$ is union and $|\bullet|$ is cardinality. The resulting similarity is

$$s_{cp_sub}(U,V) = s_{cp}(U,V) \times s_{sub}(U,V). \quad (9)$$

- *Similarity of Partial Order Relations*
  The definition of $s_{cp_sub}(U,V)$ does not take into account the similarity between the partial order relations. That is, two behaviors may share a set of non-discarded actions and have a strong similarity of actions grouping into levels (clusters), but the order of levels is not consistent. Hence, to truly compare two behaviors, the partial order relations need to be factored into the measure. We resolve this by counting the number of disagreements between U and V and weight the disagreements by their individual importance.

  First, a $|H|x|H|$ matrix, E_U, is created for behavior matrix U. For each action, the level with the greatest probability (most likely explanation) is found, i.e. $L_{i,max}$. Next, $E_U(i,j)$ is assigned a label from the set $\{B,A,S\}$, where 'B' (before) means $L_{i,max} < L_{j,max}$, 'A' (after) means $L_{i,max} > L_{j,max}$, and 'S' (same) means $L_{i,max} = L_{j,max}$. Cell $E_U(i,i) =$ *'S'* and if $E_U(i,j)$ is 'B' ('A') then $E_U(j,i)$ is 'A' ('B'). Remember, $L_{i,max}$ is the most likely level that action i belongs to. For that reason, we cannot just count the number of disagreements in E_U. Instead, we calculate an importance value per action. For action i, $\mathrm{P_{U,i}}$ measures the ability to decide that action i belongs to some particular level,

$$\mathrm{P_{U,i}} = \max_j(\mathrm{P_U(i,j)}) - \max_{\substack{k \\ j\neq k}} \big(\mathrm{P_U}(i,k)\big) \quad (10)$$

The significance weighted calculation of the similarity of partial order relations, $s_{por}(U,V)$, is based on the set of off-diagonal upper triangular indices of E_U, i.e. all (i,j) where $j > i$. In particular, the measure uses only the subset of indices, I', in which actions i and j are not most likely discarded. Based on $P_{U,i}$ and $E_U(\mathrm{i,j})$, the similarity of partial order relations is now defined as

$$s_{por}(U,V) = 1 - \left(\textstyle\sum_{(i,j)\in I'} \emptyset(\,\mathrm{E_U(i,j)}\,,\mathrm{E_V(i,j)}\,)\right)/|I'|, \quad (11)$$

where

$$\emptyset\big(\mathrm{E(i,j)},\mathrm{E_V(i,j)}\big) = \begin{cases} 0 & if\ \mathrm{E_U(i,j)} = \mathrm{E_V(i,j)} \\ \min\,(\mathrm{P_{U,i}},\mathrm{P_{V,i}}) & else \end{cases}, \quad (12)$$

and the final measure for comparing human behaviors is

$$s_{final}(U,V) = s_{cp}(U,V) \times s_{sub}(U,V) \times s_{por}(U,V) \quad (13)$$

With this measure, we are able to detect longer time period changes in the *same* behavior (days, weeks, months, etc). The anomaly detection approach in this article is independent of the success of any short time period recognition algorithm. That is, if a serious short-term event is undetected, we still expect significant change in longer time period behavior. In [11], we also presented a time series normalization of $s(U,V)$,

$$norm_1(U,V) = maximum(\, s(U,U)\,, s(V,V)\,), \quad (14)$$

$$norm_2(U,\{V_1,\dots,V_n\}) = maximum(\,\{\, norm_1(U,V_1)\,,\dots\,, norm_1(U,V_n)\,\}\,), \quad (15)$$

$$s_{cp2}(U,V_i) = s(U,V_i) \,/\, norm_2(U,\{V_1,\dots,V_n\}), \quad (16)$$

where U is the reference behavior and V_i $(1 \le i \le N)$ is an adapted behavior. We update the behavior model each day. The final measure presented in [11] is

$$s_{final2}(U,V_i) = s_{cp2}(U,V_i) \times s_{sub}(U,V_i) \times s_{por}(U,V_i) \quad (17)$$

Fig. 2 is an example time series from [11] for the behavior 'Wake up". The annotations describe what the person was doing during the one year time period. We see that the proposed similarity measure captures these important changes.

III. LINGUISTIC SUMMARIZATION

Using the measure discussed in section 2c, we are able to study longer time period changes in behavior. However, this representation is not the most understandable by nurses, social workers, families or residents. Our objective is to produce linguistic summarizations of the time series. Example summarizations include *"the quality of the 'wake up' behavior is decreasing in the last month"*, *"the quality of the 'have breakfast' behavior is slowly increasing in the last week"*, or *"the quality of 'morning routine' is constant but highly unstable in the last month"*. These examples illustrate cases in which less information is more useful. That is, summarization identifies the important trends and it is understandable by a domain expert. In the following sections, we present a method to measure the type and amount of change as well as the stability in comparing behavior time series. We then present a fuzzy set theoretic approach for linguistically interpreting the numeric values for the eldercare problem domain.

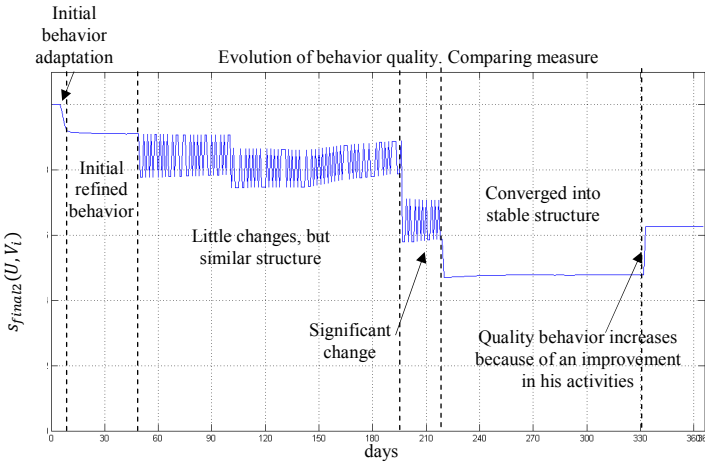

Fig 2. Output of our comparing behavior approach [10] for 360 days of adapted behavior for the activity "Wake up" (which is reported in table 1). Annotations show what happened in this year. Each day is compared to an initial base refined behavior (the base-line behavior).

A. Temporal resolution of summarization

As already discussed, in Kacprzyk et al. [20] a time series is algorithmically segmented. The proposed technique can address identifying trends that take varying amounts of time to occur, but only one set of summarizations are produced. That is, different summarizations could be produced if the problem is viewed in different ways, like being sampled differently. For example, a summary of increasing might be produced if we analyzed day by day, while a summarization of constant might be produced if the time scale is month. Our objective is not to study automatically segmented global trends, rather trends for a user specified time scale. We are interested in detecting gradual changes in the elder's behavior as soon as possible. Kacprzyk et al. differentiate between global trends, which concern the entire time series (or some, probably large, part of it), and partial trends concerning a smaller time span (e.g. a window). Our focus is on the second (partial trends). We provide the person with the option of selecting the time period that he/she would like summarized. That defined time window has a considerable influence on the linguistic summarizations produced. Thus, the user will select it based on a specific hypothesis to be tested. For example, has there been change this week, this month, etc.

B. Partial trend summarization using linear regression

The global trend segmentation and resulting variability calculations of Kacprzyk et al. did not work particulary well for our problem domain. Their focus is stock market analysis and financial domains. The particular trends that we are looking to identify are not reliably segmented using their technique. Instead, we rely on the well-known method of linear regression in order to numerically summarize a partial trend time window. Linear regression is used here to fit a predicted model (linear equation) to observed data, a window of our time series. We calculate the slope of the estimated linear equation, which resides in $[-90°, 90°]$. Additionally, we compute the mean squared error (mse), which varies in [0, 1]. This simple but effective method provides us with the two desirable quantities, the angle of the line segment that characterizes the rate of change of the time series and the variability of the samples to the estimated linear equation.

Herein, linguistic summarization of change in human

behavior over long time periods according to a reference baseline model for a given user time resolution consists of the generation of understandable sentences of the form:

Behavior [X] is [angle] with [mse] in a time period equal to [time window].

C. Fuzzy sets

In this article, we leverage the concept of *dynamics of change* (or speed of change) identified by Kacprzyk et al [20]. The authors propose linguistic terms corresponding to various inclinations of a trend line: *quickly decreasing, decreasing, slowly decreasing, constant, slowly increasing, increasing and quickly increasing*. Each term represents a fuzzy granule of direction. Following the authors' indication, we define the following trapezoidal fuzzy sets on the angle domain in degrees, and illustrated in fig. 3:

- *Quickly decreasing* [-90 -90 -80 -60]
- *Decreasing* [-75 -60 -40 -25]
- *Slowly decreasing* [-40 -30 -20 -10]
- *Constant* [-20 -10 10 20]
- *Slowly increasing* [10 20 30 40]
- *Increasing* [25 40 60 75]
- *Quickly increasing* [60 80 90 90].

Next, we define a linguistic variable for the concept stability of a time series in a user defined time window. While this is similar to Kacprzyk's notion of variability, they are calculated differently. Our terms for stability are defined using linear regression, specifically mse. The fuzzy sets represent the possible levels of instability existing in a time window. We define five terms: *no instability, low instability, medium instability, high instability* and *extreme instability*. The trapezoidal membership functions for these fuzzy sets are (see fig. 4 for a graphical representation):

- *no instability* [0 0 0.0001 0.0012]
- *low instability* [0.0001 0.0005 0.001 0.0014]
- *medium instability* [0.0001 2 0.002 0.004 0.0048]
- *high instability* [0.004 0.009 0.04 0.07]
- *extreme instability* [0.05 0.071 1 1].

These fuzzy sets have been defined as a generalization of a wide range of cases studied, using the trial and error technique.

IV. EXPERIMENTS

Our experiments study different common elderly behaviors, such as Wake Up, Morning Routine or Have Breakfast. Here, we show results for *Wake Up* and *Morning Routine*, but more results can be found in [11].

As previously indicated, the behavior model is an abstract architecture completely independent of method used to learn, recognize or adapt it. Therefore, our outcomes will be also independent of the type of sensors used to detect the user activities required to those processes. In order to test a wide range of human behavior scenarios, we have developed an

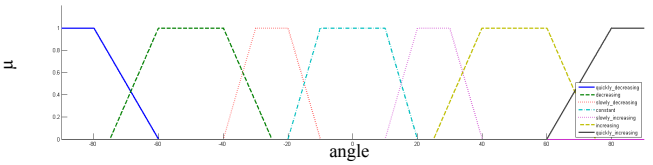

Fig. 3: Fuzzy sets for the angle of the estimated linear equation.

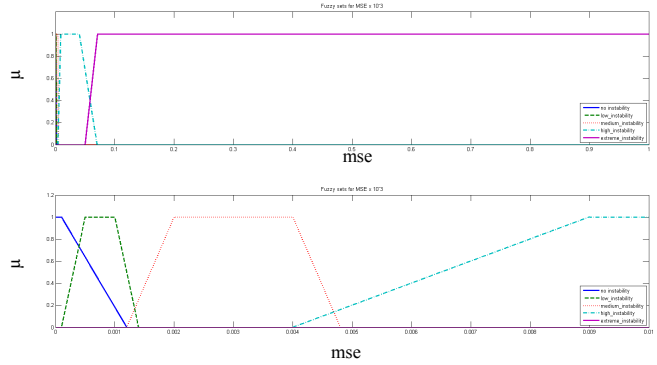

Fig. 4: Fuzzy sets for the mse in the user specified time window.

algorithm that takes action and temporal constraints and generates *synthetic data sets* [21, 22]. The input to this algorithm consists of a set of constraints (table 1), where the partial order relations between the actions are defined. These data sets are used in both learning and recognition [21]. We generated the following data sets to explore how the proposed measure responds to different scenarios.

- DS_1: The resident always performs the behavior correctly, i.e. normal behaviors. Herein, DS_1 is used to learn the initial baseline model. It has 365 days worth of behavior.
- DS_2: The resident has a degenerative disease, and his behavior deteriorates continuously and slowly.
- DS_3: The resident has a *catastrophic event*, e.g. a fall. This event is severe and it results in restricted mobility. After the event, a user's routine has changed significantly as a result. However, after a period of time the user is able to start *rehabilitation*, and his behavior improves. There

TABLE 1: BEHAVIOR AND TEMPORAL CONSTRAINTS

Behavior	Order relationship constraints	Temporal constraints
B_1 (Wake up)	AsleepInBed ≺ AwakeInBed AwakeInBed ≺ GetOutOfBed GetOutOfBed ≺ GetSlippers GetSlippers ≺ GotoBathroom	6:50 to 7:10
B_2 (Morning Routine)	GotoBathroom ≺ { UseToilet, TurnShowerOn} {UseToilet, TakePijamaOff , TurnShowerOn } ≺ TakeShower TakeShower ≺ { TurnShowerOff, UseTowel, BrushTeeth, WashFace, CombHair} UseTowel ≺ GetDressed {TurnShowerOff, UseToilet, BrushTeeth, CombHair, WashFace } ≺ GotoBedroom	7:00 to 7:40

TABLE 2: BEHAVIOR CONSTRAINTS AFTER CATASTROPHIC EVENT

Behavior	Order relationship constraints
B_1^* (Wake up)	AsleepInBed ≺ AwakeInBed AwakeInBed ≺ GetOutOfBed GetOutOfBed ≺ GotoBathroom
B_2^* (Morning Routine)	GotoBathroom ≺ { GetDressed, UseToilet, BrushTeeth, CombHair, WashFace} { UseToilet, BrushTeeth, CombHair, WashFace} ≺ GotoBedroom

are 110 days before the event, 1 day in which the event occurred (day 111), 139 days of convalescence and others 115 days of different behavior afterwards when the user is undergoing rehabilitation. During the rehabilitation, his behavior is improving slowly.

The changes in behavior due to the catastrophic event are shown in table 2.

A. *Experiment 1. Degenerative disease*

In the first experiment, we show how our system is able to detect a degenerative disease. First, we learn a correct behavior using DS_1. After that, we use DS_2 as input to the recognition and adaptation process. Once the process has finished, the evolution graph is generated using the method in [11]. This time series is used as input to our linguistic summarization method. First of all, we define the *time window resolution*. Although the system is able to deal with different resolutions, here we study the results monthly in order to simplify the problem.

The results for *Wake up* behavior are shown in fig. 5. The graph represents the measured change in behavior. The continuous curve is the similarity measure, while the discontinuous lines are the linear regression results at each non-overlapping window. The related linguistic summarization is presented in table 3.

Fig. 5 shows a behavior whose quality is decreasing very slowly. This corresponds to a resident with a degenerative disease reducing the resident mobility and, therefore, changing his normal activity. However, there are time periods when his/her behavior is considered constant although not stable. Our summary is able to detect those moments of instability, describing it as medium in *February* or low in *November,* when the behavior has a little decrease and later an increase.

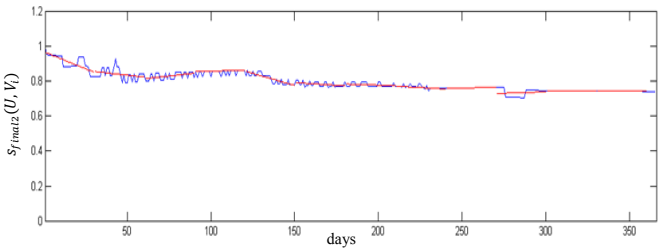

Fig. 5: Similarity of adapted behavior to a learned reference behavior for "Wake up" behavior. In this situation, we simulate a user with a degenerative disease. The rate of change for this behavior is slow.

TABLE 3: LINGUISTIC SUMMARIZATION OF TIME SERIES IN FIGURE 5

Days	Linguistic Summarization
1-30	B_1 is *slowly decreasing* in a time period equal to *30 days*
31-60	B_1 *is constant* with *medium instability* in a time period equal to *30 days*
61-90	B_1 *is constant* with *low Instability* in a time period equal to *30 days*
91-120	B_1 *is constant* with *no instability* in a time period equal to *30 days*
121-150	B_1 *is slowly decreasing* in a time period equal to *30 days*
151-180	B_1 *is constant*, with *no instability* in a time period equal to *30 days*
181-210	B_1 *is constant*, with *no instability* in a time period equal to *30 days*
211-240	B_1 *is constant*, with *no instability* in a time period equal to *30 days*
241-270	B_1 *is constant*, with *no instability* in a time period equal to *30 days*
271-300	B_1 *is constant*, with *low Instability* in a time period equal to *30 days*
301-330	B_1 *is constant*, with *no instability* in a time period equal to *30 days*
331-365	B_1 *is constant*, with *no instability* in a time period equal to *30 days*

B. *Experiment 2. Catastrophic event and rehabilitation*

For the second experiment, once again DS_1 is used to learn a reference behavior. However, DS_3 is used during the recognition and adaptation process. The database represents user activities for a year. The user suffers a *catastrophic event*, as a fall. This event provokes the elder to change his/her activity significantly, and then undergo *rehabilitation*. The linguistic summarization for *Morning Routine* behavior obtained from these results is presented in table 4 regarding fig. 6.

We would like to emphasize how the linguistic summarization is able to delineate the important changes occurring during the year. During the first three months, the behavior is *constant* because the elder maintains his/her normal activities. When the catastrophic event happens, at the middle of the fourth month, the behavior model adapts to the new normal. The model requires some time period to adapt completely. However, it does reflect those little changes, as does the linguistic summary. The forth month is characterized as *medium instability*, since the behavior is summarized as *constant*. During the fifth and sixth months, the behavior changes significantly (declines), resulting in *behavior decreasing* and *behavior slowly decreasing* respectively. These months are included in the convalescence period: the user stabilizes her behavior and she recovers from the catastrophic event. The ninth month is when the elder starts rehabilitation. As expected, rehabilitation is not an instant process, it requires effort and time. During the ninth and tenth months, she is changing her behavior slowly without great advance (*behavior constant* and *low instability*). Nevertheless, after two months undergoing rehabilitation, the elder improves her behavior more rapid than before (*behavior increasing*), until a point where the behavior is stable again (*behavior constant* and *low instability*).

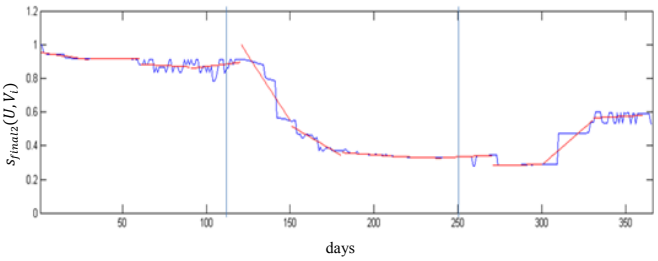

Fig. 6: Similarity of adapted behavior to a learned reference behavior for "Morning Routine" behavior. This event, e.g. a fall, results in a large change in subsequent behavior (i.e. table 2). We also simulate a scenario in which the user undergoes rehabilitation and his/her behavior improves but never goes back to what it was before.

TABLE 4: LINGUISTIC SUMMARIZATION OF TIME SERIES IN FIG. 6

Days	Linguistic Summarization
1-30	B_2 is *constant*, with *no instability* in a time period equal to *30 days*
31-60	B_2 is *constant*, with *no instability* in a time period equal to *30 days*
61-90	B_2 is *constant* with *low Instability* in a time period equal to *30 days*
91-120	B_2 is *constant* with *medium instability* in a time period equal to *30 days*
121-150	B_2 is *decreasing* in a time period equal to *30 days*
151-180	B_2 is *slowly decreasing* in a time period equal to *30 days*
181-210	B_2 is *constant*, with *no instability* in a time period equal to *30 days*
211-240	B_2 is *constant*, with *no instability* in a time period equal to *30 days*
241-270	B_2 is *constant* with *low Instability* in a time period equal to *30 days*
271-300	B_2 is *constant* with *low Instability* in a time period equal to *30 days*
301-330	B_2 is *increasing* in a time period equal to *30 days*
331-365	B_2 is *constant* with *low Instability* in a time period equal to *30 days*

V. CONCLUSIONS

In this paper, we presented a method to produce a linguistic summarization about the quality of an elder's behavior as it adapts over time. In previous work, we presented a method to obtain behavior representations [21, 22] and a measure to analyze change in behavior models [11]. This paper is focused on defining a fuzzy set-based method to summarize the measured information, with the goal of reporting information in a natural language to nurses, doctors or social workers, which makes it simpler for them to understand what is going on. We introduced a user-defined time resolution approach that allows the expert to investigate different time specific health queries. In addition, we defined a set of features that allows us to detect if the behavior is changing, the speed of the change and the stability of the behavior. Finally, we tested our method in a simulated resident scenario to show how the method helps a person (e.g. elder, caregiver, social workers or even family member) to monitor the activities of an elderly resident.

Future work includes the following. First, a synthetic data set was used to test different behavior scenarios. We will investigate using the LA approach from the University of Granada, Spain on real sensor data collected from the assisted living facility, TigerPlace [2], in Columbia MO, USA. Secondly, we propose to obtain the expert opinion to evaluate the method and improve it by adding more attributes. Both the membership functions and the methods of producing the linguistic summarization can be learned.

Abstract— **Applying best available evidences to clinical decision making requires medical research sharing and (re)using. Recently, computer assisted medical decision making is taking advantage of Semantic Web technologies. In particular, the power of ontologies allows to share medical research and to provide suitable support to the physician's practices. This paper describes a system, named ODINO (Ontological DIsease kNOwledge), aimed at supporting medical decision making through semantic based modeling of medical knowledge base. The system defines an ontology model able to represent relations between medical disease and its symptomatology in a qualitative manner by using fuzzy labels. Medical knowledge is defined according with physician experts members of INMP[1] (National Institute for Health Migration and Poverty). The main aim of ODINO is to provide an effective user interface by using ontologies and controlled vocabularies and by allowing faceted search of diseases. In particular, this work mashes the capabilities of Description Logic reasoners and information retrieval techniques in order to answer to physician's requests. Some experimental results are given in the field of dermatological diseases.**

Keywords- Semantic Web, Ontology, Clinical DSS, Diagnosis

I. INTRODUCTION

Traditional approaches to the medical diagnosis practice have many drawbacks, like as: the huge growth of biomedical information has made difficult the retraining for the individual doctors; the poor dissemination of effective research results; and so on.

New trend is the Evidence-Based Medicine (EBM) which aims to apply the best available evidences gained from the scientific methods to clinical decision making. The challenge of EBM is to define a systematic approach to integrate research results with clinical expertise and patient preferences, and exploit them during the medical diagnosis. So, it is necessary to provide a suitable model to structure medical results and to perform the knowledge spreading and sharing.

There are several ongoing efforts aimed at developing formal models of medical knowledge and reasoning to design decision support systems. These efforts have focused on representing content of clinical guidelines and their logical structure. Semantic Web technologies and ontologies are enabling elements to achieve these aims. In fact, today ontologies are assuming increasingly important role in the area of knowledge based decision support systems by introducing capabilities in terms of logic based reasoning.

This work presents ODINO, a multilingual web based application, that addresses the aim to use semantic web technologies in order to support medical practices through an effective user interface. In particular, ontologies are used to model available medical diseases features (e.g., skin diseases), symptomatologies, treatment protocols and so on. The relations between symptomatologies (i.e., symptoms and signs) and available diseases are represented by using fuzzy labels resulting from the analysis of medical expertise included in [1]. Standard formalisms, like OWL and SKOS, are used to specify domain knowledge and controlled vocabularies, i.e., diseases, symptomatology, active ingredients and clinical tests according to standard specifications, like as ICD-9-CM[2].

Ontologies, controlled vocabularies and information retrieval techniques are exploited to provide typical capabilities of Semantic Web portals [2] and medical decision support. Some of the main features of the system are:

- disease catalogue browsing including images, symptoms and signs, treatments, etc. to support rapid training;
- preliminary medical diagnosis, indeed medical knowledge querying by specifying symptoms, signs and complications, to find eligible diseases;
- faceted search of diseases by enabling multi-criteria selections (i.e., symptomatologies, complications, active ingredients, etc.) to support differential diagnosis.

ODINO results are explained to physician by highlighting symptoms/signs/complications that match the retrieved diagnosis and by suggesting other important features of founded diseases.

The paper is organized as follows. Section II introduce some related works in the applicative domain. Section III describe the knowledge layer of ODINO. The medical decision support methodology is described in Section IV. Then, Section V details features of system and provides the results of the case

study. Finally, there are conclusions of the paper.

II. Related Works

A medical diagnosis problem consists of the identification of a disease and corresponding treatments that treat it.

In the past years, a great deal of artificial intelligence research has been directed towards the development of expert systems for problem solving in medical diagnosis domain. As examples of developed medical expert systems, we mention: Mycin [3], DXplain [4], Puff [5], Cadiag2 [6], Gideon [7] and Casnet [8]. In particular, interesting approach is used in Cadiag2 that exploits fuzzy set theory to model medical concepts, and fuzzy logic to emulate diagnostic processes. As argued in [9], [10], fuzzy sets offer linguistic label that well approximate medical texts. In addition, fuzzy logic provides reasoning methods capable of making approximate inference [11],[12]. So, fuzzy set theory provides appropriate basis for the development of a computer-based diagnosis system [13]. Nevertheless, there are some problems related with these expert systems consisting in their limited [14],[15]: flexibility, adaptability, extendibility and cooperation capability. Strictly related to our approach, some works, such as [16] and [17], highlight benefits of mashing semantic and fuzzy logic in healthcare. Analogously, ODINO exploits: Semantic Web formalism to represent fuzzy relations between diseases and symptomatologies; and soft computing techniques to arrange diseases that share these relations.

Conversely, solutions like MEDBOLI [18] and ODDIN [19] use Semantic Web Technologies to develop a software that allows users to make diagnosis. In fact, since in medical discipline homogeneity of terminology is mostly problematic, the semantic technologies can be exploited to make known machine-readable latent relationships [20]. Ontologies allow users to understand meaning of each element, and improve reasoning [21], [22]. Regarding efforts which apply semantic techniques, initiatives such as OpenGalen [23] should be mentioned, a not-for-profit organization which provides downloadable open source medical terminology. Other initiatives include, for example, OBO Foundries [24], a collaborative experiment among developers of science-based ontologies. Within the scope of this research there are many resources in use such as Biological Ontologies [25], Ontology-based Support for Human Disease Study and Medical Ontologies to support human disease research and control [26], "relations in biomedical ontologies" [27], and SNOMED CT, a concept-oriented controlled vocabulary [28].

However, today, semantic annotation of Web content with metadata is not very common on health websites, but it is sometimes mandated by, e.g., government standards. The annotation processes are often tedious and require capability in the use of large vocabularies, such as Medical Subject Headings (MeSH)[3]. In this perspective, one of the major contribution of ODINO is that diseases are semantically annotated by using typical standards and controlled vocabularies of medical domain, as well as ICD9. These standards are exploited in order to provide feature of faceted based navigation of diseases. Furthermore, thanks to the benefits of semantic technologies usage (flexibility and configurability of the system), faceted navigation supports multi-criteria selection to discover right diseases. In this sense, ODINO was inspired by previous semantic portals such as SWED [2], the MultimediaN E-culture demonstrator [28] and HealthFinland [30]. Another contribution of ODINO is the definition of sharable *Medical Disease Ontology* model capable to represent relation degree between disease and symptoms coming from statistical analysis included in the book [1].

III. Knowledge Layer

ODINO is a knowledge based system that provides capabilities in terms of clinical decision support system and medical semantic web portal. In particular, ODINO makes an intensive usage of ontologies, controlled vocabularies and other standards typical in the medical domain. This section provides details about medical knowledge modeling of ODINO.

A. Technologies and Standards

Following sections provide some references to used technologies and standards, and introduce their roles in ODINO. Semantic technologies (i.e., OWL and SKOS) have been used to represent medical diseases. On the other hand, knowledge developed in ODINO have been aligned with international standard classification of medical diseases available in ICD9-CM.

1) OWL

Ontologies play an important role in ODINO. Generally, ontologies enable knowledge sharing, exchanging and reusing. Standardization of ontology languages has been an important issue in W3C for years. OWL[4] (Web Ontology Language) is their result and is the standard for ontology definition in the last decade. OWL can be used to explicitly represent the meaning of terms and their relationships. Furthermore, OWL has more facilities for expressing meaning and semantics than others W3C's standards and thus fosters availability of machine interpretable content on the Web. In particular, OWL has three sublanguages with different expressive power: OWL Lite, OWL DL, and OWL Full, respectively. OWL is based on XML and RDF and all data in an OWL file can be represented as a set of RDF triples.

In this work, we follow W3C's recommendation to build ontologies and construct knowledge bases according to the OWL-DL restrictions. In particular, a *Medical Disease Ontology* has been defined as described in Section III.C.

2) SKOS

SKOS[5] (Simple Knowledge Organization System) is a common data model for knowledge organization systems such as thesauri, classification schemes, subject heading systems and taxonomies. Using SKOS, a knowledge organization system can be expressed as machine-readable data. It can be exchanged between computer applications and published in a machine-readable format in the Web.

[4] http://www.w3.org/TR/owl-features/

[5] http://www.w3.org/TR/skos-reference/#L895

SKOS is used in our system together with OWL in order to express and share knowledge about medical domain. In particular, ODINO exploits SKOS to write vocabularies and taxonomies, like as: symptomatologies, diseases, drugs, etc. (as described in Section III.B). On the other hand, OWL is used to represent the formal model of disease ontology by defining axioms and constraints.

3) ICD-9-CM

The International Statistical Classification of Diseases and Related Health Problems (ICD) is a way to code and organize diseases and a wide variety of signs, symptoms, abnormal findings, complaints, and external causes of injury or disease, published by the World Health Organization [6] (WHO). It assigns a unique up to six characters long code to every health condition.

In this work, the ninth version of ICD (ICD-9) has been used. In particular, ODINO uses ICD9 - Clinical Modification (ICD-9-CM) that provides additional morbidity details than ICD9. ICD9-CM has been applied to align controlled vocabularies deployed during the knowledge base design. This alignment provides shareability of the knowledge base deployed for ODINO.

B. Controlled Vocabularies & Taxonomies

Some controlled vocabularies and taxonomies (i.e., diseases, symptomatology, clinical tests, active ingredients) have been deployed in ODINO by using SKOS technology. Generally, following SKOS properties have been used to represent vocabularies:

- *preferredLabel* (in both Italian and English languages), to define the favorite name of concept;
- *alternateLabels* (in both Italian and English languages), to associate alternative terms to the same concept in order to specify synonym, and so on;
- *hiddenLabel*, to associate the right ICD-9-CM code to the defined concepts (i.e., disease, symptom, etc.) taking into account results from the alignment process;
- *exactMatch,* to eventually specify relation between concepts with equivalent meaning;
- *broader* and *narrower* to specify hierarchical relations among concepts. These properties are enabling elements to create taxonomies and to support faceted navigation as described below in Section V.C;
- *prefSymbol* and *altSymbol* properties, to join one or more images to concept.

In particular, *exactMatch* allows to maintain ICD9-CM coding and to update the knowledge base with alignment to others classification systems (such as ICD-10 or ICD-11).

Controlled vocabularies and taxonomies developed in ODINO are:

- *Symptomatology* – that contains definitions of concept concerning symptoms and signs, like as: paresthesia, anhidrosis, plaque of psoriasis, etc.. Fig. 1 shows an example of SKOS concept modeling a symptomatology and their hierarchical relations;
- *Disaeses* – that contains medical diseases, their characteristics and hierarchical relations, like as: leprosy, malaria, AIDS, etc.. In particular, broader and narrower properties, in SKOS, allow to define a hierarchy of diseases;
- *Clinical Tests* – that models clinical and laboratory tests useful in diagnostic process, like as: haemochrome, urinalysis, specific blood tests for syphilis, etc.
- *Active ingredients* – that defines the drugs suitable for a specific disease treatment, like as: Dapsone, Rifampicin, Antacids, etc.. Since, ICD9 doesn't contain any drug classification, this vocabulary is not aligned with it.

C. Medical Disease Ontology

This section describes main aspects of knowledge models developed in ODINO. An ontology named *Medical Disease Ontology* has been defined. Through a set of properties and concepts, this ontology models disease characteristics and relations. In particular, *Medical Disease Ontology* includes the definition of a correlation degree between disease and its symptomatology by using fuzzy labels. These properties lead system's diagnosis processes and aid disease information consultation.

One of the main class defined is the concept of Disease which identifies condition of medical disease that causes pain, dysfunction, distress, social problems, and/or death, to afflicted person. Fig. 2 shows a sketch of the ontology by illustrating the relations between *Disease*, *Symptom/Sign* and *Complication* classes. In particular:

- *Symptom/Sign* is the class identifying symptom or sign that influences a disease. Many instances of *Symptom/Sign* may be associated to the same *Disease*. So, the relation *"has symptom"* hasn't any cardinality restriction.
- *Complication* is a medical disease or symptom that represents an unfavorable evolution of disease, health condition or medical treatment. Analogously with *"has symptom",* the relation *"has complication"* hasn't any

```
<owl:Thing rdf:about="#Sin157">

  <skos:prefLabel xml:lang="en">Hand swelling</skos:prefLabel>
  <skos:prefLabel xml:lang="it">Edema delle mani<skos:prefLabel>
  <skos:altLabel xml:lang="en">Hand edema</skos:altLabel>
   <skos:hiddenLabel>729.81</skos:hiddenLabel>
   <skos:prefSymbol>edema1.jpg</skos:prefSymbol>
   <skos:altSymbol>edema2.jpg</skos:altSymbol>
   <skos:inScheme rdf:resource="#Symptomatology "/>
</owl:Thing>
```

Figure 1. An *example* of symptom specification in SKOS.

[6] http://www.who.int/en/

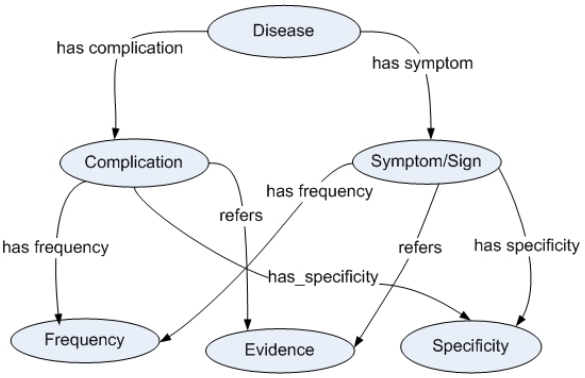

Figure 2. A sketch of *Medical Disease Ontology: Disease, Complication* and *Symptom/Sign.*

cardinality restriction.

Complication and *Symptom/Sign* are themselves related with other classes:

- *Evidence,* that represents the bridging element with the *Symptomatology* SKOS vocabulary;
- *Specificity* and *Frequency,* that allow to indicate how much *Complication* or *Symptom/Sign* implies the presence of that disease.

Furthermore, as shown in Fig. 3, *Disease* is also related with *Clinical test* class. *Clinical test* identifies each possible clinical, laboratory and diagnostic test. Analogously with *Symptom/Sign* and *Complication*, the model foresees the specification of *Precision* degree between a *Clinical test* and a *Disease* (see Fig. 3). In particular, the *Precision* defines how much a *Clinical test* result determines the presence of specific disease.

Frequency, Specificity and *Precision* are enumeration classes defined by using *oneOf* construct available in OWL. More precisely, we have defined, for each of them, some individuals that identify fuzzy labels. Values assumed by these relations are obtained from the analysis of medical practice and experience included in [1]. Specifically:

- *Frequency* - is the rate with a symptom/sign or complication is present in a given disease. Identified levels are: *very frequent, very frequent/frequent, frequent, frequent/occasional, occasional*;
- *Specificity* - is the measure with which manifestation implies a specific disease. Identified levels are: *high, high/medium, medium, medium/low, low;*
- *Precision* - is the level with which *Clinical test* result allows to include or exclude a diagnosis. Identified levels are: *high, high/medium, medium, medium/low, low*.

Furthermore, the model foresees other concepts and relations useful to define additional information of diseases, and recommendation), etiology, epidemiology, transmission of disease, prophylaxis, and so on.

Code listed in Fig. 4 shows an individual definition of Disease as an example. In particular, "Sin189" is of type

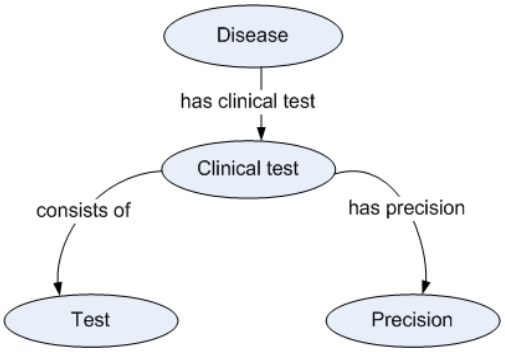

Figure 3. A sketch of some classes of *Medical Disease Ontology*: *Disease* and *Clinical test*.

Evidence and is associated with "*Medium/Low*" specificity and "*Frequent*" frequency degree to disease "*Mal002*". Furthermore, we have associated a complication (*infertility*) and a *NMR (Nuclear Magnetic Resonance)* test.

As detailed in the following section, *Medical Disease Ontology* is the baseline to build our medical diagnosis methodology.

IV. MEDICAL DIAGNOSYS METHODOLOGY

A. Mathematical model to support preliminary diagnosis

One of the main features supported by ODINO is preliminary medical diagnosis. During medical practices, physician submits a query by specifying one or more evidences that may be symptoms, signs and/or complications. So, the system evaluates correlation degree among incoming query and available diseases by means of an approach based on Information Retrieval techniques and Fuzzy Formal Concept Analysis (FFCA) [31]. Furthermore, system is capable to use relations among concepts in order to augment query results by using a Description Logic reasoner.

As described above, *Specificity* and *Frequency* are the main features to include or exclude diagnosis results. Specifically, a mathematical model of *Disease* and its correlation with *Symptom/Sign* and *Complication* may be obtained in order to perform FFCA.

```
<owl:Thing rdf:about="&Symptomatology ;Sin189">
  <rdf:type rdf:resource="#Evidence"/>
</owl:Thing>
                                ...

  <refers rdf:resource="&Symptomatology ;Sin189"/>
  <frequency rdf:resource="#Frequent"/>
  <specificity rdf:resource="#Medium-Low"/>
</owl:Thing>
                                ...
<owl:Thing rdf:about="&Diseases;Mal002">
  <rdf:type rdf:resource="#Disease"/>
  <has_semeiotics rdf:resource="#Sem_fever"/>
  <has_complication rdf:resource="#Com_infertility"/>
  <has_clinical_test rdf:resource="#Acc_RMN"/>
</owl:Thing>
```

Figure 4. *Medical Disease Ontology*: individual disease example.

The FFCA, informally, exploits a matrix that represents the fuzzy relation between objects of the input data (i.e., *Diseases*) and some attributes (i.e., *Symptoms/Signs* and *Complications*). The relation is calculated by assessing both *Frequency* and *Specificity* degree between *Disease*, *Symptom/Sign* and *Complication*. In particular, the value of relation, $\mu_{i,j}$, between $Disease_i$ and $Symptoms/Signs_j$ or $Complications_j$ is calculated by performing a linear combination (a weighted sum) of *Specificity* and *Frequency* with parameters λ_1 e λ_2. These parameters consist of constant values chosen based on medical experience, depicted in [1], which shows that, during preliminary diagnosis, *Frequency* is less important than *Specificity*. Formally:

$$\mu_{i,j} = (Specificity * \lambda_1) + (Frequency * \lambda_2), \lambda_1 > \lambda_2 \quad (1)$$

Taking into account the matrix created according to these criteria, FFCA arrange data in a corresponding lattice [31]. Specifically, diseases that share symptoms/signs or complications are arranged together. As argued, the lattice is used to retrieve concepts closer to the incoming query in order to retrieve eligible set of diseases.

B. Identification of candidate disease

In this process the main aim is to get a synthetic value which represents how each resource is relevant with respect to the user query. By revising some Information Retrieval measures (i.e., Precision and Recall), we determine what is the concept (or concepts) most related to the incoming symptoms/signs or complications in the query. In particular, the standard measures of Precision, Recall and F-measure have been adapted to our objective.

Formally, let us consider the following notions:

- $A = \{a_1, a_2, \ldots, a_n\}$ the whole set of attributes (i.e., symptoms, signs, complications) belonging to object;
- $O = \{o_1, o_2, \ldots, o_t\}$ the whole set of objects (i.e., diseases);
- $C_i = (A_i, O_i)$ *i-th* formal concept of a lattice (where A_i and O_i represent, respectively, terms and resources for the concept C_i);
- $Q_i = \{q_1, q_2, \ldots, q_m\}$ a query (e.g., set of symptoms/signs, etc.).

Thus, given a formal concept C_i, we calculate the values of precision P_i and recall R_i as follows:

$$P_i = \frac{|Q_i \cap A_i|}{|A_i|} \qquad R_i = \frac{|Q_i \cap A_i|}{|Q_i|} \quad (2)$$

where Pi is computed as ratio between the number of relevant attributes in C_i and all the attributes belonging to C_i. And, R_i represents the number of relevant attributes in C_i divided by the total number of query terms.

Consequently, F-measure value F_i, relative to concept C_i, is computed as follows:

$$F_i = 2 \times \frac{P_i \times R_i}{P_i + R_i} \quad (3)$$

Final result of this computation is the list of the F-measure values $F = \{F_1, \ldots, F_s\}$ for all formal concepts in the lattice, given a query.

In order to evaluate diagnosis results, for each object (disease), $o_i \in O$ the system evaluate score as follows:

$$score(o_i) = \sum_{j=1}^{s} \left(\mu_j(o_i) \times F_j \right) \quad (4)$$

where $\mu_j(o_i)$ represents the membership of object o_i (in according to definition of *Fuzzy Formal Context* in FFCA theory [31]). The score represents correlation degree between query and available diseases. Then, a ranked list of diseases may be retrieved in order to answer to a given query.

V. CASE STUDY

Taking into account our experimental results, next subsections detail main features of ODINO. Actually, ODINO has been tested with dermatological disease knowledge. Defined vocabularies include: 700 symptoms/signs; 150 diseases; 125 clinical tests; 260 active ingredients.

A. Disease Catalogue Browsing.

This feature accomplishes the aim to provide rapid training on specific diseases. In fact, ODINO knowledge base includes many multimedia information, such as: definition and historical data, etiological agents, disease transmission, large set of pictures revealing specific symptomatology, complications, clinical tests and treatment protocols, and so on.

B. Preliminary medical diagnosis

This functionality allows to assist physician during preliminary diagnosis practice. Physician starts the process by selecting some clinical manifestations (i.e., symptoms, signs and/or complications). As shown in Fig. 5, ODINO supports selection through two alternative interactions, namely: by browsing ICD-9 tree and specifying ICD-9 categories; by using text based search.

The matching algorithm (described in Section IV.B) allows the system to retrieve eligible diseases. So, taking into account clinical manifestations selected by the user (e.g., *Gangrene* and *Physical decay*), as highlighted in Fig. 6, the system retrieves a ranked list of eligible diagnosis. In particular, the system shows correlation degree useful to rank the results (see Fig. 6(a)) and it allows to access to motivations of each result (in Fig. 6(b)).

Result motivations consist of hints to the physicians about distinctive symptomatology of retrieved disease. These hints may be useful to suggest eventually escaped factors. For example, as shown in Fig. 7, system highlights: submitted symptoms in the request (red outlined box) and *pathognomonic signs* (green outlined box) for the retrieved disease (i.e., in the picture *"Venereal ulcer"*). This is a useful information because the presence of a *pathognomonic sign* means, beyond any doubt, that particular disease is present.

In order to validate preliminary diagnosis performed by ODINO, several queries and relevance sets have been defined with physician experts of dermatological diseases.

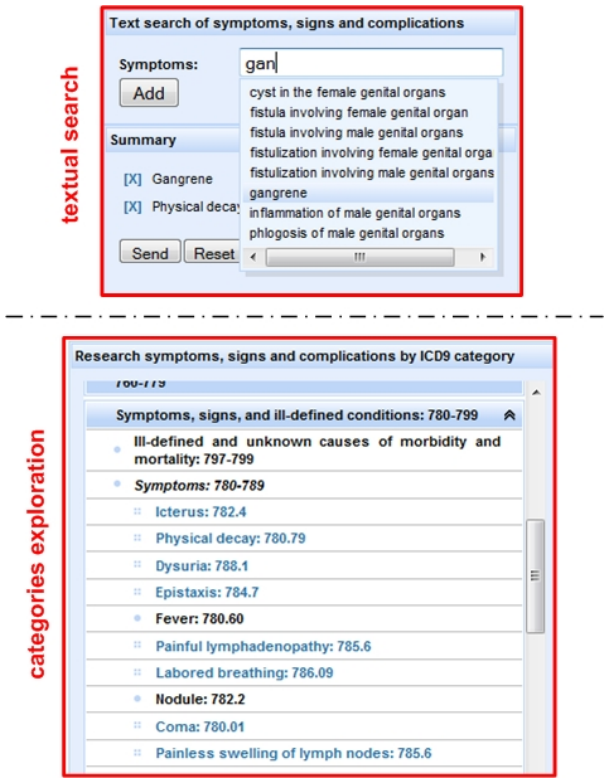

Figure 5. Selection of clinical manifestation by mean textual search (with autocomplete) or categories exploration.

In particular, through the analysis of retrieval performance, we have measured: *Average Uninterpolated Precision* (AUP) [32] and *Precision*. The AUP is defined as the ratio between the sum of the precision value at each point of hierarchical structure (or node of lattice) where a relevant item appears, and the total number of relevant items. The performance for Precision and AUP are shown in Fig. 8, considering a different number N of the clinical manifestations (e.g., *Fever*, *Headache*, *Anemia*, etc.). Let us note that, for N larger than 6, the values of Precision and AUP provide good performance results (between 0.7 and 1). Considering these results we can say that knowledge base and methodology are enough selective for available diseases.

More generally, by analyzing system usage and physician expectancy, experimental results reveal that 86% of diseases retrieved by the system are coherent with results expected by the physicians; just the remaining 14% of results emerge to be too vague. Specifically, by considering wrong results, we have identified that the problem is strictly related to ambiguous clinical manifestations. More precisely, two weakness have been revealed: cases in which huge number of clinical manifestations characterize the same disease (i.e., *AIDS*); and cases in which the same clinical manifestation characterizes many disease with similar *Frequency* and *Specificity* degree (i.e., *Fever*).

C. *Faceted search*

ODINO also provides a faceted search of diseases through taxonomy constraints (i.e., Symptomatology, etc.). Faceted search [33] is an exploration technique for structured datasets based on the facet theory.

As described in [34], in faceted search the information space is partitioned using orthogonal conceptual dimensions of the data. Each dimension is called facet and represent important disease partitioning feature. The facet has multiple restriction values and the user selects a restriction value to filter relevant items in the information space. The facet based approach can be directly mapped to navigation in semi-structured data, as well as in *Medical Diseases Ontology* model deployed in ODINO. Specifically, available facets are: symptoms, complications, clinical tests and active ingredients. All of these facets are associated with controlled vocabulary defined according to the SKOS formalism.

Obviously, items that ODINO filters step-by-step are diseases. Fig. 9 shows an example of faceted search in ODINO. The left side of Fig. 9 shows constraint "step-by-step" selection to filter diseases (constraints are highlighted with box outlined in green color). At each step of the facet-based search, the system returns an ordered list of eligible diagnosis allowing also further filtering.

With respect to text based search, a faceted search is more useful because allows navigation of an unknown dataset through system suggested restriction values at each step. Additionally, facets provide an intuitive user interface eliminating the need to write exact queries; and prevent empty query results by including restriction values that certainly lead to true results.

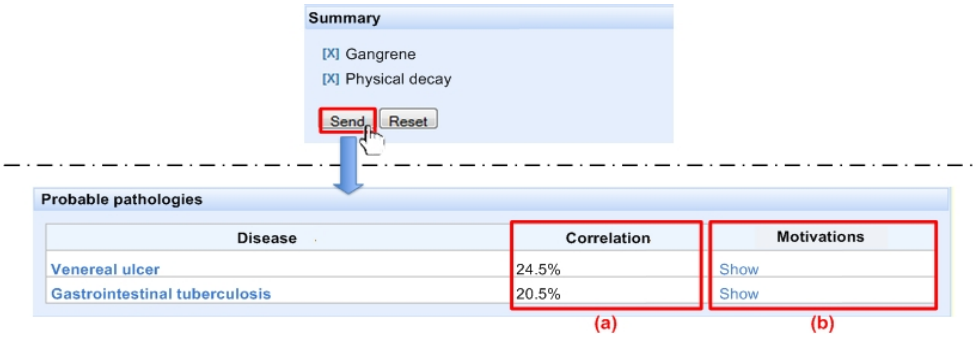

Figure 6. Preliminary diagnosis retrieved results: (a) correlation degree, (b) links to motivations of results.

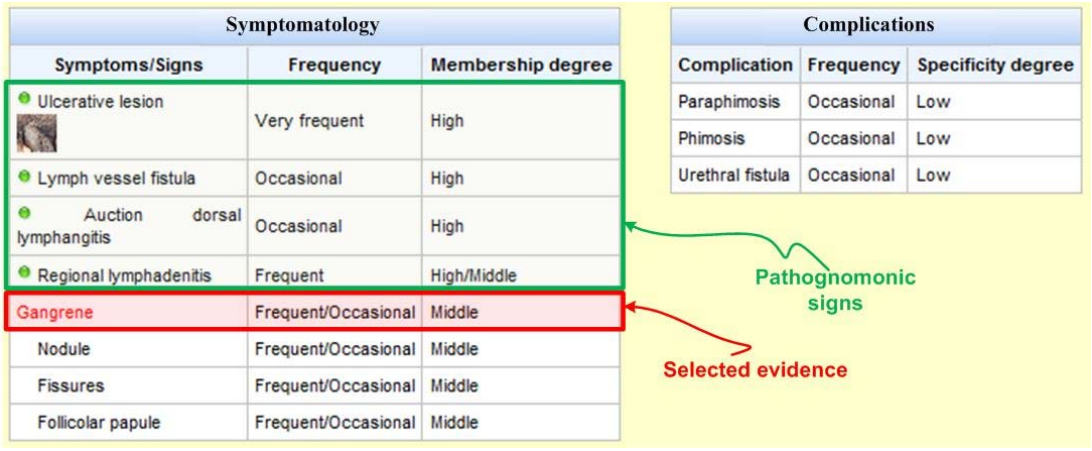

Figure 7. Example of result motivation interface.

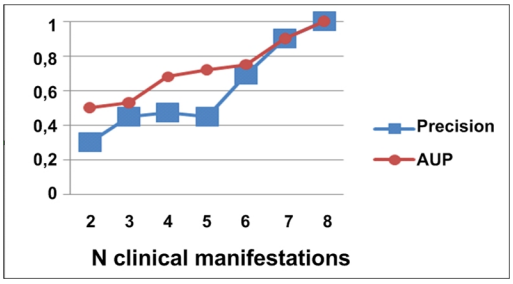

Figure 8. Performance evaluation on Precision and AUP.

VI. Conclusion & Future Works

This paper presents a project named ODINO, an ontology based web application that provides features to daily support medical practices. In particular, ODINO exploits Semantic Web formalisms in order to model medical knowledge. On the other hand, Fuzzy Formal Concept Analysis and ontology inference are applied to support preliminary medical diagnosis.

The availability of rich set of multimedia information allows to provide rapid training feature. Moreover, thanks to the semantic modeling of knowledge base, a faceted search of diseases has been developed.

Benefits deriving from the applied approach are especially related to the reusability of the knowledge layer, scalability and flexibility of the main features, like as faceted search.

The main goal of ODINO is to introduce an effective user interface to provide second opinion especially for the developing country, such as: Etiopia, Kenya, etc. where the availability of economic and human resources are limited. Future works are related to introduce support to improve the exploitation of multimedia information, available in the knowledge base, during faceted search and preliminary diagnosis.

Acknowledgment

The results of the present work have been achieved thanks to the intensive contribution of physician members of INMP that are also involved as authors of [1].

***Abstract*—Laboratory testing is a frequent activity for patients in intensive care units (ICU). Recent studies demonstrate that frequent laboratory testing does not necessarily relate to better outcomes. We hypothesize that unnecessary laboratory testing can be reduced by predicting which tests are unlikely to influence clinical management. Reducing unnecessary tests could reduce morbidity and hospitalization costs. We analyzed an ICU database containing 26,665 patient records at Beth Israel Deaconess Medical Center, Boston, and selected a subset of patients with gastrointestinal bleeding. Database knowledge discovery was applied involving data preprocessing, feature selection, and classification. Conventional soft computing tools such as fuzzy models and neural networks were utilized in this work, combined with statistical and mathematical tools. The input variables included bedside monitor trends, lab tests, arterial/central catheter information, urine collections, transfusions, indexes and scores calculated for the patients. The outcome variable was a binary classification based on falling levels of hematocrit. Feature selection was performed by a bottom-up strategy, maximizing the area under the ROC curve (AUC), the integrated discrimination improvement (IDI) and a multiobjective function primarily pondering the sensitivity of the models. A leave-one-out cross validation process was used to evaluate the overall models' performance, as well as the additional predictive value of the variables selected. Urine output was selected by all models as the best predictor of useful hematocrit testing. Our results show that it is possible to correctly classify the usefulness of a hematocrit lab test up to 81% of the time by using fuzzy models and neural networks.**

I. Introduction

Laboratory testing occurs frequently in hospitalized patients [1]. This is especially so for patients in intensive care where frequent blood draws may cause increased general phlebotomy complications such as blood loss [2], [3]. Although many lab tests are performed during the hyperacute first day of the patient's ICU stay, about two-thirds of laboratory studies are ordered later in the stay. While part of this testing reflects the intrinsic critical status of ICU patients, other tests are run almost by default, following general guidelines and not patient specific characteristics [4].

Recent data demonstrate that patients who have received more frequent laboratory tests do not necessarily have better outcomes [5]. On a cost comparative basis, patients with the highest discretionary laboratory costs are around US$273 higher per ICU stay than the lowest spenders, even when corrected for different ICU lengths of stay and hospital mortality [2]. The highest spenders also spend more on other discretionary costs, which could be driven by increased laboratory use, including pharmacy costs and blood banking costs (e.g., red blood cell transfusion in a patient with anemia attributable to laboratory testing).

A further laboratory risk is false positives associated with over-testing [6]. The probability of false positives (lab results out of the normal range, when in fact the real values are normal) depends on the laboratory equipment, employees training and correct blood draws. However, the incidence of false positives increases with the number of tests run [7]. For example, if a given lab test randomly misclassifies people as *diseased* at a 1% rate (i.e. the test is 99% *accurate*), then the probability of having a false positive in the healthy population after an arbitrary 50 lab tests is

$$P_{wrong(n)} = 1 - (P_{right})^n \tag{1}$$

$$P_{wrong(50)} = 1 - (0.99)^{50} = 0.40$$

where n is the number of lab tests, $P_{wrong(n)}$ is the probability of obtaining one wrong result (in this case, a false positive) in n lab tests and P_{right} is the probability of obtaining an

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

accurate result in a given lab test. One strategy to reduce this increasing probability of obtaining false positives is to avoid testing when no additional information is expected or, in other words, to reduce n.

In [3], it was shown that the introduction of new laboratory testing guidelines in an ICU setting resulted in a significant decrease in the number of tests performed (37%), and a significant increase in the number of tests obtained with a proper physician order (38%). These results were sustained over time, and were associated with no detectable morbidity and possibly to a decrease in red blood cell transfusions.

To prove that it is possible to model and classify the usefulness of a given lab test using information from other variables, this work focuses specifically in classifying the need for a hematocrit lab test. This measurement was chosen as a starting point because its dynamics are well understood, and specifically related to other measurable phenomena, like bleeding, transfusions, urine output and red blood cell count lab tests [8]. Also the impact of its prediction may be high, since it would be one step forward into reducing the amount of complete blood count (CBC) tests run and therefore, the amount of blood draws. We hypothesize that it is possible to reduce hematocrit laboratory testing by predicting when further testing is unlikely to provide new information that would change treatment strategy. This reduction would be achieved by assessing a range of physiological variables, and predicting when significant variations in hematocrit are likely to occur.

We apply a Knowledge Discovery in Databases (KDD) process to find the classification models on an ICU database named MIMIC II. Conventional soft computing techniques, namely fuzzy modeling and neural networks, combined with bottom-up feature selection were used to classify the usefulness of hematocrit lab tests. Other mathematical and statistical tools were also applied during data preprocessing.

This work is organized as follows. Section 2 formally describes the MIMIC II database and the methods used to preprocess, reduce and classify the outcome proposed. Section 3 describes and discusses the results obtained from these methods. Conclusions are presented in Section 4.

II. Methods

Knowledge Discovery in Databases (KDD) is an interactive and iterative process [9], involving numerous steps, which aims to discover hidden patterns and/or useful information in large datasets that do not express those patterns easily.

According to the steps described by Figure 1 for the KDD process, the following subsections define the approaches used in this work to tackle each step.

A. Application domain and target dataset

The application domain identified for this work is in the field of critical care medicine, specifically, a medical ICU. Laboratory testing guidelines are generally created according to evidence based medicine informed by different population studies. However, lab tests are frequently run by default, without considering an individual patient's condition. The main role of the KDD process in this work is to classify the relevance of hematocrit lab testing for ICU patients based on existing data specific to the patient, and whether a given test would then add information that could change management.

For this study, an ICU database named MIMIC II was used. MIMIC II was created as part of a Bioengineering Research Partnership (BRP) grant from the National Institute of Biomedical Imaging and Bioengineering entitled Integrating Data, Models and Reasoning in Intensive Care (RO1-EB001659). MIMIC II has been collected since 2001 at Beth Israel Deaconess Medical Center in Boston, MA, USA, including high frequency sampled data of bedside monitors, clinical data (laboratory tests, physicians' and nurses' notes, imaging reports, medications and other input/output events related to the patient) and demographic data [10]. All data is appropriately de-identified. As this is being written, MIMIC II continues to evolve with new versions being posted on the PhysioNet web site (http://www.physionet.org/). The version 2.5, used in this work, contains 26,665 ICU patients.

The target dataset used in this work was created using the following inclusion criteria:

- patients with Gastrointestinal (GI) bleeding were selected from MIMIC II, according to GI bleeding-related ICD9 (International Classification of Diseases) codes registered for them during their whole ICU stay [11];
- patients were required to be in the ICU for 7 days or more in order to have useful time series for analysis;
- data collection was considered to start when the first heart rate value was stored in the database, and ended with the last recorded heart rate, or a gap of 24 hours or more;
- only first ICU stays were considered, mainly to avoid patients that could have had several ICU admissions during the same hospitalization, reflecting a more complex state;
- only patients 18 years or older were included as MIMIC II also includes neonates and infants [10];
- bedside monitor trends, lab tests, ventilator variables, indexes, scores, arterial/central/catheter line monitoring were considered, while medications and demographic information were discarded (Table I).

B. Data Preprocessing

Data preprocessing is a complex and crucial step as it defines the information that will be used later in the classification process, and it has to be carefully carried out in order to obtain clean data without altering the real information contained therein. Noise and outliers removal, misalignment correction and missing data treatment are considered as substeps of the preprocessing, accounting for up to 60% of the effort in a knowledge discovery process [12], [13].

The nature and occurrence of noise in MIMIC II is difficult to manage mainly due to the low sampling frequency of most variables, and to the broad band of frequencies that originally compose them. Consequently, it was not considered during the preprocessing.

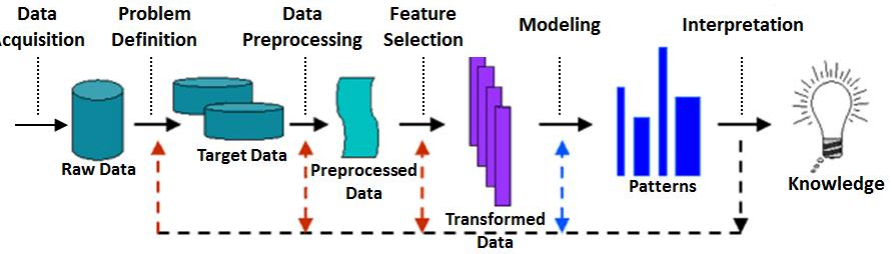

Fig. 1. Overview of the steps that compose the KDD process.

TABLE I
VARIABLES USED FOR THE MODELING PURPOSES.

Bedside monitor trends							
Heart Rate		Temperature		Respiratory Rate		Oxygen Saturation (SpO2)	
Arterial/Central/Catheter Line							
Arterial Blood Pressure (ABP)	ABP Mean	Arterial pH	Arterial CO2	Arterial PaCO2	Arterial PaO2	Arterial Base Excess	Central Venous Pressure
Laboratory results							
Hematocrit	Potassium	Glucose	Creatinine	Sodium	Chloride	Lactic Acid	Uric Acid
Carbon Dioxide	Magnesium	Ionized Calcium	Phosphorous	Calcium	SaO2	CaO2	Albumin
Ventilator monitored variables							
PEEP Set		Respiratory Rate		Minute Volume (Observed)		Low Exhaled Minute Volume	
High Inspiratory Pressure		Plateau Pressure		Mean Airway Pressure		Respiratory Rate Set	
Resp Rate (Spontaneous)		Peak Inspiratory Pressure		Tidal Volume (Observed)		Tidal Volume (Set)	
Indexes calculated for combination of variables							
Cardiac Output		Systemic Vascular Resistance		Left Ventricular Cardiac Work		Right Ventricular Cardiac Work	
Scores							
SAPS-I	SAPS-II	APACHE					
Other variables collected							
Non-invasive Blood pressure (NBP)		NBP Mean	Blood transfusions				

An outlier is defined as an observation that is markedly different in value from the others of the sample or, in other words, a value out of the normal range of occurrence. The standard approach to identify and eliminate outliers is to filter the signal by amplitude, which means that specific upper and lower thresholds are defined for the signal. Those values above or below the threshold are considered outliers and therefore, removed from the signal. Another approach is to analyze every value in its context, comparing it with its neighbors to assess the likelihood of that point of being an outlier. Since it is sometimes possible for hematocrit to change quite drastically in a short period of time (e.g. hemorrhage) and then very rapidly rebound closer to their prior value (e.g. with massive transfusion), the second approach cannot be used in this work and, because of that, a filter with upper and lower amplitude thresholds was designed considering as possible extreme values those clinically accepted as possible for humans. This was reviewed and validated under medical assessment. Those values identified as outliers were assigned as missing data for further preprocessing.

According to [14], misalignments can be corrected using one variable in the dataset as a template, and shifting the data points of other variables to align sampling times. In this work, the outcome variable (*Hematocrit*) was used as the template to unshift the values of all the other variables, as it defines the points for which the model is meant to give a classification result. Although [14] proposes to use the variable with the highest sampling rate (in this dataset it corresponds to *Heart Rate*, with a mean sampling time of 0.76±0.2 hours), in this work it would create an excessive amount of points for which the outcome is not expected to be measured (*Hematocrit* has a mean sampling time of 9.15±1.24 hours). As shown in Figure 2, all the existing entries are shifted to the closest template alignment location, and values are then obtained through an interpolation strategy using the template variable as a time reference. No new points were created in this step to fill otherwise blank values. The values for the new time positions were obtained through cubic interpolation, as suggested by [14].

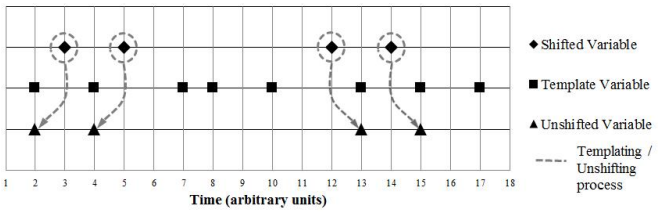

Fig. 2. Simplified representation of a *template variable*, together with the *shifted* and *unshifted* version of a second variable.

To differentiate true missing values from lack of sampling [14], a 95% confidence interval was defined for the sampling time of every variable, and absent segments inside those intervals were recovered by cubic interpolation.

In order to assess whether true missing values were recoverable or not in each specific variable, a method based in fuzzy models, which classifies every missing point according to the ability to find information about the missingness contained in other variables [15], was used. For each point of a specific variable, a binary outcome is created containing a 1 if the variable is missing or a 0 if it has a value. Using the other variables of the dataset as inputs and the binary outcome as the output, if the fuzzy model is able to correctly classify a missing point as missing it is because it found information in the other variables that explain the missingness. In [15] it was pointed out that when there is an underlying medical reason for the missingness, the value should not be imputed; information in other variables may be considered as medical reasons. After classifying missing data, those missing segments identified as *recoverable* were recovered using expectation maximization [16], [17]; those classified as *not-recoverable* caused the deletion of all the variables for that sampling time.

C. Data Reduction. Bottom-Up Feature Selection.

Data reduction involves finding those variables with useful information to model and predict the pursued outcome. A bottom-up feature selection process to reduce data dimensionality was use in this work.

A detailed description of the bottom-up approach used here may be encountered in [18]. However, it is important to note that a more recent algorithm that minimizes the computational time with similar performance has been proposed in [19]. The bottom-up approach looks for single inputs that may influence the output, and combines them in order to achieve the model with the best performance criterion. Two subsets of data are used in this stage, train and test. Using the train set, a model is built for each of the n features in consideration, and evaluated using the performance criterion upon the test set. The feature that returns the best value of the performance criterion is the one selected. Next, other feature candidates are added to the previous best model, one at a time, and evaluated. Again, the combination of features that maximizes the performance criterion is selected. When this second stage finishes, the model has two features. This procedure is repeated until the value of the performance criterion stops increasing. In the end, all the relevant features for the considered process should be obtained.

Three different performance criteria were separately tried in this work:

- the area under the ROC curve (AUC), as used by [20]
- the integrated discrimination improvement (IDI) [21], calculated in a simplified form as follows

$$IDI = (Sensitivity_{new} - Sensitivity_{old}) \quad (2)$$
$$-(Specificity_{new} - Specificity_{old})$$

  where $Sensitivity$ and $Specificity$ refer to the true positive (hematocrit correctly classified as relevant) and true negative (hematocrit correctly classified as not relevant) classification rate of a model[1], subscript new refers to the model with the new feature selected and subscript old to the model without it. The IDI can be viewed as a difference between improvement in average sensitivity and any potential increase in average specificity.
- the sensitivity, as part of a multi-objective function in which the specified criterion is considered together with specificity and percentage of correct classifications[2] (PCC), but with a higher degree of consideration through different membership functions of a fuzzy model [22].

D. Classification strategy

The data mining strategy used in this work was defined for a binary classification of every hematocrit lab test as:

- Relevant, with a value of 1, when there is a drop d (varied between 1 and 5) in the value of hematocrit, or when those values are under a certain critical threshold T (varied between 15 and 40). Both d and T were varied to find the best classification point, and then reviewed with clinicians to check their practical significance and management influence on events such as triggering a decision of start or stop a blood transfusions or medications.
- Not relevant, with a value of 0, if the variations were below the previously defined thresholds.

The preprocessed data subset was randomly divided into two equal parts, one for the feature selection process (FS dataset) and the other for the model selection (MS dataset). This was done to assess select the relevant features and to assess the model's performances over independent datasets.

The subsets of features were defined over the FS dataset by randomly selecting the train (60%), test (30%) and validation (10%) sets from the FS dataset; the subset of features resulting in the highest PCC for the validation set was selected.

A leave-one-out cross-validation (LOOCV) process was used to select the best model, by using a subset 10% of the MS dataset, defined as the validation set, and the remaining 90% as the training set. To reduce variability, 10 rounds of cross-validation were performed using different partitions, and the validation results were averaged over the rounds. The model with the best performance criteria was selected.

E. Modeling and Data Mining

The classification previously defined was performed using two different soft computing techniques and their results were compared. Namely, fuzzy models and neural networks were independently used, due to their universal approximators nature and previous results showing their performance in medical

[1]Sensitivity = TP / (TP + FN); true positives over true positives and false negatives, or total positives.
Specificity = TN / (TN + FP); true negatives over true negatives and false positives, or total negatives.

[2]The percentage of correct classifications is equal to the number of true positives (TP) together with the number of true negatives (TN) divided by the total number of patients, and then multiplied by 100.

databases [20]. For the specific case of fuzzy models, an additional motivation for their use was the easy-understandable rules they generate after classifying data, which could be useful for medical interpretation.

1) Fuzzy Models: Fuzzy modeling is a tool that allows an approximation of nonlinear systems when there is few or no previous knowledge of the system to be modeled. The fuzzy modeling approach has several advantages compared to other nonlinear modeling techniques ([23],[24]). In general, fuzzy models provide not only a more transparent model, but also a linguistic interpretation in the form of rules. A fuzzy classifier contains a rule base consisting of a set of fuzzy if–then rules together with a fuzzy inference mechanism.

In this work, Takagi-Sugeno (TS) fuzzy models [24] were used, which consist of fuzzy rules where each rule describes a local input-output relation. When TS fuzzy systems are used, each discriminant function consists of rules of the type

$$\begin{aligned} \text{Rule } R_i^c \quad : \quad & \text{If } x_1 \text{ is } A_{i1}^c \text{ and } \ldots \text{ and } x_M \text{ is } A_{iM}^c \\ & \text{then } d_i^c(\mathbf{x}) = f_i^c(\mathbf{x}),\ i = 1, 2, \ldots, K, \end{aligned}$$

where f_i^c is the consequent function for rule R_i^c. In these rules, the index c indicates that the rule is associated with the output class c. Note that the antecedent parts of the rules can be for different discriminants, as well as the consequents. Therefore, the output of each discriminant function $d_c(\mathbf{x})$ can be interpreted as a score (or evidence) for the associated class c given the input feature vector $\mathbf{x}$. The degree of activation of the ith rule for class c is given by:

$$\beta_i = \prod_{j=1}^{M} \mu_{A_{ij}^c}(\mathbf{x}) \tag{3}$$

where $\mu_{A_{ij}^c}(\mathbf{x}) : \mathbb{R} \rightarrow [0, 1]$. The discriminant output for each class c, with $c = 1, \ldots, C$, is computed by aggregating the individual rules contribution:

$$d_c(\mathbf{x}) = \frac{\sum_{i=1}^{K} \beta_i f_i^c(\mathbf{x})}{\sum_{i=1}^{K} \beta_i} \tag{4}$$

The classifier assigns the class label corresponding to the maximum value of the discriminant functions, i.e

$$\max_c d_c(\mathbf{x}) \tag{5}$$

2) Neural Networks: Artificial Neural Networks (ANN) have been largely used as input-output mapping for different applications including modeling and classification. There are typically three parts in a neural network: an input layer with neurons representing the input variables, one or more hidden layers with a definable number of neurons, and an output layer with one or more units representing the output variables(s). The neuron output signal is given by the following relationship:

$$\sigma = f\left(\mathbf{w}^T x\right) = f\left(\sum_{j=1}^{n} (w_j x_j)\right) \tag{6}$$

where $\mathbf{w} = (w_1, \ldots, w_n)^T \in \mathbb{R}^n$ is the weight vector, and $x = (x_1, \ldots, x_n)^T \in \mathbb{R}^n$ is the vector of neuron inputs. The function $f\left(\mathbf{w}^T x\right)$ is often referred to as the activation (or transfer) function. Its domain is the set of activation values, net, of the neuron model, and is often represented by $f(net)$. The variable net is defined as a scalar product of the weight and input vectors:

$$net = \sum_{j=1}^{n} (w_j x_j) = w_1 x_1 + \ldots + w_n x_n \tag{7}$$

In this work, a feed forward multilayer perceptron (FF MLP) neural network was used, with 10 neurons and logarithmic activation functions in the hidden layer, and tangential activation function in the output layer, following the structure proposed by [20].

III. Results and Discussion

A subset of GI bleeding patients was selected from MIMIC II database according to ICD9 (International Classification of Diseases) codes. After the outliers were removed and misalignment correction and missing data recovery/deletion, the resulting dataset consisted of 235 patients with 50 variables present in all of them, summing up a total of 9382 records. The variables considered for posterior modeling within this dataset were bedside monitor trends, ventilator acquired/set values, indexes, scores, urine output and blood transfusions. All lab tests were included, excluding red and white blood cell counts, hemoglobin and platelets, since they are considered to be tested together with hematocrit in a complete blood count (CBC) [25]. Hematocrit was excluded from the inputs, since it was used as the outcome to classify. After the preprocessing, a complete dataset was obtained for modeling purposes.

The outcome was created as a binary variable, taking the value 1 when the hematocrit was below a threshold T or when a drop of d points occurred on it. T was varied between 15 and 40, and d was varied between 1 and 5. Tables II and III show the values of AUC obtained when using neural networks and fuzzy modeling in the classification the resulting outcome. The maximum AUC obtained when classifying the outcomes generated with fuzzy models and neural networks agreed, and corresponded to T = 35 and d = 3. These values were validated by clinical co-authors as significant for influencing clinical management. In other words, both a drop of 3 points in the hematocrit value or a sustained hematocrit value below 35 would be triggers for urgent diagnostic activities exploring causes of blood loss (e.g. endoscopy) and urgent therapeutic activities such as insertion of a central line, cross matching blood and increased laboratory testing. The resulting outcome can be seen in Figure 3 for an arbitrarily chosen patient.

After defining the outcome, the complete dataset was randomly divided into two equal parts, one for the feature selection process (FS dataset) and the other for the model selection (MS dataset). This was done to assess model performances and to select the best model over an independent dataset not used during any step of model construction.

TABLE II

AUC FOR FUZZY AND NEURAL MODELS WHEN CLASSIFYING DIFFERENT HEMATOCRIT LOWER THRESHOLDS T, VARIED FROM 15 TO 40. FM - FUZZY MODELING; NN – NEURAL NETWORKS; HCT – HEMATOCRIT

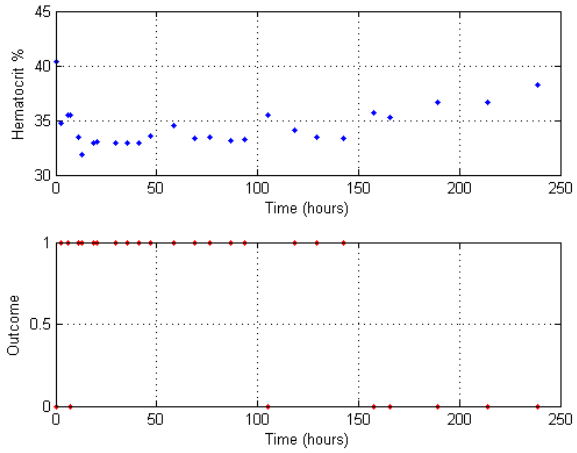

Fig. 3. Outcome generation from the original hematocrit time series for an arbitrarily chosen patient.

The subsets of features were defined over the FS dataset by maximizing AUC, IDI or sensitivity (considered in a multiobjective function). This process was performed 10 times for each maximization criterion, randomly selecting the train (60%), test (30%) and validation (10%) sets from the FS dataset, using neural networks and fuzzy models to classify the outcome; the subset of features resulting in the highest percentage of correct classifications (PCC) for the validation set was selected.

Variables selected with AUC, IDI and sensitivity maximization criteria and their respective PCC values, obtained with neural networks and fuzzy models are shown in Table IV. For both neural networks and fuzzy models, it is possible to see that when AUC was used as the maximization criterion, variables selected result in the highest PCC values. Although

TABLE IV

PCC AND VARIABLES SELECTED WHEN USING AUC, IDI AND SENSITIVITY AS THE MAXIMIZATION CRITERIA DURING A BOTTOM-UP FEATURE SELECTION, PERFORMED WITH FUZZY AND NEURAL MODELS. FM - FUZZY MODELING; NN – NEURAL NETWORKS; IDI – INTEGRATED DISCRIMINATION IMPROVEMENT

Model	Maximization	PCC	Variables Selected
NN	AUC	81.3	Urine Output Creatinine NBP Sodium
	IDI	60.1	Urine Output Creatinine Chloride
	Sensitivity	77.5	Urine Output NBP
FM	AUC	85.2	Urine Output SpO2 Creatinine
	IDI	59.7	Urine Output Chloride Blood Transfusion SpO2 Arterial CO2
	Sensitivity	78.8	Urine Output NBP Blood Transfusion Heart Rate

there was always a coincidence in the first variable selected by all models, the other features seem to respond to minor variations of the subsets used to create the models, since they varied a lot even for different runs of the same modeling technique.

Although it was expected that the use of sensitivity, as the maximization criterion, could increase the final sensitivity and maybe the AUC too, the results obtained showed no improvements (Table V). Moreover, the computational time (not shown in the results) increased for this approach. In the case of IDI, it was expected for it to result in values similar to AUC, since it integrates both sensitivity and specificity in one measurement in a similar way than AUC. However, its use resulted in the lowest PCC values.

The three resulting features subsets, one for each maximization criterion, were separately used in a leave-one-out cross-validation (LOOCV) process. A subset 10% of the MS dataset was defined as the validation set, and the remaining 90% as the training set.

Figure 4a and 4b show an accumulative representation of the results for each additional variable used as input, when AUC was previously used as the maximization criterion to obtain the subset of variables, averaged over the ten runs of cross validation. It can be seen that no improvement is obtain by the use of any variable after *Urine Output*. This, together with the variability reflected in the variables selected under the same maximization criterion (not shown in the results), suggests that only *Urine Output* has predictive value for the outcome defined, while the other variables are selected responding to the variability of the subsets used to create the models. Some other frequently selected variables such as *Non-invasive Blood Pressure* (NBP) and *Creatinine*, could relate to

specific conditions of some patients that are not shared by the whole dataset.

Table V summarizes the results obtained for fuzzy and neural networks modeling, when the three maximization criteria were separately used to select the features, averaged during the LOOCV process. It can be seen that fuzzy models perform slightly better than neural networks, expressed in higher values for almost all performance measurements.

The fuzzy models gave best results when 2 clusters were

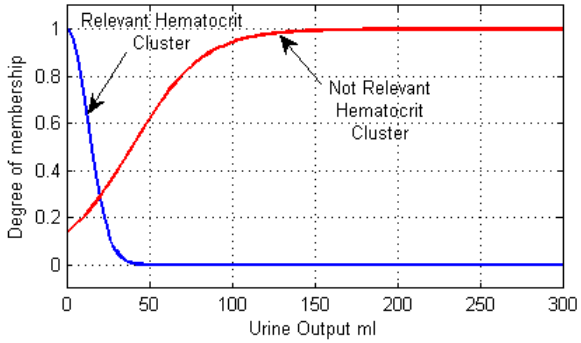

Fig. 5. Membership function for Urine Output obtained with a fuzzy model, maximizing the AUC, during the validation.

used during their training, testing and validation. Neural networks presented their best performance for one hidden layer composed by 10 neurons with logarithmic activation functions, and a linear summation in the output layer.

The selection of *Urine Output* as the primary variable in all models was reviewed and validated under medical assessment. Due to the selection of GI bleeding patients during the creation of the dataset used in this work, the presence of hemorrhage was someway proved for all patients during their ICU stay. Blood volume can be significantly affected by hemorrhage, and so the urine output. If the hematocrit is low enough or presents sudden drops, poor urine collection will reflect those states with some accuracy. This can be seen in one membership function obtained from the fuzzy models, illustrated in Figure 5. This is a positive finding since, by using a simple variable that is collected by the nurse in an hourly assessment of the patient, phlebotomy associated risks and complete blood count (CBC) testing can potentially be avoided.

IV. CONCLUSIONS

Increasing health trends towards improved efficiency seek to align evidence based medicine with cost efficient medicine, both underpinned by a drive to quality. Unnecessary phlebotomy increases clinical and fiscal risks at many levels. In this work, hematocrit lab testing usefulness was evaluated by modeling and classifying the relevance of the results when other collected variables are assessed. A properly de-identified ICU database collected at Beth Israel Deaconess Medical Center, named MIMIC II, was used to develop the models. A subset of gastrointestinal bleeding patients were selected along

with their associated physiological ICU variables, including bedside monitor trends, ventilator records, scores, indexes, lab tests, urine output and blood transfusion information.

Informed by clinical decision making, hematocrit was defined as the positive binary outcome variable set to threshold levels of hematocrit less than 35% or a drop of 3 points. All other measures were represented as the negative binary outcome.

Three maximization criteria, namely the area under the ROC curve (AUC), integrated discrimination improvement (IDI) and sensitivity, were used in a bottom-up feature selection process, combined with neural networks and fuzzy models.

A leave-one-out cross validation process was used to evaluate the overall models' performance, as well as the additional predictive value of the variables selected. Urine output was selected by all models as the most predictive variable for hematocrit levels, and consequently for potential diagnostic and therapeutic interventions. This is consistent with known physiological processes whereby deteriorating renal function occurs as a result of falling blood volume due to factors such as hemorrhage. Results showed that it was possible to correctly classify the usefulness of a hematocrit lab test up to 81% of the time by using fuzzy models and neural networks.

This work is offered as a proof of concept for the use of artificial intelligence models in predicting the usefulness of diagnostic testing. Although the dynamics of hematocrit values are used here on the basis that they are supported by a deeper body of knowledge, the results obtained showed that other routinely variables collected could also be used for predicting diagnostic testing requirements in critical care patients. Future work will focus on:

- expanding the models to a broader population of patients, under different medical conditions
- predicting/classifying different and more complex lab tests currently run on ICU patients
- creating dynamical models to perform future predictions of lab tests usefulness based on present and previous data acquired.

ACKNOWLEDGMENT

The author would like to acknowledge the assistance of the Division of Clinical Informatics at the Beth Israel Deaconess Medical Center and the Massachusetts Institute of Technology. Both human and technical resources were made available, both of which were critical for the development of this work. ***Abstract*—In this paper, a fuzzy inference system for sleep staging was developed. Nine input variables including temporal and spectrum analyses of the EEG, EOG, and EMG signals were extracted and normalization was applied to these variables to reduce the effect of individual variability. A fuzzy inference system contains fourteen fuzzy rules was designed to classify the 30-s sleep epochs as five sleep stages. Finally, a smoothing process was applied to the scoring results for fine-tuning. The average accuracy of the proposed method applied to 16 all-night polysomnography (PSG) recordings compared with the manual scorings can reach 87 %. This method can integrate with various PSG systems for sleep monitoring in clinical or homecare applications.**

Keywords-Automatic sleep staging; sleep staging, fuzzy inference systems, sleep minitoring, fuzzy rules.

I. INTRODUCTION

Sleep diseases, such as insomnia and obstructive sleep apnea, seriously affect patients' quality of life. The prevalence of insomnia symptoms is approximately 33% in the general population [1]. There are over 4% of adult men and 3% adult women be affected by obstructive sleep apnea [2]. These sleep issues may cause daytime sleepiness, irritability, depression or anxiety. For the diagnosis of sleep issues, all night polysomnographic (PSG) recordings, including electroencephalogram (EEG), electrooculogram (EOG) and electromyogram (EMG), are usually taken from the patients and the recordings are scored by a well-trained expert according to the Rechtschaffen & Kales (R&K) rules presented in 1968 [3].

According to the R&K rules, each epoch (i.e., 30 s of data) is classified into one of the sleep stages, including wakefulness (Wake), non-rapid eye movement (stages 1-4, from light to deep sleep) and rapid eye movement (REM). Recently, stages 3 and 4 were combined and are now known as the slow wave sleep stage (SWS) [4].

Because visual sleep scoring is a time consuming and subjective process, automatic sleep staging methods, including rule-based methods [5-6], numerical classification methods [7-8] and the hybrid system, that take advantage of both approaches [9], were developed. In rule-based methods, signal information and human knowledge are combined to deduce a reasonable sleep state. In contrast, numerical classification methods do not require a set of rules or any human knowledge. The overall agreement of these methods is in the range of 80% to 85%.

In this paper, a fuzzy inference system for sleep staging was proposed. The central EEG (C3-A2), the difference between two EOG and the chin EMG were analyzed, and nine features were extracted for each 30-s epoch. The features were normalized to reduce the individual variability, so that the system parameters were subject-independent. Finally, a smoothing process was applied to the scoring results for fine-tuning. In future, this method can integrate with various PSG systems for sleep monitoring in homecare applications.

II. METHOD AND MATERIALS

A. Subjects and recordings

All-night polysomnographic sleep recordings were obtained from 20 healthy subjects (12 males and 8 females) ranging from 19 to 23 years in age (mean = 21.2 ± 1.1). The data from four subjects were used to train the system, and data from 16 subjects were used for testing. The recordings included six EEG channels (F3-A2, F4-A1, C3-A2, C4-A1, P3-A2, and P4-A1, according to the international 10-20 standard system), two EOG channels (positioned 1 cm lateral to the left and right outer canthi), and a chin EMG channel (Siesta 802 PSG, Compumedics, Inc.). The sampling rate was 1 KHz with 16-bit resolution. The 20 PSG sleep recordings were visually scored by a sleep specialist using the R&K rules with a 30-s interval (termed the epoch).

B. Feature extraction

The automatic sleep staging system analyzes the data for three channels: the central EEG (C3-A2), the difference of the two EOGs, and the chin EMG. After downsampling the signals to 256 Hz, the EEG and EOG data were filtered with an eighth-order Butterworth band-pass filter with a cutoff frequency of 0.5–30 Hz, and the EMG data were filtered with a 5–100 Hz eighth-order Butterworth band-pass filter. The continuous time signals were segmented with every 30-s epoch.

This work was supported by the National Science Council of Taiwan under grant NSC 98-2221-E-006-161-MY3, 99-2220-E-009-072, 99-2632-E-233-001-MY3.

Before extracting spectral features, the signal was segmented into non-overlapping intervals of 2 seconds for a 512-point fast Fourier transformation (FFT) calculation. The spectrums corresponding to the 15 2-s segments were averaged to represent the spectrum for a 30-s epoch. Table I lists the nine features used in this paper [7-8, 10-11].

After feature extraction, normalization of features was employed to reduce the effects of individual variability. For each feature, the mean of maximal 10% data was calculated as the maximum value of the feature, and the mean of minimal 10% data was calculated as the minimum value of the feature for the subject. This process can prevent extremely high or low values from influencing any conclusions. The procedure for normalization is summarized in the following steps:

Step 1: Calculate the means of the 10% minimal and maximal values for the feature as the min and max values, respectively.
Step 2: Set the min and max values as 0 and 1, and then normalize other values from 0 to 1.
Step 3: If the value is higher than 1, the value is specified as 1. If the value is lower than 0, the value is specified as 0.

TABLE I. The features for sleep scoring

No.	Type	Feature	Source	Label
1	PS	Total power of 0-30 Hz	EEG	0-30 E
2	PS	Total power of 0-30 Hz	EMG	0-30 M
3	PR	0-4 Hz/0-30 Hz	EEG	0-4 E
4	PR	22-30 Hz/0-30 Hz	EEG	22-30 E
5	PR	0-4 Hz/0-30 Hz	EOG	0-4 O
6	SF	Mean frequency of 0-30 Hz	EEG	Mean(fre.) E
7	DR	Alpha ratio	EEG	Alpha E
8	DR	Spindle ratio	EEG	Spindle E
9	EMG energy	Mean amplitude	EMG	Amp M

*PS(=Power spectrum), PR(=Power ratio), SF(=Spectral frequency), DR(=Duration ratio)

C. Fuzzy inference system

In the proposed method, the fuzzy inference system includes 14 fuzzy rules. We use nine features as the input of the fuzzy system to build the fuzzy sets as show in Figure 1.

According to the R&K rules and distributions of the features with respect to various sleep stages, 14 fuzzy rules were constructed. Taking rule 1 as an example, during wake stage, we can observe high frequency activity of EEG such as abundant alpha activity (8-13 Hz) and gamma activity (>20 Hz) in EEG with higher muscle tone. So, The concept of rule 1 is that, when alpha EEG is high (*Alpha E* is G_3) and EMG is high (*0-30 M* is B_2) and low frequency (delta, 0-4 Hz) EEG is low (*0-4 E* is C_1); then the rule concludes that the stage is wake.

The followings are the summary of the 14 fuzzy rules:

R_1: *IF Alpha E is G_3 AND 0-30 M is B_2 AND 0-4 E is C_1 THEN out is WAKE*

R_2: *IF Alpha E is G_3 AND 0-30 M is B_2 AND Spindle E is H_3 AND (0-4 E is C_2 OR 0-4 E is C_3 OR 0-4 E is C_4) THEN out is S2*

R_3: *IF Alpha E is G_3 AND 0-30 M is B_2 AND (Spindle E is H_1 OR Spindle E is H_2) AND Mean(fre.) E is F_2 THEN out is WAKE*

R_4: *IF Alpha E is G_3 AND 0-30 M is B_2 AND (Spindle E is H_1 OR Spindle E is H_2) AND Mean(fre.) E is F_1 THEN out is S1*

R_5: *IF Alpha E is G_3 AND 0-30 M is B_1 AND Amp E is I_1 AND (Spindle E is H_1 OR (Spindle E is H_2 AND 0-30 E is A_1)) THEN out is REM*

R_6: *IF Alpha E is G_3 AND 0-30 M is B_1 AND Amp E is I_1 AND (((Spindle E is H_2 OR Spindle E is H_3) AND (0-30 E is A_2 OR 0-30 E is A_3)) OR (Spindle E is H_3 AND 0-30 E is A_1)) THEN out is S2*

R_7: *IF Alpha E is G_3 AND 0-30 M is B_1 AND Amp E is I_2 AND (Spindle E is H_1 OR Spindle E is H_2) THEN out is S1*

R_8: *IF Alpha E is G_3 AND 0-30 M is B_1 AND Amp E is I_2 AND Spindle E is H_3 THEN out is S2*

R_9: *IF (Alpha E is G_1 OR Alpha E is G_2) AND (22-30 E is D_1 AND (0-4 E is C_3 OR 0-4 E is C_4)) AND 0-4 O is E_2 THEN out is SWS*

R_{10}: *IF (Alpha E is G_1 OR Alpha E is G_2) AND (22-30 E is D_1 AND (0-4 E is C_3 OR 0-4 E is C_4)) AND 0-4 O is E_1 THEN out is S2*

R_{11}: *IF (Alpha E is G_1 OR Alpha E is G_2) AND (22-30 E is D_2 OR (22-30 E is D_1 AND (0-4 E is C_1 OR 0-4 E is C_2))) AND Amp E is I_1 AND (Spindle E is H_1 OR (Spindle E is H_2 AND 0-30 E is A_1)) THEN out is REM*

R_{12}: *IF (Alpha E is G_1 OR Alpha E is G_2) AND (22-30 E is D_2 OR (22-30 E is D_1 AND (0-4 E is C_1 OR 0-4 E is C_2))) AND Amp E is I_1 AND (((Spindle E is H_2 OR Spindle E is H_3) AND (0-30 E is A_2 OR 0-30 E is A_3)) OR (Spindle E is H_3 AND 0-30 E is A_1)) THEN out is S2*

R_{13}: *IF (Alpha E is G_1 OR Alpha E is G_2) AND (22-30 E is D_2 OR (22-30 E is D_1 AND (0-4 E is C_1 OR 0-4 E is C_2))) AND Amp E is I_2 AND (Spindle E is H_1 OR Spindle E is H_2) THEN out is S1*

R_{14}: *IF (Alpha E is G_1 OR Alpha E is G_2) AND (22-30 E is D_2 OR (22-30 E is D_1 AND (0-4 E is C_1 OR 0-4 E is C_2))) AND Amp E is I_2 AND Spindle is H_3 THEN out is S2*

The operations "AND" and "OR" in the fuzzy rules take the minimum and maximum values of the activations, respectively. For each epoch, the inference output is the determined stage that has the maximum activation value among all of the 14 rules.

D. Classification:

The classification process comprises three steps:

1) Movement epochs detection:

The movement (MT) epochs were detected with the following rules: if over 1/3 of the epoch of the absolute EMG amplitude was higher than double of Th1, or if the difference between the two consecutive epochs was higher than Th2, the epoch was defined as MT. Th1 is the mean value of the feature Amp M in Wake epochs of the training data, and Th2 is the mean value of the Amp M difference between every two consecutive epochs of the training data.

2) Fuzzy inference system:

For each epoch, the inference output is the determined stage that has the maximum activation value among all of the 14 rules.

3) Contextual rule smoothing

After classifying the sleep stage, a smoothing process, considering the temporal contextual information, was applied for continuity. Eleven rules [9][12] that refer to the relationship between epochs prior to and posterior to the current epoch were utilized for smoothing.

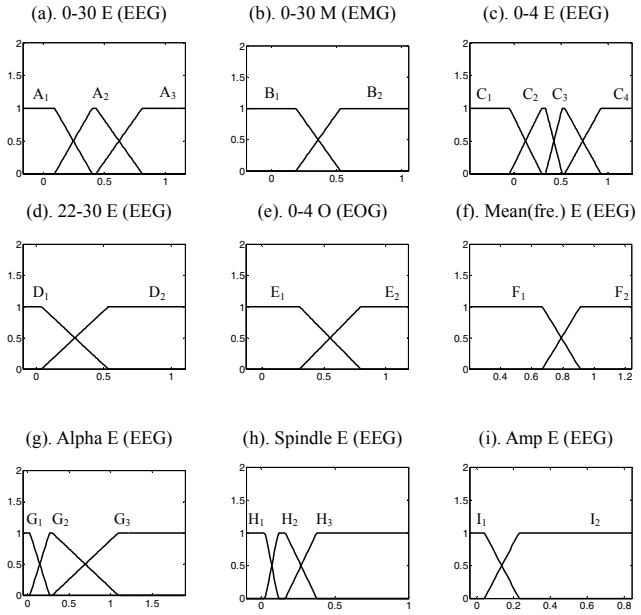

Fig 1. Fuzzy sets in our proposed method

III. EXPERIMENTAL RESULTS

To evaluate the performance of the proposed sleep staging method, 16 all-night PSG recordings from 16 subjects were used for testing. The performance was evaluated in the following aspects: the average performance of the method with smoothing and the sleep staging result of subject's overnight sleep data.

A. Performance of accuracy

TABLE II shows the confusion matrices of the five-stage epoch classification by the proposed sleep staging method. The rows and column are the results staged by expert and our fuzzy inference system, respectively. The testing dataset for performance estimation was comprised of 13,626 30-second epochs. As shown in Table 1, the overall sensitivity was 87.05% for the proposed fuzzy inference system.

B. Performance evaluation of consecutive staging

Figure 2 shows the hypnograms of one subject, including the manual scoring by the expert, the automatic staging without smoothing, and the automatic staging with smoothing.

It was observed that the hypnogram of our proposed method followed the changes in sleep stages of the subject. After smoothing, the resultant hypnogram is closer to the hypnogram scored by the expert.

TABLE II. Confusion table for comparison between computer scoring with smoothing and visual scoring for all 16 subjects.

		Computer						
		Wake	S1	S2	SWS	REM	Total	SE(%)
Expert	Wake	**323**	30	12	0	3	368	87.77
	S1	60	**194**	79	2	118	452	42.92
	S2	111	205	**6591**	258	241	7406	89
	SWS	5	17	239	**2216**	19	2496	88.78
	REM	38	172	118	38	**2538**	2904	87.4
	Overall						**13626**	87.05

* SE = sensitivity

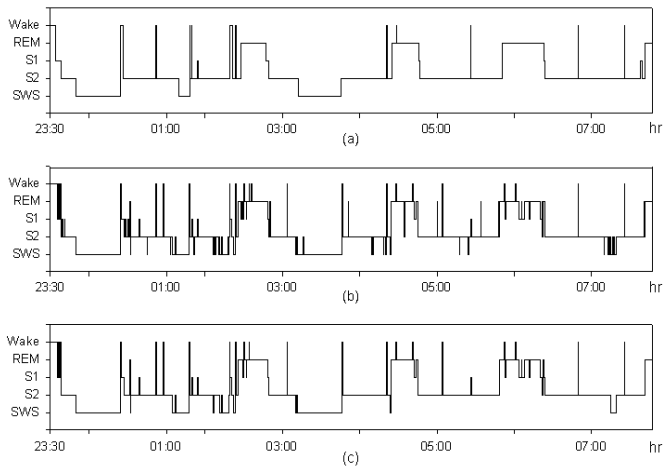

Fig 2. The sleep hypnogram of a subject: (a) the original manually score, (b) the automatic staging without smoothing, and (c) the automatic staging with smoothing.

IV. DISCUSSION

In this paper, an automated sleep staging system based on the fuzzy inference system was proposed. Temporal and spectral features of the EEG, EOG, and EMG signals were extracted and normalization was applied to these features to reduce the effect of individual variability. Experimental results show that the overall accuracy of the proposed fuzzy inference

system can reach 87.05%. Except for S1, the sensitivities of each stage are higher than 87%. The performance is superior to the previous studies [5-9, 12].

In the observation of the PSG signal for each stage, we found that there are many types of signals present in one stage, particularly during S1. So the developed multi-rule staging method that considers various kinds of situations according to the features of frequency and time domain is better than only referring to the R&K rules.

In previous studies, the sensitivity of expert and automatic sleep staging has high accuracy, but the sensitivity of S1 was about only 20% [8, 14]. Some previous studies try to improve the sensitivity of S1 to about 35% [7] [12], but the overall accuracy is about only 80%. S1 is easily mistakenly categorized as one of the other stages, except for SWS, and the number of S1 epochs is significantly lower than that of other stages. So, it is difficult to train a model with a high sensitivity for S1.

The proposed sleep staging method has high sensitivity and the resultant hypnogram is closer to the results scored by the expert. In future, we expect this method can integrate with various PSG systems for sleep monitoring in homecare applications.

***Abstract*—A hybrid of soft control technique of adaptive neuro-fuzzy inference system (ANFIS) and fuzzy logic (FL) and hard control technique of proportional-derivative (PD) for a five-fingered, smart prosthetic hand is presented. The ANFIS is used for inverse kinematics and FL is used for tuning the PD parameters with two input layers (error and error change) using 7 triangular membership functions and 49 fuzzy logic rules. Simulation results with FL-tuned PD controller exhibit superior performance compared to the PD and PID control alone.**

I. Introduction

During the recent wars in Afghanistan and Iraq, "at least 251,102 people have been killed and 532,715 people have been seriously wounded" [1]. Further, in the United States, the Amputee Coalition of America (ACA) [2] reports that there are approximately 1.9 million people living with limb loss, due to combat operations (such as conflicts, wars etc.), and non-combat operations such as accidents, or birth defects. According to a study of the 1996 National Health Interview Survey (NHIS) published by Vital and Health Statistics [3], it is estimated that one out of every 200 people in the U.S. has had an amputation. In other words, about one in every 2,000 new born babies will have limb deficiency and over 3,000 people lose a limb every week in America. By the year 2050, the projected number of Americans living with limb amputation will become 3.6 million [4]. In the past several decades, prosthetic hands have been developed by various researchers in the field [5]–[9], but reproducing the human hand in all its various functions, appearance, visibility, and weight is still a challenging task [5].

Hard computing/control (HC) techniques are used at lower levels for accuracy, precision, stability and robustness. HC comprises proportional-derivative (PD) control [10], proportional-integral-derivative (PID) control [11], [12], optimal control [12]–[15], adaptive control [16]–[19] etc. with specific applications to prosthetic devices. However, our previous works [10]–[12], [20] for a smart prosthetic hand showed that PID controller resulted in overshooting and oscillation. Soft computing (SC) or computational intelligence (CI) [21] is an emerging field based on synergy and seamless integration of neural networks (NN), fuzzy logic (FL) and optimization methods, such as genetic algorithms (GA), particle swarm (PS) [10], [22], [23], tabu search (TS) [23] and so on. The methodology based on SC can be used, in particular with FL, at upper levels of the overall mission where human involvement and decision making is of primary importance, whereas the HC can be used at lower levels for accuracy, precision, stability and robustness. Hence, we present the integration of SC and HC to solve problems that cannot be solved satisfactorily by using either HC or SC methodology alone with specific applications to prosthetics.

In this paper, we first consider briefly trajectory planning and kinematics problems associated with a five-fingered prosthetic hand. Then, adaptive neuro-fuzzy inference system (ANFIS) is used to solve inverse kinematics problem for three-link fingers (index, middle, ring, and little). Next, the dynamics of the hand is derived and feedback linearization technique is used to obtain *linear* tracking error dynamics. Then we propose the fuzzy logic-based PD (hybrid) controller, which uses fuzzy logic with 7 triangular membership functions in each input/output layer and 49 logic rules to tune PD gain parameters. The resulting overall hybrid system incorporating both soft and hard control techniques is simulated with practical data for the hand and found the performance to be superior to PD or PID alone. Finally, we provide conclusions and future work.

II. Modeling

A. Trajectory Planning and Kinematics

The trajectory planning using cubic polynomial was discussed in our previous work [10], [11], [14], [18], [19], [24] for a two-fingered (thumb and index finger) smart prosthetic hand.

Kinematics is the study of geometry in motion and is restricted to a natural geometrical description of motion by

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

the manners, including positions, orientations, and their derivatives (velocities and accelerations) [25], [26]. Forward and inverse kinematics of articulated systems study the analytical relationship between the angular positions of joints and the positions and orientations of the fingertips. A desired trajectory is usually specified in *Cartesian* space and the trajectory controller is easily performed in the *joint* space. Therefore, conversion of Cartesian trajectory planning to the joint space [26] is necessary. Using inverse kinematics, the joint angular positions of each finger need to be obtained from the known fingertip positions. Then the angular velocities and angular accelerations of joints can be obtained from the linear and angular velocities and accelerations of fingertips by differential kinematics. The inverse and differential kinematics of two-link thumb and three-link fingers were discussed in our previous publications [10], [11], [14], [18], [19], [24] for a two-fingered (thumb and index finger) smart prosthetic hand.

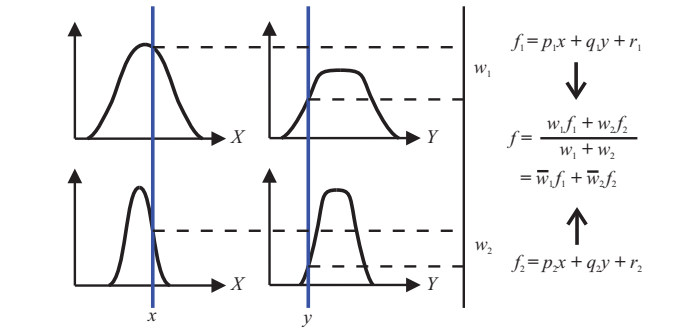
For five fingers shown in Figure 1, X^G, Y^G, and Z^G are

Fig. 1. Relationship between Global Coordinate and Local Coordinates: Local coordinate x^t-y^t-z^t of thumb can be reached by rotating through angles α and β to X^G and Y^G of global coordinate, subsequently. Local coordinate x^i-y^i-z^i of index finger can be obtained by rotating through angle α to X^G and then translating a vector $\mathbf{d^i}$ of the global coordinate.

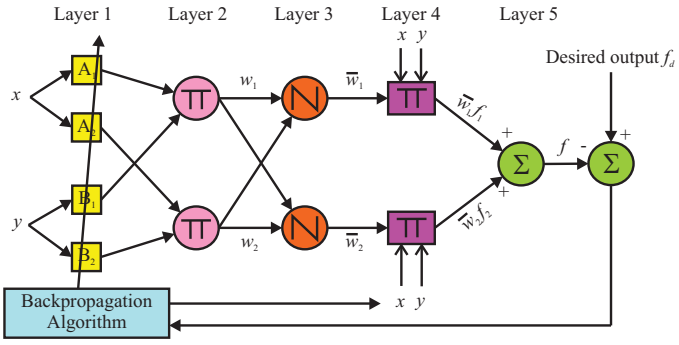
the three axes of global coordinate. Local coordinate x^t-y^t-z^t of thumb can be reached by rotating through angles α and β to X^G and Y^G of the global coordinate, subsequently. Local coordinate x^i-y^i-z^i of index finger can be obtained by rotating through angle α to X^G and then translating a vector $\mathbf{d^i}$ of the global coordinate; similarly, the local coordinate x^j-y^j-z^j of middle finger ($j = m$), ring finger ($j = r$), and little finger ($j = l$) can be obtained by rotating through angle α to X^G and then translating the vector $\mathbf{d^j}$ ($j = m$, r and l) of the global coordinate.

B. Adaptive Neuro-Fuzzy Inference System (ANFIS)

The inverse kinematics problems can be solved by using adaptive neuro-fuzzy inference system (ANFIS) method [27] where the input of fuzzy-neuro system is the Cartesian space and the output is the joint space. ANFIS is a fuzzy inference system implemented in the framework of adaptive networks which provides the best optimization algorithm to find parameters in order to fit the data. ANFIS includes *premise parameters*, that defines membership functions, and *consequent parameters*, that defines the coefficients of each output equation. ANFIS tunes the membership function and identifies the coefficients by the backpropagation gradient descent and least-squares methods, respectively. ANFIS uses a hybrid learning algorithm to identify parameters of Sugeno-type fuzzy inference systems for fuzzy modeling procedures to learn information about a data set in order to compute the membership function and track the given input/output data. Figure 2 (a) shows a two input first-order Sugeno fuzzy model with two rules and Figure 2 (b) depicts the equivalent ANFIS structure for all the computation below. Sugeno-type fuzzy



(a) A Two Input First-OrderSugeno Fuzzy Model with Two Rules



(b) Equivalent ANFIS Structures

Fig. 2. ANFIS Architecture: (a) A Two Input First-Order Sugeno Fuzzy Model with Two Rules (b) Equivalent ANFIS Structure [27]. The inverse kinematics problems are solved by using adaptive neuro-fuzzy inference system (ANFIS) method where the input of fuzzy-neuro system is the Cartesian space and the output is the joint space. ANFIS is a fuzzy inference system implemented in the framework of adaptive networks which provides the best optimization algorithm to find parameters in order to fit the data.

system has the following **Rule Base** [27]–[31].
If x is A_1 and y is B_1, then $f_1 = p_1x + q_1y + r_1$.
If x is A_2 and y is B_2, then $f_2 = p_2x + q_2y + r_2$.
Here, x and y are inputs to constitute the premise parameters A_1, A_2, B_1, and B_2 (Layer 1 in Figure 2 (b)). p_i, q_i, and r_i (i = 1,2) are the consequent parameters. We evaluate the rules by choosing *product* $\prod$ for T-Norm (Layers 2 and 3) which results in

$$w_i = \mu_{A_i}(x)\ \mu_{B_i}(y),\ i = 1, 2. \quad (1)$$

Here, $\mu_{A_i}(x)$ and $\mu_{B_i}(y)$ are designed fuzzy membership functions. Now after leaving the arguments (Layer 4), we get the output $f(x,y)$ by **Rule Consequences**.

$$f(x,y) = \frac{w_1(x,y)f_1(x,y) + w_2(x,y)f_2(x,y)}{w_1(x,y) + w_2(x,y)}. \quad (2)$$

f (Layer 5) can be written as

$$\begin{aligned} f &= \frac{w_1 f_1 + w_2 f_2}{w_1 + w_2} \\ &= \bar{w}_1 f_1 + \bar{w}_2 f_2, \end{aligned} \quad (3)$$

where

$$\bar{w}_1 = \frac{w_1}{w_1 + w_2}, \quad \bar{w}_2 = \frac{w_2}{w_1 + w_2}. \quad (4)$$

C. Dynamics of Hand

The dynamic equations of hand motion are derived via Lagrangian approach using kinetic energy and potential energy as [17], [24]–[26], [32]

$$\frac{d}{dt}\left(\frac{\partial \mathcal{L}}{\partial \dot{\mathbf{q}}}\right) - \frac{\partial \mathcal{L}}{\partial \mathbf{q}} = \boldsymbol{\tau}, \quad (5)$$

where $\mathcal{L}$ is the Lagrangian; $\dot{\mathbf{q}}$ and $\mathbf{q}$ represent the angular velocities and angle vectors of joints, respectively; $\boldsymbol{\tau}$ is the given torque vector at joints. The Lagrangian $\mathcal{L}$ can be expressed as

$$\mathcal{L} = T - V, \quad (6)$$

where T and V denote kinetic and potential energies, respectively. Substituting (6) into (5), dynamic equations of thumb can be obtained as below.

$$\mathbf{M}(\mathbf{q})\ddot{\mathbf{q}} + \mathbf{C}(\mathbf{q}, \dot{\mathbf{q}}) + \mathbf{G}(\mathbf{q}) = \boldsymbol{\tau}, \quad (7)$$

where $\mathbf{M}(\mathbf{q})$ is the inertia matrix; $\mathbf{C}(\mathbf{q}, \dot{\mathbf{q}})$ is the Coriolis/centripetal vector and $\mathbf{G}(\mathbf{q})$ is the gravity vector. (7) can be also written as

$$\mathbf{M}(\mathbf{q})\ddot{\mathbf{q}} + \mathbf{N}(\mathbf{q}, \dot{\mathbf{q}}) = \boldsymbol{\tau}, \quad (8)$$

where $\mathbf{N}(\mathbf{q}, \dot{\mathbf{q}}) = \mathbf{C}(\mathbf{q}, \dot{\mathbf{q}}) + \mathbf{G}(\mathbf{q})$ represents nonlinear terms. The dynamic relations for the two-link thumb and the remaining three-link fingers are quite lengthy and omitted here due to lack of space [24], [33], [34].

III. Control Techniques

A. Feedback Linearization

The nonlinear dynamics represented by (8) is to be converted into a linear state-variable system using feedback linearization technique [17]. Alternative state-space equations of the dynamics can be obtained by defining the position/velocity state $\mathbf{x}(t)$ of the joints as

$$\mathbf{x}(t) = \left[\mathbf{q}'(t) \quad \dot{\mathbf{q}}'(t)\right]'. \quad (9)$$

Let us repeat the dynamical model and rewrite (8) as

$$\frac{d}{dt}\dot{\mathbf{q}}(t) = -\mathbf{M}^{-1}(\mathbf{q}(t))\left[\mathbf{N}(\mathbf{q}(t), \dot{\mathbf{q}}(t)) - \boldsymbol{\tau}(t)\right]. \quad (10)$$

Thus, from (9) and (10), we can derive a linear system in *Brunovsky canonical form* as

$$\dot{\mathbf{x}}(t) = \begin{bmatrix} \mathbf{0} & \mathbf{I} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}\mathbf{x}(t) + \begin{bmatrix} \mathbf{0} \\ \mathbf{I} \end{bmatrix}\mathbf{u}(t) \quad (11)$$

with its control input vector given by

$$\mathbf{u}(t) = -\mathbf{M}^{-1}(\mathbf{q}(t))\left[\mathbf{N}(\mathbf{q}(t), \dot{\mathbf{q}}(t)) - \boldsymbol{\tau}(t)\right]. \quad (12)$$

Let us suppose the prosthetic hand is required to track the desired trajectory $\mathbf{q}_d(t)$ described under path generation or tracking. Then, the tracking error $\mathbf{e}(t)$ is defined as

$$\mathbf{e}(t) = \mathbf{q}_d(t) - \mathbf{q}(t). \quad (13)$$

Here, $\mathbf{q}_d(t)$ is the *desired* angle vector of joints and can be obtained by trajectory planning [10], [11], [14], [18], [24]; $\mathbf{q}(t)$ is the *actual* angle vector of joints. Differentiating (13) twice, to get

$$\dot{\mathbf{e}}(t) = \dot{\mathbf{q}}_d(t) - \dot{\mathbf{q}}(t), \quad \ddot{\mathbf{e}}(t) = \ddot{\mathbf{q}}_d(t) - \ddot{\mathbf{q}}(t). \quad (14)$$

Substituting (10) into (14) yields

$$\ddot{\mathbf{e}}(t) = \ddot{\mathbf{q}}_d(t) + \mathbf{M}^{-1}(\mathbf{q}(t))\left[\mathbf{N}(\mathbf{q}(t), \dot{\mathbf{q}}(t)) - \boldsymbol{\tau}(t)\right] \quad (15)$$

from which the control function can be defined as

$$\mathbf{u}(t) = \ddot{\mathbf{q}}_d(t) + \mathbf{M}^{-1}(\mathbf{q}(t))\left[\mathbf{N}(\mathbf{q}(t), \dot{\mathbf{q}}(t)) - \boldsymbol{\tau}(t)\right]. \quad (16)$$

This is often called the *feedback linearization* control law, which can also be inverted to express it as

$$\boldsymbol{\tau}(t) = \mathbf{M}(\mathbf{q}(t))\left[\ddot{\mathbf{q}}_d(t) - \mathbf{u}(t)\right) + \mathbf{N}(\mathbf{q}(t), \dot{\mathbf{q}}(t)\right]. \quad (17)$$

Using the relations (14) and (16), and defining state vector $\mathbf{x}(t) = [\mathbf{e}'(t) \quad \dot{\mathbf{e}}'(t)]'$, the *tracking error dynamics* can be written as

$$\dot{\mathbf{x}}(t) = \begin{bmatrix} \mathbf{0} & \mathbf{I} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}\mathbf{x}(t) + \begin{bmatrix} \mathbf{0} \\ \mathbf{I} \end{bmatrix}\mathbf{u}(t). \quad (18)$$

Note that this is in the form of a *linear* system such as

$$\dot{\mathbf{x}}(t) = \mathbf{A}\mathbf{x}(t) + \mathbf{B}\mathbf{u}(t). \quad (19)$$

B. Fuzzy Logic-Based PD Hybrid Control

Figure 3 shows the block diagram of the hybrid fuzzy logic-based PD controller for the presented five-fingered prosthetic hand with control signal as

$$\mathbf{u}(t) = -\mathbf{K_P}(t)\mathbf{e}(t) - \mathbf{K_D}(t)\dot{\mathbf{e}}(t) \quad (20)$$

with the proportional $\mathbf{K_P}(t)$ and derivative $\mathbf{K_D}(t)$ diagonal gain matrices with time varying. We then rewrite (17) as

$$\begin{aligned} \boldsymbol{\tau}(t) = \; & \mathbf{M}(\mathbf{q}(t))[\ddot{\mathbf{q}}_d(t) + \mathbf{K_P}(t)\mathbf{e}(t) + \mathbf{K_D}(t)\dot{\mathbf{e}}(t)) + \\ & \mathbf{N}(\mathbf{q}(t), \dot{\mathbf{q}}(t)]. \end{aligned} \quad (21)$$

Then we use mamdani fuzzy inference system to tune the time-varying parameters $\mathbf{K_P}(t)$ and $\mathbf{K_D}(t)$ of PD controller. Figure 4 shows the structural characteristics of proposed fuzzy inference system, which includes two inputs (error $\mathbf{e}$ and error change $\dot{\mathbf{e}}$) on the left and one output ($\mathbf{K_P}$) on the right. Each input or output layer contains seven triangular membership

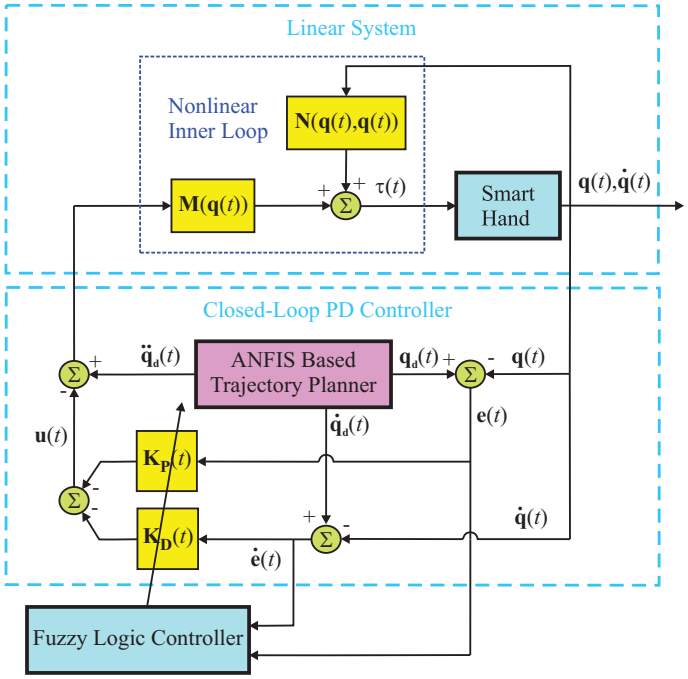


Fig. 3. Block Diagram of the Presented Hybrid Fuzzy Logic-Based Proportional-Derivative (PD) Controller for a Five-Fingered Prosthetic Hand: Errors and error changes are calculated by actual and desired angles, which are based on adaptive neuro-fuzzy inference system (ANFIS) trajectory planner. Then fuzzy logic controller tunes all parameters of closed-loop PD control so that the required torque of the prosthetic hand nonlinear system is computed by control input.

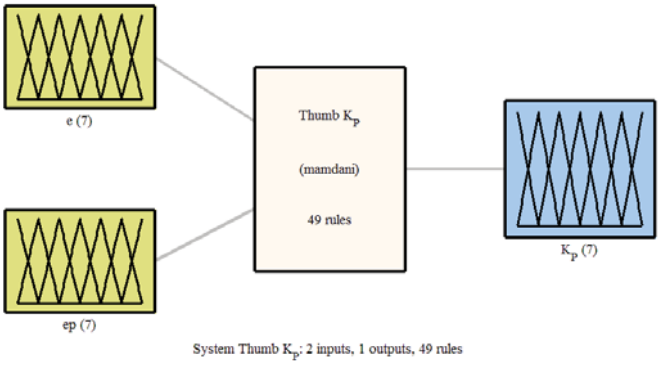

Fig. 4. The Structural Characteristics of Proposed Fuzzy Inference System: Two inputs (error $\mathbf{e}$ and error change $\dot{\mathbf{e}}$) on the left and one output (tuned $\mathbf{K_P}$) on the right with 49 logic rules

functions as shown in Figure 5 and 49 logic rules as listed in Table I. After using 49 logic rules, the output surface $\mathbf{K_P}$ of fuzzy inference system is generated as shown in Figure 6. Similarly, $\mathbf{K_D}$ can be computed by the same way.

IV. Simulation Results and Discussion

Figure 7 shows that a five-fingered prosthetic hand with 14 DOFs is reaching a rectangular rod in order to grasp the object. When thumb and the other four fingers are performing extension/flexion movements, the workspace of fingertips is restricted to the maximum angles of joints. Referring to inverse

kinematics, the first and second joint angles of the thumb fingertip are constrained in the ranges of [0,90] and [-80,0] (degrees). The first, second, and third joint angles of the other four fingers are constrained in the ranges of [0,90], [0,110] and [0,80] (degrees), respectively [35].

Next, we present simulations with PD and PID controllers and fuzzy inference system tuned PD controller for the 14 DOFs five-fingered smart prosthetic hand. The parameters of the two-link thumb/three-link fingers [36] were related to desired trajectory. All parameters of the smart prosthetic hand selected for the simulations are given in Table II and the

column) and desired/actual angles (q_1^t and q_2^t on the right column) of joints 1 (the top row) and 2 (the bottom row) for two-link thumb using PD (dash line), PID (dot line) and fuzzy logic based PD (solid line) controllers. The tracking errors for PD control are convergent within 5 seconds without overshooting, but PID control acts longer (approximate 10 seconds) with overshooting and oscillation. The proposed hybrid fuzzy logic PD control using parameters $\mathbf{K_P} \in [50, 1000]$ and $\mathbf{K_D} \in [50, 500]$ provides faster convergence than both PD and PID controllers. To further study whether the parameter range influences tracking errors, we found that the larger parameter range, the faster convergent speed after altering $\mathbf{K_P} \in [50, 2000]$ without additional computational time. We also used fuzzy logic controller with two inputs (error and error rate) and one output (control signal), but the control system could not obtain convergent tracking errors (data not shown). These data suggest that fusion of soft computing (SC) and

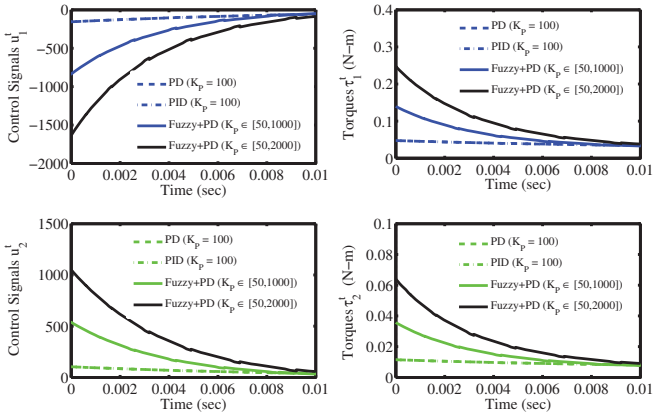

Fig. 9. Control Signals (Left) and Actuated Torques (Right) of Joints 1 (Upper) and 2 (Lower) for Two-Link Thumb Using PD (Dash Line), PID (Dot Line) and Fuzzy Logic Based PD (Solid Line) Controllers in 0.01 Second

hard control (HC) is superior to either HC or SC methodology alone.

The time-variant computed control signals (u_1^t and u_2^t) and torques (τ_1^t and τ_2^t) for two-link thumb within the first 0.01 second are shown in Figure 9, suggesting that the presented hybrid fuzzy logic PD controller requires more power (torque) than PD and PID controllers in order to obtain faster convergent tracking errors.

Similarly, Figures 10, 12, 14 and 16 show tracking errors and desired/actual angles for all remaining three-link fingers. Figures 11, 13, 15 and 17 show control signals and torques for the mapping three-link fingers.

V. Conclusions and Future Work

For a five-fingered smart prosthetic hand, a hybrid control technique involving soft control with adaptive neuro-fuzzy inference system (ANFIS) and fuzzy logic (FL) and hard control with proportional-derivative (PD) was presented. The ANFIS is used for inverse kinematics and FL is used for tuning the PD parameters with two input layers (error and

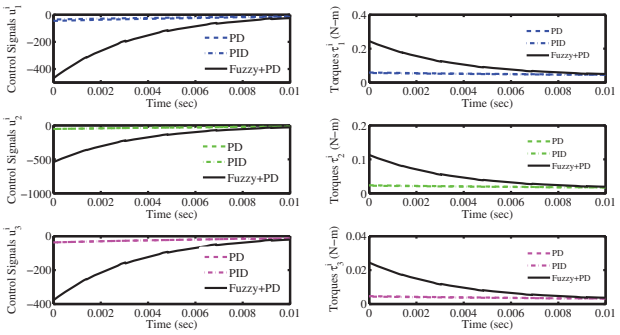

Fig. 11. Control Signals (Left) and Actuated Torques (Right) of Joints 1 (Top), 2 (Middle) and 3 (Bottom) for Three-Link Index Finger Using PD (Dash Line), PID (Dot Line) and Fuzzy Logic Based PD (Solid Line) Controllers in 0.01 Second

error change) using 7 triangular membership functions and 49 fuzzy logic rules. Simulation results with FL-tuned PD (hybrid) controller showed superior performance compared to the PD and PID control alone. Work is underway to extend this methodology to a real-time implementation on the prototype of a prosthetic hand.

***Abstract*—In this paper a method is proposed for constructing hierarchical-interpolative fuzzy rule bases in order to model black box systems defined by input-output pairs, i.e. to solve supervised machine learning problems. The resulting hierarchical rule base is the knowledge base, which is constructed by using evolutionary techniques, namely, Genetic and Bacterial Programming Algorithms. Applying hierarchical-interpolative fuzzy rule bases is an advanced way of reducing the complexity of the knowledge base, whereas evolutionary methods ensure a relatively efficient learning process. This is the reason of the investigation of this combination.**

***Index Terms*—Hierarchical-interpolative fuzzy systems, Genetic Programming, Bacterial Programming, supervised machine learning**

I. Introduction

This paper proposes a method for constructing hierarchical-interpolative fuzzy rules in order to model black box systems based on input-output pairs, i.e. to solve a certain type of supervised machine learning problem. The resulting hierarchical rule base is constructed by using evolutionary techniques, namely, Genetic and Bacterial Programming Algorithms.

There are two key elements in machine learning systems: the learning architecture including the structure of the knowledge base and the learning algorithm applied during the learning process, i.e. the technique that optimizes the knowledge base according to the particular problem. Hence, in order to establish a learning system having favorable properties (low knowledge complexity, high accuracy, fast learning process, etc.) these elements must be chosen so that they outperform other alternatives of knowledge bases and learning algorithms.

For interpretability purposes, i.e. after the learning process to have a quasi-interpretable knowledge base, this paper considers only knowledge bases realized in the form of fuzzy rule bases.

The classical approaches of fuzzy control deal with dense rule bases where the universe of discourse is fully covered by the antecedent fuzzy sets of the rule base in each dimension, thus for every input there is at least one activated rule. The main problem is the high computational complexity of these traditional approaches.

If a fuzzy model contains k variables and maximum T linguistic terms in each dimension, the order of the number of necessary rules is $\mathcal{O}(T^k)$. This expression can be decreased either by decreasing T, or k, or both. Of course, these are very different in terms of the efficiency of the complexity reduction. The first way (decreasing T) leads to sparse rule bases and rule interpolation, see e.g. [1], [2]. The second, more effective way (decreasing k) aims at reducing the dimension of the sub-rule bases by using meta-levels or hierarchical fuzzy rule bases (e.g. [3], [4]). The combination of these two methods leads to decreasing of both T and k, and was introduced in [5].

The scope of this paper focuses on this combination of complexity reduction approaches, namely, the application of hierarchical-interpolative fuzzy rule bases as previous papers [6], [7], [8] considered the other ways of complexity reduction.

Nature inspired evolutionary optimization algorithms are suitable for the global optimization of even non-linear, high-dimensional, multi-modal, and non-continuous problems. The original Genetic Algorithm (GA) was developed by Holland [9] and was based on the process of the evolution of biological organisms. Recognized as a powerful global search technique, genetic algorithms have been applied to a wide variety of problems. They exhibit a remarkable balance between search domain exploration and exploitation [10]. On one hand, every part of the domain is searched and on the other hand, the search effort is concentrated around the best solutions and their neighborhood, producing even better solutions. Bacterial Evolutionary Algorithm (BEA) [11] inspired by the microbial evolution phenomenon is similar, but based on results in the literature appearing more effective technique than GA (e.g. [12], [13], [6]). Approaches like Genetic Programming (GProg) [14] and Bacterial Programming (BProg) [15], present an alternative to the former algorithms. These techniques use the same operators as GA and BEA, respectively, though they require expression trees for gene representation, which could model hierarchical fuzzy rule bases, for example.

Evolutionary algorithms are useful tools for identification problems, they can help with finding a good compromise between the accuracy and the complexity of the model. In case of hierarchical but non-interpolative (i.e. dense) rule bases, genetic and bacterial approaches were successfully applied for fuzzy rule based learning during our previous work [7], [8]. This is the reason why Genetic and Bacterial Programming

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

is applied in our present work as the learning approaches that optimize the knowledge base (instead of using e.g. fuzzy clustering for this purpose like proposed in [16]).

Since so far no method has been invented to obtain the main properties (efficiency, accuracy, etc.) of such complex systems exactly, they can be figured out mostly by simulation. Therefore, in order to discover the capabilities of the established hierarchical-interpolative fuzzy rule based learning systems, simulation runs were carried out.

The next section gives a brief overview of the algorithms and techniques used. The third section proposes a method for constructing and optimizing hierarchical-interpolative fuzzy rule bases by Genetic and Bacterial Programming approaches. The simulation results and the observed behavior will be discussed in the fourth section. Finally, in the last section we will summarize our work and draw some conclusions.

II. Overview of the techniques and algorithms

In order to carry out this investigation, it is necessary to have familiarity with some theoretical fields including the concept of interpolative, hierarchical and hierarchical-interpolative fuzzy rule bases, structure constructing evolutionary optimization techniques (GProg, BProg) and machine learning.

The following subsections aim at giving a brief overview of some important points of these theoretical aspects, which will be repeatedly referred to later in the paper.

A. Interpolative fuzzy systems

In case of classical inference techniques (e.g. Mamdani-[17] or Takagi-Sugeno-inference [18]) in order to obtain any conclusion for an arbitrary observation, the fuzzy rules must cover the whole input space in the following sense. For every observation ($x \in X$) there must be at least one rule (in the form 'R_i: if x_1 is A_{i1} and x_2 is A_{i2} and ...and x_k is A_{ik} then y is B_i') in the rule base ($R = \{R_i\}$) so that $\wedge_{j=1}^{k} A_{ij}(x) \geq \alpha > 0$, i.e. the rule base must be α-*dense*.

Interpolative fuzzy systems calculate the conclusion by using interpolation, hence the input space need only be partially covered by the rules in the sense that there can be observations ($x \in X$) for which there is no rule in the rule base so that $\wedge_{j=1}^{k} A_{ij}(x) \geq \alpha > 0$, i.e. the rule base can be *sparse*.

The interpolative inference technique considered in this paper is the stabilized KH-interpolation [19]. This method is based on a certain interpolation of a family of distances between fuzzy sets in the rules and in the observation. Unlike the original linear KH-interpolation (cf. [1], [2]), it does not consider only the two closest surrounding rules, but it takes all the rules and computes the conclusion based on the consequent parts weighted by the distances. Furthermore, it contains an exponent determined by the number of input dimensions in the denominator in order to stabilize the interpolation function.

B. Hierarchical fuzzy rule based systems

The basic idea of using hierarchical fuzzy rule bases is the following ([3], [4]). Often the multi-dimensional input space $X = X_1 \times X_2 \times \cdots \times X_m$ can be decomposed, so that some of its components, e.g. $Z_0 = X_1 \times X_2 \times \cdots \times X_p$ determine a subspace of $X (p < m)$, so that in Z_0 a partition $\Pi = D_1, D_2, \ldots, D_n$ can be determined: $\bigcup_{i=1}^{n} D_i = Z_0$.

In each element of Π, i.e. in each D_i, a sub-rule base R_i can be constructed with local validity. In the worst case, each sub-rule base refers to exactly $X/Z_0 = X_{p+1} \times \cdots \times X_m$. The complexity of the whole rule base $\mathcal{O}(T^m)$ is not decreased, as the size of R_0 is $\mathcal{O}(T^p)$, and each R_i, $i > 0$, is of order $\mathcal{O}(T^{m-p})$, $\mathcal{O}(T^p) \times \mathcal{O}(T^{m-p}) = \mathcal{O}(T^m)$.

A way to decrease the complexity would be finding in each D_i a proper subset of $X_{p+1} \times \cdots \times X_m$, so that each R_i contains only less than $m-p$ input variables. In some concrete applications in each D_i a proper subset of $X_{p+1}, \ldots, X_m$ can be found so that each R_i contains only less than $m - p$ input variables, and the rule base has the structure shown in Table I., where $z_i \in Z_i$, $Z_0 \times Z_i$ being a proper subspace of X for $i = 1, .., n$.

TABLE I
HIERARCHICAL RULE BASE

R_0:	**If** z_0 is D_1 **then** use R_1
	If z_0 is D_2 **then** use R_2
	...
	If z_0 is D_n **then** use R_n
R_1:	**If** z_1 is A_{11} **then** y is B_{11}
	If z_1 is A_{12} **then** y is B_{12}
	...
	If z_1 is A_{1r_1} **then** y is B_{1r_1}
R_2:	**If** z_2 is A_{21} **then** y is B_{21}
	If z_2 is A_{22} **then** y is B_{22}
	...
	If z_2 is A_{2r_2} **then** y is B_{2r_2}
...	
R_n:	**If** z_n is A_{n1} **then** y is B_{n1}
	If z_n is A_{n2} **then** y is B_{n2}
	...
	If z_n is A_{nr_n} **then** y is B_{nr_n}

If the number of variables in Z_i is $k_i < m - p$ and $\max_{i=1}^{n} k_i = K < m - p$, then the resulting complexity will be $\mathcal{O}(T^{p+K}) < \mathcal{O}(T^m)$, so the structured rule base might lead to a reduction of the complexity.

The task of finding such a partition is often difficult, if not impossible, (sometimes such a partition does not even exist), however there are cases when, locally, some variables unambiguously dominate the behavior of the system, and consequently the omission of the other variables allows an acceptably accurate approximation.

C. Hierarchical-interpolative fuzzy systems

Based on [20], [21] and [22] the reduction of both the maximum number of the linguistic terms (T), and the number of variables (k) can be performed as follows when applying stabilized KH-interpolation. Let us assume that the observation on X is A^* and its projections are $A_0^* = A^*/Z_0$, $A_1^* = A^*/Z_1$,

$A_2^* = A^*/Z_2$, ..., $A_n^* = A^*/Z_n$. Using stabilized KH-interpolation, the sub-conclusions, obtained from the sub-rule bases R_1, R_2, ..., R_n are ${}^{SKH}B^{(1)*}$, ${}^{SKH}B^{(2)*}$, ..., ${}^{SKH}B^{(n)*}$, respectively. (The superscript shows the reference to the rule bases.) Then, by substituting the sub-conclusions into the meta-rule base we obtain ${}^{SKH}B_k^*$, the conclusion. The steps of the algorithm are as follows:

1) determine the projection A_0^* of the observation A^* to the subspace of the fuzzy partition Π
2) determine the distances between A_0^* and the meta-rule antecedents
3) for each R_i determine A_i^* the projection of A^* to Z_i and determine the distances between A_i^* and the rule antecedents
4) determine the sub-conclusions for each sub-rule base R_i by applying stabilized KH-interpolation
5) using the sub-conclusions from step 4, compute the final conclusion ${}^{SKH}B^*$ by applying stabilized KH-interpolation again

Fig. 1 shows a simple example of the algorithm. In step 3 and 4, in each sub-rule base, a different inference engine can be applied, e.g., if the sub-rule base itself is dense, the Mamdani-algorithm (or one of its variations), or in any case one of the interpolation algorithms can be used.

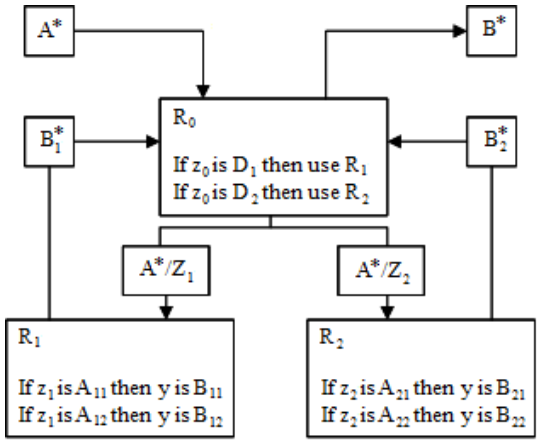

Fig. 1. Interpolation in a hierarchical-interpolative fuzzy system

D. Structure building evolutionary techniques

1) Genetic Programming: There are various optimization algorithms, which were inspired by processes in the nature. The advantage of these algorithms is their ability to solve and quasi-optimize problems with non-linear, high-dimensional, multimodal, and discontinuous character. These processes can easily be applied in optimization problems where one individual corresponds to one possible solution of the problem. In the original Genetic Algorithm (GA) [9] an individual is represented by a sequence of numbers, for example a sequence of bits. This sequence is called chromosome. GA uses three operators: selection, crossover, and mutation. A more recent approach is Genetic Programming (GProg) [14], which uses the same operators as GA, though the individuals are represented by the so called expression tree. This tree is composed of the non-terminal nodes (also called as inner or function nodes) and the terminal nodes (leaves).

The evolutionary process involves the following steps:

a) creation of an initial population
b) evaluation of the candidates
c) application of genetic operators:
   - **selection**: pairs of trees are selected based on their fitness for reproduction
   - **crossover**: nodes in the trees are selected at random and the sub-trees belonging to the selected nodes are exchanged producing a pair of offspring trees
   - **mutation**: this is performed by either replacing a node selected at random by a sub-tree generated randomly or by changing the inner properties of the node
   - **replacement**: substituting the created offsprings to the population
d) test of the termination criteria (e.g. reaching the maximum number of generations, or the time limit) and if any of the termination criteria is achieved, the algorithm stops, otherwise it continues from step b)

The cycle of evolution is summarized in Fig. 2.

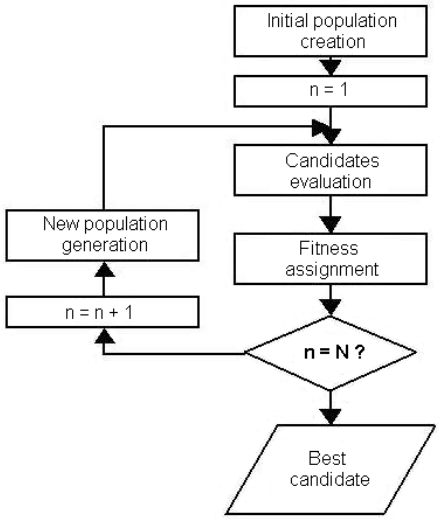

Fig. 2. Flowchart of Genetic Programming

2) Bacterial Programming: An evolutionary technique being slightly different compared to GA is called Bacterial Evolutionary Algorithm (BEA). This algorithm was introduced by Nawa and Furuhashi in [11]. The first version of this algorithm was called Pseudo-Bacterial Genetic Algorithm (PBGA) [23] which proposed a modified mutation operator called bacterial mutation, based on the natural phenomenon of microbial evolution. Bacterial Evolutionary Algorithm introduced a new operator called gene transfer operator. While PBGA incorporates

bacterial mutation and crossover operator, the BEA substitutes the classical crossover with the gene transfer operation. Both of these new operators were inspired by bacterial evolution. Bacteria can transfer genes to other bacteria. The bacterial mutation performs local optimization whilst the gene transfer allows the bacteria to directly transfer information to the other individuals in the population.

Based on these bacterial operations, but using the tree structures similar to the ones in the Genetic Programming, a new technique was proposed, named Bacterial Programming (BProg) [15].

The evolutionary process of BProg involves the following steps:

a) creation of an initial population
b) application of bacterial operators:
   - **bacterial mutation**: this is performed by either replacing a node selected at random by a sub-tree generated randomly or by changing the inner properties of the node
   - **gene transfer**: nodes in the trees are selected at random in the selected superior individual and the sub-trees belonging to the selected nodes are copied to the selected inferior individual
c) test of the termination criteria (e.g. reaching the maximum number of generations, or the time limit) and if any of the termination criteria is achieved, the algorithm stops, otherwise it continues from step b)

The cycle of evolution is summarized in Fig. 3.

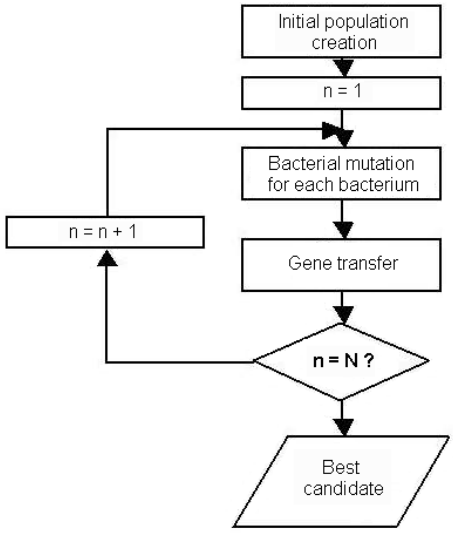

Fig. 3. Flowchart of Bacterial Programming

E. Supervised machine learning

Supervised machine learning [24] means a process where parameters of a 'model' are being adjusted so that its behavior becomes similar to the behavior of the 'system', which is to be modeled. Since the behavior can be characterized by input-output pairs, the aim of the learning process can be formulated so that the model should give similar outputs for the input as the original system does.

The model can be, for example, a simple function (e.g. a polynomial function), where the parameters are the coefficients, or it can be a neural network, where the parameters are the weights, or it can be a hierarchical fuzzy rule base together with an inference engine [25]. In this case the parameters determine the structure of the rule base as well as the membership functions of the rules in the rule base. In our work we applied a hierarchical fuzzy rule base containing trapezoidal membership functions.

If the system is denoted by $\phi(\boldsymbol{x})$ and the model is denoted by $f(\boldsymbol{x}, \boldsymbol{p})$, where $\boldsymbol{x} \in X$ is the input vector and $\boldsymbol{p}$ is the adjustable parameter vector, the previous requirement can be expressed as follows:

$$\forall \boldsymbol{x} \in \boldsymbol{X}: \ \phi(\boldsymbol{x}) \overset{!}{\approx} f(\boldsymbol{x}, \boldsymbol{p}) \tag{1}$$

In a supervised case the learning happens using a set of training samples (input-output pairs). If the number of samples is m, the input in the ith sample is $\boldsymbol{x}_i$, the desired output is $d_i = \phi(\boldsymbol{x}_i)$ and the output of the model is $y_i = f(\boldsymbol{x}_i, \boldsymbol{p})$, the following formula can be used:

$$\forall i \in [1, m]: \ d_i \overset{!}{\approx} y_i \tag{2}$$

The error (ε) shows how similar the model to the system is (see Fig. 4). It is the function of the parameter vector, so it can be denoted by $\varepsilon(\boldsymbol{p})$. A widely applied definition for the error is the Mean Squared Error (MSE):

$$\varepsilon(\boldsymbol{p}) = \frac{\sum_{i=1}^{m} (d_i - y_i)^2}{m} \tag{3}$$

Obviously, the task is to minimize this $\varepsilon(\boldsymbol{p})$ function. It can be done by numerical optimization algorithms.

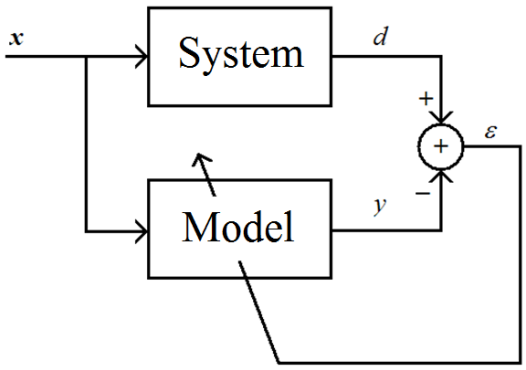

Fig. 4. Supervised machine learning

This way machine learning problems can be traced back to optimization problems.

III. The encoding method

This section describes the method how the hierarchical fuzzy rule bases are represented by the individuals, i.e. how the rule bases are encoded.

The non-terminal (inner) nodes hold the antecedent parts of one or more rules. In case of each non-terminal node the number of considered input dimensions (number of *decision variables*) is a random value, whose maximum can be parameterized. A decision variable can only be such a dimension, which has not been decision variable in the ancestors of the current node. (This way the size of the expression tree becomes limited.) The consequent part of a rule is a child node of the particular node, which can be either a non-terminal or a terminal node. Thus, the number of rules a non-terminal node holds is determined by the number of the children of the particular node. The number of children of the nodes is a random value, whose maximum, i.e. the maximum number of rules belonging to a node, can be parameterized.

Each terminal node (leaf) holds one single fuzzy set, as a conclusion (output) set.

There can be non-terminal nodes as well as terminal nodes on the same level, hence meta-rules and rules can appear together (see Fig. 5).

Since a decision variable cannot be such a dimension, which has already been a decision variable in any ancestor of the current node, in case of crossover in GProg the transfered nodes change their decision variables so that the new decision variables be such dimensions, which have not been decision variables in the ancestors. The same solution of this technical difficulty is applied in gene transfer in BProg, too.

In case of mutation in GProg and bacterial mutation in BProg there are no technical difficulties: only new sub-trees or nodes must be generated with the consideration of the above described encoding rules.

The applied inference algorithm is a simple extension of one of the first interpolation techniques, namely the stabilized KH-interpolation method [19]. This extension is necessary, because there are child nodes in the consequent parts of the rules. Since the conclusions of sub-trees are fuzzy sets (specially, the contents of terminal nodes can also be considered as conclusions), they can be substituted into the consequent parts of the rules of the parent nodes. This can be performed recursively.

IV. Simulation results

Simulation runs were carried out in order to discover the important properties of the established learning systems (speed of learning, accuracy of the resultant knowledge base, etc.).

In our work a six dimensional learning problem was applied that was also used in [11] to evaluate the performance of Bacterial Evolutionary Algorithm. This problem is to approximate the following function:

$$f_{6dim} = x_1 + \sqrt{x_2} + x_3 x_4 + 2e^{2(x_5 - x_6)} \tag{4}$$

$$x_1, x_2 \in [1, 5], \quad x_3 \in [0, 4], \quad x_4 \in [0, 0.6],$$

$$x_5 \in [0, 1], \quad x_6 \in [0, 1.2].$$

In the simulations the parameters had the following values, because after a number of test runs these values seemed to be suitable. The number of individuals in a generation was 8 in both Genetic and Bacterial Programming algorithms. The maximum number of rules belonging to a node, i.e. the maximum number of children of a node, was set to 4 and the maximum number of decision variables in a node was 3. In case of genetic techniques the selection rate was 0.3 and the mutation rate was 0.1, in case of bacterial techniques the number of clones was 5 and 4 gene transfers were carried out in each generation. The genetic methods applied elitist strategy.

The numbers of training samples were 200 in the learning processes.

Two type of simulation were carried out, which differed in the termination criteria. The runs applying the first criterion stopped after reaching the maximum number of generations, which was 2000 generations, whereas the other optimization processes stopped after reaching the time limit, which was 2000 seconds.

At the end of each optimization processes the accuracy of the resultant rule bases was measured by using three error definitions:

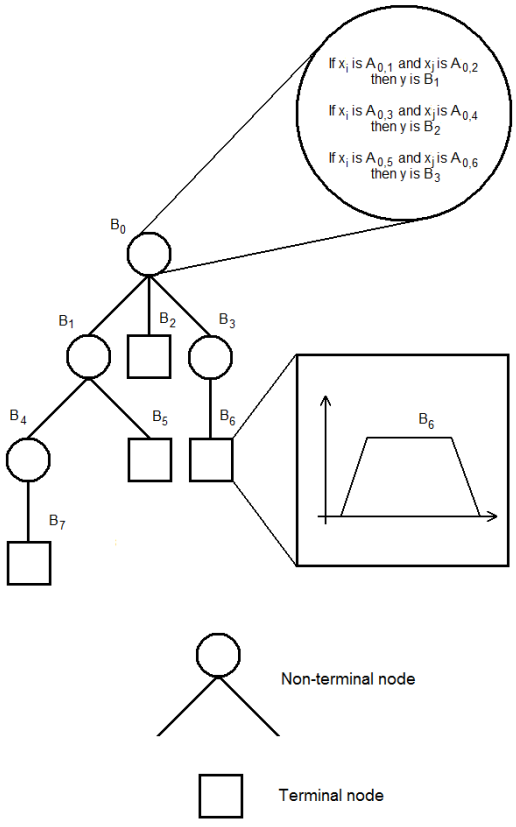

Fig. 5. Tree of a hierarchical rule base (rules and meta-rules appear together on the same levels)

- *Mean Squared Error* (*MSE*):

$$\frac{1}{m}\sum_{i=1}^{m}(d_i - y_i)^2 \tag{5}$$

- *Mean Squared Relative Error* (*MSRE*):

$$\frac{1}{m}\sum_{i=1}^{m}\frac{(d_i - y_i)^2}{y_i^2} \tag{6}$$

- *Mean Relative Error Percentage* (*MREP*):

$$\frac{100}{m}\sum_{i=1}^{m}\left|\frac{d_i - y_i}{y_i}\right| \tag{7}$$

The MSE, MSRE, and MREP values were calculated on the test samples.

The computation time and the number of executed generations were also observed.

In case of both algorithms for each parameterization 10 runs were carried out. Then we took the mean of the obtained values.

During the runs the fitness values of the best individuals were monitored. These fitness values were calculated based on the MSE values (measured on the training samples) as follows:

$$F = \frac{10}{\mathrm{MSE} + 1} = \frac{10m}{\sum_{i=1}^{m}(d_i - y_i)^2 + m} \tag{8}$$

The means of the fitness values of the best individuals during the runs were presented in Fig. 6 and Fig. 7 to get a better overview. The horizontal axes show the executed number of generations and the elapsed computation time in seconds, respectively, and the vertical axes show the fitness values of the best individuals at the current time.

In the figures the dashed lines show the results of GProg and the solid lines present the graph of BProg. For comparing purposes the results obtained in case of non-interpolative (dense) hierarchical rule bases (which can be found in our previous work [7]) are also presented in the figures (drawn with dotted and dotted-dashed lines).

The results of the simulation runs are presented in Table II and Table III. In Table II 'Comp. time' denotes the mean of the computation time (in seconds) the optimization processes required and in Table III 'No. of gen.' denotes the mean of the number of executed generations. In both tables 'No. of rules' denotes the mean of the number of rules in the resulting hierarchical rule bases (including meta-rules).

Again, for comparing purposes the results obtained in case of non-interpolative hierarchical rule bases are also presented in the tables (in columns named 'Hierarchical').

Observing the results given by the hierarchical-interpolative systems it can be seen that BProg outperformed GProg in both simulation types from the point of view of both fitness values (see Fig. 6 and Fig. 7) and the final error values (see Table II and Table III).

Compared to previous results produced by dense hierarchical, Mamdani-inference based learning systems [7], the results

No. of gen.	1914618	34627	52685	1611
No. of rules	4.2	6.4	6	6.8

given by the established hierarchical-interpolative learning systems are convincingly better in case of GProg, however it is not so unambiguous in case of BProg, because the non-interpolative hierarchical system gave higher fitness values during the learning processes (see Fig. 6 and Fig. 7), but most often the hierarchical-interpolative system had lower errors on the test samples after learning (see Table II and Table III, where bold numbers present the best error values).

In case of the time limited runs GProg with the dense hierarchical system stuck in local optima and its convergence speed became zero in 20 seconds, whereas the other combinations had a positive convergence speed even after 2000 seconds and continued advancing to better fitness values (see Fig. 7).

V. Conclusion

Our work proposed a method for constructing hierarchical-interpolative fuzzy rule bases in order to solve supervised machine learning problems. The rule bases were constructed by using Genetic and Bacterial Programming algorithms.

Simulation runs were carried out in order to discover the properties of the obtained learning systems and to compare them with previous results on non-interpolative hierarchical systems [7]. Bacterial Programming outperformed Genetic Programming in both executed simulation types. The results given by the established hierarchical-interpolative learning systems combined with GProg were unambiguously better than previous results produced by the corresponding non-hierarchical, Mamdani-inference based learning system, however in case of the systems with BProg optimization technique neither the interpolative nor the non-interpolative system showed overwhelmingly better properties.

Further research may aim at improving both the encoded learning architecture and the applied optimization methods (e.g. using gradient steps during the optimization process) and to compare the established hierarchical fuzzy systems with non-hierarchical ones.

***Abstract*—The detection of pulmonary nodules is one of the most studied areas and challenging task in the field of medical image analysis, due the current relevance of the lung carcinoma. The difficulty and complexity of this task has led to the development of CAD systems for the automated detection of lung nodules in CT scans, which provides valuable assistance for radiologists and could improve the detection rate. A common phase of these systems is the detection of regions of interest (ROIs) that could be marked as nodules, in order to reduce the searching space problem. In this paper, we evaluate and compare the combination of various approaches of supervised vector machines (SVMs) with different kinds of fuzzy clustering algorithms, so as to improve the detection and segmentation of ROIs that could represent lung nodules in high resolution CT scans. These images are provided by the LIDC database (Lung Internet Database Consortium).**

I. Introduction

The high complexity of the lung structure, with 23 airway subdivisions between trachea and alveolar sacs, and numerous lung diseases represented in images by pathological structures such as nodules, tumors, etc., have encouraged the analysis of computer pulmonary images. In this area, one of the most studied diseases is lung carcinoma, one of the most mortal carcinomas for which early detection is essential. The survival rate after 5 years for patients who were diagnosed and had surgery in a early stage is over 60%, but drops to 10% if the patients do not have surgery during these five years.[1]

Both primary and metastatic lung carcinoma most commonly manifest as pulmonary nodules, so researchers are focusing on the detection of these structures as a previous step for an early diagnosis.

The development of new modalities of image acquisition, such as high resolution CTs, has improved the detection and diagnosis of early nodules that, at their initial stage, may have a diameter below 3mm [2]. This technique offers a non-invasive way to observe the lung structure with great definition. Nevertheless, it is rarely used due to the high cost of the technology.

High resolution CTs studies may contain up to 600 images [2] whose examination and interpretation by radiologist is a very tedious and time-consuming task. Moreover, lung nodules are difficult to detect in CT images because they may appear attached to other non-pathological elements such as blood vessels or pleura, or have a small size and different shapes. For these reasons, currently new CADs (Computer Aided System) systems are being developed [3] [4] for the automated detection of lung nodules, providing support to the diagnosis of the experts. Our research group is developing such a system.

The first stage for these systems usually consists in preprocessing the CT images in order to isolate the lungs and reduce the search area where nodules could appear, removing those external elements that could interfere with the detection task. Lungs are therefore the only elements on each image of the CT scan. Our system follows this approach.

The second step consists in the detection of ROIs that could be treated as possible nodules. This paper presents the results obtained with a combination of different fuzzy clustering algorithms with various approaches of the SVM technique. The analysed fuzzy algorithms represent the state of the art in this field, obtaining good results for the detection of ROIs in lung CTs [5] [6]. The non-defuzzified output of these algorithms provides membership factors for each image pixel that represents with which grade they are classified into each segmented cluster. The principal aim of the study is to improve these results by applying the SVM technique to the membership factors, so as to obtain a better defuzzification phase with fewer rates of false positives in the segmentation of lung CT images. As this step is included in a CAD system, the analysis focuses on achieving a good method that reduces the false nodule candidate area, minimizing the deficiencies in the classification of the pixels provided by the fuzzy algorithms.

II. Materials

In this paper, we used a training and simulation set that consists in several high-resolution CT lung images, provided

by the LIDC (Lung Image Database Consortium) database. This project, developed by the NCI (National Cancer Institute), mainly aims at developing and publishing a reference repository for the evaluation and implementation of CAD systems in lung nodules detection.[7]

The database consists in a repository of images in which each has associated relevant data regarding the presence or absence and the characteristics of the observed nodule(s) if present. This information is obtained from a process whereby four expert thoracic radiologists analyse and mark, regardless, each image. Later, if discrepancies in observations exist, they can be revised and corrected. The data is provided in a XML file that indicates its type and contour, specified by the pixels coordinates that conform it.

The provided studies are stored using the DICOM standard and have a size of 512x512 pixels, with a pixel size varying from 0,5 to 0,8 mm. The grayscale is of 12 bits in Hounsfiled Units (HU).

The implementations of the different multi-class SVM approaches is provided by the BSVM library [8], that can be used freely for research purposes. The fuzzy algorithms were implemented with the ITK library, focused mainly on medical image analysis.

III. Analysed fuzzy algorithms

We selected three fuzzy clustering algorithms to carry out the detection task of the initial ROIs. They all provide less sensitivity to noise and outliers, are able to easily handle multidimensional problems, and provided the best results during the previous analysis [5] and [6] carried out on LIDC data sets.

A. SFCM (Spatial Fuzzy C-Means)

This algorithm [9] is a modified version of the FCM (Fuzzy C-Means) that incorporates spatial information in such a way that it alters the membership weighting value of each cluster after considering the distribution in the neighborhood. This spatial information provides the possibility to obtain more homogeneous regions and reduce the effect of noise.

In the first step, the algorithm calculates the initial membership values for each pixel, applying the standard FCM algorithm. Then, the spatial relationship is introduced by the following function:

$$h_{ij} = \sum_{k \in NB(x_j)} u_{ik} \tag{1}$$

where $NB(x_j)$ represents a resizable square window, centered on each pixel x_j under consideration. Therefore, the greater the value of this function, the greater the probability that pixel x_j belongs to cluster ith.

The next step calculates the new membership function using the previous spatial information:

$$u'_{ij} = \frac{u_{ij}^p h_{ij}^q}{\sum_{k=1}^{C} u_{kj}^p h_{kj}^q} \tag{2}$$

where p and q control the relevance of functions u_{ij} and h_{ij}.

In the last step, the new centroids are obtained following the same FCM procedure:

$$c_j = \frac{\sum_{i=1}^{N} u'^m_{ij} x_i}{\sum_{i=1}^{N} u'^m_{ij}} \tag{3}$$

The iteration process will stop when the maximal difference between two centroids lies below a determined threshold.

B. SKFCM (Spatial Kernelized Fuzzy C-Means)

This algorithm [11] introduces a penalty factor that contains spatial neighborhood information to the KFCM (Kernelized Fuzzy C-Means) algorithm proposed in the same work. Kernelized methods introduce a kernel function that allows us to transform the original low dimension input space into a higher dimensional feature space, where complex nonlinear problems can be treated and solved in a better way as probed by Cover [12]. The present paper only considers the Gaussian radial basis function kernel:

$$K(x, y) = exp\left(\frac{\|x - y\|^2}{\sigma^2}\right) \tag{4}$$

Therefore, modifying the objective function of the FCM in order to introduce the kernel function and add the penalty factor, we obtain the final objective function:

$$JS_m^{\phi} = \sum_{i=1}^{c}\sum_{k=1}^{N} u_{ik}^m (1 - K(x_k, v_i)) + \frac{\alpha}{N_R}\sum_{i=1}^{c}\sum_{k=1}^{N} u_{ik}^m \sum_{r \epsilon N_k} (1 - u_{ir})^m \tag{5}$$

where N_k represents the square window which includes the neighbors of pixel x_k (without considering it), N_r is the cardinality of N_k, and α ($0<\alpha<1$) is a parameter that controls the effect of the penalty term. Deriving the Eq. 5 respect the variables u_{ik} and v_i obtains the following two conditions that minimize the function. An iterative algorithm can be derived from the above conditions.

In the initialization of the algorithm, the parameters c, i.e. the number of clusters, the initial class centroids, the initial memberships, and the threshold epsilon, must be determined.

In the first step of the iterative process, the memberships are calculated as follows:

$$u_{ik} = \frac{\left((1 - K(x_k, v_i)) + \frac{\alpha}{N_R}\sum_{r \epsilon N_k}(1 - u_{ir})^m\right)^{\frac{-1}{(m-1)}}}{\sum_{j=1}^{c}\left((1 - K(x_k, v_j)) + \frac{\alpha}{N_R}\sum_{r \epsilon N_k}(1 - u_{jr})^m\right)^{\frac{-1}{(m-1)}}} \tag{6}$$

Finally, the centroids are updated as follows:

$$v_i = \frac{\sum_{k=1}^{n} u_{ik}^m K(x_k, v_i) x_k}{\sum_{k=1}^{n} u_{ik}^m K(x_k, v_i)} \tag{7}$$

As in the other algorithms, repeat these steps until condition $\max_{i,k} \|u_{ik}^t - u_{ik}^t\| \leq \epsilon$ is satisfied, where epsilon is a determined threshold.

C. MKSFCM (Modified Kernelized Spatial Fuzzy C-Means)

This algorithm was proposed by Castro et Al. in [6], and consists in the combination of the algorithms SFCM, introduced in section III-A, and the FKCM (Fuzzy Kernel C-Means) proposed in [13]. The principal purpose is to join the main advantages of both methods: homogeneity and robustness.

Initially, this algorithm calculates the kernelized membership function, using the same equation as the FKCM:

$$u_{jk} = \frac{(1/d^2(x_j, V_k))^{1/(q-1)}}{\sum_{j=1}^{C}(1/d^2(x_j, V_k))^{1/(q-1)}} \tag{8}$$

where $d^2(x_j, V_k) = K(x_j, x_j) - 2K(x_j, V_k) + K(V_k, V_k)$, q is a fuzzy index that determines the fuzziness of the clusters, C is the number of clusters, V are the centroids, and K is the kernelized function.

The second step introduces the spatial information as in the SFCM procedure through the spatial function h_{ij} in Eq. 1, after which the Eq. 2 is applied to obtain the membership factors.

Finally, the new kernel matrix $K(x_j, \hat{V}_k)$ and $K(\hat{V}_k, \hat{V}_k)$ is calculated as follows:

$$K(x_j, \hat{V}_k) = \phi(x_j) \cdot \phi(\hat{V}_k) = \frac{\sum_{i=1}^{N}(u_{ik})^q K(x_i, x_j)}{\sum_{i=1}^{N}(u_{ik})^q} \tag{9}$$

To halt the iteration process, the error must lie below a determined threshold, otherwise a new iteration will start and Eq. 8 is again applied.

IV. Support vector machine for classification problems

The standard Support Vector Machines (SVM) were designed specifically for binary classification and regression estimation. However, they have also been extended to multi-class problems [14]. We opted for the multi-class approach in order to realize a more refined classification of the lung structures segmented in the previous stages, rather than dividing the marked zones into nodule or non-nodule.

These problems are usually solved by two different approaches. One consists of decomposing and combining several binary classifiers that the binary SVM can solve, the other consists of solving it directly by considering all data in one formulation. This paper compares the two methods outlined above. In the first approach, we selected the one-against-one Kreβel implementation [15], in the other we selected the one proposed by Weston and Watkins [16]. Note that there are other implementations for multi-class SVM [14], but the proposal of this paper is not so much to compare different SVMs but rather to obtain an idea of the improvements that these SVM approaches can provide us.

A. One-against-one

This method constructs $k(k-1)/2$ classifiers, where k is the number of classes. The ith SVM is trained on data from two classes, resulting in l training data (x_1, y_1),...,(x_l, y_l), where $x_i \in R^n$, i=1,...,l and $y_i \in \{1,\ldots,k\}$ is the class of x_i. Training data from the ith and the jth classes are solved according to the following classification problem:

$$\begin{aligned} \overset{min}{w^{ij}, b^{ij}, \xi^{ij}} \quad & \frac{1}{2}(w^{ij})^T w^{ij} + C\sum_t \xi_t^{ij}(w^{ij})^T \\ & (w^{ij})^T\phi(x_t) + b^{ij} \geq 1 - \xi_t^{ij}, \quad if y_t = i \\ & (w^{ij})^T\phi(x_t) + b^{ij} \leq -1 + \xi_t^{ij}, \quad if y_t = j \\ & \xi_t^{ij} \geq 0 \end{aligned} \tag{10}$$

where the training data x_t are mapped to a higher dimensional space applying function ϕ, and parameter C represents the penalty.

The decision of the ensemble is made using the max-wins voting strategy, in which each classifier is considered to be a voting. In this approach, Hsu and Lin use $f_{ij}(x) = ((w^{ij})^T\phi(x) + b^{ij})$ as a decision function. Let us denote the voting function by:

$$V_i(x) = \sum_{j=1,\ldots,q \;\; j\neq i} s(f_{ij}(x)) \tag{11}$$

where the function s(t) maps the decision value to {0,1}

$$s(t) = \begin{cases} 1, & if \quad t \geq 0 \\ 0, & otherwise \end{cases} \tag{12}$$

Therefore, when element x_t is in the ith class ($f_{ij}(x_t) > 0$) rather than class j, the vote for this element will increase its value by one in accordance with Eq. 11; otherwise it contributes 0. At the end of the voting process, the value of $V_i(x)$ will be the sum of all votes made by all classifiers that cast one vote for the ith class.

Consequently, the final decision is made as follows:

$$\text{Class Label of i}^*(x) = argmax_{i=1,\ldots,q} V_i(x) \tag{13}$$

i.e element x is classified into class i, which is the class with most votes from the classifiers. Remark that if two or more classes have the same number of votes, the class with the smallest index is selected.

B. Multi-class SVM

This kind of approach was introduced simultaneously by Vapnik [17] and Weston and Watkins [16]. In essence, these formulations are essentially identical and propose an approach to solve multi-class problems in a single optimization.

Like the one-against-one approach, this approach constructs k two-class decision rules where the mth function $w_m^T\phi(x)+b$ separates training vectors of the m class from the other are constructed. However, unlike the previous method, even though there are k decisions functions, all are obtained by solving a single optimization problem. The formulation of this is as follows:

$$\begin{aligned} \overset{min}{w^{ij}, b^{ij}, \xi^{ij}} \quad & \frac{1}{2}\sum_{m=1}^{k} w_m^T w_m + C\sum_{i=1}^{l}\sum_{m\neq y_i} \xi_i^m w_{y_i}^T\phi(x_i) \\ & + b_{y_i} \geq w_m^T\phi(x_i) + b_m + 2 - \xi_i^m, \\ & \xi_t^{ij} \geq 0, \quad i = 1,\ldots,l, \quad m \in \{1,\ldots,k\}\setminus y_i \end{aligned} \tag{14}$$

The decision function is:

$$argmax_{m=1,\ldots,k}(w_m^T \phi(x) + b_m) \quad (15)$$

V. Methodology

For this paper we selected 23 preprocessed images of CT scans with isolated lungs, containing a representation of different kinds of lung nodules (initial phase, juxtapleural or wall-attached, isolated, etc.), as well as examples from different thoracic zones. These images, provided by LIDC database, each have an XML file with the nodule information, as specified in the material section. These files are converted into mask images so as to facilitate the measurement task of the quality results.

The process to combine the different techniques is initiated by the execution of the clustering algorithms, who perform a classification of the preprocessed images, obtaining the initial ROIs. Attending to the results in [5] and [6], it can be observed that the better results are obtained from partitioning the image into 3 clusters that represent lung tissue, regions marked as nodules, and background.

The construction of the training set, formed by the non-defuzzified output of the fuzzy algorithms as indicated in section I, follows a process that consists of several steps:

1) Select a set of pixels of each cluster, proportional to the percentage of each cluster in the segmented image. For example, if one cluster represents 20% of a segmented image, select only 20% of pixels of this cluster. Thereby, not only the training set is reduced in size, but the original characteristics of the input space are maintained as well. We observed during this analysis that better results were obtained by separating the ROI marked as nodule into two sets: one set with the true nodule pixels, another set with the remaining marked pixels, representing the false positives. Note that the results of this analysis follow this approach.
2) Obtain the membership factors for the previously selected pixels, using the non-defuzzified output of the fuzzy algorithms. These factors for each pixel are disposed as a row in the train set and represent one input for the SVM.
3) Repeat steps 1 and 2 for each image that serves as an input for the training set.

The training set used in the SVMs analysis is constructed, following this strategy, with three images of the dataset that represent different kinds of lung nodules. Since initially the dataset is not bigger, this number is sufficient to represent the input space, but it should be increased to boost the generalization capacity in the case of a bigger dataset.

The feature vector is defined as numerical values ranging from 1 to 4, and is associated to the appropriate train row, depending on the cluster that it represents.

The quality of the obtained results is quantified by means of true positives (TP) and false positives (FP), because the mask images only have information about the nodule region, omitting the information referring to the other elements of the CT image.

The comparative is divided into two approaches: first, analyse each fuzzy algorithm along with its possible combinations with the two SVM implementations, in order to select the optimal parameters; then, compare all combinations methods, to form an idea of the general improvements.

The results are represented in the form of charts and tables that summarize the best results obtained with different selections of parameters of the analysed algorithms. The principal aim is to observe the enhancement capacity of the fuzzy algorithms and its stability when they are combined with the SVM technique.

VI. Results

Table I presents the optimal parameters values obtained for the different combinations of the fuzzy algorithms with SVMs and their respective kernels. For each method, we search the optimal parameters for the SVM executions, focusing on the regularization cost C and the kernel parameter gamma. These were estimated by varying their values into the ranges of [0.05, 2] and [10, 600], respectively. Moreover, we adopt 3 different kernels for each kind of SVM: RBF, Sigmoid, and Polynomial with grade 3. Therefore, for each method we try 264 combinations.

We started by analysing the SFCM algorithm with its SVM combinations. The true and false positive rates for this algorithm can be observed in the first row of each image represented on the x-axis of Fig. 1 and Fig. 2. The success rates are 100% in most cases and 76% for the worst result. Even though the false positives rate is not too high in general, in seven images this rate is above 15%-20%, reaching 36% in image number 20.

In order to select the best combination for each SVM approach with the SFCM algorithm, we compare the results obtained for a selected group of images that are more representative of the dataset and present a significant variability in our problem. The results obtained for the remaining images are represented in the charts because of limited space and their smaller relevance in the decisions.These results are given in Table II.

This table shows that the rates obtained for the different approaches and kernels are quite similar, except for the sigmoid kernels, which obtain a better true positive rate, the improvement being approximately 12% for images 5 and 7, as well as a slightly higher false positive rate than the other kernels

[2] Polynomial

(less than 4% for most cases). These results are extended to the one-against-one approach and the approach presented by Weston and Watkins. Therefore, Fig. 1 and Fig. 2 compare the initial rates for the fuzzy algorithm with the best results obtained for each approach of the SVM, in this case, using the sigmoid kernel.

Fig. 1 shows that, in general, the success rate is good and maintains the fuzzy results with values above 80%. The worst true positive rate is for images 7 and 13, reducing the success rate with respect to the initial segmentation above 20%.

In Fig. 2 it can be observed that the false positive rates is reduced for all the datasets, except for image 5, where the rate is slightly higher but still below 0.2%, so it is not relevant. For five images, the reduction reaches 10%.

Therefore, this combination provides good results, maintaining the true positives rate of the initial fuzzy segmentation, and realizes a significant reduction of the false positive ratio for most images.

The second analysed algorithm was the SKFCM and its combinations with the approaches of the SVM. The results, indicated in the first row of each image in Fig. 3, show a high

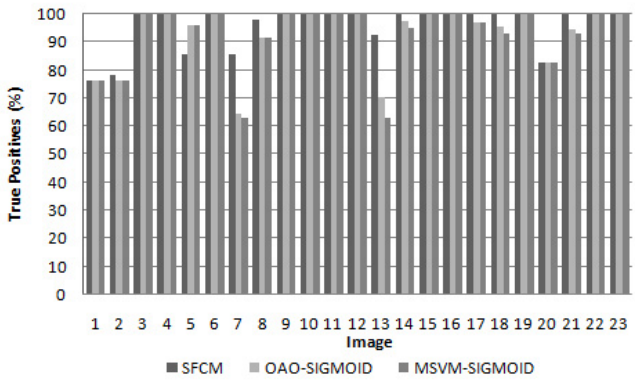

Fig. 1. True positive rates for the SFCM algorithm and the best combinations.

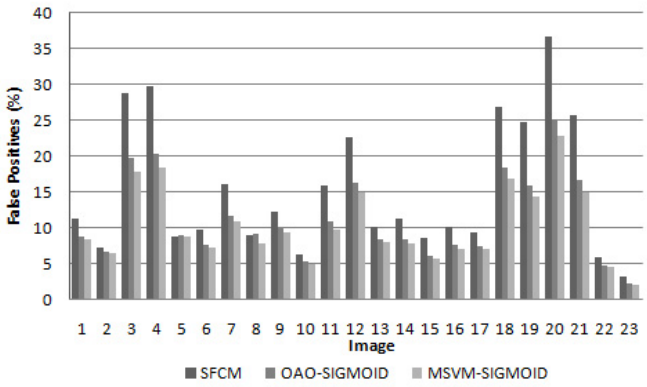

Fig. 2. False positive rates for the SFCM algorithm and the best combinations.

true positive rate for most images, the results being almost identical to those results of the SFCM method, except for small variations. Nonetheless, the false positive rate, illustrated in Fig. 4, has increased for all the images that do not fall in the 10%-20% range and reach 37% and 42% for images 22 and 2, respectively.

Table III shows the results obtained for the group of variability images. These reveal a classification problem with images number 7 and 21 in most SVM combinations with their different kernels, because the success rate decreases below 10%. This indicates that the nodules are misclassified in other cluster, probably because these images have smooth nodules with small intensity variations that are difficult to detect and distinguish form the other structures.

The best combinations for the SKFCM algorithm are the one-against-one approach with polynomial kernel and the Weston and Watkins approach with sigmoid kernel. For the one-against-one methods, the results are not good because the tests with RBF and sigmoid kernels have misclassification problems (cf. above); for the polynomial kernel, the false positive rates for some images (e.g image 20) have very high value that nullify our goals. In the same way, note that for

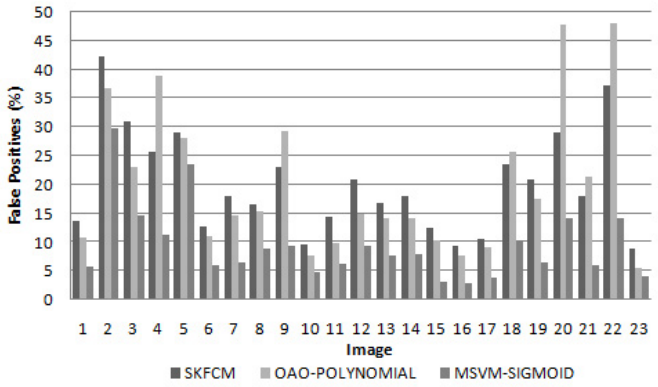

Fig. 4. False positive rates for the SKFCM algorithm and the best combinations.

this last approach, image 20 has very high false positive rates except for the sigmoid kernel; hence we choose this combination instead of others with better true positive rates.

The results obtained for the Weston approach with sigmoid kernel (Fig. 3 and Fig. 4) show the success rates for the selected variability images. These decrease in a high percentage, 54% and 29% being the true positive rate of images 7 and 13, respectively. The remaining images have rates up to 60%. In Fig. 4, the false positive rate experiments a high decrease, reaching 23% in the case of image 22, and 5%-15% for the remaining images.

In essence, the SKFCM algorithm does not function well for data sets with high variability because of the misclassification problems; it is therefore not a good election for the CAD system.

Finally, the results obtained by the MKSFCM algorithm, shown in Fig. 5 and Fig. 6, reveal success rates of approximately 100% for most images; even though in this case the worst rate is 68% rather than 76% for the previous methods, this reduction is not critical. It compensates for the decrease of the false positive ratio in all images, most of them falling into the 5%-15% rates and none above 21%.

Table IV introduces the results of the combinations for this fuzzy algorithm. These manifest a stable behavior of the

different SVM approaches, highlighting those obtained by the polynomial kernel with a slightly better success rate and a restrained false positive ratio. Fig. 5 and Fig. 6 analyse the two SVM approaches with polynomial kernel.

Fig 5 indicates a maintenance of the true positive ratio in concordance with the initial fuzzy segmentation; in some

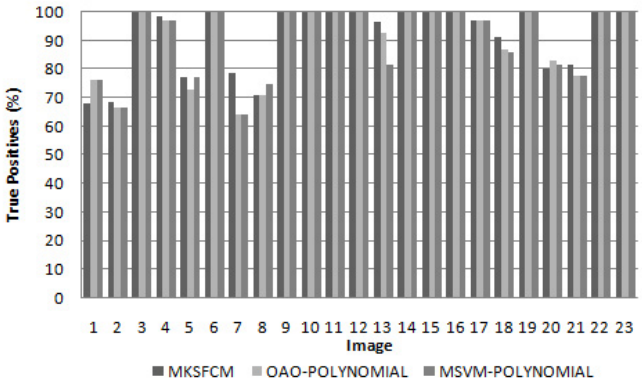

Fig. 5. True positive rates for the MKSFCM algorithm and the best combinations

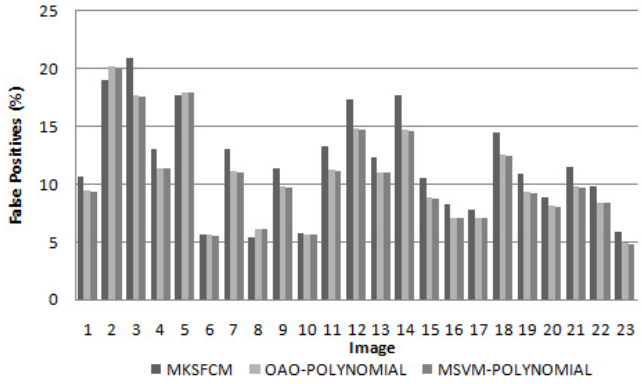

Fig. 6. False positive rates for the MKSFCM algorithm and the best combinations.

images (e.g. images 1,8, and 20) this rate is improved with an increase of up to 8% for the first image. The false positive ratio, in Fig. 6, decreases for most images in terms of a stable 2%. There are some images (e.g 2 and 8) for which this rate increases, but less than 0.5%, so the worsening is slightly marked.

The two analysed polynomial combinations of this algorithm present a stable behaviour with good rates for true and false positives, although the decrease of this final rate is not high because the initial fuzzy segmentation presented low values and it is difficult to realize a better classification.

VII. Conclusions

This paper presents an analysis of the combination of various fuzzy clustering algorithms with different approaches of the SVM technique. The principal aim of the study is to improve the defuzzification phase of the analysed fuzzy algorithms, obtaining better segmentations with fewer rates of false positives, by applying the SVM technique to the membership factors obtained in the initial ROIs classification.

The best combinations obtained for the SFCM and MKSFCM algorithms provide good results, being able to maintain and increase in some cases the fuzzy success rate and decrease the false positive ratio in a significant value for most of the images.

In the case of SFCM, the better combination was that provided by the one-against-one approach with sigmoid kernel obtaining a general true positive ratio above 80% for most images and reducing the false positives rate up to 10% for various images. Fig. 7 shows a comparative of the improvements introduced by this approach applied to an image of the dataset. The left upper image represents the preprocessed image, where the lungs are isolated, the right upper image is the output obtained by the fuzzy algorithm without any combination, and finally, the image below them is the defuzzification result provided by the best combination.

The best combination for MKFSCM was the one-against-one approach, as for SFCM, but in this case with the polynomial kernel. This obtains the best and most robust results, improving even the success rates for some images up to 8% and preserving it for the rest of images. In the case of false positive rate, the combination reduces the good rates of false positives (already obtained by previous results of the fuzzy algorithm) for all images but in a minor way if compared with the better SFCM combination. As in the previous case, Fig. 8 indicates the results obtained by this approach.

Once again, the SKFCM fuzzy combinations have classifications problems with data sets with high variability, due to the presence of images with nodules in early stages or that are hard to differentiate from the other lung structures. In this case, the results are not good for our problem, because the low true positive rate is less than 10% in some images and the high true positive rate is above 40%.

As a result, the SFCM and MKFSCM fuzzy clustering algorithms with their optimal SVM combinations can serve to improve the defuzzification phase in the task of ROIs detection.

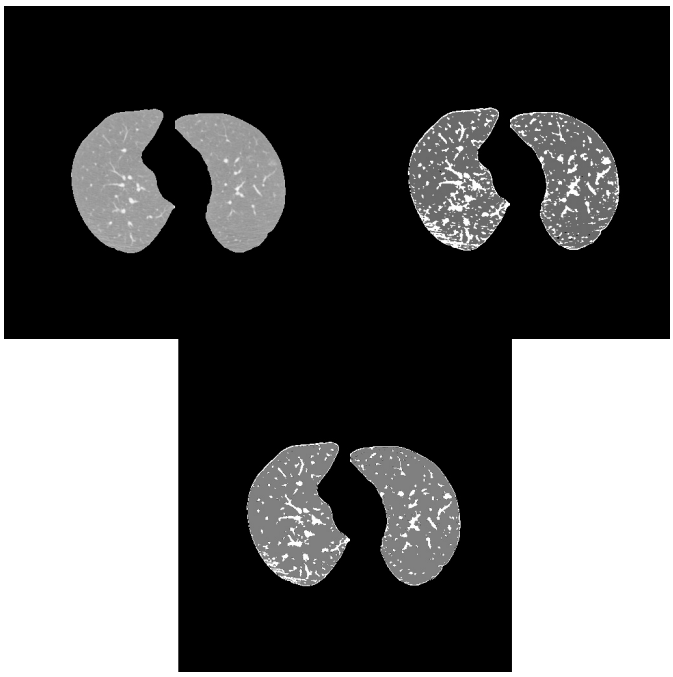

Fig. 7. Example of result obtained with the best combination of SFCM with SVM.

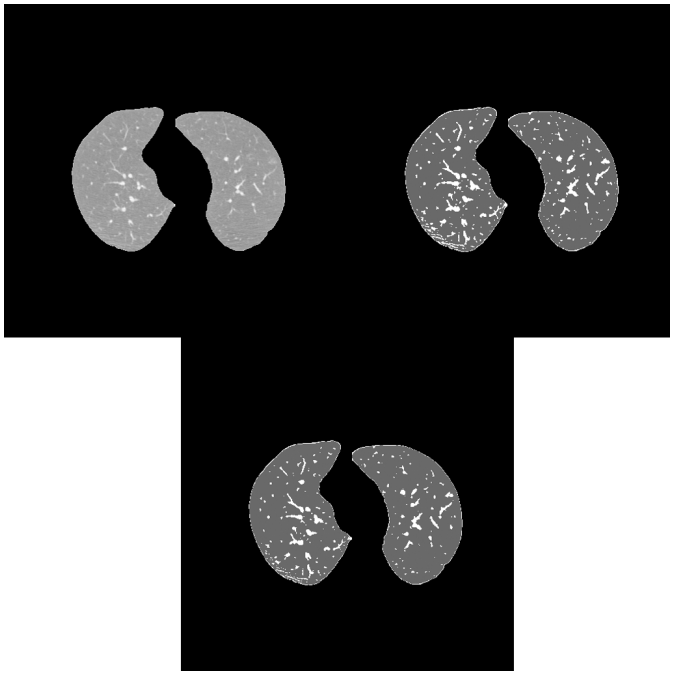

Fig. 8. Example of result obtained with the best combination of MKSFCM with SVM.

In our opinion, this result can be incorporated into the lung nodule detection CAD system.

***Abstract*—Type-reduction algorithms are very important for type-2 fuzzy sets and systems. The earliest one, and also the most popular one, is the Karnik-Mendel Algorithm, which is iterative and computationally intensive. In the last a few years researchers have proposed several other more efficient type-reduction algorithms. In this paper we also propose a new algorithm which improves over the latest results. Experiments show that it is the most efficient one to use in practice. Particularly, when the number of elements in type-reduction is smaller than 100, which is true in most practical type-reduction computations, our proposed algorithm can save over 50% computational cost over the Karnik-Mendel Algorithms. We also give the Matlab implementation of our most efficient algorithm in the Appendix. It includes preprocessing steps to eliminate numerical problems, and also improved testing criteria to prevent possible infinite loops. This program will be very helpful in promoting the popularity of type-2 fuzzy sets and systems.**

***Keywords*—Interval type-2 fuzzy sets, interval type-2 fuzzy logic systems, type-reduction, Karnik-Mendel Algorithm, Enhanced Karnik-Mendel Algorithm, computational cost**

I. Introduction

As introduced in [1], the following optimization problem is frequently met in (but not limited to) fuzzy logic theory:

Given

$$x_n \in X_n \equiv [\underline{x}_n, \overline{x}_n], \qquad n = 1, 2, \ldots, N \tag{1}$$

$$w_n \in W_n \equiv [\underline{w}_n, \overline{w}_n], \qquad n = 1, 2, \ldots, N \tag{2}$$

where

$$\underline{x}_n \leqslant \overline{x}_n, \qquad n = 1, 2, \ldots, N \tag{3}$$

$$\underline{w}_n \leqslant \overline{w}_n, \qquad n = 1, 2, \ldots, N \tag{4}$$

compute

$$Y = \frac{\sum_{n=1}^{N} X_n W_n}{\sum_{n=1}^{N} W_n} \equiv [y_l, y_r], \tag{5}$$

where

$$y_l = \min_{\substack{\forall x_n \in [\underline{x}_n, \overline{x}_n] \\ \forall w_n \in [\underline{w}_n, \overline{w}_n]}} \frac{\sum_{n=1}^{N} x_n w_n}{\sum_{n=1}^{N} w_n} \tag{6}$$

$$y_r = \max_{\substack{\forall x_n \in [\underline{x}_n, \overline{x}_n] \\ \forall w_n \in [\underline{w}_n, \overline{w}_n]}} \frac{\sum_{n=1}^{N} x_n w_n}{\sum_{n=1}^{N} w_n} \tag{7}$$

For instance, in computing the centroid of an interval type-2 fuzzy sets (IT2 FS) $\tilde{A}$ [2]–[4], $\underline{x}_n = \overline{x}_n = x_n$ represent discretizations of the primary variable x, and interval $[\underline{w}_n, \overline{w}_n]$ is the membership grade of x_n. Y is the centroid of $\tilde{A}$. In center-of-sets type-reduction of IT2 fuzzy logic systems (FLSs) [4], X_n represents the centroid of the consequent IT2 FS of the n^{th} rule, W_n is the firing level of that rule, and Y is the type-reduced set. In computing the linguistic weighted average [5]–[8], X_n and W_n are α-cuts of the upper membership functions (or lower membership functions) of the inputs signals and the weights, both of which are IT2 FSs, and Y is the corresponding α-cut on the upper membership function (or lower membership function) of the linguistic weighted average, which is also an IT2 FS.

Equation (5) is usually solved by the iterative Karnik-Mendel algorithms (KMA) [2], [4], which is computationally intensive. In the last a few years several more efficient algorithms[1] have been proposed, e.g., the enhanced Karnik-Mendel algorithm (EKMA) [1], [7], a fast recursive method for computing the generalized centroid of IT2 FSs [17], an iterative algorithm with stop condition[2] (IASC) for computing the generalized centroid[3] [18], and, an enhanced algorithm for computing the generalized centroid of general type-2 FSs [19]. For simplicity these algorithms are all referred to as type-reduction algorithms in this paper.

In this paper we focus on more efficient type-reduction algorithms. Our contributions are: 1) We propose an enhanced version of IASC and compare it with several other type-reduction algorithms; and, 2) We give an Matlab implementation of our most efficient type-reduction algorithm, which can be used freely by other researchers.

The rest of this paper is organized as follows: Section II introduces KMA. Section III introduces four more efficient type-reduction algorithms, including EKMA, EKMA with new

[1]There are also many approximations to KMA [9]–[15]. As pointed out in [16], these approximations are fundamentally different from the original KMA, and hence they are not considered in this paper.

[2]This algorithm is called IASCO in [18].

[3]Though the two algorithms in [17], [18] were initially proposed for computing the generalized centroid of IT2 FSs, they can also be used in type-reduction of IT2 FLSs.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

initialization (EKMANI), IASC, and enhanced IASC (EIASC). Section IV compares the performances of these five algorithms under three different scenarios. Finally, Section V draws conclusions. Matlab implementation of EIASC is given in the Appendix.

II. Karnik-Mendel Algorithms (KMA)

KMA consists of two parts, one for computing y_l in (6) and the other for computing y_r in (7). Define

$$f_l(k) = \frac{\sum_{n=1}^{k} \underline{x}_n \overline{w}_n + \sum_{n=k+1}^{N} \underline{x}_n \underline{w}_n}{\sum_{n=1}^{k} \overline{w}_n + \sum_{n=k+1}^{N} \underline{w}_n} \tag{8}$$

$$f_r(k) = \frac{\sum_{n=1}^{k} \overline{x}_n \underline{w}_n + \sum_{n=k+1}^{N} \overline{x}_n \overline{w}_n}{\sum_{n=1}^{k} \underline{w}_n + \sum_{n=k+1}^{N} \overline{w}_n} \tag{9}$$

where $\{\underline{x}_n\}$ and $\{\overline{x}_n\}$ have been sorted in ascending order, respectively. Furthermore, in this paper it is assumed that $\{\underline{x}_n\}$ ($\{\overline{x}_n\}$) has no duplicate elements, which can be easily achieved by combining the weights for duplicate elements. Then, y_l in (6) and y_r in (7) can also be re-expressed as [4]:

$$y_l = \min_{k=1,\ldots,N-1} f_l(k) \equiv f_l(l) \tag{10}$$

$$= \frac{\sum_{n=1}^{l} \underline{x}_n \overline{w}_n + \sum_{n=l+1}^{N} \underline{x}_n \underline{w}_n}{\sum_{n=1}^{l} \overline{w}_n + \sum_{n=l+1}^{N} \underline{w}_n} \tag{11}$$

$$y_r = \max_{k=1,\ldots,N-1} f_r(k) \equiv f_r(r) \tag{12}$$

$$= \frac{\sum_{n=1}^{r} \overline{x}_n \underline{w}_n + \sum_{n=r+1}^{N} \overline{x}_n \overline{w}_n}{\sum_{n=1}^{r} \underline{w}_n + \sum_{n=r+1}^{N} \overline{w}_n} \tag{13}$$

where l and r are switch points satisfying

$$\underline{x}_l \leqslant y_l < \underline{x}_{l+1} \tag{14}$$

$$\overline{x}_r < y_r \leqslant \overline{x}_{r+1}. \tag{15}$$

Note that in [4] these two inequalities are

$$\underline{x}_l \leqslant y_l \leqslant \underline{x}_{l+1} \tag{16}$$

$$\overline{x}_r \leqslant y_r \leqslant \overline{x}_{r+1} \tag{17}$$

because there $\{\underline{x}_n\}$ and $\{\overline{x}_n\}$ can have duplicate elements. When duplicate elements are combined, it follows that $\underline{x}_l < \underline{x}_{l+1}$ for $\forall l \in [1, N-1]$ and $\overline{x}_r < \overline{x}_{r+1}$ for $\forall r \in [1, N-1]$, and hence the two equalities in (16) or (17) cannot be satisfied simultaneously.

KMA for Computing y_l:

1) Sort $\underline{x}_n$ $(n = 1, 2, \ldots, N)$ in increasing order and call the sorted $\underline{x}_n$ by the same name, but now $\underline{x}_1 < \underline{x}_2 < \cdots < \underline{x}_N$. Match the weights W_n with their respective $\underline{x}_n$ and renumber them so that their index corresponds to the renumbered $\underline{x}_n$.
2) Initialize w_n by setting
$$w_n = \frac{\underline{w}_n + \overline{w}_n}{2}, \qquad n = 1, 2, \ldots, N \tag{18}$$
and then compute
$$y = \frac{\sum_{n=1}^{N} \underline{x}_n w_n}{\sum_{n=1}^{N} w_n}. \tag{19}$$
3) Find switch point l $(1 \leqslant l \leqslant N-1)$ such that
$$\underline{x}_l < y \leqslant \underline{x}_{l+1} \tag{20}$$
4) Set
$$w_n = \begin{cases} \overline{w}_n, & n \leqslant l \\ \underline{w}_n, & n > l \end{cases} \tag{21}$$
and compute
$$y' = \frac{\sum_{n=1}^{N} \underline{x}_n w_n}{\sum_{n=1}^{N} w_n} \tag{22}$$
5) If $y' = y$, stop and set $y_l = y$; otherwise, set $y = y'$ and go to Step 3.

KMA for Computing y_r:

1) Sort $\overline{x}_n$ $(n = 1, 2, \ldots, N)$ in increasing order and call the sorted $\overline{x}_n$ by the same name, but now $\overline{x}_1 < \overline{x}_2 < \cdots < \overline{x}_N$. Match the weights W_n with their respective $\overline{x}_n$ and renumber them so that their index corresponds to the renumbered $\overline{x}_n$.
2) Initialize w_n by setting
$$w_n = \frac{\underline{w}_n + \overline{w}_n}{2}, \qquad n = 1, 2, \ldots, N \tag{23}$$
and then compute
$$y = \frac{\sum_{n=1}^{N} \overline{x}_n w_n}{\sum_{n=1}^{N} w_n}. \tag{24}$$
3) Find switch point r $(1 \leqslant r \leqslant N-1)$ such that
$$\overline{x}_r < y \leqslant \overline{x}_{r+1} \tag{25}$$
4) Set
$$w_n = \begin{cases} \underline{w}_n, & n \leqslant r \\ \overline{w}_n, & n > r \end{cases} \tag{26}$$
and compute
$$y' = \frac{\sum_{n=1}^{N} \overline{x}_n w_n}{\sum_{n=1}^{N} w_n} \tag{27}$$
5) If $y' = y$, stop and set $y_r = y$; otherwise, set $y = y'$ and go to Step (3).

The main idea of KMA is to find the switch points for y_l and y_r. Take y_l as an example. y_l is the minimum of Y. Since $\underline{x}_n$ increases from the left to the right along the horizontal axis of Fig. 1(a), we should choose a large w_n for $\underline{x}_n$ on the left and a small w_n for $\underline{x}_n$ on the right. KMA for y_l finds the switch point l. For $n \leqslant l$, $\overline{w}_n$ is used to calculate y_l; for $n > l$, $\underline{w}_n$ is used. This ensures y_l is the minimum.

Note that the above KMA works well in most practical cases; however, sometimes due to roundoff error y' can never be equal to y and hence KMA runs into infinite loops. Special attentions need to be paid to these cases, as we have done in the Matlab program in the Appendix.

III. More Efficient Type-Reduction Algorithms

Three existing more efficient type-reduction algorithms are introduced in this section, and a new algorithm is also proposed.

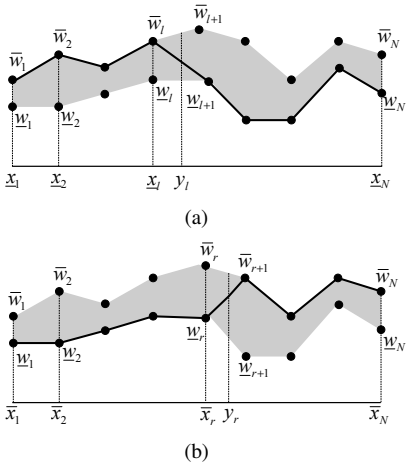

Fig. 1. Illustration of the switch points in computing y_l and y_r. (a) Computing y_l: switch from $\overline{w}_l$ to $\underline{w}_{l+1}$; (b) Computing y_r: switch from $\underline{w}_r$ to $\overline{w}_{r+1}$.

A. Enhanced Karnik-Mendel Algorithms (EKMA)

EKMA [1] has three improvements over KMA. First, a better initialization is used to reduce the number of iterations. Then, the termination condition of the iterations is changed to remove one unnecessary iteration. Finally, a subtle computing technique is used to reduce the computational cost of each iteration.

EKMA for computing y_l:

1) The same as Step (1) of KMA for computing y_l.
2) Set $l = [N/2.4]$ (the nearest integer to $N/2.4$), and compute

$$a = \sum_{n=1}^{l} \underline{x}_n \overline{w}_n + \sum_{n=l+1}^{N} \underline{x}_n \underline{w}_n \tag{28}$$

$$b = \sum_{n=1}^{l} \overline{w}_n + \sum_{n=l+1}^{N} \underline{w}_n \tag{29}$$

$$y = a/b \tag{30}$$

3) Find $l' \in [1, N-1]$ such that

$$\underline{x}_{l'} < y \leqslant \underline{x}_{l'+1} \tag{31}$$

4) If $l' = l$, stop; otherwise, continue.
5) Compute $s = \text{sign}(l' - l)$, and

$$a' = a + s \sum_{n=\min(l,l')+1}^{\max(l,l')} \underline{x}_n (\overline{w}_n - \underline{w}_n) \tag{32}$$

$$b' = b + s \sum_{n=\min(l,l')+1}^{\max(l,l')} (\overline{w}_n - \underline{w}_n) \tag{33}$$

$$y' = a'/b' \tag{34}$$

6) Set $y = y'$, $a = a'$, $b = b'$ and $l = l'$. Go to Step 3.

EKMA for computing y_r:

1) The same as Step (1) of KMA for computing y_r.
2) Set $r = [N/1.7]$ (the nearest integer to $N/1.7$), and compute

$$a = \sum_{n=1}^{r} \overline{x}_n \underline{w}_n + \sum_{n=r+1}^{N} \overline{x}_n \overline{w}_n \tag{35}$$

$$b = \sum_{n=1}^{r} \underline{w}_n + \sum_{n=r+1}^{N} \overline{w}_n \tag{36}$$

$$y = a/b \tag{37}$$

3) Find $r' \in [1, N-1]$ such that

$$\overline{x}_{r'} < y \leqslant \overline{x}_{r'+1} \tag{38}$$

4) If $r' = r$, stop; otherwise, continue.
5) Compute $s = \text{sign}(r' - r)$, and

$$a' = a - s \sum_{n=\min(r,r')+1}^{\max(r,r')} \overline{x}_n (\overline{w}_n - \underline{w}_n) \tag{39}$$

$$b' = b - s \sum_{n=\min(r,r')+1}^{\max(r,r')} (\overline{w}_n - \underline{w}_n) \tag{40}$$

$$y' = a'/b' \tag{41}$$

6) Set $y = y'$, $a = a'$, $b = b'$ and $r = r'$. Go to Step (3).

Note that similar to KMA, sometimes due to roundoff error $l' = l$ and/or $r' = r$ cannot be achieved and EKMA runs into infinite loops. Special attentions need to be paid to these cases, as done in the Appendix.

B. Enhanced Karnik-Mendel Algorithm with New Initialization (EKMANI)

Yeh et al. [19] proposed Enhanced Karnik-Mendel Algorithm with new initialization (EKMANI) to compute the generalized centroid of general T2 FSs. It is based on the observation that for two α-planes [20] close to each other, the centroids of the resulting two IT2 FSs are also close to each other. So, it may be advantageous to use the switch points obtained from the previous α-plane to initialize the switch points in the next α-plane. Though EKMANI was primarily designed for computing the generalized centroid, it may also be used in type-reduction of IT2 FLSs, especially IT2 fuzzy logic controllers (FLCs), because usually the output of an IT2 FLC changes only a small amount each step.

EKMANI for computing y_l is identical to EKMA for computing y_l, except that in Step (2), if there is a switch point obtained from previous computation, then set l to it; otherwise, set $l = [N/2.4]$.

EKMANI for computing y_r is identical to EKMA for computing y_r, expect that in Step (2), if there is a switch point obtained from previous computation, then set r to it; otherwise, set $r = [N/1.7]$.

C. Iterative Algorithm with Stop Condition (IASC)

Melgarejo and his co-authors [17], [18] proposed two efficient algorithms for computing the generalized centroid of IT2 FSs, which can also be used in type-reduction of IT2 FLSs.

The faster one, called iterative algorithm with stop condition (IASC) [18], is introduced in this subsection[4]. It is based on the fact [4] that y_l in (10) first monotonically decreases and then monotonically increases with the increase of k, and y_r in (12) first monotonically increases and then monotonically decreases with the increase of k.

IASC for computing y_l:

1) The same as Step (1) of KMA for computing y_l.
2) Initialize

$$a = \sum_{n=1}^{N} \underline{x}_n \underline{w}_n, \qquad b = \sum_{n=1}^{N} \underline{w}_n$$
$$y_l = \underline{x}_N, \qquad l = 0$$

3) Compute

$$l = l + 1$$
$$a = a + \underline{x}_l(\overline{w}_l - \underline{w}_l)$$
$$b = b + \overline{w}_l - \underline{w}_l$$
$$c = a/b$$

4) If $c > y_l$, set $l = l - 1$ and stop; otherwise, set $y_l = c$ and go to Step (3).

IASC for computing y_r:

1) The same as Step (1) of KMA for computing y_r.
2) Initialize

$$a = \sum_{n=1}^{N} \overline{x}_n \overline{w}_n, \qquad b = \sum_{n=1}^{N} \overline{w}_n$$
$$y_r = \overline{x}_1, \qquad r = 0$$

3) Compute

$$r = r + 1$$
$$a = a - \overline{x}_r(\overline{w}_r - \underline{w}_r)$$
$$b = b - \overline{w}_r + \underline{w}_r$$
$$c = a/b$$

4) If $c < y_r$, set $r = r - 1$ and stop; otherwise, set $y_r = c$ and go to Step (3).

D. Enhanced Iterative Algorithm with Stop Condition (EIASC)

An Enhanced IASC (EIASC) is proposed in this subsection. It uses the following theorem:

Theorem 1: $f_l(k)$ in (8) satisfies:

$$f_l(k) \begin{cases} \geqslant \underline{x}_k, & k \leqslant l \\ < \underline{x}_k, & k > l \end{cases} \tag{42}$$

Similarly, $f_r(k)$ in (9) satisfies:

$$f_r(k) \begin{cases} \leqslant \overline{x}_k, & k > r \\ > \overline{x}_k, & k \leqslant r \end{cases} . \quad \square \tag{43}$$

Proof: Because the proof for (43) is very similar to that for (42), we only provide the proof for (42) in this paper.

[4] [18] did not give the complete IASC presented in this subsection. It is the authors' integration of the ideas in [17] and [18].

From (10) and (14) it follows that

$$f_l(l) \geqslant \underline{x}_l. \tag{44}$$

For $\forall k \in [1, N-1]$, it is always true that

$$f_l(k) \geqslant f_l(l) \tag{45}$$

because by definition $f_l(l) = \min\limits_{k=1,\ldots,N-1} f_l(k)$. When $k \leqslant l$, it is also true that

$$\underline{x}_l \geqslant \underline{x}_k \tag{46}$$

because $\{\underline{x}_n\}$ has been sorted in ascending order and $k \leqslant l$. Considering (44)-(46) together, it follows that

$$f_l(k) \geqslant f_l(l) \geqslant \underline{x}_l \geqslant \underline{x}_k \tag{47}$$

which is the first line of (42). Next we focus on the second line of (42).

Beginning with (8), we see that

$$f_l(l)\left[\sum_{n=1}^{l} \overline{w}_n + \sum_{n=l+1}^{N} \underline{w}_n\right] = \sum_{n=1}^{l} \underline{x}_n \overline{w}_n + \sum_{n=l+1}^{N} \underline{x}_n \underline{w}_n \tag{48}$$

Let $k > l$ and add $\sum\limits_{n=l+1}^{k} \underline{x}_n(\overline{w}_n - \underline{w}_n)$ to both sides of (48), in order to see that

$$f_l(l)\left[\sum_{n=1}^{l} \overline{w}_n + \sum_{n=l+1}^{N} \underline{w}_n\right] + \sum_{n=l+1}^{k} \underline{x}_n(\overline{w}_n - \underline{w}_n)$$
$$= \sum_{n=1}^{k} \underline{x}_n \overline{w}_n + \sum_{n=k+1}^{N} \underline{x}_n \underline{w}_n \tag{49}$$

Because $k > l$, $\underline{x}_k > f_l(l)$, $\sum\limits_{n=1}^{k} \overline{w}_n + \sum\limits_{n=k+1}^{N} \underline{w}_n > 0$ and $\overline{w}_n - \underline{w}_n > 0$,

$$f_l(l)\left[\sum_{n=1}^{l} \overline{w}_n + \sum_{n=l+1}^{N} \underline{w}_n\right] < \underline{x}_k\left[\sum_{n=1}^{l} \overline{w}_n + \sum_{n=l+1}^{N} \underline{w}_n\right] \tag{50}$$

$$\sum_{n=l+1}^{k} \underline{x}_n(\overline{w}_n - \underline{w}_n) < \underline{x}_k \sum_{n=l+1}^{k} (\overline{w}_n - \underline{w}_n) \tag{51}$$

We obtain the following inequality from the above three inequalities:

$$\sum_{n=1}^{k} \underline{x}_n \overline{w}_n + \sum_{n=k+1}^{N} \underline{x}_n \underline{w}_n$$
$$< \underline{x}_k\left[\sum_{n=1}^{l} \overline{w}_n + \sum_{n=l+1}^{N} \underline{w}_n\right] + \underline{x}_k \sum_{n=l+1}^{k} (\overline{w}_n - \underline{w}_n)$$
$$= \underline{x}_k\left[\sum_{n=1}^{k} \overline{w}_n + \sum_{n=k+1}^{N} \underline{w}_n\right] \tag{52}$$

Because $\sum\limits_{n=1}^{k} \overline{w}_n + \sum\limits_{n=k+2}^{N} \underline{w}_n > 0$, it follows that

$$\underline{x}_k > \frac{\sum_{n=1}^{k} \underline{x}_n \overline{w}_n + \sum_{n=k+1}^{N} \underline{x}_n \underline{w}_n}{\sum_{n=1}^{k} \overline{w}_n + \sum_{n=k+1}^{N} \underline{w}_n} = f_l(k). \quad \square \tag{53}$$

Our proposed EIASC makes the following two improvements over the IASC:

1) New stopping criterion based on Theorem 1.
2) Both the IASC for computing y_l and the IASC for computing y_r start from switch point 1 and increase it gradually to find the correct switch points. This is reasonable for y_l, since it has been shown in [1] that for a variety of scenarios, its switch point l is smaller than $N/2$; so, it is more efficient to search from $l = 1$ instead of from $l = N - 1$. However, setting the initial switch point $r = 1$ may not be efficient for y_r, since it has been shown in [1] that generally its switch point $r > N/2$. So, it would be more efficient if for y_r one initializes the switch point as $r = N - 1$ and then gradually decreases it until the correct r is found.

In summary, the EIASC for computing y_l and y_r are:

EIASC for computing y_l:

1) The same as Step (1) of KMA for computing y_l.
2) Initialize

$$a = \sum_{n=1}^{N} \underline{x}_n \underline{w}_n, \qquad b = \sum_{n=1}^{N} \underline{w}_n$$
$$y_l = \underline{x}_N, \qquad l = 0$$

3) Compute

$$l = l + 1, \qquad a = a + \underline{x}_l(\overline{w}_l - \underline{w}_l)$$
$$b = b + \overline{w}_l - \underline{w}_l, \qquad c = a/b$$

4) If $c > y_l$, set $l = l - 1$ and stop; otherwise, set $y_l = c$ and go to Step (3).

EIASC for computing y_r:

1) The same as Step (1) of KMA for computing y_r.
2) Initialize

$$a = \sum_{n=1}^{N} \overline{x}_n \underline{w}_n, \qquad b = \sum_{n=1}^{N} \underline{w}_n$$
$$y_r = \overline{x}_1, \qquad r = N$$

3) Compute

$$a = a + \overline{x}_r(\overline{w}_r - \underline{w}_r), \qquad b = b + \overline{w}_r - \underline{w}_r$$
$$c = a/b, \qquad r = r - 1$$

4) If $c < y_r$, set $r = r + 1$ and stop; otherwise, set $y_r = c$ and go to Step (3).

Clearly, based on Theorem 1, given an initialization of l (or r), one can easily tell whether it is on the left or right of the true l (or r), and hence the new initialization idea in EKMANI can also be used in EIASC. We implemented the corresponding algorithm, where the user can specify an initial l (or r); otherwise, l is initialized to $[N/2.4]$ (r to $[N/1.7]$), the same as EKMA. Interestingly, this new algorithm only outperforms EIASC when $N > 1000$. Since in practice usually $k < 1000$, this new algorithm is not included in this paper. However, it can be downloaded from the first author's website at http://www-scf.usc.edu/~dongruiw/files/TR_Algorithms.zip.

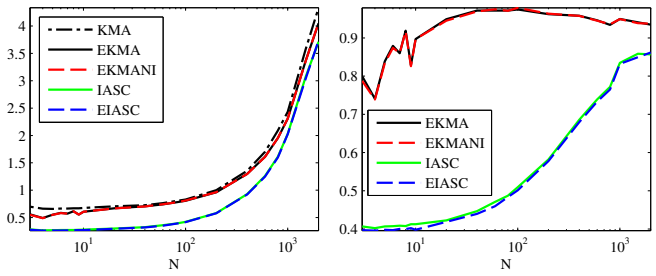
IV. Experimental Comparison

In this section we compare the performance of the five type-reduction algorithms (KMA, EKMA, EKMANI, IASC, and EIASC) using three simulations. The platform is a Lenovo Thinkpad T500 with Intel Core2 Duo CPU P8600@2.40Hz and 3GB memory, running Windows 7 32-bit Home Premium and Matlab R2009a. The computational cost is measured by the computation time, obtained from Matlab *tic* and *toc* functions.

A. Comparison 1: Uniformly Distributed X_n and W_n

In this comparison, we assume the elements in X_n and W_n are uniformly distributed, $\underline{x}_n = \overline{x}$, and $N = \{3, 4, ..., 10, 20, ..., 100, 200, ..., 1000, 1500, 2000\}$ were used. For each N, 5000 Monte Carlo simulations were used to compute y. The results are shown in Fig. 2. Observe that:

1) All four efficient algorithms outperformed KMA.
2) The performances of EKMA and EKMANI were almost identical in this simulation because for each N all 5000 Monte Carlo simulations were independent, so it does not make sense to initialize a switch point from a previous simulation. We did not supply the new initial switch points in EKMANI in this simulation, so it reduced to EKMA. Also, the performance improvement of EKMA over KMA is not as large as that reported in [1] since for each algorithm in this paper we added the same preprocessing steps to eliminate possible numerical problems and the preprocessing time was included in the computational cost, whereas in [1] preprocessing time was not considered.
3) Both IASC and EIASC significantly outperformed KMA, especially when N is small ($N \leqslant 100$). And, EIASC slightly outperformed IASC. The computational cost of both IASC and EIASC increase rapidly as N increases since they need to evaluate many possible switch points before finding the correct ones.



(a) (b)

Fig. 2. (a) Total computation time (seconds) of the 5000 Monte Carlo simulations of uniformly distributed X_n and W_n ($n = 1, 2, ..., N$) for different N. (b) The ratio of the computation time of the four efficient algorithms with respect to KMA.

B. Comparison 2: Computing the Generalized Centroid of A General Type-2 FS

In this simulation, we compare the performance of the five type-reduction algorithms in computing the generalized

centroid of a general type-2 FS, which is originally defined in [20] as:

$$\mu_{\tilde{A}}(x) = \begin{cases} \frac{z-d(x)}{p(x)-d(x)}, & d(x) \leqslant z \leqslant p(x) \\ \frac{u(x)-z}{u(x)-p(x)}, & p(x) \leqslant z \leqslant u(x) \\ 0 & \text{otherwise} \end{cases} \tag{54}$$

$$u(x) = \max(f_1(x), f_2(x)) \tag{55}$$

$$d(x) = \max(g_1(x), g_2(x)) \tag{56}$$

$$f_1(x) = \exp\left(-\frac{(x-3)^2}{8}\right) \tag{57}$$

$$f_2(x) = 0.8\exp\left(-\frac{(x-6)^2}{8}\right) \tag{58}$$

$$g_1(x) = 0.5\exp\left(-\frac{(x-3)^2}{2}\right) \tag{59}$$

$$g_2(x) = 0.4\exp\left(-\frac{(x-6)^2}{2}\right) \tag{60}$$

$$p(x) = d(x) + w(x)(u(x) - d(x)) \tag{61}$$

where $\mu_{\tilde{A}}(x)$ is the secondary membership grade, $z \in [d(x), u(x)]$ is the primary membership grade, and $w(x)$ is a random number in [0, 1]. An example of the type-2 FS is shown in Fig. 3.

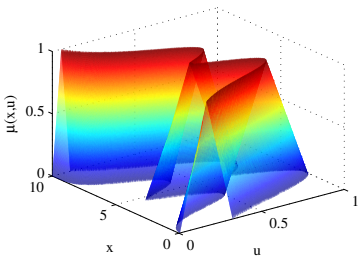


Fig. 3. An example of the type-2 FS in Comparison 2.

In [19] it has been shown that EKMANI achieved a much better performance than KMA and EKMA. As in [19], we fixed $N = 200$ and took the number of α-planes as $\{5, 10, 20, 50, 75, 100\}$. For each number of α-planes, we repeated the experiment 1000 times to get a more accurate computation time. The results are shown in Fig. 4. Observe that:

1) All four efficient algorithms outperformed KMA.
2) EKMANI outperformed EKMA significantly since in EKMANI the switch points from the previous α-plane were used as the initial switch points in the next α-plane. As usually y_l and y_r change very slightly from one α-plane to the next (especially when the number of α-planes is large), the switch points in two α-planes are very close to each other, and hence the new initialization strategy is better than that in EKMA.
3) Both IASC and EIASC significantly outperformed all other three algorithms, and EIASC also outperformed IASC slightly.

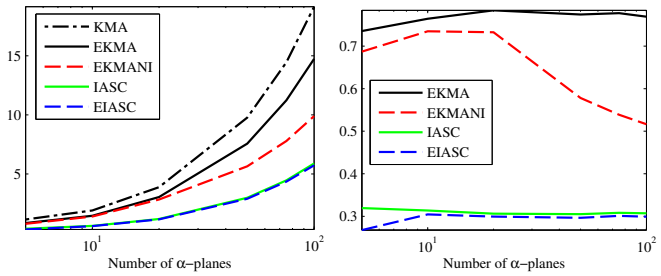

Fig. 4. (a) Total computation time (seconds) of the 1000 runs of centroid computation for different number of α-planes. (b) The ratio of the computation time of the four efficient algorithms with respect to KMA.

C. Comparison 3: IT2 Fuzzy Logic Controller Design

In this subsection we compare the performance of the five algorithms in FLC design using evolutionary computation [21], where the performance of a large number of (usually randomly generated) FLCs are evaluated. The following simple first-order plus dead-time plant is employed as the nominal system [22]:

$$G(s) = \frac{K}{\tau s + 1}e^{-Ls} = \frac{1}{10s+1}e^{-2.5s} \tag{62}$$

The goal is to design an IT2 fuzzy PI controller

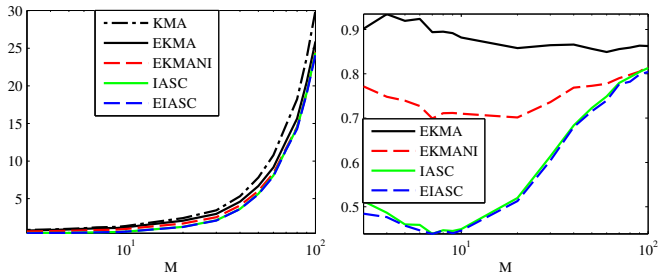
$$\dot{u} = k_P\dot{e} + k_I e \tag{63}$$

where $\dot{u}$ is the change in control signal, e is the error, $\dot{e}$ is the change of error, and k_P and k_I are proportional and integral gains. Assume there are M Gaussian IT2 FSs in each domain (e and $\dot{e}$), and each IT2 FSs is determined by three parameters (one mean, m_m, and two standard deviations, σ_m^1 and σ_m^2, $m = 1, 2, ..., M$). Each of the M^2 rule consequents is represented by a crisp number y_n, $n = 1, ..., M^2$. Then, for each input pair $(e, \dot{e})$, all $N = M^2$ rules are fired, and a type-reduction algorithm is needed to compute the output of the IT2 FLC.

Assume the population consists of 100 randomly generated IT2 FLCs (all m_m, σ_m^1, σ_m^2, and y_n are random), and the performance of each FLC is evaluated by a step response in the first 100 seconds with sampling frequency 1 Hz. We recorded the time that the five algorithms were used to perform type-reduction for these $100 \times 100 = 10000$ input pairs. $M = \{3, 4, ..., 10, 20, ..., 100\}$ were used. The results are shown in Fig. 5. Observe that:

1) All four efficient algorithms outperformed KMA.
2) EKMANI outperformed EKMA significantly since in EKMANI the switch points from the previous step were used as the initial switch points in the next step. As usually e and $\dot{e}$ change very slightly from one step to the next (especially when the sampling frequency is high, and/or during steady state), the switch points in two steps are very close to each other, and hence the new initialization strategy is better than that in EKMA.

3) Both IASC and EIASC significantly outperformed all other three algorithms when M is small ($M \leqslant 20$), and EIASC also outperformed IASC slightly.



(a) (b)

Fig. 5. (a) Total computation time (seconds) of the 100 IT2 FLCs for different M, the number of IT2 FSs in each input domain. Note that $N = M^2$. (b) The ratio of the computation time of the efficient algorithms with respect to KMA.

V. Conclusions

Type-reduction algorithms are very important for type-2 fuzzy sets and systems. However, the most popular Karnik-Mendel Algorithms is computationally intensive. In this paper we have reviewed several more efficient type-reduction algorithms, and also improved over one of them. Experimental results showed that our proposed algorithm is the most efficient one to use. Particularly, when $N \leqslant 100$, which is true in most practical type-reduction computations, our proposed algorithm (EIASC) can save over 50% computational cost over the Karnik-Mendel Algorithms. An Matlab implementation of EIASC is also given. It includes preprocessing steps to eliminate numerical problems. This algorithm will be very helpful in promoting the popularity of type-2 fuzzy sets and systems.

Appendix A
Matlab Implementation of EIASC

This appendix presents an Matlab implementation of EIASC. Note that it is more complex than the algorithm presented in Section III-D since here we include the following preprocessing steps to eliminate possible numerical problems:

1) When all $\underline{w}_n$ are zero or all $\overline{w}_n$ are very close to zero, e.g., $\overline{w}_n < 10^{-10}$ for $\forall n$, we return $y_l = \min_n \underline{x}_n$ and $y_r = \max_n \overline{x}_n$.
2) All very small $\overline{w}_n$, e.g., $\overline{w}_n < 10^{-10}$, and their associated $\underline{x}_n$, $\overline{x}_n$, and $\underline{w}_n$, are removed to prevent numerical instability.
3) $\{\underline{x}_n\}$ and $\{\overline{x}_n\}$ are made unique respectively to prevent possible infinite loops.

A user can easily modify the codes for additional computational cost saving. For example, Step (3) above may be done only once *a priori* in an FLC. Additionally, $\{\underline{x}_n\}$ and $\{\overline{x}_n\}$ can be sorted only once *a priori* in an FLC, and they do not need to be sorted in computing the generalized centroid of type-2 fuzzy sets.

The following four input parameters are mandatory:

- *Xl*: A row vector containing $\underline{x}_n$, $n = 1, 2, ..., N$.
- *Xr*: A row vector containing $\overline{x}_n$, $n = 1, 2, ..., N$. If $\underline{x}_n = \overline{x}_n$ $\forall n$, then use [] as input for *Xr*.
- *Wl*: A row vector containing $\underline{w}_n$, $n = 1, 2, ..., N$.
- *Wr*: A row vector containing $\overline{w}_n$, $n = 1, 2, ..., N$.

The following input is optional:

- *needSort*: "1" if at least one of *Xl* and *Xr* is not in ascending order. "0" if both *Xl* and *Xr* are in ascending order. Default "1."

The outputs are:

- *y*: Mid-point of Y in (5). $y = (yl + yr)/2$.
- *yl*: y_l in (6).
- *yr*: y_r in (7).
- *l*: Switch point l for computing *yl*.
- *r*: Switch point r for computing *yr*.

Matlab implementations of all other algorithms introduced in this paper can be found from the first author's website at http://www-scf.usc.edu/~dongruiw/files/TR_Algorithms.zip.

***Abstract*—Computing with Words (CWW) aims to investigate the possibility of imitating the unique ability of humans for approximate reasoning on the basis of approximately defined classes and concepts in the form of words. Type-2 fuzzy sets have been used to provide an adequate modeling basis for words in a fuzzy logic context. In the context of type-2 fuzzy sets employed as part of CWW, a variety of research efforts have been made to investigate approaches to model the meaning of specific words using type-2 fuzzy sets. In this paper we start by focusing on the interpretation of classical set-theoretical operations (complement, union and intersection) for crisp and type-1 fuzzy sets. We proceed by extending the interpretations to the results of the union and intersection operations of interval type-2 fuzzy sets, specifically indicating their effect on the uncertainty representation in the sets. We note the impact of the choice of t-norms and t-conorms in particular in the context of CWW applications where the interpretation of the resulting sets and its resemblance to the human intuitive meaning of the concept or word is essential. Finally, we provide the interpretation and reasoning behind the Multi Level Agreement (MLA) operation based on zSlices which was previously introduced and discuss the requirement for the selection of the right operations for the amalgamation of individual fuzzy sets and the potential for investigating this choice in particular in a CWW context.**

Keywords: Multi Level Agreement (MLA); zSlices; intersection; union; interpretation; Computing With Words (CWW)

I. INTRODUCTION

Fuzzy Logic Sets were initially introduced in 1965 by Zadeh [1] in order to provide a framework "which may be of use in dealing with "classes"" that are imprecisely defined such as for example "the class of tall men" or "the class of beautiful women". Since 1965, fuzzy sets and resulting fuzzy logic systems have become widely popular both in research terms as well as through a large number and variety of applications.

Further to the original concept of what is today referred to as type-1 fuzzy sets, Zadeh in 1975 introduced the concept of a linguistic variable and its application to approximate reasoning [2], providing the basis for what is referred to today as type-2 fuzzy sets and systems.

While the main focus of fuzzy logic (systems) in terms of their applications has been what could be called "traditional areas of fuzzy logic application" such as control applications (e.g.: [3],[4]), medical applications (e.g. [5]) and applications in business (e.g. [6]), in recent years a new body of research centered around the concept of "Computing With Words" (CWW) has been raising interest (e.g. [7], [8] and [9]).

At the basis of CWW is the renewed effort of investigating the possibility of imitating the unique (in the sense of outstanding, especially compared to computers) ability of humans for approximate reasoning or more specifically the reasoning with, or on the basis of approximately defined classes and concepts in the form of words. Language and the use of "words" encapsulates this human ability and as such, the "word" or more specifically, *the meaning of a word* and how it can be represented, manipulated, stored and in a general sense be computed with (including for inference purposes) is a "hot" topic of research. Type-2 fuzzy sets and specifically interval type-2 fuzzy sets have been used to provide an adequate modeling basis for words in a fuzzy logic context as their Footprint Of Uncertainty (FOU) allows for expressing a degree of uncertainty about a specific degree of membership. In the context of type-2 fuzzy sets employed as part of CWW, a variety of research efforts have been made to investigate approaches to model the meaning of specific words using type-2 fuzzy sets based on (usually survey based) data (e.g. [10], [11] [12]).

In our recent work we have developed the notion of agreement in the sense of zSlices [13] based general type-2 fuzzy sets [14], [15] with a specific focus on its application in the context of Ambient Intelligent Environment (AIE) applications. As part of our research, we have investigated the combination of several interval type-2 fuzzy sets (originating from different sources (e.g.: people) but describing the same linguistic label or word) to form an "agreement" zSlices based set which aims to preserve the interpretation of the specific concept (word) by the individual while assigning higher importance to interpretations shared amongst multiple sources (e.g. individual people). While this work was application-oriented, it is clear that the application of fuzzy sets to model human-centered concepts such as words requires a far more general investigation into the actual meaning of words and how this meaning can be captured based on individual interpretations of a given meaning. Incidentally, the role of classes and concepts in human perception and decision making has been subject to considerable study in sociology and psychology. For example, recent work has considered the investigation into whether humans categorize (make categories) according to exemplar or rule-based theories [16].

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

If fuzzy logic is to model human concepts and words, it is not farfetched to believe that it is essential to investigate the formation of such concepts in humans in order to replicate fuzzy set based models that truly reflect the human notion of concepts and/or words.

It is clear that the adoption - of existing knowledge in - and cooperation with - other fields such as social and psychological sciences is a long term endeavor. In the current paper we, are aiming to present some early and in comparison basic findings based on the previously mentioned notion of agreement for zSlices based general type-2 fuzzy sets as well the more general question of the interpretation of the "aggregation" of multiple samples of a specific concept (i.e. through finding agreement, intersection, etc.). We are not addressing the question of how individual fuzzy sets can be designed (through manual or automatic means) in order for them to represent the meaning of a specific word or concept. Instead, we focus on the investigation of the operation(s) required to extract or represent meaning based on multiple interpretations (sets) of the same concept. As an example, consider the concept of "tall people" expressed as a fuzzy set. Further, consider that this concept would most likely be expressed differently depending on the subject expressing it, i.e. a basketball player is likely to have a different interpretation of the concept than a normal citizen. The questions we are investigating as part of this paper is the following:

- How can individual interpretations (one, two, …, many) of a concept be "combined" in a useful way? I.e. how can the two interpretations of "tall men" be combined to get a better understanding of what "tall men" means – and what does "better" mean in this context?
- If the classical set theoretic operations union and intersection are employed, how can the resulting sets be interpreted? I.e. if we were to compute the intersection of the two fuzzy sets representing "tall men" – what would be the interpretation of the resulting set? (The latter is not straightforward – in particular for type-2 sets.)
- How can general type-2 fuzzy sets be employed to preserve information in "combined concepts" and how can for example zSlices based agreement sets be interpreted? I.e. If we were to employ zSlices based agreement to combine the two sets representing "tall men" – what would be the interpretation (meaning) of the resulting set?
- What is the scope to elicit existing / define new operations for (type-2) fuzzy sets that allow the "combination" of individual concept interpretations in different ways in order to imitate human concept creation? I.e. are there operations other than intersection and union that allow us to combine for example the two sets representing individual interpretations of "tall men" and is there a need or case for introducing new operations specifically for CWW?

In order to address the individual points, we will briefly review basic set theoretic operations and their interpretation as part of Section II. Section III will focus on the interpretation of the intersection and union operations of interval type-2 fuzzy sets while Section IV will focus on the agreement operation based on zSlices and their interpretation, specifically in contrast to the interval type-2 operations. Subsequently, Section V provides a discussion of the individual points and the potential for the elicitation of other operations with the view to generating representative and meaningful fuzzy set representations from series of individual fuzzy set based interpretations, specifically in a CWW context. Section VI finally provides some conclusions and describes future work.

II. Basic Set Operations and their Interpretation

A. Overview

As fuzzy logic is an extension of classical set theory, the most fundamental operations are themselves extensions of the fundamental set theoretic operations of complement, union and intersection. In the current section we revisit each of these operations by referring to both crisp sets as well as type-1 fuzzy sets and briefly discuss their interpretation with the specific aim of investigating their potential for building "agreement fuzzy set model" which incorporate multiple individual fuzzy set sources.

B. The Complement Operation

In classical crisp sets, the standard complement $\bar{A}$ of a set A describes the set of all elements which are not part of A. In fuzzy logic, the complement $\bar{A}$ of a set A describes the membership for any element to not be part of A. Fig. 1 illustrates the complement operation for both crisp and type-1 fuzzy sets. Equation (1) describes the complement operation in terms of the membership values for type-1 fuzzy sets.

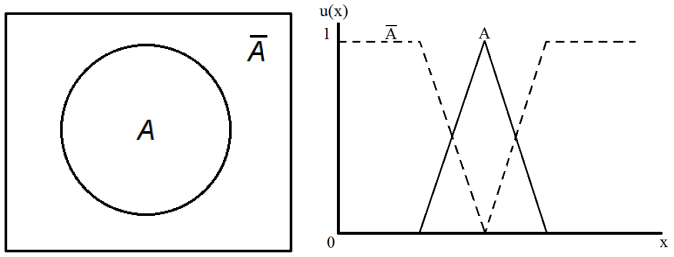

Figure 1. (a) The complement of a crisp set. (b) The complement of a fuzzy set (dashed).

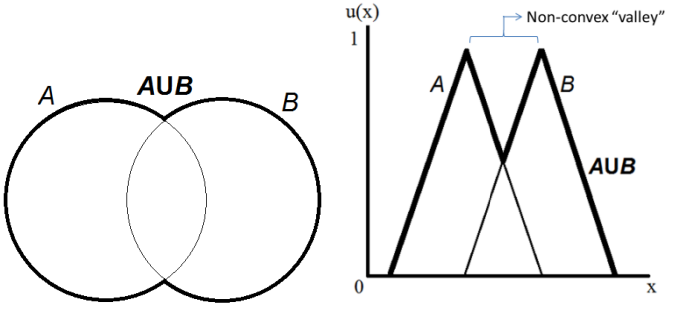
$$u_{\bar{A}} = 1 - u_A \tag{1}$$

The complement operation is straightforward in the logical sense, in terms of its interpretation in a CWW context however it should be considered with caution. For example consider in Fig. 1 the set A describing the concept "*tall people*" as defined by an individual – a person. It is not clear that $\bar{A}$ in this case reflects that person's interpretation of the concept "*not tall people*". For instance, the person may only consider shorter people as "*not tall*", while $\bar{A}$ includes for example includes "*very tall people*". The investigation of this question of what the actual meaning is or should be doubtlessly involves the incorporation of existing knowledge from the areas of psychology and social sciences - we are not addressing it in further detail as part of this paper and we merely include the review of the complement operation for completeness.

C. The Union Operation

The union operation in classical set theory results in a new set that comprises all elements of the initial sets as shown in Fig. 2a. The union of two type-1 fuzzy sets A and B is described by taking the t-conorm of the sets' membership values. One passible t-conorm is the maximum operator as used in Equation (2) and shown in Fig. 2b.

$$u_A \vee u_B = \max(u_A, u_B) \quad (2)$$



(a) (b)

Figure 2 (a) The union of two crisp sets. (b) The union of two type-1 fuzzy sets.

In terms of interpretation, the union implements the logical OR, thus reflecting that any member of the union belongs to either (one or many) of its constituting sets. In fuzzy logic the union operation is generally applied to individual sets qualifying a specific linguistic variable such as *height of people*, where for example the union of the adjacent sets *tall* and *very tall* could be computed to reflect the membership of people who are tall ***or*** very tall.

In contrast to computing the union on different sets describing a linguistic label, in this paper we are focusing on the union of different instances of the same fuzzy set or more precisely, different interpretations (expressed through a fuzzy set) of the same linguistic label, for example: *tall people*. Further, we are specifically aiming to investigate how a useful and meaningful model of a specific label can be extracted from a series of individual models/interpretations. In other words – what is an appropriate general model for *tall people* based on the sample interpretations gathered?

In this context, where for example the type-1 fuzzy sets A and B in Fig. 2b describe different interpretations of the same concept (e.g. *tall people*), the union can be interpreted as a summary of all individual interpretations or opinions in terms of the meaning of the actual concept. While this may be useful, it is clear that as the number of "opinions" (i.e. fuzzy set interpretations of the concept) increases, the resulting model (the union of the individual sets) tends to grow in terms of its support. This in turn means that the precision of the model for *tall people* decreases or perhaps more appropriately the generality of the model increases. This effect may not be desirable as part of CWW applications as a very general concept is often less useful when attempting to reason based on specific data. For example, what information can be gathered from *tall people* if the fuzzy set model covers a very large range from 1 meter – 2.5 meters? Further, applying the union operation does not allow for the modeling of where more candidate sets are in agreement. For example, the resulting union membership function does not allow differentiating between a union set formed by many similar sets or potential outliers. While one could aim to remedy this effect by pre-selecting candidate sets for *tall people* and removing outliers, we are aiming to investigate a more transparent approach to aggregating all individual interpretations while also modeling "agreement" between individual sets (i.e. to model where many sets overlap, rather than just few).

Finally, in terms of employing the union operation in CWW applications, it can be noted that in terms of its meaning / interpretation, it can be difficult to explain the usually resulting area of non-convexity or "valley" which is shown for example in Fig. 2b. Referring to our example of multiple interpretations of the concept "*tall people*", one may expect that if A and B depict two interpretations, that their union should cover the entire space between the sets (thus incorporating the range between the individual interpretations). Interestingly, replacing the most common t-conorm *maximum* to implement the union operation by the equally valid but less popular Łukasiewicz t-conorm [17] (more precisely the dual to the Łukasiewicz t-norm) for strong disjunction shown in Equation (3) results in sets which generally more closely represent the expected result as shown for example for sets A and B in Fig. 3.

$$u_A \vee_{Ł} u_B = \min(1, (u_A + u_B)) \quad (3)$$

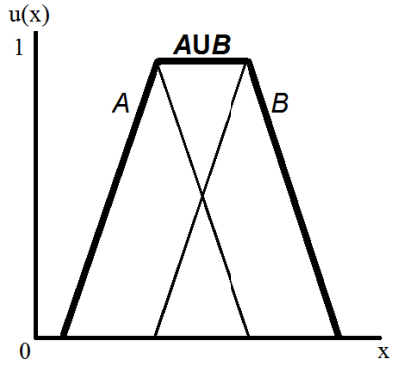


Figure 3 The union of two fuzzy sets when employing the Łukasiewicz t-conorm.

It should be noted that we are not recommending the replacement of the *t-conorm* maximum by the *Łukasiewicz t-conorm* in a general fashion. However, the example above serves the purpose to show that when considering the modeling of human concepts and words (as part of CWW), it may be appropriate to revisit the choice of t-conorms (and t-norms) with the aim of producing fuzzy sets which closely mimic the human interpretation of a given concept or word. In particular in type-2 fuzzy logic, less common t-conorms and t-norms have so far only been explored in a very limited fashion, in particular in CWW applications.

D. The Intersection Operation

While the union operation implements the logical OR, the intersection operation implements the logical AND, i.e. the conjunction operation. The intersection operation in classical set theory results in a new set that comprises the elements in common between the initial sets as shown in in Fig. 4a. The intersection of two type-1 fuzzy sets A and B is described by taking the t-norm of the sets' membership values. One possible

t-norm is the minimum operator as used in Equation (4) and shown in in Fig. 4b.

In terms of interpretation, the intersection operation extracts the "common ground" between two concepts or words. As such, following our example of two interpretations of the concept "*tall people*" expressed as sets *A* and *B* in Fig. 4, their intersection (also in Fig. 4) describes the set representing the area where both interpretations *A* and *B* "agree", i.e. where both interpretations overlap.

$$u_A \vee u_B = \min(u_A, u_B) \quad (4)$$

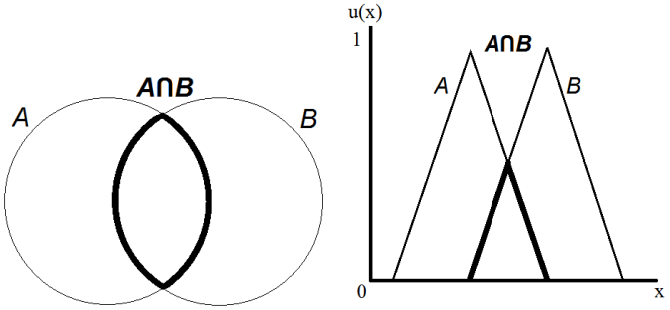

Figure 4 (a) The intersection of two crisp sets. (b) The intersection of two type-1 fuzzy sets.

Incidentally, Fig. 4 also indicates the common tendency of intersections to decrease generality in terms of support. In other words, the support of the intersection of two sets is always smaller or equal to the support of either set. This in turn can be interpreted as a "homing in" on the core meaning of the concept. In other words, the intersection in Fig. 4b can be interpreted as the core meaning of "*tall people*" in the sense that the interpretations of two individuals overlap (agree). If one imagines further sets (interpretations by other individuals), the intersection's support will tend to decrease further in size.

As exemplified in Fig. 4, the intersection of two type-1 fuzzy sets tends to result in a set with low degrees of membership **if** the sets are significantly different. This reflects the intuitive notion that the common ground between two people with vastly differing opinions tends to be small. Reciprocally, in terms of employing the intersection to extract a global meaning of many individual interpretations of a specific concept (e.g. *tall people*) rapidly tends to result in an empty set if the sample sets show any significant degree of variation. Of course, one could identify and eliminate so called outliers but by doing so one specifically excludes individual interpretations which while convenient, may not reflect the globally valid meaning. In this context, it should be noted that what "the globally valid meaning" actually is, is itself an open question and quickly leads to research in democracy and the role of an individual in a society. We are not making any claims in the direction of what a "globally valid meaning" is in reality, but as part of this paper we are considering the "globally valid meaning" as a fuzzy set which incorporates all individual interpretations of a concept and at the same time reflects the potential common ground between several interpretations where it exists.

For completeness it should be noted that, analogous to the union operation, a selection of different t-norm operations are available which slightly alter the resulting intersection and thus allow for the capturing of different interpretations.

E. Discussion

While the review of the complement, union and intersection operations can be considered trivial, their interpretation, in particular in a CWW context becomes highly significant. It lays the foundations of the idea of "agreement" as established using zSlices [15]. Specifically, considering the generalization properties of the union and the constraining properties of the intersection (in terms of the support of the resulting sets), it is clear how the latter two operations capture two very important aspects in the definition of a "globally valid meaning" in the form of a fuzzy set.

In the following section we proceed by considering the union and the intersection of interval type-2 fuzzy sets. We briefly discuss some at first glance non-intuitive properties of these basic operations when applied to type-2 fuzzy sets and provide our attempt at interpreting the sets resulting from these operations in a CWW context.

III. Interpretation of the Union and Intersection Operations for Interval Type-2 Fuzzy Sets

A. Overview

Both the union and intersection operations of interval type-2 fuzzy sets can be reduced to applying t-conorms and t-norms respectively to the upper and lower membership functions of the sets upon which the operations are to be performed [18]. Thus, it is reasonable to expect similar interpretations of the resulting sets as were described in Section II for type-1 fuzzy sets. However, while the basic properties such as the generalizing effect of the union (in terms of the support) hold both in the type-1 and in the interval type-2 case, the resulting effects on the fuzzy set Footprints Of Uncertainty (FOUs) are far less intuitive and warrant a directed effort to establish their interpretation. In the following two sections we review both the union and intersection operations for interval type-2 fuzzy sets and provide our attempt at their interpretations with a specific focus on the resulting FOUs.

B. The Union Operation for Interval Type-2 Fuzzy Sets

As noted, the union operation for interval type-2 fuzzy sets is based on computing the chosen t-conorm on the upper and lower membership functions of the specific sets. As expected, the resulting sets exhibit the same generalization tendency (i.e. a widening of the support) as was identified for their type-1 counterparts in Section II. This observation can also clearly be made in the two examples of union operations performed on different interval type-2 fuzzy sets provided in Fig. 5 and Fig. 6.

However, while it may be intuitive that the union of two interval type-2 fuzzy sets (i.e. the logical OR) should include the whole FOU of both initial interval type-2 fuzzy sets, Fig. 5 and Fig. 6 clearly indicate (by example) that this is clearly not the case.

The interpretation of this observation is not immediately straightforward. By definition, the FOU of an interval type-2 fuzzy set describes the uncertainty in terms of the degree of

membership for a given input. Consider for example the sets $\tilde{A}$ and $\tilde{B}$ as two interpretations of the concept *tall people*. As we noted, the union operation can generally be interpreted as a summary of both "opinions", i.e. in classical sets the union includes all elements of the underlying sets. In interval type-2 fuzzy sets however, the result of the union operation does not necessarily include the lower membership functions (and thus associated values) of both sets (see Fig. 5 and Fig. 6). The most obvious interpretation of this is that the union operation does not extract a "summary" of the individual sets' memberships which could be expected to include the full range from the lowest to the highest witnessed degrees of membership but actually extracts the highest degrees of membership.

In terms of our example of the union of two sets describing *tall*, the resulting set $\tilde{A} \cup \tilde{B}$ combines both individual interpretations. As a consequence the resulting model of *tall* becomes more general (wider support) and has a new uncertainty model (FOU) associated with it. Incidentally, the uncertainty (FOU) of the resulting set $\tilde{A} \cup \tilde{B}$ is generally neither the uncertainty of any one of the original interpretations (sets) but a combination of both uncertainty models.

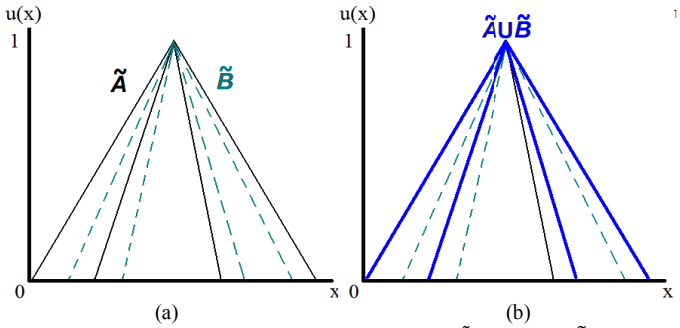

Figure 5 (a) Two example interval type-2 fuzzy sets $\tilde{A}$ (solid) and $\tilde{B}$ (dashed). (b) The union of $\tilde{A}$ and $\tilde{B}$ (bold).

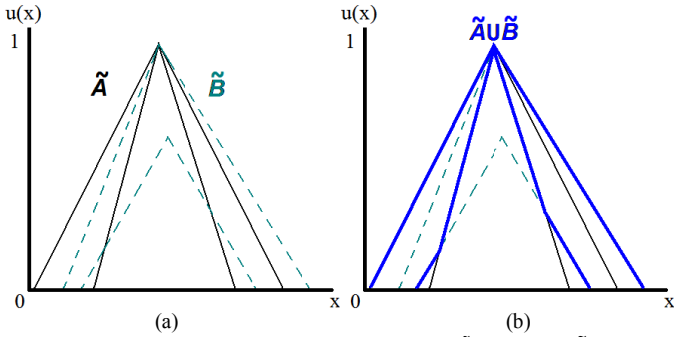

Figure 6 (a) Two example interval type-2 fuzzy sets $\tilde{A}$ (solid) and $\tilde{B}$ (dashed). (b) The union of $\tilde{A}$ and $\tilde{B}$ (bold).

In terms of CWW, the interesting question that arises is if such a recombination of "opinions" (expressed as interval type-2 fuzzy sets) indeed reflects the expected interpretation of "OR-ing" the two opinions. In the same context, to which extent can the union operation with its described results be employed as part of CWW to reflect the notion of agreement (where the incorporation of all "opinions" can be considered crucial) when computed over multiple instances (sets) describing the same concept?

The following section will review the intersection operation for interval type-2 fuzzy sets before we proceed and review the zSlices based "agreement" operation in Section IV in order to address some of the posed questions.

C. *The Intersection Operation for Interval Type-2 Fuzzy Sets*

Analogous to the union operation, the intersection operation for interval type-2 fuzzy sets can be achieved by applying a t-norm operation to the upper and lower membership functions respectively of the given candidate interval type-2 fuzzy sets.

As noted in Section II, the intersection operation, reflecting the logical AND, can be interpreted as extracting the "common ground" between the individual interval type-2 fuzzy sets. We provide two examples of the intersection operation on two interval type-2 fuzzy sets as illustrated in Fig. 7 and Fig. 8.

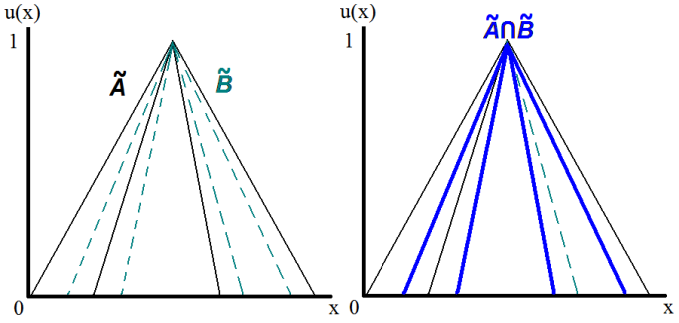

Figure 7 (a) Two example interval type-2 fuzzy sets $\tilde{A}$ (solid) and $\tilde{B}$ (dashed). (b) The intersection of $\tilde{A}$ and $\tilde{B}$ (bold).

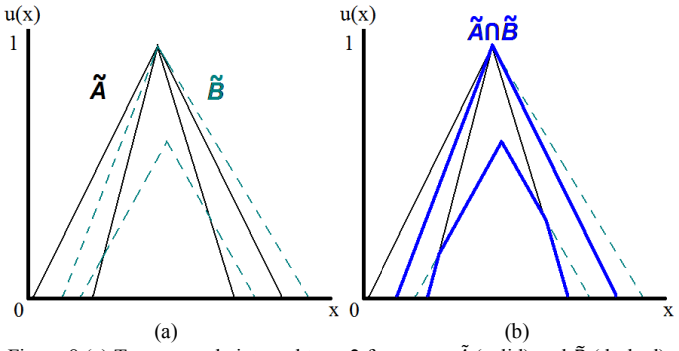

Figure 8 (a) Two example interval type-2 fuzzy sets $\tilde{A}$ (solid) and $\tilde{B}$ (dashed). (b) The intersection of $\tilde{A}$ and $\tilde{B}$ (bold).

While the fundamental interpretation of the intersection operation is straightforward and analogous to that of the intersection operation of type-1 fuzzy sets described in Section II, it is noteworthy that the results in terms of the FOU of the interval type-2 intersection are far less straightforward/intuitive to interpret. As can easily be seen in the examples in Fig. 7 and Fig. 8, the intersection operation does not result in a FOU that solely includes areas of membership that belong to both sets $\tilde{A}$ and $\tilde{B}$ but moreover it results in an FOU that ranges from the lowest lower membership function to the lowest upper membership function. To illustrate the difference in what could be considered an intuitive result of the intersection operation, consider Fig. 9 which depicts the "common ground" in terms of FOU of both fuzzy sets $\tilde{A}$ and $\tilde{B}$, while Fig. 7 shows the actual results of the intersection operation.

If we refer to our example of *tall people,* the computation of the intersection of two interpretations of this concept (i.e.

two interval type-2 fuzzy sets) could be expected to result in the overlap of the FOUs of the specific sets (as in Fig. 9). As shown, the actual result (Fig. 7) however is a set that while sharing the upper membership function with the expected result, preserves the lowest witnessed (in an input set) degree of membership.

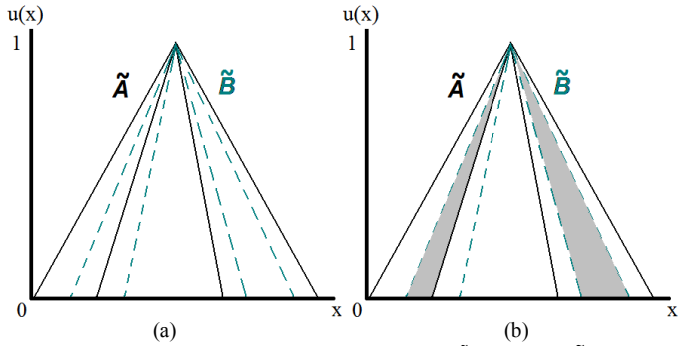

Figure 9 (a) Two example interval type-2 fuzzy sets $\tilde{A}$ (solid) and $\tilde{B}$ (dashed). (b) The potentially intuitive result of an intersection of the FOUs of $\tilde{A}$ and $\tilde{B}$ (shaded).

As for the union operation, the reason for pointing out this potential difference in the actual result of the intersection and the expected result is not to question the intersection operation as a mathematically correct operation but to provide an example of the increased complexity that results from using and particularly amalgamating (through set theoretic operations) higher order fuzzy sets. If such sets are used as part of CWW to represent and encode human-centered concepts such as words, it is essential that:

- The operations (such as intersection) employed result in sets that match our expectation – respectively reality (i.e. the concepts that are being modeled).
- We are able to accurately interpret the resulting sets in a given context.

Having explored the basic operations of union and intersection for interval type-2 fuzzy sets and briefly reflecting on their respective interpretations, we proceed in the following section to providing the underlying reasoning for introducing the agreement operation based on zSlices, followed by an overview of the actual operation and its interpretation.

IV. The Agreement Operation Based on zSlices

A. Overview

zSlices based agreement was conceptually introduced in [14] (where it was largely based around overlapping FOUs as for example in Fig. 9) and recently developed further by basing it firmly on classical set theoretical operations of union and intersection [15] (as for example in Fig. 5 and Fig. 7). While both publications addressed the operation in terms of its functionality and applicability, in this paper we are reviewing the underlying concept and need for expanding on the "basic" amalgamation operations offered by interval type-2 fuzzy set operations (specifically the union and intersection as described in Section III) which underpins the creation of the "zSlices based agreement" operation. We briefly review the operation itself in Section IV.B and proceed by focusing on its interpretation in Section IV.C.

B. Review of zSlices based notion of Agreement.

While an initial approach to developing agreement focused on overlapping FOUs was mentioned in [14] (as shown in Fig. 9), in this paper we exclusively focus on the notion of Multi Level Agreement (MLA) based firmly on the sole use of the classical set-theoretic operations of union and intersection as detailed in [15]. It is worth mentioning that the two slightly different approaches were developed as a result of the discussion raised in this paper – the requirement to employ classical firmly established set theoretical operations versus the need to develop interpretable models of agreement.

MLA describes an operation which transforms a series of interval type-2 fuzzy sets into a zSlices based set. Each of the initial interval type-2 sets is generally *one individual interpretation* of a specific concept or word, such as *tall people*. MLA subsequently aims to provide a general model which reflects all individual interpretations while considering the agreement (common ground) between multiple individual interpretations (modeled in the third dimension). In other words, it aims to preserve all "interpretation inputs" but to weight specific areas on the final MLA output set in terms of the number of input sets that intersect. An MLA zSlices based set $\tilde{Z}_{MLA}$ based on K source interval type-2 fuzzy sets $\widetilde{S_k}$, where $k \in \{1, \dots, K\}$ has a number of zLevels I equal to K (and as such zSlices $\tilde{Z}_i$, where $i \in \{1, \dots, I\}$). At low zLevels, the MLA set models the most general information provided by the individual interpretations while with increasing zLevel (third dimension), higher levels of agreement are represented. We do not repeat the full detail of the operation here for space reasons, but for a full account of the detailed steps of computing an MLA set, please see [15].

It is crucial to note the difference between MLA and employing interval type-2 fuzzy set based operations (such as union or intersection). The latter only allow for the focus on the common ground (intersection) or a generalization (union). Further, they do not allow for a modeling of the information in terms of the number of interpretations (interval type-2 sets) that are in agreement (i.e. a single outlier is weighted the same as a series of highly similar sets). MLA addresses both issues by combining union and intersection and utilizing the third dimension to weight areas of agreement where many interval type-2 sets (interpretations) are similar. As such it could be said that MLA aims to model the interpretation which the majority can agree on (and weighting it accordingly) but still preserving other interpretations (with an associated lower weight).

C. Interpretation of zSlices based Agreement.

In order to facilitate the interpretation of MLA we provide an example detailing the computation of an MLA model based on three individual "input" interval type-2 fuzzy set interpretations. The example sets have been reproduced from [15] as the in-depth review of the MLA sets in terms of their interpretation completes the theoretical background introduced in [15]. Fig. 10 depicts the three example "input" sets.

Fig. 11 shows the results of applying the basic operations of union and intersection to the "input" sets shown in Fig. 10a and Fig. 10b. The results of both operations have been included to reflect the review of the said operations in Section III and to

allow the contrasting of the resulting sets with the MLA set (Fig. 12a) computed on two interval type-2 "input" sets shown in Fig. 10a and Fig. 10b.

Fig. 12b finally shows the MLA set based on computing MLA on all three "input" sets shown in Fig. 10.

In order to interpret the MLA based sets shown in Fig. 12 it is worth recapitulating the MLA based sets are zSlices based and that higher zLevels (i.e. the third dimension) are to represent higher levels of agreement.

Considering the example of a MLA set in Fig. 12a computed on the "input" sets in Fig. 10a and Fig. 10b, it first of all becomes clear that the MLA set indeed reflects the union of both "input" sets as primary zSlices (front / dark blue). The union as a simple interval type-2 fuzzy set is provided for comparison in Fig. 11a. Further, as we have two "input" sets, the second zLevel should represent the agreement of both "input" sets which as part of MLA is modeled through the intersection operation. Considering the second zLevel (rear / light blue) in Fig. 12a and comparing it to the basic intersection shown in Fig. 11b it is clear that the MLA set reflects the expected intersection at the second zLevel.

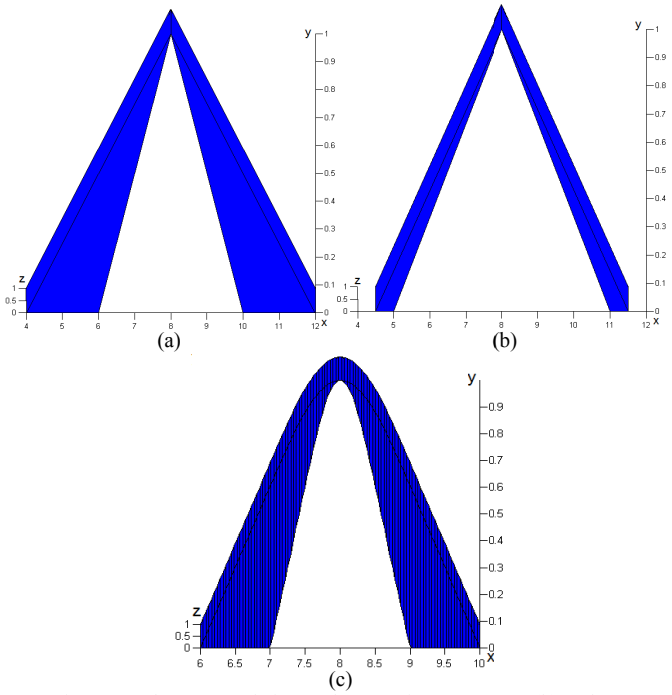

Figure 10 Three example interval type-2 fuzzy sets: (a), (b) and (c).

In terms of interpretation, the resulting MLA sets reflect the generalized amalgamation (union – see Section III.B) of the "input" sets at the lower zLevels while the common ground of the individual "input" sets is modeled (through the intersection – see Section III.C) at higher zLevels. With the zLevels acting as weights it is clear that "common ground" is weighted more heavily which is in line with the intuition that common ground between individuals should be reflected strongly in any model of agreement. The fact that levels of low "common ground", i.e. the very general low zLevels incorporate all "input set" interpretations is also in line with the intuition that an agreement model should not disregard interpretations made by only one or a few members.

Considering the common operations of union and intersection performed on interval type-2 fuzzy sets (Fig. 11), it is clear that the resulting interval type-2 sets cannot achieve both aims – the union by itself allows only to generalize while the intersection solely focuses on the common ground.

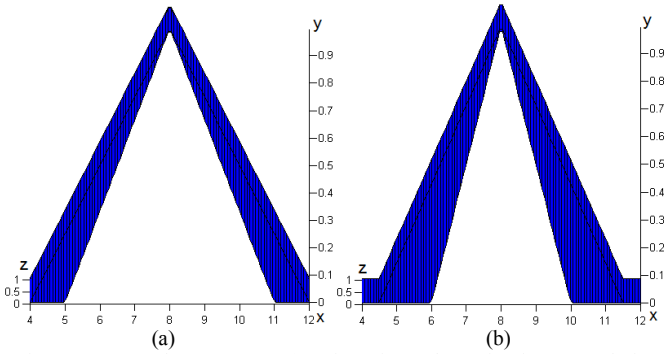

Figure 11 Interval type-2 sets: (a) Union of sets shown in Fig. 10a and Fig. 10b. (b) Intersection of sets shown in Fig. 10a and Fig. 10b.

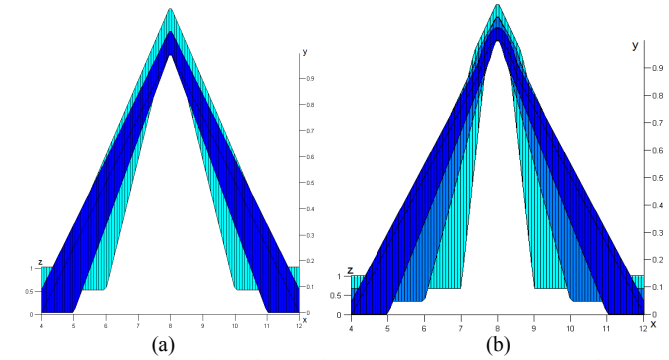

Figure 12 MLA zSlices based general type-2 sets. (a) MLA computed on sets shown in Fig. 10a and Fig. 10b. (b) MLA computed on sets shown in Fig. 10a, Fig. 10b Fig. 10c.

Finally, it is worth noting that the shape of the MLA sets as shown for two and three "input" interval type-2 fuzzy sets in Fig. 12a and Fig. 12b respectively reflects the basic properties of the underlying union and intersection operations (see Section III): a generalization effect and as such a widening of the support at lower zLevels and an increasing precision in terms of the concept (narrowing of support) as the zLevels increase.

V. Discussion and Scope for Other Operations.

This paper has mainly focused on the classical set theoretical operations of intersection and union and on their most common implementations – using the minimum t-norm and maximum t-conorms. These operations and their effect and have been shown and MLA has been interpreted being based on these classical implementations. However, as we indicated with the example of the Łukasiewicz t-conorm in Section II.C, it is clear that the common t-norms/t-conorms are by far not the only possible ones. Indeed, as was shown for the example of the Łukasiewicz t-conorm, other operations, or at the very least, the use of other t-norms and t-conorms to implement the classical set-theoretical operations of union and intersection promises great potential in the aim of actually reflecting the meaning of concepts as they are perceived by humans. In terms

of interval type-2 operations the use of different t-norm / t-conorm operations for the upper and lower membership functions could also be investigated.

As such, we believe that the choice of operation (union, intersection, …) as well as the choice of the underlying t-norm and t-conorm can be an essential component in designing CWW applications. The selection of what the "right" operations are for which application and if there are common indicators across CWW applications promises to be a fruitful ground for future multi-disciplinary research, firmly based on collaboration between human-centred sciences such as the social sciences and the fuzzy logic field.

VI. Conclusions and Future Work

As part of this paper we have reviewed the classical set-theoretical operations of complement, union and intersection for classical and type-1 fuzzy sets. Specifically, we have focused on investigating the interpretation of the latter two operations, laying the groundwork for subsequently considering the interpretation of said operations for interval type-2 fuzzy sets. We have briefly reviewed the concept of MLA based zSlices sets and have proceeded to detail their interpretation in the light of the interval type-2 operation interpretations that form the basis of MLA. We have indicated how MLA allows a more comprehensive representation of agreement compared to interval type-2 based operations through the weighting of highly similar interpretations (sets) in the third dimension while still preserving all, including infrequent interpretations (sets) at lower weights. By employing the third dimension, MLA can combine both the concept "narrowing" and "generalization" provided by the intersection and union operations.

Importantly, our efforts of interpreting the given operations and sets were focused on their use in CWW applications. As CWW aims to "compute with words", it is paramount to investigate whether the individual sets and operations really reflect words, or more explicitly, whether they reflect the interpretation that is intuitively made by humans.

As such, this paper is not aimed at providing novel results or operations, it is merely aimed at:

- Providing details on the motivation of using MLA sets based on zSlices rather than interval type-2 fuzzy sets (based on either the union or intersection) for agreement modeling.
- Providing the interpretation of MLA sets in the context of the underlying operations.
- Indicating that the choice of operations and indeed the choice of implementation of operations (t-norm / t-conorm) has a significant impact on the resulting sets and interpretations. This is of particular importance in the context of CWW application which aim to imitate the human.

The scope of this paper has only allowed for a comparatively shallow investigation of the interpretations of the sets and the additional questions raised (such as the choice of t-norm /t-conorm). A remaining question is for example the application of different t-norms and t-conorms as part of MLA. Further, in the future we aim to deepen our investigation, in particular through multi-disciplinary collaboration with the aim of advancing the goal of "imitating" human concepts and reasoning though the application of fuzzy logic in a CWW context.

***Abstract*—This paper presents an indirect adaptive type-2 fuzzy logic controller (FLC) for dynamic positioning (DP) vessels with attached thrusters under various time-varying hydrodynamic disturbances. Approximation-based adaptive control technique in combination with type-2 fuzzy logic system (FLS) is employed in the design of the control. The stability of the design is demonstrated through Lyapunov analysis where globally asymptotical convergence of the regulation error is guaranteed. Rigorous analysis shows the resultant closed-loop system is passive. The proposed adaptive type-2 FLC is able to reject the hydrodynamic disturbances without exact information on them. Comparative simulations with linear proportional derivative (PD) controller and adaptive type-1 FLC are carried out. The proposed technique is found to be effective, robust, and has better performance.**

***Index Terms*—Adaptive control, type-2 fuzzy logic system, function approximation, dynamic positioning.**

I. Introduction

The offshore exploration and exploitation of hydrocarbons have opened up an era of dynamic positioning (DP) vessels. DP systems are widely used in situations where mooring or anchoring is not feasible due to deep water, congested structures such as pipelines on the sea bottom or other economical issues. DP systems maintain floating structures in fixed position and heading for marine operation purpose exclusively by means of active propellers and thrusters. In the 1960s the first DP system was introduced for horizontal modes of motion (surge, sway, and yaw) using PID controllers in cascaded with low-pass or notch filter. In the 1970s more advanced control techniques based on optimal control and linear Kalman filter theory was proposed in [1]. This work was later improved and extended [2], [3]. In the 1990s nonlinear control techniques were employed in several works [4]. More recently, supervisory switched hybrid controllers for DP from calm to extreme sea conditions and from transit to station keeping operation were presented [5].

In parallel with the developments in control techniques, vessel modeling techniques have been improving as well [3]. One of the newest vessel models was presented in [6], [7], and there is still a lack of effective controller for this model due to the complex time-varying hydrodynamic disturbances presented in this model. One intuitive solution is adaptive control technique. For this model, traditional model-based adaptive control technique is not applicable since it is generally useful only when dealing with systems in which the dynamics are linear in the parameters, the regressors are exactly known, and the uncertainties are parametric and time-invariant [8]. As these disturbances are time-varying and changing for different sea conditions, approximation-based adaptive control technique [9], [10] is adopted to compensate for the disturbances and functional uncertainties. Such approximators can utilize a standard regressor function whose structure is independent of the disturbances' dynamic characteristics.

Type-1 fuzzy logic system (FLS) has been found to be able to approximate continuous nonlinear functions to any desired accuracy over a compact set [11]–[14], thus could be such an approximator. In recent years, studies on type-2 fuzzy sets and FLSs have drawn much attention [15]–[18]. A type-2 fuzzy set is characterized by a fuzzy membership function whose membership value for each element is a fuzzy set in [0,1], unlike a type-1 fuzzy set whose membership value is a crisp number in [0,1]. The membership functions of type-2 fuzzy sets are three dimensional, and it is the new third dimension that provides additional degrees of freedom that equip type-2 FLS with the potential to outperform its type-1 counterpart. Type-2 FLS is a fuzzy system where at least one of the antecedent or consequent fuzzy sets is a type-2 fuzzy set. The type-2 FLS has already been successfully applied to several engineering problems [19]–[22] and studied from lots of points of view. One interesting research point of view is whether the type-2 FLS could be a universal approximator for different application, and this paper is an effort along this direction.

By combining approximation-based adaptive control technique and type-2 FLS, an indirect adaptive type-2 fuzzy logic controller (FLC) is proposed. It overcomes the limitations of model-based adaptive control to provide an effective control algorithm for the newly developed vessel model [6], [7]. And the DP problem is treated as an application to investigate the approximation property of type-2 FLS.

The rest of the paper is organized as follows. Section II describes the singleton interval type-2 (IT2) FLS and expresses it in the linear in the parameters form. Next, the modeling of marine vessels in two complexity levels is introduced in

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Section III. Then the design and stability analysis of the adaptive type-2 FLC is delineated in Section IV, the passivity property of the resultant closed-loop system is illustrated in this section as well. After that, Section V describes the simulation results of the closed-loop system. Comparisons with other controllers are also shown in this section. Finally, conclusions are drawn in Section VI.

II. Description of Singleton IT2 FLS

In this paper, we consider a singleton IT2 FLS whose basic configuration is depicted in Fig. 1. It consists of fuzzifier, rule base, fuzzy inference engine, type-reducer, and defuzzifier. Here, a multi-input, single-out fuzzy system is described. And a multi-output system can always be separated into a group of single-output systems.

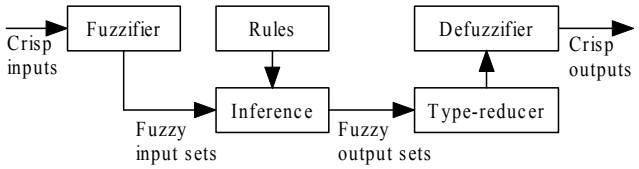

Fig. 1. A singleton interval type-2 FLS.

1) Fuzzification: The fuzzifier maps a crisp point $\mathbf{x} = (x_1, \ldots, x_n) \in \mathbf{U} \subset R^n$ into a fuzzy set $\tilde{A}_{\mathbf{x}}$ in $\mathbf{U}$. Since singleton fuzzification is employed, the membership grade of an input $\mathbf{x}$ in the fuzzy set $\tilde{A}_{\mathbf{x}}$ is as follows.

$$\mu_{\tilde{A}_{\mathbf{x}}}(\mathbf{x}) = \begin{cases} 1; & \mathbf{x} = \mathbf{x}' \\ 0; & \mathbf{x} \neq \mathbf{x}' \end{cases} \tag{1}$$

2) Rules: Rules are the heart of a FLS, and can be extracted from numerical data or provided by experts. Consider a FLS having n inputs and one output, then the lth rule in the rule base of the IT2 FLS is

$$R^l : \text{IF } x_1 \text{ is } \tilde{F}_1^l \text{ and } \cdots \text{and } x_n \text{ is } \tilde{F}_n^l \text{ THEN } y \text{ is } \tilde{G}^l \tag{2}$$

where $l = 1, 2, \ldots, M$, x_i $(i = 1, 2, \ldots, n)$ and y are the input and output variables to the fuzzy system respectively, $\tilde{F}_i^l$ and $\tilde{G}^l$ are labels of fuzzy sets in $\mathbf{U}_i$ and R, respectively.

3) Fuzzy Inference Engine: The fuzzy inference engine combines fuzzy rules with fuzzy logic principles to provide a mapping from fuzzy input sets in $\mathbf{U}$ to fuzzy output sets in R. For the singleton IT2 FLS, based on the sup-star compositional rule of inference, the output consequent set corresponding to rule R^l can be represented as
