$$\begin{aligned} \dot{V} &= \sum_{i=1}^{r} \alpha_i \Big\{ s^T \bar{C}\bar{A}_i z + s^T C_2B_2G_i \mathcal{U}_i \\ &\quad - s^T C_2B_2G_i \frac{(C_2B_2)^{-1}}{\lambda_{\min}} \mu \ s \\ &\quad - s^T C_2B_2G_i \sum_{j=1}^{r} \alpha_j \left((C_2B_2)^{-1} \psi_j \bar{C}\bar{A}_j z + \phi_j \right) \Big\} \\ &\quad - \sum_{i=1}^{r} \gamma_{1i}^{-1} \tilde{c}_i \dot{\hat{c}}_i - \sum_{i=1}^{r} \gamma_{2i}^{-1} \tilde{k}_i \dot{\hat{k}}_i \\ &= \sum_{i=1}^{r} \sum_{j=1}^{r} \alpha_i \alpha_j \Big\{ s^T \bar{C}\bar{A}_i z + s^T C_2B_2G_i \mathcal{U}_i \\ &\quad \underbrace{- s^T C_2B_2G_i \frac{(C_2B_2)^{-1}}{\lambda_{\min}} \mu \ s}_{(I)} \\ &\quad \underbrace{- s^T C_2B_2G_i (C_2B_2)^{-1} \psi_j \bar{C}\bar{A}_j z}_{(II)} \\ &\quad \underbrace{- s^T C_2B_2G_i \phi_j}_{(III)} \Big\} \\ &\quad - \sum_{i=1}^{r} \gamma_{1i}^{-1} \tilde{c}_i \dot{\hat{c}}_i - \sum_{i=1}^{r} \gamma_{2i}^{-1} \tilde{k}_i \dot{\hat{k}}_i. \end{aligned} \tag{33}$$

Let us consider $(I) - (III)$ in (33) as follows.

$$\begin{aligned} (I) &\leq -s^T C_2B_2 \lambda_{\min} \frac{(C_2B_2)^{-1}}{\lambda_{\min}} \mu \ s \\ &= -\mu ||s||, \end{aligned} \tag{34}$$

where $\lambda_{\min} > 0$ due to the assumption *A1*. As to (II), if $s^T \bar{C}\bar{A}_j z \geq 0$, we have

$$\begin{aligned} (II) &= -s^T C_2B_2G_i (C_2B_2)^{-1} \frac{1}{\lambda_{\min}} \bar{C}\bar{A}_j z \\ &\leq -s^T C_2B_2 \lambda_{\min} (C_2B_2)^{-1} \frac{1}{\lambda_{\min}} \bar{C}\bar{A}_j z \\ &= -s^T \bar{C}\bar{A}_j z; \end{aligned} \tag{35}$$

otherwise,

$$\begin{aligned} (II) &= -s^T C_2B_2G_i (C_2B_2)^{-1} \frac{1}{\lambda_{\max}} \bar{C}\bar{A}_j z \\ &\leq -s^T C_2B_2 \lambda_{\max} (C_2B_2)^{-1} \frac{1}{\lambda_{\max}} \bar{C}\bar{A}_j z \\ &= -s^T \bar{C}\bar{A}_j z. \end{aligned} \tag{36}$$

That is,

$$(II) \leq -s^T \bar{C}\bar{A}_j z \tag{37}$$

holds in any case by virtue of switching function (26). Similarly, it follows from (27) that

$$\begin{aligned} (III) &\leq -||B_2^T C_2^T s||_1 \ \hat{\rho}_j \ ||G_j|| \\ &\leq -||B_2^T C_2^T s|| \ \hat{\rho}_j \ ||G_j||, \end{aligned} \tag{38}$$

where the fact that $||x|| \leq ||x||_1$ with x being a vector is used. Substituting (34), (37) and (38) into (33) it follows that

$$\begin{aligned}
\dot{V} &\leq \sum_{i=1}^{r}\sum_{j=1}^{r}\alpha_i\alpha_j\Big\{s^T\bar{C}\bar{A}_i z + s^T C_2 B_2 G_i \mathcal{U}_i \\
&\quad -\mu||s|| - s^T\bar{C}\bar{A}_j z - ||B_2^T C_2^T s||\ \hat{\rho}_j\ ||G_j||\Big\} \\
&\quad -\sum_{i=1}^{r}\gamma_{1i}^{-1}\tilde{c}_i\dot{\hat{c}}_i - \sum_{i=1}^{r}\gamma_{2i}^{-1}\tilde{k}_i\dot{\hat{k}}_i \\
&= -\mu||s|| + \sum_{i=1}^{r}\alpha_i\Big\{s^T\bar{C}\bar{A}_i z + s^T C_2 B_2 G_i \mathcal{U}_i \\
&\quad -s^T\bar{C}\bar{A}_i z - ||B_2^T C_2^T s||\ \hat{\rho}_i\ ||G_i||\Big\} \\
&\quad -\sum_{i=1}^{r}\gamma_{1i}^{-1}\tilde{c}_i\dot{\hat{c}}_i - \sum_{i=1}^{r}\gamma_{2i}^{-1}\tilde{k}_i\dot{\hat{k}}_i \\
&\leq -\mu||s|| + \sum_{i=1}^{r}\alpha_i\Big\{||B_2^T C_2^T s||||G_i||||\mathcal{U}_i|| \\
&\quad -||B_2^T C_2^T s||\ \hat{\rho}_i\ ||G_i||\Big\} \\
&\quad -\sum_{i=1}^{r}\gamma_{1i}^{-1}\tilde{c}_i\dot{\hat{c}}_i - \sum_{i=1}^{r}\gamma_{2i}^{-1}\tilde{k}_i\dot{\hat{k}}_i. \qquad (39)
\end{aligned}$$

Further, substituting (2), (28), and adaptive laws (29), (30) into (39), we obtain

$$\begin{aligned}
\dot{V} &\leq -\mu||s|| \\
&\quad +\sum_{i=1}^{r}\alpha_i\Big\{||B_2^T C_2^T s||||G_i||(c_i^* + k_i^*||z||) \\
&\quad -||B_2^T C_2^T s||||G_i||(\hat{c}_i + \hat{k}_i||z||)\Big\} \\
&\quad +\sum_{i=1}^{r}\alpha_i\left(\epsilon_1\tilde{c}_i\hat{c}_i - ||G_i||||B_2^T C_2^T s||\tilde{c}_i\right) \\
&\quad +\sum_{i=1}^{r}\alpha_i\left(\epsilon_2\tilde{k}_i\hat{k}_i - ||G_i||||B_2^T C_2^T s||||z||\tilde{k}_i\right) \\
&= -\mu||s|| + \sum_{i=1}^{r}\alpha_i\left(\epsilon_1\tilde{c}_i\hat{c}_i + \epsilon_2\tilde{k}_i\hat{k}_i\right). \qquad (40)
\end{aligned}$$

Since the facts that

$$\begin{aligned}
\epsilon_1\tilde{c}_i\hat{c}_i &= \frac{\epsilon_1}{2}\left(2\tilde{c}_i c_i^* - 2\tilde{c}_i^2\right) \\
&= \frac{\epsilon_1}{2}\left(-\tilde{c}_i^2 - (\tilde{c}_i - c_i^*)^2 + c_i^{*2}\right) \\
&\leq -\frac{1}{2}\epsilon_1\tilde{c}_i^2 + \frac{1}{2}\epsilon_1 c_i^{*2}, \qquad (41) \\
\epsilon_2\tilde{k}_i\hat{k}_i &\leq -\frac{1}{2}\epsilon_2\tilde{k}_i^2 + \frac{1}{2}\epsilon_2 k_i^{*2} \qquad (42)
\end{aligned}$$

hold, it yields that

$$\begin{aligned}
\dot{V} &\leq -\mu||s|| - \frac{1}{2}\sum_{i=1}^{r}\alpha_i\left(\epsilon_1\tilde{c}_i^2 + \epsilon_2\tilde{k}_i^2\right) + \varepsilon \\
&= -\mu||s|| + \varepsilon \\
&\quad -\frac{1}{2}\sum_{i=1}^{r}\alpha_i\left(\epsilon_1\gamma_{1i}\gamma_{1i}^{-1}\tilde{c}_i^2 + \epsilon_2\gamma_{2i}\gamma_{2i}^{-1}\tilde{c}_i^2\tilde{k}_i^2\right), \qquad (43)
\end{aligned}$$

where

$$\varepsilon \leq \frac{1}{2}\sum_{i=1}^{n}(\epsilon_1 c_i^{*2} + \epsilon_2 k_i^{*2}). \qquad (44)$$

Let

$$\begin{aligned}
\eta_1 &= \min\{\alpha_1\epsilon_1\gamma_{11}, \alpha_2\epsilon_1\gamma_{12}, \ldots, \alpha_r\epsilon_1\gamma_{1r}\} \qquad (45) \\
\eta_2 &= \min\{\alpha_1\epsilon_2\gamma_{21}, \alpha_2\epsilon_2\gamma_{22}, \ldots, \alpha_r\epsilon_2\gamma_{2r}\}, \qquad (46)
\end{aligned}$$

then,

$$\begin{aligned}
\dot{V} &\leq -\mu s^T s - \frac{1}{2}\sum_{i=1}^{r}\left(\eta_1\gamma_{1i}^{-1}\tilde{c}_i^2 + \eta_2\gamma_{2i}^{-1}\tilde{k}_i^2\right) + \varepsilon \\
&\leq -\eta\left\{\frac{1}{2}s^T s + \frac{1}{2}\sum_{i=1}^{r}\left(\gamma_{1i}^{-1}\tilde{c}_i^2 + \gamma_{2i}^{-1}\tilde{k}_i^2\right)\right\} + \varepsilon \\
&= -\eta V + \varepsilon, \qquad (47)
\end{aligned}$$

where

$$\eta = \min\{2\mu, \eta_1, \eta_2\}. \qquad (48)$$

From (47) we have

$$V \leq \frac{\varepsilon}{\eta} + \left(V(0) - \frac{\varepsilon}{\eta}\right)e^{-\eta t}, \qquad (49)$$

where $V(0) = V(z(t))|_{t=0}$. Since that $\eta > 0$, the second block on the right side of (49) tends to 0 when $t \to \infty$. Therefore, we can get that there exists $\mathcal{T}$ such that for $t \geq \mathcal{T}$ it satisfies

$$\|s\| \leq \tau \qquad (50)$$

where

$$\tau = \sqrt{\frac{\varepsilon}{\eta}}. \qquad (51)$$

This completes the proof. □

Remark 3: In the control law, there are two switching functions, ψ_i and ϕ_i, in which ϕ_i contains a sign function. Such a sign function usually leads to control chattering, which is undesirable in practice because it involves high control activity and further may excite unmodeled high frequency plant dynamics. Fortunately, switching function ψ_i is not around the sliding surface, $s = 0$. This implies that when the system state enters the region $||s|| \leq \tau$, the chattering phenomenon can be avoided most likely, which can be confirmed in the simulation shown later on. In case the chattering phenomenon occurs, it can be eliminated by replacing all sign functions with the so-called saturation functions [9].

C. Relaxing Conservatism

In theorem 2, it is desirable to have the largest η and the smallest τ so that the sliding mode s can shrink most quickly in a ball centered at the sliding surface $s = 0$ with radius τ. Therefore, the results obtained above are basically conservative since it took no account of the matter.

On the other hand, to our best knowledge, there is not an analytical approach to solve the optimization problem with respect

to η and τ. Therefore, the only way left to us is that we do our best to increase η and reduce τ. From (45), (46) and (48), we observe that a bigger μ, ϵ_j, γ_{ji} ($j = 1, 2, i = 1, 2, \cdots, r$), can help make η larger. At the same time, from (44) and (51) we know that a bigger ϵ_j leads to a bigger ε, further to a bigger τ. That is, there is a trade-off between making τ small and η big in terms of ϵ_j. Therefore, in order to make η big, we can do something on μ, ϵ_j, and γ_{ji} as follows.

- Choosing bigger μ, γ_{ji}. In the adaptive laws (29), (30) since γ_{ji} are free design parameters, basically they can be chosen arbitrarily large. However, there is a limit that large γ_{ji} can lead to big η_j, further to a big η due to the minimum in function in (48).
- Choosing bigger ϵ_j. As γ_{ji}, they are free design parameters in (29), (30) as well and can be chosen arbitrarily large. However, large ϵ_j will lead to a large τ at the same time. That is, we have to make a compromise between making η big and τ small in terms of ϵ_j.

Next, let us consider the problem of making τ small. As mentioned previously, since choosing small ϵ_j to make τ small is in conflict with increasing η, therefore, there is a limit on doing something about ϵ_j.

Again, let us focus on (44). Instead of (29), (30), if the adaptive laws are synthesized by

$$\dot{\hat{c}}_i(t) = \alpha_i \gamma_{1i} \left\{ -\epsilon_1 (\hat{c}_i(t) - c_{0i}) + ||G_i|| ||B_2^T C_2^T s|| \right\}, \quad (52)$$

$$\dot{\hat{k}}_i(t) = \alpha_i \gamma_{2i} \left\{ -\epsilon_2 (\hat{k}_i(t) - k_{0i}) + ||G_i|| ||B_2^T C_2^T s|| ||z|| \right\} \quad (53)$$

where γ_{ji}, and ϵ_{ji} are positive design parameters, c_{0i}, k_{0i} are a priori estimates of c_i^*, k_i^*, respectively, then (44) becomes

$$\varepsilon \leq \frac{1}{2} \sum_{i=1}^{n} \left\{ \epsilon_1 (c_i^* - c_{0i})^2 + \epsilon_2 (k_i^* - k_{0i})^2 \right\}. \quad (54)$$

From (54), we can see that the better a priori estimates for c_i^* and k_i^*, the smaller ε which further leads to a smaller τ in (51) we can get. Of course, if we do not have such knowledge about c_i^* and k_i^*, we can just put $c_{0i} = 0, k_{0i} = 0$.

IV. Simulation

Consider the well-studied example of balancing an inverted pendulum on a cart. The equations of motion for the pendulum are

$$\begin{cases} \dot{x}_1 = x_2, \\ \dot{x}_2 = \frac{g \sin(x_1) - \frac{aml x_2^2 \sin(2x_1)}{2} - a \cos(x_1)(u + \mathcal{U})}{\frac{4l}{3} - aml \cos^2(x_1)}, \end{cases} \quad (55)$$

where x_1 denotes the angle of the pendulum from the vertical; x_2, the angular velocity; u, the force applied to the cart; $g = 9.8 m/s^2$, the gravity constant; m, the mass of the pendulum; M, the mass of the cart (in kilo-Newton); $\mathcal{U}$, the lumped uncertainty, which is assumed to be $\mathcal{U} = 0.5 \cos(2\pi) + 1.5 \cos(4\pi)||x||$; $a = \frac{1}{m+M}$. We choose $m = 2.0$ kg, $M = 8.0$ kg, $l = 0.5$ m in this simulation.

The control objective is to balance the inverted pendulum. Here, Referring to [11] we approximate the system by the following two-rule T-S fuzzy model:

Plant Rule 1 : IF x_1 is $\widetilde{0}$
THEN $\dot{x} = A_1 x + B_1 (u + \mathcal{U}_1)$;

Plant Rule 2 : IF x_1 is $\pm \widetilde{\pi/2}$
THEN $\dot{x} = A_2 x + B_2 (u + \mathcal{U}_2)$,

where

$$A_1 = \begin{bmatrix} 0 & 1 \\ \frac{g}{\frac{4l}{3} - aml} & 0 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 0 \\ \frac{-a}{\frac{4l}{3} - aml} \end{bmatrix},$$

$$A_2 = \begin{bmatrix} 0 & 1 \\ \frac{2g}{\pi(\frac{4l}{3} - aml\beta^2)} & 0 \end{bmatrix}, \quad B_2 = \begin{bmatrix} 0 \\ \frac{-a\beta}{\frac{4l}{3} - aml\beta^2} \end{bmatrix},$$

$\beta = \cos(88^o)$; $\widetilde{0}, \widetilde{\pi/2}$ are fuzzy sets characterized by the following membership functions:

$$\mu_{\widetilde{0}}(x_1) = \begin{cases} \cos(x_1), & -\frac{\pi}{2} \leq x_1 \leq \frac{\pi}{2} \\ 0, & \text{otherwise} \end{cases}$$

$$\mu_{\widetilde{\pi/2}}(x_1) = \begin{cases} 1 - \cos(x_1), & -\frac{\pi}{2} \leq x_1 \leq \frac{\pi}{2} \\ 0, & \text{otherwise} \end{cases};$$

$\mathcal{U}_i$ ($i = 1, 2$) is corresponding with the lumped uncertainty in the plant (55), and satisfies *A2* in section II with $c_i^* = 0.5, k_i^* = 1.5$. Regarding their estimates, $\hat{c}_i$, $\hat{k}_i$, are tuned by adaptive laws (29), and (30) with $\gamma_{1i} = \gamma_{2i} = 0.1$, $\epsilon_{1i} = \epsilon_{2i} = 0.1$, respectively.

As to the assumption *A1*, we set $B^T = [0, -1]$ and $G_1 = 0.1765, G_2 = 0.0052$ due to the facts that $B_1^T = [0, -0.1765], B_2^T = [0, -0.0052]$ in this simulation. Since B is already composed of 0 (upper part) and -1 (lower part) in the vector, there is no longer to use an orthogonal matrix T_r for B's transformation in order to get the form, $[0, B_2]^T$ in (4). By setting $C_2 = I$ and using the software package Robust Control Toolbox (MATLAB), $C_2 = -0.5$ by solving LMIs (24).

Fig. 1 depicts the response of the system state, where the solid line is x_1 and the dotted line is x_2, with initial values $x_1(0) = 87^\circ, x_2(0) = 0$ under the control law (25) where μ is set to be 0.05. The control input u, and the sliding motion s are shown in Figs. 2, 3, respectively. We observe that when system state enters around the sliding surface, the chattering phenomenon no longer exists just we claimed in Remark 3. In addition, adaptive parameters in (29) and (30) are shown in Fig. 4. From the simulation results, it can be seen that the control approach proposed in this paper works well.

V. Conclusions

An adaptive fuzzy SMC approach for a class of nonlinear dynamical systems with lumped parameter uncertainties was proposed and analyzed. In particular, the approach could deal with the T-S fuzzy model under consideration with different control matrices in the fuzzy rules. As a future work, other uncertainties including linearization error between the real system to be controlled and its T-S fuzzy model, parameter perturbations, and external disturbances will be considered in the control approach to improve its robustness.

Mixed H_2/H_∞ Optimization with Discrete Smith Predictor for Fuzzy Decentralized Control of Nonlinear Interconnected Discrete Dynamic Systems with Large Delay

Name: Chih-Lyang Hwang, *Senior Member*, *IEEE; e-mail:* chih-lyang_hwang@hotmail.com
Department of Electrical Engineering of National Taiwan University of Science and Technology, Taiwan, R.O.C.

Abstract – **Each subsystem of a nonlinear interconnected discrete dynamic delayed system is approximated by a weighted combination of *L* pulse transfer function delayed systems (PTFDS). To deal with large time-delay of the controlled system with acceptable performance, a two-degree-of-freedom control is designed. At beginning, the H_2- norm of the difference between the transfer function of a reference model and the closed-loop transfer function of the *jth* PTFDS of subsystem *i* is minimized to obtain a suitable frequency response. In addition, the $H_\infty-$ norm of the weighted sensitivity function between the output disturbance and its corresponding output of the *jth* PTFDS is simultaneously minimized to reduce its effect. In summary, the proposed control not only accomplishes the above-mentioned optimizations but also attenuates the effect of time-delay. Furthermore the comparisons between with and without discrete Smith predictor are presented. The main contributions of this paper are three folds. First, the large nominal time-delay is compensated by a discrete Smith predictor. Secondly, the proposed control can achieve the suitable response of the closed-loop system with the attenuation of output disturbance and time-varying delay. Thirdly, an observer is not needed and the discrete controller is more suitable for the implementation.**

Keywords: **Nonlinear interconnected discrete dynamic delayed system, Decentralized control, Fuzzy linear model, H_2- optimization, $H_\infty-$ optimization, Discrete Smith predictor**.

I. INTRODUCTION

Time-delay or dead time is frequently encountered in many dynamic systems. The delay of information transmission between different subsystems, such as engine idle speed control [1], damping control in power system [2], playout or monitoring [3], an internet-based control [4], -[6] and the image processing for the dynamic target tracking of visual servo system [7], teleoperation [8]-[10], results in a time-delay system. By implementing feedback control in (especial for large) time-delay system it always results in certain restrictions on achievable system bandwidth and the maximum available gain [1]-[10]. Based on the nominal delay of each subsystem, in this paper the reduced effect of time-varying delay is achieved by Smith predictor [9]-[12].

In the past three decades, the performance properties of interconnected systems have been widely studied [12]. However, the control performance of nonlinear interconnected systems has yet received sufficient attention. Due to complicated physical configuration and high dimensionality of interconnected systems, the implementation of these systems with centralized control is neither economically plausible nor technically possible. In centralized control scheme, there are drawbacks such as the complexities in the design and debugging process. These in turn require scheduling of data collection and data storage etc. As a result, decentralized control scheme is considered a more favorable alternative for interconnected systems. However due to the inherent nonlinear interconnections among subsystems and it does not exist any efficient decentralized control scheme in dealing with interconnected nonlinear systems (e.g., the attenuation of uncertainty) [12], it needs to resort to new control scheme for such interconnected nonlinear system.

Recently, the use of fuzzy control for nonlinear systems has drawn many interests. Many successful applications have been reported in the literatures (e.g., [13], [14]). In addition, fuzzy T-S model with delayed control systems have been discussed (e.g., [15], [16]). In many of the literatures on delayed control systems, *N* linear (or bilinear) continuous-time (or discrete-time) state-space or transfer function systems for different fuzzy sets are considered. Under these circumstances, an alternative method is considered by using different pulse transfer functions with the same time delay to model the consequent parts of every subsystem. The controller design is therefore directed, simplified and more implementable. In addition, certain work does not attenuate the effect of time-delay. Facing these challenges, in this paper, we propose a controller design via mixed H_2/H_∞ optimization with discrete Smith predictor to obtain a robust and desired system performance.

Mixed H_2/H_∞ control problem has become a popular research topic in recent years [12], [17]. The response shaping based on H_2- optimization to reduce the sluggish and oscillatory effects is often adopted [18]. On the other hand, $H_\infty-$ optimization is usually used as the robust control methodology for diminishing the effect of disturbance [5], [6], [17]. As a result, the mixed H_2/H_∞ control problem is developed to robust system stability and to improve system performance [12]. Differences between this paper and previous papers [12] and [17] are described as follows: The paper in [17] did not discuss the time-delay property and its compensation; the paper in [12] discussed the controller design in the continuous time system and did not compare the

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

controller with and without Smith predictor.

For an easy implementation of the proposed controller, a discrete design ([17], [19]) is considered. At the outset, a specific pulse transfer function system (PTFDS) with respect to a specific operating point is obtained by implementing the least-square parameter estimation technique. After that a nominal and large time-delay is also estimated. To enhance system performance a two-degree-of-freedom controller with discrete Smith predictor is employed to each PTFDS. Subsequently, the H_2-norm of the difference between an assigned reference model and the closed-loop transfer function of the *jth* PTFDS of subsystem *i* is minimized to attain a suitable frequency response without causing any oscillating and sluggish effects. However, the system performance may be deteriorated or even unstable due to the output disturbance caused by the interconnections among subsystems, the interactions from other PTFDSs, the error from fuzzy modeling, and/or the nonlinear time-varying uncertainties. To prevent this, the $H_\infty-$ norm of the weighted sensitivity of the *jth* PTFDS between the output disturbance and its output is minimized to reduce its effect. Moreover, a specific weighted function can be selected to reject certain mode of output disturbance or to attenuate its effect in the system frequency response. In this operation it does not need to solve the Diophantine equation; it has the computational advantage especially for low-order system.

II. Mathematical Preliminaries

A polynomial $\in \Re(z)$ is defined as $A(d)=a_{n_a}d^{n_a}+a_{n_a-1}d^{n_a-1}+...+a_0$, where a_i for $i=0,1,...,n_a$ denotes bounded coefficients, n_a stands for the system degree (i.e., if $a_{n_a}\neq 0$, $\deg\{A(d)\}=n_a$), and $d=z^{-1}$ denotes the backward shift operator (i.e., $z^{-1}y(k)\equiv y(k-1)$) or a complex variable in the z-transform. The z-transform of a discrete-time signal $y(k)$ is denoted by $Y(z^{-1})=Z\{y(k)\}$. If $a_0=1$ it is called a monotonic polynomial. The notations of $A_+(d)$ and $A_-(d)$ denote respectively the stable and unstable part of $A(d)$. The polynomial $A_+(d)$ is assumed to be monotonic to obtain a unique factorization. Define $\|G(d)\|_2=\|G(e^{-jw})\|_2=\left[\int_{-\infty}^{\infty}|G(e^{jw})|^2 dw/2\pi\right]^{1/2}$, where $G\in H_2$, the set H_2 consists of all analytic functions G in $|z|\geq 1$. A rational function $G(d)$ in H_2 is called inner if $|G(e^{-jw})|=1$ for almost all *w*, and it is outer if it has no zeros in $|z|\geq 1$. For any rational functions $G(d)$ and $H(d)$ in H_2, if $G(d)$ is inner function and $\|G(d)H(d)\|_2$ is well defined, then $\|G(d)H(d)\|_2=\|H(d)\|_2$. When a rational function multiplies by an inner function it preserves the value of the norm [12], [17]. The rational function $A_-(d)/\tilde{A}_-(d)$ is a stable, causal, and all-pass operator, i.e., $|A_-(e^{-jw})/\tilde{A}_-(e^{-jw})|=1$ for all *w*, and $\tilde{A}_-(d)=d^{n_{a-}}A_-(d^{-1})$. The notation $\|A(e^{-jw})\|_\infty=ess.\sup_w|A(e^{-jw})|$ is defined. The symbol $A_i^j(d)$ denotes a polynomial with bounded coefficients, its upper subscript *j* and lower subscript *i* respectively represent the polynomial of the *jth* PTFDS of subsystem *i*. The following lemma is given to explain the result of the minimax optimization for the *jth* PTFDS of subsystem *i*.

Lemma 1 [12], [17]: (i) The optimal $C_{2_i}^{j^*}=\left[W_i^j(d)V_i^j(d)\right]^*$, which minimizes $\|W_i^j(d)V_i^j(d)\|_\infty$, is of an all-pass form:

$$\left[W_i^j(d)V_i^j(d)\right]^*=\begin{cases}\rho_i^j\tilde{\Phi}_i^j(d)/\Phi_i^j(d), & \text{if } n_{b_{-i}}^j=n_{\phi_i}^j+1\geq 1\\ 0, & \text{if } n_{b_{-i}}^j=0\end{cases}$$

where the polynomial $\Phi_i^j(d)$ is monic and stable.

(ii) The constants ρ_i^j and $\varphi_{m_i}^j\ (1\leq m\leq n_{\phi_i}^j)$ are real and are uniquely determined by the interpolation constraints (29) as described later. Furthermore, the minimized $\|W_i^j(d)V_i^j(d)\|_\infty$ is given by

$$\min\|W_i^j(d)V_i^j(d)\|_\infty=\left\|\left[W_i^j(d)V_i^j(d)\right]^*\right\|_\infty=|\rho_i^j|.$$

III. Problem Formulation

Consider the following nonlinear interconnected discrete dynamic delayed system (NIDDDS) Σ that contains *N* subsystems Σ_i for $i=1,2,...,N$:

$$y_i(k)=f_{ii}\left[\varphi_i(k-\tau_i(k))\right]+\sum_{j=1,j\neq i}^{N}f_{ij}\left[\varphi_j(k-\tau_j(k))\right],\quad i=1,2,...,N \tag{1}$$

where $\varphi_i(k)=[y_i(k-1)\ \cdots\ y_i(k-n)\ \ u_i(k-1)\ \cdots\ u_i(k-m)]$; $y_i(k)$ and $u_i(k)$ denote the system output and the system input of the *ith* subsystem at time *k*, respectively; are the; $f_{ii}\left[\varphi_i(k-\tau_i(k))\right]$ denotes the unknown but smooth nonlinear delay function of the *ith* subsystem; $\tau_i(k)\geq 0$ is the time-varying delay of the *ith* subsystem; $f_{ij}\left[\varphi_j(t-\tau_j(k))\right]$, $j\neq i$, $i,j=1,2,...,N$, represent the smooth but unknown interconnections of the *ith* subsystem Σ_i, brought about by other subsystems Σ_m, where $m=1,...,N$, and $m\neq i$.

Based on the approximation of the fuzzy linear model [12], a fuzzy dynamic model to represent the local linear input/output relations of the *ith* subsystem (see Fig. 1) is described by the fuzzy IF-THEN rules. The *jth* rule of the fuzzy dynamic model for the *ith* subsystem Σ_i with uncertainties is expressed in the following form:

System Rule j: IF $z_{1_i}(k)$ is $M_{1_i}^j$... and $z_{\bar{m}_i}(k)$ is $M_{\bar{m}_i}^j$ THEN

$$y_i(k)=d^{\bar{\tau}_i}B_i^j(d)u_i(t)\big/A_i^j(d)+\sum_{m=1,\,m\neq i}^{N}d^{\tau_{im}(k)}B_{im}^j(d)u_m(k)\Big/A_{im}^j(d)$$
$$+\sum_{m=1,\,m\neq i}^{N}\Delta_{im}^j(u_m(k),k)+w_i(k), \qquad (2)$$

where $j=1,2,...,L$, $i=1,2,...,N$; $\bar{m}_i\le n_{a_i}^j+n_{b_i}^j+1, A_i^j(1)=1$; L is the number of IF-THEN rules; $z_{1_i}(k),...,z_{\bar{m}_i}(k)$ are premise variables, which are functions of $y_i(k-1),...,y_i(k-n)$, $u_i(k-1),...,u_i(k-m)$; $\bar{\tau}_i$ is a positive integer denoting the nominal delay of subsystem i (in this paper, it is generally several hundred); $y_i(k)$ also denotes the output from the *jth* IF-THEN rules; $d^{\bar{\tau}_i}B_i^j(d)u_i(k)\big/A_i^j(d)$ is the *jth* nominal and known PTFDS of subsystem i; $\sum_{m=1,m\neq i}^{N}d^{\tau_{im}(k)}B_{im}^j(d)u_m(d)\big/A_{im}^j(d)$ denotes the linear coupling terms; $\sum_{m=1,m\neq i}^{N}\Delta_{im}^j(u_m(k),k)$ denotes the nonlinear time-varying uncertainties, that are relatively bounded by $c_0+\sum_{i=1}^{N}c_i\|u_i(k)\|_2$, where $c_i\ge 0,\ i=0,1,...,N,$ and caused by the interconnections of other subsystems and the interactions from other PTFDSs; and $w_i(k)$ denotes the approximation error of the fuzzy model of the *ith* subsystem, e.g., time-varying delay, parameter variations. Assume that $A_i^j(d)$ and $B_i^j(d)$ for $i=1,2,...,N,\ j=1,2,...,L$ are coprime. One of main advantages of this form is that no state estimator is required; then the control design becomes simple and effective.

The output of the overall fuzzy system of the *ith* subsystem is inferred as follows:

$$y_i(k)=\sum_{j=1}^{L}\mu_i^j(k)\left\{d^{\bar{\tau}_i}B_i^j(d)u_i(k)\big/A_i^j(d)+\tilde{d}_{o_i}^j(k)\right\} \qquad (3)$$

where

$$\tilde{d}_{o_i}^j(k)=\sum_{m=1,\,m\neq i}^{N}\left\{d^{\tau_{im}(k)}B_{im}^j(d)u_m(k)\big/A_{im}^j(s)+\Delta_{im}^j(u_m(k),k)\right\}+w_i(k) \qquad (4)$$

$$\mu_i^j(k)=h_i^j(k)\Big/\sum_{j=1}^{L}h_i^j(k) \text{ and } h_i^j(t)=\prod_{m=1}^{\bar{m}_i}M_i^k(z_{i_m}(t)). \qquad (5)$$

It is assumed that

$$h_i^j(k)\ge 0,\ \sum_{j=1}^{L}\mu_i^j(k)=1 \quad \text{for } i=1,2,...,N,\ j=1,2,...,L, \text{ and } \forall k. \qquad (6)$$

It is also assumed that the fuzzy controller shares the same fuzzy sets with the fuzzy system (2).

Control Rule j: IF $z_{1_i}(k)$ is $M_{1_i}^j$... and $z_{\bar{m}_i}(k)$ is $M_{\bar{m}_i}^j$ THEN

$$u_i(k)=-S_i^j(d)y(k)\big/R_i^j(d)+T_i^j(d)r_i(k)\big/R_i^j(d)$$
$$-S_i^j(d)B_i^j(d)\left(1-d^{\bar{\tau}_i}\right)u_i(k)\Big/\left(R_i^j(d)A_i^j(d)\right) \qquad (7)$$

where the polynomials $R_i^j(d), S_i^j(d)$ and $T_i^j(d)$ are determined to achieve the control of the *jth* PTFDS of subsystem i, and the last term in (7) denotes the Smith predictor to deal with the nominal system delay. The overall fuzzy control of the *ith* subsystem is then inferred as follows:

$$u_i(k)=\sum_{j=1}^{L}\mu_i^j(k)\left\{-S_i^j(d)y(k)\big/R_i^j(d)+T_i^j(d)r_i(d)\big/R_i^j(d)\right.$$
$$\left.-S_i^j(d)B_i^j(d)\left(1-d^{\bar{\tau}_i}\right)u_i(k)\Big/\left(R_i^j(d)A_i^j(d)\right)\right\}. \qquad (8)$$

The nominal closed-loop characteristic polynomial of the *jth* PTFDS of subsystem i is also described as follows:

$$A_{c_i}^j(d)=A_i^j(d)R_i^j(d)+B_i^j(d)S_i^j(d). \qquad (9)$$

Hence, the closed-loop output response of the *ith* subsystem, i.e., $y_i(t)$, is derived from (3) and (7); i.e.,

$$y_i(k)=\sum_{j=1}^{L}\mu_i^j(k)\left\{d^{\bar{\tau}_i}B_i^j(d)\left[u_i^j(k)+u_i(k)-u_i^j(k)\right]\Big/A_i^j(d)+\hat{d}_{o_i}^j(k)\right.$$
$$=\sum_{j=1}^{L}\mu_i^j(k)\left\{d^{\bar{\tau}_i}B_i^j(d)\left[-S_i^j(d)y_i(k)+T_i^j(d)r_i(k)\right]\Big/\left[A_i^j(d)R_i^j(d)\right]\right.$$
$$\left.+\psi_i^j(k)+\hat{d}_{o_i}^j(k)\right\}$$
$$=\sum_{j=1}^{L}\mu_i^j(k)\left\{d^{\bar{\tau}_i}B_i^j(d)\left[-S_i^j(d)y_i(k)+T_i^j(d)r_i(k)\right]\Big/\left[A_i^j(d)R_i^j(d)\right]\right.$$
$$\left.+d_{o_i}^j(k)\right\} \qquad (10a)$$

where $u_i^j(k)$ denotes the control input of the *jth* PTFDS of subsystem i (i.e., (7)),

$$\psi_i^j(k)=d^{\bar{\tau}_i}B_i^j(d)\left[u_i(k)-u_i^j(k)\right]\Big/A_i^j(d),$$
$$d_{o_i}^j(k)=\hat{d}_{o_i}^j(k)+\psi_i^j(k). \qquad (10b)$$

The signal $\psi_i^j(k)$ denotes the interaction on the *jth* PTFDS of subsystem i resulting from other PTFDSs, including the error between nominal delay and time-varying delay. In summary, $d_{o_i}^j(k)$ denotes the output disturbance of the *jth* PTFDS of subsystem i caused by the interconnections stemming from other subsystems, the interactions resulting from other PTFDSs, the approximation error of fuzzy-model, and the nonlinear time-varying uncertainties. In general, the corresponding output disturbance is not small and even including various frequency components. In this situation, an effective controller is required to achieve satisfactory performance.

After some mathematical manipulations of (10a) and using (7), the following is achieved.

$$\sum_{j=1}^{L}\frac{\mu_i^j(k)A_{c_i}^j(d)}{A_i^j(d)R_i^j(d)}\left\{y_i(k)-\frac{d^{\bar{\tau}_i}B_i^j(d)T_i^j(d)}{A_{c_i}^k(s)}r_i(k)\right.$$
$$\left.-\frac{A_i^j(d)R_i^j(d)}{A_{c_i}^j(d)}d_{o_i}^j(k)\right\}=0. \qquad (11)$$

Hence, a sufficient condition for the validity of (11) is the term in the braces $\{\cdot\}$ of (11) to be equal to zero; i.e.,

$$y_i(k)=d^{\bar{\tau}_i}B_{-_i}^j(d)L_i^j(d)r_i(k)-V_i^j(d)d_{o_i}^j(k) \qquad (12a)$$

where

$$L_i^j(d)=B_{+_i}^j(d)T_i^j(d)\big/A_{c_i}^j(d),$$
$$V_i^j(d)=A_i^j(d)R_i^j(d)\big/A_{c_i}^j(d). \qquad (12b)$$

The aforementioned output disturbance is supposed to be bounded as follows (see (4), (10b)):

$$\left\| d_{o_i}^j(k) \right\|_2 \le \alpha_{0_i}^j + \sum_{m=1}^{N} \alpha_{m_i}^j \left\| u_i(k) \right\|_2 \quad (13)$$

where $\alpha_{0_i}^j$ and $\alpha_{m_i}^j$, $i, j, m = 1, 2, ..., N$ are bounded [12].

Assume that the input/output relationship between $r_i(t)$ and $\bar{y}_i^j(t)$, for a stable reference model of the *jth* PTFDS of subsystem *i*, is as follows:

$$\bar{y}_i^j(k) = d^{\bar{\tau}_i} G_i^j(d) r_i(k) / F_i^j(d) \quad (14)$$

where $G_i^j(d)$ and $F_i^j(d)$ for $i = 1, 2, ..., N, j = 1, 2, ..., L$ are coprime, and $F_i^j(d)$ is a stable monic polynomial with degree $n_{f_i}^j$. The purpose of using a reference model is to shape the response of the closed-loop of the *jth* PTFDS of subsystem *i*. For tracking a set-point, $G_i^j(1)/F_i^j(1) = 1$ is assigned.

For synthesizing the problem, two cost functions in the H_2 – norm and H_∞ – norm spaces are defined as follows [12], [17]:

$$C_{1_i}^j = \left\| d^{\bar{\tau}_i} \left[G_i^j(d)/F_i^j(d) - B_{-_i}^j(d) L_i^j(d) \right] \right\|_2 \quad \text{and} \quad C_{2_i}^j = \left\| W_i^j(d) V_i^j(d) \right\|_\infty \quad (15)$$

For $d_{o_i}^j(k) = 0$, the optimal model matching to the cost function $C_{1_i}^j$ is addressed as follows: Based on the norm-preserving property of the inner function (i.e., $\left\| e^{-jw\bar{\tau}_i} \right\| = 1 \forall w$), from eqn. (15) $C_{1_i}^j$ is reduced to the following equation:

$$C_{1_i}^j = \left\| G_i^j(d)/F_i^j(d) - B_{-_i}^j(d) L_i^j(d) \right\|_2. \quad (16)$$

At beginning, the polynomial $B_{-_i}^j(d)$ is factorized as

$$B_{-_i}^j(d) = B_{-_i}^j(d^{-1}) \cdot B_{-_i}^j(d) / B_{-_i}^j(d^{-1}) \quad (17)$$

where $B_{-_i}^j(d)/\tilde{B}_{-_i}^j(d)$ is an inner function and the remaining $\tilde{B}_{-_i}^j(d)$ is an outer function. Then

$$C_{1_i}^j = \left\| G_i^j(d)/F_i^j(d) - L_i^j(d)\tilde{B}_{-_i}^j(d) B_{-_i}^j(d)/\tilde{B}_{-_i}^j(d) \right\|_2 = \left\| B_{-_i}^j(d)/\tilde{B}_{-_i}^j(d) \left[\tilde{B}_{-_i}^j(d) G_i^j(d) / \left(F_i^j(d) B_{-_i}^j(d) \right) - L_i^j(d)\tilde{B}_{-_i}^j(d) \right] \right\|_2. \quad (18)$$

Similarly, based on the norm-preserving property of the inner function, (18) is simplified as follows:

$$\left(C_{1_i}^j \right)^2 = \left\| \tilde{B}_{-_i}^j(d) G_i^j(d) / \left(F_i^j(d) B_{-_i}^j(d) \right) - L_i^j(d)\tilde{B}_{-_i}^j(d) \right\|_2^2. \quad (19)$$

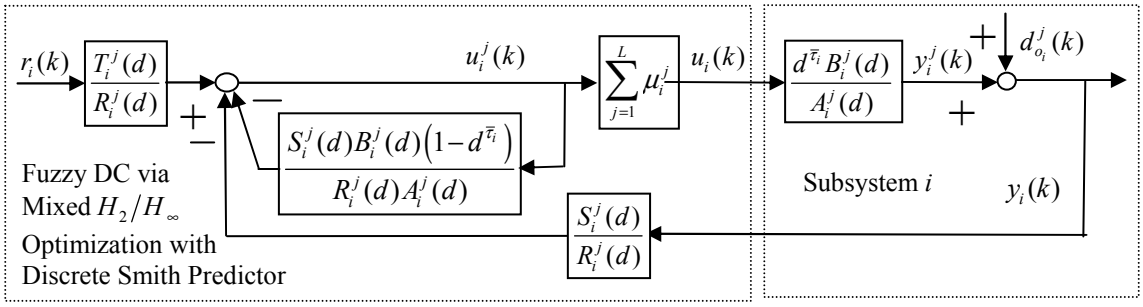

Fig.1.The overall control block diagram.

where the weighted function $W_i^j(d)$ denotes a suitable rational function for the *jth* PTFDS of subsystem *i*.

The objectives of this paper are expressed as follows (cf. Fig. 1): Search for a control function (i.e., the polynomials $R_i^j(d), S_i^j(d)$, and $T_i^j(d)$) so as to simultaneously satisfy the following two requirements: (i) For $d_{o_i}^j(k) = 0$, the cost function $C_{1_i}^j$ is minimized, (ii) The cost function $C_{2_i}^j$ is simultaneously minimized.

IV. Controller Design using Mixed H_2/H_∞ Optimization

There are two processes in the design of the decentralized fuzzy controller via mixed H_2/H_∞ optimization for the NIDDDS (1).

A. Minimization of $C_{1_i}^j$

Decomposing the first term yields

$$B_{-_i}^j(d^{-1}) G_i^j(d) / \left(F_i^j(d) B_{-_i}^j(d) \right) = \bar{F}_i^j(d)/F_i^j(d) + \bar{B}_i^j(d)/B_{-_i}^j(d) \quad (20)$$

Rewrite (20) as

$$\tilde{B}_{-_i}^j(d) G_i^j(d) = B_{-_i}^j(d) \bar{F}_i^j(d) + F_i^j(d) \bar{B}_i^j(d)$$

where $\bar{F}_i^j(d)$ and $\bar{B}_i^j(d)$ are some polynomials to be determined, which are interrelated respectively with the control polynomial $T_i^j(d)$ and the optimum value of $C_{1_i}^j$.

$$\text{or } \tilde{B}_{-_i}^j(d) G_i^j(d) - B_{-_i}^j(d) \bar{F}_i^j(d) \Big|_{d = z_1^j, ..., z_{n_{f_i}}^j} = 0 \quad (21)$$

where $z_1^j, ..., z_{n_{f_i}}^j$ are the zeros of $F_i^j(d) = 0$. Then the polynomial $\bar{B}_i^j(d)$ can be obtained from (21) by long division. Substituting (20) into (19) gives

$$\left(C_{1_i}^j \right)^2 = \left\| \bar{F}_i^j(d)/F_i^j(d) + \bar{B}_i^j(d)/B_{-_i}^j(d) - L_i^j(d)\tilde{B}_{-_i}^j(d) \right\|_2^2 \quad (22)$$

where the second term in the right hand side of (22) is

unstable, and the remaining terms are stable. By orthogonality, it follows that

$$\left(C_{1_i}^j\right)^2 = \left\| \bar{F}_i^j(d)/F_i^j(d) - L_i^j(d)\tilde{B}_{-_i}^j(d)\right\| + \left\|\bar{B}_{-_i}^j(d)/B_{-_i}^j(d)\right\|_2^2 \geq \left\|\bar{B}_i^j(d)/B_{-_i}^j(d)\right\|_2^2. \quad (23)$$

Hence, the optimal $L_i^j(d)^*$ and $C_{1_i}^{j*}$ are achieved as follows:

$$L_i^j(d)^* = \bar{F}_i^j(d)/\left(F_i^j(d)\tilde{B}_{-_i}^j(d)\right) \quad (24)$$

$$C_{1_i}^{j*} = \left\|\bar{B}_i^j(d)/B_{-_i}^j(d)\right\|_2. \quad (25)$$

Comparing (24) and (12b) and using (9) it gives

$$A_i^j(d)R_i^j(d) + B_i^j(d)S_i^j(d) = B_{+_i}^j(d)\tilde{B}_{-_i}^j(d)F_i^j(d)X_i^j(d) \quad (26)$$

$$T_i^j(d) = \bar{F}_i^j(d)X_i^j(d) \quad (27)$$

where $X_i^j(d)$ is a stable polynomial. If the reference model contains the unstable zeros of the nominal system, i.e., $G_i^j(s) = B_{-_i}^j(d)\bar{G}_i^j(d)$, for some polynomials $\bar{G}_i^j(d)$, then the perfect model matching (i.e., $C_{1_i}^{j*} = 0$) can be obtained. Then from (20) it has,

$$\bar{F}_i^j(d) = B_{-_i}^j(d^{-1})\bar{G}_i^k(s) \text{ and } \bar{B}_i^j(d) = 0. \quad (28)$$

B. Minimization of $C_{2_i}^j$

In this subsection, the task is to find the polynomials $R_i^j(d)$ and $S_i^j(d)$ such that the optimal $C_{2_i}^j$ is obtained. From previous studies [12], [17], the optimal $\left\|W_i^j(d)V_i^j(d)\right\|_\infty$ must satisfy the following interpolation constraints:

$$V_i^j(p_i^j) = 0, j = 1,2,...,n_{a_{-_i}}^j,\ 1 - V_i^j(z_i^j) = 0, j = 1,2,...,n_{b_{-_i}}^j \quad (29)$$

where $p_i^j (1 \le j \le n_{a_{-_i}}^j)$ and $z_m^j (1 \le j \le n_{b_{-_i}}^j)$ denote the zeros of $A_{-_i}^j(d)$ and $B_{-_i}^j(d)$, respectively.

Remark 1: If the inner loop of Fig. 1 disappears (e.g., [17]), then the characteristic polynomial of the closed-loop system in (9) is replaced by the following equation:

$$A_{c_i}^j(d) = A_i^j(d)R_i^j(d) + d^{\bar{\tau}_i}B_i^j(d)S_i^j(d). \quad (30)$$

Then the second interpolation constraint of (19) is modified as follows:

$$1 - V_i^j(z_i^j) = 0, j = 1,2,...,n_{b_{-_i}}^j + \bar{\tau}_i \quad (31)$$

where $z_m^j (1 \le j \le n_{b_{-_i}}^j + \bar{\tau}_i)$ denote the zeros of $d^{\bar{\tau}_i}B_{-_i}^j(d)$. The degree of $\Phi_i^j(d)$ becomes $n_{\varphi_i}^j = n_{b_{-_i}}^j - 1 + \bar{\tau}_i$, which is large especially for large time-delay system (e.g., $\bar{\tau}_i$ equals several hundred for the internet-based piezoelectric actuator driven table system). In summary, the degrees of control polynomials increase and the effect of time-delay is dominant for the control without using Smith predictor.

Based on the result of *Lemma 1* and the constraint (29), the following equation is achieved

$$V_i^j(d) = \rho_i^j W_{d_i}^j(d)A_{-_i}^j(d)\tilde{\Phi}_i^j(d)/\left[W_{n_i}^j(d)\tilde{A}_{-_i}^j(d)\Phi_i^j(d)\right] \quad (32)$$

where $W_i^j(d) = W_{n_i}^j(d)/W_{d_i}^j(d)$, $W_{n_i}^j(d)$ is a stable polynomial, and $W_{d_i}^j(d)$ contains the zeros in the region $|z| \ge 1$ for rejecting the corresponding output disturbance. In addition, the constraint (29) gives the following result:

$$W_{n_i}^j(d)\tilde{A}_{-_i}^j(d)\Phi_i^j(d) - \rho_i^j W_{d_i}^j(d)A_{-_i}^j(d)\tilde{\Phi}_i^j(d) = B_{-_i}^j(d)Q_i^j(d) \quad (33)$$

where $n_{\varphi_i}^j = n_{b_{-_i}}^j - 1$ and $n_{q_i}^j = n_{w_{n_i}}^j + n_{a_{-_i}}^j - 1$. Or, we can rewrite (33) as (34)

$$W_{n_i}^j(z_i^j)\tilde{A}_{-_i}^j(z_i^j)\Phi_i^j(z_i^j) - \rho_i^j W_{d_i}^j(z_i^j)A_{-_i}^j(z_i^j)\tilde{\Phi}_i^j(z_i^j) = 0. \quad (34)$$

By the solutions of ρ_i^j and $\Phi_i^j(d)$ for (32), the following equations are obtained from (12), (33), and (34)

$$A_{c_i}^j(d) = A_{+_i}^j(d)W_{n_i}^j(d)\tilde{A}_{-_i}^j(d)\Phi_i^j(d)B_{+_i}^j(d)\Gamma_i^j(d) \quad (35)$$

$$R_i^j(d) = \rho_i^j W_{d_i}^j(d)\tilde{\Phi}_i^j(d)B_{+_i}^j(d)\Gamma_i^j(d). \quad (36)$$

By comparing (35) and (26) and with the fact (9), one has

$$\Gamma_i^j(d) = \tilde{B}_{-_i}^j(d)F_i^j(d)\Omega_i^j(d) \quad (37)$$

$$X_i^j(d) = A_{+_i}^j(d)W_{n_i}^j(s)\tilde{A}_{-_i}^j(d)\Phi_i^j(d)\Omega_i^j(d) \quad (38)$$

where $\Omega_i^j(d)$ is a stable polynomial. Then from (35)-(38)

$$A_{c_i}^j(d) = B_{+_i}^j(d)\tilde{B}_{-_i}^j(d)F_i^j(d)A_{+_i}^j(d)W_{n_i}^j(d)\tilde{A}_{-_i}^j(d)\Phi_i^j(d)\Omega_i^j(d) \quad (39)$$

$$R_i^j(d) = \rho_i^j W_{d_i}^j(d)\tilde{\Phi}_i^j(d)B_{+_i}^j(d)\tilde{B}_{-_i}^j(d)F_i^j(d)\Omega_i^j(d). \quad (40)$$

Substituting (36), (37), and (32) into (9) yields

$$S_i^j(d) = A_{+_i}^j(d)Q_i^j(d)\tilde{B}_{-_i}^j(d)F_i^j(d)\Omega_i^j(d). \quad (41)$$

From (27) and (38), the following polynomial $T_i^j(d)$ is obtained:

$$T_i^j(d) = \bar{F}_i^j(d)A_{+_i}^j(d)W_{n_i}^j(d)A_{-_i}^j(d)\Phi_i^j(d)\Omega_i^j(d). \quad (42)$$

That is, the characteristic polynomial of the closed-loop and the control polynomials of the *jth* PTFDS of subsystem *i* for the fuzzy mixed H_2/H_∞ optimization in (15) are attained through eqns. (39)-(42).

The following theorem discusses the stability of the closed-loop interconnected system (1).

Theorem 1: Suppose the proposed controller (8) is applied to the NIDDDS (1) or an equivalent fuzzy model system (3). Suppose also the inequality (13) with the condition (43) is satisfied. Then the control system in Fig. 1 is $L_2^N -$stable.

$$\left(\Gamma_1^j\right)_{ii} = 1 - \alpha_{i_i}^j \left\|S_i^j(e^{-jw})A_i^j(e^{-jw})/A_{c_i}^j(e^{-jw})\right\|_2 > 0, \text{ for } i = 1,2,...,N, j = 1,2,...,L \quad (43a)$$

$$\Gamma_1^j(e^{-jw}) > 0 \quad (43b)$$

where $\left(\Gamma_1^j(e^{jw})\right)_{mi} = -\alpha_{m_i}^j \left\|S_i^j(e^{-jw})A_i^j(e^{-jw})/A_{c_i}^j(e^{-jw})\right\|_2$

$0 < (\Gamma_1^k)_{ii} \le 1$ and $0 \le -(\Gamma)_{ij} < 1, i \ne j$, for $i, j = 1,2,...,N$.

Proof: It can be refer to the reference [12].

C. The Proposed Control Algorithm

The design procedure of the proposed fuzzy decentralized fuzzy controller via mixed H_2/H_∞ optimization with discrete Smith predictor is as follows:

Step 1: Factorize the nominal subsystem i as $A_i^j(d) = A_{+_i}^j(d)A_{-_i}^j(d)$ and $B_i^j(d) = B_{+_i}^j(d)B_{-_i}^j(d)$.

Step 2: Assign a suitable reference model $F_i^j(d)$ and $G_i^j(d)$ for the *jth* PTFDS of subsystem *i*.

Step 3: Choose an appropriate weighted function for the second cost function (15), i.e., $W_{d_i}^j(d)$ and $W_{n_i}^j(d)$.

Step 4: Based on (21), the polynomials $\overline{F}_i^j(d)$ and $\overline{B}_i^j(d)$ are obtained. Then the optimal $C_{1_i}^{j^*} = \left\| \overline{B}_i^j(d) / B_{-_i}^j(d) \right\|_2$ is attained. If the matching condition is satisfied, then $\overline{F}_i^j(d) = \tilde{B}_{-_i}^j(d)\overline{G}_i^j(d)$ and $\overline{B}_i^j(d) = 0$.

Step 5: From (34), the scalar ρ_i^j and the polynomial $\Phi_i^j(d)$ are obtained. Then the optimal $C_{2_i}^{j^*} = \rho_i^j$ is attained. Based on the long division for (33), the polynomial $Q_i^j(d)$ is obtained.

Step 6: The characteristic polynomial of the closed-loop and the control polynomials of the *jth* PTFDS of subsystem *i*, i.e., $A_{c_i}^j(d)$, $\left\{R_i^j(d), S_i^j(d), T_i^j(d)\right\}$, for the fuzzy mixed H_2/H_∞ optimization in (15) are from (39)-(42).

VI. CONCLUSIONS

A decentralized control of nonlinear interconnected discrete dynamic systems with large delay using fuzzy mixed H_2/H_∞ optimization with discrete Smith predictor was developed. The past effort on the use of fuzzy T-S delayed control did not consider the robust tracking performance (e.g., the attenuation of uncertainty and delay, and the compensation of large delay). In this paper, a two degree-of-freedom optimization technique with discrete Smith predictor was employed to control each PTFDS. A suitable frequency response without the oscillating and sluggish phenomena was obtained. The effect of output disturbance caused by the interconnections coming from other subsystems, the approximation error of the *ith* subsystem, and the interactions resulting from other PTFDSs, was also minimized. Furthermore, the control implementation did not need to calculate the Diophantine equation. There were also computational advantages, especially for low-order system. No fuzzy observer was required; the proposed discrete controller was more suitable for the implementation. Further application to an internet-based piezoelectric actuator driven table system [17] will be progressed.

***Abstract*—Due to the under-actuated feature, the reference signals using the combination of the system outputs, whose number is larger than that of reference signal, are designed so that the number of control inputs and sliding surfaces is the same, and that the uncontrollable mode is indirectly controlled. Under the uncertain environment, the sliding-mode under-actuated control (SMUC) with the satisfaction of suitable condition is designed to asymptotically track the reference signal. Otherwise, a bounded tracking result is obtained for the mild condition. In this situation, an on-line fuzzy modeling for the uncertainty is employed to design a fuzzy model-based sliding-mode under-actuated control (FSMUC) to improve the system performance; e.g., the bounded tracking result of SMUC becomes an asymptotical tracking. The proposed hybrid fuzzy sliding-mode under-actuated control (HFSMUC) combining SMUC and FSMUC with a transition can be applied to a class of generalized, under-actuated and uncertain nonlinear systems, e.g., the trajectory tracking control of a differential mobile robot (DMR). Finally, the simulations of the HFSMUC system are presented to confirm the efficiency and effectiveness of the proposed control.**

Keywords-Under-actuated control system; Sliding-mode control; Fuzzy model-based adaptive control; Lyapunov stability theory;

I. INTRODUCTION

In recent years, the under-actuated systems are attractive due to these advantages: less energy consumption, less use of actuators, and less expense. The main feature for an under-actuated system is that the control objectives can be achieved merely using less actuators under certain constrained conditions. However, the controller design of an under-actuated system is a challenge problem. Furthermore, an under-actuated system in the presence of uncertainties is a difficult task. In this situation, a Hybrid Fuzzy Sliding-Mode Under-actuated Control (HFSMUC) is proposed to deal with a class of generalized, under-actuated and uncertain nonlinear dynamic systems.

In this paper, the reference signals for the controllable modes are designed to combine the signal of the uncontrollable modes so that the uncontrollable mode can be manipulated indirectly. As a result, the sliding surface can be represented as the combination of these signals to become controllable. At the same time, the number of control inputs is the same with that of sliding surfaces; then the sliding-mode under-actuated control (SMUC) is first designed. Moreover, to improve system performance the learning compensation for the system uncertainties called fuzzy sliding-mode under-actuated control (FSMUC) is designed. However, to avoid possible transient phenomenon, a hybrid fuzzy sliding-mode under-actuated control (HFSMUC) combining SMUC and FSMUC with a transition is suggested.

The main contribution of this paper is depicted as follows. Utilizing the reference signals including the uncontrollable mode makes the number of sliding surfaces equal that of control inputs. Then an HFSMUC for a class of generalized, under-actuated and uncertain nonlinear dynamic system is designed.

II. RELATED WORKS

Over the past decades, related works about under-actuated systems was proposed massively. Firstly, Lin and Mon used hierarchical fuzzy sliding-mode (HFSM) to investigate the decoupling control of a double inverted pendulum system [1]. Raimondi and Melluso [2] presented a new fuzzy adaptive motion control system including on-line extended Kalman's filter (EKF) for wheeled under-actuated cars with non-holonomic constraints. Besdies, in [3], Wai et al. proposed a cascade adaptive fuzzy sliding-mode control (AFSMC) scheme including inner and outer control loops for the stabilizing and tracking control of a nonlinear two-axis inverted-pendulum servomechanism. In 2008, Márton et al. [4] presented LQR, subspace stabilization controller and combined error metric controller for robust control of under-actuated robots compared on the classic ball and beam system. Furthermore, a closed-loop method was presented by Elliot and Gans [5] achieving full-state trajectory tracking via input-output linearization and asymptotically stable internal dynamics for the two-wheeled driven cart. In [6], Refsnes et al. presented an observer backstepping technique for slender-

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

body underwater vehicles to track the desired pitch and heading angle. In addition, the papers of [7]-[9] presented a sliding mode control method respectively for a class of under-actuated mechanical systems and autonomous surface vessels. Cavdaroglu and Olgac [10] designed a desirable fixed control law to successfully accomplish the trajectory tracking of an under-actuated car-and-pendulum dynamics in the presence of multiple and independent time delays. Oryschuk et al. [11] implemented and tested the real-time control of a two-wheeled under-actuated mobile robot including test motions: translational, rotational, and uphill. In [12], neural networks and output feedback were used for a quadrotor unmanned aerial vehicle (UAV) with six DOFs which were controlled by only four control inputs.

III. PROBLEM FORMULATION

In the beginning, a class of generalized, under- actuated and uncertain nonlinear dynamic systems is expressed as follows:

$$\dot{x}_1(t) = f_1(x,t) \tag{1a}$$

$$\dot{x}_2(t) = f_2(x,t) + G(x,t)u(t) \tag{1b}$$

$$y_1(t) = H_1 x_1(t),\ y_2(t) = H_2 x_2(t) \tag{1c}$$

where $x = \begin{bmatrix} x_1(t) & x_2(t) \end{bmatrix}^T$, $x_1(t), y_1(t) \in \Re^{n-m}$ and $x_2(t), y_2(t) \in \Re^m$ are respectively denoted as the uncontrollable and controllable system state and system output, $u(t) \in \Re^m$ is the control input, and H_1, H_2 are the output gain matrices. Furthermore, the system functions are described as follows:

$$f_i(x,t) = \overline{f}_i(x) + \Delta f_i(x,t), i = 1,2 \tag{2}$$

$$G(x,t) = \overline{G}(x) + \Delta G(x,t) \tag{3}$$

where $\overline{f}_1(x) \in \Re^{n-m}$, $\overline{f}_2(x) \in \Re^m$ and $\overline{G}(x) \in \Re^{n \times m}$ denote the nominal system functions, $\Delta f_i(x,t), i = 1,2$ and $\Delta G(x,t)$ are uncertain system functions. Due to the under-actuated feature, the number of the control inputs is smaller than that of the system output, i.e., $m < n$. In summary, $y_1(t)$ and $y_2(t)$ are denoted as the uncontrollable modes and controllable modes of the system output, respectively. The tracking error is defined as follows:

$$e_i(t) = r_i(t) - y_i(t), i = 1,2. \tag{4}$$

Our problem is to design the control input for the controlled system (1)~(3) such that the system output will track a reference input (refer to Fig. 1). First, a sliding-mode under-actuated control (SMUC) is designed for the uncertainty which is not huge. In this situation, the asymptotical tracking can be obtained for the smaller uncertainty; in general, a bounded tracking result is achieved. To enhance the tracking result, a fuzzy modeling is then employed to approximate the system uncertainty such that a real-time compensation of learning uncertainty is plugged into the fuzzy sliding-mode under-actuated control (FSMUC). Finally, a combination of SMUC and FSMUC with a transition is called as hybrid fuzzy sliding-mode under-actuated control (HFSMUC). It is developed such that both advantages of SMUC and FSMUC (e.g., a better transient response of SMUC, an improved tracking performance of FSMUC) are accomplished, and that both of their disadvantages (e.g., poor tracking performance of SMUC, the transient response of FSMUC) are discarded.

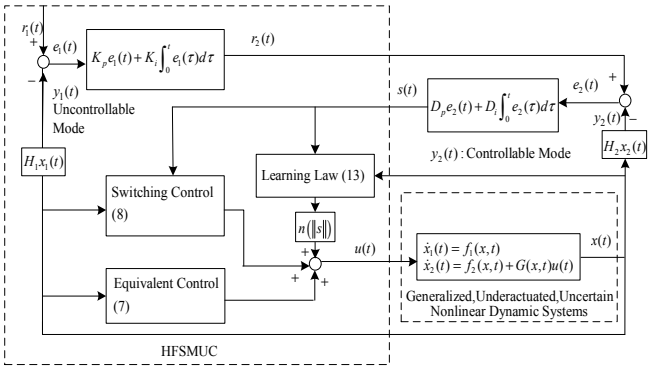

Fig. 1. Control block diagram of the overall system.

IV. FEATURES OF SLIDING SURFACE

Considering that proposed architecture is an under-actuated control system, the following sliding surface is first defined.

$$s(t) = D_p e_2(t) + D_i \int_0^t e_2(\tau)d\tau \tag{5}$$

where $D_p = diag\{d_{p1}, d_{p2}, \cdots, d_{pm}\}, D_i = diag\{d_{i1}, d_{i2}, \cdots, d_{im}\}$, $\in \Re^{m \times m}$ are constant matrices, and $s(t) \in \Re^m$. In addition, D_p and D_i are positive definite matrices, i.e., d_{pj} and $d_{ij} > 0$ for $j = 1,2,\cdots,m$. An effective reference input is assigned as follows:

$$r_2(t) = K_p e_1(t) + K_i \int_0^t e_1(\tau)d\tau \tag{6}$$

where K_p and $K_i \in \Re^{(n-m)\times(n-m)}$, their entries are chosen as $(K_p)_{jl}$ and $(K_i)_{jl} > 0 \forall j,l = 1,2,...,n-m,$ such that $r_2(t)$ is a stable reference input. The reason to design the reference signal of (6) is that the uncontrolled mode $x_1(t)$ or $y_1(t)$ should be simultaneously included into the control mode, i.e., $x_2(t)$ or $y_2(t)$, so that they are indirectly manipulated by the controllable mode. In this paper, $r_1(t) = \dot{r}_1(t) = 0$ is considered and the corresponding bounded-input-bounded-output and asymptotical tracking properties can be referred to [13], [14]. For simplicity, it is omitted.

V. CONTROLLER DESIGNS

Three design steps for the proposed controller are given as follows.

A. Sliding-Mode Under-Actuated Control

The sliding-mode under-actuated control for the controlled system (1) and (2) is designed as follows:

$$u(t) = u_{eq}(t) + u_{sw}(t) \tag{6}$$

where

$$\begin{aligned} u_{eq}(t) &= \left[D_p H_2 \bar{G}(x)\right]^{-1} \left\{ n\left(\|s(t)\|\right)\hat{W}^T(t)\Phi(z) \right. \\ &\left. + D_p\left[K_p\left(\dot{r}_1(t) - H_1\bar{f}_1(x)\right) + K_i e_1(t) - H_2\bar{f}_2(x)\right] + D_i e_2(t)\right\} \end{aligned} \tag{7}$$

$$u_{sw}(t) = \left[D_p H_2 \bar{G}(x)\right]^{-1} \left\{\Gamma_1 s(t) + \Gamma_2 s(t)/\left(\|s(t)\| + \varepsilon_b\right)\right\}/(1-\lambda) \tag{8}$$

where $D_p H_2 \bar{G}(x)$ for all $x(t)$ is nonsingular; $n\left(\|s\|\right)$ is a scalar function and here it is assigned as zero; $\hat{W}^T(t)\Phi(z)$ represents the learning compensation for system uncertainties, which will be discussed in the subsection 5B; $\Gamma_1 = diag\{\gamma_{111}, \cdots, \gamma_{1mm}\} > \delta I_m/2 > 0$ (where I_m is the unit matrix of $\Re^m$ and δ is the exponential convergent rate to the sliding surface) and $\Gamma_2 = diag\{\gamma_{211}, \cdots, \gamma_{2mm}\} > 0$ are the switching gain matrices; $\varepsilon_b \geq 0$ denotes the boundary layer of sliding surface; $\lambda > 0$ represents as the upper bound of uncertain control gain and satisfies the following inequality:

$$\left\| D_p H_2 \Delta G(x,t)\left(D_p H_2 \bar{G}(s)\right)^{-1}\right\| \leq \lambda < 1, \ \forall x(t), t. \tag{9}$$

It is assumed that the uncertain signal $K(x, u_{eq}, t)$ caused by $\Delta f_i(x,t), i = 1,2$ and $\Delta G(x,t)$ satisfying the following inequality:

$$\left\|K(x, u_{eq}, t)\right\| \leq \mu_0 + \mu_1 p(x), \ \forall x(t), u_{eq}(t), t \tag{10}$$

where

$$\begin{aligned} K(x, u_{eq}, t) &= -D_p K_p H_1 \Delta f_1(x,t) \\ &- D_p H_2 \Delta f_2(x,t) - D_p H_2 \Delta G(x,t) u_{eq}(t) \end{aligned} \tag{11}$$

$p(x)$ is a known function, and $\mu_0 \geq 0, \mu_1 \geq 0$, whose values are constrained by the stability of the closed-loop system.

B. Fuzzy Model-Based Sliding-Mode Under-Actuated Control

If the system uncertainties (10) and (11), i.e., $K(x, u_{eq}, t)$ are huge, they must be learned to compensate their effect [15]. Based on the learning model, an FSMUC is then constructed to improve system performance. First, the extension of universal approximation theory using fuzzy modeling is stated as follows [16], [17]:

Theorem 1: Suppose $z(t) \in D(z)$ (a compact subset of $\Re^n$), $K(z,t): D \times \Re^+ \to \Re^m$ is a continuous function. For an arbitrary constant $\varepsilon_0 \geq 0$, there exists an integer L (the number of membership functions) and real constant matrix $\bar{W} \in \Re^{L \times m}$, where $\|\bar{W}\| \leq W_M$, such that

$$K(z,t) = \bar{W}^T \Phi(z) + \varepsilon_K(z,t)$$

where $\Phi(z)$ denotes a known fuzzy basis function, $\|\varepsilon_K(z,t)\| \leq \varepsilon_0, \ \ \forall z(t) \in D(z)$ and $\forall t \geq 0$.

Based on the result of *Theorem 1*, the system uncertainties in a compact subset $D(z)$ and $\forall t \geq 0$, are assumed to be continuous and approximated by the following fuzzy model:

$$K(x, u_{eq}, t) = \bar{W}^T \Phi(z) + \varepsilon_K(z,t) \tag{12}$$

where $z^T(t) = \left[x^T(t) \ \ u_{eq}^T(t)\right]$, $\bar{W} \in \Re^{L \times m}$ is an unknown constant matrix which is not necessarily unique, $\|\varepsilon_k(z,t)\| \leq \varepsilon_0 \ \ \forall z(t) \in D(z)$ and $t \geq 0$. In addition, the upper bound of $\bar{W}$ is known, i.e., $\|\bar{W}\|_F \leq \bar{W}_M$, where $\|\cdot\|_F$ is the Frobenius norm.

Then the following learning laws are considered.

$$\dot{\hat{W}}(t) = \Omega \Phi(z) s^T(t) - \Omega \Psi \hat{W}(t) \tag{13a}$$

where $\hat{W}(t) \in \Re^{L \times m}$ stands for the learning weight, $\Omega = diag\{\omega_1, \cdots, \omega_L\} \in \Re^{L \times L} > 0$ is the learning matrix gain, $\Psi = diag\{\varphi_1, \cdots, \varphi_L\} \in \Re^{L \times L} > 0$ is a matrix of *e*-modification rate to ensure the boundedness of the learning weight, $\Phi(z) \in \Re^{L \times 1}$ represents the fuzzy basis function:

$$\Phi(z) = \left[1 \quad \phi_2(z) \quad \ldots \quad \phi_L(z)\right]^T \tag{13b}$$

where $\phi_j(z) = \exp\left[-\|z(t) - c_j\|^2 / \sigma_j^2\right]$, L, c_j, σ_j for j = 2, 3,…, L are known, and the centers c_j for $j = 2, 3, ..., L$ are chosen as normal distribution in the corresponding domain. Then the fuzzy model-based sliding-mode under-actuated control (FSMUC) is designed as the following equivalent control with $n\left(\|s(t)\|\right) = 1$ and the learning weight from (13).

C. Hybrid Fuzzy Sliding-Mode Under-Actuated Control

When the operating point is far away from the sliding surface, the learning law generally does not require so that the unnecessary instability and transience are avoided [15]. Although FSMUC is superior to SMUC, it is still a question when the learning law should be used. Important index for the sliding-mode control is the sliding surface. Due to the existence of system uncertainties, the operating point is always away from the sliding surface. Based on this knowledge, a scalar function $n\left(\|s\|\right)$ is designed as follows. When the norm of the sliding surfaces is inside of a defined set, the learning law (13) start; similarly, as it is outside of the other set, the learning laws shut off. For reducing the

possibility of discontinuous control input, a transition between SMUC and FSMUC is designed. Hence, we design the following scalar function:

$$n(\|s\|)=\begin{cases}0, & \text{as } \|s(t)\|>n_{s1}\\ 1, & \text{as } \|s(t)\|<n_{s2}\\ (n_{s1}-\|s(t)\|)/(n_{s1}-n_{s2}), & \text{otherwise}\end{cases} \quad (14)$$

where $n_{s1}>d_n>n_{s2}>c_n>0$. The values of d_n and c_n are respectively the upper bounds of the convergent sets of $\|s(t)\|$ for the SMUC and FSMUC. If the system uncertainties are small enough, then the value of d_n is also small enough. If the value of d_n (or the system performance) satisfies the specification, then the value of n_{s1} approaches zero, i.e., the learning laws (13) can be shut down. On the other hand, the value of d_n (or the system performance) is large, then the value of n_{s2} is away from zero, i.e., the learning law (13) nearly executes all the time. As the value of $\|s(t)\|$ is between n_{s1} and n_{s2}, the linear combination of these two conditions is obtained.

Finally, the proposed HFSMUC is summarized as follows:

Step 1: Obtain a nominal modeling of a generalized under-actuated and uncertain nonlinear dynamic system, i.e., $\bar{f}_i(x), i=1,2$ and $\bar{G}(x)$.

Step 2: Partition the uncontrollable mode (i.e., $y_1(t)$) and the controllable mode (i.e., $y_2(t)$), whose dimension is the same as that of control input $u(t)$ or sliding surface $s(t)$.

Step 3: Estimate the system uncertainty $K(x,u_{eq},t)$ such that $\mu_0+\mu_1 p(x)$ in (10) is obtained.

Step 4: Assign the suitable coefficients for the virtual reference $r_2(t)$, i.e., K_p and K_i, and the sliding surface, i.e., D_p and D_i. Then the SMUC with appropriate parameters of switching gains, i.e., Γ_1 and Γ_2, is designed.

Step 5: If the system performance is not satisfied, an on-line learning law (13) is constructed to learn the huge uncertainty, which is not tackled in a satisfactory manner by the previous SMUC. Then an FSMUC is described in (6)-(8) with $n(\|s\|)=1$ and (13).

Step 6: Besides an acceptable steady performance of an FSMUC, its transient phenomenon often occurs. In this situation, an HFSMUC is designed by the suitable selection of coefficients, i.e., n_{s1} and n_{s2} in (14) to avoid the possible transience and discontinuous control signals. Finally, the corresponding simulations are arranged to verify the effectiveness.

VI. ILLUSTRATIVE EXAMPLE

An illustrative example, namely, the trajectory tracking control of a DMR [8], is a two inputs and five states (or three outputs) under-actuated system as shown in Fig. 2 to demonstrate the validity of our proposed HFSMUC. Then the kinematic dynamic model of a DMR and the simulation results by HFSMUC are presented in the following two subsections.

A. Kinematic and Dynamic Model of a DMR

At beginning, the kinematic model of a DMR is expressed as follows:

$$\dot{x}(t)=v(t)\cos(\theta),\ \dot{y}(t)=v(t)\sin(\theta),\ \dot{\theta}(t)=\omega(t) \quad (15)$$

where the triple $(x(t),y(t),\theta(t))$ denotes the position and the orientation of the vehicle with respect to the world coordinate, and $v(t)$ and $\omega(t)$ are the linear and angular velocities of the DMR. The dynamic model is obtained by using the following relations:

$$M\dot{v}(t)-f_f(t,x)=f(t) \quad (16a)$$

$$I\dot{\omega}(t)-\tau_f(t,x)=\tau(t) \quad (16b)$$

where M is the mass of the DMR, I is the moment of inertia, $f(t)=[\tau_l(t)+\tau_r(t)]/r$ and $\tau(t)=L[\tau_l(t)-\tau_r(t)]/r$ with L being the distance between the center of mass and the wheel, $\tau_l(t)$ and $\tau_r(t)$ are the left and right wheel motor torques, and r is the radius of the rear wheel. To express the generalized form as equation (1), $x_1(t)=x(t)$, $x_2(t)=y(t)$, $x_3(t)=\theta(t)$, $x_4(t)=v(t)$ and $x_5(t)=\omega(t)$ are defined. Output gain matrices are selected as $H_1=I_3$ and $H_2=I_2$ where I_3 and I_2 respectively are 3×3 and 2×2 identity matrices. In addition, the frictional force $f_f(t,x)$ and frictional torque $\tau_f(t,x)$ are supposed to be

$$\begin{aligned}&f_f(t,x)=3\sin(tx_1)\cos(5t)+2.1x_2\sin(5tx_2)\\&-0.3x_3\cos(10tx_3)-0.2\sin(40tx_5)+0.01\sin(100tx_4)+0.2\\&\tau_f(t,x)=3x_2\cos(tx_1)\sin(10tx_3)+1.6x_2\cos(5tx_3)\\&-0.3x_2\cos(10tx_2)-0.1x_4\sin(40tx_5)+0.02x_3\sin(100tx_4)-0.3\end{aligned} \quad (17)$$

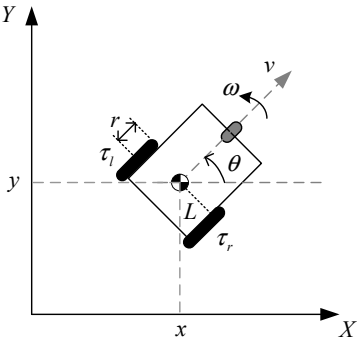

Fig. 2. Illustration of a DMR.

B. Simulation Results by HFSMUC

The simulation results by HFSMUC are considered as follows. The initial position and orientation of a DMR is selected as $\{X = 0.3m, Y = 0.1m, \theta = 1\ rad.\}$ and the physical parameters of the DMR are chosen as $M = 6.0kg$, $I = 0.157kg \cdot m^2$, $r = 0.1m$, $L = 0.25m$. The control objective is to drive the DMR from the initial position back to the origin point of the world coordinate. The above frictional force and frictional torque (17) are also considered in the simulation. The corresponding responses of the simulation are shown in Figs. 3~8. It indicates that the proposed control is effective for an under-actuate controlled system. The uncertainty and its learning uncertainty are shown in Figs. 9 and 10, which are acceptable. Moreover, the corresponding proof will be undertaken via Lyapunov stability theory in the near future.

VII. CONCLUSIONS

An HFSMUC for a class of generalized under-actuated nonlinear uncertain dynamic systems is developed by the combination of SMUC and FSMUC with a transition. The proposed scheme presents both advantages of SMUC and FSMUC and simultaneous avoids the possible disadvantages coming from SMCU and FSMUC. First, the reference signals using the combination of the system outputs, whose number is larger than that of reference signal, are designed so that the number of control inputs and sliding surfaces is the same, and that the uncontrollable mode is indirectly controlled. Under the uncertain environment, the sliding-mode under-actuated control (SMUC) with the satisfaction of suitable condition is designed to asymptotically track the reference signal. Otherwise, a bounded tracking result is obtained for the mild condition. In this situation, an on-line fuzzy modeling of the uncertainty is employed to design a fuzzy sliding-mode under-actuated control (FSMUC) to improve the system performance; e.g., the bounded tracking result of previous sliding-mode control becomes an asymptotical tracking. Finally, an illustrative example: the trajectory tracking of a DMR, confirms the usefulness of the proposed HFSMUC. It is believed that the proposed control scheme can be applied to many under-actuated nonlinear uncertain dynamic systems.

***Abstract*—A lot of companies carry out questionnaires. These questionnaires often have questions which need respondents to answer by free description. It is, however, inefficient for an analyzer to read whole texts to get outlines or classify them, or it is difficult to correctly analyze them without subjective biases. The authors have proposed "HK Graph" (Hierarchical Keyword Graph) which is a support tool for text mining. HK Graph can visualize the relationships among attributes and words with hierarchical graph structure based on frequency of co-occurrence. However, the result of HK Graph is not enough helpful for the analyzer to grasp the outlines of the texts and extract opinions from them, because it regards divided words as different ones unless they perfectly match and that makes the visualized result complicated. This paper presents a new visualization method for the HK Graph incorporating an aggregating words method based on concepts of words. An experiment is carried out by applying the proposed method to actual questionnaire data on disasters and studies the effectiveness of the proposed method.**

***Index Terms*—Text mining, HK Graph, Visualization, Questionnaire analysis, Concept.**

I. Introduction

Recently, a lot of companies often carry out questionnaires to plan marketing strategies. There are a lot of objectives in questionnaires, e.g., finding needs of products or services, predicting demand or market scale, investigating levels of customer satisfaction or images of brands, and so on. Thus, questionnaires are important information sources for companies, and effective analysis methods for them are strongly needed.

There are two types of formats in questionnaire. One is to answer from some choices or directly answer using a numerical value for a question, the other is to answer by free description. In the former case, it is easy to quantify the responses, and to apply multivariate analysis methods. It is, however, difficult to extract real opinions or impressions of respondents unless good setting of questions is done, because the respondents can respond only to the prepared questions. On the other hand, in the latter case, it is expected to extract real opinions of respondents because they can write their responses freely. However the analysis of free text data becomes difficult because numerical analysis methods can not be applied and it takes long time to aggregate and analyze them, or an analyst might be subjectively biased by same strong opinions. In many analyses of questionnaires, the analysts have to read whole text data to get outlines or manually classify them. Therefore, the demand for the support system by text mining methods for the analysis of free texts in questionnaire has been growing.

A lot of text mining methods to support the analysis of texts have been reported [1], [2], [3]. This study focuses on the approach by visualization. Analysis of free texts in questionnaires needs interactivity because a lot of grammar or syntax errors are contained in responses, and the visualization is expected to be effective for interactive analyses. There are some conventional systems to support the analysis of texts with visualization such as Key Graph [4], ACCENT [5], $KOTOBA$ network [6], and so on. Key Graph can show the relationships among words in texts based on their frequencies of co-occurrence; however, Key Graph is not designed for interactive word search. The displayed result is fixed. ACCENT and $KOTOBA$ network shows relationships of words in a form of graph structure. However, the interactivity of these methods is low because the graph has to be restructured every time a user needs to analyze further into the details.

The authors have developed Hierarchical Keyword Graph (HK Graph) [7], [8] as the support system for the analysis of texts with visualization of relationships among words. HK Graph can extract relevant words based on their co-occurrence for the words input by a user or for the groups, e.g., men and women, and visualize them as a graph structure. In addition, HK Graph can show the words as a hierarchical structure, and then a user can analyze the focused word in depth by seeing the lower layer of the word.

In HK Graph, divided words are regarded as different words except for the perfect matching ones. Therefore, synonyms such as different representation and different expression are regarded as different words even if they were used as the same meaning. Then these words are shown separately or often not presented because the frequency of appearance becomes low. In free texts of questionnaires, the representation and the

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

expression of words (Hiragana/Kanji etc.) are often different in individuals. Consequently, aggregating these synonyms has been an important issue. In addition, it is difficult to grasp the outlines of the texts and extract the opinions in them when many words are presented on HK Graph, because the visualization result becomes complicated.

The aim of this paper is to consider the similarities of words in HK Graph and make it easy to grasp the outlines of texts. This paper proposes "concept" of words defined by the thesaurus, and the words are grouped based on their concepts, and then the concept and the grouped words are visualized in HK Graph. The proposed method can aggregate the words which were separately shown in the conventional HK Graph, and it is expected that the visualization of aggregated words makes it easier to grasp the outlines of the texts and extract proper features of them. This paper applies the proposed method to actual questionnaire data on disasters and studies the effectiveness of the proposed method.

II. HK Graph

In HK Graph, users can interactively analyze text data by starting to analyze the text related to the items they are interested in, and proceeding into deeper layers of words of interest shown as a keyword graph. The algorithm of HK Graph is as follows.

A. Division into Words

The first step in the algorithm of HK Graph is to divide the target texts into words by applying Cabocha[5]. Cabocha is a Japanese language morphological and paragraphic analysis tool. Unlike English, in which each word is separated by a space, it is difficult to divide Japanese text without tools like Cabocha. Applying Cabocha to the target texts, particles, symbols (punctuation, parentheses), pronouns, conjunctions and adnouns given by morphological information are regarded as noise words which are not needed for analysis, and they are deleted.

B. Selection of Base

The second step is for users to select contents to be analyzed, e.g., sex, income, age, the texts containing a certain word or sentence, the target group, and so on. If they want to grasp the outlines or the tendency of texts, they can select all texts. The selected group is called "Base." It is one of the features of HK Graph to let users give the start nodes of their interest which create the graph structure.

C. Extraction of Main-node

High co-occurrence words in the texts with the selected Base are extracted. The extracted words are called "Main-nodes." $Jaccard's$ coefficient is used as the co-occurrence value. The equation of co-occurrence is shown below.

$$Jaccard(B_i, W_j) = \frac{N(S(B_i) \cap S(W_j))}{N(S(B_i) \cup S(W_j))} \quad (1)$$

B_i is the Base i, W_j is each word divided out in II.A., $S(X)$ is the texts including the Base/word X, and $N(S)$ is the number of texts of S. Using eq.(1), the words with high co-occurrence to all Bases (All connected Main-node), those to plural Bases (Multi connected Main-node), and those to single Base (Single connected Main-node) are extracted.

D. Extraction of Sub-node

When a user wants to know more about a certain Main-node, HK Graph can extract the words which are closely related to the selected Main-node as a lower layer. The words, called "Sub-nodes," are extracted using eq.(1) where the Base is replaced with the selected Main-node. Thus in HK Graph, the words which have high co-occurrence with the focused words can be expanded as the lower layer, then a user can analyze the texts by proceeding into deeper layers of words of his/her interest.

E. Presentation of Hierarchical Keyword Graph

The image of output of HK Graph is shown in Fig.1. In this figure, B_1-B_3 are Bases, M_{a1} is All connected Main-node, M_{m121}-M_{m231} are Multi connected Main-nodes, M_{s11}-M_{s32} are Single connected Main-nodes, and S_{211}, S_{222}, etc. are Sub-nodes. A Base and Main-nodes, a Main-node and Sub-nodes are connected with their links, and the value of co-occurrence is expressed in the thickness of each link.

In this way, the relationships of the words are hierarchically presented in HK Graph. In addition, HK Graph can show the new graph starting from the presented words, either Main-nodes or Sub-nodes, as new Bases.

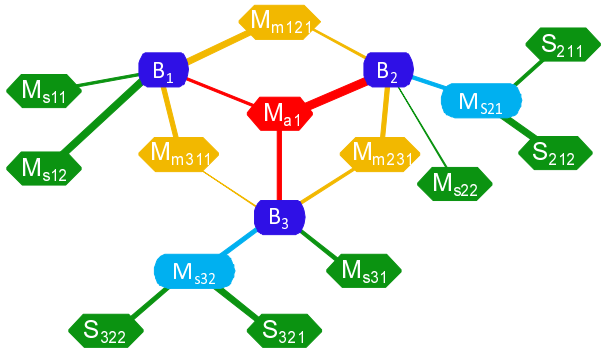

Fig. 1. Image of HK Graph

III. Proposed Method

The objective of this study is to support the analysis of free texts in questionnaires using HK Graph. However, in HK Graph, synonyms are regarded as different words, and the visualized result becomes complicated when a lot of nodes are presented as described in I. This paper considers the similarities of words in HK Graph based on their "concept" of words which are defined by the thesaurus, and proposes a method to feed back them into the visualization result with HK Graph by grouping the words based on their concepts. Moreover, the concepts are expanded using N-gram in this paper. The details of the proposed method are as follows.

A. Definition of Concept

This paper uses "Nihongo Dai-Thesaurus [9]" to define "concept." This thesaurus consists of 6 chapters. Each chapter consists of 67 sections, and each section has 1044 categories. Each category has 1-30 groups of belonging words. The small word group is the minimum unit of synonyms to be grouped. Consequently in this paper, the small word groups are defined as "concepts." Based on these concepts, the words in texts are grouped, which are called "concept groups." Each concept group is described with the label of the small word group in the thesaurus.

B. Generation of Concept Group

After the division of texts into words, it gives the label(s) of concept to each word. Concretely, each word is searched in belonging words to small word groups in the thesaurus, and the label of corresponding concept are given to the word when the word is found. Plural concepts can be given to one word because a word often has some meanings and appears in some small word groups in the thesaurus. Concept groups, in which same belonging words are, are generated based on the concept labels of words. Each concept group is shown with the corresponding label in the thesaurus.

C. Expansion of Concept Group using N-gram

Only the words in the thesaurus belong to concept groups generated in III.B. However, there are a lot of synonyms which the thesaurus does not have but shown in the texts, e.g., 'earthquake' and 'earthquake disaster,' these are originally written in Japanese, belong to the concept "earthquake," but unique nouns such as 'the Great Hanshin Earthquake' or 'a Tokai earthquake' do not belong to it. This paper expands the concept groups using N-grams [10], [11] which have been often used in the area of full-text searching. An N-gram is consist of a subsequence of n characters divided from a given sequence. In this paper, a given sequence is a word in texts (in Japanese) and a subsequence is the characters which are divided from the word. For example, in the case of N=2, from a word 'ABCDE' (each character A, B, C, D, E is a Kanji, Hiragana or Katakana), the N-grams 'AB,' 'BC,' 'CD,' 'DE,' are generated. N-grams are generated for all words presented in HK Graph, and the words which have the N-grams corresponding to those by the words in the original concept groups are put into the concept group. This expansion of concept groups can aggregate the synonyms of them which the thesaurus does not have.

D. Application to HK Graph

Words and concept groups generated in III.C. are presented in HK Graph. Concretely, as described in II.C., the high co-occurrence words in the texts with the selected Bases are extracted as Main-nodes. When 2 or more words in the extracted words belong to a same concept group, these words are aggregated into the concept group, and the label of the concept group is presented as a node in HK Graph, this paper calls these nodes "concept nodes." Links to a concept node or to Sub-nodes from a concept node are connected based on the co-occurrence values of the words belonging to the concept group. Eq.(2) shows $Jaccard's$ coefficient to calculate the co-occurrence value. The difference from eq.(1) is G_i, which is the words belonging to the concept group.

$$Jaccard(G_i, W_j) = \frac{N(S(G_i) \cap S(W_j))}{N(S(G_i) \cup S(W_j))} \quad (2)$$

IV. Experiment

A. Questionnaire Data and Division into Words

In this experiment, the proposed method was applied to 500 free texts of a questionnaire on disasters. The question of the questionnaire was "Please write your opinions or thoughts on natural disasters over 50 characters (in Japanese)." Actually, including "I don't have comments in particular" and so on, 125 respondents out of 500 wrote the responses less than 50 characters. Firstly, the text data were divided into words as described in II.A., and the words and concepts not to be needed for the analysis ('thing,' 'is,' 'there,' 'that,' and a concept "point" coming from a word 'thing') were excluded by hand. The number of N-gram N was 2. The following figures and descriptions of the results are originally written in Japanese and translated into English.

B. Study of Grasping Outline of Text

First, the easiness to grasp the outlines of texts was studied comparing with the conventional HK Graph. The conventional HK Graph was applied to the above questionnaire data, and the visualization result is shown in Fig.2 when the extracted word class was noun and the number of the presented Main-nodes was set to 100. The number of Main nodes employed here was set based on the visibility of the results. Appropriate number should be studied in the future work. Fig.3 shows the result of the proposed method with concept groups described in III.D. based on 100 words in Fig.2. Orange nodes in Fig.3 are the concept nodes.

It is slightly difficult to grasp the general outlines of the texts from Fig.2, because the number of presented words are many and the synonyms are not categorized and dispersed. On the other hand in Fig.3, main words in the texts are categorized and aggregated by the concepts, which makes it easier to grasp the outlines than Fig.2 by focusing on the concept nodes. According to the result of Fig.3, for "opinions on natural disasters," there were "Earthquake," "Flood," "Heavy rain," and they also mentioned "Environmental problem," "Broadcast" and "Prediction."

C. Study on Aggregation of Synonyms

Next, the effect of the aggregation of synonyms based on the concepts was studied. Fig.4 shows the result of the conventional HK Graph when Bases were selected as the respondents less than 40's and those more than or equal to 40's, and Fig.5 shows the result of the proposed HK Graph generated based on Fig.4. In Fig.4, 'Environmental destruction' and 'Warming temperature' are connected to the Base of the respondents less than 40's, and 'Global warming' is connected to those more than or equal to 40's. These words could be used

Fig. 2. Conventional HK Graph

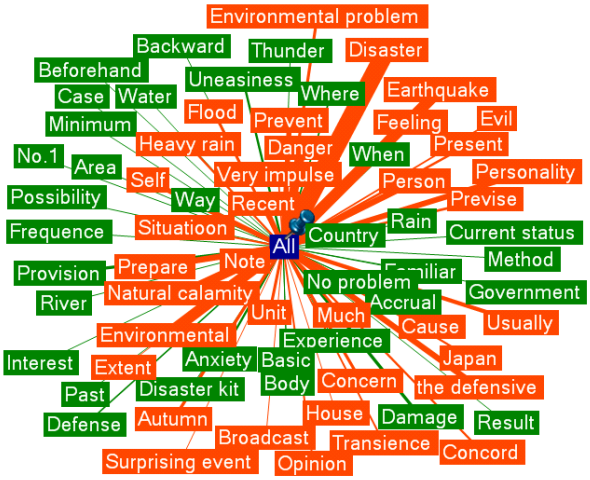

Fig. 3. Proposed method

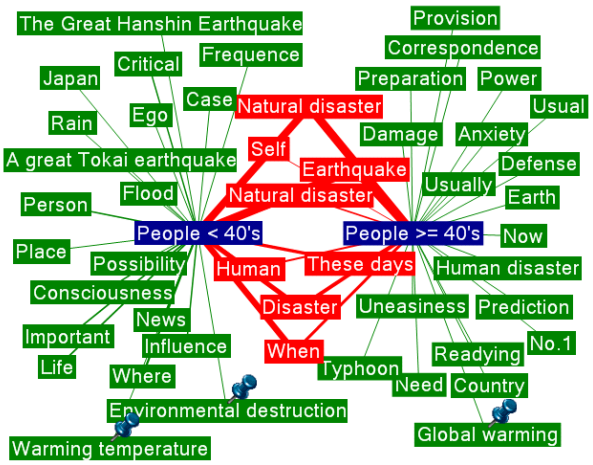

Fig. 4. Conventional HK Graph (Bases : People $<$ 40's, People $\geq$ 40's)

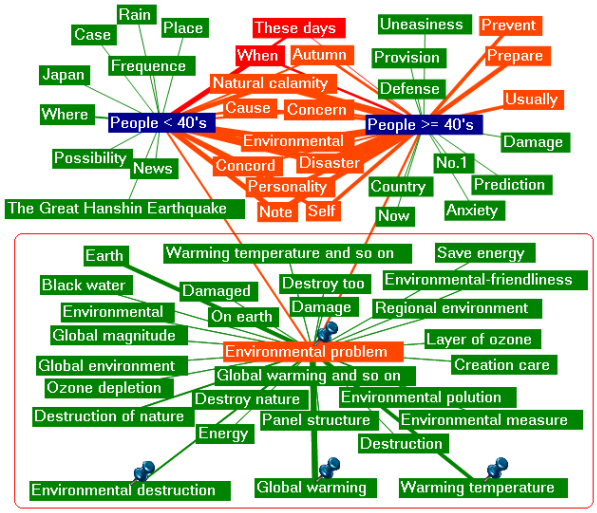

Fig. 5. Proposed method (Bases : People $<$ 40's, People $\geq$ 40's)

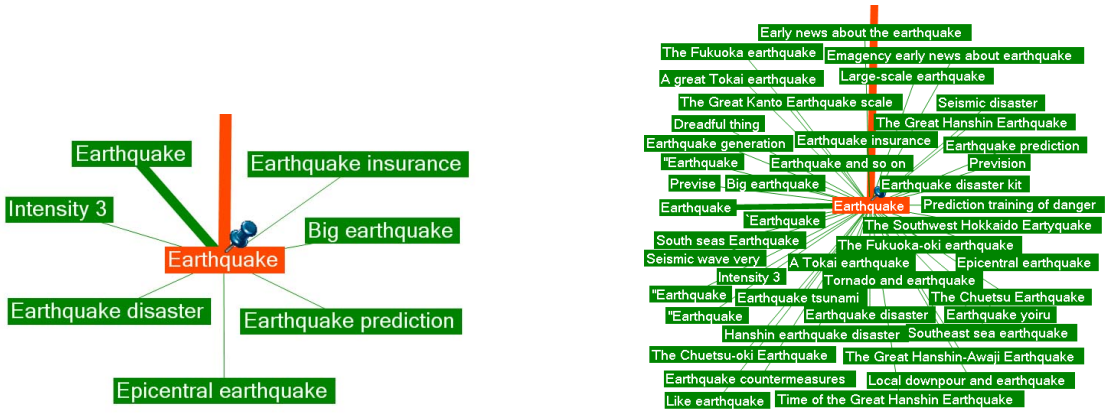
to describe "Environmental problem." However, these words were dealt with different words in the conventional method, then we might grasp that respondents less than 40's mentioned 'Environmental destruction' and 'Warming temperature,' and those of more than or equal to 40' did 'Global warming.' On the other hand, in the proposed method, 'Environmental destruction,' 'Warming temperature' and 'Global warming' were aggregated into the concept "Environmental problem," and this concept node was presented as All connected Main-node from both Bases. Therefore, it is found that the respondents for the wide generations had interest in environmental problem. In addition, in the proposed method, as the synonyms such as 'environmental pollution,' 'ozone depletion,' and so on, which were not presented in the conventional method because the number of the words in the texts were small, were belonging and presented as the same concept group, we can analyze more detail of the opinions on the environmental problem.

Finally, the effect of the expansion of concept groups using N-gram was studied. Fig.6(a) shows the belonging words to the concept "Earthquake" before the expansion, and Fig.6(b) shows after the expansion using N-gram as described in III.C. Extracted words in Fig.6(a) are only general words, e.g., 'Earthquake,' 'Earthquake disaster,' and so on. On the other hand, in Fig.6(b), the concept group have a lot of synonyms including the unique nouns, 'The Great Hanshin Earthquake,' 'The Chuetsu earthquake,' 'Early news about the earthquake,' and so on, by the expansion using N-gram. It gives us detail analysis on the opinions about earthquake.

V. Conclusion

This paper considered the similarities of words in HK Graph based on their "concept" of words which were defined by



(a) Before expansion

(b) After expansion

Fig. 6. Effect of expansion of concept group

the thesaurus, and proposed a method to feed back them into the visualization result with HK Graph by grouping the words based on their concepts. This paper also proposed the expansion of concept groups using N-gram. This paper applied the proposed method to actual questionnaire data on disasters and studied the easiness to grasp the outline of texts comparing with the conventional HK Graph. It also studied the effectiveness of the aggregation of synonyms by the concept groups and the expansion of them. Future work is more study on the expansion of concept groups and the extraction of the proper concept for the word belonging to some concepts considering the meaning in the texts.

***Abstract*—This paper addresses development of body mapping from a human demonstrator to an inverted-pendulum mobile robot for imitation. An inverted-pendulum mobile robot with torso and body links learns a dynamic kicking motion shown by a human. The robot observes the human demonstration with a camera, extracts the human region in each of images, maps the region to its own two links, estimates the link posture trajectories, and starts kicking motion learning based on the trajectory parameters for imitation. The mapping parameter gives an important role for successive imitation. A reasonable and feasible procedure of learning from observation for an inverted-pendulum robot and development of the body mapping is proposed and investigated in this paper.**

Keywords-imitation; corresponding problem; reinforcement learning; policy gradient method; inverted pendulum wheeled robot

I. INTRODUCTION

In order to develop skills, actions, behavior in a human symbiotic environment, a robot is going to learn something from behavior observation of predecessors or humans. Observation of others makes the behavior learning rapid and therefore much more efficient [1], [2], [3]. Recently, many approaches for robotics imitation have been proposed (for example, [4], [5]). It is desirable to acquire various unfamiliar behavior with some instructions from others, for example, surrounding robots and/or humans in real environment because of huge exploration space and enormous learning time to learn without any a priori knowledge. Therefore, behavior learning through observation has been more important.

However, a robot imitator does not usually share the same embodiment, for example, link configurations, constraints, dynamics, and so on, with a demonstrator. The imitator has to solve a problem of body mapping between the demonstrator and itself, so called, the correspondence problem[6], in an appropriate way. In order to avoid the problem, some conventional approaches focus not on body movement imitation but on target control imitation. For example, Bentivegna et al. [3] shows imitation of playing air hockey and marble maze. The robot does not imitate the motion of the body but the motion of the target, a paddle for the air hockey and knobs on the board for the marble maze. Another approach for the body mapping problem is to use a robot that has a similar embodiment with a demonstrator. Humanoid robots are popular for imitation of human demonstration[4], [5].They use motion capture systems to capture human body postures and map them to the body postures of a humanoid robot. They have few body mapping problems and actually it is easy to map the human body links to humanoid robot ones because the demonstrator and the imitator share similar embodiment.

For example, a dolphin imitates human motion as discussed in [6] and a child imitates a long trunk of an elephant with his/her arm. They have different embodiments with the demonstrators and show successful imitation based on mapping the body of a demonstrator to the one of the imitator The body mapping problem becomes more difficult and important if the robot imitator does not share the embodiment with a demonstrator. Therefore, an appropriate approach is necessary for the problem to realize body movement imitation learning in a human symbiotic environment.

On the other hand, two-wheeled inverted pendulum mobile robots have been developed as a realistic solution for the human symbiotic environment so far[7][8]. A inverted pendulum mobile robot has many advantages over the statically stable wheeled robots and any other biped robots. It requires a smaller amount of space to stand and stay upright than the other wheeled robots and smaller number of actuators than the conventional biped robots. Furthermore, it can easily generate more dynamic motions only by its body balancing control. The two-wheeled inverted pendulum robot has a possibility to be standard platform as a human partner robot. Most of researches regarding to the two-wheeled inverted pendulum robot focuses on the control theory for achieving stable navigation. There are few researches to realize more dynamic motions such as throwing, jumping, pushing, kicking, and so on. Takahashi et al.[9] introduced a reinforcement learning method for generating a dynamic motion such that a two-wheeled inverted pendulum robot kicks a ball far away utilizing its own body dynamics while it keeps standing. However, the learning time is too long to apply the learning method for a real mobile inverted-

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

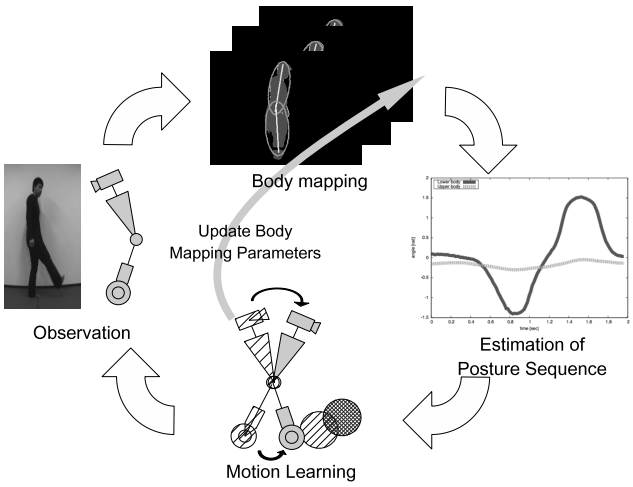

Fig. 1. Imitation Learning

pendulum wheeled robot. Furthermore, they designed initial motions by hand before learning in order to reduce unnecessary useless exploration as much as possible. In order to produce feasible initial motion for efficient learning, imitation is one of the most convincing approaches.

Tamura et al.[10] have proposed a method for recognition of demonstrator's posture for imitation based on reinforcement learning. They focus on how a two-link inverted-pendulum wheeled robot updates body mapping parameters while the demonstrator shows throwing motion after the robot learns the throwing motion. Takahashi et al.[11] investigated imitation learning performance for the two-link inverted-pendulum wheeled robot. A human demonstrator shows kicking motion and a robot learns the motion from observed data. They proposed a reasonable and feasible procedure of learning from observation for the inverted-pendulum wheeled robot. However, the body mapping parameters are tuned by hand and fixed during the imitation.

In this paper, we propose a novel learning method of body mapping parameters for imitation based on previous work[11]. A human demonstrates a ball kicking motion and a two-link inverted-pendulum mobile robot imitates the motion. Updating body mapping parameters based on gradient of evaluation of imitated motion enables the imitator to reasonably recognize demonstrator's body links for imitation and shows better performance of imitated motion than hand-tuned ones.

II. Imitation Learning

Figure 1 shows a flow of imitation learning. First, a two-link inverted-pendulum mobile robot as an imitator observes human demonstrations with a camera. A human region in the captured image is extracted and mapped to two links of the robot with a certain body mapping parameter. A sequence of link postures during the motion is estimated for imitation learning. The robot starts learning the motion from the estimated link posture sequence as initial motion parameters. After the learning, the body mapping parameter is updated based on the performance of the learned motion. This procedure repeats until the robot finds a local optimum body mapping parameter. Details of the each step are described in following sections.

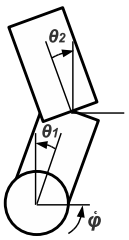

Fig. 2. Model of Two-Link Inverted-Pendulum Mobile Robot

III. Inverted Pendulum Wheeled Robot

Figure 2 shows a model of our inverted-pendulum wheeled robot. The robot body size is 20cm length, 30.5cm width, and 70cm height. The weight is 8kg including the torso, body, wheels, batteries, motors, gears, encoders, an accelerogyrometer unit, and control unit. The wheel radius is 8.5 cm and its weight is 500g each. The ball kicked by the robot is a soccer ball, roughly 22cm in diameter, and about 450g in weight. In order to perform comprehensive experiments for learning a kicking motion with the robot, we develop a computer simulation of the robot and the ball using the ODE(open dynamics engine) library.

IV. Design for Learning Kicking Motion

The kicking motion is designed with two control layers, a low-level posture controller and a posture generator. The posture controller follows a conventional torque control theory. Torque for the wheels u_1 is calculated as follows:

$$u_1 = -k_1^l(\theta_1 - \theta_d^l) - k_2^l\dot{\theta_2} - k_3^l\dot{\varphi} - k_4^l\sum(\dot{\varphi} - \dot{\varphi}_d), \qquad (1)$$

where θ_1, θ_d^l, $\dot{\varphi}$, $\dot{\varphi}_d$ are error of body angle, desired body angle, wheel angular velocity, and desired wheel angular velocity, respectively. k_1^l, k_2^l, k_3^l, k_4^l are gains for the body angle, body angular velocity, wheel angular velocity, and accumulated error of wheel angular velocity, respectively. For simplicity, torque for a joint between the body and the torso u_2 is designed as follows:

$$u_2 = -k_1^u(\theta_2 - \theta_d^u) - k_2^u\dot{\theta_2} - k_3^u\sum(\theta_2 - \theta_d^u), \qquad (2)$$

where k_1^u, k_2^u, and k_3^u are control gains.

In this work, we design the kicking motion in combination with two primitive motions (Fig.3). Each primitive motion defines the desired body and torso angles, desired wheel angular velocity, gain parameters, and a period of time. The posture generator sends the control parameters to the posture controller within the period defined by the primitive motion, one by one. The first primitive motion tries to lean forward to kick the ball and the second tries to make the robot kick the ball actually. Before and after the kicking motion, the robot controls itself to stay upright avoiding falling-down, autonomously.

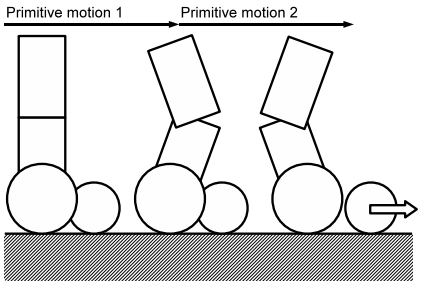

Fig. 3. Two Primitive Motions to Kick a Ball

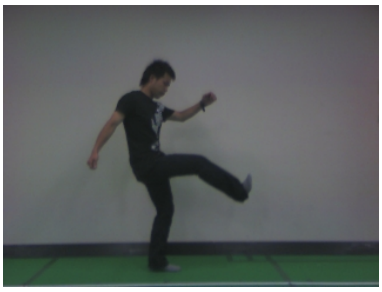
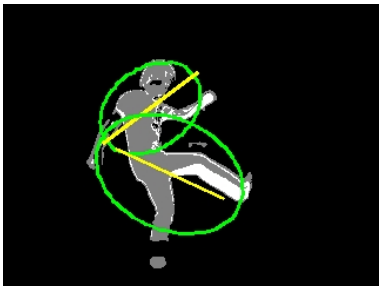


(a)



(b)

Fig. 4. View of Human Kicking Motion (a) and Upper and Lower Body Recognition (b)

V. Observation and Initial Learning Parameters

Using a camera, a robot observes a human demonstration of kicking a ball. Figure 4(a) shows a picture of observed motion of human kicking behavior. It captures pictures with 30fps and extracts regions of the human in the images with simple background subtraction and frame difference methods. Then, it estimates postures of upper and lower bodies by calculating covariances of the regions in the image. First, it divides the whole human region into two regions, upper body and lower body, with a body mapping parameter r_{bm}. The body mapping parameter r_{bm} specifies a ratio of upper and lower bodies. For example, a whole human region is divided at the center of the region when $r_{bm} = 0.5$.

Then, a region moment M_{pq} is calculated for each region:

$$M_{pq} = \sum_i \sum_j (i - i_G)^p (j - j_G)^q f(i,j) \qquad (3)$$

(i_G, j_G) is the center of the region and $f(i,j)$ is pixel value on the point (i, j) which is 1 if the point in the region, otherwise zero. The posture θ of the region (as the upper or lower body) can be calculated as:

$$\theta = \frac{1}{2} \arctan\Big(\frac{2M_{11}}{M_{20} - M_{02}}\Big) \ , \qquad (4)$$

where p and q are indexes of order of moment for x and y coordinates, respectively. Figure 4(b) shows a extracted human body region and estimated posture of upper and lower bodies.[1] Figure 5 shows a sequence of estimated postures during the observation of human kicking motion.

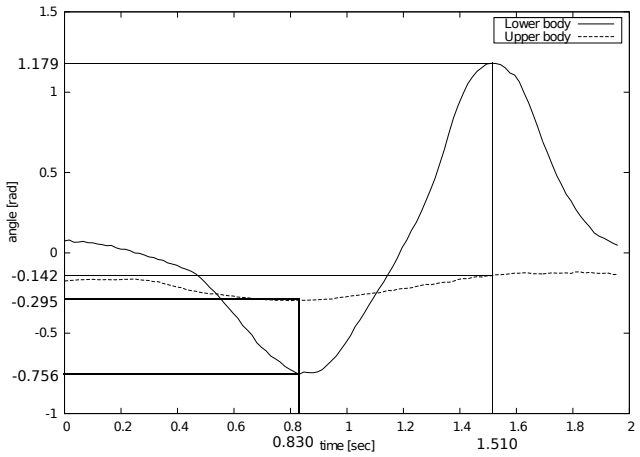


Fig. 5. Posture Estimation during Human Kicking Motion

Primitive motion parameters are initially set from the observed postures from Fig.5. In general, a human kicking motion does not consist of two primitive motions as described in Section IV. A learning robot has to extract useful parameter values from observation of human kicking motion. To be concrete, the observed human motion divided into two primitive motions for generating learning initial parameter values. A sequence of an observed trajectory is divided at points each of which lower body posture acceleration is the highest. 0.830 [sec] and 1.510 [sec] are the points to be divided from Fig.5. 0.830 [sec] and 0.680 [sec] are set as periods of time for primitive motion 1 and 2. Posture angles of lower and upper body at 0.830[sec] are -0.126 [rad] and -0.0492 [rad], respectively. Then, desired posture angles θ_d^l, θ_d^u for primitive motion 1 are set -0.126 [rad] and -0.0492 [rad]. In turn, posture angles of lower and upper body at 1.510 [sec] are -0.808 [rad] and 1.30 [rad], respectively. Then, desired posture angles θ_d^l, θ_d^u for primitive motion 2 are set 0.197 [rad] and 0.135 [rad]. Eventually, the initial parameter values with body mapping parameter $r_{bm} = 0.5$ are shown in TABLE I. The table also shows wheel angular velocity ϕ_d and initial control gains for experiments later.

The body mapping parameter r_{bm} affects not only the division of the human region into upper and lower bodies but also the estimation of body postures of the observed motion. The parameter should be tuned appropriately in order to acquire

[1]The part of ankle is failed to be extracted because the part has similar color with background. However, the effect of the extraction failure is small enough to estimate the posture of the lower body.

proper initial motion parameters for imitation learning. Figure 6 shows an example. Two pictures in Fig.6 are exactly same with different body mapping parameters $r_{bm} = 0.3$ and 0.7. TABLEs II and III show extracted primitive motion parameters with body mapping parameter $r_{bm} = 0.3$ and 0.7, respectively. They indicate that different body mapping parameters on a same observed image result in different body postures of the observed motion.

VI. MOTION LEARNING

A simple policy gradient method introduced by Kohl and Stone[12] enables the posture generator to learn the kicking motion, to say more precisely, improve the control parameters of each primitive motion by trail and error. First, it has a initial control parameter and prepares a set of similar parameters by adding small disturbances. It evaluates the control parameters one by one and estimates gradient of the evaluation of the control parameters. Finally, it updates the control parameters

TABLE II
EXTRACTED PRIMITIVE MOTION PARAMETERS WITH BODY MAPPING PARAMETER $r_{bm} = 0.3$

learning parameter	primitive motion 1	primitive motion 2
T [sec]	0.896	0.674
θ_d^l [rad]	-0.0784	0.0915
θ_d^u [rad]	-0.0770	-0.0638

TABLE III
EXTRACTED PRIMITIVE MOTION PARAMETERS WITH BODY MAPPING PARAMETER $r_{bm} = 0.7$

learning parameter	primitive motion 1	primitive motion 2
T [sec]	0.830	0.714
θ_d^l [rad]	-0.285	0.288
θ_d^u [rad]	-0.0533	0.0172

according to the estimated gradient of the evaluation. The learning system repeats this procedure and updates the motion parameters to reach the local maximum of evaluation. For further details, please refer to the original paper by Kohl and Stone[12] or our previous work[11]. Figure 7 shows the

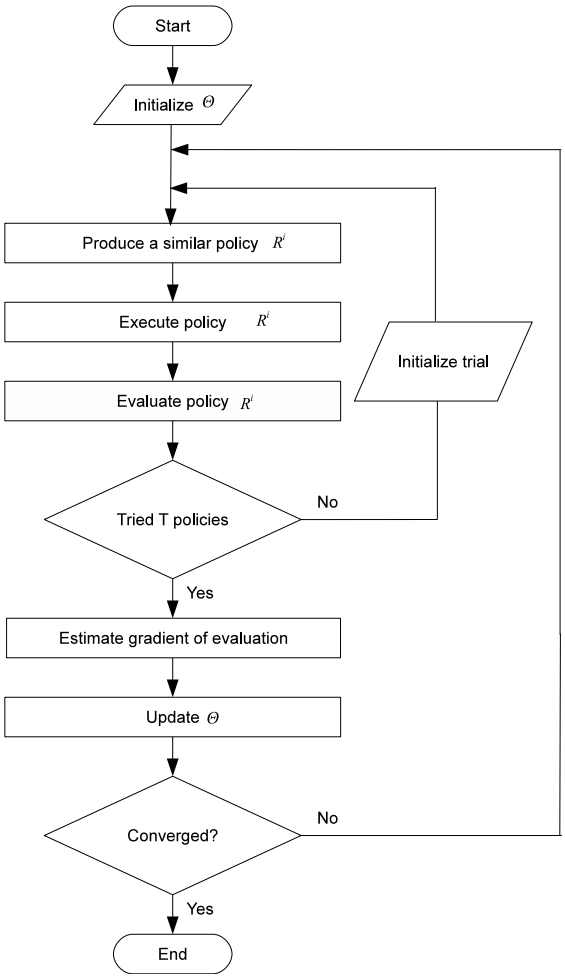

Fig. 7. Learning Procedure

learning procedure.

TABLE IV
STEP SIZE OF LEARNING PARAMETERS

learning parameter	step size
T [sec]	0.001
θ_d^l [rad]	0.01
θ_d^u [rad]	0.01
ϕ_d [rad/sec]	0
k_1	0.01
k_2	0.001
k_3	0.0001
k_4	0.00001

Each primitive motion is defined by the desired body and torso angles θ_d^l θ_d^u, the desired wheel angular velocity $\dot{\varphi_d}$, the gain parameters k_1, k_2, k_3, and k_4, and a period of time t. The learning parameters are those primitive motion parameters for each, therefore, 16 parameters in all. We determine the evaluation criterion of the kicking motion while learning process in consideration of the following points:

- Traveling distance of the robot body should be small.
- Velocity of the kicked ball should be large.
- Robot should avoid falling down by kicking the ball.

The actual evaluation is defined as follows:

$$E = \begin{cases} w_1 v_b - w_2 l_b^2 - w_f & \text{if it falls down} \\ w_1 v_b - w_2 l_b^2 & \text{else} \end{cases} \quad (5)$$

where l_b, v_b are traveling distance of the robot body during kicking motion and velocity of the kicked ball, respectively. w_1, w_2, w_f are penalty for falling down and weights and set as 2.0, 1.0, and 10.0, respectively, in the following experiments.

VII. UPDATE OF BODY MAPPING PARAMETER

Evaluation of the acquired motion $E^f(r_{bm})$ is checked after learning with body mapping parameter r_{bm}. Then, a random disturbance Δr_{bm} is added to the current body mapping parameter, estimation of sequence of upper and lower body postures and recalculation of initial motion parameters are conducted again, and motion learning is restarted. After the learning, the robot evaluates the acquired motions as $E^f(r_{bm} + \Delta r_{bm})$ and $E^f(r_{bm} - \Delta r_{bm})$. Finally, it updates the body mapping parameter to imitate the motion with higher evaluation as follows:

$$r_{bm} \leftarrow \begin{cases} r_{bm} + \Delta r_{bm} & \text{if } E^f(r_{bm} + \Delta r_{bm}) > E^f(r_{bm}) \text{ and} \\ & E^f(r_{bm} + \Delta r_{bm}) > E^f(r_{bm} - \Delta r_{bm}) \\ r_{bm} - \Delta r_{bm} & \text{if } E^f(r_{bm} - \Delta r_{bm}) > E^f(r_{bm}) \text{ and} \\ & E^f(r_{bm} - \Delta r_{bm}) > E^f(r_{bm} + \Delta r_{bm}) \\ r_{bm} & \text{else} \end{cases} \quad (6)$$

$|\Delta r_{bm}|$ is set to 0.1 in this paper.

VIII. EXPERIMENTS

A. Experiment Setup

The learning step size parameters are shown in TABLE IV. The number of deviated policies for estimating gradient of the evaluation T is set to 50 in the experiments.

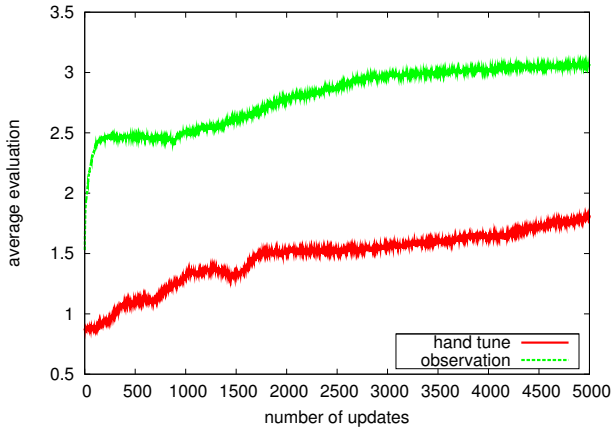

Fig. 8. Motion Evaluation during Learning with Initial Motion Parameters from Observation and Tuned by Hand

TABLE V
HAND TUNED INITIAL PARAMETERS OF PRIMITIVE MOTION 1 AND 2

learning parameter	primitive motion 1	primitive motion 2
period of time [sec]	0.500	0.500
θ_d^l [rad]	-0.052	0.052
θ_d^u [rad]	0.052	-0.052
ϕ_d [rad/sec]	0	0
k_1	15.0	15.0
k_2	-0.3	-0.3
k_3	0.01	0.01
k_4	0.0	0.0

B. Usefulness of Imitation Learning

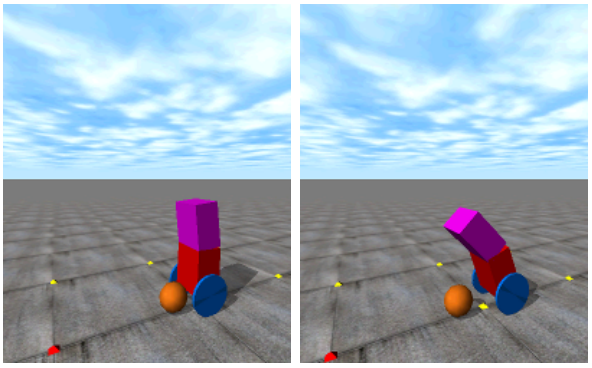
Figure 8 shows an example sequence of motion evaluation during learning with initial motion parameters from observation and tuned by hand. Acquired kicking motion with learning from observation is twice as good as the one with hand-tuned initial motion parameters. The hand-tuned parameters are shown in Table V. This result shows usefulness of the imitation learning. Figure 9 shows an example sequence of the learned kicking motion.

C. Effect of Body Mapping Parameter

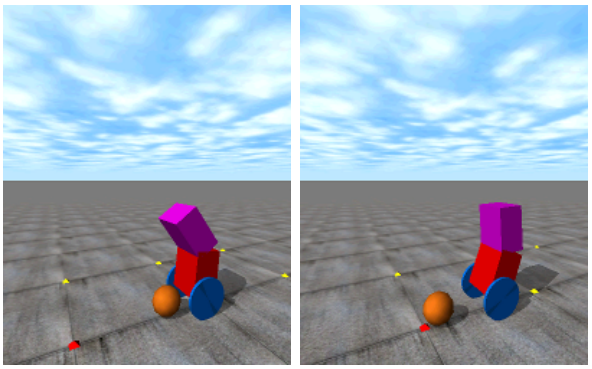
We investigated motion evaluation after learning while the body mapping parameter r_{bm} is changed gradually from 0.1 to 0.9. Figure 10 shows the result. It shows the acquired motion evaluation at $r_{bm} = 0.6$ is the best and distributed like a mountain. This means that a simple gradient method enable the imitator to find one of the best body mapping parameters by updating the parameters gradually. Figure 10 suggests that the body mapping parameter converges to the best with a simple gradient method if it starts from relatively large range (from 0.4 to 0.9) although the evaluation at $r_{bm} = 0.2$ is local maxima and it might prevent the imitator to find the best parameter value. However, a proper parameter exploration method such as simulated annealing easily avoids the local maxima.

IX. CONCLUSION

This paper addressed development of body mapping from a human demonstrator to an inverted-pendulum mobile robot



(a) 0.03 sec (b) 0.36 sec



(c) 0.56 sec (d) 0.92 sec

Fig. 9. A Sequence of Ball Kicking Motion after Learning

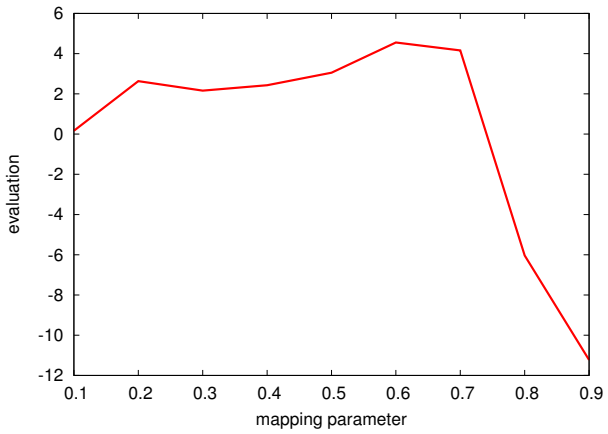


Fig. 10. Acquired Motion Evaluation with Variety of Body Mapping Parameter Values

for imitation. A human demonstrator shows kicking motion and a robot learns the motion from the observed data. In order to imitate an observed motion demonstrated by a human, the robot has to map the body of the demonstrator to its own body links. We proposed a reasonable and feasible method that enables a two-link inverted-pendulum mobile robot to learn a human motion from observation with a simple body mapping technique. Experimental results indicate that imitation gives better initial motion parameters for learning and body mapping parameter for the imitation can be updated based on the evaluation of the acquired motion after the learning. In order to show the proposed method has some generality, we are planning to apply to not only a kicking motion but also, for example, ball throwing, trapping, and so on.

***Abstract*—Recently, researches on multi-agent systems (MAS) which autonomous agents are able to learn cooperative behavior are actively performed. It is necessary for social agents to interact each other in order to have excellent cooperative performance in MAS. But it is difficult to give appropriate coordination at the right time, not to mention the generation of group behavior. We have aimed at the group behavior generation of social agents who have excellent autonomous learning ability like human through cooperative communication between agents to acquire cooperative behavior. Social agents are able to change the environment states to individual states and communicate their cooperative behavior by sending a special signal, which can not be understood originally but could be understood by other agents through reinforcement learning (RL) after some learning processes. Furthermore, if the agents could communicate their cooperative behavior successfully, their group identity will be strengthened by exchanging rewards among them. As the learning process, social agents can get the better cooperative ability than normal reinforcement learning method through group identity. Lastly, social agents not only adjust themselves to environment but also affect other agents to generate intelligent group behavior.**

***Keywords*—Reinforcement Learning; Multi-Agent Systems; Social Interaction; Cooperative Communication; Group Generation**

I. Introduction

In multi-agent systems (MAS), massive autonomous agents are required to solve complex problems by the coordination and cooperation of other agents flexibly[1]. On the other hand, reinforcement learning (RL) is an algorithm attempts to explore a suitable behavior to maximize a performance measurement based on interacting with an environment autonomously by repeating trial and error. RL adjusts behavior to a dynamic environmental without explicit teaching signals except rewards based on evaluation of current state and action. MAS is expected that it is able to learn the cooperative behavior and the group strategy by the application of the RL to autonomous agents[2], [3].

Generally, RL is basically developed for a single agent and it is used in MAS aspect, problems such that perceptual aliasing problem, concurrent learning problem and reward distribution problem occurred[4]. In a cooperative social environment, it is effective to learn by sharing sensing information, episodes, learned policies or exchanging advice. However, one of the main problems concerned learning in a MAS environment is how to benefit from mutual interaction during the learning process[5]. It is possible to develop cooperation models to unify partial action policies to create new policies which can be optimal ones[6]. But for social agents, we believe that it is necessary to communicate the cooperative behavior and to give appropriate coordination at the right time[7]. We have aimed at the group behavior generation of social agents who have excellent autonomous learning ability like human through cooperative communication between agents to acquire cooperative behavior[8].

In this paper, social agents are able to change the environment states to individual states and communicate their states with other agents by sending a new undefined signal. For other agents, they can not understand the meaning of that signal and just take it as a new state of that agent during the learning process. After massive trial and error of RL algorithm, under the hint of this undefined signal, agents could get a better optimal policy than normal RL method. Therefore, although other agents do not know the meaning of the undefined signal, the overall identity of their behavior is to achieve the task cooperating with the signal sending agent. In other words, because both sides made similar coordinate decision, it is possible to communicate their cooperative behavior by sending a new undefined signal that can not be understood originally but could be gradually understood by other agents after some learning processes.

In addition, the agents who regularly made the similar decision have an identity of cooperation like the social identity in our human society. Based on social identity theory, these agents create an in-group or self-categorization because they have stronger organization than agents of normal RL method. Therefore, we propose a method to cause group generation by exchanging rewards as group identity among themselves. All agents not only receive rewards from the environment but

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

also exchange the reward among each others based on the undefined signal hints and their decisions. It is possible for exchanging rewards among agents to reinforce the coordinative behavior autonomously when the expected actions appeared. Agents are able to acquire excellent cooperative group behavior and strength their group identity by taking reward exchanging as the social interaction strategy like human in society.

II. Social Interaction of Cooperative Communication and Group Generation

In the normal multi-agent reinforcement learning algorithm, each individual agent can only repeat trial and error through the interaction with environment. In this paper, social agents can communicate with other agents by sending an undefined special signal that can not be understood originally but could be understood by other agents after some learning processes. If the agents could communicate their cooperative behavior successfully, their group identity will be strengthened by exchanging rewards among them. Based on the group identity, group generation will be possible. The general idea of proposed Multi-agent RL systems as shown in Fig.1.

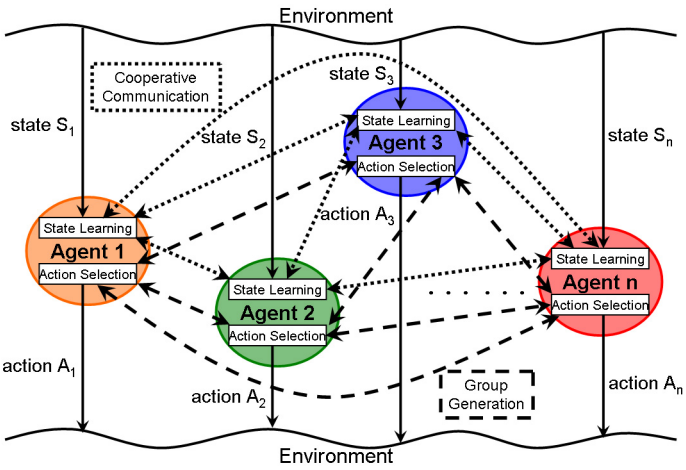

Fig. 1. Proposed Multi-agent RL systems

During the learning process, social agents can get the better cooperative ability than normal reinforcement learning method through the interaction of cooperative communication and group identity. Lastly, social agents not only adjust themselves to environment but also affect other agents to generate intelligent group behavior. Social agents will make decisions not only based on itself profit but also considering a joint profit with other agents.

A. Cooperative Communication Reinforcement Learning

For social agents, we believe that it is necessary to understand other behavior and to give appropriate coordination at the right time in MAS. In this cooperative communication reinforcement learning (CC-RL) algorithm, social agents are able to change the environment states to individual states and communicate their states with other agents by sending a new undefined signal. For other agents, they can not understand the meaning of that signal and just take it as a new states during the learning process, and try all the possible state-action strategy by trial and error using RL algorithm.

In this approach, when the target was discovered, the agent who found will change the environment state of its perception range to the state of itself, and send a special signal information (we called Help) to other agents if the task could not be achieved by itself in a dynamic environment. But other agents are uncertain this Help meaning of this special signal information and record it as a new special state S_t^n not defined in their sates. In the algorithm, S_t^n is described by a flag (0 or 1) which means a task could be achieved or not by itself.

In addition, the Help signal emerge only when an agent found target and can not achieve it. So this S_t^n information is also related to target discovering or task performing. By this way, agents can perceive other agents' states and have to adjust this new state by learning. If the overall identity of their behavior is to achieve the task cooperating with the signal sending agent, the communication of their cooperative behavior becomes possible by sending a new undefined signal.

Concretely, once the target was discovered, the agent send Help information to other agents even they are outside the range of itself perception. At the same time, other agents receive the coordinates of generated Help and compute the relative direction from itself position to Help. The emergence of Help and the relative direction will be recorded as the environment changing information like normal RL method. All the agents will perceive the signal of Help through the communication among agents if one agent found target. Therefore, this CC-RL method based on the emergence of new signal and the relative direction can partly solve the problem of incomplete perception in MAS. In Q-Learning method, Q-value is estimated on the basis of experience as follows:

Cooperative Communication Reinforcement Learning

Initialize $Q_t(S_t^e \vee S_t^n, a_t)$ arbitrarily

Repeat (for each episode)

Initialize $S_t^e \vee S_t^n$

Repeat (for each step of episode)

Observe S_t^e

Cooperative communication of individual state

Receive S_t^n from other agents

Choose a_t from $S_t^e \vee S_t^n$ using policy derived from Q-value

Take action a_t

Observe r_t and next state $S_{t+1}^e \vee S_{t+1}^n$

$Q_t(S_t^e \vee S_t^n, a_t) \leftarrow Q_t(S_t^e \vee S_t^n, a_t) + \alpha[r_t + \gamma \, max_{a \in A} \, Q_t(S_{t+1}^e \vee S_{t+1}^n, a) - Q_t(S_t^e \vee S_t^n, a_t)]$

$S_t^e \vee S_t^n \leftarrow S_{t+1}^e \vee S_{t+1}^n$

Until $S_t^e \vee S_t^n$ is terminal

---

where,

S_t^e: environment state of normal RL method,

S_t^n: the new undefined signal information state informed by other agent in current moment t. It includes the relative direction from own position to this new signal position.

The action evaluation value $w(s, b)$ becomes like in Eq.(1) in Profit Sharing method.

$$w_t(s_t^e \vee s_t^n, b) \leftarrow w_t(s_t^e \vee s_t^n, b) + f(h) \tag{1}$$

$w_t(s_t^e \vee s_t^n, b)$ is the action evaluation value when the state is $s_t^e \vee s_t^n$ and the action is b in current moment t. Reinforcement function $f(h)$ is the same as one of normal Q-Learning method. Efficient cooperative behaviors will be expected under the communication of this new signal hint among agents.

B. Group Generation Reinforcement Learning

By sending a new signal to others in the approach of CC-RL, the communication among agents is possible. But it just tells the partial information to each other not giving any evaluation for the action under this information. In our human society, if person A likes an action performed by person B, then A will praise B. The possibility of perfect action of B will be repeated in next time for the praising force. Based on this idea, we believe that if social agents want to have excellent cooperative ability like human, the agent should be praised if its action accords with the expected behavior.

In this approach, at a certain time t if the agent A_1 discovered the target but it could not achieve the task with itself power, then A_1 sent a new signal to other agents. And A_1 achieved the target with other agents A_2 and A_3 lastly, then A_1 should distribute a part of reward got from environment to A_2 and A_3 as a group reward to praise them for their help. A_2 and A_3 would receive the reward from the agent A_1 who sent a new signal information but not from the agent who did not send new signal information. Because the cooperative action of agent A_1 and agent A_2, A_3 was strengthened as the learning process, when the signal information appears in the next time, the possibility of selecting the group cooperative behavior will rise. In Q-Learning method, Q-value is estimated on the basis of experience as follows:

Group Generation Reinforcement Learning

Initialize $Q_t(S_t^e \vee S_t^n, a_t)$ arbitrarily

Repeat (for each episode)

Initialize $S_t^e \vee S_t^n$

Repeat (for each step of episode)

Observe S_t^e

Cooperative communication of individual state

Receive S_t^n from other agents

Choose a_t from $S_t^e \vee S_t^n$ using policy derived from Q-value

Take action a_t

Observe r_t and next state $S_{t+1}^e \vee S_{t+1}^n$

Distribute r_t^G among agents

$Q_t(S_t^e \vee S_t^n, a_t) \leftarrow Q_t(S_t^e \vee S_t^n, a_t) + \alpha[r_t + \beta \cdot r_t^G + \gamma \, max_{a \in A} Q_t(S_{t+1}^e \vee S_{t+1}^n, a) - Q_t(S_t^e \vee S_t^n, a_t)]$

$S_t^e \vee S_t^n \leftarrow S_{t+1}^e \vee S_{t+1}^n$

Until $S_t^e \vee S_t^n$ is terminal

---

where,

β: the rate of social interaction about group reward,

r_t^G: the group reward in current moment t.

The action evaluation value $w(s, b)$ is the same as Eq.(1) in Profit Sharing method, but reinforcement function $f(h)$ becomes as follows in Eq.(2).

$$f(h) = \alpha \cdot \gamma^h (r_t + \beta \cdot r_t^G) \tag{2}$$

For the agent of sending new signal information, it is necessary to supply a part of reward to the agents giving help and r_t^G is defined by $-\theta \cdot r_t$, and θ is the percentage of given reward as compared with r_t ($\theta \leq \theta_{lim}$). In GG-RL, the reward is re-distributed among agents, but the total reward value is not changed comparing with normal RL.

For the agents of giving cooperation, each agent will obtain a part of reward from the agent who sent signal as group reward, the reward of $\theta \cdot r_t$ is distributed by n which means the number of agents giving cooperative behavior to new signal sending agent ($n \leq n_{lim}$). Therefore, r_t^G is defined by $(\theta \cdot r_t)/n$.

In addition, the agents who regularly made the similar decision have an identity of cooperation like the social identity in our human society. Based on social identity theory, these agents create an in-group or self-categorization if they had stronger organization than agents of normal RL method. Based on group identity, we proposed group generation reinforcement learning (GG-RL) method. In GG-RL, the perfect action according with the original expected behavior will be praised through a group reward. Under the influence of group identity, group generation becomes possible.

Therefore, all agents not only receive rewards from the environment but also exchange the reward among agents to reinforce the coordinative behavior autonomously when the expected actions appeared. Agents are able to strength their group identity by taking reward exchanging as the social interaction strategy like human in society.

III. Simulation Experiments

In order to verify the effectiveness and robustness of proposed methods, we also performed the comparison prey chase simulation experiments with obstacles using Profit Sharing method. This simulation is programmed by C language with the graphic library of OpenGL executed in Linux system. The view of simulator is shown in Fig.2.

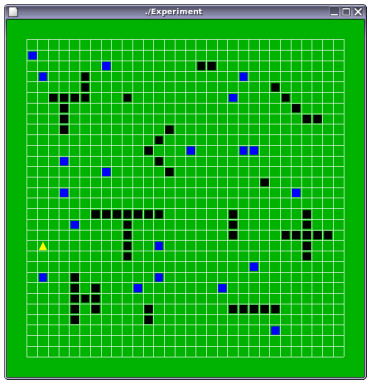

Fig. 2. The view of prey chase simulator of Exp.(1)

A. Simulation Preconditions

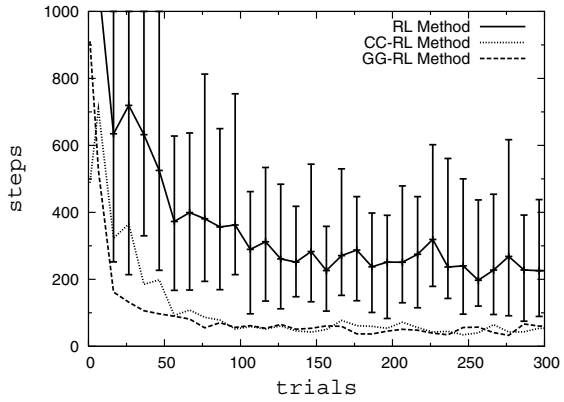
The preconditions of this simulation are set as follows:

- The field is composed by 30×30 grids in two dimensional environment. There are 62 obstacles in the learning environment.
- 20 hunter agents are set and represented as a square on the grid. The action and the perception ability of all agents are equal.
- Both the hunter and a prey represented as triangle agents can move in eight directions: up, down, left, right, up-right, up-left, down-right, down-left. They can stay at their current positions.
- The perception range is set 7×7 grids around itself.
- The default positions of all agents are arranged randomly and a prey agent moves always randomly.
- All hunter agents can obtain the other agents' perception information by sending new signal.
- When the prey agent becomes adjacent by three or more hunter agents, the task of chase is achieved. All the agents will return to the initial state after that.
- Hunter agent's task is to capture the prey agent as soon as possible. When the prey capturing is achieved, they will obtain the basic reward R assumed to be 100.

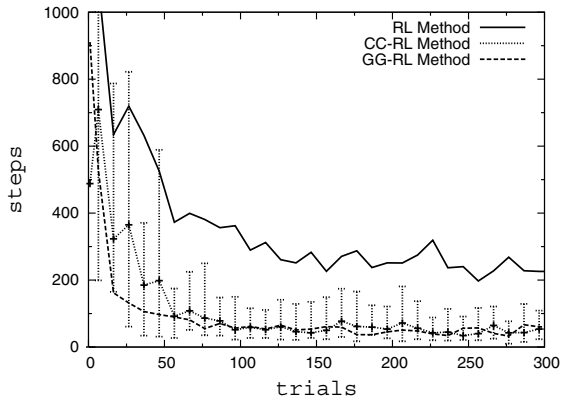
The parameters in this simulation are set as follows: $\gamma = 0.8$, $\lambda = 0.8$, $\alpha = 0.8$, $\beta = 1$,$\theta = 0.2$. To confirm the effectiveness of the proposed method, we performed comparison experiments with normal Profit Sharing reinforcement learning method. When an action is selected in Profit Sharing, the action is generally decided by the roulette selection of the action evaluation value added to the rule.

B. Simulation Results

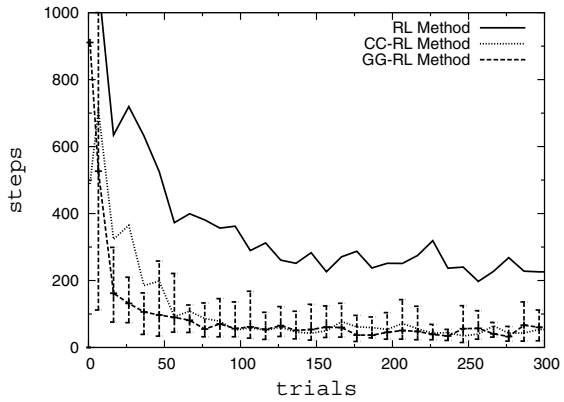
We performed two simulation experiments in different conditions: Exp.(1) with only one target; Exp.(2) with 5 targets. In each experiment we compared four learning methods of RL, CC-RL and GG-RL. All of the methods are performed 5 times in this simulation, the average and deviation of simulation results are shown in result graphs.



(a) Deviation of RL



(b) Deviation of CC-RL



(c) Deviation of GG-RL

Fig. 3. Results of Exp.(1) with one target

Exp.(1) with only one target

In this experiment, there is only one target in the learning environment as shown in Fig.2. Vertical axis shows the steps required for capturing the prey and horizontal axis shows the trials of learning. From the average results in Fig.3(a)∼(c), we confirmed that the cooperative communication reinforcement learning (CC-RL) method obtained better results than normal

RL method, the group generation reinforcement learning (GG-RL) method obtained the best learning result than the other methods. From the deviation results in Fig.3(a)∼(c), we also confirmed that the stability of CC-RL and GG-RL methods are better than normal RL method. Furthermore, we can find that GG-RL method obtained better results than CC-RL method in the average and the deviation. That shows the exchanging group rewards among agents can reinforce the group behavior to achieve the task efficiently.

Exp.(2) with 5 targets

As a social agent, it is necessary to learn the best decision even with several targets in the complex environment. So we performed the simulation experiment with 5 targets as shown in Fig.4. The comparison experiment results of 3 methods are shown in Fig.5(a)∼(c). By these results, we found that they are similar to the results of experiment with only one target. But the degree of convergence was not as good as Exp.(1) because it is more difficult naturally to capture 5 preys than only one.

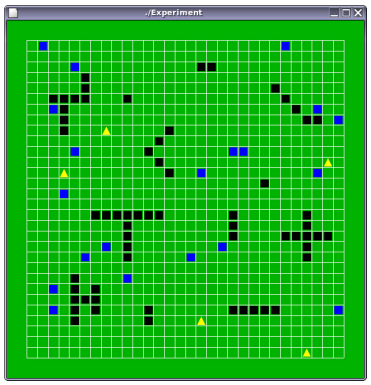


Fig. 4. Chase simulation of Exp.(2) with 5 targets

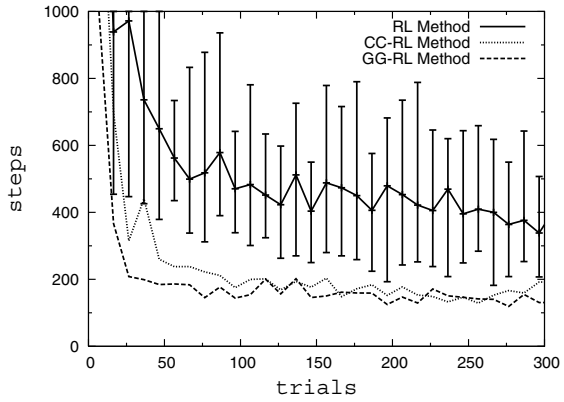
C. Individual and Group Growth

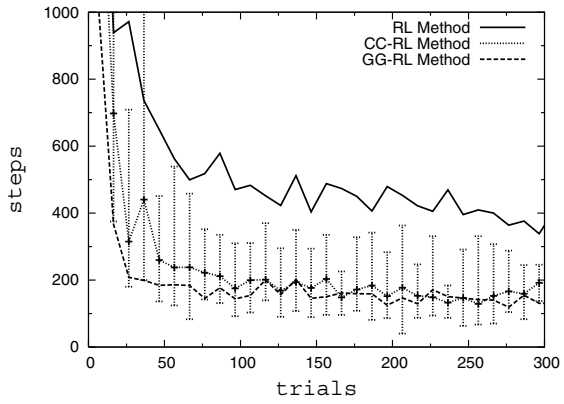
In order to distinguish the process of each individual growth, we also recorded the performance about 20 hunter agents. The growth of them is shown in Fig.6 based on catch time for preys. From this graph, we found that their performance is various after 300 trials to achieve the task. The best individual (agent 13) could get several times than the worst (agent 11) one in the achievement.

We have aimed at the generation of group behavior and recorded the interactive information among agents like Fig.7. The numbers of upside and left mean 20 agents and other numbers represent exchanging reward after 300 trials. The exchanging reward is only distributed among agent when the agents who regularly made the similar decision which means they have an identity of cooperation. Therefore, the exchanging reward represents the group identity of different agents.

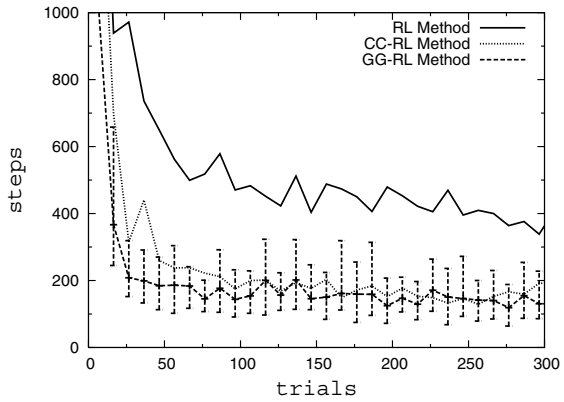
In the cooperative task, all the agents maybe chose anyone to cooperate, but the agent will more likely to cooperate with the agent who holds maximum exchanging reward. For each agent, if it holds maximum exchanging reward with many agents, it will have a greater influence in these agents. From the graph of Fig.7, agent 13 holds maximum exchanging reward



(a) Deviation of RL



(b) Deviation of CC-RL



(c) Deviation of GG-RL

Fig. 5. Results of Exp.(2) with 5 targets

with other 10 agents and we defined the pair influence of agent 13 as 10. All the agents will have a pair influence value based on this idea. Lastly we can easily get the relationship of all the agents like in Fig.8. The agent having greater pair influence is represented by wider circle area filled by color. The interactive degree of each others is represented by width of connecting lines, the wider the deeper social interactive ability. Therefore, we can easily find the relationship of all the agents in the pair influence aspect. In addition, we found that agent 13 did the best performance in individual aspect and also had the greatest influence in group generation.

IV. Conclusions

In this paper, we proposed CC-RL, GG-RL of multi-agent reinforcement learning methods with an excellent cooperative ability through the social interaction of cooperative communication and group generation by reward exchange which circulate among autonomous agents in MAS.

From the results of the comparison simulation between RL and CC-RL methods, we found that CC-RL method obtained the target state and individual information and could obtain the better cooperative ability than normal RL method. Although the outside of the perception range, the agent can obtain some environment states that can not be obtained from their restricted perception through the interaction with the other agents. The emergence of new undefined signal and the relative direction help the agent not only to perceive more learning states but also to get some information about the target in the task. Therefore, the communication of sending a new undefined signal accelerate their cooperative behavior.

Furthermore, we proposed GG-RL method that can give some evaluation to the action of agents by exchanging rewards. Rational re-distribution of reward causes the different learning results between CC-RL and GG-RL. Agents could encourage each other by exchanging reward. At last, the interaction among agents can be changed to the behavioral strategy communication like the human society and the autonomous cooperative group behavior of GG-RL method was best than the other methods.

At the same times, we can see the growth of 20 agents and group generation. The possibility of cooperation became very different from each other after learning. In the simulation, it is difficult to communicate more undefined signals, but it is possible to communicate and reinforce more complex behavior by proposed method. In the further works, we have a plan to add more communication modes to agents and let social agents have robust autonomous cooperative learning ability even in the competitive environment.

***Abstract*—It could be very important and useful to enable human stress to be estimated on basis of quantitative values via objective analysis. There have been several approaches to estimate the stress so far. Most of them need a lot of time to measure or calculate it, and what is more, they might cause physical or mental burden for human subjects. The purpose of our study is to propose and develop a method to estimate subjective stress through a simple approach which doesn't cause much burden for users. In this paper we propose a method, which is called $\mathrm{TPA_f}$ (Turning Point Amplitude via finger plethysmogram). Original TPA is a kind of heart rate variability analysis and needs to attach sensors on his/her breast. Our experimental results indicated that it has a certain relationship between subjective stress and $\mathrm{TPA_f}$. A method based on $\mathrm{TPA_f}$ could be efficient to estimate subjective stress.**

I. INTRODUCTION

Can you imagine a future society that humans and robots live together? They can talk and socialize with each other. Maybe humans and robots can understand each other through nonverbal communication. Robots can understand human feeling or emotion through his facial expression or biological signals. We consider that such a society isn't a dream or science fiction but a real society coming near future. Some studies of Human Agent Interaction(HAI) or Human Robot Interaction(HRI) focus on the communication between humans and robots. 'Palo' and 'ifbot', which are related to robot therapy, can behave based on nonverbal communication[8][9]. On the other hand, Palo and ifbot don't recognize and understand human feeling itself, of course, it is no problem from the standpoint of their design philosophy and concept. However, the near future society might require high-performance robots that have an ability to recognize human feelings or mental situation.

There have been many studies on measuring human feeling or emotions. Most of them employs subjective assessment measure, on the other hand there exist many approaches based on objective analysis. Some indexes of physiological evaluation are well known to measure human stress. For example, Immunoglobulin A type and cortisol in saliva are often used to measure the stress[1][2][3]. Stress indexes via heart rate variability (HRV) analysis is also often used [4]. The methods are very effective and useful, but there are some problems, assuming that the robots employ them to measure the stress. One problem is on sensing. In order to extract Ig. or cortisol from saliva, sensors need to be inserted in his/her mouth. HRV analysis needs to attach sensors on the breast. In daily life wearing the sensors is unnatural and it assigns a lot of burden to users. The another is on measurement time. In order to extract Ig. or cortisol from saliva, it takes only a few seconds. But HRV analysis generally takes several minutes to evaluate the electrocardiographic wave. In future daily life it would be better to employ an evaluation method based on near realtime analysis because the robots can quick respond and act according to the realtime mental situation of human.

In this study our goal is to develop a simple estimation of subjective stress which can measure the stress in near realtime. There are two kinds of subjective stress that are unconsicous and consious. People are not aware of unconsious stress existing, thus it might be important for people to care the unconsious stress in terms of medical reason. On the other hand, people could be aware of conscious stress. We consider that the conscious stress is suitable to decide and control robot behaviors for taking care of human people because users could be able to recognize the robot behaviors are due to the conscious stresses of users themselves. Unless users are aware of their stresses, they couldn't understand what the robot aims to do. The unconsicous stress to control autonomous robots would carriy a lot of risk in daily life. Our study therefore deals with consicous subjective stress. The contributions of this study to develop the estimation are as follows:

1) Proposal and development of $\mathrm{TPA_f}$ calculation via finger plethysmogram. Original TPA was developed by Yokoyama et al[5]. It could be calculated by the data of electrocardiographic wave measured for about several tens of seconds. The calculation formula of $\mathrm{TPA_f}$ is very simple, thus we could achieve near realtime processing. Furthermore, the finger plethysmogram is measured more easily than the electrocardiographic wave.
2) Investigation of a relationship between the subjective conscious stress and $\mathrm{TPA_f}$ via finger plethysmogram. $\mathrm{TPA_f}$ could have some relationship to human stress, but no experiments have been done on the relationship with conscious subjective stress so far. We employ Face Scale

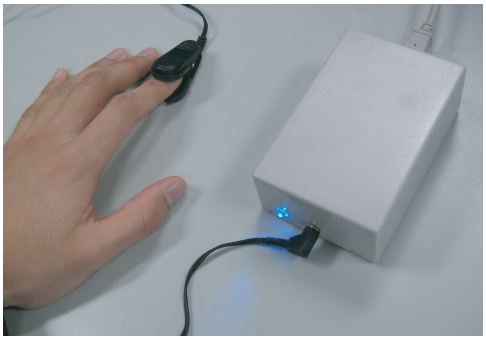

Fig. 1. Pulse sensor to measure finger plethysmogram

to measure conscious subjective stress.

II. EVALUATION INDEX OF STRESS

In this study we adopted heart rate variability (HRV) analysis via finger plethysmogram. The power spectra of heart rate variability contain the low frequency components (LF) from 0.04 to 0.15Hz and the high frequency components (HF) from 0.15 to 0.4Hz. HF is said to be mainly affected by components originated human breathing called 'Respiratory Sinus Arrhythmia (RSA)'. HF reflects the activity of the parasympathetic nerves. LF is said to be mainly affected by components originated blood pressure called 'Mayer Wave related Sinus Arrhythmia (MWSA)'. LF reflects the activity of the sympathetic nerves and parasympathetic nerves. The ratio of LF to HF reflects the activity of sympathetic nerves. It is said that the parasympathetic nerve activity becomes higher while feeling comfortable. Therefore HF is used as an index of relaxation or stress reduction. The power spectrum analysis, such as FFT, AR method and wavelet transform are generally used to calculate HF in HRV. Yokoyama et al. proposed a method which is able to estimate HF component of HRV based on local characteristics in time series[5]. Of course it has no need to use power spectrum analysis, and it is calculated by data at most of around 20-30 points. Thus the method is able to work in near real time because a calculating formula is simple. They verified that there was high correlation among the average values of HF detected with their proposed method, AR method and wavelet transform. In our study we adopted an method based on TPA (Turning Point Amplitude). TPA can be calculated in near real time, and it requires human subjects to attach sensors on their breast as mentioned in the previous section. Therefore we exploit a simple sensor to measure finger plethysmogram illustrated in Fig.1. The sensor is easier to handle than the sensors attached on the breast. In this paper $\mathrm{TPA_f}$(TPA via finger plethysmogram) is used to evaluate human stress from the objective view.

On the other hand Face Scale (FS) is a well-known index to measure human subjective feeling. FS, which is suggested by Lorish et al.[7], is a method to evaluate subjective feeling, FS is the illustrations of a person from a smile (scale 1) to a tearful face (scale 20) as shown in Fig.2. The subject has only to answer with the number of FS expressing his current feeling.

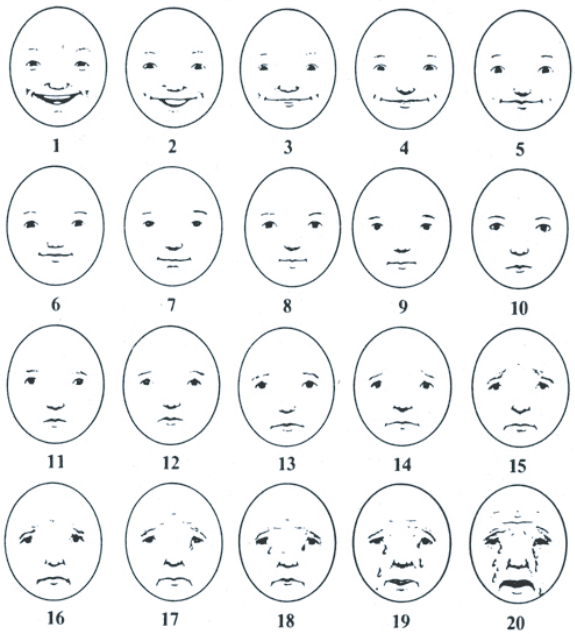

Fig. 2. Face Scale

There is a advantage to be able to perform the experiments in a short time. FS was also adopted as a method to evaluate a result of the treatment subjectively in the clinical medical field, and the effectiveness was reported[7]. This paper adopts FS to evaluate human subjective feeling, and attempts to find out a relationship between FS and $\mathrm{TPA_f}$.

III. EXPERIMENTS

We present our experimental method and the environment. We considered that it was important to measure FS and $\mathrm{TPA_f}$ at same time in order to investigate the relationship between them. Furthermore we considered that it was valid and proper to evaluate the human subjects who are in either normal mental state or stress state. Our experiment gave the subjects an artificial stressor such as mental arithmetic. The experiment evaluated the subjects in the three states that are pre-stress state, stress state and post-stress state.

A. Experimental Method

The experimental procedure is shown in Fig.3. Our experiment consists of three phases, the whole time was 15 min. In the first 5 min, human subjects closed their eyes. In the next 5 min, the subjects did mental arithmetics. While their constraining the mental arithmetic, they might have been directly under mental stress. Then they finished it and in the final 5 min, they closed their eyes or viewed the video. In the final 5 min they were not directly under mental stress, but its influences must have remained. Here we call the first 5 min, next 5 min and final 5 min 'pre-stress state', 'stress state' and 'post-stress state' respectively. After the end of each state, the human subjects chose FS number which was suitable to their own feeling at that time. In our experiment we prepared 'eyes closed' and 5 kinds of video image, each of which has

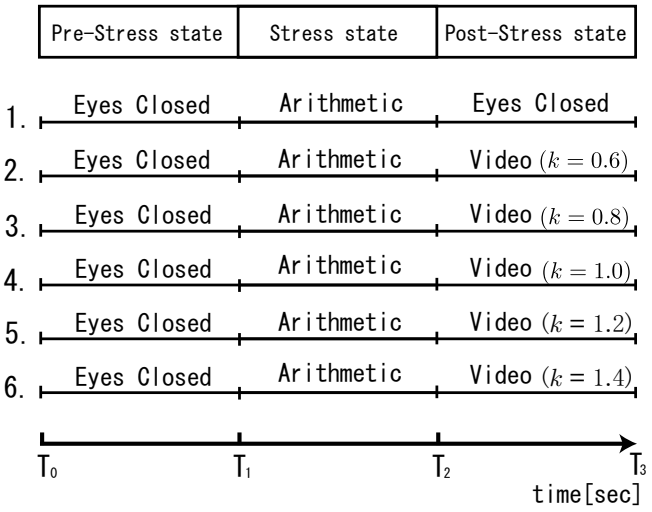

Fig. 3. Experimental Procedure

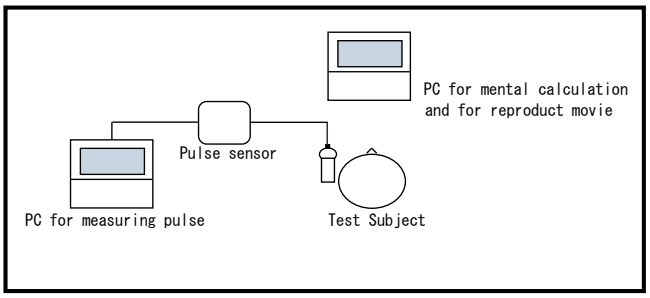

Fig. 4. Experimental Environment

different motion speed, for 'post-stress state' as shown in Fig. 3. The 'eyes closed' and the video were used for relaxation of the subjects [6]. The subjects performed all the experiments (1-6) in a different random order for each. Mental arithmetic was used as mental workload in the experiment. The details of mental arithmetic and the video images are mentioned later.

The experiment measured FS at T_1,T_2 and T_3. The time series of $TPA_f(t)$ were measured during all the time from T_0 to T_3. Here we define $TPA_f(t)$ which indicates a value of TPA_f at the time t.

The subjects were 9 males and 1 female in their 20s. Every subject didn't have the abnormal vision and were able to visually confirm the motions of the video. The experiment was conducted in the environment illustrated in Fig.4. The experiment environment was dark quiet room. The subjects kept sitting on the chair during the experiment. The computer displayed the questions of the mental arithmetic to enhance the subjects' mental workload, and the subjects answered them. The finger plethysmogram of the subjects were measured by the pulse sensor and the computer for measuring pulse wave.

B. Mental Workload

In the experiment, the mental arithmetic was used as mental workload [3]. The experiment required the subjects to repeat solving the mathematical questions: "Subtract 13 from a four-digit figure X". The first figure X_0 is given at random and you answer $X_1 = X_0 - 13$. Next you answer $X_1 - 13$. Thus the i-th question will be $X_{i+1} - 13$. When the subjects made a mistake in the arithmetic, it restarted over from the beginning: $X_i = X_0$ illustrated in Fig.5. The subjects answered questions of the mental arithmetic on the computer monitor (Fig.6).

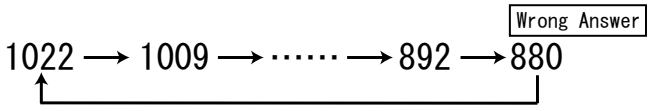

Fig. 5. Example of Mental Arithmetic the Human Subject Answered

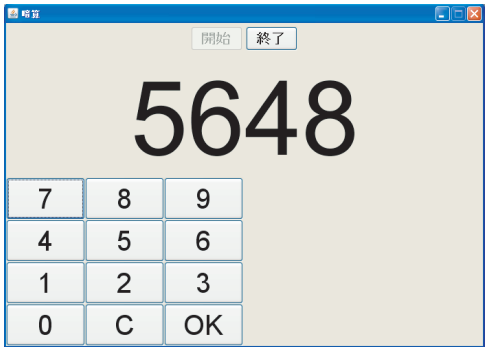

Fig. 6. Mental Arithmetic Application

Fig. 7. Capture Image of CG Video

C. Video Image

We adopt 'ripples appearing on the water surface' as a video that the subjects view in the post-stress state for their relaxation [6]. The ripples, which we use a CG technique for generating, are displayed on the monitor. Ripples appear from the center of the image and disappear outside of the image. A capture image of the video is shown in Fig.7. In the experiment 5 kinds of the video with different motion speed parameter k $(= 0.6, 0.8, 1.0, 1.2, 1.4)$.

IV. EXPERIMENTAL RESULTS AND ANALYSIS

A. Relationship between TPA_f and FS

$TPA_f(t)$ is changeable and it isn't easy to find out the relationship between $TPA_f(t)$ itself and FS at the time t. It is

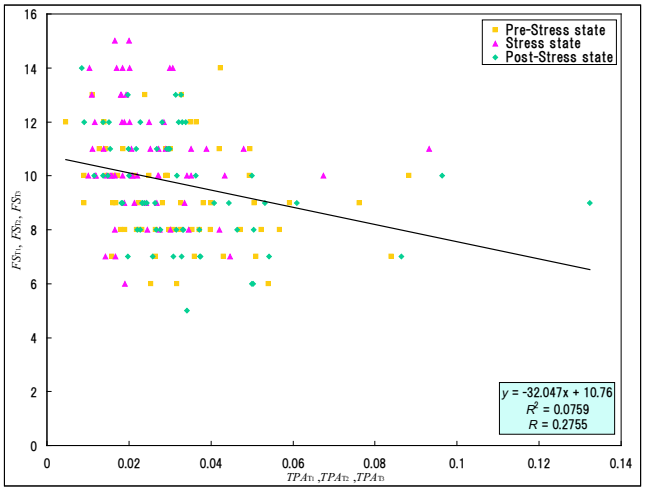

Fig. 8. Scatter plot of $\mathrm{TPA_f}$ and FS

said to be useful way to calculate the average value of 20-30 points of $TPA_f(t)$ [5].

Therefore we calculate $TPA_{\mathrm{T_i}}$ which is the average value of $TPA_f(t)$ for x seconds just before $\mathrm{T_i}$ as follows:

$$TPA_{\mathrm{T_1}} = \frac{1}{x}\int_{(\mathrm{T_1}-x)}^{\mathrm{T_1}} TPA_f(t)dt \quad (1)$$

$$TPA_{\mathrm{T_2}} = \frac{1}{x}\int_{(\mathrm{T_2}-x)}^{\mathrm{T_2}} TPA_f(t)dt \quad (2)$$

$$TPA_{\mathrm{T_3}} = \frac{1}{x}\int_{(\mathrm{T_3}-x)}^{\mathrm{T_3}} TPA_f(t)dt \quad (3)$$

In the each equation $\mathrm{T_0} = 0\mathrm{sec}$, $\mathrm{T_1} = 300\mathrm{sec}(5\mathrm{min})$, $\mathrm{T_2} = 600\mathrm{sec}(10\mathrm{min})$, and $\mathrm{T_3} = 900\mathrm{sec}(15\mathrm{min})$. x is 30 seconds in this experiment.

We use $TPA_{\mathrm{T_1}}$, $TPA_{\mathrm{T_2}}$ and $TPA_{\mathrm{T_3}}$ to evaluate pre-stress state, stress state and post-stress state respectively. As previous mentioned, each FS is also measured at $\mathrm{T_1}$, $\mathrm{T_2}$ and $\mathrm{T_3}$.

Fig.8 indicates the scatter plot of pre-stress state:($TPA_{\mathrm{T_1}}$, $FS_{\mathrm{T_1}}$), stress state: ($TPA_{\mathrm{T_2}}$, $FS_{\mathrm{T_2}}$) and post-stress state: ($TPA_{\mathrm{T_3}}$, $FS_{\mathrm{T_3}}$) of all the experiments to investigate the relationship between $\mathrm{TPA_f}$ and FS. The straight line represents the regression line in Fig.8. There is a small negative correlation (-0.2755) between $\mathrm{TPA_f}$ and FS, and Fig.8 indicates that it isn't easy to estimate the degree of FS with $\mathrm{TPA_f}$ itself.

We performed multiple comparison to confirm whether each state is different from each other or not. The multiple comparison that we apply is Kruskal Wallis test.

There is a significant difference at the 1% level between the pre-stress state and the stress state in Fig.9. What is more, there is also a significant difference at the 5% level between them in Fig.10. There are significant differences at the 5% level between the stress state and the post-stress state in Fig.9 and Fig.10. In addition, there are no significant differences between the pre-stress state and post-stress state in Fig.9 and Fig.10. In light of the results there is a possibility that $\mathrm{TPA_f}$

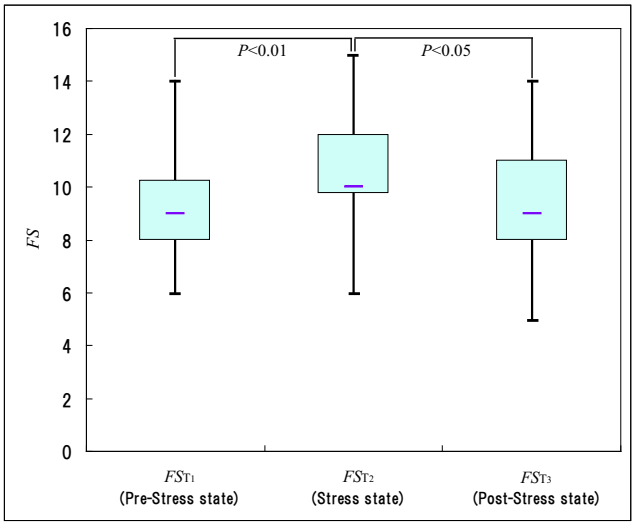

Fig. 9. Box plot of FS. Kruskal Wallis test is applied to the three states. There are significant differences at the 1% level among all of the states

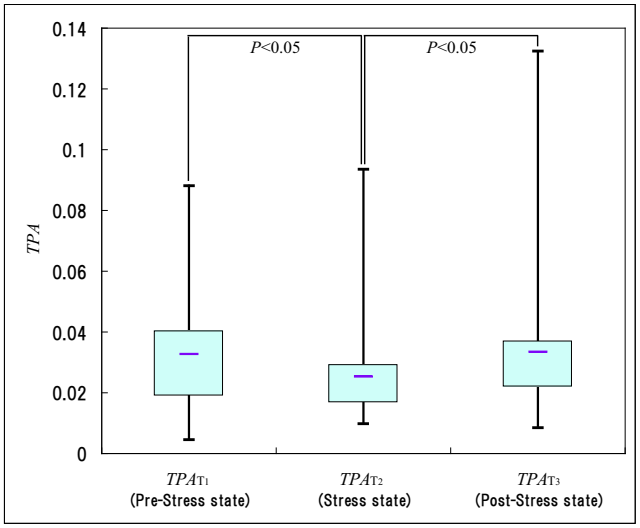

Fig. 10. Box plot of $\mathrm{TPA_f}$. Kruskal Wallis test is applied to the three states. There are significant differences at the 1% level among all of the states

can distinguish between the state under the direct stress (stress state) and the stress-free state after the stress released (pre-stress state and post-stress state). There could be a certain relationship between $\mathrm{TPA_f}$ and FS.

B. Relationship between ΔTPA and ΔFS

We focus on the amount of change of $\mathrm{TPA_f}$ and FS to discuss the relationship between them. The pre-stress state is prepared to lead the subjects to be in neutral mental state. Nonetheless, you can see and confirm $FS_{\mathrm{T_1}}$ and $TPA_{\mathrm{T_1}}$ have a large variance in Fig.9 and Fig.10 respectively. Therefore we define and adopt the amount of change of both $\mathrm{TPA_f}$ and FS from the pre-stress state(from the time $\mathrm{T_1}$). We introduced $\Delta TPA_{\mathrm{T_2T_1}}$ and $\Delta TPA_{\mathrm{T_3T_1}}$, which are defined and calculated with Eq.4 and 5. $\Delta FS_{\mathrm{T_2T_1}}$ and $\Delta FS_{\mathrm{T_3T_1}}$ are

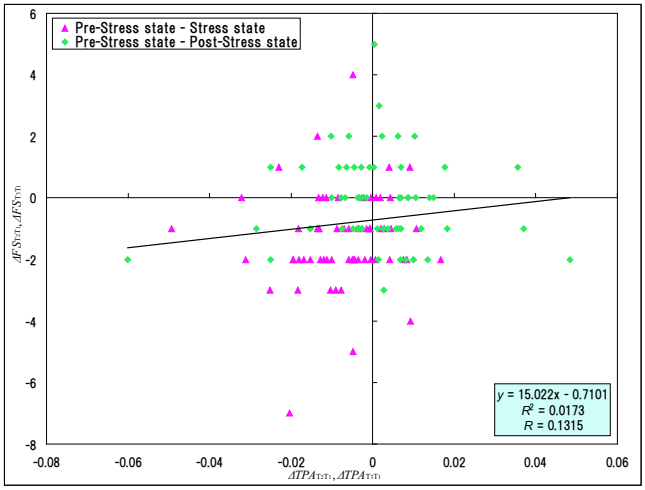

Fig. 11. Scatter plot of ($\Delta TPA_{\mathrm{T_2T_1}}$, $\Delta FS_{\mathrm{T_2T_1}}$) and ($\Delta TPA_{\mathrm{T_3T_1}}$, $\Delta FS_{\mathrm{T_3T_1}}$)

also defined as shown in Eq.6 and 7.

$$\Delta TPA_{\mathrm{T_2T_1}} = TPA_{\mathrm{T_2}} - TPA_{\mathrm{T_1}} \quad (4)$$
$$\Delta TPA_{\mathrm{T_3T_1}} = TPA_{\mathrm{T_3}} - TPA_{\mathrm{T_1}} \quad (5)$$

$$\Delta FS_{\mathrm{T_2T_1}} = FS_{\mathrm{T_1}} - FS_{\mathrm{T_2}} \quad (6)$$
$$\Delta FS_{\mathrm{T_3T_1}} = FS_{\mathrm{T_1}} - FS_{\mathrm{T_3}} \quad (7)$$

Note that Eq.4 and 5 are the subtraction from post-stress state, and Eq.6 and 7 are the subtraction from stress state.

Fig.11 shows the scatter plot of ($\Delta TPA_{\mathrm{T_2T_1}}$, $\Delta FS_{\mathrm{T_2T_1}}$) and ($\Delta TPA_{\mathrm{T_3T_1}}$, $\Delta FS_{\mathrm{T_3T_1}}$). The straight line represents the regression line in Fig.11. There might be little correlation between ΔTPA and ΔFS. Fig.11 also indicates that it is difficult to estimate the degree of FS with ΔTPA. We apply Wilcoxon test and paired t-test. Fig.12 and Fig.13 show more clearer significant differences (p&lt.; 0.01) than Fig.9 and Fig.10.

We adopt the other criteria to clarify the relationship between stress state and post-stress state. $\Delta TPA_{\mathrm{T_3T_2}}$ and $\Delta FS_{\mathrm{T_3T_2}}$ are defined and calculated with Eq.8 and 9.

$$\Delta TPA_{\mathrm{T_3T_2}} = TPA_{\mathrm{T_3}} - TPA_{\mathrm{T_2}} \quad (8)$$
$$\Delta FS_{\mathrm{T_3T_2}} = FS_{\mathrm{T_2}} - FS_{\mathrm{T_3}} \quad (9)$$

The equations represent the difference from stress state to post-stress state. In order to compare them with the difference from pre-stress state to stress state as defined in Eq.4 and 6. Fig.14 shows the scatter plot of ($\Delta TPA_{\mathrm{T_2T_1}}$, $\Delta FS_{\mathrm{T_2T_1}}$) and ($\Delta TPA_{\mathrm{T_3T_2}}$, $\Delta FS_{\mathrm{T_3T_2}}$). It is confirmed that the most of ($\Delta TPA_{\mathrm{T_2T_1}}$, $\Delta FS_{\mathrm{T_2T_1}}$) are plotted on the left low quadrant and the most of ($\Delta TPA_{\mathrm{T_3T_2}}$, $\Delta FS_{\mathrm{T_3T_2}}$) are plotted on the right upper quadrant. $\Delta TPA_{\mathrm{T_2T_1}}$ tends to take minus(-) when $\Delta FS_{\mathrm{T_2T_1}}$ is minus(-). Otherwise $\Delta TPA_{\mathrm{T_3T_2}}$ tends to take

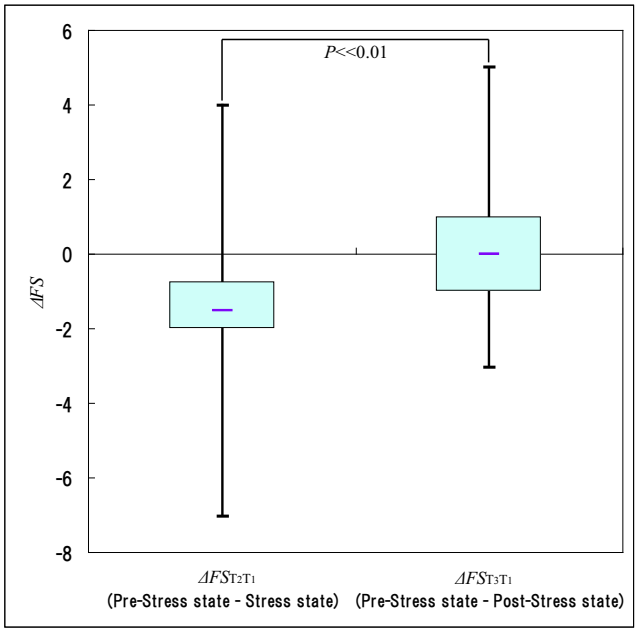

Fig. 12. Box plot of ΔFS. Wilcoxon test shows a significant differences at the 1% level between $\Delta FS_{\mathrm{T_2T_1}}$ and $\Delta FS_{\mathrm{T_3T_1}}$

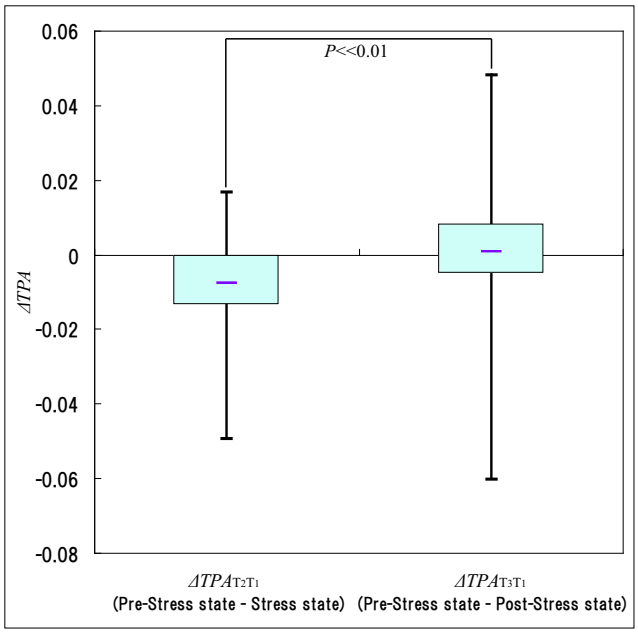

Fig. 13. Box plot of ΔTPA. Paired t-test shows a significant differences at the 1% level between $\Delta TPA_{\mathrm{T_2T_1}}$ and $\Delta TPA_{\mathrm{T_3T_1}}$

(+) when $\Delta FS_{\mathrm{T_3T_2}}$ is plus(+). Thus the change of plus-minus sign of ΔTPA could correspond to the change of the sign of ΔFS. The result of Fig.14 indicates that it might be possible that the difference of $\mathrm{TPA_f}$, which is observed objectively and quantitatively, can estimate the increase and the decrease of subjective stress.

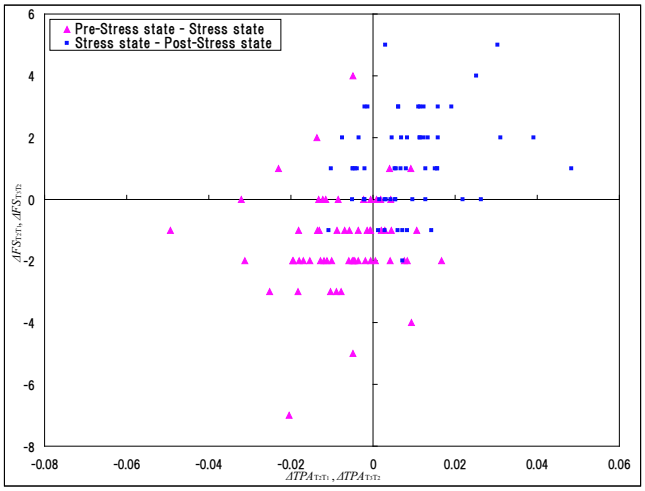

Fig. 14. Scatter plot of ($\Delta TPA_{\mathrm{T_2T_1}}$, $\Delta FS_{\mathrm{T_2T_1}}$) and ($\Delta TPA_{\mathrm{T_3T_2}}$, $\Delta FS_{\mathrm{T_3T_2}}$)

V. CONCLUSION

This study investigated the relationship between FS and $\mathrm{TPA_f}$ via finger plethysmogram. This paper shows that $\mathrm{TPA_f}$ could roughly estimate the change of human stress. We adopted a simple sensor and a simple method to measure and calculate $\mathrm{TPA_f}$. Furthermore $\mathrm{TPA_f}$ can be measured in near realtime. Therefore it couldn't be difficult to implement our method to robots. However we have some remaining problems to realize the robots that can estimate human stress or comfortableness. As first we must improve the accuracy to estimate human stress. Additon to that we might consider to combine $\mathrm{TPA_f}$ and other stress measures. The second is to conduct more experiments to collect the data from several environments and situations. The experiments woulld need to consider not only $\mathrm{TPA_f}$ but also other stress measures e.g. the amount of amylase in saliva and blood test. Addition to that, some researchers say that an effect of human stress is observed after a few seconds delay from finisning mental workload. In light of this we might consider to redesign the experiments The third is to develop a small sensor to measure finger plethysmogram like a wedding ring. We are planning to solve the problems in near future.

***Abstract*—This paper discusses human preference learning by robot partners through interaction with a person. We use a robot music player; miuro, and we focus on the music selection for providing the person with comfortable sound field. First, we propose a control architecture of miuro based on autonomous behavior mode, interactive behavior mode, and human control mode. Next, we propose a learning method of the relationship between human position and its corresponding music selection based on Q-learning. Furthermore, we proposed a similarity matrix to reduce the learning time of Q-learning. The experimental results show that the proposed method can learn the relationship between human position and its corresponding human preferable music.**

Keywords- Robot Partners; Sound Field; Q-Learning; Boltzmann Selection; Fuzzy Control; Multi-Objective Behavior Coordination

I. INTRODUCTION

Recently, various types of human-friendly robots such as amusement robots, robot pets, and robot partners have been developed until now [1-6]. The advantage of robots is to realize human- or animal-like interaction and communication with people. A robot partner will be a concierge in the information service through interaction and communication. We can have three different types of robot partners from the interactive point of view (Fig.1) [7]. One is a physical robot partner. We can interact with the physical robot partner by using multi-modal communication like a human. The next one is a virtual robot partner. The virtual robot partner is in the virtual space built in the computer, but we can interact with it through the virtual person or robot in the virtual space. The last one is a pocket robot partner, and this is considered as the overlapping subcategory of physical and virtual robot partners. The pocket robot partner has a physical body but no mobile mechanism. We can easily bring it everywhere and can interact with the robot partner by touch and physical interface. The interaction style of these three robots is different, but they share the same personal database and interaction logs, and can interact with the person based on the same interaction rules independent from the style of interfaces. The person can accept the information service ubiquitously from a change of the style of robot partners according to the situation.

In general, the basic behaviors for robots are designed beforehand, but robot partners should perform social learning through interaction and communication with people. Various types of human-friendly robots have been developed, but the aim of most previous works is in the interaction between a robot and person, not the behavioral learning. Such a robot is used for direct interaction and communication with a person, but the mood and comfort by co-existing with the robot have not been discussed so much. Therefore, we discuss the mood and comfort for a human by co-existing with a robot partner. Sound field is one of the most important roles in constructing comfortable space. We proposed the learning method of human preferable music selection based on Boltzmann selection, and showed the experimental results of the relationship learning through continuous interaction [8]. Furthermore, we showed that the learning results by the pocket robot partner could be seamlessly reflected to the interaction rules of the physical robot partner. However, we do not discuss the location- or situation-dependent learning in the learning to extract human preference. Therefore, we propose a Q-learning algorithm for acquiring the relationship between human position in a room and its corresponding preferable music selection to construct a comfortable space by a robot partner. Furthermore, we should consider the regulation of the learning speed through continuous interaction in order to reduce the human load and the times of human interactions. Therefore, we propose a learning method based on similarity matrix used for evaluating human preference according to the similarity among songs.

This paper is organized as follows. Section 2 explains the concept of informationally structured space [8,9] used for the control and information processing of robot partners through wireless network. Next, we explain the hardware of robot partners used in this study, and the control architecture of the robot partners. Section 3 proposes decision making and learning method of robot partners based on computational intelligence. Section 4 shows several experimental results of the proposed method. Section 5 discusses the effectiveness of the proposed method, and concludes this paper.

II. INFORMATIONALLY STRUCTURED SPACE FOR ROBOT PARTNERS

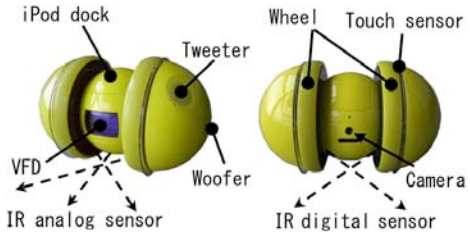
A. Informationally structured space and information service

Basically, information service to a person is used to find the required information from huge size of data, and provide them to the person in the suitable form. Robot partners are used as a concierge of daily information service, and require the emerging synthesis of information technology (IT), network technology (NT), and robot technology (RT). NT can provide the robot with computational capabilities based on various types of information outside of robots. Actually the robot directly receives the environmental information through a local area network without the measurement by the robot itself [10]. Wireless sensor networks realize to gather the huge data on environments [11]. However, it is very difficult to store all of huge data in real time. Furthermore, some features should be extracted from the gathered data to obtain the required information. Therefore, the environment surrounding people and robots should have a structured platform for gathering, storing, transforming, and providing information. Such an environment is called informationally structured space (Fig.2).

Basically, information is defined as meaningful or valuable data from the viewpoint of information science. On the other hand, sensory information includes visual information, audio information, tactile information, and olfactory information, from psychology [12-14]. This means we can perceive the meaning or value from such sensory information to perceive the environment. In this study, we try to realize information service by music, sound and voice. Especially, we discuss the method of providing a person with the comfortable mood by the sound field using music suitable to the situation.

B. A robot partner miuro

We use a robot music player called miuro as a physical robot partner developed by ZMP Inc. in Japan [4]. This robot can act in autonomous motion with the big size of wheels attached with both sides (Fig.3). The robot has many sensors such as a camera, 10 infrared distance sensors, touch sensors, and accelerometer. Furthermore, miuro can be controlled by infrared remote controller. The user can play music contents registered beforehand in miuro by the remote controller, and iPod can be connected and built within the body of miuro. The robot also can play music contents in a PC server and programs of Net Radio connected through wireless LAN (802.11b/g) by its high quality speakers.



(a)back (b)front

Fig.3. Robot partner; miuro.

Figure 4 shows the roles of miuro in information service. The most important advantage of miuro is in the high quality of music play with autonomous sensing and moving capability. Therefore, miuro can provide a person with the sound field according to the situation extracted as a result of sensing. The second advantage of miuro is in wireless communication with PC server and Internet. The extracted information on preference and custom is stored in the PC server and referred from the PC server. Furthermore, miuro can download music contents from web sites according to the extracted preference of the person, and play them. However, the downloaded music contents might be different from the preference, but sometimes this can be a new finding of music for the person. This means the person does not perform the search of music contents, but miuro can be a concierge of information service.

The roles of music plays can be divided into music appreciation and background music. A person directly enjoys listening music in the music appreciation, while the person enjoys other tasks with listening music in the mode of background music. In the latter, the background music plays the important role in entraining the person into the target task. Based on the portability and mobility of miuro, we focus on the music selection as the background music.

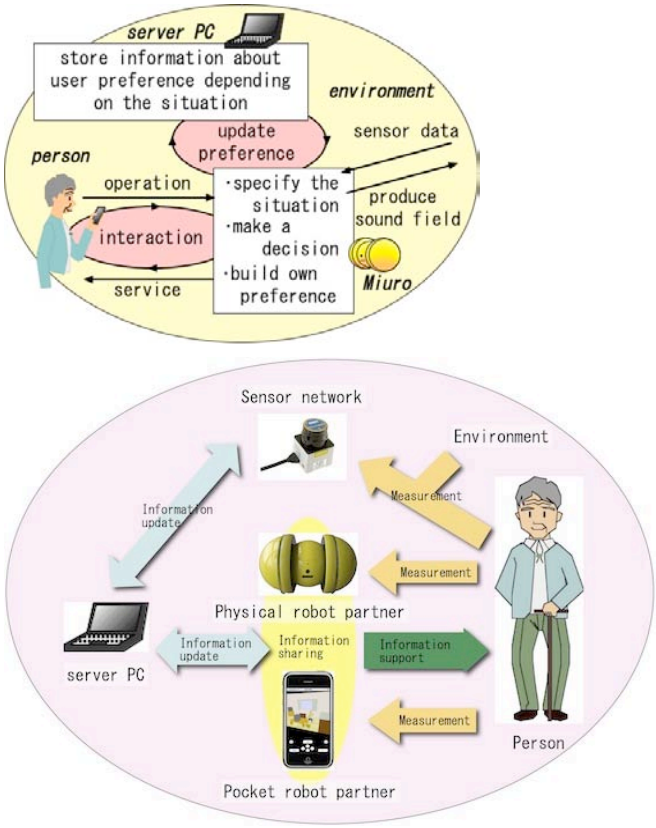


Fig.4. The roles of Miuro in information service.

C. Control architecture of Miuro

Basically, miuro has three behavior modes; human control mode, autonomous behavior mode, and interactive behavior mode. These modes are changed according to the remote controller or human interaction. In the human control mode, the user can directly control miuro, choose the predefined behaviors, and play the music contents by the remote controller. The autonomous behavior mode is composed of random walk, target tracing, information gathering, and map building. The action output of miuro is decided by the multi-objective behavior coordination according to the internal state and local sensing information from external environments. The interactive behavior mode is composed of music play, human tracking, and amusing play.

Figure 5 shows the detail of decision making of miuro. After the sensing, the behavior mode is transited to the human control mode if the remote controller is activated (Fig.5 (1)). In this mode, miuro is directly controlled and used as a music player. On the other hand, if the human interaction is extracted or recognized, the behavior mode is transited to the interactive behavior mode (Fig.5 (3)). In this mode, miuro also aggressively tries to contact and interact with the person, to collect and extract personal information such as preference and custom, and to provide various types of information suitable to the situation.

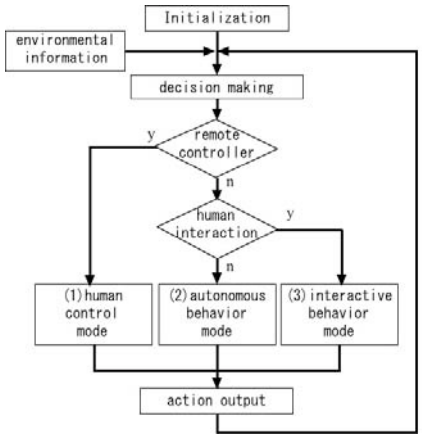

Fig.5. The total procedure of decision making of Miuro.

III. Computational Intelligence for Decision Making of Robot Partners

A. Autonomous behavior mode

Various intelligent methods for autonomous behavior control have been proposed such as production rules, Bayesian networks, neural networks, fuzzy inference systems, and classifier systems [15-20]. We have applied fuzzy inference systems to represent behavior rules of robots [10,21], because the behavioral rules can be designed easily and intuitively by human behavioral representations. We apply simplified fuzzy inference to the motion control of miuro. In general, a fuzzy if-then rule is described as follows,

If x_1 is $A_{i,1}$ and ... and x_M is $A_{i,M}$
Then y_1 is $w_{i,1}$ and ... and y_N is $w_{i,N}$

where $A_{i,j}$ and $w_{i,k}$ are the Gaussian membership function for the jth input and the singleton for the kth output of the ith rule; M and N are the numbers of inputs and outputs, respectively. Fuzzy inference is performed by,

$$\mu_{A_{i,j}}(x_j) = \exp\left(-\frac{(x_j - a_{i,j})^2}{b_{i,j}^2}\right) \tag{1}$$

$$\mu_i = \prod_{j=1}^{M} \mu_{A_{i,j}}(x_j) \tag{2}$$

$$y_k = \frac{\sum_{i=1}^{R} \mu_i w_{i,k}}{\sum_{i=1}^{R} \mu_i} \tag{3}$$

where $a_{i,j}$ and $b_{i,j}$ are the central value and the width of the membership function $A_{i,j}$; R is the number of rules. Moreover, the kth output y_k is motor output. In general, a mobile robot has a set of behaviors for achieving various objectives, and must integrate these behaviors according to the environmental conditions. Therefore, we proposed the method for multi-objective behavior coordination [22]. The multi-objective

behavior coordination can integrate outputs of several behaviors according to the time-series of perceptual information. A behavior weight is assigned to each behavior. Miuro can achieve a smooth behavior by dynamic update of the behavior weights along perceptual information. According to the behavior weights, the final output is calculated by,

$$y_k = \frac{\sum_{j=1}^{K} wgt_j(t) \cdot y_{j,k}}{\sum_{j=1}^{K} wgt_j(t)} \tag{4}$$

where K is the number of behaviors; $wgt_j(t)$ is a behavior weight of the jth behavior over the discrete trials t, and output $y_{j,k}$ is the calculation result from simplified fuzzy inference used for the jth behavior. The update amount of each behavior weight is calculated as follows,

$$\begin{bmatrix} \Delta wgt_1 \\ \Delta wgt_2 \\ \vdots \\ \Delta wgt_K \end{bmatrix} = \begin{bmatrix} dw_{1,1} & dw_{1,2} & \cdots & dw_{1,L} \\ dw_{2,1} & & & \\ \vdots & & \ddots & \vdots \\ dw_{K,1} & & \cdots & dw_{K,L} \end{bmatrix} \begin{bmatrix} ci_1 \\ ci_2 \\ \vdots \\ ci_L \end{bmatrix} \tag{5}$$

where ci_i is the parameter on the perceptual information; L is the number of perceptual inputs.

First, the multi-objective behavior coordination can integrate collision avoidance and target tracing behaviors. The inputs to the fuzzy controller for collision avoidance are the measured distance to the obstacle by infrared distance sensors equipped in front of the robot (Mc=3). The inputs to the fuzzy controller for target tracing are the estimated distance to the target point and the relative angle to the target point from the moving direction (Mt=2). Outputs are the moving velocity and the steering angle. Final outputs are calculated by the weighted average of outputs form these two behaviors based on the multi-objective behavior coordination according to the degree of danger. The degree of danger is calculated utilizing the minimum value of distances to obstacles by measurement as follows,

$$d = \left(S - \min_j x_j \right) / S \tag{6}$$

where S is the sensing range of infrared distance sensors.

B. Interactive behavior mode

The interactive behavior mode is composed of human tracking, music play, and amusing play. As mentioned before, miuro is designed as a music player, and this paper focuses on the method of providing a person with the comfortable mood by the sound field using music suitable to the situation. The individual preferable sound field corresponding to situations such as cooking, reading, studying, and sleeping is different among people. The robot music player, miuro, should provide the individual person with the comfortable mood, but it is difficult to design the relationship between a situation and its corresponding sound field. Furthermore, such relationship should be extracted and learned through communication and interaction with the person. In this paper, we assume a specific situation is corresponding to a specific human interaction.

We propose a learning method of the relationship between the human position and its corresponding music play through the interaction with the person. The robot selects human preferable music according to human position. Therefore, the learning results of the robot can reflect human preferences. Based on this assumption, we use Q-learning to obtain the relationship between the human interaction and its corresponding reaction of the robot.

C. Q-Learning for human preference extraction

Reinforcement learning methods build agents that maximize their expected utility only using reward or punishment from the environment [23]. Accordingly, the reinforcement learning does not use explicit teaching signals, but uses evaluative feedback obtained through the interaction with the environment. The tasks to be dealt with in the reinforcement learning are sequential decision problems based on four elements of a policy, a reward function, a value function, and optionally, a model of environment. In this paper, we must consider the continuity of environmental space and the discreteness of songs.

Q-learning is considered as an off-policy TD control method. Watkins proposed a simple method for assigning values to state-action pairs, and called the method incremental dynamic programming. The robot music player of the one-step Q-learning, which is the simplest method, learns the following action-value function,

$$\begin{aligned} Q(s_t, a_t) \leftarrow & (1-\alpha) \cdot Q(s_t, a_t) \\ & + \alpha \cdot \left[R_{t+1} + \eta \cdot \max_{a \in A} Q(s_{t+1}, a) \right] \end{aligned} \tag{7}$$

where R_{t+1} is a reward value, α is a learning rate ($0<a<1.0$); η is a temporal discounting rate ($0 \le \eta < 1.0$); and A is a set of songs (u_1, u_2, ..., u_S) corresponding to possible actions; S is the number of songs. It is very difficult to design the reward function for R in this application, because the reward value should be extracted through the interaction with the robot partner. In this paper, we assume a person keeps listening a favorite song. This means the human preference depends on the listening time of each song. If the person changes to another song soon, the preference is not suitable to the state s_t. Therefore, we use the following reward function,

$$R_t \leftarrow \tau(t_p) \cdot R_O \tag{8}$$

where $\tau(t_p)$ is a Sigmoid function; t_p is playing time of song a_t; R_O is a base value for the reward. Therefore, R_t is high as the playing time is long. Although the update rule is very simple, the action-value function approximates the optimal action-value function if all state-action pairs are updated repeatedly. However, the aim of this paper is not to obtain the optimal action-value function, but to obtain the feasible action-value function to extract human preference. Furthermore, as the difference from previous Q-learning, the state is not directly changed as a result of the selection by a_t. The state is updated

by the human movement in a room. This means we might not need to use Q-learning in this paper, but the advantage of Q-learning is the update of value functions in the multi-stage decision making. In this way, we apply Q-learning because we assume the selection of songs depends on the continuous space in a room.

We apply the softmax action selection (Boltzmann selection), and the ith action a_i is selected with the following probability,

$$p_t(a_i) = \frac{\exp(Q(s_t, a_i)/T)}{\sum_j \exp(Q(s_t, a_j)/T)} \tag{9}$$

where T is the temperature ($T_{\min} \le T \le T_{\max}$).When the temperature is high, the robot randomly selects a reaction. As the temperature decreases, the robot deterministically selects the reaction with the high selection strength even if the difference among selection strengths is very small. Generally, T is gradually reduced according to t, but we propose an updating method of the temperature according to the temporally changing pattern of human interactions.

$$T = \begin{cases} T \cdot \lambda & if\ x(t) = x(t-1) \\ T / \lambda & otherwise \end{cases} \tag{10}$$

where λ is the update rate ($0<\lambda<1.0$). In this paper, we use music play as reaction of the robot. Therefore, we prepare different types of songs as reaction candidates of the robot.

D. Q-Learning based on Similarity Matrix

There are two important problems in human preference extraction. As the first problem, it is very difficult to evaluate the quality of the extracted human preference. The problem of evaluation has a problem of the mutual nesting. A person can evaluate the preference of music from the candidates of music, while the candidate of music must be selected according to the human preference. This means the quality of the extracted human preference depends on the quality of the selection of music candidates. The second problem is the stability of human preference. This means the human preference can change according to the daily life. In this way, the robot music player should play various types of music, and extract human preference. However, if the robot music player prepares many songs, it takes much time to extract human preference by Q-learning because the state space is large. Therefore, we propose a Q-learning algorithm based on similarity matrix to enhance the learning of Q-learning. The similarity among songs in this paper is not only the objective similarity such as rhythm and tone, but also the subjective similarity like preference among songs.

In the above definition, $Q(v_t, a_t)$ is discretized where v_t is the state, and a_t is the song to be played. In previous works, fuzzy Q-learning was proposed to deal with continuous states and actions. In case of fuzz Q-learning, we can deal with the continuity of state and action by the shape of membership functions based on the distance space. However, it is very difficult to represent the distance based on the degree of similarity among songs by using membership functions. Therefore, we use the similarity matrix in the following;

$$\boldsymbol{M} = \begin{pmatrix} 1 & \cdots & m_{1N} \\ \vdots & \ddots & \vdots \\ m_{N1} & \cdots & 1 \end{pmatrix} \tag{11}$$

where the number of songs is N, and diagonal elements is set at 1; m_{ij} is the degree of similarity between two songs ($0 \leqq m_{ij} \leqq 1$, $m_{ij}=m_{ji}$). In the proposed method, when the kth song is selected ($a_t=u_k$), Q values are updated as follows;

$$\begin{aligned} Q(s_t, a_j) \leftarrow & (1-\alpha \cdot \mu_{k,j}) \cdot Q(s_t, a_j) \\ & + \alpha \cdot \mu_{k,j} \left[R_{t+1} + \eta \cdot \max_a Q(s_{t+1}, a) \right] \\ & \left(if\ \mu_{k,j} > 0 \right) \end{aligned} \tag{12}$$

where R_{t+1} is a reward value, α is a learning rate ($0<a<1.0$); η is a temporal discounting rate; $\mu_{k,j}$ is a similarity value between the kth and jth songs ($0<\eta<1.0$); the $\mu_{k,j}$ is calculated in the following;

$$\boldsymbol{\mu}_k = \begin{pmatrix} \mu_{k,1} \\ \vdots \\ \mu_{k,N} \end{pmatrix} = \boldsymbol{M}\boldsymbol{l} = \begin{pmatrix} 1 & \cdots & m_{1N} \\ \vdots & \ddots & \vdots \\ m_{N1} & \cdots & 1 \end{pmatrix} \begin{pmatrix} l_1 \\ \vdots \\ l_N \end{pmatrix} \tag{13}$$

$$\boldsymbol{l} = \begin{pmatrix} l_1, & \cdots, & l_N \end{pmatrix}^T, \quad l_i = \begin{cases} 1 & if\ a_t = u_k \\ 0 & otherwise \end{cases} \tag{14}$$

In the original Q-learning, the Q value of the selected action a_t at the current state s_t is only updated, but the proposed method updates the Q values of other actions not selected at the current state s_t according to the similarity matrix. In this way, the learning time of Q values is reduced.

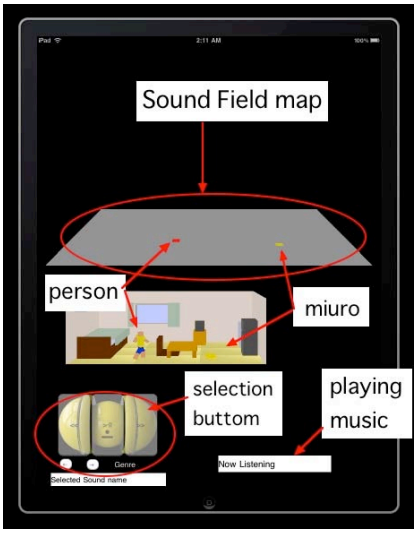

Fig.6. A simulator using iPad

IV. EXPERIMENTAL RESULTS

This section shows several experimental results of the proposed method. In order to realize the efficient and quick learning, we use iPad as the pocket robot partner. The touch interface provides a user with simple and repeatable interaction on the touch screen. After the learning on the pocket robot partner, we can transfer the learning result to the physical robot partner. The human interaction is done with Miuro on the simulator of iPad by the touch interface (Fig.6). The simulator is composed of sound preference map, environmental map simulating to a real room (Fig.7 (a)), and the control buttons of music plays. The human position is estimated by using the measured distance data of two laser range finders (Fig.7 (b)). Figure 8 shows the snapshot of autonomous behavior mode and interactive behavior mode in the pocket robot partner. The robot takes random walk in the autonomous behavior mode in Fig.8 (b), and the robot takes the human tracking behavior in the interactive behavior mode.

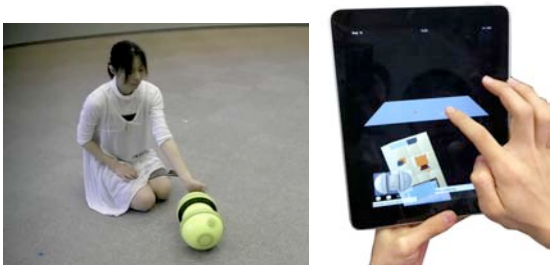
We conduct experiments on the learning of the relationship between human location and its corresponding preferable music selection as the generation of comfortable sound field.



(a) with a physical robot partner (b) with a pocket robot partner

Fig.9. Human interaction used in the experiments.

The size of environment corresponding to states is 5×10. The number of songs is 10 (S=10), and the songs are categorized into three different types of classic, rock, and jazz. The current learning states based on the played songs are visualized by using color distribution where classic, rock, and jazz are depicted in red, green, and blue colors. Table 1 shows the values of parameters used in experiments. The values of similarity matrix are designed subjectively. The human position in the simulator is updated according to the estimated position by two laser range finders.

TABLE I. ARAMETERS USED FOR THE LEARNING IN EXPERIMENTS.

Learning rate α	Discount rate η	Standard value of Reward R_O	Number of songs
0.2	0.8	0.5	Classic : 3
			Rock : 3
			Jazz : 4

We conduct an experiment for 30 minutes, and the person selects songs according to the human position in the simulator. The person moves among four points of a bed, chair, cabinet, and sink unit. Figure 10 shows the preference learning in experimental results. Figure 10 (a) shows a result of preference learning at 17 seconds after the start. In this stage, the color distribution is still dark because the learning is not done much. The red color indicates classic songs are played in the sound field map. As time passes, the color of cells is updated gradually. In the final state, the sound preference map is in tinge of red. This means the person listened classic in the bedside, and both classic and jazz in the chair. The learning result is similar with the human preference obtained by the interview after the experiment. In the initial stage of learning, songs are selected almost randomly, but the similar songs based on current learning states are gradually selected by the effect of Q-learning based on similarity matrix. In this way, the proposed method can reduce the learning time while extracting human preference dependent on the human position.

(a) t=52; 00m:17s (b) t=452; 02m:30s

(c) t=2116; 11m:45s (d) t=5364; 29m:48s

Fig.10. Preference learning in experimental results

V. SUMMARY

This paper proposed a learning method of human preference based on a Q-learning algorithm, Boltzmann selection with temperature control, and similarity matrix. Furthermore, we used a robot music player named miuro as a robot partner. The experimental results show that the proposed method can learn the relationship between human position and its corresponding played songs. Furthermore, the proposed method can provide the person with the preferable song as the comfortable sound field. The essence of the proposed method in this paper is flexibility and adaptability in the update of parameters according to the change of situation and human position. Furthermore, the similarity matrix can reduce the learning time, but the similarity matrix is designed beforehand in this paper. The similarity matrix should be also updated through the interaction with a robot partner.

As future works, we intend to develop the perceptual system of robot partners for specifying the situation sharing with people, and to improve the performance of recognition methods of human gestures and interactions. Furthermore, we will propose a method of replacing song candidates according to human selection results.

***Abstract*—This report of this paper shows a performance of the heterogeneous multi-agent system using the overlay knowledge technique. The overlay knowledge is one kind of layered rule-based system. Basic idea is the tile-coding rule on reinforcement learning. But In the tile-coding rule, all reinforced rules are spread any categorical states of rule table. Proposal style of overlay knowledge is from a tile-coding. We examined the features of the learning principle about the heterogeneous multi-agent. It was proved that the overlay knowledge was useful sufficiently for the heterogeneous multi-agent. The robust characteristic was the cause which outputs absolute behavior. By changing of the robust levels, behaviors of the agent expected a change into the flexible movement.**

Keywords-component; multi-agent system ; overlay knowledge ; reinforce learn; fire panic

I. INTRODUCTION

The report on this paper shows a performance of the heterogeneous multi-agent, which have the overlay knowledge. The overlay knowledge is one kind of the layer type rule-based system. Our basic idea is the tile-coding rule of the reinforcement learning. In the tile-coding, all reinforced rules are tiled some categorical states of the rule table. Recently, there are the shaping style rules by using other training method. So we believe the robustness and applicability phenomenon between behavior and rule's amount. Especially, rule style of the overlay knowledge easy to find that phenomenon. We would like to show that in this paper and discuss the learning theorem in Multi-agent system.

II. LEARNING THEORY OF MULTI-AGENT SYSTEM

Learning system and intelligence are related to each other. Learning always has to do about the self-improvement of future behavior based on past experiment, which agent has gone. Leaning of the multi-agent system have two principal categories. One is centralized leaning or isolated learning. Another is decentralized leaning or interactive learning. In the multi-agent system, several centralized learning would like to try to obtain same activate at same time by same goal. There are several groups of agents that involved by different decentralized learning on each agent's. Especially, the heterogeneous multi-agent system has some group agents which have different behavior. Interactive learning process is feature quality. That two learning categories are a general nature and a broad variety forms of learning. Generally, the multi-agent system has six type difference features [9].

① The degree of decentralization :
The decentralization of a learning process concerns its distribution and parallelism. One normal case is that a single agent carries out all learning behavior. Other case is that the learning system is distribute and parallelism through all agents of a group.

② Interaction-specific features :
There is a number of features that can be applied to classifying the interactions request for realizing a decentralized learning process. Examples are the level interaction, the frequency interaction, pattern interaction, the variable interaction and so on.

③ Involvement-specific features :
That feature can be used for characterizing the involvement and role played during involvement. Learning processes of agent are the relevance of involvement and role played during involvement.

④ Goal-specific features :
Learning goal of multi-agent are the type of improvement that is tried to be achieved by learning and the compatibility of the learning goals traced by the agents.

⑤ The learning method :
The following learning methods or strategies used by an agent are usually distinguished. There are rote learning, learning from instruction and advice taking. Otherwise, learning from examples, practice leaning, analogy learning, learning by discovery and so on.

⑥ The learning feedback.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

The learning feedback indicates the performance level behavior. This is leading factor to follow classification, success, and goal by some feedbacks, are supervised learning and unsupervised learning. Reinforcement learning is a kind of unsupervised learning but the feedback is only specific signal of the utility, which depends on the actual behavior of learner. And the objective is to maximize for targets.

In the heterogeneous multi-agent system, leaning system has to follow those features. Interaction's reference is key-point and the research point of using the overlay knowledge.

III. Q-LEARNING

Q-learning is a type of unsupervised learning system. The evaluation about selected behaviors and policies, make renew/reinforce by a reward/penalty. The agent selects behaviors according to the observed state. The selected behaviors become the best behavior, because Selective Unit select them according to rules reinforced by $Q(s,a)$ where a is a behavior and s is the observed state.

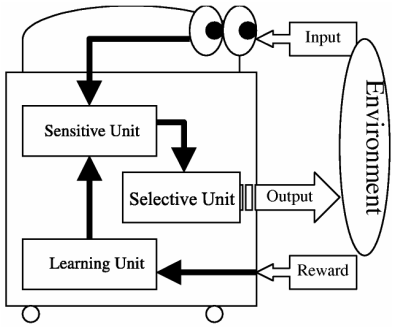

Fig.1 Framework of Q-learning

If there are no fitting rules, a new rule is created on the rule database; also rule base. Q-learning is able to learn from uncertain information. The learning systems are composed three units, including a sensitive unit, a learning unit, and a selection unit, as shown in Fig.1. If agents have received a positive reward, Q-value is renewed a positive direction. So, using rewards and penalties, the learning unit is able to change Q-value with the rules used. The renewal function f_t is given in Eq.(1) . $Q(s_t,a_t)$ is an evaluation to make renewal, shown in Eq.(2). In these cases, γ is the discount rate of $Q_{\max}$, d is the discount rate of a reward and α is the learning rate. s_t is observed state at the current time t. a_t is the selectable action at the current time t. Those parameters are in the range [0,1]. T is whole time of one episode. t is current time in one episode time T. Also, $Q_{\max}$ is the max evaluation of the best policy at the next state $S_{(t+1)}$. r is +1 as a reward or -1 as a penalty. Eq.(2) explains that Q-value is renewed by the reward.

$$f_t = \gamma Q_{\max} - Q(s_t, a_t) + d^{T-t} r \tag{1}$$

$$Q(s_t, a_t) \leftarrow Q(s_t, a_t) + \alpha f_t \tag{2}$$

An agent selects one behavior based on the view it has of the surrounding environment. The selection unit always uses probability based on Boltzman Distribution, as given Eq. (3). $Q(s,a)$ is Q-value about a target state s and a candidate action a. T is "Temperatures parameter" and p is probability to select a candidate action a.

$$p(a \mid s) = \frac{\exp(\frac{Q(s,a)}{T})}{\sum_{b \in action} \exp(\frac{Q(s,a)}{T})} \tag{3}$$

IV. THE FIRE PANIC PROBLEM

We show the fire panic problem on fig.2. In this problem, a fire exists in a field and it spreads throughout the space. The purpose of the agent is to reach an established goal without touching the fire that is in the environment. In order for the agents to avoid the fire spreading in the environment, they must acquire behaviors that allow them to reach a goal before the fire reaches them. The fire heats during three steps. After this three steps, the fire jumps to the randomly one direction (up, down, left or right) at one step. In the fire panic problem, all agents have to follow features①～④ about using the overlay knowledge. Please check a section II. LEARNING THEORY OF MULTI-AGENT SYSTEM

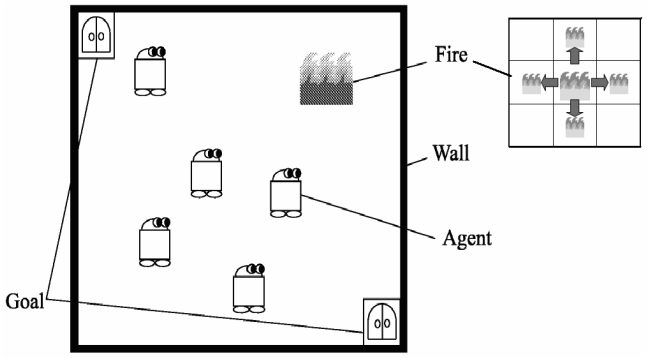

Fig.2 The fire panic problem

In this problem, we use two types of agents, A1 and A2. These agents are heterogeneous multi-agents with differing areas of view. The view area of A1 is 3x3. The view area of A2 is 5x5. Also, all agents can recognize all of these objects in the space: Fire, Wall, Agent, and Goal. All agents can select from these behaviors: Up, Down, Left, Right and Stop.

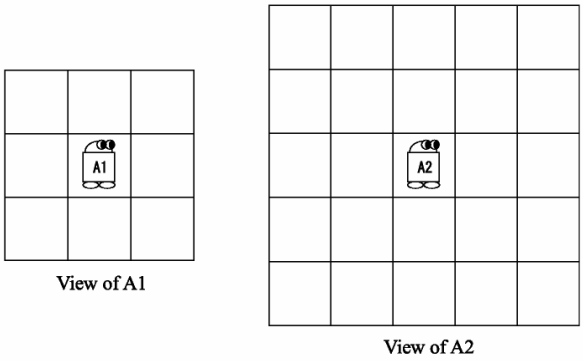

Fig. 3 Fields of view in agents A1 and A2

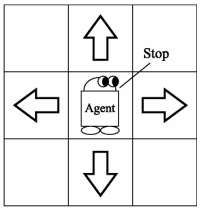

Fig. 4 Behavior of Agents

Agent is not able to enter any spaces that already contain Wall or Agent. In the fire panic problem, each action is one step. Each trial have 100 steps, all agents are able to move during 100 steps in a field. Agents learn behaviors using Q-learning or the our overlay knowledge system.

- If the agent reached a goal during the trial, the agent receives the reward r=+1.
- When a trial finished, agents on the field that are not touched by fire receive no-reword r=0.

If the agent touches the fire during the trial, the agent dies and receive the penalty r=–1.

V. APPLING Q-LEARNING

At first, we implemented Q-learning system for A2 agents in 30,000 trials. Then, after these trials, we introduce A1 agents, with smaller fields of view, into the space and we conducted 30,000 further trials in which A1 and A2 agents learn together in the same environment. Fig.5 shows the environments of the first and second trials. Fig.6 and Fig.7 show the number of times an agent reached a goal for every 1,000 trials.

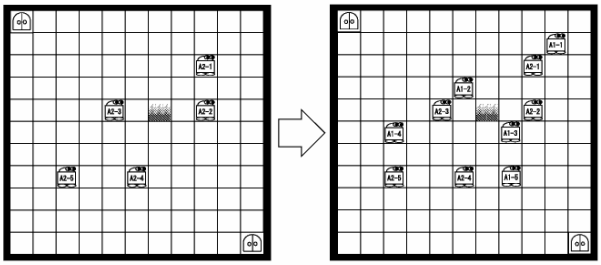

Fig. 5 First and second trials on the experiments

We could observe that A1 got the best behavior to reach a goal, show Fig.6. Then the number of goal on A2 has decreased at Fig.7. Those are results of using normal Q-Learning. About those curves, a vertical axis is a number of goal arrivals for every 1,000 trial. A horizontal axis is a number of trials. The number of goal has never increased again about A2 agents, given as Fig.7. We have kept experiment 60,000 trials, but the number of goal has maintained a low level. See Fig.8 (A), the best action of A2 is selecting a left move. During first term, A2 agents have never seen A1 type agents and finished a leaning to take the best action. But rule base is recorded view and Q-value with all action. See Fig.8 (B), if A2 agent has sensed A1 at first time, then A1 agent is not able to find an applicable rule. Because the rule base system seek a completely fitting rule. Basically, if there is not fitting rule in the rule base, then whole agents has no choice the best action. Thus, A2 agents cannot help choosing the random action, like a confusing behavior. Finally, A2 should learn same action on those views as a different situation.

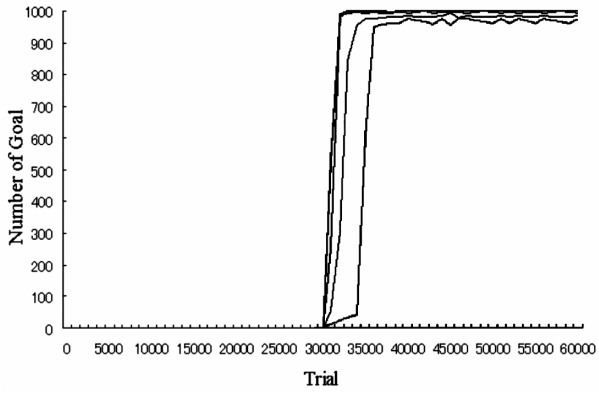

Fig. 6 Number of goal arrivals for A1 agents on Exp.1

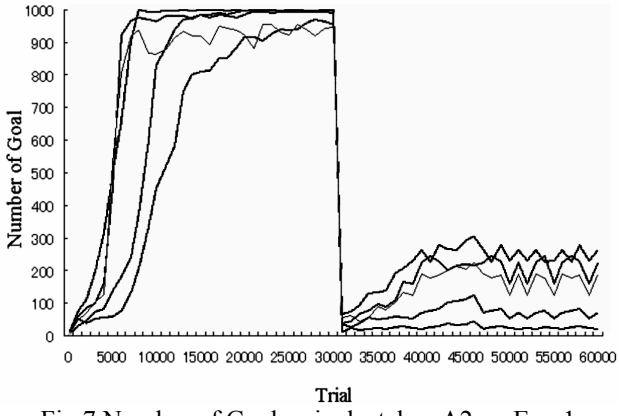

Fig.7 Number of Goal arrivals, taken A2 on Exp.1

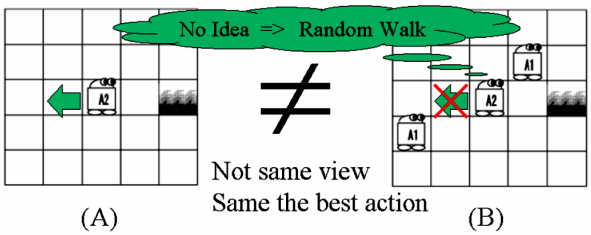

Fig.8 Process of the confusing the best action

VI. Reinforcement Learning Using The Overlay Knowledge

An applicable behavior is selected from a probability with the Boltzman distribution with Q-value. Proposal method is introduced in A2, in which the field of view is 5x5, and learning is determined in accordance with Q-learning. The proposed concept for our method used is shown in Fig. 9. The system renews Q-value with the learning layer. So this system was easy system.

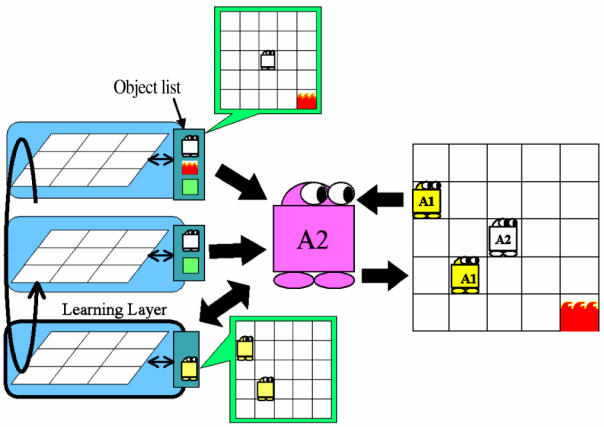

Fig.9 Framework of the overlay knowledge Method

In our learning system, we built the object list to switch layers. About an input status, the system searches object list of a current layer. Some objects are registered to the object list, if a target agent experienced objects in past times. In this fire panic problem, all agents have a possible to find A1 agent, A2 agent, fire, and wall as an object. If designer selected any items for target problem, then it is easy to add/record the object list, which would support any cases on the target problem. When the system learns by a reward, the system renews Q-value $q_{j(x,y)}$ on a current learning layer j. However before that process, the system check that observed objects exists in the object list of the learning layer j. During starting trials in the experiment, agents found new objects at all time, so adding object to the object list is anytime and quickly. When this system had some layers, the system was not able to follow the switching layers quickly. Because the system needs some layer know ledges for overlay Q-values. Then the system keep switch layers quickly, an approximating is impossible.

If new observed objects, which do not exist on the object list of the learning layer, then the system switch a current layer and create a new object list from new observed objects.

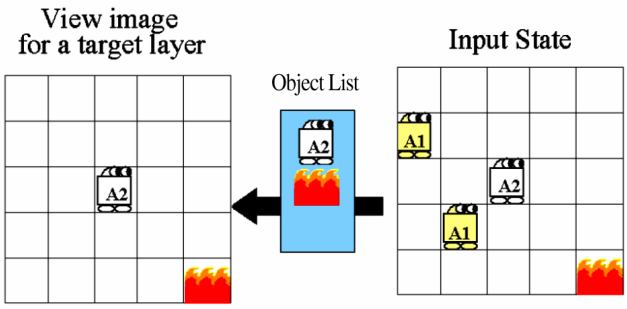

Fig.10 Object list and the masked view

The learning system adds the new rule and renews Q-value on the new learning layer. If a current layer is a last layer, then a current layer is switched to a first layer by the system; turn over to a first layer. This learning system can support several objects by the rule base on other layers. Proposal system has five layers with an object list. The input system masks out the unnecessary objects by checking the object list. And the system applies some Q-value from other masked layers, if the learning layer has no applicable rule. See Fig.10. Those preexisting Q-values on layers are possible to support an action about new situation, which the agent did not experience in past times. Additionally, proposal system has weight parameter w_i for each layer i. In a proposal system, the evaluation value $Q(s,a)$ is calculated by $q_i(s,a)$, as given Eq.(4). $q_i(s,a)$ is a output Q-value from a layer i. In this case, all q_i has evenly reach to $Q(s,a)$. The learning system searches a fitting $q_i(s,a)$ from all recorded q values with each layer i. The observed state keep changing dynamically, so the best policy will change by those situations. Weights show a possibility the applicable behavior for $q_i(s,a)$. We have tried some simulation experiment about weight parameters.

$$Q(s,a) = \sum_{i=1}^{m} w_i \times q_i(s,a) \qquad (4)$$

VII. Multi Lyaerd QL Method For Fire Panic With A1 And A2

Proposal system make Q (s,a) for select behavior by Eq.(3)(4). And we implement our overlay knowledge system for A2 agents, has **three layers**. A1 agents have normal Q-learning system. When an agent finished one trial, Q-value of used rules are renewed by the reinforce function as Eq.1 and Eq.2. And Q_{max} value is selected from a Q-value record in an experiment. Thus, this learn processes are executed when an agent finish one episode. See Fig.11. A current layer has 50.0% weight and a second layer and a last layer have 25.0% and 25.0%.

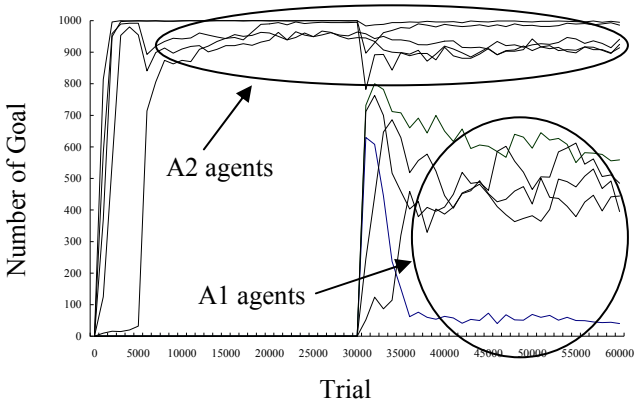

Fig.11 The curve of three layers and Result of weights are 50.0% 25.0% 25.0%

In this case, we took a good result normally, a goal number of A2 agent is decrease little bit when A1 agents came in. And the number of goal came back and kept high values. In this case, preexisting rules could work and support for new states with A1 agents coming. As a result A2 agents did not confuse about coming A1 agents in those views. Here, agent 2 supports a new condition without being confused by the show in the robust-ness of the overlaid knowledge. In this way, the overlaid knowledge is acting on the valid product. However, we can not judge applicability about behavior of the agent. Therefore, we discuss the possibility to realize applicable behavior by the weight parameter change and the algorithm change. Therefore, we change a parameter.

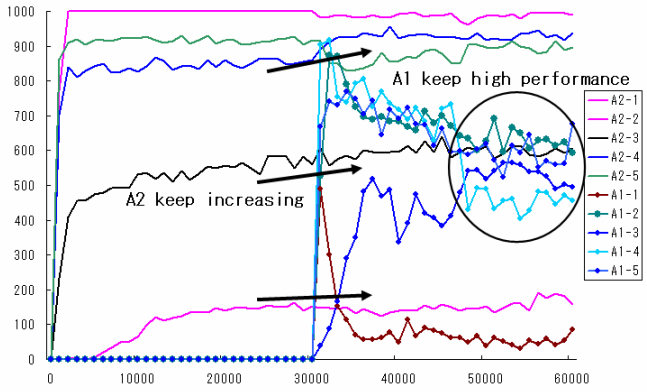

Fig.12 The curve of five layers and Result of weights are 92%, 2%, 2%, 2%, 2%

This system uses the Q value of the all layers. But layer weights, which except current layer, made low and even weight for experiment. On those weights, learning can make robust-ness to the overlay knowledge. So, a flexible action is led from the overlay. The learning uses the overlay knowledge of **five layers**. The weight of a current layer is 92%. The weights of other 2nd-5th layers are 2%. In fig.12, phenomena of curve show the flexible behavior successfully.

VIII. Conclusion

We examined the characteristic of overlay knowledge from the experiment from applying a fire panic problem. All agents have to follow features ①～④ in the fire panic. We examined the nature of the featuring learning principle about the heterogeneous multi-agent which followed features ⑤～⑥. About features ①～⑥, see. II. LEARNING THEORY OF MULTI-AGENT SYSTEM. As a result, it was proved that the overlay knowledge was useful sufficiently for the heterogeneous multi-agent. Also, we have showed the robust characteristic which depends on layer in overlay knowledge. Then, the robust characteristic was the cause which outputs absolute behavior. By the change of the robust levels, behavior of the agent expected a change into the flexible movement. The behavior which is passive about the reward is output. However, the overlay knowledge which was taken by the experimental result and we must analyze it for the rote. This is future work.

***Abstract*—In this paper, we pay attention to strong atmosphere of a group momentarily constructed by a place because the agent who expresses gesture and face expression gathers plurals. We called the atmosphere socially constructed as group pressure of agents. The purpose of the paper is to develop a group pressure and investigate the influence to human. We verify if the group pressure made by multiple life-like agents exert an influence on the judgment of player by using the cross-cultural simulation game we developed before.**

Keywords- group pressure; cross-cultural simulation game; human-agent interaction; barnga

I. INTRODUCTION

In the world of human coexistence, social adaptability should be regarded as significant in order for machines to realize flexible communication with humans. However, no essential approach for social adaptability has been shown by the current research regarding Human-Agent Interaction (HAI). Conversely, this issue about social adaptability can be expected to become an important technology to develop a robot that can communicate well with a variety of people as well as to develop such characteristic robots.

There is a cross-cultural simulation game *BARNGA* [1] which is available to experience rules on group society as based on non-verbal interaction. *BARNGA* is an easy-to-use cards game for education. This game has been adopted in a training course of company, the field of education and so on all over the world. The authors have been developed *online BARNGA* [2, 3] which can provide not only human-to-human but also human-agent cross-cultural communication on online environment based on original *BARNGA*. We have been studied and learnt many findings in the adaptability of group on the human-agent cross-cultural environment. For example, we investigated action sequential data, electroencephalography (EEG) of human by fNIRS, impression evaluation by questionnaire by using *online BARNGA* [3]. However, it has never been figured out how construct a social pressure which subjects feel subjectively in the society group on the human-agent cross-cultural environment.

In this paper, we pay attention to strong atmosphere of a group momentarily constructed by a place because the agent who expresses gesture and face expression gathers plurals. We called the atmosphere socially constructed as group pressure of agents. The purpose of the paper is to develop a group pressure and investigate the influence to human. We verify if the group pressure made by multiple life-like agents exert an influence on the judgment of player by using the cross-cultural simulation game we developed before.

II. GROUP PRESSURE GENERATION BASED ON LIFE LIKE AGENTS

A. Communication with Life Like Agents

Realization of human-artifact communication is closely-related to the recognition of human intent and the function of expression. Development of life-like artifact have been performed by using the elements like line of sight, language, gesture, posture, appearance, tactile sense, sound and motion. Generally, the communication of meaning is performed by language as typified by utterance between humans communication. Meanwhile, the importance of non-verbal information like facial expression, line of sight, gesture [4]. Moreover, Mehrabian et. al. reported that language information like contents of utterances gives 7%, hearing sense like tone or speed of talk gives 38% and visual sense like appearance gives 55% influence to a conversational partner, in the experiment of normal reaction of the partner when an utterer talks a conflicted message to emotion and attitude.

This experiment indicates that the taker of the message tends to focus non-verbal information like tone of talk and body language than contents of utterance [5]. Ito et. al. proposed the way to adjust non-verbal information like line of sight and facial expression to realize the atmosphere the user specified by using life-like agent [6]. These researches indicate the designing non-verbal interaction nicely in order to realize smooth communication between human and artifact.

However, above experiments were conducted with pair of human and a life-like agent or human and human or two life-like agents. This paper will treat plural agents to communicate with a society.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

B. Group Pressure

Generally, a person becomes a member of a group with newcomer in the real social life. There is already in being a unique basis of the group at the times like this. The members keep the basis as if it were common sense. If the opinions or perspectives of the newcomer disagree with the basis, the person will get confused. In this case, the person have to judge between following behaviors [7].

1) The person accepts and agrees with the basis.
2) The person ignores the basis and behaves absolutely.
3) The person promotes the change of the basis.
4) The person leaves the group.

When a newcomer noticed that all members have same perspective without oneself in a group, the person feels a stress and pressure. This triggers a change of the opinion. We call this stress or pressure as a "group pressure". Following this pressure is the psychology of conformity.

Ash [8] investigated what condition will generate the conformity in the group in the creative experimental way.

C. Design of Group Pressure Genaration

We develop a simulation system of a group pressure by using plural life-like agents and realize various group pressures. And then, we validate the constructed atmosphere by the evaluation experiment. Life-like agent as a CG character represented human body is used as an interface which can be reduced human's cognitive load on the various tasks. So far, Galatea and TVML [9] are proposed as tools which can be develop a life-like agent relatively-easy. We use TVML for the construction of a group pressure of multiple agents. Figure 1 shows the developed agents. We prepared 4 agents, and set up the environment with interaction between 5 characters including one human person (Figure 2).

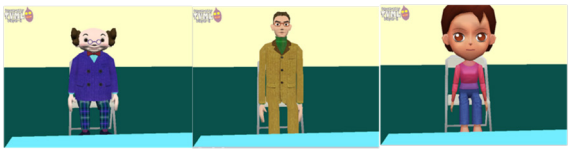
III. ONLINE BARNGA WITH GROUP PRESSURE

A. Cross-Cultural Simulation Game BARNGA

The authors have been developed *online BARNGA* which can provide not only human-to-human but also human-agent cross-cultural communication on online environment based on original *BARNGA*.

We used *online BARNGA* in this research in order to investigate an influence of the group pressure made by multiple life-like agents. In the following sections, we first explain about a trick-taking game conducted in *BARNGA* and then that is followed by an explanation about *BARNGA* itself. Afterward, *online BARNGA* is explained.

A trick-taking game is a card game. In general card games, the mark of each card, Spade, Heart, Club, and Diamond, is called a suite. The figures of each of face cards, Jack, Queen, King, and Ace, are called ranks. In this game, each player receives the same number of cards and the game is continued repeatedly until each person has used on the cards in their hand. In a trick, the dealer leads and other players do the same in order one by one. After all the players have played a card, the player who led the strongest card in that round wins the trick. Then the winner takes all the cards played in that trick. This is referred to as taking the trick and this is repeated until all the cards have been played and all the tricks taken. The player who obtains the largest number of cards becomes the winner of the trick-taking game.



Agent A Male animation agent | Agent B Male real agent | Agent C Female animation agent

Figure 1. Life-like Agents based on TVML

Figure 2. Group Pressure based on Life-like Agents

The ranking of cards in trick-taking games varies depending on the game variation. Some trick-taking games contain trumps. A trump is a special suit of card set in advance, which is stronger than any other suits.

BARNGA is a simulation game, aiming at realizing a virtual cross-cultural experience. In this game, the rules of a card game are used to resemble a culture, and players can be surprised when they notice the differences in rules so as to experience culture shock.

The rules of *BARNGA* are simple and small in size compared to general social norms, and they are inadequate for recreating a society. However, this game contains coping problem in group society on which this research puts its focus. For this reason, we adopted this game since the acquisition of adaptability of group by players can be adequately observed.

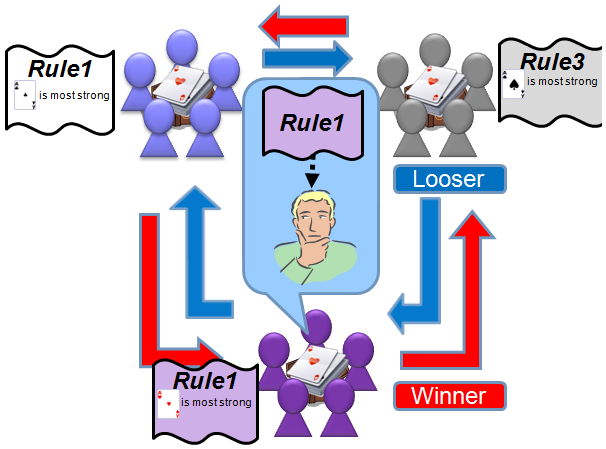


Figure 3. How a trade is done

The following explains the game content. During the game, players cannot converse. Therefore, players need to use nonverbal information such as physical gestures in order to convey their thoughts. Multiple tables are set in this game with four or five players at each table. An information sheet that contains the rules of this card game (initial rules) is distributed to each player when all the players have been seated. What is important in this game is that the game rules distributed to the players at this point vary slightly depending on each table. The differences in rules are simple regarding the types of trumps and rankings of strong cards. However, the players do not know that the rules vary slightly depending on each table. When all the players have finished reading the rules, the rule sheets are collected before the game is started. This means that the players cannot refer to the rules during the game. In this research, these small differences of the rules shows tacit rule. The players should acquire these rules actively. On the other hand, the common rules show regulations. All players acquired these rules passively in advance.

The game is played by the players on the same table. When the game advances to a certain degree, the game is stopped and those players winning and losing the most are moved to other tables by trading (Figure 3). After players have been traded, the game is restarted at each table. At this time, the traded players should experience discomfort because at the new tables, the game advances based on the different rules from the tables where they were previously seated. Similarly, those players that are not traded also feel something strange toward behavior of the new players that join in their table. *BARNGA* prohibits any conversations among players during the game. To ease this feeling of strangeness, the players need to observe the behavior and movements of the other players around them and use nonverbal information such as gestures in order to advance the game. In *BARNGA*, this feeling of strangeness is regarded as a cross-cultural experience.

The tacit rules we defined before [2] in *BARNGA* can be considered to be differences in rules. Given that, observing behavior of the players in this game serves to monitor the acquisition of tacit rules. *BARNGA* has also been utilized for agent research of group adaptability. However, interactions between players in this game are ambiguous, which makes it difficult for us to obtain and secure behavioral data from players during the game.

For this reason, we have developed *online BARNGA* in order to record behavioral data of players and clarify the interactions between players.

B. *Online BARNGA*

Going online with *BARNGA* has introduced the determination methods of winners and the scoring system into *BARNGA*, in order to realize clear interactions between players and to record the behavioral data of players. This adjustment for scoring can generate not only tacit rules as regulations, but also tacit rules as morality. In *online BARNGA*, each player joins in the game by connecting their individual computers to the server online. The gaming interface as shown in Figure 4 is displayed on each individual computer, and each player participates in the game on this interface. On the server side, the state of each player (hand, stock, and ranking) and player behavior (card led, and winner determination) are recorded as log data. Moreover, the introduction of clear determination methods for winners can offer social behavior of players as data. To realize this function, a scoring system has been introduced. The procedures of determining the winners and the flow of scoring transitions are shown as follows:

1) The dealer is selected from the table.
2) The dealer leads and the other players also play in order.
3) The dealer determines the winner.
4) The winner can get the Winner Point.
5) Non-dealers decide if they follow the decision or make complaints against the decision.
6) A non-dealer that made a complaint is given a deduction of Expense Points as a complaint cost.
7) The dealer and the winner are given a deduction in their Penalty Points on which the percentage of complaints is weighed.
8) A player that makes a complaint is given an increase in Bonus Points on which the percentage of complaints is weighed.

In *online BARNGA*, the parameters design in which the value of each score can be changed allows game designers to create group conditions. In the experiment we conducted, three kinds of group conditions were configured.

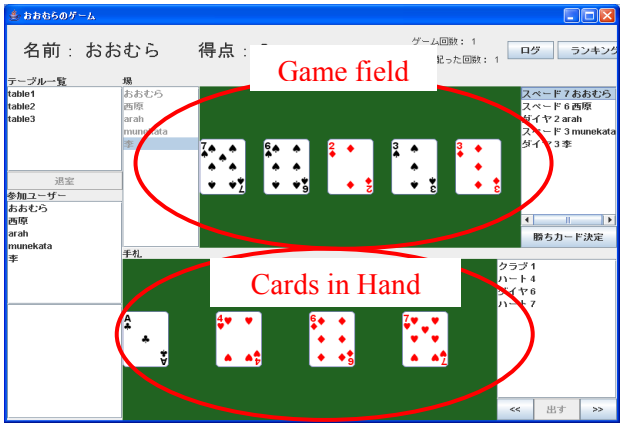

Figure 4. *Online BARNGA* Interface

C. Setting of Social Group Situation on Game

As to group conditions in the game, the following three settings which previous research [10] adopted were prepared. Standing on the viewpoint of group adaptability, we were able to examine the differences in player behavior under these conditions.

(1) Ordered condition:

This is a usual game condition before trades are conducted. Players can earn their scores by accumulating their Winner Points if they obediently follow the initial rules when leading by drawing a card necessary for winning the game. No penalty is charged by the group, there is no need to make complaints. The players almost never need to worry during the game.

(2) Cross-cultural condition:

Under this condition, only one player joins in the table traded from another table. The remaining four players on this table follow the same rules, so that there should be a variance due to the differences in initial rules. Observing behavior of other players, the traded player needs to learn the differences in the rules quickly, as well as to understand the rules commonly followed among other players at this table. The traded player needs to be free from the initial rules and take actions to learn the new rules. This should be the key to increase his score. The game result significantly varies depending on the level of player's group adaptability.

(3) Chaotic condition:

Under this condition, including the player, two other players also move in to a new table because of being traded. Three initial rules are now mixed together at this table, and high penalties also exist. At the same time, it is very hard to obtain Winners Points in a strategic sense. On the other hand, making complaints becomes a tacit rule since many complaints come to be made by players in this condition. It makes it possible for players to earn better scores by accumulating Bonus Points; however, this tacit rule is regarded as a new group rule.

D. Making Profiles based on Behavioral Logs

Behavioral logs of players obtained in *online BARNGA* consist of complaint rate, initial rule dependency rate, and acquired points. These logs can be recorded according to each social group condition. Examining these logs allow us to measure the group adaptability of players.

(1) Complaint rate (CR):

This rate indicates the probability of whether to make a complaint or not where the winner determination made by other players differs from the player's own win-loss standard. The greater this rate becomes, the more complaints the players make.

(2) Initial rule dependency rate (IR):

This rate indicates the probability of whether the complaint made by a player is dependent on the initial rules that the player follows. In the ordered condition, the greater this rate becomes, the more likely the player's behavior follows the initial rules. In the cross-cultural condition or the chaotic condition, however, the greater this rate becomes, the more the player is bound by the initial rules. This means that the player does not deal with social changes in a flexible way and continues to have headstrong attitudes.

(3) Thinking time (TT):

This is a time spent by a player in deciding whether to make a complaint or not. In the ordered condition, this time shows the discretion of individuals in thinking, that is how carefully one makes a usual decision. However, in the cross-cultural or the chaotic conditions, the longer this time is taken, the more the player thinks of dealing with a new condition in some way, thus learning the differences in the rules. This time is categorized into Total Thinking Time (TTT) and Total Thinking of Complaints (TTC).

(4) Acquired point (AP):

This indicates the points acquired by a player during the game. In the ordered condition, the player can acquire points by obediently following the rules. However, in the cross-cultural condition, the player is able to come to acquire points if he learns the differences in the rules, by demonstrating behavior that follows the new rules under the new situation and stops making complaints. On the other hand, in the chaotic condition, since there are three initial rules existing, it is difficult to learn and follow the new rules under the new situation. This is because all the players seating at the same table need to understand their initial tables (before trades are conducted twice) at the onset of the game, learning that the rules vary depending on each table. For this reason, strategic acquisition of Winner Points is difficult. However, the number of complaints made by other players naturally increases. If players can notice that Bonus Points for complaints are given every time, they can learn the tacit rule to make complaints. As a result, they can increase their scores.

IV. EXPERIMENTS

The purpose of the experiments is to investigate an influence of the group pressure made by multiple life-like agents by using *online BARNGA*.

A. Setting of Experiments

The procedures of the experiment are as follows. Three tables were prepared with 5 players at each table, a total of 15 players were allocated. Of the 15 players, one player was the test subject. The four life-like agents based on TVML works on the table with a subject and express gestures according to behavior of the player.

In the experiments, we compare between the results with group pressure by life-like agents (experimental group) and without group pressure (control group). The expressed gesture is anger face to subject when an agent player claims to judgment of dealer. If four life-like agents claimed to a player then the agents glare at the player with scary eyes.

During one turn, each player had a hand of five cards and did the trick-taking game for five sessions. Each test subject followed the following procedures to participate in the game.

1) The player does the game two sessions in the ordered condition.
2) Trades are made, and three members including the test player moves to other tables.
3) The player does the game two sessions in the cross-cultural condition.
4) Trades are made, and nine members including the test player move to other tables.
5) The player does the game two sessions in the chaotic condition.

The test subjects were 10 graduate students. TABLE I and TABLE II show the scoring settings and initial rules, respectively. All the test subjects answer questionnaires after the game has finished. Figure 5 shows the appearances of the experiments.

TABLE I. SCORING SETTINGS

Point	Description	Score
Winner Points	Winner's point	300
Penalty Points for the Winner	Penalty point against the dealer	100
Penalty Points for the Dealer	Penalty point against the winner	50
Bonus Points	Bonus point obtained in accordance with complaints	160
Expense Points	Point consumed every time a complaint is made	20

TABLE II. DIFFERENCES IN THE INITIAL RULES

	Trump	Ranking
Table 1	Heart	7>6>5>4>3>2>A
Table 2	Spade	A>7>6>5>4>3>2
Table 3	Club	2>A>7>6>5>4>3

B. Hypothesis

In the experiments, we validate following hypothesis.

1) Experimental group tends to group adaptation.

2) Experimental group tends to behave carefully with time and care compared with control group.

3) Experimental group tends to aqcuire game points compared with control group.

C. Experimental Results

Figure 6, 7, 8 and 9 show the experimental results. In the Figure 6, total thinking time (TTT) and thiking time of the claim (TTC) are not significantly different between groups. However, experimental group in both of time shows less 30 seconds on an average.

In Figure 7, experimental group in Game 1 (*Ordered condition*) shows less 50 seconds in TTT. Game 1 is significantly different between groups. In Figure 8, Game 1 shows more 5 seconds, Game 2 (*Cross-cultural condition*) and Game 3 (*Chaotic condition*) shows less 22 seconds and less 17 seconds respectively in TTC. In Figure 9, experimental group aqcuired 275 AP.

As a result, hypothesis 1) and 3) are supported and hypothesis 2) is not supported. In considersation of the results of hypothesis 2), we prospected experimental group spend much time in order to recognize emotional information of the agent players tuitively. In reverse the group can be available to cope with judgement of behavior with less time, because the group can observe and acquire the atmosphere as emotional information of a group.

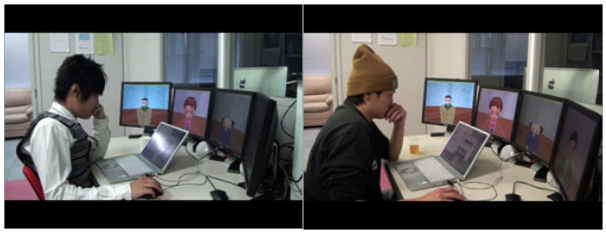

Figure 5. Appearances of The Experiments

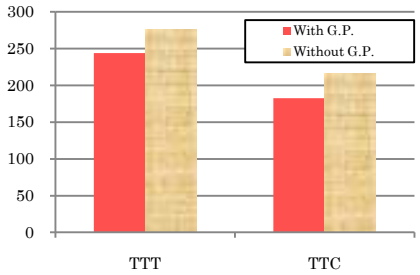

Figure 6. Thinking Time (TT) [sec]

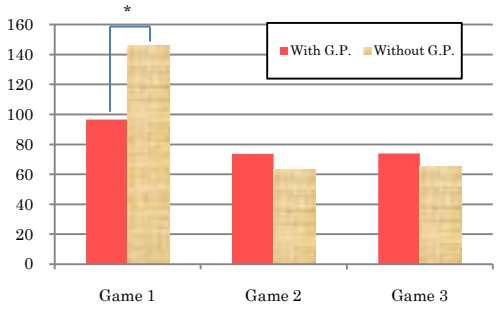

Figure 7. Total Thinking Time (TTT) [sec]

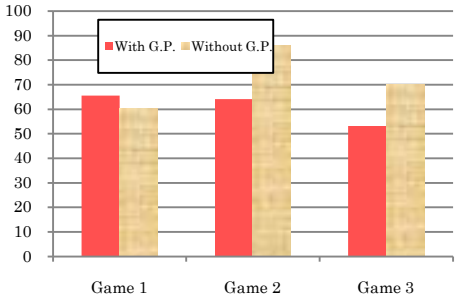

Figure 8. Thinking Time of Claim (TTC) [sec]

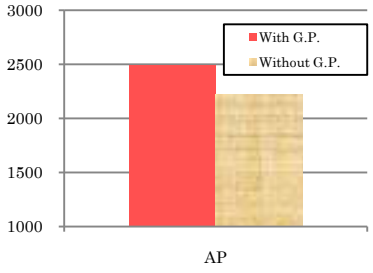

Figure 9. Acquired Points (AP)

V. CONCLUSION

We developed a virtual group pressure by using multiple life-like agents and investigate the influence to human. We verify if the group pressure made by multiple life-like agents exert an influence on the judgment of player by using the cross-cultural simulation game we developed before.

In near future, we will create a model of the mechanism of the group pressure constructed by the combination of the expressions of life-like agents.

***Abstract*—In this paper, the H_2 guaranteed cost control problem of uncertain continuous T-S fuzzy systems is investigated. We approach this problem by considering the multiple Lyapunov function and utilizing the non-PDC controller. Sufficient conditions for ensuring certain H_2 cost as well as asymptotical stability are derived and expressed in terms of LMIs. Unlike existing approaches, the assumption of known upper bounds on the time derivative of membership functions, which is quite unrealistic, is not required anymore in the present one. Numerical examples are also given to demonstrate our approach has lower H_2 guaranteed cost as well as control force in comparison with the existing ones.**

***Index Terms*—linear matrix inequality, T-S fuzzy model, H_2 guaranteed cost control.**

I. Introduction

In general, control of nonlinear systems can be a challenge task. The mathematic structure of non-linear systems makes the analysis and controller design very difficult. For the past decades, T-S fuzzy model [10] of non-linear systems has been demonstrated to be the powerful approach in non-linear system analysis and controller design. The T-S fuzzy is described fuzzy IF-THEN rules, which represent the linear input-output relations of nonlinear control systems. The main advantage of T-S fuzzy model is to express of the local dynamics of each fuzzy rule by linear system modeling to reduce the complexity of non-linear system analysis and controller design.

Stability and performance are most important issues in control systems. Once the the non-linear systems are expressed by T-S fuzzy model, stability analysis and performance design can be expressed by *linear Matrix Inequalities* (LMIs) [11], [1] and then can solved by available software. For example, the authors in [7], [5] studied the stabilization of T-S fuzzy systems. there also has been numerous results reported for design controller to ensure system performance such as mixed H_2/H_∞ [12], H_∞ [7], [8], [13], [22] and H_2 [19], [21]. On the other hand, the precise modeling of nonlinear system is sometimes impossible or difficult to achieve. The parametric uncertainties are always accompanied the system. The parametric uncertainties may degrade the system performance or even destabilize the system. Therefore, there are many researchers focusing on the issues such as robust stabilization, robust H_∞ and guaranteed cost of H_2 [19] to ensure the system stability with adequate performance level subjecting uncertainties. Comparing to the rich results in robust stabilization and robust H_∞ control for T-S fuzzy system, there are few results [19], [25] regarding to H_2 guaranteed cost control for continuous-time T-S fuzzy systems. Furthermore, although [19], [25] proposed solutions to deal with H_2 guaranteed cost control of T-S fuzzy systems, there are still some open issues to be addressed. The most results are derived based on a quadratic Lyapunov function or so-called "common" Lyapunov function(CLF) or single Lyapunov function (SLF); that is to search single P matrix in Lyapunov function to satisfy all LMI conditions. This is too conservative for some cases, especially higher number of fuzzy rules, due to less degree of freedom on P matrix. To overcome this, a nonquadratic Lyapunov function [15] or multiple Lyapunov function (MLF) [18] (or fuzzy Lyapunov function), in which the membership functions are contained , is proposed to deal with discrete-time T-S fuzzy systems . In addition, in [18], a multiple Lyapunov function is also applied to study stability of T-S fuzzy systems. From the numerical examples shown in the report [18], this type of Lyapnov function further relaxes the conservatism of stability and improve the system performance. The drawback of the approach in [18] is the upper bounds of time derivative on membership functions $|\dot{h}_i(f(t))|$ must be known as prior to derive the stability conditions. In [24], [27], [26], the information of time derivative on membership functions must be evaluated in advance as well. Finding information of time derivative on membership functions is difficult or unrealistic in some cases. Thus in [21], a line integral of multiple Lyapunov function is employed which leads to the derivative of membership functions vanishing. However, the P_i matrices in Lyapunov function must have a special structure and the conditions for controller design are in terms of BMIs. Therefore, no efficiency software exists to solve them.

Unlike the previous approaches, we introduce a slack matrix and employ the property $\sum_{i=1}^{r}(h_i(t) \pm \dot{h}_i(t)) = 1$ to deal with time derivative of membership functions. The multiple Lyapunov function and nonparallel distributed compensation

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

(non-PDC) controller [18], [15] are proposed to derive H_2 guaranteed cost of uncertain T-S fuzzy system and to ensure closed-loop system asymptotically stable for all admissible parametric uncertainty. The conditions to ensure upper bound of H_2 cost and globally asymptotically stable are all in terms of LMI form. Thus, the guaranteed minimum H_2 cost can be reformulated as minimizing the upper bound of cost subjecting to LMI constraints and becomes a generalized eigenvalue problems (GEVP), which can be solved by efficiency tools such as MATLAB LMI toolbox.

The rest of paper is organized as follows. In section 2, the problem statement is made. Section 3 is the main results of this paper. The main theorem of guaranteed H_2 cost is presented in this section. Then numerical examples to demonstrate our result are given in section 4. Finally, conclusion are made in section 5.

The notation used in this paper is quite standard. $(X+\bigstar) = X + X^T$. $X > 0$ (or $X \geq 0$) means X is positive definite (or positive semidefinite). Likewise, $X < 0$ (or $X \leq 0$) means X is negative definite (or negative semidefinite). For shorthand, $h(x(t))$ is denoted by h; " $*$ " is denoted to be the symmetric term in the symmetric matrix.

II. Problem Formulation and Preliminary

We begin with considering a class of uncertain continuous non-linear systems which can be governed by following IF-THEN rule based T-S fuzzy system,
Plant Rule i: IF $f_1(x(t))$ is M_1^i and $\ldots$ and $f_s(x(t))$ is M_s^i THEN

$$\begin{array}{rcl} \dot{x}(t) & = & (A_i + \Delta A_i)x(t) + (B_{ui} + \Delta B_{ui})u(t), \\ z(t) & = & (C_{zi} + \Delta C_{zi})x(t) + (D_{zui} + \Delta D_{zui})u(t), \end{array} \quad (1)$$

where $x(t) \in \mathbb{R}^{n\times n}$ is state vector with $x(0) = x_0$, $u(t) \in \mathbb{R}^m$ is the input vector, $z(t) \in \mathbb{R}^p$ is the controlled output vector, $A_i \in \mathbb{R}^{n\times n}$, $B_{ui} \in \mathbb{R}^{n\times m}$, $C_{zi} \in \mathbb{R}^{n\times p}$, and $D_{zui} \in \mathbb{R}^{p\times m}$ are known system matrices, M_j^i denotes an j-based fuzzy set used for the ith fuzzy rule, θ_i is $i$the premise variable, $i = 1, \ldots, r$ and r is the total number of fuzzy rules. Assume ΔA_i, ΔB_{ui}, ΔC_{zi} and ΔD_{zui} represent unknown time-varying parametric uncertainty with following structure

$$\begin{bmatrix} \Delta A_i & \Delta B_{ui} \\ \Delta C_{zui} & \Delta D_{zui} \end{bmatrix} = \begin{bmatrix} H_{xi}F_\Delta \begin{pmatrix} E_{xi} & E_{ui} \end{pmatrix} \\ H_{zi}F_\Delta \begin{pmatrix} E_{zi} & E_{zui} \end{pmatrix} \end{bmatrix}, \quad (2)$$

where H_{xi}, E_{xi}, E_{ui}, E_{zi} and E_{zui} are known matrices with appropriate dimension. F_Δ is unknown matrices with satisfying property

$$F_\Delta \in \Omega_F := \{F^T(t)F(t) < I\}$$

and the elements of $F(t)$ are Lebesgue measurable.

Given a pair of $x(t)$, $u(t)$, the final outputs of fuzzy system can be inferred as:

$$\dot{x}(t) = \sum_{i=1}^{r} h_i((A_i + \Delta A_i)x(t) + (B_{ui} + \Delta B_{ui}))u(t) \quad (3)$$

$$z(t) = \sum_{i=1}^{r} h_i((C_{zi} + \Delta C_{zi})x(t) + (D_{zui} + \Delta D_{zui}))u(t), \quad (4)$$

with $x(0) = x_0$ and $i = 1, \ldots, r$ in which $f(x(t)) = \left[f_1(x(t)),\ f_2(x(t)),\ \ldots,\ f_s(x(t))\right]$ $\mu_i(f(x(t)) = \prod_{j=1}^{s} M_i^j(f_j(x(t))), h_i(x(t)) = \mu_i(f(x(t)))/\sum_{i=1}^{r}\mu_i(f(x(t)))$. In this paper, we will assume $\mu_i(f(x(t))) \geq 0$ for all t. Then we have following properties

$$h_i(x(t)) \geq 0, i = 1, \ldots, r, \text{ and } \quad \sum_{i=1}^{r} h_i(x(t)) = 1$$

for all t.

Next we define H_2 performance index function

$$J(H_2) = \int_0^\infty z^T(t)z(t)dt. \quad (5)$$

The goal is to design a feedback controller to the system described by (3) such that the closed-loop system is asymptotically stable and the upper bound of $J(H_2)$ is as small as possible for all admissible uncertainty described by (2).

Before we start to state our main results, two lemmas, which are repeatedly used through the derivation of main results, are given.

Lemma 1. *Schur Complement: Given matrices $Q(x) = Q^T(x)$, $R(x) = R^T(x)$, and $S(x)$ with appropriate dimensions*

$$\begin{bmatrix} Q(x) & S^T(x) \\ S(x) & R(x) \end{bmatrix} < 0$$
$$\iff \quad R(x) < 0 \quad \textit{and} \quad Q(x) - S^T(x)R^{-1}(x)S(x) < 0.$$

Lemma 2. *Given matrices S, H and E with proper dimensions and symmetric matrix S. Following inequality holds*

$$S + HFE + E^TF^TH^T < 0$$

for F satisfying $F^TF \leq R$ if and only if there exists $\varepsilon > 0$ such that

$$S + \begin{bmatrix} \varepsilon^{-1}E^T & \varepsilon H \end{bmatrix} \begin{bmatrix} R & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} \varepsilon^{-1}E \\ \varepsilon H^T \end{bmatrix} < 0.$$

III. Non-PDC Nonlinear Controller Synthesis

The nonlinear controller for the nonlinear uncertain systems is type of Non-PDC controller [17] described by (3)is proposed as

$$u(t) = \sum_{i=1}^{r} h_i F_i P^{-1}(x(t))x(t), \quad (6)$$

and consider a multiple Lyapunov function

$$V(x(t)) = x^T(t)P^{-1}(x(t))x(t) \quad (7)$$

where $F_i \in \mathbb{R}^{m\times n}$ is state feedback gain and $P(x(t)) = \sum_{j=1}^{r} h_j(x(t))P_j$, $P_j = P_j^T \in \mathbb{R}^{n\times n} > 0$, $j = 1,\ldots,r$. Note that here F_i and P_i are some matrices to be determined.

Remark 3. *According to $P_j > 0, j = 1,\ldots,r$ and the property of h_i, the invertibility and the positive definiteness of P are ensured, i.e P^{-1} exists. In addition, by the property of $h_i(x(t)) \geq 0$ and $\sum_{i=1}^{r} h_i(x(t)) = 1$, we have $V(x) > 0$ $\forall x(t) \neq 0$ as well.*

Remark 4. *If let $P_1 = P_2,\ldots,= P_r = \bar{P}$, one has $P = \bar{P}$. With this assumption, multiple Lyapunov function $V(x(t))$ is reduced to common Lyapunov function and Non-PDC control law $u(t)$ is reduced to PDC one. Thus multiple Lyapunov function is more general than common Lyaupunov function.*

The following theorem gives sufficient conditions to ensure T-S fuzzy system represented by (3)) is globally asymptotically stable and H_2 cost is bounded by a prescribed level β.

Theorem 5. *Assume the membership functions, h_i, $i = 1,\ldots,r$, are differentiable. The system described by (3) is stable and $J(H_2) < \beta$ if there exist $\varepsilon_{xii} > 0$, $\varepsilon_{xij} > 0$, $\varepsilon_{zij} > 0$, $P_i > 0, F_i, i = 1,\ldots,r; Q > 0; S > 0, X_{ii}, i = 1,\ldots,r; X_{ij} = X_{ji}^T, i < j, i, j = 1,\ldots,r$; $X_{(r+i)j} = X_{j(r+i)}^T, i = 1,\ldots,r; X_{(r+i)(r+i)}, i = 1,\ldots,r; X_{(r+i)(r+j)} = X_{(r+j)(r+i)}^T, i < j, i, j = 1,\ldots,r$ and satisfy*

$$\begin{bmatrix} \Psi_{ii} + \varepsilon_{xii}H_{xi}H_{xi}^T & * \\ E_{xi}P_i + E_{ui}F_i & -\varepsilon_{xii} \end{bmatrix} < 0,\ i = 1,\ldots,r, \tag{8}$$

$$\begin{bmatrix} \Psi_{ij} + \varepsilon_{xij}H_{xi}H_{xi}^T + \varepsilon_{xji}H_{xj}H_{xj}^T & * & * \\ E_{xi}P_j + E_{ui}F_j & -\varepsilon_{xij}I & 0 \\ E_{xj}P_i + E_{uj}F_i & 0 & -\varepsilon_{xji}I \end{bmatrix} < 0,$$
$$i, j = 1,\ldots,r, i < j, \tag{9}$$

$$-P_i < X_{(r+i)j} + X_{(r+i)j}^T,\ i, j = 1,\ldots,r, i < j, \tag{10}$$

$$-S < X_{(r+i)(r+i)},\ i = 1,\ldots,r, \tag{11}$$

$$-2S < X_{(r+i)(r+j)} + X_{(r+i)(r+j)}^T,\ i, j = 1,\ldots,r, i < j, \tag{12}$$

$$\begin{bmatrix} -Q & * & * \\ C_{zi}P_j + D_{zui}F_j & -I + \varepsilon_{zij}H_{zi}H_{zi}^T & 0 \\ E_{zi}P_j + E_{zui}F_j & 0 & -\varepsilon_{zij}I \end{bmatrix} < 0,$$
$$i, j = 1,\ldots,r, \tag{14}$$

$$\begin{bmatrix} \beta & x(0)^T \\ x(0) & \sum_i h_i(x(0))P_i \end{bmatrix} > 0. \tag{15}$$

where

$$\Psi_{ii} = ((A_iP_i + B_{ui}F_i) + \bigstar) + Q + S - X_{ii}$$
$$\Psi_{ij} = ((A_iP_j + B_{ui}F_j + A_jP_i + B_{uj}F_i) + \bigstar) + 2Q + 2S - X_{ij} - X_{ij}^T$$

Proof: For simplicity, define

$$\begin{bmatrix} A_i + \Delta A_i & B_{ui} + \Delta B_{ui} \\ C_{zi} + \Delta C_{zi} & D_{zui} + \Delta D_{zui} \end{bmatrix} = \begin{bmatrix} \bar{A}_i & \bar{B}_{ui} \\ \bar{C}_{zi} & \bar{D}_{zui} \end{bmatrix}$$

With the feedback control law (6), the closed loop becomes

$$\dot{x}(t) = \sum_{i=1}^{r}\sum_{j=1}^{r} h_ih_j(\bar{A}_i + \bar{B}_{ui}F_jP^{-1})x(t)$$
$$z(t) = \sum_{i=1}^{r}\sum_{j=1}^{r} h_ih_j(\bar{C}_{zi} + \bar{D}_{zui}F_jP^{-1})x(t).$$

Next define a function $H(x)$

$$H(x) \triangleq \dot{V}(x) + z^T(t)z(t). \tag{16}$$

By taking derivative on $V(x)$, we obtain

$$\begin{aligned} &\dot{V}(x) + z^T(t)z(t) \\ &= \sum_{i}^{r}\sum_{j}^{r} h_ih_j(x^T(t)(\bar{A}_i + \bar{B}_{ui}F_jP^{-1})^TP^{-1}x(t) \\ &+ x^T(t)P^{-1}(A_i + B_{ui}F_jP^{-1})x(t) - x^T(t)P^{-1}\dot{P}P^{-1}x(t) \\ &+ x^T(t)(\bar{C}_{zi} + \bar{D}_{zui}F_jP^{-1})^T(\bar{C}_{zi} + \bar{D}_{zui}F_jP^{-1})x(t)) \end{aligned} \tag{17}$$

Let $y(t) = P^{-1}x(t)$. Thus, (17) can be rewritten as

$$\begin{aligned} H(x) = &\sum_{i=1}^{r}\sum_{j=1}^{r} h_ih_jy^T(t)((\bar{A}_iP_j + \bar{B}_{ui}F_j) + (\bigstar))y(t) \\ &- \sum_{i=1}^{r}\sum_{j=1}^{r} \dot{h}_ih_jy^T(t)P_iy(t) \\ &+ y^T(t)\left(\sum_{i=1}^{r}\sum_{j=1}^{r} h_ih_j(\bar{C}_{zi}P_j + \bar{D}_{zui}F_j)^T\right. \\ &\left.\cdot \sum_{i=1}^{r}\sum_{j=1}^{r} h_ih_j(\bar{C}_{zi}P_j + \bar{D}_{zui}F_j)\right)y(t). \end{aligned} \tag{18}$$

Since $\sum_{i=1}^{r} \dot{h}_i = 0$, we have the properties $\sum_{i=1}^{r}(h_i + \dot{h}_i) = \sum_{j=1}^{r}(h_j - \dot{h}_j) = 1$. By introducing slack variable $S > 0$, and

$$\begin{bmatrix} X_{11} & \cdots & * & * & \cdots & * \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ X_{r1} & \cdots & X_{rr} & * & \cdots & * \\ X_{(r+1)1} & \cdots & X_{(r+1)r} & X_{(r+1)(r+1)} & \cdots & * \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ X_{(r+1)r} & \cdots & X_{(r+r)r} & X_{(r+r)(r+1)} & \cdots & X_{(r+r)(r+r)} \end{bmatrix} < 0, \tag{13}$$

adding $\sum_{i=1}^{r}\sum_{j=1}^{r}(h_i+\dot{h}_i)(h_j-\dot{h_j})S>0$ to (18), one has

$$\begin{aligned} H(x) < & \sum_{i=1}^{r}\sum_{j=1}^{r} h_i h_j y^T(t)((\bar{A}_i P_j + \bar{B}_{ui}F_j) + (\bigstar) \\ & + Q + S)y(t) - \sum_{i=1}^{r}\sum_{j=1}^{r}\dot{h}_i h_j y^T(t)(P_i + S - S)y(t) \\ & - \sum_{i=1}^{r}\sum_{j=1}^{r}\dot{h}_i\dot{h}_j y^T(t)Sy(t) - y^T(t)Qy(t) \\ & + \sum_{i=1}^{r}\sum_{j=1}^{r} y^T(t)h_i h_j(\bar{C}_{zi}P_j + \bar{D}_{zui}F_j)^T \\ & \cdot \sum_{i=1}^{r}\sum_{j=1}^{r} h_i h_j(\bar{C}_{zi}P_j + \bar{D}_{zui}F_j)y(t) \\ & = \sum_{i=1}^{r} h_i^2 y^T(t)((\bar{A}_i P_i + \bar{B}_{ui}F_i) + (\bigstar) + Q + S)y(t) \\ & + \sum_{i=1}^{r}\sum_{i<j}^{r} h_i h_j y^T(t)((\bar{A}_i P_j + \bar{B}_{ui}F_j) + (\bar{A}_j P_i + \bar{B}_{uj}F_i)) \\ & + \bigstar) + 2Q + 2S)y(t) - \sum_{i=1}^{r}\sum_{j=1}^{r}\dot{h}_i h_j y^T(t)(P_i)y(t) \\ & - \sum_{i=1}^{r}\dot{h}_i^2 y^T(t)Sy - \sum_{i=1}^{r}\sum_{i<j}^{r}\dot{h}_{i=1}^{r}\dot{h}_j y^T(t)2Sy(t) \\ & - y^T(t)Qy + \sum_{i=1}^{r}\sum_{j=1}^{r} y^T(t)h_i h_j(\bar{C}_{zi}P_j + \bar{D}_{zui}F_j)^T \\ & \cdot \sum_{i=1}^{r}\sum_{j=1}^{r} h_i h_j(\bar{C}_{zi}P_j + \bar{D}_{zui}F_j)y(t). \end{aligned}$$

On the other hand, if (8) is satisfied, by Schur Complement, we have

$$\begin{aligned} & \Psi_{ii} + \varepsilon_{xii}H_{xi}H_{xi}^T + (1/\varepsilon_{xii})(E_{xi}P_i + E_{ui}F_i)^T \\ & \quad \cdot (E_{xi}P_i + E_{ui}F_i) < 0, \end{aligned} \tag{19}$$

which is further equivalent to

$$\begin{aligned} & (A_i P_i + B_{ui}F_i + H_{xi}F_\Delta(E_{xi}P_i + E_{ui}F_i) + (\bigstar)) \\ & \quad + Q + S < X_{ii} \end{aligned} \tag{20}$$

for all $F_\Delta(t) \in \Omega$ by Lemma 2.

Furthermore, following the same manner, (9) is equivalent to

$$\begin{aligned} & \Psi_{ij} + \varepsilon_{xij}H_{xi}H_{xi}^T + (1/\varepsilon_{xij})(E_{xi}P_j + E_{ui}F_j)^T \\ & \cdot (E_{xi}P_j + E_{ui}F_j) + \varepsilon_{xji}H_{xj}H_{xj}^T \\ & + (1/\varepsilon_{xji})E_{xj}P_i + E_{uj}F_i)^T(E_{xj}P_i + E_{uj}F_i) < 0, \\ & \qquad i,j = 1,\ldots,r, i<j. \end{aligned} \tag{21}$$

By Lemma 2, (21) is equivalent to

$$\begin{aligned} & ((A_i + H_{xi}F_\Delta E_{xi})P_i + (B_{ui} + H_{xi}F_\Delta E_{ui})F_j + \\ & \quad (A_j + H_{xj}F_\Delta E_{xj})P_i + (B_{uj} + H_{xj}F_\Delta E_{uj})F_i) \\ & \quad + (\bigstar) + 2Q + 2S < X_{ij} + X_{ij}^T, \quad i,j = \ldots,r, i<j \end{aligned} \tag{22}$$

for all allowable F_Δ.

By (22) together with (10)-(13), one can readily obtain (23) as shown in the top of next page. Thus if (13) is held, we have $V(x) < 0\ \forall x(t) \neq 0$. This leads to imply the closed-loop system is asymptotically stable for all allowable F_Δ.

Next we consider the H_2 performance. By Lemma 1 Schur Complement, (14) can rewritten as

$$\begin{aligned} & \begin{bmatrix} -Q & * \\ C_{zi}P_j + D_{zui}F_j & -I \end{bmatrix} + \varepsilon_{zij}\begin{bmatrix} 0 \\ H_{zi} \end{bmatrix}\begin{bmatrix} 0 & H_{zi}^T \end{bmatrix} \\ & \qquad + (1/\varepsilon_{zij})\begin{bmatrix} (E_{zi}P_j + E_{zui}F_j)^T \\ 0 \end{bmatrix} \\ & \qquad \cdot \begin{bmatrix} E_{zi}P_j + E_{zui}F_j & 0 \end{bmatrix} < 0. \end{aligned} \tag{24}$$

Then, by Lemma 2, (24) is equivalent to

$$\begin{aligned} & \begin{bmatrix} -Q & * \\ C_{zi}P_j + D_{zui}F_j & -I \end{bmatrix} + (\begin{bmatrix} 0 \\ H_{zi} \end{bmatrix} F_\Delta \\ & \qquad \cdot \begin{bmatrix} E_{zi}P_j + E_{zui}F_j & 0 \end{bmatrix}) + (\bigstar) < 0. \end{aligned} \tag{25}$$

for all $F_\Delta \in \Omega$. Again (25) is equivalent to

$$-Q + (\bar{C}_{zi}P_j + \bar{D}_{zui}F_j)^T(\bar{C}_{zi}P_j + \bar{D}_{zui}F_j) < 0$$

by Schur Complement. Hence we have

$$\begin{aligned} & -y^T(t)Qy + \sum_{i=1}^{r}\sum_{j=1}^{r} y^T(t)h_i h_j(\bar{C}_{zi}P_j + \bar{D}_{zui}F_j)^T \\ & \qquad \cdot \sum_{i=1}^{r}\sum_{j=1}^{r} h_i h_j(\bar{C}_{zi}P_j + \bar{D}_{zui}F_j)y(t) < 0. \end{aligned}$$

Combining all together, we can obtain

$$\dot{V}(x(t)) + z^T(t)z(t) < 0 \tag{26}$$

$$V(x) < \begin{bmatrix} h_1 y \\ \vdots \\ h_r y \\ \dot{h}_1 y \\ \vdots \\ \dot{h}_r y \end{bmatrix}^T \begin{bmatrix} X_{11} & \cdots & * & * & \cdots & * \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ X_{r1} & \cdots & X_{rr} & * & \cdots & * \\ X_{(r+1)1} & \cdots & X_{(r+1)r} & X_{(r+1)(r+1)} & \cdots & * \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ X_{(r+1)r} & \cdots & X_{(r+r)r} & X_{(r+r)(r+1)} & \cdots & X_{(r+r)(r+r)} \end{bmatrix} \begin{bmatrix} h_1 y \\ \vdots \\ h_r y \\ \dot{h}_1 y \\ \vdots \\ \dot{h}_r y \end{bmatrix}. \quad (23)$$

Integrating both sides of (26) from 0 to ∞, we readily obtain

$$\int_0^\infty z^T(t)z(t)dt < V(x(0)) - V(\infty) < V(x(0)) = x(0)^T(\sum_{i=1}^r h_i(x(0))P_i)^{-1}x(0).$$

Therefore, if (15) is satisfied, we have $\int_0^\infty z^T(t)z(t) < \beta$. □
From theorem 5, to minimize H_2 cost (5) of system (3), we can reformulate the problem as

$$\min_{P_i, X_{ij}, Q, S, \varepsilon_{xij}, \varepsilon_{xji}, \varepsilon_{zij}} \beta \quad \text{subject to} \quad (8)-(15). \quad (27)$$

Remark 6. *[19] If the system is stochastic system, the cost function can be written as*

$$J(H_2) = \mathbb{E}\{z^T(t)z(t)\}, \quad (28)$$

where $\mathbb{E}$ is denoted as expectation operator. Furthermore if $x(0)$ is zero mean random variables and satisfies $\mathbb{E}\{x(0)x^T(0)\} = I$, the upper bound of cost can be expressed by

$$J(H_2) < \mathbb{E}\left\{x^T(0)(\sum_{i=1}^r h_i(x(0))P_i)^{-1}x(0)\right\} = \mathit{Trace}\{\bar{P}^{-1}\}. \quad (29)$$

Moreover, by introducing an auxiliary variable $U > 0$, $\min$ $\mathit{Trace}\{\bar{P}^{-1}\}$ subject to (8)-(15) can be equivalent to

$$\min_{P_i, X_{ij}, Q, S, U, \varepsilon_{xij}, \varepsilon_{xji}, \varepsilon_{zij}} \mathit{Trace}(U) \quad \mathit{subject\ to} \quad (8)-(15) \quad \mathit{and} \quad \begin{bmatrix} U & * \\ I & \bar{P} \end{bmatrix} > 0, \quad (30)$$

where $\bar{P} = \sum_{i=1}^r h_i(x(0))P_i$.

Theorem 5 can be specialized to conditions of systems without uncertainties by simply setting all uncertain matrices to 0. Thus following corollary is made.

Corollary 7. *For the systems without uncertainties, the (8), (9) and (14) are reduced to*

$$((A_iP_i + B_{ui}F_i) + \bigstar) + Q + S - X_{ii} < 0, \quad i = 1, \ldots, r, \quad (31)$$

$$((A_iP_j + B_{ui}F_j + A_jP_i + B_{uj}F_i) + \bigstar) + 2Q + 2S - X_{ij} - X_{ij}^T < 0, \ , i, j = 1, \ldots, r, i < j, \quad (32)$$

$$\begin{bmatrix} -Q & * \\ C_{zi}P_j + D_{zui}F_j & -I \end{bmatrix} < 0, \ , i, j = 1, \ldots, r. \quad (33)$$

IV. Illustrative Examples

To show the performance of our proposed T-S fuzzy controllers, two examples are given.One is for nominal systems. the other one is for the system with uncertainties.

A. Example 1

The example one is cart-pole-typed inverted pendulum problem [9]. In this example, we consider uncertain-free model. Its dynamic equation is given by

$$\ddot{\theta} = \frac{g\sin(\theta(t)) - aml\dot{\theta}^2(t)sin(2\theta(t))/2 - a\cos(\theta(t))u(t)}{4l/3 - aml\cos^2(\theta(t))}$$

where θ is angle of displacement in radians, M is the mass of cart, m is the mass of pendulum, g is the acceleration due to gravity, l is half length of pendulum, and $a = 1/(M+m)$. Here we chose $M = 8Kg$, $m = 2Kg$, $g = 9.8m/sec^2$, $l = 0.5m$. Its nonlinear model can be exactly represented by following T-S fuzzy rules,

Plant Rule1:
If $f_1(x(t))$ is M_1^1 and $f_2(x(t))$ is M_2^1 THEN

$$\dot{x}(t) = A_1x(t) + B_{u1}u(t)$$
$$z(t) = C_{z1}x(t) + D_{u1}u(t),$$

Plant Rule2:
If $f_1(x(t))$ is M_1^1 and $f_2(x(t))$ is M_2^2 THEN

$$\dot{x}(t) = A_2x(t) + B_{u2}u(t)$$
$$z(t) = C_{z2}x(t) + D_{u2}u(t),$$

Plant Rule3:
If $f_1(x(t))$ is M_1^2 and $f_2(x(t))$ is M_2^1 THEN

$$\dot{x}(t) = A_3x(t) + B_{u3}u(t)$$
$$z(t) = C_{z3}x(t) + D_{u3}u(t),$$

Plant Rule4:
If $f_1(x(t))$ is M_1^2 and $f_2(x(t))$ is M_2^2 THEN

$$\dot{x}(t) = A_4x(t) + B_{u4}u(t)$$
$$z(t) = C_{z4}x(t) + D_{u4}u(t),$$

in which $x(t) = \begin{bmatrix} x_1(t) & x_2(t) \end{bmatrix}^T = \begin{bmatrix} \theta & \dot{\theta} \end{bmatrix}^T$,

$$f_1(x(t)) = \frac{g - aml x_2^2(t)\cos(x_1(t))}{4l/3 - aml\cos^2(\theta(t))}\left(\frac{\sin(x_1(t))}{x_1(t)}\right),$$
$$f_2(x(t)) = \frac{-aml\cos(x_1(t))}{4l/3 - aml\cos^2(x_1(t))},$$
$$M_1^1(f_1(x(t))) = \frac{-f_1(x(t)) + 18}{9},$$
$$M_1^2(f_1(x(t))) = \frac{-f_1(x(t)) - 9}{9},$$
$$M_2^1(f_2(x(t))) = \frac{-f_2(x(t)) - 0.0052}{9},$$
$$M_2^2(f_2 x(t))) = \frac{-f_2(x(t)) + 0.1765}{0.1713},$$
$$A_1 = A_2 = \begin{bmatrix} 0 & 1 \\ 9 & 0 \end{bmatrix}, \quad A_3 = A_4 = \begin{bmatrix} 0 & 1 \\ 18 & 0 \end{bmatrix},$$

$B_{u1} = B_{u3} = \begin{bmatrix} 0 & -0.1765 \end{bmatrix}^T, B_{u2} = B_{u4} = \begin{bmatrix} 0 & -0.0052 \end{bmatrix}^T C_{z1} = C_{z2} = C_{z3} = C_{z4} = \begin{bmatrix} 1 & 0 \end{bmatrix}$, and $D_{zu1} = D_{zu2} = D_{zu3} = D_{zu4} = 0.001$.

After using proposed approach, LMI toolbox gives the minimized upper bound $\beta = 0.4938$, P_i matrices, and feedback gain F_i matrices,

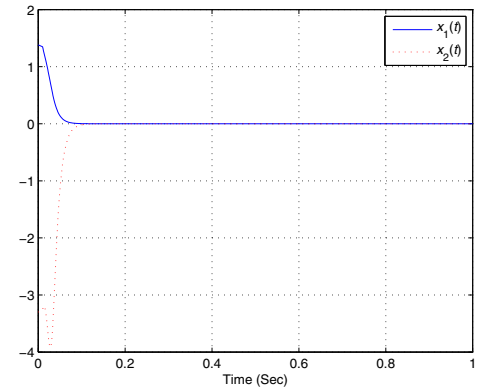
$$P_1 = \begin{bmatrix} 11.0330 & -93.0483 \\ -93.0483 & 863.8462 \end{bmatrix}, \quad P_2 = \begin{bmatrix} 10.9363 & -44.8631 \\ -44.8631 & 184.0445 \end{bmatrix}$$
$$P_3 = 10^3 \begin{bmatrix} 0.0133 & -0.1136 \\ -0.1136 & 1.0096 \end{bmatrix}, \quad P_4 = \begin{bmatrix} 13.7524 & -66.7003 \\ -66.7003 & 323.5029 \end{bmatrix}$$
$$F_1 = 10^4 \begin{bmatrix} -0.4276 & 6.9868 \end{bmatrix}, \quad F_2 = 10^4 \begin{bmatrix} -0.4175 & 2.1680 \end{bmatrix}$$
$$F_3 = 10^4 \begin{bmatrix} -0.6545 & 9.0572 \end{bmatrix}, \quad F_4 = 10^4 \begin{bmatrix} -0.6992 & 4.3518 \end{bmatrix}$$

with initial condition $x(0) = \begin{bmatrix} \frac{22\pi}{50} & -3.3 \end{bmatrix}$. The time response is shown in Figure 1. With the proposed controller, we obtain $J(H_2) \approx 0.3811$. Thus $J(H_2) < \beta = 0.4938$.

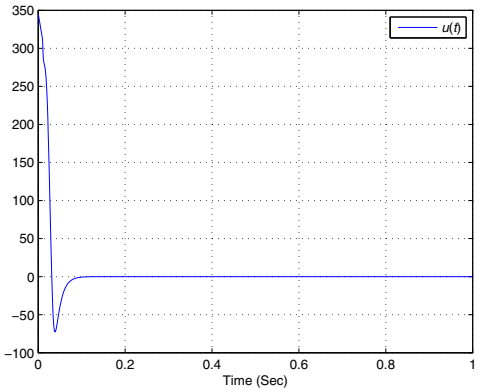
Furthermore, the Table I shown below is the comparison of performance by our proposed approach and the approach in [19]. The comparison results show our approach obtains smaller upper bound and save more control energy.

Comparison	Theorem 5	SLF [19]
upper bond β	0.4938	4.0689
$\int_0^\infty u^T(t)u(t)dt$	$\approx 1.2454 \times 10^4$	$\approx 1.3951 \times 10^6$

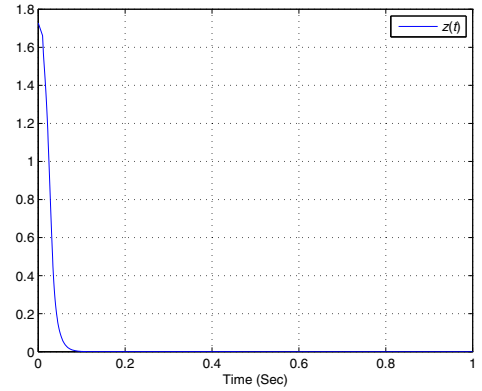
TABLE I
PERFORMANCE COMPARISON OF CONTROL OF INVERTED PENDULUM



(a) Time response of $x_1(t) = \theta(t)$ and $x_2(t) = \dot{\theta}(t)$



(b) Control action $u(t)$



(c) Controlled output $z(t)$

Fig. 1. Time response of $\theta(t), \dot{\theta}(t), u(t)$, and $z(t)$

B. Example 2

In this example, an uncertain mass-spring-damped mechanic system is to be controlled to verify our proposed fuzzy controller. Its dynamic equation is depicted by

$$\ddot{x}(t) = c(t)\dot{x}(t) - 0.02x(t) - 0.67x^3(t) + u(t)$$

The system can be modeled by T-S fuzzy system,

Plant Rule1:

If $x(t)$ is M_1 THEN

$$\dot{\tilde{x}}(t) = (A_1 + \Delta A_1)\tilde{x}(t) + (B_{u1} + \Delta B_{u1})u(t)$$
$$z(t) = C_{z1}x(t) + D_{u1}u(t)$$

Plant Rule2:

If $x(t)$ is M_2 THEN

$$\dot{\tilde{x}}(t) = (A_2 + \Delta A_2)\tilde{x}(t) + (B_{u2} + \Delta B_{u2})u(t)$$
$$z(t) = C_{z2}\tilde{x}(t) + D_{u2}u(t)$$

where $\dot{\tilde{x}}(t) = \begin{bmatrix}\dot{x}(t)\\ x(t)\end{bmatrix}, A_1 = \begin{bmatrix}-0.1125 & -0.02\\ 1 & 0\end{bmatrix}, A_2 = \begin{bmatrix}-0.1125 & -1.527\\ 1 & 0\end{bmatrix}, B_{u1} = B_{u2} = \begin{bmatrix}1\\ 0\end{bmatrix}$
$C_{z1} = C_{z2} = \begin{bmatrix}0 & 1\\ 0 & 0\end{bmatrix}, D_{u1} = D_{u2} = \begin{bmatrix}0\\ 1\end{bmatrix}, H_{x1} = H_{x2} = \begin{bmatrix}-0.1125\\ 0\end{bmatrix}, E_{x1} = E_{x2} = \begin{bmatrix}0 & 1\end{bmatrix},$
$E_{u1} = E_{u2} = 0.$

By our derived theorem, the P_i matrices and feedback gains F_i are obtained as

$$P_1 = \begin{bmatrix}0.5191 & -0.3431\\ -0.3431 & 0.7620\end{bmatrix} \quad P_2 = \begin{bmatrix}1.3949 & -0.2965\\ -0.2965 & 0.7639\end{bmatrix}$$
$$F_1 = \begin{bmatrix}-0.9690 & -0.0325\end{bmatrix} \quad F_2 = \begin{bmatrix}-1.0026 & 0.0097\end{bmatrix}.$$

Given the initial condition $\tilde{x}(0) = \begin{bmatrix}-1 & -1.3\end{bmatrix}^T$, we obtain the optimal minimum bound $\beta = 4.4223$ and $J(H_2) \approx 3.4316$. Hence we see $J(H_2) < \beta$. The response of $\tilde{x}(t)$ and $u(t)$ is shown in figure 2.

The comparison of minimized upper bound obtained by our approach and common Lyapunov function approach is shown in Table II. Therefore, as our expectation, the guaranteed

H_2 cost obtained by our proposed approach is lower than the previous common-Lyapunov function approach.

V. CONCLUSION

In this paper, we solve H_2 guaranteed cost of uncertain T-S fuzzy systems by multiple Lyapunov function. By our proposed approach, the priori information of derivative of membership functions can be completely removed. Thus, the controller is easy to implement and system is easy to analyze. Moreover, the guaranteed cost can be reformulated as minimizing an upper bound of cost function, which is a linear function, with some LMI constraints. Hence it can be efficiently solved by available software. From the numerical examples, it is also shown that the performance of designed system by our approach is better than the previous single Lyapunov function approach.

***Abstract*—A higher order sliding fuzzy type-2 controller scheme for nonlinear uncertain perturbed systems is proposed in the paper. To overcome the constraint on the knowledge of the system model, local models related to some operating points were used to synthesize a nominal fuzzy type-2 global model. The controller uses integral sliding mode concept and contains two parts. The first one leads to achieve finite time stabilization of the higher order input output dynamics without uncertainties. The second part has the object to reject bounded uncertainties throughout the entire response of the system. Two adaptive fuzzy type-2 systems have been introduced to generate the two Super Twisting signals to avoid both the chattering and the constraint on the knowledge of upper bounds of both disturbances and uncertainties. These fuzzy type-2 systems are adjusted on-line by adaptation laws deduced from the stability analysis in Lyapunov sens. The advantages of the method are that its implementation is easy, the convergence time is chosen in advance and the robustness is ensured. A robot arm actuated by a DC motor is used as illustrative example. The obtained results show the good tracking performances and the applicability of the method.**

I. Introduction

The sliding mode control (SMC) is a powerful method to control high-order nonlinear dynamic systems operating under uncertainty conditions [1],[2],[3]. The technique consists of two stages. First, a sliding surface, to which the controlled system trajectories must belong, is designed according to some performance criterion. Then, a discontinuous control is designed to force the system state to reach the sliding surface such that a sliding mode occurs on this manifold. When sliding mode is realized, the system exhibits robustness properties with respect to parameter perturbations and external matched disturbances [2]. In spite of claimed robustness properties, high frequency oscillations of the state trajectories around the sliding manifold known as chattering phenomenon [2],[3] are the major obstacles for the implementation of SMC in a wide range of applications. A number of methods have been proposed to reliably prevent chattering: among them, the boundary layer solution [4], [2], [5],[6], tangent hyperbolic [7] and observer-based solution [3]. This methods can eliminate chattering effect but a finite steady state error will exist [8] and requires a compromise between the level of tracking performance and a start-up control [9]. In [8], [9],[10] the modified switching signal (with saturation) is substituted by an adaptive fuzzy system. However, the convergence of the corresponding adaptive algorithm depends directly on the choice of the initial values of the adaptive fuzzy system. The state of the art of classical sliding mode control with soft computing has been examined in [11].

The "higher order SMC" approach has been recently proposed and developed as a generalization of the classical first order sliding mode theory [12],[13],[14],[15]. The current papers result is based on this latter approach and its main idea can be described as follows. Let $s(x,t)$ ($x \in \mathrm{R}^n$ is the state variable, $t \in \mathrm{R}^+$ the time variable) be the sliding variable and $r \in \mathrm{N}$ the sliding order. The control forces to zero in finite time s and its $(r-1)$ first higher time derivatives by acting discontinuously on the rth time derivative of s. Keeping the main advantages of standard SMC, the chattering effect is eliminated and higher order precision is provided. In the case of "real" SMC [12], if τ is the sampling time, the error is $o(\tau)$ in the case of standard SMC [16] whereas it is $o(\tau^r)$ in the rth order SMC [12].
In the case of second order SMC ($r = 2$), many works have given solutions. Several second order sliding mode algorithms are proposed in [14], [13] and [12]. Arbitrary-order sliding controllers for single-input single-output systems (SISO) with finite time convergence have been recently proposed in [15],[17],[18],[19]. In [20], the so-called terminal sliding modes control proposes a solution for arbitrary order finite time convergence sliding mode. A major drawback of this approach is that all trajectories have to start from a prescribed sector of state space in order to have finite control, which is restrictive in particular for practical applications. Many results concerning the high order SMC have been proposed for single Input single output in [13], [21] and [22]. However, the common drawback of this approach is the calculation of sliding gains used in the control law. Indeed, they are chosen to satisfy the finite time convergence condition, which required the well-knowledge of the system parameters.
The aim of this paper is to present an arbitrary-order sliding mode controller for uncertain SISO nonlinear systems. The main objective of this new approach is to propose a controller for which the implementation is easy, the convergence time is finite and well-known in advance and the computation of the gains control of the discontinuous part will be simplified. The design uses the integral sliding mode concept [23]. Actually, the problem of the higher order SMC of SISO minimum-phase uncertain systems is formulated in inputoutput terms only (as in [18]) through the differentiation of the sliding variable s, and is equivalent to the finite time stabilization of an rth order inputoutput linear dynamics with bounded uncertainties.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

The control strategy presented in the sequel, whose basic idea has been introduced in [19], contains two parts: a part is discontinuous, forces the establishment of a sliding mode on the integral sliding manifold, and ensures the robustness with respect to bounded uncertainties, throughout the entire response of the system. The other part, which is obtained through optimal feedback control over finite time interval with fixed final states [24], is used to stabilize to zero in finite time the rth order inputoutput dynamics without uncertainties. In [22], this part is based an close-loop control and has two dynamics, at $t \in [0, t_f]$ will be associated a forcing term δ and after $t > t_f$ will be removed. The computation of the control gains will be simplified by introducing two adaptive fuzzy type-2 systems in the second SMC. Their updates are performed using two adaptation laws derived from the study of stability in the sense of Lyapunov. Since the considered system is nonlinear and uncertain, we propose to use Takagi-Sugeno fuzzy system to construct a nominal model of the system. For this, we define some local models around some operating points, which will be used as conclusion of this Takagi-Sugeno system.

The paper is organized as follows. Section II gives an overview of the theory of the type-2 fuzzy systems. The problem formulation is presented in section III. The design procedure of higher SMC based an integral sliding mode and it's stability is discussed in section IV. The proposed sliding mode fuzzy type-2 interval controller is given in section V. Simulation example to demonstrate the performance of the proposed method is provided in section VI. Section VII gives the conclusions of this paper.

II. Type-2 Fuzzy Logic Systems

The main property that distinguishes fuzzy logic is its capacity of representing and modeling imprecision and uncertainty by giving each point in fuzzy set a value belonging to the interval $[0; 1]$. However, the imprecision in such classical fuzzy system, which is called some times Type-1 fuzzy logic system (T1FLS) is not fully exploited and can deliver a non-satisfactory performance. Practically, three ways of uncertainty can be observed in the fuzzy logic system (FLS): (1) the used words in antecedents and consequents of rules can mean different things to different people; (2) consequents obtained by polling a group of experts will often be different for the same rule and (3) both of training data and measurements used to activate the FLS are noisy [25],[26].

In the last few years, a markable attention has been given to another type of fuzzy system called Type-2 fuzzy logic system (T2FLS). In T2FLS, the uncertainty is represented using a function, which is it self a Type-1 fuzzy number and that is why T2FLS is referred to that fuzzy system. The membership functions of T2 fuzzy sets are three dimensional and include a foot print of uncertainty (FOU) with a new third dimension of Type-2 fuzzy sets. FOU provides additional degrees of freedom that make it possible to directly model and handle uncertainties and consequently, T2FLS has the potential to out perform T1FLS [27],[28] in such cases. Such advantage is quite important if we know that modeling of linguistic information and decision making represents the main application of FLS.

Figure 1 depicts the structure of a T2FLS [29],[30]; it is quite similar to a T1FLS, the only difference being that the antecedent and/or consequent sets in a T2FLS are type-2, so that each rule output set is a type-2. There are five principal parts in a T2FLS: fuzzifier, rule base, inference engine, type-reducer and defuzzifier.

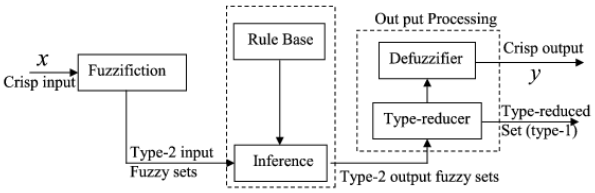

Fig. 1. The structure of T2FLS with its two out puts.

The type-reducer performs a type-reduction operation which is an extended version of T1 defuzzification. Type reduction yield a T1 set from the T2 rule output sets. The resulting T1 set is called type-reduced set. The type-reduced set can then be defuzzified to obtain a crisp output. We call the combination of type reduction and defuzzification output processing. The type reduced set of a T2FLS shows the possible variation in the crisp output of the FLS due to uncertain natures of the antecedents and/or consequents. The fuzzifier maps a crisp input vector with n inputs $x = (x_1, ..., x_n)^T \in X_1 \times X_2 \times ... \times X_n = X$ into input fuzzy sets which are T2 fuzzy input sets. However, we will use singleton fuzzification as it is fast to compute and thus suitable for real time applications. The T2 fuzzy rule base consists of a collection of IF-THEN rules in the following form [31]:

$R^i : IF\ x_1$ is $\tilde{F}_1^i$ and ...and x_n is $\tilde{F}_n^i$ THEN y is $\tilde{G}^i$

Where $\tilde{F}_j^i$s are antecedent T2 sets $(j = 1, 2, ..., n)$, $y \in Y$is the output, $\tilde{G}^i s$ are consequent type-2 sets and $i = 1, 2, ..., M$, where M is the total number of T2 fuzzy IF-THEN rules in the rule base.

The rule represents a T2 fuzzy relation between the input space $X_1 \times X_2 \times ... \times X_n$ and the output space Y of the FLS. The fuzzy inference engine is decision making logic, which employs fuzzy rules from the fuzzy rule base to determine the mapping from X to Y. A T2FLS is a mapping $f : \mathbb{R}^n \longrightarrow \mathbb{R}$. After fuzzification, fuzzy inference, type reduction and defuzzification, we obtain a crisp output. For an interval T2FLS, this crisp output is the center of type reduced set.

In interval T2FLS with meet under minimum or product t-norm, the firing interval $W^i = [\underline{w}^i, \overline{w}^i]$ of the i^{th} rule is an interval T1 set, which is determined by its left-most and right-most points $\underline{w}^i$ and $\overline{w}^i$ such that:

$$\begin{cases} \underline{w}^i = \left[\underline{\mu}_{\tilde{F}_1^i}(\underline{x}_1) \times ... \times \underline{\mu}_{\tilde{F}_n^i}(\underline{x}_n)\right] \\ \underline{w}^i = \left[\overline{\mu}_{\tilde{F}_1^i}(\underline{x}_1) \times ... \times \overline{\mu}_{\tilde{F}_n^i}(\underline{x}_n)\right] \end{cases} \quad (1)$$

Type reduction was proposed by Karnik and Mendel [32]. It is in extension of T1 defuzzification method and it is called type-reduction because this operation takes us from the T2 output sets of the FLS to a T1 set. This set may then be defuzzified to obtain a single crisp number. There exist many kinds of type-reduction [29],[33],[34]. In this paper, we will use the center of sets type reduction, which can be expressed in the case of interval T2 fuzzy sets as:

$$\begin{aligned} Y_{tr} &= \int_{y^1 \in [y_l^1, y_r^1]} \cdots \int_{y^M \in [y_l^M, y_r^M]} \int_{w^1 \in [\underline{w}^1, \overline{w}^1]} \\ &\cdots \int_{w^M \in [\underline{w}^M, \overline{w}^M]} 1 / \frac{\sum_i^M w^i y^i}{\sum_i^M w^i} \end{aligned} \tag{2}$$

$$Y_{tr} = [y_l, y_r]$$

where Y_{tr} is the interval set determined by two end points y_l and y_r, $y^i \in Y^i = \left[y_l^i, y_r^i\right]$, Y^i the centroid of the T2 interval consequent set $\tilde{G}^i$ and $w^i \in W^i = \left[\underline{w}^i, \overline{w}^i\right]$ the firing interval.

III. Problem Formulation

Consider the nth-order uncertain nonlinear system of the form:

$$\begin{cases} x^{(n)} = f(\underline{x}) + g(\underline{x}) \cdot u(t) + d \\ y = x \end{cases} \tag{3}$$

where $f(\underline{x})$ and $g(\underline{x})$ are two nonlinear continuous and uncertain bounded functions, $u \in \mathbb{R}$ and $y \in \mathbb{R}$ are the input and output of the system, respectively, d is an external unknown bounded disturbance. $\underline{x} = [x, \dot{x}, ..., x^{n-1}]^T \in \mathbb{R}^n$ is the measurable state vector and $s(\underline{x}, t)$ is the sliding variable. We assume that the two functions $f(\underline{x})$ and $g(\underline{x})$ can be written respectively as the sum of a nominal function and an unknown bounded uncertainty:

$$\begin{cases} f(\underline{x}) = f_0(\underline{x}) + \Delta f(\underline{x}); |\Delta f(\underline{x})| < \Delta_f \\ g(\underline{x}) = g_0(\underline{x}) + \Delta g(\underline{x}); |\Delta g(\underline{x})| < \Delta_g \end{cases} \tag{4}$$

where Δ_f and Δ_g are two positive constants. Replacing (4) into (3), we obtain:

$$\begin{cases} x^{(n)} = f_0(\underline{x}) + g_0(\underline{x}) \cdot u(t) + D \\ y = x \end{cases} \tag{5}$$

where

$$D = \Delta f(\underline{x}) + \Delta g(\underline{x}) u + d \tag{6}$$

The nominal model of the system can be obtained by identification or by approximation using a fuzzy system [35]. We consider the second case, because it allows us to exploit linguistic information from the expert human. The approximation can be made either using a Takagi-Sugeno classical fuzzy system or an adaptive one. This later can certainly get good results but requires a long computing time where we consider more than two inputs. Moreover, the linearisation techniques permit to transform the dynamics of the system into a local models around certain operating points. Thus, to calculate the nominal model, Takagi and Sugeno proposed in [36] a T1 fuzzy dynamic model formed by rules; where the conclusion part is a local model in the form :

$$x^{(n)} = A_i \underline{x} + B_i u \tag{7}$$

A_i and B_i are two matrix with appropriate dimension ($i = 1, 2, ..., r$). Then the corresponding IF-THEN fuzzy rule can be written as:

IF x is H_1^i and $\dot{x}$ is H_2^i and..... and $x^{(n-1)}$ is H_n^i THEN

$$x^{(n)} = A_i \underline{x}_i + B_i u \tag{8}$$

where $H_j^i, (j = 1, 2, ..., n)$ is the j^{th} fuzzy set of the i^{th} rule. However, as known in literature, the knowledge used to construct such rules are uncertain. This uncertainty leads to obtain rules whose premises or consequences uncertain, which can create uncertainty in the membership function. Since a T2 fuzzy system can take in account this uncertainties, we propose to extend the dynamic model given by (8), by introducing the concept of T2 fuzzy logic. Then, the nominal T2 fuzzy model related to the i^{th} rule will be given as follows [37]:

IF x is $\tilde{H}_1^i$ and $\dot{x}$ is $\tilde{H}_2^i$ and..... and $x^{(n-1)}$ is $\tilde{H}_n^i$ THEN

$$x^{(n)} = A_i \underline{x}_i + B_i u \tag{9}$$

Where $\tilde{H}_j^i, (j = 1, 2, ..., n)$ is the j^{th} interval T2 fuzzy set of the i^{th} rule. For a given pair $(\underline{x}, u)$, the fuzzy model resulting of the system appears as a weighted average of the local models used. If we use the product as an interference engine, the method of center set for the reduction type and center of gravity for defuzzification, the output fuzzy system will be giving by:

$$x^{(n)} = \frac{\sum_{i=1}^r w^i \left[A_i \underline{x} + B_i u\right]}{\sum_{i=1}^r w^i} = \frac{\sum_{i=1}^r w^i \left[A_i \underline{x}\right]}{\sum_{i=1}^r w^i} + \frac{\sum_{i=1}^r w^i \left[B_i u\right]}{\sum_{i=1}^r w^i} \tag{10}$$

If we denote by $f_0(\underline{x}) = \left[\frac{\sum_{i=1}^r w^i A_i \underline{x}}{\sum_{i=1}^r w_i}\right]$ and $g_0(\underline{x}) = \left[\frac{\sum_{i=1}^r w^i B_i}{\sum_{i=1}^r w^i}\right]$, the fuzzy nominal model will be giving by:

$$x^{(n)} = f_0(\underline{x}) + g_0(\underline{x}) u \tag{11}$$

where the variable w^i is the firing interval, which is determined by its most left and right points as given by (1). The reduction type algorithm given by karnik and Mendel [34] will be detailed in the third section .

The control objective is to fulfill the constraint of the sliding variable $s(\underline{x}, t) = 0$ in finite time and to keep it exactly by discontinuous feedback control, and to ensure that the system out-put y follows a reference trajectory y_d. The set:
$s^r = \{\underline{x} | s(\underline{x}, t) = \dot{s}(\underline{x}, t) = ... = s^{r-1}(\underline{x}, t) = 0\}$ called rth order sliding set, is non-empty and is locally an integral set in the Filippov sense [38], the motion on s^r is called rth order sliding mode with respect to the sliding variable s. The rth

order SMC approach allows the finite time stabilization to zero of the sliding variable s and its $r-1$ first time derivatives by defining a suitable discontinuous control function. s^r in function of the systems variables and the control variable u is given by [17]:

$$s^r = \phi(.) + \gamma(.)u \tag{12}$$

r means also the number of times to derive the sliding surface to appear explicitly the control variable.

In [22], [12], authors assume that: the functions $\phi(.)$ and $\gamma(.)$ are bounded uncertain functions, and, without loss of generality, let also the sign of the control gain $\gamma(.)$ be constant and strictly positive. Thus, there exist $K_m \in \mathrm{R}^{+*}$, $K_M \in \mathrm{R}^{+*}$, $C_0 \in \mathrm{R}^{+}$ such that $0 < K_m < \gamma < K_M$, $|\phi| \leq C_0$.
These assumption implies that this results are considered local. In the section V, we propose a method to avoid these restriction which makes the results global.
The rth order SMC with respect to the sliding variable s is equivalent to the finite time stabilization of [22]:

$$\begin{cases} \dot{z}_i = z_{i+1} \\ \dot{z}_r = \phi(.) + \gamma(.)u \end{cases} \tag{13}$$

with $1 \leq i \leq r-1$ and $z{=}[z_1\ z_2\ ...z_r]^T := [s\dot{s}...s^{(r-1)}]^T$.

IV. Control design

The control law is composed of two parts. The first one, named ideal control [23], is continuous and stabilizes in finite time (13) at the origin when there are no uncertainties. In fact, this control part is used in order to generate trajectories that the system is forced to track. The second part, named integral sliding mode control, provides the complete compensation of uncertainty for $t \geq 0$ and ensures that control objectives are reached.

A. Continuous Control Part Design

Consider system (13), according to some assumptions it can be trivially rewritten as [22]:

$$\begin{cases} \dot{z}_i = z_{i+1} \\ \dot{z}_r = \underbrace{\phi(.) + [\gamma(.) - 1]u}u + u \end{cases} \tag{14}$$

for $1 \leq i \leq r-1$, it yields

$$\begin{cases} \dot{z}_i = z_{i+1} \\ \dot{z}_r = \beta(.) + u \end{cases} \tag{15}$$

Let us define $u = u_0 + u_{dis}$, with u_0 being the ideal control, and u_{dis} being the integral sliding mode control. Consider now the particular case $\beta(.) = 0$. Then, as no control part u_{dis} is necessary in order to compensate the uncertainties, the control law u reads as $u = u_0$. One gets

$$\dot{z} = Az + Bu_0 \tag{16}$$

where A and B are defined by

$$A = \begin{bmatrix} 0 & 1 & \dots & 0 & \dots \\ \vdots & \ddots & \ddots & \ddots & \\ 0 & \ddots & \ddots & \dots & 1 \\ 0 & \ddots & \ddots & \ddots & 0 \end{bmatrix}_{r\times r}, \quad B = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}_{r\times 1}.$$

The control objective is to drive the state of (16) to $z = 0$ at the fixed final time $t = t_f < +\infty$, with $z(0)$ being a bounded initial state vector. This objective can be done through the use of optimal control laws. The control law u_0 ensures the minimization of the following criterion:

$$J = \frac{1}{2}\int_0^{t_f} z^T Q z + u_0^2 dt \tag{17}$$

with $t_f < +\infty$, $|z(0)| < +\infty$ and Q a symmetric positive definite matrix under the fixed final state constraint $z(t_f) = 0$.

Theorem 1: [24] Consider linear system (16) with (A, B) reachable. A control law u_0 minimizing the criteria (17) and driving system (16) to $z(t) = 0$ at $t = t_f$ for an initial bounded condition $z(0)$ is given by (with $0 \leq t \leq t_f < +\infty$)

$$u_0 = -B^T M z(t) + B^T \delta(t) \tag{18}$$

with $\delta(t)$ and M are defined by

$$\begin{cases} \dot{\delta} = -(A^T - MBB^T)\delta \\ 0 = MA + A^T M - MBB^T M + Q \end{cases} \tag{19}$$

Initial condition $\delta(0)$ of $\delta(t)$ is selected in order to satisfy the terminal condition $z(t_f) = 0$.

The control law u_0 is defined in order to drive in finite time the system (16) to $z(t) = 0$ at $t = t_f$, then, the state variables of (16) converge exactly to the origin at $t = t_f$. The control law u_0 will maintain the required equilibrium state $z = 0$ even after the terminal time, i.e. $t > t_f$, provided that the forcing term $\delta(t)$ is removed at the terminal time, i.e. $u_0 = -B^T M z$ for $t > t_f$ [24]. Then, in order to reach in a finite time t_f the origin $z = 0$, and to maintain the system (16) at this point for $t > t_f$, a solution is [24]:

$$u_0 = \begin{cases} -B^T M z(t) + B^T \delta(t) \text{ for } 0 \leq t \leq t_f \\ -B^T M z(t) \text{ for } t > t_f \end{cases} \tag{20}$$

B. Integral Sliding Manifold

The basic idea consists in determining a sliding manifold such that the state trajectories start on this manifold at the initial time $t = 0$, which induces a sliding mode without reaching phase [2]. One has (for $1 \leq i \leq r-1$)

$$\begin{cases} \dot{z}_i = z_{i+1} \\ \dot{z}_r = \beta(.) + u_0 + u_{dis} \end{cases} \tag{21}$$

u_{dis} is a discontinuous function designed in order to exactly reject the perturbation $\beta(.)$ throughout the entire response of the system. In order to reach this objective, the integral sliding mode control is used [23],[3]. Let $\sigma \in \mathrm{R}$ the sliding manifold defined as

$$\sigma = \sigma_0 + \zeta \tag{22}$$

where σ_0 may be designed as the linear combination of the state variables of (21). The term $\zeta \in \mathrm{R}$ induces the integral term and will be determined below. In order to determine the motion equations on the sliding manifold, the equivalent control method is used [23]. The time derivative of σ reads as

$$\dot{\sigma} = \frac{\partial \sigma_0}{\partial z}(Az + Bu_0) + \frac{\partial \sigma_0}{\partial z_r}(u_{dis} + \beta(.)) + \dot{\zeta} \tag{23}$$

A sufficient condition ensuring $\dot{\sigma} = 0$ for $t \geq 0$ is that the equivalent control u_{eq} of u_{dis} reads as

$$u_{eq} = -\beta(.) \tag{24}$$

and $\dot{\zeta} = -\frac{\partial \sigma_0}{\partial z}(Az + Bu_0)$, $\zeta(0) = -\sigma_0(z(0))$, where $\zeta(0)$ is determined based on the requirement $\sigma(0) = 0$.
In this present work, to simplify the implementation of the method we consider the particle case

$$\sigma_0 = z_r \longrightarrow \dot{\sigma} = u + \beta(.) + \dot{\zeta} \tag{25}$$

In this case, condition (24) holds if

$$\dot{\zeta} = -u_0, \zeta(0) = -z_r(0) \tag{26}$$

C. Design of the Discontinuous Control u_{dis}

The control law u_{dis} is designed in order to ensure that the sliding motion on the sliding manifold is guaranteed for $t \geq 0$ in spite of uncertainties and disturbances. Due it's relative simplicity of implementation and their robustness, Super-Twisting algorithm is among the 2-sliding algorithms which are widely used, and reads [12]:

$$u_{dis} = -u_1 - u_2 \tag{27}$$

where $\dot{u}_1 = -\lambda_1 sign(\sigma) \longrightarrow u_1 = \int_0^t \lambda_1 sign(\sigma) dt$ and $u_2 = \lambda_2 |\sigma|^{\frac{1}{2}} sign(\sigma)$.$\lambda_1$ and λ_2 are a positive constants tuned such that the η-attractiveness condition is satisfied:

$$\sigma\dot{\sigma} \leq -\eta|\sigma|, \eta > 0 \tag{28}$$

The aim of our study is to determine a control law by employing 2-order sliding modes, so that the system output y follows a reference trajectory y_r and the tracking error $e = y - y_r$ converges to zero in the presence of uncertainties and disturbances. For this, we consider the following sliding surface [5]:

$$\begin{aligned} \sigma_0 &= \left(\frac{\partial}{\partial t} + \lambda\right)^{(n-1)} e \\ &= \sum_{k=0}^{n-1} \frac{(n-1)!}{k!\,(n-k-1)!} \left(\frac{\partial}{\partial t}\right)^{(n-k-1)} \lambda^k e \end{aligned} \tag{29}$$

$\lambda > 0$, the derivative of σ_0 can be expressed as:

$$\dot{\sigma_0} = \delta_{\sigma_0} - y_r^{(n)} + f_0(\underline{x}) + g_0(\underline{x})\, u + D \tag{30}$$

which has the same form as given by equation (12), with $r = 1$, $\phi(.) = \delta_{\sigma_0} - y_r^{(n)} + f_0(\underline{x}) + D$, $\gamma(.) = g_0(\underline{x})$ and $\delta_{\sigma_0} = \sum_{k=1}^{n} \frac{(n-1)!}{k!(n-k-1)!} \left(\frac{\partial}{\partial t}\right)^{(n-k-1)} \lambda^k \dot{e}$. Since the system is relative degree 1, the seconde derivative of σ_0 is given by:

$$\ddot{\sigma}_0 = \varphi + \varrho \dot{u} \tag{31}$$

with $\varphi = \dot{\delta}_{\sigma_0} - y_r^{(n+1)} + \dot{f}_0(\underline{x}) + \dot{D} + \dot{g_0}(\underline{x})\, u$ and $\varrho = g_0(\underline{x})$. In order to satisfy the constraint (28), Levant consider the system (31) without D and it's derivative and gave the following sufficient conditions [15]:

$$\begin{cases} \Delta > 0, |\varphi| \leq \Delta, 0 < \Gamma_m \leq \varrho \leq \Gamma_M \\ \lambda_1 > \frac{\Delta}{\Gamma_m},\ \lambda_2 \geq \frac{4\Delta}{\Gamma_m^2} \frac{\Gamma_M(\lambda_1 + \Delta)}{\Gamma_m(\lambda_1 - \Delta)} \end{cases} \tag{32}$$

In steady state, we will have $\sigma = 0$, choosing these sufficient conditions allow us easily to satisfy the condition (28) at startup. However, for optimal choice of λ_1 and λ_2 in the approaching phase, the knowledge of the D and $\dot{D}$'s upper bounds are required. Nevertheless even if the problem of determining these upper bounds is resolved, the presence of the function $sign(s(\sigma))$ causes a chattering phenomenon [37],[39],[40]. Even if it's order is less important than in the classical SMC, it's still residual. One way to eliminate the chattering phenomenon consists to define a transition band near the sliding surface. But in order to keep the same tracking performances, the introduction of this band induced an important initial solicitations. Thus, there is a tradeoff between the level of performances tracking (small time response and control without chattering) and a starting suitable control. The objective of the proposed approach in the next section, is to use the same control structure with smooth control signal without reducing the tracking performances.

V. Sliding Mode Type-2 Fuzzy Controller

In this section, we will replace the two switching signals u_1 and u_2 respectively, by two control signals from two adaptive T2 fuzzy systems in order to smooth the control signal. The adaptation laws of adjustable parameters of the fuzzy systems are deduced from the stability study of the closed-loop process in the sense of Lyapunov. This adaptation in addition to smooth the control signal will enable us to better anticipate disturbances by providing us in each instant the optimal value (λ_1^* and λ_2^*) of λ_1 and λ_2, which are hard to compute [41].

A. Proposed Type-2 Fuzzy Logic System

Both adaptive systems used to approximate the control gains, have the same structure as given by (2). The antecedent T2 Membership functions $\mu_{\tilde{F_i^j}}$ will be fixed as given in figure 3. The consequent sets which are the adjustable parameters will be fuzzy centroids T1.
The output fuzzy systems are given by:

$$\begin{aligned} Y_{tr} &= [y_l, y_r] \\ &= \int_{\theta^1} \ldots \int_{\theta^M} \int_{w^1} \ldots \int_{w^M} 1 \Big/ \frac{\sum_i^M w^i \theta^i}{\sum_i^M w^i} \end{aligned} \tag{33}$$

In the case of T2 fuzzy systems, the universal approximation property is retained with an additional phase of reduction type. Since each set on the right-hand side of (33) is an interval T1 set, hence Y_{tr} is an interval T1 set. So, to find the type-reduced set Y_{tr}, we just need to compute the two end points of these interval. The maximum value of y is y_r and it's minimum value is y_l,$\forall y \in Y_{tr}$, y can be represented as:

$$y = \frac{\sum_i^M w^i \theta^i}{\sum_i^M w^i} \tag{34}$$

The y_r points are associated solely with y_r^i, in same way y_l is associated solely with y_l^i. In the center of sets, Karnik and Mendel [32] have shown that the two end points of Y_{tr}, y_r and y_l depend only on a mixture $\underline{w}^i$ or $\overline{w}^i$ of values, since $w^i \in W^i = \left[\underline{w}^i, \overline{w}^i\right]$. In this case, each y_r and y_l can be represented as a vector of fuzzy basis functions (FBFs) expansion, that is:

$$y_l = \frac{\sum_{i=1}^{M} w_l^i \theta_l^i}{\sum_{i=1}^{M} w_l^i} = \sum_{i=1}^{M} \theta_l^i \xi_l^i \tag{35}$$

where w_l^i denotes the firing strength membership grade (either $\overline{w}^i$ or $\underline{w}^i$) of the i^{th} rule contributing to the left-most point y_l and $\xi_l^i = \frac{w_l^i}{\sum_{i=1}^{M} w_l^i}$ are the components of the first FBF vector ξ_l of y. Similarly:

$$y_r = \frac{\sum_{i=1}^{M} w_r^i \theta_r^i}{\sum_{i=1}^{M} w_r^i} = \sum_{i=1}^{M} \theta_r^i \xi_r^i \tag{36}$$

where w_r^i denotes the firing strength membership grade (either $\overline{w}^i$ or $\underline{w}^i$) contributing to the right-most point y_r and $\xi_r^i = \frac{w_r^i}{\sum_{i=1}^{M} w_r^i}$ are the components of the first FBF vector ξ_r of y.

Note that whereas a T1FLS is characterized by a single FBF expansion [42], an interval T2FLS is characterized by two FBF expansions. This difference is the consequence of the reduction type operation.

To obtain a crisp outputs from the T2FLS y, we must defuzzify the type-reduced set Y_{tr}. Since these type reduced set is interval set, therefore, the defuzzified output of y will be the average of y_l and y_r, that is:

$$y = \frac{y_l + y_r}{2} \tag{37}$$

Replacing (35) and (36) into (37), we obtain:

$$y = \frac{\underline{\theta}_l^T \underline{\xi}_l + \underline{\theta}_r^T \underline{\xi}_r}{2} = \underline{\theta}^T \left[\frac{\underline{\xi}_l + \underline{\xi}_r}{2}\right] = \underline{\theta}^T \underline{\xi} \tag{38}$$

Where $\underline{\xi} = \frac{\underline{\xi}_l + \underline{\xi}_r}{2}$ is the average FBF of y. In order to compute y_l and y_r Karnik and Mendel have developed a simple iterative algorithm. This algorithm is given as follows:

1 We assume that the parameters θ^i are arranged in ascending order, that is, $\theta^1 < \theta^2 < ... < \theta^M$.

2 Compute y_r in (37) by initially setting $w_r^i = \frac{\overline{w}^i + \underline{w}^i}{2}$, for $i = 1, ..., M$ and let $\grave{y}_r \equiv y_r$.

3 Find k $(1 \leq k \leq M-1)$ such that $y_r^k \leq \grave{y}_r \leq y_r^{k+1}$.

4 Compute $y_r = \frac{\sum_{i=1}^{M} w^i \theta^i}{\sum_{i=1}^{M} w^i}$ with $w_r^i = \begin{cases} \overline{w}^i, i \leq k \\ \underline{w}^i, i > k \end{cases}$, and let $\grave{\grave{y}}_r \equiv y_r$.

5 If $\grave{\grave{y}}_r \neq \grave{y}_r$, then go to setup 6. If $\grave{\grave{y}}_r = \grave{y}_r$, stop and put $\grave{\grave{y}}_r \equiv y_r$.

6 Set $\grave{y}_r = \grave{\grave{y}}_r$ and return to setup 3.

The procedure is similar to compute y_l, substituting y_r by y_l in setup 3, The calculation is done with

$w_l^i = \begin{cases} \overline{w}^i, i \leq k \\ \underline{w}^i, i > k \end{cases}$

Following the same reasoning the nominal model of the system given by equation (11) is calculated, and u_1 , u_2 are estimated.

B. Proposed Control Synthesis

In this subsection, we study the stability and the robustness of the closed loop system using two adaptive fuzzy systems to replace the functions $u_1 = \int_0^t \lambda_1 sign(\sigma) dt$ and $u_2 = \lambda_2 |\sigma|^{\left(\frac{1}{2}\right)} sign(\sigma)$. The terms of the high frequency component control will be given by: $\hat{u}_1(\sigma) = \underline{\theta}_1^T \underline{\xi} t_c$ and $\hat{u}_2(\sigma) = |\sigma|^{\frac{1}{2}} \underline{\theta}_2^T \underline{\xi}$. $\hat{u}_1(\sigma)$ and $\hat{u}_2(\sigma)$ are two fuzzy systems defined by (38), whose only input is the value of the sliding variable σ, and the outputs give the optimal values satisfying $\hat{u}_1^*(\sigma) = \lambda_1^* t_c$ and $\hat{u}_2^*(\sigma) = \lambda_2^* |\sigma|^{\frac{1}{2}}$ [37], t_c is the convergence time. In [37],[39] it is only estimated, in the present paper with the concept of integral sliding mode it's value is exactly determined in advance and chosen to be $t_c = t_f$.

So, the proposed control law is given by:

$$u = u_0 + u_{eq} - \hat{u}_1(\sigma) - \hat{u}_2(\sigma) \tag{39}$$

We consider the Lyapunov equation:

$$V = \frac{\sigma^2}{2} + \frac{1}{2\gamma_1} \tilde{\underline{\theta}}_1^T \tilde{\underline{\theta}}_1 + \frac{1}{2\gamma_2} \tilde{\underline{\theta}}_2^T \tilde{\underline{\theta}}_2 \tag{40}$$

with: $\tilde{\underline{\theta}} = \underline{\theta} - \underline{\theta}^*$, $\underline{\theta}^*$ is the optimal value of $\underline{\theta}$, γ_1 and γ_2 are two positive training constants.

The time derivative of V is :

$$\dot{V} = \dot{\sigma}\sigma + \frac{1}{\gamma_1} \tilde{\underline{\theta}}_1^T \dot{\underline{\theta}}_1 + \frac{1}{\gamma_2} \tilde{\underline{\theta}}_2^T \dot{\underline{\theta}}_2 \tag{41}$$

By replacing the proposed control into the derivative of the sliding variable, we obtain

$$\begin{aligned} \dot{\sigma} &= -\hat{u}_1(\sigma) - \hat{u}_2(\sigma) + D \\ &= -\hat{u}_1(\sigma) - \hat{u}_1^*(\sigma) + \hat{u}_1^*(\sigma) - \hat{u}_2(\sigma) - \hat{u}_2^*(\sigma) + \\ &\quad \hat{u}_2^*(\sigma) + D \end{aligned} \tag{42}$$

where $\hat{u}_2^*(\sigma) = |\sigma|^{\left(\frac{1}{2}\right)} \underline{\theta}_2^{*T} \underline{\xi}(\sigma)$ and $\hat{u}_1^*(\sigma) = \underline{\theta}_1^{*T} \underline{\xi}(\sigma) t_c$, then the derivative on the sliding surface can be given by:

$$\begin{aligned} \dot{\sigma} &= -\left(\underline{\theta}_1 - \underline{\theta}_1^*\right)^T \underline{\xi}(\sigma) t_c - \left(\underline{\theta}_2 - \underline{\theta}_2^*\right)^T |\sigma|^{\left(\frac{1}{2}\right)} \underline{\xi}(\sigma) \\ &\quad -\hat{u}_2^*(\sigma) - \hat{u}_1^*(\sigma) + D \end{aligned} \tag{43}$$

Substituting (43) into (41), we obtain:

$$\begin{aligned} \dot{V} &= -\sigma\left(\hat{u}_2^*(\sigma) + \hat{u}_1^*(\sigma)\right) + \frac{1}{\gamma_1} \tilde{\underline{\theta}}_1^T \left(\dot{\underline{\theta}}_1 - \gamma_1 \sigma \underline{\xi}(\sigma) t_c\right) \\ &\quad + \frac{1}{\gamma_2} \tilde{\underline{\theta}}_2^T \left(\dot{\underline{\theta}}_2 - \gamma_2 \sigma |\sigma|^{\left(\frac{1}{2}\right)} \underline{\xi}(\sigma)\right) + D\sigma \end{aligned} \tag{44}$$

If we choose the following adaptation laws:

$$\dot{\underline{\theta}}_1 = \gamma_1 \sigma \underline{\xi}(\sigma) t_c \tag{45}$$

$$\dot{\underline{\theta}}_2 = \gamma_2 \sigma |\sigma|^{\left(\frac{1}{2}\right)} \underline{\xi}(\sigma) \tag{46}$$

we obtain

$$\dot{V} = |\sigma|D - \left(\lambda_1^* t_c + \lambda_2^* |\sigma|^{\left(\frac{1}{2}\right)}\right)|\sigma| \leq 0 \tag{47}$$

Thus, the proposed control law guaranties both robustness and stability of the closed loop system. Moreover its simplicity allows an implementation for a real-time control.

VI. Illustrative Example

In this section, the proposed control is used to control an arm robot with single joint, of mass m and languor l. This arm is actuated by a DC motor as shown in figure 2.

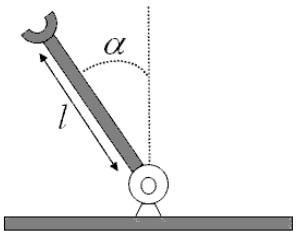

Fig. 2. Arm robot actuated by a DC motor

α means the angle rotation of the arm relative to the vertical. The dynamic of the robot is given by the $3rd$ order equation:

$$\alpha^{(3)} = f_0(\alpha, \dot{\alpha}) + g_0(\alpha, \dot{\alpha})u + D \tag{48}$$

$$\begin{cases} f_0(\alpha, \dot{\alpha}) = -\frac{R}{L}\ddot{\theta} - \left(\frac{K_b N^2 K_t}{ml^2 L} + \frac{g}{l} cos\alpha\right)\dot{\alpha} - \frac{Rg}{lL} sin\alpha \\ g_0(\alpha, \dot{\alpha}) = \dfrac{K_t N}{ml^2 L} \end{cases}$$

where $\alpha^{(3)}$, $\ddot{\alpha}$ and $\dot{\alpha}$ are the time derivatives of the angle α. g, L, R, N, K_b and K_t are respectively the gravity and the motor parameters whose signification is given in Table (1). $D = d + \Delta f + \Delta g$ means the sum of unknown external disturbances and model uncertainties.

TABLE I
Model parameters

Parameter	Notation	Value
Arm mass	m	2 Kg
Gravity	g	9.81 m/s
Arm languor	l	0.5 m
Resistance	R	1.5 Ω
Inductance	L	0.05 H
Constant EFM	K_b	0.2
Constant torque motor	K_t	0.3
Reduction ratio	N	60

As in [43],[37] the nominal fuzzy model is obtained using 2 rules describing the system dynamics around the operating points 0 and $\pm\frac{\pi}{2}$.

Rule*1*: IF $x_1(t)$ is close to 0
THEN

$$\begin{cases} \dot{x}(t) = A_1 x(t) + B_1 u(t) \\ y(t) = Cx(t) \end{cases} \tag{49}$$

Rule*2*: IF $x_1(t)$ is close to $\pm\pi/2$
THEN

$$\begin{cases} \dot{x}(t) = A_2 x(t) + B_2 u(t) \\ y(t) = Cx(t) \end{cases} \tag{50}$$

where:

$$A_1 = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ \frac{-Rg}{lL} & -\frac{g}{l} - \frac{K_b N^2 K_t}{ml^2 L} & \frac{R}{L} \end{bmatrix}, B_1 = \begin{bmatrix} 0 \\ 0 \\ \frac{K_t N}{ml^2 L} \end{bmatrix}$$

$$A_2 = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ \frac{-Rg}{lL} & -\frac{K_b N^2 K_t}{ml^2 L} & \frac{R}{L} \end{bmatrix}, B_2 = \begin{bmatrix} 0 \\ 0 \\ \frac{K_t N}{ml^2 L} \end{bmatrix}$$

$C = \begin{bmatrix} 1 & 1 & 0 \end{bmatrix}^T$ and $x(t) = \begin{bmatrix} \alpha & \dot{\alpha} & \ddot{\alpha} \end{bmatrix}^T$. The control objective is to control the state $x_1(t)$ of the system to track the reference trajectory $y_r(t) = sin(2t)$. Suppose that structural uncertainty, which represent the variation in the mass in this example, is in the form $dm = 0.02m(sin(2t)+sin(3t))$ while the external perturbation is assumed to be $d = sin(3t)$. According to the sliding surface given by Slotine [5] and since the system is of order $(n = 3)$, the sliding surface is given by $s = \ddot{e} + 2\lambda\dot{e} + \lambda^2 e$. e is the tracking error position $(e = x_1 - y_r)$, $\dot{e}$ is the tracking error velocity $(\dot{e} = x_2 - \dot{y}_r)$. To construct the nominal model as given by (10), we define three T2 fuzzy interval sets depending on the variable $x_1(t)$. Similarly to generate the two adaptive fuzzy systems allows us to approximate u_1 and u_2, we consider five interval fuzzy T2 sets: Negative, Small Negative, Zero, Small Positive and Positive, according to the variable s. In sliding regime, the transition between the approaching phase and the sliding phase occurs when the value of this one is zero. Therefore, in [9], it is showed that more the membership function corresponding to the fuzzy set zero is small, better are the tracking performances. The membership functions involved in building the model are given by the following equations:

$$\mu_{\tilde{H}_1^i} = 1/\left(1 + exp\left(1,8\left(x_1(t) + (0,61 + c_1)\right)/\left(\frac{\pi}{16}\right)\right)\right)$$
$$\mu_{\tilde{H}_2^i} = exp\left(-\left(x_1(t)/\left(\frac{\pi}{4.5+c_2}\right)^2\right)\right)$$
$$\mu_{\tilde{H}_3^i} = 1/\left(1 + exp\left(-1.8(x_1(t) + (0,61 + c_1))/\left(\frac{\pi}{16}\right)\right)\right)$$

where c_1 and c_2 designate an area of uncertainty, in the case of our application $c_1 \in [0, 0.2]$ and $c_2 \in [0, 1]$. Similarly the antecedent sets of the two adaptive systems are obtained by adding an area of uncertainty. Figure 3 (a and b) shows the shape fuzzy sets of the nominal model and the adaptive systems.

The time derivative of s reads as $\dot{s} = \phi(.) + \gamma(.)u$ with $\phi(.) = -y_r^{(3)} + f_0(x) + 2\lambda\ddot{e} + \lambda^2 e$ and $\gamma(.) = g_0(x)$. Let $z = s$, $A = [0]$ and $B = [1]$. Then as shown in section IV, the 2-order SMC is equivalent to the finite time stabilization of

$$\dot{z} = Az + Bu + [\phi(.) + (\gamma(.) - 1)u] \tag{51}$$

Let $t_f = 0.5s$. The state is initialized at $x(0) = \begin{bmatrix} 1 & 0 & 0 \end{bmatrix}$ (the others constant are:$\lambda = 20, \gamma_1 = 80$ and $\gamma_2 = 40$), which implies that $z(0) = -320$. As mentioned in [24], the initial condition of δ are computed in order that the sliding variable

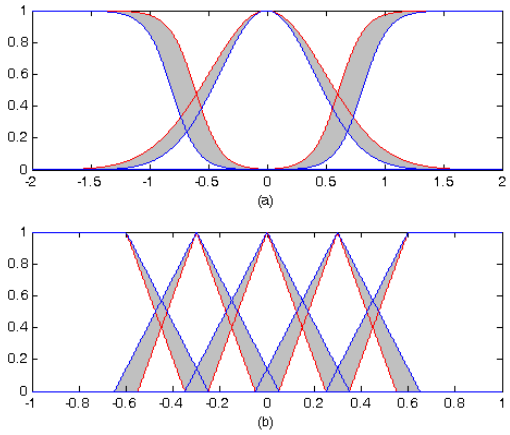

Fig. 3. (a) Interval type-2 antecedent membership functions of $x_1(t)$ defined for the interval nominal model; (b) Interval type-2 antecedent membership functions of s defined for the interval adaptive fuzzy systems.

s equal 0 at exactly $t = t_f = 0.5s$.
The first step consists in solving Riccatis equation (second line of (19) for a matrix Q which is symmetric positive definite. The solution of this equation, M, is a symmetric positive definite matrix. Q is stated as $Q = [10]$, then one gets $M = 3.1623$.
The second step consists in determining $\delta(0)$ such that $z(t_f) = 0$, knowing that only initial bounded condition $z(0)$ is known. From first line of (19), one gets

$$\delta(t) = e^{A_m t}\delta(0) \tag{52}$$

with $A_m = -[A^T - MBB^T]$. Then, by supposing that $t \leq t_f$, and from (16) and (20), one gets

$$\dot{z} = -A_m^T + BB^T e^{A_m t}\delta(0) \tag{53}$$

By multiplying both sides of previous equation by $e^{A_m^T t}$, one gets
$e^{A_m^T t}\dot{z} + e^{A_m^T t}A_m^T z = e^{A_m^T t}BB^T e^{A_m^T t}\delta(0)$
$\Rightarrow [[e^{A_m^T t}]^T z(t)] = e^{A_m^T t}BB^T e^{A_m^T t}\delta(0)$
By integrating this last equation from $t = 0$ to $t = t_f$, with $z(t_f) = 0$, one gets

$$z(0) = \left[-\int_0^{t_f} e^{A_m^T t}BB^T e^{A_m t}dt\right]\delta(0) \tag{54}$$

$H = [\int_0^{t_f} e^{A_m^T t}BB^T e^{A_m t}dt]$ is the partial reachability gramian. Then, the initial condition $\delta(0)$ ensuring that $z(t_f) = 0$ can be derived from $\delta(0) = -H^{-1}z(0)$. H is evaluated using an algorithm from [44], its Matlab code being available in [45] as grampar function. We get $\delta(0) = 89.4549$. Figure 4 and figure 5(a) display the convergence of s, $\dot{s}$ and the quadratic error e to $zero$ in exactly $0.5s$. Figure 5(b) displays the control signal which is smooth and free from chattering and abrupt variations. Figure 6 shows a good tracking of position and velocity trajectories. The state $(x_1(t), x_2(t))$ converge quickly to their references $(y_r, \dot{y}_r)$.

VII. Conclusion

In this paper, we have presented a type-2 fuzzy sliding modes controller for a perturbed uncertain nonlinear system. The control is generated from a nominal fuzzy type-2 model, who exploits the linear local models of the system. These local models are obtained by linearisation around some operating points. Two adaptive interval type-2 fuzzy systems are introduced to calculate the two switching control terms in order to overcome some restrictive constraints and to eliminate efficiency the chattering phenomenon. The stability and robustness of the closed loop system are proved analytically. The update of adjustable parameters of the two type-2 fuzzy systems are ensured by the adaptation laws derived using Lyapunov theory. The design uses the integral sliding mode concept. The controller is able to steer to zero in finite time the sliding surface and it's derivatives; the convergence time can be fixed in advance. A simulation example has been presented to illustrate the effectiveness and the robustness of the proposed approach. Currently we are working on the generalization of this approach to multi-input multi-output system with real-time implementation.

***Abstract*—This study proposes an LMI-based integral fuzzy model predictive control (MPC) for output regulation via piecewise Lyapunov function. In order to eliminate the system's bias and guarantee the zero-offset output regulation performance, firstly we take coordinate translation on equilibrium point and introduce an added integral state of output regulation error for the nonlinear plant, and then convert the resulting augmented system into a Takagi-Sugeno fuzzy model. Under the input constraint, an integrator based state feedback control law is computed by solving a convex optimization problem based on the infinite horizon predictive control scheme. Moreover, the proposed control design has following merits: i) reducing the conservatism by using piecewise Lyapunov function; ii) improving the transient performance by adding a decay rate condition; and iii) ensuring asymptotic stability for output regulation in the presence of time varying parameter. Finally, a numerical example is presented to demonstrate the effectiveness of the proposed integral fuzzy predictive controller.**

Keywords- Integral fuzzy model predictive control; linear matrix inequalities (LMIs); output regulation; Takagi-Sugeno fuzzy model; piecewise Lyapunov function

I. INTRODUCTION

Model predictive control (MPC) has developed considerably over the last two decades [1]. The strategy of MPC is to use the knowledge of the plant to predict how the system behaves and take an appropriate control action. Compared with other control techniques, the key advantage of MPC is that its control law is obtained from an optimization procedure at each sampling time, whose objective function is related to control efforts and the prediction of future states. In addition, it can handle input/output constraints directly. Recently, MPC has been applied widely to many systems, such as nonlinear complex systems, hybrid systems and piecewise affine systems [1]. In practice, most physical plants are nonlinear and contain uncertainties. For a highly nonlinear system, a linear MPC algorithm may not satisfy dynamic performance. Recently, several researchers have developed nonlinear model predictive control (NMPC) algorithms to deal with highly nonlinear industrial processes. In fact, NMPC generally requires an accurate model and then computes an optimal or suboptimal solution for a nonlinear nonconvex optimization problem at each sampling time. The increase of the prediction horizon further intensifies the time-consuming online computation load [2]. On the other hand, in order to handle the control of uncertain systems and reduce the computational burden, Kothare *et al*. [3] proposed an efficient procedure for robust constrained MPC by using linear matrix inequalities, which is suitable for online predictive controller's implementation. Since then, many LMI-based MPC approaches emerge, such as [4],[5]. More recently, the T-S fuzzy model approach has been incorporated into LMI-based MPC strategy to overcome previous drawbacks of NMPC because of its ability to accurately approximate complex nonlinear systems by a set of linear subsystems with associated membership functions [6],[7]. In stability analysis, it has been known that a common Lyapunov function might not exist for many fuzzy systems, especially for highly nonlinear complex systems. Instead, many authors [8]-[10] have presented a stability result of fuzzy systems using a piecewise Lyapunov function because of which can able to deal with a larger class of fuzzy dynamic systems in controller design.

The study of output regulation problems for nonlinear systems keeps attracting considerable attention due to demands from practical dynamical processes in mechanics, economics and biology. Based on this observation, many LMI-based fuzzy controller designs have been developed to solve output regulation control problems for nonlinear systems [11],[12]. In recently year, several well-developed approaches are proposed to design LMI-based NMPC algorithms for the purpose of regulating the system output at constant values [13],[14]. In this work, we combine coordinate translation, integral control technique, and fuzzy MPC scheme; meanwhile, a piecewise Lyapunov function is defined and utilized to synthesize the controller, to deal with the output regulation problem for nonlinear systems. As the result, at each time instant k, the fuzzy MPC controller with the input constraint is computed by solving a convex optimization problem over the infinite horizon objective function. Sufficient conditions are derived for asymptotic stabilizing the closed-loop predictive control system in linear matrix inequalities (LMIs). In addition, a decay rate conditions are also derived to improve the transient

control performance. Moreover, the piecewise Lyapunov function has been used to reduce the conservatism of the existing predictive controller. In order to reveal the validity of the proposed controller design, a nonlinear chaotic system with time varying parameter is considered to demonstrate the output regulation control task.

The contents of this paper are organized as follows. In Section II, problem formulation: coordinate translation and integral control are introduced. In Section III, Output regulation using integral fuzzy MPC based on piecewise Lyapunov functions is presented. The theorem result also includes the input constraint and decay rate conditions. Numerical simulation is carried out for the chaotic system to verify the proposed controller in Section IV. Finally, some conclusions are given in Section V.

II. Problem Formulation

A. Coordinate Translation and Integral Control

Consider a general discrete-time nonlinear system as follows:

$$\begin{aligned} x_p(k+1) &= f(x_p(k)) + g(x_p(k))u(k) + \eta \\ y(k) &= h(x_p(k)) \end{aligned} \tag{1}$$

where $x(k) \in R^{n_x}$ denotes the state variables; $y(k) \in R^{n_y}$ is the output vector; $u(k) \in R^{n_u}$ is input vector; $f(x)$, $g(x)$ and $h(x)$ are nonlinear function vectors with appropriate dimensions and η is system bias term. Note that if the system is controllable and subject to a constant bias term, it may have $f(x_p(k)) = 0$ at $x_p(k) = 0$, $g(x_p(k)) \neq 0 \ \forall \ x_p(k)$ and output function may have an offset such that $h(x_p(k)) \neq 0$ at $x_p(k) = 0$. Let $y_d \in R^{n_y}$ be a constant reference. In order to ensure zero offset output regulation performance in the presence of plant parameter variations, we want to design an integrator based controller such that $y(k) \to y_d$ as $k \to \infty$. Its principle is based on the procedure of introducing an integral action in the forward channel of tracking system to guarantee tracking property. To this end, we introduce an new state variable to account the resulting integrated tracking error, denoted by $x_e(k)$, is computed as

$$x_e(k+1) = x_e(k) + y_d - y(k) \tag{2}$$

Combining (1) with (2), we obtain the augmented dynamics as follows

$$\begin{aligned} x_p(k+1) &= f(x_p(k)) + g(x_p(k))u(k) + \eta \\ x_e(k+1) &= x_e(k) + y_d - h(x_p(k)) \end{aligned} \tag{3}$$

Let us define the regulation error as $e(k) = y_d - y(k)$. Without loss of generality, there always exists some equilibrium point for constant output reference y_d in practical industrial process control, denoted by the steady state $\bar{x}_p \in R^{n_x}$ and the corresponding input $\bar{u} \in R^{n_u}$. Then, the objective of output regulation for biased nonlinear system will be achieved by stabilizing the system at an equilibrium state which produces $e(k) = 0$. For this purpose, it follows that

$$\begin{aligned} \bar{x}_p - f(\bar{x}_p) - g(\bar{x}_p)\bar{u} - \eta &= 0 \\ y_d - h(\bar{x}_p) &= 0. \end{aligned} \tag{4}$$

Here (4) is assumed to have a unique solution $(\bar{x}_p, \bar{u})$. To eliminate the constant bias term η from the dynamics (3), we consider the coordinate translation: let $\tilde{x}_p(k) = x_p(k) - \bar{x}_p$ and $\tilde{u}(k) = u(k) - \bar{u}$. By using the property of (4), the dynamics of the system (3) can be written as follows:

$$\begin{aligned} \tilde{x}_p(k+1) &= f_s(\tilde{x}_p(k)) + g_s(\tilde{x}_p(k))\tilde{u}(k) \\ x_e(k+1) &= x_e(k) + h_s(\tilde{x}_p(k)) \end{aligned} \tag{5}$$

where $f_s(\tilde{x}_p(k)) = f(\tilde{x}_p(k) + \bar{x}_p) - f(\bar{x}_p) + [g(\tilde{x}_p(k) + \bar{x}_p) - g(\bar{x}_p)]\bar{u}$; $g_s(\tilde{x}_p(k)) = g(\tilde{x}_p(k) + \bar{x}_p)$; and $h_s(\tilde{x}_p(k)) = h(\bar{x}_p) - h(\tilde{x}_p(k) + \bar{x}_p)$. Clearly, $f_s(\tilde{x}_p(k)) = 0$, $h_s(\tilde{x}_p(k)) = 0$, $g_s(\tilde{x}_p(k)) \neq 0$, once $\tilde{x}_p(k) = 0$.

B. T-S Fuzzy Modeling

From (5), the transformed augmented system can be expressed as a state-space form with no bias terms and free-offset error signal $e(k)$:

$$\begin{aligned} \tilde{x}_p(k+1) &= A(\tilde{x}_p(k))\tilde{x}_p(k) + B(\tilde{x}_p(k))\tilde{u}(k) \\ x_e(k+1) &= x_e(k) + C(\tilde{x}_p(k))\tilde{x}_p(k) \end{aligned} \tag{6}$$

where A, B and C are the system matrix, the input matrix and the output matrix, respectively. Next, we employ the T-S fuzzy dynamic model proposed in [15] to represent the system (6) with fuzzy inference rules and local analytic linear models as follows:

Model Rule s :
IF $\tilde{z}_1(k)$ is F_{1s} and $\cdots$ and $\tilde{z}_g(k)$ is F_{gs}
THEN $\tilde{x}_p(k+1) = A_s\tilde{x}_p(k) + B_s\tilde{u}(k)$
$x_e(k+1) = x_e(k) + C_s\tilde{x}_p(k)$, $1 \leq s \leq r$

where $\tilde{z}(k) = [\tilde{z}_1(k)\, \tilde{z}_2(k) \cdots \tilde{z}_g(k)]$ are known premise variables that may be functions of the state variables; $F_{js}(j = 1, 2, \ldots, g)$ is the fuzzy set and r is the number of model rules; A_s, B_s and C_s are system matrices of appropriate dimensions. Using singleton fuzzifier, product inference and weighted average defuzzifier, the fuzzy system is inferred as follows:

$$\begin{aligned} \tilde{x}_p(k+1) &= \sum_{s=1}^{r} \mu_s(\tilde{z}(k))\{A_s\tilde{x}_p(k) + B_s\tilde{u}(k)\} \\ x_e(k+1) &= x_e(k) + \sum_{s=1}^{r} \mu_s(\tilde{z}(k))C_s\tilde{x}_p(k) \end{aligned} \tag{7}$$

where $\mu_s(\tilde{z}(k)) = w_s(\tilde{z}(k)) / \sum_{s=1}^{r} w_s(\tilde{z}(k))$ with $w_s(\tilde{z}(k)) = \prod_{j=1}^{g} F_{js}(\tilde{z}_j(k))$ for all k and $F_{js}(\tilde{z}_j(k))$ is the grade of membership of $\tilde{z}_j(k)$ in F_{js}. Note that $\sum_{s=1}^{r} \mu_s(\tilde{z}(k)) = 1$ for all k and $\mu_s(\tilde{z}(k)) \geq 0$, for $s = 1, 2, ..., r$, are regarded as grade function. Denoting the augmented state vector as $x_a(k) = \left[\tilde{x}_p(k)^T \ x_e(k)^T\right]^T$, the augmented system (7) becomes as

$$x_a(k+1) = \sum_{s=1}^{r} \mu_i(\tilde{z}(k))\{\tilde{A}_s x_a(k) + \tilde{B}_s u_a(k)\} \tag{8}$$

where

$$\tilde{A}_s = \begin{bmatrix} A_s & 0 \\ C_s & I \end{bmatrix}, \quad \tilde{B}_s = \begin{bmatrix} B_s \\ 0 \end{bmatrix}.$$

Then the resulting integral state feedback controller via the PDC

$$\begin{aligned} u_a(k) &= -\sum_{j=1}^{r} \mu_j(\tilde{z}(k)) K_j x_a(k) \\ &= -\sum_{j=1}^{r} \mu_j(\tilde{z}(k)) [K_{pt} \ K_{et}] \cdot \begin{bmatrix} \tilde{x}_p(k) \\ x_e(k) \end{bmatrix} \end{aligned} \tag{9}$$

where K_{pt} denotes the feedback gain for $\tilde{x}_p(k)$ and K_{et} is the gain associated with $x_e(k)$.

III. Output Regulation Using IFMPC Based on Piecewise Lyapunov Functions

A. Stability for Piecewise Lyapunov Functions

According to [9], the state space of the premise variable can be partitioned into a number of closed polyhedral regions, denoted as $\{\Im_m\}_{m\in N} \subseteq R^{n_x}$, where N is the index set of regions. For subsequent use, a set Γ that represents all possible transitions from one region to any region at the instant k is defined as

$$\Gamma := \{n, m | x_a(k) \in \Im_n, x_a(k+1) \in \Im_m\}. \tag{10}$$

A piecewise Lyapunov function for current region is defined as follows:

$$V(k) = x_a(k)^T P_n x_a(k), \quad x_a(k) \in \Im_n \tag{11}$$

Then we have

$$\begin{aligned} \Delta V(k) &= V(k+1) - V(k) \\ &= x_a(k+1)^T P_m x_a(k+1) - x_a(k)^T P_n x_a(k) \end{aligned} \tag{12}$$

If the Lyapunov function (12) satisfies that $\Delta V < 0$ for all time, the system can be guaranteed to be stable in the sense of Lyapunov.

B. Integral Fuzzy MPC with Input Constraint

In general, the MPC problem is formulated as solving optimal control problem subject to system dynamics and constraints involving states and controls. In this paper, we introduce a integral T-S fuzzy infinite horizon MPC scheme (IFMPC) to predict the future state of the plant (8) and state feedback control law (9) as follows:

$$\begin{aligned} x_a(k+i+1|k) = \sum_{s=1}^{r} \mu_s(\tilde{z}(k+i|k)) \{ &\tilde{A}_s x_a(k+i|k) \\ &+ \tilde{B}_s u_a(k+i|k) \} \end{aligned} \tag{13}$$

$$u_a(k+i|k) = -\sum_{j=1}^{r} \mu_j(\tilde{z}(k+i|k)) K_j(k) x_a(k+i|k). \tag{14}$$

where $x_a(k+i|k)$ denotes the system state at time $k+i$, predicted based on the measurements at time k and belongs to some region $x_a(k+i|k) \in \Im_n$; $u_a(k+i|k)$ denote the control input at time $k+i$, computed by the optimization problem at time k. The objective of the integral fuzzy predictive controller is to compute an optimal control sequence with respect to the following infinite horizon objective function [3], [4] at each time instant k.

$$\min_{u_a(k+i|k)=K_j(k)x_a(k+i|k),\ k,i\geq 0,\ 1\leq j\leq r} J_0^{\infty}(k) \tag{15}$$

subject to

$$\| u_a(k+i|k) \|_2 \leq u_{max}, \quad k, i \geq 0 \tag{16}$$

where

$$\begin{aligned} J_0^{\infty}(k) &= \sum_{i=0}^{\infty} (x_a(k+i|k)^T Q x_a(k+i|k) \\ &\quad + u_a(k+i|k)^T R u_a(k+i|k)) \\ &= x_a(k|k)^T Q x_a(k|k) + u_a(k|k)^T R u_a(k|k) \\ &\quad + J_1^{\infty}(k) \end{aligned} \tag{17}$$

with $Q \geq 0$ and $R > 0$ are weighted symmetric matrices. We introduce the following Lemmas which are needed for the proof of theorem.

Lemma 1 : Let μ_{1s}, μ_{2j} and h_r be the normalized membership functions. Then,

$$\sum_{s=1}^{p} \sum_{j=1}^{q} \mu_{1s} \mu_{2j} = \sum_{r=1}^{pq} h_r$$

with $h_r = \mu_{1\cdot s(r)} \mu_{2\cdot j(r)}$, where $s(r) = 1 + \lfloor \frac{r-1}{q} \rfloor$; $j(r) = r - \lfloor \frac{r-1}{q} \rfloor q$; and $\lfloor \cdot \rfloor$ denotes the floor function.

Lemma 2 : Let M_s be a matrix and h_s be the normalized membership function. Then,

$$\sum_{s=1}^{r} \sum_{j=1}^{r} h_s h_j M_s^T M_j \leq \sum_{s=1}^{r} h_s M_s^2$$

C. Output Regulation Using IFMPC Based on Piecewise Lyapunov Functions

Without loss of generality, suppose that the state will transit from one region $\Im_n$ to any possible region $\Im_m$ after instant k with $n, m \in \Gamma$. The piecewise Lyapunov function for predictive system at any time instant k can be defined by

$$\begin{aligned} V(i,k) &= x_a(k+i|k)^T P_n(k) x_a(k+i|k), \\ V(i+1,k) &= x_a(k+i+1|k)^T P_m(k) x_a(k+i+1|k), \\ &n, m \in \Gamma, P_n(k) > 0, P_m(k) > 0, \quad k, i \geq 0 \end{aligned} \tag{18}$$

where $P_n(k)$ denote the common positive definite matrix at time k and belong to region n. Let us suppose temporarily, that for any instant k and $i \geq 0$, the following inequality is satisfied:

$$\begin{aligned} \triangle V(i,k) \leq -((&x_a(k+i|k)^T Q x_a(k+i|k) \\ &+ u_a(k+i|k)^T R u_a(k+i|k)) \end{aligned} \tag{19}$$

Inspired by (19) and applying Lemma 1, Lemma 2 and rule reduction method in [15], we can lead to the following sufficient condition of stability:

$$\begin{aligned} G_{ss}^T P_m(k) G_{ss} - P_n(k) + Q + K_s(k)^T R K_s(k) < 0, \\ 1 \leq s \leq r \end{aligned} \tag{20}$$

$$\begin{aligned} (\frac{G_{sj} + G_{js}}{2})^T P_m(k) (\frac{G_{sj} + G_{js}}{2}) - P_n(k) + Q \leq 0, \\ 1 \leq s < j \leq r \end{aligned} \tag{21}$$

where $G_{sj} = \tilde{A}_s - \tilde{B}_s K_j(k)$. Further, summing (19) from $i = 1$ up to $i = \infty$ with $x_a(\infty|k) = 0$ and $V(\infty, k) = 0$, the following condition is obtained:

$$J_1^{\infty}(k) \leq V(1,k) = x_a(k+1|k)^T P_m(k) x_a(k+1|k) \tag{22}$$

Combining (17) and (22), we obtain the upper bound for $J_0^{\infty}(k)$ as follows

$$\begin{aligned} J_0^{\infty}(k) \leq\ & x_a(k|k)^T Q x_a(k|k) + u_a(k|k)^T R u_a(k|k) \\ & + x_a(k+1|k)^T P_m(k) x_a(k+1|k) \end{aligned} \tag{23}$$

In this paper, the output regulation problem under consideration is equivalent to design an integral fuzzy feedback controller (14) such that the resulting closed-loop fuzzy system (13) is asymptotically stable and the performance constraint (19) is fulfilled. Therefore the minimization problem (15) can be considered as $J_0^{\infty}(k) < \gamma < \infty$. Obviously, minimizing $J_0^{\infty}(k)$ with $P_t(k) > 0$ is equivalent to

$$\min_{\gamma, u_a(k|k), \bar{P}_t(k), M_t(k),\ t \in N} \gamma \tag{24}$$

subject to

$$\begin{aligned} & x_a(k|k)^T Q x_a(k|k) + u_a(k|k)^T R u_a(k|k) \\ & \quad + (\tilde{A} x_a(k|k) + \tilde{B} u_a(k|k))^T P_t(k) \\ & \quad \times (\tilde{A} x_a(k|k) + \tilde{B} u_a(k|k)) \leq \gamma \end{aligned} \tag{25}$$

where $\tilde{A} = \sum_{s=1}^{r} \mu_i(\tilde{z}(k|k)\tilde{A}_s$ and $\tilde{B} = \sum_{s=1}^{r} \mu_s(\tilde{z}(k|k)\tilde{B}_s$.

Summarizing the above arguments, the output regulation control gain via integral fuzzy MPC scheme can be obtained under the following theorem.

Theorem 1: Given $x_a(k|k)$, u_{max}, and weighting matrices Q and R for the system (1), the state feedback control law (14) will satisfy the performance constraint (19) and the minimized objective function (15) with input constraint (16) at each time instant k if there exist $u_a(k|k)$, a positive scalar γ, symmetric positive definite matrices $\bar{P}_n(k)$ and $\bar{P}_m(k)$, matrices $M_{ns}(k)$ such that the following convex objective minimization problem is feasible:

$$\min_{\gamma, u_a(k|k), \bar{P}_n(k), \bar{P}_m(k), M_{ns}(k)} \gamma$$

subject to

$$\begin{bmatrix} \bar{P}_n(k) & * \\ M_{ns}(k) & u_{max}^2 I \end{bmatrix} \geq 0, \qquad 1 \leq s \leq r \tag{26}$$

$$\begin{bmatrix} 1 & * & * & * \\ (\tilde{A} x_a(k|k) + \tilde{B} u_a(k|k)) & \bar{P}_m(k) & * & * \\ Q^{1/2} x_a(k|k) & 0 & \gamma I & * \\ R^{1/2} u_a(k|k) & 0 & 0 & \gamma I \end{bmatrix} \geq 0,$$

$$1 \leq s \leq r \tag{27}$$

$$\begin{bmatrix} \bar{P}_n(k) & * & * & * \\ \tilde{A}_s \bar{P}_n(k) - \tilde{B}_s M_{ns}(k) & \bar{P}_m(k) & * & * \\ Q^{1/2} \bar{P}_n(k) & 0 & \gamma I & * \\ R^{1/2} M_{ns}(k) & 0 & 0 & \gamma I \end{bmatrix} > 0,$$

$$n, m \in \Gamma,\ 1 \leq s \leq r \tag{28}$$

$$\begin{bmatrix} 4\bar{P}_n(k) & * & * \\ \Xi & \bar{P}_m(k) & * \\ 2Q^{1/2} \bar{P}_n(k) & 0 & \gamma I \end{bmatrix} \geq 0, \quad 1 \leq s < j \leq r \tag{29}$$

where the symbol $*$ induces a symmetric structure, $\Xi = \tilde{A}_s \bar{P}_n(k) - \tilde{B}_s M_{nj}(k) + \tilde{A}_j \bar{P}_n(k) - \tilde{B}_j M_{ns}(k)$, $\bar{P}_m(k) = \gamma P_m(k)^{-1}$, $\bar{P}_n(k) = \gamma P_n(k)^{-1}$, $M_{ns}(k) = K_s(k)\bar{P}_n(k)$. Moreover, the closed-loop regulation control system (13) is asymptotically stable.

In addition, the speed of the closed-loop system response can be influenced by specifying a desired decay rate on the piecewise Lyapunov function as follows [16]:

$$\Delta V(i,k)) \leq (\alpha - 1) V(i,k) \tag{30}$$

The requirement (30) denotes the *Decay Rate* condition which will significantly improve the transient response of the closed-loop system by carefully choosing $0 < \alpha < 1$. Hence, it can be shown that (30) becomes the LMIs as follows:

$$\begin{bmatrix} \alpha \bar{P}_n(k) & * \\ \tilde{A}_s \bar{P}_n(k) - \tilde{B}_s M_{ns}(k) & \bar{P}_m(k) \end{bmatrix} > 0, \quad 1 \leq s \leq r \tag{31}$$

$$\begin{bmatrix} 4\alpha \bar{P}_n(k) & * \\ \Pi & \bar{P}_m(k) \end{bmatrix} \geq 0, \qquad 1 \leq s < j \leq r \tag{32}$$

where $\Pi = \tilde{A}_s \bar{P}_n(k) - \tilde{B}_s M_{nj}(k) + \tilde{A}_j \bar{P}_n(k) - \tilde{B}_j M_{ns}(k)$.

Remark 1 : In above theorem 1, the controller design is called integral fuzzy MPC using piecewise Lyapunov function (IFMPC-PLF) which can directly extend to the integral fuzzy MPC with decay rate condition using piecewise Lyapunov function (IFMPC-PLFDR) by including LMIs (31) and (32).

Remark 2 : In fact, the common Lyapunov function can be considered as the special case of the more general piecewise Lyapunov function [14]. So, the integral fuzzy MPC with decay rate using common Lyapunov function method (IFMPC-CLFDR) can be obtained by replacing $\bar{P}_n(k)$ and $\bar{P}_m(k)$ with $\bar{P}(k)$, from (26) to (29) and (31) to (32).

IV. Numerical Example

The aim of this numerical section is to verify the validity of the proposed integral fuzzy MPC regulation controller for the nonlinear chaotic system with time-varying parameter. For comparing control laws, three integral fuzzy MPC approaches based on common Lyapunov function with decay rate, piecewise Lyapunov function and piecewise Lyapunov function with decay rate are investigated respectively.

A. Plant Description

Consider the Hénon map chaotic system [15], [17] given as follows:

$$\begin{aligned} x_1(k+1) &= -x_1^2(k) + \beta \cdot x_2(k) + 1.4 + u(k) \\ x_2(k+1) &= x_1(k) \\ \beta &= 0.3 \end{aligned} \tag{33}$$

For the integral output regulation control purpose, we define output equation:

$$y(k) = x_2(k) + 1 \tag{34}$$

and assume that $y(k) \to y_d$ as $k \to \infty$.

From the model (33), let the desired output $y_d = \lambda$, we can obtain the equilibrium points of the state and control input $\bar{x}_1 = \lambda - 1$, $\bar{x}_2 = \lambda - 1$ and $\bar{u} = \lambda^2 - (1+\beta)\lambda + \beta - 1.4$. Then the transformed augmented error dynamics (6) of the chaotic system is of the following form:

$$x_a(k+1) = \tilde{A}(x_p(k))x_a(k) + \tilde{B}u_a(k) \tag{35}$$

where $x_a(k) = [\tilde{x}_1(k)\ \tilde{x}_2(k)\ x_e(k)]^T$, $\tilde{B} = [1\ 0\ 0]^T$ and

$$\tilde{A}(x_p(k)) = \begin{bmatrix} -\tilde{x}_1(k) - 2\bar{x}_1(k) & \beta & 0 \\ 1 & 0 & 0 \\ 0 & -1 & 1 \end{bmatrix}$$

In the simulation, we assume the parameter β is time-varying and has ± 0.1 deviation on its nominal value. i.e., $\beta(k) = 0.1 * \sin(2\pi \cdot k/5) + \beta_0$, and $\beta_0 = 0.3$ is the nominal value. From (35), two premise variables can be defined as $\tilde{z}_1(k) = \tilde{x}_1(k)$ and $\tilde{z}_2(k) = \beta(k)$. Since having two variables in $\tilde{A}$, only four fuzzy rules are needed. Then, the dynamical equation (35) can be exactly presented as the following four-rules T-S fuzzy model:

Model Rule r :
IF $\tilde{z}_1(k)$ is $F_{1s(r)}$ and $\tilde{z}_2(k)$ is $F_{2j(r)}$
Then $x_a(k+1) = \tilde{A}_r x_a(k) + \tilde{B}_r u_a(k)$
$r = 1,2,3,4$

Let $\mu_{1s(r)}$ and $\mu_{2j(r)}$ be the normalized membership functions for $F_{1s(r)}$ and $F_{2j(r)}$ respectively, i.e., $\Sigma_{s=1}^{2}\mu_{1s} = \Sigma_{j=1}^{2}\mu_{2j} = 1$ and $0 \le \mu_{1s(r)} \cdot \mu_{2j(r)} \le 1$ for each $s(r)$ and $j(r)$. The system is inferred as follows:

$$x_a(k+1) = \sum_{r=1}^{4} h_r(\tilde{z}(k))\{\tilde{A}_r x_a(k) + \tilde{B}_r u_a(k)\} \tag{36}$$

where $h_r(\tilde{z}(k)) = \mu_{1s(r)}(\tilde{z}(k)) \cdot \mu_{2j(r)}(\tilde{z}(k))$ for $r = 1,2,3,4$. Due to the $\beta(k)$ is time-varying, the regions of the nonlinear terms are assumed with $\tilde{x}_1(k) \in [-d, d]$ and $\beta(k) \in [d_1, D_1]$, where $d = 3$, $d_1 = \beta_0 - 0.1$, $D_1 = \beta_0 + 0.1$, $\tilde{x}_1(k) = \mu_{11}d + \mu_{12}(-d)$ and $\beta(k) = \mu_{21}D_1 + \mu_{22}d_1$. According to [17], we can define the normalized membership functions as

$$\mu_{11} = \frac{1}{2} + \frac{\tilde{x}_1(k)}{2d},\ \mu_{12} = \frac{1}{2} - \frac{\tilde{x}_1(k)}{2d}$$
$$\mu_{21} = \frac{\beta(k) - d_1}{D_1 - d_1},\ \mu_{22} = \frac{D_1 - \beta(k)}{D_1 - d_1}$$

From Lemma 1, we obtain $s(r)$ and $j(r)$ and then $\tilde{A}_r$, $\tilde{B}_r$ and h_r, which are summarized in Table I. As a result, the system matrices in the consequent part are:

$$\tilde{A}_1 = \begin{bmatrix} d - 2\bar{x}_1 & d_1 & 0 \\ 1 & 0 & 0 \\ 0 & -1 & 1 \end{bmatrix},$$

$$\tilde{A}_2 = \begin{bmatrix} d - 2\bar{x}_1 & D_1 & 0 \\ 1 & 0 & 0 \\ 0 & -1 & 1 \end{bmatrix},$$

$$\tilde{A}_3 = \begin{bmatrix} -d - 2\bar{x}_1 & d_1 & 0 \\ 1 & 0 & 0 \\ 0 & -1 & 1 \end{bmatrix},$$

$$\tilde{A}_4 = \begin{bmatrix} -d - 2\bar{x}_1 & D_1 & 0 \\ 1 & 0 & 0 \\ 0 & -1 & 1 \end{bmatrix},$$

and $\tilde{B}_r = [1\ \ 0\ \ 0]^T,\ r = 1,2,3,4$.

TABLE I
System Matrices and Membership Functions of The Model

r	$s(r)$	$j(r)$	$\tilde{A}_r$	$\tilde{B}_r$	h_r
1	1	1	$\tilde{A}_1$	$\tilde{B}_1$	$h_1 = \mu_{11}\mu_{21}$
2	1	2	$\tilde{A}_2$	$\tilde{B}_2$	$h_2 = \mu_{11}\mu_{22}$
3	2	1	$\tilde{A}_3$	$\tilde{B}_3$	$h_3 = \mu_{12}\mu_{21}$
4	2	2	$\tilde{A}_4$	$\tilde{B}_4$	$h_4 = \mu_{12}\mu_{22}$

Consequently, the resulting fuzzy model can exactly represent the chaotic system, while the time varying parameter is put into the membership functions.

B. Simulation with IFMPC-CLFDR, IFMPC-PLF and IFMPC-PLFDR

To proceed on the simulation, we apply IFMPC-CLFDR, IFMPC-PLF, and IFMPC-PLFDR approaches to output regulation control the chaotic system with the same initial values and parameters for comparison as follows: $x_a(0) = [0.5\ -0.5\ 0.1]^T$, $\tilde{u}(0) = 1$, $u_{max} = 5$ and the desired output reference $y_d = 2$. Moreover, we choose $Q = 0.001 \times \mathrm{diag}\{10, 10, 5\}$, $R = 0.01$, $\gamma = 2$, and $\alpha = 0.5$ by try and error method. For the regulation control problem, there is feasible solution for IFMPC-CLFDR, and the other two methods not only lead to feasible solutions but also obtain good performance for regulation purpose even though exist the parameter variation. For IFMPC-CLFDR, the corresponding common positive definite matrix and integral fuzzy MPC state feedback gains are given as follows:

$$P = \begin{bmatrix} 5.8632 & 2.0437 & -2.2263 \\ 2.0437 & 1.3425 & -1.2982 \\ -2.2263 & -1.2982 & 1.3313 \end{bmatrix},$$

and

$$K_1 = \begin{bmatrix} 1.2522 & 0.5664 & -0.3620 \end{bmatrix},$$
$$K_2 = \begin{bmatrix} 1.2516 & 0.7654 & -0.3618 \end{bmatrix},$$
$$K_3 = \begin{bmatrix} -4.2460 & 0.6587 & -0.4702 \end{bmatrix},$$
$$K_4 = \begin{bmatrix} -4.2619 & 0.8382 & -0.4646 \end{bmatrix}.$$

For both IFMPC-PLF and IFMPC-PLFDR, the state space of premise variable is partitioned into two regions. The corresponding two different positive definite matrices and the integral fuzzy MPC state feedback gains are given, respectively,

$$P1 = \begin{bmatrix} 1.0557 & -0.0347 & -0.0006 \\ -0.0347 & 0.4289 & -0.0966 \\ -0.0006 & -0.0966 & 0.4188 \end{bmatrix},$$

$$P2 = \begin{bmatrix} 0.1028 & 0.0180 & 0.0016 \\ 0.0180 & 0.1291 & 0.0010 \\ 0.0016 & 0.0010 & 0.0954 \end{bmatrix},$$

and

$$K_1 = \begin{bmatrix} 0.5268 & 0.1651 & 0.0075 \end{bmatrix},$$
$$K_2 = \begin{bmatrix} 0.5255 & 0.3054 & -0.0008 \end{bmatrix},$$
$$K_3 = \begin{bmatrix} -2.7093 & 0.1090 & 0.0077 \end{bmatrix},$$
$$K_4 = \begin{bmatrix} -2.7068 & 0.2177 & -0.0056 \end{bmatrix},$$

for IFMPC-PLF. Similarly,

$$P1 = \begin{bmatrix} 1.4149 & -0.0431 & 0.0001 \\ -0.0431 & 0.6706 & -0.2723 \\ 0.0001 & -0.2723 & 0.6641 \end{bmatrix},$$
$$P2 = \begin{bmatrix} 0.1927 & 0.0172 & 0.0011 \\ 0.0172 & 0.1690 & 0.0011 \\ 0.0011 & 0.0011 & 0.1225 \end{bmatrix},$$

and

$$K_1 = \begin{bmatrix} 0.7880 & 0.2005 & 0.0054 \end{bmatrix},$$
$$K_2 = \begin{bmatrix} 0.7866 & 0.3856 & 0.0028 \end{bmatrix},$$
$$K_3 = \begin{bmatrix} -3.8631 & 0.1533 & 0.0023 \end{bmatrix},$$
$$K_4 = \begin{bmatrix} -3.8564 & 0.3041 & -0.0092 \end{bmatrix},$$

for IFMPC-PLFDR. The open-loop response for chaotic system is shown in Fig. 1. The closed-loop control results are shown in Figs. 2 to 5. It is shown that the proposed IFMPC-PLFDR obtains much better transient control performance than IFMPC-CLFDR and IFMPC-PLF under the same turning parameters and input constraints. Notice that three integral fuzzy MPC control methods have steered the chaotic system to regulate $y_d = 2$ trajectoy successfully. From the simulation results, we conclude that the integral fuzzy MPC scheme based on piecewise Lyapunov function with a decay rate is a powerful design. It can regularly control Hénon map system, achieving asymptotically stable, shorter transient time, lower overshot and rejecting the parameter variation.

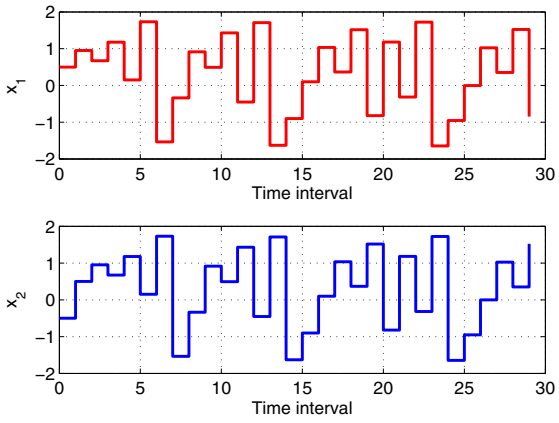

Fig. 1. Open-loop response for (a)state x_1 and (b)state x_2.

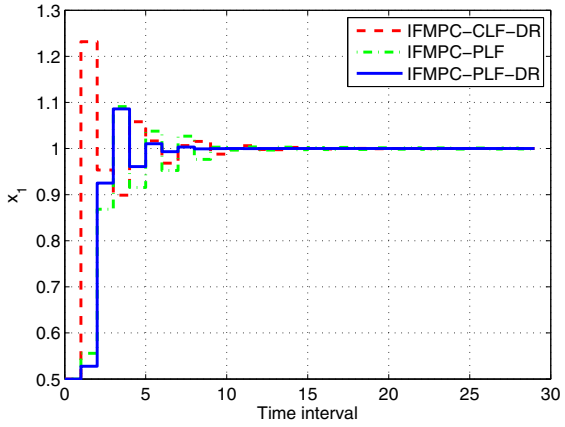

Fig. 2. Close-loop response for state x_1 controlled by three different IFMPC methods.

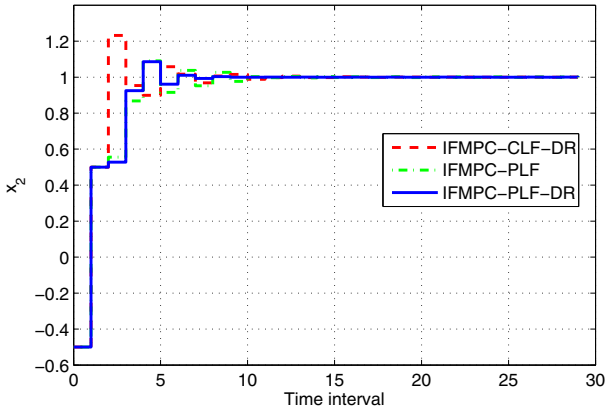

Fig. 3. Close-loop response for state x_2 controlled by three different IFMPC methods.

V. Conclusion

In this paper, an integral fuzzy MPC design for a nonlinear system using piecewise Lyapunov functions has been proposed to achieve output regulation. To this end, the nonlinear system is expressed by Takagi-Sugeno (T-S) fuzzy model via integral control and coordinate translation procedure. Then, the integral fuzzy regulation controller with input constraint is designed by infinite horizon MPC strategy and is formulated in terms of the LMIs. Finally, the numerical simulations for a chaotic system have shown the effectiveness of the proposed methods. It has been demonstrated that the IFMPC-PLFDR are less conservatism, but with short transient response, and zero-offset regulation performance when compared to IFMPC-CLF method.

***Abstract*—In this paper, a wind energy conversion system (WECS) using a variable speed synchronous generator and a battery to store extra wind energy is proposed. A fuzzy logic supervisor is developed to manage both the energy production and its storage to obtain an optimal behaviour of the system and to ensure the load requirement. Many simulation results are presented to show that the proposed method gives good performance for its application in autonomous wind energy systems and can extend battery life.**

***Keywords*—Variable speed wind turbine, synchronous generator, fuzzy logic controller, stand-alone system.**

I. INTRODUCTION

Wind power generation is more and more growing all over the world. Wind energy is called to play a crucial role in the future energy supply of the European Union and of the world. There are now thousands of wind turbines operating, with a total capacity of 121,188 MW of which wind power in Europe accounts for 55% in 2008 [1].

Wind power also offers a feasible solution to distributed power generation for isolated communities where utility grids are not available. In such cases, stand-alone wind energy systems can be considered as an effective way to provide continuous power to electrical loads. For isolated settlements located far from a utility grid, one practical approach to self-sufficient power generation involves using a wind turbine with battery storage to create a stand-alone system. If wind conditions are favourable, these stand-alone wind energy systems can provide communities with electricity at the lowest cost. Stand-alone wind energy systems often include batteries, because available wind does not always produce the required quantities of power. If wind power exceeds the load demand, the surplus can be stored in the batteries [2,3].

Synchronous generator has the capability of direct connection to wind turbines, with no gearbox. This advantage is favourable with respect to lifetime and maintenance. Synchronous machines can use either electrically excited or permanent magnet rotor [4,5].

A comparison between the variable speed wind turbine and the constant speed wind turbine shows that variable speed reduces mechanical stresses: gusts of wind can be absorbed, dynamically compensate for torque and power pulsations caused by back pressure of the tower. This backpressure causes noticeable torque pulsations at a rate equal to the turbine rotor speed times the number of rotor blades. Variable speed use is good for extracting more prime mover power as in wind turbine or for providing optimum efficiency for the prime mover by increasing its speed with power. It also allows for a more flexible generator system [6].

In ancient autonomous systems, electrical power supplied by the turbine is transmitted to a battery and then the battery transfer energy for the load [7,8]. In modern structure, wind energy is primarily provided directly to the load and the battery is in second priority [9,10]. As a result, the number of charging and discharging of the battery is greatly reduced thereby extending battery life.

Intelligent controller based on fuzzy logic capable to ensure to the networks with distributed renewable energy generation. An increasing value of the energy available to users of the power system is expected as results of the implementation of the proposed intelligent load device [11].

Fuzzy logic provides a formal methodology for representing, manipulating, and implementing human's knowledge. We do not need the accurate model of the complex system. Fuzzy logic controller is also suitable for real time applications [12]. A fuzzy logic control for the photovoltaic systems with battery has designed in [13]. It controls the rate of current injection into the battery for energy storage or increases or decreases the load in priority order to match the optimal requirement.

In this paper, we propose a fuzzy power management for a WECS including a variable speed synchronous generator and a battery bank. This controller manages power production and power storage according to wind condition and load demand. Load is provided mainly by wind power, and when this power is not enough, the battery will be switched on to discharge. A resistance is switched on to waste the surplus if needed. By controlling duty cycle of the boost converter, we can manage battery charging process according to the available power and also can provide a suitable voltage for the inverter.

II. System Description

Consider a stand-alone system with a 5.5kW pump, a 7.5kW induction motor and a 10kW water heater, powered by a 30kVA synchronous generator wind turbine and a battery storage.

In this variable speed wind turbine, a diode rectifier will rectify the AC power, then a boost converter will increase the DC voltage obtained to be suitable for both battery charging process and PWM inverter's operation.

If wind conditions are favorable, the wind turbine will be the main provider for load. If available wind does not produce the required quantities of power and battery's capacity is enough, the battery will be switched on to give power to load. If wind power exceeds load demand, the surplus can be stored in the battery and if the battery is full, the surplus will be discharged into a dumb resistance. Thus, the battery is not the main provider to load, so the charge-discharge cycle is reduced, battery life is extended.

We proposed a fuzzy controller to achieve these purposes. To do this, our controller needs two informations: the battery state-of-charge (SOC) and the error between wind power and load demand (DeltaP). Then our controller will decide the duty cycle of the boost converter (D), the moment to switch on and off the battery (S_1) and the moment to discharge the surplus into dumb resistance (S_2) (Fig. 1).

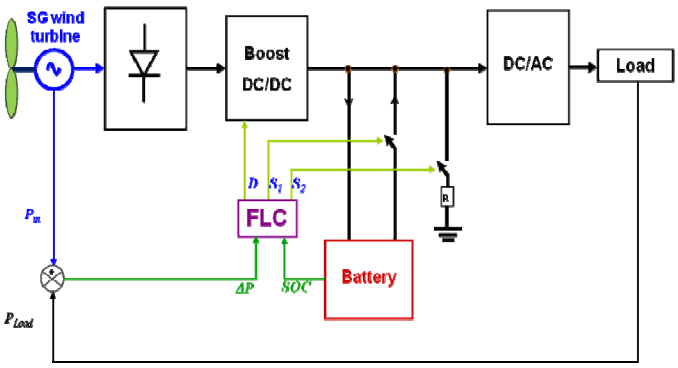

Figure 1. Proposed system with fuzzy controller.

III. Model Of Wind Turbine

The static characteristic of wind turbine can be described by the relation between total power in the wind and mechanical power of wind turbine as in (1). It presents a basic model for wind turbine in electric power system.

$$P_w = \frac{1}{2}\rho\pi R_{turbine}^2 v_{wind}^3 . \quad (1)$$

In wind power equation (1), ρ is air density (1.225 kg/m^3), $R_{turbine}$ is the turbine radius in meters, v_{wind} is the wind speed in m/s. It is not possible to extract all kinetic energy of wind, thus it is extracted a fraction of power in wind as given in (2) and it is called power coefficient C_p of the wind turbine.

$$P_m = \frac{1}{2}C_p\rho\pi R_{turbine}^2 v_{wind}^3 . \quad (2)$$

P_m is the mechanical power of wind turbine. The maximum power coefficient is given as C_p=*0.59*. This coefficient is also known as Betz's limit. It can be expressed as a function of tip speed ratio-λ and pitch angle-θ.

The tip speed ratio λ is defined as (3):

$$\lambda = \frac{\omega_{turbine} R_{turbine}}{v_{wind}} . \quad (3)$$

Assuming constant wind speed v_{wind}, the tips speed ratio λ will vary proportionally to the rotational speed of wind turbine rotor [14]. The highest value of C_p is typically obtained for λ values in the range of 8 to 9 (when the tip of the blades moves 8 to 9 times faster than incoming wind). On modern wind turbines, it is possible to adjust the pitch angle of the entire blade through servo mechanism [15]. If C_p - λ curve is known for specific wind turbine with a turbine rotor radius $R_{turbine}$, it is easy to construct the curve of C_p against rotational speed for any wind speed.

In this paper, we use a simple wind turbine model, where inputs are wind speed and rotor speed, output is the mechanical power.

IV. Power Electronic Device

A. Diode rectifier

Output voltage of the three phase diode bridge rectifier [16]:

$$V_{rec} = V_{RMS}\sqrt{2}\frac{\sin(\pi/6)}{\pi/6} = 1.35V_{RMS} . \quad (4)$$

where V_{RMS} is root-mean-square value of input line voltage.

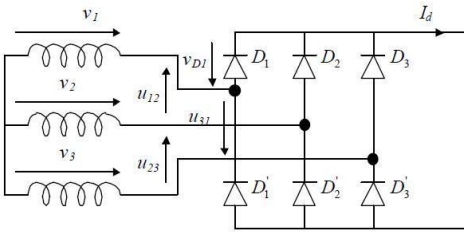

Figure 2. Three phase bridge rectifier.

B. DC-DC boost converter

Output voltage of the boost converter [17]:

$$V_{DC} = V_{rec}\cdot\frac{1}{1-D} . \quad (5)$$

where the switching frequency f_s of switch S equal to the inverse of the switching period T_s generally lies in the range of 1 kHz to 1 MHz, depending on the switching speed of the semiconductor devices. The duty ratio D is the fraction of time that the switch spends in position 1, and is a number between zero and one. Our fuzzy controller will decide the duty cycle D for this boost converter to have an output voltage suitable for the PWM inverter's functioning and battery charging process.

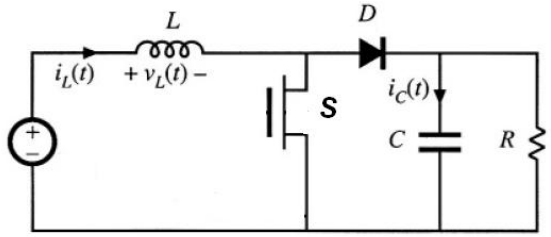

Figure 3. Boost converter.

Value of inductor L is chosen to minimize the ripple in current Δi:

$$L = \frac{V_{rec}}{2\Delta i} DT_s \cdot \tag{6}$$

Select the capacitor value C to obtain a given output voltage ripple peak magnitude Δv:

$$C = \frac{V_{DC}}{2R\Delta v} DT_s \cdot \tag{7}$$

Here we choose L=4mH, C=5000μF to have an acceptable ripple in voltage and current.

C. *Voltage source PWM inverter*

The modulation ratio is defined using reference and triangular voltage amplitudes [11]:

$$m = \frac{u_{ref}}{u_{tri}} \cdot \tag{8}$$

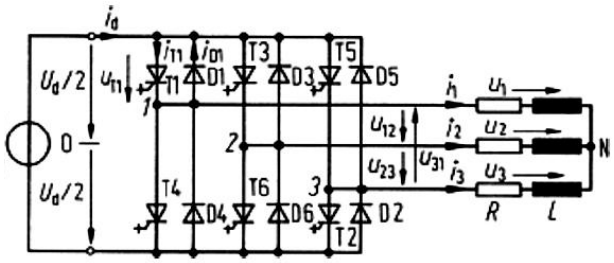

Figure 4. Voltage source PWM inverter.

In the region $m \bullet 1$ the fundamental output line-to-line voltage is a linear function of m:

$$U_{ab} = \frac{\sqrt{3}}{2\sqrt{2}} m.U_{DC} \cdot \tag{9}$$

Here we use the low-pass filter:

$$f_c = \frac{1}{2\pi\sqrt{LC}} \cdot \tag{10}$$

Choose L=8mH, C=100μF to pass the 1st and 3rd harmonic of the output voltage (f_c=177 Hz), assure the smooth sinusoidal output voltage for the load.

V. FUZZY CONTROLLER

Fuzzy controllers belong to the class of knowledge based systems. Their main goal is to implement human know-how or heuristic rules in the form of a computer program, so to provide a mathematical formalism for this goal. Fuzzy controllers make human experience in the form of linguistic if-then rules; a fuzzy inference engine computes the control actions for each given situation [12,18].

A. *Fuzzification*

The FLC controller input variables are the battery state-of-charge (SOC) and the power error DeltaP (difference between wind turbine power and load demand). The output is the duty cycle D applied to the boost converter in order to charge the battery (ensuring a safe and efficiency functioning) and to guarantee the voltage's input sufficient for the voltage-source PWM inverter.

The linguistic term sets used for:

- Error of power DeltaP [N(Negative); SP(Small Positive); P(Positive); VP(Very Positive)].
- Battery state-of-charge SOC [Empty, Average, Full], varying from 0% to 100%, SOC is smaller than 20% means the battery is empty.
- Duty cycle D [Small, Average, Big, VeryBig], varying from 22% to 34% because of the input voltage's limit of the PWM inverter and the charging voltage for the battery.
- Switch S_1 and S_2 [Open, Close].

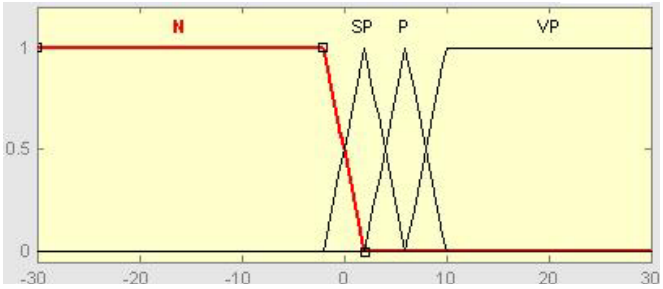

Figure 5. Five terms of error power DeltaP.

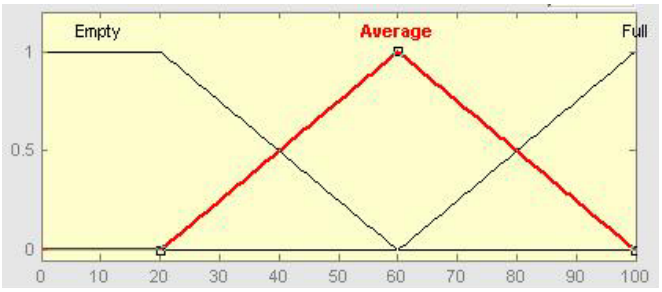

Figure 6. Three terms of battery state-of-charge SOC.

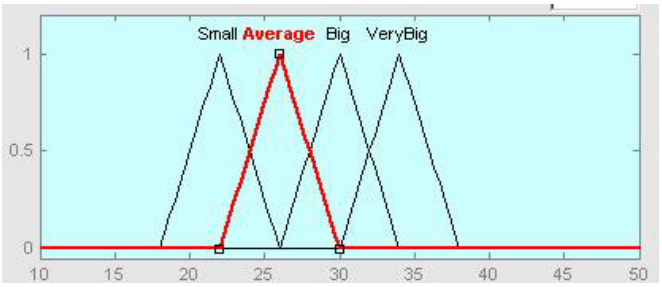

Figure 7. Five terms of duty cycle D.

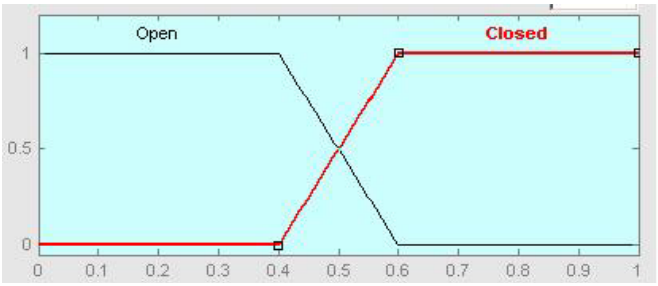

Figure 8. Two terms of state of switch S_1 and S_2.

As inference method for the rules describing FLC dynamic is used the method of inference min-max. This type of method implies a simple treatment of data and generates linear characteristics (for two or several sizes of inputs) with marked discontinuities.

$$\mu_{A\cap B}(x) = \min(\mu_A(x), \mu_B(x)) . \quad (11)$$

$$\mu_{A\cup B}(x) = \max(\mu_A(x), \mu_B(x)) . \quad (12)$$

B. *Fuzzy rules*

The design of the rules was based on Mamdani fuzzy rules [19]. Example, "If the error between wind power and load demand is VeryPositive and the battery state of charge is Full, then the duty cycle should be VeryBig, switch 1 should be Opened and switch 2 should be Closed ".

The inference mechanism and the twelve IF-THEN rules defined in relation with the considerations, generates the approximation of the FLC output represented in tables 1, 2, 3.

TABLE I. RULES OF D

D		***SOC***		
		Full	***Average***	***Empty***

C. *Defuzzification*

The overall fuzzy subset representing output control variable is defuzzified using centre of gravity method:

$$\mu_C = \frac{\sum_i \mu_C(x_i).x_i}{\sum_i \mu_C(x_i)} . \quad (12)$$

Where x_i is a point in the universe U of the conclusion (i = 1, 2…), and $\mu_c(x_i)$ its membership of the resulting conclusion set.

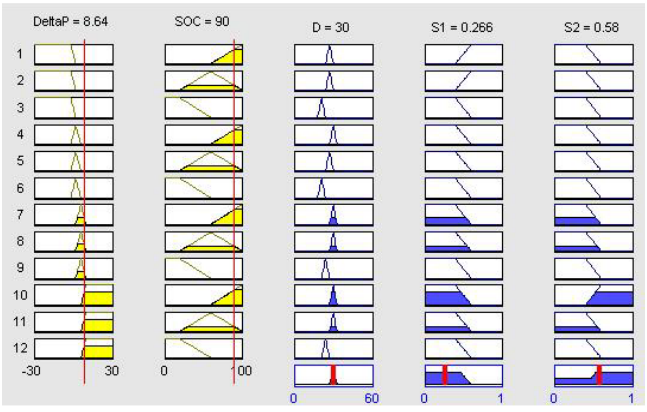

Figure 9. Defuzzification when DeltaP=8.64kW and SOC=90%.

VI. SIMULATION AND RESULTS

A. Initial condition

The system described in Section 2 is implemented in Matlab Simulink and the designed fuzzy logic controller is defined using the Fuzzy Logic Toolbox (Fig. 10).

The simulation is tested in 100 seconds, because of computer memory's limit. The water heater is supposed to work all the time, the pump and the induction motor will be switched on and off to vary load demand. Battery state-of-charge is supposed to be 95% (Full). In this case, we can verify the dissipation of surplus power to prevent the battery from gassing (operation of switch S_2). If wind power is not enough, switch S_1 will close to discharge the battery.

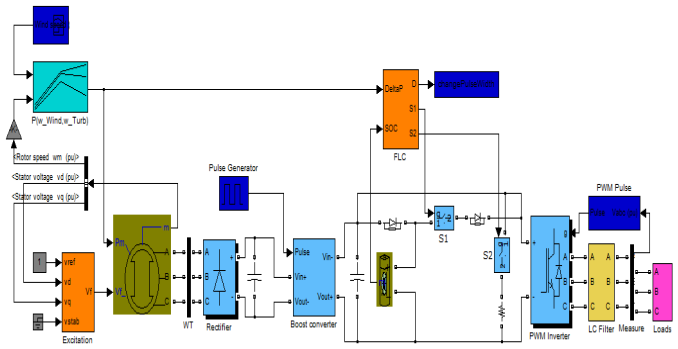

Figure 10. Implementation in Simulink.

The wind turbine output power according to wind speed and rotor speed is defined in (Fig. 11).

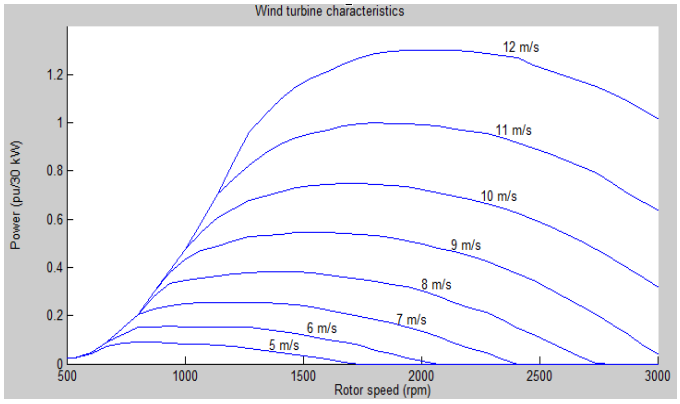

Figure 11. Wind turbine characteristics.

Supposed that at first the water heater and the pump are working (total load demand 15.5 kW). After 40 seconds, the pump is stopped (total 10 kW) and 40 seconds later, the induction motor is plugged in (total 17.5 kW). Wind speed changes from 9 m/s to 10 m/s and then slow down to 8 m/s (Fig. 12).

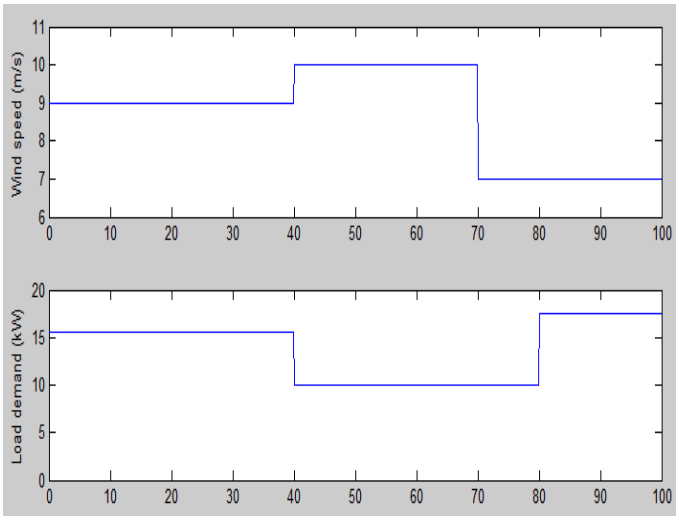

Figure 12. Wind speed and load demand

B. Results

In the first 40 seconds, the water heater and the pump are working (total 15.5 kW) while wind speed is 9 m/s, gives power output of wind turbine 16.6 kW (Fig. 13). The positive surplus (about 0.5kW) makes S_1 opened, but it's too small to charge the battery or to discharge through the dumb resistance, so S_2 is opened too. Duty cycle D is 29% (Fig. 14) makes a $715V_{DC}$ at boost converter's output, it is smaller than V_{bat} (738V) so the battery is not charged.

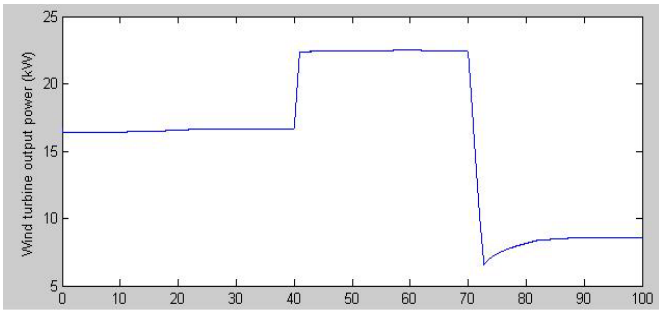

Figure 13. Wind turbine output power.

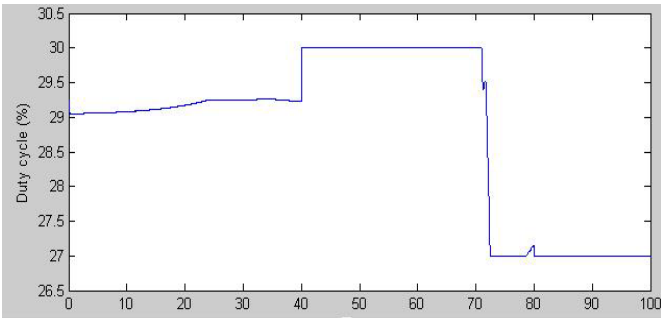

Figure 14. Duty cycle of the boost converter.

In the next 30 seconds, wind speed increases to 10 m/s while the pump is disconnected. The wind turbine output power is 22 kW while load demand is 10 kW.

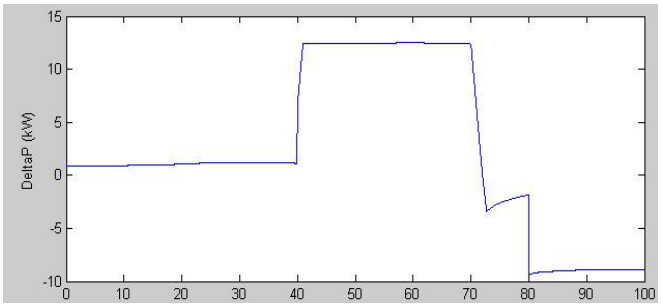

Figure 15. Error of power DeltaP.

So from now DeltaP is 12 kW (VeryPositive) (Fig. 15) while SOC is still 95% (Full), this surplus is so high for battery charging process, which may cause gassing the battery, so S_2 is closed to waste the rest into a dumb resistance (Fig. 16). Duty cycle D increases to 30%, but the battery is not charged because the voltage applied to battery's end is still smaller than 738V.

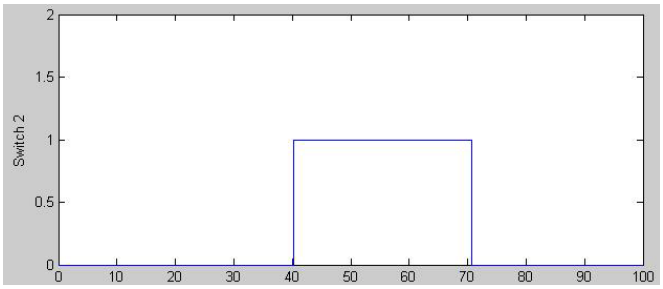

Figure 16. State of switch 2.

After 30 seconds, wind speed decreases to 8 m/s while load is still 10 kW. The wind turbine available power now is just 8 kW, we don't need to discharge no more then S_2 opened. The battery is used (S_1 closed) to provide power to load (Fig. 17), which leads to decrease SOC (Fig. 18). The duty cycle also decreases to 27% to keep the charging voltage below the battery voltage.

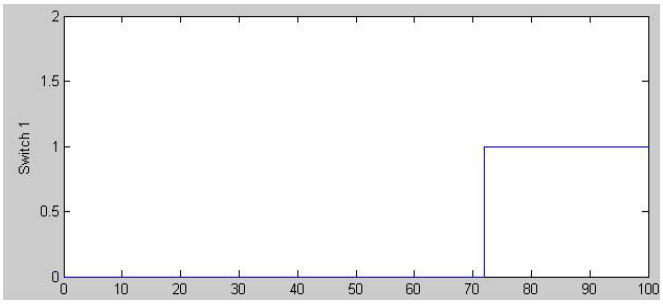

Figure 17. State of switch 1.

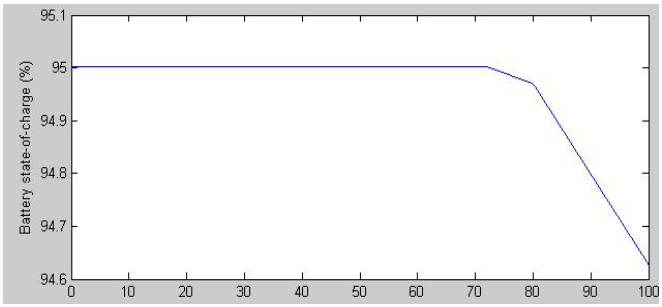

Figure 18. Battery state-of-charge.

In the last 20 seconds, the induction motor is on (load demand increases from 10 kW to 17.5 kW) while wind turbine output power now is still 8 kW, so the battery gives more power to meet load demand (Fig. 19).

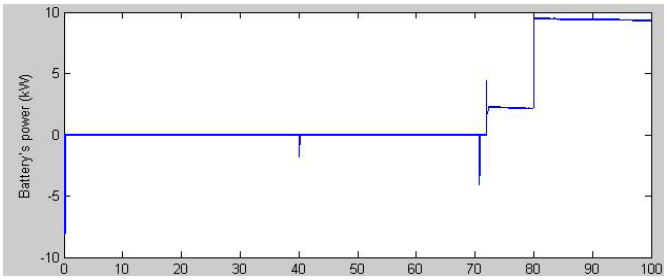

Figure 19. Battery power.

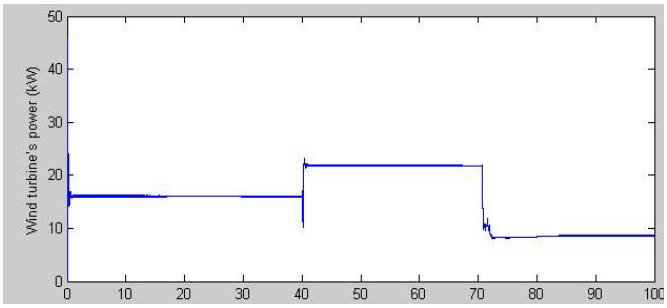

Figure 20. Wind turbine power.

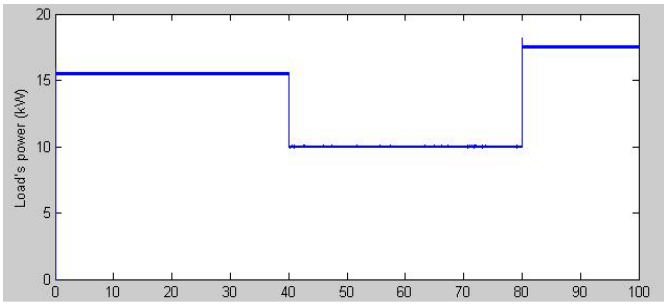

Figure 21. Load power.

Wind turbine available power is provided all before using the battery as supplement (Fig.20). Load demand is always respected despite wind speed conditions (Fig. 21).

In the load side, the DC voltage input for PWM inverter is kept in suitable value, so the load voltage quality is kept in good condition (Fig. 22). A 380V, 50 Hz voltage is always provided to load in any wind condition (Fig. 23, 24).

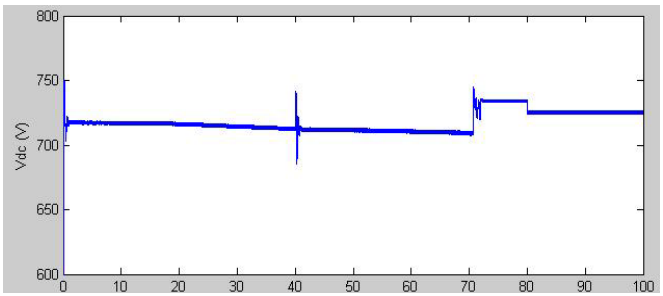

Figure 22. Output voltage of the boost converter.

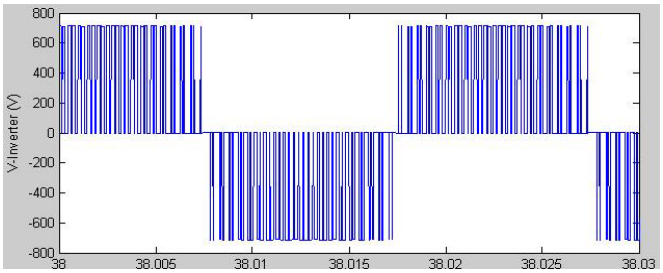

Figure 23. Output voltage of the PWM inverter.

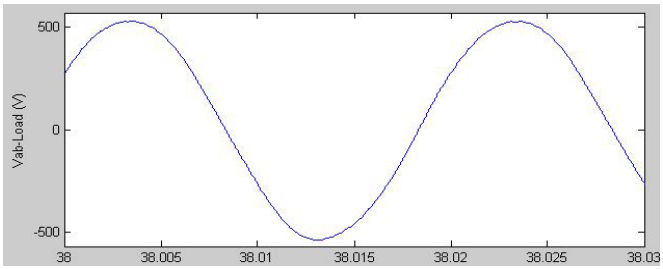

Figure 24. Load voltage.

These results show that our controller worked well. It assured the load demand despite wind condition with a good power quality and regulated battery charging process to prevent the battery from gassing and sulfating.

VII. CONCLUSIONS

This paper presents a fuzzy power management for electricity distribution for stand-alone system. With information about load and battery state-of-charge, control signals were generated to manage well the power production for any wind conditions in respecting load demand. The simulation results show a good behaviour of our controller.

Moreover, this performance has encouraged us to, in the future, develop our system by connecting with another source (photovoltaic, hydro...) and optimize the energy extraction for isolated systems. Then we'll verify it by experimental work.

***Abstract*—This paper focuses on the problem of robust control for Takagi-Sugeno (T-S) fuzzy systems with time-delay. The less conservative conditions are developed by considering a parameter dependent Lyapunov-Krasovskii functional and slack matrix variables. The design conditions are formulated as an LMI (linear matrix inequality) feasibility problem, that can be efficiently solved using convex optimization numerical techniques. Numerical examples are presented to illustrate the effectiveness of the proposed approach with the comparisons to other conditions from the literature.**

I. Introduction

In the last two decades, the stability analysis and control design of nonlinear systems described by Takagi-Sugeno (T-S) fuzzy model with time delay have been extensively studied (see [2], [4], [5], [7], [8], [12], [13], [14], [16], [18]) and references therein. Two main reasons are contributed to this fact : 1) Ability of T-S fuzzy models [17] to approximate large class of nonlinear systems; 2) The existence of delays in many industrial processes such as transportation systems, communication systems, chemical processing systems, environmental systems and power systems ... and its consequences on the stability and the performance degradation propagation/transportation of material, information, or energy [15].

Stability analysis and control design for T-S systems have been widely and systematically handled in the literature via Linear Matrix Inequalities (LMIs) approach (see [3], [9]). In this framework, several strategies have been used to overcome mathematical and numerical difficulties, promoting less-conservative conditions. The standard quadratic Lyapunov approach is the most popular one with the use of slack matrix variables into the LMI formulation [9], [10]. As an interesting alternative type of Lyapunov function, the fuzzy weighting-dependent Lyapunov function (FWLF) has been addressed for continuous-time fuzzy systems in [11].

In the context of stabilization problem of delayed systems, a very effective strategy consists on the use of the multiple Lyapunov-Krasovskii functional approach based on bounding techniques. It is well known that some weighted cross products may arise in the analysis of the delay-dependent stabilization problem. Thus, getting better bounds of them will play a key role in reduction conservatism.

Therefore, in this paper, new less-conservative conditions for stabilization of TS fuzzy systems subject to uncertainties and time delay are proposed.

This paper is organized as follows: system and some preliminaries are presented in Section 2. Section 3 contains the main result where a new delay dependent stabilization conditions are established. In Section 4, two numerical examples are given to demonstrate the effectiveness and the benefits of the proposed method. Some conclusions are drawn in Section 5.

Notations: $W+W^T$ is denoted as $Sym(W)$ for simplicity.

II. System description and preliminaries

Consider a nonlinear system with state-delay which could be represented by a (TS) fuzzy time-delay model described by Plant Rule i

IF $\theta_1(t)$ is N_{i1} and... $\theta_p(t)$ is N_{ip} THEN

$$\begin{aligned}\dot{x}(t) &= (A_i + \Delta A_i)x(t) + (A_{1i} + \Delta A_{1i})x(t-\sigma(t)) \\ &\quad + (B_i + \Delta B_i)u(t), \quad i = 1, \cdots, r\end{aligned} \tag{1}$$

Where $\theta_j(t)$ and $N_{ij}(i = 1, ..., r, j = 1, ..., p)$ are, respectively, the premise variables and the fuzzy sets ; $x(t) \in R^n$ is the state ; $u(t) \in R^m$ is the control input ; r is the number of IF-THEN rules; the time-delay, $\sigma(t)$, is a time -varying continuous function that satisfies

$$0 \leq \sigma(t) \leq \bar{\sigma}, \qquad \dot{\sigma}(t) \leq \beta \tag{2}$$

The parametric uncertainties ΔA_i, ΔA_{1i}, ΔB_i are time-varying matrices that are defined as follows: $\Delta A_i = D_A F_i(t) E_{Ai}$, $\Delta A_{1i} = D_{A1} F_i(t) E_{A1i}$, $\Delta B_i = D_B F_i(t) E_{Bi}$. Let $\bar{A}_i = A_i + \Delta A_i$; $\bar{A}_{1i} = A_{1i} + \Delta A_{1i}$; $\bar{B}_i = B_i + \Delta B_i$. Where A_i, A_{1i}, B_i, D_A, D_{A1}, D_B, E_{Ai}, E_{A1i}, E_{Bi} are constant known matrices and $F_i(t)$ is unknown and possibly time-varying matrix satisfying $F_i^T(t)F_i(t) \leqslant I$ for any given t. It is assumed the element of $F_i(t)$ are Lebesgue measurable. By using the commonly used center-average defuzzifier, product inference and singleton fuzzifier, the T-S fuzzy systems

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

can be inferred as

$$\dot{x}(t) = \sum_{i=1}^{r} h_i(\theta(t))\Big\{ \bar{A}_i x(t) + \bar{A}_{1i} x(t-\sigma(t)) + \bar{B}_i u(t) \Big\} \tag{3}$$

where $\theta(t) = [\theta_1(t), \cdots, \theta_p(t)]$ and $\upsilon_i(\theta(t)) = \prod_{j=1}^{p} N_{ij}(\theta_j(t))$ are the membership functions of the system with respect to ith plan rule. Denote

$$h_i(\theta(t)) = \upsilon_i(\theta(t)) / \sum_{i=1}^{r} \upsilon_i(\theta(t)). \tag{4}$$

$h_i(\theta(t))$ is the averaging weight for each rule, representing the normalized grade of membership, and satisfies

$$h_i(\theta(t)) \geq 0, \quad \text{and} \quad \sum_{i=1}^{r} h_i(\theta(t)) = 1, (i = 1, 2, ..., r) \tag{5}$$

In order to obtain the main results in this paper, the following lemma is needed:

Lemma *2.1:* [5] Given matrices $D, E, F(t)$ with compatible dimensions and F(t) satisfying $F(t)^T F(t) \leq I$. Then, the following inequality holds for any $\epsilon > 0$:
$DF(t)E + E^T F(t)^T D^T \leq \epsilon DD^T + \epsilon^{-1} E^T E$

III. Main Results

A. Time delay dependent stabilization conditions

We consider the problem of delay-dependent stabilization of system (3). Based on the Parallel Distributed Compensation (PDC), the following fuzzy control law is employed to deal with the problem of stabilization via state feedback.
Controller Rule i:
IF $\theta_1(t)$ is N_{i1} and... $\theta_p(t)$ is N_{ip} THEN

$$u(t) = K_i x(t), i = 1, 2, \cdots, r. \tag{6}$$

Hence, the overall fuzzy control law is represented by

$$u(t) = \sum_{i=1}^{r} h_i(\theta(t)) K_i x(t), \tag{7}$$

where $K_i (i = 1, 2, \cdots, r)$ are the local control gain matrices. In the sequel, for brevity we use h_i to denote $h_i(\theta(t))$.
Consider system (3) associated with the control law (7), then the resulting closed-loop system can be expressed as follows:

$$\dot{x}(t) = \sum_{i=1}^{r} \sum_{j=1}^{r} h_i h_j \Big\{ \hat{A}_{ij} x(t) + \bar{A}_{1i} x(t-\sigma(t)) \Big\} \tag{8}$$

Where $\hat{A}_{ij} = \bar{A}_i + \bar{B}_i K_j$.

Theorem *3.1:* Case of nominal System:
System (8) is asymptotically stable, if there exist some matrices $\bar{P}_i > 0$, $\bar{H} > 0$, $\bar{S} > 0$ and $\bar{T} > 0$, any matrices Θ_i, Y_i, U, $\bar{P}_{\Phi,i}$, $\bar{L}$, $\bar{W}$,μ_1, μ_2 and μ_3 are positive scalars satisfying the following set of LMIs:

$$P_l + \Theta_i > 0 \tag{9}$$

$$\Lambda_{ii} < 0, \quad (i = 1, \cdots, r) \tag{10}$$

$$\Lambda_{ij} + \Lambda_{ji} < 0, \quad i < j \tag{11}$$

where

$$\Lambda_{ij} = \begin{bmatrix} \Gamma_{1ij} & * & * & * & * & * \\ \Gamma_{2ij} & \Gamma_{3i} & * & * & * & * \\ \Gamma_{4ij} & \Gamma_{5i} & \Gamma_6 & * & * & * \\ -\bar{W}_1 & -\bar{W}_2^T & 0 & -\bar{T} & * & * \\ \bar{L}_1^T & \bar{L}_2^T & 0 & 0 & -\bar{\sigma}^{-1}\bar{H} & * \\ \bar{W}_1^T & \bar{W}_2^T & 0 & 0 & 0 & -\bar{\sigma}^{-1}\bar{H} \end{bmatrix} \tag{12}$$

$$P_{\Phi,i} = \sum_{l=1}^{r} \Phi_l (P_l + \Theta_i) \tag{13}$$

where

$$\begin{aligned} \Gamma_{1ij} &= Sym(A_i U + B_i Y_j + \bar{L}_1) + \bar{P}_{\Phi,i} + \bar{S} + \bar{T} \\ \Gamma_{2ij} &= \mu_1 (A_i U + B_i Y_j) + U^T A_{1i}^T + \bar{L}_2 - \bar{L}_1^T + \bar{W}_1^T \\ \Gamma_{3i} &= \mu_1 Sym(A_{1i} U - \bar{L}_2 + \bar{W}_2) - (1-\beta)\bar{S} \\ \Gamma_{4ij} &= \mu_2 (A_i U + B_i Y_j) - U^T + \bar{P}_i^T \\ \Gamma_{5i} &= \mu_2 (A_{1i} U) - \mu_1 U^T \\ \Gamma_6 &= -\mu_2 Sym(U) + \bar{\sigma}\bar{H} \end{aligned}$$

Proof: For simplicity, we set $x_\sigma = x(t-\sigma(t))$, $x_{\bar{\sigma}} = x(t-\bar{\sigma})$, $L = \begin{bmatrix} L_1 \\ L_2 \\ 0 \\ 0 \end{bmatrix}$, $W = \begin{bmatrix} W_1 \\ W_2 \\ 0 \\ 0 \end{bmatrix}$, $M = \begin{bmatrix} M_1 \\ M_2 \\ M_3 \\ 0 \end{bmatrix}$ and $\Psi(t) = \begin{bmatrix} x(t) \\ x_\sigma \\ \dot{x}(t) \\ x_{\bar{\sigma}} \end{bmatrix}$
In this part we consider that ΔA_i , ΔB_i and $\Delta A_{1i} = 0$.
Let us choose a candidate Lyapunov-Krasovskii function as follows:

$$\begin{aligned} V &= V_1(t) + V_2(t) + V_3(t) \\ V_1(t) &= x^T(t) P(t) x(t) \\ V_2(t) &= \int_{t-\sigma(t)}^{t} x^T(s) S x(s)\, \mathrm{d}s + \int_{t-\bar{\sigma}}^{t} x^T(s) T x(s)\, \mathrm{d}s \\ V_3(t) &= \int_{-\bar{\sigma}}^{0} \int_{t+\alpha}^{t} \dot{x}^T(s) H \dot{x}(s)\, \mathrm{d}s \mathrm{d}\alpha \end{aligned} \tag{14}$$

where $P(t)$ is a fuzzy weighting-dependent Lyapunov function

$$P(t) = \sum_{i=1}^{r} h_i P_i \qquad (i = 1, 2, \cdots, r) \tag{15}$$

Taking the derivative of V_i, $1, \cdots, 3$ along the trajectory of system (8) yields

$$\dot{V}_1(x(t)) = 2\dot{x}^T(t) P(t) x(t) + x^T(t) \dot{P}(t) x(t)$$

The derivative of (15) provides information about time derivative of membership functions.Then, we assume that

$$|\dot{h_l}(\theta(t))| \leq \Phi_l \tag{16}$$

where $\Phi_l \geq 0$ $(l = 1, 2, \cdots, r)$
Considering the properties in (5) we have

$$\begin{aligned}\dot{P}(t) &= \sum_{l=1}^{r} \dot{h}_l(t) P_l = \sum_{i=1}^{r} (h_i(t)) \sum_{l=1}^{r} \dot{h}_l(t) P_l \\ &= \sum_{i=1}^{r}\sum_{l=1}^{r} h_i(t)\dot{h}_l(t) P_l \end{aligned} \tag{17}$$

Once again considering (5) the following equation holds:

$$\sum_{i=1}^{r}\sum_{l=1}^{r} h_i \dot{h}_l x^T(t)\Theta_i x(t) = 0 \tag{18}$$

where $\Theta_i > 0$ are slack matrices with appropriate dimensions. Assuming that the assumption (9) and (16) hold, it is easy to have

$$\dot{P}(t) \leq \sum_{i=1}^{r}\sum_{l=1}^{r} h_i(t)\Phi_l(P_l + \Theta_i) \tag{19}$$

On the other hand, from the defintion of (8) the following equation holds

$$\begin{aligned} 2\Big[x^T(t)M_1 + x_\sigma^T M_2 + \dot{x}(t)^T M_3\Big]\Big[-\dot{x}(t) \\ + \sum_{i=1}^{r}\sum_{j=1}^{r} h_i h_j(\hat{A}_{ij}x(t) + \bar{A}_{1i}x_\sigma)\Big] = 0 \end{aligned} \tag{20}$$

Adding the null terms (20) and (18), we obtain

$$\begin{aligned}\dot{V}_1(x(t)) \leq \sum_{i=1}^{r} h_i \Big\{ & 2x^T(t)P_i\dot{x}(t) \\ & + \sum_{l=1}^{r} \Phi_l x^T(t)(P_l + \Theta_i)x(t)\Big\} \end{aligned} \tag{21}$$

$$\begin{aligned} & + 2\Big[x^T(t)M_1 + x_\sigma^T(t)M_2 + \dot{x}(t)^T M_3\Big] \\ & \times \Big[-\dot{x}(t) + \sum_{i=1}^{r}\sum_{j=1}^{r} h_i h_j \hat{A}_{ij}x(t) + \bar{A}_{1i}x_\sigma\Big] \end{aligned} \tag{22}$$

$$\begin{aligned} & \leq \sum_{i=1}^{r} h_i\Big\{2x^T(t)P_i\dot{x}(t) + x^T(t)P_{\Phi,i}x(t)\Big\} \\ & + 2\sum_{i=1}^{r}\sum_{j=1}^{r} h_i h_j \Psi^T(t) M \begin{bmatrix}\hat{A}_{ij} & \bar{A}1i & -I & 0\end{bmatrix}\Psi(t) \end{aligned}$$

$$\begin{aligned}\dot{V}_2(x(t)) &= x^T(t)Sx(t) - (1-\dot{\sigma}(t))x_\sigma^T S x_\sigma \\ &\quad + x^T(t)Tx(t) - x_{\bar{\sigma}}^T T x_{\bar{\sigma}} \end{aligned} \tag{23}$$

$$\begin{aligned}\dot{V}_3(x(t)) &= \bar{\sigma}\dot{x}^T(t)H\dot{x}(t) \\ &\quad - \int_{-\bar{\sigma}}^{0} \dot{x}^T(t+\alpha)H\dot{x}(t+\alpha)\,\mathrm{d}\alpha \end{aligned} \tag{24}$$

$$\begin{aligned} & - \int_{-\bar{\sigma}}^{0} \dot{x}^T(t+\alpha)H\dot{x}(t+\alpha)\,\mathrm{d}\alpha = -\int_{t-\bar{\sigma}}^{t} \dot{x}^T(\alpha)H\dot{x}(\alpha)\,\mathrm{d}\alpha \\ & = -\int_{t-\bar{\sigma}}^{t-\sigma(t)} \dot{x}^T(\alpha)H\dot{x}(\alpha)\,\mathrm{d}\alpha - \int_{t-\sigma(t)}^{t} \dot{x}^T(\alpha)H\dot{x}(\alpha)\,\mathrm{d}\alpha \\ & \leq \bar{\sigma}\Psi^T(t)LH^{-1}L^T\Psi(t) + 2\Psi^T(t)L\int_{t-\sigma(t)}^{t}\dot{x}(\alpha)\,\mathrm{d}\alpha \\ & + \bar{\sigma}\Psi^T(t)WH^{-1}W^T\Psi(t) + 2\Psi^T(t)W\int_{t-\bar{\sigma}}^{t-\sigma(t)}\dot{x}(\alpha)\,\mathrm{d}\alpha \end{aligned}$$

The desired results are obtained by using the upper bound of the following terms (25) and (26) :

$$\begin{aligned} -2\Psi^T(t)L\int_{t-\sigma(t)}^{t}\dot{x}(\alpha)\,\mathrm{d}\alpha &\leq \sigma(t)\Psi^T(t)LH^{-1}L^T\Psi(t) \\ &\quad + \int_{t-\sigma(t)}^{t}\dot{x}^T(\alpha)H\dot{x}(\alpha)\,\mathrm{d}\alpha \\ &\leq \bar{\sigma}\Psi^T(t)LH^{-1}L^T\Psi(t) + \int_{t-\sigma(t)}^{t}\dot{x}^T(\alpha)H\dot{x}(\alpha)\,\mathrm{d}\alpha \end{aligned} \tag{25}$$

$$\begin{aligned} -2\Psi^T(t)W\int_{t-\bar{\sigma}}^{t-\sigma(t)}\dot{x}(\alpha)\,\mathrm{d}\alpha &\leq (\bar{\sigma}-\sigma(t))\Psi^T(t)WH^{-1}W^T\Psi(t) \\ &\quad + \int_{t-\bar{\sigma}}^{t-\sigma(t)}\dot{x}^T(\alpha)H\dot{x}(\alpha)\,\mathrm{d}\alpha \\ &\leq \bar{\sigma}\Psi^T(t)WH^{-1}W^T\Psi(t) + \int_{t-\bar{\sigma}}^{t-\sigma(t)}\dot{x}^T(\alpha)H\dot{x}(\alpha)\,\mathrm{d}\alpha \end{aligned} \tag{26}$$

where the well-known inequality $-2x^Ty \leq x^TH^{-1}x + y^THy$ with $H > 0$ is used to get the last inequalities. Then, we obtain

$$\begin{aligned}\dot{V}_3(x(t)) \leq\ & \bar{\sigma}\dot{x}^T(t)H\dot{x}(t) + \bar{\sigma}\Psi^T(t)LH^{-1}L^T\Psi(t) \\ & + \bar{\sigma}\Psi^T(t)WH^{-1}W^T\Psi(t) \\ & + 2\Psi^T(t)L\begin{bmatrix}I & -I & 0 & 0\end{bmatrix}\Psi(t) \\ & + 2\Psi^T(t)W\begin{bmatrix}0 & I & 0 & -I\end{bmatrix}\Psi(t) \end{aligned} \tag{27}$$

By letting, $M_1 = G^T$, $M_2 = \mu_1 G^T$ and $M_3 = \mu_2 G^T$, with μ_1, μ_2, μ_3 being positive scalars, the derivative of (14) along the trajectory of the closed-loop system (8) can be written as

$$\begin{aligned}\dot{V}(x(t)) &\leq \sum_{i=1}^{r}\sum_{j=1}^{r} h_i h_j \Psi^T(t)\bar{\Phi}_{ij}\Psi(t) \\ &= \sum_{i=1}^{r} h_i^2 \Psi(t)^T\bar{\Phi}_{ii}\Psi(t) \\ &\quad + 2\sum_{i=1}^{r}\sum_{j>i}^{r} h_i h_j \Psi(t)^T(\bar{\Phi}_{ij} + \bar{\Phi}_{ji})\Psi(t) \end{aligned} \tag{28}$$

where $\bar{\Phi}_{ij} = \bar{\lambda}_{ij} + \bar{\sigma}LH^{-1}L^T + \bar{\sigma}WH^{-1}W^T$

$$\bar{\lambda}_{ij} = \begin{bmatrix}\Omega_{1ij} & * & * & * \\ \Omega_{2ij} & \Omega_{3i} & * & * \\ \Omega_{4ij} & \Omega_{5i} & \Omega_6 & * \\ -W_1^T & -W_2^T & 0 & -T\end{bmatrix} \tag{29}$$

with
$\Omega_{1ij} = Sym(G^T\hat{A}_{ij} + L_1) + P_{\Phi,i} + S + T$,
$\Omega_{2ij} = \mu_1(G^T\hat{A}_{ij}) + \bar{A}_{1i}^T G + L_2 - L_1^T + W_1^T$,
$\Omega_{3i} = \mu_1 Sym(G^T\bar{A}_{1i} - L_2 + W_2) - (1-\beta)S$,
$\Omega_{4ij} = \mu_2(G^T\hat{A}_{ij}) - G + P_i^T$,
$\Omega_{5i} = \mu_2 G^T\bar{A}_{1i} - \mu_1 G$
$\Omega_6 = -\mu_2 Sym(G) + \bar{\sigma}H$

From (11) we have $\Gamma_6 < 0$, this imply $0 < \bar{\sigma}H < \mu_2 Sym(U)$, this indicate that U is non singular when $\mu_2 > 0$. Define $G = U^{-1}$ and $\Upsilon = diag(G, G, G, G)$. Let $\bar{L_1} = U^T L_1 U$, $\bar{S} = U^T S U$, $\bar{T} = U^T T U$, $\bar{P}_i = U^T P_i U$, $\bar{H} = U^T H U$, $\bar{L_2} = U^T L_2 U$, $\bar{W_1} = U^T W_1 U$, $\bar{W_2} = U^T W_2 U$, and $Y_i = K_i U$.

Pre-and post multiplying (11) by Υ^T and Υ, respectively, and applying the Schur complement, we obtain $\bar{\Phi}_{ij} + \bar{\Phi}_{ji} < 0$.

By following the similar way it is easy to obtain from (10) that $\bar{\Phi}_{ii} < 0$, then we have $\dot{V}(x(t)) < 0$ when $h_i \geq 0$, therefore, the system (8) is asymptotically stable. ■

Remark *3.1:* In some existing literature, for example [6], the term $\int_{t-\bar{\sigma}}^{t} \dot{x}^T(\alpha)H\dot{x}(\alpha)\,\mathrm{d}\alpha$ in the derivative of V(t) was often estimated as $\int_{t-\sigma(t)}^{t} \dot{x}^T(\alpha)H\dot{x}(\alpha)\,\mathrm{d}\alpha$ and the term $\int_{t-\bar{\sigma}}^{t-\sigma(t)} \dot{x}^T(\alpha)H\dot{x}(\alpha)\,\mathrm{d}\alpha$ was ignored .
This may bring conservativeness. In Theorem 3.1, all these terms are reserved, which can reduce conservativeness.

Corollary 3.2:
System (8) is asymptotically stable, if there exist some matrices $\bar{P}_i > 0$, $\bar{H} > 0$ and $\bar{S} > 0$, any matrices Θ_i, Y_i, U, $\bar{P}_{\Phi,i}$, $\bar{L}$, μ_1, μ_2 and μ_3 are positive scalars satisfying the following set of LMIs:

$$P_l + \Theta_i > 0 \tag{30}$$
$$\Lambda'_{ii} < 0 (i = 1, 2, \cdots, r) \tag{31}$$
$$\Lambda'_{ij} + \Lambda'_{ji} < 0, \quad i < j \tag{32}$$

where

$$\Lambda'_{ij} = \begin{bmatrix} \Gamma'_{1ij} & * & * & * \\ \Gamma'_{2ij} & \Gamma'_{3i} & * & * \\ \Gamma'_{4ij} & \mu_2(A_{1i}U) - \mu_1 U^T & \Gamma'_5 & 0 \\ \bar{\sigma}\bar{L}_1^T & \bar{\sigma}\bar{L}_2^T & 0 & -\bar{H} \end{bmatrix}$$

where $\Gamma'_{1ij} = Sym(A_iU + B_iY_j + \bar{L}_1) + \bar{P}_{\Phi,i} + \bar{S}$
$\Gamma'_{2ij} = \mu_1(A_iU + B_iY_j) + U^T A_{1i}^T + \bar{L}_2 - \bar{L}_1^T$
$\Gamma'_{3i} = \mu_1 Sym(A_{1i}U - \bar{L}_2) - (1-\beta)\bar{S}$
$\Gamma'_{4ij} = \mu_2(A_iU + B_iY_j) - U^T + \bar{P}_i^T$
$\Gamma'_5 = -\mu_2 Sym(U) + \bar{\sigma}\bar{H}$.

Theorem *3.2:* : Case of uncertain System:
System (8) is asymptotically stable, if there exist some matrices $\bar{P}_i > 0$, $\bar{H} > 0$, $\bar{S}$ and $\bar{T} > 0$, any matrices Θ_i, Y_i, U, $\bar{P}_{\Phi,i}$, $\bar{L}$, $\bar{W}$, ϵ_i, μ_1, μ_2 and μ_3 are positive scalars satisfying the following set of LMIs:

$$P_l + \Theta_i > 0 \tag{33}$$
$$\Lambda_{ii} < 0 (i = 1, 2, \cdots, r) \tag{34}$$
$$\Lambda_{ij} + \Lambda_{ji} < 0 (i < j = 1, 2, \cdots, r) \tag{35}$$

where

$$\Lambda_{ij} = \begin{bmatrix} \Gamma_{1ij} & * & * \\ \Gamma_{2ij} & \Gamma_{3i} & * \\ \Gamma_{4ij} & \mu_2(A_{1i}U) - \mu_1 U^T & \Gamma_5 \\ -\bar{W}_1^T & \bar{W}_2^T & 0 \\ \bar{L}_1^T & \bar{L}_2^T & 0 \\ \bar{W}_1^T & \bar{W}_2^T & 0 \\ E_{Ai}U & 0 & 0 \\ E_{Bi}Y_j & 0 & 0 \\ 0 & E_{A1i}U & 0 \end{bmatrix}$$
$$\begin{bmatrix} * & * & * & * & * & * \\ * & * & * & * & * & * \\ * & * & * & * & * & * \\ \Gamma_6 & * & * & * & * & * \\ 0 & -\bar{\sigma}^{-1}\bar{H} & 0 & * & * & * \\ 0 & 0 & -\bar{\sigma}^{-1}\bar{H} & * & * & * \\ 0 & 0 & 0 & -\epsilon_i I & * & * \\ 0 & 0 & 0 & 0 & -\epsilon_i I & * \\ 0 & 0 & 0 & 0 & 0 & -\epsilon_i I \end{bmatrix} \tag{36}$$

where $\Gamma_{1ij} = Sym(A_iU + B_iY_j + \bar{L}_1) + \bar{P}_{\Phi,i} + \bar{S} + \bar{T} + \epsilon_i D_A D_A^T + \epsilon_i D_B D_B^T + \epsilon_i D_{A1} D_{A1}^T$
$\Gamma_{2ij} = \mu_1(A_iU + B_iY_j) + U^T A_{1i}^T + \bar{L}_2 - \bar{L}_1^T + \bar{W}_1^T$
$\Gamma_{3i} = \mu_1 Sym(A_{1i}U - \bar{L}_2 + \bar{W}_2) - (1-\beta)\bar{S} + \mu_1^2\epsilon_i D_A D_A^T + \mu_1^2\epsilon_i D_B D_B^T + \mu_1^2\epsilon_i D_{A1} D_{A1}^T$
$\Gamma_{4ij} = \mu_2(A_iU + B_iY_j) - U^T + \bar{P}_i^T$
$\Gamma_5 = -\mu_2 Sym(U) + \bar{\sigma}\bar{H} + \mu_2^2\epsilon_i D_A D_A^T + \mu_2^2\epsilon_i D_B D_B^T + \mu_2^2\epsilon_i D_{A1} D_{A1}^T$
$\Gamma_6 = -\bar{T}$

Proof:

In this part we consider that ΔA_i , ΔBi and $\Delta A1i$ are $\neq 0$. By using Lemma 2.1 and the Schur complement, we obtain Theorem 3.2. Where the uncertain part is represented as : $\Delta\bar{\Phi}_{ij}$=$Sym(\check{D}\check{F}(t)\check{E}) \leq \epsilon_i\check{D}\check{D}^T + \epsilon_i^{-1}\check{E}^T\check{E}$ With

$$\check{D} = \begin{bmatrix} D_A & D_B & D_{A1} & 0 & 0 & 0 \\ \mu_1 D_A & \mu_1 D_B & \mu_1 D_{A1} & 0 & 0 & 0 \\ \mu_2 D_A & \mu_2 D_B & \mu_2 D_{A1} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \tag{37}$$

$$\check{F}(t) = \begin{bmatrix} F(t) & 0 & 0 & 0 & 0 & 0 \\ 0 & F(t) & 0 & 0 & 0 & 0 \\ 0 & 0 & F(t) & 0 & 0 & 0 \\ 0 & 0 & 0 & F(t) & 0 & 0 \\ 0 & 0 & 0 & 0 & F(t) & 0 \\ 0 & 0 & 0 & 0 & 0 & F(t) \end{bmatrix} \tag{38}$$

$$\check{E} = \begin{bmatrix} E_{Ai}U & 0 & 0 & 0 & 0 & 0 \\ E_{Bi}Y_j & 0 & 0 & 0 & 0 & 0 \\ 0 & E_{A1i}U & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \quad (39)$$

■

IV. Numerical Examples

To illustrate the designed controller law for the T-S fuzzy model with time-varying delay, we consider the following examples.

Example 1. For fuzzy rules as $h_1 = 1-((x_2^2)/2.25)$ *and* $h_2 = x_2^2/2.25$, the following fuzzy T-S model is presented:

$$\dot{x}(t) = \sum_{i=1}^{r}\sum_{j=1}^{r} h_i h_j \Big\{ [(A_i + \Delta A_i) + B_i K_j]x(t) + (A_{1i} + \Delta A_{1i})x(t-\sigma(t)) \Big\} \quad (40)$$

where

$$A_1 = \begin{bmatrix} 0 & 0.6 \\ 0 & 1 \end{bmatrix}, A_2 = \begin{bmatrix} 1 & 0 \\ 1 & 0 \end{bmatrix}, A_{11} = \begin{bmatrix} 0.5 & -0.9 \\ 0 & 2 \end{bmatrix},$$
$$A_{12} = \begin{bmatrix} 0.9 & 0 \\ 1 & 1.6 \end{bmatrix}, B_1 = B_2 = \begin{bmatrix} 1 \\ 1 \end{bmatrix},$$

$$\Delta A_i = D_A F_i(t) E_{Ai}, \Delta A_{1i} = D_{A1} F_i(t) E_{A1i}, \quad (41)$$

$$D_A = D_B = D_{A1} = \begin{bmatrix} -0.03 & 0 \\ 0 & 1.6 \end{bmatrix}$$

$$E_{A1} = \begin{bmatrix} -0.15 & 0.2 \\ 0 & 0.04 \end{bmatrix}, \ E_{A2} = \begin{bmatrix} -0.15 & 0.2 \\ 0 & 0.04 \end{bmatrix},$$
$$E_{A11} = \begin{bmatrix} -0.05 & -0.35 \\ 0.08 & -0.45 \end{bmatrix}, \ E_{A12} = \begin{bmatrix} -0.05 & -0.35 \\ 0.08 & -0.45 \end{bmatrix},$$
$$E_{B1} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, E_{B2} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$$

The operating domain of the nonlinear plant are assumed to be $x_1(t) \in [-3, 3]$ and $x_2(t) \in [-1, 1]$. Thus, based on the derivative of the membership function, we assume that Φ_l= $\{3.5,3.5\}$.

It appears from Table 1 that our result improves the existing ones in the case of uncertain T-S fuzzy model with varying time-delay.

In fact, by solving the LMIs in Theorem 3 in [7], in Theorem 1 in [1] , in Corollary 3.2 and Theorem 3.2 , the maximum value of the time delay $\bar{\sigma}$ is found in theorem 3.2. Table 1 summarizes the results. By using theorem 3.2 with the choice of $\beta = 0.15$ and $\sigma(t)$=0.379+0.15 sin(t)($\bar{\sigma} = 0.529, \mu_1 = \mu_2 = 0.1$) we can obtain the following state-feedback gain matrices:

$$K_1 = 10^3.\begin{bmatrix} 0.9352 & -3.4038 \end{bmatrix} \quad (42)$$
$$K_2 = 10^3.\begin{bmatrix} 1.7298 & -6.2924 \end{bmatrix} \quad (43)$$

The simulation was tested under the initial conditions $x(t) = [2 \quad 0]^T, t \in [-0.529 \quad 0]$ and uncertainty function

$$F_i(t) = \begin{bmatrix} sin(t) & 0 \\ 0 & cos(t) \end{bmatrix} \quad (44)$$

From the simulation results in Figure 1, it can be clearly seen that our method allows to stabilize nonlinear systems represented by uncertain T-S fuzzy model with time -varying delay for the maximum value of delay which can be attain 0.529 s. Despite the presence of uncertainties, the system states converge asymptotically to zero.

TABLE I
Comparison among varying delay-dependent stabilization methods with uncertainties

Methods	Maximum allowed τ
theorem 1 of [1]	0.1498 s
theorem 3 of [7]	0.4770 s
Corollary 3.2	0.525 s
theorem 3.2	0.529 s

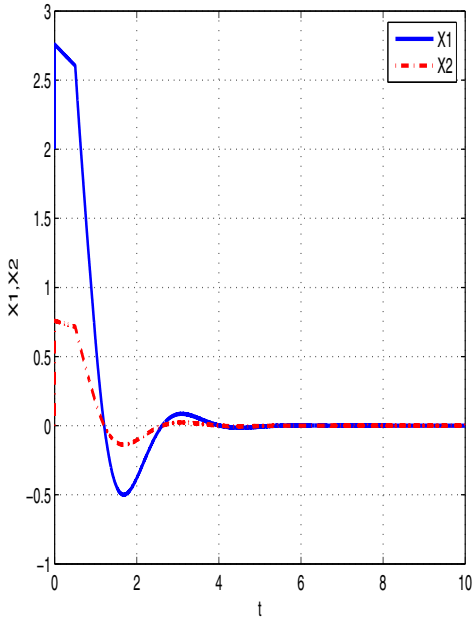

Fig. 1. Control results for system (45) with uncertainties

Example 2. To illustrate the designed controller laws for the T-S fuzzy model with time-varying delay,we consider the following example.

Example . For fuzzy rules as h_1=$1/2(1 + (c - x_1(t)/\gamma))$ and $h_2 = 1/2(1 - (c - /x_1(t)/\gamma)$

Where $\gamma = 6.3$, $a = 0.5$, $b_1 = b_2 = 0.2$, $c = 5.7$, the following fuzzy T-S model is presented:

$$\dot{x}(t) = \sum_{i=1}^{r}\sum_{j=1}^{r} h_i h_j \Big\{ [(A_i + \Delta A_i) + B_i K_j]x(t) + (A_{1i} + \Delta A_{1i})x(t-\sigma(t)) \Big\} \quad (45)$$

where

$$A_1 = \begin{bmatrix} 0 & -1 & -1 \\ 1 & b_1 & 0 \\ 0 & 0 & -\gamma \end{bmatrix}, \qquad A_2 = \begin{bmatrix} 0 & -1 & -1 \\ 1 & b_1 & 0 \\ 0 & 0 & \gamma \end{bmatrix},$$

$$A_{11} = A_{12} = \begin{bmatrix} a & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \qquad B_1 = B_2 = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix},$$

The operating domain of the nonlinear plant are assumed to be $x_1(t) \in [-10, 12]$, $x_2(t) \in [-12, 8]$ and $x_3(t) \in [0, 25]$. Thus, based on the derivative of the membership functions, we choose Φ_l= {2.15,2.15}.

The free weighting approach gives the best result in the case of uncertain T-S fuzzy model with varying time-delay.

In fact, by solving the LMIs in Theorem 3.1 , and in Corollary 3.2 , the maximum value of the time delay $\bar{\sigma}$ is found in theorem 3.1. By using theorem 3.1 with the choice of $\beta = 0.15$ and $\sigma(t)$=2.274+0.15 sin(t)($\bar{\sigma} = 2.424, \mu_1 = \mu_2 = 1$) we can obtain the following state-feedback gain matrices:

$$K_1 = \begin{bmatrix} 14.9314 & 0.8607 & -2.4751 \end{bmatrix} \tag{46}$$

$$K_2 = \begin{bmatrix} 14.9314 & 0.8607 & -15.0751 \end{bmatrix} \tag{47}$$

The simulation was tested under the initial conditions $x(t) = [1.4 \quad 0.3 \quad -2.4]^T, t \in [-2.424 \quad 0]$. From the simulation results in Figure 2, it can be clearly seen that the free weighting matrix approach allows to stabilize nonlinear systems represented by uncertain T-S fuzzy model with time -varying delay for the maximum value of delay which can be attain 2.424 s.

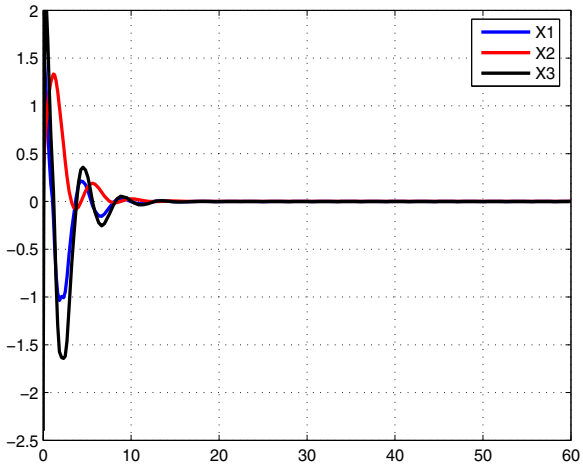

Fig. 2. Control results for system (45) without uncertainties $\bar{\sigma} = 2.424$

V. Conclusion

In this paper, we have presented new conditions for robust stabilization for uncertain fuzzy systems with time varying delay. The less conservatism sufficient conditions formulated in LMI terms are established based on the fuzzy weighting-dependent Lyapunov-Krasovskii functional method combined with the introduction of free weighting matrices. The merits and less conservatism of our method have been illustrated in comparison with existing works.

***Abstract*—This paper proposes a Splitting K-means generated Neural Fuzzy System with Support Vector Regression (SKNFS-SVR). The consequent layer in SKNFS-SVR is a Takagi-Sugeno-Kang (TSK)-type consequent. For structure learning, a splitting K-means algorithm clusters the input training data and determines the rule number. For parameter learning, a linear support vector regression (SVR) algorithm is proposed to tune free parameters in the consequent part. The motivation for using SVR for parameter learning is to improve the SKNFS-SVR generalization ability. This paper demonstrates the capabilities of SKNFS-SVR by conducting simulations in clean and noisy function approximations. This paper also compares simulation results from the SKNFS-SVR with Gaussian kernel-based SVR.**

Keywords-Fuzzy modeling, splitting K-means, support vector regression, support vectors, function approximation, fuzzy neural network.

I. INTRODUCTION

Fuzzy systems (FSs) and support vector regressions (SVRs) have been applied to solve the regression estimation and signal prediction problems in these years. FS is a well-known as a powerful tool for modeling nonlinear functions. SVR learning formulation [1, 2] is based on the principle of structural risk minimization and attempts to minimize a bound on the generalization error. The SVR learning approach also exhibits desirable properties such as generalization and over-fitting prevention capabilities.

Researchers have proposed several different neural learning techniques for constructing FSs [3]-[8], such as the self-constructing neural fuzzy inference network (SONFIN) [3] and the self-organizing fuzzy neural network (SOFNN) [7], and the Fuzzified Takagi-Sugeno-Kang (TSK)-type Neural Fuzzy Inference Network (FTNFIN) [8]. However, these neural fuzzy systems (NFS) are based on the minimization of training error (or empirical risk), they do not possess high generalization ability. For noisy regression problems, training error minimization may overtrain the noise into the learning model, leading to an unsatisfied test result. To address this problem, combination of fuzzy set theory and SVR has been proposed for regression problems [9]-[11]. In [9], the authors applied FCM clustering algorithm to obtain fuzzy rule that transforms input data to feature space. Then using SVR solves the weighting parameters. The authors in [10] introduced fuzzy SVM approach to seek a fuzzy linear function that model weights and bias term are fuzzy sets. The authors in [11] proposed a TSK FS-based SVR (TSFS-SVR) that combines the idea of TSK-type fuzzy system and SVR. The function of TSFS-SVR is a linear combination of TS-type kernel functions, where kernel and weight parameters are learned by clustering and SVR. However, there is only one free consequent parameter in each rule of the TS-kernel-based FS due to the constraint of a TS-kernel. This paper proposes an SVR-FS, whose rules are also TSK type. Different from the study in [11], all of the free consequent parameters in each TSK-type fuzzy rule are tunable.

This paper proposes a Splitting K-means generated Neural Fuzzy System with Support Vector Regression (SKNFS-SVR). The main purpose of the SKNFS-SVR is to introduce a new regression model utilizing FS and SVR. The SKNFS-SVR introduces a splitting K-means algorithm to cluster the input training data and determine the number of rules. We applied SVR to tune the consequent parameters in order to obtain a global regression model with good test performance. Representative simulation results show that the approach achieves better performance over the Gaussian kernel based SVR.

This paper is organized as follows. Section II introduces the SKNFS-SVR structure. Section III introduces splitting K-means algorithm and SKNFS-SVR structure learning. Section IV briefly reviews the basic theory of SVR and introduces SKNFS-SVR parameter learning using a linear SVR learning approach. Section V shows some representative simulations of function approximation. Section VI draws conclusions.

II. SKNFN-SVR STRUCTURE

This section introduces the structure of the SKNFS-SVR. SKNFS-SVR has a TSK-type consequent. The output is a linear combination of network inputs, i.e., $\sum_{j=1}^{n} a_{ij}x^j + a_{i0}$, where $a_{ij}s'$ are the consequent part parameters of rule i. For input variable x^j, the following Gaussian membership function is used

$$M_{ij}(x^j) = \exp\left\{-\left(\frac{(x^j - m_{ij})^2}{\sigma_{ij}^2}\right)\right\},\ i = 1,\ldots,r \text{ and } j = 1,\ldots,n \quad (1)$$

where m_{ij} and σ_{ij} denote the center and width of the Gaussian membership function, respectively, and r is the number of

rules. Using an algebraic product operation to obtain a spatial firing strength $u^i(\vec{x})$ that is determined by

$$u^i(\vec{x}) = \prod_{j=1}^{n} M_{ij}(\vec{x}^j) = \exp\left\{ -\frac{\left\| \vec{x} - \vec{m}_i \right\|^2}{\sigma_{ij}^2} \right\}. \quad (2)$$

Based on the simple weighted sum, the system output can be written as

$$y = \sum_{i=1}^{r} [u^i(\vec{x}) \cdot (\sum_{j=1}^{n} a_{ij} x^i + a_{i0})] + b \quad (3)$$

where b is a bias to account for the learning of a linear SVR (see (11)).

III. SKNFS-SVR STRUCTURE LEARNING

The primary task of SKNFS-SVR structure learning is determining the fuzzy rule number r. To generate a suitable number of clusters, a self-splitting K -means algorithm is proposed. In this algorithm, we first calculate the mean of all samples then the variance $\overline{\sigma}^2$ of a cluster is used as the criterion to decide whether or not a cluster should be split into two. The variance of a cluster i is defined as

$$\overline{\sigma}_i^2 = \sum_{j=1}^{n} \sigma_{ij}^2 \quad (4)$$

where σ_{ij} is the variance of the cluster in the j th input dimension, i.e.,

$$\sigma_{ij}^2 = \frac{1}{N_i} \sum_{\vec{x} \in C_i} (x^j - m_{ij})^2 \quad (5)$$

where $\vec{x} \in C_i$ denotes the samples belonging to cluster i 、 m_{ij} is the mean of samples and N_i is the number of samples in the cluster. For the existing r clusters, the algorithm finds

$$I = \arg\max_{1 \le i \le k} \sigma_i^2 \quad (6)$$

where σ_i^2 is the variance of clusters i . If σ_I^2 is larger than a predefined threshold V_{th} , then cluster I is split into two clusters, resulting in a total of $r+1$ clusters. Centers of the two new clusters are initially set as $\vec{m}_I + \vec{\varepsilon}$ and $\vec{m}_I - \vec{\varepsilon}$, where $\vec{m}_I = (m_1^I, \cdots, m_n^I)$ is the center I and $\vec{\varepsilon}$ is a small value. Then, new centers of these $r+1$ clusters are recomputed by splitting K-means algorithm. The whole process recurs until the maximum variance is less than V_{th} . The whole algorithm is summarized as follows:

Begin Algorithm

- ***Initialization***. *Set cluster number* r *=1. Find* $\vec{m}_1$.
- ***Step 1***. *Calculate (5) and (6).*
- ***Step 2.*** *If* $(\sigma_I^2 < V_{th})$
  {Stop}
  Else
  { Split cluster I *into two new clusters with centers* $\vec{m}_I + \vec{\varepsilon}$ *and* $\vec{m}_I - \vec{\varepsilon}$ *, Set* $r \leftarrow r+1$ *}*
- ***Step 3.*** *Find centers of these* r *clusters by K-means clustering*
  Go to Step 1.

End Algorithm

IV. SKNFS-SVR PARAMETER LEARNING

A. Basic SVR Concepts

This section briefly reviews the theory of SVR [12]. Suppose there is a labeled training set

$$S = \{(\vec{x}_1, y_1), (\vec{x}_2, y_2), \cdots, (\vec{x}_N, y_N)\} \quad (7)$$

where $\vec{x}_k \in \mathbb{R}^n$ and $y_k \in \mathbb{R}$, $k = 1, \ldots, N$. The main goal of ε -SVR regression is to find a function $f(\vec{x})$ that has no more than ε deviation from the actually obtained targets y_k for all the training data, and is as close as possible at the same time. First, consider the case of linear function $y'(\vec{x})$, taking the form

$$y'(\vec{x}) = \vec{w}^T \vec{x} + b \quad (8)$$

where $\vec{w} \in \mathbb{R}^n$ is a high dimensional weight vector and the bias $b \in \mathbb{R}$ is a scalar.

The convex optimization problem is feasible when a function $y'(\vec{x})$ exists that approximates all pairs $(\vec{x}_k, y_k)$ with ε precision in the above constraint. If the problem is infeasible or some errors are allowed, then the problem can be defined as

$$\begin{aligned} \text{Min}_{\vec{w}, \xi_k, \hat{\xi}_k} \quad & \frac{1}{2} \vec{w}^T \vec{w} + C \sum_{k=1}^{N} (\xi_k + \hat{\xi}_k) \\ \text{Subject to} \quad & y_k - (\vec{w}^T \vec{x}_k + b) \le \varepsilon + \hat{\xi}_k \\ & \vec{w}^T \vec{x}_k + b - y_k \le \varepsilon + \xi_k \\ & \hat{\xi}_k, \xi_k \ge 0, k = 1, 2, \cdots, N \end{aligned} \quad (9)$$

This formulation introduces two slack variables, $\hat{\xi}$ and ξ : one for exceeding the target value by more than ε , and the other for being more than ε below the target. The constant $C > 0$ is a user regulated positive parameter that controls the trade-off between the error and margin.

By applying the Karush-Kuhn-Tucker theorem, the constrained optimization problem above can be solved by defining a Lagrangian L [8]:

$$L(\vec{w},b,\xi_k,\hat{\xi}_k,\alpha_k,\hat{\alpha}_k)=\frac{1}{2}\vec{w}^T\vec{w}+C\sum_{k=1}^{N}(\xi_k+\hat{\xi}_k)-\sum_{k=1}^{N}(\eta_k\xi_k+\hat{\eta}_k\hat{\xi}_k) \\ -\sum_{k=1}^{N}\alpha_k(\varepsilon+\xi_k-y_k+\vec{w}^T\vec{x}_k+b) \\ -\sum_{k=1}^{N}\hat{\alpha}_k(\varepsilon+\hat{\xi}_k+y_k-\vec{w}^T\vec{x}_k-b) \tag{10}$$

where $\eta_k,\hat{\eta}_k,\alpha_k$ and $\hat{\alpha}_k$ are Lagrange multipliers. Minimizing $L(\vec{w},b,\xi_k,\hat{\xi}_k,\alpha_k,\hat{\alpha}_k)$ requires that the gradient of $L(\vec{w},b,\xi_k,\hat{\xi}_k,\alpha_k,\hat{\alpha}_k)$ with respect to $\vec{w}$, b, ξ_k and $\hat{\xi}_k$ must vanish, i.e.,

$$\frac{\partial L(\vec{w},b,\xi_k,\hat{\xi}_k,\alpha_k,\hat{\alpha}_k)}{\partial\vec{w}}=\vec{w}-\sum_{k=1}^{N}(\alpha_k-\hat{\alpha}_k)\vec{x}_k=0 \\ \Rightarrow \vec{w}=\sum_{k=1}^{N}(\alpha_k-\hat{\alpha}_k)\vec{x}_k \tag{11}$$

$$\frac{\partial L(\vec{w},b,\xi_k,\hat{\xi}_k,\alpha_k,\hat{\alpha}_k)}{\partial b}=\sum_{k=1}^{N}(\hat{\alpha}_k-\alpha_k)=0 \tag{12}$$

$$\frac{\partial L(\vec{w},b,\xi_k,\hat{\xi}_k,\alpha_k,\hat{\alpha}_k)}{\partial\xi_k}=C-\alpha_k-\eta_k=0\Rightarrow\eta_k=C-\alpha_k \tag{13}$$

$$\frac{\partial L(\vec{w},b,\xi_k,\hat{\xi}_k,\alpha_k,\hat{\alpha}_k)}{\partial\hat{\xi}_k}=C-\hat{\alpha}_k-\hat{\eta}_k=0\Rightarrow\hat{\eta}_k=C-\hat{\alpha}_k \tag{14}$$

Thus, the primal problem (9) can be converted into the following equivalent dual problem,

$$\text{Max}_{\alpha_k}L(\alpha_k)=-\frac{1}{2}\sum_{k,j=1}^{N}(\alpha_k-\hat{\alpha}_k)(\alpha_j-\hat{\alpha}_j)\vec{x}_k\cdot\vec{x}_j \\ -\varepsilon\sum_{k=1}^{N}(\alpha_k+\hat{\alpha}_k)+\sum_{k=1}^{N}y_k(\alpha_k-\hat{\alpha}_k) \tag{15}$$

$$\text{Subject to}\ \sum_{k=1}^{N}(\alpha_k-\hat{\alpha}_k)=0\ ,\ \alpha_k,\hat{\alpha}_k\in[0,C]$$

In dual problem (15), the dual variables η_k and $\hat{\eta}_k$ are eliminated through conditions (13) and (14). By substituting (11) into (8), one has

$$y'(\vec{x})=\sum_{k=1}^{N}(\alpha_k-\hat{\alpha}_k)\vec{x}_k\cdot\vec{x}+b \tag{16}$$

where the training samples for which $(\alpha_k-\hat{\alpha}_k)\neq 0$ are called support vectors (SVs).

The above linear SVR is employed to learn free parameters in a SKNFS-SVR. The advantage of using SVR instead of neural learning is that SVR is based on structural risk minimization (or minimizing the test error), so it can improve the SKNFS-SVR generalization ability.

B. SKNFS-SVR Parameter Learning

The objective of parameter learning is to tune the parameter a_{ij} of the constructed SKNFS-SVR to an optimal extent. Learning of parameter a_{ij} using a linear SVR algorithm is introduced as follows.

The output function of SKNFS-SVR in (3) can be written as follows

$$y=\sum_{i=1}^{r}u^i\cdot(\sum_{j=0}^{n}a_{ij}x^j)+b=\sum_{i=1}^{r}\sum_{j=0}^{n}a_{ij}u^ix^j+b \tag{17}$$

where $x_0(k)\triangleq 1$. Eq. (17) shows that the output y is a linear function of u^ix^j with weights a_{ij}. Therefore, linear SVR can be employed to learn parameters a_{ij}. After structure learning, the number of rules r and rule antecedent part parameters are determined. Each input data $\vec{x}_k$ at time step k is transformed to the following vector

$$\vec{\phi}(\vec{x}_k)=[u_k^1x^0,\ldots,u_k^1x^n,u_k^2x^0,\ldots,u_k^2x^n, \\ \ldots,u_k^rx^0,\ldots,u_k^rx^n]\in\mathbb{R}^{r(n+1)}. \tag{18}$$

The vector $\vec{\phi}$ is fed as input to a liner SVR, and the training data pairs in (8) are represented by

$$S=\{(\vec{\phi}(\vec{x}_1),y_1),(\vec{\phi}(\vec{x}_2),y_2),\cdots,(\vec{\phi}(\vec{x}_N),y_N)\} \tag{19}$$

According to (17), the optimal linear regression function is

$$y(\vec{x})=\sum_{k=1}^{N}(\alpha_k-\hat{\alpha}_k)<\vec{\phi}(\vec{x}),\vec{\phi}(\vec{x}_k)>+b \tag{20}$$

where α_k and $\hat{\alpha}_k$ are solved by the linear SVR in Subsection IV-A. Eq. (20) can be represented as follows

$$y(\vec{x})=\sum_{k=1}^{N}(\alpha_k-\hat{\alpha}_k)\sum_{m=1}^{r(n+1)}\phi^m(\vec{x})\phi^m(\vec{x}_k)+b \\ =\sum_{m=1}^{r(n+1)}[\sum_{k=1}^{N}(\alpha_k-\hat{\alpha}_k)\phi^m(\vec{x}_k)]\phi^m(\vec{x})+b \\ =\sum_{i=1}^{r}\sum_{j=1}^{n}[\sum_{k=1}^{N}(\alpha_k-\hat{\alpha}_k)u_k^ix_k^j]u_k^ix_k^j+b \\ =\sum_{i=1}^{r}\sum_{j=0}^{n}a_{ij}u_k^ix^j+b \tag{21}$$

where

$$a_{ij}=\sum_{k=1}^{N}(\alpha_k-\hat{\alpha}_k)u_k^ix_k^j\ ,\ i=1,\ldots,r\ \text{ and }\ j=0,\ldots,n \tag{22}$$

Eq. (21) is equivalent to the SKNFS-SVR output function in Eq. (16). That is, Equation (22) solves parameters a_{ij} in a SKNFS-SVR.

V. Simulation Results

This section uses computer simulations to illustrate the performance and capabilities of the proposed SKNFS-SVR in a function approximation problem. First, training data without noise was used to examine SKNFS-SVR performance. Training data with noise was then used to evaluate the robustness of the SKNFS-SVR. To determine the cost parameter C in a Gaussian kernel-based SVR and a linear SVR, different values ($C = 10^{-3}$, 10^{-2} , …, 10^{3}) were simulated, and only the ones that achieved relatively good performance were shown in the example.

Example 1. The approximated function is defined as follows:

$$f(x_1, x_2) = \frac{(5 - x_2)^2}{3(5 - x_1)^2 + (5 - x_2)^2}, x_1, x_2 \in [0,10] \qquad (23)$$

A clean training set containing 200 samples was randomly generated from the input domain. The testing set had 200 points randomly generated by the same way. For SKNFS-SVR training, the parameters in the clustering algorithm were set to V_{th}=0.024, and 9 clusters were generated. For the linear SVR for weight training, different insensitive values (ε=0.07, and 0.02) and cost parameters C were studied to determine their influence on performance. Table 1 shows the performance of SKNFS-SVR for the sets of parameters that achieve relatively good performance. The results show that with the same SKNFS-SVR structure, a smaller ε value generates smaller test error. The parameter set (ε, C)=(0.02, 10) achieves the minimum RMSE of 0.0641724.

A Gaussian kernel-based SVR was designed using the same set of training data. For Gaussian kernel-based SVR, different insensitive values (ε =0.07, and 0.02), cost parameters, C , and kernel width parameters, g , were studied. Table 1 shows the sets of parameters that achieve relatively good performance. The results indicate the parameter set (ε, g , C) =(0.02, 20, 10) achieves the minimum test RMSE of 0.0774.

Example 2. To compare robustness, a noisy training set was generated by adding white Gaussian noise with mean zero and standard deviation 0.05 to the output of the clean training set. The original clean test set was also used for testing. The SKNFS-SVR contains 9 clusters when V_{th}=0.024 as same as using the training data. Table 2 shows the test RMSE, and the total number of parameters in SKNFS-SVR with different ε and ε values, where it can be found that a minimum test RMSE of 0.0605 is achieved when (ε, C)=(0.02, 100). The test error may increase as ε decreases. This phenomenon is the opposite of training with clean data. The reason is that as ε decreases, more support vectors are generated and the SVR learns more noise information. This example demonstrates that SKNFS-SVR is more robust to noise than the Gaussian kernel-based SVR.

VI. CONCLUSION

This paper proposes a SKNFS-SVR for regression problems. The overall model size can be reduced because the size of SKNFS-SVR depends on the number of clusters instead of support vectors. Consequent parameters in the SKNFS-SVR are learned by a linear SVR, aiming to minimize structural risk instead of empirical risk. Such novel design provides the SKNFS-SVR with high generalization ability and noise resistance ability. Current simulation results show that the SKNFS-SVR achieves better performance over the Gaussian kernel based SVR for both noiseless and noisy data. Moreover, the SKNFS-SVR model size is relatively much smaller. In the future, comparisons with other types of regression models in different regression problems will be studied to verify the performance of the SKNFS-SVR.

Table 1. Test Results of Different Methods Using Clean Training Data .

	Gaussian SVR		SKNFS-SVR

***Abstract*—Decentralized Partially Observable Markov Decision Processes (Dec-POMDPs) offer a powerful platform for optimizing sequential decision making in partially observable stochastic environments. However, finding optimal solutions for Dec-POMDPs is known to be intractable, necessitating approximate/suboptimal approaches. To address this problem, this work proposes a novel fuzzy reinforcement learning (RL) based game theoretic controller for Dec-POMDPs. The proposed controller implements fuzzy RL on Dec-POMDPs, which are modeled as a sequence of Bayesian games (BG). The main contributions of the work are the introduction of a game based RL paradigm in a Dec-POMDP settings, and the use of fuzzy inference systems to effectively generalize the underlying belief space. We apply the proposed technique on two benchmark problems and compare results against state-of-the-art Dec-POMDP control approach. The results validate the feasibility and effectiveness of using game theoretic RL based fuzzy control for addressing intractability of Dec-POMDPs, thus opening up a new research direction.**

Keywords- Reinforcement learning, Fuzzy systems, Cooperative multiagent systems, Decentralized POMDPs

I. INTRODUCTION

Finding optimal strategies for multiple agents operating in an uncertain environment is an active field of research in Artificial Intelligence. Sequential decision making in fully observable stochastic environments has been tackled effectively via the well known Markov decision process (MDP) framework [1]. Sensor uncertainty can be addressed through partially observable Markov decision process (POMDP) framework [2] that extends the MDP model by incorporating observations and their probability of occurrence conditional on the state of the environment. Our focus herein is on learning planning and control for multiple agents in uncertain environments in a cooperative setting. This is formalized by the Decentralized POMDP (Dec-POMDP) model [3] which essentially generalizes a POMDP to multiple agents and can be used to model a team of cooperative agents. In a Dec-POMDP, agents have to cope with uncertainty regarding other agents in addition to imperfect information about the underlying state, making the task computationally intractable (NEXP-complete for the finite horizon case) [3, 4].

Reinforcement learning (RL) has now established itself as a major technique for direct adaptive optimal control of uncertain systems [5]. In the RL paradigm, agents learn to behave optimally by repeated trial and error interactions with the environment. A recent review of multiagent RL can be found in [6] with comprehensive details of such techniques for fully cooperative, fully competitive and mixed tasks. However, these methods typically assume full state observability and/or knowledge of the complete joint action at each time step [7]. In contrast, we propose and study one of the first RL approaches to Decentralized POMDPs.

Our motivation for the proposed approach is inspired by a recently proposed Q value function for Dec-POMDPs Q_{BG}, based on joint action-observation histories [8]. This Q value formulation allows us to extend RL based approximation to Dec-POMDPs akin to the MDPs for which Q learning [9] has been successfully applied for a variety of systems and processes [10]. Various approximate Q value formulations for Dec-POMDPs have been analyzed [8], which are significantly easier to compute than the optimal Q value function Q^*. These approximate Q value functions typically employ a joint belief over the state space of the underlying POMDP, which can be computed assuming agents share observations, but not in the decentralized setting.

In the proposed approach each agent g maintains tunable q^g values over a continuous global belief space of the underlying POMDP. We use fuzzy functions as a generic function approximator, which are capable of approximating any real function to an arbitrary accuracy [11]. Fuzzy systems offer an elegant way of representing Dec-POMDP policies in a compact form, i.e., with a finite amount of memory. While convergence guarantees exist for tabular Q-learning [9], the same guarantees do not hold when function approximation is introduced [10]. As has been the case with other approaches that have used function approximation for Q-learning [10, 12] or the Markov game based learning [13], theoretical convergence of the learning process with function approximation cannot be guaranteed.

To the best of our knowledge this work is the first study of applying fuzzy RL for generating a learning controller for

Dec-POMDPs in a game theoretic setting. Major contributions of our work being (i) Casting Dec-POMDPs as a game theoretic RL task (ii) Introducing Fuzzy Inference System (FIS) based generalization to Dec-POMDPs (pointed out by Seuken and Zilberstein [14] as a major need to improve scalability of Dec-POMDP solution techniques). We use RL to learn and progressively improve solution to the Dec-POMDP using FIS to effectively generalize over a continuous global belief space.

We empirically evaluate the proposed fuzzy Dec-POMDP control on the benchmark recycling robot [15] and the multi access broadcast channel [16] tasks and compare its performance against other state of the art infinite horizon Dec-POMDP control approach [15, 16, 17]. Results validate the feasibility of using a game theoretic RL controller for Dec-POMDPs, opening up a promising future research direction to improve scalability and tackle computational intractability being faced by majority of the current Dec-POMDP solution techniques.

The rest of the paper is organized as follows: Section II briefly sheds some light on background and related work, Section III describes the proposed fuzzy Dec-POMDP controller, Section IV presents empirical results on the recycling robot and multi access broadcast channel tasks, and Section V concludes the paper with a discussion on the future scope of the proposed approach.

II. BACKGROUND AND RELATED WORK

We assume prior reader familiarity with the basic concepts underlying Reinforcement Learning [5], POMDPs [2] and Fuzzy Systems [18] giving only a brief overview of the concepts that form the backbone of our work.

A. Dec-POMDPs

Multiagent sequential decision making problems under partial observability wherein agents cooperate to optimize joint performance are formalized in the Dec-POMDP model [3]. A Dec-POMDP models a number of agents that interact with their environment (system) at discrete time steps $t = 1, 2, \ldots$. At each time step t every agent takes an action and the combination of these actions (joint action) makes the system transit to the next state. At the next time step, each agent receives a local observation of the environment. State transition and observation probabilities model the dynamics of the environment while global reward specifies desired behavior or the goodness of taking joint action in a particular state. The agents optimize a form of joint long term reward. The framework is decentralized as no agent can control the whole process and none of the agent has access to the global state. Further, agents know only their own actions and observations and there is no communication between the agents.

In this paper, we define a Dec-POMDP as the following tuple $< N_a, S, \{U_g\}, P, \{\Omega_g\}, O, R, T >$ where S is the finite set of states, N_a is the number of agents, U_g is the finite set of actions available to agent g and $\bar{U} = \times_{g \in N_a} U_g$ is the set of joint actions with $\bar{u} = < u_1, \ldots, u_{N_a} >$ being joint action. P is the state transition function with $p(s' \mid s, \bar{u})$ being the probability of landing in state s' when joint action $\bar{u}$ is taken at state s. Ω_g is the finite set of observations available to the agent g and $\bar{\Omega} = \times_{g \in N_a} \Omega_g$ is the set of joint observations with $\bar{o} = < o_1, \ldots, o_{N_a} >$ being joint observation. $O : \bar{U} \times X \to P(\bar{\Omega})$ is an observation function with $O(\bar{o} \mid \bar{u}, s')$ being the probability of observing joint observation $\bar{o}$ given that joint action $\bar{u}$ was taken and led to state s'. $R : \bar{U} \times S \to \Re$ is the reward function. T is the horizon. In the infinite horizon case, we do not have the parameter T but instead a discount factor $0 \le \gamma < 1$ which limits the infinite horizon sum $\sum_{t=0}^{\infty} \gamma^t r_t$ (with r_t being the reward received at time step t) , which is what the agents optimize.

B. Dec-POMDPs as a sequence of Identical Payoff Bayesian games

A Bayesian game (BG) is an augmented normal form game in which players have some private information [19]. This private information defines the type of agent, i.e., a particular type $\theta_g \in \Theta$ of an agent g corresponds to that agent knowing some particular information. A BG is defined by the tuple $< N_a, \bar{U}, \Theta, P(\Theta), \{r^1, \ldots, r^{N_a}\} >$ where N_a is the number of agents, $\bar{U}$ is the set of joint actions, $\Theta = \times_{g \in N_a} \theta_g$ is the set of joint types over which a probability $P(\Theta)$ is defined, and $R : \Theta \times \bar{U} \to \Re$ is the payoff function.

In a BG, agents can condition their action on the private information they have. A joint policy in a BG is represented by $\beta = < \beta_1, \ldots, \beta_{N_a} >$ where individual policies are mappings from types to actions, i.e., $\beta_g : \theta_g \to U_g$ (U_g being the action set of agent g). The solution of a BG for identical payoffs is given by [19]:

$$\beta^* = \arg\max_{\beta} \sum_{\theta \in \Theta} p(\theta) r(\theta, \beta(\theta)) \qquad (1)$$

where $\beta(\theta) = < \beta_1(\theta), \ldots, \beta_{N_a}(\theta) >$ is the joint action specified by β, $p(\theta)$ is the probability associated with joint type θ and $r(\theta, \beta(\theta))$ is the payoff received.

In modeling Dec-POMDPs as a sequence of BGs [20] the payoff function of BG (one stage) for an agent g is $Q_{BG}^g(\bar{\theta}^t, \bar{u})$ where $\bar{\theta}^t = (\bar{o}^0, \bar{u}^0, \bar{o}^1 \ldots, \bar{o}^{t-1}, \bar{u}^{t-1}, \bar{o}^t)$ is the joint action-observation history up to time t, where initial joint observation $\bar{o}^0$ is assumed to be an empty observation: $\bar{o}^0 = \bar{o}_\varnothing = < o_{1,\varnothing}, o_{2,\varnothing}, \ldots, o_{N_a,\varnothing} >$. Oliehoek et. al. [8], define a new approximate Q-value function called Q_{BG} wherein BG have types that correspond to single observations instead of

complete action-observation histories leading to smaller and more tractable BGs.

C. Overview of Dec-POMDP methods

As this work concerns designing controllers for infinite horizon Dec-POMDPs, we limit this brief overview to infinite horizon Dec-POMDPs. For finite horizon counterpart we refer the interested reader to [14]. For tackling infinite horizon Dec-POMDPs most prominent and by far most successful approach envisages Dec-POMDP policy representation as a finite state controller [15]. Finite state controllers offer an elegant way of representing a Dec-POMDP policy using finite amount of memory. Finite state controllers do not store whole observation histories, instead they encapsulate key pieces of information concerning observation history with a fixed number of nodes.

The first approach by Szer and Charpillet [16] requires high memory and running time and is limited as it searches for optimal deterministic controllers. The second one proposed by Bernstein et. al. called Bounded Policy Iteration for Dec-POMDPs (Dec-BPI) [17] is a multiagent extension of the BPI algorithm [21]. Dec-BPI uses linear programming for iterating through the nodes of each agents controller and attempts to find an improvement. The methodology is promising as it offers scalability. The last one, a recent approach by Amato et al. [15] formulates fixed size controller solution as a nonlinear program (NLP) and exploits nonlinear optimization techniques to solve the problem. They also use a certain 'correlation device' which is a shared source of randomness to improve the solution quality.

Yagan and Tham [22] propose an RL solution to approximate the joint optimal policies for Dec-POMDPs by exploiting locality of interaction among agents. Effectiveness of the proposed algorithm is shown on multiagent wireless multihop networks and for cooperative retransmission in wireless networks [23]. However, the algorithm is not applicable to general Dec-POMDPs as it assumes that neighboring agents can interact and exploits the broadcast nature of wireless medium for effective retransmission of a failed packet (a domain specific feature). Recently, Wu et al. [24] propose a novel decentralized rollout sampling policy iteration algorithm for Dec-POMDPs based on a RL technique called Monte Carlo methods. The algorithm samples a set of reachable belief states based on some heuristic policies and computes a joint policy for each belief state based on rollout estimations. Algorithm claims linear time complexity over no. of agents, bounded memory usage and good solution quality.

D. FIS based Reinforcement Learning

Fuzzy logic is a mathematical approach to emulate human way of thinking and learning. In MDPs fuzzy systems have been used as function approximators to facilitate generalization in state space and for generating continuous actions. In [12], Jouffe introduced fuzzy Q learning wherein a collection of fuzzy rules is considered as an agent. The approach produces an action by triggering some rules and cooperating. Following on this idea Sharma and Gopal [13] introduced fuzzy Markov games where FIS is used to introduce generalization in Markov games. Fuzzy RL has also been used for multiagent systems, e.g., Duman et. al. [25] use fuzzy RL on a multiagent continuous pursuit domain. Tehrani et. al. [26] implement fuzzy RL on robotic soccer agents to enable them to coordinate their behavior locally and socially while learning from experience. To the best of our knowledge, until now there have been very few attempts at using fuzzy RL for effective learning in POMDPs and none for Dec-POMDPs.

III. Fuzzy Reinforcement Learning for Dec-POMDPs

In this paper, we propose a novel reinforcement learning approach for Dec-POMDPs. Given the overwhelming complexity of solving Dec-POMDPs, we propose to use a fuzzy RL based approach to learn controllers. Fuzzy membership functions are laid over the global belief space for each agent to generate what may be termed as a 'Fuzzy Dec-POMDP'. Each agent maintains its tunable parameters or the fuzzy q^g values (agent g). The use of Fuzzy Inference System (FIS) for mapping the continuous belief space of the underlying Dec-POMDP allows us to define and tune the q^g values. The Dec-POMDP is modeled as a two stage Bayesian game [19], the matrix entries for each stage being the fuzzy Q^g_{BG} values [8] obtained from the fuzzy Dec-POMDP rule base.

A. Acting in two-stage BGs

As our proposed approach uses a fuzzy RL framework, we define Q^g_{BG} at stage t as in [8] for a two stage BG corresponding to agent g. Crucially, in such a BG, (joint) types correspond to one (joint) actions and following by a (joint) observation. We define the Q function at stage t to be constructed from fuzzy q^g parameters (for agent g) defined at stage (t+1): $q^g(i,\vec{u}^t,\vec{o}^{t+1},\beta(\vec{o}^{t+1}))$ where i is an index specifying the fuzzy

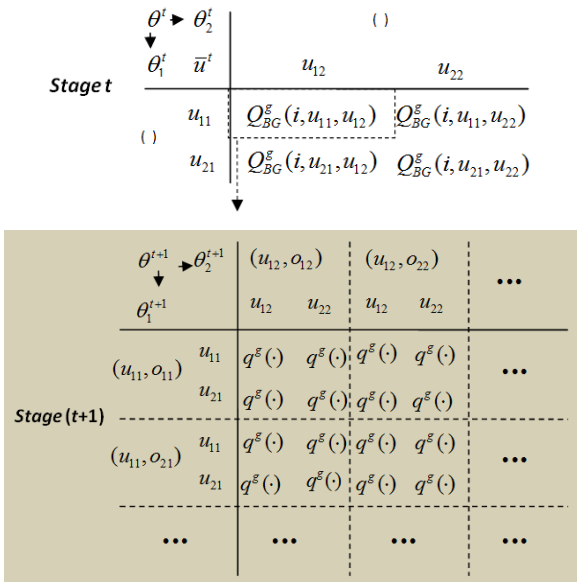

Figure 1 Fuzzy Dec-POMDP: Two stage Bayesian Game, where $q^g(\cdot) = q^g(i,\vec{u}^t,\vec{o}^{t+1},\beta(\vec{o}^{t+1}))$

rule Y_i, $\overline{u}^t$ is the joint action at stage t, $\overline{o}^{t+1}$ is the joint observation at stage (t+1), and $\beta(\overline{o}^{t+1})$ is the joint BG policy corresponding to $\overline{o}^{t+1}$ at stage (t+1). This conforms to the modeling of Dec-POMDPs as a series of BGs as introduced in [8].

Figure 1 shows the BG for time steps t and (t+1) for a fictitious Dec-POMDP with two agents each with two actions and two observations. $Q^g_{BG}(i,u_{m1},...,u_{mN_a}) \coloneqq Q^g_{BG}(i,\overline{u}^t)$ is the solution of BG defined for agent g at the next stage (t+1) corresponding to the tuple $< i,u_{m1},...,u_{mN_a} >$. It is calculated as the maximizing sum of the entries of next time step BG weighted by their respective type probabilities, i.e.,

$$Q^g_{BG}(i,\overline{u}^t) = \max_{\beta} \sum_{\overline{o}^{t+1}\in O} p(\overline{o}^{t+1} \mid \theta^t,\overline{u}^t) q^g(i,\overline{u}^t,\overline{o}^{t+1},\beta(\overline{o}^{t+1})) \tag{2}$$

The maximizing BG policy at next stage (t+1) is given by

$$\beta^*_g = \arg\max_{\beta} \sum_{\overline{o}^{t+1}\in O} p(\overline{o}^{t+1} \mid \theta^t,\overline{u}^t) q^g(i,\overline{u}^t,\overline{o}^{t+1},\beta(\overline{o}^{t+1})) \tag{3}$$

Thus, in order to code control policies, we maintain a parameter vector q^g defined as $q^g(i,\overline{u}^t,\overline{o}^{t+1},\beta(\overline{o}^{t+1}))$. These q^g values form the entries of the next step BG matrix for agent g, i.e., at time step (t+1). Type probability $p(\overline{o}^{t+1} \mid \theta^t,\overline{u}^t)\ \forall \theta^{t+1} \in \Theta$ is calculated as:

$$p(\overline{o}^{t+1} \mid \theta^t,\overline{u}^t) = \sum_{s^{t+1}\in S} \sum_{s^t\in S} O(\overline{o}^{t+1} \mid \overline{u}^t, s^{t+1}) p(s^{t+1} \mid \overline{u}^t, s^t) p(\theta^t) \tag{4}$$

It is to be noted that for updating type probability (4) the agent must have access to $\overline{o}^{t+1}$ and $\overline{u}^t$ (the joint observation and joint action, respectively) which are not available in standard Dec-POMDP setup. An agent g has access only to its own action (u^t_g) and observation (o^{t+1}_g) and the global reward signal (r_t) provided by the environment.

We propose to overcome this bottleneck by a judicious use of the information contained in the reward signal. Agent g samples action of other agents using the reward signal to get approximate $\overline{u}^t_{\neq g} \cong \hat{u}^t_{\neq g}$ ($\overline{u}^t_{\neq g}$ is the joint action of all agents except agent g). The sampled $\hat{u}^t_{\neq g}$ is combined with u^t_g to yield $\overline{u}^t = < \hat{u}^t_{\neq g}, u^t_g >$. We then update type probabilities for all $o^{t+1} \in O$ using (4). In contrast to [8], for instance, the proposed approach is an adaptive learning one based on the reinforcement learning technique. All RL techniques use the reinforcement signal (reward here) as the primary means to judge the goodness of taking a particular action. This enables the agent to discriminate amongst different actions and choose the one that produces a higher expected discounted reward [5].

Summarizing, we adapt a Dec-POMDP modeled as a sequence of BGs to fuzzy RL by using Q learning update for updating the q^g values at (t+1) stage BG matrix (Fig. 1). At each stage, we compute optimal $Q^g_{BG}(\cdot)$ value (2) and optimal joint policy β^*_g (3) corresponding to each fuzzy rule using a procedure referred to as the *forward sweep policy computation* [3].

B. *Fuzzy Dec-POMDPs*

In a POMDP an agent cannot observe state but it maintains a probability distribution over the state space called belief [2]. In a Dec-POMDP, a belief can typically not be computed as each agent only observes its own part of the joint observation. In the proposed fuzzy Dec-POMDP approach, we match an agent's perception of the global belief b^t_g (global belief state at time t) to fuzzy sets laid over the global belief space or in other words generate a fuzzy belief. We define fuzzy inference system for fuzzy Dec-POMDPs as consisting of a set of N rules (one set of rules for each agent) of the following form:

$$\begin{aligned} Y_i: \quad & \text{If } b^t_{g1} \text{ is } L^i_1 \text{ and } ... \text{ and } b^t_{gn} \text{ is } L^i_n \\ & \text{then } u_1 = u_{11} \text{ and } ... \text{ and } u_{N_a} = u_{1N_a} \text{ with } Q^g_{BG}(i,u_{11},...,u_{1N_a}) \\ & \text{or } \quad u_1 = u_{21} \text{ and } ... \text{ and } u_{N_a} = u_{1N_a} \text{ with } Q^g_{BG}(i,u_{21},...,u_{1N_a}) \\ & ..... \\ & \text{or } \quad u_1 = u_{m1} \text{ and } ... \text{ and } u_{N_a} = u_{mN_a} \text{ with } Q^g_{BG}(i,u_{m1},...,u_{mN_a}) \end{aligned} \tag{5}$$

where i is the index specifying rule Y_i, $m = \mid U_g \mid \forall g \in N_a$, i.e., action set of all agents is assumed to have same cardinality m. u_{kg} is the kth action in U_g or kth action of agent g, $b^t_g = [b^t_{g1},...,b^t_{gs},...,b^t_{gn}]$ is the global belief vector as perceived by agent g at time t, b^t_{gs} being the belief of agent g for state variable $s \in n$ (n being the number of state variables) at time t, L^i_s is the linguistic term (fuzzy label) of input variable b^t_{gs} in rule Y_i and its membership function denoted by $\mu_{L^i_s}$ corresponding to the state variable s. This matching leads to computation of rule firing strength ($\alpha^i(b^t_g)\ \forall i \in N$) as:

$$\alpha^i(b^t_g) = T(\mu_{L^i_1}(b^t_{g1}),...,\mu_{L^i_n}(b^t_{gn})) \tag{6}$$

where the T-norm is implemented by the product

$$\alpha^i(b^t_g) = \prod_{j=1}^{n} \mu_{L^i_j}(b^t_{gj}) \tag{7}$$

For each rule Y_i, we solve the BG at the next time step (t+1) as per (2) to get $Q^g_{BG}(i,\overline{u}^t)$ values that form the entries of the BG matrix at stage t (Fig. 1). Optimal one-step target value for rule Y_i, i.e., $V^i_{BG}(b^t_g)$ is the maximal value of the BG matrix at

stage t corresponding to agent g and rule Y_i and is computed as:

$$V_{BG}^{i}(b_g^t) = \max_{\bar{u}^t \in \bar{U}} Q_{BG}^{g}(i, \bar{u}^t) \tag{8}$$

and optimal one-step joint action $\bar{u}_g^*(i); i \in N$ is given by

$$\bar{u}_g^*(i) = \arg\max_{\bar{u}^t \in \bar{U}} Q_{BG}^{g}(i, \bar{u}^t) \tag{9}$$

optimal one-step policy for agent g at stage t is thus

$$\pi_g^* = [\bar{u}_g^*(1), ..., \bar{u}_g^*(i), ..., \bar{u}_g^*(N)] \tag{10}$$

index i corresponds to rule Y_i.

C. Fuzzy RL for Dec-POMDPs

In order to explore set of possible actions and to acquire experience through RL, we use pseudo stochastic exploration/exploitation (EEP) policy [10]. In the EEP strategy, we gradually reduce the exploration parameter ε according to some schedule, e.g., halve the ε value every 50 iterations (in our case). We use an ε-BG policy (ε-greedy in Q learning) meaning that we choose a random action with probability ε:

$$\bar{u}_g^{\dagger}(i) = \varepsilon\text{-BG } \bar{u}_g^*(i) = \begin{cases} \bar{u}^{rd}(i) \text{ with probability } \varepsilon \\ \bar{u}_g^*(i) \text{ with probability } (1-\varepsilon) \end{cases} \tag{11}$$

$\bar{u}^{rd}$ is a random action, i.e., $\bar{u}^{rd} = [u_1^{rd}, ..., u_{N_a}^{rd}]$ where each u_g^{rd} is an action chosen uniformly at random from the action set of the agent g: U_g, and the ε-BG policy is

$$\pi_g^{\dagger} = [\bar{u}_g^{\dagger}(1), ..., \bar{u}_g^{\dagger}(i), ..., \bar{u}_g^{\dagger}(N)] \tag{12}$$

Next, we generate global ε-BG action (agent g), $u_g^{\dagger}$ by summing the membership strength of each action in the action set of agent g under each rule and choosing the action that has the highest combined strength, i.e., one having maximum $\sum_{i \in N} \alpha^i(b_g^t)$ value. This procedure of computing $u_g^{\dagger}$ is repeated for each agent $g \in N_a$. The global ε-BG joint action is then given by $\bar{u}^{\dagger} = [u_1^{\dagger}, u_2^{\dagger}, ..., u_{N_a}^{\dagger}]$.

The computed joint action is then executed in a decentralized manner, i.e., each agent executes his component of $\bar{u}^{\dagger}$ or executes $u_g^{\dagger}$. Under this ε-BG joint action $\bar{u}^{\dagger}$ the environment transitions to the next state s^{t+1}. Each agent receives a local observation from the system, a global reward r_t and updates its perception of global belief state b_g^{t+1} using the standard Bayesian update [2] which has been adapted herein to cope with nonavailability of joint observation ($\bar{o}^t$). In particular, we loop over all possible joint observation sets given the local observation of agent g (o_g^t), by defining the joint observation as $\bar{o}^t = < o_g^t, \bar{o}_{\neq g}^t >$:

$$b_g^{t+1}(s^{t+1}) = \frac{\sum_{\bar{o}_{\neq g} \in O_{\neq g}} O(\bar{o}^t \mid \bar{u}^t, s^{t+1}) \sum_{s^t \in S} p(s^{t+1} \mid s^t, \bar{u}^t) b_g^t(s^t)}{\sum_{s^{t+1} \in S} \sum_{\bar{o}_{\neq g} \in O_{\neq g}} O(\bar{o}^t \mid \bar{u}^t, s^{t+1}) \sum_{s^t \in S} p(s^{t+1} \mid s^t, \bar{u}^t) b_g^t(s^t)} \tag{13}$$

where $\bar{o}_{\neq g}^t$ is the joint observation of all agents except agent g and $O_{\neq g}$ being observation functions of respective agents barring agent g. Each agent uses this updated belief in conjunction with the fuzzy rule base for computing rule strength values $\alpha^i(b_g^{t+1})$. The current q^g parameter estimates are used to compute global fuzzy BG target value (as in FQL [12]) as per:

$$V_{BG}^{*}(b_g^{t+1}) = \frac{\sum_{i=1}^{N} V_{BG}^{i}(b_g^{t+1}) \alpha^i(b_g^{t+1})}{\sum_{i=1}^{N} \alpha^i(b_g^{t+1})} \tag{14}$$

Global Q_{BG}^{g*} value

For each rule Y_i, one of the $Q_{BG}^{g}(i, \bar{u}^t)$ values is selected to compute global Q_{BG}^{g*} value as per the ε-BG policy (11) under each rule Y_i: $Q_{BG}^{g*}(i) = Q_{BG}^{g}(i, \bar{u}_g^{\dagger}(i))$. Global Q_{BG}^{g*} value is the weighted sum of these ε-BG (rule) values weighted by the rule firing strengths, i.e.,

$$Q_{BG}^{g*}(b_g^t) = \frac{\sum_{i=1}^{N} Q_{BG}^{g*}(i) \alpha^i(b_g^t)}{\sum_{i=1}^{N} \alpha^i(b_g^t)} \tag{15}$$

q^g update

We calculate TD(0) error [10] for tuning q^g parameter values as:

$$\Delta Q^g = r_t + \gamma V_{BG}^{*}(b_g^{t+1}) - Q_{BG}^{g*}(b_g^t) \tag{16}$$

where r_t is the global reward at stage t. Finally, q^g parameter values are updated for all rules $i \in N$ as per:

$$q^g(i, \bar{u}^t, \theta^{t+1}, \beta^*(\theta^{t+1})) \leftarrow q^g(i, \bar{u}^t, \theta^{t+1}, \beta^*(\theta^{t+1})) + \eta \Delta Q^g \frac{\alpha^i(b_g^t)}{\sum_{i=1}^{N} \alpha^i(b_g^t)}; \forall \theta^{t+1} \in \Theta \tag{17}$$

where $0 < \eta \leq 1$ is the learning rate parameter. Every agent uses (17) to independently update its q^g parameter values at

the end of each iteration.

IV. Empirical Results

This section describes the realization of the fuzzy Dec-POMDP controller and results of evaluating the approach on the recycling robot [15] and multiagent broadcast channel domains [16], which are two benchmark problems typically employed for comparing infinite-horizon Dec-POMDP methods. The first one involves robots that have the task of picking up cans in an office building, and has 4 states, 3 actions, and 2 observations. Each robot has three actions (i) search for a small can, (ii) search for a large can, or (iii) recharge the battery. The larger can be picked up only if both agents cooperate to pick it up at the same time. The robots have battery status of high and low, with an increased likelihood of transitioning to the low state or exhausting the battery after attempting to pick up the larger can.

The second problem considers two agents which need to share a communication channel, the Multiagent Broadcast Channel Access (MABC) problem. Each agent has a message buffer and it has to decide whether to send or not send the message through the channel. Only one message can go through the channel at one time, simultaneous sending results in a collision with the messages remaining in the buffers. We simulate the two agent case [16] with 4 states, 2 actions and 2 observations. New messages arrive with a rate of $p_1 = 0.9$ for agent 1 and $p_2 = 0.1$ for agent 2.

A. Recycling Robot

For the recycling robot problem, local state of either agent is battery low (BL) or battery high (BH). Global states being (BL,BL), (BL,BH),(BH,BL) and (BH,BH) or 4 states. We partition the belief corresponding to each state variable into three fuzzy subsets thereby generating $3^4 = 81$ fuzzy rules that map the global belief space to a fuzzy belief space. Linguistic terms for these fuzzy sets are Low(L), Medium(M), and High(H). The membership function for each fuzzy belief state variable (b_1, b_2, b_3, b_4) that correspond to belief over the state variables (s_1, s_2, s_3, s_4) are standard Gaussian membership functions defined by:

$$\mu_l(b_j) = e^{\frac{-(b_j - b_j^l)^2}{2(\sigma_j^l)^2}}; l = 1,2,3; \quad j = 1,2,3,4 \qquad (18)$$

where l are fuzzy labels for each variable $b_j (b_j = p(s_j))$ being the belief variable for the state variable s_j, $p_j(s_l)$ is the probability distribution over s_j. Fuzzy label centers are defined as $b_j^l = c_j + d_j(l-1)$ with $c_{1,\ldots,4} = 0, d_{1,\ldots,4} = 0.5$ and widths defined by $\sigma_j^1 = \sigma_j^3 = 0.15, \sigma_j^2 = 0.2$. The RL parameters being, discount factor $\gamma = 0.9$, learning rate $\eta = 0.9$. Exploration parameter ε is initialized from 0.9 and halved every 50 iterations. We refer to the time instant when one or both agents independently or jointly pick up a can generating a successful if the agents cooperate to lift the bigger can or pick

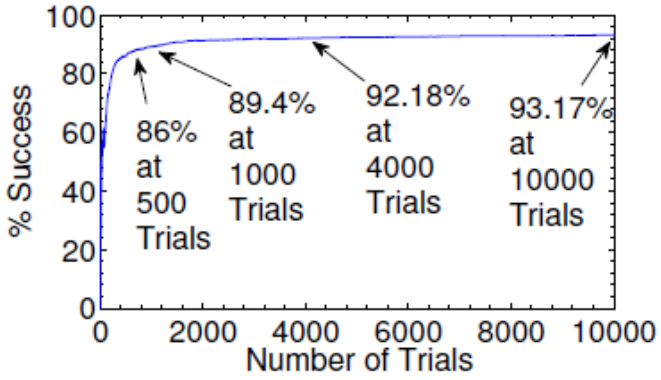

Figure 2 Fuzzy Dec-POMDP learning performance: Recycling Robot

global reward r_t as end of a trial. We consider the trial to be up smaller cans independently generating large reward. In all other cases the trial is considered a failure.

The figures 2 and 4 depict learning performance of the RL controller or how the performance improves as the controller attempts to discover the optimal policy by observing failures and rewards (while exploring). However, the figures 3 and 5 are about the performance of the learned policy, i.e., we use the final policy obtained at the end of 10000 trials and use it to find the cumulative reward (figure of merit) which is an indication of the quality of discovered policy. Episode means a set of trials; e.g., 100 trials (Fig. 2) and results have been averaged over 1000 such episodes. Figure 2 shows learning performance of the fuzzy Dec-POMDP controller, i.e., shows % success as a function of number of trials. We have averaged results over 100 episodes each of 10, 000 trials. The controller achieved a significant level of performance (86% success) in just about 500 trials. The performance reached 92.18% at 4000 trials and peaked to 93.18% success rate at the end of 10, 000 trials.

We also plot infinite horizon discounted reward achieved by the fuzzy Dec-POMDP approach (Figure 3). This value is a figure of merit for the quality of the learned policy, i.e., how much reward agents accumulate while following the discovered policy. We have averaged the results over 1000 episodes of 100 trials each. As can be seen, the value achieved is 22.80 in 20 trials and the final expected discounted infinite horizon value obtained is 26.07.

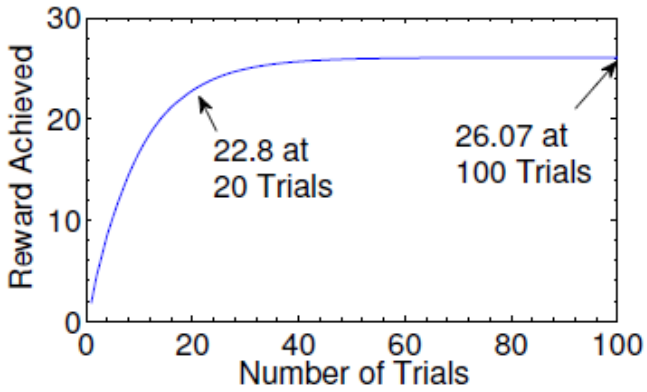

Figure 3 Quality of learned policy: Recycling robot

We compare performance of fuzzy Dec-POMDP against (i) Dec-BPI [17] which reaches a discounted reward of 26 to 27, and (ii) Finite state controller [15] which obtains 30 to 31 (read from figure). Our approach compares favorably against the Dec-BPI approach but is inferior in comparison to the fixed size controller. Fixed size controller's superior performance could be because the approach solves all the agent controllers centrally (in personal communication with the author of [15]) while in fuzzy Dec-POMDP control even the agent controllers are decentralized (solved independently). Furthermore, the performance of fixed size control approach is highly dependent on the controller size which is not the case with fuzzy Dec-POMDP control. Unlike Dec-BPI, performance of fuzzy Dec-POMDP approach does not depend on the finding appropriate fixed points on the belief space, instead it operates on the entire belief space. Even then our approach is able to find a comparable solution quality to the Dec-BPI.

B. Multiagent Broadcast Channel Access

In the MABC problem, each agent has two local buffer states (Empty, Full) resulting in 4 global states (cross product of the local buffer states). Here also we partition each belief variable into three fuzzy partitions leading to $3^4 = 81$ fuzzy rules that map the global belief space to a fuzzy belief space. Type of membership functions (18), their centers and widths are kept same as in the recycle robot task as also the RL parameters.

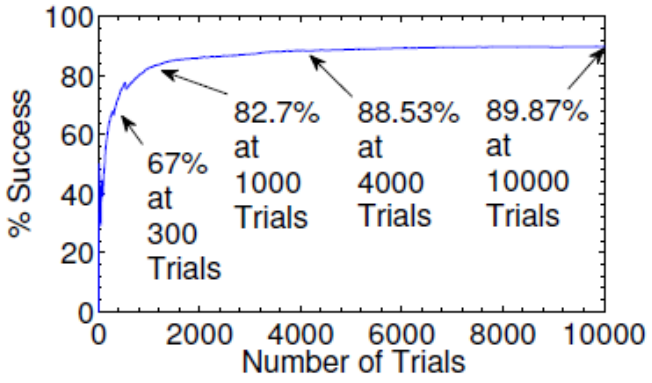

Figure 4 Fuzzy Dec-POMDP learning performance: Multiagent broadcast channel

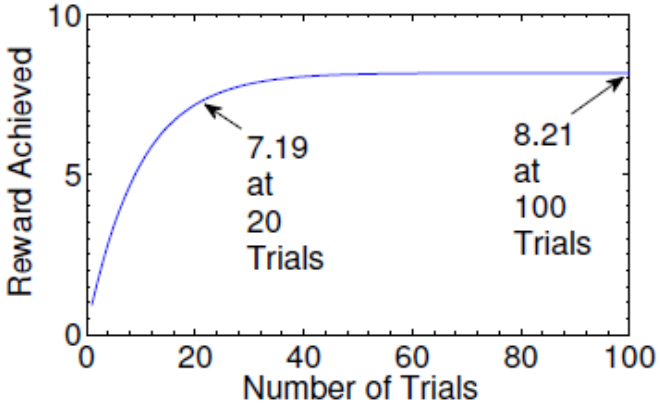

Figure 5 Quality of learned policy: Multiagent broadcast channel

Herein we consider a trial to be successful if the message (by either of the agents) gets transmitted through the channel successfully (without collision) generating a global reward of +1 or else the trial is a failure. Figure 4 shows learning performance of the fuzzy Dec-POMDP controller for the MABC task. We have averaged results over 100 episodes each of 10, 000 trials. The controller achieved a performance level of 67% success in just about 300 trials. The performance rose to 88.53% at 4000 trials and became 89.87% at the end of 10, 000 trials.

We also plot infinite horizon discounted reward achieved (Figure 5). Here also the results have been averaged over 1000 episodes of 100 trials each. As can be seen, the value achieved is 7.19 in 20 trials and the final expected discounted infinite horizon value obtained is 8.21. It is to be noted that the maximum value that can be achieved for this task with a discount factor $\gamma = 0.9$ is 9.0 [16]. The value of the proposed approach is superior to the one obtained by Szer and Charpillet [16], 8.0.

V. CONCLUSIONS

This paper presents a novel fuzzy reinforcement learning control scheme for Dec-POMDPs in a game-theoretic setting. We show how FIS based function approximation can be used as a principled means to effectively combat the time and space complexity of Dec-POMDPs. To the best of our knowledge, this work represents a first attempt in applying game theoretic learning to an FIS based Dec-POMDP setup. We elucidate feasibility of the proposed approach with empirical results on the benchmark recycling robot and multiagent broadcast channel problems. Proposed fuzzy Dec-POMDP controller successfully discovers a high quality optimal policy solution in a reasonable number of trials. Further, a comparison of the expected discounted reward value achieved against other recent state-of-the-art Dec-POMDP solution approaches [15, 16, 17] brings out the effectiveness of the proposed approach. In future work we plan to relax some of assumptions on knowledge of the system models, as well as identifying for which types of domains our approach is appropriate. Furthermore, the use of a fuzzy rule base opens the potential for generalization over continuous state spaces.

***Abstract*—This paper describes a personal verification method based on fuzzy logic using dynamic sole pressure distribution while walking. The method employs a pair id sole pressure distribution change, and it is acquired by a mat type load distribution sensor. As a preliminary experiment for shoes, we take sole pressure data by bare foot and two kind of slippered foot. We extract thirty nine gait features from each sole pressure distribution change. We calculate a fuzzy degree of a feature from two fuzzy if-then rules and them fuzzy membership functions for a feature. These fuzzy membership functions are statistically determined by learning data. The fuzzy degree of acquisition sole pressure data is calculated by total of fuzzy degree of all features. The method verifies the walking person by using the fuzzy degree of the acquisition sole pressure data. When the fuzzy degree of acquisition data higher than a threshold, we verify the walking person as the target person. In our experiments, we employed 11 volunteers and took sole pressure data six times for each volunteer and foot situation. When the learning data included same kind of test data, we obtained low equal error rate. We obtained low false acceptance rate.**

I. INTRODUCTION

Recently, personalized services are widely used for many situations. For example, we are use personal computer, e-mail services and several health monitoring services. However, these services frequently demand private and important information. Thus, personal authentication is more important technique for these personalized services. Password and PIN are major verification method, but these methods has disadvantage that we may forget these knowledge and other person can masquerade as us. To solve these problems, biometrics [1]-[3] is widely used in security field, and it has high accuracy and high user friendliness. Biometrics verifies person by physical features or behavioral features. The physical features such as fingerprint [4], [5], iris authenticate person with high accuracy. The behavioral features such as signature [6], voice [7] and walking [8]-[13] has high user friendliness. Personalized services are used in everyday lives. Thus, personal verification system required high user friendliness. By using walking, we are able to verify person passing a door or approaching a device of the service. In addition, the feature never force person to particular act such as speaking or writing. For these reasons, walking has the most high user friendliness.

In this paper, we describe a biometric personal verification method. We acquire walking data as dynamics of sole pressure. We have proposed a biometric personal authentication method using sole pressure while walking [13]. In this method, we employ a pair of right and left sole pressure distribution while walking. In past work, we have authenticated person with bare foot. However, we usually wear shoes at our everyday lives. In our goal, we aim to authenticate walking person wearing shoes. In this paper, we authenticate slippered person wearing slippers as a preliminary experiment for shoes. In this experiment, we take sole pressure data of bare foot and slippered foot, and authenticate them. We employ thinner type and thicker type slippers, and we use these data for learning data and test data. Firstly, we acquire sole pressure distribution while walking by mat type load distribution sensor. The load distribution sensor used here is good enough to obtain the walking data because it requires no special device carrying, no resistance like camera usage and easy tractable for users. Secondly, we extract thrifty nine gait features from each sole pressure data. Twelve features are based on footprint and twenty seven features are based on weight movement. Thirdly, we describe fuzzy if-then rules and fuzzy membership functions. The fuzzy membership functions are statistically determined by using learning data. Fourthly, we verify subjects by using fuzzy degree for acquisition sole pressure data. Fifthly, we show experimental result on 11 volunteers. In experiment, we took sole pressure data by three situations. Finally, we conclude the technical results.

II. PRELIMINARIES

A. Load Distribution Sensor

We acquire sole pressure data while walking by a mat type load distribution sensor (Arrow Industry Co., Ltd. AS-64X256-7PM) to authenticate person. Fig. 1 shows the load distribution sensor and our data acquisition system. This sensor is one of pressure sensors. Our experimental system consists of the load distribution sensor, a control device (Arrow Industry Co., Ltd. AS-64X256) and a personal computer. Effective sensing area of the load distribution sensor is 33 cm × 178 cm. The sensor has 64 vertical electrode sheets and 256 transverse electrode sheets. Distance between the nearest electrode sheets is 5.0 mm in a vertical direction (x-axis) and 7.0 mm (y-axis). In every intersection of vertical and transverse sheets, a resistive element is sandwiched in tow electrode sheets and this intersection point is a sensing point. The load distribution sensor has 64 × 256 sensing points. When we put pressure to

the sensing points, the corresponding resistive elements decrease electric resistance. The control device converts the electric resistances of the sensing points into 8-bit (256 level) digital signal, and provides the digital signal for all pressure values to a personal computer. The personal computer stores the pressure value at the sampling interval. In our experiment, sampling interval is 100 ms. Fig. 2 shows an example of load distribution data of one sampling time.

B. Subjects and Data Acuisition Method

In our experiment, we employ 11 volunteers shown in Table I. To acquire sole pressure data, we ask volunteers to walk on the load distribution sensor. We acquire sole pressure data the load distribution change while walking as the sole pressure data. In our experiment, the volunteer walked along *x*-axis of the sensor by bare foot and two type slippers as shown in Fig. 3. In this figure, *Slippers 1* is thinner type slippers and the thickness is 0.6 cm. On the other hand, *Slippers 2* is thicker one and the thickness is 2.5cm in heel area and 1.5cm in toe area. We acquire sole pressure data six times for each type slippers and bare foot. Fig. 4 shows examples of the right sole pressure change by bare foot.

Figure 5. Right and left sole coordinate system.

For personal verification, we extract a right sole pressure data, X_R^S, and left sole pressure data, X_L^S, from the acquisition data, X^S. The notation X^S denotes an acquisition data when person "*S*" is walking. We define the right and left sole coordinate system in Fig. 5. We set the *x*-origin at heel side of a circumscribed rectangle, and we set *y*-origin at thumb side of the circumscribed rectangle.

(c) *Slippers 2*

Figure 7. Examples of footprint of three persons.

III. Personal Verification Method

The proposed method verifies person by using fuzzy logic. We extract features based on footprint and weight movement from each sole pressure data. We calculate fuzzy degree, μ^r_{Sole}, for the target person "r". If the fuzzy degree is higher than a threshed parameter, we verify the walking person as the target person.

A. Features of Sole Pressure Chagne

We extract features from sole pressure data X_k^S, where k denotes the index of right sole ($k = R$) or left sole ($k = L$). Twelve features are based on a footprint, and twenty seven features based on weight movement. In this paper, the notation $f_i(X_k^S)$ denotes a feature with respect to a sole pressure data X_k^S where i denotes the index of each feature.

The footprint is made by combining binarized image of sole pressure distribution for all frames. Fig. 6 shows an example of footprint and its features. In this figure, the black area shows sole area, the red straight line is obtained by least squares method for footprint, and green rectangle is the circumscribed quadrangle of the footprint. The length of footprint, $f_1(X_k^S)$, is calculated by the length of long side of the green circumscribed quadrangle. The width of footprint, $f_2(X_k^S)$, is calculated by the length of short side of the green circumscribed quadrangle. The area of footprint, $f_3(X_k^S)$, is calculated by the number of pixels including the sole area. The angle of footprint, $f_4(X_k^S)$, is calculated by the angle between the red straight line and x-axis of the sensor. The distribution of footprint, $f_5(X_k^S)$,..., $f_{12}(X_k^S)$ are calculated by numbers of sole pixels in the 1-8 small areas

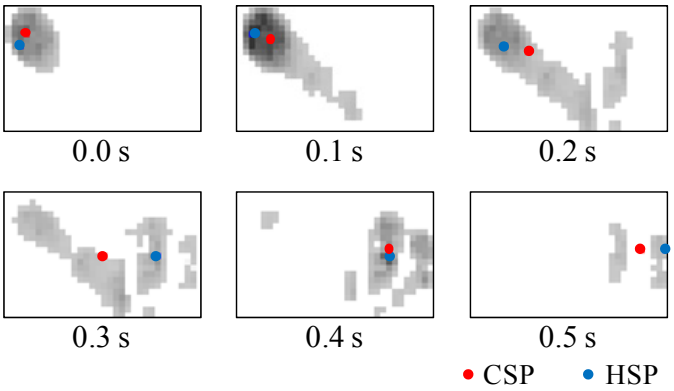

Figure 8. Examples of features from sole presure of each frame.

shown in Fig. 6. The Green dotted line quarter the circumscribed quadrangle. These features depend on the posture of walk and shape of foot. Several differences appear in the arch of a foot, the part of fingers and direction of footprint while walking. Even if persons wear same shoes, these features are different between persons. Fig. 7 shows examples of footprint of three persons.

We extract features from every frame of sole pressure data. We calculate the center of sole pressure (CSP), the highest sole pressure (HSP) and the area of footprint from each frame. The areas are calculated by the number of sole pixels from each frame. Fig. 8 shows the examples of CSPs and HSPs. There are several valuations among the sole pressure, and the numbers of frames are often different between two sole pressure data. Thus, we normalize these features to nine frames. We consider that the dynamic changes of each feature are similar in one step. We therefore interpolate nine points lining up in a polygonal line by liner interpolation and employ these points as features. The nine CSPs, $f_{13}(X_k^S)$,..., $f_{21}(X_k^S)$ and nine HSPs, $f_{22}(X_k^S)$,..., $f_{30}(X_k^S)$ are extracted from these trajectory. The nine areas, $f_{31}(X_k^S)$,..., $f_{39}(X_k^S)$ are extracted from the polygonal lines.

B. Fuzzy Degree Determination

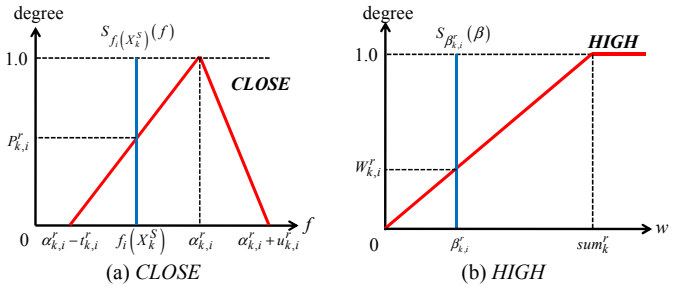
In this method, we verify walking person by fuzzy degree, μ^r_{Sole}, of the acquisition data, X^S, for the target person, r. The fuzzy degree, μ^r_{Sole}, is calculated from fuzzy degrees of every feature. Firstly, we consider Knowledge 1: features of same person are similar, and Knowledge 2: the feature with higher classification score in learning pressure data is more primary for personal verification. From these knowledge, the following fuzzy if-then rules are derived.

Rule 1: IF feature, $f_i(X_k^S)$, is *CLOSE* to $\alpha^r_{k,i}$ of the registered person y_r, THEN the degree of a feature, $P^r_{k,i}$,is high.

Rule 2: IF classification score, $\beta^r_{k,i}$, of learning sole pressure data is *HIGH*, THEN the degree of a feature, $W^r_{k,i}$, is high.

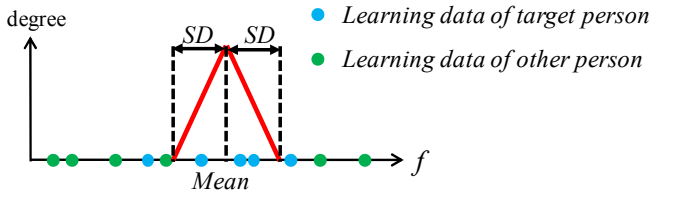
These fuzzy membership functions *CLOSE* and *HIGH* are defined by Fig. 9. These fuzzy membership functions have statistically determined parameters, $\alpha^r_{k,i}$, $t^r_{k,i}$, $u^r_{k,i}$, $\beta^r_{k,i}$, and sum^r_k, and these are determined by learning process.

Here, we explain the method to determine $\alpha^r_{k,i}$, $t^r_{k,i}$, $u^r_{k,i}$ and $\beta^r_{k,i}$ in Fig. 10 for any k and i. In our learning process, every

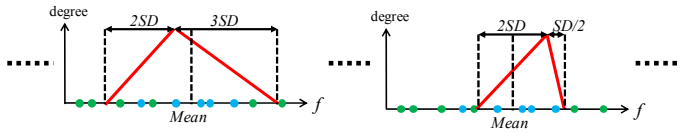


(a) *CLOSE* (b) *HIGH*

Figure 9. Fuzzy membership functions.



(a) Example of initialized fuzzy membership function *CLOSE*



(b) Example of deformed fuzzy membership function *CLOSE*

Figure 10. Examples of fuzzy membership functon deformation.

registered subject has N learning data. Firstly, we calculate the mean value $Mean^r_{k,i}$, and the standard deviation, $SD^r_{k,i}$, of learning data for k and i of the target person. Secondly, we initialize $\alpha^r_{k,i} \leftarrow Mean^r_{k,i}$, $t^r_{k,i} \leftarrow SD^r_{k,i}$ and $u^r_{k,i} \leftarrow SD^r_{k,i}$. Here, the membership function, *CLOSE*, is deformed as shown in Fig. 10(a), and we calculate the fuzzy degree, $P^r_{k,i}$, of a feature $f_i(X^S_k)$ for the target person by (1).

$$P^r_{k,i}(X) = \min\left(CLOSE, S_{f_i(X)}(f)\right) \tag{1}$$

Here, we define fuzzy singleton function $S_a(x)$ by (2).

$$S_a(x) = \begin{cases} 1 & if\ x = a \\ 0 & otherwise \end{cases} \tag{2}$$

We calculate the fuzzy degree, $P^r_{k,i}$, from every learning pressure data. From these fuzzy degree, the classification score, $\beta^r_{k,i}$, is calculated by the difference between an average fuzzy degree $P^r_{k,i}$ for other person and an average fuzzy degree $P^r_{k,i}$ for the target person. Thirdly, we repeat the calculation of $\beta^r_{k,i}$ for all domains of $Mean^r_{k,i} - SD^r_{k,i} \le \alpha^r_{k,i} \le Mean^r_{k,i} + SD^r_{k,i}$, $0 \le t^r_{k,i} \le 4\,SD^r_{k,i}$ and $0 \le u^r_{k,i} \le 4\,SD^r_{k,i}$ at the interval of $SD^r_{k,i} / 10$. Fig. 10(b) shows examples of the deformed membership function, *CLOSE*. We obtain the classification score, $\beta^r_{k,i}$, from all domains. We employ the parameters $\alpha^r_{k,i}$, $t^r_{k,i}$ and $u^r_{k,i}$ with the highest $\beta^r_{k,i}$ among all domains for a feature. Fourthly, we repeat the determination process for all k and i. The parameter, sum^r_k, of membership function, *HIGH*, is the total of classification score, $\beta^r_{k,i}$, of the one sole pressure data, X^S_k, and it is calculated by (3).

$$sum^r_k = \sum_{i=1}^{39} \beta^r_{k,i} \tag{3}$$

The fuzzy degree, $Q^r_{k,i}$, of a feature is defined by (4).

$$Q^r_{k,i}\left(X^S_k\right) = P^r_{k,i}\left(X^S_k\right) \times W^r_{k,i}\left(\beta^r_{k,i}\right) \tag{4}$$

Here, the fuzzy degree, $W^r_{k,i}$, is defined by (5), and it means the effectiveness of the feature for the target person.

$$W^r_{k,i}(\beta) = \min\left(HIGH, S_\beta(w)\right) \tag{5}$$

Finally, we calculate the fuzzy degree, $Q^r_{k,i}$, for all k and i. The fuzzy degree, $\mu^r{}_{Sole}$, of the acquisition data is calculated by (6).

$$\mu^r_{Sole}\left(X^S\right) = \frac{1}{2}\left(\sum_{i=1}^{39} Q^r_{R,i}\left(X^S_R\right)\right) + \frac{1}{2}\left(\sum_{i=1}^{39} Q^r_{L,i}\left(X^S_L\right)\right) \tag{6}$$

C. Personal verification by fuzzy degree

The proposed method verifies walking person by the fuzzy degree, $\mu^r{}_{Sole}$, of the acquisition data, X^S. For personal verification, we acquire a pair of right and left sole pressure data, and extract features from the acquisition data. We calculate the fuzzy degree, $\mu^r{}_{Sole}$, for the target person. If the fuzzy degree is higher than a threshold parameter, the proposed method verifies walking person as the target person. On the other hand, if the fuzzy degree is lower than the threshold parameter, we verify the walking person is not the target person.

IV. Experimental Results

In our experiment, we employed 11 volunteers. We took the sole pressure data 18 times for a volunteer with bare foot (6 times), *Slipper 1* (6 times) and *Slipper 2* (6 times). In this experiment, we call these data set that *BARE*, *SL1* and *SL2*, respectively. We employ equal error rate (EER) for performance test. EER is the error rate at that false rejection rate (FRR) equals to false acceptance rate (FAR). Here, FRR is concerned with the number of instance defined as an authorized individual being falsely rejected by the system. FAR is concerned with the number of instances defined as an unauthorized individual being falsely accepted by the system.

We verified these volunteers by the proposed method. First, we tested our proposed method by learning data of each data set. Table II shows the verification results of each learning data and test data and Fig. 11 shows FRR and FAR with threshold parameter change. The proposed method obtained low EER for the test data of same type data as the learning data. However, we obtained high EER for the other test data. Second, we tested the proposed method by employing two or three type learning data for a volunteer. Table III shows the verification result of employing two or three type learning data for each volunteer. We obtained low EER when the learning data included the

same type data. In addition, we obtained lower EER for the other test than that of employing one test dat. Table IV shows the FAR of threshold parameter was 0.40. From these result, the proposed method was able to reject unauthorized individual being.

V. CONCLUSION

In this paper, we have proposed a biometric personal verification system based on fuzzy logic. We employed sole pressure distribution change while walking. The sole pressure data was acquired by mat type load distribution sensor. The proposed method verified the waking person by fuzzy degree of sole pressure data. We extracted features from right and left sole pressure change, and made fuzzy if-then rules with statistically determined membership functions by learning data. The fuzzy degree of sole pressure data was calculated from total of all fuzzy degree of each feature. In the experiments, we took sole pressure data three situations; volunteers walked with bare foot, they walked with thin slipper and they walked with thick slipper. We employed 11 volunteers, and we tested the proposed method. We obtained low EER when the learning data included the same type data. However, we obtained high EER for the other test data. The verification system had low FAR in threshold parameter was 0.40 for any learning data and test data. From these result, the proposed method was able to verify sole pressure data that was acquired same situation. From these results, we think that to verify walking person wearing shoes, the system needs to employ learning data of various situation.

In the feature, we will employ newly features of sole pressure for verification. We will try to authenticate person wearing shoes. We will add other biometric feature to the method.

***Abstract*—The anterior cruciate ligament (ACL) injury can cause a reason of instability along anterior - posterior translation at extension. Thus, it is important to examine the knee joint quantitatively for understanding clinical outcome. However, an quantitative calculation method of the knee joint has not been reported. Therefore, we have developed six degree of freedom (6 DOF) calculation based on principal component analysis (PCA) for the knee joint in multi-detecter row computer tomography (MDCT) image. The proposal method was applied to six ACL injured knees obtained at two periods. As a result, the proposed methods could calculated 6 DOF of the knee joint quantitatively.**

Keywords- Six Degrees-of-freedom; ACL Reconstruction; MDCT Image; Image Analysis

I. INTRODUCTION

The ACL injury can be a reason of instability along anterior-posterior direction at extension. It might result in working and daily life faced to obstacles. As examination methods of the ACL injury, manual tests have been proposed, however, it is difficult to calculate an attitude of the knee joint by using a general commercial device quantitatively. Therefore, this study sets a goal to calculate 6 DOF of the knee joint from MDCT image. In the experiment, the accuracy of the proposed method was examined for 6 DOF of the knee joint.

II. PRELIMINARY

A. MDCT(Multidetector - row CT) Device

An MDCT device is a CT (Computed Tomography) device with the multi-row detector. The MDCT device has thinner thickness and higher resolution than the CT. The MDCT image was obtained for patients peformed with ACL reconstruction. One slice consists of 512 × 512 (X × Y) voxels (TABLE I). The number of slices (Z) differ from patient to patient. The range of image was 5 cm proximal from the femur epicondyle and 5 cm distal from the tibial tubercle (Fig. 1).

TABLE I. ACQUISITION PARAMETERS

Resolution [pixel]	512 × 512
Color Depth [bits]	16
Slice Thickness [mm]	1.0
The Number of Slice	201~202
Pixel Spacing [mm]	0.5

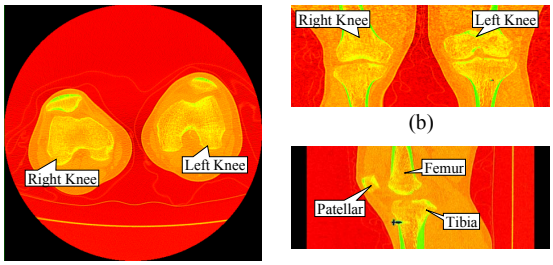

Figure 1. An Example of MDCT Image: (a) Axial (X-Y plane), (b) Coronal (X-Z plane), and (c) Sagittal (Y-Z plane).

B. ACL Injury

The ACL is a ligament which connects the femur and tibia, and plays a role of preventing an excessive anterior translation of the knee during knee rotation [1]. The ACL injury happens with high frequency among sports trautic injuries, and can cause a reason of increase of instability along anterior - posterior translation at extension [2]. When no treatment is applied to the ACL injury, it can result in secondary injuries (i.e., meniscus injury, articular cartilage lesion, etc.). Also, because a self-reparation of the ACL is rare due to its low healing ability, operative treatment is preferred rather than conservative treatment when instability of daily life is high for an active young person or a person with multiple ligament injuries [3-4].

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

C. ACL Reconstruction

The ACL reconstruction has two techniques, that are single bundle technique and double bundle technique. The single and double are performed with one and two grafts, respectively [5]. In both of techniques, a bone tunnel(s) is/are required so that the graft is passing through it. Especially, two bone tunnels in double bundle technique are called as anteromedial (AM), and posterolateral (PL) as shown in Fig. 2.

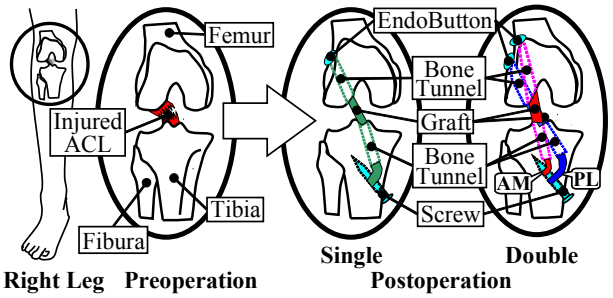

Figure 2. ACL Reconstruction.

D. Definition of Coordinate Systems

Coordinate systems are necessary to a quantitative evaluation by three dimensional attitude of the knee joint (Fig. 3). The coordinate systems consist of an anterior axis, lateral axis, distal axis, and origin point [6-8]. The coordinate systems are determined based on anatomical points and axes [9].

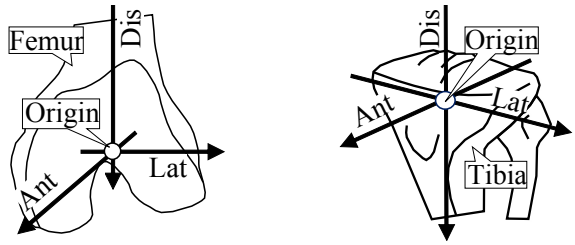

Figure 3. The coordinate systems. (a) The femur coordinate system. (b) The tibia coordinate system.

E. Six Degrees of Freedom

In the three dimensionnal space, total degree of freedom is six for summation of three translational DOF and three rotational DOF. This study calculates 6 DOF of the femur and tibia in MDCT image for analysis of attitude of the knee joint (Fig. 4).

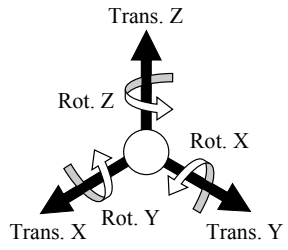

Figure 4. 6 DOF.

III. Proposed Method

The proposed method consists of three steps as shown in Fig. 5. The first step is determination of the coordinate systems in the femur and tibia. The second step is registration of the images in the femur and tibia. The third step is validation of the registration accuracy. The last step is evaluation of the 6 DOF for the coordinate systems.

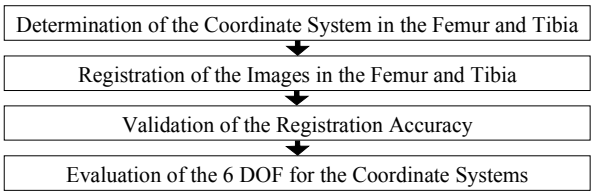

Figure 5. Procedure of proposal method.

A. Determination of the Coordinate Systems in the Femur and Tibia

The coordinate systems of the femur and of the tibia are determined from the information obtained by the following procedure.

1) The femur coordinate system

The femur coordinate system consists of five steps as shown in Fig. 6. The first step is determination of the distal axis. The second step is determination of the anterior direction in axial image. The third step is determination of the lateral axis. The fourth step is determination of the anterior axis. The last step is determination of the origin point.

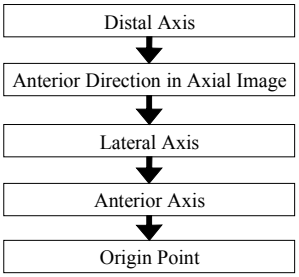

Figure 6. Procedure of the femur coordinate system.

a) Distal axis: The femur is depicted as comparatively circle in proximal slice. The gravity points of the proximal femur are detected, and are used as two points making the distal axis (Fig. 7).

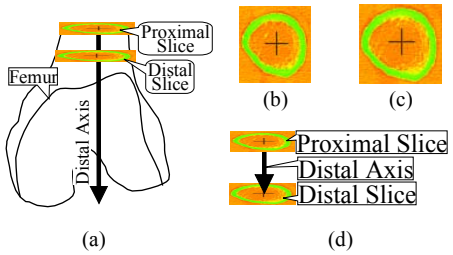

Figure 7. Distal axis: (a) the distal axis of the femur, (b) the proximal slice of the femur image, (c) the distal slice of the femur image, and (d) the calculated distal axis.

b) The anterior direction in axial Image: The epicondyles, which are necessary for determining the lateral axis and the anterior direction, are determined. Therefore, we determine the anterior direction in axial image.

Top(t), bottom(b), right(r), and left(l) points in each slice of the femur are detected (Fig. 8 (a)). Then, $t(i)$, $b(i)$, $l(i)$, and $r(i)$ that coordinate values of the s-th slice of the femur are calculated from

$$\begin{cases} 0 \le l(s) \le r(s) \le X \\ 0 \le t(s) \le b(s) \le Y \end{cases}, \quad (1)$$

where s is the slice number of the image, X and Y are the maximum coordinate values of the image, respectively.

The area of the rectangle based on these four points are calculated. Then, difference $dif_y(s)$ of t and b, and difference $dif_x(s)$ of l and r are calculated from

$$\begin{cases} dif_x(s) = |r(s) - l(s)| \\ dif_y(s) = |t(s) - b(s)| \end{cases}. \quad (2)$$

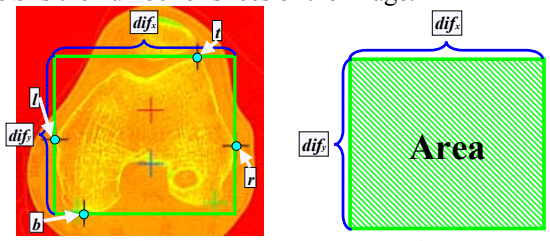
The slice with the maximum area is searched, then used as a target slice for the following process (Fig. 8 (b)). Then, an area $A(s)$ is calculated for each slice from

$$A(s) = dif_x(s) \cdot dif_y(s). \quad (3)$$

Then, the slice with the maximum area $slice_{max}$ is calculated from

$$slice_{\max} = \arg \max_{s \in [0, S-1]} (A(s)), \quad (4)$$

where S is the number of slices of the image.



(a) (b)

Figure 8. The slice with the femur maximum area: (a) the feature points (t, b, l, r) of the femur image on the slice, and (b) the rectangle area of the femur image on the slice.

The intersection point of the target slice and the distal axis is regarded as the center point. Two points are searched so that the distances between the center point and two points are longest among the contour of the bone. Then the two points are determined as two postepicondyle points for analyzing a notch position. The bisector line is calculated from two epicondyle points and the center point. Then, the maximum evaluation function R is calculated from

$$R = \arg \max_{i \in [0, 2\pi - 1]} (A(i) \cdot B(i)), \quad (5)$$

where A and B are the differences of the center point of distal axis and postepicondyles on the slice. The notch position is determined by the bisector line and the contour of the femur (Fig. 9).

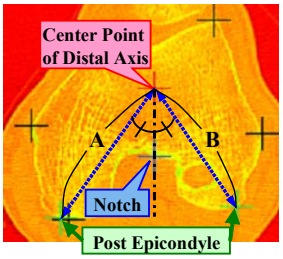


Figure 9. The notch on the slice of the maximum rectangle area.

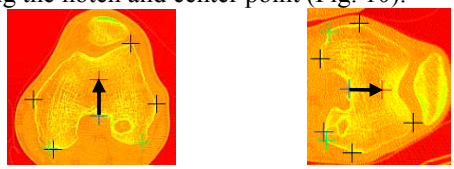
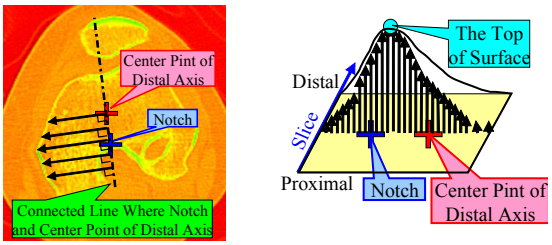
The anterior direction of the femur is determined by connecting the notch and center point (Fig. 10).



(a) (b)

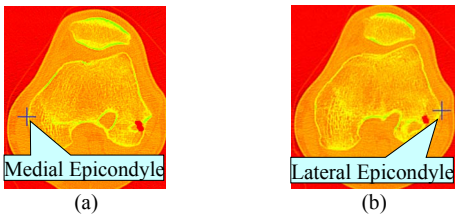
Figure 10. Anterior direction in axial image: (a) the upward position of the knee image, and (b) the rightward position of the knee image.

c) Lateral axis: Vertical vectors that indicate contour points from anterior axis are calculated (Fig. 11 (a)). The longest vecter is regarded as the epicondyle. The longest vector of the medial and lateral are determined as the medial and lateral epicondyles, respectively (Fig. 11 (b)). The lateral axis is determined by connecting the medial and lateral epicondyles (Fig. 12).



(a) (b)

Figure 11. The calculation of the top on the epicondyles: (a) the top on contour side in a slice, and (b) the three dimensional top of surface of the epicondyle .



(a) (b)

Figure 12. The determinated epicondyles: (a) the medial epicondyle, and (b) the lateral epicondyle.

d) Anterior axis: The anterior axis is an outer product of the distal axis and the lateral axis.

e) Origin point: The middle point of the segment that connects the epicondyles is determined as the origin point of the coordinate system (Fig. 13). Then, the origin point $\vec{o}(o_1, o_2, o_3)$ is calculated from

$$\vec{o} = \left(\frac{m_1 + l_1}{2}, \quad \frac{m_2 + l_2}{2}, \quad \frac{m_3 + l_3}{2} \right), \tag{6}$$

where $\vec{m}(m_1, m_2, m_3)$ and $\vec{l}(l_1, l_2, l_3)$ are the medial and lateral epicondyles.

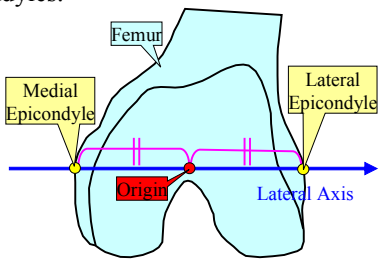


Figure 13. The origin point.

2) The tibia coordinate system

The tibia coordinate system consists of three steps as shown in Fig. 14. The first step is determination of the distal axis. The second step is determination of the anterior axis and lateral axis. The last step is determination of the origin point.

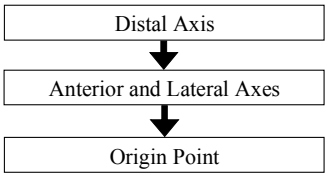

Figure 14. Procedure of the tibia coordinate system.

a) Distal axis: The tibia is depicted as comparatively circle in distal slice. The gravity points of the distal region of the tibia are detected, and are used for making the distal axis based on principal component analysis (Fig. 15).

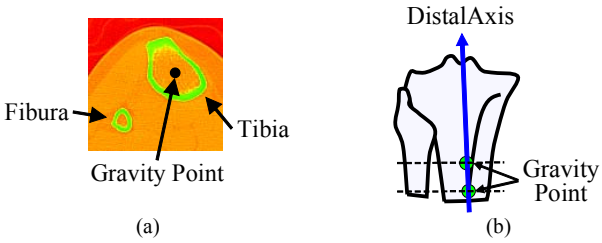

Figure 15. Determining the distal axis: (a) the gravity point on the axial image, (b) the distal axis.

b) Anterior and lateral axes: The plane which has the maximum area and is perpendicular to the calculated bone axis, is searched. Anterior axis and lateral axis are derived from the maximum area on the plane. At first, the gravity point of the bone profile is calculated. Here, two orthogonal lines are assumed so that the intersection point is located as the gravity point. The intersection points of the lines and the bone profile are regarded as points *A*, *B*, *C*, and *D*, respectively. These four distances (*a*, *b*, *c*, and *d*) from the gravity points to the four points are inserted by the following evaluation function *R*,

$$R_{\max} = \arg \max_{i \in [0, 2\pi - 1]} \frac{a(i) \cdot b(i) \cdot c(i)}{d(i)}, \tag{7}$$

The orthogonal lines are rotated based on the gravity point so that the evaluation function *R* is the maximum value. In the situation, the lines AB and CD are defined as the lateral and anterior axes, respectively.

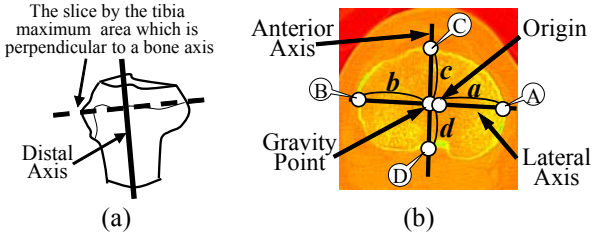

Figure 16. The tibia coordinate system: (a) The slice by the tibia maximum area which is perpendicular to a bone axis, (b) the anterior axis, the lateral axis and the origin point.

c) Origin point: The origin of a coordinate system is determined as a middle point of the line AB (Fig. 16). Then, the origin point $\vec{o}(o_1, o_2, o_3)$ is calculated from

$$\vec{o} = \left(\frac{a_1 + b_1}{2}, \quad \frac{a_2 + b_2}{2}, \quad \frac{a_3 + b_3}{2} \right), \tag{8}$$

where $\vec{a}(a_1, a_2, a_3)$ and $\vec{b}(b_1, b_2, b_3)$ are the medial and lateral epicondyles.

B. Registration of the Images in the Femur and Tibia

The 6 DOF is quantitatively evaluated in comparing to preoperative and postoperative data. In general, different acquired period data have tendency to make a little bit different coordinate system each other. To reduce the error, the data are unified by registration, and is evaluated in same coordinate system. The coordinate system are unified by registration of preoperative data and postoperative data.

Evaluation of registration is performed by using matching rate. The matching rate is calculated in each three planes (i.e., axial plane, coronal plane, and sagittal plane). The target data are projected to each planes by using maximum intensity projection (MIP) method (Fig. 17). The projected data are transformed to binary data by thresholding. These processing are applied for preoperative and postoperative data. A matching rate *R* is a value calculated by the following equation,

$$R = \frac{1}{2} \cdot \frac{S_1 + S_2}{S_1 \times S_2} S_R, \tag{9}$$

where S_R is an area of number of overlapped pixels of preoperative and postoperative data, S_1 and S_2 are areas of preoperative data and postoperative data, respectively.

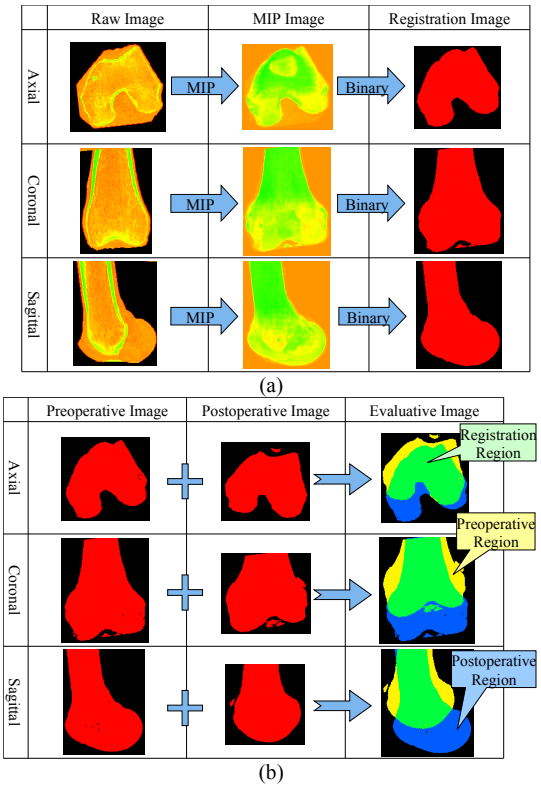

Figure 17. The evaluation of the registration: (a) Maximum Intensity Projection, and (b) the registration image.

The precise registration is performed so that the femur region of postoperative data are mostly overlapped to preoperative data (Fig. 18). After registration, the coordinate system determined from preoperative data are also used for postoperative data. It results that both of preoperative and postoperative data are evaluated on the same coordinate system.

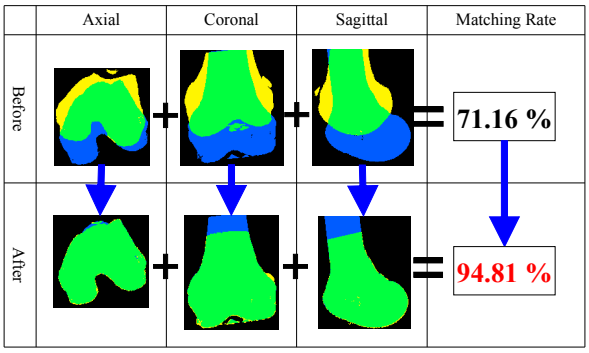

Figure 18. The precise registration.

C. Accuracy Validation of the Registration

An accuracy validation of the registration is used by the position of the screw. The intensity of screw is higher than a peripheral bone and an organization of the muscle etc. (Fig. 19 (a)). Only screw is extracted from the MDCT image (Fig. 19 (b)) by binarization with high thresholding value. The gravity point of the extracted object voxel is regarded as a barycentric position of the screw (Fig. 19 (c)).

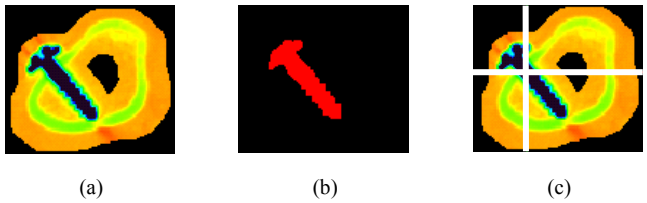

Figure 19. Evaluation of the knee joint pose.

The screw position was calculated by using the bone coordinate system of the tibia (Fig. 20). The validation of the registration accuracy is used by the position of the screw.

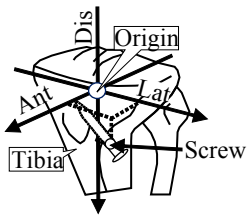

Figure 20. Evaluation of the screw.

D. Evaluation of the 6 DOF for the Coordinate Systems

Based on the femur and 6 DOF of the tibial coordinate system that we pursued, we evaluate attitude of the knee [10-11]. In general, range of motion is calculated by using this 6 DOF.

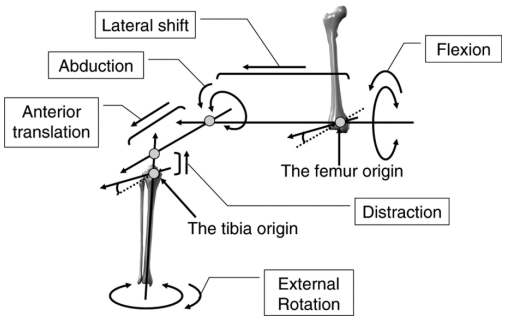

Figure 21. Evaluation of the knee joint pose.

IV. EXPERIMENTS

The subjects was fewer, because this study is a pilot study. The proposed method was applied for four subjects with single bundle that has informed consent. The sex was two males and one females. The age was 36.67 ± 13.50 (23-50). The injured knee was one right knee and two left knees (TABLE II). The one preoperative and one postoperative MDCT images were evaluated for each subjects. Quantitative comparison with the injured knee and the intact knee was performed.

TABLE II. SUBJECTS DATA

Subject	Sex	Age	Bundle	Injured Knee
1	F	37	S	L
2	M	23	S	R
3	M	50	S	L

V. RESULTS

The time-depend displacements of the screw was shown in TABLE III. The time-depend displacements of the screw were -0.28 ± 0.44 mm (anterior), 0.09 ± 0.25 mm (lateral), -0.07 ± 0.37 mm (distal), and 0.56 ± 0.24 mm (3D). "3D" was the three-dimensional time-depend displacement.

TABLE III. THE TIME-DEPEND DISPLACEMENTS OF THE SCREW.

Subject	Anterior	Lateral	Distal	3D
1	-0.79	0.24	-0.16	0.84
2	-0.02	0.23	0.34	0.41
3	-0.03	-0.20	-0.39	0.44

The results of evaluations were shown in TABLES IV - VI. In the tables, the 6 DOF (anterior, lateral, distal, flexion, rotation, and valgus) were evaluated at pre-time and post-time. The changes between the pre-time and post-time were tabulated. The difference was calculated by subtracting the injured knee from the intact knee.

TABLE IV. THE EVALUATION OF THE INJURED KNEE.

		Injured Knee (A)					
		Anterior	Lateral	Distal	Flexion	Rotation	Valgus
1	Pre-time	25.09	11.66	128.83	17.64	11.74	3.58

(Anterior, Lateral, Distal: (mm), Flexion, Rotation, Valgus: (degree))

TABLE VI. THE EVALUATION OF THE DIFFERENCE.

		Difference (B-A)					
		Anterior	Lateral	Distal	Flexion	Rotation	Valgus
1	Pre-time	-8.10	-10.86	-32.91	-8.91	-2.81	1.48
	Post-time	-3.11	-2.27	-14.67	-0.07	-17.43	1.94
2	Pre-time	9.67	-8.93	-4.06	16.49	2.38	-3.88
	Post-time	5.52	-7.25	-2.71	9.78	-2.52	2.73
3	Pre-time	0.46	-12.92	-7.98	-5.60	8.14	3.65
	Post-time	-3.14	2.74	-16.67	10.14	-12.96	5.66

(Anterior, Lateral, Distal: (mm), Flexion, Rotation, Valgus: (degree))

VI. DISCUSSION

The time-depend displacement (0.56 mm) of the screw was as small as the resolution (0.50 mm) of the image. The determination was no tendency in a direction of the displacement. This accuracy error was very small.

The changes of the injured knee were larger than the intact. It implys that the 6 DOF of the injured knee is effected by operation. The difference of post-time was close to zero more than pre-time. It might be that the 6 DOF of the injured knee was modified as the 6 DOF of the intact knee by the operation.

VII. CONCLUSION

We have proposed an analysis method of 6 DOF in the knee joint. The proposed method was applied for three patients of single bundle technique. The subjects was fewer, because this study is a pilot study. As a result, the proposed method could calculate the 6 DOF in the knee joint. This accuracy error was very small. It might be that the 6 DOF of the injured knee was modified as the 6 DOF of the intact knee by operation. We can apply the 6 DOF to the clinical examinations. This future work is to apply this method for many subjects.

***Abstract*—In this paper, for improving performance of the nursing-care text classification, we introduce a mechanism of retrieving terms from Web. Every year, the nursing-care texts are collected by using Web application to improve nursing-care quality in Japan. The collected nursing-care texts are decomposed into morphemes (i.e., terms), and then terms are stored as a term list. Each text is represented as a feature vector by using the term list and classified using a SVM based classification system. The training data sets for constructing SVM based classification system are different from the evaluation data sets. That is, there are differences between the term lists of the nursing-care texts because the nursing-care texts are collected and evaluated every year. To cover this difference, we introduce a mechanism of retrieving terms from Web. A new term which appeared in the evaluation data sets is used as a query of a search engine. The terms in the term list are also used as queries. Terms are represented by the search results, and then are compared with each other. We use the most similar term in the term list as an alternative of the new term. From experimental results, we show effectiveness of our proposed method.**

***Keywords*—nursing-care; text classification; SVM; fuzzy**

I. Introduction

In order to improve nursing-care quality, the data which consists of numerical data and freestyle texts are stored into our database. The numerical data is used for statistical analysis about the structure of hospitals. The text data is used for evaluating each nurse. In evaluating the text data, the experts need to read carefully and evaluate each nursing-care data because those data include freestyle Japanese texts which are written about actual nursing-care by nurses. For evaluating such texts automatically, we have developed several nursing-care text classification systems, such as using fuzzy classification systems [1], neural networks [2], and support vector machines (SVM) [3], [4]. In order to improve the classification performance of the SVM based classification system, we have proposed a GA-based term selection [5]–[8].

In the above mentioned classification systems, the collected nursing-care texts are decomposed into morphemes (i.e., terms), and then terms are stored as a term list. Each text is represented as a feature vector by using the term list and classified using a classification system. The training data sets for constructing classification system (e.g., SVM based classification system) are different from the evaluation data sets. That is, there are differences between the term lists of the nursing-care texts because the nursing-care texts are collected and evaluated every year. Therefore, the corresponding feature in the newer data set may not exist in the training data set because every year's term list has differences with each other. Such a feature which appears only in the new data set does not affect classification. The nursing-care texts which have such features may not be classified correctly.

In order to decrease such no-effect feature, we introduce a mechanism of retrieving terms from Web. A new term which appeared in the evaluation data sets is used as a query of a search engine. The terms in the term list are also used as queries. Terms are represented by the search results, and then are compared with each other. We use the most similar term in the term list as an alternative of the new term. Therefore, the no-effect feature can be expressed in the known feature approximately.

This paper is organized as follows. The overviews of nursing-care texts and preprocessing for classification using the morphological analysis software "MeCab" [9] are described in Section 2. In Section 3, the overview of nursing-care classification system and, in Section 4 our proposed method are explained. Then, simulation results are shown in Section 5.

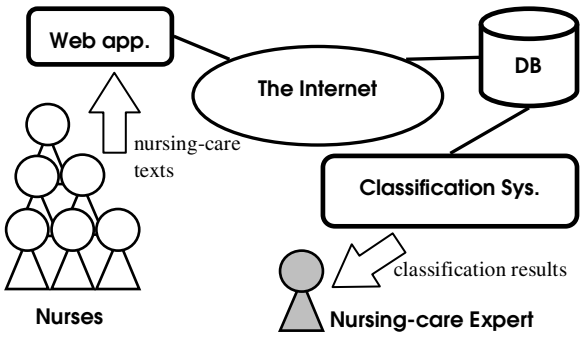

Fig. 1. Overview of our nursing-care data collection and classification

II. Nursing-care text

The nursing-care text data set consists of many freestyle Japanese texts. They are collected by using an Internet application and stored into our database. The overview of nursing-care data collection and classification is shown in Fig.1.

The nursing-care texts contain answers for a wide variety of questions from nurses about their subjects, technicality, etc. Some sample texts are shown in Fig.2. Usually long texts are good texts which explained good nursing-care. On the other hand, usually short texts are poor and lacking the appropriate technical information. Some nursing-care experts read those texts in detail, then evaluate the nursing practices of the nurses providing the information, and classify them into classes 1 (bad) to 4 (very good).

In our nursing-care text classification system, already classified nursing-care texts by experts are used as a training data set for a SVM. In preprocessing, a text set is converted from original texts to a "term-document matrix" by decomposing it into morphemes. We use "MeCab" as one of the morphological analysis software. All nouns and verbs (shown in shaded, see Fig.2) in decomposed morphemes are stored into a term list. We iterate the preprocessing until all texts are processed.

III. Nursing-care text classification system

A. Making feature vectors

A term list which stored terms collected in a certain year is represented by TL_{year}. For example, a term list of 2008 is TL_{08}. Each nursing-care text is converted into a feature vector by assigning '1' to that feature when a term in the nursing-care text existed in TL_{year}. Specifically, a nursing-care text is converted into a feature vector as the following manner.

Step 1 A nursing-care text is decomposed into morphemes.

Step 2 Nouns and verbs are selected from morphemes.

Step 3 If a selected term (i.e., a noun or verb) is appeared in the TL_{year}, then '1' is assigned to that feature. Otherwise '0' is assigned. That is, a feature vector is expressed as follows:

$$(x_1, \cdots, x_i, \cdots, x_{N_{TL_{year}}}), \tag{1}$$

$$x_i = \begin{cases} 1 & \text{if the term is appeared in } TL_{year}, \\ 0 & \text{otherwise,} \end{cases} \tag{2}$$

where $N_{TL_{year}}$ is the number of terms in the term list TL_{year}.

Step 4 Till all texts are converted, repeat Step 1 to 3.

A SVM based classification system is constructed by using the feature vectors as a training data set.

B. Discussion

In this subsection, we show some experimental results and problems for the unseen nursing-care text classification. The nursing-care classification system has been developed to classify the nursing-care text automatically. That is, in actual use, the classification system is constructed by using the last year's data set. The constructed classification system classifies the current year's data. We constructed the SVM based classification system by using 2008 nursing-care data (15 kinds of data sets). Table I shows the classification results when the 10-fold cross validation (10CV) was used on the training data set. We can see that we have good results even when the 10CV was used. This means that the SVM based classification system has good classification performance on the testing data set.

TABLE I
Classification results on the 2008 data (10CV)

Data Index	# of correctly classified patterns
P123	329/569 (57.8%)
P131	361/519 (69.6%)
P132	175/400 (43.8%)
P212	322/481 (66.9%)
P213	281/509 (55.2%)
P221	341/512 (66.6%)
P222	382/483 (79.1%)
P322	246/407 (60.4%)
P411	334/374 (89.3%)
P423	346/420 (82.4%)
P425	261/442 (59.0%)
P431	375/431 (87.0%)
P611	267/355 (75.2%)
P613	248/429 (57.8%)
P621	361/432 (83.6%)

TABLE II
Classification results on the 2009 data

Data Index	# of correctly classified patterns
P123	484/806 (60.0%)
P131	470/754 (62.3%)
P132	272/626 (43.5%)
P212	478/700 (68.3%)
P213	341/720 (47.4%)
P221	539/755 (71.4%)
P222	565/691 (81.8%)
P322	369/593 (62.2%)
P411	504/561 (89.8%)
P423	599/672 (89.1%)
P425	329/680 (48.4%)
P431	574/652 (88.0%)
P611	406/567 (71.6%)
P613	395/662 (59.7%)
P621	545/652 (83.6%)

On the other hand, Table II shows the classification results on the completely unseen data set (i.e., 2009 nursing-care data). From this table, we can see that there is classification performance deterioration on some data sets. Especially, P131, P213 and P425 have performance deterioration over 7%. We consider that this difference between the results on 2008 and 2009 data is caused by the following reasons.

1) There are some differences between TL_{08} and TL_{09}.
2) Expert's decision may be wavering every year.

Question P425
JPN: ＊＊さんの痛みの治療について医師にどのように働きかけていますか？＊＊さんにそのような状況がない場合は、違う事例や他の身体的苦痛に置き換えて考え、具体的にお答えください。
ENG: How did you work on the doctor about the medical treatment of your patient's pain? When your patient does not have such a situation, please transpose to different example and other physical pain, think, and answer concretely.

Class 4 (very good answers)
A1. JPN 牽引施行にて神経症状が悪化し疼痛も出現しているため、牽引の評価・中止を医師に提案・依頼。
ENG Since neurological symptoms got worse by traction enforcement and sharp pain has also appeared, I made a proposal and a request to my doctor, about evaluation and a stop of traction.
Morphological analysis 牽引/施行/にて/神経症/状/が/悪化/し/疼痛/も/出現/し/て/いる/ため/、/牽引/の/評価/・/中止/を/医師/に/提案/・/依頼/。
Feature vector JPN (牽引,施行,神経症,状,悪化,し,疼痛,出現,いる,評価,中止,医師,提案,依頼)
Feature vector ENG (Traction, enforcement, neurosis, state, getting worse, do, sharp pain, appear, is, evaluation, stop, doctor, proposal, request)

Class 3 (good answers)
A2. JPN: 現在の内服では疼痛は軽減しない。症状が憎悪しているのではないか。薬剤の増量か、薬剤の変更を医師に依頼する。
ENG: Sharp pain is not reduced in the present internal use. Is not the condition getting worse? I request my doctor to increase in quantity of a medicine or change a medicine.

Class 2 (almost good answers)
A3. JPN: 現在の鎮痛剤では、解熱せずに苦痛が軽減できていない。
ENG: In the present painkiller, fever is not alleviated and pain cannot be reduced.

Class 1 (bad answers)
A4. JPN: 今の鎮静剤でコントロールできているため医師に働きかけたことはない。
ENG: I have not worked on a doctor, since it is controllable with the present sedative.

A5. JPN: 特に行っていない。
ENG: I have not worked on a doctor.

Fig. 2. Examples of nursing-care texts and morphological analysis

TABLE III
DIFFERENCE BETWEEN TL_{08} AND TL_{09}

Data Index	# of terms appeared in both TL_{08} & TL_{09}	# of terms appeared in only TL_{09}
P131	489	405
P213	817	622
P425	583	599

We know the second reason is a very important problem which should be tackled. However let us assume that there is no wavering on expert's decision. In this paper, we consider only the first reason described above. We aim to reduce the differences between TL_{08} and TL_{09}, as much as possible.

Table III shows statistical information on the differences between TL_{08} and TL_{09} on P131, P213 and P425. From this table, we can see that almost 500 to 800 terms appeared in both TL. 400 to 600 terms appeared only in the TL_{09}. The features corresponding to these 400 to 600 terms in the 2009 nursing-care texts have no influence on classification, because such features were not used for training SVM based classification system.

Fig.3 shows classification results for the number of unknown terms which nursing-care texts contain. From this figure, it is shown that there is performance deterioration when the texts have two or more unknown terms. In Fig.3, classification performance of the case which has no unknown term is deteriorated from results of 10CV on the training data set. This means that the nursing-care text data set has some nature such as wavering on expert's decision.

IV. USING ADDITIONAL TERM INFORMATION FROM WEB

A simple technique is to use known terms in the term list which are most similar to the unknown terms. In order to consider that the unknown terms in the new data set (i.e., the evaluation data set which is different from the training data set) are approximately the same as the known terms, information from Web is used. We also have been considering using conceptual sets of terms. In this paper, we describe a technique of using information from Web.

A. Unknown terms

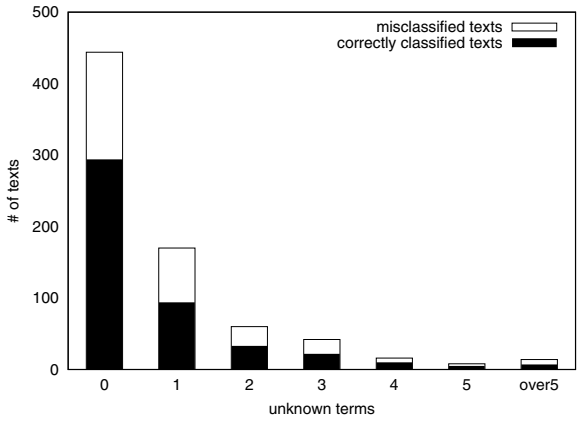
Here we define again the unknown terms as (3)-(5). The "unknown terms" are not stored terms in the term list.

$$KT_{last} = \{kt_i | kt_i \in TL_{last}, i = 1, 2, \cdots, N_{kt}\}, \quad (3)$$

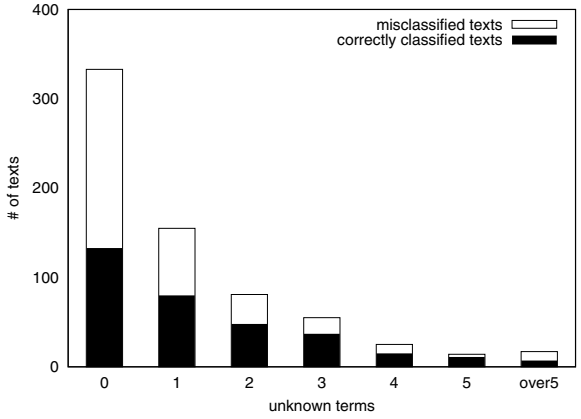
$$UT_{current} = \{ut_j | ut_j \notin TL_{last}, ut_j \in TL_{current}, j = 1, 2, \cdots, N_{ut}\}, \quad (4)$$

$$TL_{current} = KT_{last} + UT_{current}, \quad (5)$$

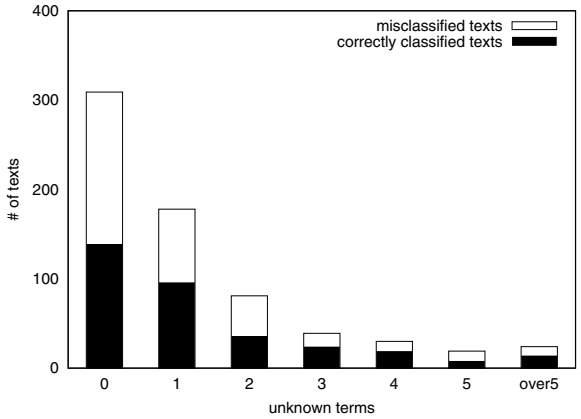
where kt_i is a known term, ut_j is an unknown term, KT_{last} is a known term set at the last year, and $UT_{current}$ is an unknown term set at the current year.



(a) P131



(b) P213



(c) P425

Fig. 3. Classification results for the number of unknown terms

B. Retrieving information from Web

When we use these unknown terms for classification the nursing-care texts, the information of similarity between unknown terms and known terms is needed. However, because there are only the nursing-care text sets of the last and current year, we have no additional information on the terms. In order to obtain information on the unknown terms, we try to retrieve information from the Internet. That is, each unknown term ut_j is used as a query to a search engine.

P best results (i.e., P pages of the search results) are used. The morphological analysis is applied to the texts in the <body> tag of the top P results. We extract nouns from the results of the morphological analysis. A set of nouns NS_{ut_j} for the unknown term ut_j is defined as,

$$NS_{ut_j} = \{noun_k | noun_k \in SR, k = 1, 2, \cdots, N_{\text{noun}}\}, \quad (6)$$

where SR is a noun set which is extracted from the set of search results. For selecting terms related to the unknown term ut_j, we consider the following three types of methods.

1) Frequency of terms: Then we count frequency of each noun in the search results. N_{FT} best nouns which are frequent terms are selected as the related terms.

$$FT_{ut_j} = \text{nbest}_n(\text{argmax}_{noun_k \in NS_{ut_j}} \ freq(noun_k)), \quad (7)$$

where $\text{nbest}_n()$ is a function which returns a subset of n-best solutions. In this paper, we use $n = 50$. On the known terms in the TL_{last}, we also apply the above mentioned procedure.

2) Weighted frequency by pages: When a $noun_k$ appeared several times in a single result, we consider the $noun_k$ is used in the specific situation. On the other hand, when a $noun_k$ appeared in some results, we consider the $noun_k$ has much relevance to the unknown term ut_j. (7) is modified by using the number of pages S in which the $noun_k$ appeared, as follows:

$$FT_{ut_j} = \text{nbest}_n(\text{argmax}_{noun_k \in NS_{ut_j}} \ freq(noun_k) \cdot S/N_{SP}), \quad (8)$$

where N_{SP} is the number of selected pages from search results. In this paper, we use $N_{SP} = 10$.

3) Weighted frequency by the distance: When a $noun_k$ appeared near the unknown term ut_j, we consider the $noun_k$ has some importance to represent the ut_j. Therefore, using the inverse of the distance between the ut_j and the $noun_k$, we modify (7) as follows:

$$dfreq(noun_k) = \sum_{p=1}^{P} \sum_{noun_k \in p} 1/D(ut_j, noun_k), \quad (9)$$

$$FT_{ut_j} = \text{nbest}_n(\text{argmax}_{noun_k \in NS_{ut_j}} \ dfreq(noun_k)), \quad (10)$$

where $D(ut_j, noun_k)$ is the distance between the ut_j and the $noun_k$, P is the number of pages of search results.

C. Selecting the similar term

Similarity between an unknown term and the known terms is measured using the cosine similarity $sim()$.

$$st_{ut_j} = \text{argmax}_{kt_l} \ sim(FT_{ut_j}, FT_{kt_l}). \quad (11)$$

A known term which has the highest similarity value to the unknown term is selected as the similar term of the unknown term.

TABLE IV
CLASSIFICATION RESULTS ON THE 2009 DATA BY USING PROPOSED THREE WEIGHTING SCHEMES

Data Index	Frequency	Weighted Frequency by pages	Weighted Frequency by the distance
P123	485/806 (60.2%)	484/806 (60.0%)	484/806 (60.0%)
P131	474/754 (62.9%)	483/754 (64.1%)	473/754 (62.7%)

P431	574/652 (88.0%)	574/652 (88.0%)	574/652 (88.0%)
P611	408/567 (72.0%)	408/567 (72.0%)	408/567 (72.0%)
P613	383/662 (57.9%)	384/662 (58.0%)	389/662 (58.8%)
P621	545/652 (83.6%)	545/652 (83.6%)	545/652 (83.6%)

V. EXPERIMENTAL RESULTS

In this section, computational experiments are described. 15 kinds of text sets collected in 2008 and 2009 were used for computer simulations. The 2008 nursing-care text sets were used for training. And the 2009 nursing-care text sets were used for testing. In the experiments, when a similar term selected by our proposed method has a similarity below the predefined arbitrary threshold value, we discarded it. It is because we consider that the terms with small similarity are not similar to the known terms.

Table IV shows the classification results on completely unseen data sets (i.e., 2009 nursing-care texts) when unknown terms are replaced by our proposed method. From experimental results, the classification performance was improved a little by our proposed method. Especially, the weighting schemes were effective over almost all data sets used in the experiments. However, since we have a slight performance improvement of classification, we have to advance our research.

VI. CONCLUSION

In this paper, to improve performance of the nursing-care text classification, a mechanism of retrieving terms from Web was proposed. The training data sets for constructing SVM based classification system are different from the evaluation data sets. That is, there are differences between the term lists of the nursing-care texts because the nursing-care texts are collected and evaluated every year. To cover the difference between the term lists of the nursing-care texts, a new term which appeared only in the evaluation data sets was used as a query of a search engine. The terms in the term list were also used as queries. Terms are represented by the search results from Web, and then are compared with each other. We used the most similar term in the term list as an alternative of the new term. From experimental results, the effectiveness of our proposed method was shown.

***Abstract*—Mosaic plasty is a surgery that transplant osteochondral grafts for osteochondritis dissecans. In mosaic plasty, cylindrical osteochondral grafts are harvested from normal area, and transplanted to injured area. The one of the most important thing of this surgery is that the graft should be perpendicular to the surface of the cartilage. The navigation system that aims improvement of precision is already studied, however cannot be applied to use an endoscope. In addition, it is a problem to have bad precision of the transplant in the freehand. Therefore, we thought that the system would widely used if we develop the mosaic plasty navigation system under an endoscope. This study proposes a navigation system to determine a proper position and pose for harvesting. In the experiments, a femoral imitation bone is used as a profile of the femoral joint surface. The experiment consists of the following three procedures: Trace and display of the femoral joint surface profile and a harvester. Display of a normal vector for the femoral joint surface. Measurement of the deviation of the normal vector. In the results, the developed system could display the femoral joint surface and the normal vector for the femoral joint surface virtually. Also, the deviation of the normal vector was an average of 7.27 degrees. As future works, there are to decrease the deviation of the normal vector by improving the precision to acquire the femoral joint surface profile, and to visualize the normal vector for the generated surface.**

I. INTRODUCTION

One of the treatment of the cartilage damages of the knee is mosaic plasty. The self cartilage transplantation method such as mosaic plasty requires precision in 3D. The navigation system that aims improvement of precision is already studied, however cannot be applied to use an endoscope. In addition, it is a problem to have bad precision of the transplant in the freehand. Therefore, we thought that the system would widely used if we develop the mosaic plasty navigation system under an endoscope. We propose a system to navigate a perpendicular transplantation with a three-dimensional electromagnetic sensor under an endoscope. The system requires to navigate with precision same as freehand. The matter evaluated with precision is the angle which a normal for the joint surface and the axis of articular cartilage which is harvested and a transplanted. In the precedent study, freehand was 10.7 degrees[1].

A. ARTICULAR CARTILAGE

The articular cartilage is covering joint surfaces, and has a role to smooth the joint move. When this articular cartilage suffers the damage, a pain occurs to the joint. For a cure for articular cartilage, drillings for the subchondral bone had been performed in 1957 by Pridie. However, that drilling restores not the hyaline cartilage but the fibro cartilage. Then, Matsue et al. [2] and Brittberg et al. [3] reported a reproduction of the articular cartilage with the hyaline cartilage.

B. MOSAIC PLASTY

A method of transplantation grafts to the femoral condyles in autologous osteochondral transplantation is named as "mosaic plasty" by Dr. Hangony, and an original surgical instrument was developed and spread out rapidly[4]. It is a transplantation surgery that a graft is harvested from a non-load part of the bone surface, and inserted to the cartilage defect as shown in Fig. 1.

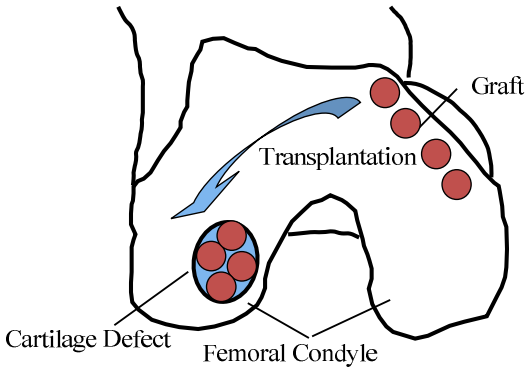

Figure 1. MOSAIC PLASTY

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

C. SURGERY PROCEDURE

For the procedure of this surgery, It consist of the four following procedures as shown in Fig. 2.

- Loose body of the cartilage defect is removed.
- The place of the cartilage defect is drilled to making a hole.
- A cartilage graft is harvested with a harvester.
- The harvested graft is inserted to the defect.

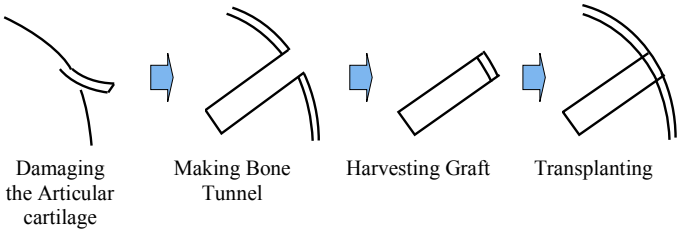

Figure 2. Surgery Procedure

D. THE PROBLEMS OF THE SURGERY

When a discontinuous surface is made after transplantation, there is a problem that it is easy to separate an articular cartilage from the bone surface. With a movement of the knee joint. It results in regenerating the cartilage defect. Therefore, it is important to harvest and transplant the cartilage graft vertically to the joint surface, so that the surface should be continuously.

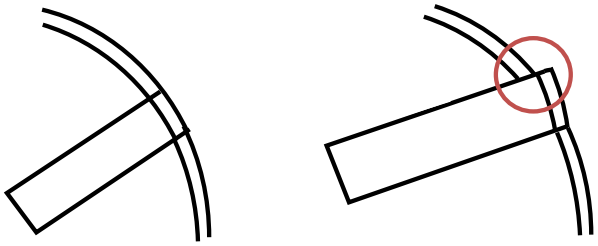

Figure 3. A proper and improper example of the transplant

II. MATERIALS AND METHODS

A. Electromagnetic Sensor

In this study, we perform the three-dimensional position and pose that we used electromagnetic sensor (Polhemus Inc., PATRIOT) as shown in Fig. 4 [5]. An electromagnetic sensor enables us to acquire data without being influenced by a physical obstacle. It is six degree of freedom measurements device consists of one transmitter, two receivers and a control unit. The precision of this device is 1.52 mm about the position 0.4 degree about the pose. This precision is guaranteed in 30 inches between a transmitter and receiver.

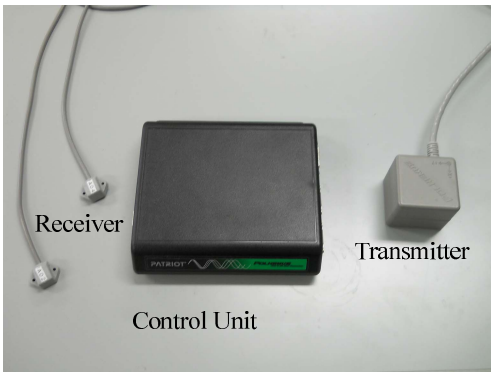

Figure 4. Electromagnetic sensor (PATRIOT)

B. Proposal Method

In this study, we use an electromagnetic sensor and propose a method to navigate the harvester which is perpendicular to the knee joint surface. The proposal method consists of three steps. The steps are A) Acquisition of the joint surface profile, B) Display of the joint surface profile and the harvester. C) Navigation of harvester.

1) Acquisition of the joint surface profile

A tracer whose tip has a force sensor is used to acquire a profit of the femoral joint surface. The receiver is attached to the tracer to obtain three-dimensional information. The joint surface is obtained by tracing the profile of the joint surface as shown in Fig. 5.

Here, to obtain information of the tip of the tracer , it is necessary to calibrate the position and pose of the sensor. Information of L_1 and L_2, that is relative position from the sensor to the tip of the tracer is known beforehand as shown in Fig. 6. In addition, Fig. 7 shows a relationship between the center of the sensor and the tip of the tracer which is determined by pose parameters of Ψ, Θ, and Φ. And positional informations of the sensor in it self are x, y, z.

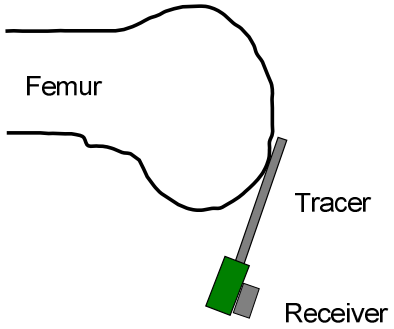

Figure 5. Tracer

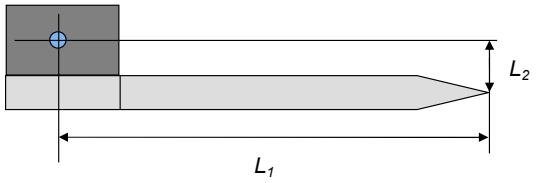

Figure 6. The distance between center of the sensor to the tip of the tracer

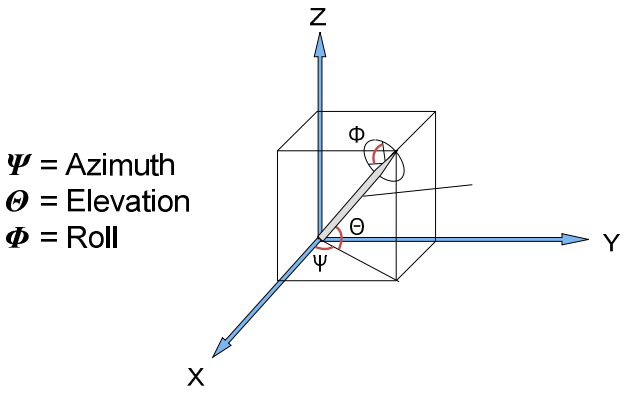

Figure 7. The pose between the center of the sensor to the tip of the tracer

The calibration is performed with the following equation,

$$x = L_1 \cos\psi\cos\theta + L_2(\sin\psi\sin\phi + \cos\phi\sin\theta\cos\phi)$$

$$y = L_1 \sin\psi\cos\theta + L_2(-\cos\psi\sin\phi + \sin\phi\sin\theta\cos\phi)$$

$$z = -L_1 \sin\theta + L_2 \cos\theta\cos\psi$$

2) Display of joint surface profile and harvester

The electromagnetic sensor is attached to the harvester which is a surgical instrument during the graft harvesting. The profile of the acquired femoral joint surface and the developed harvester are virtually visualized in a three-dimensional space on the computer.

a) Creation of virtual a joint surface profile

The information acquired using the tracer is displayed as points.Therefore a joint surface profile should be virtually created from the points.The reasons to create surface are the following things. It is easy to understand the femur profile rather than points. It shows a proper position and pose which is perpendicular to the knee joint surface. In this study, the marching cube method[6] was used to create the joint surface from the points. In the method, a data set should be three-dimensional volume data. Therefore, the collected points are approximated to the nearest points as vertexes of cube lattice of a size set beforehand as shown in Fig. 8. Vertexes *i*, *j*, *k* are set on axes *x*, *y*, *z* respectively. When a point is less than the midpoint of a distance between two vertexes, the point is set to be *i*, *j*, or *k*. In otherwise, the point is set to be *i*+1, *j*+1 or *k*+1 as shown in Fig. 9. In that process, when a point exists, it is set to be one. When no point exists, it is set to be zero. This time, to be used Marching cube method[6] as a way to create surface from point.

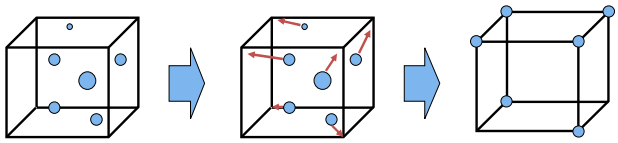

Figure 8. Similar to the vertex of the cube lattice

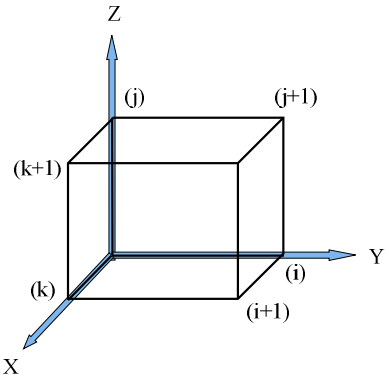

Figure 9. Approximate method to the vertex of the cube lattice

3) Navigation of harvester

The computer navigates a surgeon to hold the harvester at a proper position and pose in real-time the harvester is perpendicular to the bone surface as shown in Fig. 10.

The algorithm to display the normal vector devises the following. On real femoral joint surface, pointing the place that wants to let you display the normal vector in harvester. Existing points on a spherical surface of a radius of 10 mm around the tip of the tracer are selected as shown in Fig. 11 and Fig. 12. A spherical surface is shown as a brown line. Then points on the surface are shown as red points. Next, three points are extracted from the red points so that the three points close to be a equilateral triangle as shown in Fig. 13. Last, a normal vector could be calculated from the extracted three points, and the normal vector and the femoral joint surface are displayed simultaneously.

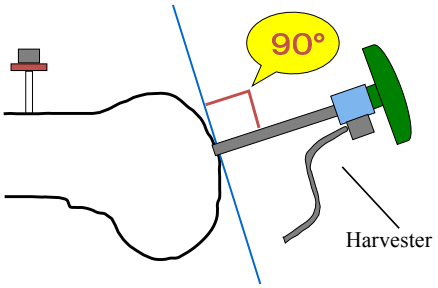

Figure 10. Navigation of harvester

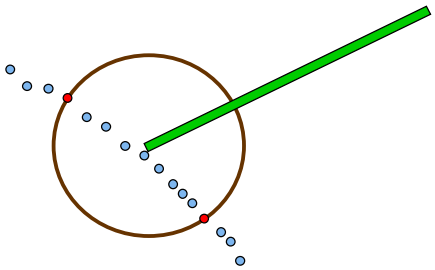

Figure 11. Normal vector indication algorithm (lateral viewpoint)

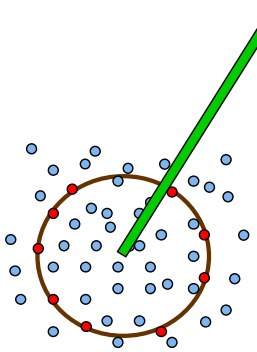

Figure 12. Normal vector indication algorithm (anterioris viewpoint)

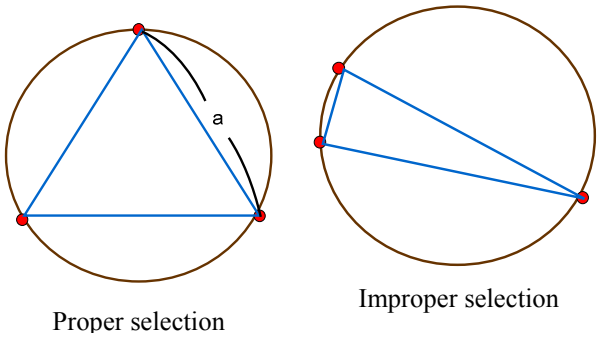

Figure 13. Three points of how to get to choose among the point

C. EXPERIMENTS

1) Display of the joint surface profile

In this experiment, the femoral sawbone is used as the shape of joint surface as shown in Fig. 14. As position and pose information is also required for sawbone, the titanium pins are inserted to the femoral sawbone approximately 80 mm in the proximal from the knee joint line, then the sensor is fixed to the pins with an attachment. Actual measurement scene is shown in Fig. 15.

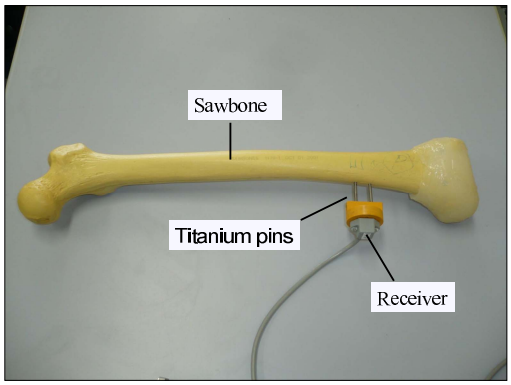

Figure 14. Femoral sawbone

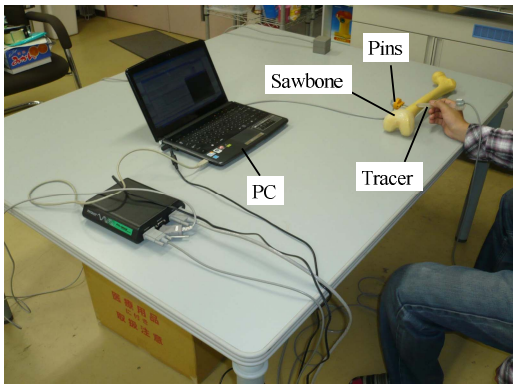

Figure 15. Measurement scene

2) Display of the normal vector for the knee surface

A place where the tip of the tracer is indicated is calculated on the computer. A normal vector which is located at the calculated position, and is perpendicular to the bone surface is analysed. The normal vector is displayed on the three-dimensional space as shown in Fig.16.

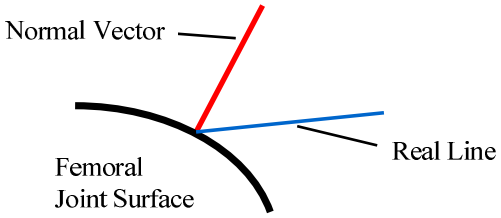

Figure 16. Normal vector

3) Measurement of deviation of the normal vector

In this experiment, we measure deviation of the normal vector. The deviation is calculated as the maximum angle between two poses of the normal vector when we keep pointing for 5 seconds to arbitrary point on the joint surface in same pose as shown in Fig. 17. The number of the measurement places is ten points at arbitrary position on the joint surface in same pose. To investigate the cause of the normal vector swing, we examine the position error of the tip of the tracer at the same time.

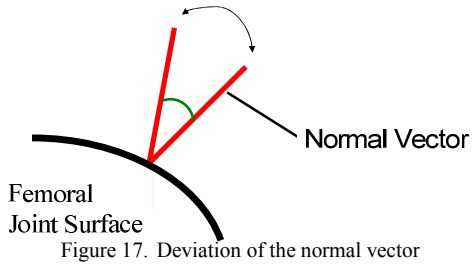

Figure 17. Deviation of the normal vector

III. RESULTS

A. Display of the joint surface profile

The obtained profile of joint surface is shown in Fig. 18. The figure is a result in the viewpoint from the frontal of the femur. Virtual display was realized by the proposal method.

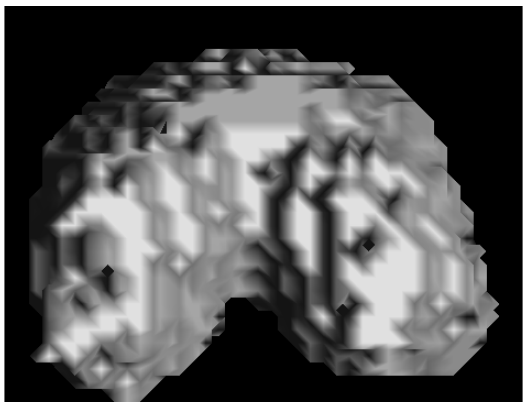

Figure 18. The acquisition of the joint surface profile

B. Display of the normal vector for the knee surface

A result of display of the normal vector is shown in Fig. 19. The figure is a viewpoint from the outside of the femur. In this figure, two lines show the normal vector for the joint surface and the real harvester. The harvester could be navigated as perpendicular to the bone surface by adjusting the pose of the harvester so that they overlap these two lines as shown in Fig. 20.

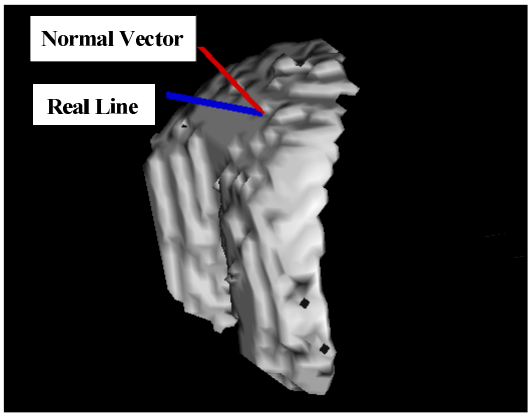

Figure 19. Display of the normal vector and the harvester

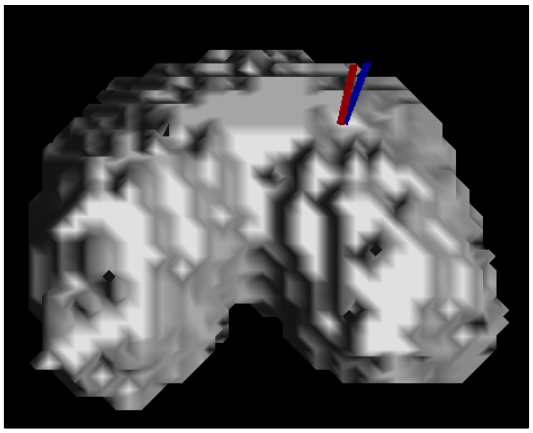

Figure 20. An example of overlap

C. Measurement of deviation of the normal vector

The result of deviation measurement of the normal vector is shown in TABLE I. From the results, the average of pose deviation of the normal vector was 7.27 degrees. The standard deviation was 3.29 degrees. The average of the position error was 0.0031 mm, the standard error was 0.001 mm. From the above, they have no association to deviation measurement of the normal vector and measurement of the position error.

TABLE I. MEASUREMENT OF THE POSITION ERROR AND MEASUREMENT POSE DEVIATION OF THE NORMAL VECTOR.

Place	*Position (mm)*	*Pose (degree)*
1	**0.00305**	**1.7819**
2	**0.00247**	**8.269**
3	**0.00352**	**12.9373**
4	**0.00531**	**10.8232**
5	**0.00236**	**6.0446**
6	**0.00328**	**4.4925**
7	**0.00234**	**4.7907**
8	**0.00211**	**6.1175**

mean	**0.0031**	**7.27**

IV. DISCUSSION

Firstly, we developed the mosaic plasty navigation. In the experiment, we installed a sensor to a tracer and a femoral sawbone. We were able to display the normal vector in this time, it was developed that there was some deviation on the normal vector. It might be influence of the position error to make a deviation. However it is difficult to be decrease the error of the position, because the current value 0.0031 mm is too small to improve. However, the pose error is too large, then it showed be improved before applying a clinical situation.

In this study, the problem of this proposal method is that the extracted three points are affected by the position error of a sensor. To solve this problem, we should examine the changing algorithm to calculate a normal vector. One of the solution is to calculate the normal vector from the surface of the profile. By doing so, we reduce the deviation of the position and pose error.

V. CONCLUSION

In this study, we developed the mosaic plasty navigation system that we used an electromagnetic sensor. We traced the femoral sawbone and tried the acquisition of the femoral joint surface and the display of the normal vector. As a result, we were able to display the femoral sawbone joint surface and the normal vector, and the deviation of the normal vector was an average of 7.27 degrees.

Future works are to depress the deviation of the normal vector, to enable automatic acquisition of the femoral joint surface by the tracer with a force sensor, and to improve the position and pose precisions of the system.

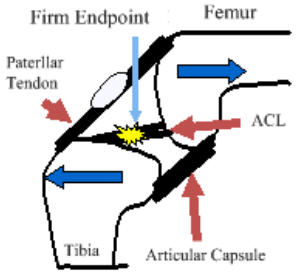
***Abstract*—Lachman test is one of manual tests for examining the anterior cruciate ligament (ACL). An examiner discreminates an injured degree of the ACL by feeling finger stress. Some measurement devices for Lachman test have been developed. However, these devices aim to analyze not the stress but a motion of the knee joint. Therefore, we set the goal of this study to develop a measurement system for the finger stress with force sensor during Lachman test. In the experiment, the developed system was applied to twelve healthy knees of six subjects by a beginner, and one injured and one healthy knee of two subjects by an expert. In the results, the maximum force of "endpoint" during Lachman test was analyzed. The variation of inter-subjects was larger than intra-subjects. Future works are to improve the finger force sensors, and to apply more subjects, so that the system could classify an examiner into a skill level.**

Keywords-Lachman test, Force Sensor, Anterior Cruciate Ligament, Manual test

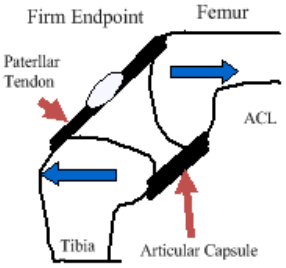
I. INTRODUCTION

Lachman test is a manual test used for examining the Anterior Cruciate Ligament (ACL) of the knee for patients where there is a suspicion of a torn ACL. The Lachman test is recognized by most authorities as the most reliable and sensitive clinical test for the determination of ACL integrity, superior to the Anterior Drawer test commonly used in the past. To do this, lay the patient supine on an examination table. Put the patient's knee in about 20-30 degrees flexion, also according to Bates' Guide to Physical Examination the leg should be externally rotated [1]. The examiner should place one hand behind the tibia and the other on the patient's thigh. It is important that the examiner's thumb be on the tibial tuberosity. On pulling anteriorly on the tibia, an intact ACL should prevent forward translational movement of the tibia on the femur ("firm endpoint") as shown in Fig. 1. Anterior translation of the tibia associated with a soft or a mushy endpoint indicates a positive test. More than about 2 mm of anterior translation compared to the uninvolved knee suggests a torn ACL ("soft endpoint"), as does 10 mm of total anterior translation. An instrument called a "KT-1000" can be used to determine the magnitude of movement in mm [2-4]. "KT-1000" was not to be used as a device to measure the injured ACL [5]. This test can be done in an on the field evaluation in an acute injury setting, or in a clinical setting when a patient presents with knee pain. In either situation, ruling out fracture is important in the evaluation process. Also when evaluating the integrity of the ACL, it is important to test the integrity of the Medial Collateral Ligament (MCL), because this is a common ligament torn in an ACL injury as well. Some studies have reported the stress during Lachman test [6], however, they could not obtain the force data dynamically.

In previous studies, quantitative measurement of Pivot Shift test by three-dimensional electromagnetic sensors have been made [7, 8]. A quantitative force measurement of fingers of examiner during Lachman test has not been developed. This study set the goal to develop a quantitative measurement system of Lachman test with force sensors. The system could enable us to analyze a mechanism of the "endpoint" that indicates an injured degree of the ACL. This study explains mainly the principle of the measurement system. In the experiment, the developed system was applied to twelve healthy knees of six subjects. In the results, the maximum force of "endpoint" during Lachman test was analyzed. The variation of inter-subjects was larger than intra-subjects.



(a) Firm Endpoint



(b) Soft Endpoint

Figure 1. Endpoint

II. METHOD

A. Force Sensor

A force sensor is made by using conductive rubber (sili-us Fuso Gomu Co. Ltd.). Thickness of this rubber is 0.05mm. The rubber is cut as dimensions of 6.0 (mm) x 7.0 (mm) x 0.05 (mm). Then, a set of pattern for the sensor is made by using an extension board (ICB-075 san-hayato Co. Ltd.) which has cupper foils over the entire surface. This process is made use of thermal transfer printing method.

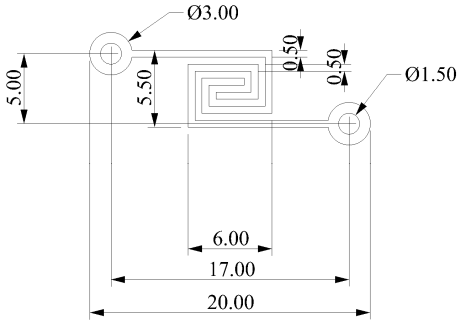


Figure 2. Design

Next, the rubber and copper foils are fixed by a laminating machine (LPD3213, Fujipura Co. Ltd.). Then, a profile of this sensor is modified as a bending shape by using a thermal heating device (EH-NW80-K, Panasonic Co. Ltd.) as shown in Fig. 3.

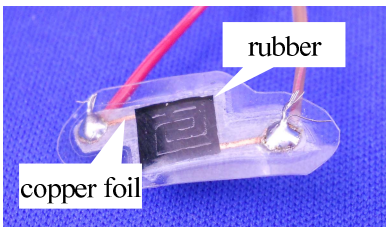

Figure 3. Real Sensor

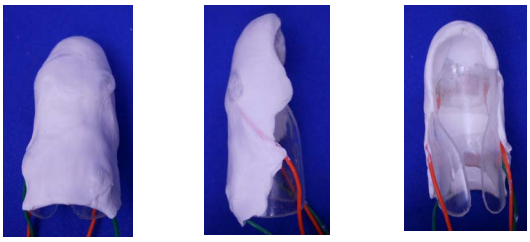
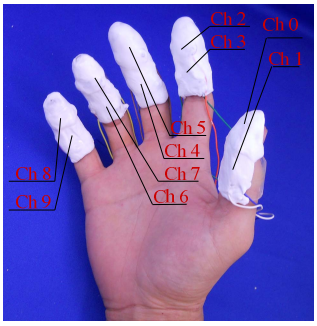
A finger brace (Sawamura prosthetics and orthotics service Co. Ltd.) is used for fixing the force sensors to fingers. Then, the force sensor is pasted double-sided tape (NW-10S, Nichiban Co. Ltd.) on the surface of the board. Two sensors are attached to one finger brace. The finger brace is molded by using thermoplastic (JJ-210, Daicel Finechem Co. Ltd.). In this study, the attached sensor is called as "Finger Force Sensor" as shown in Fig. 4.



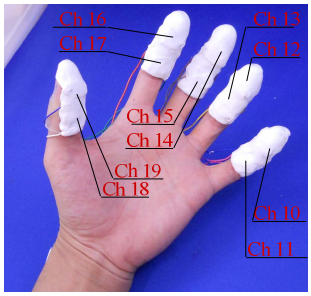
(a) Front (b) Left (c) Rear

Figure 4. Finger Force Sensor

This measurement system has ten finger force sensors. All the finger force sensors are attached to all fingers tightly. The channels number of thumb of right hand are Ch 0 and Ch 1. A channel number is allocated to sensors of right hand from thumb in order. The sensors of the little finger of the left hand are numbered as Ch 10 and Ch 11. Next channels are allocated to left thumb in order as shown in Fig. 5.



(a) Right hand



(b) Left hand

Figure 5. Finger Force Sensors

B. Measurement Circuit

1) Two Gauges Method

Sensor making use of a variable resistance as this force sensor is energy control type. Sensor of energy control type is easily affected by temperature. In this study, for guarantee of temperature two gauges method was used. This method used two sensors for one measurement as shown in Fig. 6. One of the sensors was for measurement, the another one was dummy. A measurement system measures a difference of a

measurement sensor and a dummy sensor. The measurement sensor and the dummy sensor are placed as same temperature, so that influence of temperature is same as both sensors. Thus, this system could measure without influence of any temperature.

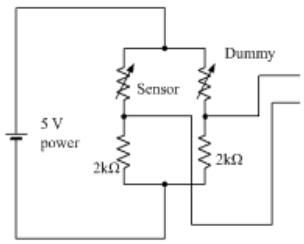


Figure 6. Two Gauges Method

2) Differential Amplifier Circuit

A differential value of the measurement sensor and the dummy sensor is small. A change of the differential value is more small. It is difficult to measure the real value due to a noise. Therefore, the differential value should be amplified. This measurement circuit has a differential amplifier circuits used by an operational amplifier (Fig. 7).

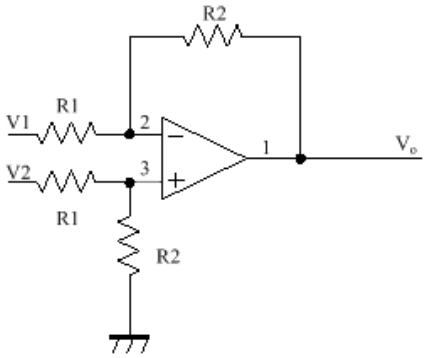

Figure 7. Differential Amplifier

The output value of this differential amplifier is

$$V_o = \frac{R_2}{R_1}(V_2 - V_1). \quad (1)$$

In this measurement circuit,

$$R_1 = 1.0 \times 10^3. \quad (2)$$

The R_2 is a variable resistance. A resistance of sensors is deviated for each sensors. Then, the resistance is adjusted so that the deviation should be controlled. In this study, a deviation of differential voltage is controled by using a factor R_2 which is a variable resistance. However, two resistances of R_2 are necessary for one measurement sensor. To control for two normal variable resistances is difficult, because values of two variable resistances must be same. In this study, control of deviation of differential voltage is used double volume resistance (RV16A01F-10-20S-B100KΩ, Aicoh electronics Co. Ltd.) as shown in Fig. 8.

Figure 8. Double Volume Resistance

C. Measurement System

A measurement system consists of a personal computer, an analog / digital (AD) converter, and finger force sensors. The A/D converter is AIO-16320FX-USB (CONTEC Co. Ltd.)(Fig. 9). This converter could connect by using USB. The data sampling is 1 [kHz]. The input range is from -10 to 10 V. The resolution is 16 bits (Table I).

Figure 9. A/D converter

TABLE I. SPECIFICATION OF A/D CONVERTER

Communication Bus	USB
Faculty	Input , output
Input ch num	Single end 32 ch（differential 16 ch）
Input range	±10 V， ±5 V， ±2.5 V， 0～10 V， 0～5 V， 0～2.5 V
Output ch num	2 ch
Output range	±10 V， ±5 V， ±2.5 V， ±1.25 V， 0～10 V， 0～5 V， 0～2.5 V
resolution	16 bit
A/D convert speed	2 μsec/ch(max.)
D/A convert speed	10 μsec(max.)

This measurement circuit is in aluminium case. In this circuit, there are a power supply, a circuit of power supply, a circuit for sensors, a circuit for differential amplifier (for right hand) and a circuit for differential amplifier (for left hand) as shown in Fig. 10. In this circuit of power supply, there are 5 [V] power supply for sensor and -15 [V] and 15 [V] power supply for operational amplifier. First, an analog amplified signal is converted to a digital signal by the A/D converter, the

digital signal is sent to personal computer by the universal serial bus. Finally, the voltage data is converted to load data by a program.

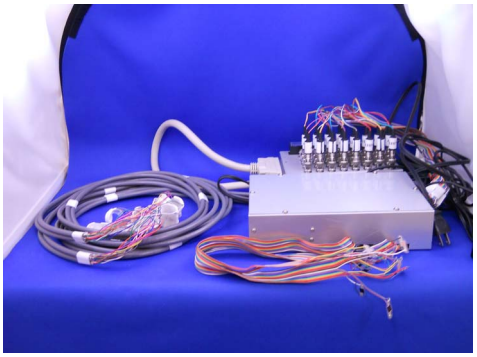

Figure 10. Measurement System

III. EXPERIMENT

A. Calibration Experiment

This system should calibrate before measuring the load data. A mechanical testing device is developed by using an electroactuation (PWA II Cyllinder, Orientalmotor Co., Ltd.), a load cell (Thin type load cell (multi-force sensor), Kyowa Electronic Instruments Co., Ltd) as shown in Fig. 11. Specification of the electroactuation is tabulated in Table II.

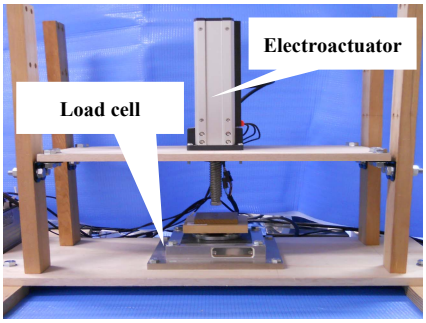

Figure 11. Mechanical testing Device

TABLE II. SPECIFICATION OF ELECTROACTUATION

Stroke (mm)	Maximum Load (N)	Resolution (mm)
100	1000	0.01

Calibration is performed for the force sensors beforehand (Fig. 12.) A plastic lump is inserted to each finger force sensor as shown in Fig. 12. Because the finger brace will be bent so that the calibration value is not measured well, if the calibration is performed without the plastic lump. These finger force sensors are calibrated at loads of 20 N, 40 N, 60N, 80 N, 100 N, 120 N, 140 N, 160 N, 180 N and 200 N. The load is vertically applied for surface of the finger force sensor. The tip of the stick of this electroactuator set to be placed the center of the conductive rubber of the sensor. On characteristic of the conductive rubber, the voltage values are measured at a few seconds later when the load had be steady condition. In this experiment, steady values are used for the calibration data .

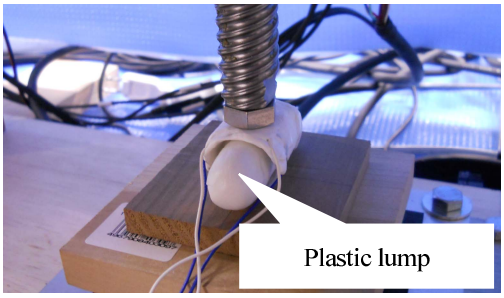

Figure 12. Calibration Scene

B. Manual test Experiment

1) Measurement by a beginner

Twelve knees joint of a subject (Table III) are observed by using the developed system. #2 and #6 in subjects had a injured knee except for the ACL. Lachman test is applied for the knee five times as usual manner. This Lachman test is expected as the finger of the right second finger, the right third finger and the left thumb are loaded. Other fingers are supported. Then, force distribution of the finger force sensors are analyzed when the maximum and minimum forces are detected. Data of 5 times of Lachman test in right and left knees of one subject are evaluated at student t-test (significance,$P \leq 0.01$).

Figure 13. Manual test Scene

TABLE III. SUBJECT INFORMATION BY A BEGINNER

Num	Sex	Height [cm]	Weight [kg]	Knee	Condition	History
#1	Male	174	66	Left	Intact	No
				Right	Intact	No
#2	Male	175	73	Left	Intact	Yes
				Right	Intact	No
#3	Male	170	78	Left	Intact	No
				Right	Intact	No
#4	Male	175	63	Left	Intact	No
				Right	Intact	No
#5	Male	163	70	Left	Intact	No
				Right	Intact	No
#6	Male	167	66	Left	Intact	Yes
				Right	Intact	No

2) Measurement by an expert

Two knees joint of a subject (TABLE IV) were observed by using the developed system. This measurement was observed by an expert who was an orthopedic surgeon in familier with Lachman test. One knee of observed knees was the injured ACL. These observed data were compared.

TABLE IV. SUBJECT INFORMATION BY A EXPERT

Num	Sex	Height [cm]	Weight [kg]	Knee	Condition	History
#1	Female			Right	Injured	No
#2	Male	168	70	Right	Intact	No

IV. RESULTS

A. Calibration Experiment

In this measurement circuit, the voltage is increased with loading, because the relationship of the voltage and the resistance has an inverse proportion. In Fig. 14, all the sensor show the relationship of the voltage and the load. This result is used for calculation of the force applied to the finger force sensors in the following experiment.

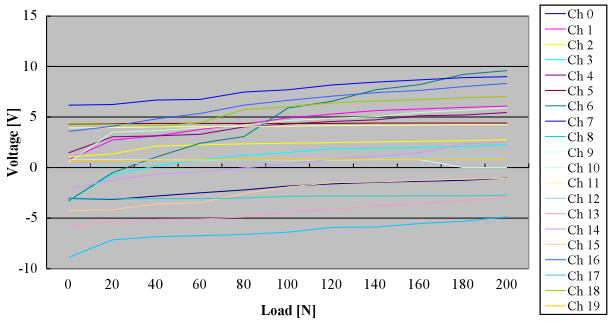

Figure 14. Result of Calibration

B. Manual test Experiment

1) Measurement of the beginner

A force changes of time course measured in the experiment is shown in Fig. 15. In this figure, only specific Chs are shown so that it is easy to understand the change. This change is dipicted as one time anterior motion of the knee. In the end period, comparatively higher force was observed. It is considered as "endpoint." The maximum force is analyzed among each trial. In the Lachman test, five endpoints were observed in one trial, because five anterior drawer motions were performed in one trial.

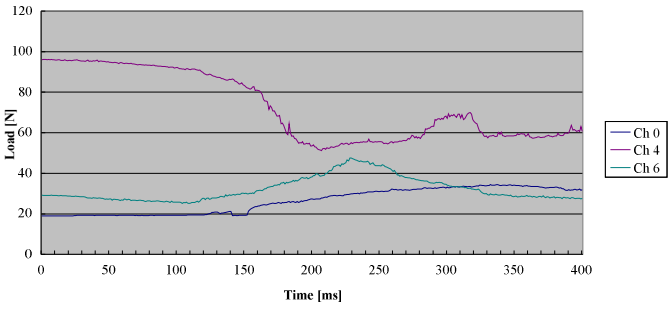

Figure 15. Result of Lachman test

The maximum forces of endpoints are shown in Fig. 16. In this figure, average and standard deviation are calculated in one trial. Then, the last column means averages of five trials. In this figure, The variation of inter-subjects was larger than intra-subjects. In the result of t-test, both knees of #2 and #6 had significant differences.

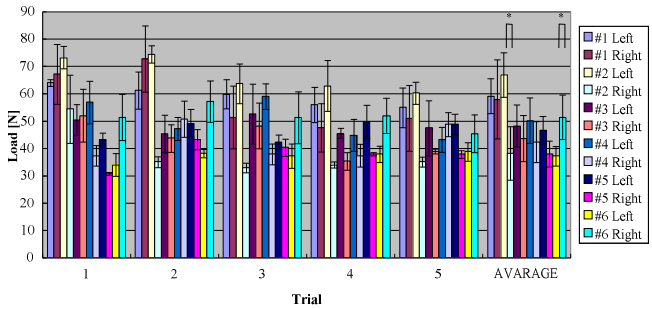

Figure 16. Result of Measured Force during Lachman test

2) Measurement of an expert

Two force changes of time course measured in the experiment are shown in Fig. 17 and Fig. 18. In this Fig.s, distinctive Chs (Ch4 and Ch5 are channels of the second finger of right hand, Ch 18 and Ch 19 are channels of the thumb of left hand) are picked up. In Fig. 17, the result of firm endpoint is shown. In this Fig., peak of Ch 5 is about 145[N]. In Fig. 18, the result of soft endpoint is shown. In this Fig., peak of Ch 5 is about 70[N]. During Lachman test, even if the ACL is injured or intact, a characteristic of left hand motion should be almost same. In fact, Ch 18 and Ch 19 of both of Fig. 17 and Fig. 18 are almost same. Thus, the result of Fig. 18 is regerded as a result of Soft endpoint.

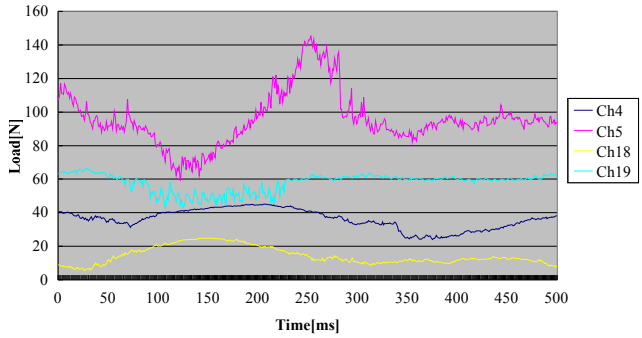

Figure 17. Result of Firm Endpoint

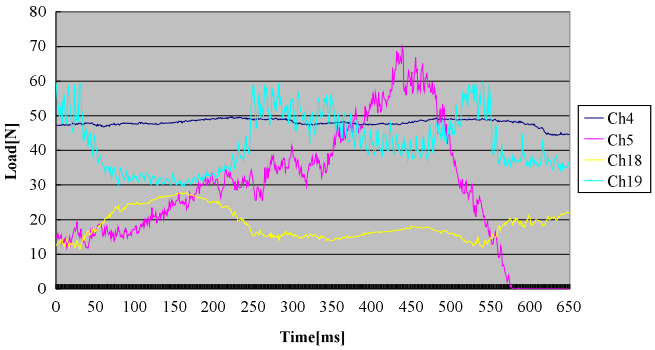

Figure 18. Result of Soft Endpoint

V. DISCUSSION

In the result of measured force during Lachman test by the beginner, both knees of #2 and #6 had significant differences. The difference was related to the injured knee except for the ACL. Both the injured knees of #2 and #6 were left knee. However the distinctive differential values were observed in in these knees. We thought a value of the injured knee was lower than the normal knee. The value of the injured knee of #6 was lower than the another knee. However #2 and #6 have a different tendency. In case of #2, subject was thought that he made his injured knee strong tension during Lachman test due to fear for the movement.

In the result of measured force during Lachman test by the expert, the difference was shown in the knee of the ACL injured knee. Because a knee in comparison with a injured knee was a normal knee of another person, a difference was seen in results. However although both of Ch 18 and Ch 19 were almost same, the largest load of Ch 5 became that the normal knee indicated twice loading of the injured knee. The difference was considered to be the difference of "soft endpoint" and "firm endpoint."

VI. CONCLUSION

This study aimed to develop a quantitative measurement system of endpoint during Lachman test using force sensor. The finger force sensor was made by attaching force sensors to finger braces. In the experiments, the developed system was applied to twelve healthy knees of six subjects. Forces of endpoints during Lachman test were analyzed. The variation of inter-subjects was larger than intra-subjects. Usually, the ACL injured knee had soft endpoint. In this experiment, the developed system showed both of firm and soft endpoint. Future works are to improve the finger force sensors, and to apply more subjects, so that the system could classify an examiner into a skill level.

***Abstract*—This paper discusses measurement methods of human behaviors based on sensor network and human interaction of rehabilitation using robot partners. First, we explain robot partners and sensor networks for rehabilitation. Next, we apply a steady-state genetic algorithm to extract human motions from 3D distance image. Finally, we discuss the effectiveness of the proposed methods through several experimental results.**

Keywords-component; Rehabilitation, Human Motion Tracking, Sensor Networks, Robot Partners, Evolutionary Computation

I. INTRODUCTION

Recently, as the increase of number of elderly people, much more caregivers are required for the support for them. The mental and physical care is very important in order to avoid the progress of dementia of elderly people living alone in home, but such people have little chances to talk with other people and to perform daily exercise. On the other hand, the number of patients of brain damage is also increasing. The cognitive therapeutic exercise is useful in the rehabilitation after brain damage [1]. In the cognitive rehabilitation, before the actual motions, a patient pays attention to the cognitive cycle of the pre-planning of actual motions and the prediction of sensing in the actual motion in order to recover the cognitive ability from perception to action. It takes much time and load for a therapist to observe and navigate the behaviors of a patient in the rehabilitation program. In the above discussion, the motion measurement, natural communication, and human-friendly interaction are very important and necessary for both elderly people and patients. Of course, it is really ideal that these roles should be done by human caregivers and therapists, but the number of caregivers and therapists is not enough in the current situation. The introduction of robot partners instead of people is one of possible solutions. Such a robot partner should understand human behaviors for natural communication with elderly people. However, it is also difficult for a robot partner to observe the human behaviors. Therefore, sensor network and portable sensing devices can be applied for observing and understanding human behaviors [2,3].

The emerging synthesis of information technology (IT), network technology (NT), and robot technology (RT) is one of the most promising approaches to realize a safe, secure, and comfortable society for the next generation [4]. NT can provide the robot with computational capabilities based on various types of information outside of robots. Actually the robot directly receives the environmental information through a local area network without the measurement by the robot itself [5,6]. Wireless sensor networks [7-9] realize to gather the huge data on environments. However, it is very difficult to store all of huge data in real time. Furthermore, some features should be extracted from the gathered data to obtain the required information. Therefore, intelligent technology is required in wireless sensor networks.

Intelligence technology and information technology have been discussed from various points of view. Information resources and the accessibility within an environment are essential for both people and robots. Therefore, the environment surrounding people and robots should have a structured platform for gathering, storing, transforming, and providing information. Such an environment is called informationally structured space [10,11] (Fig.1). The intelligent technology for the design and usage of the informationally structured space should be discussed from various points of view such as information gathering of real environment and cyber space, structuralization, visualization and display of the gathered information. The structuralization of informationally structured space realizes the quick update and access of valuable and useful information for people. It is very useful for both robots and people to easily access the information on real environments. The information is transformed into the useful form suitable to the features of robot partners and people. Furthermore, if the robot can share the environmental information with people, the communication with people might become very smooth and natural.

In this paper, we discuss the measurement method of human

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

motions in the informationally structured space including robot partners and sensing devices. First, we apply a steady-state genetic algorithm (SSGA) [12,13] to perform human hand motion tracking by using the time series of 3D distance image based on differential extraction. SSGA is one of evolutionary optimization methods using selection, mutation, and crossover operators [14]. The shape and size of a template is updated by SSGA in this study. Next, we show experimental results, and discuss the effectiveness of the proposed method.

This paper is organized as follows. Section 2 explains the robot partners, and discusses how to use robot partners for rehabilitation. Section 3 proposes methods of human detection and human hand motion extraction. Section 4 shows experimental results of the proposed method, and Section 5 summarizes the paper, and discusses the future vision of robot partners for rehabilitation.

II. INFORMATIONALLY STRUCTURED SPACE

A. Robot Partners

We can use three different types of robot partners from the interactive point of view (Fig.2). One is a physical robot partner. We can interact with the physical robot partner by using multi-modal communication like a human [15]. The next one is a pocket robot partner. The pocket robot partner has no mobile mechanism, but we can easily bring it everywhere and can interact with the robot partner by touch and physical interface. The last one is a virtual robot partner. The virtual robot partner is in the virtual space in the computer, but we can immerse into the virtual space, and interact with it through the virtual person or robot. The interaction style of these three types of robot partners is different, but they share the same personal database and interaction logs, and can interact with the person based on the same interaction rules independent from the style of interfaces.

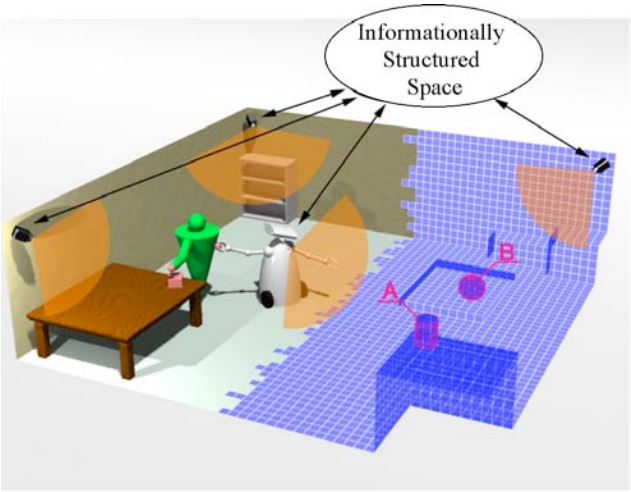

Figure 1. The concept of informationally structured space

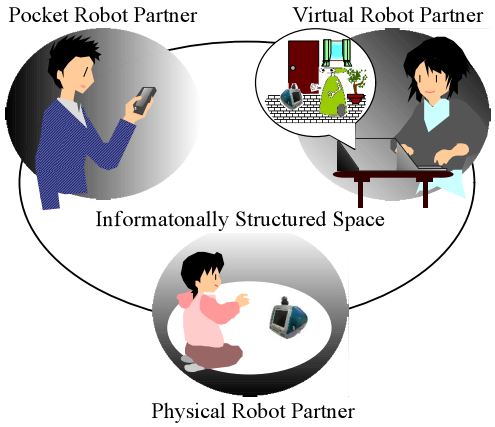

Figure 2. Interaction with robot partners

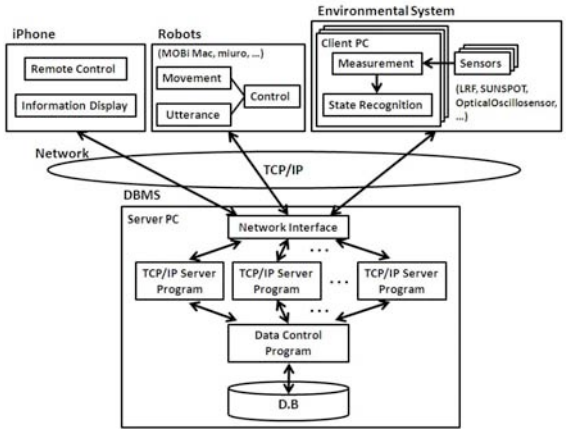

Figure 3. Data flow in informationally structured space

B. Data Flow in Informationally Structured Space

Figure 3 shows the data flow in the developed system based on informationally structured space. The developed system is divided into four components; (1) database management server, (2) robot systems, (3) environmental systems, and (4) human interface systems. The environmental system is based on a ubiquitous wireless sensor network composed of sensors equipped with wall, floor, ceiling, furniture, and home appliances. These sensors measure the environmental data and human motions. The measured data are transmitted to the database server, and then feature extraction is performed. Each robot can receive the environmental information from the database server, and serve as a partner to the person. Furthermore, the user interface device is used for the person to access the environmental information.

C. Rehabilitation Support in Informationally Structured Space

Figure 4 shows an example of rehabilitation support by a physical robot partner. A patient can perform the rehabilitation program through interaction with the robot. The robot can repeatedly show the behaviors demonstrated for the rehabilitation programs, and can observe behaviors of the

patience. The observed data can be useful and important information for the therapist to understand the state of rehabilitation, and to update the rehabilitation program. Furthermore, such a physical robot partner can avoid the progress of dementia of elderly people and urge daily routine exercises of the elderly people to make them maintain the physical and mental health.

Figure 6. Wireless accelerometer built in a building block

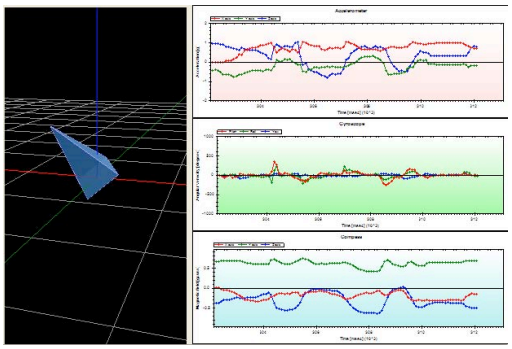

Figure 7. A measurement result of human hand motion

Next, we explain the sensor network devices. We use 3-axis accelerometer to measure the human hand posture of grasping blocks. Figure 5 shows the appearance of 3-axis accelerometer named IMU-Z developed by ZMP, Inc. [16]. The size of this device is 42[mm] x 52.5[mm] x 20.5[mm], but this device includes accelerometer, Jyro, electrical compass. The sampling interval is 10 [msec]. Furthermore, this device can be connected with PC through Bluetooth wireless communication. This device is built in a building block used for rehabilitation (Fig.6). Figure 7 shows a measurement result of posture of human grasping behavior of the block including the wireless sensor device. The experiment result shows the time-series of angle of X, Y, and Z axes. This shows the change of the posture according to the grasping behavior.

Figure 8. 3D distance image sensor of M Kinect sensor

TABLE I. SPECIFICATION OF KINECT SENSOR

Horizontal Field of View	57 degrees
Vertical Field of View	43 degrees
Physical Tilt Range	±27 degrees
Depth Sensor Range	1.2M – 3.5M
Number of Pixels	640 × 480

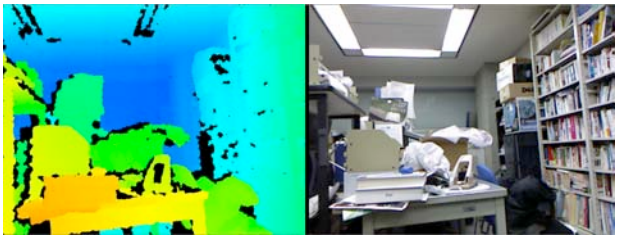

Figure 9. 3D distance image and color image

3D distance image sensor can measure the distance from the device like a camera in realtime. We use a Kinect sensor developed by Microsoft [17]. This device includes 3D distance image sensor, microphones, RGB camera, accelerometer, and tilting-up mechanism. This device can be connected with PC through USB. Table 1 shows the main specification of 3D distance image sensor. Figure 9 shows an example of the distance and color image measured by Kinect sensor.

Figure 10 shows an example of robot partner with Kinect sensor. The robot has three behavior modes of normal mode, interaction mode, and rehabilitation mode. In the normal mode, the behavior mode is transited to the interaction mode. Figure 11 shows an example of human interaction. In the normal mode, the kinect sensor is in the normal position (θ =0º) shown in Fig.11 (a). When a person approaches to a chair, the Kinect sensor is tilted up toward the human face (θ =27º) shown in Fig.11 (b). If the person tries to touch iPad built with the robot,

the robot supports the edges of iPad (Fig.11 (c). Finally, the behavior mode is transited to the normal mode after the person leaves the chair. In this way, the robot changes the behavior mode according to the human interaction.

Figure 10. A rehabilitation support system using a robot partner

III. HUMAN HAND MOTION TRACKING

A. Measurement by 3D Distance Image Sensor

We have proposed the concept of evolutionary robot vision based on the active vision and evolutionary search [15]. The time series of evolutionary search in dynamic environment is the most important in evolutionary robot vision. The structure of environmental changes is applied to the next visual search. We use a reliability space for human localization. The reliability space is built according to the temporal difference based on distance image. Figures 12 and 13 show the procedure of human hand motion extraction and an example of image processing, respectively. In the initialization, the long-term memory images of illumination and distance; $a^L_{i,j}$ is generated using the current images of distance, $a^C_{i,j}$ where i=$X_{\min}$, ..., $X_{\max}$ and j=$Y_{\min}$, ..., $Y_{\max}$. Furthermore, each value of the reliability space $b_{i,j}$ $\left(0 \le b_{i,j} \le 1\right)$ is initialized at 1. Next, the new images of illumination and distance are taken from the 3D distance image sensor. Figure 13 (a), (b), and (c) show the original images of distance, the result of edge detection, and the long-term memory images of distance, respectively. When a person enters into the view angle of the camera, we obtain the temporal difference images $d_{i,j}$ by the differential extraction between the current images and the long-term memory images in the following;

$$d_{i,j} = \left| a^C_{i,j} - a^L_{i,j} \right| \tag{1}$$

Next, the reliability space is updated in the following;

$$b_{i,j} \leftarrow \begin{cases} b_{i,j} - \alpha^B_1 & if\ d_{i,j} > \theta^B \\ b_{i,j} + \alpha^B_2 & otherwise \end{cases} \tag{2}$$

where $0 < \alpha^B_2 < \alpha^B_1 < 1$ and $\theta^B_k > 0$. The reliability of a pixel (i,j) decreases, as the temporal difference is large.

$$a^L_{i,j} \leftarrow \begin{cases} \left(1-\alpha^L_1\right) a^L_{i,j} + \alpha^L_1 \cdot a^C_{i,j} & if\ b_{i,j} > \theta^L \\ \left(1-\alpha^L_2\right) a^L_{i,j} + \alpha^L_2 \cdot a^C_{i,j} & otherwise \end{cases} \tag{3}$$

where $0 < \alpha^L_2 < \alpha^L_1 < 1$ and $0 < \theta^L < 1$. If the amount of the update of the long-term memory is large as the reliability is high. Next, we construct the search space, $c_{i,j}$ ($0 \le c_{i,j} \le 1$) by combining the temporal images of illumination and distance in the following weighted sum;

$$c_{i,j} = \alpha^S_1 \cdot d_{1,i,j} + \alpha^S_2 \cdot d_{2,i,j} \tag{4}$$

where $0 < \alpha^S_2, \alpha^S_1 < 1$.

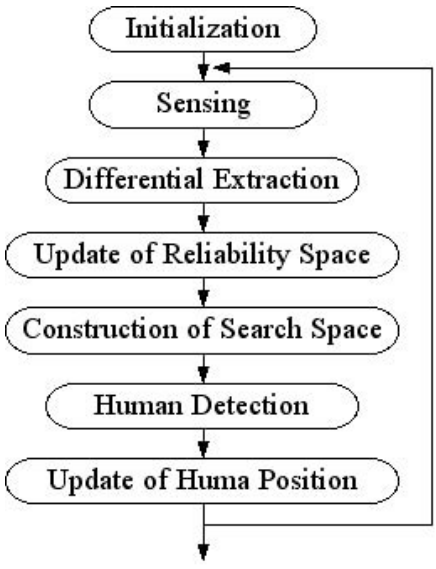

Figure 12. Procedure of human localization

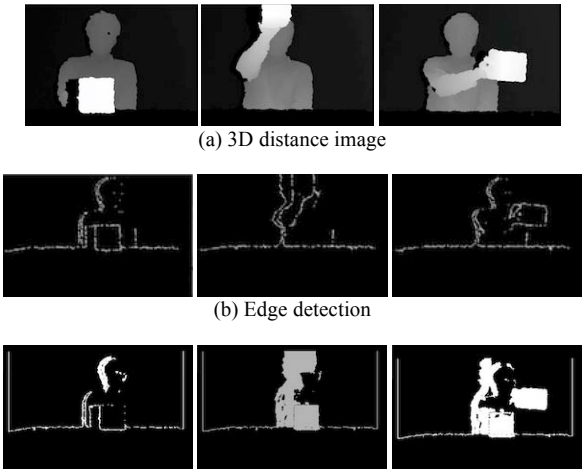

(a) 3D distance image

(b) Edge detection

(c) Differential Extraction with long term background image

Figure 13. Image processing based on distance data

B. Human Detection and Tracking

We use a steady-state genetic algorithm (SSGA) [12] based on template matching for extracting a human shape from the background image [12,13,18,19]. We assume that a person is moving in the image. Therefore, we use the search space constructed by the temporal difference. The shape of a candidate template is generated by the SSGA. We used an octagonal template. Figure 14 shows a candidate template used for detecting a target where the jth point $g_{i,j}^{O}$ of the ith template is represented by $(g_{i,1}^{O}+g_{i,j}^{O}\cos(g_{i,j+m}^{O}),\ g_{i,2}^{O}+g_{i,j}^{O}\sin(g_{i,j+m}^{O}))$, i=1, 2, ... , G^O, j=3, 4, ... , 2×m+2; O_i (=$(g_{i,1}^{O}, g_{i,2}^{O})$) is the center of a candidate template on the image; n and m are the number of candidate templates and the searching points used in a template (m=8), respectively. Therefore, a candidate template is composed of numerical parameters of $(g_{i,1}^{O}, g_{i,2}^{O},\ldots , g_{i,2m+2}^{O})$.

In SSGA, only few existing solutions are replaced with the candidate generated by genetic operators in each generation. In this paper, the worst candidate solution is eliminated ("Delete least fitness" selection), and it is replaced with the candidate solution generated by the crossover and mutation. The fitness value of kth is calculated by the following equation;

$$fit_i = \alpha_1 f_1 + \alpha_2 f_2 + \alpha_3 f_3 + \alpha_4 f_4 \qquad (5)$$

where f_1 indicates the number of pixels; f_2 indicates the evaluation value based on differential extraction; f_3 indicates the evaluation value on the degree of surface of the target building block; f_4 indicates the evaluation value of the movement of human hand; α_1 α_2 α_3 and α_4 are coefficients.

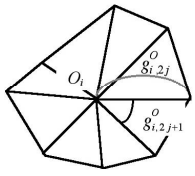

Figure 14. A template used for human detection in SSGA

We use an elitist crossover and an adaptive mutation. The elitist crossover randomly selects one individual and generates an individual by combining genetic information from the randomly selected individual and the best individual. If the crossover probability is satisfied, the elitist crossover is performed. Otherwise, a simple crossover is performed between two randomly selected individuals. Next, the following adaptive mutation is performed to the generated individual,

$$g_{i,j} \leftarrow g_{i,j} + \left(\beta_{1,j} \cdot \frac{f_{\max} - f_i}{f_{\max} - f_{\min}} + \beta_{2,j} \right) \cdot N(0,1) \qquad (6)$$

where f_i is the fitness value of the ith individual, f_{max} and f_{min} are the maximum and minimum of fitness values in the population; $N(0,1)$ indicates a normal random variable with a mean of zero and a variance of one; $\beta_{1,j}$ ($\beta_{1,j}$>0) and $\beta_{2,j}$ ($\beta_{2,j}$>0) are the coefficients and offset, respectively. In the adaptive mutation, the variance of the normal random number is relatively changed according to the fitness values of the population in case of maximization problems. Furthermore, we use k-means clustering algorithm to detect people, not a single person. The k-means is used for the clustering according to the distribution of the candidate solutions [18]. The genetic operators of selection and crossover are restricted within the subpopulation corresponding to the cluster as the result of the clustering. The candidate solutions are inherited and used in the next image. According to the evaluation based on the fitness function, some of candidate solutions are replaced with the randomly generated candidate solutions. In this way, the evolutionary search is performed to time series of 3D distance images.

The human hand motion tracking is performed according to the position of the mth candidate solution obtained by SSGA. The position of the hth human candidate in the human tracking, $(X_{h,1}^{H}, X_{h,2}^{H})$, is updated by the nearest human hand candidate position within the tracking range. The update is performed as follows (k=1, 2);

$$X_{h,k}^{H} \leftarrow (1-\alpha^{H}) X_{h,k}^{H} + \alpha^{H} \cdot \hat{x}_{m,k} \qquad (7)$$

where α^H is the update rate. The distance information $a_{i,j}^{C}$ of each pixel (i,j) is transformed into the position (x,y,z) = ($x_{1,i,j}$, $x_{2,i,j}$, $x_{3,i,j}$) in the Cartesian space. Therefore, the update amount $\hat{x}_{m,k}$ is obtained by the average of the position information of ($x_{1,i,j}$, $x_{2,i,j}$) of pixel (i,j) in the template of the mth candidate solution.

IV. Experimental Results

This section shows experimental results of the proposed method. The population size of SSGA is 100, and the number of iterations in the search is 200 per 3D distance image. The sampling interval of Kinect sensor is approximately 30 ms.

First of all, we show experimental results of human hand extraction and tracking of the triangular gesture of. Figure 15 shows the examples of the search result of the object

corresponding to human hand by SSGA. Figure 15 (a) shows the 3D distance image where the degree of gray depth indicates the distance from the 3D distance image sensor; (b) shows the result of differential extraction; and (c) hand detection and tracking results (t=10, 20, 30). The experimental results show that the proposed method can extract human hand position according to the size of the template and the distance from the distance image sensor.

Figure 15. A trajectory of human hand motion by human hand tracking (triangular gesture)

Figures 16 show the tracking results of human hand motions of a horizontal circular gesture. Figure 16 (a) shows the result of differential extraction; (c) hand detection and tracking results; and (c) the 3D distance image where the degree of gray depth indicates the distance from the 3D distance image sensor but the viewpoint is changed to the bird view from the person (t=10, 20, 30). Basically, it is very difficult to extract this gesture only by image processing, but the proposed method based on the distance image sensor can extract this complicated gesture. Furthermore, the transformed image of viewpoint from the person is very useful for a therapist to understand the hand motion of a patient.

V. SUMMARY

This paper developed a measurement system of human hand motion based on sensor network and robot partners for rehabilitation. First, we proposed the interaction system for a robot partner. Next, we applied a steady-state genetic algorithm to extract human hand motions from the 3D distance image. Experimental results show the effectiveness of the proposed methods. The obtained results are available for understanding and analysis of human hand motions.

As a future work, we intend to combine the voice recognition and visual perception to realize natural interaction of robot partners for rehabilitation. Furthermore, we use iPhone and iPod touch for cognitive rehabilitation therapy.

***Abstract*—Today elderly people are the fastest growing segment of the population in developed countries, and they desire to live as independently as possible. But independent lifestyles come with risks and challenges. Medical in-home telemonitoring (and, more generally, telemedicine) is a solution to deal with these challenges and to ensure that elderly people can live safely and independently in their own homes for as long as possible. In this context we propose an automatic in-home healthcare monitoring system for several uses and to meet the needs identified above. The proposed telemonitoring system is a multimodal platform with several sensors that can be installed at home and enables us to have a full and tightly controlled universe of data sets. It integrates elderly physiological and behavioral data, the acoustical environment of the elderly, environmental conditions and medical knowledge. Each modality is processed and analyzed by specific algorithms. A data fusion approach based on fuzzy logic with a set of rules directed by medical recommendations, is used to fuse the various subsystem outputs. This multimodal fusion increases the reliability of the whole system by detecting several distress situations. In fact this fusion approach takes into account temporary sensor malfunction and increases the system reliability and the robustness in the case of environmental disturbances or material limits (Battery, RF range, etc.). The Fuzzy logic fusion methods brings high flexibility to the telemonitoring platform especially in combining modalities or adding other sensors. The proposed telemonitoring system will ensure pervasive in-home health monitoring for elderly people.**

Keywords: fuzzy logic, fuzzy control, multimodal data fusion, telemedicine, healthcare telemonitoring.

I. Introduction

France's population continues to age significantly and a recent study carried out by the French national institute of statistic and economic studies (INSEE) shows a new distribution of age classes in France. In fact, almost one in three people will be over 60 years in 2050, against one in five in 2005, and France will have over 10 million of people over 75 years and over 4 million of people over 85 years. Therefore, the aging population and the increase in life expectancy have led to new models of aging where technology can play a role in monitoring the quality of life, by detecting or even predicting adverse events and hence supporting independence. Automatic in-home telemonitoring of distress situations has been a common focus in Gerontechnology [1] because medical telemonitoring at home, is an interesting solution compared to health facility institutions for the elderly, since it offers medical surveillance in a familiar atmosphere for the patient.

To address these issues, researchers are developing technologies to enhance a resident's safety and monitor health conditions using sensors and other devices. Numerous projects are carried out in the world especially in Europe, Asia and North America, on the home healthcare telemonitoring topic. They aim for example to define a generic architecture for such telemonitoring systems [2], to conduct experiment of a remote monitoring system on a specific category of patients [3] (Insufficient cardiac heart, asthma, diabets, patients with Alzheimer's disease, or cognitive impairement, etc.), or to build smart apartments [4], sensors and alarm systems adapted to the healthcare telemonitoring requirements [5].

However, little research exists to motivate and guide such technology. For example, most monitoring systems use some form of learning method to discriminate between different types of normal and abnormal events. These algorithms require large amounts of training data that can be dificult to obtain, especially data describing abnormal events that are by definition scarce occurrences. The most crucial issue for all these systems is the lack of experimental data and information representing many situations and several person profiles. Most of these systems also take into account only one modality, like medical sensors (Blood pressure, pulse, oxymeter) or localization sensors (Infrared or contacts) to survey patient. But among established medical remote systems, there are few commercial solutions and business models.

In this paper we present the use of the multimodal system called EMUTEM (Environnement Multimodal pour la Télévigilance Médicale) [6] for distress situations detection. The proposed system was evaluated on two data bases: one recorded by our self and another one recorded in an experimental house by elderly people. The platform developed within this framework research manages a system consisting of:

- A set of microphones placed in all rooms of the elderly's house, that allow remote monitoring of the acoustical environment of the elderly (Anason [7]).
- A wearable device called RFpat [8] that can measure physiological data like ambulatory pulse heart rate, detect posture (standing/ sitting and laying), fall of the equipped person and his activity rate.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

- A set of infrared sensors that detect the person's presence in a portion of a given home part, his posture and also his movement (Gardien [8]). Plus a set of domotic sensors like contact sensors, temperature sensors and several other domotic sensors for environment conditions monitoring.

Subsystem data streams have been separately processed with suitable algorithms for abnormal situations detection. In order to maximize correct classification performance between normal and distress situations, data fusion over the different sensors types is studied.

The originality of this research is the combination of various modalities in the home, about its inhabitant and their surroundings. The new multimodal data fusion approach based on fuzzy logic allows high flexibility for the EMUTEM platform especially in combining modalities or adding other sensors. It constitutes an interesting benefit and impact for the elderly person sufering from loneliness. This work complements the stationary smart home environment in bringing to bear its capability for integrative continuous observation and detection of critical situations.

II. The Telemonitoring System

We define a smart environment as one with the ability to adapt the environment to the inhabitants and meet the goals of comfort and efficiency. In order to achieve these goals, our first aim was focused on providing such as environment. We consider our system as an intelligent agent, which perceives the state of the environment by using sensors and acts consequently with device controllers.

A. Environment Sensing and Data Collection

The experimental area is a surface of $20m^2$ in our laboratory which is arranged in two rooms with a technical area in order to evaluate and to supervise experiments. The hardware framework is reported in Figure 1. It integrates smart sensors (Infrared, change state sensors, audio, physiological,) linked to a PC. Microphones for audio monitoring are linked to the PC through an external sound card (in order to allow good signal to noise ratio independent from the PC), and can be interpreted

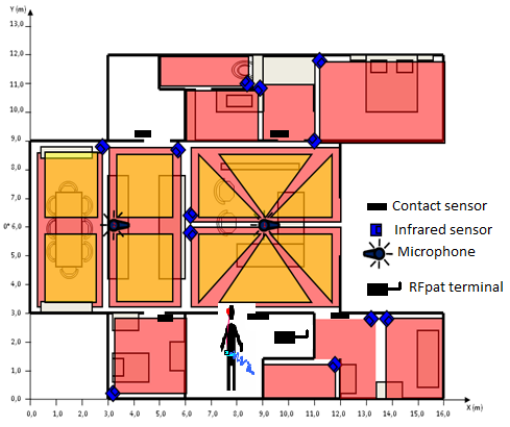

Fig. 1. In-home sensor disposal.

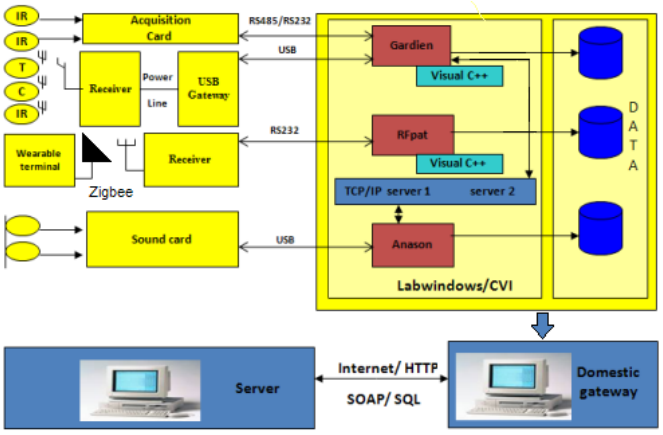

Fig. 2. EMUTEM software architecture.

as a single smart audio sensor achieved by Anason software. Infrared sensors are fixed on specific places of the house in walls and ceiling. They are in permanent communication via radio frequency communication, with one receiver, which is connected to the USB port of the PC. Change state sensors transmit also information to this receiver through radio frequency communication. The powerline is used to get back data from the receiver for software processing. The weareble device RFpat is caried by the elderly and continuously monitors his physiological data and emergency calls. It transmits these data to an indoor reception base station via ZigBee.

Figure 2 shows the software architecture of the multimodal platform EMUTEM. It provides a general user interface which encapsulates the Anason subsystem. It is implemented under LabWindows/CVI software and communicates with RFpat and Gardien sub-systems by a client-server model using TCP/IP and appropriate application protocols. Gardien is implemented in C++ and recovers data every 500 ms. RFpat is also implemented in C++ and receives data from a receiver every 30 s. The use of the inter-module communication through TCP/IP sockets allows each module (subsystem) to be run on a different computer, and to synchronize each telemonitoring modality channel.

The user can interact with the system via internet navigator and supervises the different applications. This feedback provides a significant help to the system manipulation and the system flexibility obtained through TCP/IP sockets communication allows adding other potential sensors such as a heart monitoring sensors (ECG). Data acquired from sensors are stored in the local computer directly as text files assigned to each modality. Data also could be exchanged using http or ftp protocol via web services technologies SOAP, and saved in a dedicated server.

III. Distress Situation Detection

Detecting and gathering data about the elderly person and his environment is the first step and one of the most fundamental tasks in building intelligent telemonitoring systems. With the increasing intelligence expectation, using multiple sensors

is the only way to obtain the required breadth of information, and fusing the outputs from these multiple sensors is often the only way to obtain the required depth of information when a single sensing modality is inadequate [9]. However, in our telemonitoring context different sensors use different physical principles, cover different information space, and generating data in different formats at different sampling rates. The obtained data have different resolution, accuracy, and reliability properties.

Based on those effects, the key to produce the required detection is to use the right method that properly fuses the provided data from various sources. This is what multimodal data fusion stands for. Therefore, typical multisensors data fusion methods are analyzed in this section, in seeking for a most generalizable and adaptable method.

A. Adapted Approaches for Multi-sensors Data Fusion

To select a suitable method for EMUTEM's multimodal data fusion module, we have probabilistic approaches whose performance can be reconsidered in our application for many reasons. The classical inference method quantitatively compares the probability that an observation can be attributed to a given assumed hypothesis. But it has the following major disadvantages [10], (1) difficulty in obtaining the density functions that describe observations used to classify the object, (2) complexities that arise when multivariate data are encountered, (3) its capability to assess only two hypotheses at a time, and (4) its inability to take direct advantage of a priori likelihood probabilities.

The Bayesian inference method [11] also has some weaknesses that prevent it from being used in our multimodal data fusion module. The key limits are: (1) difficulty in defining a priori probabilities, (2) complexities when there are multiple potential hypotheses and multiple conditionally dependent events, (3) mutual exclusivity required for competing hypotheses, and (4) inability to account for general uncertainty and to represent imprecision.

Even if Dempster-Shafer methods [12] use a general level of uncertainty, they cannot be the main data fusion method for two reasons: the difficulty to estimate mass function and their restrict domain of application.

The neural networks method [13] is not very well adapted to EMUTEM's Data fusion module because of drawbacks. First, the mapping mechanism is not well understood even if the network can provide the desired behavior. Second, the neural network method is, generally speaking, not suitable to work in a dynamic sensor configuration environment, because each sensor needs a unique input node and each possible sensor-set configuration needs to be specifically trained. Third, the complex architecture of neural networks prevents experts adding their knowledge easily.

SVM methods [14], despite their transit in the characteristics space which is disconnected from any physical reality, could fulfill the requirement of intelligibility because only support vectors are important in identifying margins between classes. However, it is necessary that boundaries between classes are rendered intelligible by a graphical way in the space of inputs. This vision must take into account an input space of any size even if greater than 3. In this case, the SVM identifies a large majority of learning examples as support examples. It means that an analyst should remember too many relevant individuals for the construction of boundaries between classes and this is impossible.

The fuzzy logic method [15] is the proposed way to meet these challenges of this multimodal data fusion application. According to the nature of data to process in EMUTEM platform, fuzzy logic is the well adapted approach for the telemonitoring decision. It deals with inaccuracy and uncertainty. It allows a great flexibility to combine several sensors.

IV. Implementation

A. Fuzzy Classifier

The main advantages of using fuzzy logic system are the simplicity of the approach and the capacity of dealing with the complex data acquired from the subsystems discribed previously in the second section. Fuzzy set theory offers a convenient way to do all possible combinations with these data. Fuzzy set theory is used in this system to determine the most likely distress situations that might occur for elderly persons in their home. The data fusion is carried out at three different levels: for sound/speech environement at the decision level, for smart home sensors system at the input data level and for the wearable physiological sensor at the representation level.

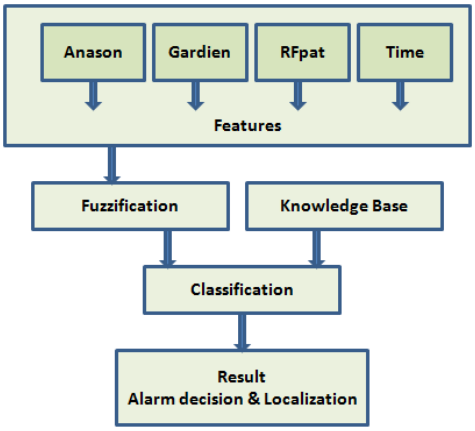

Fig. 3. Structure of the fuzzy classifier.

B. Input and Output fuzzification

The first step for implementing the fuzzy logic multimodal data fusion approach is the fuzzification of outputs and inputs of the fuzzy inference system (FIS) obtained from each subsystem.

From Anason subsystem three inputs are built. The first one is the sound environment classification. Sound classes are labeled on a numerical scale according to their alarm level. Four membership functions are set up in this numerical scale according to the following fuzzy levels: no signal, normal, possible alarm and alarm as it is shown in figure 4. The

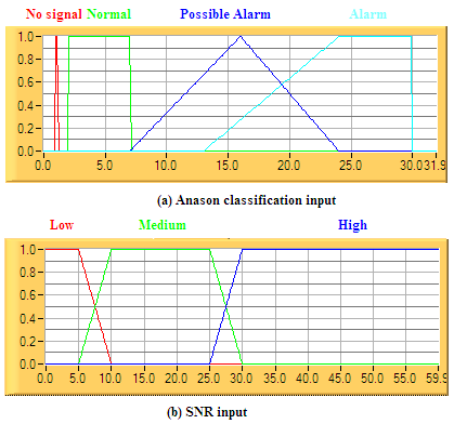

Fig. 4. Fuzzy sets defined for sound environment inputs.

second input is associated with the SNR (Signal-to-noise ratio) calculated on each microphone (two microphones are used in the current application), and this input is split into three fuzzy levels: low, medium and high.

RFpat provides physiological data to EMUTEM platform. RFpat produce five inputs:

- Heart rate is fuzzified with three fuzzy levels: normal, possible alarm and alarm.
- Activity has four fuzzy sets: immobile, rest, normal and agitation. The trapezoid function displays all these linguistic variables.
- Posture is represented by two membership functions standing up / seating down and lying.
- Fall and call have also two fuzzy levels: Fall/Call and No Fall/Call and a singleton function is associated to these linguistic variable.

Parameters of membership functions associated to the heart rate and the activity, are adjustable according to the monitored elderly person. An automatic procedure to adapt these intervals based on 30 minutes recording was proposed.

For each infrared sensor a counter of motion detection with

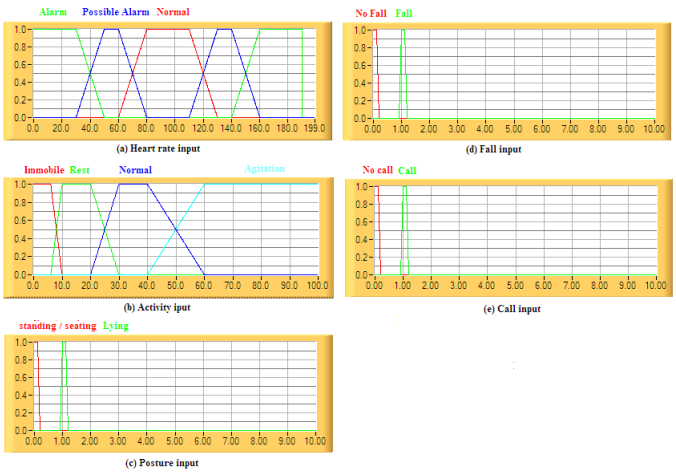

Fig. 5. Fuzzy sets defined for Vital data inputs.

three fuzzy levels (low, medium, high) is associated. It is reset every 5 seconds. A global counter for all infrared sensors with three fuzzy membership functions (low, medium, high) is also used and is reset every 60 seconds. A trapezoid membership function is chosen to characterize these fuzzy sets.

A singleton membership function is assigned to each change state sensor with two linguistic variables: On and Off.

The last input which is the time. It has two membership functions: day and night. These two membership functions are also adaptable to each patient habits. Trapezoid functions are used to divide the time input.

In order to reach the objective of the EMUTEM platform which is the identification of distress situations of an elderly person at home, two outputs are associated to the fuzzy inference engine of EMUTEM platform.

The first one is called Alarm with two linguistic variables normal and alarm.

To refine the decision of the EMUTEM platform a second output is added to its fuzzy inference system component. This second output is named Localization. It is a very important information for the diagnostic. The identification of the position of the monitored person during a distress situation is helpful knowledge for medical diagnosis.

Two membership function models are selected: Gaussian functions are chosen for the alarm outputs; Trapezoid functions for the localization output where the classical areas of a house are its fuzzy levels or linguistic variables.

C. Fuzzy Rules Aggregation and Defuzzification

The EMUTEM fuzzy inference engine is formulated by two groups of fuzzy IF-THEN rules. One group controls the output variable localization according to values of the input variables issued from infrared sensors and the SNR of each microphone. The other group controls the output linguistic variable alarm according to all inputs. These fuzzy rules are decided through experimentation and according to some expert knowledge.

A confidence factor is assigned for each rule. Outputs used in a rule are multiplied by the confidential factor issued from each subsystem. Thus the rule's output value depends on the reliability of each subsystem and the sureness of rules. To aggregate these rules we have chosen the Mamdani model [16] instead of the Takagi Sugeno. These two models are available under the EMUTEM fuzzy logic component. Mamdani model offers us a good way of modeling the normal and distress situations, because these two classes don't form a clean partition but a fuzzy one.

After rules aggregation the defuzzification is performed by the smallest value of maximum method for the alarm output in order to obtain also a confidence level of each alarm's decision, and the centroid of area for the localization output.

Each subsystem specifies the situation of the elderly person and the degree of anxiety. When a decision is very complicated, that is, there are many decisions; the fuzzy method is especially useful. It is also easy to check, modify, and add/delete every fuzzy variable for better automated analysis. To summarize the proposed data fusion method, the proposed fuzzy destress

situation classifier is comprised of two major function blocks, decisions of each subsystems and fuzzy classifier as shown in Figure 3. Decisions of subsystems are utilized as inputs for the classification using the fuzzy classifier. The derived parameters will be exported to the latter for the classification. The Mamdani fuzzy method is used. Fuzzy logic if-then rules are formed by applying fuzzy operations to these membership functions for given inputs and outputs. The resulting output membership functions are added together using desired weights yielding a sort of probability function. The resulting output areas can then be used to estimate the expected value of the output variable by using the specified defuzzification method. In general, any fuzzy classifier has to undergo iterative adjustment in terms of fuzzy variables, including the choice of membership functions, and the definition of rules in the knowledge base.

D. Software Architecture

Figure 6 provides a synoptic block-diagram scheme of the software architecture of the EMUTEM system; it is implemented under Labwindows CVI and C++ software. It is developed in a form of a design component.

We can distinguish three main components, the acquisition module, the synchronization module and the fuzzy inference component. It can run off-line by reading data from a data base or online by processing in real time data acquired via the acquisition module.

To avoid the loss of data, a real time module with two multithreading tasks is integrated in the synchronization component. The EMUTEM system is now synchronized on the smart home sensors (Gardien) subsystem because it has the lowest sampling rate (2 Hz) and periodicity. The data from others modalities are memorized and used several time in order to have the same sampling rate (RFPAT data is used 60 times).

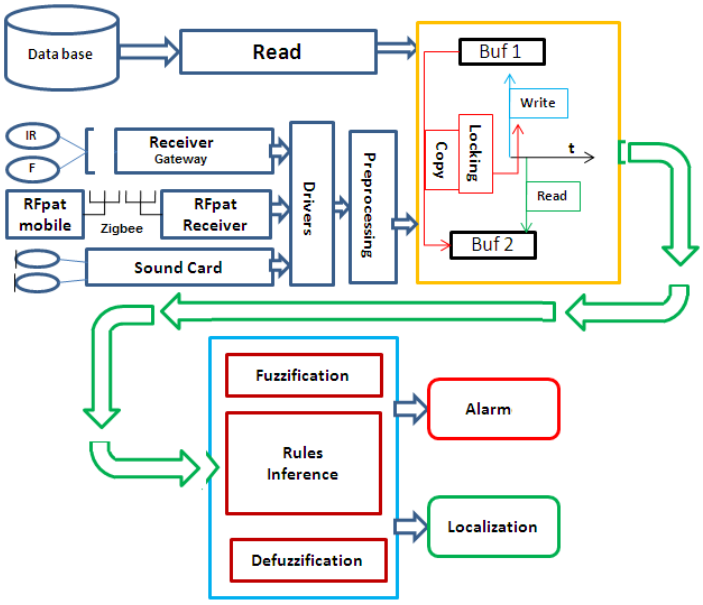

Fig. 6. EMUTEM software components design .

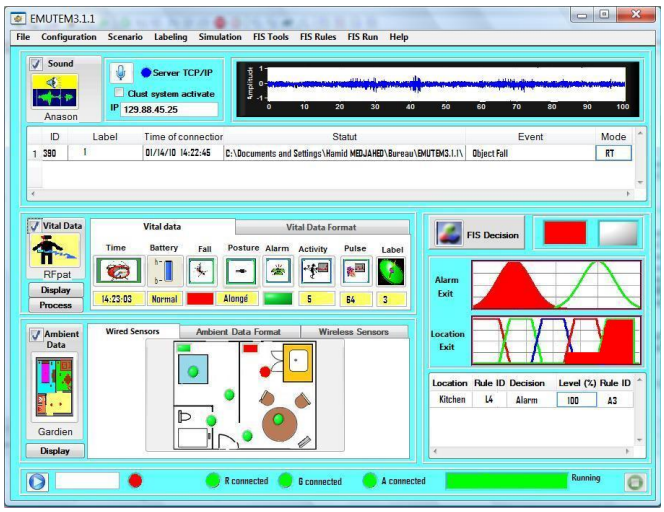

Fig. 7. Graphical Interfaces for Intelligibility.

This multithreading technique allows a maximum delay for an asynchronous data (Sound or alarm from RFPAT) of 0.5 s.

We have developed Fuzzy tools for the data fusion step. These tools allow the easy configuration of input/output intervals of Fuzzification, the writing of fuzzy rules and the configuration of the defuzzification method. It is also possible to add others modalities to this fuzzy inference system which make the EMUTEM platform flexible. Two outputs are associated to the fuzzy inference system, Alarm for distress situation detection and Localization for elderly person position detection.

E. Graphical Interfaces for Intelligibility

To offer enhanced intelligibility for the EMUTEM platform, a graphical user interface (GUI) was developed for this task. It facilitates the various configurations required for the functioning of the platform. It is very useful for users.

Figure 7 shows this general graphical interface. It is possible to build up membership functions of inputs and outputs and displaying them under this graphical interface.

We could also write rules via this graphical interface. It is also possible to write rules to text file by using a specific language, that we have developed, understandable by our system.

These Graphical interfaces provide EMUTEM with a useful simplicity for users and with a flexibility that allows adding other modalities. They allow experts to add their knowledge in a user friendly way.

V. The In Home Monitoring Database

In order to test and to validate the EMUTEM platform, an environment for acquiring and recording a multimodal database (HOMECAD [8]) is integrated under this platform. To record this multimodal database, users can interpret elderly activities by following a reference scenario which summarizes the everyday life of elderly persons. These scenarios are divided into two categories: either a critical scenario with one

or more distress events, or a normal one without any distress event. To define these scenarios a study is performed and they were instigated under CompanionAble European project. In this project, some elderly living alone were followed up by a co-worker team, in order to summarize and to describe their daily routine. The recorded multimodal database gathers physiological data, environment sounds and others different information gathered by ubiquitous sensors associated to Gardien subsystem.

First recordings were performed in our laboratory. Participants in this study were 10 adult volunteers who were recruited from the university and from the community. Participants ranged in age from 25 to 50 years. Participants were asked to perform several activities according to the used reference scenario. As each scenario lasts 10 minutes, this task corresponds to 200 minutes of recorded data.

The second stage of recording occurred in Broca Hospital in Paris under the framework of CompanionAble project. Ten adult volunteers from the community were enrolled to participate in this recording stage. The participants profile varied, ranged in age from 65 to 75 years, and the sample was 60% female and 40% male. The last stage of recording was also performed under the CompanionAble project and was performed in SmartHomes at Eindhoven. Fifteen adult volunteers were involved in this recording. For both stages of recording, a scenario lasts 15 minutes and each participant performs three different scenarios.

An additional process of simulation is also integrated in our platform as a way to overcome the lack of experimental data and the difficulty of recording some medical data such as the cardiac frequency during distress situations.

Taking into account the multimodality character of the data, a multidimensional indexing process is used in order to obtain a full description of data sets. In order to index our multimodal database, we have retained the SAM standard indexing file [17] generally used for speech database description. It indicates information about the file and describes it by delimiting the useful part for further analyzing and processing.

VI. Experimental Results and Validation

The realization of an experimental process requires the use of appropriate metrics for evaluating the performance of the platform by comparing the system's results to expected results. It is useful to describe some parameters or metrics that allows an objective evaluation of the results. To perform this experimental process we have selected the following metrics:

- *Sensitivity (Se)*: Identify patterns of real abnormal situations as distress ones.
- *Specificity (Sp)*: Don't identify normal situations as distress situations.
- *Error rate (Err)*: It is the ratio between the number of the misclassified samples and the total number of the samples.
- *Perfect classification(Pc)*: It is the ratio between the number of the correct classified samples and the total number of the samples.

		EMUTEM Classification	
		Distress sequence	Normal sequence
Simulated sequences	Distress sequence	68	2
	Normal sequence	1	29

TABLE I
Classification results for Alarm output with simulated data by using 10 rules

Indices of sensitivity (Se), specificity (Sp), error rate (Err) and perfect classification (Pc) are calculated from rates of true/false positive/negative, marked respectively with these symbols TP, FP, TN, and FN.

$$Se(\%) = \frac{TP}{TP+FN} \times 100 \quad (1)$$

$$Sp(\%) = \frac{TN}{TN+FP} \times 100 \quad (2)$$

$$Err(\%) = \frac{FN+FP}{TN+FN+FP+TP} \times 100 \quad (3)$$

$$Pc(\%) = \frac{TN+TP}{TN+FN+FP+TP} \times 100 \quad (4)$$

The just exposed metrics of the statistic data are very important to estimate the classification accuracy.

In order to demonstrate the effectiveness of this software, firstly we started by using simulated data in order to validate each rule. This first step of simulation gave very promising results for the alarm generation and localization without any false decision for each rule.

After that 100 sequences of simulation are used to test EMUTEM, where 70 sequences represent distress situation and 30 sequences represente normal situation, because we wanted especially to test the distress part that is more difficult to record in a real situation.

In order to evaluate the classification accuracy the confusion matrix has been calculated for this simulation. Table I displays the obtained results with 10 rules.

Sensitivity Se	97%
Specificity Sp	96%
Error rate Err	3%
Perfect classification Pc	97%

TABLE II
Performance indices for Alarm output obtained with simulated data by using 10 rules

From table I we can deduce some indices of performance which are displayed in table II. The obtained results of EMUTEM's performance are good and they demonstrate the reliability of the EMUTEM platform. Even if we have 3% of misclassified sequences, this error rate could be overcome by adding to the fuzzy inference system the right rules that take into account the misclassified situations, and also by associating to each rules the right weight.

For the localization output, also we have obtained about 98% of good localization.

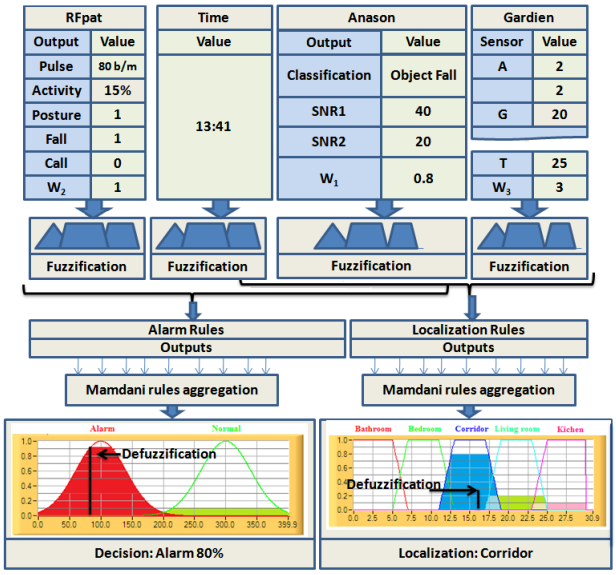

Fig. 8. Results for a stream of data

Figure 8 shows results for a steam of data and summarizes the process of the fuzzy inference system. The first step of this process is to determine the output of each membership function assigned to each input. Then the outputs of the rules are calculated by applying the fuzzy operators (AND and OR) in the antecedent part of all rules, using the T-norm and T-conform operators respectively and the implication from the antecedent to the consequent, using T-norm operator. After that the aggregation of the consequents across the rules of each output is performed by using the Mamdani model, it is the unification process of the all rule outputs. Finally the process of defuzzification is done by extracting out one crisp value as the output, the smallest value of maximum method is chosen for the alarm output and the centroid of area for the localization output.

The EMUTEM platform was tested with the HOMECAD database described in the previous section. This first study is devoted to the evaluation of the system by taking into account rules used in this fuzzy inference system. The strategy consisted in realizing several tests with different combination rules, and based on the obtained results, one rule is added to the selected set of rules, or removed from this selected set of rules in order to get the missed detection. Based on the obtained results some weights of rules are also changed. With this strategy good results are reached for the alarm output with 10 rules and 16 rules for the localization outputs. The data fusion classification using the fuzzy logic approach has given better performance results when compared to analytical method and using artificial neural networks (ANN) for classification (Table III). More over problems associated with conventional neural network architectures such as learning rate limitation and difficulty in selecting the optimal number of hidden units are eliminated.

With this strategy good results are reached for the alarm output with 10 rules and 16 rules for the localization outputs,

	Fuzzy classifier (10 rules)	ANN (3 hidden layers)
Se	95%	87%
Sp	93%	85%
Err	5%	12%
Pc	95%	88%

TABLE III
PERFORMANCE INDICES FOR ALARM OUTPUT OBTAINED WITH FUZZY CLASSIFIER AND ANN METHOD

about 95% of good Alarm detection and 97% for good Localization. The rate of misclassification for the alarm output corresponds to situation that are not detectible by the sensors used by EMUTEM and also the difficulty to find the right rule to overcome these situations. For the localization output the error rate could be justified by the fact that we use an area where an apartment is simulated thus the calibration of infrared sensors is very hard.

These first results encourage us to perform further tests in real time in order to have an effective evaluation of the EMUTEM platform.

VII. Conclusion

In this work, we focused on the area of automatic home healthcare telemonitoring, in which health information is automatically collected with the help of sensors and processed by special algorithms and fused in order to make good decisions about elderly persons living alone at home. The proposed multimodal data fusion method based on fuzzy logic represents a fast and easy tool for the interpretation of the fuzzy decision process even for very high dimensional input spaces and allows fast detection of errors. The impact of the input features plays an important role on the final decision process. The algorithm supports the implementation of the expert's knowledge and optimized the system easily. It is possible to increase the performance further by adding more related input variables and with more data to enrich the knowledge in the rules.

The EMUTEM platform which encloses this architecture is implemented and validated by simulation and by using real data. The experimental results were accurate and robust. The main advantage of the presented method consists of the low-computational expenses inherited from the characteristics of fuzzy systems. This approach allows the easiest combination between data and adding other sensors.

The fuzzy logic decision module reinforces the secure detection of older person distress events and his localization. This constitutes a great asset for the EMUTEM system, by offering the possibility in the near future, to implement a very intelligent remote monitoring system in care receiver houses, thus to build very reliable smart houses.

Abstract — **The embedded memories have already played a very important role in the modern system on a chip (SoC) designs from the aspects of performance enhancement, power reduction, form factor optimization, etc. Meanwhile, embedded memories usually occupied for the major portion of an SoC layout. Thus, how an embedded memory IP (intellectual property) provider can differentiate the product to maximize the value of that IP has already become a key factor for profit maximization. However, very few scholars tried to resolve such problems. The product and service differentiation problem of memory IPs is in nature a multiple attribute decision making (MADM) problem. Moreover, the differentiators of an embedded memory IP usually interact with each other. Furthermore, evaluations of customers' needs and wants, which are vague, are often required for such a product marketing strategy definition problem. Thus, a fuzzy DEMATEL based multiple criteria decision making (MCDM) framework will be proposed for maximizing the value of an embedded memory IP. The value driver for differentiating an embedded memory IP will first be derived by literature review. The most influential value drivers will be selected. Then, strategies will be proposed for maximizing the value through the most influential value drivers. An empirical study based on an embedded memory IP being provided by an SOC design service provider will be used for verifying the feasibility of the framework. Based on the empirical study results, both power consumption as well as the area of the embedded memory core are the most important value drivers. The proposed product marketing strategies can also be used for maximizing the value of the embedded IP.**

Keywords – Embedded memory; system on a chip (SOC); differentiation; Fuzzy DEMATEL; Fuzzy MCDM (Multiple Criteria Decision Making, MCDM).

I. INTRODUCTION

Memory plays a critical role in achieving the performance, power or cost goals of an electronic system [1]. For an SoC (System on a Chip), the memory and processors are implemented on the same chip while in this particular case, the memory is called the embedded memory [2]. Nowadays, over 50 % of the area in an SoC is occupied by the embedded memory [3]. As the integrated circuit migrates to the SoC era, the embedded memory technique is playing a daily important role. Furthermore, provisions of embedded memory intellectual properties (IP) and design services have become novel business models which emerged in the past decade.

Embedded memory may be more expensive to fabricate than separate memory chips, since the fabrication processes for memories and processors must be compatible [2]. Nevertheless, a large percentage of the total chip area maybe consumed by the memory [2]. Thus, the selection of an embedded memory IP and supplier is critical to the success of the design and the ramp to volume [3]. When designed correctly, an SoC incorporating embedded memory can offer higher speeds or lower power consumption and maintain the same or lower cost than a system designed with stand-alone memory [4].

Differentiation in the embedded memory IP can occur in the four mutually interacted dimensions, including the function, the speed, the area and the power consumption; albeit some RAMs offer functional differentiation, the key areas in which differentiation can exist are the trade-offs between the remaining three dimensions [5]. Further, from the SOC design service view, differentiation can happen in the time to market capability, SIP integration service capability, SIP verification capability, as well as the close relationship with foundries.

The embedded memories are usually provided by IP providers, design service providers or professional silicon foundries. However, providing a "me too" embedded memory product cannot assist a provider help customer maximize their value. Thus, how a design service provider can differentiate their products and maximize the value of their services has become a critical issue.

A company can differentiate its market offering through product, services, etc. [6]. The essence of differentiation advantage, to increase the perceived value of the offering to the customer either more effectively or at lower cost than do competitors, requires that the firm match the requirements and preferences of customers with its own capacity for creating uniqueness [7]. Products, services and technologies should be seen as vehicles for value creation [8]. Product managers are expected to set prices that capture the value offered by their products and that also maximize profits [9]. In order to build effective marketing strategy companies must first understand the factors that drive customer perceptions of value [10], or namely, value drivers, which can be defined as (1) customer needs upon which our product or service could have an impact [9] or (2) the decision-related attributes that are perceived by the customer to be the most important to the choice process [11].

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Apparently, how the value of a product can be maximized is a multiple attribute decision making problem (MADM) in nature. Further, due to the uncertainness of human beings' evaluations of needs, wants and intentions in their mindsets, applications of the fuzzy theory into the MADM framework(s) are very straightforward. Therefore, this research intends to define a fuzzy DEMATEL based multiple criteria decision making (MCDM) based framework for selecting product differentiation strategies for a company providing embedded memory products. At first, literature regarding to differentiating value drivers will be reviewed. The literature will serve as a basis for the MCDM framework development as well as possible alternatives for suitable fuel cell battery technologies. Then, the GRA will be used for deriving the relationships between the possible courses as well as the competences to be expanded. The courses with the highest Grey grades will be selected as the suitable courses of the curriculum.

An empirical study on maximizing the embedded memory IP belonging to an SoC design service firm will be provided for maximizing the value of the embedded memory IPs. The empirical study results can serve as a basis for the design service firm's value maximization of its IPs.

This research is organized as follows. The related literature regarding to differentiation and value drivers will be reviewed in Section II. The theory which is based on MCDM framework and using the GRA method will be introduced in Section III. An introduction to the embedded memory technologies will be given in Section IV. An empirical study on maximizing developing the product marketing strategies will be demonstrated in Section V for demonstrating the feasibility of this framework. Implications as well as discussion will be presented in Section VI. Finally, the whole article will be concluded in Section VII.

II. Product Differentiation and Profit Maximization

An early study by Dickson and Ginter [12] summarized definitions of product differentiation from marketing textbooks as an alternative to market segmentation or a complement or means of implementing market segmentation. The potential for differentiation in any business is vast while differentiation extends beyond technology, design, and marketing to include all aspects of a firm's interactions with its customers [7].

Six factors affecting customer purchase decisions include relative advantage, compatibility, complexity, trialability, ability to communicate product benefits and observability [8]. A company can differentiate its market offering through product, services, personnel, channel, and image while the decision variables belonging to the obvious means of product and services include form, features, conformance, durability, reliability, style, design, quality, ordering ease, delivery, installation, customer training, customer consulting, maintenance and repair, etc. [6]. Some physical products can be highly differentiated [13] through (1) form, (2) features, (3) performance quality, and (4) conformance quality [6]. Further, according to Kotler and Keller, Products, services and technologies should be seen as vehicles for value creation [8]. The essence of differentiation advantage, to increase the perceived value of the offering to the customer either more effectively or at lower cost than do competitors, requires that the firm match the requirements and preferences of customers with its own capacity for creating uniqueness [7]. A product's total economic value, then, is the price of the customer's best alternative (the reference value) plus the economic value of whatever differentiates the offering from the alternative (the differentiation value) [9]. Value appropriation means investing in strategies that allow the firm to differentiate its existing offerings in order extract profits in the market [8]. Even for high technology markets, the investors reacts more favorably when a firm increases its emphasis on value appropriation relative to value creation, constantly innovating and investing in R&D [8].

Only the part of economic value being associated with differentiation, or the differentiation value, can potentially be captured in the price; differentiation value comes in two forms: monetary and psychological, both of which may be instrumental in shaping a customer's choice but require very different approaches to estimate them [9]. In order to create the foundation for setting prices, it is critical to understand what the customer's value drivers are and how the purchase decision can be influenced [14]. The customers' value drivers need to be reflected in the design requirements of the software if the value is to be subsequently captured by the pricing mechanism on the product's launch [14].

In order to build effective marketing strategy companies must first understand the factors that drive customer perceptions of value [10], or namely, value drivers, which can be defined as the decision-related attributes that are perceived by the customer to be the most important to the choice process [11]. The value at the heart of pricing strategy is not use value, but is what economists call exchange value or economic value, which depends on the alternatives customers have available to satisfy the same need [9].

Value hypothesis development usually begins with a list of your offering's potential value drivers including superior performance, greater reliability, additional features, reduced maintenance costs, smaller startup costs, faster service, etc. [9]. Harmon and Laird [10] summarized the value drivers to be economic-value driver, performance/functional value, buyer's perceptions about the supplier, buyer's motivations and goals, and the buying situation.

Finally, the three steps for economic value include: study customer economics, quantify value drivers and finally, estimate differentiation value [9].

III. Analytic Framework For Maximizing Profits Through Product Differentiation

The analytical process for designing a capabilities-driven curriculum is initiated by collecting the capabilities and possible fuel cell courses being required to develop the national fuel cell industry by using the Delphi method. Then, the relations between the capabilities and the possible courses will be derived by using the Grey Relation Analysis.

A. Fuzzy DEMATEL Method

The Fuzzy DEMATEL can deal with the DEMATEL problem by introducing Fuzzy linguistic variables and matrices. According to the definition of Fuzzy DEMATEL, the linguistic matrices present the relationships between criteria. In the matrices, the numeral value depicts the influence versus each

criterion. Therefore, the Fuzzy DEMATEL method can transform the causes and effects relationship into a perspicuous structural model. The Fuzzy DEMATEL method has been studied and applied in many areas these years [15,16]. According to the advantages of Fuzzy DEMATEL, this research attempts to evaluate the preferences of lead users by using Fuzzy DEMATEL based on the definitions by Prof. Tzeng, Gwo-Hshiung [17]. The calculation process is demonstrated as below:

Step 1: Establishing the fuzzy linguistic scale

Establishing the linguistic sets of criteria is an essential procedure for Fuzzy DEMATEL. The major advantage of Fuzzy DEMATEL method is that it's effective to obtain the structural mode and divide the criteria into cause and effect groups, which consist of many complex aspects. To deal with the ambiguities of human feeling and evaluations, Li [18] introduces the fuzzy linguistic scale into the DEMATEL evaluation process. The strength of influence are divided into five linguistic levels as "Strong", "High", "Low", "No" and the linguistic levels will correspond to the triangular fuzzy numbers.

Step 2: Establishing the directed relation matrix

To measure the relationship versus each criterion $C=\{c_1,c_2,\ldots,c_n\}$, p lead users made evaluations in terms of linguistic terms toward the criteria. Thus, p fuzzy matrices $\tilde{\boldsymbol{Z}}^1,\tilde{\boldsymbol{Z}}^2,...,\tilde{\boldsymbol{Z}}^P$ each corresponds to a lead user. The Fuzzy matrix is called the initial direct relation fuzzy matrix. For simplicity, denote $\tilde{\boldsymbol{Z}}$ as $c_1,c_2...c_n$, or

$$\tilde{\boldsymbol{Z}}=\begin{matrix}c_1\\c_2\\\vdots\\c_n\end{matrix}\begin{bmatrix}0&\tilde{z}_{12}&\cdots&\tilde{z}_{1n}\\\tilde{z}_{21}&0&\cdots&\tilde{z}_{2n}\\\vdots&\vdots&\ddots&\vdots\\\tilde{z}_{n1}&\tilde{z}_{n2}&\cdots&0\end{bmatrix},$$

where $\tilde{z}_{ij}=\left(l_{ij},m_{ij},u_{ij}\right)$ are triangular fuzzy numbers, elements $\tilde{z}_{ii}=0,i=1,2...n$.

Step3: Establishing the structural model

In order to transform the criteria scales into comparable scales, the linguistic scale will be transformed into a normalization formula.

Let $\tilde{a}_{ij}=\sum_{j=1}^{n}\tilde{z}_{ij}=\left(\sum_{j=1}^{n}l_{ij},\sum_{j=1}^{n}m_{ij},\sum_{j=1}^{n}u_{ij}\right)$ and $u=\max_{1\le i\le n}\left(\sum_{j=1}^{n}u_{ij}\right)$.

Then, the normalized direct relation fuzzy matrix, denoted by $\tilde{\boldsymbol{X}}$, equals $\tilde{x}=u^{-1}\otimes\tilde{z}$. Or

$$\tilde{\boldsymbol{X}}=\begin{bmatrix}\tilde{x}_{11}&\tilde{x}_{12}&\cdots&\tilde{x}_{1n}\\\tilde{x}_{21}&\tilde{x}_{22}&\cdots&\tilde{x}_{2n}\\\vdots&\vdots&\ddots&\vdots\\\tilde{x}_{m1}&\tilde{x}_{m2}&\cdots&\tilde{x}_{mn}\end{bmatrix},$$

where $\tilde{x}_{ij}=\frac{\tilde{z}_{ij}}{u}=\left(\frac{l_{ij}}{u},\frac{m_{ij}}{u},\frac{r_{ij}}{u}\right)$. (1)

Fuzzy DEMATEL also assume that $\sum_{j=1}^{n}u_{ij}<u$ and $\lim_{k\to\infty}\tilde{x}=[0]_{0\times0}$.

Step 4: Deriving the total relation matrix

After calculating the normalized direct relation fuzzy matrix, the total relation matrix $\tilde{T}$ can be derived by the equation below:

$$\tilde{\boldsymbol{T}}=\tilde{\boldsymbol{X}}+\tilde{\boldsymbol{X}}^2+\cdots+\tilde{\boldsymbol{X}}^n=\tilde{\boldsymbol{X}}(\boldsymbol{I}-\tilde{\boldsymbol{X}})^{-1},$$

When $\lim_{k\to\infty}\tilde{X}=[0]_{n\times n}$

$$\tilde{\boldsymbol{T}}=\begin{bmatrix}\tilde{t}_{11}&\tilde{t}_{12}&\cdots&\tilde{t}_{1n}\\\tilde{t}_{21}&\tilde{t}_{22}&\cdots&\tilde{t}_{2n}\\\vdots&\vdots&\ddots&\vdots\\\tilde{t}_{m1}&\tilde{t}_{m2}&\cdots&\tilde{t}_{mn}\end{bmatrix};\tilde{t}_{ij}=\left(l_{ij}^{"},m_{ij}^{"},r_{ij}^{"}\right)$$

$$\left[l_{ij}^{"}\right]=\boldsymbol{X}_l-\left(\boldsymbol{I}-\boldsymbol{X}_l\right)^{-1},\ \left[m_{ij}^{"}\right]=\boldsymbol{X}_m-\left(\boldsymbol{I}-\boldsymbol{X}_m\right)^{-1},$$
$$\left[r_{ij}^{"}\right]=\boldsymbol{X}_r-\left(\boldsymbol{I}-\boldsymbol{X}_r\right)^{-1}$$

Step 5: Analyzing the sum of rows and columns

The row and column sums are individually indicated the sum of rows and columns of the total relation matrix $\boldsymbol{T}$ by using following equations (2), (3), and (4),

$$\tilde{\boldsymbol{T}}=[\tilde{t}_{ij}],\quad i,j\in\{1,2,...,n\} \tag{2}$$

$$\tilde{\boldsymbol{r}}=[\tilde{r}_i]_{n\times1}=\left[\sum_{j=1}^{n}\tilde{t}_{ij}\right]_{n\times1} \tag{3}$$

$$\tilde{\boldsymbol{c}}=[\tilde{c}_j]_{1\times n}=\left[\sum_{i=1}^{n}\tilde{t}_{ij}\right]_{1\times n} \tag{4}$$

where the $\boldsymbol{r}$ and $\boldsymbol{c}$ represent the sums of the rows and columns.

Step 6: Analyzing the results from $\boldsymbol{r}$ and $\boldsymbol{c}$

According to the sum of rows and columns, $(\tilde{r}_i+\tilde{c}_i)$ depicts the strength of the influence. If $(\tilde{r}_i-\tilde{c}_i)$ is positive, then criteria i is dispatching influence on other factors. On the other hand, if $(\tilde{r}_i-\tilde{c}_i)$ is negative, factor i is receiving influence from other criteria [15,19,20].

B. Analytic Network Process (ANP)

The ANP method, a multi criteria theory of measurement developed by Saaty [21], provides a general framework to deal with decisions without making assumptions about the independence of higher-level elements from lower level elements and about the independence of the elements within a level as in a hierarchy [21]. In this section, concepts of the ANP are summarized based on Saaty's earlier works [21, 22].

A component of a decision network which was derived by the DEMATEL method in Section 3.1 will be denoted by $\boldsymbol{C}_h$, $h=1,2,\cdots,m$, and assume that it has n_h elements, which we denote by e_{h1}, e_{h2}, $\cdots$, e_{hm}. The influences of a given set of

elements in a component on any element in the decision system are represented by a ratio scale priority vector derived from paired comparisons of the comparative importance of one criterion and another criterion with respect to the interests or preferences of the decision makers. This relative importance value can be determined using a scale of 1–9 to represent equal importance to extreme importance [21]. The influence of elements in the network on other elements in that network can be represented in the supermatrix as $\boldsymbol{W}_{ij} = [w_{ij}],\ i \in \{1,2,...,m\}$, $j \in \{1,2,...,m\}$. A typical entry $\boldsymbol{W}_{ij} = [w_{i_{nx} j_{ny}}],\ nx \in \{1,2,...,n_i\}$, $ny \in \{1,2,...,n_j\}$ in the supermatrix, is called a block of the supermatrix in the following form where each column of $\boldsymbol{W}_{ij}$ is a principal eigenvector of the influence of the elements (objective) in the ith component of the network on an element (objective) in the j^{th} component. Some of its entries may be zero corresponding to those elements (objective) that have no influence.

After forming the supermatrix, the weighted supermatrix is derived by transforming all columns sum to unity exactly. This step is very much similar to the concept of the Markov chain in terms of ensuring that the sum of these probabilities of all states equals 1. Next, the weighted supermatrix is raised to limiting powers, such as $\lim_{\theta \to \infty} \boldsymbol{W}^{\theta}$ to get the global priority vector or called weights [23].

In addition, if the supermatrix has the effect of cyclicity, the limiting supermatrix is not the only one. There are two or more limiting supermatrices in this situation, and the Cesaro sum would need to be calculated to get the priority.

IV. An Empirical Study of an Embedded Memory Value Maximization Strategies Definitions

As embedded memories are playing a daily critical role in modern SoC designs, novel techniques emerged. Further, embedded memory vendors, SoC design service providers, and professional foundry vendors are dedicated in providing novel services so as to fulfill customers' needs of one stop shopping, time to market, and thus, time to money.

Based on literature review and an expert's (with experiences in SoC design service and semiconductor memory sales and marketing for more than 10 years) opinions regarding to the value drivers of the embedded memory intellectual properties, the value drivers can be divided into two aspects, technology and service. From the technology aspect, the functionality (f_1), speed (f_2), area (f_3), and power consumption (f_4) of the memory IPs can be defined as the value drivers for an embedded memory IP. Further, from the service aspect, the time to market capability (f_5), the provision of the one stop shopping environment (f_6), the SIP design capability (f_7), the SIP integration service capability (f_8), the SIP verification capability (f_9) as well as the supply chain management capability (f_{10}) can be defined as the value drivers for an embedded memory IP.

At first, according the expert's opinion, the linguistic variables can be defined as Figure 1(a) while the initial direct relation fuzzy matrix $\tilde{\boldsymbol{Z}}$ can be defined as Figure 1(b).

Then, by introducing the Fuzzy DEMATEL ANP process being introduced in Section 3, the weights being associated with each work barrier can be derived (see Table II).

According to the empirical study results, the power consumption as well as the area is the most important value drivers for differentiating the embedded memory from both aspects of technology and services.

V. Discussion

In this research, embedded memory value drivers for product differentiation were derived from both aspects of technology and services. Following, managerial implications and future research possibilities will be presented.

At first, the embedded memory design and selection is in nature an MCDM problem by considering interdependences between criteria. Very limited scholars tried to address this issue by introducing the MCDM framework though the integrated circuit industry is migrating into the SoC era which embedded memories are playing a significant role from the aspects of area and its influences in SoC speed, power consumption, cost, etc. Thus, this research advanced the research in the related fields.

Variable	Upper	Medium	Lower
VL	0	30	60
L	50	60	70
M	60	68	75
H	70	78	85
VH	75	85	100

(a)

	f_1	f_2	f_3	f_4	f_5	f_6	f_7	f_8	f_9	f_{10}
f_1	0	VH	VH	VH	VH	VL	VL	VL	VL	VL
f_2	L	0	M	VH	VL	VL	VL	VL	VL	VL
f_3	VL	M	0	M	VL	VL	VL	VL	VL	VL
f_4	VL	VL	VL	0	VL	VL	VL	VL	VL	VL
f_5	VL	VL	VL	VL	0	VL	VL	VL	VL	H
f_6	VL	VL	VL	VL	VH	0	VL	VH	VL	VH
f_7	VH	VH	VH	VH	VH	VL	0	VH	VH	VH
f_8	VL	VL	VL	VL	VH	H	L	0	L	VH
f_9	VL	VL	VL	VL	VH	H	VL	VH	0	VH
f_{10}	VL	VL	VL	VL	VH	H	M	VH	M	0

(b)

Figure 1. (a) Linguistic variables and (b) the fuzzy matrix $\tilde{\boldsymbol{Z}}$

Table II. The weights versus criteria

Driver	f_1	f_2	f_3	f_4	f_5
Weight	0.068	0.068	0.114	0.341	0.068
Driver	f_6	f_7	f_8	f_9	f_{10}
Weight	0.068	0.068	0.068	0.068	0.068

Further, very few scholars tried to analyze how an embedded memory IP can analyzed from both aspects of technology and services. In this research, the authors adopted literature from both technology side and the business side and analyzed the casual relationships between two aspects. Further, the most important value drivers which can influence other criteria were also derived.

For the empirical study results, the functionality factor was weighted lower than the power consumption factor. Such tradeoff is common for SOC(s) being designed for portable devices. The empirical study results will be changed if the target applications are changed.

Finally, in this research, a conceptual framework was developed based on the opinions of sole expert. In the future,

empirical studies based on industry experts from both the management and technology departments can be very helpful for developing the embedded memory business. Further, how the innovation strategies can be introduced for differentiating the value drivers will also be beneficiary for the marketers in the future.

VI. CONCLUSIONS

Embedded memory has played a daily important role in SoC designs. However, how to differentiate an embedded memory and maximize the profits from both aspects of technology and business were seldom addressed. Due to the interdependence nature of the embedded memory technology and business models, the authors adopted a Fuzzy DEMATEL based MCDM framework for deriving the most important value drivers. In the future, the concepts and frameworks being derived in this research can further be adopted as the basis for differentiation and product marketing strategy definitions.

***Abstract*—this study is the use of fuzzy multi-attribute decision making as a business management application in the balanced scorecard performance assessment. The study expected to help enterprises to establish effective expression of those feelings with subjective indicators of weight value. In order to increase the accuracy of weight and practice, so that more perfect performance of the Balanced Scorecard in the business. The use of the Balanced Scorecard to evaluate the importance of screening criteria in Taiwan mobile industry operators and fuzzy multi attribute decision making through the match with the comparison with the fuzzy multiple criteria decision making, to establish Taiwan's mobile industry business model assessment. Fuzzy multi-attribute decision making can be vague, uncertain or unstructured problems trying to provide a solution to this. Finally, this study found results, the implementation of the model created to operate as a decision-making in Taiwan mobile industry reference, and can understand the fuzzy multiple attribute decision making not only in dealing with the definition of ambiguous or unclear information, as an effective Methods, but in the real world where a lot of created process can easily be used, it will also help assess the performance of the Balanced Scorecard.**

I. INTRODUCTION

Taiwan's communications industry and the simultaneous development of global industry trends in the case of wireless communications equipment industry accounted for the proportion of the overall communications industry, forecast to 50.7 % from the year 2001 to 2010 grew 79.6 % to 9, 064 million NT Production value, mainly due to smart phones and wireless local area network products, such as the two major types of products.

Recently, wireless communications, the global communications industry and the market has gradually focused on the mobile Internet, in addition to continued improvement related products, Smart mobile phone wireless communication contains (Smartphone) , the new models iPhone, notebook and mini-notebook (Netbook) , TV, Blu-ray players, set-top boxes, Bluetooth, Zigbee low cost and low power , RFID and other video-related consumer electronics products. We can know the future of wireless communication industry is the star, intense competition and survival, in order to enhance the overall efficiency and effectiveness of operations, in order to pin down opponents in the market in order to grasp the opportunity to ensure their long term competitive advantage. How to give real assistance from the academic point of view as to the task of balance scorecard and fuzzy multi-attribute decision theory to solve performance management and enhancing competitiveness of the push is urgent. The communication devices also show the booming trend. Taiwan's communications industry and the simultaneous development of global industry trends in the case of wireless communications equipment industry accounted for the proportion of the overall communications industry, forecast to 50.7 % from the year 2001 to 2010 grew 79.6 % to 9, 064 million NT Production value, mainly due to smart phones and wireless local area network products, such as the two major types of products.

Based on the above reason, this study was to understand the following issues:

First, explore the use of Balanced Scorecard-based applications in the Mobile Enterprise applicability.

Second, the implementation of the case company Fuzzy multiple attribute decision making problems.

Third, set for enterprise performance management strategy for Mobile program.

Mobile SMEs in an attempt to enterprise applications into the Balanced Scorecard, Balanced Scorecard of the four dimensions with the financial side, customer, internal business process perspective and learning and growth surface indicators to develop a corporate cause and effect Diagram, and to assist with the fuzzy multiple attribute decision making in the case company's balanced scorecard results further explore the issue in depth in order to understand the management decision-making reference for efficiency.

II. RELATED RESEARCH

A. Balanced Scorecard

"Balanced Scorecard" (Balanced Scorecard, referred to as BSC) from the 1990 U.S. Professor David Norton and Robert

S. Kaplan of Harvard University study "Organization of future performance evaluation system ", it is a performance measurement model, which is a strategy; remuneration means a combination of strategic management tool. Emphasis on performance measurement should be achieved: (1) to measure the balance between internal and external: internal measure of emphasis on internal business process implementation and staff learning and growth surface, and an external measure of the emphasis on the financial side and customer side. (2) The results of surface measurement surface to measure the balance and the future: the results of surface Through the Balanced Scorecard applied to SMEs. We learned that the scorecard for small and medium enterprises also is

Eastern Media International Corporation has been building a strategic performance measurement system, and the concept of the Balanced Scorecard into the case company. The company has taken the traditional way of performance evaluation system and flexibility of management by objectives, which, strategy and incentive system has a high degree of association with low correlation of performance evaluation system. Among them, the import of this approach, top managers will need the support and full participation (Yuksel, 2010).

B. Multi-attribute decision making

In general, the term commonly used in decision making, Zeleny (1982) consider multiple criteria (multiple criteria) includes a number of attributes (multiple attributes) and multi-objective (multiple objectives); generally used to describe the four elements of MADM, (1) the alternatives (Alternatives), (2) set of attributes (Attributes), (3) goal set (Objectives) and (4) preference / weight set (Preferences / Weights).

Multi-attribute evaluation criteria is when policy-makers face multiple, even conflicting objectives, the assessment criteria must be choice, and multiple criteria decision making (MCDM) is the number of evaluation criteria used to assess the merits of different alternatives and their implementation the order of the systematic scientific methods. Therefore, the generalized multiple criteria decision making methods can be divided into multiple attribute, multi-objective decision making, covering multiple attribute decision making (Multi-Attribute Decision Making; called MADM), multi-objective decision analysis (Multi-Object Decision Making; referred MODM) generalized deal with the problem.

Multi-attribute decision making is the decision-makers may also consider the number of Conflicts, in a viable alternative, the decision to choose their preferred method (Yoon & Hwang, 1995) . To be addressed include the following four basic elements (Yu, 1995) .

(1) A fixed set of alternatives (Finite Set of Alternative)

(2) The set of assessment criteria (Set of Criteria)

(3) Each program performance value (Performance Rating)

(4)Decision makers preference structure (Preference Structure of Decision Maker)

The decision makers must decide from a group of action , the trade-offs by considering a variety of property relationship, try to choose the most appropriate programs to achieve goals in the process, that is, multiple attribute decision making (Multiple Attribute Decision Making, MADM) . Bellman and Zedeh (1970) that the real environmental issues among decision-making occurred, most of the objectives, limitations, and possible options for the results are inaccurate, they are also the first to MADM fuzzy set theory is applied to the field. Therefore, the fuzzy multiple attribute decision making (Fuzzy MADM, FMADM) it will be extended to the fuzzy MADM environment, refers to the attributes in the decision-making process, weights, targets and the nature of restrictions may be vague, fuzzy sets must be said that Or property may be fuzzy linguistic variables.

C. The DEMATEL Method

The original DEMATEL (DEcision-MAking Trial and Evaluation Laboratory) method studied the disjointed and antagonistic phenomena of world and investigated integrated solutions. In 1973, the Battelle Memorial Institute conducted the DEMATEL project through its Geneva Research Centre. In recent years, this method has become very popular in Japan.

It is especially practical and useful for visualizing the structure of complicated causal relationships with matrices or digraphs, which portray the contextual relations between the elements of a system, where a numeral represents the strength of influence. Therefore, the DEMATEL method can convert the relationship between the causes and effects of criteria into an intelligible structural model of the system.

The DEMATEL method has been successfully applied in many fields. For example, Tamura et al. (2002) try to decrease anxiety of people by extracting and analyzing various uneasy factors in order to create future safe, secure and reliable (SSR) society. More recently, Chiu et al. (2005) adopted the method to study marketing strategy based on customer behavior related to LCD-TVs. Also Hori and Shimizu (1999) employed it to design and evaluate the software of a display-screen structure for analyzing a supervisory control system.

D. The Fuzzy Number and Linguistic Variables

Since fuzzy set theory was initially proposed by Zadeh, and Bellman and Zadeh (1970) subsequently described the decision-making methods in fuzzy environments, an increasing number of studies have dealt with uncertain fuzzy problems by applying fuzzy set theory. Similarly, this study adopts fuzzy decision-making theory by considering possible fuzzy subjective judgments during the evaluation process of strategic planning for the Balanced Scorecard in mobile industry.

It is very difficult for traditional quantification methods to reasonably express situations that are overtly complex or hard to define; therefore, the notion of linguistic variables is a useful tool in such situations. The theory of linguistic variables is used to represent the imprecision of spatial data and human cognition in terms of the criteria used for the evaluation

process. A linguistic variable is a variable whose values are words or sentences in a natural or artificial language. We use this approach to evaluate criteria represented by linguistic variables in a fuzzy environment as “Very high influence”, “High influence”, “Low influence”, and “No influence” on a four-level fuzzy scale.

The use of linguistic variables is widespread and, in this study, the linguistic values of alternatives are primarily used to assess the linguistic ratings given by decision-makers. Furthermore, linguistic variables are used to measure the performance value of alternatives for each criterion as “no influence”, “low influence”, “high influence”, and “very high influence”. We use triangular fuzzy numbers to express the fuzzy scale, as shown in Step 1 of the evaluation process.

E. The ANP for Calculating Weights of Criteria Based on the NRM

The analytic hierarchy process (AHP) supposes independence among criteria, which is not reasonable in the real world. Saaty (1996) thus extended AHP to ANP to resolve problems with dependence or feedback between criteria, which primarily divides problems into numerous different clusters and every cluster includes multiple criteria. Moreover, there is outer dependence among clusters and inner dependence within the criteria of clusters as illustrated in Fig. 18. In addition, we figured the relative weights of criteria of respective matrices by pair-wise comparison and modifying the weights as eigenvectors. Then we integrated multiple matrices into a super matrix, because the capacity to examine the inner and outer dependence of clusters is the largest benefit of a super matrix.

There are three steps for the decision process of ANP. First, the decision problem and the structure of problem were built to offer an evident depiction of the problem and separate it into a relation network structure as shown in Fig. 1. Second, not only is pair-wise comparison matrix established, but also eigenvalue and eigenvector were figured. Pair-wise comparison is composed of clusters and criteria. Furthermore, the pair-wise comparison of clusters was separated into comparison of criteria within and between clusters. We utilize ratio scale (1 ~ 9) to determine the level of importance of the comparison. In addition, the data deriving from the survey of ANP were combined and transferred into pair-wise comparison matrix by geometric average. After building the matrix, we received the eigenvector $\boldsymbol{W}_{ii}$ through an equation: $\boldsymbol{Aw} = \lambda_{\max}\boldsymbol{w}$, where A is pair-wise comparison matrix, $\boldsymbol{w}=\left(w_1,\ldots,w_i,\ldots,w_n\right)'$ is the eigenvector, wi is the eigenvalue, then

$$\lambda_{\max} = \frac{1}{n}\sum_{i=1}^{n}\frac{(\boldsymbol{Aw})_i}{w_i}$$

where $(\boldsymbol{Aw})_i = \sum_{j=1}^{n} a_{ij}w_j$ and n equals the number of comparative criteria. Third, the super-matrix, tagged $\boldsymbol{W}$ (as shown in Equation 6), was formed. It was constructed by the dependence table obtained from the interrelations among criteria, and the eigenvectors received from the pair-wise comparison matrix served as the weights of it. No inner dependence among criteria or clusters was shown by a blank or zero. By Wu and Lee (2007), the usage of power matrix by $\boldsymbol{W}^h$ (multiplication) and $\lim_{h\to\infty}\boldsymbol{W}^h$ is a fixed convergence value; therefore, we can acquire weights in every criterion.

III. RESEARCH METHOD

A. Case study

This study adopts a case study (Case Study Research) manner, the main purpose of the concept of Balanced Scorecard framework, supplemented by the method of fuzzy multi-attribute performance evaluation. Therefore, this chapter will be the basic concept of case study method, including its definition, types, design, procedures and applicable time, and case studies to illustrate the causes and processes. Case studies often conducted in a single case, focusing on the depth of discussion and analysis, to programs such as case studies in Table II of the program (Yin, R. K., 1989).

Scholars Yin (1989) that the conditions for case study three:

(1) When the type of research question is “ How” and “ Why”

(2) The researchers studied no significant control over the event, or no control.

(3) The focus of the present rather than past events.

Therefore, when the case study focuses on contemporary issues and problems of control is small, the use of case study research is a better strategy. In early studies, the administration should be carefully considered for the problem through the "how" and "why " of deep thinking, and determine the reach of a valid target. Scholars Yin (1994) has decided that the research methods to be used, Ke Yi in the form of research questions, study the need for behavioral control, the focus of research is focused on current events upper three dimensions, as the choice of reference.

This study investigated the balanced scorecard and fuzzy multiple attribute decision making using of the Mobile industry. The relevant departments of the operation of field observations case, the case company looking to read all relevant information, interviews, related departments, etc., the case company's strategy, processes, performance evaluation, balanced scorecard to understand, to the line of the contents into a follow-up questions Explore the implementation problems encountered and possible improvements made under the direction of the results in order to enhance the case competition in IT services. This chapter will explore the case study approach, the use of case study of the theory and process of this study.

B. Balanced Scorecard

This study investigated the balanced scorecard and fuzzy multiple attribute decision making using of the Mobile industry. From the second half of 2010, gradually forming. The relevant departments of the operation of field observations case, the case company looking to read all relevant information, interviews, related departments, etc., the case company's strategy, processes, performance evaluation, balanced scorecard to understand, to the line of the contents into a follow-up questions Explore the implementation problems encountered and possible improvements made under the direction of the results in order to enhance the case competition in IT services. This chapter will explore the case study A case in order to understand the reason of the company began promoting promote the balanced scorecard, the researchers before the interview in advance cases to understand the company's corporate mission, vision and help the goal of:

Detailed planning steps are as follows:

- Stage one, the case company executives to Balanced Scorecard Introduction
- Phase II, the case company to collect the significant information to determine the executive structure to implement the Balanced Scorecard
- Stage III, the company announced the Balanced Scorecard to determine
- Phase IV, the case company teams at all levels About the Balanced Scorecard
- Stage five, the real implementation group set up developing develop with the four factors of corporate structure chart
- Phase VI, the first interview
- Phase VII, the first discussion
- Stage eight, the second interview
- Stage nine, the second talk
- Stage ten, received fuzzy multiple attribute decision making to establish meters for the case company helping help , the use of case study of the system and process of this study.

Avoid combining SI and CGS units, such as current in amperes and magnetic field in oersteds. This often leads to confusion because equations do not balance dimensionally. If you must use mixed units, clearly state the units for each quantity that you use in an equation.

TABLE I. BSC AND THE CASE COMPANY AND ITS MEASURE OF CORPORATE STRATEGY TABLE

Dimensions	***Policy Topics***	***Measure***
Customer Perspective	Customer Loyalty	1. Loyalty 2. Satisfaction 3. partner satisfaction
Financial Perspective	Stable earnings growth	1. Orders 2. renewal rate 3. revenue 4. Gross profit / profit / profit contribution
Process dimension	Reduce operating costs Continuous improvement process Internal employee satisfaction	1. operating cost control 2. time and commitment to customers 3. whether to solve the problem on the spot
Learning and growth perspective	Understanding of a shared vision Improving the Quality of Human Performance Evaluation and Rewards	1.employees aware of their responsibilities 2. formal staff turnover rate

C. Multi-attribute decision making

Step one: to define the various sectors of the property assessment indicators

The company implemented the Balanced Scorecard will be the case in four dimensions will be the key indicators of performance evaluation

It can be easily and clearly by a clear definition into two categories, one for the clear definition of a clear assessment can be the key performance index assessment, two values for the oral assessment can be the key performance indicators, the relationship these two categories.

Step Two: Setting fuzzy linguistic variables and fuzzy numbers

Step three: assess the performance of various departments

Step Four: Collect "key performance index of the weight "

D. The Fuzzy DEMATEL Method Procedure

A unique characteristic of this method is that it shows the relationships between Balanced Scorecard items with certain scores by using matrix operations. The relationship is that of “cause and effect”. Another important characteristic is that it grasps both the direct effects, and the indirect effects of competing components.

We use triangular fuzzy numbers (TFN) with fuzzy DEMATEL to establish fuzzy weights for the Balanced Scorecard components and to determine the relative importance of the criteria. Then, the performance value of each criterion can be derived by the decision-makers. After the synthetic utility values are derived, we rank the alternatives based on the best non-fuzzy performances (BNP). The procedures of the DEMATEL method and the evaluation methods can be summarized as follows:

Step 1: Producing the direct-relation matrix

Comparison scale of the DEMATEL method

Numeral	Definition
0	No influence
1	Low influence

2	High influence
3	Very high influence

Step 2: Normalizing the direct-relation matrix

On the basis of the direct-relation matrix $\boldsymbol{A}$, the normalized direct-relation matrix $\boldsymbol{X}$ can be obtained through formulas (2) and (3):

$$\boldsymbol{X} = k \cdot \boldsymbol{A} \quad (2)$$

$$k = \frac{1}{\max\limits_{1 \le i \le n} \sum\limits_{j=1}^{n} a_{ij}}, \quad i, j = 1, 2, ..., n. \quad (3)$$

Step 3: obtaining the total-relation matrix

Once the normalized direct-relation matrix $\boldsymbol{X}$ has been obtained, the total-relation matrix $\boldsymbol{T}$ can be derived by using formula (4), in which the $\boldsymbol{I}$ denotes the identity matrix.

$$\boldsymbol{T} = \boldsymbol{X} + \boldsymbol{X}^2 + \boldsymbol{X}^3 + ...$$

$$\boldsymbol{T} = \boldsymbol{X} + \boldsymbol{X}^2 + \boldsymbol{X}^3 + ... = \boldsymbol{X}(\boldsymbol{I} + \boldsymbol{X} + \boldsymbol{X}^2 + ...)$$

$$= \boldsymbol{X}\left(\frac{\boldsymbol{I} - \boldsymbol{X}^n}{\boldsymbol{I} - \boldsymbol{X}}\right)$$

$$= \boldsymbol{X}(\boldsymbol{I} - \boldsymbol{X})^{-1}, \text{ when } n \to \infty,\ \boldsymbol{X}^n = 0$$

$$\boldsymbol{T} = \boldsymbol{X}(\boldsymbol{I} - \boldsymbol{X})^{-1} \quad (4)$$

Step 4: Analyzing the results

In this step, the sum of rows and the sum of columns are used to derive vector $\boldsymbol{s}$ and vector $\boldsymbol{r}$ respectively, as shown in formulas (5), (6), and (7). Then, the horizontal axis vector ($\boldsymbol{s} + \boldsymbol{r}$), called "Prominence", is formed by adding $\boldsymbol{s}$ to $\boldsymbol{r}$, which indicates the level of importance of the criterion. Similarly, the vertical axis ($\boldsymbol{s} - \boldsymbol{r}$) called "Relation", is formed by subtracting $\boldsymbol{s}$ from $\boldsymbol{r}$, which may divide criteria into a cause group and an effect group. When ($\boldsymbol{s} - \boldsymbol{r}$) is positive, the criterion belongs to the cause group; otherwise, it belongs to the effect group. Therefore, the causal diagram can be derived by mapping the dataset of $(\boldsymbol{s} + \boldsymbol{r},\ \boldsymbol{s} - \boldsymbol{r})$, which provides valuable insights for making decisions.

$$\boldsymbol{T} = [t_{ij}]_{n \times n}, \quad i, j = 1, 2, ..., n \quad (5)$$

$$\boldsymbol{s} = \left[\sum_{j=1}^{n} t_{ij}\right]_{n \times 1} = [t_{i\cdot}]_{n \times 1} \quad (6)$$

$$\boldsymbol{r} = \left[\sum_{i=1}^{n} t_{ij}\right]_{1 \times n}^{t} = [t_{\cdot j}]_{n \times 1}, \quad (7)$$

where vector $\boldsymbol{s}$ and vector $\boldsymbol{r}$ respectively denote the sum of rows and the sum of columns from the total-relation matrix $\boldsymbol{T} = [t_{ij}]_{n \times n}$.

IV. Conclusion and Findings

We have proposed an approach for Balanced Scorecard evaluation in mobile industry based on effective group decision-making from the perspective of fuzzy multi-attribute decision making. The fuzzy DEMATEL method is used to establish fuzzy weights for Balanced Scorecard evaluation components.

The contribution of our approach is that it overcomes the limitations of traditional methods used to evaluate performance of mobile industry by Balanced Scorecard perspectives, as it does not have to accurately estimate the considered criteria in terms of numerical values for the anticipated alternatives. Applying fuzziness and the DEMATEL method for Balanced Scorecard evaluation allows practitioners to select components according to their organizations' priorities, and gather meaningful knowledge that captures the causal relationships between criteria.

The development of performance evaluation management system: the assessment of the case company does not have too many management systems, is not quantitative assessment of the project and assess the data. The purpose of daily operations, risk factors, such as timeliness and independent evaluation of the program flow is not related to each other. Data can not be automatically collected, the data obtained did not plan, can not understand the true value of the information, no relevant department or person responsible for data collection, resulting in missing data timeliness.

Structural organization of interdepartmental communication and consensus: The case company can provide the same services many companies are all competitors, the department of civil servants between the prevailing mindset, can not actively create the company with the best chance of combining customer service, real cause for concern.

Will promote the implementation of company strategy into the details: a positive vision combined with staff training / education, coupled with effective processes, customer satisfaction goals, and create a win-win target company shareholders and employees.

When we understand the theory and the four Balanced Scorecard dimensions, the dimensions will have to quantify these indicators, we must first determine through internal discussion and consensus on which indicators must be considered, and these indicators may be due to industry Different or change the company's vision, not necessarily take into account each company will have the same index.

In terms of strategic planning for the company, whether long or short, shall be convened by the company executives in charge of all a consensus on a common resolution. According to Company the specific action plan launched by the various

units in the company's goal to complete the year. The planning process of the balanced scorecard and corporate strategy, the company's specific action plan must take into account top-down driven; the results of the implementation level, is the bottom-up implementation, the company must develop a pragmatic Dimension in the four short-term goals can achieve. Therefore, measure of all sectors of the setting is very important because it is a business process assessment standard.

For important work, that is as soon as possible to assess the use of quantitative indicators. But the focus, it is not too much. For non-focused work, it can take fuzzy judgments, qualitative or quantitative management approach to determine. So the work can be focused, but also the employees ignore the non-priority work. Based on this concept, seven departments of the key indicators of performance evaluation, divided into two, one for the quantitative indicators, indicators of non-fuzzy, two non-quantitative indicators, and the fuzzy index, and the theory of multiple fuzzy attribute decision making Sector performance evaluation, in order to understand the applicability of the model, and the advantages and disadvantages of the operation in practice. Based on this concept, seven departments of the key indicators of performance evaluation, divided into two, one for the quantitative indicators, indicators of non-fuzzy, two non-quantitative indicators, and the fuzzy index, and the theory of multiple fuzzy attribute decision making Sector performance evaluation, in order to understand the applicability of the model, and the advantages and disadvantages of the operation in practice.

***Abstract*—The essence of strategy formulation is coping with competition. Therefore, the nature and degree of competition in an industry hinge on four basic forces: Production, Technology, Marketing and R&D are defined. To establish a strategic agenda for dealing with these contending currents and to grow despite them, a company must understand how they work in its industry and how they affect the company in its particular situation. This study adopt Fuzzy MCDM methods and details how these forces operate and suggests ways of adjusting to them, and, where possible of evaluation, of taking advantage of them. Knowledge of these underlying sources of competitive pressure provides the groundwork for a strategic agenda of action. The result highlights the critical strategies distance of the company, animate the positioning of the company in its industry, clarify the areas where strategic changes may yield the greatest payoff, and highlight the places where industry trends promise to hold the greatest significance as either opportunities or threats.**

Keywords-fuzzy multiple criteria decision making (FMCDM); fuzzy analytic network process (FANP); DEMATEL; strategy evaluation

I. INTRODUCTION

Every industry has an underlying structure, or a set of fundamental economic and technical characteristics, that gives rise to these competitive forces. Decision maker, wanting to position his company to cope best with its industry environment or to influence that environment in the company's favor, must learn what makes the environment tick. The essence of strategy formulation is coping with competition. Yet it is easy to view competition too narrowly and too pessimistically. Awareness of these forces can help a company stake out a position in its industry that is less vulnerable to attack.

The nature and degree of competition in an industry hinge on four forces: Production, Technology, Marketing and R&D [1]. To establish a strategic agenda for dealing with these contending currents and to grow despite them, a company must understand how they work in its industry and how they affect the company in its particular situation. This study details how these forces operate and suggests ways of adjusting to them, and, where possible, of taking advantage of them. Knowledge of these underlying sources of competitive pressure provides the groundwork for a strategic agenda of action [2]. They highlight the critical strengths and weaknesses of the company, animate the positioning of the company in its industry, clarify the areas where strategic changes may yield the greatest payoff, and highlight the places where industry trends promise to hold the greatest significance as either opportunities or threats. Understanding these sources also proves to be of help in considering areas for diversification.

The remainder of this paper is organized as follows. In Section 2, about strategy forces for business development is reviewed and the framework of dynamic strategy forces for efficiency business is built. In Section 3, the methodology of fuzzy hybrid MCDM model based on dynamic strategy is proposed for applying strategy forces. An empirical case and result are illustrated in Section 4. Discussions and implications are presented in Section 5. Finically conclusion is offered in Section 6.

II. ABOUT STRATEGY FORCES TO EVALUATION

The essence of strategy formulation is coping with competition. For a company in the fight for market share, competition is not manifested only in the other players. Rather, a competitive strategy in an industry is rooted in its underlying economics, and competitive forces exist not only from internal considerations but also that go well beyond the established combatants in the high-tech industry. The forces sources may gestate from customers, suppliers, potential entrants, and substitute products which are all competitors that may be more or less prominent or active depending on a particular industry.

The nature and degree of competition in the companies within the high-tech industry hinge on strategy forces [1][3], such as Production Capability (PC), Technology Competence (TC), R&D (RD), Marketing & Service (MS).

- Production Capability (PC)
- Technology Competence (TC)
- R&D (RD)
- Marketing & Service (MS)

Strategy-Forces based on answers to four generic questions about the strategy to be pursued by the organization which also assume the financial support and organizational deployment is available for high-tech competition game. Therefore, as Figure 1 these four questions, one about production, one about marketing, one about Technology, and one about R&D evolved quickly into a standard set of

"perspectives". The weaker the forces is to be collectively, however, the greater the opportunity can be for superior performance. Whatever their collective strength, the corporate strategist's goal is to find a position between company and industry where can best defend itself against these forces or can influence them in its favor [4].

Understanding these sources also proves to be of help in considering areas for diversification. A strategy map is a diagram that is used to document the primary strategic goals being pursued by an organization or management team and to help managers focus their attention more closely on the interventions necessary to ensure the strategy is effectively and efficiently executed. By providing managers with the direct feedback on whether the required actions are being carried out, and whether they are working. A performance management system is deciding what activities and outcomes to monitor. By providing a simple visual representation of the strategic objectives to be focused on, along with additional visual cues in the form of the perspectives and causal arrows, the strategy map has been found useful in enabling discussion within a management team about what objectives to choose, and subsequently to support discussion of the actual performance achieved.

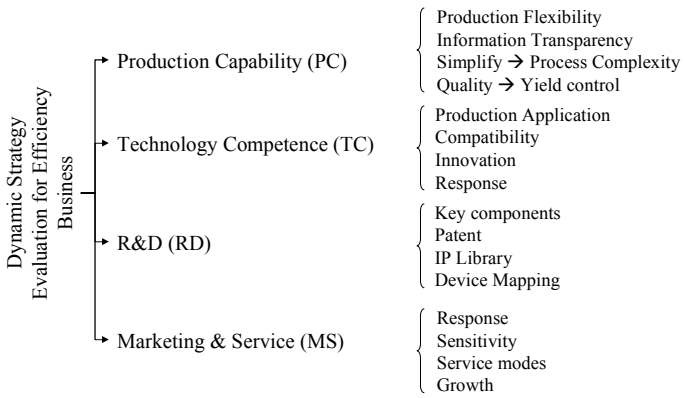

Figure 1. The Hierarchy Structure

III. MEASURING THE FORCES

This section is based on what factors the past scholars in the study of strategy forces considerations indicated and to further discuss the result of the study; hence, identify the flow of facts. This study uses the four main factors indicated by four-factor model as PC, TC, RD and MS factors to implement the strategies can be evaluated in dynamical considerations in time; identify the sub-factors that would affect the main factors, thus firmly develop evaluating criteria and its dynamic track of mapping.

A. Methodologies

The field of fuzzy multiple criteria decision making (FMCDM) concerns the problems that how decision makers should ideally do when facing multiple conflicting criteria. Group decision-making solve problems through a group of experts form their specific knowledge domain and help on business strategies decision-making [5][6]. There are considerable methods and models have been proposed for various FMCDM problems (as Figure 2) with respect to different perspectives and theories.

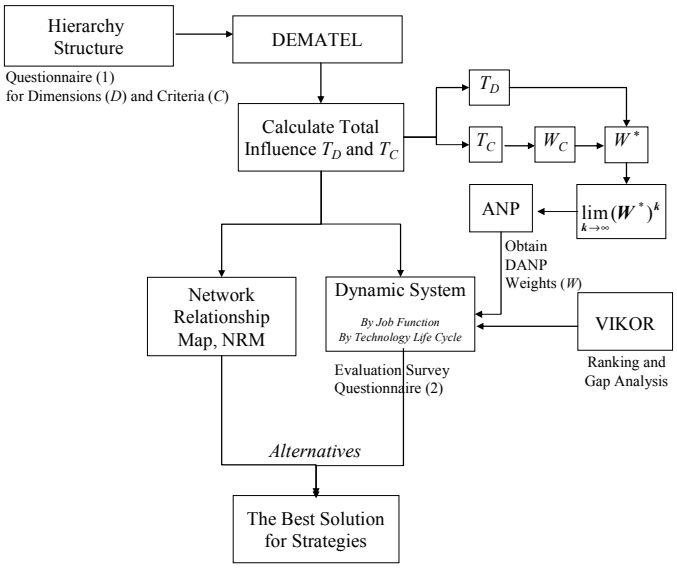

Figure 2. Framework of Hybrid Methodologies Application

B. Fuzzy Theory with AHP and ANP

Because of the subjective of the attributes used in the evaluation, AHP [7][8][9][10][11][12] is the most appropriate method for this problem. However, since the experts prefer natural language expressions rather than sharp numerical values in their assessments, the classical AHP may not yield with a satisfactory result. Expressions such as "not very clear", "probably so", and "very likely", are used often in daily life, and more or less represent some degree of uncertainty of human thought. The fuzzy set theory proposed by Zadeh [13], an important concept applied in the scientific environment, has been available to other fields as well. Consequently, the fuzzy theory has become a useful tool for automating human activities with uncertainty-based information. This study proposes a fuzzy AHP framework to weigh the talent selection implementation factors. This study model helps organizations identify the differences between the desired and current situations, and then identify the improvement areas and develop the strategies for the talent selection implementation.

In addition, the company can also use the assessment results as a benchmark with competitors and other "best-in-class" organizations. To manage talent selection successfully, its measurement indicators must be defined and prioritized. Because of the subjective of the attributes used in the evaluation, AHP [10][12] is the most appropriate method for this problem. However, since the experts prefer natural language expressions rather than sharp numerical values in their assessments, the classical AHP may not yield with a

satisfactory result. This study proposes a fuzzy AHP framework to weigh the talent selection implementation factors.

C. Fuzzy Decision-making

When people encounter uncertain or vague decision-making problems in the real world, they often express their thinking and subjective perception in words instead of probability and statistics. But the problem with words is that their meanings are often vague. Furthermore, even when people use the same words, individual judgment of events is invariably subjective and may differ. Moreover, even if the meaning of a word is well defined (e.g., the linguistic comparison labels in the standard AHP questionnaire responses), when we use the word to define a set, the boundary that separates whether an object does or does not belong to the set is often fuzzy or vague. This is why fuzzy numbers and fuzzy sets have been introduced to characterize linguistic variables. The preferences in AHP are essentially human judgments based on one's perception (this is especially true for intangibles), and we believe the fuzzy approach allows for a more accurate description of the decision making process.

FANP approach has been presented to prioritize strategy implementation factors for a manufacturing business to implement one of its most critical parts used in management decision process and under multiple criteria's decision-making in the fuzzy environment [11][14]. The main criteria and attributes have been decided which are based on the current business scenario and experience of the experts in the respective fields. The large number of criteria and attributes demonstrated the complexities being involved in the strategy implementation factors. Each factor affecting [15] as strategy forces and implementation has been analyzed and discussed. This paper has made a significant contribution to identify the important criteria and paves the way to consider these practically relevant and interesting issues of strategy forces factors in the fuzzy environment.

We emphasize that the contribution of this study which build up and apply the theoretical model of strategy implementation priority. This study takes a step in the direction of setting priorities of clarifying, guiding and integrating terms and concepts relevant to strategy implementation and management aspects in the firm process.

D. Mapping tools

A network connects the components of a decision system. According to size, there will be a system that is made up of subsystems, with each subsystem made up of components, and each component made up of elements. The elements in each component interact or have an influence on some or all of the elements of another component with respect to a property governing the interactions of the entire system.

DEMATEL

The DEMATEL method is based upon graph theory, enabling us to plan and solve problems visually, so that we may divide multiple criteria into a relationship of cause and effect group, in order to better understand causal relationships. Directed graphs (also called digraphs) are more useful than directionless graphs, because digraphs will demonstrate the directed relationships of sub-systems. A digraph typically represents a communication network, or a domination relationship between individuals, etc. The DEMATEL method can convert the relationship between the causes and effects of criteria into an intelligible structural model of the system [16][17].

A component of a decision network which was derived by the DEMATEL method is denoted by $\boldsymbol{C}_h, h = 1, \cdots, m,$ and assume that it has n_h elements (determinants), which we denote by $e_{h1}, e_{h2}, \cdots, e_{hm}$. The influences of a given set of elements (determinants) in a component on any element in the decision system are represented by a ratio scale priority vector derived from paired comparisons of the comparative importance of one criterion and another criterion with respect to the interests or preferences of the decision makers. This relative importance value can be determined using a scale of 1–9 to represent equal importance to extreme importance.

Dynamical system

A dynamical system (DS) is a concept in mathematics where a fixed rule describes the time dependence of a point in a geometrical space [18]. DS is a manifold *M* called the phase (or state) space endowed with a family of smooth evolution functions Φ^t that for any element of $t \in T$, the time, map a point of the phase space back into the phase space. The notion of smoothness changes with applications and the type of manifold. There are several choices for the set *T*. When *T* is taken to be the reals, the dynamical system is called a *flow*; and if *T* is restricted to the non-negative reals, then the dynamical system is a *semi-flow*. When *T* is taken to be the integers, it is a *cascade* or a *map*; and the restriction to the non-negative integers is a *semi-cascade*. DS is a means of describing how one state develops into another state over the course of time [19]. Technically, a DS is a smooth action of the reals or the integers on another object (usually a manifold). When the reals are acting, the system is called a continuous dynamical system, and when the integers are acting, the system is called a discrete dynamical system.

E. VIKOR method

The compromise-ranking method (VIKOR method) determines the compromise solution [20][21][22]; the obtained compromise solution is acceptable to the decision-makers because it provides a maximum group utility of the majority (represented by min *S*), and a minimum individual maximal regret of the opponent (represented by min *Q*). The model uses the DEMATEL and ANP procedures to obtain the weights of criteria with dependence and feedback and uses the VIKOR method to obtain the compromise solution.

IV. Empirical Case and Results

The example of High-Tech electronic company is illustrated to show the proposed method. Empirical findings these four factors have the relationship of mutually interactive and self-feedback. Therefore, this study provides set of patterns, and take major player of high-tech company, explained that manufacturer of using the way of business strategies in a dynamic industry nature. The result presents a comprehensive framework for making judgments to move forward about business strategies development is essential. The function is refers to completes this position or duty group of important abilities, therefore the application function examines whether matches is a very good concept.

Empirical case of high-tech company as the example is illustrated to show the proposed method. As for the numerical raw data was collected in fuzzy considerations and turned into the calculation in crisp numbers directly for further evaluation processes. The findings of these four factors have the relationship to mutually interactive and its self-feedback (as Table 1 and Table 2).

TABLE 1 The Distance of Influences by Aspects

Aspect		R	S	R+S	R-S	Rank
A	PC	4.239	4.068	8.306	0.171	3
B	TC	4.339	3.846	8.184	0.493	2
C	RD	3.571	4.908	8.479	-1.337	4
D	MS	4.485	3.813	8.298	0.673	1

Table 1 states "Market & Service" will be more important to fit the change of outside environment and close to real requirement and get the real necessity of customer needs. Besides, it shows the "Technology Competence" can be a potential to challenge and to complete rivals in a speedy growth industry nature.

TABLE 2 The Distance of Influences by Criteria

		Criteria	R	S	R+S	R-S	Rank
A	a1	Production Flexibility	5.556	4.518	10.074	1.038	1
	a2	Information Transparency	4.811	5.663	10.474	-0.852	14
	a3	Simplify operation -- Process Complexity	4.499	6.029	10.528	-1.53	16
	a4	Quality -- Yield control	5.445	4.584	10.029	0.861	3
B	b1	Production Application	4.676	5.469	10.145	-0.793	13
	b2	Compatibility	5.43	4.622	10.052	0.808	5
	b3	Innovation	5.429	4.591	10.02	0.838	4
	b4	Response	5.553	4.515	10.068	1.038	2
C	c1	Key components	4.995	5.032	10.027	-0.037	10
	c2	Patent	5.104	4.972	10.076	0.132	7
	c3	IP Library	4.925	5.054	9.979	-0.129	11
	c4	Device Mapping	4.507	5.733	10.24	-1.226	15
D	d1	Response	4.822	5.24	10.062	-0.418	12
	d2	Sensitivity	5.033	4.996	10.029	0.037	8
	d3	Service modes	5.08	5.105	10.185	-0.025	9
	d4	Growth	5.13	4.872	10.002	0.258	6

As the rank result (Table 2), "a1" and "b4" both locate higher position. Instantly, for pure foundry business, the "Production Flexibility" tasks have been always discussed by high-tech work environment. Due to the sensitivity of market and economic change, the globalized change may lead the change of corporate business strategies to fit the requirement of market (users) needs. Therefore, a continuous and monitored "Response" is required for deployment of internal resources and providing a well mechanism to feedback to end-users in time.

The essential alternatives are provides for the problems solving. According to Table 3, "R7: Financial support/ incentive program" and "R6: Competitiveness Evaluation System" are the most favor and satisfied issues while the performance evaluation to be measured. Not surprising that "R1: Innovation/Intelligent Property" reveals lowest credit which shows the importance of knowledge sharing and accumulation can possibly create a new hope of ideas generator toward a new challenge on the next business strategic move. As for the definition of those alternatives are showing as follows:

R1. Innovation/Intelligent property: build an innovative environment for continuously technology development achievement.

R2. Knowledge platform: provide a knowledge platform for knowledge accumulation, problem solving, lesson learned and information sharing.

R3. Response system: external environmental change to cause Market/Operation strategies to be adjusted.

R4. Communication system: a wide channel for customer services in viewing the progress of the on-line production and 24-hour on line service.

R5. Efficiency evaluation system: Internal and external factors to move the operation work in effectively.

R6. Competitiveness evaluation system: evaluate the way of technology adoption and shorten the time of technology development into production phase.

R7. Financial support/ incentive program: budget plan and financial support.

This research involves several objects from Taiwan High-Tech manufacturing related leaders, experts from different function which includes top management, senior R&D, the senior administrative personnel and marketing functions. The questionnaire of evaluation mainly was composed of two parts: questions for evaluating the relative importance of criteria and company's performance corresponding to each criterion.

The performance scores and gap (by VIKOR) are shown in Table 3. Using the performance values, relative results are obtained. We use the global weight in ANP to compare the performances of R1, R2, R3, R4, R5, R6, and R7 as the ANP provides significant feedback. The gap identified related needs-recognition and strategic behavior in sequence.

By integrating and calculating the investigated data, we determine the overall performance to guide the improvement of that R7 $\succ$ R6 $\succ$ R4 $\succ$ R5 $\succ$ R2 $\succ$ R3 $\succ$ R1. The overall performance value of R7 (28.613) and R6 (28.406) are close, whereas the range distance with R1 has the largest gap. Thus, R7, R6, R4, R5, R2, R3, and R1 have its sequence on enhancement of their business strategies or redefinition of management stages.

V. Discussions and Implications

There are most evidence of improvements in team performance attributed to management development, these typically related to process issues such as innovative activities, cost control, knowledge management, quality of service, better focus on customer needs, and improved customer relations etc. Managers in some organizations cited evidence of more strategic behavior and identified better procedures and monitoring of actions. Technology improvement from Cost reductions, efficiency gains and more effective quality control were also reported. To face external change and to fit the requirement of business opportunities, appropriate dynamical strategies give a challenged team performance arising from strategy.

Major difficulties of measurement of strategy forces and of attributing improvements to strategy in management development were encountered, especially where the same measures were used for function and business performance, or where the performance was regarded as a function of a manager's performance. Equally, business performance was difficult to separate from organizational performance and was affected by extraneous factors.

The alternatives which were ranked highest in terms of organizational performance improvements displayed quantified, written and corroborated evidence and respondents were unequivocal that strategic management development had contributed to all prime measures of business efficiency. The framework appears to be intuitive to managers and applicants who quickly adopt the terminology of the strategy forces. It offers a means of guiding easily recognized environmental components and provides a framework for combining these components to describe possible scenarios. In addition, it clearly distinguishes between the perspectives of different industry nature and increases the likelihood that decision makers will incorporate these perspectives into their decisions.

The decision-making and influence processes operating in decision events are likely to be advanced through a closer alignment with the problem solving and decision-making in the real world.

VI. Conclusion

The conclusions and learning points to be drawn from the research outlined above relate both to the substantive findings, which contribute to the debate on the role of business in improving performance, and the procedural aspects of the methodology developed to undertake the study.

A case-study approach was necessary in order to capture qualitative information, including such 'soft' measures as perceptions of individuals, as well as exploring the relevant development and performance processes within organizations at different functions. In adopting such a methodology, however, there was a risk of marginalizing the findings because policy makers invariably seek 'hard' measures, with quantitative data that can be subject more easily to statistical tests. The challenge, therefore, was to devise a methodology that could permit hard conclusions from soft data.

The strategy force describes the structure of business systems and the industry nature of the influence mechanisms that determine outcomes. The strategy evaluation reliance on business decisions rather than operation activities as the key structural component of the framework provides a flexible and generalizable framework around which existing strategy force research can be arrayed. It also provides a means of aligning technology research with the problem solving and decision-making literatures. More work remains to be done to fully identify and understand influence mechanisms in strategy

evaluation systems. The dynamic strategy evaluation in considering the strategic forces can assist these efforts by offering a simple and easily recognizable structure for organizing research and practice in a complex field where a great deal is yet to be learned.

***Abstract*—Standardized project management (SPM) is regarded as a well-structured system for improving the success of new product development projects. SPM can be defined as a standardized set of project management practices. It helps achieve the company's strategic goal through the effective use of project-driven approach. This paper used a Decision Making Trial and Evaluation Laboratory (DEMATEL) method to help companies to create a critical Standardized Project Management system and identify the influence of dimensions and criteria in the SPM system. First of all the dimensions and criteria of the SPM system are determined. DEMATEL approach is then applied to construct the SPM system structure model with Fuzzy number influence interrelationship among dimensions and associated criteria. An empirical case from industry is used to explore the effectiveness of the proposal approach.**

Keywords-fuzzy number; DEMATEL; Standardized project management (SPM); FDEMATEL.

I. INTRODUCTION

According to multiple empirical studies, a company's effectiveness partly depends on the success of its projects. (Kerzner and Cooper, 2000). And some companies in high-velocity industries have recognized a standardized project management (SPM) as a strategy for managing development projects (Milosevic and Patanakul, 2005).

In constructing a SPM system, the interrelationship among the dimensions and criteria is very critical for an effective SPM system. For this reason, we have adopted an integrated decision framework based on Decision Making Trial and Evaluation Laboratory (DEMATEL) and the triangular fuzzy number for constructing the most appropriate SPM system structure model.

DEMATEL method is usually applied in gathering group knowledge for forming a system structural model, as well as visualizing the causal relationship of sub-systems through a causal diagram. Here, DEMATEL is used to detect complex relationships and build relation structure among criteria for constructing SPM system. Additionally, set priorities among sub-system and criteria, and to determine the most appropriate SPM evaluation system structure.

We live in a global economy in which the turnaround of structural and technological change is rapid and sometimes unpredictable. Business processes are changing even as we speak, and traditional jobs and work settings are becoming virtual, e-driven, and mobile. This atmosphere of change creates the need to build the organization so that (1) people can create new products before they are anticipated by the customer, marketplace, or competition, and (2) the company can design, develop, and produce new products better, faster, and cheaper, and get them to market. Development life cycles have gone from years to months to days. (Barkley, 2008)

II. STANDARDIZED PROJECT MANAGEMENT SYSTEM

Some companies in high-velocity industries have recognized that a well-constructed standardized project management (SPM) is a critical success strategy for managing new product development projects. In their study, Milosevic and Patanakul (2005) have illustrated that SPM may increase new product development projects success which is approved. The Organizational Project Management Maturity Model (OPM3), a standard issued by Project Management Institute (PMI), also suggests SPM as a major strategy for projects success. These references suggest that SPM may have a significant place in many companies' approach to PM, especially to new product development (NPD) projects.

PMBOK has defined the PM life cycle which is divided into five phases: initial, planning, executing, control and closing. A company has to start to develop one NPD project in a fixed time before it has a full "strategy" to make sure achieve the goal. In the second phase, a cautious project management plan (PMP) is necessarily developed for PM. A good PMP is critical issue in the "process" planning which is required to show how to use the methodologies planning project and external environment interaction of PM. Those are the impact planning of the project processes. In the third phase, a project is executed by "people". People in the positive culture, to be independent finish missions and have a strong back-office team

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

of project in company, they are making decision correctly in a project. In the fourth phase, a project must have right tools to control processes, people and technology. Finally, the study is has constructed a standardized project management system for new product development. All of above through the expert questionnaires select the critical factors of SPM. Besides, according to the literature review the "resource" also is the main success factor of projects. The integration of project planning with resource planning ensures that the company does not take one more than it can handle, and can avoid the kind of resource constraints or bottlenecks characterized in the critical chain concept (Barkley, 2008). Because of a project is usually under limited in resource so that the SPM performance evaluation system is divided into five dimensions of seventeen criteria in this study, the result is shown in TABLE I. .

TABLE I. FACTORS AFFECTING THE CONSTRUCTION OF SPM SYSTEM

Dimensions	Factors(Criteria)
A Strategy	a_1, The project management strategy a_2, Fit with long-term strategy a_3, Fit with new strategic intent
B People	b_1, Project organization b_2, Project culture b_3, Project leadership
C Tool	c_1, PM tools / template c_2, Technology dependency c_3, Information management system c_4, Project management measure index
D Process	d_1, Project environment d_2, Project management methodologies d_3, Project management process d_4, Project management metrics
E Resource	e_1, Cost / expenses e_2, Support of facility e_3, Support of employees

III. DEVELOPING SPM EVALUATION MODEL

This study will through the expert questionnaires to select the critical success factors of SPM system. Then, DEMATEL is applied to confirm the influence on each factor and to explore the relevance of the SPM's multiple criteria. This section includes three parts: the first part is application the triangular fuzzy number; the second part is developing network relationship with the DEMATEL; the last part is according to empirical analysis result to construct the SPM system for the new product development.

A. FUZZY NUMBER

B. Buckley (1985) proposed geometric mean method to calculate the final fuzzy weights for each fuzzy matrix. Given an m × m positive reciprocal matrix $A=\lfloor a_{ij}\rceil$ is derived by pairwise comparison from m participating evaluators, then $r_i\left(\prod_{j=1}^{m} a_{ij}\right)^{1/m}$ represents the geometric mean of each raw. According to Saaty's definition, $\lambda_{\max}$ be the largest eigen value of A and the weights, w_1 as the components of the normalized eigenvector corresponding to $\lambda_{\max}$,where $w_i = r_i/(r_1+\cdots+r_m)$.

Buckley (1985) further considered a fuzzy positive reciprocal matrix $\tilde{A}=[\tilde{a}_{ij}]$,extending the geometric mean method to the fuzzy geometric mean method and exploited which to find the final fuzzy weights of each criterion as follows:

$\tilde{r}_i = (\tilde{a}_{i1}\otimes\tilde{a}_{i2}\otimes\cdots\otimes\tilde{a}_{im})^{1/m}$ and $\tilde{w}_l = \tilde{r}_l\otimes(\tilde{r}_1\oplus\tilde{r}_l\oplus\cdots\oplus\tilde{r}_m)^{-1}$

where $\oplus$ and $\otimes$ called additive and multiplicative operators of two fuzzy number, respectively. These arithmetic operations will describe in next paragraph.

The evaluators choose a performance score for each participating company based on their subjective judgments. This way of estimating the achievement level of each criterion on each strategy can use the methods of fuzzy theory for treating the fuzzy environment. In evaluating process, after well define the criteria and their relationship, we have to determine the weights or measure of these criteria, and obtain then performance score of each alternative with respect to evaluated criteria. Furthermore, choose an suitable aggregating operator to derive the synthetic value of these alternatives respectively, the final step is to assign the preferred order for all alternatives based on their synthetic values.

In general case, we can employ triangular fuzzy number to express the aggregated fuzzy weights of *j*-th criterion as follows:

$$\tilde{w}_i = (l_i, m_i, u_i) \tag{1}$$

where $\tilde{w}_i$,is derived by Eq.(1)

It can be assumed that evaluation expert *k* has his fuzzy performance score of $\tilde{E}_{ij}^{k}$ for the criteria *j* under alternative *i*, and all the items to be evaluated is defined in feasible set *S*.

$$\tilde{E}_{ij}^{k} = \left(LE_{ij}^{k}, ME_{ij}^{k}, UE_{ij}^{k}\right),\quad j\in S \tag{2}$$

Each expert may has his different academic and business careers, so as his objective understanding on the linguistic variables. This study utilizes the average number to integrate the fuzzy judgment values given by *m* experts. That is, $\tilde{E}_{ij}$ express the average fuzzy judgment given by the participated evaluators. Its triangular fuzzy number is shown below:

$$\tilde{E}_{ij} = \left(LE_{ij}, ME_{ij}, UE_{ij}\right),\quad j\in S \tag{3}$$

where

$$\tilde{E}_{ij} = \left(1/m\right)\otimes\left(\tilde{E}_{ij}\oplus\cdots\oplus\tilde{E}_{ij}^{m}\right) \tag{4}$$

Specifically, $\tilde{E}_{ij}$ can be calculated by Buckley (1985a):

$$LE_{ij} = \left(1/m\right)\times\left(\sum_{k=1}^{m} LE_{ij}^{k}\right);\ ME_{ij} = \left(1/m\right)\times\left(\sum_{k=1}^{m} ME_{ij}^{k}\right);\ UE_{ij} = \left(1/m\right)\times\left(\sum_{k=1}^{m} UE_{ij}^{k}\right) \tag{5}$$

Moreover, the fuzzy synthetic matrix *R* can then be developed from both fuzzy weighting vector and fuzzy performance matrix as following:

$$\overline{\mathrm{R}} = \overline{\mathrm{w}} \Leftrightarrow \overline{\mathrm{E}} \tag{6}$$

where

$$\widetilde{w} = (\widetilde{w}_1, \cdots, \widetilde{w}_j, \cdots, \widetilde{w}_n)^t ;\ \widetilde{E} = [\widetilde{E}_{ij}] \tag{7}$$

"$\Leftrightarrow$"in Eq.(6)indicates the aggregating operator of fuzzy weighting vector and fuzzy performance matrix.

How to assess the measure of evaluated criteria is the critical process. In traditional evaluation methods such as Analytic Hierarchy Process, ELECTRE, PROMETHEE, TOPSIS, VIKOR and Grey Relation Analysis, assume definitely mutually independent between each pair criteria, and the simple additive weighted (SAW) method is appropriately to aggregate the synthetic value from criteria weights with performance scores. However, in most of MCDM problems, dependence or feedback may exist in evaluating structure. This independent relationship can not satisfy the nature of real situations. We can not employ SAW to derive the synthetic values if the relationship among these criteria are not independent, then the other aggregating tools is more suitable. For instance, fuzzy integral will provide appropriate estimate of synthetic values while in dependent situation; Analytic Network Process (ANP) can be applied to estimate the synthetic values while in the situation of feedback exists in considered dimension with its lower level of hierarch system.

Finally, the final fuzzy synthetic judgment of individual alternative for j evaluated criteria can be illustrated as follows:

$$\widetilde{R}_i = (LR_i, MR_i, UR_i) \quad \forall i \tag{8}$$

where

$$LR_i = \sum_{j=1}^{n} l_j \cdot LE_{ij};\ MR_i = \sum_{j=1}^{n} m_j \cdot ME_{ij};\ UR_i = \sum_{j=1}^{n} u_j \cdot UE_{ij} \tag{9}$$

According to Dubois and Prade (1978), a fuzzy number $\widetilde{A}$ is a fuzzy subset of a real number, and its membership function is $\mu_{\widetilde{A}}(x): R \to [0,1]$, where x represents the criteria, and is described by enshrined with the following characteristics:

(1) $\mu_{\widetilde{A}}(x)$ is a continuous mapping from R to the closed interval [0,1]

(2) $\mu_{\widetilde{A}}(x)$ is a convex fuzzy subset.

(3) $\mu_{\widetilde{A}}(x)$ is the normalization of a fuzzy subset, which means that there exists a number such that $\mu_{\widetilde{A}}(x_0) = 1$.

It cane be called fuzzy number if all the conditions above are satisfied. The triangular fuzzy number $\mu_{\widetilde{A}}(x) = (L, M, U)$ can be defined as Eq.(10) and Figure 1. :

$$\mu_{\widetilde{A}}(x) \begin{cases} (x-L)/(M-L) & L \le M \le M \\ (U-x)/(U-M) & M \le x \le U \\ 0 & \text{otherwise} \end{cases} \tag{10}$$

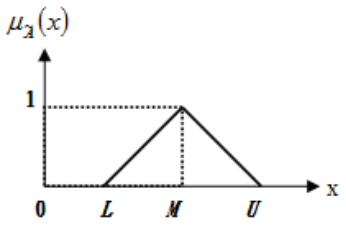

Figure 1. The triangular fuzzy number.

B. DEMATEL to develop network relationship

DEMATEL is an analytical method of structural model. It is mainly used to solve all kinds of complex problems to clarify the essential of the problem. Using matrix and related math theories to calculate the cause and effect on each element and the degree. This method widely used to solve various types of complex studies that can effectively understand the complex structure and provide viable options of problem solving (Tzeng, 2007).

DEMATEL divided into five steps. The first step is to confirm the system elements and develop the evaluating scale. To confirm the system has an elements and denoted by $E_1, E_2, \ldots, E_n$. Then, using pair of dimensions to compare and using evaluating scale ranging from 0, 1, 2, 3, and 4 which in turn represents: no influence"0", low influence"1", medium influence"2", high influence"3", and extremely high influence"4" as measuring standard. The second step is to calculate the direct relation average matrix. Using pair of degree of interaction to obtain directly influence matrix $\boldsymbol{K} = [k_{ij}]_{m \times m}$, k_{ij} represents the degree of effect on *i* factor effects *j* factor.

$$\boldsymbol{K} = \begin{bmatrix} k_{11} & k_{12} & \cdots & k_{1m} \\ k_{21} & k_{22} & \cdots & k_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ k_{m1} & k_{m2} & \cdots & k_{mm} \end{bmatrix} \tag{11}$$

When the elements of *i* have a direct effect on the elements of *j*, then $k_{ij} \neq 0$, opposite $k_{ij} = 0$. The third step is to normalize the matrix. It can be obtained from formula (12) and (13). Its diagonal is 0, and maximum sum of row and column is 1.

$$\boldsymbol{X} = \frac{\boldsymbol{K}}{s} \tag{12}$$

$$s = \max\left(\max_{1 \le i \le n} \sum_{j=1}^{n} a_{ij}, \max_{1 \le j \le n} \sum_{i=1}^{n} a_{ij} \right) \tag{13}$$

The forth step is to obtain the total effect matrix $\boldsymbol{T}$.

When $\lim_{l \to \infty} \boldsymbol{X}^l = [0]_{n \times n}$,

Its can be obtained by $\boldsymbol{T} = \boldsymbol{X} + \boldsymbol{X}^1 + \boldsymbol{X}^2 + \boldsymbol{X}^3 + \cdots + \boldsymbol{X}^m = \boldsymbol{X}(\boldsymbol{I} - \boldsymbol{X})^{-1}$.

Where $\boldsymbol{I}$ represents the unit matrix. The fifth step is to obtain prominence and relation. To sum of each row and column of the total effect matrix $\boldsymbol{T}=[t_{ij}]$. Its will obtain the sum of all rows d and the sum of all columns r. If d_i represents the sum of all rows of the total effect matrix $\boldsymbol{T}$, meaning directly or indirectly affects degree; r_j represents the sum of all columns of the total effect matrix $\boldsymbol{T}$, meaning affected by other criteria. d_i represents the factor which will affect other factors, r_j represents the factor that is affected by other factors. According to the definition, $d_i + r_j$ presents the degree of relationship between factors, meaning "prominence"; $d_i - r_j$ presents the degree of effect and effected for the facto, meaning "relation" (Tamura et al., 2002; Tzeng et al., 2007).

IV. Application of The Proposed Framewor

The standardized project management system model aims to optimize the interface and standardization. It will survey research projects in the EU funded 6'h Framework Programmed (FP6) for standards related output, and serve as a platform to those projects seeking a cost-effective interface with standards bodies. In doing so, it will help projects upgrading their output and speed up market adoption of research results. Also, COPRAS will produce generic guidelines, supporting future research projects to build an interface to standardizations into their proposals, already at an early stage. In doing so, it will bring research and standardization closer together (Brusse & Wenning, 2005).

In this study will be exploring the quality assessment for SPM system within the case study of company X. We will consider standardized project management system model on purpose to constructing the mutual maneuverability and duplication in different projects.

A. DEMATEL to develop network relationship

The template is designed so that author affiliations are not repeated each time for multiple authors of the same affiliation. Please keep your affiliations as succinct as possible (for example, do not differentiate among departments of the same organization). This template was designed for two affiliations.

In this paper, we have confirmed FUZZY DEMATEL decision-making structure, and also analyzed five dimensions with seventeen criteria of the SPM system. According to the expert questionnaires, we obtain the total effect matrix T of SPM system's dimensions and criteria as shown in TABLE II. to TABLE III. We can find the cognition and opinion of experts in five dimensions and the relationship among the extents of the impact can be found which is compared to other dimensions as show in TABLE II. .

According to the prominence (r + d), the dimension B (people) is the highest impact of the strength of relation which means the most important influencing factors; in addition, the dimension E (resource) are all the factors that affect the least degree of other factors.

According to the relation (r – d), we also can find the dimensions A (strategy) and B (people) both are the highest degree of impact relationship that affect other factors directly. They also have the interact characteristics. Otherwise, dimension C (tool) is the most vulnerable to impact that compare with other dimensions.

According to TABLE III. We can obtain all the criteria of the impact of relations with each factor. Furthermore, we also find in TABLE III. Which illustrates the criterion a_1 (project management strategy) is the highest degree of impact relationship in all the criteria. Otherwise, the criterion b_2 (project culture) is the most vulnerable to impact of criteria that compare with other criteria.

B. Identify the Headings

They show the relationship of each dimension and criterion. According to Fuzzy DEMATEL model that it indicates the dimension A (strategy) is the main influence of all dimensions. A project must give a clear definition of its goals in strategy. This step is constructing the SPM of the first importance. In the other hand, the tool in the SPM model is influenced by other dimensions. It is shows that through a complete strategy can use the right people in the right position. And then, the project usually constrained by lack of resource so a good strategy can allocate well of limed resource.

Consequently, the allocation not only influences the project process but also tool in a project. And then, people need training by company strategy to operation tools. To sum up, the company's strategy is the critical factor of constructing SPM system structure model. See following Figure 2, Tables II and III.

C. Inluence map of each dimension

In the strategy dimension, the criterion a_1 (project management strategy) is the most critical influence of the Figure 3.

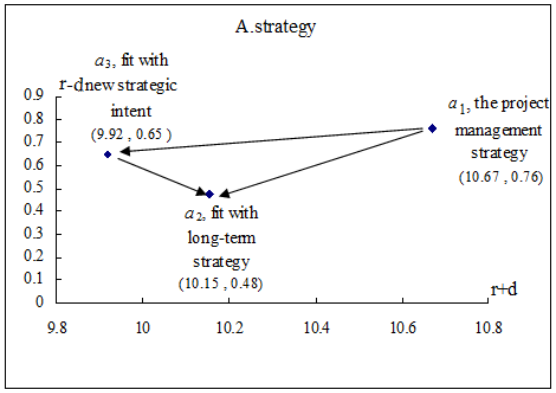

Figure 3. Influence map of strategy relationship.

In the people dimension, the criterion b_1 (project organization) is the most critical influencing factor. In a project which it has an excellent team-work to finishing the goal as soon as possible. Furthermore, the b_2 (project culture) and b_3 (project leadership) are influenced by the b_1 (project organization).

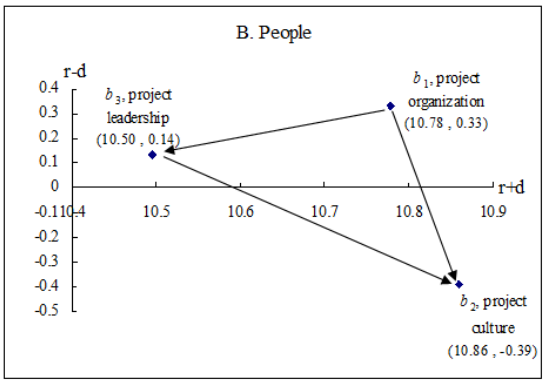

Figure 4. Influence map of people relationship.

The factor c_4 (information management system) is the infulence of the tool dimesion. In this study, we obtain that a project need a good communicate system with each team number to makesure their schedule every week.

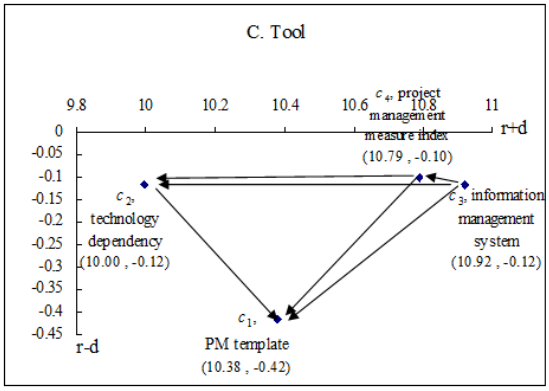

Figure 5. Influence map of tool relationship.

The factor d_2 (project methodologies) is the main influence in the dimension D "process". In this study, we obtain that a methodology made a great impact on the project process.

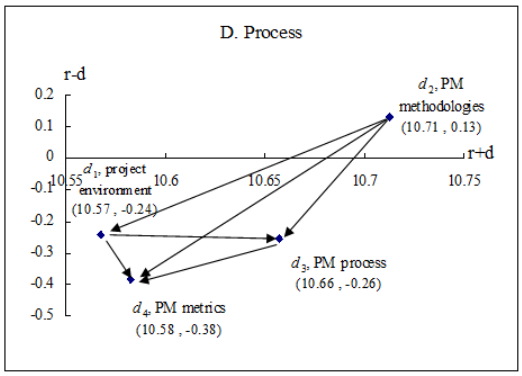

Figure 6. Influence map of process relationship.

Finally, a company always supplies a limted cost to development a project in practice. In the resource dimention, we also obtain the critical fator cost/expenses (e_1). Consequently, it is more or less of a company's budget which impactes the projcet with support of facility (e_2) and support of employee (e_3).

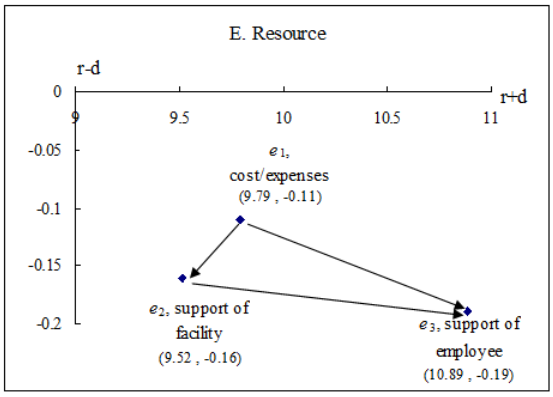

Figure 7. Influence map of resource relationship.

V. Results and Discussions

In this paper, we use FUZZY DEMATEL to develop network relationship. According to the results of empirical analysis and the literature review to the past research, the study illustrates that shows dimension A (Strategy) is the critical and dimension C (Tool) is ultimate influenced dimension in the standardized project management system, hence we can start improvement company total performance from company's strategy. Because of that the "Process" and "Tools" will be promoted to high level. And then, the Tools not only easy to using by people but also the resource are allocated efficiently. In order to achieving company's target it need change and improve all of dimensions from top to bottom.

In this paper, we find that dimensions of "Strategy", "People" and "Resource" are the critical factors for total performance evaluate of constructing standardized project management system. According to the empirical analysis, we have used DEMATEL to construct the standardized project management model especially for new product development projects. We also obtains that the dimension A "Strategy" is the main index in constructing the SPM system. The results from this study provide a project management team a guidance to satisfy the company's purpose and create the value of sustainable business.

The company must state that new product development and opportunity generation are the business. Not only remove barriers to the generation of new ideas and provide a system of information and feedback on current products and services but also create a positive, perhaps virtual place for new ideas to incubate. To generate a flexible process of filtering, evaluating and transitioning new ideas into a portfolio and new product development process and manage and control new product development and marketing. Then, real success stories are created to demonstrate that new ideas can produce products that grow the business.

***Abstract*—Although multiple objective programming (MOP) skills have been extensively studied in various issues, the problem of MOP with interdependence has received little attention. In this paper, we overcome the problem of Carlsson and Fullĕr's method and propose a novel index to measure the interdependence grade between objectives by using Monte Carlo simulation and regression analysis. Then, an interdependent multiple objective programming (IMOP) model is proposed. In addition, we give three numerical examples to demonstrate the proposed method. From the numerical results, we can conclude that the proposed method can rationally deal with the problem of MOP with interdependence.**

Keywords- Multiple objective programming (MOP); interdependence; interdependent multiple objective programming (IMOP).

I. INTRODUCTION

Since Kuhn and Tucker [1] proposed the concepts of vector optimization, and Koopmans [2] applied the efficient vector method to derive necessary conditions of efficient solution, more and more researchers engaged in studies about multiple objective programming (MOP) problems. The common characteristics of MOP can be described as: (1) a set of quantifiable objectives; (2) a set of well-defined constraints; (3) a process of obtaining some trade-off information, implicit or explicit, between the stated quantifiable objectives and also between stated or unstated non-quantifiable objectives [3]. The general form of MOP can be represented as solving the following mathematical programming problem:

$$\max_{x \in X} / \min \quad \{f_1(\boldsymbol{x}), f_2(\boldsymbol{x}), \cdots, f_n(\boldsymbol{x})\}, \tag{1}$$

$$s.t. \quad \boldsymbol{x} = \{\boldsymbol{x} \in \boldsymbol{R}^n \mid g_k(\boldsymbol{x}) \geq 0, \quad k = 1, \cdots, m\}.$$

Although MOP have been widely extended for many issues, such as global optimization [4, 5], multistage [6], and multilevel [7,8,9,10,11], the assumption of independent objectives should be released. That is, supportive and conflicting objectives usually happen in realistic multiple criteria decision making (MCDM) problems, and we should not ignore the problem of MOP with interdependence between objectives under the viewpoint of optimization.

Carlsson and Fullĕr [12-14] first proposed two methods to consider the problem of MOP with interdependence by estimating the interdependent grade between objectives. Thereafter, several issues have been proposed to consider further situations, such as uncertainty environment [13,14] and temporal interdependence [15]. However, several shortcomings of their methods should be modified so that we can employ interdependent multiple objective programming (IMOP) in practice. Firstly, their first method [12] does not precisely measure the supportive or conflicting grade between objectives and can only deal with the one-dimensional decision problem. In contrast, their second method [14] can only be suitable for symmetric linear interdependent multiple objective programming (SLIMOP). However, it can be seen that since real-life problems are usually complex and intricate, a general method should be given to handle all kinds of IMOP problems.

In this paper, Monte Carlo simulation and regression analysis are used to measure the grade of interdependence between objectives. The proposed method is suitable not only for the one-dimensional decision problem but also for the high-dimensional decision problem. In addition, the proposed index can also be suitable for asymmetric nonlinear interdependent multiple objective programming (ANIMOP). Three numerical examples are used to demonstrate the proposed method. The results are compared with the conventional MOP and Carlsson and Fullĕr's model. On the basis of the numerical results, we can conclude that the proposed method can deal with the IMOP problems and overcome the problem in [12-15].

The remainder of this paper is organized as follows. The problem of MOP is discussed in Section 2. The method to solve IMOP is proposed in Section 3. In Section 4, three numerical examples are used to demonstrate the proposed method and compared with the conventional MOP and

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Carlsson and Fullẽr's method. Discussions are presented in Section 5 and the conclusion is in the last section.

II. THE PROBLEM OF IMOP

The main problem of conventional MOP models is the unrealistic assumption of independence between objectives. In order to show the impact, we can transform the MOP model into the single-objective programming (SOP) model by using the following compromise programming [16]:

$$\begin{aligned} &\min \quad r(\boldsymbol{y}; p) = \| \boldsymbol{y} - \boldsymbol{y}^* \|_p \\ &s.t. \quad \boldsymbol{x} = \{\boldsymbol{x} \in \boldsymbol{R}^n \mid g_k(\boldsymbol{x}) \le 0, \quad k = 1, \cdots, m\}, \end{aligned} \tag{2}$$

where $r(\boldsymbol{y}; p)$ is a measurement of regret from $\boldsymbol{y}$ to $\boldsymbol{y}^*$ according to the l_p-norm, $\boldsymbol{y}$ denotes the objective vector, and $\boldsymbol{y}^*$ denotes the ideal-point vector.

Assume a biobjective problem and let $p = \infty$. Assume a biobjective problem and let $p = \infty$. Consider a case depicted in Figure 1. Then the optimal solution should be $\boldsymbol{y}^\infty$ if and only if $f_1(\boldsymbol{x})$ is independent of $f_2(\boldsymbol{x})$. However, if $f_1(\boldsymbol{x})$ supports $\hat{f}_2(\boldsymbol{x})$, the optimal solution should transfer from $\boldsymbol{y}^\infty$ to $\hat{\boldsymbol{y}}_\infty$.

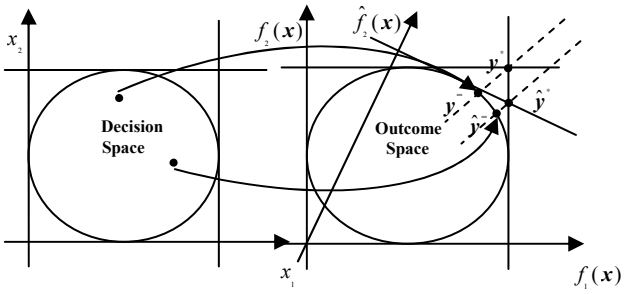

Figure 1. The optimal solution between independent and interdependent objectives

Therefore, if we want to extend MOP to IMOP, we should consider the interdependence between objectives as shown in Figure 2.

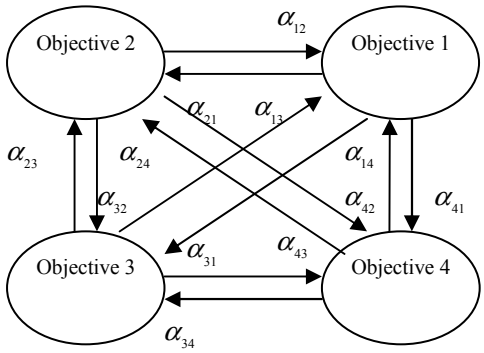

Figure 2. The interdependence with multiple objectives

From Figure 2, it can be seen that the objectives in MOP should be modified [12-14] as:

$$\hat{f}_i(\boldsymbol{x}) = f_i(\boldsymbol{x}) + \sum_{j=1, j \ne i}^{n} \alpha_{ij} f_j(\boldsymbol{x}), \quad \forall \quad 1 \le i, j \le n \tag{3}$$

where α_{ij} denotes the estimated grade of interdependence from the *j*th objective to the *i*th objective. Note that from Eq. (3), it can be seen that MOP is a special case while $\alpha_{ij} = 0$ in IMOP.

Therefore, the MOP problem should be reformulated as:

$$\begin{aligned} &\max/\min_{x \in X} \quad \{\hat{f}_1(\boldsymbol{x}), \hat{f}_2(\boldsymbol{x}), \cdots, \hat{f}_n(\boldsymbol{x})\} \\ &s.t. \quad \boldsymbol{x} = \{\boldsymbol{x} \in R^n \mid g_k(\boldsymbol{x}) \le 0, \quad k = 1, \cdots, m\}. \end{aligned} \tag{4}$$

In order to solve the IMOP problem above, the grade of interdependence should be derived first. In [12-14], they defined the grade of interdependence of the *i*th objective using the following equation:

$$\Delta(f_i) = \sum_{j=1, j \ne i}^{n} \text{sign}(\alpha_{ji}) \tag{5}$$

where $\Delta(f_i)$ is the number of objectives supported by the *i*th objective minus the number of objectives hindered by the *i*th objective.

Although using Eq. (5), we can reformulate conventional MOP to IMOP, two main shortcomings should be overcome so that we can solve IMOP problems more precisely. Firstly, it can be seen that Eq. (5) does not precisely reflect the supportive or conflicting grade between objectives because of using the sign operation. Furthermore, their method can only deal with the one-dimensional decision problem. To overcome the above problem, [4] proposed another index to measure the

grade of interdependence between objectives in the high-dimensional decision space as follows.

Assume two linear objectives, $f_i(\boldsymbol{x}) = <\boldsymbol{c}_i, \boldsymbol{x}>$ and $f_j(\boldsymbol{x}) = <\boldsymbol{c}_j, \boldsymbol{x}>$ where $\| \boldsymbol{c}_i \|$, $\| \boldsymbol{c}_j \| = 1$, then the grade of interdependence between $f_i(\boldsymbol{x})$ and $f_j(\boldsymbol{x})$ can be defined by:

$$k(f_i(\boldsymbol{x}), f_j(\boldsymbol{x})) = k(f_j(\boldsymbol{x}), f_i(\boldsymbol{x})) = \frac{1 - <\boldsymbol{c}_i, \boldsymbol{c}_j>}{2}, \quad (6)$$

where $<>$ denotes the dot product, $\| \cdot \|$ denotes the length of the specific vector, and $\alpha_{ij} = -2 \times k(f_i(\boldsymbol{x}), f_j(\boldsymbol{x})) + 1$.

According to Eq. (6), however, it can be seen the above index can only deal with the linear case. In addition, it is clear that α_{ij} is not always equal to α_{ji} in the realistic problems. In order to overcome the above problems, in this paper, we propose a novel index to measure the interdependent grade between objectives by using Monte Carlo simulation and regression analysis.

III. Interdependent Multiple Objective Programming

As mentioned above, the crucial point of dealing with IMOP is to obtain the grade of interdependence between objectives so that we can reformulate the conventional MOP model. To overcome the problem of interdependence in MOP, we first define the notations as follows.

Let $f_i(\boldsymbol{x})$ and $f_j(\boldsymbol{x})$ be two objectives. We say that

(i) $f_i(\boldsymbol{x})$ supports $f_j(\boldsymbol{x})$ on $\boldsymbol{X}$ (denoted by $f_i(\boldsymbol{x}) \uparrow f_j(\boldsymbol{x})$) if $f_i(\boldsymbol{x}') \geq f_j(\boldsymbol{x})$ entails $f_j(\boldsymbol{x}') \geq f_i(\boldsymbol{x})$, for all $\boldsymbol{x}', \boldsymbol{x} \in \boldsymbol{X}$; $\partial f_j(\boldsymbol{x}) / \partial f_i(\boldsymbol{x}) > 0, \forall \boldsymbol{x} \in \boldsymbol{R}^n$;

(ii) $f_i(\boldsymbol{x})$ is in conflict with $f_j(\boldsymbol{x})$ on $\boldsymbol{X}$ (denoted by $f_i(\boldsymbol{x}) \downarrow f_j(\boldsymbol{x})$) if $f_i(\boldsymbol{x}') \geq f_j(\boldsymbol{x})$ entails $f_j(\boldsymbol{x}') \leq f_i(\boldsymbol{x})$, for all $\boldsymbol{x}', \boldsymbol{x} \in \boldsymbol{X}$; $\partial f_j(\boldsymbol{x}) / \partial f_i(\boldsymbol{x}) < 0, \forall \boldsymbol{x} \in \boldsymbol{R}^n$;

(iii) $f_i(\boldsymbol{x})$ is independent with $f_j(\boldsymbol{x})$ on $\boldsymbol{X}$ (denoted by $f_i(\boldsymbol{x}) \perp f_j(\boldsymbol{x})$), otherwise.

If $\boldsymbol{X} \in \boldsymbol{R}^n$ then we say that $f_i(\boldsymbol{x})$ supports (or is in conflict with) $f_j(\boldsymbol{x})$ globally.

If the objective functions are differentiable on $\boldsymbol{X}$, we may define

(i) $f_i(\boldsymbol{x}) \uparrow f_j(\boldsymbol{x})$ on $\boldsymbol{X}$ $\Leftrightarrow$ $\partial_{\boldsymbol{e}} f_i(\boldsymbol{x}) / \partial_{\boldsymbol{e}} f_j(\boldsymbol{x}) \geq 0, \forall \boldsymbol{e} \in \boldsymbol{R}^n, \boldsymbol{x} \in \boldsymbol{X}$,

(ii) $f_i(\boldsymbol{x}) \downarrow f_j(\boldsymbol{x})$ on $\boldsymbol{X}$ $\Leftrightarrow$ $\partial_{\boldsymbol{e}} f_i(\boldsymbol{x}) / \partial_{\boldsymbol{e}} f_j(\boldsymbol{x}) \leq 0, \forall \boldsymbol{e} \in \boldsymbol{R}^n, \boldsymbol{x} \in \boldsymbol{X}$,

where $\partial_{\boldsymbol{e}} f_i(\boldsymbol{x})$ denotes the derivative of $f_i(\boldsymbol{x})$ with respect to the direction $\boldsymbol{e} \in \boldsymbol{R}^n$ at $\boldsymbol{x} \in \boldsymbol{R}^n$. If for a given direction $\boldsymbol{e} \in \boldsymbol{R}^n$, $\partial_{\boldsymbol{e}} f_i(\boldsymbol{x}) \partial_{\boldsymbol{e}} f_j(\boldsymbol{x}) \geq 0$ holds for all $\boldsymbol{x} \in \boldsymbol{X}$ then we say that $f_i(\boldsymbol{x})$ supports $f_j(\boldsymbol{x})$ with respect to the direction $\boldsymbol{e}$ on $\boldsymbol{X}$.

It is clear that the information of $\partial f_j(\boldsymbol{x}) / \partial f_i(\boldsymbol{x})$ is hard to obtain because it may vary with respect to different decision points. Therefore, the compromise is to find a constant estimated value of $\partial f_j(\boldsymbol{x}) / \partial f_i(\boldsymbol{x})$ by α_{ji}. Now, we depict Figure 3 to describe the concept of calculating α_{ji}. First, we transform objective value to satisfaction level $\lambda(\cdot)$. From Figure 3, it can be seen that $\partial f_j(\boldsymbol{x}) / \partial f_i(\boldsymbol{x})$ is negative because when the satisfaction level of $f_i(\boldsymbol{x})$ increases, the satisfaction level of $f_j(\boldsymbol{x})$ decreases, and vice versa. Due to the problem of obtaining the value of $\partial f_j(\boldsymbol{x}) / \partial f_i(\boldsymbol{x})$, we can calculate the estimated value of $\partial f_j(\boldsymbol{x}) / \partial f_i(\boldsymbol{x})$, i.e., α_{ji}, by using regression analysis to estimate the best fitted line and obtain the regression coefficient as α_{ji}. Note that except for linear regression analysis, we can also use spline regression analysis to calculate the piece wise situation.

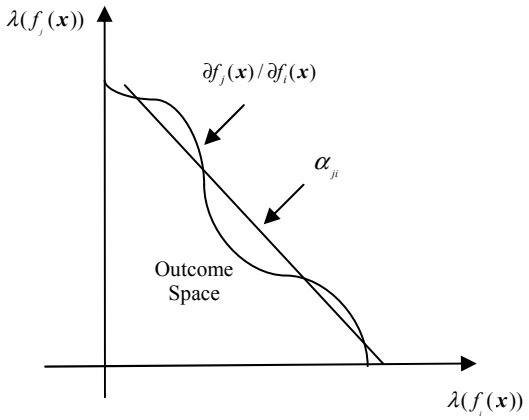

Figure 3. The concept of α_{ji}

According to the above concepts, the procedure of calculating the grade of interdependence between objectives can be developed as follows. First, we employ Monte Carlo simulation to calculate the value of each objective and the

corresponding satisfaction level ($\lambda_i(\boldsymbol{x})$) which is subject to the specific constraints, as shown in TABLE I.

TABLE I. Monte Carlo Sampling to Calculate Objective and Satisfaction Values.

Monte Carlo Simulation	*Calculate*						*Subject to*
	$f_1(\boldsymbol{x})$	⋯	$f_n(\boldsymbol{x})$	$\lambda_1(\boldsymbol{x})$	⋯	$\lambda_n(\boldsymbol{x})$	
1	f_{11}	⋯	f_{n1}	λ_{11}	⋯	λ_{n1}	$g_1(\boldsymbol{x}) \le 0$,
2	f_{12}	⋯	f_{n2}	λ_{12}	⋯	λ_{n2}	⋮
⋮	⋮	⋮	⋮	⋮	⋮	⋮	$g_m(\boldsymbol{x}) \le 0$.
N	f_{1N}	⋯	f_{nN}	λ_{1N}	⋯	λ_{nN}	

Note that the satisfaction of each objective can be represented as:

$$\lambda_i(\boldsymbol{x}) = \begin{cases} 1 & \text{if} \quad f_i(\boldsymbol{x}) \ge M_i, \\ 1 - \dfrac{M_i - f_i(\boldsymbol{x})}{M_i - m_i} & \text{if} \quad m_i < f_i(\boldsymbol{x}) < M_i, \\ 0 & \text{if} \quad f_i(\boldsymbol{x}) \le m_i, \end{cases} \qquad (9)$$

where $m_i = \min\{f_{ir}\}, \forall r = 1, \ldots, N$ and $M_i = \max\{f_{ir}\}, \forall r = 1, \ldots, N$. Next, we give two simple cases to describe the concepts of the proposed method.

Case 1. Consider the following biobjective mathematical programming:

$$\max\{f_1(\boldsymbol{x}), f_2(\boldsymbol{x})\},$$
$$\text{where } f_1(\boldsymbol{x}) = 2x_1^2 - 3x_2^2 \text{ and } f_2(\boldsymbol{x}) = -3x_1 + x_2^2.$$
$$s.t. \quad x_1 + x_2 \le 20,$$
$$x_1, x_2 \ge 0.$$

Next, we use Monte Carlo simulation with the uniform distribution and generate 5,000 samples to derive the feasible solutions of the above problem, as shown in Figure 4. It can be seen that Objective 1 and Objective 2 are in conflict with each other and the block line of the feasible solutions indicates the efficient set which represents the grade of interdependence between the objectives. Since the interdependent grade with respect to different point is a non-linear curve, we can estimate the approximate interdependent grade between the objectives by a straight line, as the dash line shown in Figure 4.

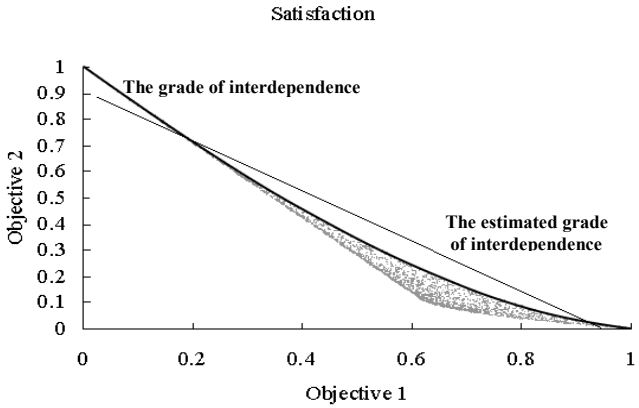

Figure 4. The conflicting case between the objectives.

Case 2. Consider the following biobjective mathematical programming:

$$\max\{f_1(\boldsymbol{x}), f_2(\boldsymbol{x})\},$$
$$\text{where } f_1(\boldsymbol{x}) = x_1^2 + 3x_2^2 \text{ and } f_2(\boldsymbol{x}) = 2x_1 + 3x_1x_2.$$
$$s.t. \quad 0 \le x_1, x_2 \le 2.$$

With the same procedures in **Case 1**, we can depict Figure 5 to represent the interdependent relationship between Objective 1 and Objective 2. From Figure 5, it can be seen that Objective 1 and Objective 2 are supportive to each other.

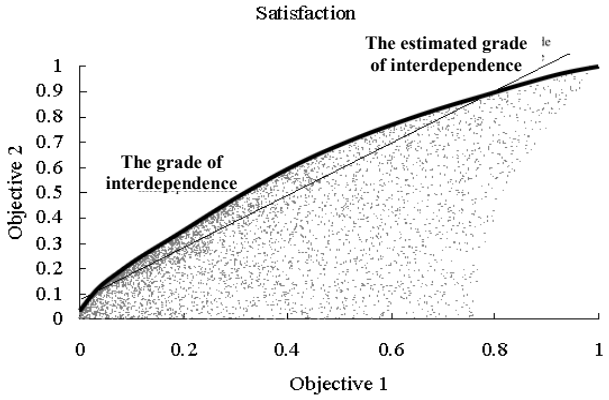

Figure 5. The supportive case between the objectives.

Then, we can calculate the estimated grade of interdependence between the objectives using the following regression equation:

$$\lambda_i(x) = \mu + \alpha_{ij} \times \lambda_j(x) + \varepsilon_{ij},$$

where μ denotes the intercept term, α_{ij} is the regression coefficient, and $\varepsilon_{ij} \sim N(0, \sigma^2)$ denotes the error term.

Now, we can incorporate the information about the grade of interdependence between objectives to developing IMOP

by adopting the ideas of Carlsson and Fullẽr [2-4] to reshape the satisfaction level. The grade of interdependence of the *i*th objective can be defined as $\Delta(f_i) = \sum_{j=1, j\neq i}^{n} \alpha_{ji}$. Then, the satisfaction level of the *i*th objective can be reformulated as:

For $\Delta(f_i) \geq 0$,

$$H_i(\boldsymbol{x}, \Delta(f_i)) = \begin{cases} 1 & if \quad f_i(\boldsymbol{x}) \geq M_i \\ \left(1 - \dfrac{M_i - f_i(\boldsymbol{x})}{M_i - m_i}\right)^{1/(\Delta(f_i)+1)} & if \quad m_i < f_i(\boldsymbol{x}) < M_i \\ 0 & if \quad f_i(\boldsymbol{x}) \leq m_i \end{cases}$$

. (12)

For $\Delta(f_i) < 0$,

$$H_i(\boldsymbol{x}, \Delta(f_i)) = \begin{cases} 1 & if \quad f_i(\boldsymbol{x}) \geq M_i \\ \left(1 - \dfrac{M_i - f_i(\boldsymbol{x})}{M_i - m_i}\right)^{|\Delta(f_i)|+1} & if \quad m_i < f_i(\boldsymbol{x}) < M_i \\ 0 & if \quad f_i(\boldsymbol{x}) \leq m_i \end{cases}$$

. (13)

The above concepts for reshaping the grade of satisfaction can be depicted by Figure 6:

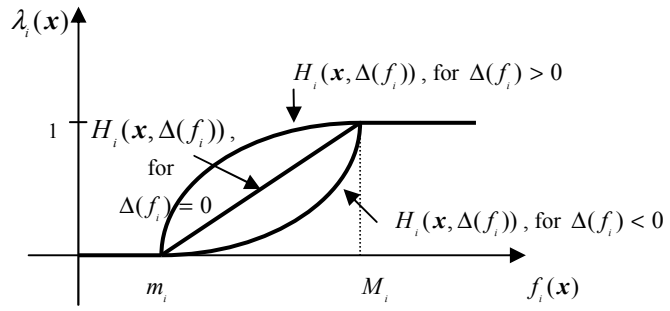

Figure 6. The reshaping grade of satisfaction

Finally, assume the optimal solution of a decision can be represented with "the average, the better." We can derive the optimal solution and reformulate the conventional MOP model to the following IMOP model:

$$\max \quad T(H_1(\boldsymbol{x}, \Delta(f_1)), \ldots, H_n(\boldsymbol{x}, \Delta(f_n)),) \quad , \quad (1 \qquad 5)$$
$$s.t. \quad \boldsymbol{x} = \{\boldsymbol{x} \in \boldsymbol{R}^n \mid g_j(\boldsymbol{x}) \geq 0, \quad j = 1, \cdots, m\},$$

where $T(\cdot)$ denotes the *t*-norm operation and indicates the preference structure of a decision maker in this paper. Note that other operations can also be used in the similar way to represent the specific preference structure of a decision maker.

IV. NUMERICAL EXAMPLES

In this section, three numerical examples are used to demonstrate the proposed method for dealing with IMOP problem. In addition, we also employ the conventional MOP model and Carlsson and Fullẽr's method to compare the results with the proposed method.

Example 1. This example contains five-objective and one-dimensional decision problem and is from Carlsson and Fullẽr [4].

$$\max\{f_1(x), f_2(x), f_3(x), f_4(x), f_5(x)\},$$
where, $f_1(x) = x$, $f_2(x) = (x+1)^2 - 1$, $f_3(x) = 2x + 1$,
$f_4(x) = x^4 - 1$, and $f_5(x) = -3x + 1$,
$s.t. \quad 0 \leq x \leq 2$.

It is easy to identify the interdependent grade between the objectives using Carlsson and Fullẽr's method as $\Delta(f_1) = \Delta(f_2) = \Delta(f_3) = \Delta(f_4) = 3 - 1 = 2$, $\Delta(f_5) = 0 - 4 = -4$. On the other hand, we can also use Monte Carlo simulation to calculate the interdependent grade between the objectives, as shown in TABLE II.

TABLE II. The Comparison of Various Methods

α_{21}	α_{31}	α_{41}	α_{51}	α_{12}
0.997	**1.000**	**0.790**	**-1.000**	**0.986**
α_{32}	α_{42}	α_{52}	α_{13}	α_{23}
0.986	**0.836**	**-0.986**	**1.000**	**0.997**
α_{43}	α_{53}	α_{14}	α_{24}	α_{34}
0.790	**-1.000**	**0.943**	**1.000**	**0.943**
α_{54}	α_{15}	α_{25}	α_{35}	α_{45}
-0.943	**-1.000**	**-0.997**	**-1.000**	**-0.790**

Next, we use MOP, Carlsson and Fullẽr's method (CF), and the proposed model (i.e., Eq. (11)) to derive the optimal solutions, as shown in TABLE III.

TABLE III. The Comparison of Various Methods

	x	$f_1(x)$	$f_2(x)$	$f_3(x)$	$f_4(x)$	$f_5(x)$
MOP	1.76	1.76	6.62	4.52	8.60	-4.28
CF	0.65	0.65	1.72	2.30	-0.73	-0.95
IMOP	0.69	0.69	1.86	2.38	-0.67	-1.07

From TABLE 3, it can be seen that the results of Carlsson and Fullẽr 's method are approximate to the proposed model, because of the similar interdependent grade between the objectives. In addition, compared to MOP, two IMOP models

suggest that we should decrease x to achieve the optimal solution.

Example 2. Consider the following three-objective and three-dimensional linear programming problem:

$$\max\{f_1(\boldsymbol{x}), f_2(\boldsymbol{x}), f_3(\boldsymbol{x})\},$$
$$\text{where } f_1(\boldsymbol{x}) = 4x_1 + 2x_2 - 3x_3,$$
$$f_2(\boldsymbol{x}) = 4x_1 + 3x_2 + 2x_3,$$
$$f_3(\boldsymbol{x}) = -7x_1 - 4x_2 + 6x_3.$$
$$s.t. \quad 0 \le x_1, x_2, x_3 \le 10.$$

To calculate the interdependent grade between the objectives, we can use Carlsson and Fullĕr 's method (i.e., Eq.(6)) and Monte Carlo simulation, respectively, as shown in TABLE IV.

TABLE IV. The interdependence grade between objectives of Example 2

	α_{21}	α_{31}	α_{12}	α_{32}	α_{13}	α_{23}
CF	0.552	-0.998	0.552	-0.517	-0.998	-0.517
IMOP	0.543	-0.988	0.544	-0.503	-1.000	-0.513

By incorporating the information of the interdependent grade between the objectives, we can derive the optimal solutions of **Example 2** using MOP, Carlsson and Fullĕr 's method, and the proposed method, respectively, as shown in TABLE V.

TABLE V. The Comparison of MOP and IMOPs in Example 2

	x_1	x_2	x_3	$f_1(\boldsymbol{x})$	$f_2(\boldsymbol{x})$	$f_3(\boldsymbol{x})$
MOP	2.8571	10.0000	10.0000	1.4286	61.4286	0.0000
CF	7.1987	2.0374	10.0000	2.8694	54.9068	1.4598
IMOP	7.3354	1.7810	10.0000	2.9036	54.6846	1.5282

Similar to Example 1, the proposed method and Carlsson and Fullĕr 's method have the approximate results. Both results show that we should decrease x_2 and increase x_1 to obtain the optimal solution.

Example 3. Consider the following three-objective and three-dimensional nonlinear programming problem:

$$\max\{f_1(\boldsymbol{x}), f_2(\boldsymbol{x}), f_3(\boldsymbol{x})\},$$
$$\text{where } f_1(\boldsymbol{x}) = 3x_1^2 + 6x_1x_2 + 2x_2x_3,$$
$$f_2(\boldsymbol{x}) = 4x_1 + 2x_2 + 3x_1x_3,$$
$$f_3(\boldsymbol{x}) = 2x_1x_3 + 3x_2 + 4x_3.$$
$$s.t. \quad 0 \le x_1 + x_2 + x_3 \le 10.$$

Note that since Carlsson and Fullĕr 's method cannot handle this nonlinear problem, only MOP is compared with the proposed model. Next, using Monte Carlo simulation and regression analysis, we can calculate the interdependent grade between the objectives, as shown in Table VI.

TABLE VI. The Interdependence Grade between Objectives of Example 3

α_{21}	α_{31}	α_{12}	α_{32}	α_{13}	α_{23}
-0.5535	-0.2577	-0.4843	0.4915	0.1738	0.5576

Next, we can solve the above problem by using MOP and IMOP to obtain the optimal solution, as shown in TABLE VII.

TABLE VII. The Comparison of MOP and IMOPs in Example 3

	x_1	x_2	x_3	$f_1(\boldsymbol{x})$	$f_2(\boldsymbol{x})$	$f_3(\boldsymbol{x})$
MOP	3.4257	2.2860	4.2883	101.7993	62.34609	53.39206
IMOP	2.7086	3.4074	3.8840	103.8525	49.20918	46.79829

Compared to the results with the conventional MOP, IMOP suggests that we should decrease both x_1 and x_3 and increase to x_2 achieve the optimal solution. Next, we give discussions in Section 5 according to the findings of our examples.

V. DISCUSSIONS

MOP has been widely applied in various areas to deal with MCDM problems. However, the problem of interdependence between objectives seems to be ignored in MOP for dealing well with the realistic decision problems. It can be seen that if we ignore the problem of interdependence between objectives, the result may be huge differences with the optimal solution.

Although Carlsson and Fullĕr have proposed several papers to deal with the IMOP problems, their method can only deal with the simple IMOP problems and cannot measure the grade of interdependence between the objectives precisely. In this paper, we propose another index by using Monte Carlo simulation and regression analysis to overcome the above problems simultaneously.

From the results of numerical examples, it can be seen that the interdependent grade of the proposed method and Carlsson and Fullĕr's method have the similar results. Therefore, it enhances the justification of the proposed method. On the other hand, it also shows that the proposed method should be more flexible and useful than Carlsson and Fullĕr's method because the proposed method can be used in the high-dimensional decision space, linear and nonlinear problems, and asymmetric interdependent grade situations. In addition, all kinds of interdependent grade between objectives can be solved using the standard operating procedures.

VI. CONCLUSIONS

In this paper, the problem of MOP with interdependence between objectives is considered. A novel index is proposed to measure the grade of interdependence between objectives by using Monte Carlo simulation and regression analysis. An IMOP model is developed to solve the IMOP problems. From the numerical results, we can conclude that the proposed method can provide a satisfactory solution to deal with the IMOP problems.

***Abstract*—Multi-criteria decision-making (MCDM) is one of the most widely used decision methodologies. Because every kind of MCDM approach has its strong point and weakness, it is hard to make sure that what kind of MCDM approach is suitable to a specific problem. Therefore, a new decision making method is proposed in this paper based on linguistic information and intersection concept which is called linguistic intersection method (LIM). The linguistic variables are used to express the opinion of each decision-maker. There are four MCDM methods such as TOPSIS, ELECTRE, PROMETHEE, and VIKOR are included in the linguistic intersection method. First, each MCDM approach is used to determine the ranking order of all alternatives in accordance with the linguistic evaluations by decision-makers. And then, the intersection set is determined for the better alternatives of all methods. Third, the final ranking order of alternatives in the intersection set can be determined by the proposed method. This study presented an example to implement and compare the proposed method with individual linguistic MCDM method. Finally, some conclusions and future research will be discussed at the end of this paper.**

Keywords- MCDM; Linguistic variables; linguistic intersection method.

I. INTRODUCTION

Decision-Making is the procedure to find the best action among a set of feasible actions [1]. Multi-criteria decision-making (MCDM) is one of the most widely used decision methodologies in the sciences, business, government and engineering worlds. MCDM methods can help to improve the quality of decisions by making the decision-making process more explicit, rational, and efficient [2].

Technique for order performance by similarity to ideal solution (TOPSIS) is first developed by Hwang and Yoon (1981) for solving a MCDM problem [3]. The concept of TOPSIS is choosing the best alternative according to the relative position [the shortest distance from the positive ideal solution (PIS) and the farthest from the negative ideal solution (NIS)] in all of the alternatives. Using TOPSIS method can make an efficacious and total ranking order of alternatives. But the drawback of TOPSIS is that it can not make a pairwise comparison and judge the degree of difference among all alternatives.

ELECTRE method is a highly developed multi-criteria analysis model which takes into account the uncertainty and vagueness in the decision process [4]. It is based on the axiom of partial comparability which is suitable for alternative selection. But the drawback of ELECTRE is that it is not easy to obtain the total ranking order of alternatives.

PROMETHEE (Preference Ranking Organization Method for Enrichment Evaluation) is a multi-criteria decision making method [5]. It is well adapted to problems where a finite number of alternative actions are to be ranked by considering several, sometimes conflicting, criteria [6]. There are six basic types of preference function in PROMETHEE method, so decision makers can establish flexible standard according to the requirement of particular decision making problem with respect to each criterion by PROMETHEE method.

VIKOR (VlseKriterijumska Optimizacija I Kompromisno Resenje in Serbian, means Multicriteria Optimization and Compromise Solution) is a multi criteria decision making method developed by Opricovic [6]. VIKOR determines a compromise solution that provides the maximum group utility for the majority and a minimum of individual regret for the opponent [7]. So, VIKOR can find a compromise priority ranking order of alternatives according to the selected criteria [8, 9]. According to the VIKOR method, the compromise ranking order could be performed by comparing the measure of closeness to the ideal alternative through the process of ranking and selecting a set of alternatives in the presence of conflicting criteria [7].

The information for choosing best alternative is including quantitative information and qualitative information. Quantitative information is easy to describe by crisp value. A more realistic approach may be to use linguistic assessments instead of crisp values [10]. The 2-tuple linguistic representation model is based on the concept of symbolic translation [11, 12]. It is an effective method to reduce the mistakes of information translation and avoid information loss by computing with words [13].

Because every kind of MCDM approach has its strong point and weakness, it is hard to make sure that what kind of MCDM approach is suitable to a specific problem. However, choosing the wrong MCDM approach to make decision will reduce the effectiveness and quality of decision-making. In order to avoid this problem, this study presented a linguistic intersection method (LIM) to handle the multi- criteria decision making problem in a fuzzy environment.

II. EVALUATION INFORMATION

The quantitative and qualitative information will be considered in the process of decision making problem.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Qualitative information can be expressed by 2-tuple linguistic variable. The membership function of 2-tuple linguistic variable can be expressed as triangle fuzzy number [14]. There are two types of 2-tuple linguistic variable are applied in this study (shown as Table 1 and Figures 1-2).

TABLE 1. DIFFERENT TYPES OF LINGUISTIC VARIABLES

Linguistic variable	
Type I:	Extremely Poor (s_0^5) , Poor (s_1^5) , Fair (s_2^5) , Good (s_3^5) , Extremely Good (s_4^5)
Type II:	Extremely Poor (s_0^7) ,Poor (s_1^7) , Medium Poor (s_2^7) , Fair (s_3^7) , Medium Good (s_4^7) , Good (s_5^7) , Extremely Good (s_6^7)

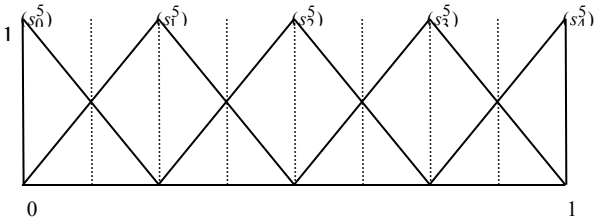

Figure. 1. Membership functions of linguistic variables at type 1 (t=1)

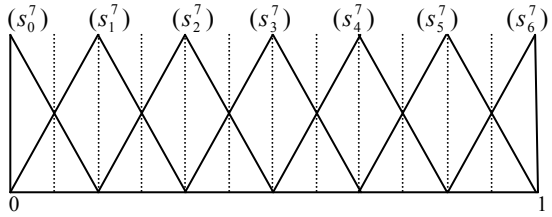

Figure. 2. Membership functions of linguistic variables at type 2 (t=2)

Let $S=\{s_0, s_1, s_2, ..., s_g\}$ be a finite and totally ordered linguistic term set. A 2-tuple linguistic variable can be expressed as $(s_i,\ \alpha_i)$, where s_i is the central value of i-th linguistic term in S and α_i is a numerical value representing the difference between calculated linguistic term and the closest index label in the initial linguistic term set. The symbolic translation function Δ is presented to translate β into a 2-tuple linguistic variable [14]. Then, the symbolic translation process is applied to translate β (β∈ [0, 1]) into a 2-tuple linguistic variable as [15]

$$\Delta(\beta)=(s_i,\alpha_i) \tag{1}$$

where $i=round(\beta\times g)$, $\alpha_i=\beta-\frac{i}{g}$ and $\alpha_i\in[-\frac{1}{2g},\frac{1}{2g})$.

A reverse function Δ^{-1} is defined to return an equivalent numerical value β from 2-tuple linguistic information $(s_i,\ \alpha_i)$. It can be represented as follows [15].

$$\Delta^{-1}(s_i,\alpha_i)=(\mathrm{i/g})+\alpha_i=\beta \tag{2}$$

Let $\mathrm{x}=\{(\mathrm{r}_1,\alpha_1),(\mathrm{r}_2,\alpha_2),...,(\mathrm{r}_\mathrm{n},\alpha_\mathrm{n})\}$ be a 2-tuple linguistic variable set and $\mathrm{W}=\{(\mathrm{w}_1,\alpha_{\mathrm{w}1}),(\mathrm{w}_2,\alpha_{\mathrm{w}2}),...,(\mathrm{w}_\mathrm{n},\alpha_{\mathrm{wn}})\}$ be the set of linguistic weight of each linguistic variable. The linguistic arithmetic mean $\bar{X}$ is computed as [16]

$$\bar{X}=\Delta\left(\frac{1}{n}\sum_{i=1}^{n}\Delta^{-1}(r_i,\alpha_i)\right)=(s_m,\alpha_m) \tag{3}$$

The linguistic weighted arithmetic mean is computed as [16]

$$\bar{X}^{\mathrm{w}}=\Delta\left(\frac{\frac{1}{n}\sum_{i=1}^{n}\left(\Delta^{-1}(r_i,\alpha_i)*\Delta^{-1}(\mathrm{w}_i,\alpha_{\mathrm{w}i})\right)}{\sum_{i=1}^{n}\Delta^{-1}(\mathrm{w}_i,\alpha_{\mathrm{w}i})}\right)=(s_{\mathrm{m}}^{\mathrm{w}},\alpha_{\mathrm{m}}^{\mathrm{w}}) \tag{4}$$

In general, decision makers would use different kind of 2-tuple linguistic variables based on their knowledge or experiences to express their opinions [17]. A transformation function is needed to transfer these 2-tuple linguistic variables from different kind of linguistic sets to a standard linguistic set at unique domain. In the method of Herrera and Martinez [18], the domain of the linguistic variables will increase as the number of linguistic variable is increased. To overcome this drawback, a translation function is applied here to transfer a crisp number or 2-tuple linguistic variable to a standard linguistic term at the unique domain [15]. Suppose that the interval [0, 1] is the unique domain. The linguistic variable sets with different semantics (or types) will be defined by partitioning the interval [0, 1]. Transforming a crisp number β (β∈ [0, 1]) into i-th linguistic term $(s_i^{n(t)},\alpha_i^{n(t)})$ of type t as

$$\Delta_t(\beta)=(s_i^{n(t)},\alpha_i^{n(t)}) \tag{5}$$

where $i=round(\beta\times g_t)$, $\alpha_i^{n(t)}=\beta-\frac{i}{g_t}$ $g_t=n(t)-1$ and n (t) is the number of linguistic variable of type t. Transforming i-th linguistic term of type t into a crisp number β as

$$\Delta_t^{-1}(s_i^{n(t)},\alpha_i^{n(t)})=\frac{i}{g_t}+\alpha_i^{n(t)}=\beta \tag{6}$$

where $g_t=n(t)-1$ and $\alpha_i^{n(t)}\in[-\frac{1}{2g_t},\frac{1}{2g_t})$.

Therefore, the transformation from i-th linguistic term $(s_i^{n(t)},\alpha_i^{n(t)})$ of type t to k-th linguistic term $(s_k^{n(t+1)},\alpha_k^{n(t+1)})$ of type t+1 can be expressed as

$$\Delta_{t+1}(\Delta_t^{-1}(s_i^{n(t)},\alpha_i^{n(t)}))=(s_k^{n(t+1)},\alpha_k^{n(t+1)}) \tag{7}$$

where $g_{t+1}=n(t+1)-1$ and $\alpha_k^{n(t+1)}\in[-\frac{1}{2g_{t+1}},\frac{1}{2g_{t+1}})$.

III. PROPOSED METHOD

In general, the content of decision making can include:

(1) A set of alternatives is called $A=\{A_1, A_2, ..., A_m\}$

(2) A set of criteria is called $C=\{C_1, C_2, ..., C_n\}$, there are n criteria which we will use. The quantitative criteria are from C_1 to C_Z. The qualitative criteria are from C_{Z+1} to C_n.

(3) A set of decision makers is called $D=\{E_1, E_2, ..., E_k\}$.

(4) $\widetilde{\mathrm{W}}=[\widetilde{w}_\mathrm{j}]_n, j=1,2,...,n$, $\widetilde{w}_j$ can be represented as the linguistic weight of j-th criterion.

(5) $\mathrm{D}=[\mathrm{x}_{\mathrm{ij}}]_{m\times n}, i=1,2,...,m, j=1,2,...,n$ is multi criteria decision making matrix. It can be represented as

$$D=\left[x_{ij}\right]_{mn}=\begin{array}{c} \\ A_1 \\ A_2 \\ \cdots \\ A_m \end{array}\begin{array}{c} \begin{array}{cccccc} C_1 & \cdots & C_z & C_{z+1} & \cdots & C_n \end{array} \\ \begin{bmatrix} x_{11} & \cdots & x_{1z} & \tilde{x}_{1z+1} & \cdots & \tilde{x}_{1n} \\ x_{21} & \cdots & x_{2z} & \tilde{x}_{2z+1} & \cdots & \tilde{x}_{2n} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ x_{m1} & \cdots & x_{mz} & \tilde{x}_{mz+1} & \cdots & \tilde{x}_{mn} \end{bmatrix} \end{array} \tag{9}$$

In quantitative criteria, x_{ij} represents the performance of i-th alternative with respect to j-th criterion. We use crisp value CV_{ij} to represent x_{ij} . In qualitative criteria, $\tilde{x}_{ij}$ represents the linguistic performance of i-th alternative with respect to j-th criterion. Decision makers can use 2-tuple linguistic variable to express their opinions about linguistic performance. Let $F_j^k(A_i)=(S_{ij}^k,\alpha_{ij}^k)$ represent the linguistic performance of i-th alternative respect to j-th criterion which is expressed by k-th decision maker.

The formula of transfer crisp value CV_{ij} to a 2 tuple linguistic variable is as follows:

$$F_j(A_i)=\Delta^{-1}\left(\left(CV_{ij}-\min_i\left(CV_{ij}\right)\right)/\left(\max_i\left(CV_{ij}\right)-\min_i\left(CV_{ij}\right)\right)\right) \tag{10}$$

The formula of aggregating all of the opinions about the linguistic performance of i-th alternative with respect to j-th criterion is as follows:

$$F_j(A_i)=\Delta\ \left(\frac{1}{K}\sum_{k=1}^{K}\Delta^{-1}(S_{ij}^k,\alpha_{ij}^k)\right)=(S_{ij},\alpha_{ij}) \tag{11}$$

The formula of aggregating all of the opinions about the linguistic weight of j-th criterion is as follows:

$$\tilde{\mathrm{W}}_j=\Delta\ \left(\frac{1}{K}\sum_{k=1}^{K}\Delta^{-1}(S_{jk}^w,\alpha_{jk}^w)\right)=(S_j^w,\alpha_j^w) \tag{12}$$

A. Linguistic TOPSIS

The formula of linguistic weighted matrix is as follows:

$$\tilde{\mathrm{V}}=[\tilde{v}_{\mathrm{ij}}]_{m\times n}, i=1,2,...,m, j=1,2,...,n \tag{13}$$

where $\tilde{V}_{ij}=\Delta\left(\Delta^{-1}\left(\tilde{x}_{ij}\right)*\Delta^{-1}\left(\tilde{w}_j\right)\right)$.

The formula of positive ideal solution and negative ideal solution is as $\tilde{\mathrm{A}}^*=(\tilde{v}_1^*,\tilde{v}_2^*,...,\tilde{v}_n^*)$ and $\tilde{\mathrm{A}}^-=(\tilde{v}_1^-,\tilde{v}_2^-,...,\tilde{v}_n^-)$, where $\tilde{\mathrm{v}}_{\mathrm{j}}^*=\Delta\left(\max_i\left(\Delta^{-1}\left(\tilde{v}_{ij}\right)\right)\right)$ and $\tilde{\mathrm{v}}_{\mathrm{j}}^-=\Delta\left(\min_i\left(\Delta^{-1}\left(\tilde{v}_{ij}\right)\right)\right)$.

The formula of calculating the distance between the positive ideal solution and negative ideal solution is as follows:

$$d_i^*=d(\tilde{\mathrm{A}}_i,\tilde{\mathrm{A}}^*)=\sqrt{\sum_{j=1}^{n}\left(\max_i\left(\Delta^{-1}\left(\tilde{v}_{ij}\right)\right)-\Delta^{-1}\left(\tilde{v}_{ij}\right)\right)^2} \tag{14}$$

$$d_i^-=d(\tilde{\mathrm{A}}_i,\tilde{\mathrm{A}}^-)=\sqrt{\sum_{j=1}^{n}\left(\min_i\left(\Delta^{-1}\left(\tilde{v}_{ij}\right)\right)-\Delta^{-1}\left(\tilde{v}_{ij}\right)\right)^2} \tag{15}$$

The closeness coefficient can be computed as

$$CC_i=d_i^-/\left(d_i^*+d_i^-\right),\quad i=1,2,...,m \tag{16}$$

The ranking order of alternatives can be determined in accordance with the closeness coefficient. If $CC_i>CC_j$, then alternative A_i is better than A_j

B. Linguistic ELECTRE

According to the ELECTRE, the threshold of criteria which is including preference threshold p_j, indifference threshold q_j and veto threshold v_j .The concordance index $C_j(A_i,A_l)$ represents the degree of alternative A_i is better than A_l with respect to j-th criterion. It can be computed as

$$C_j(A_i,A_l)=\begin{cases} 1 & ,\Delta^{-1}\left(\tilde{x}_{ij}\right)\geq\Delta^{-1}\left(\tilde{x}_{lj}\right)-q_j \\ \dfrac{\Delta^{-1}\left(\tilde{x}_{ij}\right)-\Delta^{-1}\left(\tilde{x}_{lj}\right)+p_j}{p_j-q_j} & ,\Delta^{-1}\left(\tilde{x}_{lj}\right)-q_j\geq\Delta^{-1}\left(\tilde{x}_{ij}\right)\geq\Delta^{-1}\left(\tilde{x}_{lj}\right)-p_j \\ 0 & ,\Delta^{-1}\left(\tilde{x}_{ij}\right)\leq\Delta^{-1}\left(\tilde{x}_{lj}\right)-p_j \end{cases} \tag{17}$$

The overall concordance index $C(A_i,A_l)$ can be computed as

$$C(A_i,A_l)=\sum_{j=1}^{n}\left(\Delta^{-1}\left(\tilde{\mathrm{w}}_{\mathrm{j}}\right)/\sum_{\mathrm{k}=1}^{\mathrm{n}}\Delta^{-1}\left(\tilde{\mathrm{w}}_{\mathrm{k}}\right)\right)C_j(A_i,A_l) \tag{18}$$

The discordance index $D_j(A_i,A_l)$ represents the degree of alternative A_i is not better than A_l with respect to j-th criterion. It can be computed as

$$D_j(A_i,A_l)=\begin{cases} 1 & ,\Delta^{-1}\left(\tilde{x}_{ij}\right)\leq\Delta^{-1}\left(\tilde{x}_{lj}\right)-v_j \\ \dfrac{\Delta^{-1}\left(\tilde{x}_{lj}\right)-p_j-\Delta^{-1}\left(\tilde{x}_{ij}\right)}{v_j-p_j} & ,\Delta^{-1}\left(\tilde{x}_{lj}\right)-p_j\geq\Delta^{-1}\left(\tilde{x}_{ij}\right)\geq\Delta^{-1}\left(\tilde{x}_{lj}\right)-v_j \\ 0 & ,\Delta^{-1}\left(\tilde{x}_{ij}\right)\geq\Delta^{-1}\left(\tilde{x}_{lj}\right)-p_j \end{cases} \tag{19}$$

The credibility matrix $S(A_i,A_l)$ can be computed as

$$S(A_i,A_l)=\begin{cases} C(A_i,A_l),\ \ if\ \ D_j(A_i,A_l)\leq C(A_i,A_l)\ \ \forall j \\ C(A_i,A_l)\prod_{j\in J(A_i,A_l)}\dfrac{1-D_j(A_i,A_l)}{1-C(A_i,A_l)},\ \ otherwise \end{cases} \tag{20}$$

where $J(A_i,A_l)$ represents the set of criteria which satisfy the discordance index of the criteria is larger than the overall concordance index

The degree value of alternative A_i is better than all of the other alternatives can be computed as

$$\phi_{\mathrm{e}}^+(A_i)=\sum_{Al\in A}S(A_i,A_l) \tag{21}$$

The degree value of all of the other alternatives is better than alternative A_i can be computed as

$$\phi_{\mathrm{e}}^-(A_i)=\sum_{Al\in A}S(A_l,A_i) \tag{22}$$

Calculate the net flow of alternative A_i as

$$\phi_{\mathrm{e}}(A_i)=\phi_{\mathrm{e}}^+(A_i)-\phi_{\mathrm{e}}^-(A_i) \tag{23}$$

Normalized the net flow of alternatives as

$$OTI_e(A_i)=((\phi_{\mathrm{e}}(A_i)/\mathrm{m})+1)/2 \tag{24}$$

According to the OTI_e, we can determine the ranking order of all alternatives.

C. Linguistic PROMETHEE

Determine the preference functions and thresholds of all criteria, and calculate the individual preference value of alternative A_r is better than alternative A_s with respect to each criterion. In this paper, we use two kinds of preference function.

Level criterion with linear preference is

$$H(\tilde{x}_{rj},\tilde{x}_{sj})=\begin{cases}1, \Delta^{-1}(\tilde{x}_{rj})-\Delta^{-1}(\tilde{x}_{sj})>p\\ \frac{1}{2}, q\le\Delta^{-1}(\tilde{x}_{rj})-\Delta^{-1}(\tilde{x}_{sj})\le p\\ 0, q\le\Delta^{-1}(\tilde{x}_{rj})-\Delta^{-1}(\tilde{x}_{sj})\end{cases} \quad (25)$$

Criterion with linear preference and indifference area is

$$H(\tilde{x}_{rj},\tilde{x}_{sj})=\begin{cases}1 \quad , p<\Delta^{-1}(\tilde{x}_{rj})-\Delta^{-1}(\tilde{x}_{sj})\\ \frac{\Delta^{-1}(\tilde{x}_{rj})-q}{p-q}, q\le\Delta^{-1}(\tilde{x}_{rj})-\Delta^{-1}(\tilde{x}_{sj})\le p\\ 0 \quad , \Delta^{-1}(\tilde{x}_{rj})-\Delta^{-1}(\tilde{x}_{sj})<q\end{cases} \quad (26)$$

Calculate the overall preference value to represent alternative A_r is better than A_s as

$$\pi(A_r,A_s)=\sum_{j=1}^{n}\left(\Delta^{-1}(\tilde{w}_j)/\sum_{k=1}^{n}\Delta^{-1}(\tilde{w}_k)\right)*H_j(\tilde{x}_{rj},\tilde{x}_{sj}) \quad (27)$$

The degree about alternative A_r is better than all of the other alternatives as

$$\phi_p^+(A_r)=\sum_{b\in A}\pi(A_r,b) \quad (28)$$

The degree about all of the other alternatives is better than alternative A_r as

$$\phi_p^-(A_r)=\sum_{b\in A}\pi(b,A_r) \quad (29)$$

Calculate the net flow of alternative A_r as

$$\phi_p(A_r)=\phi_p^+(A_r)-\phi_p^-(A_r) \quad (30)$$

And then, normalized the net flow of alternative A_r as

$$OTI_p(A_r)=((\phi_p(A_r)/m)+1)/2 \quad (31)$$

According to the OTI_p, we can determine the ranking order of all alternatives can rank all of the alternatives.

D. Linguistic VIKOR

The linguistic positive-ideal solution (F_j^*) of each general criterion can be calculated as

$$F_j^*=\Delta\left(\underset{i}{Max}\ \Delta^{-1}(F_j(A_i))\right), \forall A_i\in A \quad (32)$$

The linguistic negative-ideal solution (F_j^-) of each general criterion can be calculated as

$$F_j^-=\Delta\left(\underset{i}{Min}\ \Delta^{-1}(F_j(A_i))\right), \forall A_i\in A \quad (33)$$

The group utility for the majority (S_i) of each alternative can be calculated as

$$S_i=\sum_{j=1}^{n}\Delta^{-1}(\tilde{w}_j)*\frac{\Delta^{-1}(F_j^*)-\Delta^{-1}(F_j(A_i))}{\Delta^{-1}(F_j^*)-\Delta^{-1}(F_j^-)} \quad \forall i \quad (34)$$

The individual regret rating for the opponent R_i of each alternative can be calculated as

$$R_i=\underset{j}{Max}\left(\Delta^{-1}(\tilde{w}_j)*\frac{\Delta^{-1}(F_j^*)-\Delta^{-1}(F_j(A_i))}{\Delta^{-1}(F_j^*)-\Delta^{-1}(F_j^-)}\right) \quad \forall i \quad (35)$$

R_i represents as the maximum regret by choosing i-th alternative as solution according to choose the worst performance in general criteria.

The value (Q_i) of each alternative can be calculated as

$$Q_i=v*\frac{S_i-S^*}{S^--S^*}+(1-v)*\frac{R_i-R^*}{R^--R^*} \quad \forall i \quad (36)$$

$$S^*=\underset{i}{Min}\ S_i, S^-=\underset{i}{Max}\ S_i, R^*=\underset{i}{Max}\ R_i, R^-=\underset{i}{Min}\ R_i$$

v represents the decision making coefficient, v is between 0 and 1. According to the Q_i, we can determine the ranking order of all alternatives.

E. Linguistic Intersection Method (LIM)

We can consider linguistic TOPSIS, linguistic ELECTRE, linguistic PROMETHEE and linguistic VIKOR methods as four experts who provide information of each alternative, respectively. Smart manager will make a decision by considering the suggestions of experts simultaneously. Let $\Omega_t=\{A_i \mid \mathrm{Rank}(CC_i)\le SN\}$, $\Omega_e=\{A_i \mid \mathrm{Rank}(OTI_e(A_i))\le SN\}$, $\Omega_p=\{A_i \mid \mathrm{Rank}(OTI_p(A_i))\le SN\}$ and $\Omega_v=\{A_i \mid \mathrm{Rank}(Q_i)\le SN\}$. Ω_t, Ω_e, Ω_p and Ω_v represents the best alternative set of linguistic TOPSIS, ELECTRE, PROMETHEE and VIKOR method. The $\mathrm{Rank}(CC_i)$, $\mathrm{Rank}(OTI_e(A_i))$, $\mathrm{Rank}(OTI_p(A_i))$ and $\mathrm{Rank}(Q_i)$ represent the alternative ranking order of each MCDM approach. SN represents the number of alternatives which manager considers the maximum volume of alternatives where alternative is better exists in each MCDM approach. We execute the intersection from four kinds of set as $\Omega_{can}=\Omega_t\cap\Omega_e\cap\Omega_p\cap\Omega_v$. The Ω_{can} represents the common set which is agreeable by four experts (MCDM methods) and can be defined as consensus alternative set.

According to the consensus alternative set, normalized the closeness coefficient value as

$$P_t(A_i)=\begin{cases}\frac{CC_i}{\sum_{A_i\in\Omega_{can}}CC_i}, A_i\in\Omega_{can}\\ 0, \quad A_i\notin\Omega_{can}\end{cases} \quad (37)$$

Normalized the OTI_e as

$$P_e(A_i)=\begin{cases}\frac{OTI_e(A_i)}{\sum_{A_i\in\Omega_{can}}OTI_e(A_i)}, A_i\in\Omega_{can}\\ 0, \quad A_i\notin\Omega_{can}\end{cases} \quad (38)$$

Normalized the OTI_p as

$$P_p(A_i)=\begin{cases}\frac{OTI_p(A_i)}{\sum_{A_i\in\Omega_{can}}OTI_p(A_i)}, A_i\in\Omega_{can}\\ 0, \quad A_i\notin\Omega_{can}\end{cases} \quad (39)$$

Normalized the Q_i, as

$$P_{\mathrm{v}}(A_i)=\begin{cases}\dfrac{(1-\mathrm{Q_i})}{\sum_{A_i\in\Omega_{can}}(1-\mathrm{Q_i})}, & A_i\in\Omega_{can}\\ 0, & A_i\notin\Omega_{can}\end{cases} \tag{40}$$

Let $P_{imp}(A_i)$ be the comprehensive performance of each alternative in the consensus alternative set. It can be integrated from four kinds of MCDM methods as

$$P_{imp}(A_i)=v_t * P_t(A_i)+v_e * P_e(A_i)+v_p * P_p(A_i)+v_{\mathrm{v}} * P_{\mathrm{v}}(A_i) \tag{41}$$

where $v_t+v_e+v_p+v_{\mathrm{v}}=1$ .The v_t , v_e , v_p and v_{v} represent the importance of four methods from the viewpoint of manager.

IV. NUMERICAL EXAMPLE

Suppose a notable gift manufacturer wants to sell famous gift. The manufacturer wants to entry the market of China, so they have to choose a sales channel company for outsourcing retail business. There are seven criteria are considered such as the market share rate of the sales channel company ($\mathrm{C_1}$), gross profit margin ($\mathrm{C_2}$), inventory turnover ratio ($\mathrm{C_3}$), current ratio ($\mathrm{C_4}$), brand image ($\mathrm{C_5}$), retail place ($\mathrm{C_6}$) and enterprise culture ($\mathrm{C_7}$). Brand image, retail place and enterprise culture are qualitative criteria. Gift manufacturer employs four enterprise consultants to evaluate twelve sales channel companies. The process of linguistic intersection method is shown as follows.

Step1. Collect quantitative information of twelve sales channel companies as Table 2.

TABLE 2. THE QUANTITATIVE INFORMATION

	$\mathrm{A_1}$	$\mathrm{A_2}$	$\mathrm{A_3}$	$\mathrm{A_4}$	$\mathrm{A_5}$	$\mathrm{A_6}$
C_1	4%	0.7%	3%	2.7%	1.6%	2.1%
C_2	10.2%	9.8%	7%	6.6%	12%	8%
C_3	7	6.8	8	4.2	7.5	6
C_4	1.5	1.2	1.4	1.8	2	1.5
	$\mathrm{A_7}$	$\mathrm{A_8}$	$\mathrm{A_9}$	$\mathrm{A_{10}}$	$\mathrm{A_{11}}$	$\mathrm{A_{12}}$
C_1	4.2%	1.2%	4%	1.6%	3%	0.5%
C_2	7.2%	6.4%	11.2%	5.6%	8%	7.5%
C_3	4.3	6.5	7	4.5	8	5.6
C_4	1.4	1.3	2	2.1	2.2	1.8

Step2. Transform quantitative information of twelve sales channel companies into 5 scale linguistic variable.

Step3. Four enterprise consultants choose linguistic variable flexibly to express their opinions about performance of each sales channel company with respect to each qualitative criterion as Table 3 and the weight of each criterion as Table 4. Enterprise consultants $\mathrm{E_1}$ and $\mathrm{E_2}$ choose 5 scale linguistic variable to express their opinions. Enterprise consultants $\mathrm{E_3}$ and $\mathrm{E_4}$ use 7 scale linguistic variable to express their opinions.

TABLE 3. THE WEIGHT LINGUISTIC VARIABLES

	$\mathrm{A_4}$	$(s_4^5,0)$	$(s_4^5,0)$	$(s_5^7,0)$	$(s_2^7,0)$	$\mathrm{A_{10}}$	$(s_0^5,0)$	$(s_1^5,0)$	$(s_4^7,0)$	$(s_3^7,0)$
	$\mathrm{A_5}$	$(s_3^5,0)$	$(s_0^5,0)$	$(s_6^7,0)$	$(s_4^7,0)$	$\mathrm{A_{11}}$	$(s_4^5,0)$	$(s_0^5,0)$	$(s_4^7,0)$	$(s_4^7,0)$
	$\mathrm{A_6}$	$(s_1^5,0)$	$(s_3^5,0)$	$(s_4^7,0)$	$(s_3^7,0)$	$\mathrm{A_{12}}$	$(s_0^5,0)$	$(s_0^5,0)$	$(s_6^7,0)$	$(s_6^7,0)$
C_7	$\mathrm{A_1}$	$(s_4^5,0)$	$(s_0^5,0)$	$(s_3^7,0)$	$(s_4^7,0)$	$\mathrm{A_7}$	$(s_2^5,0)$	$(s_0^5,0)$	$(s_5^7,0)$	$(s_2^7,0)$
	$\mathrm{A_2}$	$(s_3^5,0)$	$(s_2^5,0)$	$(s_3^7,0)$	$(s_6^7,0)$	$\mathrm{A_8}$	$(s_0^5,0)$	$(s_4^5,0)$	$(s_4^7,0)$	$(s_2^7,0)$
	$\mathrm{A_3}$	$(s_3^5,0)$	$(s_2^5,0)$	$(s_6^7,0)$	$(s_5^7,0)$	$\mathrm{A_9}$	$(s_2^5,0)$	$(s_0^5,0)$	$(s_3^7,0)$	$(s_3^7,0)$
	$\mathrm{A_4}$	$(s_0^5,0)$	$(s_4^5,0)$	$(s_3^7,0)$	$(s_5^7,0)$	$\mathrm{A_{10}}$	$(s_1^5,0)$	$(s_2^5,0)$	$(s_3^7,0)$	$(s_6^7,0)$
	$\mathrm{A_5}$	$(s_0^5,0)$	$(s_4^5,0)$	$(s_6^7,0)$	$(s_5^7,0)$	$\mathrm{A_{11}}$	$(s_0^5,0)$	$(s_3^5,0)$	$(s_6^7,0)$	$(s_3^7,0)$
	$\mathrm{A_6}$	$(s_3^5,0)$	$(s_2^5,0)$	$(s_4^7,0)$	$(s_2^7,0)$	$\mathrm{A_{12}}$	$(s_1^5,0)$	$(s_0^5,0)$	$(s_3^7,0)$	$(s_4^7,0)$

Step4. Manager determines the number of better alternatives (SN) in each MCDM approach. By the purpose of fairness, we set the number of better alternatives (SN) in each MCDM is the same and equal to six (fifty percent of number of alternatives). And then, the selected alternative set by TOPSIS is $\Omega_t=\{A_1,A_2,A_9,A_{11},A_5,\mathrm{A_3}\}$, the selected alternative set by ELECTRE is $\Omega_{\mathrm{e}}=\{A_5,A_{11},A_4,A_1,A_9,\mathrm{A_8}\}$, the selected alternative set by PROMETHEE method is $\Omega_{\mathrm{p}}=\{A_5,A_{11},A_1,A_4,A_9,\mathrm{A_8}\}$ and the selected alternative set by VIKOR is $\Omega_{\mathrm{v}}=\{A_{11},A_5,A_9,A_1,A_4,\mathrm{A_6}\}$. Final, we calculate the intersection set as $\Omega_{can}=\Omega_t\cap\Omega_e\cap\Omega_p\cap\Omega_{\mathrm{v}}=\{A_1,A_5,A_9,A_{11}\}$.

Step5. Manager determines the relative importance of TOPSIS $v_t=1/4$, ELECTRE $v_e=1/4$, PROMETHEE $v_{\mathrm{p}}=1/4$ and VIKOR $v_{\mathrm{v}}=1/4$. And calculate the relative evaluation value of TOPSIS(P_t), ELECTRE(P_e),PROMETHEE(P_p) and VIKOR(P_{v}). And then, calculate the overall performance of each alternative P_{imp} (see Table 11). Finally, the ranking order of alternatives is $A_{11}>\mathrm{A_5}>\mathrm{A_1}>\mathrm{A_9}$.

V. MCDM METHOD COMPARISON

In order to justify the effectiveness of proposed method, this paper compares the ranking result of the LIM with original linguistic TOPSIS, linguistic ELECTRE, linguistic PROMETHEE and linguistic VIKOR. It finds that alternative A_1, A_5, A_9 and A_{11} which are in intersection set are relatively stable and stand on the top 5 positions, no matter what kind of MCDM approach we use. On the other hand, the alternatives which are not in intersection set don't have a relatively consistent rank in every kind of linguistic MCDM method. If we consider that the sum ranking order of each alternative in each linguistic MCDM method, the final ranking order of alternatives is the same as LIM method (see Table 5).

TABLE 5 THE RANKING ORDER INFORMATION

Alternative	Rank of TOPSIS	Rank of ELECTRE	Rank of PROMETHEE	Rank of VIKOR	Sum of Rank	Overall Rank
A_{11}	4	2	2	1	9	1
A_5	5	1	1	2	9	1
A_1	1	4	3	4	12	3
A_9	3	5	5	3	16	4
A_4	10	3	4	5	22	5
A_2	2	7	7	11	27	6
A_3	6	8	8	8	30	7
A_8	12	6	6	9	33	8
A_6	11	10	10	6	37	9
A_7	9	9	9	10	37	9
A_{12}	8	12	11	7	38	11
A_{10}	7	11	10	12	40	12

VI. CONCLUSION AND FUTURE RESEARCH

In this paper, a linguistic intersection method (LIM) is presented to handle the MCDM problems in the fuzzy environment. The advantage of linguistic intersection method is illustrated as follows.

1. The picked alternative which is executed by LIM in accordance with the agreement of each MCDM approach. It can promote effectiveness of decision making.
2. Although LIM is a little complexity in executing decision making process, but all of the process is easy to calculate and can be done by computer program.
3. Linguistic TOPSIS, linguistic ELECTRE, linguistic PROMETHEE and linguistic VIKOR are used to determine the performance of each alternative in this study. In reality, LIM is an extendable method which can extend by adding new developed MCDM approach by empowering new developed MCDM approach.
4. The LIM can effective deal with MCDM problems based on quantitative and qualitative information simultaneously.

In the future, an interactive program will be developed to handle the fuzzy MCDM problems based on linguistic intersection method (LIM).

***Abstract*— The weapon identification and selection issue is an important and strategic component and has a significant impact on the efficiency of defense system in US. The main purpose of this research is to develop a universal model and system to effectively assess, evaluate and identify the optimal weapons from a large collection of available weapon systems that have multiple criteria based on a fuzzy multiple criteria decision making (FMCDM) model. A simple but effective weight estimation method is adopted in this paper to make this selection more objective and reliable. There are some different weight estimation methods reported by researchers, however, most methods need a lot of mathematical operations and make the process very time consuming and even more complicated. In this paper, we utilized a weight estimation method based on the paired comparison matrix to simplify this estimation process. The evaluation and selection process can be significantly simplified and improved by using this method.**

Keywords- Optimal weapon systems; fuzzy multi-criteria decision making; similarity measure; decision matrix

I. INTRODUCTION

One of the most important and critical issues related to the national defense is to correctly evaluate and assess the optimal weapons or weapon systems from a large collection of weapons to improve and enhance the overall performance and productivity of the national defense system. This evaluation and assessing issue becomes more important after September 11, 2001 since some enemy countries have defined US as their target and began to attack the US territory in an offensive way. In order to effectively protect our country from being attacked by any foreign country who has offensive weapons and effectively attack back those enemy countries, developing and building efficient models and systems to correctly evaluate and assess the optimal weapons or weapon systems is a prerequisite task to the US defense system. In this research, we will develop and build a fuzzy multiple criteria decision making model (FMCDM) to perform this evaluation and assessing task in a more efficient and reliable way. The FMCDM technique is based on multiple criteria decision making (MCDM) technique.

The MCDM technique can be divided into two major categories: crisp or classical and fuzzy MCDMs. In recent years, many researchers have attempted to use fuzzy MCDM methods for optimal equipment selection problems. Such as Lin and Yang using the AHP method to build a machine selection model [1], Tabucanon et al. developed a decision support framework for selecting the most appropriate machines in flexible manufacturing systems (FMS) [2], Atmani and Lashkari developed a model for machine tool selection and operation allocation in FMS [3], Wang et al. presented a fuzzy multiple attribute decision making model to select the appropriate machines for FMS [4], Arslan et al. presented a multi-criteria weighted average (MCWA) method for machine tool selection [5]. Yurdakul proposed a model linking machine alternatives to manufacturing strategy for machine tool selection [6]. Ayag and Ozdemir used the fuzzy AHP technique to weight the machine tool alternatives under eight main and nineteen sub-criteria and then carried out benefit/cost ratio analysis by using both the fuzzy AHP score and procurement cost, of each alternative [7].

Some other researchers reported different methods to perform the optimal evaluations and estimations for various machine tools and equipments [8-13]. Although weapon evaluation and selection play an important role in the design of an effective defense system, however, the publications and researches on this subject are very limited [14-20].

Basically, correct evaluating and assessing of the optimal weapon systems can be defined as a decision making process. In recent years, different conventional decision making methods and models have been developed and adopted, such as the optimal estimation, linear programming and Karman filter. However, the fuzzy decision making model is a good candidate among those methods. As we know, one of the most useful aspects of fuzzy set theory is its ability to represent mathematically a class of decision problems called multiple objective decisions (MODs). This class of problems often involves many vague and ambiguous (and thus fuzzy) goals and constraint factors. The object of the fuzzy decision methodology is to obtain a decision, optimum in the sense that some set of goals is attained while observing (i.e. not violating) a simultaneous set of constraint factors.

The paper is organized as follows. The scope and objectives of this paper, combined with a technique review to FMCDM, are provided in section 1. The detailed description of the FMCDM model is described in section 2. The adopted method used to estimate the weight to the associated criteria or objectives is discussed in section 3. A case study with an example of evaluating and assessing the optimal weapon

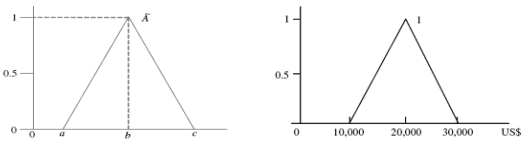
system (missiles) is given in section 4. Section 5 provides the conclusion for the paper.

II. FUZZY MCDM MODEL

Normally, a triangular fuzzy number A can be defined by a triplet *(a, b, c)* shown in Fig.1a. An example of a fuzzy member of an equipment cost is shown in Fig.1b. The membership function is defined as (1).



(a) (b)

Figure 1. A representation of a triangular fuzzy member

$$\mu_A(x)=\begin{cases}0, & x<a,\\ \dfrac{x-a}{b-a}, & a\le x\le b,\\ \dfrac{c-x}{c-b}, & b\le x\le c,\\ 0, & x>c.\end{cases} \tag{1}$$

The general multi-attribute decision making (MADM) model can be described as follows [11]:

- Let $X = \{X_i | i = 1, \ldots, m\}$ denote a finite discrete set of m *(≥2)* possible alternatives (courses of action, candidates);
- Let $A = \{A_j \mid j = 1, \ldots, n\}$ denote a finite set of n *(≥2)* criteria according to which the desirability of an alternative is to be judged,
- Let $\omega = (\omega_1, \omega_2, \ldots, \omega_n)^T$ be the vector of weights, where $\sum_{j=1}^{n} \omega_j = 1$, $\omega_j \ge 0$, $j = 1, \ldots, n$, and ω_j denotes the weight of criterion A_j,
- Let $R = (r_{ij})_{m\times n}$ denote the $m \times n$ decision matrix, where r_{ij} *(≥0)* is the performance rating of alternative X_i with respect to criterion A_j.

In this section, we will introduce in details the algorithm based on the theory of fuzzy MCDM, which includes the following steps [11].

A. Representation of Fuzzy Requirements

When evaluating and assessing the optimal weapon system from a number of similar alternatives, a decision maker normally develops in his/her mind some sort of ambiguity. Representation of fuzzy requirements has been introduced in the beginning of this section.

B. Similarity Measure

In step A, the requirements of selecting optimal weapon systems have been described as the triangular fuzzy number with respect to different criteria. In this step, we will take the requirement vector as the ideal weapon system, with the purpose to measure the similarity degree with the existing candidate weapon vectors, in which the specification values are known and determinate. As we know, a fuzzy number cannot be compared with a crisp one directly unless a non-fuzzy number has to be transformed into the form of fuzzy number firstly. For example, for a crisp number b, the form of its triangular fuzzy can be written as (2).

$$b = (b^L, b^M, b^U) \tag{2}$$

where $b^L = b^M = b^U$, and Similarity measure between two triangular fuzzy numbers can be calculated with (3) [21].

$$s(a,b)=\frac{a^L b^L + a^M b^M + a^U b^U}{\max[(a^L)^2+(a^M)^2+(a^U)^2,\,(b^L)^2+(b^M)^2+(b^U)^2]} \tag{3}$$

where two triangular fuzzy numbers are $a = (a^L, a^M, a^U)$ that represents the ideal number and $b = (b^L, b^M, b^U)$ that represents the real number, respectively.

Because there are various types of criteria for different weapon systems, in which some criteria, such as the missile launching distance, warhead and speed, are not suitable to be represented as a fuzzy number. Therefore these numbers can be expressed as crisp numbers.

C. Construction of Decision Matrix

Calculation result of the similarity measure between alternate weapon systems and the ideal weapon system can be concisely expressed in a matrix format, which is called decision matrix in MCDM problems, and in which columns indicate weapon criteria and rows alternate weapons. Thus, an element s_{ij} in the in Eq. (4) denotes the similarity degree to the ideal weapon of the ith weapon with respect to the jth criterion.

$$DM=\begin{bmatrix} s_{11}\ s_{12}\ s_{13}\ \ldots\ldots\ldots s_{1n}\\ s_{21}\ s_{22}\ s_{23}\ \ldots\ldots\ldots s_{2n}\\ \ldots\ldots\ldots\ldots\ldots\ldots\ldots\\ s_{m1}\ s_{m2}\ s_{m3}\ \ldots\ldots\ldots s_{mn}\end{bmatrix} \tag{4}$$

D. Normalization

In order to eliminate the difference of dimension among different criteria, the operation of normalization is needed to transform various criteria dimensions into the non-dimensional criteria. Generally, the criteria of alternative weapons can be divided into two categories: the 'benefit' type attributes (the larger the better) and the 'cost' type attributes (the smaller the better). For example, the cost and weight belong to the 'cost' attributes, and the range and speed are 'benefit' attributes. In order to normalize those 'cost' attribute values to make them equivalent to the 'benefit' attributes (the larger the better), we developed a converting equation similar to [11] for those attribute values. The 'cost' attribute is calculated as (5):

$$x_{cj} = \frac{x_{j\max} - x_j}{x_{j\max}} \quad j = 1, 2, 3, \ldots\ldots m \tag{5}$$

For instance, the converted weapons' cost values are: $c_{cj} = (c_{jmax} - c_j)/c_{jmax}$, ($j$=1, 2,…18), and c_{jmax}= 1200k in this study. Similar processing is performed for the weapons' weight attributes $w_{cj} = (w_{jmax} - w_j)/w_{jmax}$, where w_{jmax}= 3700 in this research.

Equations (6) and (7) are utilized to perform the normalization for the fuzzy attributes or criteria [11].

$$r_i = \left(\frac{a_i}{c_i^{\max}}, \frac{b_i}{b_i^{\max}}, \frac{c_i}{a_i^{\max}} \wedge 1 \right) \quad \text{for benefit criteria} \tag{6}$$

$$r_i = \left(\frac{a_i^{\min}}{c_i}, \frac{b_i^{\min}}{b_i}, \frac{c_i^{\min}}{a_i} \wedge 1 \right) \quad \text{for cost criteria} \tag{7}$$

where $(\bullet)^{\max}{}_i = \max\{(\bullet)_i\}$ and $(\bullet)^{\min}{}_i = \min\{(\bullet)_i\}$.

E. Rank of Alternate Weapons

The element s_{ij} in the decision matrix reflects the closeness degree of the ideal weapon with the ith alternate weapon with respect to the jth criterion. In this step, we can use the simple additive weighting (SAW) method, which is widely used in MCDM, to calculate the relative importance value with respect to all criteria, with which the ranking order of alternate weapons according to the relative importance value can be obtained. And we can consider the weapon with the highest relative importance value as the closest one to that of the decision maker requires. The relative importance value of ith alternate weapon can be calculated with (8).

$$U_i = \sum_{j=1}^{n} x_{ij}\omega_j \quad i = 1, 2, \ldots, m \tag{8}$$

And the maximum of relative importance value can be written as (9).

$$U_{max} = \max_i \sum_{j=1}^{n} x_{ij}\omega_j \quad i = 1, 2, \ldots, m \tag{9}$$

III. ALGORITHM OF THE WEIGHT ASSIGNMENT

Compared with most MCDM methods, the FMCDM model reported by Bin Zhu et al. is one of the simplest and most effective methods [11]. A similarity measure method is utilized to build the decision matrix. However, one problem of this method is that the weight associated with each alternative is estimated or determined by the decision maker or an evaluation team based on their experience. Generally, this kind of weight estimation is acceptable for a small set of alternatives, such as 5 or less than 10. However, for a large set of alternatives, which is a popular situation, this weight estimation is not accurate and correct based only on the decision make's experience.

A simple but effective weight estimation method is adopted in this paper to make this evaluation process more objective and reliable. There are some different weight estimation methods reported by researchers, such as Saaty who developed a paired comparison matrix and then an eigenvector that is equivalent to the weight for an associated alternative can be calculated based on that paired comparison matrix [22]. Yager multiplied the normalized eigenvector by the order of the system to obtain exponents for weighting the fuzzy criteria in a decision problem [23]. However, both methods need a lot of mathematical operations and therefore make the process very complicated and time consuming.

In this paper, we adopted a weight estimation method based on the paired comparison matrix to simplify this estimation process. The operational procedure is completed by the following steps:

1. List the degree of importance or importance level of each criterion relative to another criterion based on Table I [24].
2. Construct a paired comparison matrix W based on the importance levels in step 1. Each element w_{ij} in the matrix W is a ratio of the importance level of the *ith* criterion over to the *jth* criterion.
3. Add each row $\omega_i = \sum_{j=1}^{n} \omega_{ij}$; where i = 1 ~ n and n is the total number of criteria.
4. Calculate the normalized weight factor for each criterion using $\omega_{ni} = \frac{\omega_i}{\omega_n}$; where $\omega_n = \sum_{i=1}^{n} \omega_i$.
5. These weight factors can be used to build the decision matrix based on the similarity measure method.

TABLE I. WEIGHT ASSIGNMENT TO A PAIRED COMPARISON CRITERIA

Importance Value	Definition
1	Equal Importance
3	Weak importance of one over the other.
5	Strong importance of one over the other.
7	Demonstrated importance of one over the other.
9	Absolute domination of one over the other.
2, 4, 6, 8	Intermediate values between the two adjacent judgements..

In the following section, we will use an example to illustrate this weight estimation method.

IV. CASE STUDY

In this section, we use a group of weapon information [25-30], which is collected by Federation of American Scientists (FAS) and contains the updated missiles, as an example to illustrate the weight estimation method we adopted in this paper with the Fuzzy MCDM model we discussed in section 2 to evaluate and assess the optimal weapon systems (missiles) currently used in the U.S. defense system.

Based on the different target locations and launching methods, all missiles can be divided into four categories: Air-launched, Ground-launched, Ship-launched and Submarine-launched. In this study, we concentrate on the Air-launched guided missiles with the ground targets because this is a kind of popular missiles and widely utilized in the U.S. defense system. First let us create a specification table for those missile alternatives based on twelve (12) criteria, which is shown in Table II. The 'cost' type criteria such as weapon's cost and weight have been converted to the 'benefit' type criteria in columns c3 and c7, respectively.

It can be found from Table II that some criteria contain vague and ambiguous (and thus fuzzy) definitiions, such as Guidance, Propulsion, Platform and Fuse system. The reason for that is because those criteria cannot be determined or described by crisp variables, and some human-being-language related terminologies must be applied to define them. For instance, a guidance system of a missile can be evaluated as a *low* if only manual guidance system is adopted for that missile, and a *mid* can be used to describe a guidance system that contains passive radar homing system, and a *high* can be used for a guidance system that uses an Inertial Navigation System (INS) and Global Position System (GPS).

TABLE II. AIR-LAUNCHED GUIDED MISSILE ALTERNATIVES

Missile	c1	c2	c3	c4	c5	c6	c7	c8	c9	c10	c11	c12

AGM-158	H	200	0.392	0.9	S	G	0.417	H	1000	14	18.0	95

- c1: Guidance (L-low, M-mid, H-high)
- c2: Range (nautical miles)
- c3: Weight (pounds)
- c4: Speed (Mach)
- c5: Propulsion (W-weak, M-mid, S-strong)
- c6: Platforms (P-poor, M-mid, G-good)
- c7: Cost (US$ thousands dollars - k)
- c8: Fuse system (L-low, M-mid, H-high)
- c9: Warhead (pounds)
- c10: Length (feet)
- c11: Diameter (inches)
- c12: Wingspan (inches)

The mapping relationships between some non-crisp parameters and fuzzy definitions for each missile should be indicated clearly. Table III shows an example of this kind of mapping for the Platform parameter.

TABLE III. MAPPING BETWEEN PLATFORM AND FUZZY DEFINITIONS

Missile	Platform Description	Fuzzy Definitiion
AGM-12	F-4, F-105	poor
AGM-45	F-4, F-16, F-105, A-4, A-6, A-7, B-2	good
AGM-62	F-18, F-4, A-4, A-7	mid

AGM-86	B-52H	poor
AGM-88	F-4, F-16C, F/A-18, EA-6B	mid
AGM-114	AH-1G, AH-64, MD-530, OH-58D, SH-60, HH-60 UH-60A, S-70 RAH-66, SA-342, F-4, F-5E, F-16 F/A-18, OV-10D	good
AGM-122	F-8, F-14, F-15, F/A-18, AH-1, AV-8B, OV-10 Fighters/Bombers	good
AGM-123	A-6E, A-7, F/A-18	mid
AGM-129	B-52H	poor
AGM-130	F-4E, F-15E, F-111	mid
AGM-136	B-52H, All Fighters and Bombers	good
AGM-137	All Fighters and Bombers	good
AGM-142	F-4, F-15, F-111, B-52H	mid
AGM-154	F-14, F-15, F-16, F-117, B-1B, F/A-18, AV-8B B-52H, All Other Fighter and Bombers	good
AGM-158	All Fighters and Bombers	good

Next we need to build the relative important levels for all criteria. This level is represented by a ratio between two or a paired of criteria. The ratio between the same criteria is 1 and a number represented in the intersection of a row and a column represnets the importance ratio between that row and that column. For example, the number in the intersection cell of row c5 and column c4 is 2, which means that the criterion c5 (Propulsion of a missile) is 2 times more important than that of criterion c4 (Speed of the missile). A completed importance level of this example is shown in Table IV.

TABLE IV. RELATIVE IMPORTANT LEVEL OF ALL CRITERIA

	c1	c2	c3	c4	c5	c6	c7	c8	c9	c10	c11	c12
c1	1	2	3	5	2	5	6	6	4	8	8	8
c2	1/2	1	3	2	1	3	3	5	2	7	7	7
c3	1/3	1/3	1	1/2	1	2	3	5	1	5	5	5
c4	1/5	1/2	2	1	1	3	3	5	1/2	3	3	3
c5	1/2	1	1	1	1	3	4	3	1/2	3	3	3
c6	1/5	1/3	1/2	1/3	1/3	1	3	3	1/2	3	3	3
c7	1/6	1/3	1/3	1/3	1/4	1/3	1	3	1/2	3	3	3
c8	1/6	1/5	1/5	1/5	1/3	1/3	1/3	1	1/5	2	2	2
c9	1/4	1/2	1	2	2	2	2	5	1	5	5	5
c10	1/8	1/7	1/5	1/3	1/3	1/3	1/3	1/2	1/5	1	1	1
c11	1/8	1/7	1/5	1/3	1/3	1/3	1/3	1/2	1/5	1	1	1
c12	1/8	1/7	1/5	1/3	1/3	1/3	1/3	1/2	1/5	1	1	1

Table IV is exactly a paired comparison matrix **W** and the diagonal weight element $\omega_{ji} = 1/\omega_{ij}$.

Now let's calculate the overall weight for each row by adding each row $\omega_i = \sum_{j=1}^{n} \omega_{ij}$; where i = 1 ~ n and n=12 is the total number of the criteria. The result of this calculation is shown in Table V.

TABLE V. THE OVERALL WEIGHT FOR EACH CRITERION

	c1	c2	c3	c4	c5	c6
ω_i	58.00	41.50	29.17	25.20	24.00	18.20
	c7	**c8**	**c9**	**c10**	**c11**	**c12**
ω_i	15.25	8.97	29.75	5.50	5.50	5.50

The total weight is obtained by adding all weights of criteria together, which is 266.54. The normalized weight for each criterion is shown in Table VI.

TABLE VI. THE NORMALIZED WEIGHT FOR EACH CRITERION

	c1	c2	c3	c4	c5	c6
$\hat{\omega}_i$	0.218	0.156	0.109	0.095	0.090	0.068
	c7	**c8**	**c9**	**c10**	**c11**	**c12**
$\hat{\omega}_i$	0.057	0.034	0.112	0.021	0.021	0.021

Now we can perform step 4 in section II to add these normalized weight for each criterion with all criteria to construct the ideal and criteria weight table, which is shown in Table VII.

TABLE VII. THE IDEAL MISSILE AND CRITERIA WEIGHT

Criterion	Ideal	Lower	Upper	Normalized Weight
c1	4	1	8	0.218
c2	600	4	1620	0.156
c3	0.9	0.0	1.5	0.109
c4	2.0	0.5	2.5	0.095
c5	4	1	8	0.090
c6	4	1	8	0.068
c7	0.9	0.0	1.5	0.057
c8	4	1	8	0.034
c9	1500	18	2200	0.112
c10	15.0	5.0	21.0	0.021
c11	15.0	5.0	30.0	0.021
c12	60	12	125	0.021

The vector of the ideal missile can be represented as the following form of the triangualr fuzzy number (Table VII):

T = [(1 4 8), (4 600 1620), (0.0 0.9 1.5), (0.5 2.0 2.5), (1 4 8), (1 4 8), (0.0 0.9 1.5), (1 4 8), (18 1500 2200), (5.0 15.0 21.0), (5.0 15.0 30.0), (12 60 125)]

The corresponding vector of the criteria weight can be expressed as:

ω = (0.218, 0.156, 0.109, 0.095, 0.090, 0.068, 0.057, 0.034, 0.112, 0.021, 0.021, 0.021)

The decision matrix, which can be calculated based on the similarity degree with respect to each criterion between the ideal missile and the alternatives, is shown in Table VIII by using (3) – (7). The relative importance value of *ith* alternate missile with respect to all criteria can be computed by (8), and the final calculating results are shown in Table IX.

TABLE VIII. DECISION MATRIX

Missile	c1	c2	c3	c4	c5	c6	c7	c8	c9	c10	c11	c12
AGM-12	0.1605	0.0075	0.4060	0.8571	0.1605	0.1605	0.7745	0.1605	0.5086	0.8069	0.7826	0.4882
AGM-45	0.3210	0.0209	0.7016	0.8333	0.3210	0.6420	0.7634	0.1605	0.0760	0.5933	0.3478	0.3662

TABLE IX. THE FINAL RESULT

AGM-12	AGM-45	AGM-62	AGM-65	AGM-78	AGM-84
0.3374	0.3864	0.3290	0.3271	0.3804	0.4368
AGM-86	**AGM-88**	**AGM-114**	**AGM-122**	**AGM-123**	**AGM-129**
0.4493	0.4010	0.4265	0.3684	0.4068	0.3684
AGM-130	**AGM-136**	**AGM-137**	**AGM-142**	**AGM-154**	**AGM-158**
0.4106	0.3816	0.4605	0.3881	0.4297	0.4864

The relative importance level of *ith* alternate missile can be calculated with Eq. (8) as:

$$U_i = \sum_{j=1}^{n} s_{ij}\omega_j \qquad i = 1, 2, \ldots \text{m} \ \ (\text{m} = 12)$$

The maximum important level of missiles can be obtained as:

$$U_{\max} = \max_i \sum_{j=1}^{n} s_{ij}\omega_j \qquad i = 1, 2, \ldots \text{m} \ \ (\text{m} = 12)$$

The missile that has the maximum important level can be found from Table IX, which is the **AGM-158** with a most important level of **0.4864**. The order that shows the top-10 closeness degree to the missiles that have the more important levels is:

AGM-158 >AGM-137 >AGM-86 >AGM-84 >AGM-154 > AGM-114 >AGM-130 >AGM-123 >AGM-88 >AGM-142

This is the optimal missile sequence estimated and evaluated based on the FMCDM system we developed in this paper. This evaluation and estimation is based on multiple

criteria and missile properties given by some references listed on our reference list.

One point to be noted from this assessing result is that the data we collected and used for this FMCDM system come from different reports issued by different agencies since 1993. Since the defense situation is always changing, therefore this result may not make very sense to today's situation. We just use these data as an example to illustrate the effectiveness and avalibility of our proposed method. The real and actual assessing result is dependant on the updated data.

V. CONCLUSION

Decision making is one of the most important and popular research and application topics in the national defense and security. To assess and evaluate the optimal weapon system such as missiles from a large group of alternatives that contain multiple criteria is a challenging, sometimes may be a headach task to decision makers in the defense system. A correct or optimal model and the associated algorithm are critical tools to complete this task. In this paper, a fuzzy multi-criteria decision making model is developed to help decision makers to correctly estimate weight factors for all criteria to make this process simplier and easier. To correctly pridict and effectively protect our nationa's safety, accurately evaluate and correctly assess the optimal weapon system is a prerequsite and critical task. In this paper, we used a collection of weapon information reported by different agencies in recent years with a target example to illustrate how to use FMDCM model to simplify this assessing process. The actual and more updated assessing result depends on the updated information reported by different sources in the future.

***Abstract*—Classifier ensembles constitute one of the main research directions in machine learning and data mining. Ensembles allow higher accuracy to be achieved which is otherwise often not achievable with a single classifier. A number of approaches have been adopted for constructing classifier ensembles and aggregate ensemble decisions. In most cases, these constructed ensembles contain redundant members that, if removed, may further increase ensemble diversity and produce better results. Smaller ensembles also relax the memory and storage requirements of an ensemble system, reducing its run-time overhead while improving overall efficiency. In this paper, a new approach to classifier ensemble selection based on fuzzy-rough feature selection and harmony search is proposed. By transforming the ensemble predictions into training samples, classifiers are treated as features. Harmony search is then used to select a minimal subset of such artificial features that maximises the fuzzy-rough dependency measure. The resulting technique is compared against the original ensemble and ensembles formed using random selection, under both single algorithm and mixed classifier ensemble environments.**

Keywords: Classifier Ensemble Selection; Feature Selection; Harmony Search; Fuzzy-rough Sets

I. Introduction

The main purpose of a classifier ensemble is to improve the performance of single classifier systems. Different classifiers usually make different predictions on certain samples, caused by their diverse internal models. Combining such classifiers became the natural way of trying to increase classification accuracy, by exploiting their uncorrelated errors. Also, each ensemble member can potentially be trained using a subset of training samples, which may reduce the computational complexity issue which arises when a single classification algorithm is applied to very large datasets. Additionally, an ensemble can operate in a distributed environment, where datasets are physically separated and are cost ineffective or technically difficult to combine into one database, in order to train a single classifier. A typical approach to building classifier ensembles involves building a group of classifiers with diverse training backgrounds, before aggregating their decisions together to produce the final prediction.

The target of Classifier Ensemble Selection (CES) [21] is to select a subset from a pre-constructed pool of base classifiers, in order to form a reduced group that is still capable in producing good classification results. This is an intermediate stage between the ensemble building and aggregation. Efficiency is one of the obvious gains from CES. Having a reduced number of classifiers can eliminate a portion of run-time overheads, making the ensemble processing quicker; having fewer models also means relaxed memory and storage requirements. Removing redundant ensemble members can also lead to improved diversity within the group, further increase potential ensemble prediction performance. A number of existing techniques use clustering [9] to discover groups of models that share similar predictions, and subsequently prune each cluster separately. Alternative selection methods [22] focus on selecting potentially optimal subsets to maximise a pre-defined diversity measures.

Feature selection [4] (FS) aims to determine a minimal feature subset from a problem domain while retaining a suitably high accuracy in representing the original features. In dealing with real-world problems FS is usually necessary due to the abundance of noisy, irrelevant, redundant or misleading features [13]. For instance, by removing these factors, learning from data techniques such as text processing and web content classification can benefit greatly. Given a feature set size n, the task of FS can be seen as a search for an "optimal" feature subset through the competing 2^n candidate subsets. The definition of an optimal subset may vary, depending on the problem at hand. A data reduction approach for fuzzy-rough feature selection (FRFS), based on fuzzy-rough sets [7], has been developed [14]. Fuzzy-rough sets encapsulate the related but distinct concepts of vagueness (for fuzzy sets) and indiscernibility (for rough sets [19]),both of which occur as a result of uncertainty in knowledge. The fuzzy-rough set-based techniques consider the extent to which fuzzified values are similar. By employing fuzzy-rough sets, it is possible to perform better feature selection. An unsupervised FRFS method was also proposed [17].

Many existing FS algorithms employ heuristic search strategies in an attempt to avoid the prohibitive complexity of exhaustive method. For instance, FRFS uses an incremental hill-climbing algorithm to discover the best feature subset. However, this often led to the discovery of non-optimal feature subsets, both in terms of the resulting subset quality and the subset size. Other search mechanisms may help, harmony search (HS) [8] in particular, is a meta-heuristic algorithm that mimics the improvisation process of music players. It imposes only limited mathematical requirements and is insensitive to initial value settings. Due to its simplistic structure and powerful performance, HS algorithm has been very successful in a wide variety of optimisation problems [8], presenting several advantages with respect to traditional optimisation techniques. The basic HS algorithm has been improved by

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

introducing methods to tune parameters dynamically [6] and also successfully applied to solve FS problems [5].

In this paper, a new CES approach based on FRFS is proposed. Inspired by the analogies in between CES and FS, fuzzy-rough CES aims to tackle CES problems from a different angle: by transforming the classifier predictions, each classifier is treated as an artificial feature in the transformed dataset, and classifier predictions as feature values. FS algorithms can then be used to remove redundant features (classifiers) in the present context, in order to select a minimal classifier subset while maintaining original ensemble diversity, and preserving ensemble prediction accuracy.

The rest of this paper is structured as follows. Section II describes the theory behind FRFS, and a most recently proposed unsupervised FRFS method which will be utilised in this work. Section III explains the basic structure of HS, and how it is applied to FRFS. Section IV introduces the key concepts of fuzzy-rough CES, demonstrates how CES can be modelled as an FS problem, and details the approaches developed to tackle the problem. Section V presents the experimentation results along with discussions. Section VI concludes the paper and proposes further work in the area.

II. Fuzzy-Rough Feature Selection

Rough set theory (RST) has been successfully used as an attribute selection tool to discover data dependencies and reduce the number of attributes contained in a dataset by purely structural means [20]. Given a dataset with discretised attribute values, RST can find a subset (termed *reduct*) of the original attributes that are the most informative; all other attributes can be removed from the dataset with minimal information loss. However, it is most often the case that the values of attributes may be both crisp and real-valued, and this is where traditional rough set theory encounters a problem. It is not possible in the theory to say whether two different attribute values are similar and to what extent they are the same. For example, two close values may only differ as a result of noise, but in the standard RST-based approach they are considered to be as different as two values of a different order of magnitude. Dataset discretisation must therefore take place before reduction methods based on crisp rough sets can be applied. This is often still inadequate, however, as the degrees of membership of values to discretised values are not considered and thus can result in information loss. In order to combat this, extensions of rough sets based on fuzzy-rough sets [7] have been developed. A fuzzy-rough set is defined by two fuzzy sets, fuzzy lower and upper approximations, obtained by extending the corresponding crisp rough set notions. In the crisp case, elements either belong to the lower approximationwith absolute certainty or not. In the fuzzy-rough case, elements may have a membership in the range [0,1], allowing greater flexibility in handling uncertainty.

A. Supervised Fuzzy-rough Feature Selection

Fuzzy-rough feature selection [14] (FRFS) is concerned with the reduction of information or decision systems through the use of fuzzy-rough sets. Let $I = (\mathbb{U}, \mathbb{A})$ be an information system, where $\mathbb{U}$ is a non-empty set of finite objects (the universe) and $\mathbb{A}$ is a non-empty finite set of attributes such that $a : \mathbb{U} \rightarrow V_a$ for every $a \in \mathbb{A}$. V_a is the set of values that attribute a may take. For decision systems, $\mathbb{A} = \{\mathbb{C} \cup \mathbb{D}\}$ where $\mathbb{C}$ is the set of input features and $\mathbb{D}$ is the set of decision features.

$$\mu_{\underline{R_P}X}(x) = \inf_{y \in \mathbb{U}} I(\mu_{R_P}(x,y), \mu_X(y)) \tag{1}$$

$$\mu_{\overline{R_P}X}(x) = \sup_{y \in \mathbb{U}} T(\mu_{R_P}(x,y), \mu_X(y)) \tag{2}$$

Here, I is a fuzzy implicator and T is a t-norm. R_P is the fuzzy similarity relation induced by the subset of features P,

$$\mu_{R_P}(x,y) = T_{a \in P}\{\mu_{R_a}(x,y)\} \tag{3}$$

where $\mu_{R_a}(x,y)$ is the degree to which objects x and y are similar for feature a.

FRQuickReduct($\mathbb{C}$,$\mathbb{D}$).
$\mathbb{C}$, the set of all conditional features;
$\mathbb{D}$, the set of decision features.

Fig. 1. The fuzzy-rough QuickReduct algorithm

A fuzzy-rough QuickReduct algorithm, based on the crisp version [20], has been developed as given in Fig. 1. It employs a quality measure termed the fuzzy-rough dependency function γ' to choose which features to add to the current reduct candidate, which is defined by:

$$\gamma'_{P(Q)} = \frac{\sum_{x \in \mathbb{U}} \mu_{POS_{R_P}(Q)}(x)}{\|\mathbb{U}\|} \tag{4}$$

where the fuzzy positive region is defined as:

$$\mu_{POS_{R_P}(Q)}(x) = \sup_{q \in \mathbb{Q}} \mu_{\underline{R_P}Q}(x) \tag{5}$$

The algorithm terminates when the addition of any remaining feature does not increase the dependency. As with the original algorithm, for a dimensionality of n, the worst case dataset will result in $(n^2 + n)/2$ evaluations of the dependency function. However, as fuzzy-rough set based feature selection is used for dimensionality reduction prior to any involvement of a given

application which will exploit those features belonging to the resultant reduct, this operation has no negative impact upon the run-time efficiency of the system.

B. Unsupervised Fuzzy-rough Feature Selection

The central idea behind unsupervised FRFS (U-FRFS) [17] is that, as with the supervised FRFS, the fuzzy dependency measure can also be used to discover the inter-dependency of features. This can be achieved by simply substituting the decision feature(s) $\mathbb{D}$ of the supervised approach for any given feature or group of features Q. In this case, the fuzzy positive region defined in Eq 5 becomes:

$$\mu_{POS_{R_P}(Q)}(x) = \sup_{z \in \mathbb{U}} \mu_{\underline{R_P} R_Q z}(x) \tag{6}$$

where $R_Q z$ indicates the fuzzy tolerance class (or fuzzy equivalence class) for object z, and the lower approximation now becomes:

$$\mu_{\underline{R_P} R_Q z}(x) = \inf_{y \in \mathbb{U}} I(\mu_{R_P}(x, y), \mu_{R_Q}(y, z)) \tag{7}$$

III. Harmony Search for Fuzzy-rough Feature Selection

Harmony Search (HS) [8] mimics the improvisation process of musicians, during which, each musician plays a note for finding a best harmony all together. The basic concepts of HS and application of such concepts in performing optimisation are outlined below, together with an introduction to the dynamic parameter control involved in HS.

A. Key Concepts

The key concepts of HS are musicians, notes, harmonies and harmony memory. In most optimisation problems solvable by HS, the musicians are the decision variables of a certain function being optimised. The notes played by the musicians are the values each decision variable can take. The harmony contains the notes played by all musicians, or an emerging solution vector containing the values for each decision attribute. The harmony memory contains harmonies played by the musicians, or a storage place for potential solution vectors. A more concrete representation of harmony memory is a two dimensional matrix, where the rows contain harmonies (solution vectors) with the number of rows being predefined and bounded by the harmony memory size. Each column is dedicated to one musician, and the entire column stores all the notes played by the musician in all saved harmonies, referred to as the working note domain for each musician in this paper.

Harmony Search for Feature Selection (HSFS) [5] treats musicians as independent experts, and each musician can vote for one feature to be included in the feature subset when improvising a new harmony. The harmony is then the combined vote from all musicians, indicating which features are being nominated. The entire pool of original features forms the range of notes available to the musicians. Multiple musicians are allowed to choose the same attribute, and they may opt to choose no attribute at all. For example, the harmony {A,-,B,B,C,-} will translate into feature subset {A,B,C}, − here represents a null note.

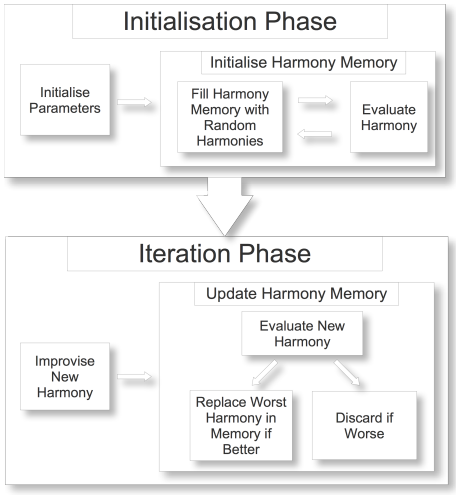

Fig. 2. Illustration of Harmony Search

B. Iteration Steps

HS can be divided into two core phases, initialisation and iteration, as illustrated in Fig 2.

a) Initialise Problem Domain: The parameters of HS are assigned according to the problem, including: size of harmony memory, number of musicians, max iteration, and the harmony memory considering rate (HMCR). The harmony memory of size m is initialised by random generation. This provides each musician a working note domain of m values, which may include identical notes, and nulls. A new harmony is produced by each musician randomly choosing one attribute from their note domain. The new harmony is then evaluated using the given cost function. It is used to replace the worst harmony in the harmony memory if a better score is achieved, or discarded otherwise.

b) Improvise New Harmony: A new value is chosen randomly by each musician out of their note domain, and together forms a new harmony. There are two factors which affect the note choice of a musician, HMCR and PAR. HMCR, ranging from 0 to 1, is the rate of choosing one value from the historical notes stored in the harmony memory, with $(1 - HMCR)$ set to be the rate of randomly selecting one value from the range of all possible notes of the corresponding variable. If HMCR is set low, the musicians will constantly explore other areas of the solution space, and a higher HMCR will restrict the musicians to historical choices.

The PAR parameter causes the musicians to select a neighbouring value based on the following formula $a + (random * bw)$, where bw is an arbitrary distance bandwidth, with $(1 - PAR)$ set to be the probability of using the chosen value without further alteration. The pitch adjustment is applied after a note is chosen by the musician, either from the HM or from the domain of all possible values. For FS problems that are dealt with in this paper, the PAR parameter is not used. This is because the underlying assumption of using PAR is that values that are very close by may provide more optimal solutions. However, when such values represent feature

indices, each index, and its neighbouring features, have no such general dependency in between.

c) Update Harmony Memory: If the new harmony is better than the worst harmony in the harmony memory, judged by the objective function, the new harmony is then included in harmony memory and the existing worst harmony is removed. The algorithm continues to iterate until the maximum number of iterations has been reached.

C. Parameter Control

TABLE I
PARAMETER SETTINGS IN DIFFERENT SEARCH STAGES

	Initialisation	Intermediate	Termination
HMCR	Small	Medium	Large
MS	Small	Medium	Large
Effect	High diversity. Deep Exploration	Steady improvement in harmonies	Fine tuning. Fast convergence

To improve HS and eliminate the drawbacks lying with the use of fixed parameter values, a dynamic parameter adjustment scheme [6] was proposed to modify parameter values at run time. Parameters are dynamically changed, and different settings are provided for different search stages. Table I shows the parameters relevant to FS. These parameters then gradually change through the initial solution space exploration, intermediate solution refinement, and fine tune optimal solution towards termination.

IV. FUZZY-ROUGH CLASSIFIER ENSEMBLE SELECTION

The overall approach developed in this work can be summarised in Fig 3, with each of the four key components described below.

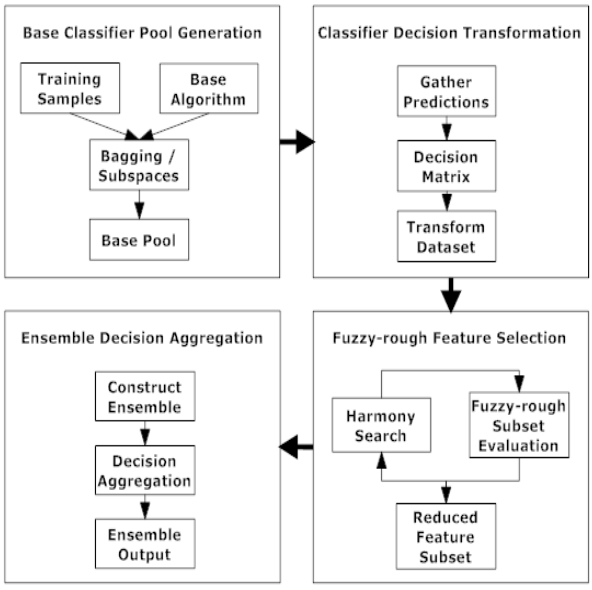

Fig. 3. Fuzzy-rough CES Flow Chart

A. Base Classifier Pool Generation

Forming a diverse base classifier pool (BCP) is the first step in producing a good classifier ensemble. Any preferred methods can be used to build the base classifiers, *Bagging* [2] and *Random Subspaces* [11] methods are adapted here. BCP can be created using a single classification algorithm as well as a mixed classifier scheme. *Bagging* randomly selects different subsets of training samples in order to build diverse classifiers. Differences in the training data present extra or missing information for different classifiers, resulting in different models. The *Random Subspaces* method randomly generates different subsets of domain attributes and builds various classifiers on top of each of such subsets. The differences between the subsets creates different view points of the same problem [3], typically resulting in different borders for classification. For a single base classification algorithm, these two methods both provide good diversities. In addition, a mixed classifier scheme is implemented in the presented work. By selecting classifiers from different schools of classification algorithms, the diversity is naturally achieved through the various foundations of the algorithms themselves.

B. Classifier Decision Transformation

TABLE II
DECISION MATRIX

	C_1	C_2	$\cdots$	C_i	$\cdots$	C_{N_C}
I_1	D_{1j}	D_{21}	$\cdots$	D_{1j}	$\cdots$	D_{N_C1}
I_2	D_{12}	D_{22}	$\cdots$	D_{2j}	$\cdots$	D_{N_C2}
$\vdots$	$\vdots$	$\vdots$		$\vdots$		$\vdots$
I_j	D_{1j}	D_{2j}	$\cdots$	D_{ij}	$\cdots$	D_{N_Cj}
$\vdots$	$\vdots$	$\vdots$		$\vdots$		$\vdots$
I_{N_I}	D_{1N_I}	D_{2N_I}	$\cdots$	D_{iN_I}	$\cdots$	$D_{N_CN_I}$

Once the base classifiers are built, their decisions on the training instances are also gathered. For base classifiers $C_i, i = 1, 2, \ldots, N_C$, and training instances $I_j, j = 1, 2, \ldots, N_I$, where N_C is the total number of base classifiers, and N_I is the total number of training instances, a decision matrix as shown in Table II can be constructed. The value D_{ij} represents the ith classifier's decision on the jth instance. For supervised FS, a class label is required for each training sample, the same class attribute is taken from the original dataset, and assigned to each of the instances. Note that both the total number of instances and the relations between instances and their class labels remain unchanged. Although all attributes and values are completely replaced by transformed classifier predictions, the original class labels remain the same. A new dataset is therefore constructed, each column represents an artificially generated feature, each row corresponds to a training instance, the cell then stores the transformed feature value.

C. Feature Selection on the Transformed Dataset

FRFS is then performed on the transformed dataset, evaluating each artificial feature subset using the fuzzy-rough dependency measure. HS optimises the quality of

discovered subsets, while trying to reduce subset sizes. A detailed explanation is already given in Section III. When HS terminates, its best harmony is translated into a feature subset and returned as the FS result. The features then indicate their corresponding classifiers which should be included in the learnt classifier ensemble. For example, if the best harmony given by HS is $\{-, C_9, C_3, C_{23}, C_3, C_5, C_{17}, -\}$, the translated artificial feature subset is then $\{C_3, C_5, C_9, C_{17}, C_{23}\}$. Thus, the 3rd, 5th, 9th, 17th and 23rd classifiers will be chosen from the BCP to construct the classifier ensemble. Note that the application of unsupervised FRFS is the same as above and hence is omitted to avoid repetition.

D. Ensemble Decision Aggregation

Once the classifier ensemble is constructed, new objects are classified by the ensemble members, and their results are aggregated to form the final ensemble decision output. The *Average of Probability* aggregation method is used in the paper. Given ensemble members $E_i, i = 1, 2, \ldots, N_E$, and decision classes $D_j, j = 1, 2, \ldots, N_D$, where$N_D$ is the ensemble size and N_D is the number of decision classes, classifier decisions can be viewed as a matrix of probability distributions $\{P_{ij}\}$. Here, P_{ij} indicates prediction from classifier C_i for decision class D_j. The final aggregated decision is the winning classifier that has the highest averaged prediction across all classifiers: $\{\sum_{i=1}^{N_E} P_{i1}/N_E, \sum_{i=1}^{N_E} P_{i2}/N_E, \ldots, \sum_{i=1}^{N_E} P_{iN_D}/N_E\}$. Note that this is effective because redundant classifiers are now removed. As such, the usual alternative aggregation method: *Majority Vote* is no longer favourable since the "majority" has been significantly reduced.

V. Experimentation and Discussion

To demonstrate the capability of fuzzy-rough CES, a number of experimentations have been carried out. These experiments are divided into three groups, based on the main methods adapted to generate the BCP: *Bagging*, *Random Subspaces*, and the mixed classifier scheme. For single base algorithm experiments, the facilitate comparative studies, the state of the art fuzzy-rough nearest neighbour (FRNN) [12] classifier is used. Both ordinary FRFS and unsupervised FRFS methods are examined. Classification accuracies are collected under stratified 10 fold cross validation, and each set of experiments is run 10 times with results averaged. Ten 10-fold cross validations are used as random factors are involved in creating the *Bagging* and *Random Subspaces* BCPs, as well as in the artificial feature selection process using HS. For comparison, the accuracy of the base algorithm, when trained using the original dataset without alteration is included, the averaged accuracy of the full BCP is also included. A total of 9 real-valued UCI datasets [18] are used in the experiments. Parameters used in the experiments and dataset information are summarised in Table III.

TABLE III
HS Parameter Settings and Dataset Information

Harmony Memory Size	# Musicians	HMCR	Max Iteration

water 2	390	38	2
wine	178	14	3

A. Bagging

In this set of experiments, the BCP is built using *Bagging* with FRNN being the base algorithm. Table IV shows the results of applying fuzzy-rough CES and unsupervised fuzzy-rough CES, as compared against the results of using: (1) the base algorithm, (2) the full base classifier pool, and (3) randomly formed ensembles. Entries annotated with *v* indicates that the selected ensemble performance is statistically significant when compared against random pick, using paired t test with two-tailed P threshold = 0.005.

TABLE IV
Fuzzy-rough Nearest Neighbour using Bagging

Dataset	Base	Full	FRFS	U-FRFS	Random
cleveland	53.20	57.91	57.21 (11.8) *v*	56.30 (8.9)	56.03
ecoli	81.85	86.01	85.97 (11.9)	85.52 (7.9)	85.52
glass	72.43	73.36	73.18 (11.3) *v*	73.04 (8.1)	73.04
heart	76.30	81.19	79.78 (8.0) *v*	79.22 (8.2)	78.69
ionosphere	90.43	88.43	88.70 (7.4) *v*	88.83 (7.5) *v*	87.85
sonar	85.10	85.72	85.96 (8.0)	85.91 (7.9)	85.32
water 3	80.26	81.51	81.38 (8.8)	81.62 (7.9) *v*	80.94
water 2	84.62	85.23	85.05 (7.9) *v*	84.69 (7.8)	84.35
wine	97.19	96.91	96.46 (7.6)	96.63 (7.8) *v*	96.35

The results show that the *Bagging* method improved over the base classifier. Column *Full* displays aggregated predictions from the entire base classifier pool of size 50. For 7 out of 9 datasets, greater classification accuracies have been achieved using the ensemble approach. The CES+FRFS method successfully selected classifier ensembles with reduced size, as shown in column *FRFS* with the numbers in the brackets indicating the selected ensemble sizes. Because ten fold cross validation is used, different classifiers are constructed and selected for each individual fold, hence performed in general differently, but the reported sizes are an average of 100 ensembles. Despite the reduced ensemble size, classification accuracies are further improved for the *sonar* and *ionosphere* datasets. For the other datasets, the accuracies are reduced very marginally, with less than 0.2% in 5 of the 7 total cases, and the greatest reduction being 0.7% (*cleveland*).

When compared against the use of supervised FRFS, CES equipped with unsupervised FRFS finds more compact ensembles with an averaged size of 8. This is possibly due to the fact that the class label is no longer considered in the dependency calculation, and therefore less consistency constraints are placed upon the construction of ensembles

(artificial feature subsets). The reduced ensembles still maintain reasonable classification accuracies, in comparison to the use of supervised FRFS, and the base pool. Both approaches generally deliver better results than randomly picked ensembles, except for *ecoli* and *glass* datasets, the unsupervised method seems to have an equal performance as random picking. One possible explanation is that the number of classes for a given training dataset has direct impact upon unsupervised FRFS performance. The more classes there are, the more various the classifier predictions become, thereby providing more available values for the artificial features. The transformed dataset is therefore more complex than ones originated from the training datasets with 2 or 3 classes. For such datasets like *cleveland* (5), *ecoli* (8), and *glass* (6), the extra consistency constraint from the class label itself must have aided the supervised method in selecting better artificial feature subsets, with the sacrifice of having larger ensembles.

B. Random Subspaces

TABLE V
FUZZY-ROUGH NEAREST NEIGHBOUR USING RANDOM SUBSPACES

Dataset	Base	Full	FRFS	U-FRFS	Random
cleveland	53.20	58.25	57.00 (8.1)	57.78 (7.4) *v*	56.37
ecoli	81.85	80.33	81.85 (9.8) *v*	78.63 (7.8)	77.98
glass	72.43	76.96	76.78 (7.6) *v*	76.87 (7.6) *v*	75.05
heart	76.30	82.59	80.89 (7.7)	79.96 (7.6)	80.28
ionosphere	90.43	89.87	89.87 (7.8) *v*	89.83 (7.7) *v*	89.48
sonar	85.10	88.89	88.22 (7.1) *v*	87.88 (7.4) *v*	87.24
water 3	80.26	80.97	81.90 (7.7) *v*	81.59 (7.8) *v*	80.63
water 2	84.62	85.46	85.15 (7.6) *v*	85.00 (7.6)	84.83
wine	97.19	97.81	97.02 (7.5) *v*	97.02 (7.8)	96.41

Table V shows the use of *Random Subspaces* builds slightly better quality base classifiers. In comparison with the base algorithm, the pool gains better accuracy in 8 out of 9 cases, except for dataset *ionoshpere*; and in 7 out of 9 cases, the averaged accuracies are higher than pools using *Bagging*. The FRFS method successfully reduced ensembles, and the ensemble sizes are smaller than previous discoveries for all datasets. A likely indication from these results is that the classifiers created using *Random Subspaces* contain more redundancy. Although the overall accuracies of the reduced ensembles are higher than those obtained by their counterpart via using the *Bagging* method, greater accuracy decrease is observed when compared with the base pools.

Unsupervised FRFS also finds smaller ensembles, with comparable accuracies except for *ecoli*, the reduced ensembles suffered more than 3% loss of accuracy when compared against the case when supervised FRFS is used. Both selection methods however entail better results than random selection.

C. Mixed Classifier Scheme

A total of 10 different base algorithms are selected for this experiment, one or two distinctive classifiers from each representative classifier groups, including fuzzy-based FuzzyNN [16], FuzzyRoughNN [12], VQNN [12], lazy-based IBk [1], tree-based J48 [23], REPTree [23], rule-based JRip [23], PART [23], NaiveBayes [15] and MultilayerPerceptron [10]. Given only 10 base algorithms, more variations are needed to produce as pool of size 50, *Bagging* and *Random Subspaces* are again used to create differentiation between classifiers. Tables VI and VII show the experimental results, using these two methods respectively.

For mixed classifiers created using *Bagging*, the FRFS method finds ensembles with much greater size variation and overall, considerably larger ensembles than previous experiments. For the *ecoli* dataset in particular, the averaged ensemble size is 15.98. Even with such a large ensemble, the underlying artificial feature subset still did not achieve 1 for the fuzzy-rough dependency measure. However, the results indicate that many distinctive features (i.e. classifiers) are present, therefore a larger subset is necessary to maintain consistency. For classifier ensembles, this means good diversity and many distinctive classifiers co-exist in the base pool, and thus less redundancy exists. This particular ensemble also results in the highest accuracy for *ecoli* compared against other approaches, with 87.67% BCP accuracy, and 86.66% ensemble accuracy. Although most ensembles can achieve comparable performance, large performance decreases are also noticed for the *sonar* and *heart* datasets. Interestingly, the use of the unsupervised method achieves better overall performance than its supervised counterpart, with smaller selected ensemble sizes. Reasons for such performance is unknown yet, but further investigation into this aspect is currently ongoing.

TABLE VI
MIXED CLASSIFIERS USING BAGGING

Dataset	Full	FRFS	U-FRFS
cleveland	54.94	52.92 (11.2)	54.27 (9.32)
ecoli	87.67	86.66 (15.98)	85.77 (8.7)
glass	71.12	69.62 (12.2)	69.62 (9.2)
heart	82.07	75.40 (8.76)	77.62 (8.42)

TABLE VII
MIXED CLASSIFIERS USING RANDOM SUBSPACES

Dataset	Full	FRFS	U-FRFS
cleveland	56.57	57.85 (11.82)	57.10 (9.08)
ecoli	79.17	84.64 (12.16)	84.40 (7.8)
glass	75.61	71.50 (11.28)	73.08 (8.18)
heart	82.44	80.89 (7.96)	80.44 (8.16)
ionosphere	89.30	87.39 (8.1)	88.00 (7.58)
sonar	82.69	86.06 (7.86)	83.17 (7.88)
water 3	80.26	80.41 (9.16)	80.92 (8.04)
water 2	83.18	85.85 (7.86)	85.74 (7.92)
wine	98.09	97.53 (7.82)	97.75 (7.46)

The *Random Subspaces* based mixed classifier scheme produces better base pools in 7 out of 9 cases. Both FRFS and U-FRFS find smaller ensembles on average than the case where *Bagging* is used. Neither method suffers from extreme performance decreases following reduction unlike the results obtained when single base algorithm is employed. Despite having a BCP that under performs for the *ecoli* dataset, both methods manage to achieve an increase of 5% in accuracy.

However, the general quality of the mixed classifier group is lower than that of the FRNN based single algorithm approach. This is largely caused by the employment of non-optimised base classifiers. It can be expected that the results achievable after optimisation would be even better. Note that certain ensemble methods are less desirable for some datasets. For example, using the mixed classifier scheme can achieve an accuracy of 86.66% for *ecoli*, but using partition based approach only leads to an accuracy of 81.85%. Yet, the partition based approach results in 88.22% for *sonar*, while the mixed classifier scheme obtains a result as low as 73.55%. Further experimental investigation revealed that *ecoli* involves the least number (8) of attributes. Therefore *Random Subspaces*, which creates attribute subsets randomly, can easily remove an essential attribute, making it less suitable for ensemble generation. The massive performance gain for *sonar* dataset can be explained in a similar way: *Random Subspaces* can construct diverse classifiers reasonably well with 60 attributes.

VI. Conclusion

This paper has presented a new approach to classifier ensemble selection. It works by applying fuzzy-rough feature selection technique to minimise redundancy in an artificial dataset generated via transforming a given classifier pool's decision matrix. The aim is to further reduce the size of a classifier ensemble, while maintaining and improving classification accuracy, making the ensemble more efficient. Experimental comparative studies show that both supervised and unsupervised FRFS approaches can entail good solutions. Reduced ensembles are found with comparable classification accuracies as the base pools, and in most cases provide good improvements over the performance achievable by the base algorithms. In particular, the use of the unsupervised FRFS method can help create smaller ensembles, especially when complex mixed classifiers are used.

Although promising, much can be done to further improve the potential of the presented work. In particular, an alternative classifier decision matrix transformation procedure may be formulated. Some classifiers first produce a distribution of the likelihood that a particular instance may belong to the available classes, and the class with highest probability is then taken as the final prediction. These probability distributions may contain more information and are potentially more suitable to be used as the artificial feature values. In addition, other statistical information from the classifiers such as variance, may also be good candidates for use as part of the artificially generated features, in order to create a more comprehensive dataset for feature selection. Experimental evaluation of these ideas remains as active research, as well as the aforementioned investigation into the underlying reasons why the use of unsupervised FRFS helps more significantly overall, in simplifying the complexity of the leant ensembles.

Finally, it is worth noting that, instead of fully relying on FRFS and HS methods, the proposed approach can be generalised to work with other feature selection techniques and heuristic search strategies, making it a generic CES framework for future extensions. Fuzzy-rough CES can also be used in conjunction with other CES methods, in particular those that maximise a certain diversity measure, in order to further reduce ensemble size, whilst preserving ensemble performance.

***Abstract*—Fuzzy-rough sets play an important role in dealing with imprecision and uncertainty for discrete and real-valued or noisy data. However, there are some problems associated with the approach from both theoretical and practical viewpoints. These problems have motivated the hybridisation of fuzzy-rough sets with kernel methods. Existing work which hybridises fuzzy-rough sets and kernel methods employs a constraint that enforces the transitivity of the fuzzy T-norm operation. In this paper, such a constraint is relaxed and a new kernel-based fuzzy-rough set approach is introduced. Based on this, novel kernel-based fuzzy-rough nearest-neighbour algorithms are proposed. The work is supported by experimental evaluation, which shows that the new kernel-based methods offer improvements over the existing fuzzy-rough nearest neighbour classifiers. The abstract goes here.**

***Keywords*—Fuzzy-rough sets; Fuzzy tolerance relation; Kernel theory; Nearest neighbour classification**

I. Introduction

Fuzzy-rough set theory [1] is a hybridisation of rough sets [2] and fuzzy sets [3], which is capable of dealing with imprecision and uncertainty in data. As a hybridisation of fuzzy set theory and rough sets, fuzzy-rough sets not only inherit the domain independence of rough sets, but also address the inability of rough sets in handling real-valued data. That is, fuzzy-rough sets provide a means to deal with discrete or real-valued noisy data (or a mixture of both) without the need for user-supplied thresholding or domain information. As such, this technique can be applied to regression as well as classification tasks. The only additional information required is in the form of fuzzy partitions for each feature which can be automatically derived from the data [4].

Kernel methods [5] have the ability to deal with non-linear models by mapping a given problem from the (low dimensional) input space onto a new (higher-dimensional) space via a non-linear transformation. The resulting structure of the classification task is then linearly separable. From another perspective, the kernel defines a similarity measure between two data objects and thus allows the utilisation of prior knowledge of the problem domain. More importantly, the kernel provides all of the information about the relative positions of the inputs in the feature space so that the associated learning algorithm is based only on the kernel function. Classification can be carried out without explicit use of the feature space.

The initial work on hybridising fuzzy-rough sets and kernel methods is presented in [6]. This work exploited the approach as described in [7], which explored the relationship between kernels and T-transitivity. In particular, kernel methods are integrated into fuzzy-rough sets (and more recently gaussian kernels [8]). In the work of [6], the concept of *kernelised fuzzy-rough sets* was proposed, in which kernel functions are employed to compute the fuzzy similarity relations between samples. One of the shortcomings of this approach however, is the fact that the fuzzy relations are limited only to T_{cos} equivalence relations [7] in an attempt to guarantee T-transitivity. However, as argued in [9], T-transitivity does not necessarily need to be enforced for fuzzy-rough sets [10], as the use of fuzzy tolerance relations [11] may be sufficient [12].

In this paper, an improved approach to using kernel methods with fuzzy-rough sets is presented. The reason why the proposed method is termed *kernel-based fuzzy-rough sets* rather than *kernelised fuzzy-rough sets*, is that in such a combination, kernels are employed as a special means to construct fuzzy tolerance relations. The framework of fuzzy-rough sets is preserved, whilst a statistical perspective is used in order to investigate the properties of kernels which may be suitable for integration into fuzzy-rough sets. To demonstrate the utility of the new kernel-based fuzzy-rough sets approach, a new form of nearest-neighbour classifier is proposed. This type of classifier also employs a vaguely-quantified rough set measure [13], which is robust in the presence of noisy data.

The remainder of this paper is structured as follows. The theoretical background is presented in Section 2 with a short review of existing methods. The proposed kernel-based fuzzy-rough set approach and the associated nearest neighbour algorithms are described in Section 3. The new kernel-based classifier is compared to others, with experimental results shown in Section 4. Finally, section 5 concludes the paper with a short discussion of future work.

II. Theoretical Background

A. Hybridisation of Rough Sets and Fuzzy Sets

The work on rough set theory (RST)[2] provides a methodology that can be employed to extract knowledge from a

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

domain in a concise way: It is able to minimise information loss whilst reducing the amount of knowledge involved. Central to rough set theory is the concept of indiscernibility. Let $I = (\mathbb{U}, \mathbb{A})$ be an information system, where $\mathbb{U}$ is a non-empty set of finite objects (the universe) and $\mathbb{A}$ is a non-empty finite set of attributes so that $a : \mathbb{U} \longrightarrow V_a$ for every $a \in \mathbb{A}$. V_a is the set of values that attribute a may take. For any $P \subseteq \mathbb{A}$, there exists an associated equivalence relation $IND(P)$:

$$IND(P) = \{(x, y) \in \mathbb{U}^2 \mid \forall a \in P, a(x) = a(y)\}. \quad (1)$$

The partition generated by $IND(p)$ is denoted $\mathbb{U}/IND(P)$ or abbreviated to $\mathbb{U}/P$ and is calculated as follows:

$$\mathbb{U}/IND(P) = \otimes\{a \in P : \mathbb{U}/IND(\{a\})\} \quad (2)$$

where,

$$\mathbb{U}/IND(\{a\}) = \{\{x \mid a(x) = b,\ x \in \mathbb{U}\} \mid b \in V_a\} \quad (3)$$

and,

$$A \otimes B = \{X \cap Y \mid \forall X \in A, \forall Y \in B, X \cap Y \neq \emptyset\}. \quad (4)$$

If $(x, y) \in IND(P)$, then x and y are indiscernible by attributes from P. The equivalence classes of the P-indiscernibility relation are denoted $[x]_P$. Let $X \subseteq \mathbb{U}$. X can be approximated using only the information contained in P by constructing the P-*lower* and P-*upper* approximations of X:

$$\underline{P}X = \{x \mid [x]_P \subseteq X\} \quad (5)$$

$$\overline{P}X = \{x \mid [x]_P \cap X \neq \emptyset\}. \quad (6)$$

The tuple $\langle \underline{P}X, \overline{P}X \rangle$ is called a rough set.

The process described above although useful can only operate effectively on datasets containing discrete values. As most datasets contain real-valued attributes, a subjective judgement or threshold must therefore be employed in order for RST to operate on such data. The imposition of such a subjective threshold is however, contrary to the concept of domain independence of RST. An appropriate way of handling the problem of real-valued data is the use of fuzzy-rough sets (FRS) [1]. FRS offers a high degree of flexibility in enabling the vagueness and imprecision present in real-valued data to be modelled effectively.

Definitions for the fuzzy lower and upper approximations can be found in [10], [14], where a T-transitive fuzzy similarity relation is used to approximate a fuzzy concept X:

$$\mu_{\underline{R_P}X}(x) = \inf_{y \in \mathbb{U}} I(\mu_{R_P}(x, y), \mu_X(y)) \quad (7)$$

$$\mu_{\overline{R_P}X}(x) = \sup_{y \in \mathbb{U}} T(\mu_{R_P}(x, y), \mu_X(y)). \quad (8)$$

Here, I is a fuzzy implicator and T is a T-norm. R_P is the fuzzy similarity relation induced by the subset of features P:

$$\mu_{R_P}(x, y) = T_{a \in P}\{\mu_{R_a}(x, y)\}. \quad (9)$$

$\mu_{R_a}(x, y)$ is the degree to which objects x and y are similar for feature a, and may be defined in many ways, for example:

$$\mu_{R_a}(x, y) = 1 - \frac{|a(x) - a(y)|}{|a_{max} - a_{min}|} \quad (10)$$

$$\mu_{R_a}(x, y) = \max\left(\min\left(\frac{(a(y) - (a(x) - \sigma_a))}{(a(x) - (a(x) - \sigma_a))}, \frac{((a(x) + \sigma_a) - a(y))}{((a(x) + \sigma_a) - a(x))}\right), 0\right) \quad (11)$$

where ${\sigma_a}^2$ is the variance of feature a. As these relations do not necessarily display T-transitivity, fuzzy transitive closure must be computed for each feature [9]. In other words, T-transitivity is not required for fuzzy-rough sets. Instead, fuzzy tolerance relations [11] can be employed to construct fuzzy-rough sets [12]. This technique is adopted in this paper also.

Note that formulas (7) and (8) are quite sensitive to noisy values, just like their crisp counterparts. Thus, the concept of vaguely-quantified rough set (VQRS) has been introduced in [13]. Following this approach, given a pair of fuzzy quantifiers (Q_u, Q_l), which are an increasing $[0, 1] \to [0, 1]$ mapping, the lower and upper approximation of X by R are defined by

$$\mu_{\underline{R_P}X}^{Q_u}(x) = Q_u\left(\frac{|R_P(x, y) \cap X|}{|R_P(x, y)|}\right) = Q_u\left(\frac{\sum_{y \in \mathbb{U}} \min(\mu_{R_P}(x, y), \mu_X(y))}{\sum_{y \in \mathbb{U}} \mu_{R_P}(x, y)}\right) \quad (12)$$

$$\mu_{\overline{R_P}X}^{Q_l}(x) = Q_l\left(\frac{|R_P(x, y) \cap X|}{|R_P(x, y)|}\right) = Q_l\left(\frac{\sum_{y \in \mathbb{U}} \min(\mu_{R_P}(x, y), \mu_X(y))}{\sum_{y \in \mathbb{U}} \mu_{R_P}(x, y)}\right), \quad (13)$$

The fuzzy set intersection is defined by the T-norm *min* and the fuzzy set cardinality by the sigma-count operation. As an important difference to (7) and (8), the VQRS approximations do not extend the classical rough set approximations, in a sense that when X and R are crisp, (12) and (13) may still be fuzzy.

B. Fuzzy-rough Nearest Neighbour Algorithm

A number of techniques have been developed for building fuzzy-rough nearest neighbour (FRNN) classifiers [15], [16]. Based upon such techniques, an approach which utilises the fuzzy upper and lower approximations to determine class membership is proposed in [17].

FRNN works by examining each of the decision classes in the training data in-turn. It computes the membership of a test object to the fuzzy lower and upper approximations of each class. These values are then compared with the highest existing values: $\mu_1(y)$ and $\mu_2(y)$. If the approximation membership

values for the currently considered class are higher, then both $\mu_1(y)$ and $\mu_2(y)$ are assigned these values and the class label is assigned to this test object. If not, the algorithm continues to iterate through all remaining decision classes. Classification accuracy is calculated by comparing the output with the actual class labels of the test objects.

An extension of FRNN is vaguely quantified rough nearest neighbour (FRNN-VQRS) [13] which employs (12) and (13), to determine class membership of test objects. The underlying learning mechanism is very similar to that of FRNN.

C. Classes of Kernels in Statistics

In a kernel algorithm, a mapping ϕ from the original space to a possibly high-dimensional space is employed to change the distribution of the data from nonlinear problem to linearly separable problem. By replacing the inner product with an appropriate kernel function, one can implicitly perform a nonlinear mapping to a high dimensional feature space without increasing the number of parameters. Consider the case of mapping an n-dimensional feature space to an m-dimensional feature space:

$$\phi : \mathbf{x} \to \phi(\mathbf{x}), \quad \mathbf{x} \in \mathbb{R}^n,\ \phi(\mathbf{x}) \in \mathbb{R}^m \tag{14}$$

A kernel denotes a function K such that for all $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$:

$$K(\mathbf{x}, \mathbf{y}) = \phi(\mathbf{x}) \cdot \phi(\mathbf{y}). \tag{15}$$

In statistics, symmetric positive definite functions are called covariances. Hence, kernels are covariance-based in essence. From a statistics perspective, generally, two important classes of kernels are: stationary kernels and non-stationary kernels [18]. The work in this paper focuses on stationary kernels.

Stationary kernels $K(\mathbf{x}, \mathbf{y}) = K_S(\mathbf{x} - \mathbf{y})$ do not depend on the data object values themselves, but only on the lag vector separating the two objects $\mathbf{x}$ and $\mathbf{y}$. Isotropic stationary kernels, which depend only on the norm of the lag vector, are most commonly used. For isotropic stationary kernels, the covariance form is:

$$K_{cov}(\mathbf{x}, \mathbf{y}) = K_I(\|\mathbf{x} - \mathbf{y}\|), \tag{16}$$

and the correlation form is

$$K_{cor}(\mathbf{x}, \mathbf{y}) = K_I(\|\mathbf{x} - \mathbf{y}\|)/K_I(0). \tag{17}$$

A *non-stationary* kernel $K(\mathbf{x}, \mathbf{y})$ is one which depends explicitly on the two data objects $\mathbf{x}$ and $\mathbf{y}$. Note that a special kind of non-stationary kernel, called a *reducible kernel*, can be reduced to a stationary kernel.

III. Kernel-based Fuzzy-rough Nearest Neighbour Classification

A. Kernel-based Fuzzy-rough Sets

The relationship between T-transitivity and kernels has been explored [7]. It has been shown that any kernel $K : X \times X \to [0, 1]$, $K(x, x) = 1\ \forall x \in X$, is T_{cos}-transitive, where $T_{cos}(a, b) = max(ab - \sqrt{1 - a^2}\sqrt{1 - b^2}, 0)$. As an initial attempt, kernelised fuzzy-rough sets, which combine kernel methods with concepts from fuzzy-rough set theory, have been presented in [6], [8]. In this approach, kernels $K(x, y)$ are constrained such that they impose: a) reflexivity, b) symmetry, and c) T_{cos}-transitivity. Such kernels are employed to calculate the degree to which objects x and y are similar for every feature. The fuzzy lower and upper approximations in kernelised fuzzy-rough sets are defined by:

$$\mu_{\underline{K_P}X}(x) = \inf_{y \in \mathbb{U}} I_{cos}(K_P(x, y), \mu_X(y)) \tag{18}$$

$$\mu_{\overline{K_P}X}(x) = \sup_{y \in \mathbb{U}} T_{cos}(K_P(x, y), \mu_X(y)), \tag{19}$$

where, the implicator

$$I_{cos} = \begin{cases} 1, & a \le b \\ ab + \sqrt{(1 - a^2)(1 - b^2)}, & a > b \end{cases}.$$

However, as shown previously, in fuzzy-rough sets, T-transitivity is not necessarily displayed, and fuzzy tolerance relations may be sufficient [12]. Moreover, as (9), the fuzzy similarity relation induced by the subset of features P should be a combination by T-norm. Specifically, for kernelised fuzzy-rough sets, it is:

$$K_P(x, y) = T_{a \in P}\{\mu_{R_a}(x, y)\}. \tag{20}$$

In this case, the choice of a kernel function becomes limited. This is due to the fact that not many kernel functions can be denoted by a T-norm-based combination of reflexive functions. For instance, the Gaussian kernel employed in [8] and [6] is workable, because for: $\mathbf{x} = (x_1, x_2, \ldots, x_n) \in \mathbb{R}^n$, $\mathbf{y} = (y_1, y_2, \ldots, y_n) \in \mathbb{R}^n$

$$\exp\left(-\frac{\|\mathbf{x} - \mathbf{y}\|^2}{\theta}\right) = \prod_{i=1}^{n} \exp\left(-\frac{(x_i - y_i)^2}{\theta}\right) \tag{21}$$

and because its product is still a T-norm. However, for most kernels, such as the rational quadratic kernel and the wave kernel (see below), this property may not hold. In order to address these problems, kernel-based fuzzy-rough sets are proposed in this paper.

In geometry, the inner product of two vectors is the projection of one onto another. Actually, the square of the norm distance in Hilbert space can be expressed by the inner product. In this case, the inner product can measure the similarity between the images of two features by mapping into a Hilbert space. Therefore, given a non-empty set $\mathbb{U}$ and a kernel function K being reflexive, (that is $K(x, x) = 1$), for an arbitrary fuzzy concept X, the lower and upper approximations of a kernel-based fuzzy-rough set can be defined as:

$$\mu_{\underline{R_P^K}X}(x) = \inf_{y \in \mathbb{U}} I(\mu_{K_P}(x, y), \mu_X(y)) \tag{22}$$

$$\mu_{\overline{R_P^K}X}(x) = \sup_{y \in \mathbb{U}} T(\mu_{K_P}(x, y), \mu_X(y)). \tag{23}$$

It is important to note that the framework of fuzzy-rough sets remains intact using the definition described in this paper. In other words, the kernel methods play a special role in calculating the fuzzy tolerance relations. It is because of this

fact that the term *kernel-based fuzzy-rough sets* (KFRS) is employed here rather than *kernelised fuzzy-rough sets*.

As well as fuzzy-rough sets, the corresponding the lower and upper approximations of the kernel-based vaguely quantified rough set (KVQRS) can be also be defined:

$$\mu_{\underline{R_P^K}X}^{Q_u}(x) = Q_u\left(\frac{|R_P^K(x,y)\cap X|}{|R_P^K(x,y)|}\right) = Q_u\left(\frac{\sum\limits_{y\in\mathbb{U}}\min(\mu_{K_P}(x,y),\mu_X(y))}{\sum\limits_{y\in\mathbb{U}}\mu_{K_P}(x,y)}\right) \quad (24)$$

$$\mu_{\overline{R_P^K}X}^{Q_l}(x) = Q_l\left(\frac{|R_P^K(x,y)\cap X|}{|R_P^K(x,y)|}\right) = Q_l\left(\frac{\sum\limits_{y\in\mathbb{U}}\min(\mu_{K_P}(x,y),\mu_X(y))}{\sum\limits_{y\in\mathbb{U}}\mu_{K_P}(x,y)}\right), \quad (25)$$

where, $\mu_{K_P}(x,y)$ is induced by the subset of features P and kernel function K:

$$\mu_{K_P}(x,y) = T_{a\in P}\{\phi(a(x))\cdot\phi(a(y))\} = T_{a\in P}\{K(a(x),a(y))\} = T_{a\in P}\{K_a(x,y)\}. \quad (26)$$

As established previously, all isotropic stationary kernels in correlation form (17) are suitable for being integrated into KFRS. A collection of certain commonly used isotropic stationary kernels in correlation form are listed as follows:

- Gaussian kernel: $K(\mathbf{x},\mathbf{y}) = \exp\left(-\frac{\|\mathbf{x}-\mathbf{y}\|^2}{\theta}\right)$
- Exponential kernel: $K(\mathbf{x},\mathbf{y}) = \exp\left(-\frac{\|\mathbf{x}-\mathbf{y}\|}{\theta}\right)$
- Rational quadratic kernel: $K(\mathbf{x},\mathbf{y}) = 1 - \frac{\|\mathbf{x}-\mathbf{y}\|^2}{\|\mathbf{x}-\mathbf{y}\|^2+\theta}$
- Wave kernel: $K(\mathbf{x},\mathbf{y}) = \frac{\theta}{\|\mathbf{x}-\mathbf{y}\|}\sin(\frac{\|\mathbf{x}-\mathbf{y}\|}{\theta})$.

It is worth noting that for specific non-stationary kernels, the reflexivity holds also. For instance, the non-stationary kernel [18],

$$K(\mathbf{x},\mathbf{y}) = \frac{\|\mathbf{x}\| + \|\mathbf{y}\| - \|\mathbf{x}-\mathbf{y}\|}{2\sqrt{\|\mathbf{x}\|\|\mathbf{y}\|}}, \quad (27)$$

is reflexive. This kernel is also reducible.

B. Kernel-based Fuzzy-rough Nearest Neighbour Classification

The present work initially aims to investigate the combination of kernel methods with conventional fuzzy-rough nearest neighbour approaches (FRNN and FRNN-VQRS) [17]. The resulting combined learning algorithm is outlined in Figure 1. As with FRNN, the rationale behind this algorithm is that the the lower and the upper approximations of each decision class (calculated by means of the nearest neighbours of a test object y) will provide helpful clues to predict the membership of a test object to any given class. The complexity of this algorithm is: $O(|\mathcal{C}|\cdot 2|\mathbb{U}|)$.

KFRNN($\mathbb{U}$,$\mathcal{C}$,y)
$\mathbb{U}$, the training set; $\mathcal{C}$, the set of decision classes;
y, the object to be classified.

(1) $N \leftarrow$ get Nearest Neighbour(y,k)
(2) $\mu_1(y) \leftarrow 0, \mu_2(y) \leftarrow 0, Class \leftarrow \emptyset$
(3) $\forall X \in \mathcal{C}$
(4) **if**$(\mu_{\underline{R_P^K}X}(y) \geq \mu_1(y) \&\& \mu_{\overline{R_P^K}X}(y) \geq \mu_2(y))$
(5) $\overline{Class} \leftarrow X$
(6) $\mu_1(y) \leftarrow \mu_{\underline{R_P^K}X}(y), \mu_2(y) \leftarrow \mu_{\overline{R_P^K}X}(y)$
(7) **output** $Class$

Fig. 1. The kernel-based fuzzy-rough nearest neighbour algorithm

The algorithm in Figure 1 can be further adapted to perform kernel-based vaguely quantified rough nearest neighbour (KFRNN-VQRS) classification, by replacing: $\mu_{\underline{R_P^K}X}(y)$ and $\mu_{\overline{R_P^K}X}(y)$ with $\mu_{\underline{R_P^K}X}^{Q_u}(y)$ and $\mu_{\overline{R_P^K}X}^{Q_l}(y)$, respectively.

In statistics, the stationary property is often mathematically assumed to describe the ability of ensuring that a random process maintains the same probabilistic characteristics such as mean, variance and autocorrelation. Typically, non-stationary and bifurcated regimes are always observed in the case of datasets with class imbalance [19]. Class imbalance occurs when one or more classes are over or under represented as a total number of objects of the whole dataset. Thus, for datasets which suffer from class imbalance, the distribution of and the similarity between the objects may be non-stationary. From this point of view, if a dataset is extremely imbalanced, the use of non-stationary kernels would be more appropriate. Further investigation would help to confirm this - see conclusion section for further discussion.

IV. Experimental Results

This section presents an experimental evaluation of the proposed algorithms (KFRNN-FRS and KFRNN-VQRS) using two different kernels: 1) an isotropic stationary kernel, and 2) a non-stationary kernel. Nine benchmark datasets obtained from[20] are employed. These datasets are small-to-medium in size, containing between 178 and 683 objects with feature numbers ranging from 6 to 279.

TABLE I
Evaluation Datasets

Dataset	Objects	Attributes
Arrhythmia	452	279
Glass	214	9
Heart	270	13
Liver	345	6
Sonar	208	60
Water 2	390	38
Water 3	390	38
Wine	178	14
Wisconsin	683	9

For the evaluation described here, k is set at an initial value of 10 for FRNN-VQRS and KFRNN-VQRS. For FRNN

the relation given in equation (10) is used. For the kernel-based methods, an exponential kernel (used as the isotropic stationary kernel), and the non-stationary kernel of (27) are employed. In the FRNN and KFRNN approaches, the Kleene-Dienes T-norm is used to implement the implicator, which is defined by $I(x,y) = \max(1-x,y)$. The FRNN-VQRS and KFRNN-VQRS approaches are implemented with $Q_l = Q_{(0.1,0.6)}$ and $Q_u = Q_{(0.2,1.0)}$, according to the general formula

$$Q_{(\alpha,\beta)}(x) = \begin{cases} 0, & x \leq \alpha \\ \frac{2(x-\alpha)^2}{(\beta-\alpha)^2}, & \alpha \leq x \leq \frac{\alpha+\beta}{2} \\ 1 - \frac{2(x-\beta)^2}{(\beta-\alpha)^2}, & \frac{\alpha+\beta}{2} \leq x \leq \beta \\ 1, & \beta \leq x \end{cases} . \quad (28)$$

Stratified 10 $\times$ 10-fold cross-validation (10-FCV) is employed for result validation. In 10-FCV, the original dataset is partitioned into 10 subsets. Of these 10 subsets, a single subset is retained as the testing data for the model, and the remaining 9 subsets are used for training. The cross-validation process is then repeated 10 times (the number of folds). The 10 sets of results are then aggregated via averaging to produce a single model estimation. The advantage of 10-FCV over random sub-sampling is that all objects are used for both training and testing, and each object is used for testing only once per fold. The stratification of the data prior to its division into folds ensures that each class label (as far as possible) has equal representation in all folds, thus helping to alleviate bias/variance problems. In order to investigate the level of 'fit' of these models, the root mean squared error (RMSE) measure is used. The RMSE is the squared root of the variance of the residuals. It indicates the absolute fit of a model to the data and how close the observed data objects are to the model predicted values. Note that, RMSE is an absolute measure. As the squared root of a variance, RMSE can be viewed as the standard deviation of the unexplained variance. Lower values of RMSE indicate better fit. RMSE is a good measure of how accurately the model predicts the response, and is a generally accepted criterion for assessing fit, if the purpose of the resulting model is for prediction. In addition, conventional classification accuracy is also used to assess the performance of learnt classifiers.

A. Performance Evaluation

A comparison of the kernel-based and FRFS-based nearest-neighbour techniques is shown in Tables II and III, where sKFRNN and nonsKFRNN stand for stationary kernel-based fuzzy-rough nearest neighbour and non-stationary kernel-based fuzzy-rough nearest neighbour methods, respectively. Correspondingly, stationary kernel-based vaguely quantified rough nearest neighbour and non-stationary kernel-based vaguely quantified rough nearest neighbour approaches are denoted by sKFRNN-VQRS and nonsKFRNN-VQRS, respectively.

Note that the *Water2* and *Water3* datasets, both suffer from class imbalance. In particular, the ratios of data between different classes are: 312 objects to 78 objects for classes 1 and 2 for *water2*, and 378 objects for class 1 and 12 objects for class 2 for *water3*. It can be seen from the experimental results that the non-stationary kernel based approaches, nonsKFRNN and nonsKFRNN-VQRS, consistently achieved the highest classification accuracy and smallest RMSE over all other methods for these datasets. However, for the rest datasets which are not highly imbalanced, the differences between the performance of two new approaches and existing techniques are not that significant. In fact, for *Liver* and *Glass*, both of sKFRNN and sKFRNN-VQRS reached the highest classification accuracy and smallest RMSE values. For *Heart*, *Sonar*, *Wine* and *Wisconsin*, the competitiveness of the kernel-based fuzzy-rough nearest neighbour classifiers are obvious. Putting these results together, it is clear that the present work helps to improve the quality of fuzzy-rough nearest neighbour classifiers.

B. Statistical Analysis

To further evaluate the kernel-based fuzzy-rough techniques, a paired t-test with significance level of 0.05 has been carried out. The baseline references for the tests are the results obtainable from FRNN and FRNN-VQRS classification, respectively. This is done in order to ensure that the aforementioned results are not discovered by chance. The statistical significance results are shown in Table IV and V, where the symbols 'v', '*' and '-' indicate that the results are statistically better, worse, or have no statical significance.

The results once again demonstrate that the kernel-based approaches achieve best performances overall for *Water2*, *Water3*, *Heart* and *Arrythmia*, etc. In particular, compared to FRNN, the non-stationary kernel-based methods are shown to be statistically better than the other methods for these datasets. Note however that no statistical differences are found amongst all tested algorithms for the *Glass*, *Liver*, *Wine* and *Wisconsin* datasets. Only a single dataset (*sonar*), do the proposed techniques occasionally return a result which is statistically worse than that attainable using FRNN. This may well be due to the use of the fuzzy quantifiers in FRNN-VQRS, though further experimental evaluation is required in order to verify this. For FRNN-VQRS, the kernel-based modification leads to a statistically similar performance generally. sKFRNN and nonsKFRNN are better than FRNN-VQRS statistically for the *Glass* and *Sonar* datasets, although worse for the *Arrythmia* and *Heart* datasets. This may possibly be caused by the existence of noisy data in *Arrythmia* and *Heart*.

V. Conclusion

This paper has presented a new technique for the hybridisation of fuzzy-rough sets and kernel methods, called kernel-based fuzzy-rough sets (KFRS). In contrast to previous work, the T_{cos}-transitivity constraint is relaxed. The only remaining constraint which the proposed approach imposes is reflexivity.

Whilst attempting to identify suitable kernels, the properties are analysed from statistics perspective. It has been demonstrated that all isotropic stationary kernels in the correlation form of (17) are suitable for use with the KFRS

approach. Two kernel-based fuzzy-rough set classifiers: kernel-based fuzzy-rough nearest neighbour (KFRNN) and kernel-based vaguely quantified rough nearest neighbour (KFRNN-VQRS) have been introduced. The experimental results over 9 datasets, show that the new methods are effective, and that they generally outperform the original techniques.

Topics for further investigation include the impact of the choice of kernel, connectives and quantifiers on performance. Also, (and as mentioned previously), the relationship between the class imbalance of datasets and the statistical property of kernels is a worthwhile avenue of exploration. Considering hierarchical classification, another further extension to this

work would be to examine how KFRS performs for the task of feature selection [4].

***Abstract*—Most existing neural fuzzy systems either overlook the importance of feature analysis; or it is performed as a separate phase prior to the design stage of the systems. This paper proposes a novel neural fuzzy system, named *Feature Analysis Enhanced Pseudo Outer-Product Fuzzy Rule Identification System* (FAPOP), which integrates its design with feature analysis. The objective is two-folds; namely, (1) to improve the interpretability of the system by identifying features relevant to its computational structure; and (2) to improve the accuracy of the system by identifying features relevant to the application problem. The proposed FAPOP model is subsequently employed in a series of benchmark simulations to demonstrate its efficiency as a neural fuzzy modeling system, and excellent performances have been achieved.**

***Index Terms*—Feature analysis, Pseudo-outer product (POP), Categorical Learning Induced Partitioning (CLIP), Nakanishi dataset, Mackey-Glass prediction.**

I. Introduction

Existing neural fuzzy systems can be broadly classified into two classes; namely, linguistic fuzzy models [1] [2], which are focused on delivering a good level of interpretability to the structures of the models, and precise fuzzy models [3] [4], which are focused on achieving high accuracies in the modeling tasks. While Mamdani models [5] form the main focus in the former class; the latter class comprises mainly of the Takagi-Sugeno-Kang models [6] [7]. In general, having a good fuzzy rulebase interpretability and a high modeling accuracy are two contradictory requirements in the design of a neural fuzzy system [8].

With its success in data-mining applications, feature analysis techniques [9] are often performed either implicitly or explicitly as a *pre-processing* phase prior to the design stage of a neural fuzzy system. The main advantage is an improvement to the modeling accuracy through the removal of redundant/derrogative features and the identification of relevant features for the underlying application problem. Nevertheless, the decoupled stages do not consider the close relationship between feature analysis and system design [10], i.e., to identify features that are important for the application problem *and* are relevant to the output of the neural fuzzy system.

This paper presents the *Feature Analysis Enhanced Pseudo-Outer Product Fuzzy Rule Identification System* (FAPOP), a novel neural fuzzy system which integrates its design with feature analysis. An initial fuzzy rulebase is obtained via Quek and Zhou's pseudo-outer product (POP) rule identification algorithm [11]. Knowledge are then extracted simultaneously from the initial rulebase and a single-pass of the training data to incrementally update a relevance weight for each input feature. All input features are relevant by default; while irrelevant/redundant input features are marked by decreasing relevance weights. Since knowledge from both the initial rulebase and the training data are utilized to determine the relevance weights, this allows FAPOP to identify features that are important for both the system and the application. The objective is to provide a regulated balance between the two contradictory requirements; namely, (1) to improve the interpretability of the system by identifying features relevant to its computational structure; and (2) to improve the accuracy of the system by identifying features relevant to the application problem. Following that, irrelevant input features, together with contradictory and/or identical rules, are removed to maintain a compact structure in FAPOP.

The rest of the paper is organized as follows. The computational structure and the reasoning process of the FAPOP model are described in Section II. The proposed rule identification and feature selection methodologies are introduced in Section III. Section IV evaluates the learning and generalization abilities of FAPOP through a series of benchmark experimental simulations. Lastly, Section V concludes the paper.

II. FAPOP: Architecture and Reasoning Process

The proposed FAPOP model is a five layers neural fuzzy system as shown in Fig. 1. Layer 1 is the input variable nodes IV_i; layer 2 is the antecedent nodes A_{i,j_i}; layer 3 is the rule nodes R_k; layer 4 is the consequent nodes $C_{l_m,m}$; and layer 5 is the output variable nodes OV_m. In the FAPOP model, the input vector is denoted as $x = [x_1, \ldots, x_I]^T$ with corresponding desired output vector denoted as $d = [d_1, \ldots, d_M]^T$; while the computed output vector is denoted as $y = [y_1, \ldots, y_M]^T$. Each input variable node consists of J_i number of antecedent fuzzy labels; while each output variable node consists of L_m number of consequent fuzzy labels. Layer 3 of FAPOP represents the K fuzzy rules in the system such that each node encodes a

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

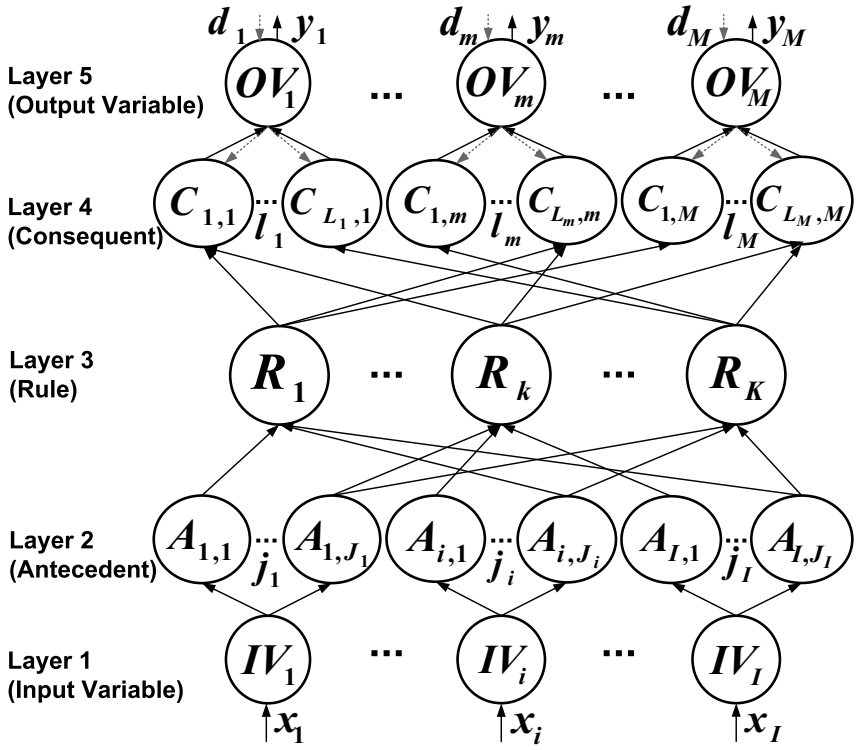

Fig. 1. Architecture of FAPOP.

fuzzy rule of the form given as in (1):

$$R_k : \text{IF } x_1 \text{ is } A^{(k)}_{1,j_1} \text{ and } \ldots \text{ and } x_I \text{ is } A^{(k)}_{I,j_I} \quad \text{THEN } y_1 \text{ is } C^{(k)}_{l_1,1} \text{ and } \ldots \text{ and } y_M \text{ is } C^{(k)}_{l_M,M} \tag{1}$$

where $A^{(k)}_{i,j_i}$ (resp. $C^{(k)}_{l_m,m}$) is the j_i-th antecedent (resp. l_m-th consequent) node associated with the i-th input (resp. m-th output) variable that is connected to the rule node R_k. The tunable parameters of FAPOP are the centres and widths of the fuzzy labels embedded in the antecedent and consequent nodes, where each node defines a gaussian membership function described as in (2):

$$\mu(c,\sigma;x) = e^{-((x-c)^2/\sigma^2)} \tag{2}$$

such that c and σ are the centre and width of the function respectively. Adaptation of the parameters is performed using backpropagation [12].

The reasoning process of FAPOP is represented by the forward solid arrows in Fig. 1 where the input vector x is presented to the system at layer 1. The proposed system then performs inference based on the input vector by propagating the information through layers 2 to 4. Consequently, the system produces a computed output vector y at layer 5. Each corresponding output for an arbitrary node is denoted as fo such that the reasoning process of FAPOP is discussed below:

Layer 1: The input node IV_i directly passes on the input value to the next layer such that its neural operation is described as in (3):

$$fo_i = x_i \ . \tag{3}$$

Layer 2: The antecedent node A_{i,j_i} performs similarity matching of the input value with the corresponding fuzzy label such that its neural operation can be described as in (4):

$$fo_{i,j_i} = \mu_{i,j_i}(c_{i,j_i}, \sigma_{i,j_i}; fo_i) \tag{4}$$

where $\mu_{i,j_i}(c_{i,j_i}, \sigma_{i,j_i}; x)$ refers to the gaussian membership function embedded in A_{i,j_i}.

Layer 3: Each rule node R_k computes the overall degree of similarity between the input vector and the antecedent part of the k-th fuzzy rule such that its firing rate is computed as in (5):

$$fo_k = \min_{i \in \{1 \ldots I\}} fo^{(k)}_{i,j_i} \ . \tag{5}$$

Layer 4: The consequent node $C_{l_m,m}$ performs consequent derivation for the fuzzy rules based on the information from the input vector. Since $C_{l_m,m}$ may serve as output to more than one fuzzy rule, its cumulative neural operation can be described as in (6):

$$fo_{l_m,m} = \max_{k \in \{1 \ldots K_{l_m,m}\}} fo^{(l_m,m)}_k \tag{6}$$

where $K_{l_m,m}$ is the total number of fuzzy rules in FAPOP that shares the same consequent node $C_{l_m,m}$ and $fo^{(l_m,m)}_k$ is the output of the k-th rule that shares $C_{l_m,m}$.

Layer 5: The output node OV_m performs defuzzification via the center of averaging method [13] to obtain a crisp output value such that its neural operation can be described as in (7):

$$y_m = fo_m = \frac{\sum_{l_m \in \{1 \ldots L_m\}} fo_{l_m,m} c_{l_m,m} \sigma_{l_m,m}}{\sum_{l_m \in \{1 \ldots L_m\}} fo_{l_m,m} \sigma_{l_m,m}} \tag{7}$$

where $c_{l_m,m}$ and $\sigma_{l_m,m}$ are the centre and width of the gaussian function embedded in $C_{l_m,m}$ respectively.

III. Learning Mechanisms of FAPOP

In the proposed FAPOP model, an initial fuzzy rulebase is obtained via Quek and Zhou's POP rule identification algorithm [11]. A relevance weight for each input feature is then incrementally determined using knowledge extracted from both the initial fuzzy system and a single-pass of the training data. The relevance weight of an input feature reflects its role in describing the underlying application problem and the output of the system. As stated before, all input features are assumed relevant at the beginning. Input features with consistently high relevance weights are selected; while input features with decreasing relevance weights are regarded as redundant and discarded. Subsequently, irrelevant input features, together with contradictory and/or identical rules, are removed to maintain a compact structure in the FAPOP model.

The learning mechanisms of FAPOP are discussed here as follows. Details of the neural computations in the proposed system are described in Section III.A.; Section III.B. reviews the POP algorithm; Section III.C. introduces the feature analysis technique in FAPOP; and Section III.D. illustrates the ideas discussed using a case study.

A. Neural Computations in FAPOP

Neural computations in the proposed FAPOP model are bi-directional, in the forward and backward sense as described below:

1. Forward Operation: The forward operation of FAPOP coincides with its reasoning path as described in Section II.
2. Backward Operation: The backward operation of FAPOP is represented by dotted arrows in Fig. 1, which is a mirrored computation of the forward operation. Each corresponding output for an arbitrary node is denoted as bo.

   Layer 5: The output node OV_m directly passes on the output value to the next layer such that its neural operation is described as in (8):

$$bo_m = d_m \ . \tag{8}$$

   Layer 4: The consequent node $C_{l_m,m}$ performs similarity matching of the output value with the corresponding fuzzy label such that its neural operation can be described as in (9):

$$bo_{l_m,m} = \mu_{l_m,m}(c_{l_m,m}, \sigma_{l_m,m}; bo_m) \tag{9}$$

   where $\mu_{l_m,m}(c_{l_m,m}, \sigma_{l_m,m}; x)$ refers to the gaussian membership function embedded in $C_{l_m,m}$.

B. POP algorithm

The POP algorithm consists of two phases in its learning process; namely, fuzzy partitioning and rule identification. In this paper, fuzzy partitioning is performed using the Categorical Learning Induced Partitioning (CLIP) [14]; while a description of the rule identification follows.

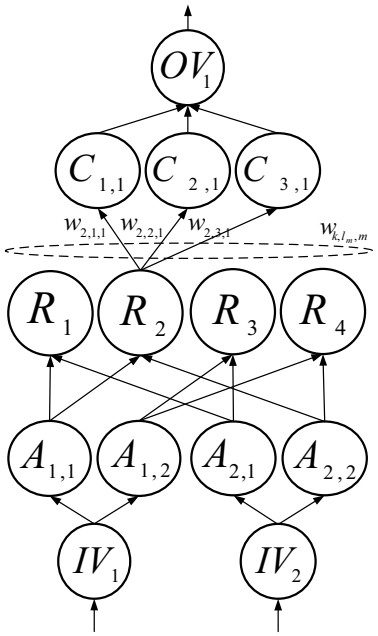

Fig. 2. Illustration for POP rule identification algorithm.

For simplicity, assume an application problem with 2 inputs-1 output as shown in Fig 2. Two fuzzy labels are determined by the CLIP algorithm for each input space; while three fuzzy labels are determined for the output space. The POP algorithm considers all possible rules, such that four fuzzy rules are initialized. The system is fully connected from the rule layer to the consequent layer with weights $w_{k,l_m,m}$, $k = 1 \ldots 4,\ l_m = 1 \ldots 3,\ m = 1$. Fig 2 illustrates the rule identification process for the rule node R_2:

1. Initialization: Set $w_{k,l_m,m} = 0$.
2. Weight Update: Through a single-pass of the training data, update the weights as follows:

$$w_{k,l_m,m} = \sum_N fo_k \cdot bo_{l_m,m}$$

   where N is the size of the training data.
3. Rule Formulation: Select the m-th consequent node for R_k as one with the maximum weight given as follows:

$$C^{(k)}_{l_m,m} = C_{l^\star_m,m}$$

   where $w_{k,l^\star_m,m} = \max_{l_m} w_{k,l_m,m}$.

C. Feature Analysis in FAPOP

The forward-and-backward neural computations (as described in Section III.A.) are defined to compute the instantaneous relevance weight of an input feature i when a data pair $[x, d]$ is presented to FAPOP. The instantaneous relevance weight $\widehat{\omega_i}$ is computed as in (10):

$$\widehat{\omega_i} = \max_{j_i} \left[\min_k \left(fo^{(k)}_{i,j_i}, bo^{(k)}_{l_m,m} \right) \right] \tag{10}$$

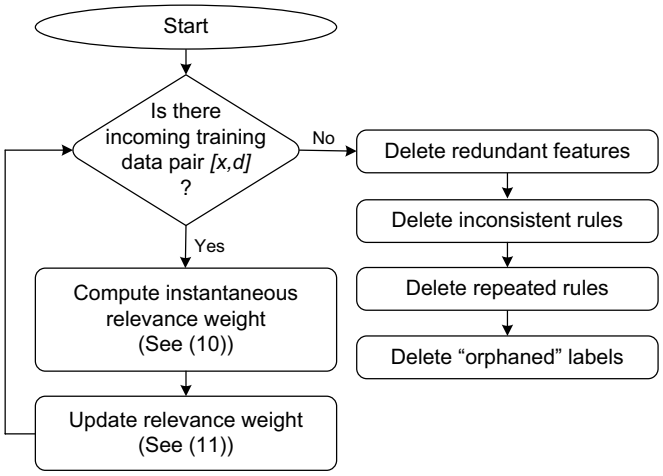

Fig. 3. Flowchart of the feature analysis process employed in FAPOP.

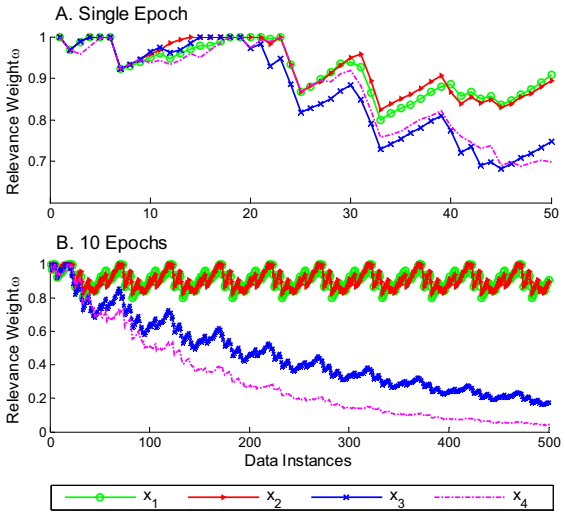

Fig. 4. Updates of the relevance weights for input features x_1–x_4 in the case study: A. For a single-pass of the training data; and B. For 10 passes of the training data.

where $fo_{i,j_i}^{(k)}$ (resp. $bo_{l_m,m}^{(k)}$) is the computed output of the antecedent node A_{i,j_i} (resp. consequent node $C_{l_m,m}$) that is connected to the rule node R_k. Knowledge is extracted from the structure of each rule node R_k, consisting of its antecedent and consequent parts, for the computation of the instantaneous relevance weight $\widehat{\omega}_i$. Subsequently, $\widehat{\omega}_i$ is given by the maximum activations of its respective fuzzy labels. That is, the instantaneous relevance weight $\widehat{\omega}_i$ of an input feature i represents the activation level of feature i by the current data pair based on the knowledge encoded in FAPOP.

Feature analysis in FAPOP proceeds with incrementally updating a relevance weight for each input feature. The relevance weight ω_i for an input feature i is computed as in (11):

$$\begin{aligned} \omega_i\,(0) &= 1\;; \\ \omega_i\,(t+1) &= \min\left[1,\ \omega_i\,(t) - \omega_i\,(t)\cdot(\eta_d - 1)\cdot(\widehat{\omega}_i\,(t) - h)\right] \end{aligned} \tag{11}$$

where $\eta_d < 1$ is a natural decaying constant and h is the harsh factor. The relevance weight of an input feature i is initialized to unity, assuming a high level of relevance since $0 < \omega_i \leq 1$. Harsh factor h, $0 \leq h \leq 1$, determines the level of stringency in the feature selection process, i.e., for a large value of h, only highly relevant features are selected; while for a lower value of h, some redundant features might be included in the selection. This is because when $\widehat{\omega}_i\,(t) < h$, we have $\omega_i(t+1) < \omega_i(t)$. Hence when h is a large value and most instants of $\widehat{\omega}_i$ fall below h, the resultant relevance weight of input feature i will be decreasing over time. On the other hand, when $\widehat{\omega}_i\,(t) > h$, we have $\omega_i(t+1) > \omega_i(t)$. Hence when h is a small value and most instants of $\widehat{\omega}_i$ are greater than h, the resultant relevance weight of input feature i will be increasing over time. Nevertheless, ω_i will be cap at unity.

Fig. 3 shows a flowchart of the feature analysis process employed in the proposed FAPOP model. With each incoming training data pair $[x, d]$, the instantaneous relevance weight $\widehat{\omega}_i$ of an input feature i is computed as the activation of the input feature by this current data pair based on the knowledge encoded in the system. FAPOP then proceeds with updating the relevance weight ω_i of an input feature i using (11). After a single-pass of the training data, redundant features in the proposed model are identified and removed from the system. Redundant features are recognized by their decreasing relevance weights. Subsequently, contradictory/inconsistent rules with lower weightages are removed. An inconsistent rulebase occurs when there exists two rules such that the antecedent conditions are similar but the resultant consequences differ; while the weightage of a fuzzy rule is defined as $\sum_m w_{k,l_m^\star,m}$. Following that, the system deletes repeated rules, i.e. , rules with similar antecedent and consequent segments. Finally, some of the fuzzy labels might be "orphaned" when all fuzzy rules associated with them have been deleted. The orphaned fuzzy labels are also removed to ensure that the resultant structure of FAPOP is compact.

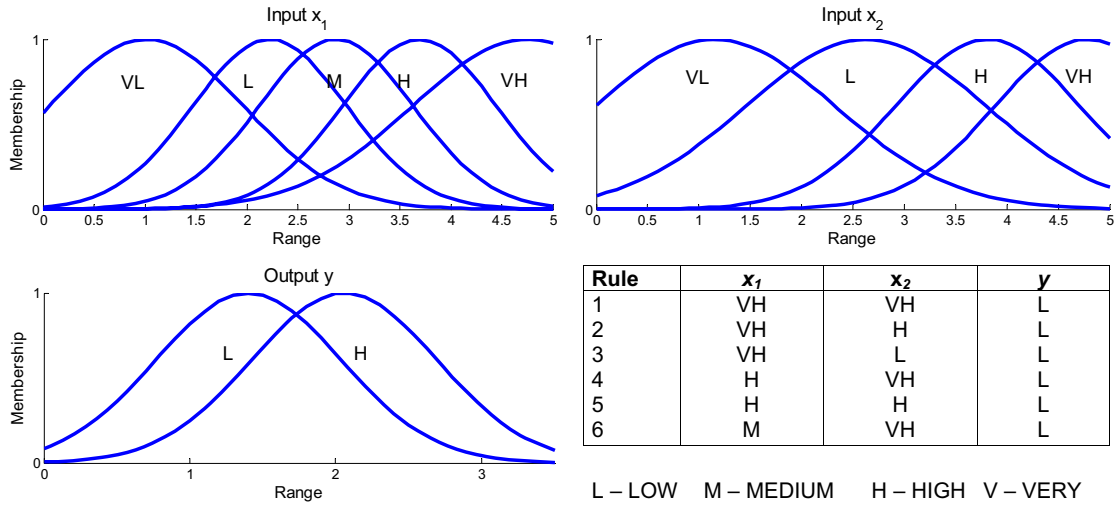
D. Case Study

This section illustrates the proposed learning mechanisms in the FAPOP model with a case study. The dataset is generated by a nonlinear equation as described in (12):

$$y = \left(1 + x_1^{-2} + x_2^{-1.5}\right)^2 \tag{12}$$

where x_1 and x_2 are the two inputs in the system; while y is the output. Following the problem described in [15], a total of 50 data pairs are generated for $0 \leq x_1, x_2 \leq 5$. Two random variables x_3 and x_4, in the range of $[0, 5]$, are subsequently added as dummy inputs. Hence, the application problem is a 4 inputs-1 output system, such that input features x_3 and x_4 are expected to be indifferent to the output.

A total of 5, 4, 7 and 5 fuzzy labels are identified by the CLIP algorithm for the four input spaces respectively; and 3 fuzzy labels are determined for the output space. That means, 700 fuzzy rules have been initialized by the POP algorithm such that the initial structure of FAPOP is given



Rule	x_1	x_2	y
1	VH	VH	L
2	VH	H	L
3	VH	L	L
4	H	VH	L
5	H	H	L
6	M	VH	L

L – LOW M – MEDIUM H – HIGH V – VERY

Fig. 5. Fuzzy clusters identified for inputs x_1–x_2 and output y in the case study; and part of the identified rulebase in FAPOP.

by the configuration 4-21-700-3-1. Following that, FAPOP proceeds with the feature analysis process to identify relevant input features to the system and the application. Fig. 4 shows the updates for the relevance weights for the four inputs. After a single-pass of the training data (see Fig. 4.A.), the decline in the relevance weights for input features x_3 and x_4 are much faster compared to those for x_1 and x_2, indicating that they might be irrelevant. To emphasize the disparity in the relevance weights between the relevant and irrelevant features, the training data are cycled for ten epochs in this experiment as shown in Fig. 4.B. From the figure, the relevance weights of the redundant input features x_3 and x_4 approach zero with the increase in the number of running epochs, while that of the relevant input features x_1 and x_2 are maintained consistently at a high level. In general, irrelevant/redundant input features are marked by decreasing relevance weights, where the decline can be emphasize with an increase in the number of running epochs. Nevertheless, it should be noted that a large training dataset will lead to an increase in the time complexity with an increase in the number of running epochs. In this paper, the number of running epochs for the experiments is capped at 10.

After the redundant features (x_3 and x_4) have been identified, they are removed from the FAPOP model. Inconsistent rules of lower weightages, as well as identical rules, are also removed to maintain a compact structure in FAPOP. Finally, orphaned fuzzy labels are deleted from the system. The final structure of FAPOP is given by the configuration 4-9-20-2-1, i.e., there are 20 identified rules in the proposed model and one orphaned fuzzy label in the output space is also deleted. As seen, there is a significant reduction of 97% in the the number of identified rules.

Fig. 5 illustrates the identified fuzzy clusters in FAPOP for the input spaces x_1 and x_2, and that for the output space y. Since the fuzzy clusters are highly ordered, clear semantic meanings can be attached to the fuzzy clusters. A total of 20 fuzzy rules are identified by the FAPOP model, with six rules corresponding to a low output value, and fourteen rules corresponding to a high output value. Subsequently, the six rules are listed in Fig. 5. One can easily verify that the derived rulebase is consistent, with the identified fuzzy rules reflecting the relationship between the inputs and the output of the system, i.e., based on (12), for relatively high values of inputs x_1 and x_2, the resultant output y of the system is low. The reverse is also true for a high output value y.

IV. Experimental Results

This section illustrates the effectiveness of the proposed FAPOP model as a neural fuzzy modeling system by employing it in two benchmarking simulations; namely, (1) the three sets of experiments in Nakanishi's dataset [16] [17]; and (2) the prediction of Mackey-Glass chaotic system [18].

A. Nakanishi Dataset

The learning and modeling abilities of the proposed FAPOP model are evaluated using three sets of experiments; namely, (a) a nonlinear system; (b) the human operation of a chemical plant; and (c) the daily pricing of a stock in a stock market. The datasets are extracted from published papers in [16] and [17]. Each of the three datasets is split into three groups A, B, and C where A and B form the training dataset and C is the testing data. The benchmark for comparisons are the accuracies on the testing data (calculated as the mean squared error MSE) and the correspondence between the computed output with the testing data (calculated as the Pearson correlation coefficient R). The experimental results of FAPOP are subsequently benchmarked against the following models; namely, Hebb-R-R [2]; POPFNN [19]; RSPOP [8]; five of the six reasoning methods in [16] (Sugeno P&P-G, Sugeno P, Sugeno P-G, Mamdani, and Turksen IVCRI); ANFIS [3]; EFuNN [20]; DENFIS [4]; and FITSK [21].

1) A Nonlinear System: The objective of this experiment is to identify and model the underlying principles of a nonlinear system. In the original dataset, there were four inputs x_1–x_4 and one output y. Before the feature analysis process,

MSE	0.186	1.440×10^{4}	38.47
R	0.951	0.999	0.898

108 fuzzy rules are initialized in FAPOP; while FAPOP identifies input feature x_3 as redundant after feature analysis. Subsequently, the application problem becomes a 3 inputs-1 output system. A total of twelve fuzzy rules are then identified by FAPOP for this experiment (see Table I). Consolidated experimental results on the benchmarking measures are given in Table II.

2) Human Operation of a Chemical Plant: The proposed FAPOP model is employed to model the human operation of a chemical plant in this experiment. Although there were five inputs x_1–x_5 and one output y in the original dataset, only selected relevant input features, x_1–x_3 and x_5, are used in defining the rules. Subsequently, a total of twelve fuzzy rules are extracted from the FAPOP model as shown in Table I. Consolidated experimental results on the benchmarking measures are given in Table II.

3) Daily Pricing of a Stock in a Stock Market: Using various statistics concerning a stock collected from a stock market, the proposed FAPOP model is employed to perform stock price prediction. Out of the original ten input features x_1–x_{10}, two features, x_7 and x_9, are redundant and discarded from the FAPOP model. A total of six fuzzy rules are then identified by FAPOP, indicating a remarkable reduction of 99% in the number of identified rules (see Table I). For comparison, the consolidated experimental results on the benchmarking measures are given in Table II.

4) Discussion: Table I shows the experimental results for the proposed FAPOP model in the Nakanishi dataset. There are significant reductions in the number of identified rules in all the three experiments. By keeping the number of identified rules low, this helps to improve the overall interpretability of the system.

Table II shows the consolidated experimental results for the Nakanishi dataset between FAPOP and the benchmarking models. FAPOP outperforms all the benchmarking models in the first two tasks by consistently ranking first in terms of MSE and R. In the task of modeling a nonlinear system, FAPOP achieves a MSE value of 0.186, similar to Hebb-R-R. In addition, there is a slight improvement of 4.39% in the R value compared to second place Hebb-R-R. For the second task of modeling a chemical plant, the proposed FAPOP model delivers an outstanding performance by achieving a reduction of 40.6% in terms of calculated MSE and a slight improvement of 0.001 in terms of correlation R compared to the second position Hebb-R-R. For the final task of stock prediction, the performance of FAPOP is comparable with FITSK, Sugeno P and ANFIS. It should also be noted that Hebb-R-R uses 20 fuzzy rules; while RSPOP uses 29 fuzzy rules [2]. Comparatively, FAPOP uses only six rules in the prediction task. This explains the slight compromise in the MSE and R values achieved. On average, the proposed FAPOP model achieves a ranking of 2.3 for all the three tasks, putting it at second position. This is a significant improvement compared to respective members in the family of pseudo outer-product-based neural fuzzy systems, i.e., POPFNN with an average ranking of 7.2, and RSPOP with an average ranking of 4.5. As a further comparison, the training time of the three members in the POP neural fuzzy systems are listed in Table III. As seen, the time complexity of the proposed FAPOP model is comparable with the first generation POPFNN model. This is a direct consequence of the POP rule identification algorithm,

TABLE III
TRAINING TIME(MS) OF MEMBERS OF THE POP NEURAL FUZZY SYSTEMS.

Model	Nonlinear System	Chemical Plant	Stock Prediction
POPFNN	46	485	1,082,866
RSPOP	188	202	184
FAPOP	62	468	1,012,500

where all possible combination of rules is considered, and hence the size of the initial rulebase increases exponentially with an increase in the number of input dimensions. This can be seen in the stock prediction experiment where the initial number of rules is 17496 in FAPOP (see Table II). As a result, it is time consuming and memory dependent at the beginning of the learning. On the other hand, RSPOP proposes a new rule identification algorithm, where the initial identified rulebase consists of only 50 rules prior to rule reduction [8]. This, subsequently, results in a significant saving in the time complexity. In conclusion, one can reduce the time complexity of the proposed FAPOP model by adopting alternative rule identification algorithms [22] [14] which are tailored to the numerical training data.

B. Prediction of Mackey-Glass Chaotic System

The learning and generalization abilities of the proposed FAPOP model is evaluated by employing it in a benchmark comparison involving the prediction of a chaotic system. The chaotic system is generated by a delay differential equation as described in (13):

$$\frac{\partial x(t)}{\partial t} = \frac{0.2x(t-\tau)}{1+x^{10}(t-\tau)} - 0.1x(t) \tag{13}$$

which was first investigated by Mackey and Glass [18]. A fourth-order Runge-Kutta method was applied to compute the numerical approximation of the series with conditions as follows: $\tau = 17$ and initial condition $x(0) = 1.2$. Four past values are used to predict the present value, where

$$\begin{aligned} \text{input vector} &= [x(t-24), x(t-18), x(t-12), x(t-6)] \ ; \\ \text{output vector} &= [x(t)] \ . \end{aligned}$$

A total of 1000 data pairs are extracted from the interval $t \in [118, 1117]$. The first 500 pairs are then used as training set; while the remaining 500 pairs are used for testing. The benchmark for comparisons are the accuracies on the testing data (given as the root mean squared error RMSE) and the interpretability of the systems (given as the number of identified fuzzy rules). The experimental results of FAPOP are subsequently benchmarked against the following models; namely, FALCON-ART [1]; FITSK [21]; and EFuNN [20].

Table IV shows the performance comparison for the Mackey-Glass chaotic system between the proposed FAPOP model and the benchmarking models. FAPOP achieves a RMSE value of 0.017, falling behind only the EFuNN model in terms of accuracy achieved on the testing data. Nevertheless, EFuNN uses 330% more rules compared to FAPOP (a jump from 20 to 86) in this prediction task, greatly decreasing the interpretability of the system. On the average, the proposed FAPOP is able to maintain a good balance between the two contradictory requirements, i.e., delivering a good fuzzy rulebase interpretability by identifying 20 fuzzy rules, and achieving a high modeling accuracy of 0.017.

TABLE IV
CONSOLIDATED EXPERIMENTAL RESULTS FOR THE MACKEY-GLASS SYSTEM.

Model	RMSE	# Rules
FALCON-ART	0.040	30
FITSK	0.034	16
EFuNN	0.010	86
FAPOP	0.017	20

V. CONCLUSION

This paper presents a novel neural fuzzy system named *Feature Analysis Enhanced Pseudo-Outer Product Fuzzy Rule Identification System* (FAPOP). A key strength of FAPOP is its feature analysis integrative design such that a regulated balance is achieved between the two contradictory interpretability-accuracy requirements in the design of a neural fuzzy system. This is done via two channels; namely, (1) improve the interpretability of the system by identifying features relevant to its computational structure; and (2) improve the accuracy of the system by identifying features relevant to the application problem. Subsequently, the learning mechanisms in the proposed FAPOP model are showcased through a case study where the system is able to identify a compact and highly interpretable rulebase by identifying relevant features to the system and application. Finally, FAPOP is employed in a series of benchmarking simulations to demonstrate its effectiveness as a neural fuzzy modeling system, and excellent performances have been achieved.

***Abstract*—This paper presents an indirect adaptive type-2 fuzzy logic controller (FLC) as well as a direct adaptive type-2 FLC for tracking control of surface vessels under time-varying hydrodynamic disturbances. The combination of approximation-based adaptive control technique and type-2 fuzzy logic system (FLS) allows us to handle time-varying disturbances without exact information on them. The stability of the design is proved through Lyapunov analysis where globally asymptotical convergence of the tracking errors is guaranteed. Although designed from different points of view, both indirect and direct adaptive type-2 FLC yield same and passive closed-loop systems. Comparative simulations with their adaptive type-1 counterparts are carried out. The proposed techniques are found to be effective, robust, and reduce tracking errors.**

***Index Terms*—Adaptive control, type-2 fuzzy logic system, marine vehicle control, function approximation, tracking.**

I. Introduction

Essential to any controller design process is knowledge of the dynamic characteristics of the plant or physical system to be controlled. Accurate modeling of the plant can increase the probability that a satisfactory controller, designed based on mathematical plant model, achieves similar performance in reality. For this reason, more and more realistic dynamic models for surface vessels have been proposed [1]. One of the latest vessel models was presented in [2], [3]. Due to the time-varying hydrodynamic disturbances in this model, few controllers are designed for it. In [4], an indirect adaptive type-2 fuzzy logic controller (FLC) is proposed for regulation control of the vessels. As a complementary work to [4], this paper considers the tracking control of the vessels. In marine vessels tracking and guidance applications, the weakness of traditional model-based adaptive control is the requirement that uncertainties are parametric, time-invariant, and linear in the parameters [5]. Hence, approximation-based adaptive control technique [6], [7], which do not require parametric or functional certainty, is adopted to compensate for functional uncertainties and disturbances from environment. Such approximators normally have a standard regressor function whose configuration is independent of the dynamic characteristics of the vessel model.

It has been proved in [8]–[11] that type-1 fuzzy logic system (FLS) are universal approximators, i.e., for any given continuous nonlinear function, there exists a type-1 FLS such that it can uniformly approximate the function to any desired accuracy. As a extension of type-1 FLS, type-2 FLS has been proposed and drawn much attention [12]–[15]. The main differences between type-1 and type-2 FLS lie in for type-2 FLS at least one of the antecedent or consequent fuzzy sets is a type-2 fuzzy set, whose membership value is a type-1 fuzzy set. Thus a type-reducer is needed to convert the type-2 fuzzy output sets into type-1 sets so that they can be processed by the defuzzifier to produce a crisp output. The type-2 FLS has already found its applications to several engineering problems [16]–[19]. This paper serves as another engineering application to investigate the approximation property of type-2 FLS.

By combining approximation-based adaptive control technique and type-2 FLS, an indirect as well as a direct adaptive type-2 FLC are proposed for tracking control of newly developed vessel model [2], [3]. It is proved that the tracking errors under these two controller globally asymptotically converge to zero and the resultant closed-loop systems are passive.

The rest of the paper is organized as follows. Section II describes the singleton interval type-2 (IT2) FLS and constructs it in the linear in the parameters form. Next, the modeling of marine vessels is introduced in Section III. Then the design and stability analysis of the two adaptive type-2 FLCs is delineated in Section IV. After that, Section V describes the simulation results of the closed-loop system. Comparisons with their type-1 counterparts are also shown in this section. Finally, conclusions are drawn in Section VI.

II. Description of Singleton IT2 FLS

In this paper, a singleton IT2 FLS whose general configuration is depicted in Fig. 1 is considered. It contains five components which are fuzzifier, rule base, fuzzy inference engine, type-reducer, and defuzzifier. Here, a multi-input, single-out fuzzy system is described, as a multi-output system can generally be separated into several single-output systems.

1) Fuzzification: The fuzzifier maps a crisp point $\mathbf{x} = (x_1, \ldots, x_n) \in \mathbf{U} \subset R^n$ into a IT2 fuzzy set $\tilde{A}_{\mathbf{x}}$ in $\mathbf{U}$. In the singleton fuzzification, the input fuzzy set $\tilde{A}_{\mathbf{x}}$ has only a single point of nonzero membership as follows.

$$\mu_{\tilde{A}_{\mathbf{x}}}(\mathbf{x}) = \begin{cases} 1; & \mathbf{x} = \mathbf{x}' \\ 0; & \mathbf{x} \neq \mathbf{x}' \end{cases} \tag{1}$$

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

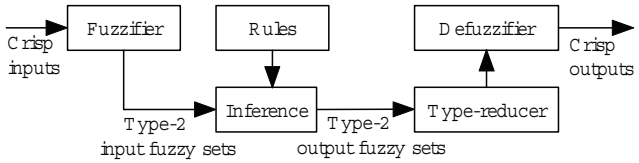

Fig. 1. A singleton interval type-2 FLS.

2) Rule Base: The fuzzy rule base consists of a group of fuzzy **IF-THEN** rules, which can be extracted from numerical data or provided by experts. Consider a IT2 FLS having n inputs and one output, then the lth rule in the rule base can be written as

$$R^l: \text{IF } x_1 \text{ is } \tilde{F}_1^l \text{ and } \cdots \text{and } x_n \text{ is } \tilde{F}_n^l \text{ THEN } y \text{ is } \tilde{G}^l \quad (2)$$

where $l = 1, 2, \ldots, M$, x_i $(i = 1, 2, \ldots, n)$ and y are the inputs and output to the IT2 FLS respectively, $\tilde{F}_i^l$ and $\tilde{G}^l$ are labels of antecedent and consequent fuzzy sets in $\mathbf{U}_i$ and R, respectively. This rule represents a type-2 relation between the input space $\mathbf{U}$ and output space R.

3) Fuzzy Inference Engine: The fuzzy inference engine combines fuzzy **IF-THEN** rules and provides a mapping from input IT2 fuzzy sets in $\mathbf{U}$ to output IT2 fuzzy set in R. Each rule is interpreted as a fuzzy implication. For the singleton IT2 FLS, using the extended sup-star compositional rule of inference, the output consequent set corresponding to rule R^l can be expressed as

$$\mu_{\tilde{B}^l}(y) = \mu_{\tilde{G}^l}(y) \sqcap \left[\sqcap_{i=1}^n \mu_{\tilde{F}_i^l}(x_i')\right]. \quad (3)$$

where the firing set $\sqcap_{i=1}^n \mu_{\tilde{F}_i^l}(x_i') \equiv F^l(\boldsymbol{x}')$ is an interval type-1 fuzzy set, i.e.,

$$F^l(\boldsymbol{x}') = \left[\underline{f}^l(\boldsymbol{x}'), \overline{f}^l(\boldsymbol{x}')\right] \quad (4)$$

$$\underline{f}^l(\boldsymbol{x}') = \underline{\mu}_{\tilde{F}_1^l}(x_1') \bigstar \cdots \bigstar \underline{\mu}_{\tilde{F}_1^n}(x_n') \quad (5)$$

$$\overline{f}^l(\boldsymbol{x}') = \overline{\mu}_{\tilde{F}_1^l}(x_1') \bigstar \cdots \bigstar \overline{\mu}_{\tilde{F}_1^n}(x_n'). \quad (6)$$

Here $\underline{\mu}_{\tilde{F}_i^l}(x_i')$ and $\overline{\mu}_{\tilde{F}_i^l}(x_i')$ are the lower and upper membership grade of IT2 fuzzy set $\tilde{F}_i^l$, respectively, symbol $\bigstar$ denotes the t-norm corresponding to the conjunction "and" in (2). The fired output consequent set $\mu_{\tilde{B}^l}(y)$ for the lth rule can be written as

$$\mu_{\tilde{B}^l}(y) = \int_{b^l \in \left[\underline{f}^l \bigstar \underline{\mu}_{\tilde{G}^l}(y), \overline{f}^l \bigstar \overline{\mu}_{\tilde{G}^l}(y)\right]} 1/b^l \quad (7)$$

where $\underline{\mu}_{\tilde{G}^l}$ and $\overline{\mu}_{\tilde{G}^l}$ are the lower and upper membership grades of consequent fuzzy set, $\tilde{G}^l$.

4) Type-Reduction and Defuzzification: By Passing through the type-reduction operator, the IT2 fuzzy sets, which are outputs of the inference engine, are type-reduced into a type-1 fuzzy set. This type-1 fuzzy set is then defuzzified to obtain crisp output. So far, there are many kinds of type-reduction method available, such as centroid, center of sums, height and center of sets type-reduction. In this paper, center of sets type-reduction is used, as it has reasonable computational complexity. Assume maximum t-conorm, product t-norm, and product implication are used. Then in the type-reduction, the type-reduced set is an interval type-1 fuzzy set $[y_l', y_r']$, whose left end point y_l' and right end point y_r' can be computed using the Karnik-Mendel iterative procedure [13]. In this procedure, assume singleton consequent sets are used, the consequent parameters have to be reordered in ascending order first. Let $\mathbf{y} = (y^1, \ldots, y^M)^{\mathrm{T}}$ represent the original rule-ordered consequent values, and let $\hat{\mathbf{y}} = (\hat{y}^1, \ldots, \hat{y}^M)^{\mathrm{T}}$ denote the reordered sequences, where $\hat{y}^1 \leq \hat{y}^2 \leq \ldots \leq \hat{y}^M$. The formula illustrating relationship between $\mathbf{y}$ and $\hat{\mathbf{y}}$ is

$$\hat{\mathbf{y}} = \mathbf{Q}\mathbf{y} \quad (8)$$

where $\mathbf{Q}$ is $M \times M$ permutation matrix with elementary vectors as columns, and these vectors are permuted to move elements in $\mathbf{y}$ to new reordered locations in ascending order in the transformed vector $\hat{\mathbf{y}}$. The original rule firing strength $\underline{\mathbf{f}} = (\underline{f}^1, \underline{f}^2, \ldots, \underline{f}^M)^{\mathrm{T}}$ and $\overline{\mathbf{f}} = (\overline{f}^1, \overline{f}^2, \ldots, \overline{f}^M)^{\mathrm{T}}$ are accordingly reordered. To compute the end points, the new orders for $\underline{\mathbf{f}}$ and $\overline{\mathbf{f}}$ are $\mathbf{Q}\underline{\mathbf{f}}$ and $\mathbf{Q}\overline{\mathbf{f}}$ respectively. According to [20], [21], the left end point y_l' can be computed as

$$\begin{aligned} y_l' &= \frac{\sum_{i=1}^L (\mathbf{Q}\overline{\mathbf{f}})_i \hat{y}^i + \sum_{i=L+1}^M (\mathbf{Q}\underline{\mathbf{f}})_i \hat{y}^i}{\sum_{i=1}^L (\mathbf{Q}\overline{\mathbf{f}})_i + \sum_{i=L+1}^M (\mathbf{Q}\underline{\mathbf{f}})_i} \\ &= \frac{\overline{\mathbf{f}}^{\mathrm{T}}\mathbf{Q}^{\mathrm{T}}\mathbf{E}_1^{\mathrm{T}}\mathbf{E}_1\mathbf{Q}\mathbf{y} + \underline{\mathbf{f}}^{\mathrm{T}}\mathbf{Q}^{\mathrm{T}}\mathbf{E}_2^{\mathrm{T}}\mathbf{E}_2\mathbf{Q}\mathbf{y}}{\mathbf{p}_l^{\mathrm{T}}\mathbf{Q}\overline{\mathbf{f}} + \mathbf{g}_l^{\mathrm{T}}\mathbf{Q}\underline{\mathbf{f}}} \end{aligned} \quad (9)$$

where L denotes the left crossover point,

$$\begin{aligned} \mathbf{p}_l &= (\underbrace{1, 1, \ldots, 1}_{L}, 0, \ldots, 0)^{\mathrm{T}} \in R^{M\times 1} \\ \mathbf{g}_l &= (0, \ldots, 0, \underbrace{1, 1, \ldots, 1}_{M-L})^{\mathrm{T}} \in R^{M\times 1} \\ \mathbf{E}_1 &= (\mathbf{e}_1, \mathbf{e}_2, \ldots, \mathbf{e}_L, \mathbf{0}, \ldots, \mathbf{0})^{\mathrm{T}} \in R^{L\times M} \\ \mathbf{E}_2 &= (\mathbf{0}, \ldots, \mathbf{0}, \boldsymbol{\varepsilon}_1, \boldsymbol{\varepsilon}_2, \ldots, \boldsymbol{\varepsilon}_{M-L})^{\mathrm{T}} \in R^{(M-L)\times M} \end{aligned}$$

and where $\mathbf{e}_i \in R^L$ and $\boldsymbol{\varepsilon}_i \in R^{M-L}$ are elementary vectors. Similarly, the output y_r' can be expressed as

$$\begin{aligned} y_r' &= \frac{\sum_{i=1}^R (\mathbf{Q}\underline{\mathbf{f}})_i \hat{y}^i + \sum_{i=R+1}^M (\mathbf{Q}\overline{\mathbf{f}})_i \hat{y}^i}{\sum_{i=1}^R (\mathbf{Q}\underline{\mathbf{f}})_i + \sum_{i=R+1}^M (\mathbf{Q}\overline{\mathbf{f}})_i} \\ &= \frac{\underline{\mathbf{f}}^{\mathrm{T}}\mathbf{Q}^{\mathrm{T}}\mathbf{E}_3^{\mathrm{T}}\mathbf{E}_3\mathbf{Q}\mathbf{y} + \overline{\mathbf{f}}^{\mathrm{T}}\mathbf{Q}^{\mathrm{T}}\mathbf{E}_4^{\mathrm{T}}\mathbf{E}_4\mathbf{Q}\mathbf{y}}{\mathbf{p}_r^{\mathrm{T}}\mathbf{Q}\underline{\mathbf{f}} + \mathbf{g}_r^{\mathrm{T}}\mathbf{Q}\overline{\mathbf{f}}} \end{aligned} \quad (10)$$

where R denotes the right crossover point,

$$\begin{aligned} \mathbf{p}_r &= (\underbrace{1, 1, \ldots, 1}_{R}, 0, \ldots, 0)^{\mathrm{T}} \in R^{M\times 1} \\ \mathbf{g}_r &= (0, \ldots, 0, \underbrace{1, 1, \ldots, 1}_{M-R})^{\mathrm{T}} \in R^{M\times 1} \\ \mathbf{E}_3 &= (\mathbf{e}_1, \mathbf{e}_2, \ldots, \mathbf{e}_R, \mathbf{0}, \ldots, \mathbf{0})^{\mathrm{T}} \in R^{R\times M} \\ \mathbf{E}_4 &= (\mathbf{0}, \ldots, \mathbf{0}, \boldsymbol{\varepsilon}_1, \boldsymbol{\varepsilon}_2, \ldots, \boldsymbol{\varepsilon}_{M-R})^{\mathrm{T}} \in R^{(M-R)\times M} \end{aligned}$$

and where $\mathbf{e}_i \in R^R$ and $\boldsymbol{\varepsilon}_i \in R^{M-R}$ are elementary vectors. Finally, the interval type-1 fuzzy set is defuzzified to generate

the system output by means of computing the average of y'_l and y'_r. Hence the defuzzified output is

$$y' = \frac{y'_l + y'_r}{2}. \tag{11}$$

View the consequent parameters $\boldsymbol{\theta} = \mathbf{y} = (y^1, \ldots, y^M)^{\mathrm{T}}$ as adjustable parameters, then (11) can be written as

$$y' = \boldsymbol{\phi}^{\mathrm{T}} \boldsymbol{\theta} \tag{12}$$

where

$$\begin{aligned} \boldsymbol{\phi}^{\mathrm{T}} = & \frac{\overline{\mathbf{f}}^{\mathrm{T}} \mathbf{Q}^{\mathrm{T}} \mathbf{E}_1^{\mathrm{T}} \mathbf{E}_1 \mathbf{Q} + \underline{\mathbf{f}}^{\mathrm{T}} \mathbf{Q}^{\mathrm{T}} \mathbf{E}_2^{\mathrm{T}} \mathbf{E}_2 \mathbf{Q}}{2(\mathbf{p}_l^{\mathrm{T}} \mathbf{Q} \overline{\mathbf{f}} + \mathbf{g}_l^{\mathrm{T}} \mathbf{Q} \underline{\mathbf{f}})} \\ & + \frac{\underline{\mathbf{f}}^{\mathrm{T}} \mathbf{Q}^{\mathrm{T}} \mathbf{E}_3^{\mathrm{T}} \mathbf{E}_3 \mathbf{Q} + \overline{\mathbf{f}}^{\mathrm{T}} \mathbf{Q}^{\mathrm{T}} \mathbf{E}_4^{\mathrm{T}} \mathbf{E}_4 \mathbf{Q}}{2(\mathbf{p}_r^{\mathrm{T}} \mathbf{Q} \underline{\mathbf{f}} + \mathbf{g}_r^{\mathrm{T}} \mathbf{Q} \overline{\mathbf{f}})} \end{aligned} \tag{13}$$

is a regressive vector. Now as illustrated in (12), the singleton IT2 FLS using maximum t-conorm, product t-norm, product implication, and center of sets type-reduction can be expressed as linear in the parameters.

III. Modeling of Marine Vessels

The model of surface vessels may be classified into two categories [22], namely process plant model and control plant model. The process plant model, which simulates the real plant dynamics as closely as possible including process disturbance, sensor outputs and control inputs, is used for numerical analysis and simulation of the performance and stability of the closed-loop system. The control plant model, which is a simplified form of the complicated process plant model, is used for controller design and theoretical stability analysis (e.g., in the sense of Lyapunov).

A. Process Plant Model

1) Kinematics: The motions and state variables of the surface vessels are conventionally defined and measured with respect to two coordinate frames as shown in Fig. 2, namely earth-fixed frame and body-fixed frame. The earth-fixed frame,

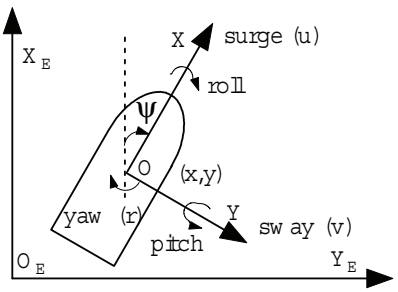

Fig. 2. 2D earth-fixed and body-fixed coordinate frames.

denoted as $\mathrm{X_E Y_E Z_E}$, is assumed fixed on the earth surface with X_E axis pointing north, the Y_E axis pointing east, and the Z_E axis down of the earth tangent plane. It is mainly used for global guidance and navigation. The body-fixed frame, denoted as XYZ, is fixed to the hull of the vessel, with X axis positive toward the bow, the Y axis positive towards starboard, and the Z axis positive downward. The origin of this frame is normally located at the vessel's center of gravity. The motion of a surface vessel has 6 degrees of freedom (DOF), which are surge, sway, heave, roll, pitch, and yaw. Let $\boldsymbol{\eta}' = [x, y, z, \phi, \theta, \psi]^{\mathrm{T}}$ be the vector representing the position and orientation of the vessel with respect to an earth-fixed frame, and let $\boldsymbol{\nu}' = [u, v, w, p, q, r]^{\mathrm{T}}$ denote the translation and rotation velocities of the vessel decomposed in the body-fixed frame. Then, the transformation between the earth-fixed and body-fixed velocity vectors is

$$\dot{\boldsymbol{\eta}}' = \mathbf{J}'(\boldsymbol{\eta}')\boldsymbol{\nu}'. \tag{14}$$

where $\mathbf{J}'(\boldsymbol{\eta}')$ is a state dependent transformation matrix, whose detailed definition can be found in [1].

2) Dynamics: The 6 DOF model formulation introduced here is based on [2], [3]. The equation of motion, which is in body-fixed frame, for a surface vessel whose speed is not low, is given by

$$\mathbf{M}'\dot{\boldsymbol{\nu}}' + \mathbf{C}'_{RB}\boldsymbol{\nu}' + \mathbf{C}'_A\boldsymbol{\nu}'_r + \bar{\mathbf{B}}'\boldsymbol{\nu}'_r + \mathbf{G}'\boldsymbol{\eta}' + \boldsymbol{\mu}' = \boldsymbol{\tau}' + \boldsymbol{\tau}'_{\mathrm{h}} \tag{15}$$

where $\mathbf{M}' = \mathbf{M}'_{RB} + \bar{\mathbf{A}}' \in R^{6\times 6}$ is the sum of the system inertia matrix and added mass matrix, $\mathbf{C}'_{RB} \in R^{6\times 6}$ is the Coriolis-Centripetal matrix, $\mathbf{C}'_A \in R^{6\times 6}$ is the constant infinite frequency added mass matrix, $\bar{\mathbf{B}}' \in R^{6\times 6}$ is the constant infinite frequency potential damping matrix, $\mathbf{G}' \in R^{6\times 6}$ is the restoring matrix, $\boldsymbol{\mu}' \in R^6$ is computed using a state space model to represent the fluid memory effect,

$$\dot{\boldsymbol{\chi}} = \mathbf{A}_r\boldsymbol{\chi} + \mathbf{B}_r\boldsymbol{\nu}'_r \tag{16}$$

$$\boldsymbol{\mu}' = \mathbf{C}_r\boldsymbol{\chi} + \mathbf{D}_r\boldsymbol{\nu}'_r \tag{17}$$

and where $(\mathbf{A}_r, \mathbf{B}_r, \mathbf{C}_r, \mathbf{D}_r)$ are constant matrices of appropriate dimensions. $\boldsymbol{\tau}' \in R^6$ is control force vector produced by thruster system, $\boldsymbol{\tau}'_{\mathrm{h}} = \boldsymbol{\tau}'_{\mathrm{CFD}} + \boldsymbol{\tau}'_{\mathrm{wave}} \in R^6$ is the sum of the cross-flow drag and surge resistance vector and wave load vector, which is computed according to Response Amplitude Operator tables, and $\boldsymbol{\nu}'_r = \boldsymbol{\nu}' - \boldsymbol{\nu}'_c \in R^6$ is the relative velocity vector between vessel velocity vector $\boldsymbol{\nu}'$ and sea current velocity vector $\boldsymbol{\nu}'_c$. All the detailed definition and computation of the above matrices and vectors can be found in [1], [2] and references therein.

B. Control Plant Model

The process plant model described in previous subsection is simplified on the basis of the following assumptions to facilitate the controller design and analytical stability analysis.

Assumption 1: The motions along heave, roll, and pitch directions are ignored for surface vessels. As a conventional vessel is metacentric stable, which means that there are restoring force and moments along those directions, this assumption is appropriate. As an application of this assumption, the dimension of the restoring matrix $\mathbf{G}' \in R^{6\times 6}$ in (15) is reduced to generate $\mathbf{G} \in R^{3\times 3} = \mathbf{0}$.

Assumption 2: The state variables of the vessel, i.e. displacements and velocities along surge, sway, and yaw, are measured by its own on-board devices such as gyro system, GPS, and accelerometers. Due to the development of modern

integration system of inertial sensors and satellite navigation system, this assumption is also appropriate.

Assumption 3: The influence of sea current is ignored. This assumption is mainly for the convenience of theoretical analysis.

Assumption 4: The time-varying hydrodynamic disturbances, i.e. $\boldsymbol{\mu}'$ and $\boldsymbol{\tau}'_{\rm h}$ in (15), could be estimated by singleton IT2 FLSs in the form of

$$\begin{aligned} \boldsymbol{\tau}'_d &= -\Phi'(\boldsymbol{\nu}')\Theta'. \\ &= \boldsymbol{\tau}'_{\rm h} - \boldsymbol{\mu}' \end{aligned} \tag{18}$$

where

$$\Theta' = (\boldsymbol{\theta}'^{\rm T}_1, \boldsymbol{\theta}'^{\rm T}_2, \ldots, \boldsymbol{\theta}'^{\rm T}_6)^{\rm T} \in R^{6M\times 1} \tag{19}$$

is a weighting vector and

$$\Phi'(\boldsymbol{\nu}') = {\rm diag}[\boldsymbol{\phi}'^{\rm T}_1, \boldsymbol{\phi}'^{\rm T}_2, \ldots, \boldsymbol{\phi}'^{\rm T}_6] \in R^{6\times 6M} \tag{20}$$

is a regressive matrix, M is the total number of rules for each sub-FLS. Thus far, this assumption has not been well established, for there is still a lack of rigorous proof showing singleton IT2 FLS could be universal approximator, but the propriety of this assumption will be checked by subsequent simulations.

1) Control Plant Model for Indirect Adaptive Control: Applying Assumptions 1-4 to (14) and (15), the following control plant model for indirect adaptive type-2 FLC design is obtained.

$$\dot{\boldsymbol{\eta}} = \mathbf{J}(\boldsymbol{\eta})\boldsymbol{\nu} \tag{21}$$

$$\mathbf{M}\dot{\boldsymbol{\nu}} + \mathbf{D}\boldsymbol{\nu} = \boldsymbol{\tau} - \Phi(\boldsymbol{\nu})\Theta \tag{22}$$

where $\boldsymbol{\eta} = [x, y, \psi]^{\rm T}$ is the displacement vector along surge, sway, and yaw, whereas $\boldsymbol{\nu} = [u, v, r]^{\rm T}$ is velocity vector, $\mathbf{J}(\boldsymbol{\eta}) \in R^{3\times 3}$ is the rotation matrix, note that $\mathbf{J}\mathbf{J}^{\rm T} = \mathbf{I}$ ($\mathbf{I}$ is the identity matrix), $\mathbf{M} \in R^{3\times 3}$ is the system inertia matrix including added mass, $\mathbf{D} = \mathbf{C}_{RB} + \mathbf{C}_A + \bar{\mathbf{B}} \in R^{3\times 3}$ is the damping matrix, and where $\mathbf{C}_{RB} \in R^{3\times 3}$, $\mathbf{C}_A \in R^{3\times 3}$, and $\bar{\mathbf{B}} \in R^{3\times 3}$ are three dimensional version of their corresponding matrices.

$$\Theta = (\boldsymbol{\theta}^{\rm T}_1, \boldsymbol{\theta}^{\rm T}_2, \boldsymbol{\theta}^{\rm T}_3)^{\rm T} \in R^{3M\times 1} \tag{23}$$

is the weighting vector and

$$\Phi(\boldsymbol{\nu}) = {\rm diag}[\boldsymbol{\phi}^{\rm T}_1(\boldsymbol{\nu}), \boldsymbol{\phi}^{\rm T}_2(\boldsymbol{\nu}), \boldsymbol{\phi}^{\rm T}_3(\boldsymbol{\nu})] \in R^{3\times 3M} \tag{24}$$

is the regressive matrix. Thus, here three sub-FLSs are used to approximate the hydrodynamic disturbances.

2) Control Plant Model for Direct Adaptive Control: Application of Assumptions 1-3 to (14) and (15) yields the following control plant model for direct adaptive type-2 FLC design.

$$\dot{\boldsymbol{\eta}} = \mathbf{J}(\boldsymbol{\eta})\boldsymbol{\nu} \tag{25}$$

$$\mathbf{M}\dot{\boldsymbol{\nu}} + \mathbf{D}\boldsymbol{\nu} + \boldsymbol{\mu} = \boldsymbol{\tau} + \boldsymbol{\tau}_{\rm h} \tag{26}$$

where $\boldsymbol{\mu} \in R^3$ and $\boldsymbol{\tau}_{\rm h} \in R^3$ are three dimensional version of $\boldsymbol{\mu}'$ and $\boldsymbol{\tau}'_{\rm h}$ respectively.

IV. Adaptive Fuzzy Logic Controller Design

The control objective in this paper is to manipulate a surface vessel to track the desired trajectory $\boldsymbol{\eta}_d = [x_d, y_d, \psi_d]^{\rm T}$, whose second derivative is continuous, as close as possible. In this section, both indirect and direct adaptive fuzzy logic controller are proposed for this control objective. However, the closed-loop systems under these two control schemes turn out to be same. The tracking error under these two control techniques is proved to globally asymptotically converge to zero. Rigorous analysis shows the closed-loop system is passive.

A. Indirect Adaptive Fuzzy Control

In indirect adaptive fuzzy control, the disturbances of the plant model are estimated by singleton IT2 FLSs as illustrated in (18) and the controller is designed assuming that the estimated disturbances represent the true time-varying disturbances. The control and adaptive law of the indirect adaptive type-2 FLC for plant (21), (22) are as follows.

$$\boldsymbol{\tau} = \mathbf{M}\dot{\boldsymbol{\nu}}_t + \mathbf{D}\boldsymbol{\nu}_t - \lambda_1\mathbf{s} + \Phi(\boldsymbol{\nu})\hat{\Theta} \tag{27}$$

$$\dot{\hat{\Theta}} = \lambda_2\Phi^{\rm T}(\boldsymbol{\nu})\mathbf{s} \tag{28}$$

where $\boldsymbol{\nu}_t = \boldsymbol{\nu}_d - \lambda_3\mathbf{J}^{\rm T}(\boldsymbol{\eta})\boldsymbol{e} = \mathbf{J}^{\rm T}(\boldsymbol{\eta})\dot{\boldsymbol{\eta}}_d - \lambda_3\mathbf{J}^{\rm T}(\boldsymbol{\eta})\boldsymbol{e} = \mathbf{J}^{\rm T}(\boldsymbol{\eta})(\dot{\boldsymbol{\eta}}_d - \lambda_3\boldsymbol{e})$, $\tilde{\Theta} = \Theta - \hat{\Theta} \in R^{3M}$ is the error vector between true Θ in (22) and adapted $\hat{\Theta}$, λ_i $(i = 1, 2, 3)$ are positive constant, and $\mathbf{s} = \boldsymbol{\nu} - \boldsymbol{\nu}_t = \mathbf{e}_\nu + \lambda_3\mathbf{J}^{\rm T}(\boldsymbol{\eta})\boldsymbol{e} = \mathbf{J}^{\rm T}(\boldsymbol{\eta})\dot{\boldsymbol{e}} + \lambda_3\mathbf{J}^{\rm T}(\boldsymbol{\eta})\boldsymbol{e} = \mathbf{J}^{\rm T}(\boldsymbol{\eta})(\dot{\boldsymbol{e}} + \lambda_3\boldsymbol{e})$, and where $\boldsymbol{e} = \boldsymbol{\eta} - \boldsymbol{\eta}_d \in R^3$ is the tracking error vector of vessel displacement, whereas $\boldsymbol{e}_\nu = \boldsymbol{\nu} - \boldsymbol{\nu}_d \in R^3$ is the tracking error vector of vessel velocity.

B. Direct Adaptive Fuzzy Control

In direct adaptive fuzzy control, the parameters of the controller are directly adjusted to reduce the tracking error. The direct adaptive type-2 FLC is designed based on the following assumption.

Assumption 5: The function of $\mathbf{M}\dot{\boldsymbol{\nu}}_t + \mathbf{D}\boldsymbol{\nu}_t - \boldsymbol{\tau}_{\rm h} + \boldsymbol{\mu} - \lambda_1\mathbf{s}$ could be estimated by singleton IT2 FLSs, i.e.,

$$\mathbf{M}\dot{\boldsymbol{\nu}}_t + \mathbf{D}\boldsymbol{\nu}_t - \boldsymbol{\tau}_{\rm h} + \boldsymbol{\mu} - \lambda_1\mathbf{s} = \Phi(\boldsymbol{\nu})\Theta. \tag{29}$$

The control and adaptive law of the indirect adaptive type-2 FLC for plant (25), (26) are as follows.

$$\begin{aligned} \boldsymbol{\tau} &= \Phi(\boldsymbol{\nu})\hat{\Theta} \\ &= \mathbf{M}\dot{\boldsymbol{\nu}}_t + \mathbf{D}\boldsymbol{\nu}_t - \boldsymbol{\tau}_{\rm h} + \boldsymbol{\mu} - \lambda_1\mathbf{s} - \Phi(\boldsymbol{\nu})\tilde{\Theta} \end{aligned} \tag{30}$$

$$\dot{\hat{\Theta}} = \lambda_2\Phi^{\rm T}(\boldsymbol{\nu})\mathbf{s} \tag{31}$$

C. Stability Analysis

Application of indirect and direct adaptive control and adaptive law (27), (28) and (30), (31) respectively to the plant (21), (22) and (25), (26) yields the same closed-loop system

$$\mathbf{M}\dot{\boldsymbol{s}} + \mathbf{D}\boldsymbol{s} = -\lambda_1\boldsymbol{s} - \Phi(\boldsymbol{\nu})\tilde{\Theta} \tag{32}$$

$$\dot{\tilde{\Theta}} = \lambda_2\Phi^{\rm T}(\boldsymbol{\nu})\boldsymbol{s} \tag{33}$$

$$\dot{\boldsymbol{e}} = -\lambda_3\boldsymbol{e} + \mathbf{J}(\boldsymbol{\eta})\boldsymbol{s}. \tag{34}$$

Theorem 1: The states $(\boldsymbol{s}, \boldsymbol{e})$ of the closed-loop system (32)-(34) globally asymptotically converge to $(\mathbf{0}, \mathbf{0})$.

Proof: Consider the following Lyapunov function candidate, which is positive definite.

$$V = \frac{1}{2}\boldsymbol{s}^{\mathrm{T}}\mathbf{M}\boldsymbol{s} + \lambda_1\lambda_3\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e} + \frac{1}{2\lambda_2}\tilde{\Theta}^{\mathrm{T}}\tilde{\Theta} \tag{35}$$

Differentiation of V along the trajectory of the closed-loop system (32)-(34) yields

$$\begin{aligned}\dot{V} =& \boldsymbol{s}^{\mathrm{T}}(-\mathbf{D}\boldsymbol{s} - \lambda_1\boldsymbol{s} - \Phi(\boldsymbol{\nu})\tilde{\Theta}) + \tilde{\Theta}^{\mathrm{T}}\Phi^{\mathrm{T}}(\boldsymbol{\nu})\boldsymbol{s} \\ &+ 2\lambda_1\lambda_3\boldsymbol{e}^{\mathrm{T}}(-\lambda_3\boldsymbol{e} + \mathbf{J}(\boldsymbol{\eta})\boldsymbol{s}) \\ =& -\frac{1}{2}\boldsymbol{s}^{\mathrm{T}}(\mathbf{D} + \mathbf{D}^{\mathrm{T}})\boldsymbol{s} - \lambda_1\dot{\boldsymbol{e}}^{\mathrm{T}}\dot{\boldsymbol{e}} - \lambda_1\lambda_3^2\boldsymbol{e}^{\mathrm{T}}\boldsymbol{e} \\ \leq& 0\end{aligned}$$

which means the derivative of the Lyapunov function candidate is semi-negative definite. Moreover, the largest invariant set contained in the set $\dot{V} \equiv 0$ is contained in the set $(\boldsymbol{s}, \boldsymbol{e}) = (\mathbf{0}, \mathbf{0})$.

Now, according to Krasovskii-La Salle Invariant Set Theorem, we may conclude the point $(\boldsymbol{s}, \boldsymbol{e})$ globally asymptotically converges to $(\mathbf{0}, \mathbf{0})$ as time tends to infinite, and $\dot{\tilde{\Theta}} = 0$, which means $\hat{\Theta}$ is bounded. ■

Remark 1: Here, the theorem is developed for the case where the gains λ_i $(i = 1, 2, 3)$ are scalar, the case where the gains are matrices can be extended to in a similar approach.

D. Passivity Interpretation

According to energy-related considerations, by means of an input-output description passivity theory provides a framework for the design and analysis of control systems. And the input-output description further allows for a modular method of control systems design and analysis [23]. As shown in Fig. 3, the closed-loop system (32)-(34) can be interpreted as the negative feedback interconnection of three subsystems with respective inputs u_1, u_2, u_3 and outputs y_1, y_2, and y_3, with $y_1 = u_2 = u_3$ and $u_1 = -y_2 - y_3$, and the three subsystems as follows.

Subsystem 1:

$$\begin{cases}\mathbf{M}\dot{\boldsymbol{s}} + \mathbf{D}\boldsymbol{s} = u_1 \\ y_1 = \boldsymbol{s}\end{cases} \tag{36}$$

Subsystem 2:

$$\begin{cases}\dot{\tilde{\Theta}} = \lambda_2\Phi^{\mathrm{T}}(\boldsymbol{\nu})u_2 \\ y_2 = \Phi(\boldsymbol{\nu})\tilde{\Theta}\end{cases} \tag{37}$$

Subsystem 3:

$$\begin{cases}\dot{\boldsymbol{e}} = -\lambda_3\boldsymbol{e} + \mathbf{J}(\boldsymbol{\eta})u_3 \\ y_3 = \lambda_1 u_3\end{cases} \tag{38}$$

Theorem 2: The closed-loop system (32)-(34) is passive.

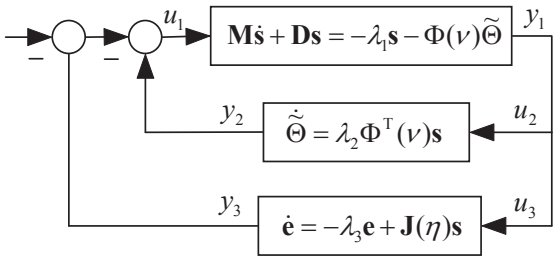

Fig. 3. Closed-loop equivalent representation.

Proof: For subsystem 1, its supply rate is

$$\begin{aligned}&\int_0^t u_1^{\mathrm{T}} y_1 dr \\ =& \int_0^t (\mathbf{M}\dot{\boldsymbol{s}} + \mathbf{D}\boldsymbol{s})^{\mathrm{T}}\boldsymbol{s} dr \\ =& \int_0^t \boldsymbol{s}^{\mathrm{T}}\mathbf{M}\dot{\boldsymbol{s}} dr + \int_0^t \boldsymbol{s}^{\mathrm{T}}\mathbf{D}\boldsymbol{s} dr \\ =& \frac{1}{2}\boldsymbol{s}^{\mathrm{T}}(t)\mathbf{M}\boldsymbol{s}(t) - \frac{1}{2}\boldsymbol{s}^{\mathrm{T}}(0)\mathbf{M}\boldsymbol{s}(0) + \int_0^t \boldsymbol{s}^{\mathrm{T}}\mathbf{D}\boldsymbol{s} dr\end{aligned}$$

Thus, the subsystem 1 is output strictly passive with supply rate $\int_0^t u_1^{\mathrm{T}} y_1 dr$ and storage function $\frac{1}{2}\boldsymbol{s}^{\mathrm{T}}\mathbf{M}\boldsymbol{s}$.

For subsystem 2 its supply rate is

$$\begin{aligned}\int_0^t u_2^{\mathrm{T}} y_2 dr =& \int_0^t \tilde{\Theta}^{\mathrm{T}}\Phi^{\mathrm{T}}(\boldsymbol{\nu})u_2 dr \\ =& \int_0^t \tilde{\Theta}^{\mathrm{T}}\frac{1}{\lambda_2}\dot{\tilde{\Theta}} dr \\ =& \frac{1}{2\lambda_2}\tilde{\Theta}^{\mathrm{T}}(t)\tilde{\Theta}(t) - \frac{1}{2\lambda_2}\tilde{\Theta}^{\mathrm{T}}(0)\tilde{\Theta}(0)\end{aligned}$$

which means the subsystem 2 is passive with supply rate $\int_0^t u_2^{\mathrm{T}} y_2 dr$ and storage function $\frac{1}{2\lambda_2}\tilde{\Theta}^{\mathrm{T}}\tilde{\Theta}$.

For subsystem 3, its supply rate is

$$\begin{aligned}\int_0^t u_3^{\mathrm{T}} y_3 dr =& \int_0^t u_3^{\mathrm{T}}\lambda_1 u_3 dr \\ =& \int_0^t \frac{1}{\lambda_1} y_3^{\mathrm{T}} y_3 dr \\ =& \frac{\lambda_1}{2}\int_0^t u_3^{\mathrm{T}} u_3 dr + \int_0^t \frac{1}{2\lambda_1} y_3^{\mathrm{T}} y_3 dr\end{aligned}$$

which means the subsystem 3 is very strictly passive with supply rate $\int_0^t u_3^{\mathrm{T}} y_3 dr$.

According to the fact that the negative feedback interconnection of two passive systems is passive, the closed-loop system (32)-(34), which can be interpreted as negative feedback interconnection of subsystem 1 and subsystem 2, then together with subsystem 3, is passive. ■

V. Simulation Studies

Marine System Simulator, which is developed in Norwegian University of Science and Technology [24], is employed as the platform for the simulation studies. The International Towing

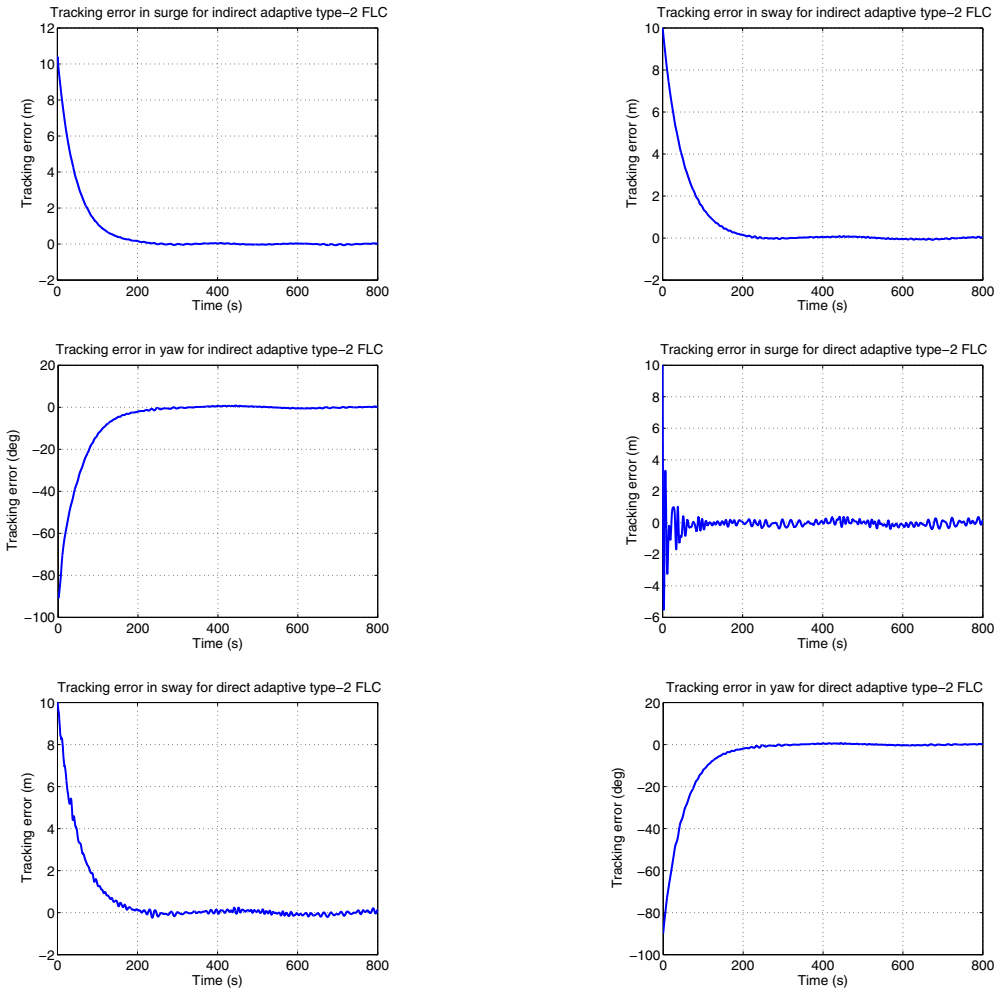

Fig. 4. Plots 1-3 show the tracking errors for indirect adaptive type-2 FLC. Plots 4-6 show the tracking errors for direct adaptive type-2 FLC.

Tank Conference (ITTC) wave spectrum with significant wave height $H_s = 3$ m and peak frequency $\omega_0 = 0.56$ rad/s is used to imitate rough sea with large waves. Sea current with speed $V_c = 0.2$ m/s and direction $\beta_c = 30^\circ$ is also included in the simulations, although ignored during the controller design. A container ship named as S-175 is used as case study. The control objective is to control the vessel to track the desired trajectory $\boldsymbol{\eta}_d = [x_d, y_d, \psi_d]^{\mathrm{T}}$, where $x_d = 8t$, $y_d = 200\cos(0.005\pi t)$, and $\psi_d = \arctan(y_d/x_d)$. The initial states are set as $[\boldsymbol{\eta}_0^{\mathrm{T}}, \boldsymbol{\nu}_0^{\mathrm{T}}] = [10, 210, 0, 0, 0, 0]$. All the IT2 FLSs in indirect adaptive fuzzy controller (27), (28) and direct adaptive fuzzy controller (30), (31) are configured as follows. As there are three degrees of freedom considered for the motion of the vessel, three singleton IT2 sub-FLSs are employed for each controller, which is demonstrated in (23) and (24). For each sub-system, three fuzzy membership functions labeled as **N**, **Z**, and **P** are employed to partition each of the input domain. As there are three inputs, there are totally 27 rules and 27 adjustable consequent parameters. Gaussian function with uncertain standard deviation is chosen to be the primary membership functions of the antecedent IT2 fuzzy sets and in the following form.

$$\mu_{\tilde{F}_i^j}(x_j) = \exp[-\frac{1}{2}(\frac{x_j - m_i}{\sigma})^2] \quad \sigma \in [\underline{\sigma}, \overline{\sigma}] \tag{39}$$

where $j = 1, 2, 3$ is the index of three inputs and $i = 1, 2, 3$ is the index of three fuzzy membership functions for jth input. For each input, the means of the Gaussian functions are $m_1 = -1$, $m_2 = 0$, and $m_3 = 1$, the standard deviations of the lower membership functions are $\underline{\sigma} = 0.6$, and the standard deviations of the upper membership functions are $\overline{\sigma} = 0.8$.

A. Closed-loop Performance

Although the indirect and direct adaptive fuzzy controllers (27), (28) and (30), (31) are designed based on the control plant models (21), (22) and (25), (26) respectively, they are tested with the process plant model (14), (15) in the simulations.

1) Indirect Adaptive Control: Set $\lambda_1 = 4.3 \times 10^8$, $\lambda_2 = 1 \times 10^8$, and $\lambda_3 = 0.02$ in (27) and (28). The tracking errors of the vessel to the desired trajectory under the indirect adaptive fuzzy controller are shown in plot 1-3 of Fig. 4, from which it can be observed that the tracking errors asymptotically

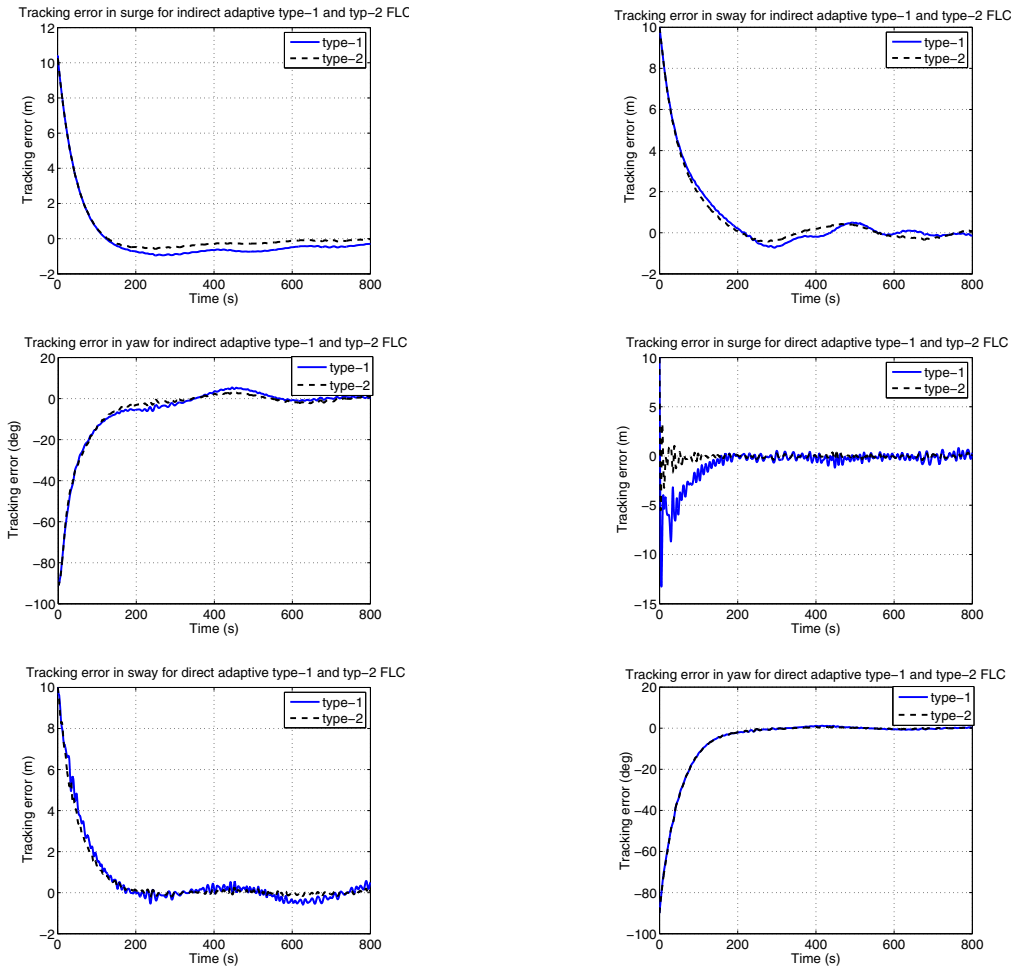

Fig. 5. Plots 1-3 show the tracking errors for indirect type-1 and type-2 FLC. Plots 4-6 show the tracking errors for direct type-1 and type-2 FLC.

converge to zero despite the time-varying hydrodynamic disturbances and the sub-FLSs effectively approximate the complex disturbances.

2) Direct Adaptive Control: Set $\lambda_2 = 1 \times 10^8$ and $\lambda_3 = 0.02$ in (30) and (31). The tracking errors under the direct adaptive fuzzy controller are shown in plot 4-6 of Fig. 4. The tracking performance is satisfactory in the presence of the time-varying disturbances, and the sub-FLSs effectively generate the control forces and moment. Fluctuations in the tracking errors are observed, that is because the inputs to the sub-FLSs are insufficient to make the sub-FLSs accurately approximate the complex function (29).

The control performance under indirect adaptive fuzzy control is noted to be better than that under direct adaptive fuzzy control. One may conclude without hesitation that the indirect adaptive fuzzy controller is better than the direct one, however, the direct adaptive fuzzy controller has an advantage over the indirect one, i.e., the direct adaptive fuzzy controller does not need the knowledge of inertial matrix $\mathbf{M}$ and damping matrix $\mathbf{D}$, thus can be used under the situation where such knowledge is not available.

B. Comparison with Adaptive Type-1 Fuzzy Controllers

Replace the components in (24) and correspondingly in indirect adaptive controller (27), (28) and direct adaptive controller (30), (31) with fuzzy basis function vector [7], [8],

$$\boldsymbol{\phi}^{\mathrm{T}} = (\phi^1(\mathbf{x}), \ldots, \phi^M(\mathbf{x})) \tag{40}$$

where fuzzy basis function is defined as

$$\phi^l(\mathbf{x}) = \frac{\Pi_{i=1}^n \mu_{F_i^l}(x_i)}{\Sigma_{l=1}^M (\Pi_{i=1}^n \mu_{F_i^l}(x_i))}, \tag{41}$$

the controllers (27), (28) and (30), (31) become adaptive type-1 FLCs. In this subsection, the adaptive type-2 FLCs are compared with their type-1 counterparts. For each sub-FLS in the type-1 cases, five fuzzy membership functions labeled as **NL**, **NS**, **Z**, **PS**, and **PL** are employed to partition each of the input domain. As there are three inputs, there are 125 rules and 125 adjustable consequent parameters in contrast to 27 rules and parameters for type-2 cases. Gaussian functions are chosen to be the membership functions of the antecedent sets for each input, they can be written as

$$\mu_{F_i^j}(x_j) = \exp[-\frac{1}{2}(\frac{x_j - m_i}{\sigma})^2], \tag{42}$$

where $j = 1, 2, 3$ is the index of three inputs and $i = 1, \ldots, 5$ is the index of five fuzzy membership functions for jth input. The means are fixed as $(m_1, \ldots, m_5) = (-1, -0.5, 0, 0.5, 1)$, whereas the standard deviations for all the Gaussian functions are set as $\sigma = 0.4$.

1) Indirect Adaptive Control: Set $\lambda_1 = 4.3 \times 10^8$, $\lambda_2 = 1 \times 10^7$, and $\lambda_3 = 0.02$ in (27) and (28) for both indirect adaptive type-1 and type-2 FLCs, the tracking errors are shown in plot 1-3 of Fig. 5.

2) Direct Adaptive Control: Set $\lambda_2 = 1 \times 10^8$ and $\lambda_3 = 0.02$ in (30) and (31) for both direct adaptive type-1 and type-2 FLCs, the tracking errors are depicted in plot 4-6 of Fig. 5.

It can be observed from Fig. 5 that the adaptive type-2 FLCs perform comparably with, if not better than, their type-1 counterparts, even though type-1 cases use more than four times the number of the rules. In order to quantify the performance differences between adaptive type-1 and type-2 FLCs, the integral of time-weighted absolute errors (ITAE) for all the above four cases in the following form are calculated.

$$P_x = \int_0^T t|e_x|dt \tag{43}$$

$$P_y = \int_0^T t|e_y|dt \tag{44}$$

$$P_\psi = \int_0^T t|e_\psi|dt \tag{45}$$

where T is the total simulation time and e_x, e_y, and e_ψ are three components of tracking error vector $\boldsymbol{e}$. According to the results shown in Table I, the values of the ITAE for the adaptive type-2 FLCs are smaller than those for type-1 cases along all the three degrees of freedom. As regards the computational burden, type-reductions for type-2 cases do take some time, but the time is very little as only a few rules are fired at the same time and Karnik-Mendel algorithm has been proved to be super-exponentially convergent [25]. Furthermore, it has been reported the type-2 FLS can be implemented in real-time applications [26]. Thus, type-reduction should not be an issue and will not cause any stability problem. In conclusion, It seems that the type-2 FLS has better approximation property with less rules than its type-1 counterpart in this application.

TABLE I
ITAE FOR ADAPTIVE TYPE-1 AND TYPE-2 FLCS

Cases	Indirect T1	Indirect T2	Direct T1	Direct T2
P_x	192746	81796	162892	53917
P_y	85064	66428	78648	43013
P_ψ	14154	9592	5680	4660

VI. CONCLUSIONS

In this paper, indirect and direct adaptive type-2 FLCs have been designed for tracking control of surface vessels in the presence of time-varying hydrodynamic disturbances. It has been proved the tracking errors under both of the proposed controls globally asymptotically converge to zero. Although designed through different approaches, the closed-loop systems for both indirect and direct type-2 FLCs are same and passive. Simulation results have demonstrated that the two controllers are effective and robust. Comparison with their type-1 counterparts suggests the type-2 FLS has comparable approximation property.

***Abstract*—This paper deals with the problem of stability analysis of dynamic local model networks. Established methods in this context are mainly based on Lyapunov stability theory and are targeted to be as little conservative as possible. In this respect it is essential to take into account the transitions between the different local models. For that purpose this paper presents and discusses a method to determine possible model transitions of such dynamic local model networks utilizing identification or simulation data. The effectiveness of the proposed method is shown by a simulation example in connection with the fuzzy Lyapunov approach as a stability criterion. The example demonstrates how identification data can be used to reduce the conservatism compared to standard approaches.**

***Keywords*—local model networks, fuzzy Lyapunov function, stability, system identification**

I. Introduction

Local model networks (LMN) are a versatile architecture for the representation of a large class of nonlinear systems. The approximation is based on a partitioning of the nonlinearities into subdomains which can be accurately represented by simpler submodels, for example linear models [1]. The architecture of LMN offers good interpretability which is an important advantage for the design of controllers or observers. LMN are usually generated from measured input and output data of the process to be approximated.

When the structure of LMN is applied to nonlinear dynamic systems a main challenge is to provide stability criteria. A major difficulty lies in the fact that a dynamic LMN can become unstable in the large even when all local linear models are stable, [2].

Stability proofs of local model networks are mainly based on Lyapunov's direct method which results in linear matrix inequalities (LMIs) as stability criterion. Lyapunov stability criteria provide *sufficient* rather than a necessary conditions for stability. In this context the issue of *conservatism* is inherently linked to these methods: Depending on the type and structure of the chosen Lyapunov function a stability proof may fail even though the investigated system is stable.

The basic criterion is the so-called common quadratic Lyapunov approach, [2]. The main drawback of this approach is its conservatism since it aims to find one common Lyapunov function for all local linear models in an LMN. The reason lies in the fact that the LMI solver has to find a single positive definite matrix and must simultaneously fulfill as many LMIs as the number of local models. Thus, by increasing the number of local models, and increasing the accuracy of the LMN, it will be more difficult to find a common Lyapunov function.

In recent years advanced methods, based on the less conservative fuzzy Lyapunov approach have been developed, [3], [4], [5], [6], [7]. Basically this approach aims to find a Lyapunov function for each local model which are connected by so-called model transitions. A model transition occurs when the system state transits from one local model to another. The conservatism of the stability criterion is directly increased with the number of model transitions. Thus, in order to prove stability using the fuzzy Lyapunov approach without any additional structural information of the LMN it is mandatory to take into account how state trajectories can progress through different local models. This helps to reduce the conservatism because impossible transitions need not be considered. Due to the nature of local model networks only a limited number of model transitions actually take place or are theoretically feasible. Note, that the number of theoretically possible model transitions is increased with the number of local models.

For simple and low dimensional partitioning strategies (e.g. two dimensional trapezoid validity functions) it is possible to determine the model transition using the phase portrait of the considered local model network or the method presented in [4]. For high dimensional partition spaces and complex partitioning strategies such as [8], [9], [10], [11] and [12] the method of [4] is no longer feasible.

In this paper a systematic approach is introduced to determine all occurring model transitions in a dynamic LMN. The basic idea is to capture the model transitions by means of simulation data. Therefore an optimally designed input data sequence

This work was supported by Christian Doppler Research Association and AVL List GmbH

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

regarding design of experiment (DoE) is required which must be *extensive* and *tight*, see [13]. For local model networks generated from a real physical process the identification data sequence can be used because it must fulfill the same requirements to capture the dynamics of the considered system within the operating area. For artificial local model networks the input data sequence has to be generated. Thus, all occurring model transition can be determined using simulation data generated by an optimally designed input data sequence. It must be noted, however, that the characteristics of the simulation data significantly contribute to the effectiveness of the proposed method. This is not a severe disadvantage, because the range of the excitation signal is either given (identification data) or user defined and can be chosen to the area of interest (e.g. operating area) for the stability criterion.

With the proposed method the conservatism of the fuzzy Lyapunov approach is reduced significantly making it a feasible method to prove stability of LMN. The main advantages of the transition determination of dynamic local model networks by utilizing the identification data sequence or an optimally designed excitation data sequence are:

- The conservatism does not grow automatically with the number of local models.
- It is independent regarding the dimensions of the partition space and the type of the validity function.
- It is applicable to arbitrary partitioning strategies, such as: equidistant grid [4]; recursive, axis orthogonal [8], [9], [14]; axis oblique [10], [15]; arbitrary functions [12]; hinging hyperplanes [11].

This paper is organized as follows: The architecture of local model networks is briefly described in section II. Section III generally addresses stability, the common quadratic Lyapunov approach, and the fuzzy Lyapunov approach for discrete-time LMN. Section IV describes the proposed procedure to determine all occurring model transitions utilize a DoE optimal excitation signal. In section V on the one hand the transition determination is described and on the other hand the improvement of finding a fuzzy Lyapunov function to prove stability using the proposed concept is demonstrated by means of illustrative examples. The paper is concluded by some remarks in section VI.

II. Local Model Networks

The architecture of dynamic local model networks is illustrated in Fig. 1.

First, an ordered set for the indices of the local models is defined as:

$$\mathcal{I} = (i \in \mathbb{N} | 1 \leq i \leq I) \tag{1}$$

where I denotes the number of local models. Local model networks with external dynamics have an input vector $\boldsymbol{z}(k)$ with past inputs and outputs according to Fig. 1:

$$\boldsymbol{z}(k) = [\boldsymbol{u}_{\mathcal{J}}(k - \mathcal{M})\ \hat{\boldsymbol{y}}(k - \mathcal{N})],\ \boldsymbol{z}(k) \in \mathbb{R}^O \tag{2}$$

where the ordered sets for the number of the input channels $\mathcal{J}$, the orders of the inputs $\mathcal{M}$, the orders of the feedback output

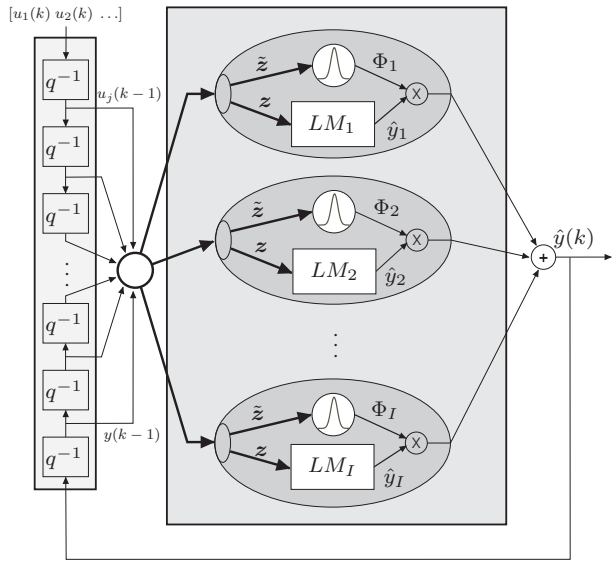

Fig. 1. Architecture of a local model network with external dynamics [15]

(=system order) $\mathcal{N}$ and the index $\mathcal{O}$ are as follows:

$$\mathcal{J}(j) = (j \in \mathbb{N} | 1 \leq j \leq J) \tag{3}$$

$$\mathcal{M}(m) = (m \in \mathbb{N} | 1 \leq m \leq M) \tag{4}$$

$$\mathcal{N}(n) = (n \in \mathbb{N} | 1 \leq n \leq N) \tag{5}$$

$$\mathcal{O}(o) = (o \in \mathbb{N} | 1 \leq o \leq O). \tag{6}$$

where J denotes the number of inputs, M denotes the order of the inputs, N denotes the system order and O denotes the dimension of the input vector. From Fig. 1 it becomes obvious that the input vector for the validity functions $\Phi_{\mathcal{I}}(\tilde{\boldsymbol{z}}(k))$ can be chosen differently to the input vector for the local model:

$$\tilde{\boldsymbol{z}}(k) = [\boldsymbol{u}_{\tilde{\mathcal{J}}}(k - \tilde{\mathcal{M}})\ \hat{\boldsymbol{y}}(k - \tilde{\mathcal{N}})] \subseteq \boldsymbol{z}(k),\ \tilde{\boldsymbol{z}}(k) \in \mathbb{R}^{\tilde{O}} \tag{7}$$

where the ordered sets $\tilde{\mathcal{J}}, \tilde{\mathcal{M}}, \tilde{\mathcal{N}}, \tilde{\mathcal{O}}$ are subsets of their corresponding sets as follows:

$$\tilde{\mathcal{J}}(\tilde{j}) \subseteq \mathcal{J}(j) \tag{8}$$

$$\tilde{\mathcal{M}}(\tilde{m}) \subseteq \mathcal{M}(m) \tag{9}$$

$$\tilde{\mathcal{N}}(\tilde{n}) \subseteq \mathcal{N}(n) \tag{10}$$

$$\tilde{\mathcal{O}}(\tilde{o}) \subseteq \mathcal{O}(o) \tag{11}$$

All local model outputs

$$\hat{y}_i(k) = \boldsymbol{z}(k)\boldsymbol{\theta}_i, \tag{12}$$

with the local parameter vector $\boldsymbol{\theta}_i$ are used subsequently to form the global model output $\hat{y}(k)$ by weighted aggregation, see Fig. 1:

$$\hat{y}(k) = \sum_{\mathcal{I}} \Phi_i(k)\hat{y}_i(k) \tag{13}$$

where the validity functions are constrained:

$$\sum_{\mathcal{I}} \Phi_i = 1 \tag{14}$$

$$0 \leq \Phi_i \leq 1,\ \forall i \in \mathcal{I}. \tag{15}$$

For stability analysis using Lyapunov approaches the local dynamics must be defined in state space notation. Thus, the discrete-time state space notation of local model networks can be generally defined using (1):

$$\begin{aligned} \boldsymbol{x}(k+1) &= \sum_{\mathcal{I}} \Phi_i(\tilde{\boldsymbol{z}}(k))(\boldsymbol{A}_i\boldsymbol{x}(k) + \boldsymbol{B}_i\boldsymbol{u}(k)) \\ \hat{y}(k) &= \boldsymbol{c}^T\boldsymbol{x}(k). \end{aligned} \tag{16}$$

III. Stability Concepts for Local Model Networks

In this section stability for discrete-time systems in general, the common quadratic Lyapunov approach and the fuzzy Lyapunov approach are described.

A. General

An autonomous dynamic system in discrete-time is represented by a set of difference equations in the form

$$\boldsymbol{x}(k+1) = \boldsymbol{f}(\boldsymbol{x}(k)), \;\; \boldsymbol{f} \in \mathbb{R}^{n\times 1} \tag{17}$$

where $\boldsymbol{f}$ is a nonlinear vector function, $\boldsymbol{x}$ is the $n \times 1$ state vector, and k denotes the sampling instant.
Nonlinear systems can have much more complex behavior than linear systems. A number of refined stability concepts, such as marginal stability and asymptotic stability, are needed, [16]:

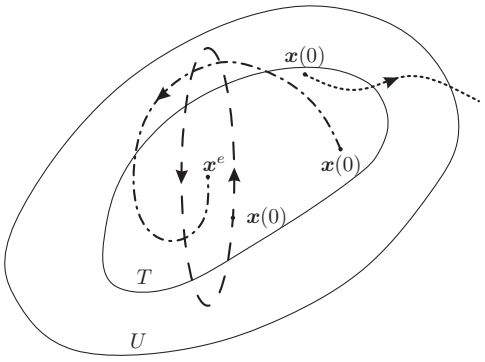

Fig. 2. Stability definitions

Definition 3.1: An equilibrium state $\boldsymbol{x}^e$ is *marginally stable* (Fig. 2, dashed line) if for every neighborhood $U > 0$ of $\boldsymbol{x}^e$ there is a neighborhood $T > 0,\ T \subseteq U$ of $\boldsymbol{x}^e$ such that every solution $\boldsymbol{x}(k)$ starting within $T(\boldsymbol{x}(0) \in T)$ remains within U for all $k > 0$. Otherwise the equilibrium point $\boldsymbol{x}^e$ is *unstable* (Fig. 2, dotted line).
Note that $\boldsymbol{x}(k)$ need not approach $\boldsymbol{x}^e$.

Definition 3.2: An equilibrium state $\boldsymbol{x}^e$ is *asymptotically stable* (Fig. 2, dash-dotted line) if it is marginal stable and additionally T can be chosen so that $\|\boldsymbol{x}(k) - \boldsymbol{x}^e\| \to 0$ as $k \to \infty$ for all $\boldsymbol{x}(0) \in T$.

B. Lyapunov Stability for Discrete-Time Local Model Networks

The stability of LMN can be proved by Lyapunov's direct method. This general approach is based on a state space formulation of the system, such as (16), and one has to find a suitable Lyapunov function, [9]. Since this is generally difficult it is common to restrict the search to the class of quadratic Lyapunov functions

$$V(k) = \boldsymbol{x}^T(k)\boldsymbol{P}\boldsymbol{x}(k) > 0, \quad \boldsymbol{P} \succ 0 \tag{18}$$

where $\boldsymbol{P}$ is a positive definite matrix and $\boldsymbol{x}(k)$ is the state of the model according to (16). For asymptotic stability, the Lyapunov function must be strictly monotonically decreasing over time k:

$$V(k+1) - V(k) < 0, \quad \forall k. \tag{19}$$

C. Common Quadratic Lyapunov Approach for Discrete-Time Systems

The common quadratic Lyapunov approach was the first stability criterion to be proposed for local model networks, [2]. It aims to find one common quadratic Lyapunov function for all local models. Using (16), (18) and (19) the common quadratic Lyapunov approach can be formulated as:

Theorem 1: A dynamic local model network is globally asymptotically stable if there exists *a common positive definite matrix* $\boldsymbol{P}$ for all local models:

$$\boldsymbol{P} \succ 0 \tag{20}$$

such that the following condition is satisfied:

$$\boldsymbol{A}_i^T\boldsymbol{P}\boldsymbol{A}_i - \boldsymbol{P} \prec 0, \quad \forall i \in \mathcal{I} \tag{21}$$

with $\boldsymbol{A}_i$ taken from (16), [2].
The proof of Theorem 1 is given in [2].

The stability condition (21) constitutes a set of *linear matrix inequalities* (LMIs) which is usually solved by numerical optimization.
In (21) a *common* matrix $\boldsymbol{P}$ must be found for *all* local system matrices $\boldsymbol{A}_i$. This is a much stronger condition than the individual stability of the local linear models, for which only $\boldsymbol{A}_i^T\boldsymbol{P}_i\boldsymbol{A}_i - \boldsymbol{P}_i \prec 0$ with individual $\boldsymbol{P}_i$ would be required, [9]. Note that it may not be possible to find a $\boldsymbol{P}$ that fulfills (21), although the global model may be stable. The condition (21) is therefore sufficient but not necessary.

D. Fuzzy Lyapunov Approach for Discrete-Time Systems

As the common quadratic Lyapunov approach tends to be conservative, it is desirable to have less conservative stability methods available. The fuzzy Lyapunov approach [3], [4], [5], [6], [7], [17] is one of the options for this purpose.
This approach aims to find a non-quadratic Lyapunov function for the global model

$$V(k) = \boldsymbol{x}^T(k)\Big(\sum_{\mathcal{I}} \Phi_i(\tilde{\boldsymbol{x}}(k))\boldsymbol{P}_i\Big)\boldsymbol{x}(k) > 0, \tag{22}$$

where each local model independently fulfills (18) (there is an individual $\boldsymbol{P}_i$ matrix associated to each local model).

Remark 1: The validity functions of the $\boldsymbol{P}_i$ matrices in (22) are equivalent to the validity functions of the local models in (16).

To fulfill (19) all local models must be stable as a prerequisite. Second, every possible trajectory must also satisfy (19). This

shows, that the occurring model transitions are of high interest when using the fuzzy Lyapunov approach:

Theorem 2: The dynamic local model network is asymptotically stable in the region U if there exists a *set of positive definite matrices* $\boldsymbol{P}_i$:

$$\boldsymbol{P}_i \succ 0, \quad \forall i \in \mathcal{I} \tag{23}$$

such that the following condition is satisfied:

$$\boldsymbol{A}_i^T \boldsymbol{P}_j \boldsymbol{A}_i - \boldsymbol{P}_i \prec 0, \quad \forall i \in \mathcal{I}, j \in \Omega_i \tag{24}$$

where the set Ω_i defines all possible model transitions of model i within region U, [4]. Defining the dominant region of a local model, according to [18], as

$$S_i = \{\tilde{\boldsymbol{x}} | \Phi_i(\tilde{\boldsymbol{x}}) > \Phi_l(\tilde{\boldsymbol{x}}),\ l \in \mathcal{I}, l \neq i\}, i \in \mathcal{I} \tag{25}$$

the possible transitions can be defined, as

$$\Omega_i = \{j | (\tilde{\boldsymbol{x}}(k) \in S_i \wedge \tilde{\boldsymbol{x}}(k+1) \in S_j) \vee (\tilde{\boldsymbol{x}}(k) \in S_j \wedge \tilde{\boldsymbol{x}}(k+1) \in S_i),\ j \in \mathcal{I}\},\ \forall i \in \mathcal{I}. \tag{26}$$

This includes the case $i = j$ which requires that every local model must have stable dynamics as a necessary condition. The proof of Theorem 2 is given in [4].

IV. Transition Determination

To reduce the conservatism of the fuzzy Lyapunov approach it is essential to determine all occurring model transition Ω_i. If no information about the model transitions is available, then transitions to all other models must be taken into account:

$$\Omega_i = \mathcal{I}, \quad \forall i \in \mathcal{I}. \tag{27}$$

Due to (26) each model transition results in two additional LMIs. Thus, the difficulty of finding a suitable Lyapunov function for the considered system is increased when additional model transitions are taken into account. Therefore, a proper determination of the occurring model transitions will help to reduce conservatism on the one hand, and often even makes a stability check on complex LMNs possible at all. Thus, in this section a method for the determination of all occurring model transitions is presented. One important point is the independency regarding the partitioning strategy of the considered local model network. Fig. 3 illustrates four common partitioning strategies of local model networks.

Obviously the determination of the model transitions by using the information of the partitioning can become difficult or impossible particularly for high order partition spaces and complex partitioning strategies as [10], [12] and [14]. Further, different types of validity functions are commonly used, see Fig. 4.

Thus, a method for the determination of the occurring model transitions, which is independent regarding the partitioning strategy and the type of validity function, is essential for the application of the fuzzy Lyapunov approach to local model networks.

The methodology proposed in this paper determines the possible transitions in a local model network by utilizing a simulation

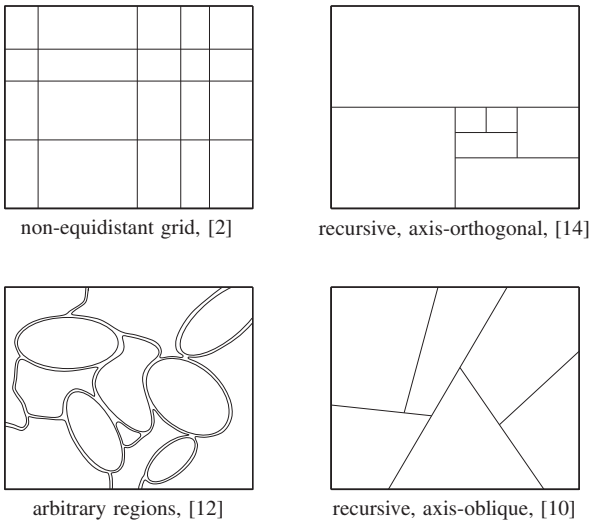

Fig. 3. Common partitioning strategies of local model networks

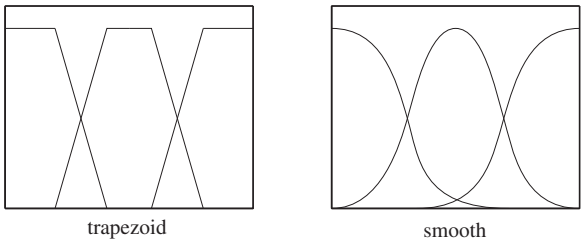

Fig. 4. Common validity functions of local model networks

result with an optimally designed excitation data sequence and is independent regarding the partitioning strategy and the used validity function. As a consequence the stability region U (Fig. 2) in the present paper is aimed to be identical to the convex hull of the used data sequence. In contrast, most available stability criteria for LMN aim to show *unbounded* global stability which can become too expensive when only a certain part of the LMN describes the actual dynamic operating range of the process. On the other hand, when using the approach of this paper all detected model transitions take place within the convex hull U of the identification data sequence. It can not be ruled out that outside of this hull unnoticed transitions could occur. Especially for the design of controllers or observers stability close to or beyond that boundary is of only limited interest.

Note that stable local dynamics are a prerequisite of the fuzzy Lyapunov approach. Thus, for unstable local dynamics, which could lead to an improper data sequence for the determination of the model transitions, the fuzzy Lyapunov approach will fail anyway, independent to the investigated model transitions.

The information about the model transitions for the local model network under consideration will be represented by a so-called *transition matrix* $\boldsymbol{\Xi}$. It is based on the simulation result with an excitation data sequence and the method to generate it will be described in the following.

The excitation signals $\boldsymbol{u}_{\mathcal{J}}(\mathcal{K})$, which are generated by a proper DoE [13] and the model output $\hat{\boldsymbol{y}}(\mathcal{K})$, which is generated by simulating the process using the considered LMN with the

excitation signal, are merged to a matrix

$$\boldsymbol{L}(k) = [\boldsymbol{u}_{\mathcal{J}}(k-\mathcal{M})\ \hat{\boldsymbol{y}}(k-\mathcal{N})],\ \forall k \in \mathcal{K},\ \boldsymbol{L} \in \mathbb{R}^{K \times O} \quad (28)$$

which rows correspond to the input vector $\boldsymbol{z}(k)$. The ordered set for the samples of the data sequence is given by

$$\mathcal{K} = (k \in \mathbb{N} | 1 \leq k \leq K) \quad (29)$$

where K is the number of samples. Those signals which are used as input arguments to the validity function form a subset of the data sequence. The choice of such a particular subset is strongly dependent on the system's nonlinearities and is thus usually done by the user. The input arguments to the validity function are denoted by $\tilde{\boldsymbol{L}}$ indicating that it is a sub-matrix of $\boldsymbol{L}$:

$$\tilde{\boldsymbol{L}} = \boldsymbol{L}(\mathcal{K}, \tilde{\mathcal{O}}),\ \tilde{\boldsymbol{L}} \in \mathbb{R}^{K \times \tilde{O}} \quad (30)$$

which rows correspond to $\tilde{\boldsymbol{z}}(k)$. Consequently the output of a validity function $\boldsymbol{C}$ can be formulated as

$$\boldsymbol{C}(\mathcal{K}, \mathcal{I}) = \Phi_{\mathcal{I}}(\tilde{\boldsymbol{L}}(\mathcal{K})),\ \boldsymbol{C} \in \mathbb{R}^{K \times I}. \quad (31)$$

When the state trajectory evolves over time and transits through different local models a matrix of indices of the two most dominant local models $\boldsymbol{D}$ (= local models with maximum Φ) can be generated in a similar way as $\boldsymbol{L}$ by using $\boldsymbol{C}$:

$$\begin{aligned}\boldsymbol{D}(k) = [&\{i_1 | \boldsymbol{C}(k, i_1) = \max(\boldsymbol{C}(k, \mathcal{I}))\} \\ &\{i_2 | \boldsymbol{C}(k, i_2) = \max(\boldsymbol{C}(k, \mathcal{I} \setminus i_1))\}], \\ &\forall k \in \mathcal{K},\ \boldsymbol{D} \in \mathbb{N}^{K \times 2}. \quad (32)\end{aligned}$$

The matrices $\boldsymbol{C}$ and $\boldsymbol{D}$ inherently contains the relevant information required to determine the actual model transitions. They are used to generate the *transition matrix* $\boldsymbol{\Xi}$ which compactly describes possible local model transits for the local model network under consideration. $\boldsymbol{\Xi}$ is a square matrix with boolean entries and has the following properties:

$$\dim \boldsymbol{\Xi} = I \times I \quad (33)$$

$$\boldsymbol{\Xi}(\xi_r, \xi_c) \in \{0, 1\},\ \forall \xi_r, \xi_c \in \mathcal{I} \quad (34)$$

The elements of $\boldsymbol{\Xi}$ can be interpreted as follows:

$\boldsymbol{\Xi}(\xi_r, \xi_c) =$1 if there is a transition from model ξ_r to ξ_c
and zero otherwise

Note that $\boldsymbol{\Xi}$ is generally *symmetric*, because the fuzzy Lyapunov approach requires that (24) is fulfilled for both interacting models.

To generate the transition matrix $\boldsymbol{\Xi}$ two steps are necessary:

① *Initialize $\boldsymbol{\Xi}$ as identity matrix*

$$\boldsymbol{\Xi} = \boldsymbol{I}_I \quad (35)$$

The main diagonal entries which formally refer to an interaction of a local model with itself must be set to one since the fuzzy Lyapunov approach requires stable local models.

② *Set the occurring model transitions*
From (32) the two most dominant local models are determined for each sample. A valid transition is detected whenever the dominant models change or when the validity functions do not change:

$$\begin{aligned}\boldsymbol{D}(k,1) = \boldsymbol{D}(k-1,2) \wedge \boldsymbol{D}(k,2) = \boldsymbol{D}(k-1,1) \vee \\ \boldsymbol{C}(k,\mathcal{I}) = \boldsymbol{C}(k-1,\mathcal{I}) \wedge \boldsymbol{D}(k,\mathcal{I}) = \boldsymbol{D}(k-1,\mathcal{I}), \\ \forall k \in \mathcal{K} \quad (36)\end{aligned}$$

Condition (36) is examined for all rows of $\boldsymbol{C}$ and $\boldsymbol{D}$, respectively. The detected transition directly follows when (36) is true for a k and the respective entry is set in the transition matrix:

$$\begin{aligned}\boldsymbol{\Xi}(\boldsymbol{D}(k-1,1), \boldsymbol{D}(k,1)) = \\ = \boldsymbol{\Xi}(\boldsymbol{D}(k,1), \boldsymbol{D}(k-1,1)) = 1 \quad (37)\end{aligned}$$

Using $\boldsymbol{\Xi}$ for the fuzzy Lyapunov approach (24) the set Ω_i corresponds to the i-th row of $\boldsymbol{\Xi}$:

$$\Omega_i = \{j | \boldsymbol{\Xi}(i,j) = 1,\ \forall j \in \mathcal{I}\},\ \forall i \in \mathcal{I} \quad (38)$$

V. Examples

In section V-A a simple example exemplarily shows a single transition from one model to another. The effectiveness of the fuzzy Lyapunov approach in conjunction with the proposed method is demonstrated by means of an illustrative nonlinear process in section V-B.

A. Single Transition

Fig. 5 illustrates an exemplary trajectory of an identification data sequence with constant input $u(k)$ and the 50% contour lines of the validity functions of the local models. The timestep from $k = 2$ to $k = 3$ is considered in detail.

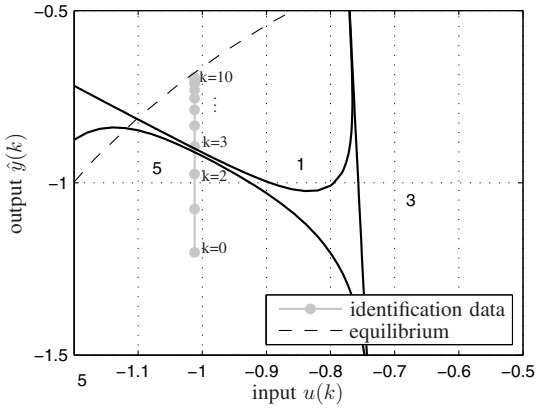

Fig. 5. Trajectory within partition space

The analysis of the trajectory by the method proposed in this paper is illustrated in Fig. 6.

The upper plot of Fig. 6 shows the system output over time, the middle one shows how the validity function outputs of local models 1 and 5, and the bottom one illustrates how the two most dominant models were determined by (37).

At $k = 2$ local model 5 is most dominant $(D(2,1) = 5)$ and

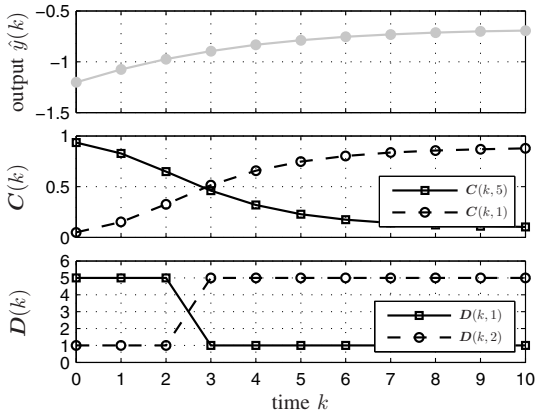

Fig. 6. Validity sequence

at $k = 3$ $(D(3,1) = 1)$ which indicates that model 1 is now dominating:

$$\boldsymbol{D}(2,1) = 5,\ \boldsymbol{D}(2,2) = 1,\ \boldsymbol{D}(3,1) = 1,\ \boldsymbol{D}(3,2) = 5 \quad (39)$$

Thus, according to (36) a valid transition is detected and the corresponding entry is set in the transition matrix according to (37):

$$\boldsymbol{\Xi}(5,1) = \boldsymbol{\Xi}(1,5) = 1$$

B. Nonlinear Dynamic Process

For illustrative purposes a nonlinear dynamic process is considered, which possesses strongly operating point dependent dynamics. This process is adopted from [9], [19] and can be described by the following difference equation:

$$\begin{aligned} y(k) &= 0.133u(k-1) - 0.0677u(k-2) + 1.5y(k-1) \\ &\quad - 0.7y(k-2) + u(k)[0.1y(k-1) - 0.2y(k-2)] \end{aligned} \quad (40)$$

In this example the input $u(k)$ is bounded to the interval $[-1.5\ 0.5]$.

Fig. 7 demonstrates that the system has weakly damped oscillatory behavior for large inputs whereas for small inputs strongly damped aperiodic behavior is present. For system

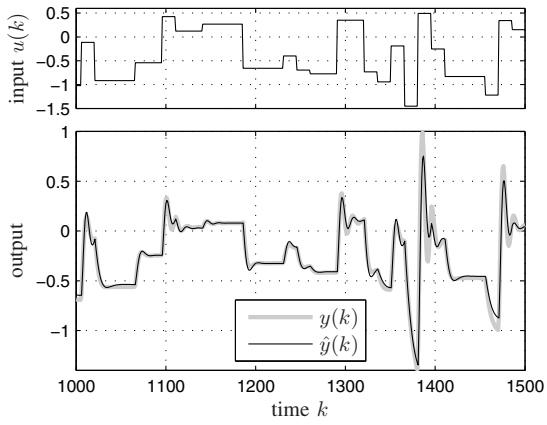

Fig. 7. In- and output of the system and the LMN

identification an excitation signal was generated to capture both the nonlinear dynamic and static behavior, [13].

From these data a local model network comprising six local models was generated by the algorithm presented in [10], where the local models are defined by an axis oblique decomposition of the partition space. Fig. 8 shows the partition space

$$\tilde{\boldsymbol{x}}(k) = [u(k-1)\ \hat{y}(k-1)] \quad (41)$$

as well as the identification data. The partitioning strategy of [10] uses statistical methods to avoid overfitting by local models generated with only few points.

The comparison of the system output and the output of the LMN in Fig. 7 shows that the LMN is accurately approximating the system within the whole operating range. The following system

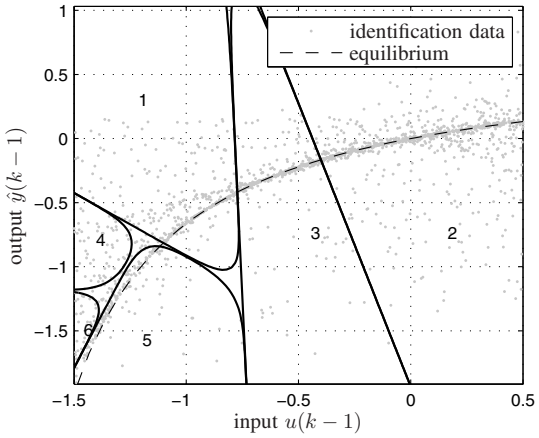

Fig. 8. Partition space and identification data sequence

matrices are obtained from the LMN when the discrete-time transfer functions of the local linear dynamics are represented in controllability canonical form:

$$\begin{aligned} \boldsymbol{A}_1 &= \begin{bmatrix} 0 & 1 \\ -0.71 & 1.668 \end{bmatrix},\ \boldsymbol{A}_2 = \begin{bmatrix} 0 & 1 \\ -0.736 & 1.525 \end{bmatrix} \\ \boldsymbol{A}_3 &= \begin{bmatrix} 0 & 1 \\ -0.622 & 1.488 \end{bmatrix},\ \boldsymbol{A}_4 = \begin{bmatrix} 0 & 1 \\ -0.844 & 1.832 \end{bmatrix} \\ \boldsymbol{A}_5 &= \begin{bmatrix} 0 & 1 \\ -0.767 & 1.74 \end{bmatrix},\ \boldsymbol{A}_6 = \begin{bmatrix} 0 & 1 \\ -0.733 & 1.702 \end{bmatrix} \end{aligned} \quad (42)$$

The local models have very different damping ratios, Fig. 9 shows their eigenvalues for illustration.

Fuzzy Lyapunov Approach with Transition Determination

The following transition matrix is generated using the proposed method of section IV):

$$\boldsymbol{\Xi} = \begin{bmatrix} 1 & 0 & 1 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 1 & 1 & 1 \end{bmatrix} \quad (43)$$

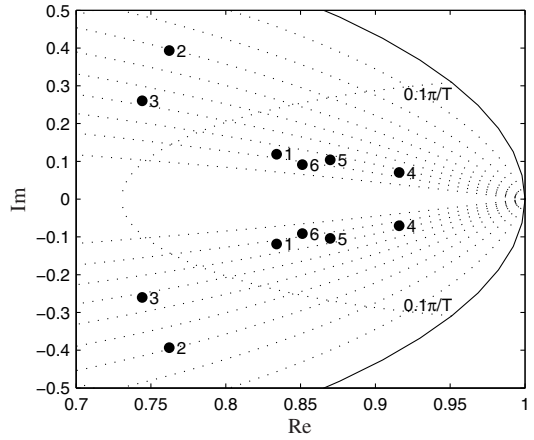

Fig. 9. Eigenvalues of the local models

Defining the model transitions Ω_i, according to (38) with (43):

$$\begin{aligned}&\Omega_1 = \{1,\ 3,\ 4,\ 5\},\ \Omega_2 = \{2,\ 3\},\\ &\Omega_3 = \{1,\ 2,\ 3,\ 5\},\ \Omega_4 = \{1,\ 4,\ 5,\ 6\},\\ &\Omega_5 = \{1,\ 3,\ 4,\ 5,\ 6\},\ \Omega_6 = \{4,\ 5,\ 6\}\end{aligned} \tag{44}$$

for the fuzzy Lyapunov approach, according to Theorem 2 and using the MATLAB LMI Toolbox® the following positive definite $\boldsymbol{P}_i$ matrices are determined:

$$\boldsymbol{P}_1 = \begin{bmatrix} 0.14 & -0.152 \\ -0.152 & 0.175 \end{bmatrix},\ \boldsymbol{P}_2 = \begin{bmatrix} 0.715 & -0.726 \\ -0.726 & 0.856 \end{bmatrix}$$
$$\boldsymbol{P}_3 = \begin{bmatrix} 0.082 & -0.086 \\ -0.086 & 0.1 \end{bmatrix},\ \boldsymbol{P}_4 = \begin{bmatrix} 0.191 & -0.209 \\ -0.209 & 0.237 \end{bmatrix}$$
$$\boldsymbol{P}_5 = \begin{bmatrix} 0.148 & -0.162 \\ -0.162 & 0.188 \end{bmatrix},\ \boldsymbol{P}_6 = \begin{bmatrix} 0.139 & -0.153 \\ -0.153 & 0.177 \end{bmatrix}$$

which satisfy (23) and (24). Thus it is guaranteed, that the considered LMN is asymptotically stable within U.

Common Quadratic- and Fuzzy Lyapunov Approach without Transition Determination

In this section it is assumed that no information about the model transitions is available for the fuzzy Lyapunov approach. Consequently all entries of $\boldsymbol{\Xi}$ are set to one. This leads to a more conservative result, because of additional LMIs. Thus, the classic fuzzy Lyapunov approach fails to prove stability of the considered LMN with six local models.
Using the common quadratic Lyapunov approach

$$\boldsymbol{A}_i^T \boldsymbol{P} \boldsymbol{A}_i - \boldsymbol{P} \prec 0 \tag{45}$$

for all $\boldsymbol{A}_i$ of (42) it is not possible to prove stability of the nonlinear dynamic process neither because of the different dynamic behavior. This is independent of the number of local models.

Influence of the number of local models

For the considered local model network with six local models it is only possible to prove stability using the proposed concept. Using the common quadratic Lyapunov approach or the fuzzy Lyapunov approach without the proposed concept increasing the number of local models result in an increased complexity of the stability criterion because of additional LMIs. Thus, in this section the influence of the number of local models and the number of the considered transitions on the stability criteria will be shown. For that purpose four different local model networks, comprising tree to six local models, are compared in the following. These local model networks are generated utilizing the same identification data sequence. Fig. 10 illustrated that the complexity of the local model network is generally increased by the number of local models.

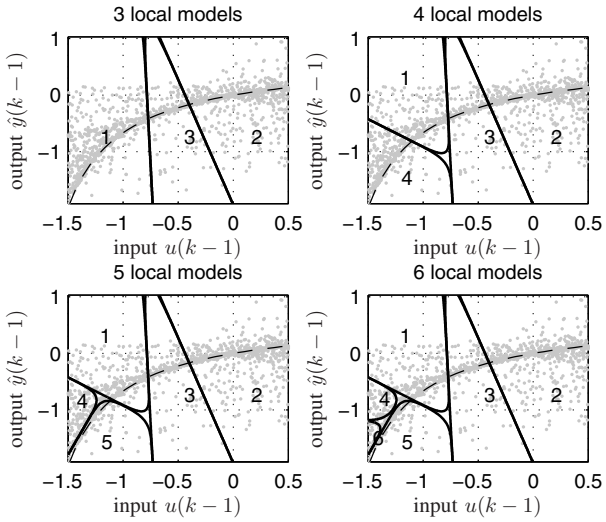

Fig. 10. Partition Space of local model networks with different number of local models

Fig. 11 shows that the complexity of the fuzzy Lyapunov approach can be significantly reduced by using the proposed method, particularly for local model networks with an high number of local models.

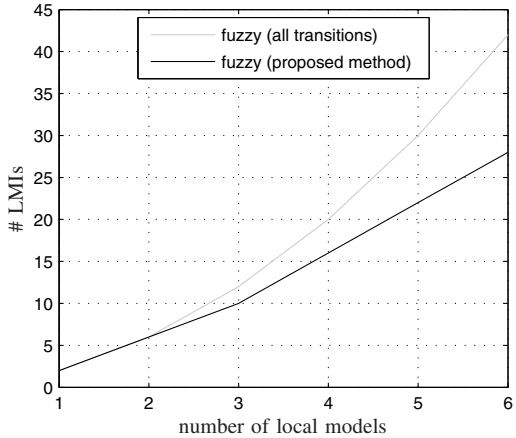

Fig. 11. Number of LMIs for different stability criterions and different number of local models

Table I shows an overview of the common quadratic Lyapunov approach, the fuzzy Lyapunov approach with all transitions and the fuzzy Lyapunov approach using the proposed method. Further, the influence of the number of local models on the stability criteria is presented utilizing the considered nonlinear dynamic process.

TABLE I
NONLINEAR DYNAMIC PROCESS: STABILITY CRITERIA

Method	# LMI variables	# LMIs	stable
6 local models			
common quadratic	1	7	
fuzzy (all transitions)	6	42	
fuzzy (proposed method)	6	28	✓
5 local models			
common quadratic	1	6	
fuzzy (all transitions)	5	30	✓
fuzzy (proposed method)	5	22	✓
4 local models			
common quadratic	1	5	
fuzzy (all transitions)	4	20	✓
fuzzy (proposed method)	4	16	✓
3 local models			
common quadratic	1	3	
fuzzy (all transitions)	3	12	
fuzzy (proposed method)	3	10	✓

The analysis of Table I shows that the conservatism of the Lyapunov approach can be generally reduced by using the proposed method because the number of LMIs is reduced in all cases. Further, it is even possible, that the conservatism decreases when the number of local models is increased. Using the common quadratic Lyapunov approach no stability proof is possible.

VI. CONCLUSION

This article addresses the problem of stability analysis of dynamic local model networks. In order to reduce the conservatism of established Lyapunov approaches a new method for the determination of the local model transitions in a dynamic local model network is proposed. The concept can be used for arbitrary partitioning strategies and high dimensional partition spaces and uses identification data to determine feasible model transitions. For artificial local model networks, which are not generated from identification data, the concept is also applicable using a proper excitation signal.

The effectiveness of the proposed method is shown by a simulation example with the fuzzy Lyapunov approach as a stability criterion. It is demonstrated how the information inherently contained in a proper simulation data sequence can be utilized to reduce conservatism and thus to extend the applicability of established stability criteria to more sophisticated dynamic local model networks.

***Abstract*—This paper focuses on vehicle warning system based on fuzzy decision making for lane departure and forward collision avoidance for dealing with driver assistant system. The proposed system is composed of vision-based preprocessing and a fuzzy decision making. The objective of vision-based preprocessing part is lane tracking and forward vehicle detection, and provides the necessary information for fuzzy decision making to trigger the warning device. The fuzzy decision making unit can adjust the fuzzy decision rule base follow the driving behavior to increase the warning strength for lane departure and/ or forward collision.**

Keywords: lane departure, forward collision avoidance, vehicle warning system, fuzzy decision making.

I. INTRODUCTION

Traffic accident happens throughout the world in nearly every single second, the issue should be considered with high priority to deal with. A traffic environment is complicated and most sudden situations are hardly predicted. Driver-assistance systems that monitor driver intent, warn drivers of lane departures, or assist in vehicle guidance are all being actively considered [1]. Although lane position determination is an important component in driver-assistance systems, it is noticed that either lane departure assist or dynamic control assist alone is inadequate to construct a reliable driving assistant system. For drowsy or unawareness drivers, it is hazardous for both himself and other road users as the host vehicle may not be on the track of lane and keeping safety distance with the forwarding vehicles to avoid collision accident[2].

In this paper, we combine the two into a combo driving-assistant system. The concept is to create a fuzzy decision making for driver warning based on lane departure detection and forward vehicle collision detection. Therefore, this paper focuses on vehicle warning system based on fuzzy decision making for lane departure and forward collision avoidance for dealing with driver assistant system. The proposed system is composed of vision-based preprocessing and fuzzy decision making. The objective of vision-based preprocessing part is lane tracking and forward vehicle detection, and provides the necessary information for fuzzy decision making to trigger the warning device, while the increasing possibility for lane departure and/ or forward collision. The proposed system always supervises the vehicle driver on track in safe and stable velocity incorporated with collision avoidance to aid vehicle to keep safety distance apart.

In this paper, the vision-based preprocessing is composed of lane-marking tracking and vehicle detection. In the preliminary studies, we have proposed a new detection and tracking algorithm by means of Kalman Filter for lane detection [3], [4] and implemented the algorithm in a Multi-core DSP embedded system [5]. The proposed lane tracking system can reduce the operations of image data and increase the operating speed. Following the result of lane-making tracking, the region of interest (ROI) for detection forward vehicle and lane departure information can be obtained. Based on the preliminary study on collision-avoidance [6], an effective method for detecting forward vehicle was proposed in this paper.

This paper contains six sections. Section I is the Introduction. Section II describes the overview architecture of the proposed system. Section III introduces the two parts of preprocessing unit algorithm based on a moving object trajectory tracking. Section IV describes the proposed fuzzy decision making unit. The experimental results describe in Section V and conclusions in section VI.

II. SYSTEM ARCHITECTURE OVERVIEW

The proposed system, which architecture depicted as Fig. 1, consists of preprocessing unit and fuzzy making unit. The preprocessing unit is composed of lane-marking tracking (LMT) part and forward vehicle detection (FVD) part. It receives the image frames from the video camera to obtain the lane-marking area (LMA) in the image plane and lane-departure degree (LDD) follow the result of LMT. The LMA is regards as the region of interest (ROI) for FVD part to detect and compute information of the forwarding vehicle effectively. The output of FVD is velocity (V) of host vehicle, and relative distance between (D) the forward and host vehicle can be derived if a forward vehicle is detected in the ROI.

Fuzzy decision making (FDM) unit receives the outputs of preprocessing unit to identify the situations for warning decision of land-departure and/ or forward vehicle collision. When a forward vehicle is detected, the collision inference part receives V and D from FVD. Then, a predefined safety distance (SD) infers the measured D with current V to estimate time-to-collision (TTC) using a fuzzy inference. TTC is a measure for evaluating the emergent collision situation. The warning decision generates different types of alarm message based on the situations of the TTC and LDD. The proposed AFDM consists of collision inference and warning decision.

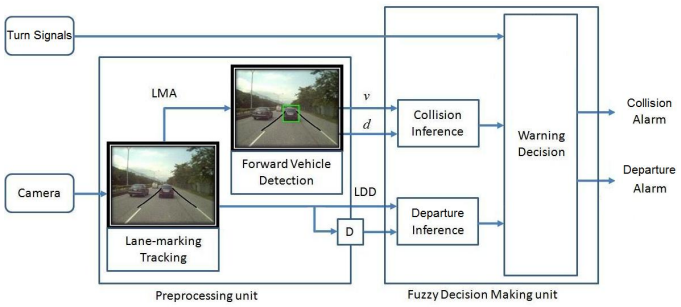

Fig. 1. Architecture of the proposed system

III. PREPROCESSING UNIT

The vision-based preprocessing unit is composed of lane-marking tracking (LMT) and forward vehicle detection (FVD).

A. Lane-marking Traking

This subsection describes the lane-marking Tracking (LMT) in detail. As shown in Fig. 2, the proposed algorithm consists of four steps.

Step 1. to convert input frame to a grayscale "R+G-B". This special intensity information can enhance the character of the lane-marking.

Step 2. to decide that an initial point is found out by lane-marking detection for initialization or updated by Nearest Neighbor Peak (NNP).

Step 3. to track the lane-marking trend. Kalman filter and NNP is used to track the trend of lane-markings in each frame. The flowchart is shown as Fig. 3. First, the tracking system is set the initial $x(0)$ which is found out from the Step 2. The predicting part is used to predict the next row of lane-marking location by NNP. If the successful measure is obtained, the predicted value will be updated by the predicting part and to next iteration. However, if the lane-marking is not a continuous type, the measure could not be found out. Therefore, Kalman filter uses the predicted location to present the trend of lane. Finally, if the iteration number k is to meet conditions which is tracking length. Then the tracking step will be stopped.

Step 4. to utilize the result of current tracking initiation to predict the tracking initiation of the next frame.

The proposed LMT algorithm needs only partial region to detect lane-marking location in each frame. The tracking results of LMT are lane-marking area (LMA) in the image plane shown as Fig. 4. The results show that it can reduce the complexity of vision data processing and meet the real-time requirements.

Fig. 4 LMA Results of LMT

B. *Forward Vehicle Detection*

This subsection describes the forward vehicle detection (FVD) in detail. As shown in Fig. 5, the proposed algorithm consists of four steps. The LMA, the tracking result from LMT, is the ROI for detecting forward vehicle in each image frames. There are three objectives of FVD. The first one is to derive the velocity of host vehicle (V) from global positioning system (GPS) module and the temporal-spatial measure between image frames. The second one is to detect the forward vehicle and calculate the relative distance (D) between forward and host vehicles. The third objective is to measure the lane-departure degree (LDD) of host vehicle for the triggering condition of the warning system.

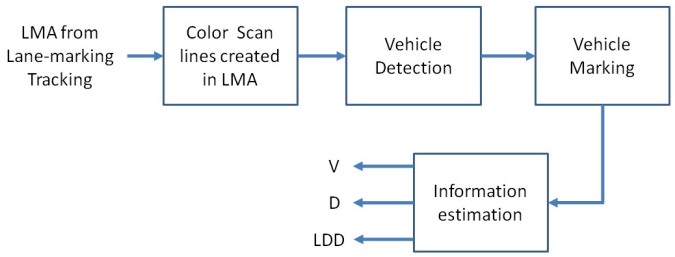

Fig. 5 Flowchart of Forward Vehicle Detection (FVD)

A set of color scan lines are created follow the obtained LMA, and convert into YCbCr color model. A threshold, L, could be decided using (1), where N denotes the total amount of scan line pixels. The set of shadowed pixels of the forward vehicle, E, is derived from (2). Following (3), the forward vehicle could be detected as V_p at the last pixel. The demonstrated examples are shown as Fig. 6. The red line is scan line. The row of detected V_p is sketched by yellow line.

$$L = \frac{\sum_{k=1}^{N} Y(k)}{N} \times \frac{3}{4} \quad (1)$$

$$E = \{e_i = e(k) \mid i = 1,2,...,n \text{ and } e(k) = k, \forall Y(k) < L\} \quad (2)$$

$$V_p = e(\text{end}),\ \text{end}: \text{the last pixel} \quad (3)$$

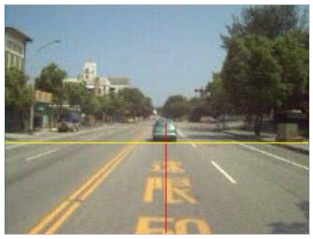
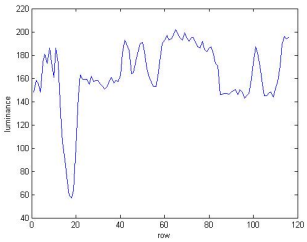
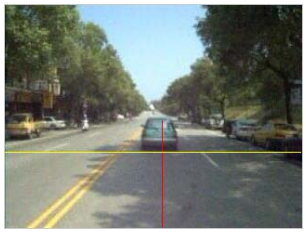
(b) Y values of scan line

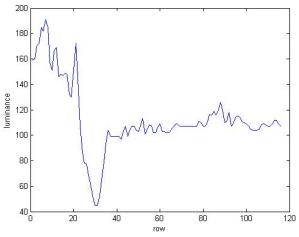


(c) marking in road



(d) Y values of scan line





(e) vehicle in shadowed road (f) Y values of scan line

Fig. 6 Vehicle detection under different road conditions

When V_p is detected, coordinate mapping relationship (CMR) performs the distance measurement. CMR is the transformation between 2-D and 3-D coordinates systems [4]. If the information of one of coordinates is given, the other is obtained by mapping procedure. The proposed CMR not only derive the distance between image frame and forward vehicle but also the height and width of forward vehicle could be measured.

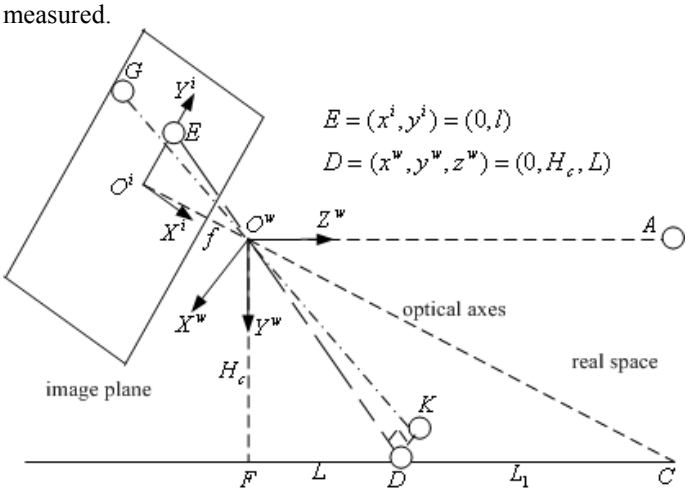


Fig 7. The geometric relationship

The geometric relationship between 2-D image plane and 3-D real-world illustrated as Fig.7. (X^i, Y^i) and (X^w, Y^w, Z^w) present the coordinate of image plane and real world respectively. O^i and O^w denote the geometric center of image plane and CCD lens respectively. H_c denote the height from O^w to ground. The focal length of CCD lens denote as f. Line $\overrightarrow{O^iO^w}$ is the focal axis of CCD and intersects to ground at point C. D and F present the shadow location of the bottom of forward vehicle and the location of CCD lens installed at host vehicle respectively. Therefore, point D is mapping to point E in image plane. Let L denotes the distance between D and F. If H_c and f are fixed, then L can be calculated by (4). In (4), $\theta_1 = \angle AO^wC$ is the depression angle of CCD which is calibrated by (5). c is half of vertical resolution of image plane (example for c=120 when image plane is 320*240). y_1 denote the location of image plane which is mapping the vanish point of road. $\triangle p_l$ is according to the resolution specification of image plane. It can be calculated by (6), where S is the diagonal length of CCD. In (4), $\theta_2 = \angle cO^wD$ is derived by (7),

where $l = \overline{O^i E}$ presents the distance in image plane which is calculated by (8).

$$L = \frac{H_c}{\tan(\theta_1 + \theta_2)} \tag{4}$$

$$\theta_1 = \tan^{-1}\left(\frac{H_c}{L_1}\right) = \tan^{-1}\left(\frac{\Delta p_l \times (c - y_1)}{f}\right) \tag{5}$$

$$\Delta p_l = S \times \frac{p_y}{\sqrt{p_x + p_y}} \times \frac{1}{p_y} \tag{6}$$

$$\theta_2 = \tan^{-1}\left(\frac{l}{f}\right) \tag{7}$$

$$l = p_l \times \Delta p_l \tag{8}$$

In Fig. 8, the size of the length of detection window l_{dw} could be calculated via (9) while the distance of the detected forward vehicle L is obtained by (4). In (9), c is half of vertical resolution of image plane (example for c=120 when image plane is 320*240), m is the vertical coordinate value of image plane which presents the bottom location of the detected forward vehicle. p_l' can be obtained from (10), where H_v and H_c denote the height and width of vehicle respectively. In (10), L_p denote the depth of 3-D space mapped to m, different L_p could derive different l_{dw}. Therefore, we require (11) to obtain L_p under different m, where θ_1 is the depression angle of CCD.

$$l_{dw} = C + p_l' - m \tag{9}$$

$$p_l' = \begin{cases} \frac{f}{\Delta p_l} \times \tan(\theta_1 - \tan^{-1}\left(\frac{H_C - H_V}{L_p}\right)) & \text{,if } H_V \le H_C \\ \frac{f}{\Delta p_l} \times \tan(\theta_1 + \tan^{-1}\left(\frac{H_V - H_C}{L_p}\right)) & \text{,if } H_V > H_C \end{cases} \tag{10}$$

$$L_p = \begin{cases} \frac{H_C}{\tan(\theta_1 + \theta_2)} & \text{,if } m \in [1, c] \\ \frac{H_C}{\tan(\theta_1 - \theta_2)} & \text{,if } m \in [c^+, 240] \end{cases} \tag{11}$$

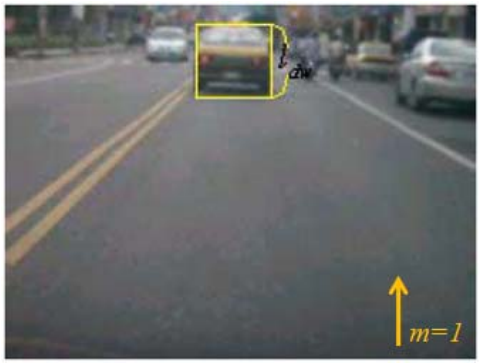

Fig. 8. The detection window of forward vehicle

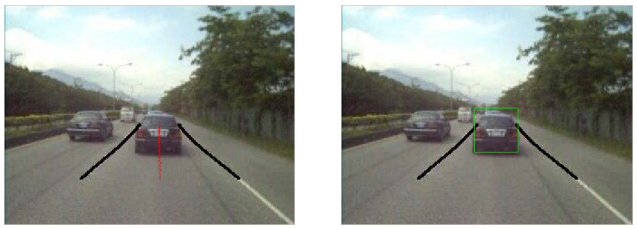
Following the two stages of preprocessing unit, Fig. 9(a) presents original situation of a red scan line created by LMT part. In Fig. 9(b), a forward vehicle can be detected by FVD part and completely marked by a precise green box. The distance between the forward and host vehicles measured by CMR is 18.14 m.



(a) original situation by L (b) detected result by FVD

Fig. 9 The result of preprocessing unit.

IV. Fuzzy Decision Making

FDM unit receives the outcomes of preprocessing unit. The objective is to identify different triggering situations under different conditions for warning decision of land-departure and/ or forward vehicle collision. When there are no detected forward vehicles, the LDD is calculated by FVD to check the departure situation of the host vehicle for lane-departure warning. When there are any forward vehicles detected by FVD, the collision inference part receives V and D from FVD. Then, a predefined safety distance (SD) infers the measured D with related V_r which is difference between V and velocity of forward vehicle, to estimate TTC for evaluating the emergent collision situation using a fuzzy inference; the departure index (DI) is estimated by departure inference simultaneously. Therefore, the warning decision generates different types of alarm message based on the situations of the TTC and LDD.

Collision inference is used to estimate dangerous level with forward vehicle, and departure inference is used to estimate host vehicle is inside the area of departure lane or not. Then, the warning decision is consider the dangerous level and alert driver. For collision inference, first, related velocity Vr between host vehicle and forward vehicle is calculated by FVD. Then, two input, D and V_r are considered to infer TTC, as Fig. 10. The domain of collision inference is defined by SD and V. It should note that boundary of domain is varied because SD and V are re-calculated in each sampling. The rule of collision inference is described as TABLE I. If D is less than SD and V_r is negative, then the TTC become small (C^+ become larger) that it represents host vehicle is near the forward vehicle. The smaller value the TTC is, the more dangerous vehicle will be.

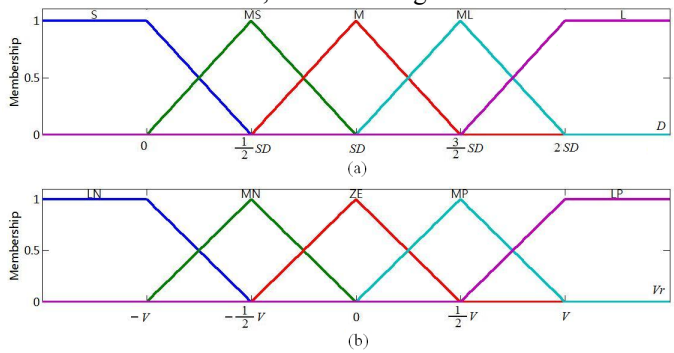


Fig. 10. The membership function of collision inference: (a) distance and (b) velocity membership function.

TABLE I. RULE TABLE FOR COLLISION INFERENCE

V_r \ D	S	MS	M	ML	L
LM	C^+	C^+	C	C^-	N
MN	C^+	C	C^-	N	S^-
ZE	C	C^-	N	S^-	S
MP	C^-	N	S-	S	S^+
LP	N	S^-	S	S^+	S^+

*C is collision index, N is normal index and S is safe index.

For departure inference, first, lane vanish point is set in center of video camera that it is ensure the vehicle locating the center of lane at initial setup. In other word, if the lane center is the center column of video frame C_{im}. Then, the right lane y_r and left lane y_l can be gotten by LMT, the lane center C_L is calculated as follows:

$$C_L = \frac{y_l + y_r}{2} \tag{12}$$

and the departure pixel P_{offset} is calculated as follows:

$$P_{offset} = C_L - C_{im} \tag{13}$$

The P_{offset} and ΔP_{offset} are consider to be input in departure inference and their membership function are designed as Fig 11. Values of both membership domains represent the departure pixel in video frame. By experiment result, it is normal driver with departure pixel form 30 to 40 on the way, and the larger ΔP_{offset} *is*, the more unusual driver is. The rule of departure inference is described as TABLE II, if P_{offset} is large negative and the ΔP_{offset} is negative, then the LDD left alarm is large; if if P_{offset} is large negative and the ΔP_{offset} is positive, then the LDD alarm is zero. Right alarm is similar to left rules.

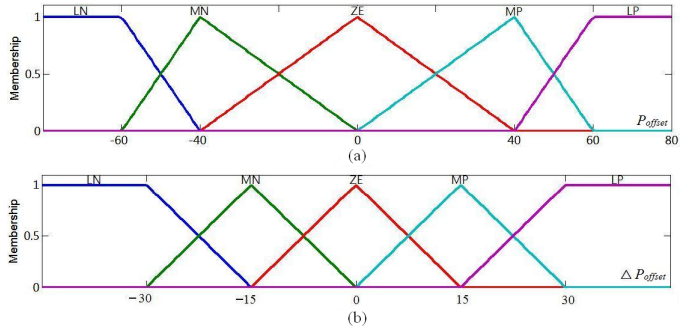

Fig. 11. The membership function of departure inference: (a) distance and (b) velocity membership function.

TABLE II. RULE TABLE FOR DEPARTURE INFERENCE

V_r \ D	LM	MN	ZE	MP	LP
LM	L^+	L	L^-	N	N
MN	L^+	L	L^-	N	N
ZE	L^-	L^-	N	R^-	R^-
MP	N	N	R^-	R	R
LP	N	N	R^-	R	R^+

*L is left departure index, N is normal index and R is right departure index.

The warning decision is used to warn the dangerous situation. When the TTC and *DI* are estimated by collision inference and departure inference, the warning decision is active to alarm that it is alert driver that this situation will be dangerous. For FVD, if the collision index is larger than safe index, the collision alarm is alerted which has several alarm level; if the departure index are larger than normal index, the departure alarm is alerted.

V. EXPERIMENTAL RESULTS

Now, it is consider the real driver behavior in the road. Experiment has two parts to show the performance of proposed system: *A*. Lane marking and forward vehicle detection, then the FVD is estimated. *B*. Lane marking, then LDD is estimated. the frame rate is 30 frame/sec in all of experiments.

A. FVD experiment

In this experiment, host vehicle accelerated to close the forward vehicle during 50 sec, the situation is shown as Fig. 12. The LMT and LDD results are shown in right column.

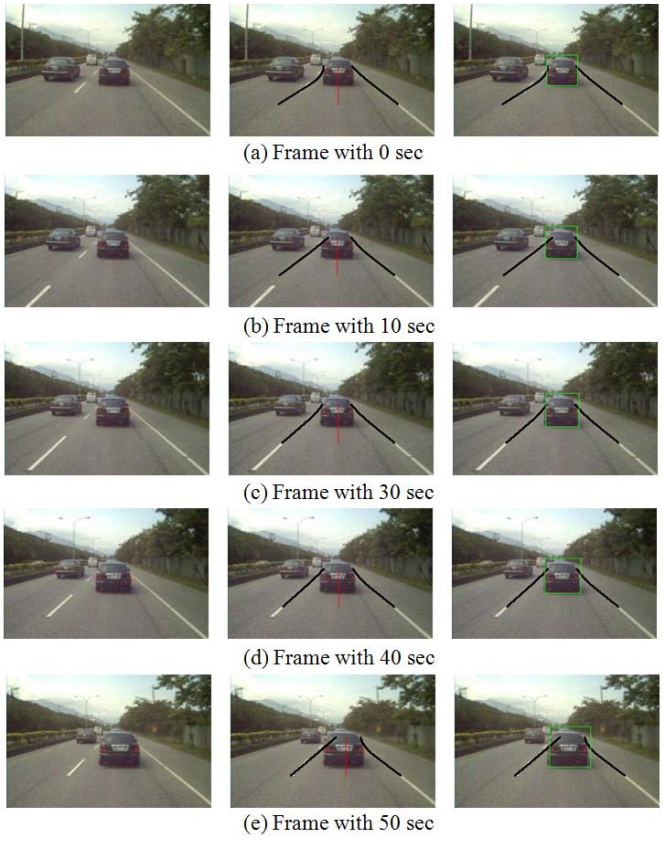

Fig. 12. Lane marking and FVD results

The result of collision inference is shown in Fig. 13, the host vehicle is safe at 20 sec ago. At 30 sec, the host vehicle approaches safety distance, however, it is alarm at 20 sec because the host vehicle accelerated to close the forward vehicle and forward vehicle braked at the same time. After 30 sec, the host vehicle accelerated still to close the forward vehicle lead alarm to be critical by the collision inference.

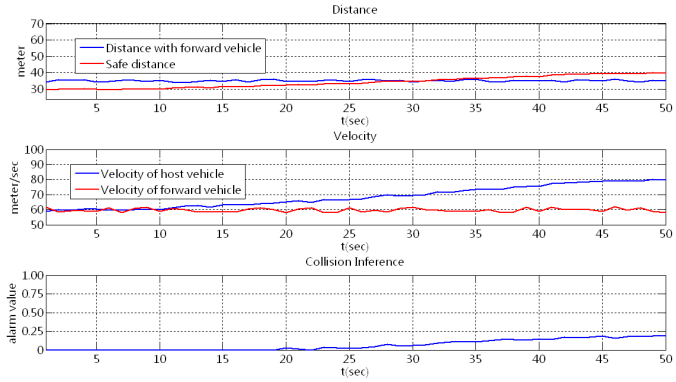

Fig. 13. The distance, velocity, and collision alarm value

B. *LDD experiment*

In this experiment, vehicle change from left lane to right lane, as Fig. 14. During total of 120 frames with 4 second, the host vehicle changes from left lane to right lane in frame 60 to 75, as Fig. 14 (g) to (h). In departure inference, the negative and positive alarm indicates that the host vehicle is departed to right side and left side respectively. In frame 68, the vehicle just enters the right lane lead inference value has a peak to indicate the left side departure from the lane center.

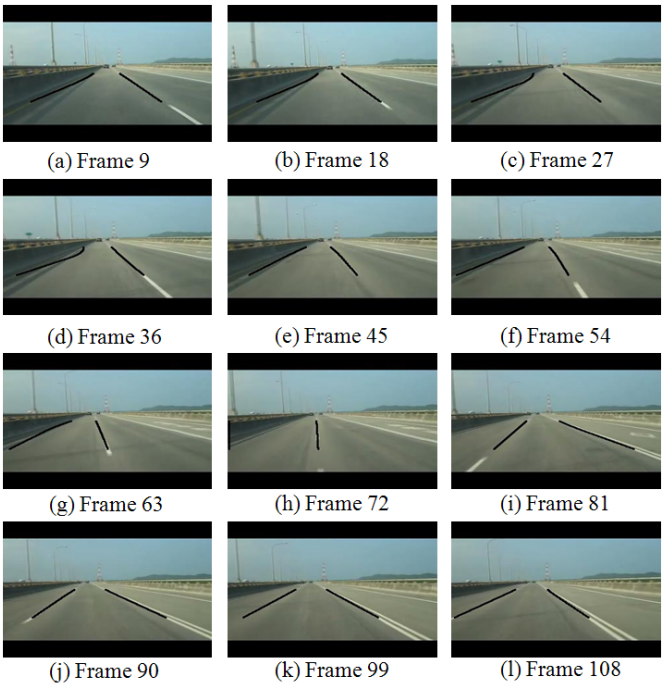

Fig. 14. Situation of change lane during 120 frames

In fact, vehicle always has departure values because video detection error and the behavioral of human driver. So the alarm has a threshold to restrain small departure value. By experiment, the threshold is set ±0.3.

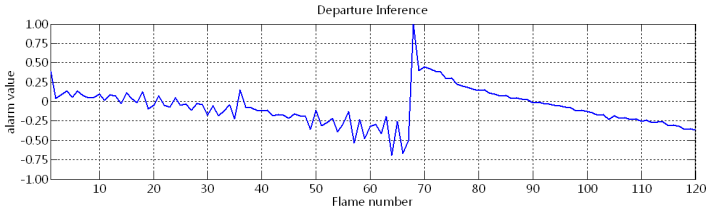

Fig. 15. The departure alarm value in departure inference

VI. CONCLUSION

This paper presents a fast lane-marking tracking, forward vehicle detection, and fuzzy inference to complete a driver assistance system for warning the situations of lane departure and the forward vehicle detection. Following the experiment results, the LMT has better preference and accuracy. Although the detection precision is influenced by the detection area and accuracy of LMT, the FVD also presents high grade. The designed fuzzy inferences are reliable to alert driver no matter departure lane or close the forward vehicle.

Centroid Density of Interval Type-2 Fuzzy Sets: Comparing Stochastic and Deterministic Defuzzification

Ondrej Linda, Milos Manic
University of Idaho
Idaho Falls, ID, USA
olinda@uidaho.edu, misko@ieee.org

Abstract— **Recently, Type-2 (T2) Fuzzy Logic Systems (FLSs) gained increased attention due to their capability to better describe, model and cope with the ubiquitous dynamic uncertainties in many engineering applications. By far the most widely used type of T2 FLSs are the Interval T2 (IT2) FLSs. This paper provides a comparative analysis of two fundamentally different approaches to defuzzification of IT2 Fuzzy Sets (FSs) - the deterministic Karnik-Mendel Iterative Procedure (KMIP) and the stochastic sampling defuzzifier. As previously demonstrated by other researchers, these defuzzification algorithms do not always compute identical output values. In the presented work, the concept of centroid density of an IT2 FS is introduced in order to explain such discrepancies. It was demonstrated that the stochastic sampling defuzzification method converges towards the center of gravity of the proposed centroid density function. On the other hand, the KMIP method calculates the midpoint of the interval centroid obtained according to the extension principle. Since the information about the centroid density is removed via application of the extension principle, the two methods produce inevitably different results. As further demonstrated, this difference significantly increases in case of non-symmetric IT2 FSs.**

I. INTRODUCTION

Type-2 Fuzzy Logic Systems (T2 FLSs), originally proposed by Zadeh [1], constitute powerful tool for dealing with dynamic uncertainty. The T2 Fuzzy Sets (FSs) introduce additional design dimension for modeling and describing the uncertainty in the specific problem domain [2]. Unlike the Type-1 (T1) FSs with fixed membership functions, the T2 fuzzy membership functions are defined using the Footprint-of-Uncertainty (FOU) offering more design degrees of freedom [3]. The defuzzification of T2 FSs contains a type-reduction phase, which acts as a mapping between the original T2 FS and the type-reduced T1 FS, also called the centroid of the T2 FS [2], [3]. Despite some new recently introduced representations of general T2 FSs such as geometric T2 fuzzy sets [4], *zSlices* [5], α - planes [6], [7] or α - cuts [8], the Interval T2 (IT2) FSs are still most commonly used [9]. IT2 FLSs have been successfully applied in a wide range of applications [10]-[15].

This paper provides a comparative analysis of two fundamentally different approaches to defuzzification of IT2 FSs [9], the Karnik-Mendel Iterative Procedure (KMIP) [16] and the sampling defuzzification method [17]. The KMIP is a deterministic approach, which concentrates on bounding the type-reduced centroid of the IT2 FS by its left-most and right-most points [18]. The sampling defuzzification method, proposed by Greenfield et al., uses stochastic sampling method to sample the set of all embedded fuzzy sets and provide an estimate of the true defuzzified value [19]. The sampling defuzzification method was developed as a cut-down version of the original exhaustive defuzzification method, which enumerates and defuzzifies all available embedded fuzzy sets [20]. Other available methods for defuzzification of IT2 FSs are the direct defuzzifier [21], the Nie-Tan method [22], or the collapsing method [23].

As demonstrated by other researchers, the KMIP method and the sampling defuzzification method do not always compute identical solutions [24]. In this paper, the concept of centroid density of an IT2 FS is introduced to provide an experimental explanation for such discrepancies. The concept of centroid density describes the histogram of defuzzified embedded fuzzy sets within the boundaries of the type-reduced centroid. It is shown through experimental study that the stochastic sampling defuzzification method converges towards the center of gravity of the proposed centroid density function. On the other hand, the KMIP method computes the midpoint of the interval centroid obtained according to Zadeh's extension principle. Because the information about the centroid density is removed via application of the extension principle, the two methods produce inevitably different results. This difference becomes especially significant in case of non-symmetric IT2 FSs.

The rest of the paper is organized as follows. Section II provides an overview of IT2 FSs together with a review of the considered defuzzification techniques. Section III introduced the concept of centroid density for an IT2 FS. The comparative analysis is presented in Section IV and the paper is concluded in Section V.

II. INTERVAL TYPE-2 FUZZY SETS

This section reviews fundamentals about the IT2 fuzzy sets together with a brief description of the defuzzification techniques considered in this work.

A. Interval Type-2 Fuzzy Sets

The IT2 FSs were introduced as a simplification to the general T2 FSs, which have been rarely applied to engineering problems due to their immense computational complexity. An IT2 FS $\widetilde{A}$ can be described as:

$$\widetilde{A} = \int_{x \in X} \int_{u \in J_x} 1/(x,u) \qquad J_x \subseteq [0,1] \tag{1}$$

Here, x and u constitute the primary and the secondary variables and J_x is the primary membership of variable x. The secondary grades of IT2 FS are all limited to 1. Hence, the IT2 FS can be completely described by its Footprint of Uncertainty (FOU), which is the area of non-zero secondary grade.

The vertical slice of an IT2 fuzzy set defines the secondary membership function. It can be obtained by instantiating the primary variable x into a specific value x':

$$\mu_{\widetilde{A}}(x = x', u) \equiv \mu_{\widetilde{A}}(x') = \int_{u \in J_{x'}} 1/u \quad J_{x'} \subseteq [0,1] \tag{2}$$

Using the concept of vertical slices the FOU can be expressed as follows:

$$FOU(\widetilde{A}) = \bigcup_{x \in X} J_x \tag{3}$$

According the Mendel-John representation theorem [25], the IT2 FS can be also seen as a collection of all its embedded fuzzy sets. An embedded fuzzy $\widetilde{A}_e$ can be described as:

$$\widetilde{A}_e = \sum_{i=1}^{N} [1/\theta_i]/x_i \qquad \theta_i \in J_{x_i} \subseteq U \in [0,1] \tag{4}$$

Using this concept the IT2 FS $\widetilde{A}$ can be also expressed as:

$$\widetilde{A} = \bigcup_{j=1}^{n} \widetilde{A}_e^j \tag{5}$$

Alternatively, the FOU of an IT2 fuzzy set $\widetilde{A}$ can be conveniently and completely described by its upper and lower membership functions $\underline{\mu}(x)$ and $\overline{\mu}(x)$:

$$FOU(\widetilde{A}) = \bigcup_{\forall x \in X} (\underline{\mu}_{\widetilde{A}}(x),\ \overline{\mu}_{\widetilde{A}}(x)) \tag{6}$$

During the output processing stage the output IT2 FS $\widetilde{B}$ must be first type-reduced, which results in the centroid of the IT2 FS $C(\widetilde{B})$ [20]:

$$C(\widetilde{B}) = \int_{\theta_1 \in J_{x_1}} \cdots \int_{\theta_N \in J_{x_N}} 1 \Big/ \frac{\sum_{i=1}^{N} x_i \theta_i}{\sum_{i=1}^{N} \theta_i} \tag{7}$$

This formula was derived using Zadeh's extension principle [28]. In the special case of IT2 FSs the centroid $C(\widetilde{B})$ is an interval T1 FS, which can be described by its left and right boundary points y_L and y_R. Finally, this interval centroid can be defuzzified to obtain the final output value.

B. Exhaustive Defuzzification

The definition of the generalized centroid of the IT2 FS presented in (7), describes the centroid as a composition of individual centroids of all of its embedded fuzzy sets. The exhaustive defuzzification method constructs this interval centroid by enumerating all the embedded fuzzy sets and calculating their respective centroids. This exhaustive algorithm for defuzzification of general T2 FSs can be adapted for the case of IT2 FSs as follows [20]:

Step 1: Enumerate all possible interval type-2 embedded fuzzy sets. The are $n = \prod_{i=1}^{N} M_i$ embedded fuzzy sets, where N is the resolution of the primary domain and M_i is the resolution of the secondary domain at the i^{th} slice.

Step 2: For each embedded fuzzy set find the minimum secondary grade. This is trivial as all secondary membership grades equal to 1.

Step 3: For each embedded fuzzy set calculate the domain value of the centroid of the type-2 embedded fuzzy set.

Step 4: Pair the computed domain value from **Step 3** with the secondary grade of 1.

Step 5: For each unique domain value, the maximum secondary grade is selected. In case of IT2 FSs, this means that only a single record about a defuzzified embedded FS is kept for each unique domain value.

The set of ordered pairs defines the centroid. The crisp output can then be calculated as the average of all calculated centroid coordinates. The average will be uniformly weighted, as the secondary grade of each defuzzified embedded FS equals to 1. Note that if the primary domain is considered to be continuous as opposed to the discretized one, the centroid becomes a continuous interval T1 FS.

C. Karnik-Mendel Iterative Procedure (KMIP)

The centroid of the IT2 FS is an interval T1 FS. According to Karnik and Mendel, it can be completely described by its left and right end points y_L and y_R. As derived by Karnik and Mendel, these boundary points can be expressed as in [20]:

$$y_L = \frac{\sum_{i=1}^{L} x_i \overline{\mu}_{\widetilde{B}}(x_i) + \sum_{i=L+1}^{N} x_i \underline{\mu}_{\widetilde{B}}(x_i)}{\sum_{i=1}^{L} \overline{\mu}_{\widetilde{B}}(x_i) + \sum_{i=L+1}^{N} \underline{\mu}_{\widetilde{B}}(x_i)} \quad (8)$$

$$y_R = \frac{\sum_{i=1}^{R} x_i \underline{\mu}_{\widetilde{B}}(x_i) + \sum_{i=R+1}^{N} x_i \overline{\mu}_{\widetilde{B}}(x_i)}{\sum_{i=1}^{R} \underline{\mu}_{\widetilde{B}}(x_i) + \sum_{i=R+1}^{N} \overline{\mu}_{\widetilde{B}}(x_i)} \quad (9)$$

Points L and R are important switching points computed by the KMIP algorithm. Using the boundary values of the type-reduced centroid $C(\widetilde{B})$ the final crisp defuzzified value y can be computed as the mean of the centroid interval:

$$y = \frac{(y_L + y_R)}{2} \quad (10)$$

The KMIP algorithm calculates the switching points L and R in (8) and (9) and the boundaries y_L and y_R of the centroid of the respective IT2 FS. The description of the KMIP algorithm given below was adopted from [20]. The algorithm consists of two phases, which independently compute the values of y_L and y_R. The algorithm for computing the left boundary y_L can be described in several steps as follows:

Step 1: Initialize a vector of weights w_i as follows:

$$w_i = \frac{1}{2}\left[\overline{\mu}_{\widetilde{B}}(x_i) + \underline{\mu}_{\widetilde{B}}(x_i)\right] \qquad i = 1,..N \quad (11)$$

And compute the value of y:

$$y = \frac{\sum_{i=1}^{N} x_i w_i}{\sum_{i=1}^{N} w_i} \quad (12)$$

Step 2: Find switching point k ($1 \le k \le N-1$) such that

$$x_{k+1} \le y \le x_{k+1} \quad (13)$$

Step 3: Set

$$w_i = \begin{cases} \overline{\mu}_{\widetilde{B}}(x_i) & i \le k \\ \underline{\mu}_{\widetilde{B}}(x_i) & i \ge k+1 \end{cases} \quad (14)$$

And compute the value of y' as:

$$y' = \frac{\sum_{i=1}^{N} x_i w_i}{\sum_{i=1}^{N} w_i} \quad (15)$$

Step 4: If $y' = y$, stop and set $y_L = y$ and $L = k$. Otherwise, go to **Step 5**.

Step 5: Set $y = y'$ and go to **Step 2**.

The procedure for computing the value of y_R is identical to computing y_L except that in **Step 3** different update of weights w_i is used as follows:

$$w_i = \begin{cases} \underline{\mu}_{\widetilde{B}}(x_i) & i \le k \\ \overline{\mu}_{\widetilde{B}}(x_i) & i \ge k+1 \end{cases} \quad (16)$$

The final output value is assigned to y_R and $R=k$.

In [16], the Enhanced KMIP algorithm was presented. However, the proposed enhancements only improved the convergence of the algorithm. As both approaches produce numerically identical results, only the original KMIP algorithm is considered in the rest of this paper.

D. Sampling Defuzzification

The sampling defuzzification method for T2 FS was presented and analyzed in [17], [19], [24] and [27]. This method follows the steps of the exhaustive defuzzification method. The major difference is that only a subset of randomly sampled embedded fuzzy set is considered during the calculation. According to the description in [24] the sampling defuzzification for IT2 FS can be described in several steps as follows:

Step 1: Select the required number of embedded fuzzy sets to be sampled.

Step 2: Repeat for each sample:

Step 2.1: Select an embedded fuzzy set at random.

Step 2.2: Find the domain value by defuzzifying the sampled embedded fuzzy set.

Step 2.3: Find the minimum secondary grade. In case of IT2 FSs this is trivial as the secondary grade equals to 1.

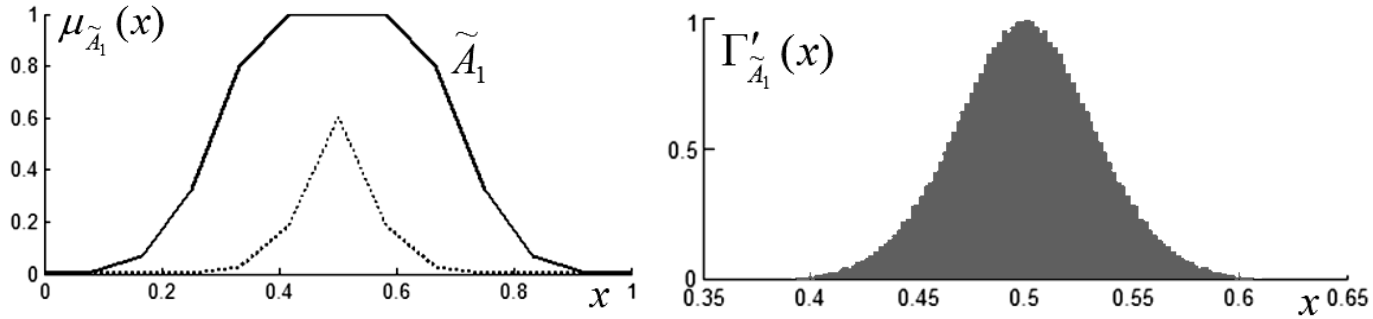
Step 2.4: Add the paired defuzzified value with its secondary grade to the list of pairs constituting the type-reduced centroid.

Step 3: Defuzzify the type-reduced centroid.

The method was experimentally tested, showing a fast convergence towards the expected defuzzification value [17]. The convergence speed was dependent on the cardinality of the sampled set. Extension to the sampling defuzzification method via using the importance sampling technique was proposed in [28]. It was demonstrated that this modification resulted in reduced statistical variance of the computed defuzzified value.

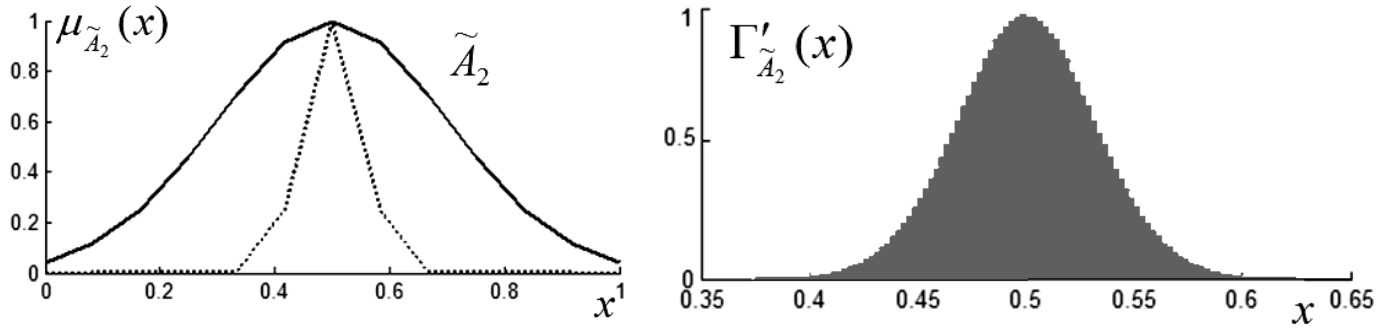
III. CENTROID DENSITY OF IT2 FUZZY SETS

The exhaustive defuzzification method defuzzifies all embedded fuzzy sets and then constructs the interval centroid



(a) (b)

Fig. 1 Interval Type-2 Gaussian fuzzy set with uncertain mean (a) and its corresponding discrete centroid density (b).



(a) (b)

Fig. 2 IT2 Gaussian fuzzy sets with uncertain standard deviation (a) and its corresponding discrete centroid density distribution (b).

as a composition of the calculated domain values. However, in **Step 5** of the exhaustive defuzzification method as described in Section II.B the set of defuzzified embedded fuzzy sets is considerably reduced. This is achieved via application of Zadeh's extension principle, which maps the IT2 FS back to its interval centroid. Here, only a single centroid of the embedded fuzzy sets per each unique domain value remains in the solution and have an impact on the geometrical properties of the final interval centroid. Hence, from the perspective of the type-reduction algorithm, all embedded fuzzy sets, which are defuzzified to an identical domain value form an equivalence class. The members of each such class are here termed *redundant* embedded fuzzy sets.

Definition 1: Two embedded fuzzy sets A_1 and A_2 are redundant if they both defuzzify into an identical domain value as $C(A_1) = C(A_2)$.

As an example, consider a group of embedded fuzzy sets that are vertically shifted in the domain of the secondary variable *u*. In **Step 5** of the exhaustive defuzzification method, those embedded fuzzy sets are treated as redundant and only a single representative one remains after the type-reduction process.

This redundancy pruning significantly simplifies the complex inner structure of the centroid. This inner structure is similar to the stratified structure of the type-reduced set presented in [19]. This paper further demonstrates that the distribution of redundant embedded fuzzy sets provides an insight into the discrepancies in the convergent behavior of the KMIP algorithm and the sampling defuzzification method [1].

Next, assume that apart from applying the extension principle, also the number of redundant embedded fuzzy sets for each unique domain value is being recorded during the exhaustive defuzzification process. The distribution function $\Gamma_{\tilde{A}}(x)$ of this quantity is denoted here as the centroid density function of the IT2 FS $\tilde{A}$.

Definition 2: The centroid density $\Gamma_{\tilde{A}}(x)$ for domain value *x* denotes the normalized number of redundant embedded fuzzy sets that are defuzzified to the identical domain value *x*:

$$\Gamma_{\tilde{A}}(x) = \alpha \sum_{i=1}^{N} f(A_i), \quad f(A_i) = \begin{cases} 0 & C(A_i) \neq x \\ 1 & C(A_i) = x \end{cases} \tag{17}$$

Here, *N* is the number of all embedded fuzzy sets, A_i is the embedded fuzzy set and α is the normalization factor, which denotes the maximum number of redundant embedded fuzzy sets for any value of the domain variable *x*, scaling it into the interval between 0 and 1.

Property 1: The value of the centroid density is zero outside the boundaries of the interval centroid:

$$\Gamma_{\tilde{A}}(x) = 0 \quad \forall\, x \notin [y_L, y_R] \tag{18}$$

Proof: By the definition of the KMIP method, bound y_L constitutes the left most location of any centroid of the available embedded fuzzy sets. Similarly, bound y_R is the right most location of any centroid of all available embedded fuzzy sets. Hence, the centroids of all embedded fuzzy sets are

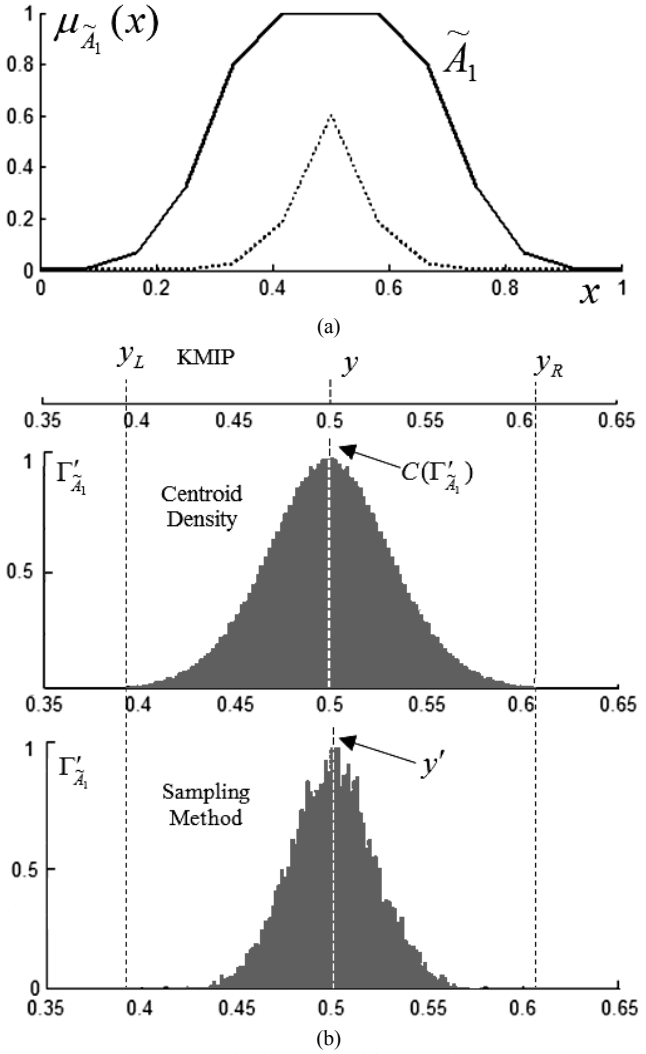


Fig. 3 Symmetric IT2 Gaussian fuzzy set with uncertain mean (a), its centroid density and the defuzzified values (b), y – center of gravity of the centroid density distribution, y ' – sampling defuzzifier.

located in this interval and the centroid density is thus zero outside this interval.

From the computational perspective, the discrete centroid density $\Gamma'_{\tilde{A}}(x)$ is more practical, since the primary domain must be discretized for practical implementations.

Definition 3: Assume that the primary domain is discretized into N samples $x_1, x_2, \ldots, x_N$ with an ε distance between two consecutive samples Then the discrete centroid density $\Gamma'_{\tilde{A}}(x_i)$ for value x_i denotes the normalized number of redundant embedded fuzzy sets that are defuzzified into the discretized interval around x_i:

$$\Gamma'_{\tilde{A}}(x_i) = \alpha \sum_{i=1}^{N} f(A_i), \quad f(A_i) = \begin{cases} 0 & C(A_i) \notin [x_i \pm \frac{\varepsilon}{2}] \\ 1 & C(A_i) \in [x_i \pm \frac{\varepsilon}{2}] \end{cases} \tag{19}$$

Again, the normalization factor α is the maximum number of redundant embedded fuzzy set for any discrete interval in the primary domain, scaling it to the interval between 0 and 1.

Finally, consider the center of gravity of function $\Gamma'_{\tilde{A}}(x)$, which can be denoted as $C(\Gamma'_{\tilde{A}})$ and computed as follows:

$$C(\Gamma'_{\tilde{A}}) = \frac{\sum_{i=1}^{N} \Gamma'_{\tilde{A}}(x_i) x_i}{\sum_{i=1}^{N} \Gamma'_{\tilde{A}}(x_i)} \tag{20}$$

An example of centroid density for two different IT2 FSs is presented in Fig. 1 and Fig. 2. The figures show symmetric Gaussian interval type-2 fuzzy set with uncertain mean and uncertain standard deviation, respectively. In both cases, variable x was discretized into 13 samples and each secondary membership function was sampled using 3 samples, leading to a total of 1,594,323 embedded fuzzy sets.

The centroid density function provides valuable insight into the inner structure of the interval centroid. The only available method for computing the centroid density function is the exhaustive defuzzification method that accounts for all available embedded fuzzy sets. However, the applicability of this approach is hindered by the vast amount of embedded fuzzy sets, which makes this method computationally intractable even for modest discretization levels.

The KMIP method offers an opposite approach. This algorithm only considers two special embedded fuzzy sets and only computes the two boundary points y_L and y_R of the interval centroid. In the final step of the KMIP defuzzification approach, the center of gravity of this interval centroid is computed as the mid-point between the boundary values y_L and y_R. One of the greatest advantages of the KMIP approach is its computational speed.

The sampling defuzzifier can be seen as a middle way between the KMIP method and the exhaustive defuzzification approach. This method approximates the final result by considering only a subset of the available embedded fuzzy sets.

IV. Experimental Results

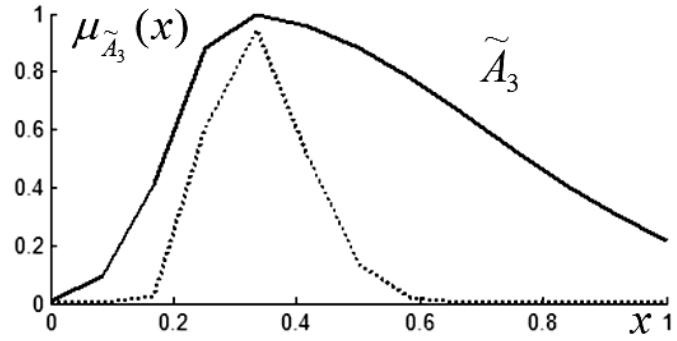
In this section the convergent behavior of the sampling defuzzifier is experimentaly compared to the deterministic result produced with the KMIP. It is shown that unlike the KMIP approach, the sampling algorithm converges towards the center of gravity of the respective centroid density distrubution function. Two types of IT2 FS are considered in the study, symmetric and non-symmetric.

A. Symmetric IT2 fuzzy sets

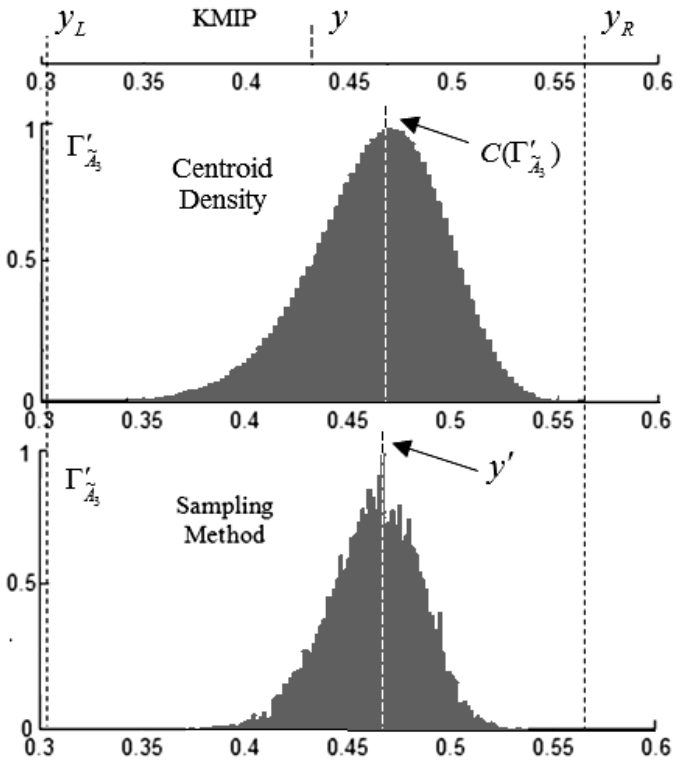
Consider a symmetric IT2 fuzzy set $\tilde{A}$ the FOU of which is symmetrical about its mean m:

$$\overline{\mu}_{\tilde{A}}(m+x) = \overline{\mu}_{\tilde{A}}(m-x) \tag{21}$$

$$\underline{\mu}_{\tilde{A}}(m+x) = \underline{\mu}_{\tilde{A}}(m-x) \tag{22}$$



(a)



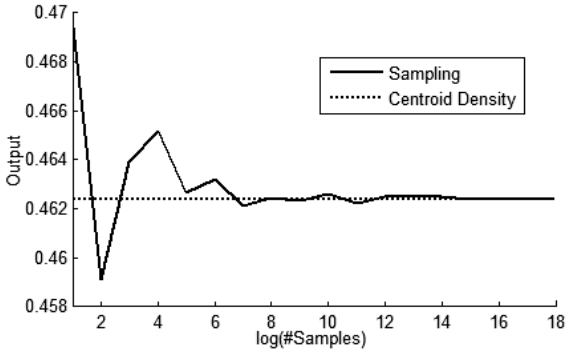
(b)

Fig. 4 Non-symmetric Interval Type-2 Gaussian fuzzy set (a), its centroid density distribution and the defuzzified values (b)), y – center of gravity of the centroid density distribution, y' – sampling defuzzifier.

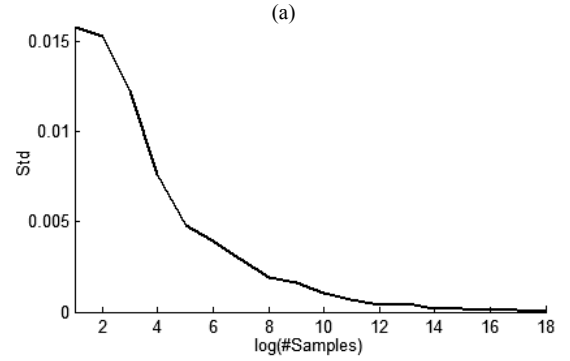
TABLE I
COMPARISON OF THE DEFUZZIFIED OUTPUT VALUES

Fuzzy Set	Centroid Density	KMIP Method			Sampling Method
	$C(\Gamma'_{\tilde{A}})$	y	y_L	y_R	y'
Symmetric	0.5	0.5	0.3940	0.3001	0.5004 ± 0.0005
Non-Symmetric	0.4624	0.4311	0.6060	0.5621	0.4625 ± 0.0003

A symmetrical Gaussian IT2 FS $\tilde{A}_1$ with uncertain mean is denoted in Fig. 3(a). The domain of FS $\tilde{A}_1$ was again discretized into 13 samples in the x domain and 3 samples for each secondary membership function yielding a total of



(a)



(b)

Fig. 5 The convergence of the mean (a) and the standard deviation (b) of the output value produced by the sampling defuzzifier with increasing number of samples.

1,594,323 available embedded fuzzy sets. This FS was first defuzzified using the KMIP algorithm. Next, the centroid density function was computed using the exhaustive defuzzification method evaluating all 1,594,323 embedded fuzzy sets. Finally, the IT2 FS $\tilde{A}_1$ was also defuzzified using the sampling defuzzifier randomly selecting only 10,000 embedded fuzzy sets. The comparison of the defuzzified values and a graphical view of the discrete centroid density function $\Gamma'_{\tilde{A}_1}(x)$ are presented in Table I and Fig. 3(b).

It can be observed, that the centroid density distribution $\Gamma'_{\tilde{A}_1}(x)$ follows approximately a symmetric Gaussian normal distribution. As demonstrated in Table I, the defuzzified values produced by the KMIP algorithm and the center of gravity of the centroid density function are in agreement. The defuzzified value produced by the sampling defuzzifier is shown to be converging towards the correct value. In order to obtain an accurate picture, the average of 20 defuzzification cycles is reported in Table I for the sampling defuzzifier, together with the standard deviation of the result.

B. Non-Symmetric IT2 Fuzzy Sets

Next, a non-symmetric IT2 FS $\tilde{A}_3$ with uncertain standard deviation was considered with its FOU as depicted in Fig. 4(a). All defuzzification methods have been applied with the same parameters as in the previous experiment.

The defuzzified values and the discrete centroid density function $\Gamma'_{\tilde{A}_3}(x)$ are reported in Table I and in Fig. 4(b). It could be observed that despite the centroid density function

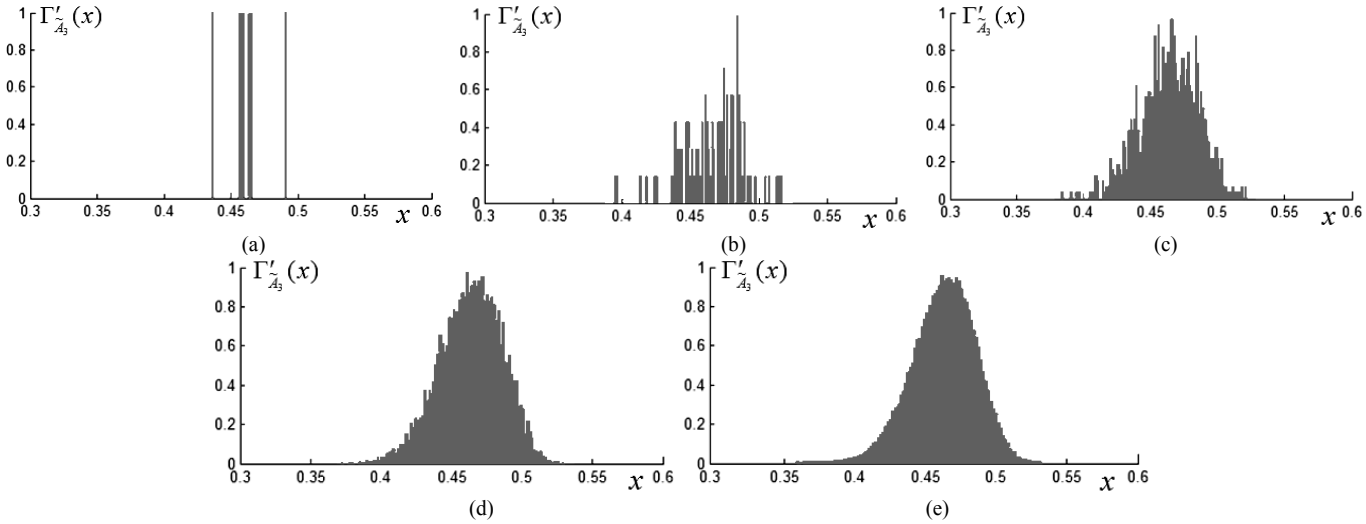


Fig. 6 The sampled centroid density distribution for the sampling defuzzifier using 10, 100, 1.000, 10.000, 100.000 (a)-(e) sampled embedded fuzzy sets.

$\Gamma'_{\tilde{A}_3}(x)$ having the nature of a Gaussian distribution, it is far from being symmetric. This observation can be attributed to the non-symmetric distribution of the width of the FOU of the original IT2 FS. This non-symmetric nature is also reflected in the centroid density function produced by the sampling defuzzification method. Both functions are shifted away from the mid-point of the centroid interval computed by the KMIP algorithm. The actual defuzzified values can be compared in Table I.

As it can be seen from the shown examples, given a non-symmetric IT2 FS, which is a typical case for the output fuzzy sets of IT2 FLSs, a significant difference between the defuzzified values produced by the KMIP algorithm and the sampling defuzzifier can be expected. The interpretation of these discrepancies is an open issue.

Recently, novel representations for general T2 fuzzy sets using α -planes [7] and *zSlices* [5] have been introduced. In [24] the results of defuzzification of α -plane based general T2 FS using the KMIP algorithm, sampling defuzzification and exhaustive defuzzification have been reported. It was demonstrated that for increasing number of α -planes the KMIP and the sampling method did not converge to identical values. The authors believe that the introduced concept of centroid density can provide further insight and explanations into such discrepancies.

C. Convergence of the Sampling Defuzzification

An additional set of experiments have been carried out in order to verify the convergence of the sampling defuzzifier towards the center-of-gravity of the centroid density function, which was computed using the exhaustive defuzzification technique. The sampling defuzzifier was applied to the non-symmetric IT2 FS $\tilde{A}_3$ depicted in Fig. 4(a). The number of sampled embedded fuzzy sets ranged from 2^2 to 2^{18}. Each experiment was repeated 20 times. The mean and the standard deviation of the defuzzified values are reported in Fig. 5. In addition, Fig. 6(a)-(e) visually demonstrates the convergence of the sampled centroid density function. From the presented results it can be noted that the sampling defuzzification method provides a steady convergence towards the center of gravity of the centroid density function.

Hence, it can be concluded that the sampling defuzzifier converges to the output value obtained by applying the weighted average to the centroid density function. On the other hand, the KMIP method computes the mid-point of the interval centroid calculated with accordance to the extension principle. The interval centroid does not maintain information about the centroid density function, since it was removed during the application of Zadeh's extension principle.

V. Conclusion

This paper presented a comparative analysis of the performance of two fundamentally different defuzzification techniques for IT2 FSs. The stochastic sampling defuzzification method and the deterministic KMIP method were considered in this work. The concepts of redundant embedded fuzzy sets and the notion of centroid density function of an IT2 FS were introduced. These novel concepts provided explanation for some of the discrepancies between the results produced by the KMIP method and the sampling defuzzifier.

It was shown that the sampling defuzzification approach converges towards the center of gravity of the centroid density function, which can be computed using the exhaustive defuzzification method. On the other hand, the KMIP algorithm calculates the results as the mid-point of the interval centroid computed with accordance to the extension principle. Since the application of the extension principle during the type-reduction removes the information about the centroid density, the KMIP and the sampling defuzzification techniques inevitable converge towards different results. This difference becomes especially significant for non-symmetric IT2 FS.

***Abstract*—In this paper we show a new statistical scheme to find the optimal cut off level in fuzzy clustering which is an improvement of Uesu and Shinkai et. al [4]~[7]. Deterministic algorithms which seek a certain equilibrium cluster level have essential disadvantage in principle. We focus in it and propose a statistical scheme via AIC.**

Keywords-component; fuzzy clustering; AIC; cut off level; partition tree

I. INTRODUCTION

When we analyze ambiguous information such as human behavior, mental process, social structure and so on, a fuzzy graph of the information is very useful in these problems (see e.g. Romsburg [3]). Since the fuzzy graph is constructed with clusters of some levels, the clustering level analysis of fuzzy graph is required for the above applications.

Let Fig.3 is a preference relationship between 26 students {1,2,…,26} of a high school. Fig.1 is a partition tree constructed from Fig.3 with 17 clustering cut off levels {**R**0.00, **R**0.08, **R**0.15, **R**0.28, **R**0.35, **R**0.38, **R**0.44, **R**0.45, **R**0.48, **R**0.54, **R**0.57, **R**0.65, **R**0.67, **R**0.71, **R**0.79, **R**0.83, **R**1.00} and there are 17 sets of clusters according to these clustering levels each other. For example the level **R**0.08 means that the set of ten points {1,2,…,26} is divided by 5 clusters {15,17}, {2,18,7,4,13,11,8,20,19,12}, {14,24,3,22,1, 26,16,5,9}, {21,25}, {6}, {10}, {23}. As for the selection of the optimal level in a partition tree in Fig.1 the gradient method in the multivariate analysis has been used very often.

On the other hand, in 1994 Tsuda and Yamashita [5] suggested a new method to estimate the optimal level to find a unique equilibrium point for the cluster number and the cluster size. It means to know a kind of stable classification of clusters for {1,2,…,26}. Their method fits in well with actual examples. Moreover Uesu and Shinkai et. al [4], [6]~[8] proposed a rational method to decide the optimal level of fuzzy clustering with a partition tree. However we have also had two questions about an objective validity of these deterministic algorithms which seek a certain equilibrium cluster level.

The first problem is that the above deterministic algorithms cannot easily make effective use of all the information of the partition tree. Especially, in principle, the gradient method uses only local information of the partition tree. From the view point we define a configuration of points {1,2,…,26} on the interval [0,16] measuring the distance between each adjoining two points in the partition tree (see Fig.3). For example, the clustering cut off level **R**0.83 implies that the distance between {2} and {18} is 0.17=1-0.83. Furthermore the distance between {14} and {27} is 0.21=1-0.79 from **R**0.79, and so on. Then we can construct a configuration of {1,2,…,26} on the interval [0,16] in Fig.3. Next we consider a distribution of the configuration. Every clustering cut off level corresponds to a histogram of the configuration, respectively. Therefore we can choose the optimal cut off level by comparing AIC of each histogram.

Figure 1. Partition tree *P*.

Another problem is "Does the true cluster level always mean an equilibrium or well balanced state?". From the point of a statistical view, we would reconsider the clustering level analysis in the past and propose a new scheme by applying the AIC method and obtain a statistically equilibrium optimal level of fuzzy clustering. Although we have proposed such statistical scheme in [2], we improve the scheme and show its

[1] The research of the first author was supported, in part, by Grant-in-Aid Scientific Research, No. 20540140, Ministry of Education, Science and Culture, Japan.

advantage to the deterministic algorithms since [2] can not apply to small sample size data.

II. UESU'S METHOD

Next, according to Uesu [7], we introduce Uesu's method to estimate the optimal clustering level for the partition tree P in Fig.1. His method shows that the optimal cut level is **R**0.38 from Fig. 2 by the following method.

Definition 1 *Crisp Node Fuzzy Graph*

A crisp node fuzzy graph G is defined by

$$G=(V,F):V=\{v_i\},F=(f_{ij}),0\le f_{ij}\le 1,$$

where V is the set of the nodes and F is an $n\times n$ matrix whose (i, j) component f_{ij} is a fuzziness of the arc from the node v_i to the node v_j.

Definition 2 *Fuzzy Node Fuzzy Graph*

A fuzzy node fuzzy graph G is defined by

$$G=(V,F):V=\{v_i/u_i\},Y=(y_{ij}),0\le u_i\le 1,\ 0\le y_{ij}\le 1,$$

where V is the set of the nodes and the fuzziness u_i is a fuzziness of the node v_i. Y is an $n\times n$ matrix whose (i, j) component y_{ij} is a fuzziness of the arc from the node v_i to the node v_j.

Definition 3 *Transformation from Fuzzy Node Fuzzy Graph to Crisp Node Fuzzy Graph*

A fuzzy node fuzzy graph $G=(V, Y)$ can be transformed to a crisp node fuzzy graph $G=(V,F)$ by the following method: Let

$$G=(V,F):V=\{v_i\},F=(f_{ij}),f_{ij}=T(u_i,y_{ij}),$$

where the fuzziness f_{ij} of the arc from the node v_i to the node v_j could be defined by applying T-norms. A fuzzy graph G is defined by

$$G=(V,Y),\ V=\{v_i\},\ F=(f_{ij}),\ 0\le f_{ij}\le 1,\ f_{ii}=1,1\le i\le n$$

where f_{ij} is a fuzziness of the arc from the node v_i to the node v_j . A symmetric relation matrix S is defined by

$$S=(s_{ij}),\quad \frac{2}{s_{ij}}=\frac{1}{f_{ij}}+\frac{1}{f_{ji}}$$

where $s_{ij}=0$ if $f_{ij}\cdot f_{ji}=0$.

Let $x(c)$ and $y(c)$ be the branching number and maximum cluster size of each Rc, respectively. The more the level Rc increases, the more the branching number $x(c)$ increases. On the other hand, the more the level Rc increases, the more the maximum cluster size $y(c)$ decreases. Since there is an inevitable trade off between the branching number $x(c)$ and the maximum cluster size $y(c)$ in this situation, we would decide the optimal cut level c_0.

Based on $x(c)$ and $y(c)$, we could define the cluster branch function $p(c)$ and the cluster size function $q(c)$ as follows:

Definition 4 The cluster branch function $p(c)$ and cluster size function $q(c)$ are defined by

$$p(c)=\frac{x(c)-1}{x(1)-1},\ q(c)=\frac{y(c)-1}{y(0)-1},$$

respectively.

Definition 5 Decision of Optimal Cut Level c_0

$$r(c)=p(c)\wedge q(c)$$

and

$$c_0=\max\{c:r(c)=\max r(x)\}. \qquad (1)$$

Then, by using these notions, an optimal cut level c_0 of the partition tree Fig.1 is decided as follows.

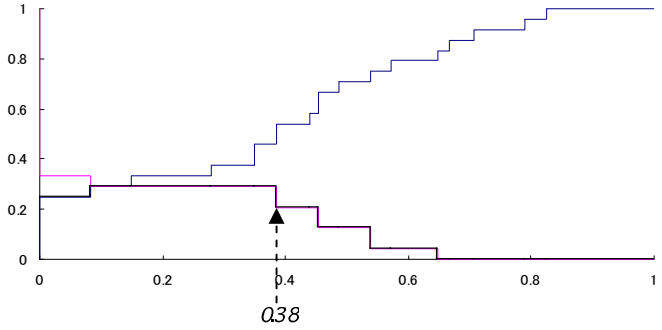

Figure 2. Fuzzy decision $r(c)$.

Applying the fuzzy decision, we obtain that the optimal cut off level is **R**0.38 as shown in Fig.2.

III. AIC

We shall define AIC as followings. Let $X_1, X_2, \ldots, X_n$ be independent and identically distributed random variables with the probability density function $f(x;\theta^*)$, where $\theta^*=(\theta_1^*,\theta_2^*,\cdots,\theta_K^*)$ is an unknown parameter of the distribution. Furthermore, for n random sample points $(x_1,x_2,\cdots,x_n)$,

$$\ell(\theta)=\sum_{i=1}^{n}\log f(x;\theta_i)$$

is the log likelihood and $\hat{\theta}_K$ is the maximal likelihood estimator for $\theta^*=(\theta_1^*,\theta_2^*,\cdots,\theta_K^*)$ defined by

$$\hat{\theta}_K=\max_{\theta\in\Theta_K}\ell(\theta),$$

where Θ_K is the space of all candidates $\theta=(\theta_1,\theta_2,\cdots,\theta_K)$ for the real parameter θ^* . The Kullback-Leibler information number $KLI(\theta^*,\theta)$ for the samples $(x_1,x_2,\cdots,x_n)$ is defined by

$$KLI(\theta^*,\theta)=\sum_{i=1}^{n}f(x;\theta^*)\log f(x;\theta^*)-\sum_{i=1}^{n}f(x;\theta^*)\log f(x;\theta),$$

which metrizes the distance between $f(x;\theta^*)$ and $f(x;\theta_i)$ using entropy. It is easy to see that $\hat{\theta}_K$ minimize the Kullback-Leibler information number $KLI(\theta^*,\theta)$ such that

$$KLI(\theta^*,\hat{\theta}_K) = \min_{\theta\in\Theta_K} KLI(\theta^*,\theta).$$

Now we define AIC (Akaike's information criterion) by

$$AIC(K) = -2\ell(\hat{\theta}_K) + 2K. \quad (2)$$

For comparing several models of $\theta^* = (\theta_1^*,\theta_2^*,\cdots,\theta_K^*)$ for known *K,* we can find the optimal $\theta = (\theta_1,\theta_2,\cdots,\theta_K)$ in Θ_K with large probability when it attains the smallest $AIC(K)$ for $(x_1,x_2,\cdots,x_n)$. In general, when *K* is unknown, $-2\ell(\hat{\theta}_K)$ decreases as the number of parameters *K* increases. Therefore $AIC(K)$ also gives the optimal *K* from the definition. By its sensitivity the AIC method is applied to various types of the model selection in many fields.

Let $\mathbf{q} = (q_1,q_2,\cdots,q_m)$ be a discrete distribution for integers $\{1,2,\cdots,m\}$. Put $\{x_1,x_2,\cdots,x_n\}$ be samples from a proportion of $\{1,2,\cdots,m\}$. Let n_i be a number of samples of each integer $i\in\{1,2,\cdots,m\}$ satisfying $n_1+n_2+\cdots+n_m = n$. From $K = m-1$ for the distribution $\mathbf{q}$, AIC of $\mathbf{q}$ is defined by

$$AIC(\mathbf{q}) = -2\sum_{i=1}^{m} n_i \log q_i + 2(m-1). \quad (3)$$

IV. Statistical Scheme via AIC

Step 1. *Find the configuration of {1,2,...,26} on the interval [0,16]. See Fig.3.*

Step 2. *Divide the interval [0,16] into 16 subintervals [i,i+1] for i=0,1,...,15.*

Step 3. *Make histograms and calculate AIC for each histogram.*

Make histogram for {1,2,…,26} according to each fuzzy clustering level. We can find which histogram (cluster level) is the best by comparing AIC's of each histogram. For example, Fig.4 and Fig.5 correspond to clustering levels $\mathbf{R}_{0.35}$ and $\mathbf{R}_{0.15}$, respectively. From (3) we have

AIC($\mathbf{R}_{0.45}$)= -2{2log[3/26] +log[3/26] + 10log[1/26] + log[2/26] + 4log[7/104]}+ 28= 132.837

AIC($\mathbf{R}_{0.44}$)= -2{3log[2/26] + log[3/26] + 8log[1/26] + 4log[7/104]} + 26= 119.426

AIC($\mathbf{R}_{0.38}$)= -2{2log[2/26] + log[3/26] + 2log[3/52] + 7log[1/26] + 5log[9/130]}+ 22= 120.306

AIC($\mathbf{R}_{0.35}$)= -2{2log[2/26] + log[3/26] + 3log[5/78] + 2log[1/26]+5log[9/130]+log[2/26]+3log[1/26]}+18= 101.83

AIC($\mathbf{R}_{0.28}$)= -2{6log[2/26] + 5log[1/26] + 5log[9/130]} + 16= 106.063

AIC($\mathbf{R}_{0.15}$)= -2{2log[2/26] + 4log[1/26] + 10log[9/130]} + 14= 92.6404

AIC($\mathbf{R}_{0.08}$)= -2{2log[2/26] + 6log[10/156] + 5log[9/130] + 3log[1/26]}+ 12= 101.479

Step 4. *Conclusion*

Since AIC($\mathbf{R}_{0.15}$) is smaller than other clustering cut off levels, we can evaluate that $\mathbf{R}_{0.15}$ is optimal.

V. Conclution

From the above statistical scheme we conclude that the optimal clustering cut off level is $\mathbf{R}_{0.15}$ which is different from Uesu's method ($\mathbf{R}_{0.38}$). Although it is difficult to discuss which level is better, we could evaluate with greater accuracy as we have a lot of criteria for judgment. Furthermore an example in [2] shows that the statistical scheme has an advantage over deterministic methods when $\mathbf{R}_{0.00}$ is the optimal cut off level. From the point of view we would like to propose the scheme in addition to deterministic methods.

Acknowledgment

The authors kindly thank three anonymous referees for their useful comments. They also would like to express their thanks to Professors H. Yamashita and T. Takizawa of Waseda University for useful discussions.

***Abstract*—In this paper, an integration of fuzzy logic controller (FLC) and genetic algorithm (GA) is developed with a view to make the design process fully automatic, without requiring any human expert knowledge. Here, GA is used in two stages simultaneously: the first stage involves selection and definition of fuzzy rules, while the second stage performs an optimal selection of membership function types associated to the fuzzy rules. It is argued that the performance of an FLC greatly depends on the fuzzy rules as well as the types of membership functions associated to the fuzzy sets. Thus, the aforementioned two-stage GA is a viable solution for designing an efficient FLC system. In order to evaluate performance, the proposed approach is applied to a well-known benchmarking controller design task, "backing up a truck reversing system". The simulation result exhibits superior performance and thereby validates the proposed integrated GA and FLC system.**

Index Terms- Fuzzy Logic Controller; Fuzzy Rule Base; Genetic Algorithm; Optimization; Backing up a truck reversing problem

I. INTRODUCTION

Fuzzy logic controllers (FLCs) have numerous practical applications in control [1], [2], prediction [3] and inference [4]. Specifically, they have been used for designing a robust controller that can yield satisfactory performance and deal with uncertainty and imprecision. However, the vast majority of FLCs developed to date are based on the expert knowledge base derived from imprecise heuristic knowledge of experienced control engineers. Such manual approach is very time-consuming as it requires trial and error method to generate fuzzy rules and membership functions (MFs). Moreover, manual design does not guarantee generating optimal or near optimal fuzzy rules and MFs [5], [6]. Clearly, there is a need for developing an automatic FLC design procedure that would not involve any expert knowledge base derived from heuristic knowledge of experienced control operators/engineers.

The main issue in the FLC design includes deciding membership functions' parameters and types, and generating fuzzy rules. Even though all of these are subject to optimization for a better design, many efforts has been directed to the partial optimization, not the entire system. For example, some works optimize the parameters of MFs, while others optimize the fuzzy rules. The parameters of MFs are either decided on the basis of control operator's/person's experience or are generated automatically. Some methods, such as genetic algorithm (GA), tabu search (TS), particle swarm optimization (PSO) and self-organizing feature map (SOFM) can be used to improve the behavior of this parameter optimization problem [5]-[8], [9], [10].

GA was used by Arslan and Kaya [9] in the determination of membership functions. They applied GA to design a fuzzy logic control system having a single input and output. Bagis [6] proposed a method based on TS algorithm for the determination of membership functions. Bai and Chen [7] proposed an automatic method for students' evaluation task. Its purpose was to automatically construct the grade membership functions of lenient-type grades, strick-type grades, and normal-type grades of fuzzy rules, respectively. The system performs fuzzy reasoning to infer the scores of students based on the constructed grade-membership functions. Meredith et al. [11] presented an approach based on GA to the tuning of membership functions in a FLC for a helicopter. Wong et al. [8] applies PSO to determine appropriate membership functions of the fuzzy system (FS) automatically and presented a motion control structure with a distance fuzzy controller and an angle fuzzy controller for the two-wheeled mobile robot. Yang and Bose [10] presented a method for generating fuzzy membership functions with unsupervised learning using SOFM. The SOFM approach is a two-step procedure: firstly, generate the proper clusters and secondly, generate the fuzzy membership function according to the clusters in the first step. They applied this method to pattern recognition problems.

In this paper, an integrated architecture of FLC and GA has been developed for intelligent control of backing up a truck reversing problem. Here, GA is employed in two simultaneous stages; the first one, referred in this paper as module-1, for the selection and definition of fuzzy rules and the second one, module-2, for the selection of membership function type of each rule. The suggested method can deal with any type of membership functions (i.e., fuzzy sets). The method focuses on finding an optimum set of fuzzy rules and their respective types of membership functions. It is shown that the proposed innovative integrated architecture can generate comprehensible and reliable fuzzy rules and at the same time select the effective type of fuzzy sets (MFs) for each rule by a self-learning adaptive method.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

The organization of this paper is as follows: in Section II, we review the literature relevant to the FLCs. In Section III, we provide key ideas of integrated FLC and GA architecture and discuss how GAs can be used to generate a satisfactory fuzzy rule base and to select appropriate types of MFs simultaneously for FLCs. We also show how our proposed approach can be used to solve highly nonlinear complex problems such as backing up a truck control. In Section IV, we explain the problem of backing up a truck in a greater detail. In Section V we present our simulation results and finally section VI presents some concluding remarks based on the present study conclusions and some future directions.

II. FUZZY LOGIC CONTROLLER (FLC)

An FLC comprises four components, which are fuzzifier, knowledge base consisting of rule base (RB) and database (DB), fuzzy inference engine, and defuzzifier as depicted in Fig.1. The FLC works as follows, the crisp inputs are first fuzzified into, in general, input fuzzy sets (however, we will consider only non-singleton fuzzification) which then activate the inference engine and the knowledge base to produce output fuzzy sets. The defuzzifier can then defuzzify fuzzy outputs from the inference engine in order to produce crisp outputs. A brief description of each of the FLC components is given in the following subsections.

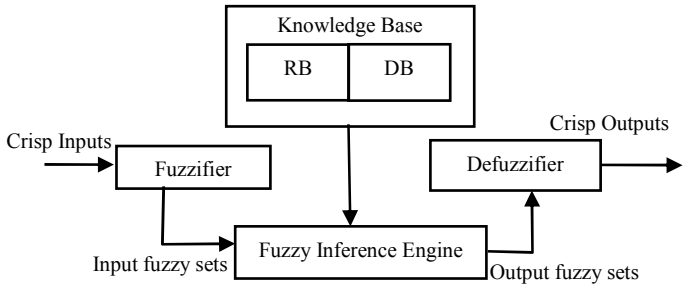

Figure 1. Fuzzy Logic Controller (FLC)

A. Membership functions

Triangular/Trapezoidal MF:

It has the function name *trimf* defined by three points delimiting a triangle.

$$f_{triangulae}(x)=\begin{cases}0, & \text{if } x<x_1\\ 2\dfrac{x-x_1}{x_2-x_1}, & \text{if } x_1\le x\le \dfrac{x_2+x_1}{2}\\ 2\dfrac{x_2-x}{x_2-x_1}, & \text{if } \dfrac{x_2+x_1}{2}<x\le x_2\\ 1, & \text{if } x>x_2\end{cases} \quad (1)$$

Gaussian MF:

Gaussian membership functions are built on the Gaussian distribution curve and are denoted by *gauss_mf*.

$$f_{Gaussian}(x)=e^{-0.5y^2} \quad \text{where } y=\frac{8(x-x_1)}{x_2-x_1}-4 \quad (2)$$

B. Fuzzifier

Since the input is in crisp normalized values, a fuzzification operator *fuzz* is used to fuzzify it in fuzzy form. The fuzzifier maps a crisp input vector with p inputs $x=(x_1,.....x_p)^T \in X_1\times X_2\times.....\times X_p\equiv X$ into input fuzzy set, A_x In Non-singleton fuzzifier: $\mu_A(x_i)$ realizes maximum value 1 at $x=x_i$ and decrease from 1 to 0 while moving away from $x=x_i$ [12]. The fuzzification of the input variable should be realistic. Experience and different procedures as well as different types of MFs should be followed while designing a large fuzzy system for the realistic and accurate output. The wrong fuzzification of the input variable(s) might cause instability and error in the system. Figure 2 shows how fuzzified inputs are calculated from its related different membership forms.

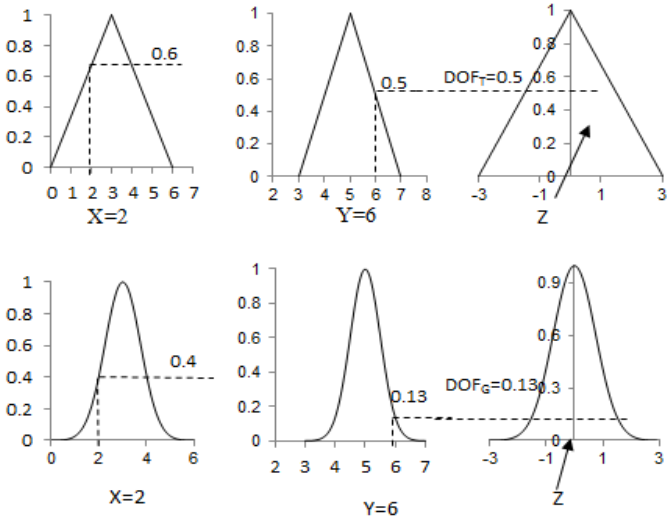

Figure 2. Two different kinds of fuzziness degrees (depends on type of MFs) for a crisp value X=2 and Y=6

C. Fuzzy Inference Engine

The fuzzy inference engine combines rules and gives a mapping from fuzzy sets in the input universe of discourse $U\in R^n$ to fuzzy sets in the output universe of discourse $V\in R$ based on the fuzzy logic principle. In the inference engine, multiple antecedents in the rules are connected using AND operation, and the degree of membership in the input set sets are combined using those in the output sets using sub-star composition, described in detail in [13]. Multiple rules are then combined by using a join operation.

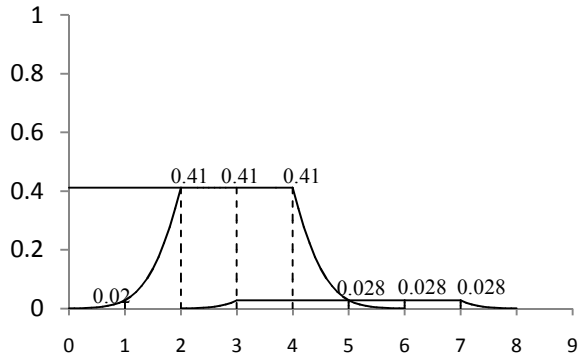
D. Defuzzifier

The defuzzifier performs a mapping from the fuzzy sets in R to crisp points in R. It involves the selection, from the output fuzzy set, the numerical value v^* which can be considered as the best representative element of the fuzzy output set. Maximum defuzzifier produces a numerical value which exhibits the highest degree of membership. The most frequently used center of gravity (COG) defuzzifier takes output as the COG of the fuzzy output. The expression generally used for a discrete fuzzy set is as follows:

$$x_{n+1} = \frac{\int_{X \in U_{n+1}} X \mu_U(X) dX}{\int_{X \in U_{n+1}} \mu_U(X) dX} = \theta^{COG} = \frac{\sum_{j=1}^{p} \theta_j m_o(\theta_j)}{\sum_{j=1}^{p} m_o(\theta_j)}$$

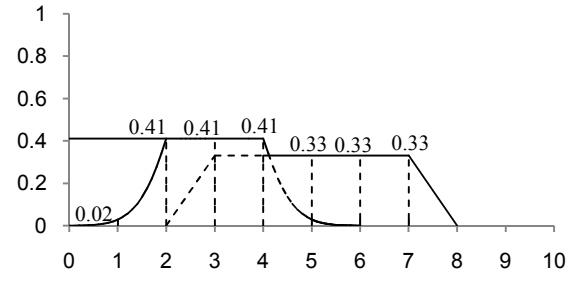
where θ_j denotes the center of gravity (COG) of the consequent label C_j of the rule R_j, $m_o(\theta_j)$ is the firing strength of this rule, and p is the number of rules.

Consider a fuzzy controller with one output variable, and suppose that a given input datum excites two rules of the rule base. Now defuzzification process would yield an output value according to the membership function types associated to linguistic output labels of the two rules. In order to explicate this fact, we consider two cases; gaussian, and mixed MFs. Figure 3 shows that in each case results are different defuzzified value. However, it is easily conceivable that some value would be better than the others. Thus we need a way to define different member function types across the rule base. Some rule may prefer a particular type of MF than the others so as to make an optimal final decision.



(a) Gaussian MFs for FLC

$$x_{n+1} = \frac{1*0.028 + 2*0.41 + 3*0.41 + 4*0.41 + 5*0.028 + 6*0.028 + 7*0.028}{0.028 + 0.41 + 0.41 + 0.41 + 0.028 + 0.028 + 0.028} = 3.14$$



$$x_{n+1} = \frac{1*0.028 + 2*0.41 + 3*0.41 + 4*0.41 + 5*0.33 + 6*0.33 + 7*0.33}{0.028 + 0.41 + 0.41 + 0.41 + 0.33 + 0.33 + 0.33} = 4.31$$

(b) Mixed MFs (Gaussian and Triangular) for FLC

Figure 3. Effect of defuzzification process for selecting different types of MFs

The value of fuzzified and defuzzified may vary according to the type of MFs (Fig. 2 & 3). In this study, the effect of the type of the MF on fuzzification and defuzzification process to construct the fuzzy model is investigated along with the selection and definition of fuzzy rules.

E. Fuzzy Rule Base

The general form of a fuzzy rule used in most FLCs is as follows:

IF (*a* set of condition is satisfied)

THEN (a conclusions can be inferred)

Each fuzzy IF-THEN rule has a premise (or IF) part containing several preconditions and the conclusion (THEN) part describing the output action. The premise and conclusion parts are characterized by some fuzzy sets (or MFs). Suppose that we need to design a multiple-input-multiple-output (MIMO) FLC having p inputs $x_1 \in X_1, \ldots\ldots, x_p \in X_p$ and c outputs $y_1 \in Y_1, \ldots\ldots, y_c \in Y_c$ with i-th fuzzy rule of the form:

$$R^i_{MIMO}: \text{IF } x_1 \text{ is } F^i_1 \ldots\ldots \text{and } x_p \text{ is } F^i_p, \quad \text{THEN}$$

$$y_1 \text{ is } G^i_1 \ldots . y_c \text{ is } G^i_c, \quad i = 1, \ldots, M$$

where $F^i_1, \ldots\ldots, F^i_p$ and $G^i_1, \ldots\ldots, G^i_c$ are the antecedent and consequent MFs associated with the linguistic p input variables and c output variables, respectively; and M is the number of rules in the rule base.

III. Integration of FLCs and GA

The first step in designing an integrated FLCs and GA architecture, as depicted in Fig. 4, is to decide which parts of the knowledge base are subject to be optimized by the GA. Knowledge base of an FLC system is made up of two components: the parameters of the fuzzy rule base, constituted by the collection of fuzzy rules and MF types associated with the linguistic labels of each fuzzy rule. In this study, both of these two components of knowledge base are adapted using GA.

The integrated FLC and GA architecture consists of following basic steps:

Step1: Identify the variables (inputs, states, outputs) of the plant/problem.

Step 2: Partition the input and output universe of discourses or the interval spanned by each of the variables into a number of fuzzy regions (fuzzy sets) and assign a fuzzy MF i.e., linguistic label to each region.

Step 3: Encode fuzzy regions of the input and output spaces into bit-strings (0 or 1). Encode the MF types using bit-strings as follows: 00, 01, 10 and 11 for the triangular (T), left-triangular (LT), right-triangular (RT), and gaussian (G) respectively.

Step 4: Here, use GA in two stages, module-1 and module-2 (see Fig. 5), as self-learning adaptive methods to generate a set of fuzzy rules and select the MF types, respectively, for each rule.

Step 5: Decode the chromosome in both modules into fuzzy rules and their associative MFs type to determine the performance of a FLC and assign to a fitness value.

In order to clarify the basic ideas of our proposed approach, we have chosen backing up a truck reversing problem having

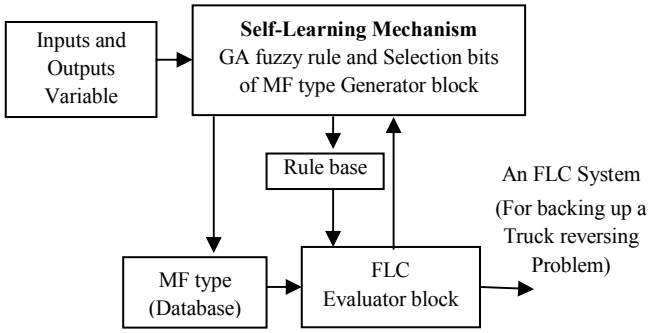


Figure 4. Integrated FLC and GAs Architecture

two inputs x, ϕ and one output θ. It is should be mentioned that there can be any number of input and output variables. In order to design an FLC, first divide the range of each variable, the inputs x and ϕ, and the output θ into fuzzy regions and assign a fuzzy MF to each region. We divide the domain regions for x into 5, ϕ into 7, and θ into 7 regions (The usual way to select an odd number between 3 and 9, which is usually same for all the variables). Consequently, there are 35 fuzzy rules (fuzzy rule base or FAM can be formed as a 5× (1×7) tables with rows to hold the corresponding actions (outputs).

After the division of input output spaces into fuzzy regions, each fuzzy rule can be represented as a bit string and the entire rule base as a table of strings as shown in Table I. Corresponding MFs selection bits are also included in each rule. Before the evolution process of GA the bit string is translated into fuzzy production rules like as Table IV.

To make calculations convenient, the consequent part of each rule and the associated type of MF is automatically set by two parallel GA modules, module-1 and module-2. The FLC generates a fitness value for each rule base according to the following fitness function:

$$Trajectory \quad \text{error/fitness} = \frac{\text{Length of Truck Trajectory}}{\text{Distance(Initail Position, Desired final Position)}}$$

We stop the simulation process and accept the fuzzy rules with respective type of fuzzy sets with fitness>Ω, where Ω defined as a specified number.

For the integrated architecture, the GA works in the following ways as shown in Fig.5 for graphical illustration:

Step1: Initialization: Some pairs of strings, each pair representing a potential solution, are generated by randomly chosen binary numbers (0 or 1). In each pair, the first string corresponds to a set of fuzzy rules of FLC (GA module-1) and the second string (GA module-2) denotes the types of MFs for corresponding fuzzy rules. Initialize P=1, N=65, g=1 and G=100 respectively (Fig. 5).

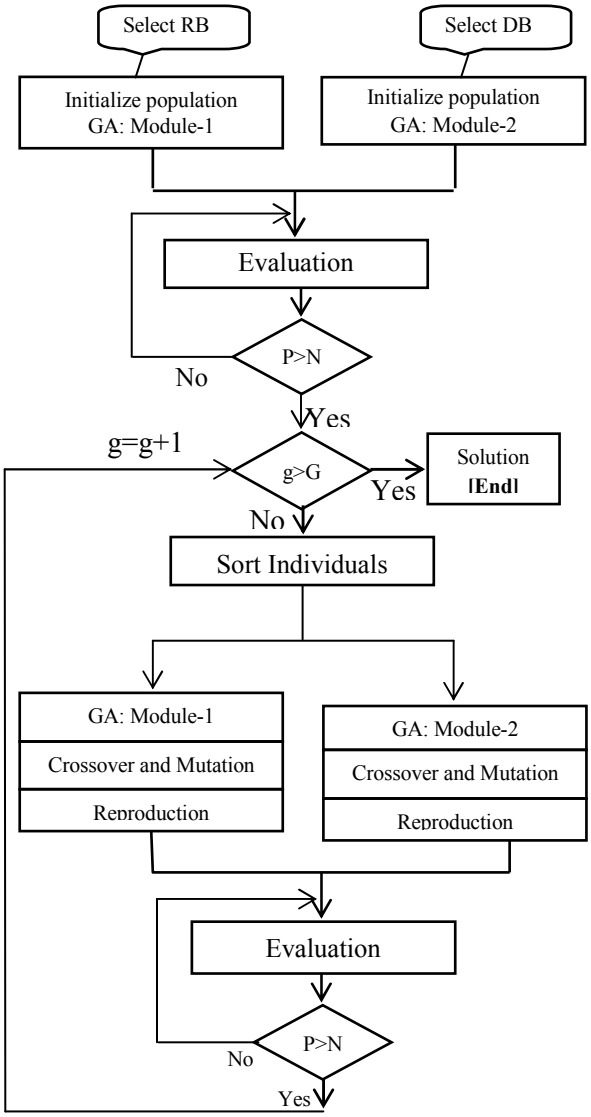

Figure 5. Flow chart for the design of FLC using GAs

Step2: Evaluation: Each potential solution is evaluated and assigned to a fitness value according to the solving performance of the problem. Sort the individuals according to their fitness value.

Step3: Recombination: Apply crossover and mutation operators to individuals of both modules and generate new individuals as well as new generation.

Step4: Evaluation: Evaluate the potential solution and check the termination condition.

Step5: Termination: If termination condition is satisfied then stop and return the best fitted chromosome (set of fuzzy rules of a FLC and membership function types) otherwise go to step3.

TABLE I. OPTIMAL CHROMOSOME OF GA

Input (x)					Input (ϕ)							Output (θ)							MF-Selection bits
LE	LC	CE	RC	RI	RB	RU	RV	VE	LV	LU	LB	NB	NM	NS	ZE	PS	PM	PB	
1	0	0	0	0	1	0	0	0	0	0	0	0	0	0	1	0	0	0	00 (Rule-1)
1	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	1	00 (Rule-2)
1	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	1	0	01 (Rule-3)
.	.	.	.	.	.	.	.	.	.	.	.	.	.	.	.	.	.	.	.
.	.	.	.	.	.	.	.	.	.	.	.	.	.	.	.	.	.	.	.
0	0	0	0	1	0	0	0	0	0	0	1	0	0	0	1	0	0	0	11 (Rule-35)

It is worth mentioning that the number of parameters such as the size of the population and the probability of applying the genetic operators (i.e., crossover and mutations) influence GAs.

IV. PROBLEM SPECIFICATION: BACKING UP A TRUCK CONTROL

Normal driving instincts can cheat us when attempting to back up a truck to a loading dock [14]. The task is such a difficult one that even for a highly skilled driver needs to go forward and backward numerous times in order to position the truck at the dock successfully. If the driver is not allowed to make forward movements, successful backing becomes improbable. So, the main challenge for the backing up a truck reversing control problem is to design a controller to successfully back up a truck to a loading dock from any initial position.

The problem, to back up a simulated truck to a loading dock in a planner parking lot is depicted in Fig. 6 with simulated geometry. The fuzzy logic control system must find incrementally a path to the loading dock independent of the initial position (x_0, y_0) of the truck. A state vector, consisting of the coordinates of the position of rear center of the truck (x, y) and the angle ϕ of the truck with the horizontal line define the actual position of the truck. The motion of the truck can be described by the following set of equations:

$$\begin{cases} x(t+1) = x(t) + b * \cos(\phi(t)) \\ y(t+1) = y(t) + b * \sin(\phi(t)) \\ \phi(t+1) = \phi(t) + \theta(t) \end{cases} \quad (3)$$

where θ is the steering angle. An FLC receives this state variable as input and calculates the appropriate steering angle $\theta = f(x,.\phi)$ that drives the truck toward the goal. The controller have to make the truck reach the loading dock at a right angle ($\phi = 90^0$) and to align the position (x, y) of the truck with the desired location (x_f, y_f). The truck should move backward for some fixed distance b at every stage. Assuming enough clearance between the truck and the loading dock we can ignore the y coordinate at the time of output (steering angle θ) calculation. There is no predefined path for each truck location and therefore the optimum steering angle is unknown. So, at every stage our proposed approach should calculate the steering angle $\theta = f(x, \phi)$ to back up the truck to a loading dock from any position and initial truck angle in the loading zone. The loading zone corresponds to the plane {0, 0} × {100, 100}.

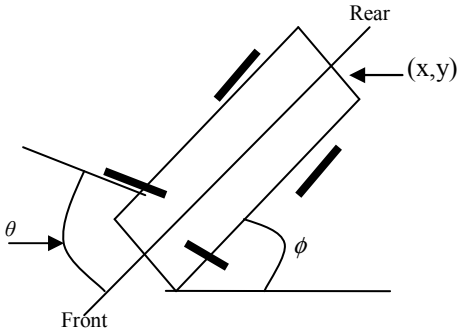

Figure 6. Diagram of Simulated Truck

This experiment is regarded as an example of highly nonlinear complex problems. The fuzzy logic controller must find the correct function that maps points from the three dimensional input-space to the appropriate output variable, continuously from the initial point until the loading dock, and for all combinations of the initial position.

The input and output variable domains are set to be as follows:

$$0 \le x \le 100$$
$$-90 \le \phi \le 270$$
$$-30 \le \theta \le 30$$

V. EXPERIMENTAL RESULTS AND COMPARATIVE ANALYSIS

To evaluate the accuracy of the proposed system, we have carried out a series of experiments in which the controller were evolved in our simulated arena. In this paper fuzzy control rules and MFs types associated to fuzzy control rules are adjusted based on GAs which enables the FLCs to backing up the truck with minimum trajectory error (fitness value).

A. Results

We have obtained the fuzzy control rules from the best chromosomes of GAs (module-1&2) after 100 generations. At the beginning of the simulation, the consequent part of each rule i.e., FAM (Fuzzy Associative Memories) cell is empty. To get the consequent part of each rule in terms of linguistic language form from the developed fuzzy rule generator block, let us start the simulation from thirty initial positions (x_0, y_0, ϕ_0): (25, 30, 60^0), (80, 30, 150^0), (30, 40, 90^0).. etc.

For all the given initial positions the GA converges to some sets of fuzzy control rules. During the simulation, we generate thirty sets of fuzzy rules (FAM) from thirty different initial positions. Then these rule bases are combined together to form the final FAM shown in table-II, using fuzzy amalgamation (FA) methodology [15, 16]. Table III shows the respective MFs type of fuzzy rules (FAM).

Figure 7 shows (example) the optimal fuzzy sets or membership function of the input and output terms. The MFs and the fuzzy rules specify a particular input-output mapping within a given range. In order to show the complete input-output relationship graphically, when the total number of input and output variables is no more than three, we can construct a control surface. The control surface is a convenient way to examine a two input/one-output control strategy and controller properties. It is obvious that using this useful feature one can more precisely fulfill a quality criterion in full operational range. Figure 8 shows the control surface defined with the *35* fuzzy control rules of Table II.

(c)

Figure 7. Variable domain and MFs for (a) x, (b) ϕ and (c) θ

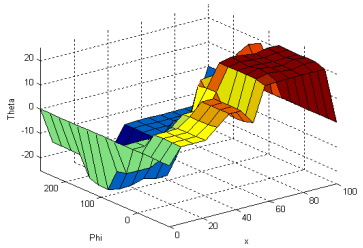

Figure 8. Surface generated by applied FLC

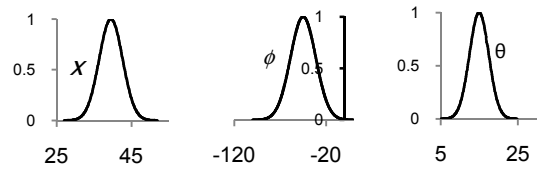
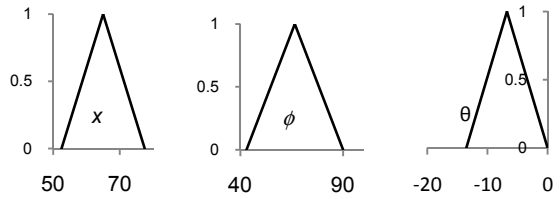
Figure 9 shows the example of two fuzzy control rules with two different types (gaussion and triangular) of MFs. After applying the FAM and their associated types of fuzzy sets (MFs), we obtain the trajectories with trajectory errors by the controller shown in Fig. 10 (a, b) for two different initial positions. The truck should hit the loading dock at a right angle, $\theta_f = 90°$, and the final position at (x_f, y_f)= (50, 100), for any initial state (x_0, y_o, ϕ_0) given to back up. The desired trajectory can be that the truck moves along the target line or coincides with the target line and then goes along y-axis to arrive at the goal.



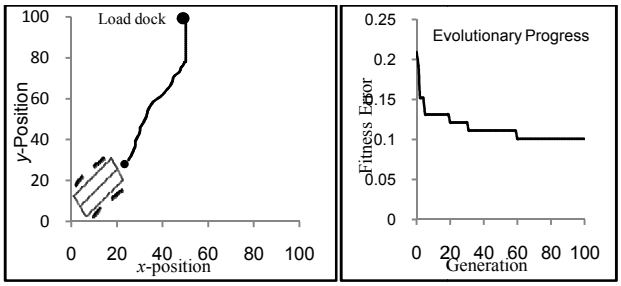
(a) RULE 8: IF x=LC ABD ϕ=RB THEN θ=PM



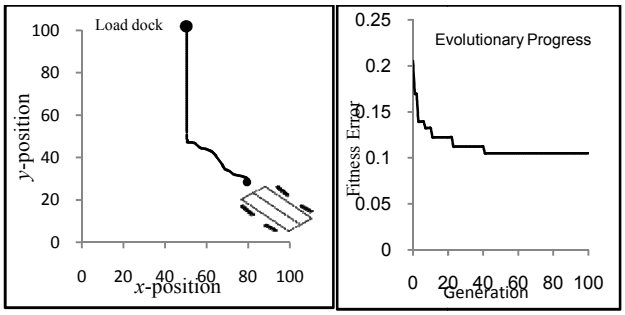
(b) RULE 24: IF x=RC AND ϕ=RV THEN θ=NS

Figure 9. Two different MFs form of fuzzy rule (a) Gaussian (b) Triangular

The minimized error after 100 generations for two positions (a, b) are 0.100996 and 0.104841. From Fig. 10 (a) it can be seen that for the initial position (25, 30, 60^0) the truck moves towards its goal with comparatively minimum trajectory error because the FLC can make the truck towards the goal position very quickly than that of other initial position, (80, 30, 150^0).



(a) Initial position (x_0, y_0, ϕ_0): (25, 30,60^0)



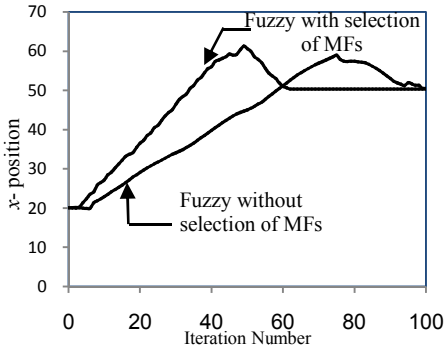
(b) Initial position (x_0, y_0, ϕ_0): (80, 30,150^0)

Figure 10. Trajectories and Fitness value of the backing up a truck controlled by the proposed approach.

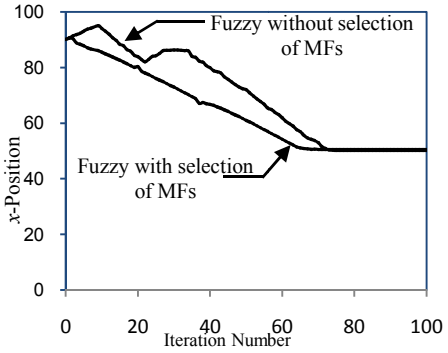
B. Comparative Analysis:Effect for selecting different type of membership function

In this section, we investigate the FLC response with selection of different types of MFs and compared FLC response without section of MFs types. Here, we have used different types of MFs for fuzzy partitions to design an FLC called FLC-1 as shown in Fig. 7. The simple triangular, left-triangular, right-triangular or gaussian membership functions are often used, but they may not be the best choices. Using different MF types decreases the number of trajectory steps and improves the trajectories path that is found by applying only single type of MF. The following (Fig. 11) comparative analysis illustrates this fact.

The FLC-1 is generated by our proposed two-stage GA (module-1&2), while the standard FLC is based on the only single type of MF (triangular/Gaussian). The performance of each controller was observed for backing up a truck reversing problem. It can be seen from Fig. 11 that standard FLC need more time and iteration to converge (meets at $x=50$). On the other hand, FLC-1 reached faster in terms of iteration to converge.



(a)



(b)

Figure 11. Comparison results between fuzzy with SMF and without SMF (a) Case-1: (20, 20, and 80^0) (b) Case-2: (90, 10, 110^0)

From the result given (Fig. 11), we can see standard FLC and FLC-1 have converged ($x=50$) at iteration 96 and 62, respectively for the case 1 (20, 20, and 80^0). FLC-1 also has achieved better precise value at position 50.2635 compare to 51.6439 for standard FLC. The second case (90, 10, 110^0) has achieved the same, FLC-1 achieve better convergence and closer to destination than standard FLC and get more precisely than standard FLC. The genetic progress is presented in Fig. 12 which demonstrations the performance of FLC with selection of different type of MFs is better than the response of FLC without selection of type of MFs.

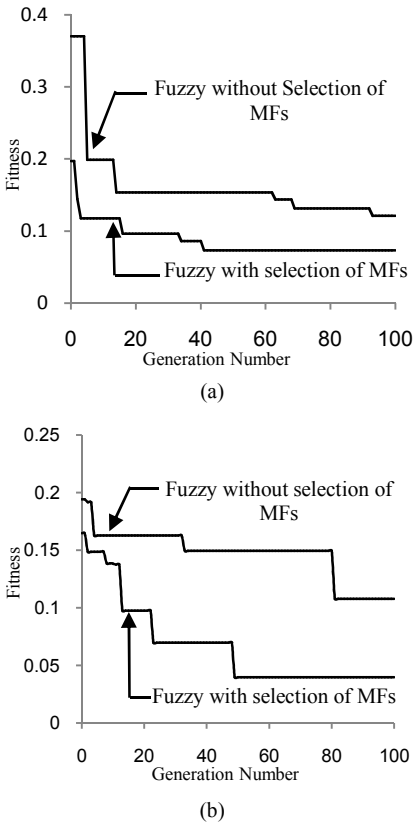


Figure 12. Fitness function value of the solution populations of the methods (a) Initial position (x_0, y_0, ϕ_0): (20, 20,80^0)) (b) Initial position (x_0, y_0, ϕ_0): (90, 10, 110^0)

Finally, we have shown that the shape and type of the MFs have a significant influence on the behavior of FLC response. Both the improvement and the deterioration of the systems' performance due to the changes in the MFs have been reported also.

VI. CONCLUSIONS

In this paper, we have found that the innovative integrated FLC and GA architecture is able to construct comprehensible and reliable fuzzy control rules by a self-learning adaptive technique. At the same time, we employed a two-stage GA to select the optimal type of MFs for FLC. The main features of the integrated FLCs and GAs architecture are given below.

The system is an automatic knowledge acquisition method and it is able to learn the fuzzy control rules without any prior knowledge. It also selects optimal types of MFs for FLC. In this way, GAs can build an effective controller relatively quickly. The comprehensive experimental studies also quantify a superb performance of the FLC with selection of different type of MFs when compared with the fuzzy controller without selection of type of MFs. This technique may lead to an increase in the use of FLCs as the previously time-consuming design procedure can be reduced dramatically. The architecture has a self-adaptive learning capability for constructing FLCs.

Suggestions for follow-up work that may come after this paper are as follows. This research work is to be extended for the intelligent control of a mobile robot, truck-trailer controller and control of a robotic arm in the presence of moving or fixed obstacle. This research work is also to be extended to the path planning problem for multiple mobile robots with more than one obstacles either moving or fixed in the workspace.

A Comparison of Distance-based Semi-Supervised Fuzzy c-Means Clustering Algorithms

Daphne Teck Ching Lai and Jonathan M. Garibaldi
School of Computer Science, University of Nottingham
Email: dtl@cs.nott.ac.uk and jmg@cs.nott.ac.uk

***Abstract*—There are many issues to be considered in the design of distance-based fuzzy semi-supervised clustering (FSSC) algorithms. To identify these issues, we compare the performance of four such algorithms. We describe the properties of these algorithms, highlighting their key differences, and then experimentally compare their performance on common datasets. Several experimental conditions are investigated. Firstly, two forms of initialisation of the membership values of unlabelled patterns are used; $1/c$ and 0. Secondly, the algorithms are run with varying proportions of labelled patterns in the datasets, ranging from 2% to 40%. We find that no algorithm outperforms the others in all the datasets. We also observe that small modifications in similar objective functions can improve clustering, and that most of the algorithms perform slightly better with zero initialisation of unlabelled patterns. An interesting observation is that the increase in labelled patterns does not always improve clustering. From these results, we conclude that the number and scale of dimensions in the data set, initial partition matrix, distance metrics and objective functions, together, affect clustering results. In addition, we conclude that not all initially labelled patterns are good candidates for supervision.**

Keywords: **Fuzzy c-means, semi-supervised learning.**

I. Introduction

Clustering organises similar unlabelled patterns into clusters and is an unsupervised form of learning. In classification, however, labelled patterns are required to teach the algorithm the characteristics of classes, which is used to organise and tag unlabelled patterns. Thus, classification is supervised. Both techniques are widely applied in pattern recognition and data mining, often for investigation or decision-making. Good reviews of both techniques, particularly covering approaches and design issues, can be found in [1] and [2].

In fuzzy clustering [3], [4] and classification [5], membership values are assigned to patterns to indicate the degree of belongness each pattern has to clusters or classes respectively. These give a more realistic representation of patterns, as compared to a binary-valued approach.

In reality, labelled patterns are often scarce because they are difficult or expensive to record. To increase accuracy, clustering algorithms can take advantage of available labelled patterns as examples to learn from. These algorithms that make use of unlabelled data and available labelled patterns are termed *semi-supervised clustering* algorithms. There are three main types of fuzzy semi-supervised clustering (FSSC) algorithms; constraint-based [6], distance-based [7], [8], [9] and hybrids [10]. Distance-based FSSC algorithms are found to be popular and are approached using different techniques such as RBF mapping [11], evolutionary clustering [12] and adaptive metrics [13].

Different FSSC algorithms have previously been evaluated on different datasets using various ranges of labelled patterns, which makes fair comparison difficult. This motivated our study into a comparison of four distance-based semi-supervised Fuzzy c-Means (FCM) algorithms proposed by Pedrycz and Waletzky [14], Zhang et al. [15], Li et al. [16] and Endo et al. [17]. These were chosen because we found them to be simple in operation and they have been shown to produce good results. Our objectives are to (i) compare their performances with varying quantities of labelled patterns, and (ii) explore how issues that are common to fuzzy semi-supervised clustering, such as the number of dimensions, choice of datasets, initial membership values, objective functions, distance metrics and labelled patterns affect their clustering performance. Some of these issues have already been discussed in [18] in an investigation into different distance metrics of similar objective functions. We, however, compared algorithms with different objective functions that use three different distance metrics, and algorithms with similar objective functions that employed different forms of balance between supervised and unsupervised learning. In addition, we compared experimental results from two forms of initialisation for the cluster membership of unlabelled patterns; $1/c$ and 0.

One way of comparison is by using cluster validity indices, such as those discussed in [19] and particularly in FSSC algorithms [18]. In this preliminary work, however, we use classification rate to compare clustering performance among the algorithms, as was used in [14], [15], [16], [17]. We assume that algorithms that perform well are those that achieve a high percentage of correct classifications with a low percentage of labelled patterns.

II. Semi-Supervised FCM Clustering Algorithms

FCM was introduced by Dunn [20] and formalised by Bezdek [4]. Gustafson and Kessel [21] introduced fuzzy covariance to generalise the distance metric, which represents patterns in a more natural manner. Early semi-supervised fuzzy clustering algorithms [22], [23], [14] adopted these techniques and produced good clustering results. Today, many FSSC algorithms [24], [13], [10], [16], [17], [15], [8] exhibit new ways to exploit FCM. Further developments of FSSC clustering are found in [25], where Pedrycz discussed the

idea of fuzzy semi-supervised clustering as a knowledge-based guidance mechanism to provide additional hints about data sets. Information can be represented in different levels of granularity, allowing it to represent heterogeneous data in both parametric and non-parametric models.

A. The Selected Algorithms

Tables I, II, III and IV illustrate the components in the semi-supervised FCM algorithms selected for study in this paper; Pedrycz-97 [14], Li-08 [16], Zhang-04 [15] and Endo-09 [17], respectively. The notation used is as follows: N, c, U and L denote the number of patterns, the number of clusters, the partition matrix and the number of labelled patterns, respectively. v_i, u_{ik}, f_{ik} (u_{ik}^l and $\bar{u}_{ik}$) and d_{ik} indicate, respectively, the prototype of cluster i, the membership value for pattern k in cluster i, the membership value of labelled pattern k in cluster i, and the distance between pattern k and prototype of cluster i. The equations for calculating the centroid and partition matrix are found in these tables. They are derived using a standard optimization technique called the Lagrange multipliers, the derivations are found in their respective papers and will not be discussed here. A semi-supervised FCM clustering algorithm iterates a series of steps to minimize the objective function until a termination criterion is satisfied. These steps are as follows:

1) Initialise c, U with known memberships and matrix F containing membership values of labelled patterns.
2) Calculate the centroids (prototypes of the clusters), v_i.
3) Calculate the similarities between clusters and patterns, d_{ik} using a chosen distance metric.
4) Update partition matrix U.
5) If $||U - U'|| < \epsilon$ (ϵ being a threshold value), stop. Else go to step 2.

B. Differences

Both Pedrycz-97 and Li-08 use Mahalonobis distance to update their partition matrix. In the objective function of Pedrycz-97, all patterns participate in unsupervised and supervised learning with parameter α to maintain a balance between the two types of learning. Li-08 is an improvement to avoid the redundant unsupervised learning of all labelled patterns in Pedrycz-97. Instead, it takes all unlabelled patterns and $1-a$ of

labelled patterns to participate in unsupervised learning, and a of labelled patterns to undergo supervised learning. Though presented separately for labelled and unlabelled patterns in Li-08, the equation to update the partition matrix is similar to Pedrycz-97 except for their balance parameters, a and α, respectively. Unlabelled patterns are not used in the calculation of Li-09's centroids, unlike the other algorithms. Like Pedrycz-97, the objective function of Endo-09 trains both labelled and unlabelled patterns in both unsupervised and supervised fashion, but using the Euclidean distance metric. The supervised training function, however, is entropy-regularised. Zhang et al. retained the objective function from the original FCM but replaced the Euclidean distance metric with a Gaussian kernel-based one. Unlike Pedrycz-97 and Li-08, in Zhang-04 only unlabelled patterns undergo supervised learning. This means that labelled patterns never gets updated or improved. As the unlabelled patterns do not contribute to the initial centroid, the labelled patterns act as seeds to form initial clusters, applied in FSSC learning [26] and non-fuzzy semi-supervised learning [27]. The trouble with using membership values of labelled patterns in both the calculation of centroids and the partition matrix, is that it makes the algorithm highly dependent on the initial membership values of labelled patterns, which can negatively impact the clustering results if they contain errors. This highlights the importance of balance parameters like α and a. In Endo-09's partition matrix equation, the membership values of labelled patterns themselves, denoted by $\bar{u}_{ik}$, are both learning components and balance parameters. In doing so, the reliance on initial membership values of labelled patterns is higher than the other three algorithms.

C. Summary

Three distance metrics are used by the four algorithms; Mahalanobis distance by Pedrycz-97 and Li-08, kernel-based distance by Zhang-04 and Euclidean distance by Endo-09. Pedrycz-97, Li-08 and Endo-09 algorithms use different approaches to incorporate the supervised learning element into the objective function of the original unsupervised FCM algorithm. We can observe this element in the second component of Pedrycz-97's and Endo-09's objective functions, and third component in Li-08's. The extended objective functions are then used to derive calculations of centroids and the partition matrix. Rather than using this extension in the objective function, Zhang-04 incorporated supervised learning during the calculation of the centroids. Thus, variations of both unsupervised and supervised learning components feature in these algorithms.

III. Experiments

Each algorithm, written in R, was run on ten datasets taken from non-linearly separable datasets Iris, Wine, XOR, Wisconsin Original Breast Cancer (WOBC), Pima Indians Diabetes (PID) and Wisconsin Diagnostic Breast Cancer (WDBC). Note that in Iris, the first class is linearly separable but the other two are not. The specifications of the datasets are shown in Table V. Apart from the XOR dataset which is manually built, all datasets are obtained from the UCI Machine Learning Repository [28]. For each dataset, experiments were repeated with different percentages of labelled patterns, 2%, 4%, 6%, 8%, 10%, 15%, 20%, 25%, 30% and 40%. Using the semi-supervised FCM algorithms, we can perform classification by having the labels replaced with numerals and the labelled patterns ordered such that the clusters and the numerically labelled classes will match. In this way, the unlabelled patterns after clustering can be matched with the numerically labelled classes from the datasets to verify correctness before counting the number of correctly matched patterns.

TABLE V
Datasets used in the experiments, where N, n and c are the number of patterns, features and clusters respectively.

dataset	N	n	c
Iris-2	150	2	3
Iris-4	150	4	3
Wine-2	178	2	3
Wine-13	178	13	3
XOR-2	200	2	4
WOBC-8	699	8	2
WOBC-2	699	2	2
PID-8	768	8	2
PID-2	768	2	2
WDBC-30	569	30	2

The following settings and modifications were made:

- Zhang et al. [15] used initial membership values of 1's and 0's to represent labelled and unlabelled patterns respectively. The assignment of initial membership values are not mentioned in the other algorithms. Like [18], however, we assume unlabelled patterns to hold equal initial memberships of all the clusters, having membership values of $1/c$ (where c is the number of clusters). The idea here is to improve learning using not only labelled patterns, but also unlabelled patterns.
- The membership value of each arbitrarily chosen labelled pattern belonging to a cluster is 0.9, with 0.1 membership divided among the other clusters. This is applied for the initial partition matrix of all datasets.
- From the Iris, Wine, WOBC and PID datasets, we created 2-dimensional datasets from these to observe the effects of number of attributes in datasets on clustering. We did not do this for WDBC because we felt that arbitrarily reducing a 30-dimensional image dataset to 2 dimensions was unlikely to improve clustering.
- Dimensions with missing values in the WOBC datasets were removed.
- The boolean matrix in Pedrycz-97 was removed since labelled and unlabelled patterns can be detected from the F matrix.
- We modified Endo-09 to compute prototypes from the initial partition matrix, like Pedrycz-97, rather than manually initialising them as the original algorithm did.
- Endo-09 ran into an infinity problem with datasets Wine-13, PID-8, PID-2 and WDBC-30. This will be discussed in the next section. We modified these datasets to Wine-10, PID-6, PID-2* and WDBC-23. The modified PID-2

contains two attributes that are different from the previous version.

- The stopping criterion used in all four algorithms is taken from Pedrycz-97 [14] as follows: $||U' - U|| = \sum_{i=1}^{c}\sum_{k=1}^{N}(u'_{ik} - u_{ik})^2$, where the threshold value is set to 0.01.
- In Pedrycz-97, α is calculated by N/L while a in Li-08 is calculated by $1-L/N$, where L is the number of labelled patterns and N is the total number of patterns.
- Following the original algorithms, p in Pedrycz-97 and m in Zhang-04 and Li-08 are set to 2 and λ in Endo-09 is set to 1.
- At least c labelled patterns, each an example of a different cluster, is required for the clustering to run properly (although semi-supervised algorithms for incomplete labelled patterns already exist [27]).
- Separate experiments were conducted on all algorithms and datasets with zero membership values for unlabelled patterns.
- Separate experiments with manual initialisation of Endo-09 prototypes were conducted.

IV. Results and Discussion

Table VI and Figure 1 show the percentage of correct classifications produced by each algorithm on different datasets. The symbol $*$ in this table indicates that the algorithm runs into an infinity problem. Overall, Li-08 performs better than the other algorithms, achieving more than 80% correct classifications in seven out of ten datasets with 4% of labelled patterns. With 4% of labelled patterns, it produces similar results to Pedrycz-97 in the Wine dataset and Zhang-04 in the WOBC dataset but, outperformed all in the XOR dataset. With 40% labelled data, it produces nearly 100% correct classification in six out of ten datasets. Pedrycz-97 achieves more than 80% correct classification in six out of ten datasets with 6% labelled patterns, while Zhang-04 achieves this with 15% labelled patterns and Endo-09 with 30% labelled patterns. We observe that Li-08 performs slightly better than Pedrycz-97 with its modified objective function.

The results of Pedrycz-97 and Li-08 are based on a Mahalanobis distance metric, which measures similarity using the sum of squared errors and the correlation with the membership values of the patterns. The presence of the inverse covariance matrix helps to normalise dimensions of different scales, preventing dominance from dimensions with greater scales. This may give a more realistic representation of the patterns. Zhang et al. replaced the Euclidean distance metric in FCM with a Gaussian kernel-induced distance metric. The Gaussian kernel measures similarity by $K(x,y) = exp(-||x-y||^2/\sigma^2)$, with the kernel width defined by the variance σ^2. This variance keeps the kernel value of patterns normalised. The idea behind kernel methods are their ability to solve non-linear problems by mapping the input space into higher dimensional space (the 'kernel trick' [29]), which is applied to distances [30]. We see this applied in Zhang-04 with prior information of data space computed in the variance. Both Mahalanobis and kernel-based distance metrics are competitive, each doing better than the other in different datasets with 2% of labelled patterns.

The 'curse of dimensionality' problem is apparent in the results produced by Endo-09. The Euclidean distance metric does not reflect scale differences among dimensions in high-dimensional datasets. Dimensions with smaller scales will have less influence on the distance in the presence of dimensions with larger scales. This results in biased distance values that decrease accuracy in classification. With increasing number of dimensions, distance increases exponentially. This makes Euclidean distance tricky to use in an exponential function, derived from the Endo-09 objective function. Large distance values yield a zero value in the exponential function of Endo-09 partition matrix update equation, which in turn returns infinity. Hence, the infinity problem arises in datasets with high dimensions, large scale differences in dimensions and/or large scales in dimensions such as Wine-13, PID-8, PID-6 and WDBC-30. When we removed three dimensions (those with higher scales) from the Wine dataset, the results improved drastically. Du and Urahama tackled this problem using a parameter δ, which is computed by the inverse sum of average distances with its nearest neighbours and average distances with its furthest neighbours [11].

The algorithms do not always produce better classifications using datasets that have more dimensions. For example, as can be seen in Figure 1, Pedrycz-97, Li-08 and Zhang-04 produce better results for WOBC-2 than for WOBC-8. This is because some features have higher discrimination power compared to others. Those that have low discrimination power add more computational cost and can deteriorate clustering results [2]. Through the selection of a subset of features, those that have high discrimination power can be retained while others discarded. Kong et al. [8] incorporated feature selection with fuzzy semi-supervised learning using a feature weight variable in its objective function.

All algorithms were able to cluster most of the non-linearly separable datasets, achieving more than 80% correct classifications with at most 30% labelled patterns. Zhang-04 and Endo-09 achieve less in the XOR dataset and none of the algorithms could achieve more than 80% classification with 40% labelled patterns in the PID datasets except Pedrycz-97. According to [31], the two classes in the PID dataset are not well separated, which makes it a challenge for the algorithms.

Interestingly and unexpectedly, increases in the number of labelled patterns do not always improve classification, indicated by the troughs in the graphs of Figure 1. This observation holds for all algorithms except Pedrycz-97 in Wine-2 dataset with 8% to 10% labelled patterns. Having said this, there is still a general trend of increasing correct classifications with increase in labelled patterns. This may suggest that not all labelled patterns are good candidates to guide clustering. The choice of suitable labelled patterns, prior to clustering, lies in their features, their initial membership values and the objective function of the algorithm. The presence of labelled patterns that do not strongly belong to one class but have high membership values will hinder the clustering process, reducing

accuracy. The objective function of the algorithm must have some corrective property to handle such patterns, such as in [24]. The authors extended the objective function to include the relationship between classes and clusters, and parameterised the confidence in the accuracy of data labels. The presence of labelled patterns with strong features of a cluster helps give a solid definition of a class. The idea of choosing unlabelled patterns to label before they are used to supervise clustering has been previously used in FSSC learning [6].

Two other separate experiments were conducted; one with zero membership values for unlabelled patterns and another on Endo-09 with manual initialisation of prototypes as performed in the original work. The results using zero membership values for unlabelled patterns are shown in the right half of Table VI. The key observations are as follows:

- In contrast to the previous experiment, Endo-09 achieves more than 80% correct classification in six out of nine datasets with 4% of labelled patterns. We observe that this algorithm is more sensitive to initial partition matrix for supervision than the other algorithms. Thus, unlabelled patterns with $1/c$ membership values may confuse prototypes and hinder good clustering results. This causes restricted learning and is not favourable in situations when there are weak labelled patterns. Pedrycz-97, Li-08 and Zhang-04 perform slightly better with zero initial membership values for unlabelled patterns in six, three and seven out of nine datasets, respectively.
- With manually initialised prototypes, the original Endo-09 produced final prototypes that are slightly different from those produced by the modified version, and so the results produced by these two versions are different. The dataset used in this experiment is provided in the original

paper [17], which is too small to deduce which of the two produced better results. Manually initialising prototypes of datasets with large dimensions will be impractical and can make the clustering highly inaccurate.

V. Conclusion

As preliminary work in fuzzy semi-supervised clustering, this study is aimed at investigating some existing distance-based semi-supervised fuzzy c-means algorithms running on popular datasets. We compared the clustering results of four such algorithms, testing them on two forms of initialisation of unlabelled patterns membership values; $1/c$ and zero. In most cases, results were more favourable when using zero membership for unlabelled patterns rather than using $1/c$. We observed that issues such as scale differences of dimensions in the data set, distance metrics, objective functions and quality of labelled patterns affect clustering results. From our experimental results, we observe that Mahalanobis distance provides slightly better performance than Gaussian kernel-based distance, and that the Euclidean distance metric performs least well, on the selected data sets.

We recognise that algorithms that can achieve very high percentage of correct classifications with few labelled patterns are desirable. Also, the percentage of correct classifications should increase with increasing percentage of labelled patterns since more examples are available to guide the clustering. However, some labelled patterns with poor discriminating power, when used in some algorithms, can negatively impact on clustering results. Research into algorithms that can filter out 'poorly' labelled patterns or identify 'good' unlabelled patterns to label prior to the clustering process is of interest to us. It would also be interesting to incorporate such features into existing dimensionality reduction algorithms and run comparative performance tests.

***Abstract*—Since learning Bayesian networks from data is difficult, a new approach is proposed. The particle swarm optimization (PSO) and minimum description length (MDL) are combined to obtain a suitable Bayesian network. MDL is the fitness function in this learning algorithm to evaluate the goodness of the network. By adopting MDL, the balance between simplicity and accuracy is assured, which enables the optimal solution for complex models to be found in reasonable time. Base on the MDL principle, the PSO is used to enhance the structure learning in Bayesian networks. Moreover, conditional probabilities associated with the Bayesian networks are then statistically derived from these data. In the end, the Stroke data set is used for testing the efficiency and effectiveness of the stable network. Experimental results show that the proposed approach has a good accuracy than the comparative methods.**

Keywords- Bayesian networks; particle swarm optimization; minimum description length

I. INTRODUCTION

Bayesian networks provide an efficient method for representing conditional probabilities among a set of variables. A Bayesian network is a graphic representation that encodes probabilistic relationships among variables. Since it only depicts the known conditional dependencies among variables rather than consider all variables in the domain, it provides efficiency for acquiring and representing domain knowledge [1]. Because of the ability to properly express expert knowledge and to handle well for the uncertain-reasoning problems, Bayesian networks have increasingly gained popularity in the community of artificial intelligence in recent years [2].

Many approaches have been proposed to induce the structure of Bayesian Networks. Typically, a Bayesian network is constructed by eliciting knowledge from domain experts. It is however a labor intensive process and may generate some biases. To reduce these biases due to subjective judgments of experts and increase efficiency, learning a Bayesian network from collected data or past observations has become an active area of research. Several heuristic searching techniques have been used to create a Bayesian network. Among those heuristics, evolution computation has been intensively researched and proved to be effective in learning Bayesian networks [3-4].

Numerous evolution techniques such as ant colony optimization, genetic algorithm and evolutionary programming were developed for Bayesian network structure discovery from data. Compared with these algorithms, particle swarm optimization (PSO) has strong sociological activities that promote information sharing and, in addition, it stores the previously best explored areas of the search space among all particles. By well communicating with others, each particle thus shares the information and has more opportunities to trend to better places. Moreover, PSO converges rapidly and requires only primitive mathematical operators. It is easy to implement but has great capability to handle optimization problems with multiple local optima reasonably well with fairly high accuracy. PSO has been found being robust in solving nonlinear and high dimensional problems [5-6].

In this paper, PSO and minimum description length (MDL) are combined to obtain a well-defined Bayesian network to assist domain experts in making decisions. Since the experts may be uncertain about their diagnoses, the results predicted by Bayesian networks will be a direction to help them consider how to solve the uncertainty. Even if the experts can make their own decisions, a Bayesian network can be taken as a reference to make them assure the results and even inspire them to think about some implications behind the relations among random variables. Moreover, PSO algorithm is used to learn the structure of a Bayesian network and the MDL is applied as the fitness function of the algorithm so that the final network will be useful and having a good accuracy at the same time. Further, the less complicated structure allows the domain experts to easily understand and quickly catch the causes and effects between the variables.

The remainder structure of the research is organized as follows: Section II briefly addresses the concept of Bayesian networks, PSO algorithms and MDL metric. It also discusses how they work together in various different domains. The proposed scheme is shown in Section III. The experimental

results are shown in Section IV. Finally, some conclusions are described in Section V.

II. RELATED WORKS

A. Particle Swarm Optimization

Particle swarm optimization (PSO) is a searching algorithm proposed by Kennedy and Eberhart [7]. Social behaviors of bird flocking motivated them to search and observe the effect of collaboration of species onto achieving their goals as a group. In PSO, a number of candidates, called particles, are placed in a *D*-dimensional search space looking for the optimal position to land. The particles will memorize the locations where they have their best locations and make this information available to its neighbors. Each particle adjusts its position by combining its own experience and the experience of other swarms as time passing. The next iteration takes place after all particles have been moved. In the end, the swarm is able to move close to an optimum of the fitness function.

Figure 1 shows the flow diagram of original PSO algorithm, and the corresponding Algorithm is given in Algorithm 1 [8]. In PSO, three parameters determine a particle's position including the current position $\vec{x_i}$, the previous best position $\vec{p_i}$, and the velocity $\vec{v_i}$. Each particle keeps track for the best solution called pbest. On the other hand, gbest is the best value tracked by the global version of the entire swarm. $U(0,\varphi_i)$ represents a vector of random numbers uniformly drawn on the interval (0, 1).

Algorithm 1. Original PSO algorithm.

Step 1. Initialize a population array of particles with random positions and velocities on *D* dimensions in the search space.
Step 2. Loop
Step 3. For each particle, evaluate the desired optimization fitness function in *D* variables.
Step 4. Compare particle *i*-th fitness evaluation with its pbesti . If current value is better than pbesti, then set pbesti equal to the current value, and $\vec{p_i}$ equal to the current location $\vec{x_i}$ in D-dimensional space.
Step 5. Compare particle *i*-th fitness evaluation with the population's overall previous best gbest. If current value is better than gbest, then reset gbest to the current particle's array index and value.
Step 6. Change the velocity and position of the particle according to the following equation:

$$\vec{v_i} \leftarrow \vec{v_i} + U(0,\varphi_1) \otimes \left(\vec{p_i} - \vec{x_i}\right) + U(0,\varphi_2) \otimes \left(\vec{p_g} - \vec{x_i}\right) \quad (1)$$

$$\vec{x_i} \leftarrow \vec{x_i} + \vec{v_i} \quad (2)$$

Step 7. If a criterion is met (usually a sufficiently good fitness or a maximum number of iterations), exit loop.
Step 8. End loop

The parameters φ_1 and φ_2 are often called acceleration coefficients which determine the weight of the random forces in the direction of personal best $\vec{p_i}$ and global best $\vec{p_g}$. φ_1 represents the attraction that a particle has toward its own success while φ_2 represents the attraction that a particle has toward the success of its neighbors. It is almost ubiquitously adopted to set $\varphi_1 = \varphi_2 = 2.0$, Each component of $\vec{v_i}$ is kept within the range $[-V_{\max}, +V_{\max}]$. The choice of the parameter $V_{\max}$ requires consideration since it appears to influence the balance between exploration and exploitation. If $V_{\max}$ is too high, particles may fly past the good positions. On the other hand, the particles could become trapped in local optima if $V_{\max}$ is too low.

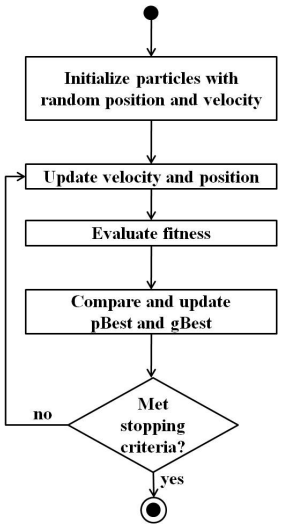

Figure 1. Particle Swarm Optimization flow diagram

B. Minimum Description Length

The minimum description length (MDL) principle proposed by Rissanen [9] is a learning criterion that selects the rule to find the best balance between the simplicity of a model and the goodness of fit to examples based on a data compression context. The fundamental insight behind the MDL Principle is that any regularity in a given set of data can be used to compress the data, that is, to describe it using fewer symbols than the number of symbols needed to describe the data literally [10]. Therefore, it embodies a form of Occam's Razor, a principle that claims the simpler one is the better when two competing theories that make exactly the same predictions. This idea can be applied to all sorts of inductive inference problems, and it turns out to be most fruitful in problems of model selection and, more generally, dealing with overfitting [11].

C. Bayesian networks

The Bayesian network which can also be referred to as a probabilistic network, belief network, Bayesian Belief Network and causal network was introduced for representing and reasoning with uncertainty [12]. In general, it consists of a graphical structure G which is a directed acyclic graph (DAG) and an associated probability distribution Pr. There are two parts to the Bayesian network. One is the qualitative relationships between the random domain variables, and the

other is the quantitative part, the probabilities over the variables.

Figure 2 shows a simple Bayesian network. Formally, let $N=[N_1,\cdots, N_n]$ be a set of nodes. Each node which is represented in the graph corresponds to a discrete random variable in the domain. The variables in a Bayesian network could be everything such as people, events and may be continuous or discrete. Each node has a number of states, that is, a set of probable values for each variable. There is a parent set, denoted by Π_p, for each node. For example, according to Figure 2, lung cancer may be caused by smoking or air pollution. Therefore, smoking and pollution together form the parent set of the node cancer.

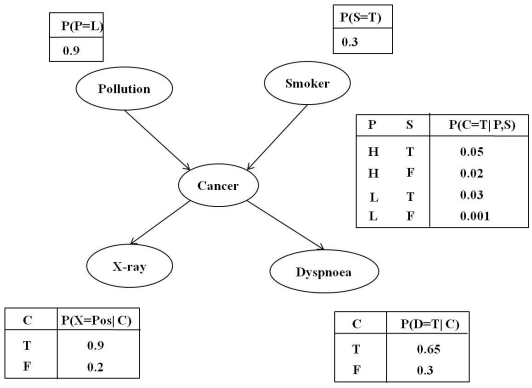

Figure 2. A simple Bayesian network representing the lung cancer problem

If a node has no parent nodes, its parent set would be empty and its probability table gives the marginal probabilities of the node. The directed arrows correspond to the dependence relationships between variable-pairs. It is usually called edge or arc. A node is taken to be dependent of its parents and children in the digraph, but is conditionally independent of any of its non-descendants given its parent.

In the Bayesian network, prior probabilities are assigned to source nodes (i.e., nodes without any incoming arcs), and conditional probabilities are associated with arcs. If a node X has only one parent Y, node X's probability table will contain the conditional probability $P(X|Y)$. Moreover, if X has multiple parents $(Y_1, Y_2,\cdots, Y_k)$, the table will contain the conditional probability $P(X|Y_1,Y_2,\cdots,Y_k)$.

This quantitative part encodes the joint probability distribution of these variables. The joint probability of any instantiation of all variables can be calculated as follows:

$$P(N_1,N_n)=\Pi_i p(N_i|Parents(N_i)) \tag{3}$$

where N_i represents the variables, and the value of the node is conditional only on the values of its parent nodes. Bayes' rule is used to update the conditional probabilities given evidence so the probabilities for all the nodes in the Bayesian network can be calculated. For example in Figure 2, the probability of the patient having cancer with smoking habit when the air pollution is high and the result of X-ray is true is $0.005-0.9/0.005-0.9+0.95-0.2=0.191$.

Building a Bayesian network involves three tasks. The first task is to identify the domain variables to be captured with the values they may adopt. Once the variables are decided, the causality relationships between these variables are identified and analyzed, and are expressed in a graphical structure. After creating the qualitative architecture, the next important task is to obtain the probabilities for each variable. The three tasks are typically iterated in a cyclic fashion since building the Bayesian network is flexible and creative.

D. Applying the MDL principle to Bayesian networks

MDL is first adopted for evaluating Bayesian networks by Lam and Bacchus [13]. The MDL principle suggests that the rule g that minimizes the description length given examples should be the output of the learning algorithm. As used in Bayesian belief network, each rule is views as a possible network structure and sequence given the rule g can be seen as the value of the *j*-th attribute. So in Bayesian belief network, the MDL principle is based on the idea that the desired model of a collection of data items is the model that minimizes the sum of the length of the encoding of the model and the length of the encoding of the data given the model. Even if the minimal network can't be found, structures with lower total description lengths are to be preferred. Such structures are superior to structures with longer total description lengths, in the precise sense that they are either more accurate, or are less complex, or are closer in structure to the original network. Hence, the total description length provides a metric by which alternate candidate structures can be compared [14].

The minimum description length metric can be expressed as:

$$D_t(B)=\sum_{N_i\in N} D_t(N_i,\Pi_{N_i})=\sum_{N_i\in N}\left(D_n(N_i,\Pi_{N_i})+D_d(N_i,\Pi_{N_i})\right) \tag{4}$$

where $D_t(B)$ is the total length of a network which is based on two components: the network description length D_n and the data description length D_d. The network description length (D_n) includes:

1. A list of the parents of each node.
   Suppose there are n nodes in the network, and each node has k different parents. For a node, $k\cdot\log_2(n)$ bits are needed to encode its parents.
2. The set of conditional probabilities associated with each node.
   To encode this part, it firstly needs to count the total number of conditional probabilities of each node. The number of bits required to store the numerical value of each conditional probability is also required. The encoding length will be the product of the number of bits and the number of conditional probabilities. Suppose a node takes on s_i values, F_i different parents each of which with distinct s_j values and d represents the number of bits required to store a numerical value. Thus for a node, $d(s_i-1)\Pi_{j\in F_i}s_j$ bits are needed.

Due to above two mentioned parts, the total description length for a particular network will be defined as

$$\sum_{i=1}^{n}\left[k_i \log_2(n) + d(s_i - 1)\Pi_{j \in F_i} s_j\right] \quad (5)$$

The data description length (D_d) is the length of the string encoding the database which can be expressed as

$$-N\sum_i p_i \log_2(q_i) \quad (6)$$

where N is the total number of records in the database, p_i is the true probability of an event and $-\log_2(q_i)$ is a codeword of length when run using this probability according to Huffman's algorithm. It is close to $-\log_2(p_i)$ since the probability q_i is determined by the network. Each event will have N_{pi} occurrences in the database.

III. Proposed Scheme

In this paper, construction of the Bayesian network is divided into two steps. The first step is network structure learning, and the second step is probability estimation. The whole process is represented in Figure 3. In the structure learning, a set of Bayesian networks are first randomly generated. Then, PSO is used to enhance these structures. After getting the best network, the probabilities associated with the networks are calculated according to the database. When the structure and probabilities are acquired, the final Bayesian network is obtained and can be used for prediction or classification.

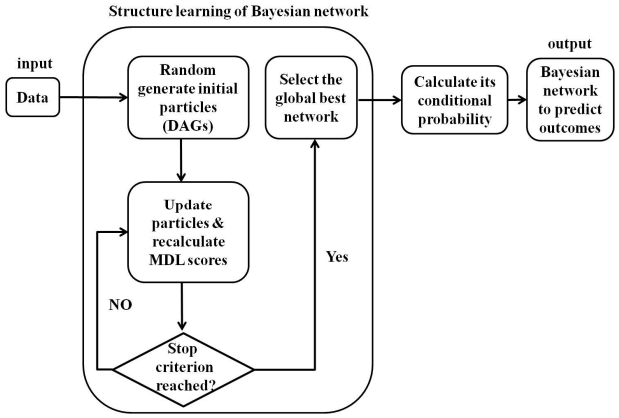

Figure 3. Bayesian Networks Learned by PSO

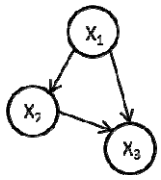
In structure learning, the PSO is adopted as a search algorithm which attempts to find an optimal Bayesian network. The search space of the networks is a DAG space, that is, every individual in the space is a directed acyclic graph (DAG). Before using PSO in a DAG space, several mathematical functions including (1) each particle's position, (2) each particle's velocity, (3) how to determine the new position of the particle, and (4) how to determine the new velocity of the particle should be defined.

In the research space, each particle represents a candidate Bayesian structure. The position of a particle is represented as an n x n adjacent matrix where n is the number of nodes in the problem. Elements in the matrix represent the dimension of the particle. The presence of zero in any element indicates that these two nodes have no linkage and one indicates that there is a connecting edge between the two nodes. An example of a matrix and its corresponding Bayesian Network structure is shown in Figure 4.

Velocity is used to determine the new position of a particle. It can measure the difference between two positions and thus move the particle. The velocity of a particle is also defined as an n x n matrix. The elements in the matrix are represented as discrete values {-1, 0, 1}. A velocity with -1 in an element means that the existing edge between two specified nodes in the DAG will be removed in the next generation, 0 means that the edge between two nodes remains unchanged, and 1 means that a new edge will be added between two specified nodes. In the velocity for each element indicates whether the edge represented by the element is to be removed, added or left unchanged.

$$\begin{bmatrix} & X_1 & X_2 & X_3 \\ X_1 & 0 & 1 & 1 \\ X_2 & 0 & 0 & 1 \\ X_3 & 0 & 0 & 0 \end{bmatrix}$$

(a)



(b)

Figure 4. (a) Matrix of position. (b) Corresponding Bayesian network.

TABLE I. Velocity Update

Previous position	Current velocity	Current position	Action
0	0	0	Unchanged
0	-1	0	Unchanged
0	1	1	Add
1	0	1	Unchanged
1	1	1	Unchanged
1	-1	0	Remove

Since the constriction factor has a better performance than inertia weight [15], it is used to compute the new velocity of a particle, which is defined as Eq.(7).

$$\vec{v_i} \leftarrow \chi\left(\vec{v_i} + c_1 * rand(\,) * \left(\vec{p_i} - \vec{x_i}\right) + c_2 * rand(\,) * \left(\vec{p_g} - \vec{x_i}\right)\right) \quad (7)$$

$$\chi = \frac{2}{\varphi - 2 + \sqrt{\varphi^2 - 4\varphi}} \quad (8)$$

$$\varphi = c_1 + c_2 > 4 \quad (9)$$

In the initial generation, $\vec{v_1}$ is created randomly. Beginning from the second generation, it is updated by combining the current $\vec{v_1}$ and the cognitive and social influences respectively, working as the formula above. After updating the velocity, the value has to be translated into discrete values {-1, 0, 1}. To partition values of a continuous variable into a discrete variable, K equal lengths (equal intervals) is used since it is one of the most familiar methods to create partitions. K is chosen to provide a manageable number of discrete values, which gives a fair approximation of the continuous frequency distribution [16]. In this paper, K is set to 3.

In order to get the optimal network, a fitness function is necessary to evaluate the goodness of all candidate networks. In this paper, the Minimum description length (MDL) metric is applied to assess the models. In the MDL principle, the best model of a collection of data items is whose length is the minimum. The length is the sum of two parts: (1) the length of the encoding of the model, and (2) the length of the encoding of the data given the model. Both can be measured in bits. [13]

The structure learning of Bayesian network algorithm combines PSO and MDL, which includes two steps: create and update. The first step is the creation of a set of particles (DAGs) and initialization of the personal and global best positions. The second step is the calculation of velocities and update of the positions of the particles. The details of the algorithm are shown in Figure 5.

Let *N* be the set of all nodes.
Randomly generate *K* particles.
Set *round* to 0.
While *round* is smaller than the maximum number of generations,
  Each particle is evaluated with the fitness function. The best position of each individual and the best position of the global swarm are determined by the MDL scores.
  For each particle,
    Determine the next velocity and position of each particle using the velocity update equation.
    For each node,
      Run the *validation algorithm* of the structure to check whether it violates the Bayesian network standards. If cycles are not generated by inserting new edges into the DAG, then add the edges. If it creates cycles, then delete the edges or skip the generation.
  Perform the fitness function to assess the goodness of the DAG.
  Increase *round* by 1.
Let the DAG with the lowest fitness value found in any generation be the final best network.
Estimate the probabilities of the network.
Return this network as the result of the optimal Bayesian network.

Figure 5. Algorithm for PSO to learn Bayesian networks

After the validations, each particle is again evaluated by the MDL metric. This can ensure that the best particle of this generation will be stored to the next generation. After running a preset number of generations, an optimal particle is acquired. Probabilities of the nodes in the network are then calculated as described in the next section. There are two types of probabilities in a Bayesian network, which include prior probabilities and conditional probabilities. If a node has no parents, it is assigned to the prior probability. The prior probability is measured as the number of cases of this event divided by the total number of cases in the database, which is shown as:

$$P(N_i = c) = N_i / N \tag{10}$$

If a node has parents, it is assigned to the conditional probability. The conditional probability can be calculated as follows:

$$P\left(N_i = c \middle| \Pi_{N_i} = p\right) = \frac{N_{i,j,k} + 1}{N_{i,j} + r_i} \tag{11}$$

where r_i is the number of different values of variable N_i , $N_{i,j,k}$ is the number of cases in the database in which variable N_i has the value set c and Π_{N_i} has the value set p. $N_{i,j}$ is the sum of cases of different value that the variable Ni takes on in the database, which can be instantiated as

$$N_{i,j} = \sum_{k=1}^{r_i} N_{i,j,k} \tag{12}$$

After acquiring all prior and conditional probabilities, the Bayesian network can be used for probabilistic inference which refers to the process of computing the posterior probability of a query variable after obtaining observable variables [17], which can be defined as

$$P\left(N_i \middle| N_j\right) = \frac{P(N_i)P\left(N_j \middle| N_i\right)}{P(N_{i1})P\left(N_j \middle| N_{i1}\right) + P(N_{i2})P\left(N_j \middle| N_{i2}\right) + \cdots + P(N_{in})P\left(N_j \middle| N_{in}\right)} \tag{13}$$

where N_i is the query node, and N_j is the observable nodes. N_j is the child of N_i. $N_{i1}, \cdots, N_{in}$ are states of node N_i.

IV. EXPERIMENTAL RESULTS

In order to show that the proposed method has a good performance, the Stroke data set which is collected from a neurological clinic is used. There are 350 instances gathered from 2009 to 2010, in which 176 instances are with stroke and 174 instances without stroke. The details of the data set are presented in Table II. Each instance comprises 11 attributes, including age, gender, obesity, hypertension, diabetes mellitus, coronary artery disease, left ventricular hypertrophy, atrial fibrillation, smoking, cholesterol and high-density lipoprotein. The class is whether the patient suffers from stroke. All attributes are binary except for age which is trinary.

MDL is a measure to evaluate the learned Bayesian network. The lower the measure, the better the network is. In the first generation, the MDL score of the model is around 4320.55. Then the MDL metric of Bayesian network declines as the PSO algorithm learns better network models. The optimal network appeared at the 1050th generation, with a MDL score of 4122.54. Due to the fast learning rate to achieve optimal model, the proposed method is efficient. The trend of MDL scores is presented in Fig. 6.

The algorithm runs with particles set to 20, 50, 100, 150, and 200, respectively. Executing the algorithm over different particles can evaluate whether a better scoring Bayesian network can be generated by more explorations. 5000 iterations are executed. Other parameters such as constriction factor are set to 0.729, and the two learning factors are set to 2.05. Different values of particles of PSO are conducted to study its effect on the stroke problem. Structural difference is the measure to evaluate Bayesian network structure. It is defined as: $\sum_{i=1}^{n} \varphi_i$ where φ_i is the sum of the symmetric difference between the parent sets of node i in the learned network and the known network [3]. Ten trials of experiments are performed. The structural differences between the best Bayesian network structure found in each trial. There is no significant difference for various values of particles by using One-way analysis of variance (ANOVA) (F = 1.464, P = 0.228).

Accuracy of classification, sensitivity and specificity have been commonly used as indices to evaluate the quality of algorithms. Waikato Environment for Knowledge Analysis

(WEKA) system release no. 3.6.1 [18] thus is used as reference because it contains a large number of techniques divided into seven groups (Bayesian, based on functions, lazy, meta techniques, tree, rule and others). Support vector machine (SVM) and Bayes network are chosen to compare the classification performance with MDL-PSO. Parameters of each technique are the default values set in WEKA. The comparison results of Stroke breast cancer database are presented in Table III. The first row of Table III is the average accuracy of classification of each classifier. For the Stroke data set, MDL-PSO performs both better than SVM and BayesNet. The second and third rows are respectively sensitivity and specificity of the classifiers, which PSO-MDL got higher specificity than the other two classifiers. Sensitivity of PSO-MDL is lower than SVM but higher than BayesNet.

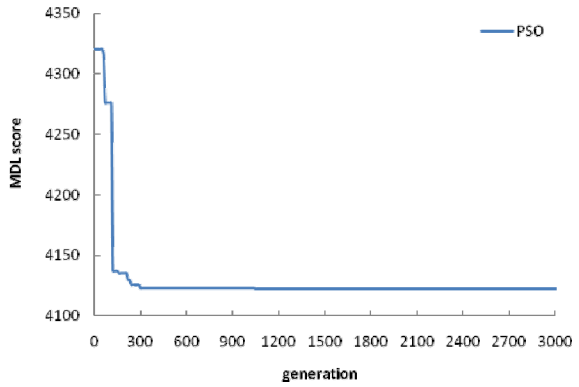


Figure 6. The MDL metric for Stroke data set

TABLE II. SUMMARY OF THE STROKE DATASET

Attribute	Data Type	Possible value
Age (<45, 45~65,>65)	Nominal	Young/Mid/Old
Gender	Nominal	Male/Female
Obesity (BMI>27)	Nominal	Yes/No
Hypertension	Nominal	Yes/No
Diabetes mellitus	Nominal	Yes/No
Coronary artery disease (>200)	Nominal	Yes/No
Left ventricular hypertrophy (<40)	Nominal	Yes/No
Atrial fibrillation	Nominal	Yes/No
Smoking	Nominal	Yes/No
Cholesterol(mg/dl)	Nominal	Normal/Abnormal
High-density lipoprotein(mg/dl)	Nominal	Normal/Abnormal
Class: Stroke or not	Nominal	Yes/No

V. CONCLUSION

PSO was adopted as the searching algorithm to learn the structure of Bayesian networks in this paper, and MDL was its fitness function. In addition, several constraints were used in order to keep the learning network from violating the standards of Bayesian networks. The learned Bayesian networks were also validated upon real data sets such as Stroke. The experimental results revealed that PSO-MDL was an efficient learning algorithm due to its fast learning rate. The accuracy is used to evaluate the effectiveness of PSO-MDL. As compared to SVM and BayesNet, the proposed method has a good accuracy.

TABLE III. THE COMPARISON RESULTS OF STROKE DATA SET

	MDL-PSO	SVM	BayesNet
Average accuracy	73.81%	68.86%	67.14 %
Sensitivity	70.5%	73.3%	65.3%
Specificity	65.5%	64.4%	63.2%

***Abstract*— Generally, we could efficiently analyze the inexact information and investigate the fuzzy relation by applying the fuzzy graph theory[1].**

We would extend the fuzzy graph theory, and propose a fuzzy node fuzzy graph. Since a fuzzy node fuzzy graph is complicated to analyze, we would transform it to a simple fuzzy graph by using T-norm family. In addition, to investigate the relations between nodes, we would define the fuzzy contingency table.

In this paper, we would discuss about five subjects, (1) new T-norm "Uesu product", (2) fuzzy node fuzzy graph, (3) fuzzy contingency table, (4) decision analysis of the optimal fuzzy graph G_{λ_0} in the fuzzy graph sequence $\{G_\lambda\}$ and (5) its application to sociometry analysis.

By using the fuzzy node fuzzy graph theory, the new T-norm and the fuzzy contingency table, we could clarify the relational structure of fuzzy information. According to the decision method in section 2, we could find the optimal fuzzy graph G_{λ_0} in the fuzzy graph sequence $\{G_\lambda\}$, and clarify the structural feature of the fuzzy node fuzzy graph .

Moreover, we would illustrate its practical effectiveness with the case study concerning sociometry analysis.

Keywords-component; fuzzy node fuzzy graph; optimal fuzzy graph; sociometry analysis; T-norm; contingency table

I. T-NORM, FUZZY NODE FUZZY GRAPH AND FUZZY CONTINGENCY TABLE

A. T-norm and its Family

T-norm (Triangular Norm) is a binary operation that is defined by the following:

Definition 1 T-norm is a binary operation

$p, q \in [0,1] \to T(p,q) \in [0,1]$

satisfying the following properties:

(1) Commutativity :

$T(p,q) = T(q,p)$

(2) Associativity :

$T(p,T(q,r)) = T(T(p,q),r)$

(3) Monotonicity :

$p \le q, \quad r \le s \Rightarrow T(p,r) \le T(q,s)$

(4) Boundary conditions :

$T(p,0) = 0, \quad T(p,1) = p$

The typical T-norms are the followings:

(1) Logical product :

$T_L(p,q) = p \wedge q$

(2) Algebraic product :

$T_A(p,q) = pq$

(3) Multi-valued product (Lukaszewicz product) :

$T_M(p,q) = (p+q-1) \vee 0$

(4) Drastic product :

$$T_D(p,q) = \begin{cases} 0 & , p \vee q < 1 \\ p \wedge q & , p \vee q = 1 \end{cases}$$

Here, " $a \wedge b$ " means " $\min(a,b)$ ", " $a \vee b$ " means " $\max(a,b)$ ".

Definition 2 Order of T-norms

For two T-norms T_α and T_β, if a relation

$$\mathsf{T}_\alpha(p,q) \le \mathsf{T}_\beta(p,q), \ (p,q) \in [0,1]^2$$

holds, we denote it by $\mathsf{T}_\alpha \le \mathsf{T}_\beta$.

For any T-norm T, a relation $\mathsf{T}_D \le \mathsf{T} \le \mathsf{T}_L$ always holds.

Definition 3 T-norm Family

For any $\lambda \in [a,b]$, when T_λ is T-norm, then we say that $\{T_\lambda\}$ is T-norm family that connects T_a with T_b.

The typical T-norm families are

(1) Dubois product :

$$T_\lambda(p,q) = \frac{pq}{p \vee q \vee \lambda}, \lambda \in [0,1]$$

(2) Weber product :

$T_\lambda(p,q) = 0 \vee \{(1+\lambda)(p+q-1) - \lambda pq\}, \lambda \ge -1$

(3) Schweizer product :

$T_\lambda(p,q)=\sqrt[\lambda]{0\vee(p^\lambda+q^\lambda-1)},\lambda>0$

(4) Uesu product :

$$T_\lambda(p,q)=\begin{cases}0 & ,p\vee q<1-\lambda\\ p\wedge q & ,p\vee q\geq 1-\lambda\end{cases},\lambda\in[0,1]$$

and so on.

The relation of typical T-norm families and Uesu product could be illustrated in Fig.1.

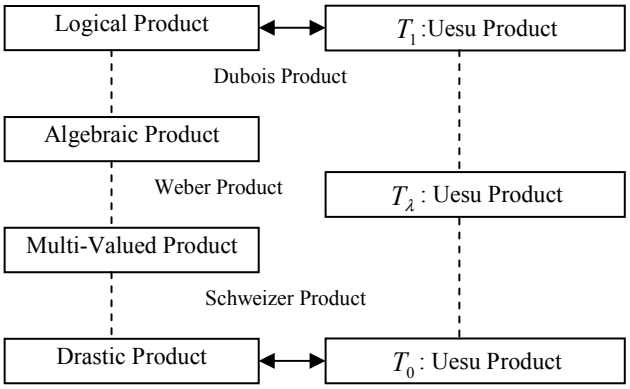

Figure 1. Relation of Typical T-norm Families

Here, in Fig.1, we could understand that Dubois product connects "logical product" with "algebraic product", Weber product does "algebraic product" with "multi-valued product", Schweizer product does "mulch-valued product" with "drastic product" and Uesu product does "logical product" with "drastic product".

B. *Fuzzy Node Fuzzy Graph*

Definition 4 Crisp Node Fuzzy Graph

A crisp node fuzzy graph G[6] is defined by

$$G=(V,F):V=\{v_i\},F=(f_{ij}),0\leq f_{ij}\leq 1$$

where V is the set of the nodes and F is an $n\times n$ matrix. (i, j) component f_{ij} of F is a fuzziness of the arc from the node v_i to the node v_j.

Definition 5 Fuzzy Node Fuzzy Graph

A fuzzy node fuzzy graph G[14] is defined by

$$G=(V,F):V=\{v_i/u_i\},Y=(y_{ij}),0\leq u_i\leq 1,\ 0\leq y_{ij}\leq 1$$

where V is the set of the nodes and the fuzziness u_i is a fuzziness of the node v_i. Y is a $n\times n$ matrix whose (i, j) component y_{ij} is a fuzziness of the arc from the node v_i to the node v_j.

A fuzzy node fuzzy graph is characterized by the fuzziness of the nodes and the fuzziness of the arcs. Therefore, the structure of a fuzzy node fuzzy graph is usually very complicated. Then, it should be interesting to transform a fuzzy node fuzzy graph to a crisp node fuzzy graph and we present a method to transform a fuzzy node fuzzy graph to a crisp node fuzzy graph.

Definition 6 Transformation from Fuzzy Node Fuzzy Graph to Crisp Node Fuzzy Graph

A fuzzy node fuzzy graph $G=(V, Y)$ can be transformed to a crisp node fuzzy graph $G=(V,F)$ by the following method: Let

$$G=(V,F):V=\{v_i\},F=(f_{ij}),f_{ij}=T(u_i,y_{ij})$$

where the fuzziness f_{ij} of the arc from the node v_i to the node v_j could be defined by applying T-norms.

This fuzzy node fuzzy graph analysis would be applied to the sociometry analysis, the instruction structure analysis and so on.

C. *Fuzzy Contingency Table*

Definition 7 Fuzzy Contingency Table

Let $\boldsymbol{x}$ and $\boldsymbol{y}$ be two vectors as follows:

$$x=(x_i),\ y=(y_i):0\leq x_i,y_i\leq 1,\ 1\leq i\leq n.$$

Then the fuzzy contingency table of $\boldsymbol{x}$ and $\boldsymbol{y}$ defined accordingly:

TABLE I. FUZZY CONTINGENCY TABLLE

$\boldsymbol{x}$ \ $\boldsymbol{y}$	1	0	Sum
1	a_{xy}	b_{xy}	$\sum_{k=1}^{n}x_k$
0	c_{xy}	d_{xy}	$n-\sum_{k=1}^{n}x_k$
Sum	$\sum_{k=1}^{n}y_k$	$n-\sum_{k=1}^{n}y_k$	n

$$a_{xy}=\sum_{k=1}^{n}T(x_k,y_k),\ b_{xy}=\sum_{k=1}^{n}x_k-a_{xy},$$

$$c_{xy}=\sum_{k=1}^{n}y_k-a_{xy},\ d_{xy}=n-\sum_{k=1}^{n}y_k-b_{xy}$$

From the fuzzy contingency table, we could computes any similarity coefficients. The typical similarity coefficients are

(1) Jaccard : $s_{xy}=\dfrac{a}{a+b+c}$

(2) Sorensen-Dice : $s_{xy}=\dfrac{2a}{2a+b+c}$

(3) Russell and Rao : $s_{xy}=\dfrac{a}{a+b+c+d}$

(4) Simple Matching : $s_{xy}=\dfrac{a+d}{a+b+c+d}$

(5) Rogers-Tanimoto : $s_{xy}=\dfrac{a+d}{a+2b+2c+d}$

(6) Simpson : $s_{xy}=\dfrac{a}{(a+b)\wedge(a+c)}$

(7) Ochiai : $s_{xy} = \dfrac{a}{\sqrt{(a+b)(a+c)}}$

(8) Phi : $s_{xy} = \dfrac{ad-bc}{\sqrt{(a+b)(a+c)(b+d)(c+d)}}$

(9) Yule : $s_{xy} = \dfrac{ad-bc}{ad+bc}$

and so on.

II. Fuzzy Graph and its Analysis

A. Cluster Analysis of Fuzzy Graph

A fuzzy graph G is defined by

$$G=(V,Y), V=\{v_i\}, F=(f_{ij}), 0\le f_{ij}\le 1, f_{ii}=1, 1\le i\le n$$

where f_{ij} is a fuzziness of the arc from the node v_i to the node v_j.

In order to analyze the similarity structure among nodes of a fuzzy graph, we use the symmetric relation matrix $S=(s_{ij})$. A symmetric relation matrix S could be defined by using the fuzzy contingency table and any similarity coefficients. Here, we define the symmetric relation matrix S by using the simple matching similarity coefficient.

In order to analyze the clustering structure among nodes, we have its max-min transitive closure $\hat{S}=(\hat{s}_{ij})$ which is computed by $\hat{S}=S^n$.

After that, we define the c-cut matrix S_c of $\hat{S}=(\hat{s}_{ij})$ as follows:

$$S_c=(s_{ij}^c),\quad s_{ij}^c=\begin{cases}1 & (\hat{s}_{ij}\ge c)\\ 0 & (\hat{s}_{ij}<c)\end{cases}, 0\le c\le 1$$

From the matrix S_c, we define the cluster $CL_{Sc}(i)$.

$$J_c(i)=\{j \mid s_{ij}^c=1, 1\le j\le n\}$$

$$CL_{Sc}(i)=\{v_j \mid j\in J_c(i)\}$$

The cluster $CL_{Sc(i)}$ gives an equivalence relation among nodes.

Thence, we can construct the partition tree by changing the level c of the c-cut matrix which represents the clustering situation of nodes in a fuzzy graph.

B. Decision Analysis of Optimal Value λ_0

Concerning the transformation from a fuzzy node fuzzy graph $G=(V,Y)$ to a fuzzy graph $G_\lambda=(V,F_\lambda)$, we could analyze a fuzzy node fuzzy graph by using Uesu product T_λ.

By changing the parameter λ, a sequence $\{G_\lambda\}$ of fuzzy graphs is composed.

Here, we would choose the optimal fuzzy graph G_{λ_0} from this fuzzy graph sequence $\{G_\lambda\}$.

Then, we would discuss the decision method of the optimal parameter λ_0.

In order to decide the optimal fuzzy graph G_{λ_0}, we would define two functions $d(\lambda)$ and $e(\lambda)$ as follows:

Definition 8 Distance Function $d(\lambda)$ and Connectivity Function $e(\lambda)$

$$d(\lambda)=d(F_\lambda,S_{c_0})=\frac{1}{n^2-n}\sum_{i=1}^{n}\sum_{j=1}^{n}\left|f_{ij}-s_{ij}^{c_0}\right|$$

$$e(\lambda)=e(F_\lambda)=\frac{\gamma(F_\lambda)}{n^2-n}$$

where, $\gamma(F_\lambda)=\#(\Gamma_\lambda), \Gamma_\lambda=\{f_{ij}^\lambda\in F_\lambda \mid f_{ij}^\lambda>0\}$.

And F_λ, S_{c_0} are given as follows:

$$F_\lambda=(f_{ij}^\lambda),$$

$$f_{ij}^\lambda=\begin{cases}0 & ,u_i\vee y_{ij}<1-\lambda\\ u_i\wedge y_{ij} & ,u_i\vee y_{ij}\ge 1-\lambda\end{cases}$$

$$S_{c_0}=(s_{ij}^{c_0}),\quad s_{ij}^{c_0}=\begin{cases}1 & (\hat{s}_{ij}\ge c_0)\\ 0 & (\hat{s}_{ij}<c_0)\end{cases}$$

Here, $d(\lambda)$ evaluates the feature between the fuzzy node fuzzy graph $G_\lambda=(V,F_\lambda)$ and the optimal clustering cut level c_0. If the value of $d(\lambda)$ is large, then G_λ reasonably shows the feature of the clustering level c_0.

On the other hand, $e(\lambda)$ evaluates the connectivity information of G_λ. If the value of $e(\lambda)$ is small, then G_λ reasonably shows the feature of the connectivity information.

Here, we would normalize the values of $d(\lambda)$ and $e(\lambda)$ respectively, and define $f_d(\lambda)$ and $f_e(\lambda)$ as follows:

Definition 9 Fuzzy Distance Function $f_d(\lambda)$ and Fuzzy Connectivity Function $f_e(\lambda)$

$$f_d(\lambda)=\frac{d_M-d(\lambda)}{d_M-d_m},\quad f_e(\lambda)=\frac{e(\lambda)-e_m}{e_M-e_m}$$

where,

$d_M=\bigvee_{\lambda\in[0,1]}\{d(\lambda)\}$, $d_m=\bigwedge_{\lambda\in[0,1]}\{d(\lambda)\}$, $e_M=\bigvee_{\lambda\in[0,1]}\{e(\lambda)\}$ and $e_m=\bigwedge_{\lambda\in[0,1]}\{e(\lambda)\}$.

By applying the maximal decision of the fuzzy decision, we could reasonably find the optimal value λ_0 concerning the sequence $\{G_\lambda\}$.

Definition 10 Decision of Optimal Value λ_0

$$f_m(\lambda)=f_d(\lambda)\wedge f_e(\lambda)$$

$$\lambda_0=\wedge\{\lambda : f_m(\lambda)=\bigvee_{x\in[0,1]} f_m(x)\}$$

III. Application to Sociogram Analysis

We would present a practical case study of the fuzzy sociogram analysis[5],[11] that has been experimented in high

school.

If we executed the questionnaires in Fig.2 to 10 students, we could obtain the response table *L*.

From the table *L*, we obtained the response matrix $K^{(1)}, K^{(2)}, K^{(3)}$ and the evaluation matrix *R*.

By analyzing the matrix *R*, we have the preferring matrix *Y*=(y_{ij}) in Fig.3 and the amicable matrix *S*=(s_{ij}) in Fig.4. From the amicable matrix *S*, we obtained the fuzziness u_i of member v_i. We illustrated the fuzzy node fuzzy graph *G*=(*V*, *Y*).

We could transform the fuzzy node fuzzy graph *G*=(*V*, *Y*) to the fuzzy graph *G*=(*V*, *F*) by applying Uesu product . By changing parameter λ, we obtained fuzzy graph sequence $\{G_\lambda\}$.

Next, we could obtain the partition tree *P* in Fig.5 if we execute the cluster analysis concerning the amicability matrix *S*.

Here, we could decide the optimal cut level c_0 =0.78.

By using c_0-cut matrix Sc_0 and the fuzzy graph sequence $\{G_\lambda\}$, we could decide the optimal fuzzy graph G_{λ_0}. Here, by calculating the distance function $d(\lambda)$ and the connectivity function $e(\lambda)$.

$$d(\lambda)=\frac{1}{90}\sum_{i=1}^{10}\sum_{j=1}^{10}\left|f_{ij}^{\lambda}-s_{ij}^{c_0}\right|$$

$$e(\lambda)=\frac{\gamma(F_\lambda)}{90}$$

where, $\gamma(F_\lambda)=\#(\Gamma_\lambda), \Gamma_\lambda=\{f_{ij}^{\lambda}\in F_\lambda \mid f_{ij}^{\lambda}>0\}$.

Then, we have normalized the value of $d(\lambda)$ and $e(\lambda)$, so we have calculated $f_d(\lambda)$ and $f_e(\lambda)$ as follows:

$$f_d(\lambda)=\frac{0.23-d(\lambda)}{0.23-0.15},\ f_e(\lambda)=\frac{e(\lambda)-0.21}{0.64-0.21}.$$

Select your friends and write them in order for each group activities.

Figure 4. Amicable Matrix *S*

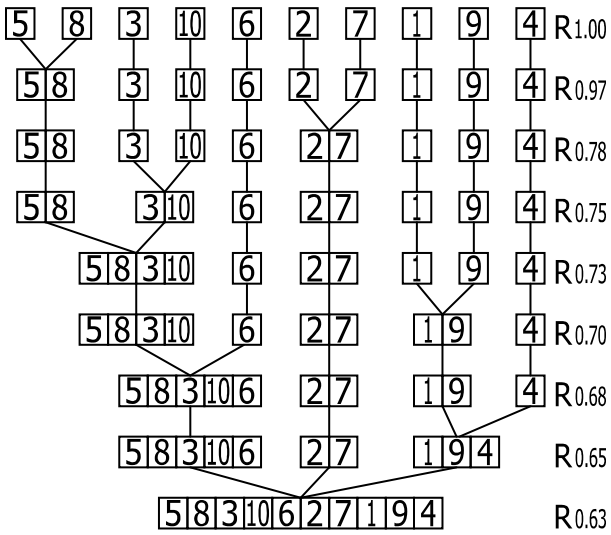

Figure 5. Partition Tree *P*

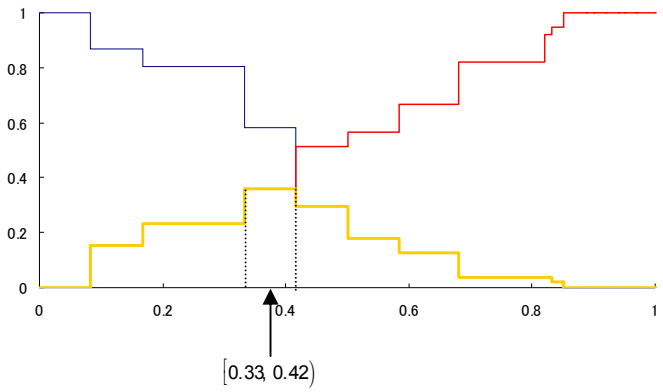

Figure 6. Fuzzy Decision $f_d(F) \wedge f_e(F)$

By applying the fuzzy decision, we could obtain the optimal value $\lambda_0 = 0.33$ as shown in Fig.6.

We would illustrate the fuzzy sociogram U^F, $z = c_0 = 0.58$ in Fig.7 which is based on the fuzzy graph $G_{\lambda_0} = (V, F_{\lambda_0})$, $\lambda_0 = 0.33$ in Fig.7. In this graph, we indicated the students in the same cluster at the optimal cut level $z = c_0 = 0.58$ with the same color and the opinion leaders are boldly marked.

This fuzzy sociogram U^F effectively represents the following results:

(1) The opinion leaders are 2 and 7 because these nodes is connected with many other nodes.
(2) The relatively isolated member is 10 because this node has not been connected with the others.
(3) The subgroups are {5, 8, 3, 10} and {2, 7}.

In this way, we could effectively analyze and clarify the interpersonal relation among members by applying the fuzzy node fuzzy graph and our analysis method.

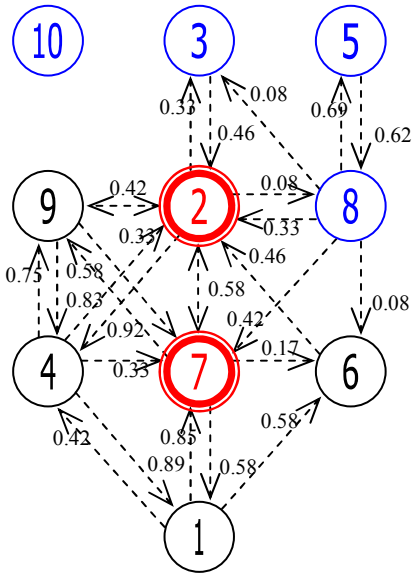

Figure 7. Fuzzy Sociogram U^F, $\lambda_0 = 0.33$, $z = 0.73$

IV. Conclusion

In this paper, we have mainly discussed the followings;

(1) fuzzy node fuzzy graph
(2) new T-norm "Uesu product"
(3) decision analysis of the optimal fuzzy graph G_{λ_0} in the fuzzy graph sequence $\{G_\lambda\}$
(4) fuzzy contingency table
(5) practical application and its effectiveness concerning the sociometry analysis

We have illustrated the practical effectiveness of the analysis method with the case study concerning the sociometry analysis. This method is also available for the instruction/ cognition analysis in education[10], the opinion poll in psychology and so on.

Finally, the author would be grateful to Prof. H.Yamashita of Waseda University for his helpful advices.

***Abstract*—We continue to develop a construction of an L-fuzzy valued measure extending a crisp measure defined on a σ-algebra of crisp sets to an L-fuzzy valued measure defined on a T_M-tribe. We describe two equivalent approaches to define an L-fuzzy valued integral of non-negative measurable functions.**

***Index Terms*—L-set, L-fuzzy real number, L-fuzzy valued measure, L-fuzzy valued integral.**

I. Introduction

One can find a lot of works regarding fuzzy approach to measure and integral. The biggest scope on this subject can be found in [1], [2], [3]. Our interest is in developing a theory where not only sets are fuzzy, but also measure and integral take fuzzy real values. In the serious of our previous papers [4], [5], [6] the concepts of an L-fuzzy valued measure and integral were studied throughly. We continue to develop results obtained in the previous papers and show that L-fuzzy valued measure and integral preserve most of the properties of it's crisp analogues (see e.g. [7]).

Inspired by the fact from the classical measure theory stating that an integral of a given non-negative function can be considered as a measure we obtain two different approaches to define an L-fuzzy valued integral.

The idea of the first approach is to extend a crisp measure ν to the L-fuzzy valued measure μ by using the construction described in [5] and then defining the L-fuzzy valued integral

$$\mu_f(E) = \int_E f \, d\mu,$$

where f is an integrable real-valued function and E is a measurable L-set [6].

The second approach shows that an L-fuzzy valued integral can be obtained by considering the measure ν_f using a crisp measure ν as following:

$$\nu_f(M) = \int_M f \, d\nu,$$

where f is an integrable non-negative function and M is a measurable set. And then extending it to the L-fuzzy valued measure $\tilde{\mu}_f$ according to the construction described in [5].

Finally we show that both approaches give us equivalent ways to define the L-fuzzy valued integral, i.e. $\mu_f = \tilde{\mu}_f$. This result can be described by the following diagram:

$$\begin{array}{ccc} \nu & \longrightarrow & \mu \\ \downarrow & & \downarrow \\ \nu_f & \rightarrow & \mu_f \end{array}$$

The second approach to the definition gives us an opportunity to simplify calculations of the L-fuzzy valued integral.

Our investigations of the L-fuzzy valued integral are motivated by our intention to develop results on approximation from [8], [9]. For the problems that can be solved only approximately the notion of the error of a method of approximation plays the fundamental role. In order to estimate the quality of approximation on an L-fuzzy set, we need an appropriate L-fuzzy analogue of a norm. Our intention is to use the L-fuzzy valued integral to define an L-fuzzy valued norm for investigation of the error of approximation on an L-set.

II. Preliminaries

A. L-sets

Given a (crisp) universe X and a complete, completely distributive lattice $L(\wedge, \vee, 0_L, 1_L)$, an *L-subset* A of X (or, briefly, an L-set A) is a function $A : X \longrightarrow L$. The class of all L-subsets of X is denoted L^X. The operations for L-sets A, B are defined by using the minimum triangular norm T_M, its corresponding conorm S_M and decreasing involution N:

$$\begin{gathered}(A \wedge B)(x) = T_M(A(x), B(x)), \\ (A \vee B)(x) = S_M(A(x), B(x)), \\ A^c(x) = N(A(x)).\end{gathered}$$

A finite family of L-sets $A_1, A_2, \ldots, A_n$ is said to be *T_M-disjoint* (see e.g.[1]) iff for each $k \in \{1, \ldots, n\}$ we have

$$(\bigvee_{j=1, j\neq k}^{n} A_j) \wedge A_k = \emptyset.$$

A countable family of L-sets is said to be T_M-disjoint iff every finite subfamily of this family is T_M-disjoint.

We consider a class of L-sets called T_M-tribe (see e.g. [1]).

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Definition II.1. *A subclass $\Sigma \subset L^X$ is called a T_M-tribe on X if the following properties are satisfied:*

- $\emptyset \in \Sigma$;
- *for all* $A \in \Sigma$ *we have* $A^c \in \Sigma$;
- *for all sequences* $(A_n)_{n\in N} \subset \Sigma$ *we have* $\bigwedge_{n=1}^{\infty} A_n \in \Sigma$.

B. L-fuzzy real numbers

For our purposes we use the L-fuzzy real numbers as they were first defined by B. Hutton [10].

Definition II.2. *An L-fuzzy real number is a function $z : \mathbb{R} \to L$ such that*

- z *is non-increasing;*
- $\bigwedge_t z(t) = 0_L$, $\bigvee_t z(t) = 1_L$;
- z *is left semi-continuous, i.e. for all* $t_0 \in \mathbb{R}$ *we have* $\bigwedge_{t<t_0} z(t) = z(t_0)$.

In the original papers of this subject (see [10], [11], [12]) the L-fuzzy real numbers were defined not as order reversing functions, but as equivalence classes of such functions. However each class of equivalence has a unique left semi-continuous representative and therefore an L-fuzzy real number can be identified with this representative.

The set of all L-fuzzy real numbers is called *the L-fuzzy real line* and it is denoted by $\mathbb{R}(L)$. An L-fuzzy number z is called *non-negative* if $z(0) = 1_L$. We denote by $\mathbb{R}_+(L)$ the set of all non-negative L-fuzzy real numbers.

Operations with L-fuzzy real numbers such as addition $\oplus$ and multiplication by a real positive number are defined as following:

$$(z_1 \oplus z_2)(t) = \bigvee_{\tau} \{z_1(\tau) \wedge z_2(t-\tau)\},\ (zr)(t) = z(\frac{t}{r}).$$

The supremum and the infimum of a set of non-negative L-fuzzy numbers $F \subset \mathbb{R}_+(L)$ are defined by the formulas (see e.g. [8], [9]):

$$(Inf\ F)(t) = \bigwedge \{z(t) \mid z \in F\},\ t \in \mathbb{R},$$

$$Sup\ F = Inf\{z \mid z \in \mathbb{R}(L), z \geq z' \text{ for all } z' \in F\}.$$

Taking into account that F is bounded from below it is easy to see that $Inf\ F$ is an L-fuzzy real number. In case F is bounded from above (i.e. there exists $z_0 \in \mathbb{R}(L)$ such that $z \leq z_0$ for all $z \in F$), $Sup\ F$ is an L-fuzzy real number, otherwise the condition

$$\bigwedge_t SupF(t) = 0_L$$

does not necessarily hold.

Going forward we will need also the countable addition of non-negative fuzzy real numbers. Given a sequence of non-negative fuzzy real numbers $(z_n)_{n\in\mathbb{N}} \subset \mathbb{R}_+(L)$ we consider the countable sum

$$\bigoplus_{n=1}^{\infty} z_n = Sup\{z_1 \oplus z_2 \oplus \ldots \oplus z_n \mid n \in \mathbb{N}\}.$$

For $a \in \mathbb{R}_+$ and $\alpha \in L$ by $z(a,\alpha)$ we denote a special type of non-negative L-fuzzy real numbers

$$(z(a,\alpha))(t) = \begin{cases} 1, & t \leq 0, \\ \alpha, & 0 < t \leq a, \\ 0, & t > a, \end{cases}$$

that will play an important role in our work.

III. L-fuzzy valued measure

A. Definition of an L-fuzzy valued measure

We consider a measure that is defined on a T_M-tribe and takes values in $\mathbb{R}_+(L)$.

Definition III.1. *Let Σ be a T_M-tribe. A function $\mu : \Sigma \to \mathbb{R}_+(L)$ is called an L-fuzzy valued measure if it satisfies the following conditions:*

- $\mu(\emptyset) = z(0, 1_L)$;
- μ *is T_M-valuation, i.e. for all* $A, B \in \Sigma$ *it holds*

$$\mu(A \wedge B) \oplus \mu(A \vee B) = \mu(A) \oplus \mu(B);$$

- μ *is left T_M-continuous, i.e.*

$$Sup\{\mu(A_n) | n \in \mathbb{N}\} = \mu(A),$$

where $(A_n)_{n\in N} \subset \Sigma$, $\bigvee_{n\in\mathbb{N}} A_n = A \in \Sigma$.

B. Construction of an L-fuzzy valued measure

For a given σ-algebra of crisp sets $\Phi \subset 2^X$ and a finite measure $\nu : \Phi \to \mathbb{R}_+$ an L-fuzzy valued measure can be obtained by the following schema (see e.g. [4], [5]):

- For $M \in \Phi$, $\alpha \in L$ we define an L-fuzzy set

$$(A(M,\alpha))(x) = \begin{cases} \alpha, x \in M, \\ 0, x \notin M. \end{cases}$$

  All these L-sets form a class of L-sets that we denote by $\wp$.
- Next we define an L-fuzzy valued function $m : \wp \to \mathbb{R}_+(L)$ by

$$m(A(M,\alpha)) = z(\nu(M), \alpha),$$

  and we extend it to the L-fuzzy valued function $m^* : L^X \to \mathbb{R}_+(L)$ as following:

$$m^*(E) = Inf\ \{\bigoplus_{n=1}^{\infty} m(E_n) \mid (E_n)_{n\in\mathbb{N}} \subset \wp : E \leq \bigvee_{n=1}^{\infty} E_n\}.$$

- We denote by Σ the T_M-tribe of all so called m^*-measurable L-sets $E \in L^X$ such that for all $B \in L^X$ it holds

$$m^*(E) \oplus m^*(B) = m^*(E \wedge B) \oplus m^*(E \vee B),$$
$$m^*(E^c) \oplus m^*(B) = m^*(E^c \wedge B) \oplus m^*(E^c \vee B).$$

- Finally, we define μ as the restriction of m^* to Σ we can state that μ is an L-fuzzy valued measure and

$$\mu(E) = m^*(E),\ \text{for all } E \in \Sigma.$$

IV. An L-fuzzy valued integral

A. Definition of an L-fuzzy valued integral

In this section we define an L-fuzzy valued integral

$$\int_E f \, d\mu,$$

where $E \in \Sigma$ and $f : X \to \mathbb{R}$ is a non-negative measurable function with respect to σ-algebra Φ.

By analogy with the classical case ([7]) we define an L-fuzzy valued integral stepwise, first considering the case of simple non-negative measurable functions (for short SNMF):

$$\int_E (\sum_{i=1}^{n} c_i \chi_{C_i}) \, d\mu = \bigoplus_{i=1}^{n} (c_i \, \mu(C_i \wedge E)),$$

whenever

- $c_i \in \mathbb{R}_+, C_i \in \Phi$ for all $i = 1, ..., n$,
- χ_{C_i} is the characteristic function of C_i , $i = 1, ..., n$,
- $C_1, ..., C_n$ are pairwise disjoint sets.

Then considering the case for non-negative measurable function f (for short NMF):

$$\int_E f \, d\mu = Sup\{\int_E g \, d\mu \mid g \leq f \text{ and } g \text{ is SNMF}\}.$$

For $\mathbb{I}_f = \int_E f \, d\mu$ due to properties of the supremum of a set of L-fuzzy numbers, we have

- $\mathbb{I}_f$ is non-increasing,
- $\bigvee_t \mathbb{I}_f(t) = 1_L$,
- $\mathbb{I}_f$ is left semi-continuous, i.e. $\bigwedge_{t<t_0} \mathbb{I}_f(t) = \mathbb{I}_f(t_0)$.

Definition IV.1. *We say that a non-negative measurable function f is L-fuzzy integrable over L-set E iff*

$$\bigwedge_t \mathbb{I}_f(t) = 0_L.$$

Let us note that if f is non-negative integrable over X then it is also L-fuzzy integrable over every $E \in \Sigma$. Going forward we consider only such functions.

B. Properties of L-fuzzy valued integral

For L-fuzzy integrable non-negative functions $f, f_1, f_2, ..., f_n, ...$ and measurable L-sets $E, E_1, E_2, ..., E_n, ... \in \Sigma$ the following properties of L-fuzzy valued integral are true (see e.g. [6]).

($\mathbb{I}$1) $\int_E d\mu = \mu(E)$

($\mathbb{I}$2) $r \in \mathbb{R}_+ \Rightarrow \int_E r f d\mu = r \int_E f d\mu$

($\mathbb{I}$3) $f_1 \leq f_2 \Rightarrow \int_E f_1 d\mu \leq \int_E f_2 d\mu$

($\mathbb{I}$4) $E_1 \leq E_2 \Rightarrow \int_{E_1} f \, d\mu \leq \int_{E_2} f \, d\mu$

($\mathbb{I}$5) $\int_E (f_1 + f_2) d\mu = \int_E f_1 d\mu \oplus \int_E f_2 d\mu$

($\mathbb{I}$6) $E_1 \wedge E_2 = \emptyset \Rightarrow \int_{E_1 \vee E_2} f d\mu = \int_{E_1} f d\mu \oplus \int_{E_2} f d\mu$

($\mathbb{I}$7) $(E_n)_{n\in\mathbb{N}} : E_n \leq E_{n+1}$ and $\bigvee_{n\in\mathbb{N}} E_n = E \Rightarrow$
$\int_E f d\mu = Sup\{\int_{E_n} f d\mu \mid n \in \mathbb{N}\}$

($\mathbb{I}$8) $(f_n)_{n\in\mathbb{N}} : f_n \leq f_{n+1}$ and $\lim_{n\to\infty} f_n = f \Rightarrow$
$\int_E f \, d\mu = Sup\{\int_E f_n \, d\mu \mid n \in \mathbb{N}\}$

V. Two approaches to define L-fuzzy valued measure based on a function

A. The first approach

From the classical measure theory (see e.g [7]) it is known that having a measure ν and non-negative measurable function f we can get a new measure ν_f defined as following

$$\nu_f(M) = \int_M f \, d\nu.$$

By using the same logic in the fuzzy case we want to make sure that this statement will be preserved.
We define

$$\mu_f(E) = \int_E f \, d\mu,$$

where $\mu_f : \Sigma \to \mathbb{R}_+(L)$ and f is a real valued non-negative L-fuzzy integrable function.

Theorem V.1. *μ_f is an L-fuzzy valued measure.*

Proof: Due to integral property μ_f is left T_M-continuous. We need to prove that μ_f is T_M-valuation, i.e.

$\mu_f(E_1 \vee E_2) \oplus \mu_f(E_1 \wedge E_2) = \mu_f(E_1) \oplus \mu_f(E_1)$ for all $E_1, E_2 \in \Sigma$.

Considering $M_1 = \{x \in X \mid E_1(x) \geq E_2(x)\}$ and $M_1 = \{x \in X \mid E_1(x) < E_2(x)\}$ we can split L-sets E_1, E_2 into two T_M-disjoint L-sets as following:

$$E_1 = (E_1 \wedge M_1) \vee (E_1 \wedge M_2) \text{ and } E_2 = (E_2 \wedge M_1) \vee (E_2 \wedge M_2).$$

Obviously,

$$E_1 \vee E_2 = (E_1 \wedge M_1) \vee (E_2 \wedge M_2)$$

and

$$E_1 \wedge E_2 = (E_1 \wedge M_2) \vee (E_2 \wedge M_1).$$

Hence,

$$\int_{E_1} f \, d\mu \oplus \int_{E_2} f \, d\mu = \int_{(E_1\wedge M_1)\vee(E_1\wedge M_2)} f \, d\mu \oplus \int_{(E_2\wedge M_1)\vee(E_2\wedge M_2)} f \, d\mu =$$

$$= \int_{E_1\wedge M_1} f \, d\mu \oplus \int_{E_1\wedge M_2} f \, d\mu \oplus \int_{E_2\wedge M_1} f \, d\mu \oplus \int_{E_2\wedge M_2} f \, d\mu =$$

$$= \int_{E_1\vee E_2} f \, d\mu \oplus \int_{E_1\wedge E_2} f \, d\mu.$$

■

As we can see L-fuzzy valued measure μ_f was obtained by the following scheme:

- first extending crisp measure ν with construction described in section III-B;
- second defining a measure by using an integral with respect to L-fuzzy valued T_M-measure μ .

B. The second approach

Now if we change the order in scheme described above we get L-fuzzy valued measure $\tilde{\mu}_f$.

For a given σ-algebra $\Phi \subset 2^X$ and a finite measure $\nu : \Phi \to \mathbb{R}_+$ we define measure ν_f as following:

$$\nu_f(M) = \int_M f \, d\nu.$$

An L-fuzzy valued measure $\tilde{\mu}_f$ can be obtained by using the same scheme as in section III-B :

- We define an L-fuzzy valued function $m_f : \wp \to \mathbb{R}_+(L)$ by
$$m_f(A(M,\alpha)) = z(\nu_f(M),\alpha),$$
and we extend it to the L-fuzzy valued function $m_f^* : L^X \to \mathbb{R}_+(L)$ as following:
$$m_f^*(E) = Inf\ \{\bigoplus_{n=1}^{\infty} m_f(E_n) \mid (E_n)_{n\in\mathbb{N}} \subset \wp : E \le \bigvee_{n=1}^{\infty} E_n\}.$$
- We denote by Σ_f the class of all so called m_f^*-measurable L-sets $E \in L^X$ such that for all $B \in L^X$ it holds
$$m_f^*(B) \oplus m_f^*(E) = m_f^*(B \wedge E) \oplus m_f^*(B \vee E),$$
$$m_f^*(E^c) \oplus m_f^*(B) = m_f^*(E^c \wedge B) \oplus m_f^*(E^c \vee B).$$
- Finally, considering $\tilde{\mu}_f$ as restriction of m_f^* to Σ_f we obtain the L-fuzzy valued measure: $\tilde{\mu}_f = m_f^*(E)$.

VI. The equivalence of two definitions of an L-fuzzy valued integral

In this section we show that two approaches to define an L-fuzzy valued integral described in the previous section give us the equivalent result.

Theorem VI.1. *For all integrable non-negative functions f it holds:*

(T1) $\Sigma \subset \Sigma_f$,

(T2) *for all $E \in \Sigma$ we have $\mu_f = \tilde{\mu}_f$.*

To prove the Theorem VI.1 we use the following Lemma.

Lemma VI.2. *For all $E \in L^X$ it holds:*

(L1) *if f is SNMF (i.e. $f = \sum_{i=1}^{n} c_i \chi_{C_i}$), then*
$$m_f^*(E) = \bigoplus_{i=1}^{n} c_i \ m^*(E \wedge C_i);$$

(L2) *if $(f_n)_{n\in\mathbb{N}}$ is a sequence of SNMF such that $f_n \le f_{n+1}$ and $\lim_{n\to\infty} f_n = f$, then*
$$m_f^*(E) = Sup\{m_{f_n}^*(E) | n \in \mathbb{N}\}.$$

Proof: (L1) First we show that equality holds for L-set $E = A(M,\alpha) \in \wp$. Taking into account the properties of L-fuzzy real numbers we get:

$$m_f(A(M,\alpha)) = z(\nu_f(M),\alpha) = z(\int_M f \, d\nu, \alpha) =$$

$$= z(\int_M \sum_{i=1}^{n} c_i \ \chi_{C_i} \, d\nu, \alpha) = z(\sum_{i=1}^{n} c_i \ \nu(M \wedge C_i), \alpha) =$$

$$= \bigoplus_{i=1}^{n} c_i \ z(\nu(M \wedge C_i), \alpha) = \bigoplus_{i=1}^{n} c_i \ m(A(M,\alpha) \wedge C_i).$$

Now for the sequence of L-sets $(E_k)_{k\in\mathbb{N}} \subset \wp : E \le \bigvee_{k=1}^{\infty} E_k$ we obtain:

$$\bigoplus_{k=1}^{\infty} m_f(E_k) = \bigoplus_{k=1}^{\infty} \bigoplus_{i=1}^{n} c_i \ m(E_k \wedge C_i) = \bigoplus_{i=1}^{n} c_i \ \bigoplus_{k=1}^{\infty} m(E_k \wedge C_i).$$

Finally, recalling the definition of m_f^*:

$$m_f^* = Inf\ \{\bigoplus_{k=1}^{\infty} m_f(E_k) \mid (E_k)_{k\in\mathbb{N}} \subset \wp : E \le \bigvee_{k=1}^{\infty} E_k\} =$$

$$= \bigoplus_{i=1}^{n} c_i \ Inf\ \{\bigoplus_{k=1}^{\infty} \bigoplus_{k=1}^{\infty} m(E_k \wedge C_i) \mid (E_k)_{k\in\mathbb{N}} \subset \wp : E \le \bigvee_{k=1}^{\infty} E_k\} =$$

$$= \bigoplus_{i=1}^{n} c_i \ m^*(E \wedge C_i).$$

(L2) We start with an L-set $E = A(M,\alpha) \in \wp$. Using the properties of L-fuzzy real numbers we get:

$$Sup\{m_{f_n}(A(M,\alpha)) | n \in \mathbb{N}\} = Sup\{z(\nu_{f_n}(M),\alpha) | n \in \mathbb{N}\} =$$

$$= z(\sup_n(\nu_{f_n}(M)),\alpha) = z(\nu_f(M),\alpha) = m_f(A(M,\alpha)).$$

Now taking any $E \in L^X$ and the fact that L if completely distributive lattice we obtain:

$$Sup\ \{m_{f_n}^*(E) | n \in \mathbb{N}\} =$$

$$= Sup\{\ Inf\ \{\bigoplus_{k=1}^{\infty} m_{f_n}(E_k) \mid (E_k)_{k\in\mathbb{N}} \subset \wp : E \le \bigvee_{k=1}^{\infty} E_k\} | n \in \mathbb{N}\} =$$

$$= Inf\{\ Sup\ \{\bigoplus_{k=1}^{\infty} m_{f_n}(E_k) | n \in \mathbb{N}\} | (E_k)_{k\in\mathbb{N}} \subset \wp : E \le \bigvee_{k=1}^{\infty} E_k\} =$$

$$= Inf\{\bigoplus_{k=1}^{\infty} m_f(E_k) | (E_k)_{k\in\mathbb{N}} \subset \wp : E \le \bigvee_{k=1}^{\infty} E_k\} = m_f^*(E).$$

■

Coming back to theorem VI.1.

Proof: (T1) We consider $E \in \Sigma$ and start with the case when f - SNMF or $f = \sum_{i=1}^{n} c_i \chi_{C_i}$. For every $i \in \{1,...,n\}$ if $E \in \Sigma$ then $E \wedge C_i \in \Sigma$ and following for all $B \in L^X$ we have

$$m^*(E \wedge C_i) \oplus m^*(B \wedge C_i) =$$

$$= m^*(E \wedge B \wedge C_i) \oplus m^*((E \wedge C_i) \vee (B \wedge C_i)).$$

Now multiplying equality by c_i and summing up by i we obtain.

$$\sum_{i=1}^{\infty} c_i \ m^*(E \wedge C_i) \oplus \sum_{i=1}^{\infty} c_i \ \wedge m^*(B \wedge C_i) =$$

$$= \sum_{i=1}^{\infty} c_i \; m^*(E \wedge B \wedge C_i) \oplus \sum_{i=1}^{\infty} c_i \; m^*((E \wedge C_i) \vee (B \wedge C_i)).$$

And finally applying Lemma VI.2:

$$m_f^*(E) \oplus m_f^*(B) = m_f^*(E \wedge B) \oplus m_f^*(E \vee B).$$

By analogy we can prove the second equality

$$m_f^*(E^c) \oplus m_f^*(B) = m_f^*(E^c \wedge B) \oplus m_f^*(E^c \vee B).$$

In the case when f is NMF there exists a sequence of SNMF $(f_n)_{n\in\mathbb{N}}$ such that $f_n \leq f_{n+1}$ and $\lim_{n\to\infty} f_n = f$. For all f_n it holds

$$m_{f_n}^*(E) \oplus m_{f_n}^*(B) = m_{f_n}^*(E \wedge B) \oplus m_{f_n}^*(E \vee B).$$

Now taking *Sup* we obtain

$$Sup\{m_{f_n}^*(E) | n \in \mathbb{N}\} \oplus Sup\{m_{f_n}^*(B) | n \in \mathbb{N}\} =$$

$$= Sup\{m_{f_n}^*(E \wedge B) | n \in \mathbb{N}\} \oplus Sup\{m_{f_n}^*(E \vee B) | n \in \mathbb{N}\}.$$

And due to Lemma VI.2

$$m^*(E) \oplus m^*(B) = m^*(E \wedge B) \oplus m^*(E \vee B).$$

The same logic can be used to prove the second equality.

(T2) We start again with SNMF f. Using Lemma VI.2 we see that

$$\mu_f(E) = \int_E f \; d\mu = \bigoplus_{i=1}^{n} c_i \; \mu(E \wedge C_i) =$$

$$= \bigoplus_{i=1}^{n} c_i \; m^*(E \wedge C_i) = m_f^*(E) = \tilde{\mu}_f(E).$$

In the case when f is NMF we use a sequence $(f_n)_{n\in\mathbb{N}}$ such that $f_n \leq f_{n+1}$ and $\lim_{n\to\infty} f_n = f$. By using Lemma VI.2 and the fact that for the simple functions $\mu_{f_n} = \tilde{\mu}_{f_n}$ we get:

$$\mu_f(E) = \int_E f \; d\mu = Sup\{\int_E f_n \; d\mu \; | n \in \mathbb{N}\} = Sup\{\mu_{f_n}(E) \; | n \in \mathbb{N}\} =$$

$$= Sup\{\tilde{\mu}_{f_n}(E) \; | n \in \mathbb{N}\} = m_f^*(E) = \tilde{\mu}_f(E).$$

■

This result gives us an opportunity to define an L-fuzzy valued integral by applying the following formula:

$$\int_E f \; d\mu = \tilde{\mu}_f(E).$$

Summarizing, we want to mention that both ways of defining the L-fuzzy valued integral have their own motivation. The first approach (see V-A) has a theoretical foundation, while the second approach (see V-B) gives us an opportunity to simplify calculations of the L-fuzzy valued integral.

***Abstract*—Image segmentation is the process of assigning a label to every pixel in an image such that pixels with the same label are connected and meaningful, and share certain visual characteristics. Pixels in a region are similar with respect to some features or property, such as color, intensity, or texture. Adjacent regions may be significantly different with respect to the same characteristics. Therefore, it is difficult for a static (non-learning) segmentation technique to accurately segment different images with different characteristics. In this paper, an evolving fuzzy system is used to segment medical images. The system uses some training images to build an initial fuzzy system which then evolves online as new images are encountered. Each new image is segmented using the evolved fuzzy system and may contribute to updating the system. This process provides better segmentation results for new images compared to static paradigms. The average of segmentation accuracy for test images is calculated by comparing every segmented image with its gold standard image prepared manually by an expert.**

Keywords– Image segmentation, Evolving fuzzy systems, SIFT.

I. Introduction

Evolving fuzzy systems are a recent approach used in many applications to solve diverse problems through evolution of fuzzy rules. Evolving fuzzy systems, however, have not been used for image segmentation. Their dynamic capability could improve the segmentation accuracy of different images especially for real-world applications. In this paper, we propose a method that uses evolving fuzzy systems to segment digital images. The motivation for using evolving fuzzy systems is the higher degree of adaptability to the complex and dynamic nature of the segmentation problem. The experiments are performed on breast ultrasound images.

This paper is organized as follows: In section II, SIFT will be briefly described. In section III, the literature on fuzzy image segmentation techniques is briefly reviewed. In section IV, a review of the evolving fuzzy image segmentation is provided. Section V, the proposed evolving fuzzy image segmentation is described. In section VI, the results of applying the proposed system to a set of image data is presented and analysed. Section VII summarizes the paper.

II. Scale invariant feature transform (SIFT)

SIFT is an approach developed by Lowe [1] as a method for object recognition. It depends on detecting a set of key points in an object and calculates a set of descriptors (features) for these points. These features can be used to recognize one object from among different objects. The process of detecting key points and calculating descriptors consist of four stages:

1) Scale-space extrema detection: it uses a difference-of-Gaussian function in different scales and locations to calculate the potential of interest points that are invariant to scale and orientation.
2) Key point localization: for each candidate point, a measure of their stability is performed to discard points with low contrast or poorly located along the edges.
3) Orientation assignment: local image gradient directions are used to assign one or more orientations to each key point location, to make sure that the candidate points are invariant to orientation.
4) Key point descriptor: after selecting the candidate points, the local image gradients are measured in the region around each key point.

We use SIFT method to locate the key points inside the image that seems to be the most descriptive points. The features are extracted from a rectangle around each point.

III. Fuzzy image segmentation

Fuzzy approaches are relatively popular methods for image segmentation. Here we provide a brief review of fuzzy segmentation techniques that may be related to our work.

Fuzzy image segmentation has been used for processing color images. In an approach [2], the segment (separated by edges) within the image is treated as a fuzzy set and can grow using fuzzy criteria. Moreover, the edge detection and region growing algorithms are combined to find larger segments. In a different approach [3], fuzzy c-mean (FCM) and principle component analysis are combined to segment color images using eigen-based membership fuzzy function.

Karmakar et al. [4] propose a generic fuzzy rule-based segmentation technique that tries to solve the problem of manual selection of the parameters of the fuzzy membership in previous fuzzy segmentation techniques. This proposed technique is unlike the previous fuzzy segmentation as it is application-independent and incorporates spatial relationships between pixels.

Tao et al. [5] present a new algorithm for image segmentation by a three-level thresholding technique based on maximum fuzzy entropy and genetic algorithms. They divide the image into three parts and determine the width and attribute of the fuzzy region by maximizing fuzzy entropy. They use a genetic algorithm to find the optimal combination of all parameters.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

Cinque et al. [6] suggest a modification to the existing fuzzy approach for image segmentation adaptive reasoning theory (ART) model. They state that their proposed approach solves the problems of the existing ART model such as overfiting, complexity and inability to measure the extent of match between any two patterns.

Zhang et al. [7] suggest a new algorithm that uses a kernel-induced distance metric instead of the original Euclidean distance in the FCM and adding a spatial penalty on the membership functions to modify the objective function in the fuzzy C-means (FCM). They use their approach for segmentation of magnetic resonance imaging (MRI) data.

Cai et al. [8] propose a new fuzzy c-means clustering algorithm that combines spatial and gray-level information of the image for image segmentation. They called their algorithm fast generalized fuzzy c-means (FGFCM).

Fuzzy clustering is used for segmenting noisy images. That could be done by combining the spatial information which is the summation of the membership functions in the neighbourhood of each pixel under consideration of the image into the membership function for clustering [9]. In a different method, Fuzzy Tree Algorithm is used to represent the data (spatial) and the path compression which helps in reducing the CPU time [10]. In another approach, a modification of the existing fuzzy c-means is used to segment noisy images [11].

Zhuge et al. [12] present a fuzzy connected-based image segmentation to segment vectorial images. Their technique extends the previous work on scalar images to vectorial images. They apply their method on arbitrary dimensional vectorial medical MR images.

Dou et al. [13] propose a fuzzy fusion technique to segment brain tumours in MR images automatically. They suggest to build a separate fuzzy model for each type of MRI image that they may have some prior information about. The different fuzzy models are then fused into one model.

Ma et al. [14] present a modification to the fuzzy C-means image segmentation algorithm to be used with uneven illumination patterns. They insert biased illumination field estimation to the existing recursive FCM algorithm. Moreover, they used the intensity and average intensity of a pixel neighbourhood to define new clustering centre and fuzzy clustering functions and to dilate the initial segment to improve the segmentation process.

Han et al. [15] propose an improvement of the Ant Colony Algorithm (ACA) previously used in image segmentation but with high complexity. They suggest to improve the algorithm to reduce the computation time in image segmentation with a modified fuzzy clustering method.

Hata et al. [16] propose a fuzzy technique for the segmentation of the endorrhachis in magnetic resonance images. This algorithm checks the possibility of the endorrhachis regions in the image and gives the higher possibility a high fuzzy degree. Moreover, they describe a fuzzy maximum intensity projection (FMIP) technique that maps the higher fuzzy membership degrees to brighter values in the data set.

Fan et al. [17] propose a new remote sensing image segmentation approach that solves the problems of the clustering quality caused by the position of the initialization of the cluster centroids in the existing fuzzy C-means algorithm. They suggest to use a single point iterative procedure in the fuzzy C-means clustering to segment remote sensing images.

Foo et al. [18] propose a fuzzy rule-based image segmentation method to mark tumours in a three-dimensional CT data using initial selection of a region of interest (ROI) by the user.

Di Martino et al. [19] use fuzzy transform technique to compress images and then use the Fast Generalized Fuzzy C-Means clustering algorithm to segment the compressed images.

All previous fuzzy segmentation techniques used fuzzy rules and fuzzy clusters, or combined fuzzy rules with other techniques such as principle component analysis approach (PCA) to segment images. There is still need for a fuzzy method that can update the fuzzy rules during the segmentation process. Such dynamic approaches may help in improving the segmentation accuracy and reduce the time required for updating the rules manually.

IV. Evolving Fuzzy Systems

Evolving fuzzy systems are a rather recent development used for many applications. Fuzzy rules could evolve using different methods either by combining with neural networks or genetic algorithms or other techniques that update the fuzzy rules online. Evolving fuzzy rules have not been used for medical image segmentation. We provide here a review of evolving fuzzy systems and their applications.

Kasabov [20] proposed evolving fuzzy neural networks that can learn and perform reasoning, rule extraction and aggregation online. This network is applied to a bench-mark problem. The evolving fuzzy neural network system uses locally tuned elements to perform the process of incremental online learning. When there are more data, the network should be updated by pruning of the nodes, or aggregation of nodes. The network consists of five layers with nodes that are created and connected when data becomes available. The authors compare their algorithm with the fuzzy neural networks and the knowledge-based neural networks.

Futschik et al. [21] use evolving fuzzy neural networks to overcome the problem of transparency in the classification process of the existing statistical and machine learning methods. They used the evolving fuzzy neural networks to classify cancer tissue. They extract fuzzy rules associated with genes that are evidence of specific types of cancer.

Rivas et al. [22] propose a method to design fuzzy membership functions and fuzzy rules using evolutionary computation. They state that their design is simultaneous and its elements are mutually dependent. They also develop an algorithm that is applied directly to the data structure of the fuzzy logic system instead of a binary representation.

Angelov [23] proposed a fuzzy controller of Takagi-Sugeno type with evolving structure. He proposed a new technique for online identification of Takagi-Sugeno systems. He uses the data collected during the process of control to build up the Fuzzy rules of the structure of the controller. The fuzzy

controller is trained using the data collected during the process of control in a non-iterative, recursive way. He provides an example from air-conditioning systems to explain his method.

Chang et al. [24] propose a new hybrid model to forecast the future sales of a printed circuit board factory. They use Self Organization Maps (SOM) along with a Genetic Algorithm (GA) and Fuzzy Rule-Based system to build their hybrid model. They reduced the interaction between fuzzy rules by clustering the fuzzy rules into different clusters. They optimize the number of fuzzy terms of the input and output which turns the fuzzy rules into evolving fuzzy rules. Chang et al. [25] propose an approach that uses a weighted evolving fuzzy neural network system to forecast the future sales of printed circuit board.

Rong et al. [26] use the functional equivalence between a radial basis function network and a fuzzy inference system to develop a sequential adaptive fuzzy inference system. The proposed algorithm is an adaptive technique that depends on the input data to decide whether to add or remove a fuzzy rule from/to the fuzzy rule base.

Xydeas et al.[27] propose two new models to solve the problem of the classification of the brain signals (electroencephalogram (EEG)). They use dependant hidden Markov models to represent the inputs in their first method. In the second method, they use a recursive, online, and evolvable fuzzy rule base to classify the EEG signals.

Lin et al. [28] propose a self-adaptive neural fuzzy network with group-based symbiotic evolution to be used in prediction applications. Their approach contains a self-clustering algorithm (SCA) that addresses the internal structure in which the number of clusters (fuzzy rules) is equal to the true number of clusters in a given training data set. They use a group-based symbiotic evolution learning method that is used to get the desired output by adjusting the parameters.

Barros et al. [29] propose a model that makes an online identification of computationally undemanding evolving fuzzy models. They propose an approach that models non-linear dynamic systems using an online evolving fuzzy model. The rule base is built via incremental learning when accepting new input by adding new rule or deleting, updating existing rule base.

Linden et al. [30] use evolving fuzzy rules and genetic algorithm (in which the rules are represented as an expression in reverse Polish notation) to extract rules from micro array data. They apply their algorithm to problems arising in the construction of gene regulatory networks.

Angelov et al. [31] proposed an evolving fuzzy classifier using different model architectures. They suggest two different approaches for online evolving fuzzy classifiers that could work with different model architectures. Moreover, their first approach can have a multi-input-multi-output architecture. They apply their approach on handwriting recognition and, real-life problem of image classification.

Phan et al. [32] propose a direct self-structuring adaptive fuzzy control approach for affine nonlinear single-input-single output systems. This approach is a self-structuring approach that adds new membership functions and rules to adjust the system and reduce the number of rules by replacing the old membership functions by new ones.

Du et al. [33] study the application of evolving Takagi-Sugeno fuzzy model to non-linear system identification. The authors use genetic algorithm to propose a new encoding approach for learning the Takagi-Sugeno model. They suggest to represent the rules and the inputs and membership functions of the fuzzy system in one chromosome to be evolved.

Lai et al. [34] propose an evolving fuzzy decision tree for financial time series data forecasting for stocks in Taiwan Stock Exchange Corporation. They build a decision-making system by combining a clustering technique, a fuzzy decision tree, and genetic algorithms.

Lughofer [35] study the application on surface inspection using two different on-line evolving image classifiers. The first one is a supervised classification approach that uses conventional vector quantization and forming an incremental evolving variant around it.

Juang et al. [36] provide a dynamic system processing using recurrent self-evolving fuzzy neural network with local feedbacks. Their approach is an online approach that uses a learning process of the structures (generating the fuzzy rules online) and the parameters. A Kalman filter is used to learn the consequent parameters. As well, a gradient descent algorithm is used to learn the antecedent parameters.

V. Evolving Fuzzy Image Segmentation

The idea of evolving fuzzy image segmentation is straightforward: generate a rule-base for segmentation and then let the rules evolve to reach or maintain a high accuracy level.

We start with a set of training images randomly selected from the available set of test images along with their gold standard image. The algorithm should start with **extracting features**. For this purpose we use a set of points detected by the SIFT within a rectangle around the region of interest in these training images. We focus on the simplest form of segmentation, namely thresholding. A set of initial fuzzy rules can be built using the features of the training images as antecedent and their optimal threshold values as consequent. The remaining images in our test set are segmented using the initial fuzzy rules. Based on the quality of the result for any new image, the initial fuzzy rules are evolved. This process is repeated multiple times as long as new images coming, rules are updated. This should increase the segmentation accuracy of the coming new images. The results of segmentation of new images are recorded by calculating the average accuracies by comparing it with its gold standard image prepared manually by an expert.

A. Detection Algorithm

Since features would make more sense if they are calculated for the "region of interest", all images are first processed by a detection algorithm which finds the position of the first seed point inside the region of interest and create a rectangle R around this point. The algorithm performed as follow:

- The seed point P is calculated by tracing a 10×10 mask over the image I and calculating the sum and the standard deviation of every mask and the correlation between the mask and its neighbour. Based on empirical knowledge about our test images, the region of interest has low gray-level intensities and generally a low standard deviation. The mask that has minimum sum and minimum standard deviation is considered the mask contains the seed point. The correlation coefficients between the mask and its preceding mask are used to select the mask containing the seed point if the minimum sum and minimum standard deviation are in two different masks. Hence, for every 10×10 part of the image the minimum sum, standard deviation and correlation are considered to mark the position of a seed point inside the region of interest.
- The algorithm proceeds by constructing a rectangle around the region of interest using the point P as the center of the rectangle. Based on the empirical knowledge, the algorithm starts by finding a region around P as a $n \times n$ window (e.g. 100×100) and incrementally enlarges the window (e.g. with 10×10). This process stops when the standard deviation of one window becomes greater than or less than the standard deviation of the previous region by a certain limit ϵ (e.g. 3%); the last window is considered the region of interest R. These images are stored to be used for extracting feature in the training and testing phases. In most images, the detection algorithm detects a correct point inside the region of interest. For other images, it failed to detect a correct point but we proceed with the rectangle generated by the algorithm.

B. Training Phase

In this phase, we start with the process of feature extraction then the initial fuzzy system will be built (Fig. 1).

1) Feature Extraction: The proposed technique starts with extracting a set of features from training images and uses these features to assign best thresholds to different images using a fuzzy system consisting of fuzzy rules. The process of extracting features is performed as follow:

- The algorithm randomly selects 5 of 20 medical images (breast ultrasound scans) as a training set and the remaining 15 images are used for testing.
- For each training image, the rectangle R around the region of interest created by the detection algorithm is used.
- The rectangle around the region of interest R is provided to the SIFT algorithm which then returns a set of key points $p_1, p_2, \cdots, p_n$ within the rectangle R.
- For each key point assigned by SIFT a 40×40 rectangle is constructed around the point and a set of features are extracted.
- For each image, the optimal threshold is calculated in order to be used for rule generation.

We use simple features that can be calculated fast:

- The mean gray-level μ_S for each 40×40 rectangle S around each key point generated by SIFT: The average gray-level of a sub-image is an indication of its darkness/brightness.
- The standard deviation σ_S for each 40×40 rectangle S around each key point generated by SIFT: The intensity variation captured by the standard deviation quantifies our confidence in darkness/brightness of the sub-image.
- The distance $d_S = \max S - \min S$ between the maximum and the minimum of each 40×40 rectangle S around each key point generated by SIFT: This distance provides additional information to distinguish between different variation levels captured by standard deviation.

Using the SIFT guarantees that the features are extracted in regions with invariant significant characteristics.

2) Building the Initial Fuzzy System: The initial fuzzy system is built from a set of images randomly selected from the set of available images. The input to the fuzzy system consists of the three features calculated around each key point generated by SIFT:

- The mean gray-level μ_S
- The standard deviation σ_S
- The distance $d_S = \max S - \min S$ between the maximum and the minimum of each 40×40 rectangle S .

For each training image, SIFT assign n points inside the region of interest. The features are extracted and calculated from every training image from the rectangles around the n points assigned by SIFT. All features are recorded in a matrix called *Input* matrix. The Input matrix consists of three columns describing the three features and number of rows is equal the number of SIFT points in each image multiplied by the number of training images. In our case, we use five images for training, and the SIFT technique detects ten key points in every image. So the Input matrix has $5 \times 10 = 50$ rows.

The Output (optimal threshold) is a matrix consisting of the optimal thresholds for every training image.

We used the Matlab function "genfis" to generate the rules from the data. The *genfis* function takes two parameters, namely the Input and the Output matrix. A general example for the rules generated is as follows:
IF (μ IS μ_1) AND (σ IS σ_1) AND (d IS d_1)
THEN (Threshold IS th1)

C. Testing phase

After building the initial fuzzy system using randomly selected images, the remaining set of test images can be segmented using the evolving fuzzy system (Fig. 1) which can be described as follows:

1) For each image, the rectangle R around the region of interest created by the detection algorithm is used.
2) The rectangle R is fed into SIFT which returns a set N of key points inside R.
3) The set of features are now calculated from a 40×40 rectangle around each point in N.
4) For every coming new image,
   - The extracted features from every point are used to run the initial fuzzy system which assigns the image a threshold for each point in N.

- The extracted features are stored to be added to the Input matrix later.
- The threshold T^* for segmenting the image is calculate by taking the average of all thresholds for each point $n_i \in N_1$: $T^* = \frac{1}{|N_1|}\sum_{i=1}^{|N_1|} T_i$
- For each Image, the assigned threshold is used to segment the image I.
- The thresholded image is preseneted to an expert to judge its quality. The expert's evaluation may be:
  a) The threshold is too high (threshold adjustment set to $\Delta = -25$), *OR*
  b) The threshold is high (threshold adjustment set to $\Delta = -15$), *OR*
  c) The threshold is low (threshold adjustment set to $\Delta = +15$), *OR*
  d) The threshold is too low (threshold adjustment set to $\Delta = +25$).
- The adjusted threshods along the newly extracted features are inserted to the Output and Input matrices, respectively.
- The new Input and Output matrices are used in the Matlab function "genfis" to evolve the initial fuzzy rules.
- The next new image is segmented using the newly generated rules and the process repeated.

5) After finishing all test images, the average of segmentation accuracy and other statistics are now calculated.

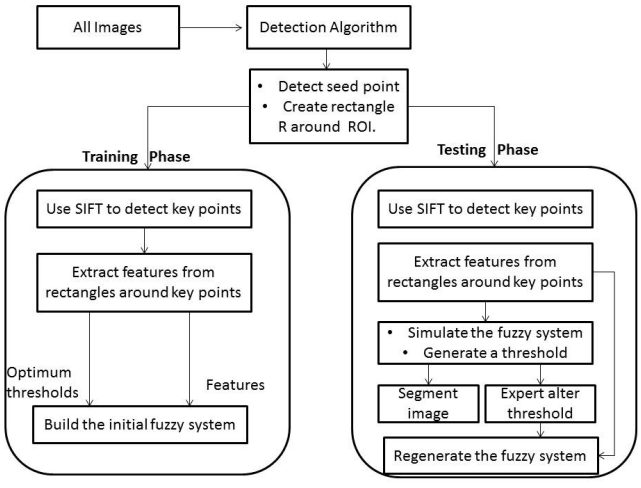

Fig. 1. The evolving fuzzy segmentation

VI. Experiment and Results

The proposed approach randomly selects 5 of 20 medical images as a training set and the remaining 15 images are used for testing. All results of 10 different training sets are calculated and recorded in the Table I.

The following metrics have been employed to verify the performance of the proposed approach (A and B are two segments, one of them being the gold standard):

1) The Dice coefficient D of segmentation accuracy,
$$D(A,B) = \frac{2 * |A \cap B|}{|A| + |B|} \quad (1)$$
2) The standard deviation σ_D of the Dice coefficient.
3) The average of segmentation accuracy J is calculated using the area overlap (also called Jaccard Index)
$$J(A,B) = \frac{|A \cap B|}{|A \cup B|} \quad (2)$$
4) The standard deviation σ_J of the Jaccard index.
5) The confidence interval (CI) of Jaccard index CI_J.
6) The null hypothesis (T-test) between the fuzzy results and the evolving fuzzy results helps to ensure that they are really different.

Sample results of the proposed algorithm are shown in Figure 2. In all images, there is a high improvement in the segmentation accuracy when applying the evolving fuzzy proposed algorithm compared with the ordinary fuzzy rule-based segmentation.

Generally, it is obvious from the Table I that the proposed algorithm performs segmentation more accurately than the conventional fuzzy algorithm. The proposed algorithm has the highest segmentation accuracy and the lowest standard deviation in all training sets. For example, in the fourth training set, the segmentation accuracy increases from 64% in the fuzzy segmentation to 74% in the proposed evolving fuzzy segmentation, and the standard deviation decreased from 25% to 18%. On the other hand, the dice value increased from 75% to 84% and its standard deviation decreased from 22% to 14%. Moreover, the 95% confidence interval of the Jaccard index increased from 50%-78% to 64% - 84%. As well, the 95% confidence interval of the dice value increased from 63%-88% to 76% - 92% which means that the proposed system is more consistent. The validation of the null hypothesis indicates that in the half of the training sets the segmentation accuracy improved.

VII. Conclusions

An evolving fuzzy system was used to segment images by updating the fuzzy rules. Initial fuzzy rules were generated and then updated online. Initial fuzzy rules were created from a number of images randomly selected from the available image set of medical images. The remaining set of images was segmented using the initial fuzzy rules. New images were segmented using the evolving fuzzy rule base. Based on expert's evaluation, the new rules were calculated for every new image and used to evolve the existing fuzzy rules to segment the following images more accurately. Results show clear improvements in segmentation accuracy.

***Abstract*—This work is closely related to our previous papers on algorithms of approximation under *L*-fuzzy information. In the classical theory of approximation central algorithms were worked out on the basis of usual, that is crisp splines. We describe central methods for solution of linear problems with balanced *L*-fuzzy information and develop the concept of *L*-fuzzy splines.**

***Index Terms*—Error of approximation, central algorithm of approximation, spline, *L*-fuzzy real number, *L*-fuzzy information, *L*-fuzzy spline.**

I. Introduction

In the literature one can find two different approaches to the approximation problem when the conditions which must be satisfied under the process of approximation are not strictly defined. One of them, we call it *the statistical approach*, is applicable in cases when the approximation relies on information given with some error and is based on the use of distribution functions. The second, so called *interval method* considers approximation when imprecision of the used information is implied by inevitable interval estimation. As different from these two approaches we propose here an alternative approach to approximation problem which could be helpful in cases when the imprecision of information used in the approximation process has fuzzy, or vague nature.

We consider the problem of approximation of an operator B defined on a set X and taking values in a normed space Y. To find an approximation of the exact value Bx, we must know something about the problem element $x \in X$. We denote the information of x by Ax and suppose that this information is given by an information vector z. Usually the information is imprecise, thus there may exist many different information vectors z, corresponding to one problem element $x \in X$. Under such interpretation it seems natural to consider information Ax as a fuzzy, rather than as a crisp one, i.e. to realize it as an L-fuzzy set Ax by using a lattice L.

In order to estimate the "quality" of *approximation under fuzzy data*, we need an appropriate L-fuzzy analogue of a real number. Notice that the error of a method of approximation in this case is characterized by the supremum of the corresponding L-fuzzy set of real numbers. The principal aim of our work (see also [1], [2], [3]) is to generalize for the case of L-fuzzy information the idea of an *optimal error method* of approximation (the method whose error is the infimum of the errors of all methods for a given problem using the same information) and the concept of a *central algorithm*, which is always an optimal error algorithm and in the crisp case is useful in practice as well as in the general theory (see e.g. [4]).

In the classical approximation theory central methods for solution of linear problems with balanced information usually are based on splines. In the crisp case (see e.g. [5], [6], [7], [8]) one can distinguish three types of splines used in the study of approximation problems: they are respectively *the interpolation splines, the smoothing splines* and, the most general, *splines on the basis of convex sets*. Generalizing the last type of crisp splines, here we introduce the concept of *an L-fuzzy spline* on the basis of L-fuzzy sets and with the help of such splines initiate to develop an approach to study of the approximation problem in case when L-fuzzy information is taken as the basis for this approximation.

We suppose that $L = (L, \leq, \wedge, \vee)$ is a complete, completely distributive lattice, and denote its bottom and top elements by 0 and 1 respectively.

II. Preliminaries

A. L-fuzzy real numbers

In the literature on fuzzy mathematics one can find several different schemes for defining fuzzy real numbers. For our purposes the most appropriate is the approach originating in B. Hutton's paper [9] and further developed by several authors (see e.g. [10], [11], [12], [13], [14], [15]). However, we had to modify it a little.

Definition II.1. *An L-fuzzy real number is a function $z : \mathbb{R} \to L$ such that*

- *z is non-increasing;*
- *$\bigwedge_t z(t) = 0$;*
- *z is left semi-continuous, i.e. for all $t_0 \in \mathbb{R}$ we have $\bigwedge_{t<t_0} z(t) = z(t_0)$.*

Thus we omit the condition $\bigvee_t z(t) = 1$, which is requested by B.Hutton and his followers.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

In the original papers on this subject L-fuzzy real numbers were defined not as order reversing functions, but as equivalence classes of such functions. However, as noticed in [13], each class of equivalence has a unique left semi-continuous representative and therefore an L-fuzzy real number can be identified with this representative.

The set $\mathbb{R}(L)$ of all L-fuzzy real numbers is called *the L-fuzzy real line*.

Given $z_1, z_2 \in \mathbb{R}(L)$ let

$$(z_1 \oplus z_2)(t) = \bigvee_{\tau} \big(z_1(\tau) \wedge z_2(t-\tau)\big).$$

The operation of fuzzy addition $\oplus$ is a jointly continuous extension of addition $+$ from the real line $\mathbb{R}$ to the fuzzy real line $\mathbb{R}(L)$.

The operation $\oplus$ can be naturally extended to the case of L-fuzzy subsets M, N of a linear space X (that is mappings $M, N : X \to L$) as follows:

$$M \oplus N : X \to L : \quad (M \oplus N)(x) := \bigvee_{y \in X} (M(y) \wedge N(x-y)).$$

The definition of the product $\odot$ of L-fuzzy numbers is more complicated if compared with the definition of their sum. However, for our purposes we need only to multiply an L-fuzzy number by a real number $\gamma \in \mathbb{R}$. In this case we define the multiplication by the following simple formula:

$$(\gamma \odot z)(t) = z\left(\frac{t}{\gamma}\right) \text{ if } \gamma \neq 0,$$

and

$$(0 \odot z)(t) = \begin{cases} \bigvee\limits_{\tau \in \mathbb{R}} z(\tau) & \text{for } t \leq 0, \\ 0 & \text{for } t > 0. \end{cases}$$

In case $\gamma > 0$ this definition is equivalent to the standard one (see e.g. [11]). The operation of product is in accordance with the addition and is jointly continuous.

The operation $\odot$ can be naturally extended to the case of an L-fuzzy subset M of a linear space X as follows:

$$(\gamma \odot M)(x) = M\left(\frac{x}{\gamma}\right), \ x \in X, \text{ for any real number } \gamma \neq 0.$$

B. Infimum and supremum

Here we recall some concepts and results from [1], [2].

Definition II.2. *The infimum and the supremum of a set of L-fuzzy numbers $F \subset \mathbb{R}(L)$ are defined by the formulas :*

$$(Inf\ F)(t) = \bigwedge \{z(t) \mid z \in F\}, \ t \in \mathbb{R},$$

$$Sup\ F = Inf\{z \mid z \in \mathbb{R}(L), z \geq z' \text{ for all } z' \in F\}.$$

It is easy to see that $Inf\ F$ is an L-fuzzy real number. In case F is bounded from above (i.e. there exists $z_0 \in \mathbb{R}(L)$ such that $z \leq z_0$ for all $z \in F$), $Sup\ F$ is an L-fuzzy real number, otherwise the condition

$$\bigwedge_t SupF(t) = 0$$

does not necessarily hold.

Definition II.3. *By the supremum of a bounded L-fuzzy set $M : \mathbb{R} \to L$ we call the L-fuzzy real number*

$$\mathcal{S}up(M) : \mathbb{R} \to L$$

defined by the equality

$$\mathcal{S}up(M)(t) = \bigwedge_{u<t} \big(\bigvee_{\tau>u} M(\tau)\big).$$

One can prove that $\mathcal{S}up(M)$ is an L-fuzzy real number. Let us note that we define the supremum only for the case of a bounded L-fuzzy set. Recall that in case X is metric, an L-fuzzy set $M : X \to L$ is called *bounded* if $M^{-1}[\alpha, 1]$ is a bounded subset of X for any $\alpha \neq 0$. Similarly the supremum for an unbounded L-fuzzy set could be defined, however in this case it woudn't be a fuzzy number: the condition $\bigwedge\limits_t z(t) = 0$ will be violated.

Obviously, in case when M is crisp, this definition reduces to the classical definition of the supremum.

In case $M = \varphi(\mathcal{V})$, where $\mathcal{V} : X \to L$ and $\varphi : X \to \mathbb{R}$, we write

$$\mathcal{S}up_{x \tilde{\in} \mathcal{V}} \varphi(x) \quad \text{or} \quad \mathcal{S}up\{\varphi(x) : x \tilde{\in} \mathcal{V}\}$$

instead of

$$\mathcal{S}up(\varphi(\mathcal{V})).$$

Recall that the image $\varphi(\mathcal{V})$ of a fuzzy set $\mathcal{V} \in L^X$ under a mapping $\varphi : X \to \mathbb{R}$ is defined by the equality

$$\varphi(\mathcal{V})(x) = \bigvee \{\mathcal{V}(y) : \varphi(y) = x\}.$$

Given an L-fuzzy set $M : X \to L$, where X is a normed space, we define its L-valued norm as an L-fuzzy number

$$\|M\|^L : \mathbb{R} \to L$$

given by the equality

$$\|M\|^L(t) = Sup\{M(x) \mid \|x\|_X = t\}.$$

One can prove that

$$\|\gamma \odot M\|^L = |\gamma| \odot \|M\|^L$$

and

$$\|M \oplus N\|^L \leq \|M\|^L \oplus \|N\|^L$$

for any L-fuzzy sets $M, N : X \to L$, and hence

$$\| \ \|^L : L^X \to L^{\mathbb{R}}$$

inherits the standard properties of a norm.

C. Radius, diameter and centre of an L-fuzzy set

Here we recall some concepts and results from [3]. Given an L-fuzzy set $V : X \to L$, where X is a normed space.

Definition II.4. *The radius and the diameter of a bounded L-fuzzy set V are defined, respectively by*

$$rad(V) = Inf_{x\tilde{\in}X} Sup_{y\tilde{\in}V} \|x-y\|_X$$

and

$$diam(V) = Sup_{x,y\tilde{\in}V} \|x-y\|_X.$$

Definition II.5. *If for a bounded L-fuzzy set V there exists $c \in X$ such that*

$$rad(V) = Sup_{x\tilde{\in}V} \|c-x\|_X$$

then c is called a centre of V and it is denoted by $c(V)$.

Note that $c(V)$ can be an element "outside" V and need not be unique.

We say that an L-fuzzy set V is symmetric with respect to an element $x_0 \in X$, if for any element $x \in X$ it holds

$$V(x_0+x) = V(x_0-x).$$

We call an L-fuzzy set symmetric in case it is symmetric with respect to some element.

Proposition II.6. *If a bounded L-fuzzy set V is symmetric with respect to an element $c \in Y$, then c is the centre of V.*

III. On methods of approximation under L-fuzzy information

A. Approximation under L-fuzzy information

In this section, following [2], [3] we generalize the well known notions of "classic" or "crisp" approximation theory (see, e.g. [4]) to the L-fuzzy case. We consider the problem (A,B) of approximation of an operator $B : X \to Y$ defined in a set X and taking values in a normed space Y under information given by an operator $A : X \to L^{\mathbb{R}^n}$.

By a method (an algorithm) of solution of the problem (A,B) we mean any operator $\varphi : \mathbb{R}^n \to Y$. For an information vector $z \in \mathbb{R}^n$ the value $\varphi(z)$ must approximate the exact value of solution Bx for the problem element x corresponding to the information vector z:

$$x \in X \Longrightarrow z\tilde{\in}Ax \in L^{\mathbb{R}^n} \Longrightarrow \varphi(z) \approx Bx \in Y.$$

For most problems the information operator is not one-to-one and a given information vector z does not determine the problem element x (the solution element Bx) in the unique way. Thus there may exist many different problem elements (solution elements) with the same information. Such problems also cannot be solved exactly. For problems which can be solved only approximately the notion of the error of a method of approximation plays the fundamental role.

B. Error of a method of approximation under L-fuzzy information

We investigate the error of approximation on a non-empty subset X_0 of the set X. Let $\varphi : \mathbb{R}^n \to Y$ be a method for solving the problem (A,B). Our aim is to define the error of the method for an element $x \in X_0$. There may exist many different elements $u \in X_0$ corresponding to the same information Ax. Since each of them has the correspondness degree characterized by the value $Ax(z)$, such elements form an L-fuzzy subset of X_0. Let us denote it by U_z:

$$U_z(x) = Ax(z) \quad \text{for all} \quad x \in X_0; \quad U_z(x) = 0 \quad \text{for all} \quad x \notin X_0.$$

Thus knowing only z it is impossible to recognize which problem element $x\tilde{\in}U_z$ is being actually approximated and we consider all of them.

Definition III.1. *The error of approximation an element $x \in X_0$ by a method φ is given by the value*

$$e(\varphi,z) = Sup_{x\tilde{\in}U_z} \|Bx - \varphi(z)\|_Y.$$

It is easy to see that the radius of the L-fuzzy set $V_z = B(U_z)$ plays the essential role for the value $e(\varphi,z)$.

Proposition III.2. $rad(V_z) \le e(\varphi,z)$.

Definition III.3. *The error of approximation by a method φ is given by the value*

$$e(\varphi) = Sup_{z\in\mathbb{R}^n} e(\varphi,z).$$

Definition III.4. *A method φ^o is called an optimal error method iff*

$$e(\varphi^o) = Inf_{\varphi} e(\varphi).$$

C. Central methods of approximation under L-fuzzy information

In [2] it is proved that for any method φ

$$e(\varphi) = Sup_{x\in X_0} Sup_{z\tilde{\in}Ax} \|Bx - \varphi(z)\|_Y$$

and

$$r(A,B) \le e(\varphi),$$

where $r(A,B)$ is the radius of information for a problem (A,B) defined by

$$r(A,B) = Sup_z \ rad(V_z).$$

In the sequel we assume that the radius $r(A,B)$ of information is finite.

Definition III.5. *A method φ^c is called a central method on $\mathbb{R}^n$ iff*

$$\varphi^c(z)) = c(V_z) \quad \textit{for all} \quad z \in \mathbb{R}^n.$$

Proposition III.6. *For any central algorithm φ^c*

$$e(\varphi^c) = r(A,B).$$

This proposition implies that:

1) any central algorithm φ^c is an optimal error algorithm;

2) if for problem (A,B) there exists a central algorithm, then

$$r(A,B) = e(\varphi^o).$$

IV. Spline methods for solving linear problems of approximation

A. Linear problems with balanced information

In this work we consider algorithms of approximation of a linear operator under balanced L-fuzzy information, i.e. we investigate approximation methods under assumptions that

$$A : X \to L^{\mathbb{R}^n}$$

is a linear operator defined on a vector space X, i.e.

$$A(\gamma_1 x_1 + \gamma_2 x_2) = \gamma_1 A x_1 \oplus \gamma_2 A x_2 \text{ for all } x_1, x_2 \in X,\ \gamma_1, \gamma_2 \in \mathbb{R},$$

and an information A is balanced in the following sense: for any $x \in X$ the set $Ax \in L^{\mathbb{R}^n}$ is symmetric, i.e. there exists an element $z_x \in \mathbb{R}^n$ such that

$$Ax(z_x + z) = Ax(z_x - z) \quad \text{for all} \quad z \in \mathbb{R}^n$$

and

$$\bigvee_{z \in \mathbb{R}^n} Ax(z) \quad = \quad Ax(z_x).$$

Under these assumptions (A,B) is called a linear problem with balanced information.

We assume also that the set X_0 is given by a linear operator T defined on X and taking values in a Hilbert space W as follows

$$X_0 = \{x \in X : \quad \|Tx\|_W \le 1\}.$$

Note that central methods for solution of linear problems with balanced information worked out on the basis of *usual*, that is *crisp* splines. To define them we use the defuzzyfication

$$a : X \to \mathbb{R}^n$$

of an operator A:

$$a(x) = z_x \quad \text{for all} \quad x \in X.$$

B. Spline methods

In the sequel assume that $T(Ker(a))$ is closed and $a(X) = \mathbb{R}^n$. Under this assumption for any $z \in \mathbb{R}^n$ there exists an element $s_z \in X$ such as

$$\|Ts_z\|_W = \inf_{x \in X, z_x = z} \|Tx\|_W,$$

called *a spline interpolating z*. The space of all interpolating splines $S(T,a)$ is described by the formula

$$S(T,a) = \{s \in X : \quad < Ts, Tx >_W = 0 \quad \text{for all} \quad x \in Ker(a)\},$$

where $Ker(a)$ is the kernel of an operator a.

For the notions and results on splines see e.g. [5], [6], [7], [8].

The spline algorithm may be derived as follows. Let

$$e^i = (0,0,...,0,1,0,...,0) \in \mathbb{R}^n$$

denote the i-th unit vector, $i = 1,2,...,n$. Find a spline s_i interpolating e^i. The spline algorithm φ^s is of the form:

$$\varphi^s(z) = Bs(z), \quad \text{where} \quad s(z) = \sum_{i=1}^{n} z_i s_i \quad \text{for all} \quad z \in \mathbb{R}^n.$$

Proposition IV.1. *The method φ^s is a central method.*

This proposition implies that:
1) the spline algorithm φ^s is an optimal error algorithm;
2) for linear problems (A,B) with balanced information:

$$r(A,B) = e(\varphi^s).$$

C. L-fuzzy splines

In this section we generalize the concept of a spline. For a given vector $z \in \mathbb{R}^n$ we consider the following problem of minimization

$$\|TS_z\|^L = Inf_{x \in A^{-1}(z)} \|Tx\|_W,$$

where S_z is an L-fuzzy set in X. A solution of this problem $S_z : X \to L$ is called *an L-fuzzy spline interpolating z*. We denote by $S(T,A,L)$ the set of all L-fuzzy splines.

Proposition IV.2. *If an information operator $A : X \to L^{\mathbb{R}^n}$ is given by a usual operator $a : X \to \mathbb{R}^n$ as follows*

$$Ax(z) = \begin{cases} 1, \text{ if } z = a(x), \\ 0, \text{ if } z \neq a(x), \end{cases}$$

then for any vector $z \in \mathbb{R}^n$ an interpolating L-fuzzy spline $S_z \in S(T,A,L)$ is the crisp set of all splines $s_z \in S(T,a)$ interpolating z, i.e.

$$S_z(X) = \{0,1\}, \quad \text{and} \quad S_z(s_z) = 1$$

iff

$$\|Ts_z\|_W = \inf_{x \in X, a(x) = z} \|Tx\|_W.$$

Proposition IV.3. *If an information operator $A : X \to L^{\mathbb{R}^n}$ is given by a usual operator $a : X \to \mathbb{R}^n$ and a positive number ε as follows*

$$Ax(z) = \begin{cases} 1, \text{ if } \|a(x) - z\| \le \varepsilon, \\ 0, \text{ if } \|a(x) - z\| > \varepsilon, \end{cases}$$

then for any vector $z \in \mathbb{R}^n$ an interpolating L-fuzzy spline $S_z \in S(T,A,L)$ is the crisp set of all splines $s_z \in S(T,a)$ smoothing z with parameter ε, i.e.

$$S_z(X) = \{0,1\}, \quad \text{and} \quad S_z(s_z) = 1$$

iff

$$\|Ts_z\|_W = \inf_{x \in X, \|a(x) - z\| \le \varepsilon} \|Tx\|_W.$$

V. Conclusion

Central algorithms play fundamental role in classical approximation theory. In our previous work [3] we have introduced the generalized concept of a central algorithm of approximation of an operator under L-fuzzy information. The central methods for solution of linear problems with balanced information relay on splines. In [3] we studied central algorithm of approximation of an operator under L-fuzzy information which is based on usual, that is crisp splines. As different from that research the aim of this work is to start further development of the approximation theory in the context of fuzzy information which would be based on the use of L-fuzzy splines - the concept introduced and studied here. The research developed here embraces the case when an L-fuzzy spline $S_z \in S(T,A,L)$ interpolating vector z, is the crisp set of all splines $s_z \in S(T,a)$ interpolating or smoothing it. The general case of an L-fuzzy interpolating spline will be the subject of a forthcoming research.

***Abstract* — This paper extends to H_∞ performance design a recent local approach for non-quadratic stabilization of continuous-time Takagi-Sugeno (TS) models based on the fuzzy Lyapunov function (FLF). The main obstacle for using FLFs altogether with TS models consists in handling the time-derivatives of the membership functions (MFs). By reducing global stability goals via local considerations, the aforementioned impediment has been removed leading to stabilization domains where H_∞ disturbance rejection is guaranteed. Conditions are expressed as linear matrix inequalities (LMIs), thus enabling systematic and efficient solutions which are solved by convex optimization techniques.**

***Keywords* — Fuzzy Lyapunov Function (FLF), Linear Matrix Inequality (LMI), Local Stabilization, H_∞ disturbance rejection, Takagi-Sugeno (TS) models.**

I. Introduction

SINCE its appearance, Takagi-Sugeno models (TS) [1] have attracted the interest of researchers in control because of their systematic construction methodology which leads to exact convex representations of nonlinear models in a compact set of the state variables [2]. These convex representations facilitate system analysis and control design [3], [4] via the direct Lyapunov method with quadratic Lyapunov functions [5]. Parallel distributed compensation (PDC) is widely used among quadratic schemes because it naturally fits with the structure of TS models providing a fuzzy controller that allows performance design via linear matrix inequalities (LMIs) [6].

Despite its success, there are several sources of pessimism for stabilization of TS models: model construction is not unique [7], membership functions (MFs) can only be partially taken into account through different and not necessarily compatible approaches [8], [9], [10], [11], quadratic Lyapunov functions are a subclass of more complex and powerful choices that may not be easy to implement. This work extends the existing results in the latter direction since it uses a fuzzy Lyapunov function which includes the quadratic case. Nevertheless, an important feature of the proposed approach lies on its local nature which exploits the fact that TS models are only valid in a compact set of the state space. Global stabilization results as those available in the quadratic case prove to be more restrictive than local results in a non-quadratic framework.

Otherwise than the quadratic framework, piecewise [12], [13], integral [14], and fuzzy Lyapunov functions [15] have been proposed. Among the latter, continuous-time results have not been as powerful as those for the discrete-time case [16], [17], [18]. This unevenness is caused by the presence of time-derivatives of the MFs in the analysis, which destroys the convex structure leading to LMIs. Most of the palliative solutions to this problem assume the knowledge of bounds for the time-derivatives of the MFs, which is an unrealistic assumption especially concerning algebraic loops in control design [19]. Other solutions lead to bilinear matrix inequalities, which cannot be guaranteed to be optimally solved [14].

The approach first appeared in [20] and further extended in [21] for local stability analysis of continuous-time TS models is formulated in LMIs and does not require more than a-priori-known bounds from the TS model construction. Based on these works, a paper proposing a control law for local stabilization has been proposed in [22]. This paper extends the former results for local stabilization of a TS model with H_∞ disturbance rejection.

The paper is organized as follows: section II introduces notation, the considered TS model, the Lyapunov function candidate, and the proposed control law; section III extends to H_∞ disturbance rejection the results in [22]; in section IV some illustrative examples are shown; finally section V closes the paper providing some conclusions and perspectives.

II. Preliminaries

Consider the following nonlinear affine-in-control model:

The present paper has been supported by the National Council of Science and Technology of Mexico (CONACYT-SNI), the French National Center for Scientific Research (CNRS), and the PROMETEO project from the Comunitát Valenciana (Spain). The authors gratefully acknowledge the support of these institutions.

$$\begin{aligned}\dot{x}(t) &= f_1(z)x(t)+f_2(z)u(t)+f_3(z)\omega(t)\\ y(t) &= f_4(z)x(t)+f_5(z)u(t)+f_6(z)\omega(t)\end{aligned} \quad (1)$$

with input vector $u(t)\in\mathbb{R}^m$, disturbance vector $\omega(t)\in\mathbb{R}^q$, $\|\omega(t)\|_2 \le \bar{\omega}$, state vector $x(t)\in\mathbb{R}^n$, premise vector $z(x(t))\in\mathbb{R}^p$ bounded in a compact region $\Delta \supset \mathbf{0}$, output vector $y(t)\in\mathbb{R}^o$, and $f_1(\cdot),\ldots,f_6(\cdot)$ nonlinear functions depending on $z(x(t))$. Let $nl_j(\cdot)\in\left[\underline{nl_j},\overline{nl_j}\right]$, $j\in\{1,\cdots,p\}$ be the bounded nonlinearities of (1) in the compact region Δ. By sector nonlinearity approach [3] the following weighting functions are defined to capture nonlinearities in (1):

$$w_0^j(\cdot)=\frac{\overline{nl_j}-nl_j(\cdot)}{\overline{nl_j}(\cdot)-\underline{nl_j}},\quad w_1^j(\cdot)=1-w_0^j(\cdot),\ j\in\{1,\cdots,p\} \quad (2)$$

from which membership functions (MFs)

$$h_i = h_{1+i_1+i_2\times 2+\cdots+i_p\times 2^{p-1}} = \prod_{j=1}^{p} w_{i_j}^j(z_j), \quad (3)$$

$i\in\{1,\cdots,2^p\}$, $i_j\in\{0,1\}$, are defined satisfying the convex-sum property $\sum_{i=1}^{r} h_i(\cdot)=1$, $h_i(\cdot)\ge 0$ in Δ.

Notation: Arguments are omitted where convenient. An asterisk $(*)$ inside a block matrix represents the transpose of the symmetric element. Sums $\Upsilon_z=\sum_{i=1}^{r}h_i\Upsilon_i$, $\Upsilon_z^{-1}=\left(\sum_{i=1}^{r}h_i\Upsilon_i\right)^{-1}$ will be used to simplify expressions. Thus, an exact representation of nonlinear model (1) in Δ can be written as the following TS model:

$$\begin{aligned}\dot{x}(t) &= \sum_{i=1}^{r} h_i(z(t))\left(A_i x(t)+B_i u(t)+E_i\omega(t)\right)\\ &= A_z x(t)+B_z u(t)+E_z\omega(t)\\ y(t) &= \sum_{i=1}^{r} h_i(z(t))\left(C_i x(t)+D_i u(t)+F_i\omega(t)\right)\\ &= C_z x(t)+D_z u(t)+F_z\omega(t)\end{aligned} \quad (4)$$

where A_i, B_i, C_i, D_i, E_i, F_i, $i=1,\ldots,r$ are matrices of the proper size and $r=2^p\in\mathbb{N}$ is the number of rules (linear models) of the fuzzy interpretation of (4).

Double convex sums involving MFs will appear in the sequel. In order to obtain LMI conditions these MFs must be removed. The following result will be applied to perform this task since it combines simplicity and a good solutions' quality:

Relaxation Lemma [8]: Let Υ_{ij}, $i,j\in\{1,\cdots,r\}$ be matrices of certain dimension. Condition

$$\sum_{i=1}^{r}\sum_{j=1}^{r} h_i(z(t))h_j(z(t))\Upsilon_{ij}<0 \quad (5)$$

is verified if:

$$\begin{aligned}&\Upsilon_{ii}<0,\quad \forall i\in\{1,\cdots,r\}\\ &\frac{2}{r-1}\Upsilon_{ii}+\Upsilon_{ij}+\Upsilon_{ji}<0,\quad \forall(i,j)\in\{1,\cdots,r\}^2,\ i\ne j.\end{aligned} \quad (6)$$

A non-quadratic control law taken from [16] will be used:

$$u(t)=G_z P_z^{-1}x(t)=\left(\sum_{i=1}^{r}h_i(z)G_i\right)\left(\sum_{i=1}^{r}h_i(z)P_i\right)^{-1}x(t) \quad (7)$$

where $G_i\in\mathbb{R}^{m\times n}$ are gains and $P_i\in\mathbb{R}^{n\times n}$, $P_i=P_i^T>0$ are matrices associated with a fuzzy Lyapunov function. Thus, the closed-loop TS model is:

$$\begin{aligned}\dot{x}(t) &= \left(A_z+B_zG_zP_z^{-1}\right)x(t)+E_z\omega(t)\\ y(t) &= \left(C_z+D_zG_zP_z^{-1}\right)x(t)+F_z\omega(t)\end{aligned} \quad (8)$$

The following candidate fuzzy Lyapunov function will be adopted [15]:

$$V(x(t))=x^T(t)P_z^{-1}x(t)=x^T(t)\left(\sum_{i=1}^{r}h_i(z(t))P_i\right)^{-1}x(t). \quad (9)$$

III. H_∞ CONTROL

The nonlinear model (1), or its equivalent TS model (4), satisfy the H_∞ attenuation criterion in Δ if disturbances $\omega(t)$ are bounded at the output by:

$$\sup_{\|\omega(t)\|_2\ne 0}\frac{\|y(t)\|_2}{\|\omega(t)\|_2}\le\gamma \quad (10)$$

where $\|\bullet\|_2$ stands for the L_2-norm.

As shown in [3], condition (10) is satisfied if:

$$\dot{V}(x(t))+y^T(t)y(t)-\gamma^2\omega^T(t)\omega(t)\le 0. \quad (11)$$

Taking into account (4) and (9), (11) can be rewritten by developing the time-derivative of $V(x(t))$ along the trajectories of (8):

$$\begin{aligned}&\dot{V}(x(t))+y^T(t)y(t)-\gamma^2\omega^T(t)\omega(t)\\ &=x^T(t)P_z^{-1}\dot{x}(t)+\dot{x}^T(t)P_z^{-1}x(t)+x^T(t)\left(\dot{P}_z^{-1}\right)x(t)-\gamma^2\omega^T(t)\omega(t)\\ &+\left(\left(C_z+D_zG_zP_z^{-1}\right)x(t)+F_z\omega(t)\right)^T\left(\left(C_z+D_zG_zP_z^{-1}\right)x(t)+F_z\omega(t)\right)\\ &=x^T\left(P_z^{-1}\left(A_z+B_zG_zP_z^{-1}\right)+\left(A_z+B_zG_zP_z^{-1}\right)^TP_z^{-1}+\dot{P}_z^{-1}\right.\\ &\left.+\left(C_z+D_zG_zP_z^{-1}\right)^T\left(C_z+D_zG_zP_z^{-1}\right)\right)x+\omega^T\left(F_z^TF_z-\gamma^2I\right)\omega\\ &+x^T\left(\left(C_z+D_zG_zP_z^{-1}\right)^TF_z+P_z^{-1}E_z\right)\omega+\omega^T\left(F_z\left(C_z+D_zG_zP_z^{-1}\right)+E_z^TP_z^{-1}\right)x\\ &=\begin{bmatrix}x\\ \omega\end{bmatrix}^T\begin{bmatrix}\Gamma_1 & (*)\\ F_z^T\left(C_z+D_zG_zP_z^{-1}\right)+E_z^TP_z^{-1} & F_z^TF_z-\gamma^2I\end{bmatrix}\begin{bmatrix}x\\ \omega\end{bmatrix}\le 0\end{aligned} \quad (12)$$

with $\Gamma_1=P_z^{-1}\left(A_z+B_zG_zP_z^{-1}\right)+\left(A_z+B_zG_zP_z^{-1}\right)^TP_z^{-1}+\dot{P}_z^{-1}+\left(C_z+D_zG_zP_z^{-1}\right)^T\left(C_z+D_zG_zP_z^{-1}\right)$.

Obviously, (12) is satisfied if the block-matrix therein is not positive-definite. Pre- and post-multiplying the referred matrix in (12) by full-rank matrix $\begin{bmatrix}P_z & 0\\ 0 & I\end{bmatrix}$ as well as using the property $P_z\dot{P}_z^{-1}P_z=-\dot{P}_z$, it is possible to guarantee (12) if

$$\begin{bmatrix}\Gamma_2 & P_zC_z^TF_z+G_z^TD_z^TF_z+E_z\\ F_z^TC_zP_z+F_z^TD_zG_z+E_z^T & F_z^TF_z-\gamma^2I\end{bmatrix}\le 0 \quad (13)$$

with $\Gamma_2 = A_z P_z + B_z G_z + P_z A_z^T + G_z^T B_z^T - \dot{P}_z + P_z C_z^T C_z P_z + P_z C_z^T D_z G_z + G_z^T D_z^T C_z P_z + G_z^T D_z^T D_z G_z = A_z P_z + B_z G_z + P_z A_z^T + G_z^T B_z^T - \dot{P}_z + \left(P_z C_z^T + G_z^T D_z^T\right)\left(C_z P_z + D_z G_z\right)$.

Applying Schur complement to expression (13) gives

$$\begin{bmatrix} A_z P_z + B_z G_z + P_z A_z^T + G_z^T B_z^T - \dot{P}_z & (*) & (*) \\ C_z P_z + D_z G_z & -I & \mathbf{0} \\ F_z^T C_z P_z + F_z^T D_z G_z + E_z^T & \mathbf{0} & F_z^T F_z - \gamma^2 I \end{bmatrix} \le 0 . \quad (14)$$

Any term in inequality (14) is an LMI except for the term $\dot{P}_z = \sum_{i=1}^{r} \dot{h}_i\left(z(t)\right) P_i$ which includes the time-derivatives of the MFs. To deal with this problem, most of the published works on the subject propose a bound of the form $\left\|\dot{P}_z\right\| < \phi_z$ [23], [24]. Nevertheless, these bounds cannot be established a priori and can create algebraic loops when applied to stabilization problems. The approach here employed overcomes the aforementioned problem by focusing on local stabilization.

In [20] it has been shown that

$$\begin{aligned} \dot{P}_z &= \sum_{k=1}^{p} \frac{\partial w_0^k}{\partial z_k}\left(P_{g_1(z,k)} - P_{g_2(z,k)}\right)\dot{z}_k \\ &= \sum_{j=1}^{r}\sum_{k=1}^{p} h_j \frac{\partial w_0^k}{\partial z_k}\left(P_{g_1(j,k)} - P_{g_2(j,k)}\right)\dot{z}_k \end{aligned} \quad (15)$$

with

$$\begin{aligned} g_1(j,k) &= \left\lfloor (j-1)/2^{p+1-k} \right\rfloor \times 2^{p+1-k} + 1 + (j-1) \bmod 2^{p-k} \\ g_2(j,k) &= g_1(j,k) + 2^{p-k} \end{aligned} \quad (16)$$

and $\lfloor \cdot \rfloor$ standing for the floor function. Note that

$$\dot{z}_k = \left(\frac{\partial z_k(t)}{\partial x(t)}\right)^T \dot{x}(t) = \left(\frac{\partial z_k(t)}{\partial x(t)}\right)^T \left(A_z x(t) + B_z u(t) + E_z \omega(t)\right), \quad (17)$$

so expression (15) can be rewritten as:

$$\begin{aligned} \dot{P}_z &= \sum_{k=1}^{p} \frac{\partial w_0^k}{\partial z_k}\left(P_{g_1(z,k)} - P_{g_2(z,k)}\right)\left(\frac{\partial z_k(t)}{\partial x(t)}\right)^T \left(A_z x(t) + B_z u(t) + E_z \omega(t)\right) \\ &= \sum_{k=1}^{p}\sum_{v=1}^{n}\sum_{s=1}^{n} \frac{\partial w_0^k}{\partial x_v} x_s \left(A_z\right)_{vs}\left(P_{g_1(z,k)} - P_{g_2(z,k)}\right) \\ &\quad + \sum_{k=1}^{p}\sum_{v=1}^{n}\sum_{e=1}^{m} \frac{\partial w_0^k}{\partial x_v} u_e \left(B_z\right)_{ve}\left(P_{g_1(z,k)} - P_{g_2(z,k)}\right) \\ &\quad + \sum_{k=1}^{p}\sum_{v=1}^{n}\sum_{d=1}^{q} \frac{\partial w_0^k}{\partial x_v} \omega_d \left(E_z\right)_{vd}\left(P_{g_1(z,k)} - P_{g_2(z,k)}\right). \end{aligned} \quad (18)$$

The terms $\left|\frac{\partial w_0^k}{\partial x_v} x_u\right|$, $\left|\frac{\partial w_0^k}{\partial x_v} u_e\right|$, and $\left|\frac{\partial w_0^k}{\partial x_v} \omega_d\right|$ can now be bounded since their components are known *a priori* or can be designed to be bounded.

In order to bund the input $\|u\|_2 < \mu$, consider $|x(0)| < c$ and $P_z \ge c^2 I$ (or $P_z^{-1} \le c^{-2} I$); this provided, since the Lyapunov function is a monotonous decreasing function, it can be shown that $V\left(x(t)\right) \le x^T(t) P_z^{-1} x(t) \le x^T(0) P_z^{-1} x(0) \le 1$, from which $\|u\|_2 < \mu$ if $\frac{1}{\mu^2}\|u\|_2^2 \le x^T(t) P_z^{-1} x(t) \le 1$, i.e.:

$$\frac{1}{\mu^2} x^T(t) P_z^{-1} G_z^T G_z P_z^{-1} x(t) \le x^T(t) P_z^{-1} x(t) \quad (19)$$

which by Schur complement can be written as:

$$\begin{bmatrix} P_z & G_z^T \\ G_z & \mu^2 I_m \end{bmatrix} > 0 \quad (20)$$

Then, the aforementioned bounds can be written as:

$$\left|\frac{\partial w_0^k}{\partial x_v} x_s\right| \le \lambda_{kvs}, \left|\frac{\partial w_0^k}{\partial x_v} u_e\right| \le \mu \eta_{kv}, \left|\frac{\partial w_0^k}{\partial x_v} \omega_d\right| \le \bar{\omega} \eta_{kv} \quad (21)$$

In order to use (21) taking into account (18) as to obtain LMI conditions implying (14), expression

$$W + \left(\frac{\partial w_0^k}{\partial x_v} x_s\right) X + \left(\frac{\partial w_0^k}{\partial x_v} u_e\right) Y + \left(\frac{\partial w_0^k}{\partial x_v} \omega_d\right) Z \le 0 \quad (22)$$

is going to be guaranteed by

$$W \pm \lambda_{ksv} \times X \pm \eta_{kv} \times \mu Y \pm \eta_{kv} \times \bar{\omega} Z \le 0, \quad (23)$$

which represents all the possible sign combinations for every bounded term.

Theorem: If there are matrices of proper size $P_i = P_i^T > c_i^2 I$, G_i, satisfying the following LMI conditions for $i, j, k \in \{1, \cdots, r\}$, $\alpha \in \left\{1, \cdots, 2^{p \times n \times (n+m+q)}\right\}$:

$$\begin{bmatrix} P_j & G_j^T \\ G_j & \mu^2 I \end{bmatrix} > 0 \quad (24)$$

$$\frac{2}{r-1} \Upsilon_{iik}^{\alpha} + \Upsilon_{ijk}^{\alpha} + \Upsilon_{jik}^{\alpha} < 0, \quad (25)$$

with $\Upsilon_{ijk}^{\alpha} = \begin{bmatrix} A_i P_j + B_i G_j + P_j A_i^T + G_j^T B_i^T - \bar{P}_{ij}^{\alpha} & (*) & (*) \\ C_i P_j + D_i G_j & -I & \mathbf{0} \\ F_k^T C_i P_j + F_k^T D_i G_j + E_i^T & \mathbf{0} & F_i^T F_j - \gamma^2 I \end{bmatrix}$,

$$\begin{aligned} \bar{P}_{ij}^{\alpha} &= \sum_{k=1}^{p}\sum_{v=1}^{n}\sum_{s=1}^{n} (-1)^{b_{kv(s+m+q)}^{\alpha}} \lambda_{kvs} \left(A_i\right)_{vs}\left(P_{g_1(j,k)} - P_{g_2(j,k)}\right) \\ &\quad + \sum_{k=1}^{p}\sum_{v=1}^{n}\sum_{e=1}^{m} (-1)^{b_{kv(e+q)}^{\alpha}} \eta_{kv} \mu \left(B_i\right)_{ve}\left(P_{g_1(j,k)} - P_{g_2(j,k)}\right) \\ &\quad + \sum_{k=1}^{p}\sum_{v=1}^{n}\sum_{d=1}^{q} (-1)^{b_{kvd}^{\alpha}} \eta_{kv} \bar{\omega} \left(E_i\right)_{vd}\left(P_{g_1(j,k)} - P_{g_2(j,k)}\right), \end{aligned}$$

b_{kvl}^{α} defined from the binary representation of $\alpha - 1 = b_{pn(n+m+q)}^{\alpha} + b_{pn(n+m+q-1)}^{\alpha} \times 2 + \cdots + b_{111}^{\alpha} \times 2^{pn(n+m+q)-1}$, and $g_1(j,k)$, $g_2(j,k)$ defined as in (16), then $x(t)$ in (8) is locally asymptotically stable for every initial condition $x(0)$, $|x(0)| < c$, inside the biggest equipotential R_o contained in $R = \bigcap_{e,k,s,v} \left\{x : \left|\frac{\partial w_0^k}{\partial x_v} x_s\right| \le \lambda_{kvs}, \left|\frac{\partial w_0^k}{\partial x_v} u_e\right| \le \mu \eta_{kv}\right\}$; moreover, the model output $y(t)$ satisfies the H_∞ criterion in (10) for disturbances holding the property $\left\|\omega(t)\right\|_2 \le \bar{\omega}$.

Proof: By relaxation lemma in (6), LMI (25) implies:

$$\Upsilon_{zz}^{\alpha}=\begin{bmatrix} A_zP_z+B_zG_z+P_zA_z^T+G_z^TB_z^T-\bar{P}_{ij}^{\alpha} & (*) & (*) \\ C_zP_z+D_zG_z & -I & \mathbf{0} \\ F_z^TC_zP_z+F_z^TD_zG_z+E_z^T & \mathbf{0} & F_z^TF_z-\gamma^2 I \end{bmatrix}\le 0 \quad (26)$$

Since all the possible sign combinations in $\bar{P}_{ij}^{\alpha}$ are taken into account and inequalities in (21) bound the time-derivative $\dot{P}_z$, it follows that (26) is a simple extension of property (22); in other words, (26) implies (14), which guarantees the H_∞ criterion in (10) to be satisfied.

Note that bounds in (21) are essential to guarantee implication (26) $\Rightarrow$ (14); these bounds stem from a) the fact that $x(t)$ belongs to a compact set Δ in which the TS model is defined, b) the bounds on the input which are designed via LMIs (24), and c) from the disturbances bound $\bar{\omega}$.

Remark 1: Writing $\dot{P}_z$ in the form described in (18) plays a fundamental role in the proposed local approach. The interested reader is referred to [20] for more details.

Remark 2: Besides the region on which the TS model has been defined, other design parameters intervene in the control law: the bound on the input, the bound on the initial conditions, and the attenuation factor $\gamma>0$. Bounding the disturbance vector is also a reasonable requirement in this kind of problems.

Remark 3: The theorem above guarantees H_∞ performance in the region $R_o \subseteq R$. Should the biggest region R_o be of interest, a simple algorithm can be implemented by linear programming to find it [20]: a) initialize η_{kv}, λ_{kvs} to any initial feasible bounds η_{kv}^0, λ_{kvs}^0; b) search the biggest value $\varepsilon>0$ such that conditions in the theorem above are satisfied with $\eta_{kv}=\varepsilon\eta_{kv}^0$ and $\lambda_{kvs}=\varepsilon\lambda_{kvs}^0$. Consider $R_o \subseteq R$ defined from the last values thus found.

Remark 4: The previous algorithm is compatible with the minimization of the attenuation factor γ. Once ε is established, the minimum attenuation factor γ guaranteeing H_∞ performance design in the region thus defined can be searched as an LMI problem.

IV. Examples

Two examples are shown in this section to illustrate the advantages of the proposed methodology. The first one is stabilized in the absence of disturbances to show the influence of certain design parameters; the second one shows the effectiveness of the H_∞ control design for different regions and parameters.

Example 1 : Consider the following TS model:

$$\dot{x}(t)=\sum_{i=1}^{2} h_i\left(z(t)\right)\left(A_i x(t)+B_i u(t)\right) \quad (27)$$

with system matrices

$$A_1=\begin{bmatrix} 2 & -10 \\ 2 & 0 \end{bmatrix},\ A_2=\begin{bmatrix} -20 & -5 \\ 1 & 2 \end{bmatrix},\ B_1=\begin{bmatrix} 0.1 \\ 1 \end{bmatrix},\ B_2=\begin{bmatrix} 0.3 \\ 0.2 \end{bmatrix},$$

and MFs

$$h_1(x_1)=\frac{1-\sin(x_1)}{2},\ h_2(x_1)=\frac{1+\sin(x_1)}{2},$$

defined in $\Delta=\left\{x\in\mathbb{R}^2, |x_i|<\frac{\pi}{2}\right\}$.

When no perturbations are considered, the proposed approach depends upon the parameter μ (bound on the input $|u|<\mu$) and parameter c (bound on the initial conditions $|x(0)|<c$). In practice, these bounds are directly derived from the model, so LMI conditions in the theorem above are fully determined.

Fig. 1 shows the influence of parameter μ for the model (27) with $|x(0)|<c=\sqrt{2}\pi/2$. As expected, the bigger the values of μ, the bigger the stabilization region R_0. To determine the biggest stabilization region, the algorithm in Remark 3 has been used. Four state trajectories are shown to illustrate the effectiveness of the stabilization method with $|u|<\mu=40$ (solid trajectories with arrows pointing towards the origin).

In Fig. 2 the effects of changing the modelling region of the TS model (27) for $\Delta=\left\{x\in\mathbb{R}^2, |x_i|<\pi/4\right\}$ are studied. In both regions, bounds $|x(0)|<c=\pi/2$ and $|u|<\mu=30$ are assumed. Dotted lines show the borders of R for the original case.

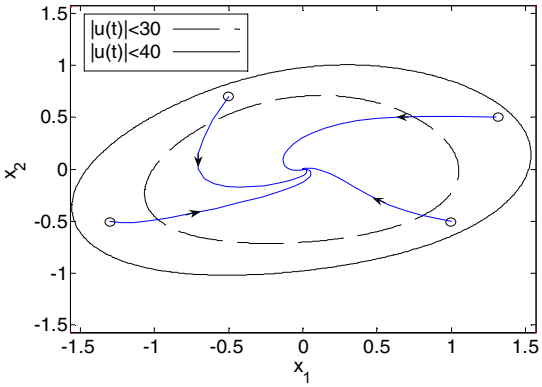

Figure 1: Effects of the input bound μ.

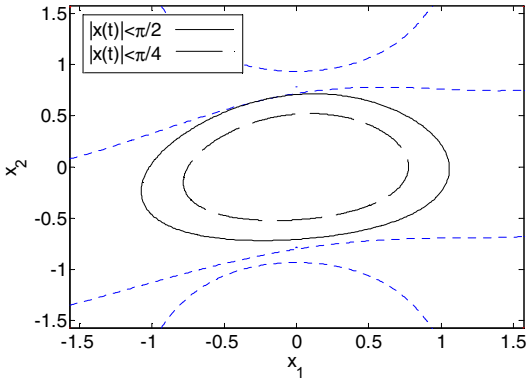

Figure 2: Effects of the region Δ.

It is important to notice that augmenting the modelling region of the TS model do not necessarily mean that a bigger stabilization region will be found. Bigger modelling regions imply that the initial conditions can be further from the origin, thus reducing feasibility of LMIs in (24) since $P_i = P_i^T > c_i^2 I$, $|x(0)| < c$.

Example 2: Consider the following TS model subject to scalar perturbations $\omega(t) = e^{-t}\cos(t)$, $|\omega(t)| \le 1$:

$$\dot{x}(t) = \sum_{i=1}^{2} h_i(z(t))\left(A_i x(t) + B_i u(t) + E_i \omega(t)\right)$$
$$y(t) = \sum_{i=1}^{r} h_i(z(t)) C_i x(t) \qquad (28)$$

with system matrices

$$A_1 = \begin{bmatrix} -5 & -4 \\ -1 & -2 \end{bmatrix}, \quad A_2 = \begin{bmatrix} -2 & -4 \\ 20 & -2 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 0 \\ 10 \end{bmatrix}, \quad B_2 = \begin{bmatrix} 0 \\ 3 \end{bmatrix},$$

$$C_1 = C_2 = \begin{bmatrix} 1 \\ 0 \end{bmatrix}^T, \; E_1 = E_2 = \begin{bmatrix} 1 \\ 1 \end{bmatrix},$$

and MFs $h_1(x_1) = \dfrac{1-\sin(x_1)}{2}$, $h_2(x_1) = \dfrac{1+\sin(x_1)}{2}$ defined in $\Delta = \left\{ x \in \mathbb{R}^2, |x_i| < \dfrac{\pi}{2} \right\}$.

As mentioned in Remark 4, given a specific region $R = \bigcap_{e,k,s,v} \left\{ x : \left| \dfrac{\partial w_0^k}{\partial x_v} x_s \right| \le \lambda_{kvs}, \left| \dfrac{\partial w_0^k}{\partial x_v} u_e \right| \le \mu \eta_{kv} \right\}$, the theorem above can be used to minimize the attenuation H_∞ factor $\gamma > 0$.

Since for TS model (28) in Δ the following bounds hold $\left| \dfrac{\partial w_0^k}{\partial x_1} x_s \right| \le \left| \dfrac{\cos(x_1)}{2} \cdot \dfrac{\pi}{2} \right| \le \dfrac{\pi}{4}$, and $\left| \dfrac{\partial w_0^k}{\partial x_2} x_s \right| = 0$, let's define $R_{l,\mu} = \bigcap_{e,k,s,v} \left\{ x : \left| \dfrac{\partial w_0^k}{\partial x_v} x_s \right| \le \dfrac{\pi}{4} l, \left| \dfrac{\partial w_0^k}{\partial x_v} u_e \right| \le \dfrac{\pi}{2} \mu l \right\}$ in order to check the behaviour of the minimum γ found with the aforementioned algorithm under the testing values $(l, \mu) = ((11-i)/10, 1)$ (different sizes of R) and $(l, \mu) = (1, 10^{i-1})$ (different bounds for μ), $i = 1, \ldots, 9$.

Fig. 3 shows the behaviour of the minimum γ found via the proposed theorem when parameter l varies, thus changing the modelling region of the TS model. As expected, since this is a local approach, the smaller the modelling region, the smaller minimum attenuation factor γ. In other words, restricting the state space it is easier to satisfy the constraints for H_∞ disturbance rejection.

Fig. 4 shows the behaviour of the minimum attenuation factor γ found through the theorem above when the input bound μ varies. Logically, bigger values of μ allow smaller values of γ, since bigger control gains provide higher flexibility in (7).

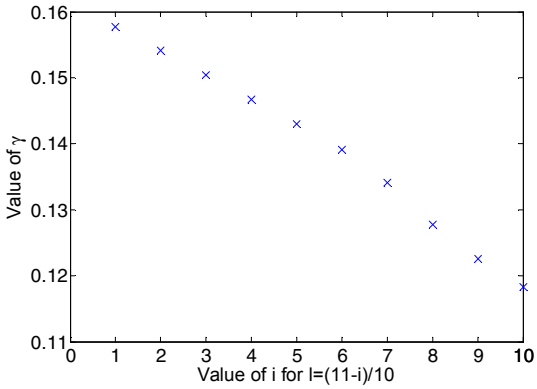

Figure 3: Attenuation factor with different regions (parameter l) and fixed input bound $\mu = 1$.

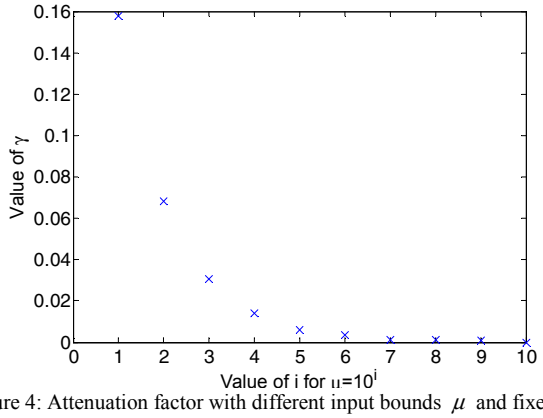

Figure 4: Attenuation factor with different input bounds μ and fixed region size $l = 1$.

V. Conclusions and Perspectives

This paper presented a novel non-quadratic approach for stabilization of continuous-time TS models with H_∞ disturbance rejection. Based on a recently appeared local approach that solves the problem of handling time-derivatives of the MFs, fuzzy Lyapunov functions have been used to design a non-quadratic control law which stabilizes and performs H_∞ disturbance rejection for nonlinear models locally exactly represented via TS models. Two examples are included to illustrate the effectiveness of the approach and to show the effect of the different design parameters.

***Abstract*—This paper presents a Fuzzy Active Contour Model for image segmentation using three variations. The proposed models are based on the Fuzzy Energy-Based Active Contour model introduced by Krinidis and Chatzis. First, an update criteria that changes only localized membership values at each iteration is introduced. Second, the model is extended to a type-2 fuzzy logic. And finally, a multiple object segmentation schema is applied to the original model. We present some experimental results, showing the performance for each modification and some of its advantages.**

***Keywords*—Image segmentation, active contour models, fuzzy logic**

I. Introduction

In problems related to image processing and computer vision, image segmentation is an important task that can be critical for the success of any image related procedure. Image segmentation is defined as the process to localize or isolate regions or object of interest in a particular image. Several different procedures for image segmentation have been proposed [1]. However, the segmentation procedure is still considered an essential and a difficult process, specially due to the complexity presented by several images.

Active contour models (ACM) are a well known technique used in image segmentation. Due to its capabilities, ACM are successfully applied in object detection and motion tracking [2], [3]. The idea behind active contour models (or snakes) is a curve that evolves subject to restrictions imposed by characteristics of the images and the curve itself. This evolution is guided by a minimization of an energy function.

The classical active contour models use energy functions based on edge information. Therefore they can only detect objects defined by explicit edges. Objects with smooth or discontinuous edges may not be properly detected. Many authors developed different techniques to overcome this limitation [3], [4], [5]. Chan and Vese proposed a well-known model called Active Contours Without Edges. This model uses an energy function based on the Mumford-Shah segmentation technique and is able to detect contour both with or without gradient information [3].

In Fuzzy Energy-Based Active Contour model [6], proposed by Krinidis and Chatzis, the clustering capabilities presented by fuzzy systems are combined with active contour methodology. It uses fuzzy logic to define the membership of each pixel in the image to the object. So, the fuzzified energy is able to reject local minima, which is a characteristic of fuzzy models. Krinidis and Chatzis used a pseudo level-set formulation that allows the minimization not to be computed using the Euler-Lagrange equations. This procedure decreases the computational time compared with other techniques that use Euler-Lagrange approach. The model is also able to detect objects with discontinuous or smooth edges.

The Fuzzy Energy-Based Active Contour model achieves good segmentation results when applied to two phase images, but it is not appropriate when gradual tonality variations appears in the image. Since it fails to find the object contour, it considers as object other elements of the scene. We propose to modify the Fuzzy Energy-Based Active Contour model so that it is able to deal with more complex images. Besides that, we also extend the model to type-2 fuzzy, in which each primary membership value has a correspondent secondary membership. Increasing the fuzziness of the model means increase the ability to handle inexact information [7]. Last but not least, we present a generalization on the base model that allows it to segment images in more than two areas.

This paper is organized as follows. The base model is described in Section 2. In Section 3, we describe the proposed modifications to the base model: the Morphological Fuzzy Active Contour, Morphological Type-2 Fuzzy Active Contour and Fuzzy Multi Active Contour models. Section 4 describes the experimental results and Section 5 presents the conclusions.

II. Fuzzy Energy-Based Active Contour model (FEB-AC)

The Fuzzy Energy-Based Active Contour model consists in an algorithm that aims to segment regions of interest in a two phase image. First, it is provided to the algorithm an initial partition of the image, i.e., an initial contour. This partition defines the curve that will iteratively evolve by a minimization process. This curve defines the boundaries of the segmented region.

Considering C a curve that is able to evolve in the image domain Ω and I an image composed by two regions, the energy function to be minimized is defined by [6]:

$$\begin{aligned} F(C, c_1, c_2, u) = \mu \cdot Length(C) \\ +\lambda_1 \int_{\Omega} [u(x,y)]^m |I(x,y) - c_1|^2 dxdy \\ +\lambda_2 \int_{\Omega} [1 - u(x,y)]^m |I(x,y) - c_2|^2 dxdy, \quad (1) \end{aligned}$$

This work was partially supported by CAPES.

where u is the membership function, m is a weighting exponent to the fuzzy membership, $\mu \geq 0$ and λ_1, $\lambda_2 > 0$, are fixed values. c_1 and c_2 are the average intensity of the inside and outside areas of the object, respectively, both taking into account their correspondent membership values. c_1 and c_2 are defined by:

$$c_1 = \frac{\int_\Omega [u(x,y)]^m I(x,y) dxdy}{\int_\Omega [u(x,y)]^m dxdy}, \tag{2}$$

$$c_2 = \frac{\int_\Omega [1-u(x,y)]^m I(x,y) dxdy}{\int_\Omega [1-u(x,y)]^m dxdy}. \tag{3}$$

Keeping the values of c_1 and c_2 fixed, the membership of each pixel, $u(x,y)$, is then computed using:

$$u(x,y) = \frac{1}{1 + \left(\frac{\lambda_1 (I(x,y)-c_1)^2}{\lambda_2 (I(x,y)-c_2)^2} \right)^{\frac{1}{m-1}}}. \tag{4}$$

In (1), the length term is approximated by:

$$Length(C) = \sum_{i,j} \sqrt{(Q_{i+1,j} - Q_{i,j})^2 + (Q_{i,j+1} - Q_{i,j})^2}, \tag{5}$$

where $Q_{i,j} = H(u(i,j) - 0.5)$, and $H(\cdot)$ is the Heaviside function [6].

Instead of using a Lipschitz function ϕ, Krinidis and Chatizis used a pseudo level-set formulation, based on the membership function u, to represent different areas of the image, i.e., the curve and the inner and outer regions. The pseudo level-set formulation is defined as:

$$\begin{cases} C & = & \{(x,y) \in I \,|\, u(x,y) = 0.5\} \\ inside(C) & = & \{(x,y) \in I \,|\, u(x,y) > 0.5\} \\ outside(C) & = & \{(x,y) \in I \,|\, u(x,y) < 0.5\}. \end{cases}$$

The algorithm that minimizes the fuzzy energy function $F(C, c_1, c_2, u)$ is described as follows [6]:

1) Assign an initial partition to the image. For the inner part use $u > 0.5$, for the outer part use $u < 0.5$;
2) Compute c_1 and c_2 using equations (2) and (3), respectively;
3) Update the membership value u_o of the pixel I_o with u_n, following equation (4), only if the total energy decreases. That is, $\Delta F < 0$, where this variation is defined by:

$$\Delta F = \lambda_1 s_1 \frac{[u_n^m - u_0^m](I_o - c_1)^2}{s1 + u_n^m - u_0^m} + \lambda_2 s_2 \frac{[(1-u_n)^m - (1-u_0)^m](I_o - c_2)^2}{s2 + (1-u_n)^m - (1-u_0)^m}, \tag{6}$$

   where $s_1 = \sum_{i,j} [u(i,j)]^m$ and $s_2 = \sum_{i,j} [1-u(i,j)]^m$;
4) Repeat Step 3 for each pixel of the image;
5) Repeat Steps 2 to 4 while the total energy keeps changing.

This model achieves good results detecting objects with boundaries that are not defined by gradient and also in the presence of noise. However, it has some drawbacks when dealing with images that present strong pixel intensity variation in its background. The proposed method tries to overcome this limitation by applying an evolving curve procedure similar to other active contour techniques.

III. Proposed Modifications

Active contour models that possess a geometric formulation, as in level-sets, use a high order function ϕ to define the curve boundaries and to control its evolution. This kind of model evolves the contour in regions near to the boundaries.

Due to the pseudo level-set formulation used in Fuzzy Energy-Based Active Contour model, the membership of all pixels in the image may be updated in a single iteration. Consequently, the curve can evolve not only in regions near to its boundaries. In this situation the contour is not continuous, leading to incorrect segmentation results.

A. Morphological Fuzzy Active Contour Model (MF-AC)

In this work we propose a modification of the model introduced by Krinidis and Chatizis that enables the contour to evolve gradually. The main idea is to limit the update area in each iteration to those close to the current contour boundaries. Thus, as the membership function is updated, the border moves, therefore, enabling new areas to be updated. To limit the update area it is necessary to modify the membership values update equation (4) to:

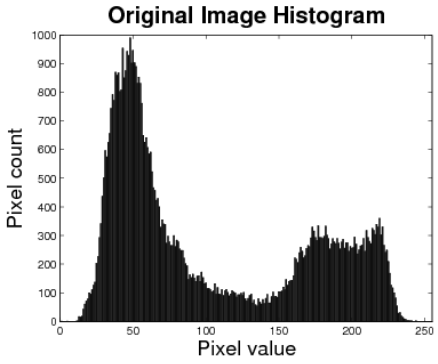
$$u'(x,y) = \frac{\delta\left(u'(x,y) - 0.5\right)}{1 + \left(\frac{\lambda_1 (I(x,y)-c_1)^2}{\lambda_2 (I(x,y)-c_2)^2} \right)^{\frac{1}{m-1}}}, \tag{7}$$

where $\delta(\cdot)$ is the δ Dirac function. Thus, δ act as a weighting coefficient to control the update of the membership values. In this way only the pixels at the boundaries are allowed to update their membership values. However, due to the expression in the denominator of (7), it is not easy to accurately find the boundaries of the contour using this function.

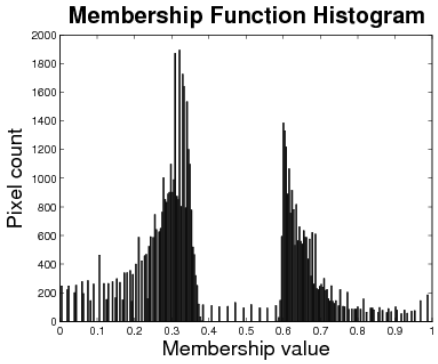
Figure 1 shows this situation: (a) shows the original histogram of an image and (b) shows the histogram of the membership values after the first iteration. The fuzzy energy pushes the membership values towards the centers c_1 and c_2, creating a region with low pixel density close to the value 0.5. Due to this behavior, it is hard to define the boundaries using the δ function. To overcome this problem, we applied mathematical morphology to obtain this desired behavior. Therefore, the new update rule is stated as follows:

$$u'(x,y) = \frac{\beta(H\left(u'(x,y) - 0.5\right)) \oplus R}{1 + \left(\frac{\lambda_1 (I(x,y)-c_1)^2}{\lambda_2 (I(x,y)-c_2)^2} \right)^{\frac{1}{m-1}}}, \tag{8}$$

where $\beta(A) = A - (A \ominus B)$ is a morphological boundary extraction operation from image A using suitable structuring element B to cause an erosion and R is another structuring element used to expand the boundaries to neighbor areas. We used the structuring elements B and R, respectively, as a 3x3 square and a circle with radius 5.



(a)



(b)

Figure 1: Histogram comparison. (a) Histogram of the original image. (b) Histogram of the membership function after the first iteration.

B. Morphological Type-2 Fuzzy Active Contour Model (MT2F-AC)

Type-2 fuzzy sets are a generalization of common type-1 fuzzy sets. In type-2, the membership value itself is a fuzzy set. In that way, with type-2 fuzzy is possible to model uncertainties because their membership functions are fuzzy themselves. This does not happen with type-1 fuzzy, in which membership functions are totally crisp [8].

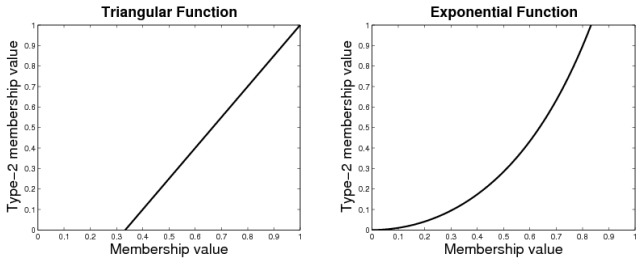
In this model we used interval type-2 fuzzy set, that are also called first-order uncertainty fuzzy models. In this case, secondary memberships are either zero or one, reducing the complexity compared when dealing with general type-2 fuzzy [7]. To do so, we extend the type-1 membership values u, calculated using (4), to the type-2 $\tilde{u}$ by assigning a membership function to each membership value of type-1. We have tried four different functions (graphically shown in Figure 2):

- Triangular (Figure 2a):

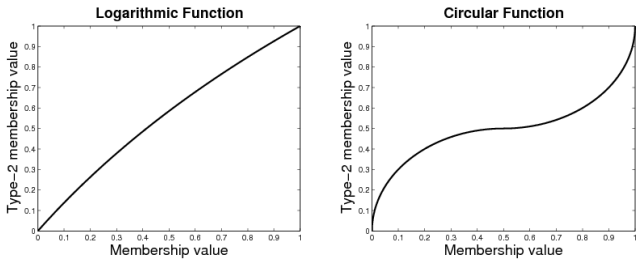
$$\tilde{u}(x,y) = u(x,y) - \frac{1-u(x,y)}{2} \tag{9}$$

- Exponential (Figure 2b):

$$\tilde{u}(x,y) = e^{u(x,y)^2} - 1 \tag{10}$$



(a) Triangular. (b) Exponential.



(c) Logarithmic. (d) Circular.

Figure 2: Type-2 membership functions.

- Logarithmic (Figure 2c):

$$\tilde{u}(x,y) = \log_2(u(x,y)+1) \tag{11}$$

- Circular (Figure 2d):

$$\tilde{u}(x,y) = \begin{cases} \sqrt{u(x,y) - u(x,y)^2}, & \text{if u(x,y) } <0.5 \\ 1 - \sqrt{u(x,y) - u(x,y)^2}, & \text{else} \end{cases} \tag{12}$$

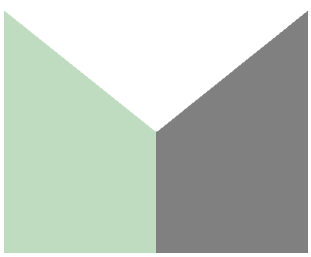
Then, instead of using u, which is type-1, we applied the type-2 values $\tilde{u}$ in equations (2) and (3), represented now by $\tilde{c_1}$ and $\tilde{c_2}$, respectively. So, the total energy is given by:

$$\begin{aligned} F(C, \tilde{c_1}, \tilde{c_2}, \tilde{u}) &= \mu \cdot Length(C) \\ &+\lambda_1 \int_\Omega [\tilde{u}(x,y)]^m |I(x,y) - \tilde{c_1}|^2 dxdy \\ &+\lambda_2 \int_\Omega [1-\tilde{u}(x,y)]^m |I(x,y) - \tilde{c_2}|^2 dxdy, \end{aligned} \tag{13}$$

Similarly, the length term (5) and the partial energy variation (6) are computed applying new type-2 membership values.

C. Fuzzy Multi Active Contour Model (FM-AC)

The method described in this section extends the Morphological Fuzzy Active Contour Model to use multiple centers, allowing multiple regions be segmented at once. The main difference from the FEB-AC model relies on the pseudo level-set formulation. Instead of using a (similar) distance function to define inner and outer areas (because only two regions are assumed) the new formulation use group indexes to define regions. In this case, the contour is extracted finding the boundaries between groups.

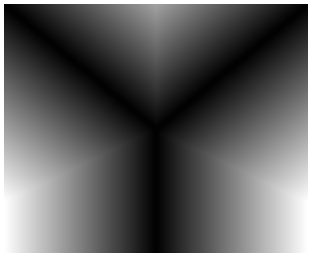


(a) Three groups.

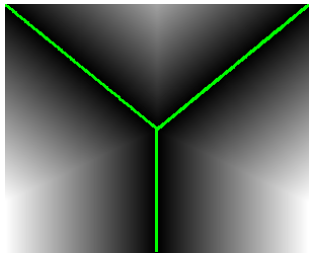
(b) Computed distance for group one.

(c) Computed distance for group two.

(d) Computed distance for group three.



(e) Combined distances.



(f) Combined distances with contour extracted.

Figure 3: The process used to identify the contour between different groups. The most distant pixels to any other group are displayed in white.

In this proposed modification, the membership function u is used to assign pixels to each of the K disjoint groups ($K > 2$). This process is represented by:

$$I(x,y) \in k \mid u_k = \max\left(u_j\right),\ j = 1,\ 2,\ \ldots,\ K.$$

Then, the contour is extracted, finding the borders between regions. To perform this operation we first find all pixels that belongs to a disjoint group k, then we compute the distance d_k from these pixels to the nearest pixel that belongs to any other group. In each group, pixels that are neighbor with other group will have a distance value equals to 1, and the pixels in other groups will have the value equals to zero. This process is repeated for every group and the distances $d_k(x,y)$ are combined (summed). Finally, the contour C is extracted by finding the positions (x,y) with minimal distance (in this case the minimum value is one):

$$C = \left\{ (x,y) \in I \mid \sum_{k=1}^{K} d_k(x,y) = 1 \right\}. \tag{14}$$

Figure 3 shows an example on how to obtain the contour: (a) a general partition with three groups; (b, c and d) the computed distances d_k for each group; (e) the combined distances; and (f) the combined distances with the contour highlighted.

To allow the use of multiple centers, the fuzzy energy (1) is modified to:

$$F(C) = \mu \cdot Length(C) + \sum_{k=1}^{K} \lambda_k \int_{\Omega} [u_k(x,y)]^m |I(x,y) - c_k|^2 dxdy, \tag{15}$$

where $Length(C)$ is just the number of pixels in the C set.

The centers c_k are now computed using:

$$c_k = \frac{\int_{\Omega} [u_k(x,y)]^m I(x,y) dxdy}{\int_{\Omega} [u_k(x,y)]^m dxdy}, \tag{16}$$

and the membership update rule follows:

$$u_k(x,y) = \frac{1}{\sum_{j=1}^{K} \left(\frac{\lambda_k (I(x,y) - c_k)^2}{\lambda_j (I(x,y) - c_j)^2} \right)^{\frac{1}{m-1}}}. \tag{17}$$

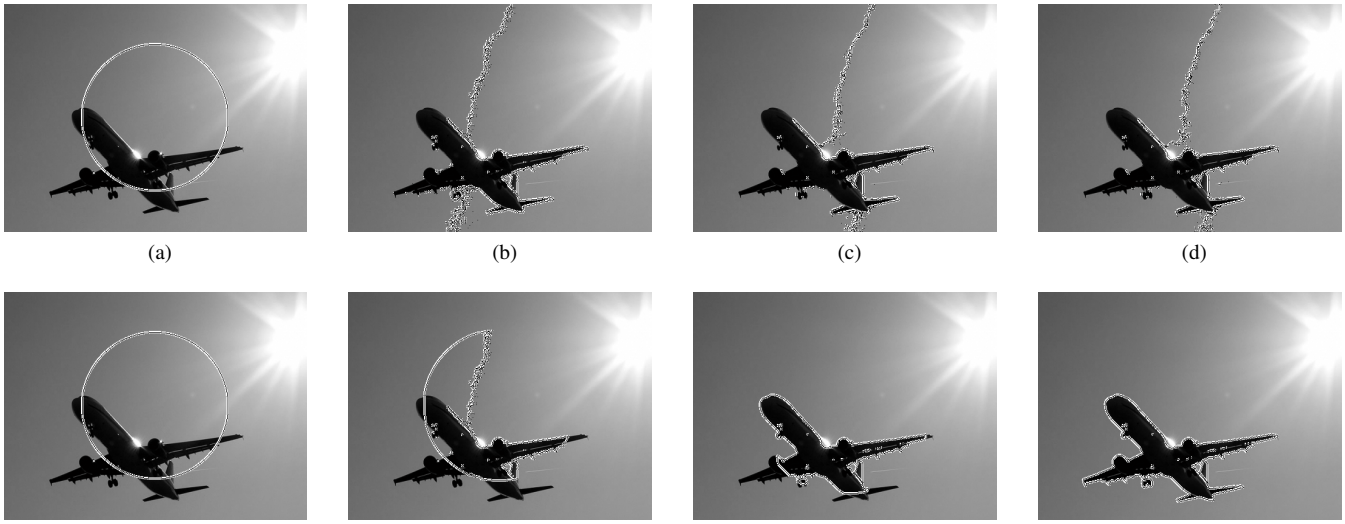
The algorithm is stated as:

1) Provide an initial partition with K disjoint groups and compute the initial membership values. We used:
$$u_k(x,y) = \begin{cases} 0.5 & , if\ (x,y) \in k \\ 0.5/(K-1) & , elsewhere \end{cases} \tag{18}$$
2) Compute the centers c_k using (16);
3) Update the membership values using (17) where $(x,y) \in I \mid \sum_{k=1}^{K} d_k(x,y) \leq \alpha$; α defines the thickness around the contour;
4) Compute the total energy of the model using (15);
5) Repeat Steps 2 to 4 while the total energy keeps changing.

IV. Experimental Results

The experimental results are presented by applying the proposed models to both natural and artificial images. First, we compare the results using the FEB-AC and the MF-AC models. Then, we applied the type-2 fuzzy model (MT2F-AC). Finally, a FM-AC segmentation experiment is also presented. In all experiments we used $\lambda_1 = \lambda_2 = \lambda_k = 1$, and $m = 2$. The initial membership value to the inner region of the contour was set to $u = 0.8$, except for the FM-AC model which follows (18). Finally, the value of μ showed minor changes to the final contour and its value was set empirically to zero.

We present in Figure 4 a comparison of some intermediary steps between FEB-AC and MF-AC models. Note that the original model converges to a wrong configuration that is close to the final solution in early steps of the procedure. On the other hand, with the proposed modifications the contour evolves gradually, correcting the initial partition and approaching to the desired solution. In the FEB-AC model the update of the membership values can occurs on the whole image. In the MF-AC model, only the pixels in a narrow band



(a) (b) (c) (d)

(e) (f) (g) (h)

near the boundaries are able to have their membership updated. In this case there is a localized energy decrease.

Figure 5 shows the segmentation results for FEB-AC and MF-AC models, using a flower image. This image has a distinct and well defined foreground and background and both models have similar results, except in the area near the center of the flower. The FEB-AC model correctly find the borders between the flower and the background but the interior, which is darker then the petals, is excluded from the object. The MF-AC model in addition to correctly detect the borders, was also able to include the interior of the flower. This behavior results from the localized membership update.

(b) Initial Contour.

(c) Final segmentation using FEB-AC model.

(d) Final segmentation using MF-AC model.

Figure 5: A flower image and the segmentation results using the FEB-AC and MF-AC models.

Figure 6 shows a comparison between the segmentation results between FEB-AC and MF-AC models. Note that the background in the space shuttle image presents high variation. As the FEB-AC model allows all pixels to have their membership updated at once, this variation in the background interfere in the computation of c_1 and c_2 constants and in the membership u itself. Due to this fact, the model was unable to correctly segment the contour of the desired object. In this image, the MF-AC model was able to extract the desired object because of the restriction on membership update.

(c) FEB-AC.

(d) MF-AC.

(e) Triangular.

(f) Exponential.

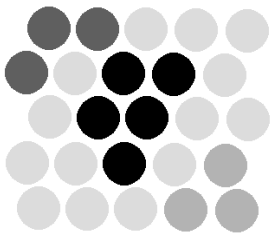
(g) Logarithmic.

(h) Circular.

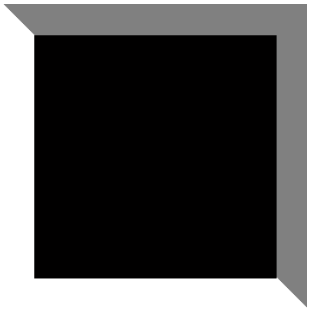
Figure 7: Segmentation results using: (c) FEB-AC; (d) MF-AC; (e, f, g, and h) MFT2-AC with different type-2 functions. The comparison shows that type-2 models are able to detect the airplane under high background variation.

In Figure 7 experimental results using another airplane image are presented. In this case the MFT2-AC model was used. This image presents a strong spot of light that contributes to a high illumination variation in the background of the scene, causing the FEB-AC and MF-AC models to loose the contour of the central object. This effect does not happen with any of the versions of the proposed MFT2-AC model. The introduced type-2 mapping functions contribute to the algorithm to find the correct contour of the object.

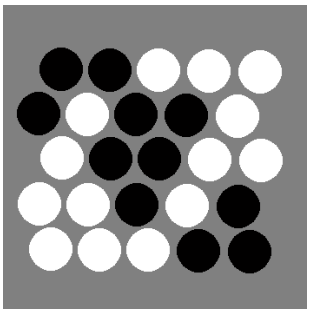
The use of triangular, exponential, and logarithmic type-2 functions spreads the membership values between inner and outter regions. The circular type-2 function, however, narrows membership values to a small range near the value of the contour ($u = 0.5$). Besides that, in this image, the circular function was also able to segment the airplane.



(a) Original.



(b) Initial partition (three groups).



(c) Final segmentation.

Figure 8: An artificial grayscale image, segmented using FM-AC model.

The use of fuzzy mutiple centers model (FM-AC) is showed in Figure 8. In this experiment, an artificial image composed by dots of different grayscale intensities was used. The image, originally with five different intensities was segmented in three groups using pixel intensity similarity to join the groups.

These experiments give an overview of the capabilities of proposed models: by applying an evolution scheme in the base model, the algorithm is capable to handle the segmentation more efficiently. Type-2 fuzzy sets can deal with some scenes that the MF-AC is not able to correctly segment. The change in the membership function may, for instance, give more importance to a higher membership values and decreases even more the memberships that are already small. This adjustment, depending on the image, contribute to the separation process between the object and the background, by adding a new level of uncertainty. The multiple centers model generalizes the base model so that its is able to identify an arbitrary number of groups in a given image. It is useful when one needs to separate multiple objects.

V. Conclusions

In this paper, we proposed a time step evolution to the Fuzzy Energy-Based Active Contour model. In order to achieve this behavior, morphological operators are used to limit the fuzzy membership updates at each iteration. We also extended

this new model to use type-2 fuzzy sets, assigning to each membership value a secondary membership, that adds a new level of uncertainty to the membership. We also generalized the original algorithm to allow the division of the image in an arbitrary number of groups. The experiments showed that each proposed modification improves the power of the model to segment correctly certain types of images.

***Abstract*—Fuzzy transitivity is a key property for many fuzzy relational structures, such as Fuzzy Preorders and Equivalences. Theoretical models for practical problems which are based on fuzzy relations make use of continuous scales, mostly the unit interval [0,1]. Practical implementation of these models though, involves their discretization into finite scales, which generally results in some loss of transitivity. In this paper we study if there are any transitivity preserving discretization strategies. Also, we evaluate the loss of transitivity in some commonly used discretization approaches**

Keywords - fuzzy relation; fuzzy equivalence; T-transitivity; indistinguishability operator

I. INTRODUCTION

Fuzzy relational structures play an important role in fuzzy modelling. Fuzzy transitivity is probably the most important property among those involved in the definition of the more complex relational structures, such as *Fuzzy Preorders* and *Fuzzy Equivalence Relations* [1,2].

Generally speaking, theoretical models of continuous problems make use of continuous scales. In the case of fuzzy modelling, the paradigm of such scales is the real unit interval [0,1]. For computing purposes though, discretization has to be inevitably introduced at some stage, resulting in a distortion of the original modelling structure.

The discrete, finitely-valued operations on the unit interval, such as t-norms, t-conorms and OWA operators, have been widely studied by G.Mayor et al. See [3] for an excellent survey. On the other hand, the topic of fuzzy relational structures based on finitely-valued operations has been developed by J. Recasens et al. [4]. A comprehensive and readable introduction can be found in [2].

The present paper is about the fuzzy relations which are obtained from continuously valued fuzzy relations through a process of discretization. Those relations are not necessarily *finitely valued* preorders or equivalences in the sense of [3,4] owing to two reasons: the involved continuous t-norm is not required to become a finitely valued one, and fuzzy transitivity is not always preserved through discretization.

Let us recall some basic definitions the present work relies upon.

Definition 1.1: An operation T on the unit interval [0,1] is called a *t-norm* if it is associative, commutative and it satisfies the boundary conditions $T(x,0) = T(0,x) = 0$ and $T(x,1) = T(1,x) = x$ for all x in [0,1].

Definition 1.2: A fuzzy relation R on a universe X, i.e. a mapping $R : X \times X \to [0,1]$, is:

Reflexive, if $R(x,x) = 1$ for every x in X.

Symmetric, if $R(x,y) = R(y,x)$ for every x and y in X.

Transitive with respect to a given t-norm T, or *T-transitive*, if $T(R(x,y),R(y,z)) \le R(x,z)$ for every x, y and z in X.

Definition 1.3: A *Fuzzy Proximity* is a reflexive and symmetrical fuzzy relation.

Definition 1.4: A *Fuzzy Preorder* is a reflexive and *T*-transitive fuzzy relation.

Definition 1.5: A *Fuzzy Equivalence Relation*, or *Indistinguishability Operator* is a reflexive, symmetrical and *T*-transitive fuzzy relation.

There are other names in use such us Zadeh's original *Similarity Relations* [5] or *T-Indistinguishability Operators* [6].

The concept of t-norm has become a standard in fuzzy logic. The reader is referred to [7] for an excellent state of the art on the subject. Throughout this paper, we will assume t-norms to be continuous, which in practice means only T=MIN (the *minimum* t-norm), T=LUK (the *Lukasiewicz* t-norm) and T=PROD (the *standard product* t-norm) are considered. Any other continuous t-norm is either isomorphic to one of these, or is isomorphic to an ordinal sum of many of these.

Fuzzy transitivity introduced via a t-norm, or *T-transitivity* for short, is closely related to the *triangle inequality* for distances, $d(x,z) \le d(x,y) + d(y,z)$, where the standard sum of real numbers play a similar role to that of the t-norm T. The standard order is though reversed, so that equivalence degrees near 1 correspond to distances near 0. Thus, points linked by high degrees of equivalence become close points. Consequently, the results we present in this paper also apply to the discretization of metric spaces.

Let us state precisely what is to be understood by discretization in the context of this paper.

This work was supported in part by the Spanish DGI research project TIN2009-07235

Definition 1.6: A discrete scale $L_N = \{a_N \ldots a_0\}$, a_i in [0,1], is a finite ordered subset such that:

1. $a_0 = 1$ and $a_N \geq 0$
2. $a_j < a_k$ if $j > k$.

Definition 1.7: A *discretization function* is a mapping $\Delta : [0,1] \to L_N$ such that:

1. $\Delta(a) \leq \Delta(b)$ if $a \leq b$, for all a, b in [0,1].
2. $\Delta(\Delta(a)) = \Delta(a)$ for all a in [0,1].
3. $\Delta(1) = 1$

A discretization of a fuzzy relation E is simply the fuzzy relation $\Delta(E)$, that is, the image of E through a discretization function.

Note that no specific assumptions are made on E, and consequently no specific requirements can be stated regarding t-norms, not being any involved at this stage.

Having fuzzy transitivity in mind makes it very tempting to tie the previous definitions to a t-norm by asking, for example, that $T(a_i, a_j) \in L_N$ for all a_i, a_j in L_N (definition 1.6), or that for $T(\Delta(a), \Delta(b)) \in L_N$ for all a and b in [0,1] (definition 1.7). Although for practical reasons this becomes very often the case, such an assumption would confine our research to the topics of finitely valued t-norms and finitely valued fuzzy preorders and equivalences, which is too restrictive a setting. Our only concern here has to do with assessing the regularity of the distorted relation $\Delta(E)$ with respect to its continuously valued original model E and therefore, the originally involved continuous t-norm.

This section ends with a simple yet fundamental example showing that T-transitivity is not necessarily preserved through discretization.

Example 1.8 Let X be the unit interval [0,1], T=T_{LUK} the Lukasiewicz t-norm, i.e. $T_{LUK}(a,b) = \max\{a + b - 1, 0\}$, the discrete scale $L_1 = \{a_0\ a_1\} = \{0, 1\}$ and the discretization function $\Delta : [0,1] \to L_1$ defined by $\Delta(a) = 1$ if $a \geq 0.5$ and $\Delta(a) = 0$ otherwise, where a,b are in [0,1].

The fuzzy relation considered will be $E(x,y) = 1 - |x - y|$ for all x,y in X=[0,1]. E is called the *residuated biimplication*, or *natural equivalence relation*, associated with the t-norm T_{LUK} so it is a fundamental example [2].

Consider any three real numbers such that $0 \leq x_1 \leq x_2 \leq x_3 \leq 1$, $x_2 - x_1 \leq 0.5$ and $x_3 - x_2 \leq 0.5$, but $x_3 - x_1 > 0.5$. Then $\Delta(E(x_1, x_2)) = 1$ and $\Delta(E(x_2, x_3)) = 1$, but $\Delta(E(x_1, x_3)) = 0$, so that

$1 = T(\Delta(E(x_1, x_2), \Delta(E(x_2, x_3)) > \Delta(E(x_1, x_3)) = 0$

and thus the breach of transitivity. ■

II. Proximity relations and min-transitive relations

Let us start with two kinds of fuzzy relations which behave in a way of their own with respect to discretization: proximity relations (definition 1.3) where transitivity is not involved, and those which are transitive with respect to the minimum t-norm, with Zadeh's *Similarity Relations* standing as their most prominent example [5].

Proposition 2.1 Let E be a proximity relation on a universe X. Then $\Delta(E)$ is also a proximity relation.

The result is an obvious one. More interesting is the case of *MIN*-transitive relations.

Proposition 2.2 Let E be a *MIN*-transitive relation on a set X. Then $\Delta(E)$ is also *MIN*-transitive.

Proof: We need to prove *MIN*-transitivity for $\Delta(E)$, that is, $MIN(\Delta(E(x,y)), \Delta(E(y,z))) \leq \Delta(E(x,z))$

Since $MIN(E(x,y), E(y,z)) \leq E(x,z)$ we apply 1.7.1 to obtain $\Delta(MIN(E(x,y), E(y,z))) \leq \Delta(E(x,z))$

Also, since [0,1] is a totally ordered set $MIN(E(x,y), E(y,z))$ equals either $E(x,y)$ or $E(y,z)$, or both. Without loss of generality we may assume it is $MIN(E(x,y), E(y,z)) = E(x,y)$. Then $E(x,y) \leq E(y,z)$, $\Delta(E(x,y)) \leq \Delta(E(y,z))$ (1.7.1), and

$\Delta(MIN(E(x,y), E(y,z))) = MIN(\Delta(E(x,y), \Delta(E(y,z))$.

As a consequence, $MIN(\Delta(E(x,y)), \Delta(E(y,z))) =$

$\Delta(MIN(E(x,y), E(y,z))) \leq \Delta(E(x,z))$ ■

Next is a corollary of propositions 2.1 and 2.2.

Corollary 2.3 Let E be a similarity relation on a set X. Then $\Delta(E)$ is also a similarity relation.

Corollary 2.4 Let E be a *MIN*-transitive relation on a set X. Then $\Delta(E)$ is T-transitive for any continuous t-norm T.

Corollary 2.4 follows from the fact that $MIN \geq T$ for any t-norm T (a well known fact. See, for example, [3]).

III. The case of transitivity with respect to Archimedean t-norms

Continuous Archimedean t-norms are either strict or non-strict. Strict Archimedean t-norms are isomorphic to the product t-norm, i.e. $T_{PROD}(a,b) = a \cdot b$ for all a,b in [0,1], while the non-strict ones are isomorphic to the Lukasiewicz t-norm (introduced above). Archimedean t-norms can be obtained from decreassing mappings $f : [0,1] \to [0, f(0)] \subseteq [0, +\infty]$ called additive generators by $T(a,b) = f^{[-1]}(f(a) + f(b))$. The symbol $f^{[-1]}$ stands for the pseudo-inverse of f, that is, the mapping $f^{[-1]} : [-\infty, +\infty] \to [0,1]$ defined by $f^{[-1]}(a) = f^{-1}(a)$

if $a \in [0, f(0)]$, $f^{[-1]}(a) = 1$ if $a < 0$ and $f^{[-1]}(a) = 0$ if $a \geq f(0)$. Strict Archimedean t-norms are those with $f(0) = \infty$, in which case $f^{[-1]} = f^{-1}$ and they are isomorphic to the sum of positive real numbers, while the non-strict ones are those with $f(0) < \infty$ and their behaviour is that of a bounded sum of positive real numbers.

The following theorem characterizes those discretization functions that preserve *T*-transitivity, provided that *T* is Archimedean.

Theorem 3.1 Let *T* be an Archimedean t-norm, $L_N = \{a_N \ ... \ a_0\}$ a discrete scale and Δ a discretization function. Then, $\Delta(E)$ is *T*-transitive for any *T*-transitive fuzzy relation *E* on some universe *X* if, and only if, $T(\Delta(a), \Delta(b)) \leq \Delta(T(a,b))$ for all *a*, *b* in [0,1].

Proof. [$\Rightarrow$] Given *a* and *b* in [0,1] let *E* be the *T*-transitive relation defined on *X*=[0,1] by $E(x,y) = f^{[-1]}(f(x) - f(y))$ where *f* is an additive generator of *T*. *E* is *T*-transitive because

$T(E(x,y), E(y,z)) =$

$f^{[-1]}(f(f^{[-1]}(f(x) - f(y))) + f(f^{[-1]}(f(y) - f(z)))) \leq$

$f^{[-1]}(f(x) - f(y) + f(y) - f(z)) =$

$f^{[-1]}(f(x) - f(z)) = E(x,z)$

and, under the hypothesis, so is $\Delta(E)$. We may then consider $x = 1$, $y = a$, $z = T(a,b)$ so that $E(x,y) = a$, $E(y,z) \geq b$ and $E(x,z) = T(a,b)$. Since $\Delta(E)$ is T-transitive we have that

$T(\Delta(a), \Delta(b)) \leq T(\Delta(E(x,y)), \Delta(E(y,z)) \leq$

$\Delta(E(x,z)) = \Delta(T(a,b))$

[$\Leftarrow$] Let us suppose now that $T(\Delta(a), \Delta(b)) \leq \Delta(T(a,b))$ for all *a*, *b* in [0,1]. If *E* is a T-transitive fuzzy relation on a set *X*, then $T(E(x,y), E(y,z)) \leq E(x,z)$ for all *x*, *y*, *z* in *X*. By taking $a = E(x,y)$ and $b = E(y,z)$ we obtain:

$T(\Delta(E(x,y)), \Delta(E(y,z)) = T(\Delta(a), \Delta(b)) \leq$

$\Delta(T(a,b)) = \Delta(T(E(x,y), E(y,z))) \leq \Delta(E(x,z))$

thus proving the T-transitivity of $\Delta(E)$ ■

An important consequence of theorem 3.1 is that arbitrarily chosen discretization functions and scales do not necessarily preserve transitivity with respect to Archimedean t-norms. We will focus on *homogeneous* (or *equidistant*) finite scales, where lower truncation is (almost) the only discretisation strategy that may be applied to the unit interval as a whole.

Definition 3.2 Let *T* be an Archimedean *t*-norm, and $L_N = \{a_N \ ... \ a_0\}$, a_i in [0,1], a finite scale such that $a_N > 0$ if *T* is strict. In this situation, L_N is homogeneous or equidistant with respect to the t-norm *T* if $f^{[-1]}(f(a_i) - f(a_{i+1})) = f^{[-1]}(f(a_{i-1}) - f(a_i))$, *i* = 1 ... *N*-1 for some additive generator *f* of *T*.

NOTES: 1. Either all the additive generators of *T* satisfy the condition or all of them fail to satisfy it (see [3]).

2. $a_N > 0$ in the strict Archimedean case because $f(0) = \infty$, which makes equidistance impossible.

Example 3.3 Consider $L_N = \{a_N \ ... \ a_0\}$ with $a_i = \frac{N-i}{N}$, *i* = 0 ... *N*. L_N is a homogeneous finite scale with respect to the Lukasiewicz t-norm T_{LUK} but it is not homogeneous with respect to the product t-norm T_{PROD}.

This is a consequence of the different behaviour of the two t-norms' additive generators with respect to L_N. Taking $f(a) = f_{LUK}(a) = 1 - a$ and $g(a) = f_{PROD}(a) = -\ln(a)$ as generators, while $g^{[-1]}(g(a_{i+1}) - g(a_i)) = \frac{N-i}{N-i+1}$ depends on *i*, $f^{[-1]}(f(a_{i+1}) - f(a_i)) = \frac{N-1}{N}$ remains constant. ■

Example 3.4 Consider $L_N = \{a_N \ ... \ a_0\}$ with $a_i = p^i$ for a fixed *p*, $0 < p < 1$, *i* = 0 ... *N*. L_N is a homogeneous finite scale with respect to the product t-norm T_{PROD} but it is not homogeneous with respect to the Lukasiewicz t-norm T_{LUK}.

In the present case $g^{[-1]}(g(a_{i+1}) - g(a_i)) = p$ does not depend on *i*, while $f^{[-1]}(f(a_{i+1}) - f(a_i)) = 1 - |\, p^{i+1} - p^i \,|$ obviously does. Also, note that $a_N > 0$ no matter how big the chosen *N* for the particular scale, which makes the cardinality of the scale as big as required. ■

Within any fixed interval $[a_{i+1}, a_i]$ there are only three possible discretization functions: lower truncation, upper truncation and rounding.

Upper truncation is defined by $\Delta_U(a) = \overline{a} = a_i$ if $a_{i+1} < a \leq a_i$. Lower truncation by $\Delta_L(a) = \underline{a} = a_{i+1}$ if $a_{i+1} \leq a < a_i$. In order to precisely define rounding, an additional b_{i+1} between a_i and a_{i+1} is to be considered. Then $\Delta_R(a) = \widehat{a} = a_{i+1}$ if $a_{i+1} \leq a < b_i$, or $\Delta_R(a) = \widehat{a} = a_i$ if $b_i \leq a \leq a_i$. The fact that no more discretization functions are possible inside $[a_{i+1}, a_i]$ is a simple consequence of 1.7.1 and 1.7.2.

When it is the whole unit interval that is taken into account, things become a bit more complicated. Roughly speaking, only lower truncation keeps *T*-transitivity in a general sense, although some especial situations may occur when slightly different discretization functions may perform as well.

Lemma 3.5 Let *T* be an Archimedean *t*-norm, and $L_N = \{a_N \ ... \ a_0\} \subseteq [0,1]$ a homogeneous finite scale. If $i + j \leq N$ then $T(a_i, a_j) = a_{i+j}$

Proposition 3.6 (*strict case*) Let $L_N = \{a_N \ldots a_0\}$ be a homogeneous finite scale w.r.t. a strict Archimedean t-norm T. Then the discretization function

$$\Delta(a) = \begin{cases} \overline{a} & \text{if } 0 \le a < a_N \\ \underline{a} & \text{if } a_N \le a \le a_0 \end{cases}$$

preserves *T*-transitivity.

Proof: For any *a*, *b* in [0,1] we need to prove that $T(\Delta(a),\Delta(b)) \le \Delta(T(a,b))$. There are two different situations, depending on the value of $T(a,b)$.

Case 1. If $T(a,b) \le a_N$ then $\Delta(T(a,b)) = \overline{T(a,b)} = a_N$. Now, if $a \le a_N$ or $b \le a_N$ then $\Delta(a) = a_N$ or $\Delta(b) = a_N$ so that $T(\Delta(a),\Delta(b)) \le a_N$ and therefore $T(\Delta(a),\Delta(b)) \le \Delta(T(a,b))$ On the other hand, if $a > a_N$ and $b > a_N$ then $\Delta(a) = \underline{a} \le a$ and $\Delta(b) = \underline{b} \le b$ so that $T(\Delta(a),\Delta(b)) \le T(a,b) \le a_N$ and we also conclude $T(\Delta(a),\Delta(b)) \le \Delta(T(a,b))$.

Case 2. If $T(a,b) > a_N$ then let *i* and *j* be such that $a_{i+1} \le a < a_i$ and $a_{j+1} \le b < a_j$. Then, by Lemma 3.5 we have $a_{i+j+2} = T(a_{i+1}, a_{j+1}) \le T(a,b) < T(a_i, a_j) = a_{i+j}$ so that $\Delta(T(a,b)) \ge \underline{T(a,b)} \ge a_{i+j+2}$. On the other hand, since

$$\Delta(a) = \underline{a} = a_{i+1} \text{ and } \Delta(b) = \underline{b} = a_{j+1}$$

then $T(\Delta(a),\Delta(b)) = T(a_{i+1}, a_{j+1}) = a_{i+j+2}$ follows (Lemma 3.5), and again $T(\Delta(a),\Delta(b)) \le \Delta(T(a,b))$. ■

Proposition 3.7 (*non-strict case*) Let $L_N = \{a_N \ldots a_0\}$, a_i in [0,1], be a homogeneous finite scale w.r.t. a non-strict Archimedean t-norm T. Then the discretization function $\Delta(a) = \underline{a}$ preserves *T*-transitivity.

Proof: Similar to proposition 3.6, the only difference being $a_N = 0$ which hardly matters. ■

Now we will show that both upper truncation and rounding fail to preserve *T*-transitivity at some point.

Lemma 3.8 Let $L_N = \{a_N \ldots a_0\}$ be a finite scale and Δ a discretization function such that $\Delta(\alpha) = a_0 = 1$ for some $a_1 < \alpha < a_0$. Then Δ does not preserve *T*-transitivity with respect to any Archimedean t-norm.

Proof: Consider $x_1 = \alpha < x_2 < \ldots < x_{k-1} \le a_1 < x_k$ where $x_2 = T(\alpha,\alpha) = \alpha^2$, ... $x_k = T(\alpha, \alpha^{k-1}) = \alpha^k$. Such a chain exists for *T* is Archimedean. Then $\Delta(E(x_1, x_k)) \le a_1$ while $T(\ldots(T(\Delta(E(x_1,x_2)),\Delta(E(x_2,x_3))))\ldots) = T(\ldots(T(1,1))\ldots) = 1$ which is against the *T*-transitivity of $\Delta(E)$. ■

As a consequence the next two propositions naturally follow.

Proposition 3.9 Upper truncation discretization does not preserve *T*-transitivity with respect to any Archimedean t-norm.

Proposition 3.10 Rounding discretization does not preserve *T*-transitivity with respect to any Archimedean t-norm.

Propositions 3.9 and 3.10 exclude upper truncation and rounding as global discretization strategies when the whole unit interval is considered. However, they say nothing of their suitability to handle *T*-transitivity when mixed with lower truncation at specific, on-purpose chosen intervals $[a_i, a_{i+1}]$. A such 'custom-made' discretization is shown in the next example.

Example 3.11 Let L_4 be the finite scale $\{a_4 = 0,\ a_3 = 0.25,\ a_2 = 0.5,\ a_1 = 0.75,\ a_0 = 1\}$ which is homogeneous with respect to T_{LUK}, the Lukasiewicz t-norm. The discretization function $\Delta(a) = \begin{cases} \underline{a} & \text{if } a_4 \le a < a_2 \\ \overline{a} & \text{if } a_2 \le a \le a_0 \end{cases}$ preserves T_{LUK}-transitivity.

IV. TRANSITIVITY LOSS IN UPPER TRUNCATION AND ROUNDING

Fuzzy transitivity is not a crisp notion [8,9,10]. Even when a fuzzy relation *E* fails to be strictly *T*-transitive with respect to a given *t*-norm *T*, some degree of transitivity can still be assigned to it depending on how strongly the relation fails to comply with that property, or how far it falls from any truly *T*-transitive relation of reference.

Since we know that both upper truncation and rounding fail to preserve *T*-transitivity for Archimedean *t*-norms, it makes sense to ask ourselves about the extent of the transitivity loss through these two discretization functions.

Transitivity with respect to a t-norm can be turned into a gradual concept in mostly two different ways. The first way assigns a transitivity degree to any fuzzy relation on a triplet by triplet basis:

Definition 4.1: A fuzzy relation *R* on a universe *X* is *a-Transitive* with respect to a given t-norm *T*, or *a-T-transitive*, if $T(a, T(R(x,y), R(y,z))) \le R(x,z)$ for a given *a* in [0,1], and for every *x*, *y* and *z* in *X*.

The second way takes an overall criteria in order to assign a degree of transitivity, which is called the *strong T-transitivity* degree. Strong T-transitivity is based on the closeness between the actual fuzzy relation *E* and its transitive closure $\overline{E}$ [11]. The *transitive closure* $\overline{E}$ of an arbitrary fuzzy relation *E* is the lowest *T*-transitive relation which is above *E* with respect to the pointwise order ($E \le_X \overline{E}$). The closer *E* is to $\overline{E}$, the higher its degree of transitivity. Closeness in that context is measured through the *natural indistinguishability operator*, defined as follows.

Definition 4.2: Let T be an Archimedean t-norm, and f one of its additive generators. The fuzzy relation

$E_T(x,y) = f^{[-1]}(|f(x)-f(y)|)$ for all x and y in [0,1] is called the natural indistinguishability associated with T.

NOTE: E_T does not depend on the particular f chosen.

Definition 4.3: The natural indistinguishability between two fuzzy relations E and F defined on a set X is $\mathcal{E}_T(R,S) = \inf_{x,y\in X} E_T(R(x,y),S(x,y))$

Definition 4.4: A fuzzy relation E on a universe X is *strong a-Transitive* with respect to a given t-norm T, or *a-T-strong transitive*, if $\mathcal{E}_T(E,\overline{E}) \geq a$ for a given a in [0,1].

The general idea is that both upper truncation and rounding behave quite similarly, showing a loss of transitivity degree (in the sense of definition 4.1) which is in accordance with the coarseness of the finite scale in use.

Proposition 4.5: Let E be a fuzzy T-transitive relation, f an additive generator of the t-norm T, and $L_N = \{a_N \ldots a_0\}$ a homogeneous finite scale of [0,1]. Then:

4.5.1 The fuzzy relation $\Delta_U(E)$ (upper truncation of E) is δ-T-transitive with $\delta \geq f^{[-1]}(f(a_i)-f(a_{i+1}))$

4.5.2 The fuzzy relation $\Delta_R(E)$ (rounding) is δ-T-transitive with $\delta \geq f^{[-1]}(f(a_i)-f(a_{i+1}))$

NOTE: The expression $\delta \geq f^{[-1]}(f(a_i)-f(a_{i+1}))$ includes the case when $\delta = 1$, i.e. E is fully T-transitive. This situation occurs, for example, when the fuzzy relation E is *MIN* transitive (Corollary 2.4).

Proof: 4.5.1 For a given tern x, y and z in X let i and j be such that $a_{i+1} < E(x,y) \leq a_i$ and $a_{j+1} < E(y,z) \leq a_j$. Then $\Delta_U(E(x,y)) = a_i$, $\Delta_U(E(y,z)) = a_j$ and

$T(\Delta_U(E(y,z)),\Delta_U(E(y,z))) = a_{i+j}$

On the other hand $a_{i+j+2} < T(E(x,y),E(y,z) \leq a_{i+j}$. Since $T(E(x,y),E(y,z) \leq E(x,z)$ (E is T-transitive), the inequality $a_{i+j+2} < E(x,z)$ also holds, and thus $a_{i+j+1} \leq \Delta_U(E(x,z))$.

Finally, $T(T(\Delta_U(E(y,z)),\Delta_U(E(y,z))),\delta_0) =$

$T(a_{i+j},\delta_0) = a_{i+j+1} \leq \Delta_U(E(x,z))$

where $\delta_0 = f^{[-1]}(f(a_i)-f(a_{i+1}))$.

The proof of 4.5.2 involves a tedious case by case study of four different possible situations. We will skip that, as the ideas involved in there have already been shown in 4.5.1 ■

Proposition 4.5 provides an easy criterion to decide whether a finitely valued fuzzy relation can be obtained from a continuously valued T-transitive one. Finitely valued relations with a breach of transitivity heavier than the step of the mesh $\delta = f^{[-1]}(f(a_i)-f(a_{i+1}))$ are automatically discarded. The question of whether this criterion is actually a characterization remains open, though.

However, when the strong transitivity degree is considered (definition 4.2), both upper truncation and rounding may end up in heavy loss of transitivity, even if precise, very fine scales are used. The problem is illustrated by the following example.

Example 4.6 (Upper truncation) Let us consider X=[0,1], T=T_{LUK} the Lukasiewicz t-norm, E the fuzzy relation on X defined by $E(x,y) = 1-|x-y|$, $L_N = \{a_N \ldots a_0\}$ with $a_i = \frac{N-i}{N}$ and upper rounding, i.e. $\Delta(a) = \Delta_U(a) = a_i$ for all a in $(a_{i+1}, a_i]$, as the chosen discretization function. Then the transitive closure of $\Delta(E)$ is the relation $F = \overline{\Delta(E)} = 1$, and the strong transitivity degree is then 0.

Proof. The strong transitivity degree is (definition 4.2)

$\mathcal{E}_T(\Delta(E),F) = \inf_{x,y\in X} E_T(\Delta(E(x,y)),F(x,y)) =$

$\inf_{x,y\in X} E_T(\Delta(E(x,y)),1) = 0$

which accounts for the last part of the example.

To prove that $F = 1$ is the transitive closure of $\Delta(E)$, notice that for any pair x, y such that $E(x,y) > a_{N-1} = \frac{N-1}{N}$ its discretized value is $\Delta(E(x,y)) = a_N = 1$ and therefore $F(x,y) = 1$.

Now, if x and y are such that $E(x,y) \leq a_{N-1} = \frac{N-1}{N}$ with $x < y$, we may consider

$x_0 = x,\ x_1 = x+\varepsilon,\ x_2 = x+2\varepsilon \ldots x_M = x+M\varepsilon$

such that $E(x_i,x_{i+1}) = 1-|x_i - x_{i+1}| = 1-\varepsilon$, where $\frac{1}{N} > \varepsilon > 0$ with $y < x_M = x+M\varepsilon$. Since F is T-transitive,

$F(x,y) \geq T(\ldots T(T(F(x,x_1),F(x_1,x_2)))\ldots F(x_{M-1},y)) =$

$T(\ldots T(T(1,1))\ldots 1) = 1$ and thus $F(x,y) = 1$ for all x, y in X.

■

The previous example can be easily adapted to the case of rounding by choosing an ε which is small enough in relation to the finite scale L_N.

More generally, the situation illustrated by the previous example occurs in all those situations where the elements of X may be linked to each other by chains of closely enough laid elements.

Theorem 4.7 Let T be an Archimedean t-norm, E a T-transitive relation on a set X and $L_N = \{a_N \ldots a_0\} \subseteq [0,1]$ an homogeneous finite scale. If for all x and y in X there is a chain $x = x_0, x_1, x_2 \ldots x_M = y$ with $E(x_i,x_{i+1}) > \delta$ for all i, then $\overline{\Delta(E)} = 1$ ■

In that case, the strong transitivity degree may fall to 0.

V. CONCLUSIONS

Fuzzy transitive relations with respect to a continuous t-norm are a prominent class of fuzzy relations. They include fuzzy preorders and fuzzy equivalence relations, which are widely used in a variety of soft-computing areas ranging from approximate reasoning to clustering or pattern recognition.

From any practical purpose, discretization of the continuously valued models remains crucial. However, discretized *T*-transitivity fuzzy relations when *T* is an Archimedean t-norm do not always behave as expected. Only lower truncation discretization succeeds at preserving *T*-transitivity.

At the other end, *MIN*-transitivity is always preserved regardless the discretization strategy adopted, a fact that boosts the theoretical soundness of Similarity Relations, a class of fuzzy relations which is the choice of reference in many applied domains.

***Abstract*—A tridimensional fuzzy pain assessment for representing professional, social, and sexual aspects concerned to the fifth vital sign of medical condition is proposed in this paper. According to the 3D fuzzy pain assessment herein, pain is not only caused by activity in nociceptive information in the brain. The proposed approach embodies such sensorial information simultaneously that contextualize it within cultural aspects that permeate the human life. This paper extends both previous unidimensional fuzzy pain intensity scale and the accepted professional-social–sexual pain assessment to fuzzy inference systems. The fuzzy professional–social–sexual pain assessment is able to represent the inherent physiological, psychological characteristics by taking into account the emotional, complex perceptual, subjective, and personal phenomenon involving all domains of an individual meanwhile can deal with cultural mechanisms within individual life experience. According to the proposed approach, not only fuzzy set theory but fuzzy systems can also direct and immediately improve medicine and healthcare in general, and pain assessment, in particular, in a subjective and multi–dimensional model.**

I. Introduction

Pain afflicts postoperative patients, patients with advanced cancer, residents in long-term care facilities, recipients of end–of–life care, for one side, and the elderly, the young, and minorities, on other side [1]. Further, there is no distinction between economical-social-sexual-racial characteristics; all individuals are subject to this vital signal in medicine and healthcare. Understood as the signal for diagnosing medical conditions related to the presence of disease or abnormality [2], [3], pain assessment is still a challenge for medical and healthcare professionals.

Many are the sources of difficulties for medical and healthcare professionals. The foremost challenge is, mostly, concerned to the patient's self-report intensity during physical examinations; the preferable indicator of pain. Pain is, primary, determined by sensorial information. Stimulus in free endings of thin myelinated and nonmyelinated fibers sends nociceptive information to pain receptors (Nociceptors) in the brain that detect noxious agents [4]. Related to genetic composition, there is a huge variability in the pain perception and pain expression for the same painful stimuli [5].

Intensity is, however, not the only aspect employed to define pain. Due to its nature, it is not only physiological but psychological, as well. Being a perception, pain is considered an emotional, complex perceptual, subjective, and personal phenomenon involving all domains of individual life experiences [5]. The challenge in pain assessment for representing basic bodily functions and health quality of life also encompass pain-related disability, pain duration, pain affect etc. [6]. Cultural mechanisms and derived social aspects such as individual life experience, learned behavior, daily life activities, only to mention few, affect patient's pain perception [7], [8]. Pain is, thus, understood as a multi-faceted subjective response related to a biopsychosocial experience.

All these characteristics encompass a variety of clinical scenarios and make pain assessment and management a complex task for therapeutic decisions. To improve pain assessment and management, fuzzy set theory is employed in [5] to address the subjectivity of the pain intensity reported by patients. The most common, international standards (systematic mechanisms) related to unidimensional intensity rating assessment are modified by using fuzzy set theory yielding fuzzy visual analog scale (FVAS), fuzzy numerical rating scale (FNRS), fuzzy qualitative pain scale (FQPS), and fuzzy face pain scale (FFPS). Therein, possibility distribution functions are used to best represent the inherent imprecision, uncertainty and vagueness related to the fifth vital sign of medical condition, present in the pain report and assessment. Such an approach is used as an alternative to build up a fuzzy pain assessment system [9].

Unidimensional fuzzy pain intensity scale was first chosen due to its immediate and general applications, for one side, and the reinforcement of the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) for using easier tools as the key element for successful pain assessment and treatment [10], on the other side. Nevertheless, unidimensional pain measurements fail in capturing other elements and aspects that

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

can influence the perception of the patients.

Pain can be assessed by employing unidimensional or multidimensional mechanisms according to the objective and interests to be achieved during diagnosis. This paper addresses the use of fuzzy set theory and fuzzy logic to represent multi-faceted, tridimensional pain assessment encompassing pain-related disability, i.e., pain-related interference with activities. Along with this real-world, ordinary life activities are professional, social, and sexual (PSS) features as examples of cultural mechanisms that compose such a behavior pain assessment. This paper extends both previous unidimensional fuzzy pain intensity scale and the international professional–social–sexual pain assessment to synthesis a fuzzy inference system able to gather the inherent physiological, psychological, and cultural mechanisms within individual life experiences.

II. Tridimensional Fuzzy Pain Assessment

For each of the different aspects concerning pain, different assessment instruments should exist. Measurement of pain intensity does not capture sensory, affective, behavioral, social, and attitudinal factors. Along with pain intensity, pain-related interference with activities is seen as a major indicator for the severity of a pain condition [6], [11].

A. 3–D Professional–Social–Sexual Pain Assessment

Behavioral and social limitations are important elements for pain measurement. For instance, dressing, walking, family life, sexual relationship, professional performance etc. are examples from simple to complex activities affected by pain. Unfortunately, this list extends so far.

Several pain assessment approaches have been developed to assess the pain-related disability. These approaches assess the limitations in different activities of daily living. A list of multi-faceted, multi-items, multidimensional pain measures is detailed in [11].

The literature points out professional, social, and sexual limitations as three great groups for classifying pain-related disabilities. Tridimensional Fuzzy Professional–Social-Sexual (FPSS) Pain Assessment is, thus, proposed in this paper.

B. 3–D Fuzzy Professional–Social–Sexual Pain Assessment

Taking into account the inherent imperfection (uncertainty, imprecision, vagueness) present in this natural phenomenon, fuzzy set theory is a primary approach for representing pain [5]. While a unidimensional fuzzy set, M_i, can immediately be employed to represent unidimensional pain intensity, n-dimensional fuzzy sets:

$$M_{(1,\ldots,i,\ldots n)} = M_1 \ \cap \ldots \cap \ M_i \ \cap \ldots \cap \ M_n \qquad (1)$$

can be an alternative for describing multidimensional pain conditions. N-dimensional fuzzy sets advantage of gathering distinct characteristics associated to an object under analysis, each one represented, respectively, by distinct universes of discourse, X_i. The fuzzy sets can be represented by simple fuzzy propositions, $P_i = \langle x_i \text{ is } M_i \rangle$, in a natural or synthetic

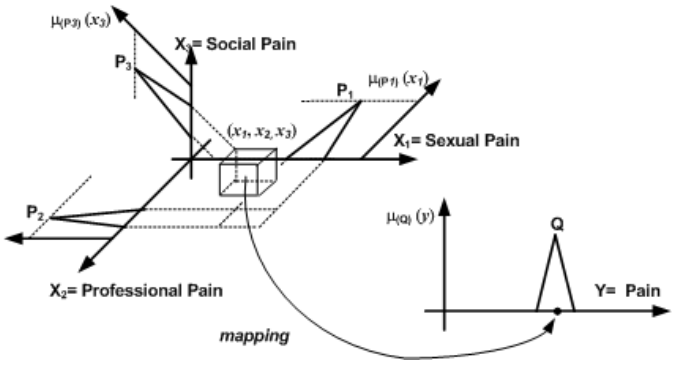

Fig. 1. Tridimensional Fuzzy Pain Measurement

language. In general, simple fuzzy propositions when put together allow building compound fuzzy propositions:

$$P_1 \text{ AND} \ldots \text{AND } P_i \text{ AND} \ldots \text{AND } P_n \qquad (2)$$

such that, the intersection set operation, $\cap$, in (1) corresponds to the linguistic expression, AND in (2). Further, the resulting value can yet be related to fuzzy classes by employing a fuzzy inference mechanism also denominated *fuzzy conditional proposition* as given as:

$$\text{IF } P_1 \text{ AND} \ldots \text{AND } P_i \text{ AND} \ldots \text{AND } P_n \text{ THEN } P_{n+1} \ , \qquad (3)$$

Due to its equivalence to linguistic expressions in the form of arguments to represent rules of inference it is associated to human approximate reasoning.

In this paper, professional–social–sexual pain-related disabilities are simultaneously represented in a tridimensional premise space, as depicted in Fig. 1, and mapped into an output associated to pain assessment, in the general form:

$$\begin{aligned} \mathrm{R}_i : \text{IF } & \left\langle \textit{professional pain} \text{ is } M_{ij_{professional}}^{professional} \right\rangle \text{ AND } \ldots \\ & \left\langle \textit{social pain} \text{ is } M_{ij_{social}}^{social} \right\rangle \text{ AND } \ldots \\ & \left\langle \textit{sexual pain} \text{ is } M_{ij_{sexual}}^{sexual} \right\rangle \\ \text{THEN } & \left\langle \textit{disability pain} \text{ is } N_{ij_{disability-pain}}^{disability-pain} \right\rangle \ , \end{aligned} \qquad (4)$$

where the elements $M_{ij(\cdot)}^{(\cdot)}$ and $N_{ij(\cdot)}^{(\cdot)}$ are fuzzy sets (also named *linguistic terms*) partitioning the respective universes of discourse, X_k and Y. The amount of partitions is given by $j(\cdot) = 1, \ldots, m_{(\cdot)}$ such that $M_{j(\cdot)}^{(\cdot)}(x_k) \subset X_k \ \forall k = 1, \ldots, n$ and $N^{disability-pain} \subset Y$. The number of rules is given by $i = 1, \ldots, N_r$. The input vector of the premise is given by $x = [x_1, x_2, x_3]^T$, while the output is associated to y. The input variables are *professional pain* $\in X_1$, *social pain* $\in X_2$, *sexual pain* $\in X_3$ while the output variable is *disability pain* $\in Y$. As proposed, $n = 3$ in this paper determines the number of input universes of discourse and represents the tridimensionality of the premises.

The universes of discourse of the proposed 3–D fuzzy pain measurement is equivalent in structure to Fuzzy Qualitative Pain Scale (Fig. 1). The FQPS consists of a verbal rating

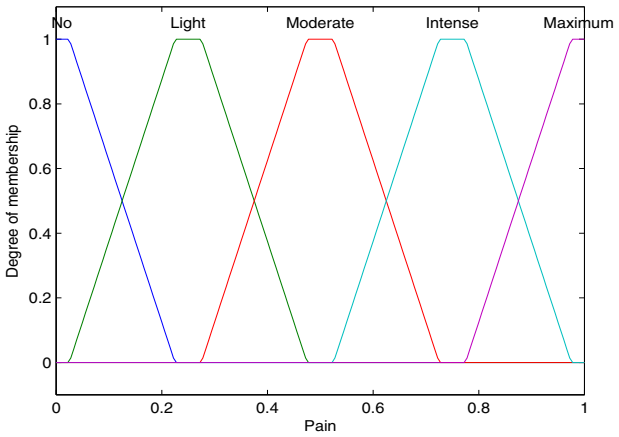

Fig. 2. Equivalent structure of Unidimensional Fuzzy Quality Pain Scale (FQPS) to input and output universes of discourse for Fuzzy Professional–Social–Sexual (FPSS) pain assessment

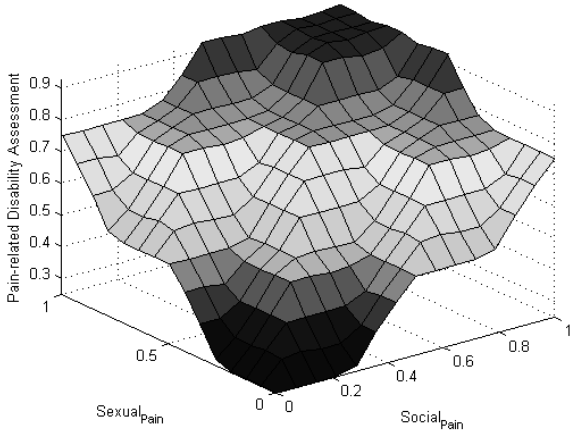

Fig. 4. Sexual and Social input relationship to pain–related disability degree of severity.

scale in which categories are labeled with words. Each of the input and output universes of discourse can, thus, adopt the same linguistic terms and number of partitions. In the FQPS, the patient is asked to classify the pain intensity according to linguistic expressions (adjectives) from a list of (1) *no pain*, (2) *light pain*, (3) *moderate pain*, (4) *intense pain*, (5) *maximum pain*. The linguistic expressions for representing pain may be directly represented by fuzzy sets as depicted in Fig. 2 [5]. In so doing, the linguistic terms $M^{professional}_{j_{professional}}$, $M^{social}_{j_{social}}$, and $M^{sexual}_{j_{sexual}}$, respectively, with $j_{professional} = j_{social} = j_{sexual} = 1, \ldots, 5$, yield a set of 125 fuzzy regions in the tridimensional input space, as illustrated in Fig. 1.

The 3D Fuzzy PSS pain assessment is, thus, represented as

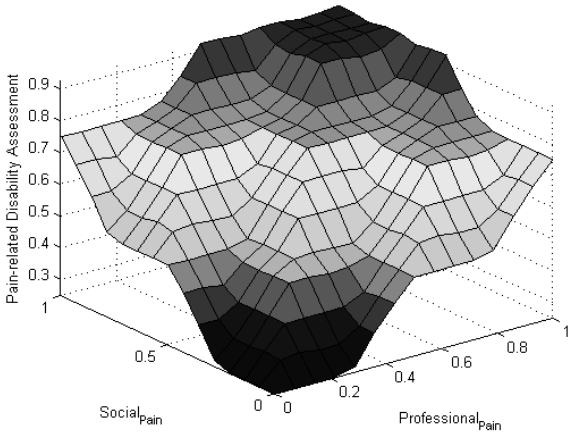

Fig. 3. Social and professional input relationship to pain–related disability degree of severity.

IF-THEN *fuzzy rules* in the form:

$$
\begin{aligned}
\mathrm{R}_1 : \text{IF } &\langle \textit{professional}_{pain} \text{ is } \mathrm{No}_{professional} \rangle \text{ AND } \ldots \\
&\langle \textit{social}_{pain} \text{ is } \mathrm{No}_{social} \rangle \text{ AND } \ldots \\
&\langle \textit{sexual}_{pain} \text{ is } \mathrm{No}_{sexual} \rangle \\
\text{THEN } &\langle \textit{disability pain} \text{ is } \mathrm{No}_{disability} \rangle \ , \\
\mathrm{R}_2 : \text{IF } &\langle \textit{professional}_{pain} \text{ is } \mathrm{No}_{professional} \rangle \text{ AND } \ldots \\
&\langle \textit{social}_{pain} \text{ is } \mathrm{No}_{social} \rangle \text{ AND } \ldots \\
&\langle \textit{sexual}_{pain} \text{ is } \mathrm{Light}_{sexual} \rangle \\
\text{THEN } &\langle \textit{disability pain} \text{ is } \mathrm{Light}_{disability} \rangle \ , \\
&\ldots \\
\mathrm{R}_{124} : \text{IF } &\langle \textit{professional}_{pain} \text{ is } \mathrm{Maximum}_{professional} \rangle \text{ AND } \ldots \\
&\langle \textit{social}_{pain} \text{ is } \mathrm{Maximum}_{social} \rangle \text{ AND } \ldots \\
&\langle \textit{sexual}_{pain} \text{ is } \mathrm{Intense}_{sexual} \rangle \\
\text{THEN } &\langle \textit{disability pain} \text{ is } \mathrm{Maximum}_{disability} \rangle \ , \\
\mathrm{R}_{125} : \text{IF } &\langle \textit{professional}_{pain} \text{ is } \mathrm{Maximum}_{professional} \rangle \text{ AND } \ldots \\
&\langle \textit{social}_{pain} \text{ is } \mathrm{Maximum}_{social} \rangle \text{ AND } \ldots \\
&\langle \textit{sexual}_{pain} \text{ is } \mathrm{Maximum}_{sexual} \rangle \\
\text{THEN } &\langle \textit{disability pain} \text{ is } \mathrm{Maximum}_{disability} \rangle \ .
\end{aligned}
\tag{5}
$$

The fuzzy IF-THEN rules in (5) are denominated *fuzzy model*, as well. In this way, the proposed 3D Fuzzy PSS pain assessment is, actually, a fuzzy model for pain assessment when behavior and disability aspects are taken into account.

The proposed fuzzy professional–social–sexual pain assessment may be employed with any shape of fuzzy sets available in literature. Here, trapezoidal membership functions are utilized to illustrate the proposed approach. The resulting fuzzy pain-related disability assessment when concerning social–professional input variables, sexual–social input variables, and

professional–sexual input variables are, respectively, depicted in Fig. 3, Fig. 4, and 5.

C. Singleton Pain and Fuzzy Pain Measurements in Fuzzy PSS Pain Assessment

The fuzzy model for PSS pain assessment works as an alternative when interested in reporting behavior and disability aspects. The fuzzy professional–social–sexual pain assessment advantages in being able to deal with both singleton and fuzzy pain measurement for any of the input dimension (Fig. 6).

Singleton pain measurement can be obtained by employing, for instance, but not limited to, visual analog scale, numeric rating scale, verbal rating scale, change in back pain intensity, increased pain during or after exercise, low back pain rating scale, pain frequency, pressure pain threshold, 5-point categorical, 6-point categorical, 11-point intensity. They can immediately be used to supply singleton inputs for the fuzzy PSS assessment system, as depicted in Fig. 6(a).

Nevertheless, emotional states and in doubt individuals when reporting their pain perception are related to the absence of crisp boundaries and singleton values. An international standard proposed for pain assessment based on fuzzy sets and fuzzy numbers for representing inaccuracy, flexibility, doubt, and emotionality in pain intensity measurement is described in [5]. Likewise occurs with singleton pain measurement scales, fuzzy visual analog scale (FVAS) and fuzzy numerical rating scale (FNRS) are alternatives for supplying fuzzy inputs for the fuzzy PSS assessment system, as depicted in Fig. 6(b).

Visual comparative analysis among classic Visual Analog Scale (VAS) and Numerical Rating Scale (NRS) and FVAS, FNRS are, respectively, depicted in Figs. 7 and 8. When using the fuzzy visual analog scale, the value of pain intensity is obtained by the distance from the beginning of a 10 cm single line assigned in one border labeled *no pain* and in the other extremity *maximum pain* to the patient's marks. This distance is directly measured in centimeters by employing a ruler or by using a computational system [9]. While the classic visual

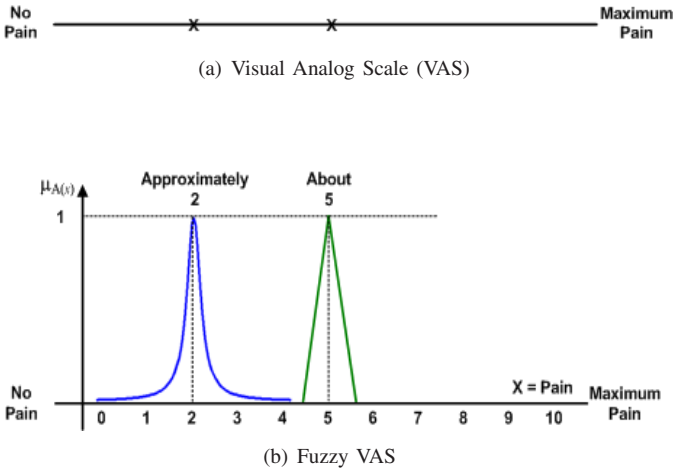
(b) Fuzzy Pain Measurement into FPSS.

Fig. 6. Both types of singleton and fuzzy pain measurement supplied to FPSS pain assessment, for instance, into professional pain dimension.

analog scale is represented as a singleton value, the fuzzy visual analog scale is able to represent the inaccuracy in the pain indication (Fig. 7(b)) by using fuzzy sets [5].

Similarly, fuzzy numerical rating scale consists of a graded line scale identified by eleven numbers from 0 to 10 (Fig. 8(a)). The patient marks this scale with the pain intensity that better represents the assumed physical discomfort. The value of pain intensity is obtained by the distance from the beginning of the graded line to the patient's marks. This distance is directly measured in centimeters by employing a ruler or by using a computational system [9]. While the classic numerical rating scale is represented as a singleton value, the fuzzy numerical rating scale uses a fuzzy set to represent the subjectivity, vagueness in indication of the pain (Fig. 8(b)) [5].

It is worth mentioning that nothing prevents the use of mixed singleton and fuzzy pain measurements for representing behavior and disability pain condition.



(a) Visual Analog Scale (VAS)

(b) Fuzzy VAS

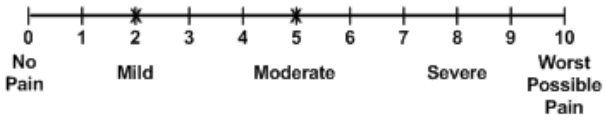
Fig. 7. Unidimensional Fuzzy Visual Analog Scale (FVAS).

D. Exemplifying Patient's Self-Report Fuzzy Behavioral and Disability Pain Modeling

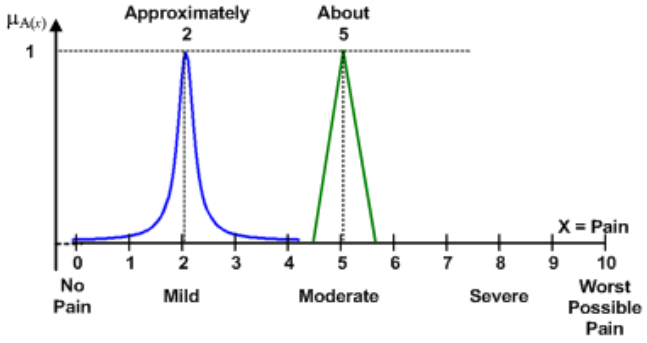
Consider a patient who reports social and professional difficulties due to the presence of a back pain during medical diagnosis. The patient declares the interest in not getting out due to the pain. Working in security, the back pain assumes a more important role because the patient carries a revolver. Further, the afflicted pain does not limit the sexual experience but a patient's self-report pain measurement indicates a small discomfort.

Simple, unidimensional pain scales can, at first, be used to identify the pain intensity, be it a singleton or fuzzy measure. Nevertheless, being able to capture presence and intensity, they do not determine the real significance of the pain. The preferable indicator of pain must capture the importance of not being able to adequately handle a revolver. The intensity pain scale does not measure the impact and social frustration upon patient's family due to the limitation imposed by the patient's pain. Neither, the sexual discomfort is taken into account.

The tridimensional pain-related disability model presented in (4) is a feasible alternative for comprehensively representing the inherent complexity, subjectivity comprising this sort of pain. In this illustrative example, it is considered the simplest condition. A singleton pain scale is furnished to the patient who, in turn, marks three distinct amplitudes for professional, social, and sexual pain according to the well established NRS. It was required first to the patient to mark the intensity of pain, i.e., marking a unidimensional pain scale. Second, it is asked to the patient to include not only intensity of pain but limitations and other aspects concerning each one of the input premises for completely describing the suffering. These marks are presented in Fig. 9. Distinct values among the four pain measurements based on real–world data (patients)



(a) Numerical Rating Scale (NRS)



(b) Fuzzy NRS (FNRS)

Fig. 8. Unidimensional Fuzzy Numerical Rating Scale (FNRS)

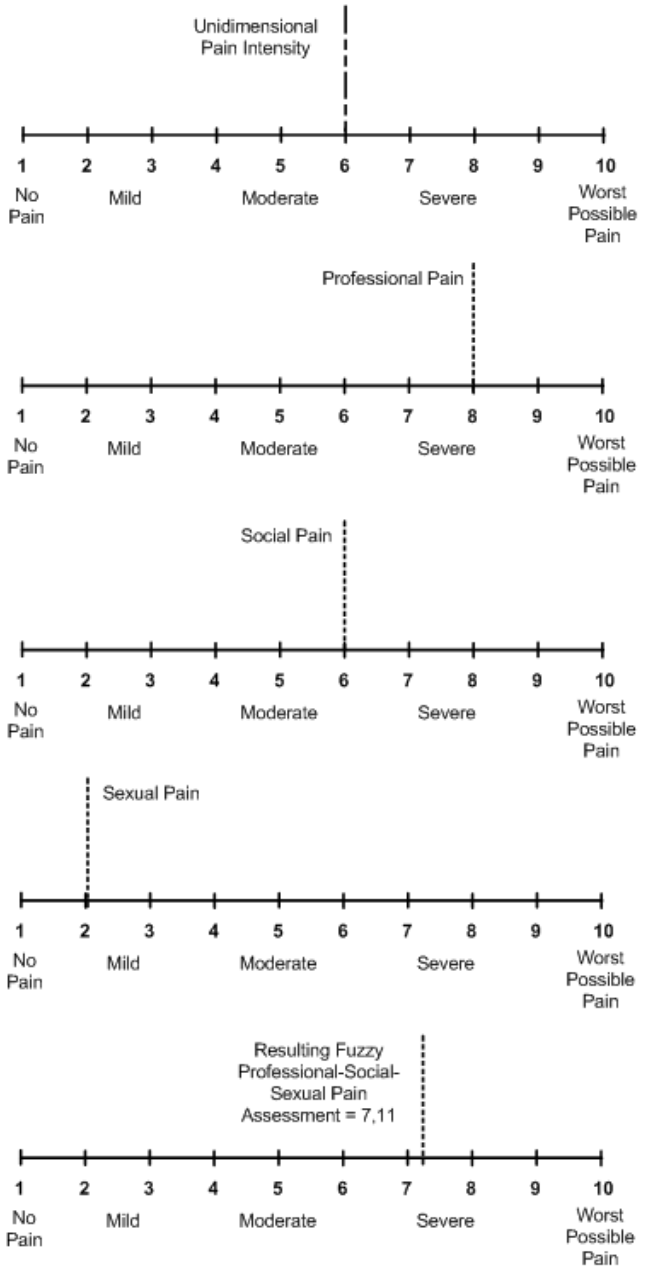


Fig. 9. Trade–off between Fuzzy Professional–Social–Sexual Pain Assessment and Classic Unidimensional Pain Intensity Measurement.

are: (a) simple intensity of pain, (b) professional pain, (c) social pain, and (d) sexual pain. Notice yet the (e) resulting fuzzy professional–social–sexual pain value computed by a 3D Fuzzy PSS pain assessment system.

III. Conclusion

In this paper a novel, feasible approach for modeling pain-related behavioral and disability assessment based on fuzzy set theory and fuzzy logic is presented. Professional pain, social pain, and sexual pain are three great groups for classifying pain-related disabilities used for generating a tridimensional fuzzy pain modeling. The proposed approach advantages of

being able to deal with both with singleton and fuzzy pain input measurements. Each input dimension can assume singleton pain values, or fuzzy pain values, or yet a mixed singleton and fuzzy pain values. The proposed fuzzy professional–social–sexual pain assessment is able not only of capturing sensory, affective, behavioral, social, and attitudinal factors concerning presence and intensity of afflicted pain but determine the real significance of the pain according to the inherent complexity, subjectivity comprising behavioral and disability aspects. The 3–D FPSS is a comprehensively manner to describe the physiological, psychological, and cultural present in mankind pain condition.

***Abstract*—This study proposes a method for partitioning and classifying complex datasets using a hybrid method based on Fuzzy C-Means (FCM) method, Variable Precision Rough Set (VPRS) theory and a modified form of the PBMF index function (a cluster validity index function). The proposed VPRS index method partitions the attributes within the dataset rather than the data and achieves both the optimal number of clusters and the optimal classification accuracy. The validity of the proposed approach is confirmed by comparing the clustering results obtained from the VPRS method for a hypothetical function and a typical stock market system with those obtained from the conventional RS and PBMF methods, respectively. Overall, the results show that the VPRS index method not only has a better clustering performance than the PBMF method, but also achieves greater classification accuracy, and therefore provides a more reliable basis for the extraction of decision-making rules.**

I. INTRODUCTION

Classification, which is a task of grouping data with multiple attributes into relevant categories, has become the most valuable process to learn the implicit knowledge among dataset. However, difficulties have been found in many classification approaches, and one of the major problems is related to clustering－partition the real-value attributes into discrete groups. In order to conduct a dataset classification, attribute clustering must be performed in prior, and accurate clustering is the premise to meaningful classifications.

In general, the problem of evaluating the optimality of the clustering results obtained for a particular dataset is referred to as the cluster validity problem [1]. Many methods have been proposed for assessing the validity of the clustering results obtained using fuzzy clustering schemes [2]. Amongst these methods, early indices such as the partition coefficient [3, 4] and classification entropy [5, 6] are based simply on the membership values of the instances within the dataset and are therefore computationally straightforward. In general, existing clustering methods cluster the dataset in accordance with the norms of the instances rather than the values of the individual attributes. The results obtained using traditional clustering methods fail to take sufficient account of the complex interrelationships amongst the various attributes of the dataset. Therefore, in constructing data partitioning and classification algorithms, it is preferable to apply some form of classification-defining knowledge to the attribute values of the dataset such that the complex interrelationships amongst the various attributes can be taken more properly into account.

The literature contains many algorithms for automatic classification purposes, including decision-tree algorithms such as ID3 [7], rule-based algorithms such as CN2 [8], back-propagation networks [9], support vector machines [10], conformal predictors [11], Bayesian classifiers [12], and so forth. Whilst such algorithms have found widespread use in a diverse range of applications, including weather prediction, manufacturing process planning, medical diagnosis, and so on, they can not deal effectively with systems characterized by uncertain or missing information. Furthermore, to the best of the current authors' knowledge, only few attempts [13] have so far been made to integrate these classification algorithms with any form of cluster validity index in order to evaluate the optimality of the clustering results.

Rough Set (RS) theory was first introduced more than twenty years ago [14] and has emerged as a powerful technique for the automatic classification of instances [15]. However, performing a classification operation with a controlled degree of uncertainty or misclassification error is beyond the ability of the RS approach [16]. In an attempt to extend RS theory to such classification applications, Ziarko proposed a Variable Precision Rough Set (VPRS) methodology in which the instances within the dataset were analyzed and classified in terms of their statistical tendencies rather than their functional patterns [16, 17]. In VPRS theory, the uncertain nature of the information within the system of interest is handled using the concept of β-lower and β-upper approximate sets. However, as with the RS method, the classification performance of VPRS models is constrained by the quality of the original clustering results. Therefore, in meeting the needs of decision-makers for

* Corresponding author

sophisticated methods capable of extracting reliable decision rules from complex information systems, it is necessary to integrate the VPRS method with some form of optimized clustering scheme.

Accordingly, this study proposes a hybrid scheme for the partitioning and classification of complex datasets based upon the FCM clustering method and a VPRS model in which the optimal threshold parameter β is determined using the method presented by Huang [18]. In the proposed approach, the dataset is partitioned in terms of the attribute values of the instances rather than the norms of the instances in order to capture the complex interactions amongst the various instances.

The remainder of this paper is organized as follows. Section II presents the fundamental principles of the FCM method, VPRS theory and the conventional PBMF clustering validity index, respectively. Section III describes the integration of these concepts to create the proposed VPRS partitioning and classification scheme. Section IV compares the performance of the proposed scheme with that of the conventional RS index function method and the PBMF (FCM-based) clustering method, respectively. Finally, Section V presents some brief concluding remarks and indicates the intended direction of future research.

II. Review of Related Methodologies

A. Index function $I_{\max}$

Assume that each instance x_i in the dataset has has m conditional attributes and the l -th attribute a_l can be partitioned into p_l clusters, then $C_{a_l}(x_i)$ gives the index of the cluster to which the l -th attribute a_l of instance x_i belongs. Here $C_{a_l}(x_i)$ is given by $C_l(x_i) = I_{\max}(\mu_j(x_i(a_l))) = \text{Index}(\max(\mu_j(x_i(a_l))))$ for $1 \le l \le m, 1 \le i \le n$, where $I_{\max}(\mu_j(x_i(a_l)))$ returns the index of the cluster corresponding to the maximum value amongst all the membership functions of the l -th attribute of x_i.

B. Fundamental principles of VPRS theory

VPRS operates on what may be described as a knowledge-representation system, or information system [16]. The basic principles and notations of information systems (S) and the application of VPRS theory to the processing of such systems are described in the sections below.

1) β -lower and β -upper approximate sets: For a given dataset, any instances which are indistinguishable from one another when evaluated using a particular subset of all the attributes define an equivalence or indiscernibility relationship. In RS theory, this indiscernibility concept is handled using approximate sets. A typical information system has the form $S = (U, A, V_q, f_q)$, where U is a non-empty finite set of instances, A is a non-empty finite set of attributes describing these instances and $X \subseteq U$ and $R \subseteq A$. Generally speaking, the attributes in set A can be partitioned into a set of conditional attributes $C \neq \{\}$ and a set of decision attributes $d \neq \{\}$, i.e. $A = C \cup d$ and $C \cap d = \{\}$. For each attribute, $q \in A$, V_q represents the domain of q, i.e. $V = \cup V_q$. Finally, $f_q : U \times A \to V$ is an information function defined such that $f(x,q) \in V_q$ for $\forall q \in A$ and $\forall x \in U$. The VPRS method proposed in this study utilizes the systematic method presented by the current author in [18] to determine an appropriate value of the threshold parameter β, i.e., the value of β at which a certain proportion of the instances in a particular conditional class are classified into the same decision class. When processing an information system using a VPRS model with $0.5 < \beta \le 1$, the objective is to identify the β -lower and β -upper approximate sets associated with each cluster of the decision attribute. In general, the β -lower approximation of sets $X \subseteq U$ and $P \subseteq C$ can be expressed as

$$\underline{R}_P^{\beta}(X) = \{x \in U : P(X/[x]_P) \ge \beta\} = \cup\{[x]_P : P(X/[x]_P) \ge \beta\}$$

Similarly, the β -upper approximation of sets $X \subseteq U$ and $P \subseteq C$ is given by

$$\overline{R}_P^{\beta}(X) = \{x \in U : P(X/[x]_P) > 1-\beta\} = \cup\{[x]_P : P(X/[x]_P) > 1-\beta\}$$

Note that $P(X/Y) = \dfrac{|X \cap Y|}{|Y|}$ if $|Y| > 0$, and $P(X/Y) = 1$ otherwise. Note also that $|X|$ denotes the cardinality of set X.

In the particular case of $\beta = 1$, $\underline{R}_P^{\beta}(X)$ and $\overline{R}_P^{\beta}(X)$ are equivalent to the lower and upper approximate sets in RS theory. In other words, the VPRS model reverts to the traditional RS model.

2) Accuracy of VPRS classification results: The accuracy of the VPRS classification results can be quantified as follows:

$$\alpha_c^{\beta} = \left|\underline{R}_P^{\beta}(d \mid C_d(x) = c)\right| \Big/ \left|\overline{R}_P^{\beta}(d \mid C_d(x) = c)\right|,$$

where $\left|\underline{R}_P^{\beta}(d \mid C_d(x) = c)\right|$ and $\left|\overline{R}_P^{\beta}(d \mid C_d(x) = c)\right|$ are the cardinalities of the β -lower and β -upper approximate sets obtained when ranking the elements (x) in terms of the c -th cluster of the decision attribute d.

C. PBMF index function

The PBMF cluster validity index function [19] ensures the formation of a small number of compact clusters within the dataset and maximizes the separation distance between at least two of these clusters. The PBMF index function is formulated as $PBMF(K) = \left(\frac{1}{K} \times \frac{\overline{E_1}}{J_{m'}} \times D_K\right)$, where K is the number of clusters, $J_{m'} = \sum_{k=1}^{K}\sum_{j=1}^{n} \mu_{kj}^{m'} \left\| x_j - z_k \right\|$, $\overline{E_1}$ is constant for a given dataset and is used to prevent the value of the second term from approaching zero, and $D_K = \max_{i,j=1}^{K} \left\| z_i - z_j \right\|$. In addition, n is the total number of instances in the dataset, $U(X) = \lfloor \mu_{kj} \rfloor_{K \times n}$

is the matrix used to partition the data, m' is the fuzzification parameter, and z_k is the centroid of the k-th cluster. In utilizing the PBMF index function for data clustering purposes, the objective is to find the value of K (i.e. the number of clusters) which maximizes the index value.

III. VPRS INDEX METHOD

This study proposes a hybrid scheme comprising a Variable Precision Rough Set (VPRS) model and a modified form of the PBMF index function for optimizing both the number of clusters within the dataset and the corresponding classification accuracy. Assuming that U is the domain of discourse and R is the set of equivalences of U, the VPRS classification problem can be formulated as

$$X \subseteq U \text{ is : } (\underline{R}_P^{\beta}(X), \overline{R}_P^{\beta}(X)), BND_P^{\beta}(X),$$

where X is the set of instances; U/I_P is the quotient set of U; I_P is the indiscernibility of R; {} is the empty set; R is the attribute set of X and includes both the conditional attribute set（C） and the decision attribute set (d), $P \subseteq C$; $\underline{R}_P^{\beta}(X)$ is the β-lower approximate set of X; $\overline{R}_P^{\beta}(X)$ is the β-upper approximate set of X; and $BND_P^{\beta}(X)$ is the boundary set of X.

Significantly, the VPRS index method proposed in this study clusters the attribute values of the instances within the dataset rather than the norms of the instances. Thus, in contrast to the PBMF index function method, the proposed approach takes better account of the intrinsic interrelationships amongst the various independent parameters of the dataset. The detailed parameters of the VPRS index function are discussed in the following section.

A. Parameters of VPRS index function

The VPRS index function proposed in this study has the form

$$VPRS(N, \alpha_c^{\beta}) = \left(\frac{1}{N} \times \frac{\overline{E_1}}{F'_N} \times D'_N \right)$$

where N is the number of clusters assigned to the conditional and decision attributes and α_c^{β} is the classification accuracy when evaluated in terms of the c-th cluster of the decision attribute. In addition, F'_N is obtained by aggregating the value of E'_c for each cluster of the decision attribute (d), where E'_c is given by $E'_c = \sum_{j=1}^{n} \overline{\mu}_{cj}^{m'}(x_j(d)) \left\| x_j - z'_c \right\| \Big/ \alpha_c^{\beta}$, in which $\overline{\mu}_{cj}(x_j(d))$ is the membership function of instance x_j in the c-th cluster of the decision attribute d and z'_c is the multi-dimensional centroid of the β-lower approximate sets associated with the c-th cluster of the decision attribute d and is obtained by computing the mean values of the conditional and decision attributes of each instance within the corresponding sets. Furthermore, m' is the fuzzification parameter and n is the total number of instances in the dataset. Finally, the value of D'_N is equal to the maximum separation distance amongst the centroids of all the β-lower approximate sets associated with the different clusters of the decision attribute, i.e. $D'_N = \max_{i,j=1}^{N} \left\| z'_i - z'_j \right\|$. Note that the value of $D_N{}'$ is upper bounded by the maximum separation distance amongst all possible pairs of data points in the dataset.

Note that parameter F'_N in the VPRS index function differs slightly from parameter $J_{m'}$ in the PBMF index function in that its value depends on E'_c and therefore takes the classification accuracy into account.

B. Tendencies of terms within VPRS index function

As discussed in Section III.A, the VPRS index function has the form $VPRS(N, \alpha_c^{\beta}) = \left(\frac{1}{N} \times \frac{\overline{E_1}}{F'_N} \times D'_N \right)$. In other words, the index function comprises three terms, namely, $1/C$, $\overline{E_1}/F'_N$ and $D_N{}'$. Clearly, the value of the first term decreases as the number of clusters assigned to the conditional and decision attributes, N, increases. In other words, the value of the index function decreases with an increasing value of N. Regarding the second term in the index function, the value of $\overline{E_1}$ is constant for a given dataset and is equal to $\overline{E_1}$ in the conventional PBMF index function. Meanwhile, as discussed in the previous section, F'_N is equal to the sum of all $E_c{}'$, where each $E_c{}'$ includes the classification accuracy α_c^{β} associated with the c-th cluster of the decision attribute d. Hence, the VPRS index function increases as $E_c{}'$ decreases. The third term, $D_N{}'$, measures the maximum distance between the centroids of the β-lower approximate sets associated with the different clusters of the decision attribute, and increases as N increases. Thus, the contribution of $D_N{}'$ to the value of the VPRS index function increases as the number of decision attribute clusters increases.

C. Detailed processing steps in proposed VPRS index function method

The details of each processing step are summarized in the following paragraphs.

Step 1: Specify number of clusters per attribute in interval [2, N_{max}]

As described in Section I, the proposed VPRS index method utilizes an iterative procedure to optimize the number of clusters assigned to each conditional and decision attribute

within the system of interest. (Note that the number of conditional attributes to be considered in the optimization process is specified in advance by the user and the number of decision attributes is set by default to one.) As described in Section III, the conditional and decision attributes are partitioned into an equal number of clusters, N, where N is bounded by the interval $[2, \mathrm{N}_{\max}]$, in which 2 represents the minimal number of clusters per attribute (and is the default setting) and $\mathrm{N}_{\max}$ represents the maximum permissible number of clusters per attribute and is set on a case-by-case basis in such a way as to achieve a satisfactory trade-off between the classification performance and the computational complexity of the solution procedure.

Step 2: Fuzzify attributes of information system using FCM method.

In general, a continuous-value information system can only be converted into an equivalent fuzzy information system once a classified fuzzy set has been obtained. In the FCM clustering procedure performed in the VPRS index function method, the interval values $[\alpha, \beta]$ of all the conditional and decision attributes are assigned to p_l fuzzy clusters. The continuous-value information system (U, A, V_q, f_q) is then converted into the fuzzy information system $(U, \widetilde{A}, \Phi, d)$, where $\Phi = \{\widetilde{A}_{lj} \mid l \le m, j \le p_l\}$, in which $\widetilde{A}_{lj} = \mu_j(x_i(a_l))$ and indicates the values of the membership functions associated with the l-th conditional attribute a_l of the i-th instance.

Step 3: Assign each instance attribute to appropriate conditional or decision attribute cluster.

Utilizing the index function $C_{a_l}(x_i) = I_{\max}(\mu_j(x_i(a_l))) = Index(\max(\mu_j(x_i)))$ for $1 \le l \le m, 1 \le i \le n$, the membership functions of each attribute of each instance are processed in order to determine the cluster to which the attribute value belongs.

Step 4: Identify VPRS sets and compute corresponding classification accuracy.

Having mapped the attribute values of all the instances to the appropriate conditional or decision attribute clusters, the procedure described in [18] is applied to determine an appropriate value of the threshold parameter β in the VPRS model. The β-lower approximate sets and boundary sets associated with each cluster c of the decision attribute d are then extracted in accordance with the definitions presented in Section II.C. Finally, the classification accuracy associated with each cluster of the decision attribute is evaluated by computing the cardinality ratio of the corresponding β-lower approximate sets to the β-upper approximate sets.

Step 5: Calculate centroids of β-lower approximate sets associated with each cluster of decision attribute.

The multi-dimensional centroids of the β-lower approximate sets associated with each cluster of the decision attribute d are obtained by calculating the mean values of the conditional and decision attributes of all the instances within the corresponding sets.

Step 6: Determine the value of the VPRS cluster validity index.

Having determined the classification accuracy and centroids of the β-lower approximate sets, the optimality of the clustering solution is evaluated using the VPRS cluster validity index given in Section III.A.

Step 7: Check termination criterion.

Having computed the value of the index function for the current number of clusters per attribute N, a check is made to see whether or not N is equal to the upper bound value ($N = \mathrm{N}_{\max}$). In the event that N is not equal to $\mathrm{N}_{\max}$, the value of N is incremented by 1, and the FCM, VPRS and cluster validity index computation procedures are repeated. Once the termination criterion is satisfied, the iteration procedure ceases and the computational process moves to the final step.

Step 8: Identify value of VPRS cluster validity index.

Once the termination criterion has been satisfied, the values of the VPRS index function obtained for $N = 2 \sim \mathrm{N}_{\max}$ are compared. The maximum value of the index function amongst all $2 \sim \mathrm{N}_{\max}$ solutions is taken as the VPRS cluster validity index and corresponds to the clustering solution which optimizes both the number of clusters per attribute and the overall classification accuracy of the dataset.

IV. Performance Evaluation of VPRS Index Method

In this section, the validity and effectiveness of the proposed VPRS index method is evaluated by considering three illustrative examples, namely one example relating to a dataset in which the conditional and decision attributes are related via a hypothetical function and two examples relating to electronic stock data extracted from the financial database maintained by the Taiwan Economic Journal (TEJ) [18]. In performing the evaluations, the effectiveness of the proposed method is explored by comparing the partitioning and classification results obtained for the three illustrative examples with those obtained from a Rough Set (RS) method and the conventional PBMF index (FCM-based) method, respectively. The PBMF index method clusters the norms of the instances within the dataset, whereas the VPRS and RS index methods cluster the attribute values. Note that the RS index method [13] is a particular case of the VPRS index method in which the cluster indices obtained from the FCM procedure are processed using a RS model rather than the VPRS model.

A. An illustrative example

The performance of the VPRS index method in partitioning and classifying real-world complex datasets was evaluated using electronic stock data extracted from the financial database maintained by the Taiwan Economic Journal (TEJ) [18] for the first quarter of 2008. The database maintains a total

of 53 financial indices for each company. However, for simplicity, the performance evaluations considered just one decision attribute, i.e. EPSNet Income, and 12 conditional attributes, i.e. (i) Business Profit Rate, (ii) PreTax Income %, (iii) Net Nonop.Inc./Rev, (iv) PSPre_Tax Income, (v) Oper.Income/Capital, (vi) PreTax Income/Capital, (vii) DaysA/R Turnover, (viii) DaysInventory Turn, (ix) DaysA/P Turnover, (x) Net Operating Cycle, (xi) PSOperating Income, and (xii) D/E Ratio. Having deleted the records for which one or more fields were incomplete, a total of 327 records were obtained (see Table 1 for representative values of each index for a selected subset of these 327 records).This illustrative example considers the performance improvement obtained in the VPRS method when increasing both the number of attributes considered within the clustering process and the number of clusters assigned to each attribute. Accordingly, the stock market data was processed repeatedly by the FCM clustering process with the number of conditional attributes specified in the range $[2,12]$, respectively, and the number of clusters specified in the range $[2,39]$.

The results presented in Table 2 show that the cardinality of the β-lower approximate sets obtained in the VPRS index method is larger than or equal to that of the lower approximate sets obtained in the RS index method. In other words, the VRPS β-lower approximate sets contain a greater number of instances than the RS lower approximate sets. For the case in which the clustering process is based on a small number of conditional attributes, i.e. {2, 3, 4, 5}, the approximate sets obtained using the RS index method contain a very small number of instances, while those obtained using the VPRS index method contain virtually all of the instances within the dataset. However, some of the instances within the VPRS approximate sets are subject to uncertainty. For example, when the number of conditional attributes and the number of clusters are both specified as 2, the RS index method yields only 3 instances, whereas the VPRS index method clusters all 327 instances. In other words, neither method accurately captures the relationship between the conditional attributes and the decision attribute. Thus, when classifying complex datasets using either method, a greater number of conditional attributes should be considered in the clustering process in order to ensure the completeness and reliability of the clustering results.

V. CONCLUSIONS

This paper has presented a cluster validity index method based on a Variable Precision Rough Set (VPRS) model and a modified form of the PBMF index function for the partitioning and classification of complex, real-world datasets. In the proposed approach, designated as the VPRS index method, the dataset is partitioned in accordance with the specified number of attributes and attribute clusters by the Fuzzy C-Means (FCM) clustering method and the resulting cluster indices are then processed by a VPRS model in order to identify the β-lower approximate sets associated with each cluster of the decision attribute and to evaluate the corresponding classification accuracy. Finally, the quality of the clustering solution is evaluated using a modified form of the PBMF index function. The effectiveness of the proposed approach has been confirmed by comparing the results obtained for the partitioning and classification of a real-world database containing stock market information with the corresponding results obtained using the RS index method. The evaluation results support the following major conclusions:

(1) In the PBMF index method, the optimality of the clustering results is evaluated in accordance with (a) the distance between each instance and the cluster centroids, and (b) the maximum separation distance between the cluster centroids. By contrast, in the VPRS index method, the quality of the clustering solution is evaluated in terms of (a) the distance between the instances and the centroids of the β-lower approximate sets associated with each cluster of the decision attribute, (b) the maximum distance between the centroids of the β-lower approximate sets associated with the different clusters of the decision attribute, and (c) the classification accuracy of the clustering results as evaluated by the cardinality ratio of the β-lower approximate sets to the β-upper approximate sets for each cluster of the decision attribute. In other words, in contrast to the conventional PBMF index method which only determines the optimal clustering of the data within the dataset given a specified number of clusters, the VPRS index method determines both the optimal number of attribute clusters within the dataset and the optimal classification accuracy.

(2) The PBMF index method clusters the norms of the instances within the dataset, whereas the VPRS and RS index methods cluster the attribute values. As a result, the VPRS and RS index methods take better account of the intrinsic interrelationships amongst the various conditional and decision attributes in the dataset when partitioning the instances and prevent the clustering results from being dominated by the attribute(s) with a higher order of magnitude.

(3) When using the RS and VPRS index methods to classify complex datasets based on a limited number of attributes, the cardinality of the β-lower approximate sets obtained in the VPRS index method is larger than or equal to that of the lower approximate sets obtained in the RS index method. As the number of attributes considered in the clustering process is increased, the difference between the cardinality of the β-lower approximate sets and that of the lower approximate sets classified by the two methods reduces. However, the number of instances classified by the VPRS method is still greater than that classified by the RS method.

(4) Although the VPRS index method classifies a far larger subset of the instances than the RS method when used to cluster complex datasets on the basis of a limited number of attributes, some of the

instances are characterized by uncertainty. In other words, the VPRS model fails to capture the true relationship between the conditional attributes and the decision attribute. Therefore, a greater number of conditional attributes are required in order to accurately model the interdependencies between the conditional attributes and decision attribute of the dataset.

Overall, the results presented in this study have confirmed that the proposed VPRS index method provides an effective tool for optimizing both the number of attribute clusters and the classification accuracy when applied to the partitioning and classification of complex, real-world datasets. However, the quality of the clustering results is degraded as the number of attributes considered in the clustering process is reduced. Therefore, reducing the number of uncertain instances in the β -lower approximate sets of the dataset is essential in improving the performance of the proposed method. Thus, a future study will explore the feasibility of improving the performance of the proposed VPRS classification method by processing (simplifying) the dataset utilizing a β -reducts method when applying the FCM, VPRS and cluster validity index function computation procedures.

Anti-Swing Control of A New Container Crane With Fuzzy Uncertainties Compensation

Weimin Xu, Wei Gu, Aidi Shen, Janxin Chu, Wangqiang Niu
Key Laboratory of Marine Technology and Control Engineering
Shanghai Maritime University
Shanghai, China

Abstrac —**A class of new container cranes with eight-link lifting mechanics which can reduce sway efficiently as a result of improved lifting structure have been put to use recently, and both modeling and swing control of such a crane system attracts a lot attention in the field of control technology development. In this paper, dynamics model of the new container crane is investigated, an anti-swing control scheme with fuzzy uncertainty compensation is proposed to ensure the positioning control as well as overall closed-loop system stability. None of the system parameters is required for the controller design in a priori. In the proposed control laws, the position error can be driven to a bounded area while the swing angle can also be rapidly damped so as to achieve minimal sway of the crane system. Stability analysis of the controller is also given. Finally, simulation results show the performance successfully.**

Keywords-container crane; eight-link lifting; anti-swing control; fuzzy uncertainty compensation; positioning control

I. INTRODUCTION

Container crane systems are widely used throughout the world in thousands of harbors, warehouses, and etc. for loading and transporting heavy cargos. Crane systems are desired to be able to move to the required position as fast and as accurate as possible while placing the payload at the appropriate position, meanwhile, the payload swing angle should be kept as small as possible. However, these crane structures are highly flexible in nature, apart from their underactuated dynamics property in control, some external disturbances, such as wind, hit or motion of the crane support unit can cause the payload to oscillate, as a result, this oscillation may bring damage to surrounding equipment and the payload itself, also, swing of the payload or hook makes precision positioning time consuming and inefficient for transporting operation.

Generally, difficulties in using a container crane lies in three aspects: motion-induced oscillation, disturbance-induced oscillation, and positioning capability. Many works have been done to improve the structure of container cranes practically, e.g. enhance the stiffness of lifting-link mechanism, and develop swing-free equipments, as well as investigate new control methods for crane system.

Many solutions [1]-[14] have been extensively studied in recent years for the simultaneous control of payload swing and of crane trajectory tracking, and some of them have led to industrial applications. Generally speaking, the dynamic equations of a crane are coupling, nonlinear and time-varying differential equations. The control schemes developed in the literature may be broadly grouped into three categories [11]: optimal control and linearized control [1], [4], and [5], command shaping control [6], [8], and nonlinear control [2], [9]. The implementation of these various control methods still presents several challenges. A common difficulty is the nonlinear behavior of drives and motors that actuate crane motion. Nonlinear behaviors such as friction, variables coupling of overhead crane system have been difficult to evaluate with traditional analysis techniques, and are, therefore, often neglected in controller design.

Resort to linearized theorem and optimal control approaches, many work has been done to design controller according to linearized crane model. A problem related to linearized control is its inability to be implemented in real-time, owing to the necessity of precomputation of system trajectories. Moreover, these linearized methods (such as time-optimal control etc.) cannot provide the sufficient accuracy of information about position error and load swing. Besides, the uncertain nonlinear factors such as the wind, the hit, and the friction of track will also reduce the performance of linearized crane control systems [12]. Command shaping is a reference signal modification technique that is implementable in real time [7]. Input shaping techniques have proven effective at significantly reducing motion-induced cable sway during crane motion. However, approaches on input shaping control which is naturally of open-loop control focused on the suppression of load swing but not solve the problem of position error during crane motion. Besides, the time period between the impulses of the input shaping method was also hard to obtain [11]. Nonlinear control is the most common strategy used in research efforts to mitigate positioning and cable sway errors, and some wonderful solutions for crane control have been derived by this means. However, these methods unavoidably need the prior knowledge of the crane dynamics which is actually hardly acquired, moreover, it is not easy for an engineer to design an industrial crane controller based on the mathematic model of the crane. For many years, the intelligent control (such as fuzzy-based methods and neural network-based methods) [13], [14] has been considered as a none-model based solution to nonlinear systems. It is well known that intelligent control derived from the desire of linguistic description or approximation of the whole nonlinearity for complex system, and it can be utilized to

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

formulate and imitate the human intelligence to construct control strategies, as well as approximate arbitrarily nonlinear dynamics.

In this paper, dynamics model of a new container crane system is investigated, then, an anti-swing tracking control law for this container crane system with fuzzy uncertainties compensation is presented to ensure the positioning control as well as overall closed-loop system stability. None of the crane dynamics parameters are needed for the controller design in a priori. In the developed control laws, the position error will be driven to zero while the sway angle being also rapidly damped so as to achieve minimal swing of the payload. Stability analysis of the proposed control law is given. Finally, simulation results show the performance successfully.

This paper is organized as follows. The modeling of the new container crane system and trajectory tracking problem is presented in Section II. The proposed adaptive anti-swing control law is illustrated in Section IV. In Section V, simulation results are given. This paper concludes with a summary in Section VI.

II. PROBLEM FORMULATION

A. Container Crane Dynamics

The schematic drawing in figure 1 presents a structure of a new container crane system with eight-link lifting mechanism which has been put in use recent years.

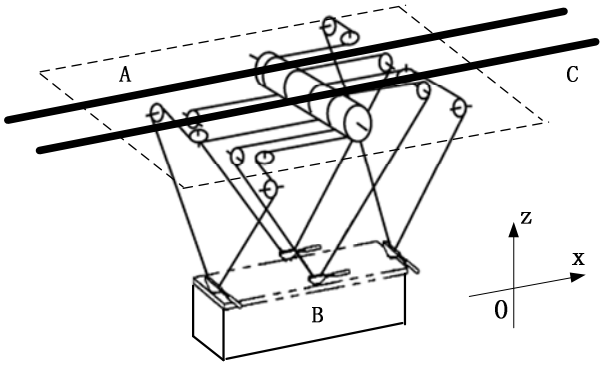

Figure 1. a new container crane system with eight-link lifting mechanism.

A – trolley system B – payload C – track

To facilitate modeling the new container crane system, it is assumed that the crane system possesses the following characteristics:

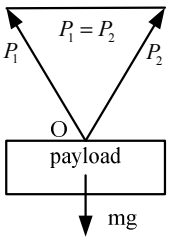

Figure 2. inverted-triangle and payload with $P_1 = P_2$.

- The payload mass B and crane trolley A are assumed to be connected by eight massless, rigid links
- The payload mass B is assumed to be concentrated at a point and the value of this payload mass and the overall trolley mass are known exactly.
- The pulley wheels in A and hinged joints, where the payload links connect to crane trolley are assumed to be frictionless.

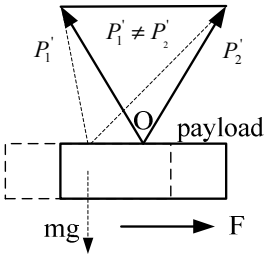

Figure 3. inverted-triangle link and payload with $P_1 \neq P_2$.

- The control input to the system is the mechanical force applied directly to the trolley.

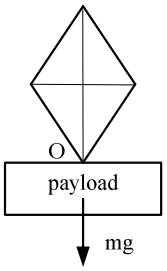

Figure 4. equivalent parallelogram mechanism for an inverted-triangle link system.

- To simplify the analysis, only trolley moving along x-axis direction will be considered.

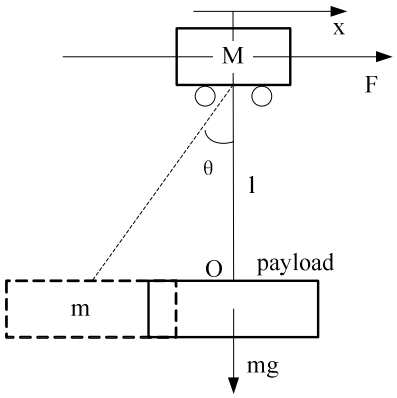

Figure 5. swing of the payload in x-z plane.

In figure 1, when the trolley moves at a constant speed, the inverted-triangle link mechanism endures a balanced force $P_1 = P_2$ as shown in figure 2, and the payload moves accompanying with crane trolley at the same velocity. When the trolley starts up or brakes down, an inertial force coming from payload drives the inverted-triangle link frame

distorted, then $P_1^{'} < P_2^{'}$ as shown in figure 3, while the projection force F of $P_1^{'}$ and $P_2^{'}$ on x-axis given by the distorted inverted-triangle system tries to reject this distortion and draw back the payload mass to its 'origin' O, as a result, swing of payload along x-axis shrinks. Furthermore, when the inverted-triangle link frame is forced to distort due to starting up or braking down, the link system is therefore equivalently stretched along x-axis. This effect of interplay force given by link system can be described using a parallelogram mechanism as shown in figure 4 [15]. The complex force F of the parallelogram system eventually has the payload move along horizontal direction rather than arc of a pendulum as shown in figure 5. Then, this kind of linear motion of payload under effect of parallelogram mechanism can be modeled as a spring oscillator system, the new container crane finally can be present as figure 6, where M, m are mass of the trolley and payload respectively, x position of the trolley, l the equivalent length of link, θ payload angle with respect to the vertical.

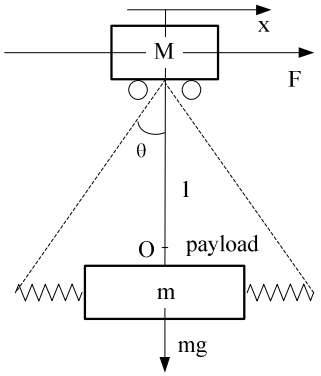

Figure 6. equivalent model for the container crane system

The purpose of this paper is to control the motion of the container crane in figure 6 to achieve the desired position of its payload along a given trajectory.

To derive dynamic equation of the above crane system, the total energy associated with the crane system needs to be computed using the Lagrangian approach. The kinetic energy of the above crane can be divided into two parts: $K = K_{trolley} + K_{payload}$, where $K_{trolley} = \frac{1}{2} M \dot{x}^2$ denotes trolley kinetic energy and $K_{payload} = \frac{1}{2} m(\dot{x} + l\dot{tg}\theta)^{'2}$ is payload kinetic energy. Finally, we have

$$K = \frac{1}{2}(M+m)\dot{x}^2 + ml\sec^2\theta \cdot \dot{\theta} \cdot \dot{x} + \frac{1}{2} ml^2 \sec^4\theta \cdot \dot{\theta}^2 \quad (1)$$

The potential energy of the payload shifting from its origin can be express using spring oscillator system, i.e.

$$P = -\frac{1}{2} k_s (ltg\theta)^2 = -\frac{1}{2} k_s l^2 tg^2\theta \quad (2)$$

where k_s is an equivalent spring coefficient which relates to the structure of reverted-triangle system and its links.

The Lagrange equations of motion are formed as

$$\frac{d}{dt}\left[\frac{\partial L}{\partial \dot{x}}\right] - \frac{\partial L}{\partial x} = u$$
$$\frac{d}{dt}\left[\frac{\partial L}{\partial \dot{\theta}}\right] - \frac{\partial L}{\partial \theta} = 0 \quad (3)$$

where u represents control force acting on the trolley.

After calculation about above equations, the dynamics of the new container crane depicted in figure 6 may be expressed in the Lagrange form as

$$M(q)\ddot{q} + C(q,\dot{q})\dot{q} + G(q) + \tau_d = U \quad (4)$$

where $q(t) = [x(t), \theta(t)]^T$ is position and swing angle variable vector, $M(q)$ is the inertia matrix, $C(q,\dot{q})$ is the coriolis/centripetal matrix, $G(q)$ is the gravity vector, τ_d denotes bounded unknown disturbance (including e.g. unstructured unmodeled dynamics), and $U = [u(t), 0]^T$ is the control input torque. For the 2D container crane shown in Figure 6, we have the followings,

$$M(q) = \begin{bmatrix} M_{pp} & M_{p\theta} \\ M_{p\theta} & M_{\theta\theta} \end{bmatrix}, \quad C(q,\dot{q}) = \begin{bmatrix} C_{pp} & C_{p\theta} \\ C_{p\theta} & C_{\theta\theta} \end{bmatrix},$$
$$G(q) = \begin{bmatrix} G_p \\ G_\theta \end{bmatrix}, \quad \tau_d = \begin{bmatrix} \tau_p \\ \tau_\theta \end{bmatrix}, \quad U = \begin{bmatrix} u \\ 0 \end{bmatrix} \quad (5)$$

The following properties are easily be demonstrated for the container crane [16]:

Property 1: $M(q)$ is a positive definite symmetric matrix bounded by $\alpha_1 I \le M(q) \le \alpha_2 I$ with $\alpha_{1,2}$ positive constant.

Property 2: $C(q,\dot{q})$ is bounded by $c_b(q)\left\|\dot{q}\right\|$ with $c_b(q) \in R$.

Property 3: The matrix $\dot{M} - 2C$ is skew-symmetric.

B. Trajectory Tracking Problem

Given a desired trajectory within a compact set, i.e. $q_d(t) \in R^{2\times 1}$, the tracking error is $e(t) = q_d(t) - q(t)$ and the filtered tracking error may be defined as

$$s(t) = [s_x(t), s_\theta(t)]^T = \dot{e}(t) - \lambda e(t) \quad (6)$$

where $\lambda = \lambda^T > 0$ is a design parameter matrix, usually selected diagonal. A controller will be designed to keep the filtered tracking error $s(t)$ bounded.

Since the linear time-invariant system (6) is exponentially stable from the input $s(t)$ to output $e(t)$, the boundedness of the $s(t)$ implies the boundedness of the output tracking error $e(t)$. In fact, these ultimate bounds can be related as

$$\|e\|_2 \le \frac{\|s\|_2}{\sigma_{\min}(\lambda)}, \quad \left\|\dot{e}\right\|_2 \le \|s\|_2 \tag{7}$$

where $\sigma_{\min}(\lambda)$ is the minimum singular value of λ.

Differentiate $s(t)$ and using (6), the crane dynamics (4) may be written in terms of the filtered tracking error as

$$M\dot{s} = -Cs + f + \tau_d - U \tag{8}$$

where the nonlinear function $f(X)$ is

$$f(X) = \left[f_x, f_\theta\right]^T = M(q)(\ddot{q}_d + \lambda\dot{e}) + C(q,\dot{q})(\dot{q}_d + \lambda e) + G(q) \tag{9}$$

The generalized input vector $X \in R^{N\times 2}$ may be selected as $X = \left[q^T, \dot{q}^T, q_d^T, \dot{q}_d^T \ddot{q}_d^T\right]^T$.

Let's define a computed-torque like input in terms of a feedback linearization estimate plus PD control law as

$$U_0 = \hat{f} + K_v s \tag{10}$$

where $\hat{f}(X)$ is any estimate of $f(X)$ and $K_v = K_v^T > 0$ is a gain matrix. The closed-loop error system then becomes

$$M\dot{s} = -(K_v + C)s + \tilde{f} + \tau_d \tag{11}$$

where the functioned estimate error is $\tilde{f} = f - \hat{f}$.

Therefore, (11) is an error system wherein the filtered tracking error $s(t)$ is driven by the functional error $e(t)$ and the disturbances. Define a lumped system uncertainty $\zeta = \tilde{f} + \tau_d$, then (11) can be rewritten as

$$M\dot{s} = -(K_v + C)s + \zeta \tag{12}$$

Lemma 1: The system (12) with input ζ and output $s(t)$ is BIBS stable.

Proof: Let the Lyapunov function be

$$L = \frac{1}{2}s^T M s \tag{13}$$

Differentiation L along (12) obtains

$$\dot{L} = -s^T K_v s + \frac{1}{2}s^T\left(\dot{M} - 2C\right)s + s^T\zeta \tag{14}$$

Using property 3 results in

$$\dot{L} = -s^T K_v s + s^T\zeta \le -\|s\|^T\left(K_{v\min}\|s\| - \|\zeta\|\right) \tag{15}$$

Let $\zeta \in L_\infty$ be bounded by b_ζ. Then $\dot{L}$ is decreasing when

$$\|s\| > b_\zeta / K_{v\min} \tag{16}$$

As inside the bounded region defined by (16) about the origin, $s(t)$ is bounded, and outside of it, $s(t)$ is a non-increasing function, i.e. there exist some constant $\gamma_1, \gamma_2 > 0$ such that $\|s(t)\| < \gamma_1 b_\zeta + \gamma_2$, thus, $s(t) \in L_\infty$. This shows that bounded input results in bounded states. □

III. Adaptive Anti-Swing Controller Design

A. Fuzzy Uncertain Compensator

In this paper, a fuzzy uncertainty observer (FUO) $\hat{f}(X)$ is applied to estimate the nonlinear dynamics $f(X)$, moreover, a parameter adaptive law is also provided so that the estimate is guaranteed to monitor and represent well the whole uncertain dynamics existing in the container crane, as well as the asymptotic stability is preserved.

The basic configuration of a fuzzy system consists of fuzzifier, fuzzy rule base, fuzzy inference engine, and defuzzifier. The fuzzy inference engine maps from input vector $X = \left(x_1, x_2 \cdots, x_n\right)^T \in R^n$ to an output variable $Y \in R$ for single output case, which is based on the fuzzy IF-THEN rules. The *ith* IF-THEN rule of k fuzzy rules defining fuzzy implication can be written as

$Rule^i$: If x_1 is A_1^i and $\cdots$ and x_n is A_n^i,
then y is y^i

where A_j^i and y^i denote a fuzzy variable for premise part and a singleton for consequent part respectively. Then, the output of the fuzzy system with center average defuzzifier, product inference engine and singleton fuzzifier can be obtained as

$$y(x) = \frac{\sum_{i=1}^{k} y^i\left(\prod_{j=1}^{n}\mu_{A_j^i}\left(x_j\right)\right)}{\sum_{i=1}^{k}\left(\prod_{j=1}^{n}\mu_{A_j^i}\left(x_j\right)\right)} = \hat{\phi}^T\xi(x) \tag{17}$$

with $\xi^T = \left(\xi^1, \xi^2, \cdots \xi^k\right)$, where ξ^i is fuzzy basis function, expressed as

$$\xi^i = \frac{\prod_{j=1}^{n}\mu_{A_j^i}\left(x_j\right)}{\sum_{i=1}^{k}\left(\prod_{j=1}^{n}\mu_{A_j^i}\left(x_j\right)\right)} \tag{18}$$

and $\hat{\phi}^T = \left(y^1, y^2, \cdots, y^k\right)$ is an adjustable parameter vector, $\mu_{A_j^i}(\cdot)$ is the membership function of fuzzy variable A_j^i.

In this paper, the universal approximation capability of above fuzzy system will be implemented as a fuzzy uncertain observer (FUO) [18].

To construct a FUO for estimating $\hat{f}(X)$ in (9), we have the following assumption:

Assumption 1: Let the input vector X for the fuzzy logic system (17) belong to a compact set M_X, the optimal parameter vector ϕ of (17) is defined as

$$\phi^* = \arg\min_{\phi\in M_\phi}\left(\sup_{X\in M_X}\left|f(X) - \hat{f}(X\,|\,\hat{\phi})\right|\right) \tag{19}$$

which exists in a convex region $M_\phi = \{\phi \| \phi \| \le m_\phi\}$, where m_φ is a design parameter. Then, the fuzzy logic system (17), which is a zero-order TS fuzzy system, is employed as a FUO for the estimate of the uncertain f as follows:

$$\hat{f} \triangleq \hat{\phi}^T \xi(X) \tag{20}$$

Remark 1: to avoid algebraic loop in the implementation of FUO [18], $X = \left[q^T, \dot{q}^T, q_d^T, \dot{q}_d^T \ddot{q}_d^T \right]^T$ is used instead of control input U, Since the control input is a function of the state q and reference trajectory q_d, Then, the following observation dynamics is applied [18],

$$\dot{\mu}_i = -\sigma \mu_i + p_i(i, \dot{i}, \hat{\phi}) \tag{21}$$

where $p(i, \dot{i}, \hat{\phi}) \triangleq \hat{f}(X \mid \hat{\phi}) + F + GU + \sigma_i \dot{i}$, $\sigma_i > 0$ is an observer design parameter, and an observer error variable is defined as $\varsigma_i = \dot{i} - \mu_i$, moreover, observation error dynamics can be obtained as

$$\dot{\varsigma}_i = -\sigma \varsigma_i + f(X) - \hat{f}(X \mid \hat{\phi}) \tag{22}$$

By assumption 1 and the universal approximation capability of the FUO in (20), the nonlinear dynamics $f(X)$ can be described as

$$f(X) = \hat{f}(X \mid \phi^*) + \varepsilon(X) \tag{23}$$

where $\varepsilon(X)$ denotes an uncertain estimation error satisfying $|\varepsilon(X)| \le \bar{\varepsilon}$, and its upper bound $\bar{\varepsilon}$ can be arbitrarily shrunk by increasing the number of the fuzzy rules.

Then (22) becomes

$$\dot{\varsigma}_i = -\sigma \varsigma_i + \hat{f}(X \mid \hat{\phi}^*) - \hat{f}(X \mid \hat{\phi}) + \varepsilon(X) \tag{24}$$

Remark 2: if the bounded and adjustable parameter vector $\hat{\phi}$ is updated by adaptive law

$$\dot{\hat{\phi}} = \rho \varsigma \xi(X) \tag{25}$$

where $\rho > 0$ is an observer design parameter, then the uncertainty observation error is uniformly ultimately bounded within a region of which size can be kept arbitrarily small (see Theorem 1 in [18]). Therefore, if the observation error ς converges to zero, $\hat{f}(X)$ converges to the close neighborhood of the actual nonlinear $f(X)$.

B. Controller Design

A FUO is employed as uncertainty compensator for the container crane dynamics in above section. The nonlinear crane function $f(X)$ in (9) can be uniformly approximated by the FUO in (23) for some optimal parameter ϕ^*, where the estimate error $\varepsilon(X)$ is bounded by a known $\bar{\varepsilon}$ constant. Note that ε becomes smaller as the number of the fuzzy rules increases.

Assumption 2: The desired trajectory is bounded, i.e. $\left\| q_d^T, \dot{q}_d^T, \ddot{q}^T \right\| \le Q_d$ with Q_d known constant.

Assumption 3: The unknown disturbance τ_d in (4) is bounded, i.e. $\|\tau_d\| \le b_{\tau_d}$ with b_{τ_d} known.

Assumption 4: The fuzzy logic input X is bounded above by $\|X\| \le c_1 + c_2 \|s\|$ with c_1, c_2 known computable constants.

Define now a control input torque as

$$U_c = U_0 - V = \hat{f} + K_v s - V \tag{26}$$

with an addition $V(t)$ to enhance robustness of the system is given as

$$V = K_z \left(\left\| \hat{\varphi} \right\| + m_\phi \right) s \tag{27}$$

where m_ϕ is a design parameter which satisfies $\|\phi\| \le m_\phi$, and $K_z = K_z^T > 0$ a design parameter. Observer that $V(t)$ vanishes when $s(t) \to 0$.

Substituting the control (26) into (8) results in

$$M \dot{s} = -(K_v + C) s - V + \begin{bmatrix} f_p - \hat{f}_p \\ f_\theta - \hat{f}_\theta \end{bmatrix} + \tau_d \tag{28}$$

Let $f = \left[f_p, f_\theta \right]^T$, and $s = \left[s_p, s_\theta \right]^T$, the functional approximation error $\tilde{f}$ is

$$\tilde{f} = f - \hat{f} = \hat{f}\left(X \mid \hat{\phi}^* \right) - \hat{f}\left(X \mid \hat{\phi} \right) + \varepsilon(X) \tag{29}$$

Then, substitute (29) into (28) yields the final form of the closed-loop error system dynamics as

$$\begin{aligned} M \dot{s} = & -(K_v + C) s \\ & + \begin{bmatrix} \hat{f}_x\left(x \mid \hat{\phi}_x^* \right) - \hat{f}_x\left(x \mid \hat{\phi}_x \right) + \varepsilon(x) \\ \hat{f}_\theta\left(\theta \mid \hat{\phi}_\theta^* \right) - \hat{f}_\theta\left(\theta \mid \hat{\phi}_\theta \right) + \varepsilon(\theta) \end{bmatrix} - V + \tau_d \end{aligned} \tag{30}$$

Rewriting (30), we have closed-loop error dynamics as

$$M \ddot{e} + (\lambda M + K_v + C) \dot{e} + (K_v + C) \lambda e = \tilde{f} + \tau_d - V \tag{31}$$

Moreover, by define $\mathrm{E} = \left(e, \dot{e}, \varsigma \right)^T$ and using (24) and (31), the augmented closed-loop trajectory tracking error dynamics becomes

$$\dot{\mathrm{E}} = \Pi \mathrm{E} + \Gamma \phi^T \xi(X) + \Gamma_1 V + \Gamma \tau_d \tag{32}$$

with $\Pi = \begin{bmatrix} A & B^T \\ B & D \end{bmatrix}$ is a stable matrix, $\Gamma = \begin{bmatrix} H \\ I \end{bmatrix}$, $\Gamma_1 = -\begin{bmatrix} H \\ O \end{bmatrix}$, where $A = \begin{bmatrix} O & I \\ -k_1 & -k_2 \end{bmatrix}$, $D = \begin{bmatrix} -\sigma_x & 0 \\ 0 & -\sigma_\theta \end{bmatrix}$, $H = \begin{bmatrix} O \\ I \end{bmatrix}$, and $B \in R^{2\times 4}$, $I \in R^{2\times 2}$, $O \in R^{2\times 2}$ denote identity and null matrices, respectively, k_1, k_2 are known matrices relate to M, C, K_v, and λ.

Remark 3: there exists a positive definite matrix P such that

$$\Pi^T P + P\mathrm{E} = -R \tag{33}$$

for an arbitrary positive definite matrix R [20].

Theorem: Consider the 2D container crane with uncertainties in (4), let assumption 1~4 hold, the control input torque (26) with $K_z > c_2$ is given as (26) and (28), the filtered trajectory tracking error dynamics $s(t)$ is asymptotically stable, and FUO estimate is uniformly ultimately bounded with the specific bounds. Moreover, the tracking error may be kept arbitrarily small by increasing the gain K_v.

Proof: Let the Lyapunov function candidate be

$$L = \frac{1}{2}\mathrm{E}^T P \mathrm{E} + \frac{1}{2}\tilde{\phi}^T \tilde{\phi} \tag{34}$$

which is a positive definite function since assumption 4 holds.

Differentiate (34) with respect to time along the solution of the error dynamics (31) yields,

$$\begin{aligned} \dot{L} &= \mathrm{E}^T P \Pi \mathrm{E} + \mathrm{E}^T P \Gamma \phi^T \xi + \mathrm{E}^T P \Gamma \tau_d + \mathrm{E}^T P \Gamma_1 V + \tilde{\phi}^T \dot{\tilde{\phi}} \\ &= \mathrm{E}^T P \Pi \mathrm{E} + \mathrm{E}^T P \Gamma \tau_d + \mathrm{E}^T P \Gamma_1 V + \tilde{\phi}^T \left(\mathrm{E}^T P \Gamma \xi + \dot{\tilde{\phi}} \right) \end{aligned} \tag{35}$$

By choosing fuzzy rule tuning methods as

$$\dot{\tilde{\phi}} = -\mathrm{E}^T P \Gamma \xi \ , \ (\dot{\hat{\phi}} = -\mathrm{E}^T P \Gamma \xi) \tag{36}$$

and using $\Lambda = \Gamma \varepsilon + \Gamma_0 V$, then we have

$$\dot{L} \le -\frac{1}{2}\mathrm{E}^T Q \mathrm{E} + \mathrm{E}^T P \Lambda \tag{37}$$

By completing the square, after adding and subtracting $\frac{\alpha}{4}\mathrm{E}^T P \mathrm{E} + \frac{1}{\alpha}\Lambda^T P \Lambda$, (37) becomes

$$\begin{aligned} \dot{L} &\le -\frac{1}{2}\mathrm{E}^T Q \mathrm{E} + \frac{\alpha}{4}\mathrm{E}^T P \mathrm{E} + \frac{1}{\alpha}\Lambda^T P \Lambda \\ &\le -\frac{1}{4}\lambda_{\min}(Q)\|\mathrm{E}\|^2 + \frac{\lambda_{\max}(P)^2}{\lambda_{\min}(Q)}\|\Lambda\|^2 \\ &\le -\frac{1}{4}\lambda_{\min}(Q)\|\mathrm{E}\|^2 + \frac{\lambda_{\max}(P)^2}{\lambda_{\min}(Q)}\left(2\|\tau_d\|^2 + \|V\|^2\right) \end{aligned} \tag{38}$$

where $\alpha = \lambda_{\min}(Q)/\lambda_{\max}(P)^2$, $\lambda_{\max}(\cdot)$ and $\lambda_{\min}(\cdot)$ denote maximum and minimum eigenvalues respectively.

Thus, $\dot{L}$ is negative outside a compact set and the augmented error E is uniformly ultimately bounded. Moreover, using Barbalat's Lemma [19], $\|\mathrm{E}(t)\| \to 0$ as $t \to 0$.

IV. Simulation Results

The proposed controller performance is tested under two different payload conditions, first set is selected to mimic a light weight application condition where $M = 10kg$, $m = 5kg$, $l = 1m$ and $k_s = 50$, then, change the crane payload with $M = 10kg$, $m = 50kg$, and $l = 1m$ to simulate a heavy load application, and test the performance of the proposed controller without incorporating any additional information about the system. Normal parameters employed in simulation are given as gain $K_v = [12,5]^T$, and $\lambda = (1.2,1.2)^T$. For the premise parts of the FUO in (20), seven Gaussian functions and two sigmoid functions are used as in [18]. Both simulation results are compared with performance of PID controller for container crane, given in [21], where parameters of PID controller are $(20, 0.1, 40)$.

(c) control force

Figure 10 performance of PID controller with heavy payload

From figure 7 to figure 10, it is shown that the proposed controller guarantees robust performance against payload variations and system parameters changing, and shows good transient response performance compared with PID controller.

V. CONCLUSION

Dynamics model of a new container crane system is investigated. A FUO based controller law is proposed for the container crane with underactuated dynamics problem. Multi-loop controller compromising an inner loop consisting of fuzzy uncertain observer with online adaptive update law and robustness terms making the whole system to remain bounded, hence keeping the internal signals in a compact region. Controller design does not rely on any prior knowledge of crane nonlinear system dynamics. The developed controller has been applied to two different crane applications for simulation study, and the simulation results have shown performance of the controller successfully.

***Abstract*— A robust image segmentation algorithm called Extended Fuzzy C means (EFCM) is presented in this paper which preprocesses the image to reduce the noise effect and then apply FCM algorithm for image segmentation. Preprocessing of image is influenced by the direct eight neighborhood pixels of study pixel of an image under consideration. The advantages of the propose algorithm is: (1) Least execution time compared to other techniques. (2) It yields regions more homogeneous than those of other techniques. (3) It removes noisy spots and is less sensitive to noise. The propose technique is a powerful method for noisy image segmentation with least computation time and convergence rate compared to other image segmentation techniques.**

Keywords—Fuzzy Clustering, Fuzzy C-Means, Robust Image Segmentation

I. INTRODUCTION

A. Image segmentation

Image segmentation plays an important role in image analysis and computer vision. The goal of image segmentation is partitioning of an image into a set of disjoint regions with uniform and homogeneous attributes such as intensity, color, tone etc. The image segmentation approaches can be divided into four categories; thresholding, clustering, edge detection, and region extraction. In image processing, two terms are usually seen very close to each other: clustering and segmentation. When analyzing the color information of the image, e.g. trying to separate regions or ranges of color components having same characteristics, the process is called color clustering. Mapping the clusters onto the spatial domain and physically separated regions in the image is called segmentation. In color images, the boundaries between objects are blurred and distorted due to the imaging acquisition process. Furthermore, object definitions are not always crisp and knowledge about the objects in a scene may be vague. Fuzzy set theory and Fuzzy logic are ideally suited to deal with such uncertainties. Fuzzy clustering models have proved a particularly promising solution to the color clustering problem. Such unsupervised models can be analysis, clustering, and classifier designs in fields such as astronomy, geology, medical imaging, target recognition, used with any number of features and clusters. The Fuzzy C means (FCM) [1] algorithm, proposed by Bezdek (1981), is the most widely used algorithm in image segmentation because it has robust characteristics for ambiguity and can retain much more information than hard segmentation methods. FCM has been successfully applied to feature and image segmentation. An image can be represented in various feature spaces and the FCM algorithm classifies the image by grouping similar data points in the feature space into clusters. In case the image is noisy or distorted then FCM technique wrongly classify noisy pixels because of its abnormal feature data. Various approaches are proposed by researchers to compensate this drawback of FCM.

B. FCM Related Extensions

Tolias and Panas post-processed the membership function to smooth the noise effect [2]. Acton and Mukherjee incorporated multiscale information to enforce spatial constraints [3]. The most popular approach for increasing the robustness of FCM is to modify the objective function directly. Dave proposed the idea of a noise cluster to deal with noisy data using the technique, known as Noise Clustering [4]. He separated the noise into one cluster but this technique is not suitable for image segmentation, since we cannot separate pixels from the image. Noisy pixels can be processed and assigned to most appropriate cluster. Another similar technique, PCM, proposed by Krishnapuran and Keller [5] interprets clustering as a possibilistic partition. However, it caused clustering being struck in one or two clusters. Ahmed et al. [6] modified the objective function of FCM by introducing a term that allowed the labeling of a pixel to be influenced by the labels in its immediate neighborhood. Zhang Yang, Fu-lai Chuang et al. [7] developed a robust clustering technique by deriving a novel objective function for FCM. Jiayin Kang et al. [8] proposed another technique which modified FCM objective function by incorporating the spatial neighborhood information into the standard FCM algorithm. Y. Yang et al. [9] proposed a noval penelized FCM (PFCM) for image segmentation where penalty term acts as a regulizer in the algorithm which is inspired by neighborhood maximization (NEM) algorithm [10] and is modified in order to satisfy the criterion of FCM algorithm. S. Shen, W. Sandham et al. [11] presented an algorithm called Improved FCM (IFCM) which changed the distance function used in FCM i.e. the distance between pixel intensity and cluster intensities and applied neural network

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

optimization technique to adjust parameters in the modified distance function. Keh-Shih Chuang, Hong-Long Tzeng et al. [12] presented a FCM algorithm that incorporated spatial information into the membership function of clustering. The membership weighting of each cluster is altered after the cluster distribution in the neighbourhood is considered. Rhee and Hwang [13] proposed Type 2 fuzzy clustering. Type 2 fuzzy set is the fuzziness in a fuzzy set. In this algorithm, the membership value of each pattern in the image is extended as Type 2 fuzzy membership by assigning membership grades (triangular membership function) to Type 1 fuzzy membership. The membership values for the Type 2 membership are obtained as:

$$a_{ik} = u_{ik} - \frac{1 - u_{ik}}{2}$$

where a_{ik} and u_{ik} are the Type 2 and Type 1 fuzzy membership respectively. The cluster centers are updated accordingly using conventional FCM taking into account the new Type 2 fuzzy membership.

Problem with all these methods is that they increase the complexity of the algorithms by introducing new equations into the standard equations of FCM algorithm which inevitably introduced computation issues. By changing the objective function and membership function of standard FCM algorithms, we are losing the continuity from FCM, which is well-realized function in many types of software, such as MATLAB. In this paper, a new extension to FCM is proposed, which consists of image enhancement and segmentation. We are pre-processing the image before segmentation to reduce the noisy pixels which is influenced by the direct eight neighborhood pixels of noisy pixels. Strength of the propose algorithm is its least execution time and convergence rate compare to other robust image segmentation techniques.

The organization of the paper is as follows: Section II, briefly review Fuzzy C-Means (FCM) [1], Spatial FCM (sFCM) [12], and cluster validity functions for the evaluation of segmentation performance. Section III describes the proposed algorithm, Extended Fuzzy C Means (EFCM). Section IV evaluates the performance of the proposed EFCM algorithm and compares it with sFCM, FCM type-II, and conventional FCM algorithm followed by concluding remarks in Section V.

II. Background Information

This section briefly discusses the Fuzzy C-Means (FCM) and Intuitionistic Fuzzy C means (IFCM) algorithms. In this paper, the data-set is denoted by 'X', where $X=\{x_1, x_2, x_3, \ldots\ldots x_n\}$ specifying an image with 'n' pixels in M-dimensional space to be partitioned into 'c' clusters. Centroids of clusters are denoted by v_i and d_{ik} is the distance between x_k and v_i.

A. The Fuzzy C-Means Algorithm

FCM [1] is the most popular fuzzy clustering algorithm. It assumes that number of clusters 'c' is known in priori and minimizes the objective function (J_{FCM}) as:

$$J_{FCM} = \sum_{i=1}^{c}\sum_{k=1}^{n} u_{ik}^{m} d_{ik}^{2} \tag{1}$$

Where $d_{ik} = \|x_k - v_i\|$, and u_{ik} is the membership of pixel 'x_k' in cluster 'i', which satisfies the following relationship:

$$\sum_{i=1}^{c} u_{ik} = 1; \;\; i = 1,2,\ldots\ldots n \tag{2}$$

Here 'm' is a constant, known as the fuzzifier (or fuzziness index), which controls the fuzziness of the resulting partition. m=2 is used in this paper. Any norm $\|\bullet\|$ can be used for calculating d_{ik}. Minimization of J_{FCM} is performed by a fixed point iteration scheme known as the alternating optimization technique. The conditions for local extreme for (1) and (2) are derived using Lagrangian multipliers:

$$u_{ik} = \frac{1}{\sum_{j=1}^{c}\left(\frac{d_{ik}}{d_{jk}}\right)^{\frac{2}{m-1}}} \quad \forall \; k, i \tag{3}$$

where $1 \le i \le c; \;\; 1 \le k \le n$
and

$$v_i = \frac{\sum_{k=1}^{n}(u_{ik}^{m} x_k)}{\sum_{k=1}^{n}(u_{ik}^{m})} \;\; \forall \; i \tag{4}$$

The FCM algorithm iteratively optimizes $J_{FCM}(U,V)$ with the continuous update of U and V, until $|U^{(l+1)} - U^{(l)}| <= \varepsilon$, where 'l' is the number of iterations. FCM works fine for the images which are not corrupted with noise but if the image is noisy or distorted then it wrongly classifies noisy pixels because of its abnormal feature data which is pixel intensity in the case of images, and results in an incorrect membership and improper segmentation.

B. Spatial Fuzzy C Means (sFCM)

Spatial Fuzzy C means [12] algorithm modifies FCM membership function by introducing spatial information into it. sFCM defines spatial function as:

$$h_{ij} = \sum_{k \in NB(x_j)} u_{ik} \tag{5}$$

where $NB(x_j)$ represents a square window centered on pixel x_j in the spatial domain. sFCM considered 5x5 window. Just like the membership function, the spatial function 'h_{ij}' represents the probability that pixel x_j belongs to i^{th} cluster. Spatial function is incorporated into membership function as:

$$u'_{ij} = \frac{u_{ij}^p h_{ij}^q}{\sum_{k=1}^{c} u_{ij}^p h_{ij}^q} \quad (6)$$

where 'p' & 'q' are parameters which control the relative importance of both functions. For a noisy pixel, this formula reduces the weighting of a noisy cluster by the labels of its neighboring pixels. Disadvantage of this algorithm is that it is a two-pass process for every pass of FCM algorithm. In the first pass, conventional FCM algorithm is used to calculate membership function and in the second pass, the membership information of each pixel is mapped to the spatial domain, and the spatial function is calculated from that. The FCM iteration proceeds with the new membership that is incorporated with the spatial function. Hence, the complexity of this algorithm is very high compared to FCM technique, which introduces computational issues.

C. Cluster Validity Functions

To evaluate the performance of segmentation quantitatively, two types of cluster validity functions are generally used: the fuzzy partition and the feature structure. The representative functions for the fuzzy partition are partition coefficient [14] and partition entropy [15]. They are defined as:

$$V_{pc}(U) = \sum_{i=1}^{n}\sum_{k=1}^{c} u_{ki}^2 \quad (7)$$

$$V_{pe}(U) = -\frac{1}{n}\left\{\sum_{i=1}^{n}\sum_{k=1}^{c}[u_{ki} log u_{ki}]\right\} \quad (8)$$

Best clustering results can be achieved when the value V_{pc} is maximal or V_{pe} is minimal. Disadvantage of V_{pc} and V_{pe} are that they measure only the fuzzy partition and do not specify featuring property. To solve this problem, other validity functions based on the feature structures are used [16], [17]. They are defined as:

$$V_{fs}(U,V;X) = \sum_{k=1}^{c}\sum_{i=1}^{n} u_{ik}^m(\|x_i - v_k\|^2 - \|v_k - \bar{v}\|^2) \quad (9)$$

Where $\bar{v} = \frac{1}{c}\sum_{k=1}^{c} v_k$

$$V_{xb}(U) = -\frac{\sum_{k=1}^{c}\sum_{i=1}^{n} u_{ki}^2\|x_i - v_k\|^2}{n * \left(\min_{k\neq j}\left\{\|v_k - v_j\|^2\right\}\right)} \quad (10)$$

Where V_{fs} is a Fukuyama-Sugeno function and V_{xb} is Xie-Beni function. When either V_{fs} or V_{xb} is minimal, a better clustering result is achieved [16], [17].

III. The Proposed Technique, Extended Fuzzy C Means (EFCM)

Earlier, we proposed a robust clustering algorithm, called Density Oriented Fuzzy C-Means (DOFCM) [18] for numerical data. The concept of DOFCM was to identify noise points, based upon the number of other points in its neighborhood, before clustering and separate it into one cluster. In case of image segmentation that algorithm is not appropriate as we cannot separate noisy pixels from the image. But noisy pixels can be processed and assign to the appropriate cluster. Here, in the propose technique, we are using the same concept i.e. processing image before segmentation and modifies DOFCM algorithm for image segmentation.

FCM is a good segmentation technique if there is no noise in the image. Keeping this in view, we are proposing a very simple and effective method, which preprocess noisy pixels in the image and then apply conventional FCM algorithm for segmentation.

The pixels in an image are highly correlated i.e. the pixels in the immediate neighborhood possess nearly the same feature data. In the propose technique, we are trying to regenerate the value of noisy pixels by processing every pixel of an image based upon its immediate neighborhood pixels. Neighborhood structure considered in the propose technique is shown in Fig. 1. Value of every pixel is influenced by its eight direct neighborhood pixels. We are considering an image in RGB format. Let size of an image is R*C*K, where R is the number of rows, C is the number of columns, and K is 3 (for color image). So every pixel will be processed using equation:

$$pixel(l,m,k) = \sum_{k=1}^{3}\frac{1}{N}\left(\left(\sum_{i=l-1}^{l+1}\sum_{j=m-1}^{m+1} pixel(i,j,k)\right) - pixel(l,m,k)\right) \quad (11)$$

Where N = 8, denoting 8 neighborhood points of a study pixel

pixel (i, j, k) = intensity value of pixel at i,j,k location

pixel (l, m, k)= intensity value of study pixel

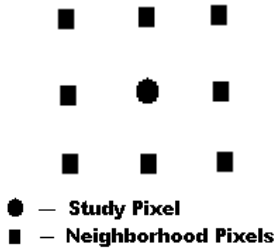

Figure 1. Neighborhood structure for study pixel

In the homogeneous region, this function simply fortifies the same characteristics and the clustering result remains unchanged. However, for a noisy pixel, this formula tries to regenerate the value of original pixel. As a result, misclassified pixels from noisy regions can easily be corrected. After processing the noisy pixels, FCM is used to do segmentation. Here, we are processing the image only once before segmentation, which does not increase the complexity of the program compare to Spatial FCM and other robust clustering algorithms for image segmentation. Other methods mostly changed the standard FCM equations and introduced new functions which are calculated for every pass of the FCM algorithm i.e. they are extremely computationally intensive so the strength of the proposed technique is its least execution time, which is approximately equal to the conventional FCM method. Also, it does not modify FCM algorithm so does not lose the continuity of FCM function which is given in many softwares like MATLAB. Various steps involved in the proposed technique used for image segmentation are shown in Fig. 2.

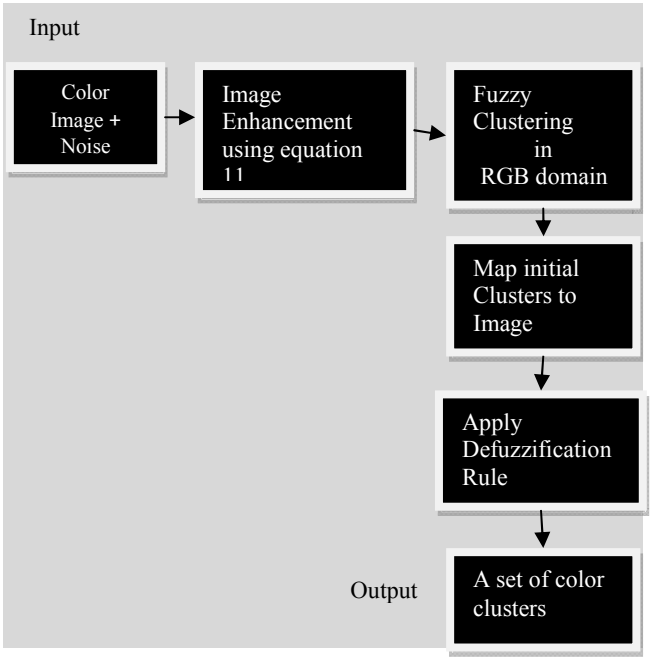

Figure 2. Block diagram of the steps used for image segmentation using proposed method along with input and output.

IV. RESULTS

In this section, experimental results are presented to compare the segmentation performance of EFCM with FCM, FCM Type II, and sFCM. Two types of images are used: (1) Synthetic images (2) Real world image. For all data-sets, we are assuming the following computational protocols: $\varepsilon = 0.00001$, Total number of iterations = 100. We chose m=2, which is a common choice for fuzzy clustering. Experiments are implemented and simulated using MATLAB Version 7.0.

A. Circle Image

A grayscale circle image (256x256 pixels) representing two intensity levels is used. It is corrupted with gaussian noise. The intensity levels of two classes are 0 and 255. Fig. 3(a) & 3(b) show original and noisy version of circle image. Fig. 3(c)-(f) shows the segmentation result of FCM, sFCM, EFCM, and Fuzzy Type-II respectively. Although FCM, Fuzzy Type-II, and sFCM successfully segmented the image into the desired regions but did not totally recover it from the noise whereas, EFCM totally recovered the image from noise.

In addition to the analyses of the qualitative evaluation presented above, a quantitative evaluation using several cluster validity functions is necessary. As described in part II.C, the better performance of clustering is achieved if the partition coefficient V_{pc} is maximal and/or the partition entropy value V_{pe}, the Fukuyama-Sugeno function V_{fs}, and the Xie-Beni function V_{xb} are minimal. Table I shows performance comparison of FCM, Fuzzy type-II, sFCM, and our proposed EFCM in terms of cluster validity functions.

B. Square Image

A synthetic square image (160 x 170 x 3 pixels) consisting of 9 squares is generated. It contains gaussian noise to create noisy version of original image (Fig. 4a) as shown in Fig. 4(b). The image represents three intensity levels with the values 255, 128 and 0. Fig. 4(c)-(f) shows segmentation results of FCM, sFCM, EFCM, and Fuzzy Type-II. FCM, Fuzzy type-II, and sFCM did not completely remove the noise where as EFCM totally removed noise in the same intensity region but noise effect can be seen at the boundaries where the intensity level is changing. TABLE-I shows performance comparison of these algorithms in terms of cluster validity functions.

C. Bacteria Image

A real bacteria image (126 x 140 x 3 pixels) consisting of two classes is considered and it is corrupted with gaussian noise to show the performance of purpose technique. The bacteria are separated from its background using all the three methods. Fig. 5(a)-(b) show original image and its noisy version respectively. Fig. 5(c)-(f) shows segmentation result and 5(g)-(j) shows clustering result of FCM, sFCM, EFCM, and Fuzzy type-II respectively. It is observed that EFCM is able to retain the boundary of bacteria more effectively as compared to other methods. TABLE-I shows

performance of these algorithms quantitatively using cluster validity functions.

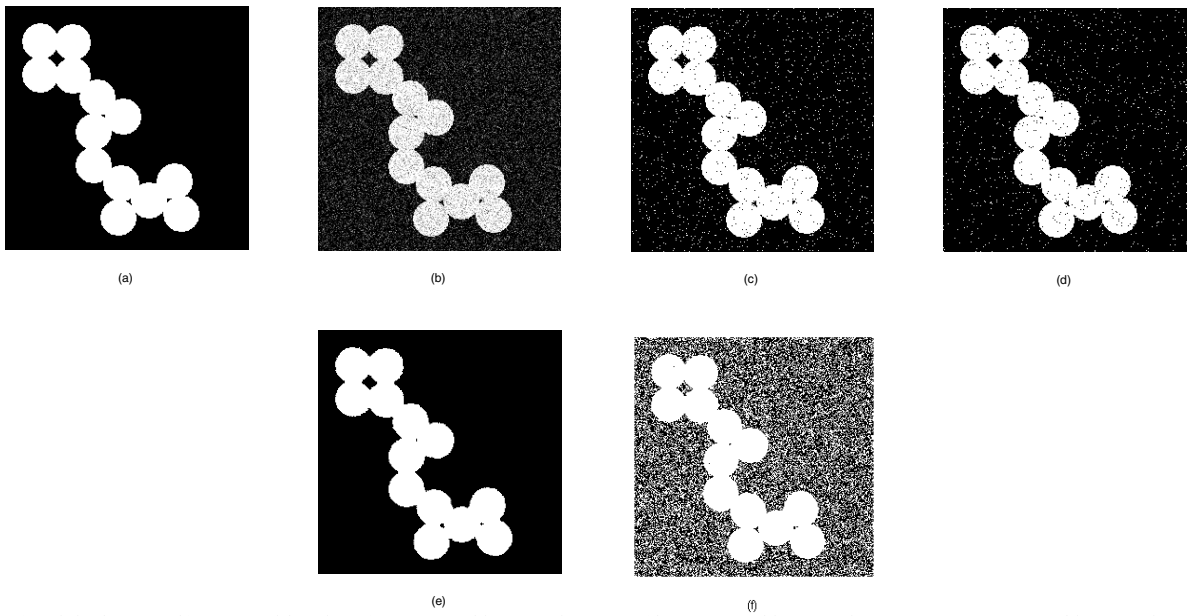

Figure 3. (a) Original Image (b) Image with noise (c) Segmented image using FCM (d) Segmented image using sFCM (e) Segmented image using EFCM (f) Segmented image using FCM Type-II

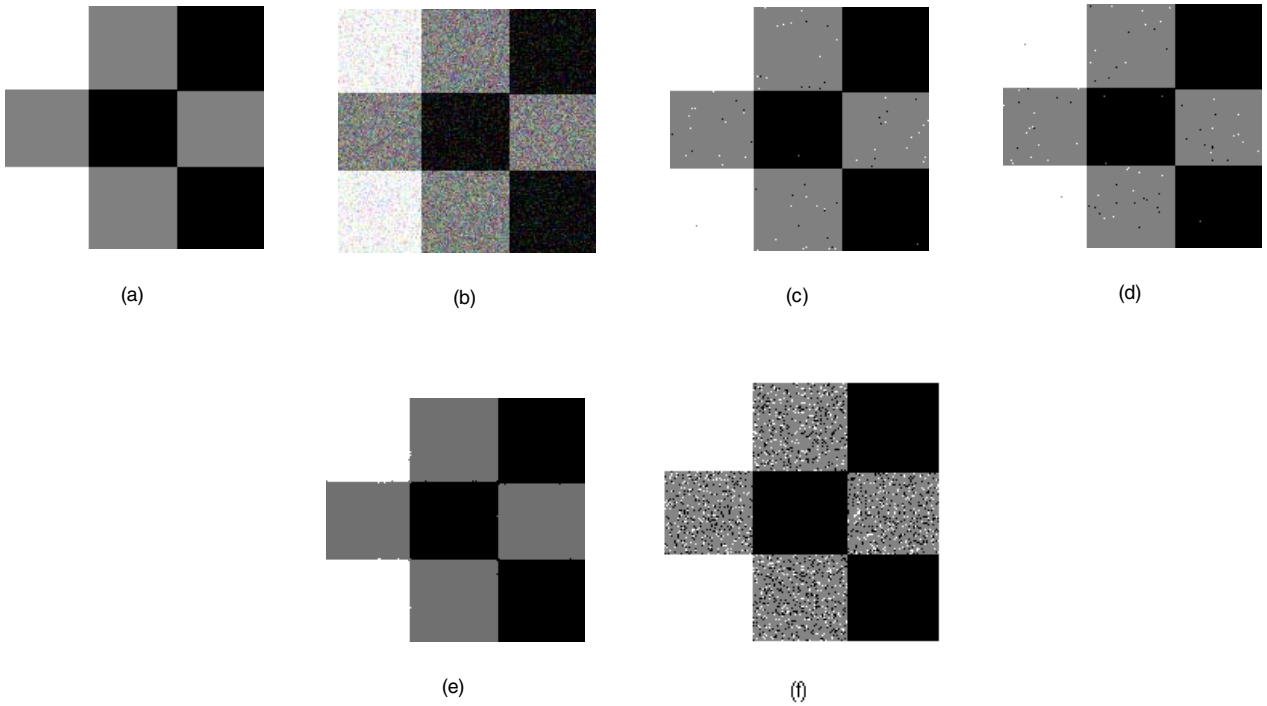

Figure 4. (a) Original Image (b) Image with noise (c) Segmented image using FCM (d) Segmented image using sFCM (e) Segmented image using EFCM (f) Segmented image using FCM Type-II

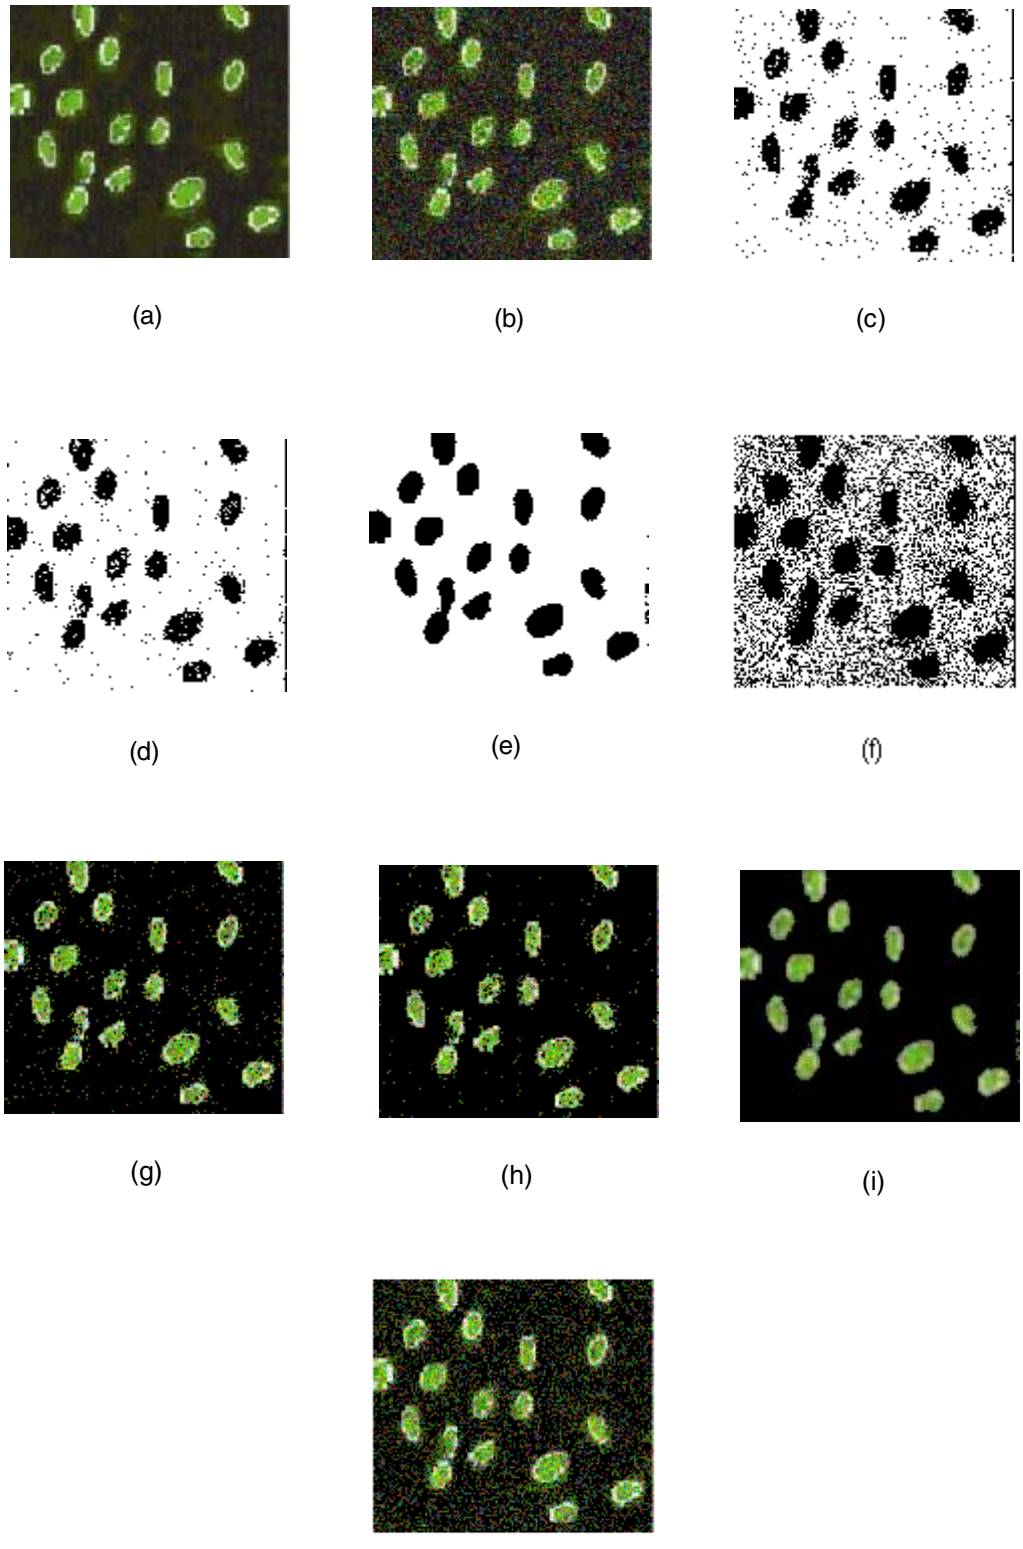

Figure 5. (a) Original Image (b) Image with noise (c)-(f) Segmented image using FCM, sFCM, EFCM, and FCM Type-II respectively (g)-(j) Objects shown in one cluster using FCM, sFCM, EFCM, and FCM Type-II respectively

Performance of algorithms based upon execution time

Fig. 6 shows bar chart of the execution time of FCM, Fuzzy type-II, sFCM, and EFCM for the above three images. TABLE-II lists execution time and number of iterations of the algorithms. Advantage of the propose technique is that it has least execution time compared to other color image segmentation techniques. From TABLE-II, it is observed that almost in all cases, proposed technique converges even before FCM algorithm because it is preprocessing the image before applying FCM technique which increases the convergence rate. Its execution time is almost close to FCM technique.

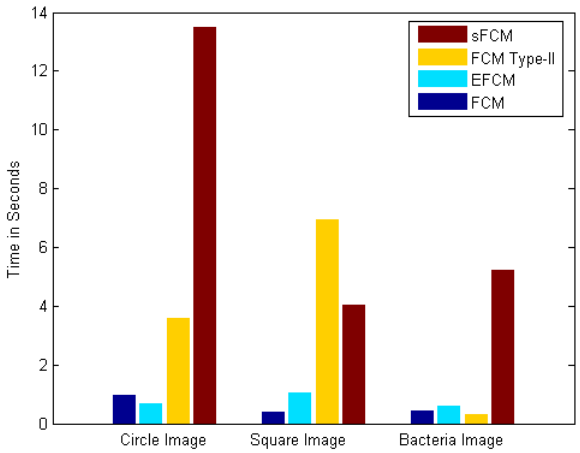

Figure 6. Performance of algorithms based upon execution time

TABLE-I
PERFORMANCE COMPARISON OF FCM, SFCM, FCM TYPE-II, AND EFCM IN TERMS OF CLUSTER VALIDITY FUNCTIONS

Image Name	Number of Clusters	Technique	The value of Validity Functions			
			V_{pc}	V_{pe}	V_{xb}	V_{fs}

	sFCM	5.235	62
	FCM TYPE-II	0.312	23
	EFCM	0.578	15

V. CONCLUSION

Digital images generally contain unknown noise and considerable uncertainty. Traditionally, FCM is a popular segmentation method for digital images. However, it is an intensity-based clustering algorithm which is not robust against noisy images. The pixels in an image are highly co-related and this spatial information is an important characteristic for color image segmentation which is not utilized in FCM. Although, many extended algorithms based upon FCM have been developed to overcome this shortcoming by incorporating spatial information either in the objective function or in the membership function of FCM algorithm. But they all have increased the complexity of the standard algorithm by introducing new equations for spatial membership that are calculated for every pass of FCM algorithm.

In this paper, we proposed an extended FCM (EFCM) algorithm which preprocesses the image before segmentation. Preprocessing of image is influenced by the direct eight neighborhood pixels of every pixel of an image under consideration. Its strength is its least execution time and fast convergence rate compared to other image segmentation techniques. It is tested on noisy synthetic images and real images and evaluated quantitatively with four different cluster validity functions. Results showed that the performance of proposed technique is best over FCM, Fuzzy Type-II, and sFCM.

Abstract — **The job accommodation, the redesign of a job or the creation of new vacancies for optimizing the utilization of manpower through job analysis, has become an important concept during the past decades. Effective job accommodation strategies can assist the people with disabilities in general, and hearing impaired people, who accounted for a majority of the disabilities in the labor market, in special, to expand their capability set and maximize their work performance. However, very few researches have been developed on how the job accommodation strategies can be defined. Furthermore, most available job accommodation strategies as well as assistive technologies were based on researches being developed one decade ago, which are not feasible and should be updated for modern industries. Thus, a fuzzy DEMATEL based MCDM framework will be introduced for deriving suitable accommodation strategies. An empirical study based on the operators from the electronic industry advanced and verified both available job accommodation strategies as well as job accommodation research methods. In the future, the proposed strategies as well as the research framework can be used to enhance the welfare of the disabilities.**

Keywords – Job accomodation strategy; Fuzzy DEMATEL; Fuzzy MCDM (Multiple Criteria Decision Making, MCDM).

I. INTRODUCTION

People with disabilities work in a variety of environments including management, administration, technology, design, and industry settings [1]. The potential for and importance of job accommodations, the redesign of a job or the creation of new vacancies for optimizing the utilization of manpower through job analysis, for qualified individuals with disabilities is clear in light of developments in human rights, technological innovations, and changing perceptions of the environmental barriers and facilitators for inclusion in work and in society at large [2]. Effective workplace accommodations are essential for the economic independence and self-determination of people with disabilities, and to maintain a productive workforce [2]. However, a large portion of adults with disabilities had no jobs though these people are willing to work. Recent studies reveal a paucity of workplace accommodations to compensate for loss of hearing [3]. Thus, researches on how job accommodation strategies and use of assistive technology resources and services can be defined can help to level the playing field for persons with disabilities so that they can compete on an equal basis in finding and maintaining employment [4].

Severity of a disability impacts an individual's ability to work [1]. People with physical and sensory limitations are more likely to have lost work days than the general population [1]. As summarized by Zolna et al. [5], reviews and reports of general accommodation strategies, specific interventions, vocational rehabilitation methods, etc. have all addressed the use of specialized designs and assistive technologies (AT) as workplace accommodations for people with disabilities. However, some accommodations have been successful, whereas others have not [5].

The existing knowledge base of accommodations contains a wealth of information about the needs, functional abilities, and criteria for successful intervention. While aggregated, these data can be crucial in informing [5]. Employers and persons with disabilities are likely to enjoy successful employment outcomes through increased knowledge and information sharing [2]. Proactive policies that allow for matching between employees' needs and job skills and available resources may help to bridge the gap between current and state of the art accommodations [2].

The total, civilian, non-institutionalized hearing-impaired population is estimated at 9.4% while the world population percentage is expected to be similar [6]. Further, recent statistics demonstrate that the people with hearing impairments has accounted for about 40% of the labor market. Apparently, employees with hearing impairments can be classified as one of the major groups of employees with disabilities to be focused. Further, in some electronic industries of the developed East Asian countries like Taiwan, the hearing impaired operators have already accounted for a significant percentage to the total employees with disabilities. Job accommodation strategy definitions for the hearing impaired operators are worth further study.

Albeit important, very limited study has empirically evaluated the importance of on-the-job accommodations for persons who are hard of hearing while accommodation practices were found to be a significant factor in employment success for persons who were deaf [7]. Allaire et al. also mentioned that relatively little is known about the kinds of work barriers experienced by employed persons with arthritis and other rheumatic diseases and to what extent these individuals utilize job accommodations. Further, the job accommodation is by nature an MCDM problem. According to the job accommodation procedure being proposed by Schneider [8], the major steps include determine alternatives and outline strategies for modifying the specific job task in question, review the alternatives/strategies with the employer and finally, agree on the appropriate modification or

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

adaptation. The availability of accommodations, therefore, is likely to be related to attributes of employees and employers but limited attention has been paid to identifying covariates of either the availability of, or the need for, accommodations for people who are deaf or hard-of-hearing [3].

Therefore, this research intends to define a fuzzy DEMATEL based multiple criteria decision making (MCDM) based framework for selecting defining job accommodation strategies for operators with hearing impairments. At first, literature regarding to job accommodation strategies for disabilities and the selection criteria will be reviewed. The literature will serve as a basis for the MCDM framework development as well as possible alternative derivations for suitable job accommodation strategies. Then, the fuzzy DEMATEL will be used for constructing the structure of the decision problem. The weights being versus the criteria will be derived by using the ANP then. Finally, the GRA will be used for deriving the relationships between the possible job accommodation strategies as well as the criteria. The job accommodation strategies with the highest Grey grades will be selected as the suitable ones.

This research is organized as follows. The related literature regarding to capability set expansions and the job accommodation strategies will be reviewed in Section II. The theory which is based on MCDM framework and using the fuzzy DEMATEL based MCDM method will be introduced in Section III. An empirical study on expanding the capabilities of hearing impaired people will be used for demonstrating the feasibility of the proposed fuzzy MCDM framework in Section IV. Implications as well as discussion will be presented in Section V. Finally, the whole article will be concluded in Section VI.

II. Capability Set Expansions and Accomodation Strategies

An adoption of the accommodation strategies for the people with disabilities is a typical example for capability set expansion problem. By introducing the accommodation strategies, persons with disabilities can be assisted to expand their capability set and then level the playing field for persons with disabilities so that they can compete on an equal basis in finding and maintaining employment [4]. Following, past researches and concepts regarding to the capability, the capability set, people with disabilities as well as accommodation strategies with a focus on accommodation strategies for people with hearing impairments will be reviewed as a basis for the decision making framework.

Capability is an integration of knowledge, skills, personal qualities and understanding used appropriately and effectively - not just in familiar and highly focused specialist contexts but in response to new and changing circumstances while competence is primarily about the ability to perform effectively, concerned largely with the here and now [9]. Stephenson argued that narrowly defined competencies were only part of human capability [10]. Fraser and Greenhalgh [11] mentioned that capability is more than competence since competence is what individuals know or are able to do in terms of knowledge, skills, attitude while the capability is the extent to which individuals can adapt to change, generate new knowledge, and continue to improve their performance. Doncaster and Lester [12] further argued that capability is not restricted to being "almost synonymous with competence, but with less of a normative connotation" [13], but also implies a capacity to develop additional competence and to move beyond competence to being able to work effectively in unpredictable and changing contexts [12].

According to Yu [14-16], for each decision problem (e.g. job selection, corporate strategic definition, conflict resolution, etc.), a competence set consisting of ideas, knowledge, information and skills for its satisfactory solution exists. However, since competencies were only part of human capability, the concept of the competence set can further be expanded to the capability set. According to the definition by Srinivasan [17], the capability set is the set of vectors of functions the states of being and doings such as being healthy and avoiding premature mortality, available to a person.

People with disabilities work in a variety of environments and accommodations in these environments enable them to enter and remain in the workplace while the rate of employment is dependent on the educational level of the person as well as the physical and cognitive capacities of the person [1]. However, workplace environments are not optimally suited for people with disabilities even when people with disabilities are more likely to remain employed if their employer provides necessary accommodations [1].

Workplace accommodations, by their very nature, are solutions that are either individualized for specific employees or for groups of employees (e.g., wheelchair users or aging workers) [5]. The most frequently mentioned direct benefits from implementing workplace accommodations were retained a qualified employee, increased worker productivity, eliminated the cost of training a new employee, etc. [18]. As a result, specialized accommodations, such as those for people with mobility and dexterity impairments are not typically considered to be usable by all people, to the greatest extent possible [5].

According to the summarization in the work by Zolna et al. [5], the most commonly seen barriers to work include functional limitations due to the design of furnishings and workstations, computer-related difficulties, macro environmental barriers included transportation problems (e.g. parking and commuting) as well as and access to specific spaces required for activities of daily living (e.g. bathrooms), functional limitations including fatigue, pain, physical weakness, inability to stand for long periods, changes in physical sensation which become barriers to work. Scherich [19] further identified the six difficult workplace situations being identified by workers with hearing impairments: receiving instructions/supervision, department/staff meetings, in-service or training activities, performance evaluations, socializing with co-workers, and work-related social functions.

According to Schneider [8], it is possible to minimize the effect of a functional impairment by working in two different areas: the functional level of the individual and the environment. Butterfield and Ramseur [1] further summarized that types of accommodations include workplace provisions for computer technologies, environmental access such as ramps, elevators, parking and new workstations as well as structural changes to the physical workplace to promote participation in work activities including provisions for general access accommodation, floor surface changes, environmental control, signage, and evacuation routes, tool operation including telecommunication aids and assistive technology devices, workstation modifications and adaptive strategies, and seating and positioning such as equipment modifications. Zolna et al. [5] also summarized that type of accommodations include assistive technology, physical work environment, job requirements and personal assistance and training.

Finally, for accommodation strategies being suitable for workers with hearing impairments, Scherich [19] summarized devices as well as equipment, support personnel (ex:

interpreters, job coaches), job restructuring, etc. are accommodation strategies to be suitable for workers with hearing impairments. Geyer and Schroedel further identified sixteen feasible strategies, including TDD or TTY, phone amplifier, flashing lights for fire alarm, flashing lights on machines for safety, assistive listening device for meetings, pager device or beeper, e-mail, note-taking assistances by computers, sign class for co-workers who hear, co-worker takes notes for you at meetings, summary of meeting notes, interpreters, improved lighting in your work area, moved things around so you can see other people better, hearing people answer the phone, changed job duties for working better.

The extent of a functional impairment can be defined as the difference or gap between the level of function for the individual, and what the environment demands of him or her [8]. Apparently, appropriate accommodation strategies can be introduced so as to expand the capabilities, or capability set, of people with disabilities to close the gap. In the following Section, a fuzzy DEMATEL based MCDM framework will be proposed for correlating difficulties being faced by persons with hearing impairments

III. Analytic Framework For Defining Accomodation Strategies

The analytical process for deriving the job accommodation strategy is initiated by deriving the possible strategies and criteria being required to evaluating the strategies based on literature review. Then, the relations between the criteria will be derived by using the DEMAETL. The weights versus the criteria will be derived by using the ANP then. Finally, possible strategies will be derived by using the Grey Relation Analysis.

A. Fuzzy DEMATEL Method

The Fuzzy DEMATEL can deal with the DEMATEL problem by introducing Fuzzy linguistic variables and matrices. According to the definition of Fuzzy DEMATEL, the linguistic matrices present the relationships between criteria. In the matrices, the numeral value depicts the influence versus each criterion. Therefore, the Fuzzy DEMATEL method can transform the causes and effects relationship into a perspicuous structural model. The Fuzzy DEMATEL method has been studied and applied in many areas these years [20,21]. According to the advantages of Fuzzy DEMATEL, this research attempts to evaluate the preferences of lead users by using Fuzzy DEMATEL based on the definitions by Prof. Tzeng, Gwo-Hshiung [22]. The calculation process is demonstrated as below:

Step 1: Establishing the fuzzy linguistic scale

Establishing the linguistic sets of criteria is an essential procedure for Fuzzy DEMATEL. The major advantage of Fuzzy DEMATEL method is that it's effective to obtain the structural mode and divide the criteria into cause and effect groups, which consist of many complex aspects. To deal with the ambiguities of human feeling and evaluations, Li [23] introduces the fuzzy linguistic scale into the DEMATEL evaluation process. The strength of influence are divided into five linguistic levels as "Strong", "High", "Low", "No" and the linguistic levels will correspond to the triangular fuzzy numbers.

Step 2: Establishing the directed relation matrix

To measure the relationship versus each criterion $C = \{c_1, c_2, \ldots, c_n\}$, p lead users made evaluations in terms of linguistic terms toward the criteria. Thus, p fuzzy matrices $\tilde{\boldsymbol{Z}}^1, \tilde{\boldsymbol{Z}}^2, ..., \tilde{\boldsymbol{Z}}^P$ each corresponds to a lead user. The Fuzzy matrix is called the initial direct relation fuzzy matrix. For simplicity, denote $\tilde{\boldsymbol{Z}}$ as $c_1, c_2 ... c_n$, or

$$\tilde{\boldsymbol{Z}} = \begin{matrix} c_1 \\ c_2 \\ \vdots \\ c_n \end{matrix} \begin{bmatrix} 0 & \tilde{z}_{12} & \cdots & \tilde{z}_{1n} \\ \tilde{z}_{21} & 0 & \cdots & \tilde{z}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \tilde{z}_{n1} & \tilde{z}_{n2} & \cdots & 0 \end{bmatrix},$$

where $\tilde{z}_{ij} = \left(l_{ij}, m_{ij}, u_{ij}\right)$ are triangular fuzzy numbers, elements $\tilde{z}_{ii} = 0, i = 1, 2 ... n$.

Step3: Establishing the structural model

In order to transform the criteria scales into comparable scales, the linguistic scale will be transformed into a normalization formula.

Let $\tilde{a}_{ij} = \sum_{j=1}^{n} \tilde{z}_{ij} = \left(\sum_{j=1}^{n} l_{ij}, \sum_{j=1}^{n} m_{ij}, \sum_{j=1}^{n} u_{ij} \right)$ and $u = \max_{1 \le i \le n} \left(\sum_{j=1}^{n} u_{ij} \right)$.

Then, the normalized direct relation fuzzy matrix, denoted by $\tilde{\boldsymbol{X}}$, equals $\tilde{x} = u^{-1} \otimes \tilde{z}$. Or

$$\tilde{\boldsymbol{X}} = \begin{bmatrix} \tilde{x}_{11} & \tilde{x}_{12} & \cdots & \tilde{x}_{1n} \\ \tilde{x}_{21} & \tilde{x}_{22} & \cdots & \tilde{x}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \tilde{x}_{m1} & \tilde{x}_{m2} & \cdots & \tilde{x}_{mn} \end{bmatrix},$$

where $\tilde{x}_{ij} = \frac{\tilde{z}_{ij}}{u} = \left(\frac{l_{ij}}{u}, \frac{m_{ij}}{u}, \frac{r_{ij}}{u} \right)$. (1)

Fuzzy DEMATEL also assume that $\sum_{j=1}^{n} u_{ij} < u$ and $\lim_{k \to \infty} \tilde{x} = [0]_{0 \times 0}$.

Step 4: Deriving the total relation matrix

After calculating the normalized direct relation fuzzy matrix, the total relation matrix $\tilde{\boldsymbol{T}}$ can be derived by the equation below:

$$\tilde{\boldsymbol{T}} = \tilde{\boldsymbol{X}} + \tilde{\boldsymbol{X}}^2 + \cdots + \tilde{\boldsymbol{X}}^n = \tilde{\boldsymbol{X}}(\boldsymbol{I} - \tilde{\boldsymbol{X}})^{-1},$$

When $\lim_{k \to \infty} \tilde{X} = [0]_{n \times n}$

$$\tilde{\boldsymbol{T}} = \begin{bmatrix} \tilde{t}_{11} & \tilde{t}_{12} & \cdots & \tilde{t}_{1n} \\ \tilde{t}_{21} & \tilde{t}_{22} & \cdots & \tilde{t}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \tilde{t}_{m1} & \tilde{t}_{m2} & \cdots & \tilde{t}_{mn} \end{bmatrix}; \tilde{t}_{ij} = \left(l_{ij}^{"}, m_{ij}^{"}, r_{ij}^{"} \right)$$

$$\left[l_{ij}^{''}\right]=\boldsymbol{X}_l-\left(\boldsymbol{I}-\boldsymbol{X}_l\right)^{-1},\ \left[m_{ij}^{''}\right]=\boldsymbol{X}_m-\left(\boldsymbol{I}-\boldsymbol{X}_m\right)^{-1},$$
$$\left[r_{ij}^{''}\right]=\boldsymbol{X}_r-\left(\boldsymbol{I}-\boldsymbol{X}_r\right)^{-1}$$

Step 5: Analyzing the sum of rows and columns

The row and column sums are individually indicated the sum of rows and columns of the total relation matrix $\boldsymbol{T}$ by using following equations (2), (3), and (4),

$$\tilde{\boldsymbol{T}}=[\tilde{t}_{ij}],\ \ i,j\in\{1,2,...,n\} \quad (2)$$

$$\tilde{\boldsymbol{r}}=[\tilde{r}_i]_{n\times 1}=\left[\sum_{j=1}^{n}\tilde{t}_{ij}\right]_{n\times 1} \quad (3)$$

$$\tilde{\boldsymbol{c}}=[\tilde{c}_j]_{1\times n}=\left[\sum_{i=1}^{n}\tilde{t}_{ij}\right]_{1\times n} \quad (4)$$

where the $\boldsymbol{r}$ and $\boldsymbol{c}$ represent the sums of the rows and columns.

Step 6: Analyzing the results from $\boldsymbol{r}$ and $\boldsymbol{c}$

According to the sum of rows and columns, $(\tilde{r}_i+\tilde{c}_i)$ depicts the strength of the influence. If $(\tilde{r}_i-\tilde{c}_i)$ is positive, then criteria i is dispatching influence on other factors. On the other hand, if $(\tilde{r}_i-\tilde{c}_i)$ is negative, factor i is receiving influence from other criteria [20, 24, 25].

B. Analytic Network Process (ANP)

The ANP method, a multi criteria theory of measurement developed by Saaty [26], provides a general framework to deal with decisions without making assumptions about the independence of higher-level elements from lower level elements and about the independence of the elements within a level as in a hierarchy [26]. In this section, concepts of the ANP are summarized based on Saaty's earlier works [26, 27].

A component of a decision network which was derived by the DEMATEL method in Section 3.1 will be denoted by $\boldsymbol{C}_h,\ h=1,2,\cdots,m,$ and assume that it has n_h elements, which we denote by $e_{h1}, e_{h2},\cdots, e_{hm}$. The influences of a given set of elements in a component on any element in the decision system are represented by a ratio scale priority vector derived from paired comparisons of the comparative importance of one criterion and another criterion with respect to the interests or preferences of the decision makers. This relative importance value can be determined using a scale of 1–9 to represent equal importance to extreme importance [26]. The influence of elements in the network on other elements in that network can be represented in the supermatrix as $\boldsymbol{W}_{ij}=[w_{ij}],\ i\in\{1,2,...,m\}$, $j\in\{1,2,...,m\}$. A typical entry $\boldsymbol{W}_{ij}=[w_{i_{nx}j_{ny}}]$, $nx\in\{1,2,...,n_i\}$, $ny\in\{1,2,...,n_j\}$ in the supermatrix, is called a block of the supermatrix in the following form where each column of $\boldsymbol{W}_{ij}$ is a principal eigenvector of the influence of the elements (objective) in the ith component of the network on an element (objective) in the j^{th} component. Some of its entries may be zero corresponding to those elements (objective) that have no influence.

After forming the supermatrix, the weighted supermatrix is derived by transforming all columns sum to unity exactly. This step is very much similar to the concept of the Markov chain in terms of ensuring that the sum of these probabilities of all states equals 1. Next, the weighted supermatrix is raised to limiting powers, such as $\lim_{\theta\to\infty}\boldsymbol{W}^{\theta}$ to get the global priority vector or called weights [28].

In addition, if the supermatrix has the effect of cyclicity, the limiting supermatrix is not the only one. There are two or more limiting supermatrices in this situation, and the Cesaro sum would need to be calculated to get the priority.

The weights of the k^{th} criteria being derived by using the above ANP processes, namely $\omega_k,\ k\in\{1,2,...,n\}$, will be used as the weight for the k^{th} criteria in the following Section 3.3.

C. GRA

GRA is used to determine the relationship between two sequences of stochastic data in a Grey system. The procedure bears some similarity to pattern recognition technology. One sequence of data is called the 'reference pattern' or 'reference sequence,' and the correlation between the other sequence and the reference sequence is to be identified [29-32]. To apply the GRA, definitions were cited from the early works by Tzeng and Huang [25, 33].

According to Deng, the mathematical equation for deriving the grey relation coefficient is:

$$\gamma(x_0(k),x_i(k))=$$
$$(\min_{\forall i}\min_{\forall k}\left|(x_0(k)-x_i(k))\right|+\zeta\max_{\forall i}\max_{\forall k}\left|(x_0(k)-x_i(k))\right|)\times$$
$$(\left|(x_0(k)-x_i(k))\right|+\zeta\max_{\forall i}\max_{\forall k}\left|(x_0(k)-x_i(k))\right|)^{-1}$$

where ζ is the distinguished coefficient ($\zeta\in[0,1]$). Generally, we pick ζ =0.5. When the grey relational coefficient is conducted with respect to the courses, we then can derive the grade of the grey relation $\gamma(\boldsymbol{x}_0,\boldsymbol{x}_i)$ between the reference alternative $\gamma(\boldsymbol{x}_0,\boldsymbol{x}_i)=\sum_{k=1}^{n}n^{-1}\gamma(x_0(k),x_i(k))$, where k is the number of capabilities while the weight being associated to the criterion is assumed to be equal. $\gamma(\boldsymbol{x}_0,\boldsymbol{x}_i)$ represents the grade of grey relation in x_i (the k^{th} strategy) correspondence to x_0. In this study, we make the order of the strategies following the grade of grey relation.

IV. ACCOMODATION STRATEGY DEFINITIONS FOR OPERATORS WORKING IN THE ELECTRONIC INDUSTRY

The electronic industry of the developed East Asian countries, including Japan, South Korea and Taiwan have already been well developed and contributed to a significant percentage of the GDPs of the countries. In Taiwan, the electronic industry has also become the major source of job vacancies for workers with disabilities. In the electronic factories, operators accounted for significant share of the total employers. To maximize the capability of operators with disabilities in general and the hearing impaired operators in

special, an empirical study based on interviews of the Taiwanese hearing impaired operators as well as an industry expert was introduced for verifying and demonstrating the feasibility of the proposed Fuzzy DEMATEL based MCDM framework for job accommodation strategy definitions.

Based on the interview results from seven operators who have been working in Taiwanese high technology firms, including the semiconductor testing houses as well as liquid crystal display panel vendors, following work barriers were summarized: colleagues' low/no intention to communicate by pen (p_1), managers' terrible attitude (p_2), noisy work environment (p_3), no hearing aid or requirements for better hearing aid (p_4), lip reading difficulties (p_5), no idea regarding to how capabilities can be enhanced (p_6), requirements in word processing software training (p_7), and no idea(s) regarding to possibilities of career development (p_8).

Since the former accommodation strategies being proposed by Geyer and Schroedel [3] cannot fulfill the needs of the electronic industry, seven novel accommodation strategies are proposed. The strategies include the electronic white board (a_1), digital electronic hearing aid (a_2), summary meeting notes (a_3), interpreters (a_4), on-job training of computer software (a_5), career planning courses (a_6) as well as assistances by hearing co-worker(s) (a_7).

At first, according the expert's opinion, the linguistic variables can be defined as Figure 1(a) while the initial direct relation fuzzy matrix $\tilde{Z}$ can be defined as Figure 1(b).

Variable	Upper	Medium	Lower
VL	0	30	50
L	40	50	60
M	60	70	80
H	75	85	95
VH	85	95	100

(a)

$$\begin{bmatrix} 0 & H & VL & H & H & VL & L & VL \\ M & 0 & VL & VL & VL & VL & M & VL \\ M & L & 0 & H & VL & VL & VL & VL \\ VL & M & VL & 0 & VL & VL & VL & VL \\ H & H & VL & H & 0 & VL & VL & VL \\ VL & VL & VL & VL & VL & 0 & VL & VL \\ VL & M & VL & VL & VL & VL & 0 & VL \\ VL & VL & VL & VL & VL & VH & VL & 0 \end{bmatrix}$$

(b)

Figure 1. (a) Linguistic variables and (b) the fuzzy matrix $\tilde{Z}$

Then, by introducing the Fuzzy DEMATEL ANP process being introduced in Section 3, the weights being associated with each work barrier can be derived (see Table I).

Table I. The weights versus criteria

Barrier	p_1	p_2	p_3	p_4	p_5	p_6	p_7	p_8	Sum
Weight	0.133	0.133	0.167	0.167	0.133	0.100	0.067	0.100	1.000

Finally, by introducing the GRA being introduced in Section 3.3, the Grey grades versus each accommodation strategy can be derived (see Table II). Based on the derivation results, the electronic white board (a_1), digital electronic hearing aid (a_2), interpreters (a_4), and assistances by hearing co-worker(s) (a_7) are the most helpful strategies.

Table II. The Grey Coefficients and Grey Grades

Strategy \ Barrier	p_1	p_2	p_3	p_4	p_5	p_6	p_7	p_8	Grey Grades
a_1	0.133	0.067	0.167	0.056	0.089	0.033	0.022	0.033	0.511
a_2	0.133	0.133	0.111	0.167	0.133	0.033	0.022	0.033	0.678
a_3	0.089	0.089	0.056	0.056	0.089	0.033	0.022	0.033	0.378
a_4	0.133	0.089	0.167	0.056	0.133	0.033	0.022	0.033	0.578

a_6	0.044	0.053	0.056	0.056	0.044	0.100	0.033	0.100	0.253
a_7	0.133	0.133	0.167	0.167	0.133	0.050	0.044	0.050	0.733

V. DISCUSSION

In this research, accommodation strategies for hearing impaired operators were derived by introducing the Fuzzy DEMATEL based MCDM approach. Following, the managerial implications as well as advances in research methods of job accommodation strategy definitions will be discussed.

For the accommodation strategies being suitable for the electronic industry, the past researches or assistive technologies are very limited. The accommodation strategies being developed one decade ago cannot fulfill modern requirements. Further, modern electronic technologies have already advanced the assistive technologies. Apparently, updates of both work barriers in the modern industry as well as available accommodation strategies are very helpful. The research results being demonstrated in this paper advanced both aspects of the job accommodation strategies as well as work barriers in the electronic industry.

For the research results, the electronic white board, digital electronic hearing aid, interpreters, and assistances by hearing co-worker(s) are the most helpful accommodation strategies. However, these results were derived based on one expert's opinion by summarizing interview results of the hearing impaired operators. How the accommodation strategies can be derived based on the viewpoints of the business managers will also be very helpful and make the accommodation strategies really feasible. Thus, further researches by introducing the opinions from the industry managers, experts from the academic or social welfare institutes as well as the hearing impaired operators will be very helpful.

For the advances in incorporating the idea of MCDM into researches of accommodation strategy definitions, the perfect match between the MCDM methods as well as the job accommodation strategy definition process being proposed by the job accommodation procedure being proposed by Schneider [8] have already been addressed in the first Section. Further, the empirical study based on the case studies on the hearing impaired operators from the electronic industry has verified the effectiveness of the proposed MCDM framework. In the future, the MCDM framework can be applied in the job accommodation strategy definition problems for other disabilities. Meanwhile, the effectiveness of the strategies can further be compared with the job accommodation strategies being derived by other research methods.

VI. CONCLUSIONS

Job accommodation strategies have become daily important for the people with disabilities in general and hearing impaired people in special. However, very few researches have been developed on how the job accommodation strategies can be defined. Meanwhile, job accommodation strategy definitions based on research results being developed one decade ago are not feasible for modern

industries. In this paper, the fuzzy DEMATEL based MCDM framework was first introduced into the job accommodation strategy definition problem due to the nature match between the job accommodation strategy definition process as well as the MCDM framework. An empirical study based on the operators from the electronic industry advanced and verified both available job accommodation strategies as well as job accommodation research methods. In the future, the proposed strategies as well as the research framework can be used to enhance the welfare of the disabilities.

***Abstract*- In this paper, we propose an expert decision making method, UL-TOPSIS. Through giving experts the flexibility of evaluation, they can choose two items of linguistic variables by the multiple-choice method, with an interval range of uncertain linguistic variables to express their real thinking. The method is also used to resolve the problem of too wide range of an individual expert opinion or too large differences between experts opinions. We hope that the new method can capture the opinions of experts better, integrate the opinions of all experts appropriately, and make more accurate decisions for decision makers.**

Keywords-expert decision making; fuzzy sets theory; uncertain linguistic variable; TOPSIS

I. INTRODUCTION

It is well-known that the quality of decision-making affects the organizational operation and performance deeply. In the process of decision-making, how to capture the opinion of decision makers exactly is extremely important. In tradition, MADM methods often solve the problems involving the crisp ratings of alternatives under attributes with crisp weights. However, in real cases the available data used in decision-making problems are often imprecise and vague. For example, the linguistic statement is very often used to evaluate alternatives and/or to indicate the importance of attributes. Linguistic variables are variables whose values (interpretation) are not numbers but words or sentences in a natural or artificial language [1]. The concept of linguistic variable is very useful to treat situations that are too ill-defined or too complicated to be appropriately described in traditional quantitative expressions. Xu(2004) presented that it is unavoidable that experts can only provide uncertain linguistic information due to time pressure and/or lack of sufficient information. Therefore it derived to use linguistic variables to show expression of opinions and preferences [3]. For giving decision-makers the flexibility of evaluation, they can choose two items of linguistic variables by the multiple-choice way with an interval range of uncertain linguistic variables to express their real thinking. For instance, if one decision-maker wants to give the evaluation that is between "fair" and "satisfied", then the decision-maker is able to evaluate with such uncertain linguistic variable [fair, satisfied]. Nevertheless, we find it also brings another problem which may produce too large interval range. It includes two kinds of situations. One is too wide range of evaluation from a decision-maker, and the other is too large differences between these evaluations from decision-makers. Therefore, for decision quality, it is necessary to overcome these problems when using such uncertain linguistic variable in evaluation.

Therefore, in this study we develop the UL-TOPSIS (Uncertain Linguistic Technique for Order Preference by Similarity to Ideal Solution), which is used uncertain linguistic variable as input value and applied the theory and spirit of TOPSIS to lead to develop a new operational process. We call the method as Uncertain Linguistic Technique for Order Preference by Similarity to Ideal Solution, UL-TOPSIS, hope to use it to capture the opinions of exports better and make more accurate

II. LITERATURE REVIEW

A. Linguistic Variable

In order to be able to transform the description of natural language into logical description by logic speculation, linguistic variable in fuzzy sets is used to describe the natural language under the domain of specification,. The linguistic variable is based on word or sentence as a variable rather than a number [1]. According to Zadeh (1975) description of linguistic variables, the linguistic terms is referred to the adjective phrase that is used by describing their own feelings of external things in human daily life [1]. For example, the linguistic variable "satisfaction", which can be used in linguistic terms "very dissatisfied ", "not satisfied" and " fair", "satisfied", "very satisfied" and other words to express.

B. Likert Scale

About the questionnaire design of expert opinions for the

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

criteria, the quantitative method of traditional rating scale is based on using a single value that corresponding to the opinion. That is Likert Scale which is generally familiar with. It is shown in Table I [4].

TABLE I. LIKERT SCALE

Linguistic variable	Very dissatisfied	dissatisfied	general	satisfied	Very satisfied
Corresponding function value	1	2	3	4	5

Likert Scale is used the value of equal difference to converse the answer that is chosen from all options by experts. That is conversed through the correlation between function, as shown in Table I. For different linguistic variables "very satisfied, satisfied, general, satisfactory, very satisfactory " to give the value "1,2,3,4,5," and then to quantify the linguistic variables and proceed follow-up calculation and decision-making.

C. Nine-point Scale

In the decision making methods AHP and ANP that Saaty proposed, it must be evaluate the importance of criteria before decision-making. It is divided into nine levels of importance for experts based on the questionnaire format Saaty designed. Levels of importance are separated into "Equal Importance", "Moderate Importance ", "Strong Importance", "Demonstrated Importance ", "Extreme Importance ", and take intermediate value between each level [6]. So we can let the experts proceed evaluating between two levels .The measure scale is shown in Table II as follow:

TABLE II. MEASURE SCALE

measure scale	Intensity of Definition Importance	Description
1	Equal Importance	Two activities contribute equally to the objective
3	Moderate Importance	Experience and judgment slightly favor one activity over another
5	Strong Importance	Experience and judgment strongly favor one activity over another
7	Demonstrated Importance	An activity is favored very strongly over another; its dominance demonstrated in practice
9	Extreme Importance	The evidence favoring one activity over another is of the highest possible order of affirmation
2, 4, 6, 8	Intermediate Value between two level	Between above of description

source：Saaty, 2006

D. Uncertain Linguistic Variable

In real life, when the experts or policy makers in the assessment criteria, the individual's thinking and cognitive differences have in determining the degree of differentiation, and implied uncertainty. In order to reflect model of human thinking more closely, we can let the experts use uncertain linguistic directly for expression. The uncertain linguistic representation is an "interval range" of linguistic variables. It is used an "interval range" to replace the option of single linguistic variables, and hoping to more fully express a personal thought and cognition by giving experts flexibility of evaluation, in order to facilitate more effective decision-making activities.

By using the example Xu(2004) mentioned in his study to illustrate that when evaluating criteria, linguistic variable is distinguished between nine terms. S represents a set which include nine linguistic variables:

$$S=\{s_1 = \text{extremly dissatisfied}, s_2 = \text{very dissatisfied}, s_3 = \text{dissatisfied}, s_4 = \text{slightly dissatisfied}, s_5 = \text{fair}, s_6 = \text{slightly satisfied}, s_7 = \text{satisfied}, s_8 = \text{very satisfied}, s_9 = \text{extremly satisfied}\}$$

where s_i represents a possible value for a linguistic variable [3].

However today expert A wants to give the evaluated value which has no clear boundary. He considers that it is fall between "fair" and "satisfaction." Therefore expert A could use [s4, s6] such a uncertain linguistic for expression. According to expert B's thinking, the evaluated value he given is between "very dissatisfied" and "slightly satisfied", so he can represent it with [s0, s3].

E. TOPSIS

TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) is a multi-attributed evaluation method that have developed by Hwang and Yoon (1981) [7]. It is applied widely in decision-making problems. Followed developing by Yoon (1987) and Hwang and others, the theory have been more complete.

The basic concept of TOPSIS is that the decision-maker based on all evaluated criteria of alternatives to find out the Positive Ideal Solution which is composed of the greatest value of those criteria and the Negative Ideal Solution which is composed of the worst value of those criteria for comparison. The so-called positive ideal solution is to enable the alternatives to be increased to the greatest of effectiveness attribute and reduced to the smallest of cost attribute; The negative ideal solution is to enable the alternatives to be dropped to the smallest effectiveness attribute and to be increased to the greatest of cost attributes.

III. UNCERTAIN LINGUISTIC TECHNIQUE FOR ORDER PREFERENCE BY SIMILARITY TO IDEAL SOLUTION

Uncertain Linguistic Technique for Order Preference by Similarity to Ideal Solution, UL-TOPSIS, which is used uncertain linguistic variable as input value and applied the theory and spirit of TOPSIS. Moreover, it can extend to deal with too much difference of expert opinions, and led to develop a new operational process.

UL-TOPSIS that developed in this study is the assessment of experts in order semantic uncertainty expressed, one expert expressed by the interval range of input values, applied to make expert decisions TOPSIS methods, procedures and contents are described below:

UL-TOPSIS developed in this study is expressed the opinion of experts by the uncertain linguistic, and used the interval range of expert expression as the input value for applying TOPSIS method to make expert decision. The steps and description as follow:

Step1. Establish a multi-criteria decision-making matrix

$$D_e = \begin{array}{c} \\ A_1 \\ A_2 \\ \vdots \\ A_m \end{array} \begin{array}{c} \begin{array}{cccc} C_1 & C_2 & \dots & C_n \end{array} \\ \begin{bmatrix} x_{11}^e & x_{12}^e & \dots & x_{1n}^e \\ x_{21}^e & x_{22}^e & \dots & x_{2n}^e \\ \dots & \dots & \dots & \dots \\ x_{m1}^e & x_{m2}^e & \dots & x_{mn}^e \end{bmatrix} \end{array}, e = 1,2,\dots,h \qquad (1)$$

$$W_j = [w_1, w_2, \dots, w_n].$$

D_e is the multi-criteria decision-making matrix of the eth expert, e=1, 2, …, h, A_i indicate the ith alternative, i=1, 2, …, m ; C_j indicate the jth *criteria*, j = 1, 2, …, n ; x_{ij}^e indicate the value that expert e give the jth criteria for ith alternative, x_{ij}^e = [a_{ij}^e , b_{ij}^e] ; and w_j indicate the importance relative to criteria C_j, $j = 1,2,\dots,n$。

Let $b_j - a_j$ be the difference between expert opinions. If $b_j - a_j \geqq 5$, we define this as the difference between expert opinions too much.

Step2. To integrate the opinions of each expert who give the same criteria under the same alternative.

$$X_{ij} = \left[\min_{e=1}^{h} a_{ij}^e, \max_{e=1}^{h} b_{ij}^e \right] = [a_{ij}, b_{ij}] \qquad (2)$$

Step3. To use the method when the differences between expert opinions are too much

if $b_j - a_j \geqq 5$, then do the following steps:

1. Under the same alternative, for the same criteria (j), to calculate the distance of each S_{ij}

$$d(x_{ij}^e, x_{ij}^k) = \sqrt{(b_{ij}^k - b_{ij}^e)^2 + (a_{ij}^k - a_{ij}^e)^2} \qquad (3)$$

$e \neq k$, e=1, 2, …, m-1

k=e+1, e+2, …, h , for each i, j

2. To compare the distance $d(S_{ij}, S_{kj})$ and eliminate the outlier

   Finding the maximum $d(S_{ij}, S_{kj})$ and eliminate it. We will not to consider the score which the expert given.
3. Then come back to Step 2.

Step4. To normalized the evaluated values of each alternative for the criteria.

$$r_{ij} = \frac{x_{ij}}{9}, \quad i = 1, 2, \dots, m \quad ; \quad j = 1, 2, \dots, n \qquad (4)$$

The normalized decision-making matrix could be displayed with $R = [r_{ij}]_{m \times n}$

$$R = \begin{array}{c} \\ A_1 \\ A_2 \\ \vdots \\ A_m \end{array} \begin{array}{c} \begin{array}{cccc} C_1 & C_2 & \dots & C_n \end{array} \\ \begin{bmatrix} r_{11} & r_{12} & \dots & r_{1n} \\ r_{21} & r_{22} & \dots & r_{2n} \\ \dots & \dots & \dots & \dots \\ r_{m1} & r_{m2} & \dots & r_{mn} \end{bmatrix} \end{array}, \qquad (5)$$

$$W_j = [w_1, w_2, \dots, w_n].$$

Step5. To make the relative weight of each criteria multiply into the standard matrix to create a normalized weighted matrix

$$V_{ij} = w_j r_{ij}, \quad i = 1,2,\dots,m \quad ; \quad j = 1,2,\dots,n \qquad (6)$$

where w_j is the weight of C_j

Step6. To determine the positive ideal solution and negative ideal solution

let [9,9] and [1,1] separately be the positive ideal solution and negative ideal solution of single criteria that not yet be added the weight and normalized.

After normalizing, $r^* = \left[\frac{9}{9}, \frac{9}{9}\right]$ $r^- = \left[\frac{1}{9}, \frac{1}{9}\right]$

After multiplying the weight value,

$$V^* = w_j r^* \quad ; \quad V^- = w_j r^- \qquad (7)$$

Then the positive ideal solution A^* of each criteria could be showed as follow:

$$A^* = [V_1^*, V_2^*, \dots, V_j^*, \dots, V_n^*] \qquad (8)$$

And the negative ideal solution A^- of each criteria could be showed as follow:

$$A^- = [V_1^-, V_2^-, \dots, V_j^-, \dots, V_n^-] \qquad (9)$$

Step7. To calculate the Separation measure

The distance between each alternative and the positive

ideal solution, represents as Separation measure Si*:

$$S_i^* = \left\{ \sum_{j=1}^{n} \left(V_{ij} - V_j^* \right)^2 \right\}^{1/2}, i = 1,2,\ldots,m \qquad (10)$$

The distance between each alternative and the negative ideal solution, represents as Separation measure Si—:

$$S_i^* = \left\{ \sum_{j=1}^{n} \left(V_{ij} - V_j^* \right)^2 \right\}^{1/2}, i = 1,2,\ldots,m \qquad (11)$$

Step8. To calculate the relative similarity to the positive ideal solution and negative ideal solution of the compared alternatives, RC_i^* is obtained:

$$RC_i^* = \frac{S_i^-}{S_i^* + S_i^-}, \; i = 1,2,\ldots, m, \; 0 \le RC_i^* \le 1 \qquad (12)$$

Step9. By the relative similarity RC_i^* to the positive ideal solution and negative ideal solution of the compared alternatives, we can know the relative position of compared alternatives to the positive and negative ideal solution, to rank the order of all alternatives. When the value RC_i^* is getting more close to 1, it means the alternative is getting more near the positive ideal solution, and more away from negative ideal solution. Which alternative is the better one. Otherwise, When the value RC_i^* is getting more close to 0, it means that the alternative is getting more near the negative ideal solution, and more away from positive ideal solution. Which alternative is the worse one. Therefore, the greater value RC_i^* of alternative is the priority.

IV. CONCLUSION

The purpose of this study is to provide a practical reference through proposing a new expert decision-making method and applying it to deal with the decision-making problems that practical business management often faced. So we develop the UL-TOPSIS which is used uncertain linguistic variable as input value and applied the theory and spirit of TOPSIS. Moreover, it can extend to deal with too much difference of expert opinions, and led to develop a new operational process. We could use it to capture the opinions of exports better, integrate the opinions of all experts appropriately, and make more accurate decisions for decision makers.

However, there are many multi-criteria decision-making methods, for example: AHP, ANP, etc. In the future, the researchers that interested in it can also use the uncertain linguistic variables and the concepts of dealing with too large differences in this study to apply in the multiple-criteria decision making method. And use it to develop the more diversified approach of decision-making and operational processes to provide a reference that could handle the more complex problems of management decision-making in practice.

Abstract—**This paper applies fuzzy vector quantization (FVQ) to the modeling of observation-based Discrete Hidden Markov Model (DHMM) and then to improve the speech recognition rate for the Mandarin speech. Vector quantization based on a codebook is a fundamental process to recognize the speech signal by DHMM. A codebook will be first trained by K-means algorithms using Mandarin training speech. Then, based on the trained codebook, the speech features are quantized by the fuzzy sets defined on each vectors of the codebook. Subsequently, the quantized speech features are statistically applied to train the model of DHMM for the speech recognition. All the speech features to be recognized should go through the FVQ based on the fuzzy codebook before being fed into the DHMM model for recognition. Experimental results in this paper shows that the speech recognition rate can be improved by using FVQ algorithm to train the model of DHMM.**

Keywords- Fuzzy Vector Quantization, EEG signal, Discrete Hidden Markov Model

I. INTRODUCTION

Recently, the Hidden Markov Model (HMM) is applied in many applications for prediction duo to its statistic properties [1]. It is especially successful on the automatic speech recognition (ASR). According to the type of the probability distributions used in HMMs, HMMs can be categorized as Continuous Hidden Markov Model (CHMM) and Discrete Hidden Markov Model (DHMM). The DHMM provides more stable recognition results and faster training with the recognition accuracy that is no less than CHMM. Therefore, the DHMM is adopted in this paper. The codebook for the feature quantization of the target signal will be recognized plays an important role on the training of DHMM model. A well-trained codebook will enhance the total performance of the recognition systems. In the past, the features are quantized by a codebook trained by K-means algorithm. This winner-take-all algorithm can not perform well on vector quantization, since multiple level of an element in some vectors exists in many applications. Consequently, the fuzzy vector quantization is used improve the performance of the vector quantization. Many research shows that the fuzzy vector quantization outperform VQ [2]. Besides, the relative works of fuzzy vector quantization, e.g. the fuzzy clustering [3-4] and fuzzy data retrieval systems [5] also demonstrate the benefit of fuzzy quantization method.

Besides, sleep is very importance to human's health. Humans spend averagely about 7 to 8 hours a day on sleep, which is equivalent to one third of our lifetime. At night, an 8-hour sleep contains about 4 to 5 sleep cycles and each cycle lasts about 90 minutes with different stages including light sleep (Stages 1 & 2), deep sleep (Slow Wave Sleep) and rapid eye movement (REM). The deep sleep stages become shorter as sleep cycle progresses. In human physiology, a good deep sleep (SWS) stage can help with physical recovery; as well, a good rapid eye movement (REM) stage can improve one's learning abilities and memories. Sleep diseases, such as insomnia and obstructive sleep apnea, seriously affect patients' quality of life. Without restrictive criteria, the prevalence of insomnia symptoms is approximately 33% in the general population. Obstructive sleep apnea affects over 2% of adult women and 4% of adult men [6]. These sleep issues may cause daytime sleepiness, irritability, depression, anxiety or even death.

For the diagnosis of sleep issues, all night polysomnographic (PSG) recordings, including electroencephalogram (EEG), electrooculogram (EOG) and electromyogram (EMG), are usually taken from the patients and the recordings are scored by a well-trained expert

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

according to the Rechtschaffen & Kales (R&K) rules presented in 1968. According to the R&K rules, each epoch (i.e., 30 s of data) is classified into one of the sleep stages, including wakefulness (Wake), non-rapid eye movement (stages 1-4, from light to deep sleep) and non-rapid eye movement (NREM).

Consequently, in this paper, the recognition of the sleep stage form EEG signal is used as an example to demonstrate the improvement of DHMM by FVQ.

II. FVQ AND DHMM

This paper introduces the proposed fuzzy vector quantization for the features used to train DHMM through a well trained codebook.

A. Fuzzy Vector Quantization

In order to train the DHMM model, a codebook should be set up first. In the codebook, feature vector must be classed as by vector quantization [1]. The *K*-means algorithm is adopted to train the codebook at head. Then, combing the fuzzy set, the codebook is arranged as a fuzzy codebook and all the features in training phase and in testing phase will be fuzzy vector quantized through the fuzzy codebook. Suppose a set of real numbers are expressed as $\{v_1, v_2, \cdots, v_n\}$ in which $v_i \in R$ and the corresponding fuzzy set is expressed as $\{u_i(x) \mid i = 1, 2, \cdots n\}$, where $\sum_1^n u_i(x) = 1, \forall x \in R.$ The triangular fuzzy set is depicted in Fig. 1. It is noted that since the elements of the codebook are not uniformly distributed in the domain of the speech signal after the training by *K*-means algorithm, the triangular fuzzy set is not symmetric in this application. The membership function in Fig. 2 is described as [2]:

$$u_i(x) = \begin{cases} \dfrac{x - v_{i-1}}{v_i - v_{i-1}}, & \forall x \in [v_{i-1}, v_i], \\ \dfrac{x - v_{i+1}}{v_i - v_{i+1}}, & \forall x \in [v_i, v_{i+1}]. \end{cases}$$

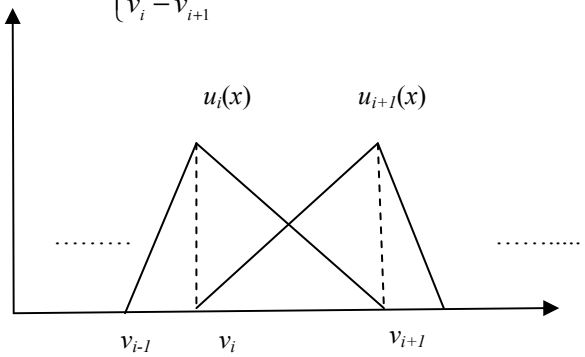

Fig. 1 Fuzzy set corresponding to each element of codebook

B. Discrete Hidden Markov Model (DHMM)

The DHMM is a double layers random process. The transfer of hidden states will correspond to the transfer of observations. Each model of DHMM can describe a specific signal to be recognized. The features of a signal are the observations used to estimate the hidden states. The target signal can be recognized by calculating the probability of the DHMM model. The model with highest probability in all DHMM models represents the most possibility of the recognized signal corresponding to the model [1].

In this section, the DHMM model is denoted as

$$\lambda = \{A, B, \pi, S, V\} \tag{1}$$

in which

$S = \{s_1, s_2, \cdots, s_N\}$ is the hidden state;

$V = \{v_1, v_2, \cdots, v_M\}$ is the output set of the DHMM model;

$A = \{a_{ij}\}, a_{ij} = P(q_t = s_j \mid q_{t-1} = s_i)$ is the probability matrix of state transfer;

$B = \{b_j(k)\}, b_j(k) = P(o_t = v_k \mid q_t = s_j)$ is the probability matrix of transfer out from each states;

$\pi = \{\pi_i\}, \pi_i = P(q_1 = s_i), 1 \le i \le N$ is the initial state probability;

$O = \{o_1, o_2, \cdots, o_T\}$ is the observation sequence;

$Q = \{q_1, q_2, \cdots, q_T\}$ is the state sequence.

As for the training of the DHMM model, the matrices *A*, *B*, and π are randomly generated initially. Then, the matrices are updated by the following algorithm.

$$state_t = \arg \max_{0 \le i \le 6} \alpha_t(i) \tag{2}$$

in which $state_t$ is the best estimated hidden state at time *t*; $\alpha_t(i)$ is the probability for *i*th guessed state at time *t* according to *A*, *B*, and π. Moreover, the matrices *A* and *B* are trained as follows.

The trained parameter $\overline{a}_{ij}$ of a_{ij} and $\overline{b}_j(k)$ of $b_j(k)$ is described as

$$\overline{a}_{ij} = \frac{n(u_{ij})}{n(u_{i\bullet})} \tag{3}$$

$$\overline{b}_j(k) = \frac{n(u_{\bullet j}, o = v_k)}{n(u_{\bullet j})} \tag{4}$$

in which

u_{ij} is the event that the state s_i transfer to s_j;

$u_{i\bullet}$ is the event that the state s_i transfer to other states;

$u_{\bullet j}$ is the event that enter the state s_j;

$n(u_{ij})$ is the number of times that s_i transfer to s_j;

$n(u_{i\bullet})$ is the number of times s_i transfer to other states;

$n(u_{\bullet j})$ is the number of times that enter the state s_j;

$n(u_{\bullet j}, o = v_k)$ is the number of times that the observation v_k occur when enter the state s_j.

The number $n(u_{\bullet j}, o = v_k)$ is obtained through the fuzzy codebook as follows. Suppose that the features are classified into *n* classes by *K*-means algorithm, i.e., the trained codebook is expressed as $CB_{n\times m} = \{FK_1, FK_n, \cdots, FK_n\}^T$ where $FK_i \in R^m$ is the center vector of *i*th class. The fuzzy degree contribute to the number $n(u_{\bullet j}, o = v_k)$ for each feature $f \in R^m$ is computed as $u_i(v_i + \|FK_i - f\|)$ for $n(u_{\bullet j}, o = v_i)$ and $u_i(v_{i+1} - \|FK_{i+1} - f\|)$ for $n(u_{\bullet j}, o = v_{i+1})$. This tactic is not only used for the training phase of the DHMM model but also for the testing phase of the speech recognition. In this paper, the strategy of using DHMM to recognize the signal is that we train first DHMM model λ for each corresponding signal by fuzzy codebook. Then, in testing phase, the tested signal features which is viewed as a sequence of observation *O* are fed into each DHMM model. The highest probabilities are found from computing the probability for all models by using the following equation:

$$P(O|\lambda) = \sum_{allQ} P(O,Q|\lambda) = \sum_{q1,q2,\ldots,qT} \pi_{q1} \cdot b_{q1}(o_1) \cdot a_{q1q2} \cdot b_{q2}(o_2) \cdot a_{q2q3} \cdots a_{qT-1qT} \cdot b_{qT}(o_T). \quad (5)$$

Figure 2 shows the processes for the training of the fuzzy codebook and DHMM model. Besides, the speech recognition process also can be found in the figure.

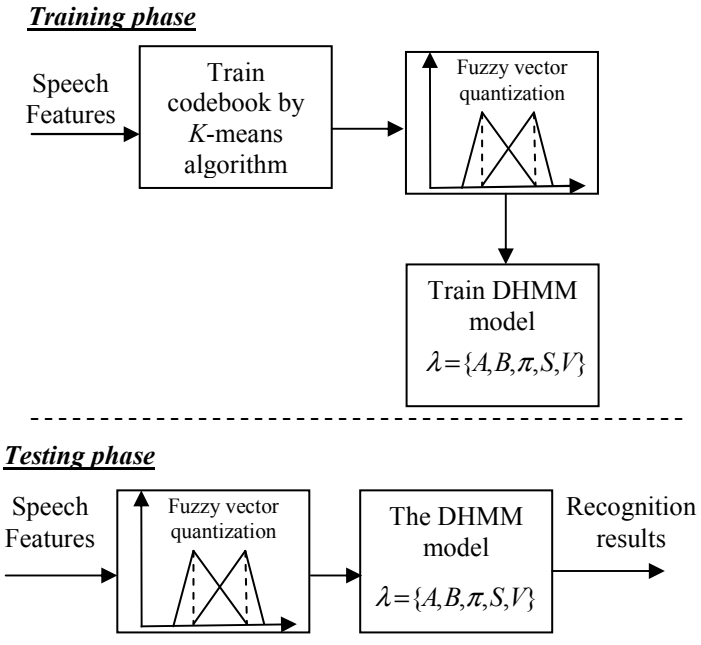

Fig. 2 Strategy of the proposed FVQ on speech recognition by DHMM

III. SLEEP STAGE AND EEG

The main purpose of this section is to enable the understanding of the basic elements of sleep stages. First, we introduce polysomnography, which includes electroencephalogram (EEG), electrooculogram (EOG), electromyogram (EMG) [7]. Then, we introduce the classification of sleep stages used in the R&K rules, and explain why we adopte the new sleep staging classification.

Polysomnography (PSG) is a multi-parametric test used in the study of sleep, as well, it is used as a diagnostic tool in sleep clinical trials. The test result is called a polysomnogram. Polysomnography is a comprehensive recording of the biophysiological changes that occur during sleep. The PSG monitors many body functions including brain activities (Electroencephalogram), eye movements (Electrooculogram), muscle activity or skeletal muscle activation (Electromyogram) and heart rhythm (Electrocardiogram) during sleep [8].

Electroencephalography (EEG) is the recording of electrical activity along the scalp produced by the firing of neurons within the brain. The sleep analysis, the EEG, is based on the characteristics of brain activities, and it can be divided into several different frequency bandwidths. The main EEG frequency bandwidths are given below in Table 1 [9]:

Table 1 Various signals in EEG [9]

Type	Frequency (Hz)	Waveform
Delta	0 – 4 Hz	Theta	4 – 8 Hz	Alpha	8 – 13 Hz	Beta	13 – 30 Hz	
Electrooculogram (EOG) is the resulting signal of a technique for measuring the resting potential of the retina. Eye movements are usually measured by placing pairs of electrodes either above and below, or to the left and right of the eye [10]. If the eye is moved from the center position towards one electrode, this electrode realizes the positive side of the retina, and the opposite electrode realizes the negative side of the retina. Consequently, a potential difference occurs between the electrodes. Assuming that the resting potential is constant, the recorded potential is a measurement for the eye

position [11]. In this paper, we use one EOG feature to recognize mainly the REM stage.

Electromyogram (EMG) is a technique for evaluating and recording the electrical activities produced by skeletal muscles. In sleep analysis, the electrodes are typically placed on the chin of the subject. The impulse (action potential) for muscle activation begins from the central nervous system, and it reaches the muscle via the spinal cord and the motor neuron. The action potential can be measured as EMG signals [12]. From the EMG signal, we will be able to tell whether the subject has entered deep sleep, and whether his muscles are in a relaxed state. In this paper, we will use three EMG features to recognize mainly the Wake stage.

3.1 Sleep Stages

In this subsection, we introduce the manual sleep staging rules by R&K rules and new sleep stage by AASM. Furthermore, the Mov stage which is used in previous research is included in this study and will be explained later.

2.2.1 Manual Staging Rules

The standard of manual sleep staging is R&K rules, which is proposed by Rechtschaffen and Kales in 1968 [13]. According to R&K rules, the stages are scored epoch-by-epoch in 20-30 second intervals. Then, the sleep is divided into six stages: stage wake(Wake), stage 1(S1), stage 2(S2), stage 3(S3), stage 4(S4), and stage rapid eye movement (REM). The details of each stage in R&K rules are described as follows [14].

Stage wake (Wake):

There is a low voltage (10−30μV) and mixed frequency (2-7 Hz) EEG during wakefulness. Possible features are alpha (8-13 Hz) activity in EEG and relatively high tonic EMG, about > 50% of the epoch.

Stage 1 (S1):

S1 is characterized by low voltage, mixed frequency EEG with the highest amplitude in the 2-7 Hz range. The vertex sharp waves may occur, and their amplitude can reach the value of about 200 μV. The alpha activity is less than 50% of an epoch.

Stage 2 (S2):

S2 is characterized by wave-pattern sleep spindles (12–15 Hz), K-complexes (sharp negative waves) and the absence of slow waves. The duration of these patterns should be a minimum of 0.5 second. If the time duration between two succeeding occurrences of sleep spindles or K-complexes is less than 3 minutes, this epoch is scored as S2, otherwise it is scored as S1.

Stage 3 (S3):

S3 is characterized by the presence of a minimum of 20-50% delta waves ranging from 0.5-2 Hz EEG and having a peak-to-peak amplitude > 75 μV. Sleep spindles and K-complexes may occur during S3.

Stage 4 (S4):

S4 has the same attributes as S3, 0.5-2 Hz EEG and amplitude > 75 μV. The only difference is the delta waves are more than 50% of an epoch.

Stage REM (REM):

REM shows low voltage and mixed (2-7 Hz) frequency of EEG similar to S1. Sawtooth wave patterns in EEG is often present. Moreover, EMG reaches the lowest level in this stage. In 2007, the American Academy of Sleep Medicine (AASM) group decided the new stage name terminology as follow: Stage W (Wakefulness), Stage N1 (NREM 1 sleep), Stage N2 (NREM 2 sleep), Stage N3 (NREM 3 sleep), Stage R (REM sleep). It is noted that NREM is non-REM stage, which consists of three stages N1, N2 and N3 [15]. The stages N1 and N2 are equivalent to S1 and S2 in the R&K rules respectively, and are light sleep. The stage N3 is equivalent to the stage that combined S3 and S4 in the R&K rules. Because the characteristics of the two stages S3 and S4 are much similar, in order to facilitate simplicity and accuracy of sleep staging, AASM group hence decided to combine stages S3 and S4 as N3. Stage N3 is also called deep sleep, or slow wave sleep (SWS) stage. The term SWS is used for revealing the physical meaning of this stage, therefore, in this paper, we adopt the five stages classification: Wake, S1, S2, SWS, and REM.

IV. Sleep Stage by Observation-Based DHMM

In observation-based DHMM, the DHMM are modeled for each sleep stage. Therefore, there are five DHMM models corresponding to each sleep stage. The transition for each DHMM model is illustrated in Fig. 3. The hidden states are arbitrarily defined in this strategy. The features become the observation codes via vector quantization. For the DHMM $\lambda = (A, B, \pi)$, A is the probability matrix of the transference from one hidden state to another hidden state. The matrix B is the probability matrix of the observation of a hidden state. The matrix π is the probability of the hidden state at the beginning. In this strategy, we focus on the probability of the five DHMM models, corresponding to the five sleep stages for a feature vector (observation). The DHMM model with maximum probability among all models is distinguished, and the corresponding sleep stage is the estimated stage for the feature vector. This strategy is shown in Fig. 4. In the Fig. 4, P_{Wake}, P_{S1}, P_{S2}, P_{SWS} and P_{REM} are the probability of the five DHMM models for feature vectors calculated from a 30-second sample of a sleep stage, corresponding to the five sleep stages Wake, S1, S2, SWS and REM, respectively.

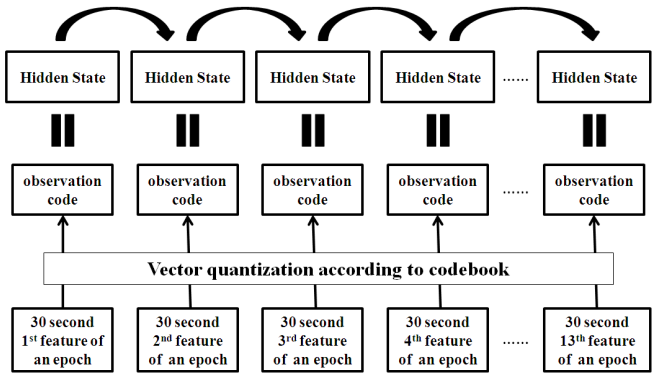

Fig. 3 DHMM for sleep staging.

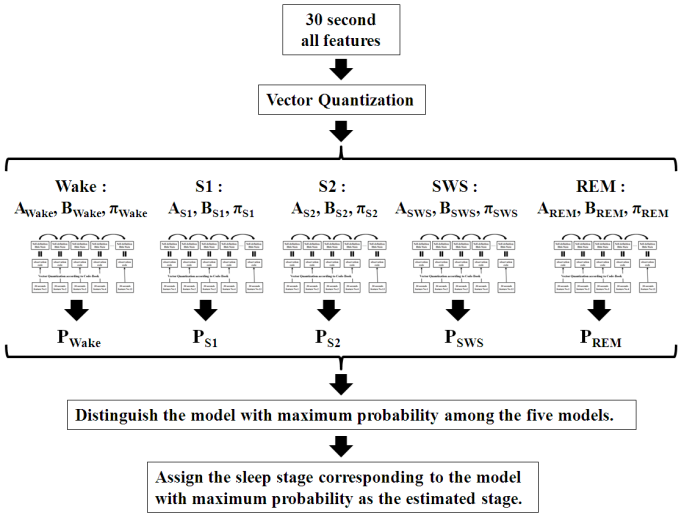

Fig. 4 Strategy of observation-based DHMM sleep staging.

Based on the above discussion, the sleep staging procedure by observation-based DHMM is then summarized as follows.

Procedure of observation-based DHMM sleep staging

Step 1. Train codebook by K -mean method.

Step 2. Generate five DHMM models by finding (A,B,π) of the corresponding sleep stages.

Step 3. Generate the observation codes by quantizing the feature vectors based on the codebook.

Step 4. Calculate the probability of all sleep models using the corresponding (A,B,π).

Step 5. Choose the model with the highest probability among all of the sleep models for the feature vector and assign the corresponding sleep stage as the estimated sleep stage.

Step 6. Repeat Steps 3 to 5 until all the feature vectors of the epochs are completed.

V. SLEEP STAGE BY OBSERVATION-BASED DHMM

In our experiment, we use the signals measured from three EEG channels (C3, F3, and P3), EMG and EOG to generate the features for training and testing. The sleep data used in the experiments are collected from twenty subjects and are numbered from No. 1 to No. 20 for convenience. The 158 hours of sleep data are recorded, and then used to train seventeen subjects and test three subjects. There are three different combinations of the training and testing set, named Set 1, Set 2 and Set 3, are used in this experiment and are listed in Table 2.

Table 2 Former class with three testing subjects.

Combination sets	Training subjects	Testing subjects
Set 1	{No. 1 ~ No. 20}/{Testing subjects}	No. 10, No. 14, No. 17
Set 2	{No. 1 ~ No. 20}/{Testing subjects}	No. 3, No. 9, No. 20
Set 3	{No. 1 ~ No. 20}/{Testing subjects}	No. 5, No. 12, No. 19

Table 3 shows the recognition rates of the proposed various tactics which are designed based on the DHMM without FVQ while Table 4 is those with FVQ. A more detail comparison on the recognition rate of each sleep stage and means for the three sets Set 1, Set 2 and Set 3 are depicted in Fig. 5 – Fig. 8. These figures reveal that the DHMM with FVQ performs much better than DHMM without FVQ. This verify that the proposed FVQ on DHMM is efficient.

VI. CONCLUSIONS

The fuzzy vector quantization (FVQ) had been used on the modeling of Discrete Hidden Markov Model (DHMM) to improves the recognition rate for the sleep stages based on EEG, EOG and EMG signals. First, a codebook was trained by *K*-means algorithms. Based on the trained codebook, the features are quantized by the fuzzy sets defined on the trained codebook. Subsequently, the quantized features are used to the modeling of DHMM for the sleep stage recognition. All the features should go through the FVQ based on the fuzzy code book before being fed into the DHMM model for recognition. Experimental results reveal that the speech recognition rate can be improved by using FVQ algorithm to train the model of DHMM.

***Abstract*—The paper presents the methods of integrating prior knowledge with a first-order Single-Input Single-Output (SISO) Interval Type-2 Takagi-Sugeno-Kang (TSK) Fuzzy Logic System (IT2FLS) for function approximation under noisy circumstances. Firstly, sufficient conditions on the antecedent and the consequent parameters of the IT2FLS are given to ensure that three kinds of prior knowledge – monotonicity, symmetry and special points, can be embedded into the IT2FLS. And then, we use three optimization algorithms – constrained least squares algorithm, active-set algorithm and hybrid learning algorithm to design the IT2FLS, respectively. The effectiveness of the three algorithms and the comparisons of their performance are demonstrated by simulation examples.**

Keywords* – *interval type-2 fuzzy logic system; optimization algorithm; prior knowledge

I. Introduction

Prior knowledge is a kind of important information sources and can play a significant role in many real problems, especially when input-output data are not informative enough or corrupted by noise. For a grey-box identification problem, it is not necessary to estimate what we already know, but instead we should take advantage of the prior knowledge of plants or systems. In the past several years, some work was done to incorporate some prior knowledge with neural network systems [1] or fuzzy logic systems [2] – [4]. In [1], Joerding studied methods for incorporating the monotonicity into feedforward networks. Lindskog [2] proposed a fuzzy model structure to ensure monotonic gain characteristics in identified models. Li [3, 4] integrated the prior knowledge of bounded range, symmetry and monotonicity into a zeroth-order IT2FLS and designed the fuzzy system by constrained least squares algorithm.

Type-2 Fuzzy Logic Systems (T2FLSs) can better handle different sources of uncertainties and debilitate noisy disturbance than traditional or type-1 fuzzy logic systems (T1FLSs) [5, 6]. A lot of excellent work focused on how to design T1FLSs and T2FLSs. Jang [7] presented the ANFIS architecture which is a type-1 fuzzy inference system implemented in the framework of adaptive network, and by using hybrid learning procedure, the ANFIS can yield remarkable results. In [8], Castro proposed an efficient mechanism for modeling by combined hybrid learning algorithm with an interval type-2 fuzzy neural network. Méndez [9] presented a novel hybrid learning method to construct an interval type-2 TSK fuzzy model capable of approximating the behavior of steel strip temperature based on orthogonal least squares and back propagation methods. At present, to the authors' knowledge, there is no literatures about designing first-order SISO IT2FLSs with prior knowledge description via constrained hybrid method. In this paper, we first give the sufficient conditions which ensure the above-mentioned three kinds of prior knowledge can be combined with the IT2FLS. And then, we design the first-order SISO IT2FLS via constrained least squares algorithm, active-set algorithm and hybrid learning algorithm, respectively.

II. IT2FLSs and Parameter Conditions for Prior Knowledge

In this section, the basic concepts about first-order SISO IT2FLSs are introduced. And then, we give the sufficient conditions on the parameters of the IT2FLS which ensure that the prior knowledge of monotonicity, symmetry and special points can be integrated into the IT2FLS.

A. First-order SISO IT2FLSs

Consider a first-order SISO IT2FLS whose fuzzy rule base consists of M fuzzy rules. The ith rule R^i is denoted as

$$R^i: \text{ IF } x \text{ is } \widetilde{A}^i, \text{ THEN } y^i = w_0^i + w_1^i x,$$

where $i = 1, 2, \ldots, M$; x is the input variable, $\widetilde{A}^i$s are triangular IT2FSs which can be completely depicted by the lower and the upper membership functions – $\underline{\mu}_{\widetilde{A}^i}(x)$ and $\overline{\mu}_{\widetilde{A}^i}(x)$ which are expressed by (1) and (2), as illustrated in Fig. 1.

$$\underline{\mu}_{\widetilde{A}^i}(x) = \begin{cases} 0, & x < \underline{a}^i; \\ \frac{\underline{h}^i(x-\underline{a}^i)}{b^i-\underline{a}^i}, & \underline{a}^i \le x < b^i; \\ \frac{\underline{h}^i(\underline{c}^i-x)}{\underline{c}^i-b^i}, & b^i \le x < \underline{c}^i; \\ 0, & x \ge \underline{c}^i. \end{cases} \tag{1}$$

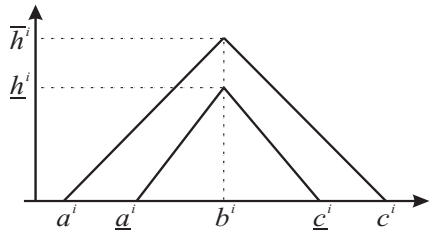

Fig. 1. Interval type-2 triangular membership function.

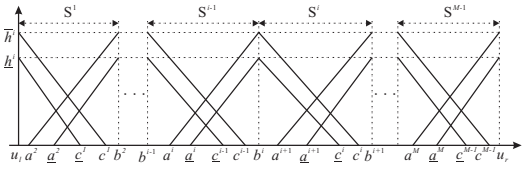

Fig. 2. Interval type-2 fuzzy partition.

$$\overline{\mu}_{\widetilde{A}^i}(x) = \begin{cases} 0, & x < a^i; \\ \frac{\overline{h}^i(x-a^i)}{b^i-a^i}, & a^i \le x < b^i; \\ \frac{\overline{h}^i(c^i-x)}{c^i-b^i}, & b^i \le x < c^i; \\ 0, & x \ge c^i. \end{cases} \tag{2}$$

where $a^i \le \underline{a}^i \le b^i \le \underline{c}^i \le c^i$.

The firing set F^i of rule R^i is an interval type-1 set, i.e., $F^i = [\underline{\mu}_{\widetilde{A}^i}(x), \overline{\mu}_{\widetilde{A}^i}(x)]$. w_0^i and w_1^i are real constants of the consequent part, so the consequent output y^i of each rule is a crisp value.

Then, using the center-of-sets (COS) type-reducer and the center average defuzzifier [5], the defuzzification output $\widehat{y}(x)$ of the IT2FLS is inferred as

$$\widehat{y}(x) = \frac{1}{2}\big(y_l(x) + y_r(x)\big). \tag{3}$$

where $y_l(x)$ and $y_r(x)$ are the left and the right end points of a type-reduced interval set and can be expressed as

$$y_l(x) = \frac{\sum_{i=1}^{L} \overline{\mu}_{\widetilde{A}^i}(x) y^i + \sum_{i=L+1}^{M} \underline{\mu}_{\widetilde{A}^i}(x) y^i}{\sum_{i=1}^{L} \overline{\mu}_{\widetilde{A}^i}(x) + \sum_{i=L+1}^{M} \underline{\mu}_{\widetilde{A}^i}(x)}, \tag{4}$$

$$y_r(x) = \frac{\sum_{i=1}^{R} \underline{\mu}_{\widetilde{A}^i}(x) y^i + \sum_{i=R+1}^{M} \overline{\mu}_{\widetilde{A}^i}(x) y^i}{\sum_{i=1}^{R} \underline{\mu}_{\widetilde{A}^i}(x) + \sum_{i=R+1}^{M} \overline{\mu}_{\widetilde{A}^i}(x)}, \tag{5}$$

in which L and R can be computed by the iterative Karnik-Mendel algorithm [5].

B. Prior Knowledge of Monotonicity

We shall study the prior knowledge of monotonicity which includes the monotonically increasing and the monotonically decreasing properties. Here, for conciseness, we give the sufficient conditions to ensure that IT2FLSs monotonic properties without proof.

Theorem 2.1: Assume that an IT2FLS is single-input single-output, and that the input domain of the IT2FLS is $U = [u_l, u_r]$. The IT2FLS increases monotonically with respect to x, if the following conditions are satisfied:

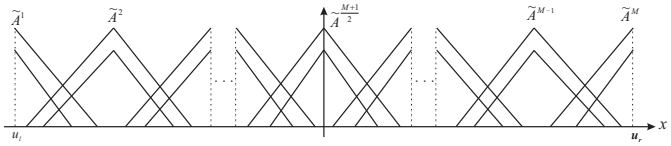

Fig. 3. Interval type-2 fuzzy symmetric partition with M triangular membership function.

1) The input domain U is partitioned by IT2FSs $\widetilde{A}^1, \widetilde{A}^2, \ldots, \widetilde{A}^M$ shown in Fig. 2, that is, $a^1 = b^1 = \underline{a}^1 = \underline{b}^1 = u_l$, $b^M = c^M = \underline{b}^M = \underline{c}^M = u_r$, $a^{i+1} \ge b^i$, $b^{i+1} \ge c^i$, $\underline{c}^i \ge \underline{a}^{i+1}$, for $i = 1, 2, \ldots, M-1$;
2) $w_1^i \ge 0$, for $i = 1, 2, \ldots, M$;
3) $w_0^{i+1} + w_1^{i+1} x \ge w_0^i + w_1^i x$, for all $x \in S^i$, and $i = 1, 2, \ldots, M-1$.

Theorem 2.2: Assume that an IT2FLS is single-input single-output, and that the input domain of the IT2FLS is $U = [u_l, u_r]$. The IT2FLS decreases monotonically with respect to x, if the following conditions are satisfied:

1) The input domain U is partitioned by M IT2FSs $\widetilde{A}^1, \widetilde{A}^2, \ldots, \widetilde{A}^M$ shown in Fig. 2, that is, $a^1 = b^1 = \underline{a}^1 = \underline{b}^1 = u_l$, $b^M = c^M = \underline{b}^M = \underline{c}^M = u_r$, $a^{i+1} \ge b^i$, $b^{i+1} \ge c^i$, $\underline{c}^i \ge \underline{a}^{i+1}$, for $i = 1, 2, \ldots, M-1$;
2) $w_1^i \le 0$, for $i = 1, 2, \ldots, M$;
3) $w_0^{i+1} + w_1^{i+1} x \le w_0^i + w_1^i x$, if $u_l \ge 0$ or $u_r \le 0$ for all $x \in S^i$ and $i = 1, 2, \ldots, M-1$; if $U \in \mathbb{R}$ for all $x \in U$ and $i = 1, 2, \ldots, M-1$.

C. Prior Knowledge of Symmetry

In this subsection, we give the sufficient conditions about the prior knowledge of symmetry which includes even symmetry and odd symmetry without proof.

Theorem 2.3: An IT2FLS is even symmetric, that is, $\widehat{y}(x) = \widehat{y}(-x)$, if the following conditions are satisfied:

1) The input domain of x is partitioned symmetrically around 0 by triangular IT2FSs $\widetilde{A}^1, \widetilde{A}^2, \ldots, \widetilde{A}^M$ shown in Fig. 3, where M is an odd number.
2) The consequent parameters of the rules R^i and R^{M-i+1} satisfy that $w_0^i = w_0^{M-i+1}$, $w_1^i = -w_1^{M-i+1}$ $(i \ne \frac{M+1}{2})$, and $w_1^{\frac{M+1}{2}} = 0$.

Theorem 2.4: An IT2FLS is odd symmetric, that is, $\widehat{y}(x) = -\widehat{y}(-x)$, if the following conditions are satisfied:

1) The input domain of x is partitioned symmetrically around 0 by triangular IT2FSs $\widetilde{A}^1, \widetilde{A}^2, \ldots, \widetilde{A}^M$ shown in Fig. 3, where M is an odd number.
2) The consequent parameters of the rules R^i and R^{M-i+1} satisfy that $w_0^i = -w_0^{M-i+1} (i \ne \frac{M+1}{2})$, $w_0^{\frac{M+1}{2}} = 0$ and $w_1^i = w_1^{M-i+1}$

D. Prior Knowledge of Special Points

In many practical systems the initial status is usually zero, and a lot of function curves pass through some special points such as origin. Hence, the prior knowledge of special points is widespread and important.

From a purely mathematic viewpoint, we formulate the prior knowledge of special points as follows

$$\widehat{y}(x)\big|_{x=x_0} = y(x_0), \tag{6}$$

where $\widehat{y}(x)$ is the output of the above-mentioned SISO IT2FLS. $y(x_0)$ is the known special point.

For example, when $\widehat{y}(x)\big|_{x=0} = 0$ for the first-order SISO IT2FLS in Theorem 2.1, from (4) and (5) we have $y_l(x) = y_r(x) = w_0^{\frac{M+1}{2}}$. Then, it follows from (3) that $\widehat{y}(x) = w_0^{\frac{M+1}{2}}$. Therefore, we can derive the constraint condition of the prior knowledge, i.e., $w_0^{\frac{M+1}{2}} = 0$.

III. Design of IT2FLSs via optimization algorithms

Suppose there exist r input-output data pairs (x_1, y_1), $\ldots, (x_r, y_r)$. And our objective is that the parameters of the IT2FLS can be optimized subject to the following training criteria (7) such that the overall error measure E is minimal.

$$\min_{\boldsymbol{\theta}} E = \min_{\boldsymbol{\theta}} \sum_{k=1}^{r} \big(\widehat{y}(x_k) - y_k\big)^2, \tag{7}$$

where $\boldsymbol{\theta}$ is all the parameters which need to be optimized, and $k = 1, 2, \ldots, r$. Next, according to this objective, we design the IT2FLS based on prior knowledge and sample data via constrained least squares algorithm, active-set algorithm and hybrid learning algorithm, respectively.

A. Design of IT2FLSs via Least Squares Algorithm

In this subsection, we design the IT2FLS via constrained least squares algorithm. Firstly, we should determine whether the output of the IT2FLS is linear with its consequent parameters.

Since no more than two fuzzy rules are fired, Equations (4) and (5) can be rewritten as

$$y_l(x) = \frac{\sum_{i=1}^{M} \mu_{\widetilde{A}_l^i}(x) w_0^i}{\sum_{i=1}^{M} \mu_{\widetilde{A}_l^i}(x)} + \frac{\sum_{i=1}^{M} \mu_{\widetilde{A}_l^i}(x) x w_1^i}{\sum_{i=1}^{M} \mu_{\widetilde{A}_l^i}(x)}, \tag{8}$$

$$y_r(x) = \frac{\sum_{i=1}^{M} \mu_{\widetilde{A}_r^i}(x) w_0^i}{\sum_{i=1}^{M} \mu_{\widetilde{A}_r^i}(x)} + \frac{\sum_{i=1}^{M} \mu_{\widetilde{A}_r^i}(x) x w_1^i}{\sum_{i=1}^{M} \mu_{\widetilde{A}_r^i}(x)}. \tag{9}$$

where

$$\mu_{\widetilde{A}_l^i}(x) = \begin{cases} \underline{\mu}_{\widetilde{A}^i}(x), & x \in S^{i-1}, \quad y^{i-1} \le y^i; \\ \overline{\mu}_{\widetilde{A}^i}(x), & x \in S^{i-1}, \quad y^{i-1} > y^i; \\ \overline{\mu}_{\widetilde{A}^i}(x), & x \in S^{i}, \quad y^{i} \le y^{i+1}; \\ \underline{\mu}_{\widetilde{A}^i}(x), & x \in S^{i}, \quad y^{i} > y^{i+1}. \end{cases}$$

$$\mu_{\widetilde{A}_r^i}(x) = \begin{cases} \overline{\mu}_{\widetilde{A}^i}(x), & x \in S^{i-1}, \quad y^{i-1} \le y^i; \\ \underline{\mu}_{\widetilde{A}^i}(x), & x \in S^{i-1}, \quad y^{i-1} > y^i; \\ \underline{\mu}_{\widetilde{A}^i}(x), & x \in S^{i}, \quad y^{i} \le y^{i+1}; \\ \overline{\mu}_{\widetilde{A}^i}(x), & x \in S^{i}, \quad y^{i} > y^{i+1}. \end{cases}$$

in which $y^i = w_0^i + w_1^i x$.
Then, it follows from (3), (8) and (9) that

$$\widehat{y}(x) = \boldsymbol{\phi}^{\mathrm{T}}(x)\boldsymbol{\omega}, \tag{10}$$

where

$$\boldsymbol{\omega} = [w_0^1, w_0^2, \ldots, w_0^M, w_1^1, w_1^2, \ldots, w_1^M]^{\mathrm{T}},$$
$$\boldsymbol{\phi}(x) = [\phi_0^1(x), \phi_0^2(x), \ldots, \phi_0^M(x), \phi_1^1(x), \phi_1^2(x), \ldots, \phi_1^M(x)]^{\mathrm{T}},$$

in which

$$\phi_0^i(x) = \frac{1}{2}\Big(\frac{\mu_{\widetilde{A}_l^i}(x)}{\sum_{i=1}^{M} \mu_{\widetilde{A}_l^i}(x)} + \frac{\mu_{\widetilde{A}_r^i}(x)}{\sum_{i=1}^{M} \mu_{\widetilde{A}_r^i}(x)}\Big),$$
$$\phi_1^i(x) = \frac{1}{2}\Big(\frac{\mu_{\widetilde{A}_l^i}(x)x}{\sum_{i=1}^{M} \mu_{\widetilde{A}_l^i}(x)} + \frac{\mu_{\widetilde{A}_r^i}(x)x}{\sum_{i=1}^{M} \mu_{\widetilde{A}_r^i}(x)}\Big).$$

From (10), we can conclude that the output of the IT2FLS is linear with its consequent parameters. Furthermore, the training criteria (7) can be rewritten as:

$$\min_{\boldsymbol{w}} E = \min_{\boldsymbol{w}} (\Phi\boldsymbol{w} - \boldsymbol{y})^{\mathrm{T}}(\Phi\boldsymbol{w} - \boldsymbol{y}), \tag{11}$$

where

$$\boldsymbol{y} = [y_1, y_2, \ldots, y_r]^{\mathrm{T}},$$
$$\Phi = \big[\boldsymbol{\phi}^{\mathrm{T}}(x_1), \boldsymbol{\phi}^{\mathrm{T}}(x_2), \ldots, \boldsymbol{\phi}^{\mathrm{T}}(x_r)\big]^{\mathrm{T}} \in \mathbb{R}^{r \times 2M}.$$

If the partitions of the IT2FLS are determined beforehand according to the conditions in the above theorems, we can use the sample data to train the consequent parameters of the IT2FLS via constrained least squares algorithm. Note that the given sample data (x_k, y_k) $(k = 1, 2, \ldots, r)$ should conform to the above-mentioned some or all prior knowledge. Also, in Theorems 2.1 – 2.4, if antecedent parameters are determined, the conditions on the consequent parameters can be expressed as linear inequalities and/or linear equalities with respect to the parameters. Then, the minimization problem (11) can be abstractly formulated as the following constrained least squares optimization problem,

$$\begin{cases} \min\limits_{\boldsymbol{w}} (\Phi\boldsymbol{w} - \boldsymbol{y})^{\mathrm{T}}(\Phi\boldsymbol{w} - \boldsymbol{y}) \\ \text{subject to} \quad C\boldsymbol{w} \le 0 \ \text{ and/or } \ C_{eq}\boldsymbol{w} = 0 \end{cases} \tag{12}$$

where both C and C_{eq} are linear constraint matrixes.

Next, we deduce the definite form of $C\boldsymbol{w} \le 0$ or $C_{eq}\boldsymbol{w} = 0$ according to the different prior knowledge.

1) Monotonically increasing property: The constraints on the consequent parameters of the IT2FLS in Conditions 2) and 3) of Theorem 2.1 can be expressed as

$$-w_1^i \le 0, \ \text{for } \ i = 1, 2, \ldots, M,$$
$$w_0^i - w_0^{i+1} + w_1^i x_k - w_1^{i+1} x_k \le 0,$$
$$\text{for } \ x_k \in S^i, \ i = 1, 2, \ldots, M-1.$$

Here, assume there are n_i data pairs on interval S^i. Hence, there exist $M + \sum_{i=1}^{M-1} n_i$ linear inequality constraints for these consequent parameters, and the constraints can be written as the following matrix form.

$$\begin{bmatrix} V_0 \\ V_1 \\ \vdots \\ V_{M-1} \end{bmatrix} \boldsymbol{w} \le \mathbf{0}_{(M+\sum_{i=1}^{M-1} n_i)\times 1}, \tag{13}$$

where

$$V_0 = \begin{bmatrix} \mathbf{0}_M & -I_M \end{bmatrix},$$

$$V_i = \begin{array}{c} \\ \\ \\ \\ \\ \\ \end{array} \begin{array}{c} \begin{array}{cccccccc} & & & i & i+1 & & & \end{array} \\ \begin{bmatrix} 0 & \dots & 0 & 1 & -1 & 0 & \dots & 0 \\ \vdots & \dots & \vdots & \vdots & \vdots & \vdots & \dots & \vdots \\ 0 & \dots & 0 & 1 & -1 & 0 & \dots & 0 \end{bmatrix} \\ \begin{array}{cccccccc} & & & M+i & M+i+1 & & & \end{array} \\ \begin{bmatrix} 0 & \dots & 0 & x_{i,1} & -x_{i,1} & 0 & \dots & 0 \\ \vdots & \dots & \vdots & \vdots & \vdots & \vdots & \dots & \vdots \\ 0 & \dots & 0 & x_{i,n_i} & -x_{i,n_i} & 0 & \dots & 0 \end{bmatrix} \end{array},$$

in which x_{i,n_i} denotes the n_ith datum on interval S^i. $\mathbf{0}_M$ is M by M zero matrix, I_M is M by M identify matrix, $V_0 \in \mathbb{R}^{M\times M}$, and $V_i \in \mathbb{R}^{(M-1)\times 2M}$.

Remarks: Especially, when $U \in [0, +\infty]$, inequalities

$$w_1^i \geq 0, \text{ for } i = 1, 2, \dots, M,$$
$$w_0^i \leq w_0^{i+1},\ w_1^i \leq w_1^{i+1} \text{ for } i = 1, 2, \dots, M-1,$$

can ensure that Conditions 2) and 3) hold, and can be expressed as the following matrix form.

$$\begin{bmatrix} \mathbf{0}_M & -I_M \\ \Lambda_M & \mathbf{0}_{(M-1)\times M} \\ \mathbf{0}_{(M-1)\times M} & \Lambda_M \end{bmatrix} \boldsymbol{w} \leq \mathbf{0}_{(3M-2)\times 1}, \tag{14}$$

where

$$\Lambda_M = \begin{bmatrix} 1 & -1 & 0 & \dots & 0 & 0 \\ 0 & 1 & -1 & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 1 & -1 \end{bmatrix} \in R^{(M-1)\times M}.$$

2) Monotonically decreasing property: If $U \in [0, +\infty]$ or $U \in [-\infty, 0]$, the constraints on the consequent parameters of the IT2FLS in Conditions 2) and 3) of Theorem 2.2 can be expressed as $M + \sum_{i=1}^{M-1} n_i$ linear inequalities, and can be transformed into the following matrix form.

$$\begin{bmatrix} -V_0 \\ -V_1 \\ \vdots \\ -V_{M-1} \end{bmatrix} \boldsymbol{w} \leq \mathbf{0}_{(M+\sum_{i=1}^{M-1} n_i)\times 1} \tag{15}$$

Remarks: Especially, when $U \in [-\infty, 0]$, inequalities

$$w_1^i \leq 0, \text{ for } i = 1, 2, \dots, M,$$
$$w_0^i \geq w_0^{i+1},\ w_1^i \leq w_1^{i+1}, \text{ for } i = 1, 2, \dots, M-1,$$

can ensure that Conditions 2) and 3) hold, and can be expressed as the following matrix form.

$$\begin{bmatrix} \mathbf{0}_M & I_M \\ -\Lambda_M & \mathbf{0}_{(M-1)\times M} \\ \mathbf{0}_{(M-1)\times M} & \Lambda_M \end{bmatrix} \boldsymbol{w} \leq \mathbf{0}_{(3M-2)\times 1} \tag{16}$$

3) Even symmetry: The constraints on the consequent parameters of the IT2FLS in Condition 2) of Theorem 2.3 can be expressed as

$$w_0^i - w_0^{M-i+1} = 0,$$
$$w_1^i + w_1^{M-i+1} = 0,$$
$$w_1^{\frac{M+1}{2}} = 0, \text{ for } i = 1, 2, \dots, \frac{M-1}{2}.$$

Furthermore, the M inequalities can be written as the following matrix form.

$$\begin{bmatrix} I_{\frac{M-1}{2}} & \mathbf{0}_{\frac{M-1}{2}\times 1} & -I^R_{\frac{M-1}{2}} & \mathbf{0}_{\frac{M-1}{2}\times M} \\ \mathbf{0}_{\frac{M-1}{2}\times M} & I_{\frac{M-1}{2}} & \mathbf{0}_{\frac{M-1}{2}\times 1} & I^R_{\frac{M-1}{2}} \\ \mathbf{0}_{1\times M} & \mathbf{0}_{1\times \frac{M-1}{2}} & 1 & \mathbf{0}_{1\times \frac{M-1}{2}} \end{bmatrix} \times \boldsymbol{w} = \mathbf{0}_{M\times 1} \tag{17}$$

where I^R_M is the $M \times M$ matrix which is obtained by rotating I_M 90 degrees clockwise.

4) Odd symmetry: The constraints on the consequent parameters of the IT2FLS in Conditions 2) of Theorem 2.4 can be expressed as M linear inequalities, and can be transformed into the following matrix form.

$$\begin{bmatrix} I_{\frac{M-1}{2}} & \mathbf{0}_{\frac{M-1}{2}\times 1} & I^R_{\frac{M-1}{2}} & \mathbf{0}_{\frac{M-1}{2}\times M} \\ \mathbf{0}_{1\times \frac{M-1}{2}} & 1 & \mathbf{0}_{1\times \frac{M-1}{2}} & \mathbf{0}_{1\times M} \\ \mathbf{0}_{\frac{M-1}{2}\times M} & I_{\frac{M-1}{2}} & \mathbf{0}_{\frac{M-1}{2}\times 1} & -I^R_{\frac{M-1}{2}} \end{bmatrix} \times \boldsymbol{w} = \mathbf{0}_{M\times 1} \tag{18}$$

In conclusion, we make use of the following steps to construct the IT2FLS:

step 1) Determine the membership functions of IT2FSs $\widetilde{A}^1$, $\widetilde{A}^2$, $\dots$, $\widetilde{A}^M$ according to condition 1) in the Theorems 2.1 – 2.4 and the corresponding prior knowledge.

step 2) Let $C\boldsymbol{w} \leq 0$ in (12) be (13) for monotonically increasing property; (15) for monotonically decreasing property. Let $C_{eq}\boldsymbol{w} = 0$ be (17) for even symmetry; (18) for odd symmetry. Solve the constrained least squares optimization problem (12). Obtain the consequent parameter vector $\boldsymbol{w}$.

B. Design of IT2FLSs via Active-set Algorithm

In this subsection, we use active-set algorithm [10] to optimize all the parameters of the IT2FLS subject to (7).

Let us define $\boldsymbol{v}_i = [a^{i+1}, \underline{a}^{i+1}, \underline{c}^i, c^i, b^{i+1}]^{\mathrm{T}} (i \neq M-1)$ and $\boldsymbol{v}_{M-1} = [a^M, \underline{a}^M, \underline{c}^{M-1}, c^{M-1}]$, where M is the number of IT2FSs. Furthermore the antecedent parameters can be defined as $\boldsymbol{v} = [\boldsymbol{v}_1, \boldsymbol{v}_2, \dots, \boldsymbol{v}_{M-1}]^{\mathrm{T}} \in \mathbb{R}^{5M-6}$. Then, we can use the active-set algorithm to determine all the antecedent parameters $\boldsymbol{v}$ and the consequent parameters $\boldsymbol{w}$ according to different prior knowledge.

1) Monotonically increasing property: According to Condition 1) in Theorems 2.1, the constraints on the antecedent parameters can be expressed as

$$a^{i+1} \leq \underline{a}^{i+1} \leq \underline{c}^i \leq c^i, \text{ for } i = 1, 2, \dots, M-1;$$
$$c^i \leq b^{i+1}, \text{ for } i = 1, 2, \dots, M-2;$$

Furthermore, the $5M-7$ inequalities can be written as the following matrix form.

$$\Lambda_{5M-6}\boldsymbol{v} \le \mathbf{0}_{(5M-7)\times 1}, \tag{19}$$

Since b^i $(i=2,\ldots,M-1)$ is optimization parameters, in Condition 3) $x \in S^i$ should be changed into $x \in U$. Hence, V_i can be written as

$$V_i = \begin{array}{c} \\ \\ \\ \\ \\ \end{array} \begin{array}{c} \begin{array}{cccccccc} & & & & i & i+1 & & \end{array} \\ \begin{bmatrix} 0 & \ldots & 0 & 1 & -1 & 0 & \ldots & 0 \\ \vdots & \ldots & \vdots & \vdots & \vdots & \vdots & \ldots & \vdots \\ 0 & \ldots & 0 & 1 & -1 & 0 & \ldots & 0 \end{bmatrix} \\ \begin{array}{cccccccc} & & & & M+i & M+i+1 & & \end{array} \\ \begin{bmatrix} 0 & \ldots & 0 & x_1 & -x_1 & 0 & \ldots & 0 \\ \vdots & \ldots & \vdots & \vdots & \vdots & \vdots & \ldots & \vdots \\ 0 & \ldots & 0 & x_k & -x_k & 0 & \ldots & 0 \end{bmatrix}, \end{array}$$

According to Condition 3), since $b^i, b^{i+1} \in S^i$ and w^i are unknown variables, if we want to determine all the antecedent and the consequent parameters, there exist $2M-4$ nonlinear inequality constraints as follows:

$$\begin{aligned} w_0^{i+1} - w_0^i + \left(w_1^{i+1} - w_1^i\right)b^i \ge 0, \text{ for } i = 2,\ldots,M-1 \\ w_0^{i+1} - w_0^i + \left(w_1^{i+1} - w_1^i\right)b^{i+1} \ge 0, \text{ for } i = 1,\ldots,M-2 \end{aligned} \tag{20}$$

Hence, the minimization problem (7) can be abstractly formulated as the following constrained optimization problem:

$$\begin{cases} \min\limits_{\boldsymbol{v},\boldsymbol{w}} \sum\limits_{k=1}^{r} \left(\widehat{y}(x_k) - y_k\right)^2 \\ \text{subject to} \quad (13),\ (19) \text{ and } (20). \end{cases} \tag{21}$$

2) Monotonically decreasing property: Similarly, when $u_l \ge 0$ and $u_r \le 0$, according to the conditions in Theorems 2.2, the minimization problem (7) can be abstractly formulated as the following constrained optimization problem:

$$\begin{cases} \min\limits_{\boldsymbol{v},\boldsymbol{w}} \sum\limits_{k=1}^{r} \left(\widehat{y}(x_k) - y_k\right)^2 \\ \text{subject to} \quad (15),\ (19) \text{ and} \end{cases} \tag{22}$$

$$\begin{aligned} w_0^{i+1} - w_0^i + \left(w_1^{i+1} - w_1^i\right)b^i \le 0 \text{ for } i = 2,\ldots,M-1, \\ w_0^{i+1} - w_0^i + \left(w_1^{i+1} - w_1^i\right)b^{i+1} \le 0 \text{ for } i = 1,\ldots,M-2. \end{aligned}$$

3) Even Symmetry: According to Condition 1) in Theorems 2.3, the constraints on the antecedent parameters can be expressed as

$$\begin{aligned} &a^{i+1} \le \underline{a}^{i+1} \le \underline{c}^i \le c^i, \text{ for } i = 1,2,\ldots,\tfrac{M-1}{2}; \\ &c^i \le b^{i+1}, \text{ for } i = 1,2,\ldots,\tfrac{M-3}{2}; \\ &a^i = c^{M-i+1},\ \underline{a}^i = \underline{c}^{M-i+1}, \text{ for } i = 2,\ldots,M; \\ &b^{\frac{M+1}{2}} = 0,\ b^i = b^{M-i+1}, \text{ for } i = 2,\ldots,M-1,\ i \ne \tfrac{M-1}{2}; \end{aligned}$$

Furthermore, the $\frac{5M-9}{2}$ inequalities and the $\frac{5(M-1)}{2}$ equalities can be written as the following matrix form.

$$\begin{bmatrix} W & \mathbf{0}_{\frac{5M-7}{2}\times\frac{5M-7}{2}} \end{bmatrix}\boldsymbol{v} \le \mathbf{0}_{\frac{5M-7}{2}\times 1}, \tag{23}$$

$$\begin{bmatrix} I_{\frac{5M-7}{2}} & \mathbf{0}_{\frac{5M-7}{2}\times 1} & I^R_{\frac{5M-7}{2}} \\ \mathbf{0}_{1\times\frac{5M-7}{2}} & 1 & \mathbf{0}_{1\times\frac{5M-7}{2}} \end{bmatrix}\boldsymbol{v} = \mathbf{0}_{\frac{5(M-1)}{2}\times 1}. \tag{24}$$

where

$$W = \begin{bmatrix} 1 & -1 & 0 & \ldots & 0 & 0 \\ 0 & 1 & -1 & \ldots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \ldots & 1 & -1 \end{bmatrix} \in R^{\frac{5M-7}{2}\times\frac{5M-5}{2}}$$

Hence, the minimization problem (7) can be abstractly formulated as the following constrained optimization problem:

$$\begin{cases} \min\limits_{\boldsymbol{v},\boldsymbol{w}} \sum\limits_{k=1}^{r} \left(\widehat{y}(x_k) - y_k\right)^2 \\ \text{subject to} \quad (17),\ (23) \text{ and } (24). \end{cases} \tag{25}$$

4) Odd Symmetry: Similarly, according to Condition 1) in Theorems 2.4, the minimization problem (7) can be abstractly formulated as the following constrained optimization problem:

$$\begin{cases} \min\limits_{\boldsymbol{v},\boldsymbol{w}} \sum\limits_{k=1}^{r} \left(\widehat{y}(x_k) - y_k\right)^2 \\ \text{subject to} \quad (18),\ (23) \text{ and } (24). \end{cases} \tag{26}$$

In conclusion, we utilize the following steps to construct the IT2FLS via the active-set algorithm:

step 1) Determine the initial value of the antecedent and the consequent parameters of the IT2FLS according to the conditions in Theorems 2.1 – 2.4 and the corresponding prior knowledge.

step 2) Solve (21) for monotonically increasing property; (22) for monotonically decreasing property. Solve (25) for even symmetry; (26) for odd symmetry. And then obtain the antecedent and the consequent parameters of the IT2FLS.

C. Design of IT2FLSs via Hybrid Learning Algorithm

The fuzzy rules of IT2FLSs consist of the antecedent part and the consequent part. We use constrained least squares algorithm to determine the consequent parameters, and then use active-set algorithm to determine the antecedent parameters. The procedure is repeated on the specified demand. Next, we give the design steps of monotonic IT2FLSs and symmetric IT2FLSs, respectively.

1) Design steps of monotonic IT2FLSs:

Step 1) Determine the number of the fuzzy system rules and the initial antecedent and consequent parameters of the IT2FLS, and then solve the following optimization problems to obtain the consequent parameters via constrained least squares algorithm. If a target function monotonically increases, then (27) should be solved.

Else if the target function monotonically decreases, then (28) should be solved.

$$\begin{cases} \min\limits_{\boldsymbol{w}} (\Phi \boldsymbol{w} - \boldsymbol{y})^{\mathrm{T}} (\Phi \boldsymbol{w} - \boldsymbol{y}) \\ \text{subject to} \quad (13). \end{cases} \tag{27}$$

$$\begin{cases} \min\limits_{\boldsymbol{w}} (\Phi \boldsymbol{w} - \boldsymbol{y})^{\mathrm{T}} (\Phi \boldsymbol{w} - \boldsymbol{y}) \\ \text{subject to} \quad (15). \end{cases} \tag{28}$$

Step 2) The consequent parameters are fixed, and only the antecedent parameters are adjusted by solving the following constraint optimization problem via the active-set algorithm.

$$\begin{cases} \min\limits_{\boldsymbol{v}} \sum\limits_{k=1}^{r} \left(\widehat{y}(x_k) - y_k \right)^2 \\ \text{subject to} \quad (19). \end{cases} \tag{29}$$

Step 3) If the overall error measure E is less than a desired level or the number of the iterative steps reaches a specified value, then stop. Otherwise return to Step 1.

2) Design steps of symmetric IT2FLSs:

Step 1) Determine the number of the fuzzy system rules and the initial antecedent and consequent parameters of the IT2FLS, and then solve the following optimization problems to obtain the consequent parameters via constrained least squares algorithm. If a target function is even symmetry, then (30) should be solved. Else if the target function is odd symmetry, then (31) should be solved.

$$\begin{cases} \min\limits_{\boldsymbol{w}} (\Phi \boldsymbol{w} - \boldsymbol{y})^{\mathrm{T}} (\Phi \boldsymbol{w} - \boldsymbol{y}) \\ \text{subject to} \quad (17). \end{cases} \tag{30}$$

$$\begin{cases} \min\limits_{\boldsymbol{w}} (\Phi \boldsymbol{w} - \boldsymbol{y})^{\mathrm{T}} (\Phi \boldsymbol{w} - \boldsymbol{y}) \\ \text{subject to} \quad (18). \end{cases} \tag{31}$$

Step 2) The consequent parameters are fixed, and only the antecedent parameters are adjusted by solving the following constraint optimization problem via the active-set algorithm.

$$\begin{cases} \min\limits_{\boldsymbol{v}} \sum\limits_{k=1}^{r} \left(\widehat{y}(x_k) - y_k \right)^2 \\ \text{subject to} \quad (23) \text{ and } (24). \end{cases} \tag{32}$$

Step 3) If the overall error measure E is less than a desired level or the number of the iterative steps reaches a specified value, then stop. Otherwise return to Step 1.

IV. Simulation

In this section, we will give a simulation to show the usefulness of the prior knowledge and compare constrained least squares algorithm, active-set algorithm and hybrid learning algorithm when the output of a target function is corrupted by white noise.

Consider the following nonlinear function:

$$y = \left(\frac{x}{3} \right)^2 \tanh(|x|), \tag{33}$$

where $x \in U = [-3, 3]$. It is obvious that the curve of Function (33) passes through origin, is even symmetric, monotonically increases when $x \geq 0$, and monotonically decreases when $x \leq 0$.

In order to demonstrate the superiority of IT2FLSs, the output of the target function is corrupted by $Noise$ which is the uniformly distributed noise on interval $[-n_b, n_b]$ $(n_b = 0.2)$. From $\widetilde{y} = y + Noise$, we can create 500-sample-data set $\mathfrak{D}$ whose elements are $(x_i, \widetilde{y}_i)$ $(i = 1, \ldots, 500)$, in which r_k training data were randomly chosen as the elements of training data subset $\mathfrak{D}_k$. From (33), we can create 500-sample-data set $\mathfrak{E}$ whose elements are (x_i, y_i) $(i = 1, \ldots, 500)$, in which r_k sample data were randomly chosen as the elements of test data subset $\mathfrak{E}_k$. In this simulation, five cases are considered, that is, r_k equals 12, 25, 45, 70, 90, where $k = 1, \ldots, 5$.

Firstly, we design a first-order SISO IT2FLS via the above-mentioned three optimization algorithms with and without Prior Knowledge description (PK), and then evaluate the approximation performance and the generalization performance of the IT2FLS, which are measured by Root Mean Square Error (RMSE) of the training data and the test data, and the two performance indices are formulated as follows:

$$ap_k = \left(\frac{1}{r_k} \sum_{i=1}^{r_k} \left(\widehat{y}(x_i) - \widetilde{y}_i \right)^2 \right)^{\frac{1}{2}}, \tag{34}$$

$$gp_k = \left(\frac{1}{r_k} \sum_{i=1}^{r_k} \left(\widehat{y}(x_i) - y_i \right)^2 \right)^{\frac{1}{2}}, \tag{35}$$

where r_k is the size of the training data subset $\mathfrak{D}_k$ and the test data set $\mathfrak{E}_k$ in case k; ap_k can reflect the approximation ability of the IT2FLS for the training data; gp_k can reflect the generalization ability of the IT2FLS for test data. For the two indices, the less the values are, the better the performances are. Also, the statistical indices, ap_{sk} and gp_{sk}, which are the arithmetic mean of the corresponding indices obtained by the random training-test-data-selection process from 30 runs, are shown in Fig. 4 in semilogarithmic coordinates. For the sake of clarity, we plot the performance curves of the three algorithm with PK in cartesian coordinates once again shown in Fig. 5.

From Fig. 4, we observe that, generally, for generalization performance the algorithms with PK perform better than the ones without PK, and for approximation performance the algorithms without PK outperform the ones with PK except for the active-set algorithm. Furthermore, from Fig. 4 and Fig. 8, using the algorithms with PK can obtain better the overall performance, especially when the element number of a data subset is few.

From Fig.5, among the three optimization algorithms with PK, we can observe that the approximation performance and the generalization performance of the IT2FLS are the worst via the active-set algorithm. The IT2FLS achieves the best approximation performance via hybrid learning algorithm, and achieves the best generalization performance via constrained least squares algorithm. The least squares algorithm can overcome overfitting, and can obtain good results for generalization performance. For each iteration, the consequent parameters

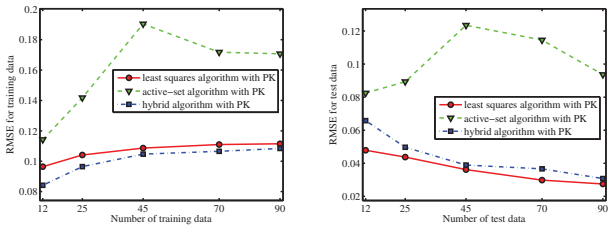
(b)

Fig. 4. The performance curves of the three algorithms with and without prior knowledge description in semilogarithmic coordinates when $r_k \in \{12, 25, 45, 70, 90\}\,(k = 1, \ldots, 5)$ and $n_b = 20\%$: (a) approximation performance (b) generalization performance.



(a) (b)

Fig. 5. The performance curves of the three algorithms with prior knowledge description when $r_k \in \{12, 25, 45, 70, 90\}\,(k = 1, \ldots, 5)$ and $n_b = 20\%$: (a) approximation performance (b) generalization performance.

are updated via the constrained least squares estimator of the hybrid learning algorithm, and then the antecedent parameters are adjusted via the active-set algorithm part of the hybrid learning algorithm. In this case, by adjusting the antecedent parameters the overall error measure E is reduced further, but the algorithm needs iterative computation to achieve the smaller

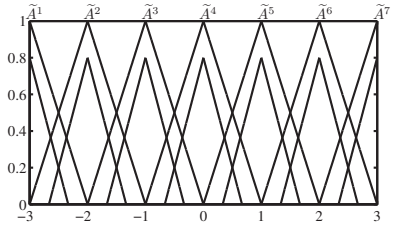


Fig. 6. Type-2 initial fuzzy partition of the IT2FLS.

E. Hence the hybrid learning algorithm can better improve the approximation and the generalization performance than the active-set algorithm, but it consumes more computation time and more computer resources.

We use 7 fuzzy rules to describe the first-order SISO IT2FLS. For each optimization algorithm, the initial fuzzy partitions are shown in Fig. 6. After optimization computation with PK via active-set algorithm and hybrid learning algorithm, the fuzzy partitions of the IT2FLS are shown in Fig. 7(a) and 7(c), and the fuzzy partitions via the algorithms without PK are shown in Fig. 7(b) and 7(d). The consequent parameters of the IT2FLS via the three algorithms with and without PK are listed in Table I and Table II. Note that the fuzzy partitions in Fig. 7(a) and 7(c) and the consequent parameters satisfy the conditions in Theorem 2.1 – 2.3. Fig. 8 is one of identification results of the target function (33). From the figures, we can observe that the identification results are consistent with Fig. 4 and Fig. 5 on the whole.

In conclusion, from the standpoint of the approximation performance, generally speaking, the hybrid learning algorithm is the best among the three optimization algorithm. From the standpoint of the generalization performance and computational complexity, the constrained least squares algorithm is the best among the three optimization algorithm.

V. CONCLUSION

We have presented three efficient methods to design a first-order SISO IT2FLS for function approximation under noisy circumstances. The three kinds of prior knowledge – symmetry, monotonicity and special points are combined with the IT2FLS to solve the grey-box identification problem via constrained least squares algorithm, active-set algorithm and hybrid learning algorithm. From the simulation results and comparisons, we can conclude that the three kinds of prior knowledge can improve the generalization performance of the IT2FLS, and that the hybrid learning algorithm with PK performs best among the three optimization algorithms for approximation capability, and constrained least squares algorithm performs best for the generalization capability and computational complexity.

***Abstract*— The System of Systems (SOS) technology is an advanced technology for Intelligent Systems that is developed with multiple intelligent systems. Recently, there has been a growing interest in a class of complex systems (robotic swarm as an example) whose constituents are themselves complex. Performance optimization, robustness and reliability among an emerging group of heterogeneous systems in order to realize a common goal have become the focus of various applications including military, security, aerospace, space, manufacturing, service industry, environmental systems, and disaster management, to name a few. In this paper, we discuss how Fuzzy Reinforcement Learning (FRL) can be used in SOS.**

Keywords- System of Systems (SOS); Fuzzy Reinforcement Learning (FRL); robots; cooperation; Unmanned Ground Vehicles (UGVs)

I. INTRODUCTION

This paper proposes SOS-Robotics, a software-hardware environment for planning and simulating a group of complex subsystems for management all within a System of Systems (SoS) environment. SOS-Robotics uses DEVS-Java for mathematically simulating the performance of a group of Unmanned Automated Systems (UAS) and assures the correctness of the group performance. The SOS-Robotics will be in demand by many of NASA and DOD organizations that have to manage the performance of groups of highly complex air, land, and undersea robots. SOS-Robotics generates plans for achieving a goal assigned by an operator and can quickly re-plan due to some unexpected events such as weather changes. It will also find many applications in group operations such as response to threats and robotic searches.

A. System of Autonomous Rovers

The system of autonomous rovers, at the IIS Corp-ACE Center, the University of Texas, San Antonio, comprises four components: Base Rover, Swarm Robots, Sensors and a Threat. The sensors represent a standalone system able to sense a Threat and ability to communicate with the Base Rover. The Thereat is spatially dynamic and it is assumed that it is detectable by the chosen sensors. Fig. 1 shows a system of two rovers working outdoor to coordinate Thereat detection collectively. The navigation of this system of rovers was done using GPS along with other sensors. In order to facilitate reasonable outdoor navigation, a task-relevant augmentation of the track rover (Fig. 1), with various sensory and control systems has been realized ([14]). The rover's onboard sensors include a GPS for absolute positioning in outdoor environments, wireless video for a view of the remote environment, ultrasonic range-finding for obstacle detection, 3-axis gyro for orientation, 3-axis accelerometer for motion capture and encoders for monitoring the vehicles velocity. The rover's computation is achieved through an on-board Windows-based PC.

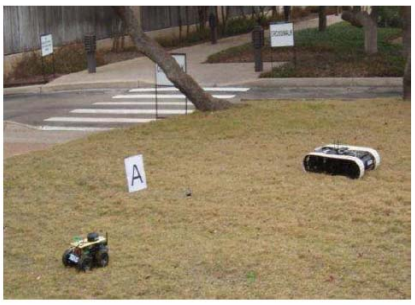

Figure 1. A system of two rovers performing a joint task on a field (Courtesy, ACE Center, University of Texas, San Antonio)

B. Navigation and Task Distribution for a System of Rovers

It is a state-of-the art approach for the coordination of a large number of robots. Fig. 2 shows such a scenario where ground robots are working together with a UAV. The UAV can survey a particular zone of interest. If it finds an object of interest (or a potential threat) in this zone then it can communicate to the ground robots and instruct them to further check it out. The ground robots can also communicate and coordinate among themselves to accomplish the task properly. They can also send the status report of their individual tasks back to the UAV or to a manned supervisory station for further instructions. To achieve such coordination capabilities, swarm robotics have many underlying issues that need to be addressed in order to create a practically applicable system. Robot communication, path planning, tracking, workload distribution, choice of sensors, system reliability, is just some of the most basic issues that need to be addressed. This work addresses the path planning, tracking and navigation so that mobile robots can reach to the object of interest effectively. In order to interact and distribute the task among the members, it is needed to create a communication system with a common protocol.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

The communication protocol needs to be dynamically expandable where additional robots can be added easily during a real-time application. Exact requirements of data types in the communication protocol can vary depending upon the swarm mission. On the ground domain, two wheeled robots, one track-robot and four small scout robots work together (two Pioneer P2-AT8 slip-drive robots from ActivMedia Mobile Robotics and one custom built track-robot). To coordinate commands within the ground swarm, one robot acts as the master. These are equipped with GPS receivers and radio modems for proper navigation and communication. The aerial domain consists of one fixed-wing aircraft (KADET, LT-40) with radio modem, GPS and a camera for proper communication, navigation and surveillance. Utilizing the GPS, camera and the processing suite on-board the aircraft, an estimated location of an object of interest is identified. This estimated GPS location can be sent to the master on the ground in order to investigate the object of interest. Once the master of the ground swarm evaluates the transmitted commands to investigate GPS coordinates, it directs the slave robots to search the surrounding areas of the object of interest. When the slave robots reach their destination, the mission task can be performed as directed by the ground master. Fig. 3 shows the real time GPS based navigation of Pioneer II P2AT-8 robot.

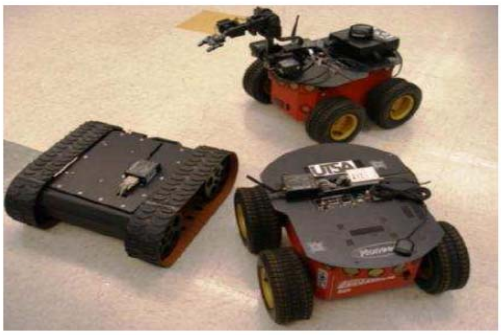

Figure 3. Pioneer II P2AT-8 Detector-Robot, Loader-Robot, Carrier-Robot and custom built robots at ACE Lab. (Courtesy, ACE Center, University of Texas, San Antonio)

In this approach, the environment and the Robotic agents will be simulated including real Robots in the environment. Without a real UAS in the field, a simulation of UAST specific scenarios cannot generate realistic test and evaluation parameters and results. Thus, in the proposed approach, the environment and UAS agents need be modeled accurately such that the simulation environment can have real UAS agents as well as virtual agents. This is extremely critical if the emergent or social behaviors of a team of UAS are being evaluated. For example, a UAS agent can be evaluated in a swarm of UAS agents by creating virtual swarms in the simulation environment and assigning a task to the swarm. The same approach can be used when a multi-modal decision making capabilities of a team of UAS is being evaluated.

II. TECHNICAL APPROACH

The problem of threat detection in an environment is considered. Three systems, comprising of robots and sensors, are proposed to form a system of systems to find a solution to this problem. In the land part of the proposed work, three wheel robots and a track robot comprise a system of rovers. The small wheel robots are in charge of detecting spots which are considered as threatening spots and they communicate with the big track robot to report the fire to the master robot (the track robot) and send and receive data through the designed communication scheme in order to do the desired tasks as a part of a system of systems.

A set of independent robots managed by System of Systems (SoS) architecture and programmed in DEVSJAVA [15-16] is proposed to serve as long term. The IIS Corp- University of Texas at San Antonio's Autonomous Control Engineering (ACE) lab has the objective to build and deploy Land, Air and Sea autonomous robotic vehicles that can independently operate toward a common pre-programmed objective.

In real world systems, the problem is addressed in a higher level where the systems send and receive data from other systems in the SoS and make a decision that leads the SoS to its global goals. Let's take the military surveillance example where different units of the Army collect data through sensors to locate a threat or to determine the identity of a target. In this type of situations, army command center receives data from these heterogeneous sensor systems such as AWACS, ground RADARS, and submarines. These systems are the parts of the SoS that make the decision; say the command and control station. However, they may be developed with different technologies. This will create a huge barrier in data aggregation and data fusion using the data received from these systems because they would not be able to interact successfully without hardware and/or software compatible [14]. In addition, the data coming from these systems are not unified which will add to the barrier in data aggregation and cooperation among the SoS components.

One solution to the problem is to modify the communication medium among the SoS components. Two possible ways of accomplishing this task are:

A. *Create a Software Model of Each System*

In this approach, each component in the SoS talks to a software module embedded in itself. The software module collects data from the system and through the software model generates outputs and sends to the other SoS components. If these software modules are written with a common architecture and a common language, then the SoS components can communicate effectively regardless of their internal hardware and/or software architectures [14].

Create a common language to describe data, where each system can express its data in this common language so that other SoS components can parse the data successfully.

The overhead that needs to be generated to have software models of each system on a SoS could be enormous and must be redone for new member of the SoS. In addition, this requires the complete knowledge of the state-space model of each SoS components, which is often not possible.

Consequently, recent research on SoS concepts focus on the study of coming up with a common language to describe the data of each system in a SoS in order to create an effective communication medium in the SoS. There are some research activities on using a language based on Extensible Markup Language (XML) in order to wrap data coming from different sources in a common way [13-14]. In these research activities, the XML is used to describe each component of the SoS and their data in a unifying way. If XML based data architecture is used in a SoS, only requirement for the SoS components is to understand/parse XML file received from the components of the SoS [13-14].

B. *Integration*

Integration is extremely important for both SoS and robotic swarms since both needs to expand and shrink with ease during the operation. In a SoS, it is critical to have the ability to bring a system into the SoS without any major problem such as redesign, restart, and/or reprogram the system. Integration in a SoS has two main components. The first one is to have adaptive communication schemes which allow the inclusion of a new system member. The second one is to have a common language which any new system can send its data to other systems in the SoS without any difficulty or major effort. The common language such as XML is a critical necessity for a SoS. The architecture for such as language can be incorporated with a discrete event simulation tool so that the SoS concepts can be simulated before they are applied to real problems. Consequently, the integration characteristics of a SoS require effective and adaptive communication among the systems. When the systems in a SoS are heterogeneous in hardware and software, the XML like common language becomes very essential. However, since all the members in a swarm have either identical or very similar hardware and software components, necessity of a common language is not so critical. Thus, in a robotic swarm, the design need not have an XML like common language. Instead, a common protocol or a common format will suffice.

The communication scheme needs to have ability to adapt itself for the population changes in the swarm. In order to achieve this goal, processes for accepting new members to the swarm and removing a member from a swarm need to be implemented as part of the communication scheme.

III. FUZZY REINFORCEMENT LEARNING (FRL) IN SOS

In this section, we discuss how fuzzy control can be used for an unmanned Air Vehicle. This is based on the works of Gomez and Jamshidi [8]. There are a total of six output variables that need to be fuzzified and they are: roll, pitch, airspeed, airspeed error, heading error and altitude error. The ranges of these variables are given in Table I.

TABLE I. VARIABLE RANGES

Variable	Actual Range		Range Used	
Altitude Error	-1 km	1 km	-0.5 m	0.5 m
Heading Error	-360°	360°	-1°	1°
Pitch	-180°	180°	-10°	10°
Roll	-180°	180°	5°	5°
Airspeed Error & Heading Control	-100 m/s	100 m/s	-100 m/s	100 m/s
Altitude & Throttle Control	-0.1	0	-0.01	0

It is possible to create a fuzzy controller that will encase the whole range of values for each variable, but it will take a large number of rules making the calculation of the control much slower. The range used to decide the placement of the membership functions was decided by the fact that we want to reduce the number of rules. By taking a small range and scaling the different variables allows for a smaller number of rules, and the precision will not be lost.

The following figures represent the membership functions of the linguistic variables used for the creation of the different controls. The higher the precision the better the fuzzy controller will function, but it also means more memory needed to store those values. The same can be said about the number of membership functions, a bigger number usually means a smoother control output. Thus, the increase in membership functions leads to an increase in the number of rules

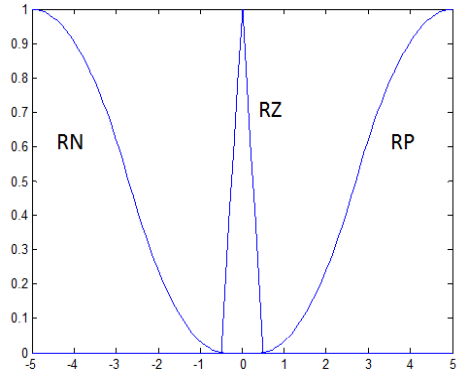

Figure 4. Roll membership functions

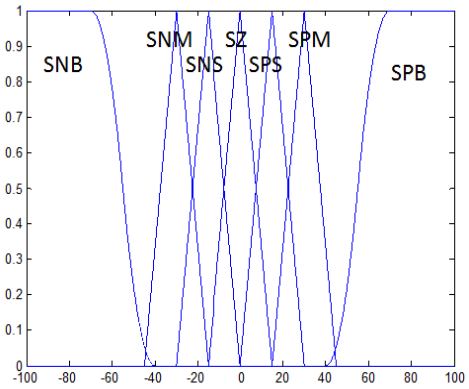

Figure 5. Control output membership functions

If Heading Error is HP and Roll is RP
then Heading Control is SNB
⋮
If Heading Error is HN and Roll is RN
then Heading Control is SPB

The relationship between the altitude error and the pitch angle create the control surface. The higher the precision the better the fuzzy controller will function, but it also means more memory needed to store those values. The same can be said about the number of membership functions, a bigger number usually means a smoother control output. Thus, the increase in membership functions leads to an increase in the number of rules

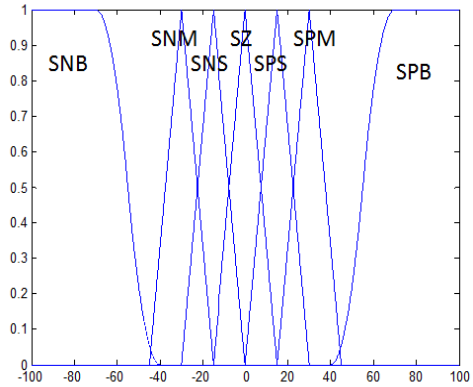

Figure 6. Control output membership functions

If Heading Error is HP and Roll is RP
then Heading Control is SNB
⋮
If Heading Error is HN and Roll is RN
then Heading Control is SPB

If Heading Error is HP and Roll is RP
then Heading Control is SNB
⋮
If Heading Error is HN and Roll is RN
then Heading Control is SPB

A simple graphical example of how the different rules give us the control output is shown in the figure below.

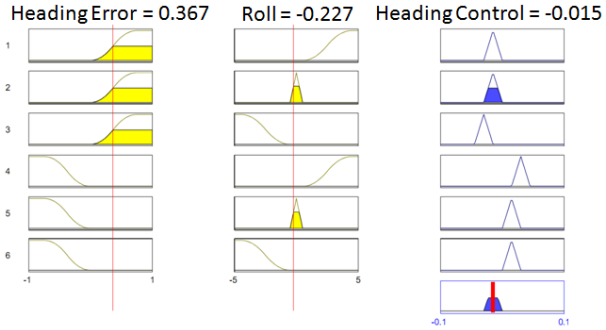

Figure 7. Visual representation of the altitude control rules

The same procedure was followed to create the heading control, six rules relating the heading error and the roll, and an extra rule to maintain the airplane from over rolling.

FRL can be applied for formation control of UGVs according to [3]. For navigation of UGVs, Fuzzy rules can be written according to the above and their parameters can be updated based on GARIC-Q [5,6] and MULTI-GARIC-Q [6]. The use of FRL is not limited to UGVs only and any system of our SOS can use FRL for updating its parameters. For example, [1] focuses on using the FRL for UAVs.

IV. SYSTEM OF SYSTEMS SIMULATION

In a System of Systems, systems and/or subsystems often interact with each other because of interoperability and over all integration of the SoS. These interactions can be achieved by efficient communication among the systems using either peer-to-peer communication or through central coordinator in a given SoS. Since the systems within a SoS are operationally independent, interactions between systems are generally asynchronous in nature. A simple yet robust solution to handle such asynchronous interactions (specifically, receiving messages) is to throw an event at the receiving end to capture the messages from single or multiple systems. Such system interactions can be represented effectively as discrete-event models [15]. In discrete-event modeling, events are generated at variable time intervals as opposed to some pre-determined time interval seen commonly in discrete-time systems. More specifically, the state change of a discrete-event system happens only upon arrival (or generation) of an event, not necessarily at equally spaced time intervals. To this end, a discrete-event model is a feasible approach in simulating the proposed SoS framework and its interaction [15]. Several discrete-event simulation engines [13-16] are available that can be used in simulating interaction in a heterogeneous mixture of

independent systems. We consider one such simulation framework – Discrete Event System Specification (DEVS) because of the available effective mathematical representation and its support to distributed simulation using DoD's High Level Architecture (HLA).

A. DEVS Modeling and Simulation

Discrete Event System Specification (DEVS) [13-16] is a formalism, which provides a means of specifying the components of a system in a discrete event simulation. In DEVS formalism, one must specify *Basic Models* and how these models are connected together. These basic models are called *Atomic* models and larger models which are obtained by connecting these atomic blocks in meaningful fashion are called *Coupled* models. Each of these atomic models has *inports* (to receive external events), *outports* (to send events), a set of *state variables*, *internal transition*, *external transition*, and *time advance functions*.

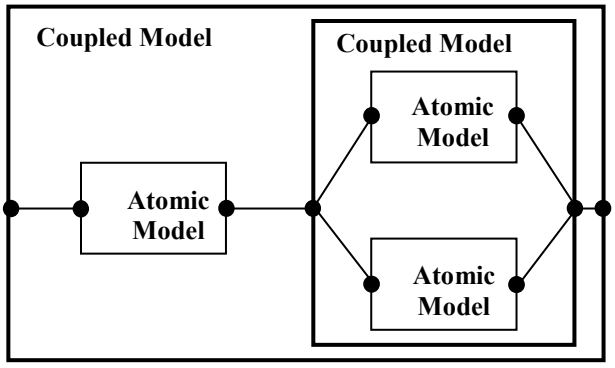

Figure 8. DEVS models for system and sub-systems

Next we present a simulation example using the DEVS simulation environment [13-16]. This is a scenario where a target is being tracked by a group of sensors deployed in the region of interest. The sensors are grouped to form clusters, with each cluster having a cluster-head that can send and receive information to a command center (base-station). The entire simulation can be performed by "coupling" all the DEVS atomic models together with meaningful interconnections. In order to test our SoS architecture in the DEVS environment, our XML based data representation needs to be embedded in to the simulation environment.

B. XML and DEVS

In DEVS, messages can be passed from one system (coupled or atomic model) to another using either predefined or user-defined message formats. Since the systems within a SoS maybe different in hardware and/or software, there is a need for a unifying language for message passing. Each system need not necessarily have the knowledge (operation, implementation, timing, data issues, and so on) of another system in a SoS. Therefore, one has to work at a high-level (information or data level) in order to understand the present working condition of the system. Fig. 9 describes conceptually a SoS simulation example to show the use of XML in the DEVS formalism.

C. SOS Simulation Framework

Based on the system of systems architecture, we have simulated robust threat detection data aggregation Scenario) where there is a base robot, two swarm robots, five sensors, and a threat. The sensors are stationed such that they represent a sensor network covering an area. The threat is moving in the area and is detected by sensors when the threat is sufficiently close to a sensor node. All sensors communicate with a base robot which itself does not actively seek threat. Instead, the base robot processes the information using sensor data and data sent by swarm robots. A command center can collect processed data (aggregated data) from the base robot without interacting with other components of the SoS such as sensors and swarm robots. Robust threat detection works as follows. When a sensor detects the threat, they notify the Base Robot. Then, the Base Robot sends the Swarm Robots the location of the threat based on the information sent by the sensors. This is crucial in order to get rid of false detections as they can cause inefficient usage of system components.

D. XML Format

As mentioned before, the hardware and/or software architectures of these systems will not be the same in reality. Thus, they may not able to talk to each other successfully even though they can operate independently. We have implemented XML based SoS, message architecture in DEVSJAVA software [15]. In this XML based message architecture, each system has an XML-like message consisting of their name and a data vector. The name of each system represents an XML tag. The data vectors are used to hold the data of the systems. The length of the data vectors in each system can be different based on the amount of data each system contains.

***Abstract*—Sequential fuzzy co-cluster extraction has been proven to be useful for collaborative filtering tasks by extracting user-item co-clusters, in which promising items are connected to the corresponding users in each co-cluster. Since some popular items can be shared by multiple clusters in collaborative filtering problems, exclusive conditions, which force objects to belong to only one cluster, were used only for users. In this paper, it is demonstrated that such user-only exclusive conditions may cause poor clustering results, and partially exclusive conditions, in which part of items are also forced to be exclusive, are introduced. In addition, connections with neural approaches for co-clustering are discussed, in which co-clustering problems are identified using a modified model of principal component analysis.**

***Keywords*—co-clustering, collaborative filtering, principal component analysis.**

I. Introduction

Collaborative filtering is a promising approach for achieving personalized recommendation in network communities [1]. Many collaborative filtering algorithms are based on the concept of connecting promising items to users by considering mutual similarities among users (and/or items) [2], [3]. Co-clustering is a direct approach for extracting user-item clusters, in which not only similar users but also their associated items are gathered into a cluster. Once we estimate co-cluster structures buried in user-item relational data matrices, items that are supposed to be closely related are recommended to their corresponding users [4], [5].

Honda *et al.* [6], [7] proposed a sequential approach for the fuzzy co-clustering model, which is a combination of the structural balancing model in social science [9] and sequential fuzzy cluster extraction [10]. In collaborative filtering tasks, the co-clustering model plays a role for simultaneously partitioning users and items into several clusters by calculating the principal eigenvector of a modified adjacency matrix. In order to disjoint clusters, penalty weights are added to the diagonal elements of the adjacency matrix. Besides the fully exclusive condition where all users and items can belong to only a single cluster, the user-only exclusive condition can also be applied in such a case where some popular items are shared by multiple clusters. In a collaborative filtering problem, it was demonstrated that the sequential co-clustering model obtained using the user-only exclusive condition has a high recommendation ability with a low memory requirement. In addition, a modified calculation algorithm for reducing computational costs in cluster structure estimation was proposed, which makes it possible to easily apply the co-cluster structural information to new users [8].

In collaborative filtering tasks, it is also possible that some typical items can be used to distinguish a small community having a special preference. Such typical items should be assigned to only a single cluster, while popular items can be shared by multiple clusters. In this paper, a partially exclusive condition is introduced, in which some items are forced to be exclusive, while other popular items can be shared.

Recently, Oja [11] discussed co-clustering problems (bi-clustering problems) in the context of a modified principal component analysis (PCA) approach. This paper also discusses some connections with such neural approaches.

The remainder of this paper is organized as follows: Section II briefly reviews the sequential approach for fuzzy co-cluster extraction. Section III introduces the partially exclusive condition for items and presents a discussion of the relationship with other co-clustering models. Section IV presents several experimental results in order to demonstrate the characteristic features of the proposed approach. Section V summarizes the conclusions of this paper.

II. Brief Review of Sequential Approach for Fuzzy Co-cluster Extraction

A. Structural Balance and Sequential Fuzzy Cluster Extraction

Assume that we have a graph G defined by an adjacency matrix $A(G) = [a_{ij}]$, the elements of which are

$$a_{ij} = \begin{cases} 1 & : \text{if } i \text{ and } j \text{ have positive relation,} \\ -1 & : \text{if } i \text{ and } j \text{ have negative relation,} \\ 0 & : \text{if the relation of } i \text{ and } j \text{ does not exist.} \end{cases} \quad (1)$$

The structure theorem proposed by Cartwright and Harary [9] revealed that the set of vertices (notions) can be partitioned into two subsets (one of which may be empty), the elements of which have positive relations with members of the same subset and negative relations with members of different subsets in a balanced system.

Katai and Iwai [12] discussed how to derive an approximately optimum two-cluster structure and proposed a tech-

This work was funded in part by the Ministry of Internal Affairs and Communications, Japan, under the Strategic Information and Communications R&D Promotion Programme (SCOPE) and in part by the Ministry of Education, Culture, Sports, Science and Technology, Japan, through a Grant-in-Aid for Scientific Research (20700214).

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

nique for calculating a cluster indicator using the eigenvector of $A(G)$ corresponding to the maximum eigenvalue.

The calculation procedure in the eigenvalue problem has some connections with sequential fuzzy clustering models although they use different types of similarity matrices. Fuzzy clustering, most of the algorithms of which are motivated by fuzzy c-Means (FCM) [13], is an unsupervised classification method that can deal with ambiguous boundaries among clusters or overlapping clusters using fuzzy memberships. In addition to FCM-like batch algorithms, sequential clustering models extract clusters having high degrees of aggregation one by one.

Sequential fuzzy cluster extraction (SFCE) [10] estimates cluster memberships by calculating the eigenvector of a modified similarity matrix. Let e_{ij} be the similarity between samples i and j ($e_{ij} = e_{ji}$, $e_{ij} \geq 0$). Here, the goal is to extract a fuzzy cluster having the maximum degree of aggregation. The criterion function to be maximized is formulated as:

$$L_{sfce} = \sum_{i=1}^{n} \sum_{\substack{j=1 \\ j \neq i}}^{n} e_{ij} w_{1i} w_{1j}, \tag{2}$$

where $\boldsymbol{w}_1 = (w_{11}, \ldots, w_{1n})^\top$ is an n-dimensional membership indicator vector satisfying the following constraints:

$$0 \leq w_{1i} \leq 1, \quad i = 1, \ldots, n, \tag{3}$$

$$||\boldsymbol{w}_1||^2 = \sum_{i=1}^{n} w_{1i}^2 = 1. \tag{4}$$

The optimal cluster indicator for the first cluster $\boldsymbol{w}_1$ is derived as the eigenvector corresponding to the largest eigenvalue of the modified similarity matrix $S = \{s_{ij}\}$ [10]:

$$s_{ij} = \begin{cases} e_{ij} & ; i \neq j \\ 0 & ; i = j \end{cases}$$

In order to obtain K disjoint clusters one by one, the optimization problem must be solved repeatedly under the additional constraint that $\boldsymbol{w}_k^\top \boldsymbol{w}_{k-1} = \cdots = \boldsymbol{w}_k^\top \boldsymbol{w}_1 = 0$.

Tsuda et al. [10] introduced a penalty term to the aggregation criterion in order to avoid duplication, as follows:

$$L_{sfce} = \sum_{i=1}^{n} \sum_{\substack{j=1 \\ j \neq i}}^{n} e_{ij} w_{ki} w_{kj} - \frac{1}{k-1} \sum_{t=1}^{k-1} \beta_t \mathrm{dup}(\boldsymbol{w}_k, \boldsymbol{w}_t), \tag{5}$$

where the penalty term $\mathrm{dup}(\boldsymbol{w}_k, \boldsymbol{w}_t)$ is the duplication measure to be minimized, and β_t is the weight for the penalty to be set by users. In [10], β_t was determined by the degree of cluster aggregation, as follows:

$$\beta_t = \eta \sum_{i=1}^{n} \sum_{\substack{j=1 \\ j \neq i}}^{n} e_{ij} w_{ti} w_{tj}. \tag{6}$$

The weight η is tuned so that the additional penalty term is sufficiently larger than the aggregation criterion.

The optimal solution for $\boldsymbol{w}_k$ is then given as the eigenvector corresponding to the largest eigenvalue of the modified similarity matrix $S_k = \{s_{kij}\}$:

$$s_{kij} = \begin{cases} e_{ij} & ; i \neq j \\ -\dfrac{1}{k-1} \displaystyle\sum_{t=1}^{k-1} \beta_t w_{ti}^2 & ; i = j \end{cases}$$

B. Sequential Fuzzy Co-cluster Extraction

In order to apply the SFCE clustering model to rectangular relational matrices given in collaborative filtering problems, Honda *et al.* [6], [7] combined the concepts of the structural balancing approach. Davis [14] implied that a signed graph having two clusters is further clusterable if each positive line joins two nodes in the same subset but is not clusterable for different subsets. Taking Davis's suggestion into account, Honda et al. introduced a modified relational data matrix, in which only positive relations in the rectangular relational matrix were considered in order to extract subsets.

Assume that there are n users and m items and that we have an $n \times m$ partial adjacency matrix $Z = [z_{ij}]$, where z_{ij} is given by:

$$z_{ij} = \begin{cases} 1 & \text{if } x_{ij} \geq \epsilon \text{ (positive relation)}, \\ -1 & \text{if } x_{ij} < \epsilon \text{ (negative relation)}, \\ 0 & \text{if } i \text{ did not evaluate } j, \end{cases} \tag{7}$$

where x_{ij} is the evaluation value for item j by user i and ϵ is a pre-defined threshold.

This type of relational matrix is called "a rectangular relational" matrix and most relational clustering models can be applied only after reconstruction of the full-square relational matrix. For example, Bezdek *et al.* [15] performed visual assessment of the cluster tendency by imputing missing relations (user-user relations and item-item relations) based on a concept similar to the Expectation-Maximization (EM) algorithm [16]. The goal of collaborative filtering, however, is the estimation of missing relations, and such preprocessing as imputation is not applicable.

In [6], the influences of missing relations (user-user relations and item-item relations) were ignored based on the concept of the structural balancing approach, and the diagonal block matrices corresponding to user-user relations and item-item relations were given by zero-matrices. In addition, all elements of the relational data matrix must be non-negative elements if we want to apply SFCE to the square relational matrices. Taking Davis's suggestion into account, in [6], only positive relations in the rectangular relational matrix are considered to extract subsets, such that each positive line joins users and items in the same subset, and the partial adjacency matrix $Z = [z_{ij}]$ is generated by ignoring not only negative relations but also unknown relations, as follows:

$$z_{ij} = \begin{cases} 1 & \text{if } x_{ij} \geq \epsilon \text{ (positive relation)}, \\ 0 & \text{if } x_{ij} < \epsilon \text{ (negative relation)}, \\ 0 & \text{if } i \text{ did not evaluate } j. \end{cases} \tag{8}$$

For example, this type of relational data is common in purchase history data, in which the zero-relation of 'not yet bought'

includes both 'negative feelings toward an item' and 'not yet but might buy'.

Then, the modified similarity matrix $S = \{s_{ij}\}$ is given as the following $(n+m) \times (n+m)$ block matrix:

$$S = \begin{pmatrix} O & Z \\ Z^\top & O \end{pmatrix}. \tag{9}$$

If all users and items are disjoint, then the constraint for indicator vectors $\boldsymbol{w}_1, \ldots, \boldsymbol{w}_k$ is given by $\boldsymbol{w}_k^\top \boldsymbol{w}_{k-1} = \cdots = \boldsymbol{w}_k^\top \boldsymbol{w}_1 = 0$. On the other hand, if all users are disjoint, but some items can be shared, then the exclusive condition is forced only on users. Let $\boldsymbol{w}_t = (\boldsymbol{w}_t^{u\top}, \boldsymbol{w}_t^{i\top})^\top$, where $\boldsymbol{w}_t^u = (w_{t1}, \ldots, w_{tn})^\top$ and $\boldsymbol{w}_t^i = (w_{t(n+1)}, \ldots, w_{t(n+m)})^\top$. The user-only exclusive constraint is given as $\boldsymbol{w}_k^{u\top} \boldsymbol{w}_{k-1}^u = \cdots = \boldsymbol{w}_k^{u\top} \boldsymbol{w}_1^u = 0$, and the diagonal elements of the modified similarity matrix s_{ii} for k-th cluster are re-formulated as

$$s_{ii} = \begin{cases} -\frac{1}{k-1} \sum_{t=1}^{k-1} \beta_t w_{ti}^2 & ; i \leq n \\ 0 & ; i > n \end{cases} \tag{10}$$

In order to reduce the computational cost of eigenvalue problems, an improved procedure was proposed [8], in which two membership vectors of $\boldsymbol{w}_1^u$ for users and $\boldsymbol{w}_1^i$ for items are calculated separately. In the improved procedure, either of $\boldsymbol{w}_1^u$ or $\boldsymbol{w}_1^i$ is first calculated by solving an eigenvalue problem of a smaller relational matrix (the size of the relational matrix is reduced by 75% or more) and the remaining membership indicator is calculated by a simple calculation process. Divided calculation processes are also useful for handling new users or items without re-calculating the eigenvalues.

III. Partially Exclusive Condition and Connection With Other Models

A. Partially Exclusive Condition for Sequential Fuzzy Co-cluster Extraction

In collaborative filtering tasks, it is often the case that some popular items may be preferred by many people having various preference characteristics. Therefore, such popular items should be shared by multiple clusters and the user-only exclusive condition appears to be reasonable for finding items to be recommended to users classified into disjoint clusters. It is also possible that some typical items can be used to distinguish a small community having special preferences. Such typical items should be assigned to only a single cluster in order to be assigned to users having such special preferences for the single cluster while popular items can be shared by multiple clusters. In this paper, a partially exclusive condition is introduced, in which certain items are forced to be exclusive while other popular items can be shared.

Without loss of generality, assume that the first p among m items are to be assigned only to a single cluster and the others can be shared by multiple clusters. The exclusive condition, which forces an item to have a large membership value only in a single cluster, is used only for certain items.

$$w_{k(n+j)} \cdot w_{(k-1)(n+j)} = \cdots = w_{k(n+j)} \cdot w_{1(n+j)} = 0, \quad j = 1, \ldots, p. \tag{11}$$

Here, all users are forced to be exclusive as $\boldsymbol{w}_k^{u\top} \boldsymbol{w}_{k-1}^u = \cdots = \boldsymbol{w}_k^{u\top} \boldsymbol{w}_1^u = 0$.

Then, in order to achieve the partially exclusive condition, the diagonal elements of the modified similarity matrix s_{ii} for the k-th cluster are re-defined as

$$s_{ii} = \begin{cases} -\frac{1}{k-1} \sum_{t=1}^{k-1} \beta_t w_{ti}^2 & ; i \leq n+p \\ 0 & ; i > n+p \end{cases} \tag{12}$$

The clustering algorithm is equivalent to the conventional clustering algorithm without the penalty weights.

B. Connection With Other Models

Fuzzy clustering for categorical multivariate (FCCM) data [17] and fuzzy co-clustering of documents and keywords (Fuzzy CoDoK) [18] are FCM-type co-clustering models, in which the relational fuzzy c-Means (RFCM) [19] for square relational matrices is extended for rectangular matrices using two different types of memberships. The first type of membership is the conventional fuzzy membership for objects, which are forced to be exclusive, and the second type of membership is the additional membership for items, which represents the relative typicalities of items in each cluster. In this clustering model, the item memberships are used not for partitioning items, but rather for finding representative items in each cluster. Therefore, certain items can be shared by multiple clusters, and the clustering model has similar features to sequential fuzzy co-cluster extraction under the user-only exclusive condition although FCM-type models are easily influenced by model parameters and missing elements [7]. In addition, FCM-type models cannot consider the partially exclusive condition for items.

Recently, Oja [11] discussed co-clustering problems (bi-clustering problems) in the context of a modified principal component analysis (PCA) approach. When we have an $n \times m$ data matrix X and the m columns are considered to be data vectors, the approximation $X \approx WW^\top X$ performs sparse feature extraction. On the other hand, if n rows are considered to be data vectors, an approximation $X \approx XWW^\top$ performs clustering of the rows. If all of the elements of the data matrix X are non-negative, as in the case of the modified adjacency matrix given by Eq.(9) for sequential fuzzy co-cluster extraction, the matrix factorization process can be reduced to the estimation of an almost orthogonal non-negative matrix W [20]. Then, a biclustering model is constructed based on the approximation $X \approx LL^\top XRR^\top$, in which L and R are the cluster indicators for row and column objects, respectively. The multiplicative rules for neural learning have been reported in [11]. In addition, as suggested in [21], non-negative learning tends to yield high orthogonality. Therefore, the biclustering model essentially forces the exclusive condition to both row and column objects and has features similar to sequential fuzzy co-cluster extraction under the fully exclusive condition. In order to achieve the partially exclusive condition in the neural approach, some modifications are necessary in the approximation part.

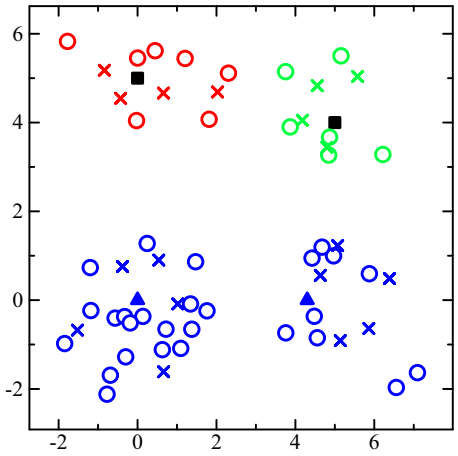

Fig. 2. Cluster partition obtained under fully exclusive condition

IV. Numerical Experiments

In this section, experimental results are presented in order to demonstrate the characteristic features of the proposed approach.

A. Artificial Data Set

Figure 1 shows the artificially generated data set used in this experiment, in which ○ and × denote users and items, respectively. The data set, which was composed of 40 users and 20 items, formed four loose clusters in a 2-D space, and the lower two masses are larger than the upper two masses. Black triangles and squares are shared items that should belong to two clusters, e.g., the item shown in the black triangle is shared by the lower two clusters. Then, a 40×20 relational data matrix $Z = [z_{ij}]$, the elements of which are given by an alternative process, was constructed by calculating mutual Euclidean distances d_{ij} among users and items. Here, d_{ij} for the shared items (black triangle and square) is given by the distance to the nearest mark. The element z_{ij} was given by

$$z_{ij} = \begin{cases} 1 & \text{if } d_{ij}^2 \leq 10, \\ 0 & \text{if } d_{ij}^2 > 10, \end{cases} \tag{13}$$

which is calculated by Eq.(8) with $\epsilon = 10$. The modified similarity matrix $S = \{s_{ij}\}$ was calculated using Eq.(9). The cluster number k and the penalty weight η were set as $k = 3$ and $\eta = 10$, respectively.

First, the data set was partitioned by sequential fuzzy co-cluster extraction under the fully exclusive condition. The maximum membership partition is shown in Fig. 2. The item indicated by the black square had very small membership degrees in all clusters. Because of the strong influence of the most popular item (blue triangle), the lower two masses (larger data masses) were merged into a dominant single cluster. The exclusive condition forcing all items to belong to only one cluster tends to generate a far more dominant cluster and may fail to find useful structural information.

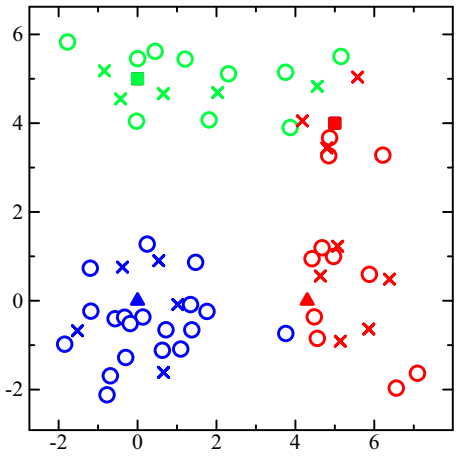

Fig. 3. Cluster partition obtained under user-only exclusive condition

Second, the data set was partitioned under the user-only exclusive condition. Figure 3 shows the derived cluster partition. Since the most popular item (filled triangle) is shared by two clusters (blue and red clusters), the lower two data masses were successfully partitioned. However, the items denoted by the filled squares were also illegally shared by the green and red clusters because these items were weakly shared by many users. Then, the upper right cluster was divided into two clusters. The results imply that the user-only exclusive condition may destroy the cluster structure of small data masses.

Third, the data set was partitioned with the proposed partially exclusive condition and the cluster partition shown in Fig. 4 was derived. Here, only the item indicated by the black square was forced to be exclusive. Using a partially exclusive condition, the intrinsic co-cluster structure was clarified.

In this way, the proposed approach, in which only some of the items are forced to be exclusive, is useful for decreasing the inappropriate influences of popular items and weakly shared items.

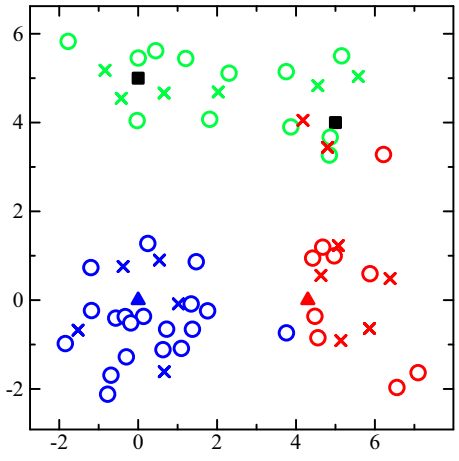

Fig. 4. Cluster partition obtained under partially exclusive condition

B. Purchase History Data

Next, a purchase history data set collected by Nikkei Inc. in 2000 is used in a collaborative filtering task. The data set used in [7] includes the purchase history of 996 users ($n = 996$) on 18 items ($m = 18$). The elements z_{ij} of 996×18 relational data matrix $Z = [z_{ij}]$ is 1 if user i has item j while otherwise 0. In this experiment, Piano (the 2nd item), VD (the 8th item) and Oven (the 14th item), which relatively fewer users have, are selected for items to be predicted, and the goal is to predict the applicability of the items for the second half of 996 users whose corresponding element z_{ij} were all withheld so as to be '$z_{ij} = 0$'.

First, the users and items were partitioned into 10 co-clusters under the constraint of $\boldsymbol{w}_k^{u\top}\boldsymbol{w}_{k-1}^{u} = \cdots = \boldsymbol{w}_k^{u\top}\boldsymbol{w}_1^{u} = 0$, where all items can be shared by multiple clusters. Then, the applicability of the target items for each user was predicted by considering the fuzzy membership degrees of the items to the cluster, in which the user have the maximum membership. If the membership degree of the target item to the cluster is higher than a threshold, the item is recommended to the user.

Second, 10 co-clusters were extracted by forcing the 15th item (Coffee Maker) to be exclusive. The 15th item was selected because its average membership degree was the smallest in the first co-cluster extraction, i.e., it might be only weakly shared by all clusters without belonging to a certain cluster. So, in this second co-cluster extraction, the 15th item was assigned only to a single cluster under exclusive condition without belonging to all clusters.

Table I compares the recommendation abilities of the two co-cluster partitions. The recommendation ability is assessed by ROC sensitivity [22]. The ROC curve is a true positive rate vs. false positive rate plots drawn by changing the threshold of the applicability level in recommendation, and the lower are of the curve becomes large as the recommendation ability is higher. The table implies that the proposed model with the partially exclusive condition has higher recommendation ability than the conventional model.

TABLE I
COMPARISON OF RECOMMENDATION ABILITIES: AREA OF LOWER PART OF ROC CURVES

item	conventional	partial exclusive
Piano	0.644	0.651
VD	0.547	0.578
Oven	0.575	0.598

V. CONCLUSION

In this paper, a modified condition for fuzzy co-clustering was considered. It was demonstrated that the partially exclusive condition is useful for clarifying intrinsic co-cluster structures when some items are very popular with or are weakly shared by many users. In a comparative discussion, it was revealed that the sequential fuzzy co-clustering model can derive similar partitions to both FCM-type co-clustering models and neuro-learning-based biclustering models using different exclusive conditions while the partially exclusive condition yields another type of cluster partition.

In a collaborative filtering task, an item that was weakly shared by all clusters was forced to be exclusive so that it assigned to a single cluster without evenly belonging to all clusters. Then, the recommendation ability for items that relatively fewer users have could be improved by considering the partially exclusive condition.

A potential future work is to develop a technique for evaluating the degree of responsibility of items in order to automatically select items to be made exclusive.

Abstract— **Data Envelopment Analysis (DEA) is a method for evaluating the management efficiency of Decision Making Units (DMUs) relatively. However, when the number of inputs and outputs items is increased, the results of evaluation value are similar regretfully. In order to evaluate Japanese universities which have various activities, this study proposed the hierarchical structure DEA model which is divided into some activities (finance, achievement, attractiveness, research, and education). Hierarchical structure has constructed by some layers based on the theory that the efficiencies of lower layer can not exceed the ones of upper layer. In addition, this paper proposed the visualization method that the analyst can visually understand which field is strong or weak. Using proposed DEA model and visualizing method, the numerical study showed us to be able to understand the feature of each university.**

I. INTRODUCTION

Data Envelopment Analysis (DEA) is a nonparametric method for evaluating relative efficiency of Decision Making Unit (DMU) [1]. DEA assumes DMU's activity that multiple inputs to yield multiple outputs, and estimates this converting process as one evaluation value, so called "efficiency score". DEA has been applied to a variety of managerial and economic problem situations in both public and private sectors [2, 3, 4, 5, 6].

However, there are some problems in applying DEA to data set that consists of a lot of activities such as university [7]. In order to express a lot of activities, it is necessary to prepare a lot of inputs and outputs data. A use of larger data set causes following DEA problems: (1) evaluation does not make sense because the values of efficiency scores for each DMU may be similar, (2) understanding the strong points or weak points of DMU are difficult for analyst because complex relations among a lot of inputs and outputs data is expressed by tablet type result.

To deal with upper DEA problem, DEA analyst uses tacit knowledge that the number of DMUs should be satisfied with restriction of n > max {m*s, 3*(m+s)}. Where, n indicates the number of DMUs, and m, s indicate the number of inputs and outputs [2]. Therefore, if analyst can not collect an enough number of DMUs (n), analyst should decrease the number of inputs and outputs data (m, n). A difficult problem of extracting effective data set for a larger data set still remains.

To deal with lower DEA problem, traditional studies make an attempt to develop the visualization method [8, 9, 10]. These techniques help to understand the shape of efficiency frontier which is used as evaluation criteria. Using these methods, analyst can visually capture the existence of his competitors. However, these methods can not support to know the reason why specific DMU is his competitor.

In order to overcome above two DEA problems, this paper proposes the hierarchical structure DEA model which is divided into some activities and proposes the visualization method that analyst can understand which field is strong or weak.

II. DATA ENVELOPMENT ANALYSIS

A. Overview

DEA is a nonparametric method for identifying efficient production frontiers and evaluating the relative efficiency of DMUs, each of which is a company responsible for converting multiple inputs into multiple outputs. DEA assumes DMUs activity that uses multiple inputs to yield multiple outputs, and defines the process which changes multiple inputs into multiple outputs as efficiency. By comparison with Pareto optimal solution so called "efficient frontier", performance of DMUs is measured relatively.

B. Evaluation Value

In order to describe the mathematical structure of the evaluation value, this paper assumes that there are n DMUs ($DMU_1, DMU_2, \cdots, DMU_k, \cdots, DMU_n$), where each DMU is characterized by m inputs ($x_{1k}, x_{2k}, \cdots, x_{ik}, \cdots x_{mk}$) and s outputs ($y_{1k}, y_{2k}, \cdots, y_{rk}, y_{sk}$). Evaluation value of DMU_k is mathematically formulated by

$$\text{Evaluation value of DMU}_k = \frac{u_1 y_{1k} + u_2 y_{2k} + \cdots + u_s y_{sk}}{v_1 x_{1k} + v_2 x_{2k} + \cdots + v_m x_{mk}} \qquad (1)$$

Here u_r is multiplier weight given to the r^{th} output, and v_i is multiplier weight given to the i^{th} input. In DEA, the optimal weights may vary from on DMU to another DMU. Each DMU is assigned a best set of weights with values. There are some calculation algorisms [2, 11] of input/output weights in formula (1). This paper uses the BCC model which is one of basic model. The optimal weights u_r and v_i are measured by following linear programming:

$$\begin{aligned} \text{Maximize} \quad & \sum_{r=1}^{s} u_r y_{rk} + \delta \\ \text{subject to} \quad & -\sum_{i=1}^{m} v_i x_{ij} + \sum_{r=1}^{s} u_r y_{rj} + \delta \le 0 \\ & (j = 1,2,\ldots,n) \qquad (2) \\ & \sum_{i=1}^{m} v_i x_{ik} = 1 \\ & v_i \ge 0, u_r \ge 0, \delta : \text{free} \end{aligned}$$

Here, first restriction represents the condition that the productivity of all DMU becomes 100% or less. And the objective function represents the maximization of the virtual outputs of DMU_k, setting that the virtual inputs of DMU_k is equal to one which represented second restriction. Therefore, the optimal weights represent the convenient weight for DMU_k. Using these optimal weights, the evaluation value of DMU_k is called "efficiency score" in the manner that $\theta_k = 1 (100\%)$ means the state of efficiency, while $\theta_k < 1$ means the state of inefficiency.

III. PROPOSED METHOD

A. Overview

This paper proposes the hierarchical structure DEA model and visualization method in order to overcome following two problem: (1) there are similar evaluation values among competitors due to a use of larger data set, (2) understanding the strong points or weak points of DMU are difficult.

B. Hierarchical structure DEA model

Hierarchical structure DEA model makes layered structure based on evaluation perspective and assigns input and output elements to each node that is perspective. Then input and output of upper layer include those of lower layer. It is possible to evaluate based on each perspective by calculating efficiency value of each node.

There are n evaluated DMUs. And they have m input elements and s output elements. Here input elements are $X = (X_1, \ldots, X_m)$ and expressed as $X_i = (x_{i1}, \ldots, x_{in})$. So X_i indicates i input group of all DMUs. Equally, $Y = (Y_1, \ldots, Y_s)$, $Y_r = (y_{r1}, \ldots, y_{rn})$ are defined. The efficiency value of DMU_k shown as θ_K is calculated by formula (2). Moreover, efficiency value is calculated based on possible production set S formed by input and output.

Next it is necessary to consider the case that specific input and output are utilized for analysis. New input and output groups are selected and they are denoted as $X' = \{X' \in X, X' \neq \phi\}$, $Y' = \{Y' \in Y, Y' \neq \phi\}$. Then the efficiency value of DMU_k shown as θ'_K based on this data set (X', Y') is calculated by formula (2). It means this efficiency value is calculated based on possible production set S'. Thus $S' \in S$ is satisfied and two different efficiency values θ_K, θ'_K are followed inequality $\theta_K \ge \theta'_K$. The efficiency value of selected data is less than that of original data.

The proposed method hierarchizes by resolving the evaluation perspective and assigns input and output elements to each node. In this time, input and output of upper layer have to include those of lower layer. Then analysis is carried out in each node. Thanks to the proposition in previous section, the efficiency value of lower layer never exceeds that of upper layer. Therefore, it is possible to treat the efficiency value of each node evenly since efficiency signifies the state of each DMU by unified way. Thus inefficient DMU as a whole never be the state of efficient in some node. And the reason for decline about efficiency is revealed. For example, which parts of node affect to the efficiency badly or how degree the specific DMU influences the efficiency. It is possible to analyze these kinds of knowledge from all perspective analyst prepares.

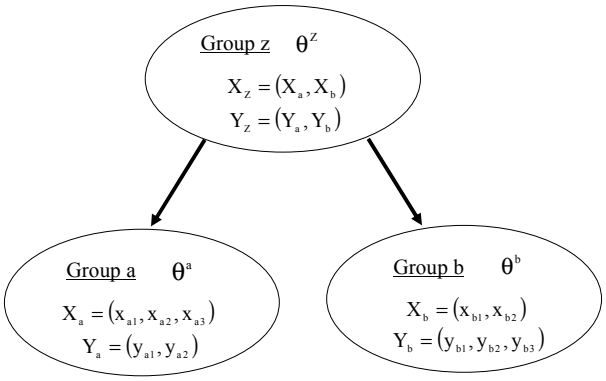

Figure 1. The example of hierarchical structure

Fig 1 shows the example of hierarchical structure. There are two layers (Group z and Group a plus Group b). Group z is divined into two another group (Group a, Group b). Lower nodes use a part of input and output elements in upper layer (Group z). So, proposed structure utilizes the DEA sensitivity analysis technique [2]. Therefore, the efficiency value of the lower nodes (θ^a, θ^b) cannot be exceed the one's of upper node (θ^z).

Using this mathematical character, this paper overcomes first problem that there are similar evaluation values among

competitors due to a use of larger data set. So, this example assumed that Group z has a larger data set. If there is no difference of the efficiency value θ^z among competitors, the analyst can make a search for own character by digging down the layer.

C. Visualizaiton Method

This paper proposed the visualization method in order to overcome the problem that understanding the strong points or weak points of DMU is difficult.

This study puts the each node in 2D map. Coordinate is sets the efficiency value of each node to vertical axis, and sets the difference with average of each efficiency value to horizon axis.

Fig 2 shows the example of visualization. The node of Group z is set at high-middle position. This means that a similar evaluation among the competitors occurs because Group z has a larger data set. So, this evaluation criterion in Group z does not make a sense. However, second layer shows the difference with Group z. The node of Group a is set at high-right position. This mean that DMU has the strong points in the evaluation criterion Group a because a high efficiency value is maintained compared with competitors. Oppositely, the node of Group b is set at low-left position and analyst can understand the weak point in the evaluation criteria Group b.

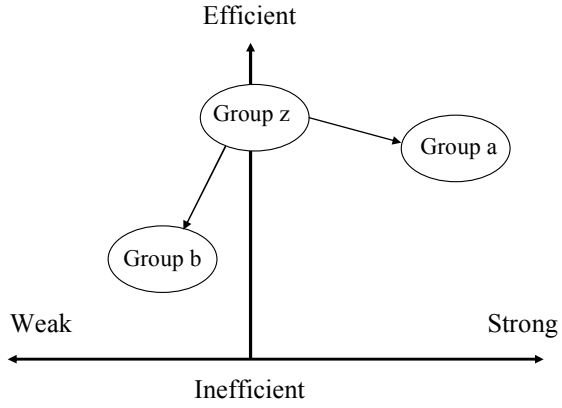

Figure 2. Example of visualization method

IV. NUMERICAL STUDY

A. Data Set

This paper carried out the numerical study using data of Japanese thirty-one universities [7]. There are following six input and eight output data:

Input:

x_1 : number of faculty,

x_2 : number of worker,

x_3 : education and research expense,

x_4 : grant-in aid for management,

x_5 : general and administrative expenses,

x_6 : profit of donation,

Output:

y_1 : maximum T-score,

y_2 : number of paper,

y_3 : number of graduate student,

y_4 : number of undergraduate student,

y_5 : number of books,

y_6 : grant-in-aid for scientific research,

y_7 : contract research funds,

y_8 : profit of business.

B. Hierarchical Structure

These data set is not satisfied the following tacit knowledge that the number of DMUs should be satisfied with restriction of $n > \max\{m*s, 3*(m+s)\}$. Where, n indicates the number of DMUs, and m, s indicate the number of inputs and outputs.

Then, this paper divided this data set into three layers which has eight nodes (University, Management, Research and Education, Finance, Achievement, Attractiveness, Research, and Education). Each layer and node has following input and output data.

<Third layer>

"Finance" uses three input and one output data (x_4, x_5, x_6, y_8). This efficiency value signifies how much university can get profit with possible funds that are input.

"Achievement" uses four input and one output data $(x_2, x_4, x_5, x_6, y_1)$. This efficiency value signifies how high university has T-score with possible funds and human resources.

"Attractiveness" uses four input and two output data $(x_2, x_4, x_5, x_6, y_3, y_4)$. This efficiency value signifies how many university gather students with possible funds and human resources.

"Research" uses two input and two output data (x_1, x_3, y_3, y_4). This efficiency value signifies how many university get external funds or accomplishments of research.

"Education" uses two input and three output data $(x_1, x_3, y_2, y_6, y_7)$. This efficiency value signifies how much university invests funds and human resources to education for students.

<Second layer>

"Management" is combined by three lower nodes "Finance", "Achievement", and "Attractiveness". Therefore, this node uses four input and four output data $(x_2, x_4, x_5, x_6, y_1, y_3, y_4, y_8)$.

"Research and Education" is combined by two lower nodes "Research" and "Education". This node uses two input and five output data $(x_1, x_3, y_2, y_3, y_4, y_6, y_7)$.

<First layer>

"University" uses all input and output data ($x_1 \sim x_6, y_1 \sim y_8$). This node estimates the total efficiency of university.

C. *Result of Hierarchical Sturcture*

Figure 3 shows the result of hierarchical structure in one university. Score in box shows the each efficiency values. And the box also includes the following information: Range, Average, and Variance.

In the node "University", we confirm that the high efficiency value "Score" is caused by a large data set. So, we can not estimate the character of DMU with only this node. However, we can make a search for DMU's character by dipping down the layer. This DMU has a strong point in the evaluation criteria "Management", "Achievement", and "Attractiveness". This means that proposed hierarchical structure overcome the following problem: (1) there are similar evaluation values among competitors due to a use of larger data set, (2) understanding the strong points or weak points of DMU are difficult.

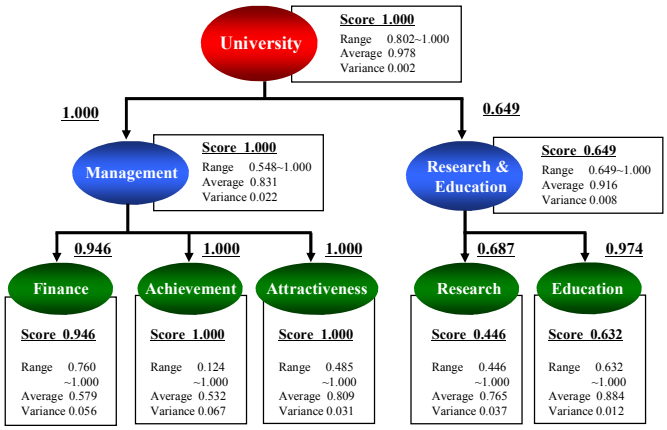

Figure 3. The result of hierarchical structure

D. *Visualizaiton Method*

Figure 4 shows the result of the visualization method in one university (University A). This figure has same volume of information as Figure 3. This method can intuitively understand the feature of DMU by seeing whether to be located right or left without seeing the numerical data of the score and average.

V. CONCLUSION

In order to evaluate Japanese universities which have various activities, this study proposed the hierarchical structure DEA model which is divided into some activities. Hierarchical structure has constructed by some layers based on the theory that the efficiencies of lower layer can not exceed the ones of upper layer. In addition, this paper proposed the visualization method that the analyst can visually understand which field is strong or weak. Using proposed DEA model and visualizing method, the numerical study showed us to be able to understand the feature of university.

***Abstract*—This paper investigates a group decision problem focusing on outliers in a group. The group decision in this paper is considered as approximation of all individual opinions, which are given normalized crisp or interval values. The difference of an individual opinion from the group opinion represents his/her compromise in order to reach a consensus so that it should be minimized. The first step is to detect outliers in a group and assign outlier degree to individual. The outlier degree is distance of an individual from the group of others and defined as the reduction of compromise by excluding him/her from the group. The outlier degree of a unique individual is more than those of other general individuals. Similarly to outlier degree, inlier degree is closeness of others to an individual and defined as the compromise of the group without him/her. The second step is to approximate individual opinions so as to be a group opinion. The weighted sum of compromises of all individuals is minimized introducing the outlier degrees as the weights of individuals. In this model, outliers are considered positively into account for a group opinion. Therefore, based on compromises of individuals, the models to define outlier degree and to obtain group opinion by approximating individual opinions are proposed in this paper.**

***Index Terms*—Group decision making, Outlier, Compromise**

I. Introduction

A group decision is often believed to be better than individual decision simply because of cumulating all members' knowledge, being able to check errors carefully and so on. Although it is mentioned that a group performs better than "average" individual but worse than "best" individual [1], the developed techniques of integrating and combining individual judgments are effective in part. Aside from the issues on managements of decision makers and their characters, the technique in group decision making can be applied not only when decision makers give their judgments but when various evaluations from different viewpoints, such as time series, are given. One of the advantages of group decision making over individual one is that it facilitates creativity and develops new ideas by inspiring each other [1]. It often happens that when the discussion is stable and static, a unique opinion stimulate it and it becomes active again. Individuals may realize that relatively extreme individual holds opinion closer to the group's most admired position and this comparison may act to move moderate individuals toward a more extreme position [2]. In this sense, a unique opinion might be worth being paid attention. In case of the group consisting of various stakeholders, powerful or major opinion sometimes breaks down the other small or minor opinions, even if they are important. Such a situation as depending on majority too much might be controlled by including unique opinion positively in the decision. In this way, outlier helps to induce a fresh and fair decision. This paper emphasizes group opinions in which a unique opinion is positively reflected. While, for instance, the decision problem to determine next year's plan from past years' results, it is reasonable to consider an average and general year more than unique years. In the case where it is not necessary to pay attention to a unique individual and/or generality is important, inlier degree is considered, instead of outlier degree.

The situation that a group reaches a consensus is explained in various ways; such that all individuals are unanimous for the decision, they agree to support or practice the decision, or the decision meets their interests [3]. It is also assumed that the compromises of all individuals are limited to be as less as possible [4], [5]. So, the group opinion in this study is obtained, in other words, by approximating individual opinions so as to minimize the errors of estimated value from the observed value. The concept is similar to regression analysis, except that it assumes a linear or other regression model beforehand.

This paper consists as follows. In Section II, when individual opinions are given as crisp or interval, individual compromise in order to reach a consensus is measured as difference between individual and group evaluations. In Section III, from the viewpoint of compromises, outlier degree representing distance of an individual from the group of others is defined, and inlier degree as well. Then, in Section IV, the model to obtain a group opinion as the approximation of individual opinions is shown. The compromises of all individuals are weighted by their outlier degrees and minimized so as to reach a consensus. Finally, in Section V, the proposed compromise-weighted model is tested with two numerical examples on budget.

II. Compromises of individuals

At first, both the individual and group opinions are assumed as crisp evaluations of alternatives as in Table I. Individual i gives his/her opinion as evaluation of alternative j, w_{ij}, and for all alternatives they are normalized as $\sum_j w_{ij} = 1$. A group opinion in this problem setting is an approximation of individual opinions so that they are normalized as:

$$\sum_j w_j = 1.$$

The group opinion w_j can be smaller or greater than the

GIVEN INDIVIDUAL EVALUATIONS AND OBTAINED GROUP EVALUATIONS

Individual	Alternative 1	$\cdots$	j	$\cdots$	n	Sum
1	w_{11}	$\cdots$	w_{1j}	$\cdots$	w_{1n}	1
$\vdots$	$\vdots$	$\ddots$	$\vdots$	$\ddots$	$\vdots$	$\vdots$
i	w_{i1}	$\cdots$	w_{ij}	$\cdots$	w_{in}	1
$\vdots$	$\vdots$	$\ddots$	$\vdots$	$\ddots$	$\vdots$	$\vdots$
m	w_{m1}	$\cdots$	w_{mj}	$\cdots$	w_{mn}	1
Group	w_1	$\cdots$	w_j	$\cdots$	w_n	1

corresponding individual opinion w_{ij};

$$\begin{array}{rlll} & w_j \leq w_{ij} & \text{or} & w_j > w_{ij} \\ \Leftrightarrow & w_j = w_{ij} - \underline{d}_{ij} & \text{or} & w_j = w_{ij} + \overline{d}_{ij}. \end{array}$$

The positive and negative deviations from a group opinion, $\overline{d}_{ij}$ and $\underline{d}_{ij}$, represent compromise of individual i in order to reach a consensus on alternative j. In other words, his/her compromised opinion is denoted as interval $[w_{ij} - \underline{d}_{ij}, w_{ij} + \overline{d}_{ij}]$ and should include the obtained group opinion as;

$$w_{ij} - \underline{d}_{ij} \leq w_j \leq w_{ij} + \overline{d}_{ij}.$$

In interval regression analysis, errors between observed values and estimated intervals by the regression model are minimized [6] and their relations are also considered in [7]. Here, no regression models are assumed so that the simple sum of errors between all the given individual opinions and the obtained group opinions should be minimized as:

$$\min \textstyle\sum_i (\overline{d}_{ij} + \underline{d}_{ij}),$$

which is, in other words, the compromise of all individuals to reach the group decision.

Following these conditions, total compromise of the group is obtained as follows:

$$\begin{array}{rl} c = & \min \sum_{i,j} (\overline{d}_{ij} + \underline{d}_{ij}), \\ \text{s.t.} & w_{ij} - \underline{d}_{ij} \leq w_j \ \forall i, j, \\ & w_j \leq w_{ij} + \overline{d}_{ij} \ \forall i, j, \\ & \sum_j w_j = 1 \ \forall j, \\ & w_j, \underline{d}_{ij}, \overline{d}_{ij} \geq 0 \ \forall i, j, \end{array} \tag{1}$$

where the variables are group evaluations, w_j, and positive and negative compromises, $\overline{d}_{ij}$ and $\underline{d}_{ij}$. It is apparent that positive and/or negative compromise is 0, since both group and individual evaluations, $w_{ij}$and w_j, in the first two constraints are crisp. By approximating observed values; individual evaluations, so as to minimize errors of estimated values, group evaluations; total compromise of the group is obtained as sum of errors.

Next, both the individual and group opinions are extended into interval evaluations of alternatives as $W_{ij} = [\underline{w}_{ij}, \overline{w}_{ij}]$ and $W_j = [\underline{w}_j, \overline{w}_j]$, respectively. In order to normalize intervals, definition of interval probability, originally proposed in [8] and also used in [9], [10], is used.

Definition of Interval Probability The set of intervals denoted as $\{W_1, ..., W_n\}$ where $W_i = [\underline{w}_i, \overline{w}_i]$ are called interval probabilities if and only if

$$\begin{array}{ll} 1) & 0 \leq \underline{w}_i \leq \overline{w}_i, \ \forall i, \\ 2) & \sum_{i \neq j} \overline{w}_i + \underline{w}_j \geq 1, \ \forall j, \\ 3) & \sum_{i \neq j} \underline{w}_i + \overline{w}_j \leq 1, \ \forall j. \end{array} \tag{2}$$

From (2), the following two inequalities hold:

$$\textstyle\sum_i \underline{w}_i \leq 1 \text{ and } \sum_i \overline{w}_i \geq 1.$$

Then, (2) is regarded as the normality condition of intervals corresponding to the conventional one; $\sum_i w_i = 1$. It is noted that in interval probabilities there are many combinations of crisp values whose sum is one. The conventional probabilities, such as $\underline{w}_i = \overline{w}_i = w_i \geq 0 \ \forall i$, also satisfy the requirements in (2) as follows: 1) is apparent and 2) and 3) are verified as

$$\textstyle\sum_{i \neq j} w_i + w_j = \sum_i w_i = 1.$$

Therefore, the interval probability is an extension of the conventional probability.

As an extension of crisp evaluation, the compromised opinion with interval evaluation is denoted as interval $[\underline{w}_{ij} - \underline{d}_{ij}, \overline{w}_{ij} + \overline{d}_{ij}]$ which should include group opinion as:

$$\underline{w}_{ij} - \underline{d}_{ij} \leq \underline{w}_j \ \text{ and } \overline{w}_j \leq \overline{w}_{ij} + \overline{d}_{ij}.$$

Similarly to (1) with crisp evaluations, the total compromise is obtained as the optimal objective function value of the following problem:

$$\begin{array}{rl} c = & \min \sum_{i,j} (\overline{d}_{ij} + \underline{d}_{ij}), \\ \text{s.t.} & \underline{w}_{ij} - \underline{d}_{ij} \leq \underline{w}_j \ \forall i, j, \\ & \overline{w}_j \leq \overline{w}_{ij} + \overline{d}_{ij} \ \forall i, j, \\ & \sum_{j \neq k} \overline{w}_j + \underline{w}_k \geq 1 \ \forall k, \\ & \sum_{j \neq k} \underline{w}_j + \overline{w}_k \leq 1 \ \forall k, \\ & \underline{d}_{ij}, \overline{d}_{ij} \geq 0 \ \forall i, j, \\ & 0 \leq \underline{w}_j \leq \overline{w}_j \ \forall j. \end{array} \tag{3}$$

Focusing on the first two constraints, when the following relation is satisfied, i.e.,:

$$\max_i \underline{w}_{ij} < \min_i \overline{w}_{ij}, \tag{4}$$

the solutions of (3), $\underline{w}_j$ and $\overline{w}_j$, may be interval included in interval $[\max_i \underline{w}_{ij}, \min_i \overline{w}_{ij}]$ and the positive and negative compromises are 0; $\underline{d}_{ij} = \overline{d}_{ij} = 0 \ \forall i$. However, since interval evaluation reflects fluctuations of judgments on alternatives, relation (4), where the upper bound of interval evaluation given by any individual should be more than the lower bound given by anyone, is strict. It often happens that relation (4) is not satisfied, i.e.,:

$$\max_i \underline{w}_{ij} \geq \min_i \overline{w}_{ij}.$$

In such a case, solutions of (3) are $\underline{w}_j = \overline{w}_j$ so as to satisfy the first two constraints and minimize the sum of positive and negative compromises. Then, when even individual opinions are given as interval evaluations, the group evaluations are

often obtained as crisp, much less when they are given as crisp. In case of crisp individual evaluations, the interval group evaluations are never obtained because two constraints contradict to be interval as follows.

$$\begin{cases} \underline{w}_j = \max_i w_{ij} \\ \overline{w}_j = \min_i w_{ij} \end{cases} \not\Rightarrow \quad \underline{w}_j \le \overline{w}_j.$$

Only in case that the given individual evaluations are similar enough to satisfy relation (4), the group evaluation is obtained as interval. In other cases, by assuming group evaluation as crisp, it is also rewritten as (1).

III. Detection of outliers based on compromises

The first step of this paper is to detect outliers in a group and determine their outlier degrees based on individual compromises. The outlier degree represents distance of an individual from the group of others and is measured as the difference between the compromises of groups with and without the individual. Therefore, the outlier degree of a unique individual is more than those of other general individuals. In this section, we assumed that crisp individual evaluations are given so that group opinions are also obtained as crisp. The total compromise of the group without individual k, is obtained as the optimal objective function value by the following problem based on (1).

$$\begin{array}{rl} c_k = & \min \sum_{i \neq k, j} (\overline{d}_{ij} + \underline{d}_{ij}), \\ \text{s.t.} & w_{ij} - \underline{d}_{ij} \le w_j \ \forall i \neq k, j, \\ & w_j \le w_{ij} + \overline{d}_{ij} \ \forall i \neq k, j, \\ & \sum_j w_j = 1, \\ & w_j, \underline{d}_{ij}, \overline{d}_{ij} \ge 0 \ \forall i \neq k, j, \end{array} \tag{5}$$

where the optimal solutions satisfying the optimal objective function value are not unique because of LP problem, but they are not used in the following. For interval group evaluations, constraints are transformed as in (3).

The optimal objective function value c_k, which is smaller than that of (1), denotes the compromise remained in the group by excluding individual k. It is explained from two viewpoints and illustrated conceptually in Fig. 1, where large and small circles denote total compromises without and with individual k, respectively. From the viewpoints of individuals except k, compromise increases more from c_k to c as k is farther from them. While, from the viewpoint of individual k, compromises decreases more from c to c_k as other individuals are closer to him/her. The former viewpoint leads to outlier degree and the latter one leads to inlier degree, respectively.

As for outlier degree, the distance of individual k from the group of others is measured as reduction of total compromise by excluding him/her; $c - c_k$. Based on such a difference of total compromises with and without an individual in the group, outlier degree is defined as follows:

$$p_k = \frac{c - c_k}{\sum_i (c - c_i)} \ \forall k, \tag{6}$$

where distances for all individuals are normalized so are individual and group evaluations. The outlier degree of a unique individual is more than those of general ones.

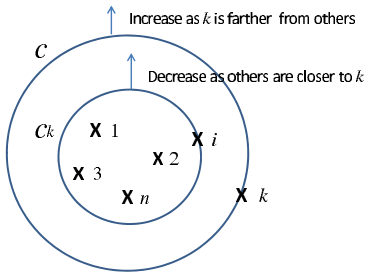

Fig. 1. Total compromises with and without an individual

Similarly to outlier degree, inlier degree is measured as the closeness of other individuals to individual k, which is the total compromise without k. Based on such a remained compromise by normalizing for all individuals, inlier degree is defined as follows.

$$q_k = \frac{c_k}{\sum_i c_i} \ \forall k, \tag{7}$$

where a general individual has more inner degree than unique ones do.

IV. Group opinions considering outlier degrees

The second step of this paper is to approximate individual opinions so as to be a group opinion. Group decision making is discussed in many literatures. For instance, in the well-known method, AHP (Analytic Hierarchy Process), by adding a decision makers' hierarchy to the top of the problem structure, the priority weights of alternatives are summed up reflecting the decision makers' weights obtained at the hierarchy [11], [12], [13]. Such a weighted summation technique is useful to take all decision makers' judgments into account. In order to determine the decision makers' weights, the corresponding pairwise comparison matrix should be given in AHP or they might be given directly. Here, the proposed outlier degree by (6) are introduced as the weight of an individual in the group so that no one needs to give the corresponding judgments. Then, the group evaluation is obtained as:

$$w_j = \sum_i p_i w_{ij} \ \forall j, \tag{8}$$

where the weights of individuals are directly multiplied to their evaluations.

It is also practical to measure fairness of consensus by individual compromises. From individual viewpoint, his/her difference from a group decision is one of concerns since it is recognized just by comparing two values. Considering such a difference, in other words, an individual compromise, the other model to obtain group opinion is formulated as follows:

$$\begin{array}{rl} & \min \sum_{i,j} p_i (\overline{d}_{ij} + \underline{d}_{ij}), \\ \text{s.t.} & \text{constraints in (1)}, \end{array} \tag{9}$$

where the objective function in (1) is transformed into outlier degree based weighted compromises so that (9) is called compromise-weighted model. In the sense of focusing on

TABLE II
RATIONS OF SIX EXPENSES OF FIVE TOWNS IN 2004, THEIR GROUP DECISION, AND THE MERGED CITY IN 2005

Year	Town	Budget size billion	Ratio Expense 1	Expense 2	Expense 3	Expense 4	Expense 5	Expense 6
2004	A	2.4	0.232	0.267	0.046	0.253	0.092	0.109

	Group decision by (9)		0.237	0.267	0.049	0.192	0.129	0.126
	Group decision by (8)		0.254	0.298	0.053	0.160	0.120	0.116
2005	City	15.2	0.244	0.219	0.064	0.254	0.128	0.090

the difference between given individual and obtained group evaluations, individuals in a group can easily understand the procedure and accept the results. This model is based on the idea that outliers are taken positively into account for a group opinion.

Since outlier degree represents the distance of an individual from the group, the unique opinion is reflected in group opinion positively in (8) and (9). While, such a decision problem that unique opinion is not welcomed to the group one, inlier degrees are introduced as weights of individuals. The models are formulated by replacing outlier degrees p_i in (8) and (9) into inlier degrees q_i.

V. NUMERICAL EXAMPLES

From the viewpoint of a group decision making, two examples on planning budgets of local governments are tested. One is the case of new city consisting of several towns and its budget is estimated from the member towns' results [14]. In order not to neglect smaller or unique town's status, outlier degrees are used. The other is the case of prefecture running stable for recent years and its budget is estimated from its past years' results [15]. In order not to be affected by transient situation, inlier degrees are used. Although all the given ratios are crisp in both examples, in case of interval ratios, the similar procedure can be applied.

A. Group decision with outlier degrees

Table II shows ratios on six expenses, such as 1-personnel 2-public loan, 3-aid, 4-investment, 5-nonpersonnel and 6-subsidy, of five small towns in 2004 and their budget sizes. They were merged into a city in 2005 so that at that time the new city is forced to plan new budget referring to the results of five towns in 2004. This decision problem is used in this section. As show in Table II, the size of Town E is almost one third of the largest one, Town C, and Expense 2 of Town E is apparently different from other towns. Though, since small towns often have some difficulties to adapt a new situation, the status of Town E is also or more carefully considered. First, by (5) total compromise without each town is obtained and by (6) the outlier degrees are obtained as shown in Table III. The smallest budget Town E has the greatest outlier degree. Then, introducing outlier degrees as weights of towns, the approximations of five towns' ratios as a group decision are obtained by compromise-weighted model (9) and shown at the third bottom line of Table II. The obtained ratios equal to the medians of the corresponding five given ratios, except expense 4, whose obtained ratio is around the median so as to normalize for all expenses. To comparison, those by (8), where given ratio is weighted directly, and the results of the city in 2005 are shown at the bottom two lines of Table II. The budget size was enlarged by merging but the ratios by (9) are more similar to the real ratios than those by (8). The compromise, which is the difference of each town's ratio from the group ratio by both models are shown in Table III. The total compromise of Town E, which might be an outlier so that its weight is the largest among five towns, by (8) is restrained to be 0.281, less than 0.342 by (9). In details, Town E compromises on six expenses by (8) as 0.281=0.017+0.140+0.011+0.060+0.023+0.030 and by (9) as 0.342=0.000+0.171+0.008+0.092+0.032+0.039. As for Expense 2, on which Town E is different from other towns, its compromise by (8) is less than that by (9). These facts might refer that when individual towns' ratios are weighted directly as in (8), group ratio might be overfitted to Town E. By weighting individual towns' compromises as in (9), the compromise of Town E is fairly and properly reflected in the obtained group ratio.

TABLE III
OUTLIER DEGREES AND COMPROMISES OF TOWNS

Town	Outlier degree	Compromise By (8)		By (9)
A	0.217	0.187	$>$	0.123

C	0.187	0.223	$>$	0.128
D	0.180	0.238	$<$	0.239
E	0.292	0.281	$<$	0.342
Sum of compromises		1.098	$>$	0.996

B. Group decision with inlier degrees

Table IV shows ratios of four cost divisions, such as 1-personnel related cost 2-nonpersonnel related cost, 3-investment related cost, 4-other cost of the prefecture from 2004 to 2008 and their budget sizes. The decision problem for the prefecture is to plan its next fiscal year's budget referring to its past five years' results. As shown in Table IV, the differences of ratios between years are smaller comparing to Table II. It may not be necessary to pay attention to a unique year because of similar results; moreover, it may not be reasonable to be affected by transient year. Therefore, inlier

INLIER DEGREES AND DIFFERENCES FROM PAST RESULTS

Year	Inlier degree	Compromise By (8)		By (9)
2008	0.222	0.031	$>$	0.020
2007	0.197	0.041	$>$	0.039
2006	0.213	0.034	$>$	0.030
2005	0.183	0.052	$<$	0.054
2004	0.184	0.045	$<$	0.053
Sum of compromises		0.204	$>$	0.196

degree of each year is obtained by (7) from total compromise without a year by (5) and shown in Table V. Although the inlier degrees of all years are around 0.2, it could be said that those of 2004 and 2005 are less than those of 2006, 2007 and 2008, the more recent three years. This might be because the budget has been changed gradually for years and reflecting the recent years' results in a plan is practical. Then, introducing inlier degrees as weights of years, the approximations of five years results as a group decision are obtained by compromise-weighted model (9) and to comparison by (8). They are shown at the second and third bottom lines of Table IV and differences from past years' result is shown in Table V. Those of 2008, 2007 and 2006 by (9) are smaller than those by (8). The obtained ratios by compromise-weighted model (9) are more similar to the more recent three years. Comparing the deviations between the ratios by (8) and (9) to real ratios of 2009 shown at the right row of Table IV, those by (9) are slightly smaller than those by (8).

VI. CONCLUSION

Focusing on outliers, group decision is obtained as the approximation of the given individual opinions. The models to define outlier degree and to obtain group opinion are proposed from the viewpoint of compromise. Since one of the major concerns of an individual in the group decision making is the difference of the obtained group opinion from his/her opinion, the compromise represented as such a difference is focused on in this paper. The outlier degree is used as an individual weight based on the idea that a unique opinion is sometimes worth being paid attention. It is measured as the distance of an individual from the group of others and defined as the reduction of total compromise by excluding the individual from the group. Similarly, inlier degree is used, when general opinions seem to be paid more attention. Then, the group opinion is obtained by minimizing weighted compromises so as to reach a consensus. The easily recognized compromise for group members is a useful and reasonable measurement and the proposed models based on it are practical in real problems.

***Abstract*—This paper considers k-Means clustering of incomplete data sets including missing values. Although the main purpose of k-Means clustering is to partition samples into several homogeneous clusters by minimizing within-cluster errors, it has been shown that a relaxed solution of k-Means can be recovered in a PCA-guided manner. In this paper, the PCA-guided k-Means procedure is extended to a situation in which some observations are missing. Principal component scores, which can be identified with a rotated solution of cluster indicators of k-Means clustering, are estimated in an iterative process without imputation. Besides solving the eigenvalue problem of covariance matrices, k-Means-like partitions are derived through lower rank approximation of the data matrix ignoring missing elements. Several experimental results demonstrate that the PCA-guided process is more robust to initialization problems even though it is based on iterative optimization, just as the k-Means procedure is.**

***Keywords*—k-means clustering, missing value, principal component analysis.**

I. Introduction

k-Means clustering [1] is a fundamental technique for revealing intrinsic cluster structures of multivariate data sets. Although the k-Means process has been demonstrated to be very useful for extracting spherical clusters based on iterative optimization, it often suffers from initialization problems such that bad initializations lead to convergence to the wrong local minima. Recently, Ding and He [2] discussed a close relation between k-Means solutions and principal component scores, and proposed the principal component analysis (PCA)-guided k-Means procedure based on a deterministic method for finding the optimal (unique) k-Means partition. In the clustering model, a relaxed k-Means cluster indicator is identified with a rotated principal component score matrix, although the rotation matrix cannot be explicitly estimated and an approach such as visualization by ordering of samples in connectivity matrices [3] has to be used in order to visually access the cluster structures.

In [4], a noise rejection mechanism was introduced on the basis of noise fuzzy clustering [5]. In the fuzzy PCA-guided robust k-Means (FPR k-Means) procedure, both the responsibility weight of each sample with respect to the k-Means process and a rotated-cluster indicator are estimated by an iterative procedure. Removing the noise samples, a robust cluster indicator is estimated in a deterministic manner.

In addition to noisy data, incomplete data are common in real applications where some observations are missing. In order to apply k-Means-like clustering algorithms to incomplete data sets without a priori imputation, Hathaway and Bezdek [6] introduced four strategies in the Fuzzy c-Means (FCM) clustering algorithm [7]. Although the simple whole data strategy (WDS) eliminating all incomplete samples can be adopted if there are have only a few missing elements, it is useless in many real applications. In the partial distance strategy (PDS), clustering criteria of distances between samples and prototypes are calculated using observed coordinates only. In [6], it was also shown that some iterative completion strategies such as the optimal completion strategy (OCS) and nearest prototype strategy (NPS) also work well, although they require more computational effort.

In the application of PCA to incomplete data sets, several methods that extract principal components without any preprocessing of data have been proposed. Ruhe [8], Wiberg [9], and Shibayama [10] proposed PCA-like methods for capturing the structure of incomplete multivariate data without any imputations or statistical assumptions. Especially, Shibayama's approach made it possible to calculate principal components by a computationally efficient algorithm. Shum *et al.* [11] applied such techniques to object modeling. These methods are based on the lower rank approximation of the data matrix, which accomplishes the minimization of the least square criterion, and the methods extract principal components of the covariance matrix of the sample data set. Honda *et al.* [12] extended the PCA model to a linear fuzzy clustering algorithm by considering the close connection between PCA and linear fuzzy clustering algorithms such as Fuzzy c-Varieties (FCV) and Fuzzy c-Elliptotypes (FCE) [13].

In this paper, Shibayama's PCA-like method is applied to the k-Means problem with incomplete data in order to estimate a relaxed solution. Several experimental results demonstrate that the PCA-guided process is more robust to initialization problems, even though it is also based on iterative optimization, the same as the k-Means procedure.

The remainder of this paper is organized as follows: Section II briefly reviews k-Means and PCA-guided k-Means. Section III introduces Shibayama's PCA-like method for incom-

plete data, which is then applied to k-Means tasks. Section IV presents several experimental results to demonstrate the characteristic features of the proposed approach. Section V summarizes the conclusions of this paper.

II. Brief Review of k-Means and PCA-guided k-Means

A. k-Means Clustering and Partial Distance Strategy

Assume that we have n samples with m-dimensional observation $\boldsymbol{x}_i$, $i = 1, \ldots, n$, and the goal is to partition the samples into several clusters where samples belonging to the same cluster are similar while samples belonging to different clusters are dissimilar.

k-Means [1] is a non-hierarchical prototype-based clustering in which prototypes (centroids) are used for representing clusters and the objective function is defined as the sum of within-cluster errors:

$$\begin{aligned} L_{km} &= \sum_{k=1}^{K} \sum_{i \in G_k} d_{ki} \\ &= \sum_{k=1}^{K} \sum_{i \in G_k} ||\boldsymbol{x}_i - \boldsymbol{b}_k||^2, \end{aligned} \tag{1}$$

where K is the pre-defined number of clusters and $\boldsymbol{b}_k$ is the representative prototype (centroid) of cluster G_k.

The k-Means process is composed of two phases: prototype estimation and sample assignment. The two phases are iterated until the solution is trapped at a local minimum. Because of the greedy nature of the updating algorithm, the k-Means procedure often suffers from the initialization problem that the process converges to a different local optimum for a different initialization.

When some observations are missing, we need a modified clustering criterion d_{ki} that can be reconstructed using only the remaining observations. PDS is a simple but useful approach in which squared distances are calculated considering the observed coordinates only.

$$d_{ki} = \sum_{j=1}^{m} z_{ij} (x_{ij} - b_{kj})^2, \tag{2}$$

where z_{ij} is a bivariate variable as follows:

$$z_{ij} = \begin{cases} 1 & ; \text{if } x_{ij} \text{ is observed.} \\ 0 & ; \text{if } x_{ij} \text{ is missing.} \end{cases} \tag{3}$$

B. PCA-guided k-Means

Ding and He [2] revealed a close relation between PCA and k-Means clustering. The k-Means objective function of Eq.(1) can be re-defined by a centroid-less formulation as follows:

$$L_{km} = \sum_{i=1}^{n} ||\boldsymbol{x}_i||^2 - \sum_{k=1}^{K} \frac{1}{n_k} \sum_{i,j \in G_k} \boldsymbol{x}_i^\top \boldsymbol{x}_j, \tag{4}$$

where n_k is the number of samples belonging to cluster G_k. Because the first term is a constant, the optimal k-Means partition is derived by minimizing the second term, which is the sum of within-cluster (inner product) similarities. In this contex, the (hard) k-Means cluster partition is represented by K non-negative bivariate indicator vectors $H_K = (\boldsymbol{h}_1, \ldots, \boldsymbol{h}_K)$,

$$h_{ki} = \begin{cases} \frac{1}{n_k^{1/2}} & ; \text{if sample } i \text{ belongs to cluster } G_k. \\ 0 & ; \text{otherwise.} \end{cases}$$

In order to relax the k-Means problem, Ding and He introduced a rotated solution Q_K by considering $K \times K$ orthogonal transformation $T = \{t_{ij}\}$,

$$Q_K = (\boldsymbol{q}_1, \ldots, \boldsymbol{q}_K) = H_K T, \tag{5}$$

where, avoiding redundancies, the last column of T is set as:

$$\boldsymbol{t}_n = (\sqrt{n_1/n}, \ldots, \sqrt{n_K/n})^\top, \tag{6}$$

which brings $\boldsymbol{q}_K = (\sqrt{1/n}, \ldots, \sqrt{1/n})^\top$. Considering the mutual orthogonality of $\boldsymbol{h}_k$, we have the following conditions:

$$Q_{K-1}^\top Q_{K-1} = I_{K-1}, \tag{7}$$

$$\sum_{i=1}^{n} q_{ki} = 0, \qquad k = 1, \ldots, K-1, \tag{8}$$

where $Q_{K-1} = (\boldsymbol{q}_1, \ldots, \boldsymbol{q}_{K-1})$ and $\boldsymbol{q}_k = (q_{k1}, \ldots, q_{kn})^\top$. Then, the k-Means objective function can be written as

$$L_{km} = \sum_{i=1}^{n} ||\boldsymbol{x}_i||^2 - \frac{1}{n} \boldsymbol{e}^\top X^\top X \boldsymbol{e} - \mathrm{Tr}(Q_{K-1}^\top X^\top X Q_{K-1}), \tag{9}$$

where $X = (\boldsymbol{x}_1, \ldots, \boldsymbol{x}_n)$, and $\boldsymbol{e}$ is the n-dimensional vector whose elements are all 1.

Here, we can see that the k-Means problem is free from the influences of parallel transformation and that the original data $\boldsymbol{x}_i$ can be replaced with the centered data $\boldsymbol{y}_i$ without loss of generality. Then, the objective function can be written as:

$$L_{km} = \sum_{i=1}^{n} ||\boldsymbol{y}_i||^2 - \mathrm{Tr}(Q_{K-1}^\top Y^\top Y Q_{K-1}), \tag{10}$$

where $Y = (\boldsymbol{y}_1, \ldots, \boldsymbol{y}_n)$ and $Y\boldsymbol{e} = \boldsymbol{0}$.

The optimal solutions for the transformed discrete membership indicator vectors Q_{K-1} are derived by maximizing $\mathrm{Tr}(Q_{K-1}^\top Y^\top Y Q_{K-1})$, and continuous (relaxed) solutions are the eigenvectors corresponding to the $K-1$ largest eigenvalues of $Y^\top Y$. Therefore, the optimal Q_{K-1} can be identified with the principal component scores in PCA, and a continuous solution for k-Means clustering is derived in a PCA-guided manner.

If we want to know the cluster structure from the (continuous) solution for Q_{K-1}, we need to compute the optimal transformation T, although this is not easy in many case. In [2], cluster connectivity analysis is performed by calculating the following connectivity matrix C:

$$C = \frac{1}{n} \boldsymbol{e}\boldsymbol{e}^\top + \sum_{k=1}^{K-1} \boldsymbol{q}_k \boldsymbol{q}_k^\top, \tag{11}$$

and a probability for the connectivity between samples i and j is given as:

$$p_{ij} = \frac{c_{ij}}{\sqrt{c_{ii}c_{jj}}}. \tag{12}$$

Cluster structure is shown in the diagonal block structure using the spectral ordering [3].

III. Principal Components Estimation from Incomplete Data and Its Application to k-Means Cluster Indicator Estimation

A. PCA-like Method for Incomplete Data

Assume that a data set is represented by the $m \times n$ data matrix $X = (\boldsymbol{x}_1, \ldots, \boldsymbol{x}_n)$ and the goal is to extract a p ($p < m$)-dimensional principal component score for each sample. The PCA process is achieved by estimating the lower rank approximation of X as follows:

$$X \approx AF + \boldsymbol{v}\boldsymbol{e}^\top, \tag{13}$$

where A is the $m \times p$ principal component matrix $A = (\boldsymbol{a}_1, \ldots, \boldsymbol{a}_p)$, and F is the $p \times n$ principal component score matrix $F = (\boldsymbol{f}_1, \ldots, \boldsymbol{f}_n)$. $\boldsymbol{v}$ is the centering vector.

In order to estimate principal components from incomplete data, Shibayama [10] considered minimization of the following least square criterion:

$$\begin{aligned} L &= \mathrm{Tr}\big(Z \odot (X - AF + \boldsymbol{v}\boldsymbol{e}^\top)\big)^\top \big(Z \odot (X - AF + \boldsymbol{v}\boldsymbol{e}^\top)\big) \\ &= \sum_{i=1}^{n}\sum_{j=1}^{m} z_{ij}\left(x_{ij} - \sum_{k=1}^{p} f_{ik}a_{kj} - v_j\right)^2, \end{aligned} \tag{14}$$

where $Z = \{z_{ij}\}$ is given by Eq.(3) and $\odot$ denotes the Hadamard product.

This model is based on a concept similar to PDS in k-Means clustering, namely that the partial errors calculated only by the observed elements are minimized.

If the data matrix X does not include any missing elements, the PCA model is equivalent to the standard formulation in which the centering vector $\boldsymbol{v}$ is given by the mean vector and the principal component vectors $\boldsymbol{a}_k$, $k = 1, \ldots, p$ are derived as the eigenvectors corresponding to the principal eigenvalues of the scatter matrix. However, if the data matrix includes missing elements, the PCA process cannot be reduced to an eigen problem.

In the Shibayama's PCA-like method [10], principal components are estimated on the basis of an iterative optimization scheme. Under the constraints $F\boldsymbol{e} = \boldsymbol{0}$ and $FF^\top = I$, the updating rule for each step is derived as follows:

$$\tilde{\boldsymbol{a}}_j = (F\tilde{Z}_j F^\top)^{-1} F\tilde{Z}_j(\tilde{\boldsymbol{x}}_j - v_j\boldsymbol{e}), \tag{15}$$

$$v_j = (\boldsymbol{e}^\top \tilde{Z}_j \boldsymbol{e})^{-1}\boldsymbol{e}^\top \tilde{Z}_j(\tilde{\boldsymbol{x}}_j - F^\top \tilde{\boldsymbol{a}}_j), \tag{16}$$

$$\boldsymbol{f}_i = (A^\top Z_i A)^{-1} A^\top Z_i(\boldsymbol{x}_i - \boldsymbol{v}), \tag{17}$$

where $A = (\tilde{\boldsymbol{a}}_1, \ldots \tilde{\boldsymbol{a}}_m)^\top$, $X = (\tilde{\boldsymbol{x}}_1, \ldots, \tilde{\boldsymbol{x}}_m)^\top$ and $Z_i = \mathrm{diag}(z_{i1}, \ldots, z_{im})$, $\tilde{Z}_j = \mathrm{diag}(z_{1j}, \ldots, z_{nj})$.

Beside random initialization, initial values for A, F and $\boldsymbol{v}$ can be estimated by WDS in which the standard PCA model is applied after removing all samples including missing elements. The iterative procedure of updating A, F, and $\boldsymbol{v}$ is continued until convergence while normalizing F in each iteration.

B. k-Means Cluster Indicator for Incomplete Data

Although the iterative optimization process of the PCA-like method with bad initialization may become trapped at local minima, we can expect that a plausible estimator of principal component scores can be obtained using the multi-starting strategy even when data matrices include missing elements. Therefore, the derived principal component scores F are promising candidates for the relaxed cluster indicator in the PCA-guided k-Means procedure.

The procedure for deriving the relaxed cluster indicator matrix Q_K in the K cluster case can be summarized as follows:

Step.1 Set the dimension of principal components as $p = K - 1$ and initialize A, F, and $\boldsymbol{v}$.
Step.2 Repeat the PCA-like process until convergence.
Step.3 Substitute F into Q_{K-1}.
Step.4 Set $\boldsymbol{q}_K$ as $\boldsymbol{q}_K = (\sqrt{1/n}, \ldots, \sqrt{1/n})^\top$.

Once the relaxed cluster indicator Q_K is estimated, cluster structures can be captured by a technique such as cluster connectivity analysis.

IV. Numerical Experiments

In this section, several experimental results are shown in order to demonstrate the characteristic features of the proposed approach.

A. Iris Data Set

The first experiment was performed with the Iris data set that is available from the UCI Machine Learning Repository [14]. In this experiment, 150 instances ($n = 150$) with four-dimensional observation ($m = 4$) drawn from three classes were partitioned into three clusters without using the class label. The data set does not include any missing elements. It is well known that the k-Means model can capture the three dense masses of the three labeled classes in many trials using the multi-starting strategy, although whereas one class is well separated from others, the remaining two classes somewhat overlap.

In this experiment, the frequencies of good results in the proposed approach using the multi-starting strategy are compared with that in the k-Means using PDS. Here, a "good" result does not necessarily mean that all instances are correctly classified into the three classes without using class labels, but rather it means that the three cluster centers were located near the center of each class.

Table I compares the clustering performances of the proposed approach and the k-Means procedure using PDS with incomplete data. Various incomplete data sets were generated by withholding one observation (attribute) from randomly selected instances. The table shows the average frequencies of good results in 100 different data sets with 100 trials

TABLE I
AVERAGE FREQUENCIES (%) OF "GOOD" RESULTS IN 10000 TRIALS WITH INCOMPLETE DATA SET (IRIS DATA SET)

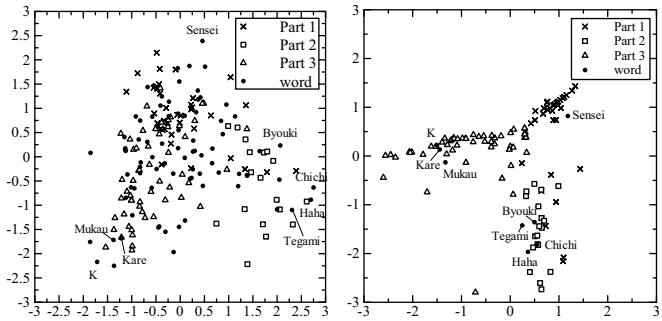
# missing elements	PCA-guided	k-Means (PDS)
0	100.00	79.01
50	100.00	85.01
60	95.84	82.46
70	92.23	79.04
80	90.37	78.58
90	84.19	75.49
100	82.46	73.20
110	82.34	69.57
120	79.34	67.47
130	74.84	65.15
140	71.91	63.42
150	70.14	60.21

with random initialization. The result of the no missing value situation for the PCA-guided approach is the same as that given by the conventional PCA-guided k-Means procedure and is free from random initialization based on the deterministic procedure. Note that the k-Means procedure may become trapped at a local minimum even when the data set includes no missing values.

The table demonstrates that the proposed PCA-guided approach is still robust to initialization when the number of missing values is not too large, e.g., 50 missing elements, although the PCA process is based on an iterative optimization scheme. As the number of missing elements increase, the frequency of good results decrease. However, the proposed PCA-guided approach is always more robust than the k-Means procedure using PDS. This result implies that the PCA-guided approach is more reliable than the conventional k-Means procedure even when data sets includes missing elements.

B. Document Clustering

Next, the characteristic feature of the proposed approach is demonstrated in a document clustering task using the Japanese novel *Kokoro* by Soseki Natsume, which can be downloaded from Aozora Bunko (http://www.aozora.gr.jp). The novel is composed of three chapters ("Sensei and I", "My Parents and I", "Sensei and His Testament") and the chapters include 36, 18, and 56 sections, respectively. In this experiment, the sections are regarded as individual text documents (number of samples is $n = 110$) and the documents are partitioned into three clusters ($K = 3$) without using the chapter information. This data set forms roughly three clusters in the 83-dimensional data space [16], as shown in Fig. 1-(a). Thus, the goal of the experiment is to reconstruct the intrinsic chapter information from a word analysis. The text documents were preprocessed using a morphological analysis system software "Chasen" (http://chasen.naist.jp/hiki/ChaSen/), which segments Japanese text strings into morphemes and tags these morphemes with their parts of speech and pronunciations. The 83 most frequently used substantives and verbs (they were used more than 50 times in the novel) were used as attributes to be analyzed with their tf-idf weights [15].



(a) 83 words (b) 8 words

Fig. 1. 2-D biplots of Japanese novel *Kokoro* [16]: (a) 83 words, (b) 8 words

TABLE II
AVERAGE FREQUENCIES (%) OF "GOOD" RESULTS USING AN INCOMPLETE DATA SET (JAPANESE NOVEL *Kokoro* WITH 83 WORDS (ATTRIBUTES))

# missing elements	PCA-guided	k-Means (PDS)
0	100.00	100.00
10	100.00	88.12
20	99.30	76.24
30	99.40	72.28
40	98.73	59.45
50	98.68	48.56
60	98.69	43.61
70	98.50	38.64
80	95.51	26.81
90	96.20	18.87
100	94.91	7.98
110	93.39	1.10

A comparison of the frequencies of good results is shown in Table II. Various incomplete data sets were generated in a similar manner as in the previous experiment. The proposed PCA-guided approach is much more robust than the k-Means procedure using PDS when data sets include many incomplete instances. This is because very ambiguous cluster boundaries easily trap the k-Means procedure using PDS at local minima whereas the PCA-guided approach is seldom influenced by a slight loss of information (in only 1 of 83 attributes).

Second, the same experiment was repeated, but using fewer words (attributes). In [16], it was shown that the three-cluster structure is clarified by using eight significant words. Therefore, only wight words (eight attributes) were used for this experiment. Table III shows a comparison of the results. The performance of the proposed PCA-guided approach is inferior to that shown in Table II because information loss became relatively large (in 1 of 83 attributes). On the other hand, the performance of the k-Means procedure using PDS is almost equivalent to that shown in Table II, although in this case as well, it is inferior to the PCA-guided approach.

These experimental results imply that the PCA-guided procedure for k-Means is also useful for incomplete data sets.

TABLE III
AVERAGE FREQUENCIES (%) OF "GOOD" RESULTS USING AN INCOMPLETE DATA SET (JAPANESE NOVEL *Kokoro* WITH 8 WORDS (ATTRIBUTES))

# missing elements	PCA-guided	k-Means (PDS)
0	100.00	100.00
10	98.62	88.12
20	96.81	76.25
30	93.32	72.29
40	91.86	59.47
50	90.05	48.57
60	88.92	43.61
70	77.59	38.61
80	67.05	26.80
90	65.84	18.93
100	54.35	8.00
110	54.64	1.07

V. CONCLUSION

In this paper, a PCA-guided procedure for k-Means clustering of incomplete data sets is proposed. Although the PCA-like method is not a deterministic procedure but rather is based on an iterative optimization scheme, the PCA-guided approach is still more robust to initialization problems than the k-Means procedure using PDS.

Comparison with other techniques for handling missing values, such as OCS, remains for future work. Other potential future work involves component-wise robust PCA [17], [18], in which component-wise noise is ignored by means of an M-estimation scheme [19].

***Abstract*—We propose a novel action-search particle-filtering algorithm for reinforcement learning processes. This algorithm is designed to perform search domain reduction and heuristic space segmentation. In this method, each action space is divided into several new segments using particles. Appropriate search domain reduction can minimize learning time and enable the recognition of the evolutionary process of learning. In a numerical experiment, the proposed filtering method is applied to a single-pendulum simulation in order to demonstrate the adaptability of this simulation model.**

***Index Terms*—reinforcement learning, particle-filter, space segmentation.**

I. Introduction

This paper proposes a novel particle-filtering algorithm for reinforcement learning that periodically divides the agent environment and action search space during the learning process. The standard reinforcement learning algorithm [1], [2] requires well-suited segmentation before learning. In the proposed method, each state is searched by several particles, and distances between states are fixed according to the importance of each state. Herein, human-like space segmentation in actor-critic learning, which we investigated previously [3], [4], is further refined.

In post-supervised design, clustering, which is done after many trial and error iterations, is a probabilistic method. A genetic algorithm representative of these schemes is called a learning classifier system [5], [6]. In this system, inputted data are encoded as binary rules that a genetic algorithm alters before selecting from them the best rules. However, inputted data can be encoded during the learning, as in the previously investigated method. Our proposed algorithm is applicable not only to reinforcement learning but also to social simulation, which requires each agent to behave rationally during the trial and error iterations. Such an approach provides clues for understanding culture and language.

II. Reinforcement learning

Reinforcement learning assumes that agents can visit only a finite number of states, and that when visiting a state, they will collect a numerical reward (which can be interpreted as a punishment in the case of a negative reward [7]). Each state has a different value associated with it. Given an initial state, subsequent states are reached according to actions. The value of a given state is defined as the average reward that can be collected by selecting actions available in that state.

A. Particle in state and action space

A high-performance agent usually needs appropriately segmented state set S and action set A because of agent state-space explosion. Generally, a genetic algorithm is used to search for appropriate segmentation in such individual double-loop learning. In particular, we use a particle swarm, which is a classification system in which a minimization of (2) under the following condition takes place:

$$\sum_{i=1}^{c} u_{ki} = 1, \tag{1}$$

where c is the number of clusters and u_{ki} is called a membership function.

$$L = \sum_{i=1}^{c} \sum_{k=1}^{N} u_{ki} D\left(x_k, v_i\right), \tag{2}$$

where N is the amount of data, c is the number of clusters, and $D\left(x_k, v_i\right)$ denotes the distance between data vector x_k and cluster center v_i: the difference between expected utility V and observed utility V' in the learning process.

B. Actor-critic

The actor-critic method includes the critic, which maintains the state value estimate V, and the actor, which is responsible for choosing the appropriate actions at each state (Fig. 1).

Value function approaches attempt to find a policy that maximizes the return by maintaining a set of estimates of expected rewards based on a policy π. In this method, an agent attempts to estimate the expected reward $V(s)$:

$$V(s) = E\left[R|s_t, \pi\right] = r_t + \gamma E\left[R|s_{t+1}, \pi\right] \tag{3}$$

for an agent following π and taking an action in state s.

step 1 Agent observes state s and actor selects action a according to its stochastic policy π.

step 2 Critic receives reward and calculates the following TD-error.

$$\text{TD-error} = r_t + \gamma V(s_{t+1}) - V(s_t), \tag{4}$$

where γ is discount factor.

step 3 Actor updates its stochastic policy π according to the TD-error.

(TD-error)> 0 Selected action a is favorable, so increase action a selection probability.

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

(TD-error)<0 Selected action a is not favorable, so decrease action a selection probability.

step 4 Update value function (Fig. 2).

$$V(s_t) \leftarrow V(s_t) + \alpha \text{TD-error}, \tag{5}$$

where α is the learning rate.

step 5 Go to **step 1**.

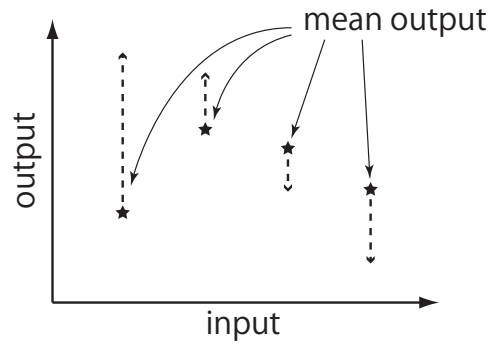

Fig. 1. Actor-critic

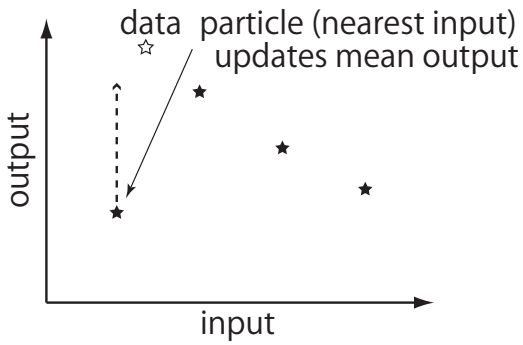

Fig. 2. Actor-critic

In this paper, we use a normal distribution as stochastic policy π (Fig. 3). Updating the stochastic policy is carried out by adjusting the particle's mean $\boldsymbol{a}$ and variance v of output (which is an agent's action).

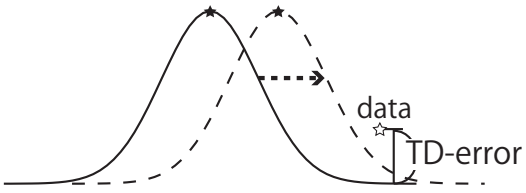

Fig. 3. Updating stochastic policy π

If (TD-error)>0,

$$\boldsymbol{a} \leftarrow (1-\alpha_a)\boldsymbol{a} + \alpha_a \text{vector[output]} \tag{6}$$

$$v \leftarrow (1-\beta_1)v. \tag{7}$$

Else if (TD-error)<0,

$$\boldsymbol{a} \leftarrow (1+\alpha_a)\boldsymbol{a} - \alpha_a \text{vector[output]} \tag{8}$$

$$v \leftarrow (1-\beta_2)v. \tag{9}$$

Here, α_a, β_1, and β_2 are parameters.

C. Particle filter

The particle-filtering method is a model estimation technique based on Bayesian models in which the latent variables are connected in a Markov chain. A particle filter estimates the sequence of hidden parameters on the basis of only on the observed data.

The method assumes that x_k and the observations y_k can be modeled in the following form:

$x_0, x_1, \ldots$ is a first-order Markov process such that

$$x_k|x_{k-1} \sim p_{x_k|x_{k-1}}(x|x_{k-1}), \tag{10}$$

where the initial distribution $p(x_0)$ is given.

Although each particle filter yields only a rough approximation, with enough particles, the estimate can be quite accurate.

The particle-filtering method generates a set of samples that approximate the filtering distribution $p(x_k|y_0,\ldots,y_k)$. With P samples, expectations with respect to the filtering distribution are approximated by

$$\int f(x_k)p(x_k|y_0,\ldots,y_k)dx_k \approx \frac{1}{P}\sum_{L=1}^{P} f(x_k^{(L)}), \tag{11}$$

and $f(\cdot)$ can provide all the moments of the distribution up to some degree of approximation.

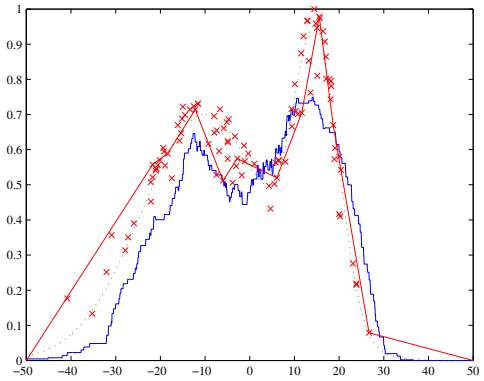

Fig. 4. Example of a particle filter

III. Particles in each action space

We propose particles in the action space. The proposed method using particles can search for the global solution (best output) and a local solution, which has the potential of being the global solution.

In each state, several particles have expected rewards according to expected utility V. If inputted data have a positive TD-error, the nearer particle is updated (shown in Fig. 5). This method decreases the probability of the local solution.

In addition, because an evenly segmented state is not always good for learning, we also propose adjusting the distance

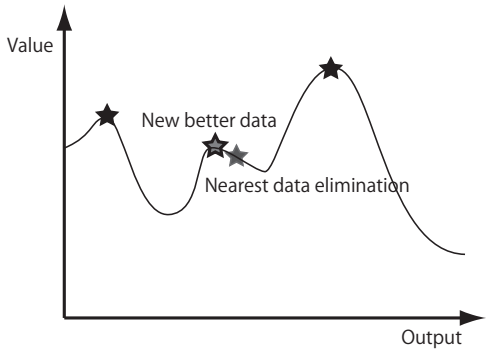

Fig. 5. Updating the output according TD-error

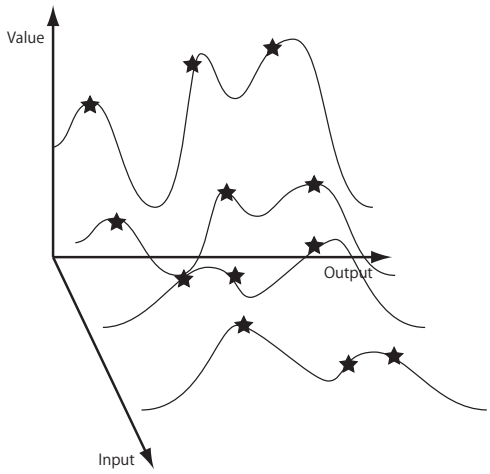

Fig. 6. Particles in the space

between state prototypes by setting the distance between successive best particles in the output-input space (in fig. 7). This is based on the fact that if the best output is quite different, near states should be searched closely, and otherwise do not need to be. In the process, the updated particle entrains the state particle.

Therefore, our proposed method requires that the input and output spaces be normalized.

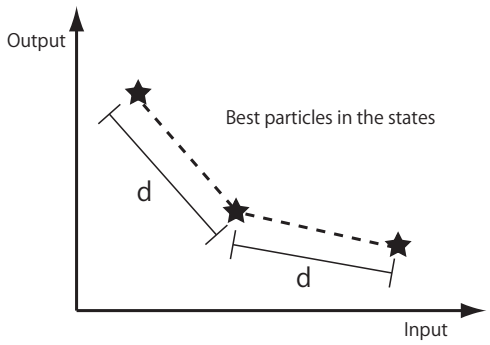

Fig. 7. Updating the input space distribution by distance

IV. Single-pendulum simulation

We simulated the single-pendulum standing task (fig. 8). This physical calculation is performed by a Runge–Kutta method.

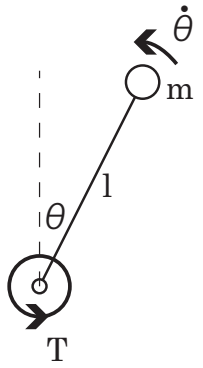

Fig. 8. Single pendulum

The following motion equation is simulated in increments of 0.05 seconds:

$$m\ddot{\theta} = -mgl\sin(\pi - \theta) + T + (-k\dot{\theta}) \tag{12}$$

where the parameters and variables are define as

- $m = 1$ (kg)
- $l = 1$(m)
- $k = 0$
- $g = 9.8(m/s^2)$
- $-\pi < \theta \leq \pi$
- $-3\pi < \dot{\theta} \leq 3\pi$
- $-20 < \ddot{\theta} \leq 20$
- 1 episode = 5 seconds
- 1 learning cycle = 0.2 seconds
- $\theta = \pi, \dot{\theta} = \ddot{\theta} = 0$, in the initial state
- $R = (\pi - |\theta|)/\pi - T/40$
- $\alpha = 0.1$
- $\gamma = 0.9$
- variance $V_0 = \pi/2, V_{1000} = V_0 \cdot \beta^{1000} = 0.0001 \cdot V_0$ for constant β.

Figs. 9 to 11 show the results of several simulations. The vertical axes in these figures show the reward and the horizontal axes show episode times. In each figure, the left panel shows the 100-trial mean of the reward and the right panel shows the best reward. The shown results are for the normal method (blue), our proposed method in which couple particles are applied (green), and our proposed method along with adjusting the distance between state prototypes (red). The agent has 100 states in the learning process. In the simulations shown in Fig. 9, each state is segmented evenly. As shown, the proposed method is not always good for learning; however, it does not inhibit the learning process.

In Figs. 10 (over-segmented position space) and 11 (over-segmented velocity space), the state is not segmented appropriately. As shown, the proposed method leads to a better reward history in terms of speed and value.

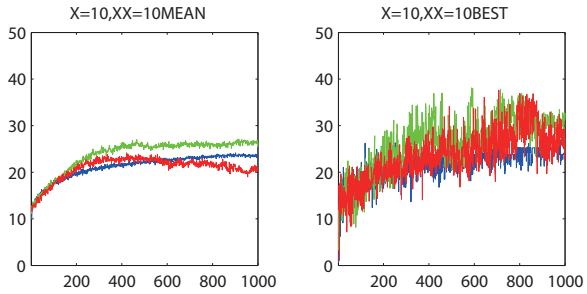

Fig. 9. Results in better segmentation by the particles

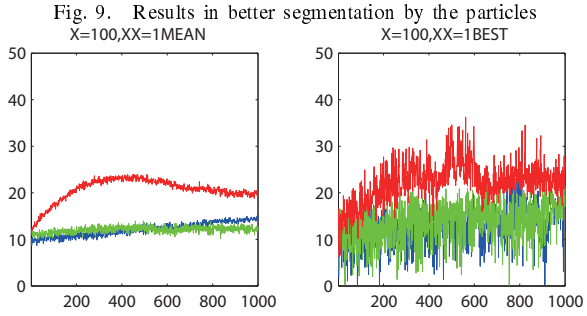

Fig. 10. Results in worse segmentation by the particles

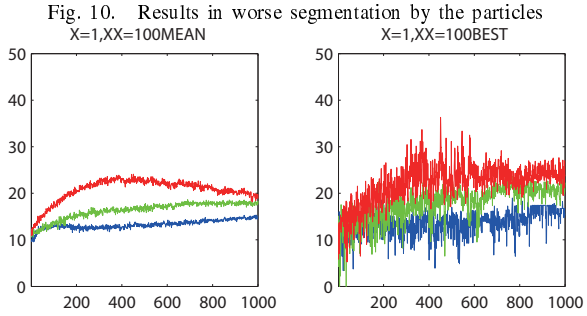

Fig. 11. Results in worse segmentation by the particles

Our simple segmentation method, especially in the state space, worked very well. Further adjustments in the parameters of the proposed method have the potential of further improving the results.

V. Conclusion

We proposed a novel particle-filtering approach to create a novel reinforcement learning algorithm that segments the agent's environment and action. The proposed filtering method is applied to a single-pendulum simulation in order to demonstrate the adaptation ability of the model.

***Abstract*—In this paper, we formalize the object membership in fuzzy ontology with property importance and property priority, while previous models lack building blocks to handle the importance and priority of properties. A formal mechanism used to measure object memberships in concepts is proposed. Such a mechanism can measure object memberships in concepts defined by properties with importance or priority well. We show that our model is more reasonable in measuring object memberships in concepts than previous models by examples and experiments.**

***Index Terms*—Fuzzy ontology, Property importance, Property priority**

I. Introduction

Traditional ontology is represented as a crisp set of objects [1] and objects are considered either to belong to or not to belong to a concept. However, there are many fuzzy concepts (e.g., 'hot water' and 'yellow car') in reality, and traditional ontology cannot handle these fuzzy concepts. Fuzzy ontologies are proposed to extend the representation ability of ontologies to handle fuzzy concepts such as [2] [3] [4]. Object membership is an important measurement of objects in fuzzy concepts and it refers to the degree of an object belonging to a concept. However, object memberships are given by users manually or obtained by fuzzy functions defined by users in these fuzzy ontologies. While concepts, objects and properties are building blocks of ontologies, these fuzzy ontologies lacks of a formal mechanism to determine memberships of objects in concepts automatically based on the defining properties of concepts and properties which objects possess.

Au Yeung and Leung [5] formalize object memberships in concepts based on theories in cognitive psychology and present a mechanism to measuring object memberships based on properties of concepts and objects automatically. Their work is extended by Cai and Leung [6]. Besides, all these works consider that properties used to define a concept are equivalent. In other words, all properties have the same importance or the same priority, and we name them as **equivalent properties**. However, some properties are more important than other properties in many situations. We name the properties with different importance in concepts as **weighted properties**. For example, when some one wants to rent a house, he may consider price of the house is more important than the location of the house. In addition, some properties are priori to other properties in measuring object memberships. We name the properties with different priorities in concepts as **prioritized properties**. For example, when measuring how great an athlete is in the Olympic Games, the number of goal medals the athlete obtained is priori to the number of silver medals the athlete obtained. The effect of an athlete obtaining one goal medal cannot be substituted by that of no matter how many silver medals the athlete obtained. Although different properties having different importance or priorities are prevalent, previous works cannot handle object memberships in concepts defined by weighted properties or prioritized properties well. For the rifeness of property importance and priority, we consider that it is necessary to model them in ontology.

In this paper, we formalize the object membership in fuzzy ontology with property importance and property priority. The formal mechanism we proposed for measuring object memberships in concepts can handle not only concepts defined by equivalent properties, but also concepts defined by weighted properties or prioritized properties well, which cannot be handled well in previous models. Besides, we formally model property importance and property priority in fuzzy ontology, and point out and discuss the differences between property importance and property priority. Experiments are conducted to validate the proposed model. To the best of our knowledge, it is the first work of modeling object memberships in fuzzy ontology with weighted properties and prioritized properties.

II. Background and Related Work

A. Classical View of Concept Representation

In cognitive psychology, it is generally accepted that concepts are characterized by properties [7]. One important model of concept representation based on properties is classical view. The classical view [8] [9] of concepts posits that each concept is defined by a set of properties which are individually necessary and collectively sufficient. Properties are atomic units which are the basic building blocks of concepts. In classical view, there are clear-cut boundaries between members and non-members of the category. As a result, the classical view cannot handle the vague concepts.

B. Fuzzy Ontology and Object Membership

Currently, most ontologies are based on DLs (description logics) [10] and concepts are represented as crisp sets of ob-

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

jects (e.g., ontologies written in OWL DL) [11]. These ontologies cannot represent the fuzzy concepts. Several fuzzy DLs are proposed to handle the fuzzy concepts by combining fuzzy set theory [12] and description logics. For example, Straccia proposes a fuzzy $\mathcal{ALC}$ in [2] and a fuzzy $\mathcal{SHOIN}(\mathcal{D})$ in [3]. Stoilos et al. present a fuzzy $\mathcal{SHIN}$ in [4]. These fuzzy DLs vary in possessing different expressive power, complexity and reasoning capabilities. Some fuzzy ontologies are constructed based on fuzzy DLs or fuzzy logic [13]. Besides, some works apply fuzzy ontologies for some applications. For instance, Cross and Voss [14] explore the potential that fuzzy mathematics and ontologies have for improving performance in multilingual document exploitation. These works lack a formal mechanism to obtain the membership degrees of objects in concepts automatically, and they do not take how people representing concepts in their mind into consideration.

Recently, Au Yeung and Leung [5] propose a formal model for fuzzy ontology based on the idea of classical view. They have formalized the membership degrees of objects in concepts by constructing several vectors in ontologies. To overcome previous models' limitations, Cai and Leung [6] propose a novel formal model of fuzzy ontology with property hierarchy and object membership. However, all these works cannot handle the concepts defined by properties which have different importance degrees or priorities. They lack formal mechanisms for measuring object memberships in concepts defined by weighted properties and prioritized properties. Besides, Bobillo and Straccia explore an expressive fuzzy description logic reasoner [15], which include the weighted sum constructor.

III. Limitations of Previous Models

We use some motivating examples to illustrate the limitations of previous models and make our motivation more clear in this section.

Example 1. Suppose that Bob wants to rent a room for 10 months from a real estate agent when he visits the Chinese University of Hong Kong. The rent of such a room would be the best if it is less than or equal to 2800 HKD each month, and he cannot offer too much more for the rent. He would like the room with a short walk distance to the university and there are some living facilities such as a bed, internet, TV, refrigerator and so on. He takes these requirements into consideration synthetically and defines the concept 'The suitable room to rent' (denoted as S_r) by some properties which are 'Price', 'Rental period', 'Time cost of walk' and 'Facilities'. In his consideration, some properties are more important than other properties. He concentrates more on the 'Price' and less on 'Rental period', 'Time cost of walk' and 'Facilities' for the reason that he has limited budget for rent. The importance weights of these properties are given in table I. The concept S_r is defined as following:

$$S_r : [A]_{0.95}, [B]_{0.9}, [C]_{0.85}, [D]_{0.8}$$

where the subscript of each property is the minimal requirement of the property. Objects (e.g., all candidate rooms) satisfying all minimal requirements of defining properties of S_r (e.g., 'The suitable room to rent') belong to S_r to a degree 1 [5] [6]. Suppose there are two candidate rooms denoted by O_1 and O_2 as following (properties of O_1 and O_2 are shown in table II).

TABLE I
Importance weights of properties of the concept Sr.

	A	B	C	D
	Price	Rental period	Time cost of walk	Facilities
weight	0.4	0.3	0.2	0.1

TABLE II
Properties of the Objects O_1 and O_2.

	Price	Rental period	Time cost of walk	Facilities
O_1	2600 HKD	10 months	11 minutes	basic
O_2	3500 HKD	12 months	8 minutes	convenience

$$O_1 : [A]_1, [B]_1, [C]_{0.9}, [D]_{0.4}; O_2 : [A]_{0.6}, [B]_{0.8}, [C]_1, [D]_1$$

The subscript of each property is the degree of an object possessing the property. We want to calculate object memberships for two rooms O_1 and O_2 in concept S_r.

We use equations in AuYeung-Leung model [5] to measure the memberships of O_1 and O_2 and obtain the following results:

$$\mu_{S_r}(O_1) = 0.52, \mu_{S_r}(O_2) = 0.604$$

Besides, we also calculate the memberships of O_1 and O_2 in S_r according to the axioms and equations in Cai-Leung model [6] and get the results as following:

$$\mu_{S_r}(O_1) = 0.5, \mu_{S_r}(O_2) = 0.6136$$

We can find that the results calculated by previous models are not intuitive. The room O_1 satisfies properties A and B to high degrees and these properties are considered as top two important properties for Bob. Although O_2 possesses properties C and D to high degrees, it possesses the more important (more considerable) properties A and B to lower degrees. What is more, the rent of O_2 also are too much more than the budget of rent that Bob can offer, and it requires Bob to rent the room for at least 12 months which is longer than the visiting period of Bob. Thus, it is clearly that O_1 should be a better candidate than O_2 for Bob to rent and should be given a higher object membership in S_r. Previous models take all properties into account equivalently and cannot reflect the importance of properties, thus the object memberships in concepts defined by properties with different importance are not intuitive and reasonable.

Example 2. Suppose in an IT company, a secretary need to find a suitable time slot to arrange a meeting for discussing a project. The CTO of the company, the project team leader, project coordinator and the team members must attend the meeting. To which a time slot is a suitable one for the meeting depends on preference degrees (PDs) of the people who attend the meeting. Besides, from the point of view of the secretary, the priorities of preferences of these people are different. The preference of the CTO is prior to that of others. The

TABLE III
DEFINING PROPERTIES AND THEIR PRIORITIES IN CONCEPT S_t

A	PDs of CTO	first priority
B	PDs of team leader	second priority
C	PDs of project coordinator	second priority
D	PDs of team member	third priority

preference of the team leader is as the same as that of the project coordinator, and is priori to the team members. Thus, for the concept 'suitable time slot for the meeting' denoted by S_t, it is defined by four properties with priorities shown in table III.

We consider that the concept S_t is defined as following:

$$S_t : [A]_1, [B]_{0.95}, [C]_{0.9}, [D]_{0.8}$$

where the subscript of each property is the minimal requirement of the property. For three time slots denoted by O_{t1}, O_{t2}, O_{t3} as following, we want to calculate object memberships for them in concept S_t.

$$O_{t1} : [A]_1, [B]_{0.9}, [C]_{0.65}, [D]_{0.5}$$

$$O_{t2} : [A]_{0.9}, [B]_{0.72}, [C]_{0.65}, [D]_1$$

$$O_{t3} : [A]_{0.9}, [B]_{0.85}, [C]_{0.75}, [D]_{0.6}$$

The subscript of each property is the degree of an object possessing the property. We use equations in AuYeung-Leung model [5] to measure the memberships of O_{t1}, O_{t2} and O_{t3} and obtain the following results:

$$\mu_{S_t}(O_{t1}) = 0.6, \mu_{S_t}(O_{t2}) = 0.685, \mu_{S_t}(O_{t3}) = 0.68$$

Similarly, we calculate the memberships of O_{t1}, O_{t2} and O_{t3} in S_t according to the axioms and equations in the [6] and get the results as following:

$$\mu_{S_t}(O_{t1}) = 0.6667, \mu_{S_t}(O_{t2}) = 0.8667, \mu_{S_t}(O_{t3}) = 0.8$$

We can find that the results calculated by previous models are not intuitive. The CTO and the team leader prefer time slot O_{t1} to a higher degree than other time slots, while the project coordinator prefer O_{t3} and other team members prefer O_{t2}. O_{t1} should be a more suitable time slot for the meeting than O_{t2} and O_{t3} for the reason that the CTO has the highest priority. Similarly, O_{t3} should have higher membership in S_t than O_{t2} for the similar reason.

According to the above examples, we can find that previous models cannot handle the cases of which defining properties of concepts have different importance degrees or priority degrees.

IV. A FORMAL MODEL OF ONTOLOGY WITH PROPERTY IMPORTANCE AND PROPERTY PRIORITY

In this section, we propose a novel formal model of fuzzy ontology with property importance and property priority.

A. A Conceptual Model of Fuzzy Ontology

Following the works in [6], we consider a fuzzy ontology O in a particular domain Δ consisting of a set of fuzzy concepts, a set of fuzzy properties and a set of objects.[1]

An object in an ontology is represented by a set of properties named **object property vector**. An object property vector $\overrightarrow{P}_a$ of an object a is a vector of $property^{value}$ pairs as following:

$$\overrightarrow{P}_a = (p_{a,1}^{v_{a,1}}, p_{a,2}^{v_{a,2}}, ..., p_{a,n}^{v_{a,n}}), 1 \leq i \leq n$$

where $p_{a,i}$ is a property a possessing, $v_{a,i}$ is the degree to which a possesses property $p_{a,i}$. The relation among properties in the object property vector is conjunction.

We combine the classical view and fuzzy set theory so that our model can handle vague concepts. We consider that all members of a concept should possess all defining properties of the concept to some degrees. A concept can be defined by a set of properties. Besides, there is a minimal requirement for each defining property of concepts. If an object possesses all defining properties of a concept to higher degrees, then it means that the object satisfies the minimal requirements of defining properties to higher degrees. Thus the object is given a higher membership degree in the concept.

Based on classical view and fuzzy set theory, the generation of representation of a concept C is as following [6]:

$$\overrightarrow{C} = (\overrightarrow{S}_1, \overrightarrow{S}_2, ..., \overrightarrow{S}_m), 1 \leq i \leq m$$

and

$$\overrightarrow{S}_i = (p_{i,1}^{w_{i,1}}, p_{i,2}^{w_{i,2}}, ..., p_{i,n_i}^{w_{i,n_i}}), 1 \leq j \leq n_i$$

where n_i is the number of properties in $\overrightarrow{S}_i$. A $\overrightarrow{S}_i$ is named a **characteristic vector** of C which consists of a set of defining properties. The relation among characteristic vectors is union, and the relation among defining properties in a $\overrightarrow{S}_i$ is conjunction. $p_{i,j}$ is a defining property in a $\overrightarrow{S}_i$. $w_{i,j}$ is considered as a minimal requirement of property $p_{i,j}$ and $w_{i,j} \in (0, 1]$. Thus, a concept can be defined by some characteristic vectors, and such a representation of a concept can handle conjunction concepts, disjunction concepts and combination concepts [6].

B. Modeling Property Importance

The membership of an object in a concept is affected by the satisfaction degrees of the object satisfying minimal requirements of all defining properties of the concept. Among all defining properties, some properties have more affection on the object membership measurement than others and we consider that such properties are more important than other properties for object membership calculation. For different concepts, their defining properties are different and the importance of those defining properties are different also. The effect caused by decreasing of the degree of an object possessing a property with a higher importance may be compensated by (be substituted by) increasing more degrees of the object possessing other properties with relative lower priority in a

[1]In the rest of this paper, all concepts, and properties are referred to fuzzy concepts and fuzzy properties respectively unless otherwise specified.

concept. For example, although the location of a house is worse than that of another one, if its rent is much more cheaper than that of the other one then it still is a better candidate to rent.

According to some main dictionaries, importance means a quality or aspect having great worth or significance, and it implies a value judgment of the superior worth or influence of something or someone. What is more, weight implies a judgment of the immediate relative importance of something. Thus, we can consider that there is a weight distribution among all defining properties, and such weights are corresponding to the importance of the corresponding defining properties, the sum of all weights is 1.

The importance of properties in a concept are represented by a **property importance vector** in which values are used to indicate effect of corresponding defining properties on object membership measurement in the concept.

Definition 1. A **property importance vector** of a concept c, denoted by $\overrightarrow{t}^c$, is a vector of $property^{value}$ pairs as following:

$$\overrightarrow{t}^c = (p_1^{r_1}, p_2^{r_2}, \cdots, p_n^{r_n}), 1 \leq i \leq n, r_i \in (0, 1]$$

where n is the number of properties in the domain, r_i is the importance value of property p_i.

If a property p_i is more important than another property p_j in a concept definition, i.e., p_i has more affection on object membership than p_j, then importance value r_i of p_i is greater than that (i.e., r_j) of p_j in $\overrightarrow{t}^c$. If $r_i = 1$ and $\sum_{i=1}^{n} r_i = 1$ means that there is only one defining property for the concept, and this single defining property is absolutely important. $\sum_{i=1}^{n} r_i = 1$ means that measuring memberships of objects in a concept is based on all defining properties of the concept. In different application domains, users have different perspective for concepts. Thus, such a property importance vector is given by users.

C. Modeling Property Priority

According to main English dictionaries, priority is used to measure the relative precedence among things in a group. The higher the priority of one thing, the earlier the thing should be handled or the more preferred is the thing.

According to people's intuition and the explanation of main English dictionaries, the essential meaning of priority is that, the effect of a property with higher priority on object membership is in a higher level than that of property with lower priority. In other words, the effect caused by any decreasing of the degree of an object possessing a property with a higher priority cannot be compensated by increasing no matter to what degrees the object possessing other properties with lower priority in a concept. If one wants to raise the object membership of an object in a concept, a defining property with a relatively higher priority must be sufficiently satisfied prior to a defining property with a relatively lower priority.

We consider that priorities of properties in a concept are represented by a property priority vector of the concept, in which are used to indicate preference order of satisfying properties on measuring object memberships.

Definition 2. A **property priority vector** of a concept c is a vector of $property^{value}$ pairs as following:

$$\overrightarrow{\rho}^c = (p_1^{u_1}, p_2^{u_2}, \cdots, p_n^{u_n}), 1 \leq i \leq n, u_i \in \Omega$$

where n is the number of properties in the domain, u_i is the priority value of property p_i and Ω is a total order set.

Such a property priority vector is given by users for the reason that different users have different consideration on property priorities. In the property priority vector, u_i is the priority value of corresponding property p_i, and it is used to indicate the priority (preference order) of p_i. Furthermore, we present two propositions for priority ordering.

Proposition 1. If a property p_i **is prior to** (more preference than) property p_j in concept c, then u_i is succeeded by u_j in Ω, denoted by $u_i \succ_c u_j$.

Proposition 2. If a property p_i **is prior to or have the same priority with** property p_j in a concept c, then u_i is succeeded by u_j or u_i is equal to u_j, denoted by $u_i \succeq_c u_j$.

V. Formalizing Object Memberships

As mentioned above, the membership of an object in a concept depends on aggregating satisfaction degrees of the object satisfying the minimal requirements of all defining properties of the concept.

A. Local Satisfaction Degrees

Definition 3. The **local satisfaction degree** (LSD) of an object a for a properties p_i in a characteristic vector $\overrightarrow{S}_x$ is the degree of object a satisfying the minimal requirement of p_i in $\overrightarrow{S}_x$.

The local satisfaction degree (LSD) of object a for property p_i in a characteristic vector $\overrightarrow{S}_x$ is a degree in the range of [0,1] and it is given by a local satisfaction function ℓ.

$$\ell : Q \times O \rightarrow [0, 1]$$

where Q is the set of defining properties, O is the set of object property vector. If $\ell(p_i, \overrightarrow{P}_a) = 1$, it means that object a definitely satisfies the minimal requirement of property p_i. If $\ell(p_i, \overrightarrow{P}_a) = 0$, it means that object a does not satisfy the minimal requirement of property p_i at all. We present some axioms for the local satisfaction function ℓ to observe.

Axiom 1. For an object a, a defining property $p_{S,i}$ in characteristic vector $\overrightarrow{S}$, if a possesses property $p_{S,i}$ to a degree greater than the minimal requirement of $p_{S,i}$, i.e., $v^a_{S,i} \geq w_{S,i}$, then $\ell(p_{S,i}, \overrightarrow{P}_a) = 1$.

Axiom 2. For an object a, a defining property $p_{S,i}$ in characteristic vector $\overrightarrow{S}$, if a possesses property $p_{S,i}$ to a degree 0, i.e., $p^a_{S,i} = 0$, then $\ell(p_{S,i}, \overrightarrow{P}_a) = 0$.

Axiom 3. For an object a, two defining properties $p_{S,i}$ and $p_{S,j}$ in characteristic vector $\overrightarrow{S}$, $v^a_{S,i} < w_{S,i}$ and $v^a_{S,j} < w_{S,j}$, and $v^a_{S,i} = v^a_{S,j}$, $w_{S,i} \geq w_{S,j}$, then $\ell(p_{S,i}, \overrightarrow{P}_a) \leq \ell(p_{S,j}, \overrightarrow{P}_a)$

Axiom 4. For an object a, two defining properties $p_{S,i}$ and $p_{S,j}$ in characteristic vector $\overrightarrow{S}$, $v^a_{S,i} < w_{S,i}$, $v^a_{S,j} < w_{S,j}$ and $v^a_{S,i} \geq v^a_{S,j}$, if $w_{S,i} = w_{S,j}$, then $\ell(p_{S,i}, \overrightarrow{P}_a) \geq \ell(p_{S,j}, \overrightarrow{P}_a)$

Axiom 5. For two objects a and b, a defining property $p_{S,i}$ in characteristic vector $\overrightarrow{S}$, $v^b_{S,i} \leq v^a_{S,i} < w_{S,i}$, then $\ell(p_{S,i}, \overrightarrow{P}_a) \geq \ell(p_{S,i}, \overrightarrow{P}_b)$

Theorem 1. For an object a, two defining properties $p_{S,i}$ and $p_{S,j}$ in characteristic vector $\overrightarrow{S}$, $v^a_{S,i} < w_{S,i}$, $v^a_{S,j} < w_{S,j}$ and $v^a_{S,i} \geq v^a_{S,j}$, if $w_{S,i} \leq w_{S,j}$, then $\ell(p_{S,i}, \overrightarrow{P}_a) \geq \ell(p_{S,j}, \overrightarrow{P}_a)$

Axioms 1 and 2 specify the boundary cases of local satisfaction degrees of objects for properties. Axioms 3 specifies the influence of minimal requirements of properties, and it means that the higher minimal requirement of a property is the stricter requirement of the property, thus the less LSDs for an object for the property. Axioms 4 and 5 specify the influence of degrees of objects possessing properties, and they show the monotonic increase of the LSDs of objects for properties as the increase of degrees of objects possessing properties.[2]

We propose a possible function which satisfies the Axioms 1 to 5.

$$\ell(p_{S,i}, \overrightarrow{P}_a) = \begin{cases} v_{S,i} + (1 - w_{S,i}) & v^a_{S,i} < w_{S,i} \\ 1 & v^a_{S,i} \geq w_{S,i} \end{cases} \quad (1)$$

B. Global Satisfaction Degrees with Weighted Properties

After obtaining all local satisfaction degrees of an object for all defining properties in a characteristic vector, we need to aggregate all of them and the aggregation degree is named as **Global Satisfaction Degree** (GSD). There are two kinds of Global Satisfaction Degree. One is corresponding to characteristic vectors defined with weighted properties and another is corresponding to characteristic vector defined with prioritized properties.

Definition 4. The global satisfaction degree (GSD) of an object a for a characteristic vector $\overrightarrow{S}$ defined with weighted properties is an aggregation degree of aggregating all local satisfaction degrees of a for properties in $\overrightarrow{S}$, which is in the range of [0,1].

While a concept is defined by a set of weighted properties, the global satisfaction degree of an object for a characteristic vector depends on aggregating not only all local satisfaction degrees, but also the importance of the corresponding properties. The higher degree of an object satisfying an property and the more importance of the property are, the higher object membership.

We consider that the global satisfaction degree of an object for a characteristic vector consisting of weighted properties is given by a function:

$$g^t : (T \times L)^n \rightarrow [0, 1]$$

where T is the set of property importance vectors, L is the set of LSDs of objects for properties and n is the set of numbers of defining properties in characteristic vectors.

We also can represent such a function as the following:

$$g^t_{S,a} = \oplus^n_{i=1}\{(r_{S,i}, \ell(p_{S,i}, \overrightarrow{P}_a)) | p_{S,i} \in \overrightarrow{S}\}$$

[2]We do not show the verification of all axioms and the proof of all theorems in the paper for the limitation of space.

where $p_{S,i}$ is a defining property of a characteristic vector $\overrightarrow{S}$, $r_{S,i}$ is the importance value of property p_i in a concept C where $\overrightarrow{S} \in \overrightarrow{C}$ and $\oplus$ is an aggregation function.

Properties with higher importance have more effects on the global satisfaction degrees than other properties with lower importance while aggregating all local satisfaction degrees. It means that an object can possess a higher GSD if it satisfies properties which are more important to higher degrees. This is in line with the intuition of people and the essence of the importance.

The function $g^t_{S,a}$ should observe the following axioms:

Axiom 6. For an object a and a characteristic vector $\overrightarrow{S}$, if $\exists i$ where $p_{S,i} \in \overrightarrow{S}$, $\ell(p_{S,i}, \overrightarrow{p}_a) = 0$, then $g^t_{S,a} = 0$

Axiom 7. For an object a and a characteristic vector $\overrightarrow{S}$, if $\forall i$ where $p_{S,i} \in \overrightarrow{S}$, $\ell(p_{S,i}, \overrightarrow{p}_a) = 1$, then $g^t_{S,a} = 1$

Axiom 8. For two objects a and b, a characteristic vector $\overrightarrow{S}$, if for some properties $p_{S,i} \in \overrightarrow{S}$, $\ell(p_{S,i}, \overrightarrow{p}_a) \geq \ell(p_{S,i}, \overrightarrow{p}_b)$, and $\forall x$ where $x \neq i, p_{S,x} \in \overrightarrow{S}$ and $\ell(p_{S,x}, \overrightarrow{p}_a) = \ell(p_{S,x}, \overrightarrow{p}_b)$, then $g^t_{S,a} \geq g^t_{S,b}$

Axiom 9. For an object a, two characteristic vectors $\overrightarrow{S}$ and $\overrightarrow{K}$, if for property $p_{S,i} \in \overrightarrow{S}$ and property $p_{K,j} \in \overrightarrow{K}$, $i \neq j, r_{S,i} = r_{K,j}$, $\ell(p_{S,i}, \overrightarrow{p}_a) \geq \ell(p_{K,j}, \overrightarrow{p}_a)$, and for all other properties x in $\overrightarrow{S}$ are also shared by $\overrightarrow{K}$, $x \neq i \neq j, \ell(p_{S,x}, \overrightarrow{p}_a) = \ell(p_{K,x}, \overrightarrow{p}_a)$, then $g^t_{S,a} \geq g^t_{K,a}$

Axiom 10. For two objects a and b, two defining properties $p_{S,i}$ and $p_{S,j}$ in a characteristic vector $\overrightarrow{S}$, $r_{S,i} > r_{S,j}$, if $r_{S,i} - r_{S,j} = \gamma, \gamma > 0$, $\ell(p_{S,i}, \overrightarrow{P}_a) - \ell(p_{S,i}, \overrightarrow{P}_b) = \delta, \delta \geq 0$ and $\ell(p_{S,j}, \overrightarrow{P}_b) - \ell(p_{S,j}, \overrightarrow{P}_a) = \delta', \delta' \geq 0$, and $\forall x$ where $x \neq i \neq j, \ell(p_{S,x}, \overrightarrow{P}_a) = \ell(p_{S,x}, \overrightarrow{P}_b)$, and $\exists \epsilon \geq 0, \delta' - \delta = \epsilon$, then $g^t_{S,b} \leq g^t_{S,a}$.

Axioms 6 and 7 specify the boundary cases of global satisfaction degrees of objects for characteristic vectors. Axioms 8 and 9 specify the influence of the LSDs of objects for properties on GSDs of objects for characteristics vectors consisting of weighted properties. They show the monotonicity of the aggregation, i.e., the global satisfaction degree of an object for a characteristic vector should increase when the local satisfaction degrees of the objects for defining properties in the characteristic vector increase.

Axiom 10 shows the essential of importance of properties. The effect of a more important property on GSDs of objects for a characteristic vector is greater than that of less importance properties. Besides, the effects reduced by decreasing the importance of properties can be compensated by increasing LSDs of objects for other properties.

We present a possible function which satisfies Axiom 6 to 10 as following:

$$g^t_{S,a} = \begin{cases} \sum^n_{i=1} r_{S,i} \times \ell(p_{S,i}, \overrightarrow{p}_a) & others \\ 0 & \exists i, \ell(p_{S,i}, \overrightarrow{p}_a) = 0 \end{cases} \quad (2)$$

If all properties in a characteristic vector have the same importance (i.e., the same weight), it is a special case of characteristic vector with weighted properties. In such a special case, all properties in a characteristic vector are equivalent properties and the function $g^t_{S,a}$ does not need to satisfy Axiom

10 (only need to observe Axioms 6 to 9) for the reason that all property importance are the same. In this special case, the GSD of an object for a characteristic vector defined by equivalent properties is given by a function denoted by $g^l_{S,a}$:

$$g^l_{S,a} = \Phi^n_{i=1}\{\ell(p_{S,i}, \overrightarrow{P}_a)|p_{S,i} \in \overrightarrow{S}\}$$

where Φ is an aggregation function only satisfying Axioms 6-9. We present a possible function for $g^l_{S,a}$ as following:

$$g^l_{S,a} = \begin{cases} \frac{\sum_{i=1}^{n} \ell(p_{S,i}, \overrightarrow{p}_a)}{n} & others \\ 0 & \exists i, \ell(p_{S,i}, \overrightarrow{p}_a) = 0 \end{cases} \quad (3)$$

Equation 3 observes Axioms 6 to 9 and does not observe Axiom 10, and it is also a special case of Equation 2. In such a special case, for Equation 2, the weight of each property in characteristic vector $\overrightarrow{S}$ is $\frac{1}{n}$, i.e., $\forall i, r_{S,i} = \frac{1}{n}$.

C. Global Satisfaction Degrees with Prioritized Properties

Property priority is different from property importance. The affections of properties with different priority on object membership are in different level. Each priority value in Ω is corresponding to a priority level. The effect of increase of LSDs of an object for lower priority properties cannot be cumulated so as to compensate that of decrease of LSDs of the object for higher priority properties. In other words, if the local satisfaction degree of an object O_a for the highest priority property in a concept C is greater than that of another object O_b, then the object membership of O_a in C is greater than that of O_b no matter to what degrees the LSDs of these two objects for other properties with lower priorities are. For example, the vetoes of permanent member of the UN Security Council (i.e., USA, UK, France, Russia and China) have higher priority than that of other members, and if a proposal is not approved by any one of the permanent members, then the proposal cannot be passed even if all non-permanent members agree to it. Thus, we cannot combine the LSDs of objects for higher priority properties with that of the LSDs of objects for lower priority properties by simply aggregation as introduced in Section 5.2.

To reflect the characteristics of priority of properties, we consider that there is a corresponding global satisfaction degree for each priority level.

Definition 5. The **ith-level global satisfaction degree** of object a for a characteristic vector $\overrightarrow{S}$ denoted by $g^{\rho,i}_{s,a}$ is an aggregation degree of aggregating all local satisfaction degrees of the object for properties with a priority i ($i \in \Omega$) in $\overrightarrow{S}$, which is in the range of [0,1].

There may be some properties which have the same priority. In other words, there are some properties in ith priority level, and these properties are considered as equivalent properties in ith priority level. We consider that ith-level global satisfaction degree of an object a for a characteristic vector $\overrightarrow{S}$ is determined as following:

$$g^{\rho,i}_{S,a} = \Phi^n_{x=1}\{\ell(p_{S,x}, \overrightarrow{P}_a)|p_{S,x} \in \overrightarrow{S}, u_{S,x} = i\} \quad (4)$$

where $\ell(p_{S,x}, \overrightarrow{P}_a)$ is the local satisfaction degree of object a for property $p_{S,x}$, $u_{S,x}$ is the priority of $p_{S,x}$ and Φ is an aggregation function as introduced in Section 5.2.

Definition 6. The global satisfaction degree of object a for a characteristic vector $\overrightarrow{S}$ with prioritized properties is a tuple consists of all ith-level GSDs, i.e.,

$$g^{\rho}_{S,a} = (g^{\rho,1}_{S,a}, g^{\rho,2}_{S,a}, ..., g^{\rho,n}_{S,a})$$

where n is the number of priority levels of properties in $\overrightarrow{S}$.

For the reason that global satisfaction degrees of objects for a characteristic vectors with prioritized properties are tuples, we present some axioms for comparing them.

Axiom 11. For two objects a and b, a characteristic vector $\overrightarrow{S}$ with prioritized properties, if for a priority level i, $g^{\rho,i}_{S,a} > g^{\rho,i}_{S,b}$, and for those priority levels x where $u_{S,x} \succeq u_{S,i}$ we have $g^{\rho,x}_{S,a} = g^{\rho,x}_{S,b}$, then $g^{\rho}_{S,a} > g^{\rho}_{S,b}$.

Axiom 12. For two objects a and b, a characteristic vector $\overrightarrow{S}$ with prioritized properties, if for all priority levels i where $g^{\rho,i}_{S,a} = g^{\rho,i}_{S,b}$, then $g^{\rho}_{S,a} = g^{\rho}_{S,b}$.

Theorem 2. For two objects a and b, a characteristic vector $\overrightarrow{S}$ with prioritized properties, if for all priority levels i, $g^{\rho,i}_{S,a} \geq g^{\rho,i}_{S,b}$, then $g^{\rho}_{S,a} \geq g^{\rho}_{S,b}$.

Axiom 11 shows the essential of priorities of properties. If the LSD of an object a for a property with a priority (i.e., priority level i) is greater than that of another object b, and the LSDs of a and b for properties with higher priorities are the same (i.e., priority level x), then the GSD of a will greater than that of b no matter to which degree of object a and b satisfy other properties with lower priority than i. Axiom 12 specifies the case that when two objects' GSDs are the same. If all LSDs of the two objects for all defining properties in a characteristic vector are the same, then the GSDs of them for the characteristic vector are the same.

If all properties in a characteristic vector have the same priority, it is a special case of characteristic vector with prioritized properties. In such a special case, there is only one priority level (i.e., 1st-level), and all properties in a characteristic vector are equivalent properties in the same priority level. Thus, the GSD of an object a for a characteristic vector $\overrightarrow{S}$ is equal to the 1st-level GSD (a tuple consisting only the 1st-level global satisfaction degree), i.e.,

$$g^{\rho}_{S,a} = g^{\rho,1}_{S,a} = \Phi^n_{i=1}\{\ell(p_{S,i}, \overrightarrow{P}_a)|p_{S,i} \in \overrightarrow{S}, u_{S,i} = 1\}$$

D. Measuring Object Membership

We consider the fuzzy membership of an object a in fuzzy concept C depends on the following equation:

$$\mu_C(a) = max(g'_{S_1,a}, g'_{S_2,a}, ..., g'_{S_m,a}) \quad (5)$$

where m is the number of characteristic vectors in concept C and $g'_{S_i,a}$ is the global satisfaction degree of object a for characteristic $\overrightarrow{S}_i$ in concept C. If the properties in $\overrightarrow{S}_i$ are weighted properties, then $g'_{S_i,a} = g^t_{S_i,a}$, which is a numerical value defined in Section 5.2; if the properties in $\overrightarrow{S}_i$ are prioritized properties, then $g'_{S_i,a} = g^{\rho}_{S_i,a}$, which is a tuple defined in Section 5.3.

An object may satisfy all the property minimal requirements of more than one characteristic vectors. We use the maximal value of $g'_{S_i,a}$ as the membership of a in C because that the relation among $\overrightarrow{S}_i$ is disjunction.

TABLE IV
LSDs OF O_1 AND O_2 IN THE CONCEPT S_r

	$p_{S_r,A}$	$p_{S_r,B}$	$p_{S_r,C}$	$p_{S_r,D}$
O_1	1	1	1	0.65
O_2	0.65	0.9	1	1

TABLE V
LSDs OF O_1, O_2 AND O_3 IN S_t

	$p_{S_t,A}$	$p_{S_t,B}$	$p_{S_t,C}$	$p_{S_t,D}$
O_1	1	0.95	0.75	0.7
O_2	0.9	0.77	0.75	1
O_3	0.9	0.9	0.85	0.8

VI. ILLUSTRATING EXAMPLES

Let us revisit the Example 1 in Section 3. For our model, the property importance vector of S_r is given as following:

$$\overrightarrow{t}^{S_r} = (A^{0.4}, B^{0.3}, C^{0.2}, D^{0.1})$$

Based on Equation 1, we obtain the local satisfaction degrees of O_1 and O_2 for properties in S_r shown in table IV.

We use Equations 2 and 5 to calculate the object memberships for O_1 and O_2 and get the following results:

$$\mu_{S_r}(O_1) = 0.96, \mu_{S_r}(O_2) = 0.83$$

Such a result is more intuitive than previous models. Based on our model, the room O_1 satisfies the top two importance properties A and B to higher degrees than O_2 even though it possesses properties C and D to lower degrees than O_2, thus the global satisfaction degree of O_1 for concept S_r is greater than that of O_2. Previous models do not take property importance into consideration and cannot handle objects memberships in concepts with weighted properties.

For the Example 2 in Section 3, in our model, the property importance vector of S_t is given as following:

$$\overrightarrow{\rho}^{S_t} = (A^{first}, B^{second}, C^{third}, D^{fourth})$$

Based on Equation 1, we obtain the local satisfaction degrees of O_{t1}, O_{t2} and O_{t3} for properties in the concept S_t shown in table V.

We use Equation 3, 4 and 5 to obtain the global satisfaction degree of object O_{t1}, O_{t2} and O_{t3} as following:

$$\mu_{S_t}(O_{t1}) = (1, 0.85, 0.7), \mu S_t(O_{t2}) = (0.9, 0.76, 1)$$

$$\mu S_t(O_{t3}) = (0.9, 0.875, 0.8)$$

Based on Axioms 11 and 12, the object membership comparison result of O_{t1}, O_{t2} and O_{t3} is as following:

$$\mu_{S_t}(O_{t1}) > \mu_{S_t}(O_{t3}) > \mu_{S_t}(O_{t2})$$

Such a result is more reasonable than previous models.

In the above two examples, both concepts S_r and S_t have only one characteristic vector (i.e., in Equation 5, $m = 1$), and the object memberships of objects in these two concepts depend on the object property vectors, the unique characteristic vector for each concept and property importance vector (or property priority vector).

VII. EXPERIMENT

A. Evaluation on Concepts with Property Importance

We collect the information of 200 rental houses in Hong Kong. We want to measure the membership degrees of these 200 houses for the concept of 'suitable houses to rent' for users. There are four properties for each house, which are 'Price', 'Rental period', 'Time cost of walk' and 'Facilities'. We let each user input his personal importance degrees of properties for measurement. Different users may give different importance weights for properties.

In our experiment, the standard result is a ranking of object memberships given by users through questionnaires. It is not suitable to ask people to rank too many objects based on memberships because people may be confused with too many objects in a questionnaire, so we randomly select 10 houses from those 200 houses for questionnaires of users. For each user, the randomly selected 10 houses may be different. We evaluate the calculation results of our model on the 10 houses by comparing them with the standard results given by users.

We propose a measure function $Precision$ for evaluating the calculation results based on the questionnaire.

$$Precision = 1 - \frac{\sum_{i=1}^{n} |CRank_i - QRank_i|}{m}$$

where n is the number of objects, m is the possible maximal difference between the calculation ranking of objects and questionnaire ranking of objects, $CRank_i$ is the rank number of the ith object obtained by calculation, $QRank_i$ is the rank number of the ith object given by the user. The $Precision$ function is a decreasing function of average of distances between corresponding objects' memberships rankings in calculation and questionnaire. There are 10 objects and thus m (the denominator in the equation) is 50. The precision comparison of our model and the model in [6] on concepts with property importance are shown in Fig. 1.

According to Fig. 1, our method is more accurate than previous method without property importance. The reason is that our method takes the property importance into consideration and this is in line with users. Previous method just treats all properties equivalently, thus the results of membership ranking are the same for all users, i.e., it does not distinguish different users' requirements on property importance.

B. Evaluation on Concepts with Property Priority

To evaluate our method on handling the cases with property priority, we collect the medal information of 87 countries that have medals in 2008 Olympic Games. We want to measure the membership degrees of these countries for the concept of 'Outstanding Country in 2008 Olympic Games'. There are three properties for each country, which are 'Number of Gold Medals', 'Number of Silver Medals', and 'Number of Bronze Medals'. In our method, we give the first priority to 'Number of Gold Medals', the second priority to 'Number of Silver Medals' and third priority to 'Number of Bronze Medals'. We also use the precision metric and the standard answer is obtained from the 'medal table' in 2008 Olympic Games

Fig. 1. Comparison of precision with concepts with property importance

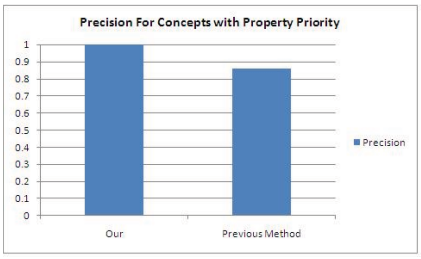

Fig. 2. Comparison of precision with concepts with property priority

website.[3] The precision comparison of our method and the method in [6] on concepts with property importance are shown in Fig. 2. According to Fig. 2, similar to Fig. 2, our method is more accurate (the same ranking as the standard answer) than previous method without property priority.

VIII. Discussions

Importance and priority are two different subjective judgements of people on properties.

Property importance is used to indicate the influence effects of corresponding properties on a cognitive task (e.g., measuring object membership in this paper). One interesting characteristic of weighted property is that the effect of a weighted property on object membership measurement can be substituted (compensated) by effects of other weighted properties. For a concept defined by weighted properties, the membership of an object in the concept is the combination degree of the object satisfying all defining properties. Properties having different importance in a characteristic vector can form a weight distribution among properties, the more important the more weight of a property. All the weighted properties can affect the object membership measurement simultaneously instead of a sequence comparison of defining properties. For instance, in Example 1, the membership of a candidate room in concept S_r depends on aggregating the local satisfaction degrees of the house for all defining properties of S_r simultaneously.

Property priority is used to indicate the preference order of satisfying defining properties for increasing object memberships. For a concept defined by prioritized properties, object membership of an object in the concept is a tuple of degrees instead of a number in the range of [0,1], and the object membership comparison depends on a sequence comparison from properties with higher priority to properties with lower priority. For a prioritized property with higher priority, the effect of it on object membership measurement cannot be substituted by effects of other prioritized properties with lower priority values. Thus, it is more reasonable to model the membership of an object in a concept defined by prioritized properties as a tuple consisting of different level GSDs instead of a number and compare the memberships of two objects level-by-level (from higher to lower priority) as a sequence comparison. For instance, in Example 2, the choose of a suitable time slot for the meeting depends on comparing the different level GSDs from high to low priority level.

[3]http://match.2008.sina.com.cn/bj2008/all_medal.php

IX. Conclusion

In this paper, we formalize object membership in fuzzy ontology with property importance and property priority. We also show that our model is more reasonable and intuitive in measuring object memberships in concepts with property importance or property priority than previous models by examples. Our formal mechanism used to measure object memberships in concepts can handle not only concepts defined by equivalent properties, but also concepts defined by weighted properties or prioritized properties well, which cannot be handled well in previous models.

***Abstract*—Fuzzy Description Logics (Fuzzy DLs) are logics that allow to deal with structured knowledge affected by fuzziness. Fuzzy DLs are at the heart of Fuzzy OWL 2, a fuzzy version of the standard ontology language OWL 2. Although a relatively important amount of work has been carried out in the last years, fuzzy DLs are open to be extended with several features worked out in other fields. In particular, the integration of aggregation operators (AOs) in fuzzy DLs has received little attention so far.**

In this work, we show how to support aggregation operators in fuzzy DLs. We provide syntax and semantics of a fuzzy DL extended with AOs, and provide a calculus for a family of AOs (weighted sum, OWA and quantifier-guided OWA). We also show how to encode them into our proposal for Fuzzy OWL 2.

***Keywords*—Fuzzy ontologies, Fuzzy Description Logics, Fuzzy OWL 2, Aggregation operators, OWA operators**

I. Introduction

Description Logics (DLs) [1] play a key role in the design of *Ontologies*. An Ontology consists of a hierarchical description of important concepts in a particular domain, along with the description of the properties (of the instances) of each concept. In this context, DLs are important as they are essentially the theoretical counterpart of the *Web Ontology Language OWL 2* [2], the standard language to represent ontologies.

It is well-known that "classical" ontology languages are not appropriate to deal with *vague knowledge*, which is inherent to several real world domains [3], [4]. *Fuzzy ontologies* emerge as useful in several applications, such as (multimedia) information retrieval, image interpretation, ontology mapping, matchmaking, multi-criteria decision making [5] and the Semantic Web [6]. So far, several fuzzy extensions of DLs can be found in the literature (see the survey in [6]).

A representation of fuzzy ontologies using OWL 2 annotation properties has been recently proposed (in this paper, we will call it *Fuzzy OWL 2*) [7]. The use of annotation properties makes it possible to use current OWL 2 editors for fuzzy ontology representation, such as Protégé. This approach has reached a sufficient level of maturity and there exists a Protégé plug-in to edit fuzzy ontologies, as well as some parsers that translate fuzzy ontologies represented using this approach into the languages supported by some fuzzy DL reasoners.

Aggregation Operators (AOs) are mathematical functions that are used to combine information [8]. The arithmetic mean, the weighted sum, the median and, more generally Ordered Weighted Averaging (OWA) [9] are the most well-known AOs. AOs have been widely used in computational intelligence because of their ability to fuse linguistically expressed pieces of information.

The integration of AOs and fuzzy ontologies is of great interest, in order to combine the advantages of both formalisms. In this work, we show *how to support AOs in fuzzy ontologies*. In particular, we provide syntax and semantics of a fuzzy DL extended with AOs, provide a calculus for a family of aggregation operators, such as weighted sum, OWA and quantifier-guided OWA, and show how to represent them using our previous proposal for Fuzzy OWL 2 [7].

There is little related work combining AOs and fuzzy DLs. [10] presents a fuzzy DL with AOs, but the expressivity is very limited. Also, weighted sum concepts have been proposed in the literature (see e.g., [11]). Our contributions consists of a more expressive fuzzy DL, independent of the fuzzy operators considered, together with a reasoning algorithm and a representation using OWL 2, for a family of AOs.

In the following, we proceed as follows. Section II recalls basic notions on mathematical fuzzy logic and aggregation operators. Then, Section III introduces fuzzy DLs that support aggregation operators. We provide the syntax, semantics, and reasoning algorithms for a family of AOs. Then, Section IV shows how to support them within fuzzy OWL 2 [7]. Finally, Section V sets out some conclusions and discusses future work.

II. Preliminaries

A. Mathematical Fuzzy Logic

In *Mathematical Fuzzy Logic* [12], the convention prescribing that a statement is either true or false is changed and is a matter of degree measured on an ordered scale that is no longer $\{0,1\}$, but the $[0,1]$. This degree is called *degree of truth* of the statement ϕ in the interpretation $\mathcal{I}$. In this section, *fuzzy statements* have the form $\phi \geqslant r$ or $\phi \leqslant r$, where $r \in [0,1]$ (see, e.g. [12], [13]) and ϕ is a statement, which encode that the degree of truth of ϕ is *at least* r (resp. *at most* r).

A *fuzzy interpretation* $\mathcal{I}$ maps each basic statement p_i into $[0,1]$ and is then extended inductively to all statements: $\mathcal{I}(\phi \wedge \psi) = \mathcal{I}(\phi) \otimes \mathcal{I}(\psi)$, $\mathcal{I}(\phi \vee \psi) = \mathcal{I}(\phi) \oplus \mathcal{I}(\psi)$, $\mathcal{I}(\phi \rightarrow \psi) = \mathcal{I}(\phi) \Rightarrow \mathcal{I}(\psi)$, $\mathcal{I}(\neg\phi) = \ominus\mathcal{I}(\phi)$, $\mathcal{I}(\exists x.\phi(x)) = \sup_{a\in\Delta^{\mathcal{I}}} \mathcal{I}(\phi(a))$, $\mathcal{I}(\forall x.\phi(x)) = \inf_{a\in\Delta^{\mathcal{I}}} \mathcal{I}(\phi(a))$, where $\Delta^{\mathcal{I}}$ is the domain of $\mathcal{I}$, and $\otimes$, $\oplus$, $\Rightarrow$, and $\ominus$ are *t-norms*, *t-conorms*, *implication functions*, and *negation functions*, respectively, which extend the Boolean conjunction, disjunction, implication, and negation, respectively, to the fuzzy case.

One usually distinguishes three different logics, namely Łukasiewicz, Gödel, and Product logics [12]. Zadeh logic,

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

	Łukasiewicz logic	Gödel logic	Product logic
$a \otimes b$	$\max(a+b-1,0)$	$\min(a,b)$	$a \cdot b$
$a \oplus b$	$\min(a+b,1)$	$\max(a,b)$	$a+b-a \cdot b$
$a \Rightarrow b$	$\min(1-a+b,1)$	$\begin{cases} 1 & \text{if } a \leq b \\ b & \text{otherwise} \end{cases}$	$\min(1,b/a)$
$\ominus a$	$1-a$	$\begin{cases} 1 & \text{if } a=0 \\ 0 & \text{otherwise} \end{cases}$	$\begin{cases} 1 & \text{if } a=0 \\ 0 & \text{otherwise} \end{cases}$

namely $a \otimes b = \min(a,b)$, $a \oplus b = \max(a,b)$, $\ominus a = 1-a$ and $a \Rightarrow b = \max(1-a,b)$, is entailed by Łukasiewicz logic.

A *fuzzy set* R over a countable crisp set X is a function $R\colon X \to [0,1]$. The trapezoidal (Fig. 1 (a)), the triangular (Fig. 1 (b)), the L-function (left-shoulder function, Fig. 1 (c)), and the R-function (right-shoulder function, Fig. 1 (d)) are frequently used to specify membership degrees.

The notions of satisfiability and logical consequence are defined in the standard way. A fuzzy interpretation $\mathcal{I}$ *satisfies* a fuzzy statement $\phi \geqslant r$ (resp., $\phi \leqslant r$) or $\mathcal{I}$ is a *model* of $\phi \geqslant r$ (resp., $\phi \leqslant r$), denoted $\mathcal{I} \models \phi \geqslant r$ (resp., $\mathcal{I} \models \phi \leqslant r$), iff $\mathcal{I}(\phi) \geqslant r$ (resp., $\mathcal{I}(\phi) \leqslant r$).

B. Aggregation Operators

Aggregation Operators (AOs) (see, e.g. [8]) are mathematical functions that are used to combine information. There exist a large number of different AOs that differ on the assumptions on the data (data types) and about the type of information that we can incorporate in the model. To what concerns us, an AO of dimension n is a mapping $@ : \mathbb{R}^n \to \mathbb{R}$ that satisfies:

1) $@(a) = a$ (idempotent if unary)
2) $@(0,\ldots,0) = 0$ and $@(1,\ldots,1) = 1$ (boundary conditions)
3) $@(a_1,\ldots,a_n) \leq @(b_1,\ldots,b_n)$ if $\forall i, a_i \leq b_i$ (monotone)

Note that we always have that

$$\min(a_1,\ldots,a_n) \leq @(a_1,\ldots,a_n) \leq \max(a_1,\ldots,a_n) \ .$$

Often, an AO $@$ is parameterised with a vector of n weights $W = [w_1,\ldots,w_n]$ such that $w_i \in [0,1]$ and $\sum_i w_i = 1$. In that case we will denote the AO as $@_W$.

Examples of AOs are the *arithmetic mean*,

$$@^{\text{avg}}(a_1,\ldots,a_n) = \frac{1}{n}\sum_i a_i \tag{1}$$

the *weighted sum*

$$@^{\text{ws}}_W(a_1,\ldots,a_n) = \sum_i w_i a_i \ , \tag{2}$$

and the *Ordered Weighted Averaging* (OWA) operators and the quantifier-guided OWAs that we shall present next.

The OWA operators [9], [14], [15] provide a parameterised class of mean type AOs. Formally, an OWA operator of dimension n is an AO such that

$$@^{\text{owa}}_W(a_1,\ldots,a_n) = \sum_j w_j b_j \ , \tag{3}$$

where b_j is the j-th largest of the a_i.

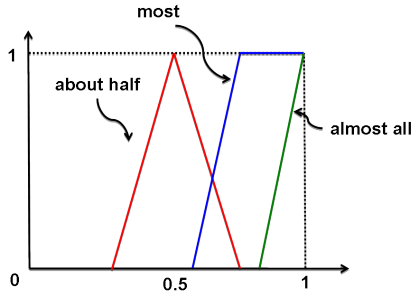

Fig. 2. Some examples of fuzzy quantifiers.

A fundamental aspect of these operators is the reordering step. In particular, a weight w_i is not associated with a specific argument but with an ordered position of the aggregate. By choosing different W we can implement different AOs. The OWA operator is a non-linear operator as a result of the process of determining the b_j. An OWA operator $@$ is a mean operator and is also symmetric and idempotent:

$$\begin{aligned} &\textit{Symmetric} : @(a_1,\ldots,a_n) = @(a_{\pi(1)},\ldots,a_{\pi(n)}) \\ &\textit{Idempotent} : @(a,\ldots,a) = a \end{aligned}$$

where π is a permutation. Notable OWA operators are:

$$\begin{aligned} f(a_1,\ldots,a_n) &= \max(a_1,\ldots,a_n) \text{ for } W = [1,0,\ldots,0] \\ f(a_1,\ldots,a_n) &= \min(a_1,\ldots,a_n) \text{ for } W = [0.\ldots,0,1] \\ f(a_1,\ldots,a_n) &= \text{avg}(a_1,\ldots,a_n) \text{ for } W = [1/n,1/n,\ldots,1/n] \\ f(a_1,\ldots,a_n) &= \text{med}(a_1,\ldots,a_n) \text{ for } w_i = 0, \\ &\qquad n \text{ odd and } w_{(n+1)/2} = 1, \text{ or} \\ &\qquad n \text{ even and } w_{n/2} = 0.5 = w_{n/2+1} \end{aligned}$$

In the equations above, avg and med are the average and median value of the a_i, respectively.

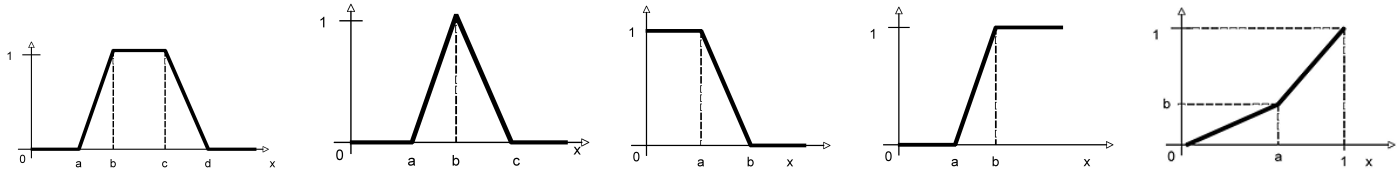
As next we recap *quantifier aggregations* [14], [16], [17], [18]. Classical logic has two quantifiers, the universal $\forall$ and the existential $\exists$ quantifier. These are extremal ones among several other linguistic quantifiers such as *most, few, about half, some, many*, etc. Quantifiers can be seen as absolute of proportional (see, e.g. [18]). To what concerns us, we consider the proportional ones. In this case, a proportional type quantifier, such as *most*, can be represented as a fuzzy subset $Q : [0,1] \to [0,1]$ such that for each $r \in [0,1]$, the membership grade $Q(r)$ indicates the degree to which the proportion r satisfies the linguistic quantifier that Q represents. See Figure 2 for examples of fuzzy quantifiers.

An important class of quantifiers are the *monotone quantifiers* that satisfy the following conditions:

1) $Q(0) = 0$,
2) $Q(1) = 1$,
3) $Q(r_1) \leq Q(r_2)$ if $r_1 \leq r_2$.

Essentially, these quantifiers are characterised by the idea that as the proportion increases, the degree of satisfaction does not decrease. For two quantifiers Q_1, Q_2, we write $Q_1 \leq Q_2$ if for all r, $Q_1(r) \leq Q_2(r)$. We recall that the two classical quantifiers $\exists, \forall$ may be defined as the monotone quantifiers $Q_\exists(r) = 0$ if $r \neq 1$ and $Q_\forall(r) = 1$ if $r \neq 0$, respectively. Note that for any monotone quantifier Q, we have that

$$Q_\forall \leq Q \leq Q_\exists \tag{4}$$



(a) (b) (c) (d) (e)

Fig. 1. (a) Trapezoidal function; (b) Triangular function; (c) L-function; (d) R-function; (e) Linear function .

dictating that $\forall$ and $\exists$ are indeed the lower and upper bounds of monotone quantifiers.

To introduce quantifier-guided aggregation, we consider first the evaluation of quantified propositions. So, let Y be a (crisp) set of objects and B some fuzzy subset of Y. A quantified proposition is a statement of the form

$$QY\text{'s are } B \quad .$$

An example of such a statement is "most students are young". Yager [16] suggested an approach to evaluate the truth of such quantified propositions using OWA. In the following we will assume that Q is a monotone quantifier. The first step consists in associating to Q an OWA weighting vector W_Q of dimension $n = |Y|$, where $|S|$ is the cardinality of a denumerable set S. The weights are obtained as

$$w_j = Q(\frac{j}{n}) - Q(\frac{j-1}{n}) \ . \tag{5}$$

Note that for Q monotone, $w_j \in [0,1]$ and $\sum_j w_j = 1$. Now, we can obtain the truth t of the statement "QY's are B" as

$$t = @^{\text{owa}}_{W_Q}(a_1, \ldots, a_n) \tag{6}$$

where $a_i = B(y_i)$, $y_i \in Y$ and $@^{\text{owa}}_{W_Q}$ is the OWA operator obtained using the weights W_Q found from Q as above.

We turn now to the issue of quantifier-guided aggregation, that have been shown to be useful for evaluating multi-criteria decision problems [19]. So, assume X to be a set of alternatives and we have a collection of n criteria A_i that are of concern in a given problem. For $x \in X$, with $A_i(x)$ we indicate the degree to which the i-th criterion is satisfied by alternative x. It is easily verified that the degree to which *all* criteria are satisfied by x can be determined by $D(x) = \min(A_1(x), \ldots, A_n(x))$ while the degree to which *some* criteria is satisfied by x can be determined by $D(x) = \max(A_1(x), \ldots, A_n(x))$. In general, for a monotone quantifier Q, the degree to which

$$Q \text{ of the criteria are satisfied by } x$$

can be formalised as

$$D(x) = @^{\text{owa}}_{W_Q}(A_1(x), \ldots, A_n(x)) \ , \tag{7}$$

where $@^{\text{owa}}_{W_Q}$ is the OWA operator obtained using the weights W_Q found from Q.

Thus, by selecting an appropriate weighting vector W, we are essentially implementing a kind of quantifier-guided aggregation.

III. Aggregation Operators and Fuzzy DLs

The aim of this section is to show how current fuzzy DLs can be extended to support AOs. For illustrative purposes and for reasons of space, we will just consider a minimal fuzzy DL (see, e.g. [11] for a more expressive fuzzy DL). For the sake of our purpose, we will consider $\mathcal{ALCF}(\mathbf{D})$ [20], which is the basic DL $\mathcal{ALC}$ extended with functional roles (letter $\mathcal{F}$) and fuzzy concrete domains (letter $\mathbf{D}$).

A. The Fuzzy DL $\mathcal{ALCF}(\mathbf{D})$ with Aggregation Operators

In general, a *fuzzy concrete domain* (or simply *fuzzy domain*) is a pair $\langle \Delta_{\mathbf{D}}, \Phi_{\mathbf{D}} \rangle$, where $\Delta_{\mathbf{D}}$ is an interpretation domain and $\Phi_{\mathbf{D}}$ is the set of *fuzzy domain predicates* $\mathbf{d}$ with a predefined arity n and an interpretation $\mathbf{d}^{\mathbf{D}} \colon \Delta^n_{\mathbf{D}} \to [0,1]$, which is a n-ary fuzzy relation over $\Delta_{\mathbf{D}}$ [20]. In our specific fuzzy DL, we assume that predicates are unary and $\Delta_{\mathbf{D}}$ are non-negative real numbers.

Now, consider pair wise disjoint alphabets of *concepts names* (denoted A), *abstract roles names* (denoted R) and *concrete roles names* (denoted T). Within the alphabet of abstract and concrete roles, we have distinguished subsets of *abstract functional roles names* (denoted f) and *concrete functional roles names* (denoted t), respectively. Functional roles are also called *features*.

Concepts (denoted C or D) of the language can be built inductively from atomic concepts (A), top concept $\top$, bottom concept $\bot$, abstract roles (R), concrete roles (T) as follows. The syntax of fuzzy concepts is as follows [11]:

$$\begin{array}{rcl} C, D & \to & \top \mid \bot \mid A \mid C \sqcap D \mid C \sqcup D \mid \neg C \mid \\ & & \forall R.C \mid \exists R.C \mid \forall T.\mathbf{d} \mid \exists T.\mathbf{d} \\ \mathbf{d} & \to & ls(a,b) \mid rs(a,b) \mid tri(a,b,c) \mid trz(a,b,c,d) \end{array}$$

where ls, rs, tri, trz stand for left-shoulder, right-shoulder, triangular and trapezoidal membership functions. These are our concrete domain predicates. So, for instance the expression $Human \sqcap \exists hasChild.Lovely$ is a concept (unary predicate), which will denote the fuzzy set of humans that have a lovely child, while $Human \sqcap \forall hasChild.Lovely$ will denote the fuzzy set of humans that have only lovely children. Also, the expression $Human \sqcap \exists hasAge.ls(10,30)$ will denote the set of young humans (their age is $ls(10,30)$).

We next extend fuzzy DLs to support AOs. Consider a family of AOs $(@_n)$, $n \in \mathbb{N}$, each of arity $a(n)$. Then, similarly to [10], the following are concept expressions

$$C \quad \to \quad C \mid @_n(C_1, \ldots, C_{a(n)}) \ .$$

Example 1: The following concept expressions denote the fuzzy set of hotels that are cheap, close to the venue and comfortable, in which the degree is computed respectively as the weighted sum, the OWA aggregation and the quantifier-guided aggregation.

$$Hotel \sqcap @^{\text{ws}}_{W}(Cheap, CloseToVenue, Comfortable)$$
$$Hotel \sqcap @^{\text{owa}}_{W}(Cheap, CloseToVenue, Comfortable)$$
$$Hotel \sqcap @^{\text{owa}}_{W_Q}(Cheap, CloseToVenue, Comfortable)$$

It is interesting to note that a weighted sum concept $@^{\text{ws}}_{W}(C_1, \ldots, C_n)$ cannot be represented using an OWA operator $@^{\text{owa}}_{W}(C_1, \ldots, C_n)$, because in a weighted sum concept every weight is assigned to a specific concept, whereas in OWA operators every weight is associated to the concept that corresponds to a specific position after a reordering step.

A *Fuzzy Knowledge Base* (or *fuzzy Ontology*) comprises a fuzzy ABox $\mathcal{A}$ and a fuzzy TBox $\mathcal{T}$. A *fuzzy ABox* consists of a finite set of *fuzzy assertions* of one of the following types: a fuzzy *concept assertion* of the form $\langle a{:}C, r\rangle$ (with informal meaning, individual a is an instance of concept C with degree at least r), or a fuzzy *role assertion* of the form $\langle (a,b){:}R, r\rangle$ (the pair of individuals (a,b) is an instance of role R with degree at least r), with $r \in [0,1]$. In FOL, $\langle a{:}C, r\rangle$ may be seen as a fuzzy statement of the form $C(a) \geqslant r$, while $\langle (a,b){:}R, r\rangle$ may be seen as a fuzzy statement of the form $R(a,b) \geqslant r$.

A *fuzzy TBox* consists of a finite set of *fuzzy General Concept Inclusions (fuzzy GCIs)*, which are expressions of the form $\langle C \sqsubseteq D, r\rangle$ (with informal meaning, the degree of subsumption between concept C and D is not less than r). $C \equiv D$ is a shorthand for both $\langle C \sqsubseteq D, 1\rangle$ and $\langle D \sqsubseteq C, 1\rangle$.

From a semantics point of view, a *fuzzy interpretation* $\mathcal{I} = (\Delta^{\mathcal{I}}, \cdot^{\mathcal{I}})$ relative to the fuzzy concrete domain $\langle \Delta_{\mathbf{D}}, \Phi_{\mathbf{D}}\rangle$, consists of a nonempty set $\Delta^{\mathcal{I}}$ (the *domain*), disjoint from $\Delta_{\mathbf{D}}$, and of a *fuzzy interpretation function* $\cdot^{\mathcal{I}}$ that coincides with $\cdot_{\mathbf{D}}$ on every fuzzy concrete predicate, and it assigns: (i) to each abstract concept C a function $C^{\mathcal{I}}\colon \Delta^{\mathcal{I}} \to [0,1]$; (ii) to each abstract role R a function $R^{\mathcal{I}}\colon \Delta^{\mathcal{I}} \times \Delta^{\mathcal{I}} \to [0,1]$; (iii) to each abstract feature f a partial function $f^{\mathcal{I}}\colon \Delta^{\mathcal{I}} \times \Delta^{\mathcal{I}} \to \{0,1\}$ such that for all $u \in \Delta^{\mathcal{I}}$ there is an unique $w \in \Delta^{\mathcal{I}}$ on which $f^{\mathcal{I}}(u,w)$ is defined; (iv) to each concrete role T a function $T^{\mathcal{I}}\colon \Delta^{\mathcal{I}} \times \Delta_{\mathbf{D}} \to [0,1]$; (v) to each concrete feature t a partial function $t^{\mathcal{I}}\colon \Delta^{\mathcal{I}} \times \Delta_{\mathbf{D}} \to \{0,1\}$ such that for all $u \in \Delta^{\mathcal{I}}$ there is an unique $v \in \Delta_{\mathbf{D}}$ on which $t^{\mathcal{I}}(u,v)$ is defined.

Given arbitrary t-norm $\otimes$, t-conorm $\oplus$, negation function $\ominus$ and implication function $\Rightarrow$, the fuzzy interpretation function is extended to *complex concepts* and *fuzzy axioms* as in Figure 3, where @ is an AO[1].

Now, we will define some common reasoning tasks [3]. Let $\alpha \in \{a{:}C, (a,b){:}R, C \sqsubseteq D\}$ and $\tau = \langle \alpha, r\rangle$. A fuzzy interpretation $\mathcal{I}$ *satisfies* (is a *model* of) a fuzzy axiom τ iff $\alpha^{\mathcal{I}} \geq r$. A fuzzy KB $\mathcal{K}$ is *satisfiable* iff there is a model $\mathcal{I}$ which satisfies each of the fuzzy axioms in $\mathcal{K}$. A fuzzy axiom τ is a *logical consequence* of a fuzzy KB $\mathcal{K}$ iff, for every model $\mathcal{I}$ of $\mathcal{K}$, $\mathcal{I} \models \tau$. The *Best Entailment Degree* (BED) of an axiom α w.r.t. a fuzzy KB $\mathcal{K}$ is defined as $bed(\mathcal{K}, \alpha) = \sup\{r \mid \mathcal{K} \models \langle \alpha, r\rangle\}$. The *Best Satisfiability Degree* (BSD) of a concept C w.r.t. a fuzzy KB $\mathcal{K}$ as $bsd(\mathcal{K}, C) = \sup_{\mathcal{I} \models \mathcal{K}} \sup_{x \in \Delta^{\mathcal{I}}} C^{\mathcal{I}}(x)$ [11].

Example 2: Suppose we have some data about hotels, as shown in the following table:

$hotel$	$price$	$distance$	$star$
h_1	150	300	4
h_2	100	500	2

Assume that we are looking for a cheap, close to the venue and comfortable hotel. To this end, we may encode the problem using a fuzzy KB $\mathcal{K}$ with the following ABox $\mathcal{A}$:

$$Hotel(h_1), Hotel(h_2), price(h_1, 150), price(h_2, 100),$$
$$distance(h_1, 300), distance(h_2, 500), star(h_1, 4), star(h_2, 2)$$

where $price, distance$ and $star$ are concrete features.

The TBox $\mathcal{T}$ holds some definitions for cheap, close and comfortable hotels and contains the following axioms:

$$\begin{aligned} Cheap &= Hotel \sqcap \exists price.ls(60, 120) \\ CloseToVenue &= Hotel \sqcap \exists distance.ls(200, 400) \\ Comfortable &= Hotel \sqcap \exists star.ls(3, 5)\ . \end{aligned}$$

Note that, e.g., we have that $\mathcal{K} \models \langle h_2{:}Cheap, 0.33\rangle$, i.e., h_2 is a cheap hotel to degree no less than 0.33 (it is easily verified that this degree is also tight). Now, for some suitable AO @, we may compute the degree n_i to which hotel h_i satisfies our request as

$$n_i = bed(\mathcal{K}, h_i{:}@(Cheap, CloseToVenue, Comfortable))$$

B. A Reasoning Algorithm

We next provide a reasoning procedure that supports a family of AOs for fuzzy DLs. To simplify our exposition, we will make the following assumptions. We restrict the fuzzy DL to the case of Lukasiewicz fuzzy logic (and, thus, support "Zadeh logic" as well). Other fuzzy logics could be dealt with similarly as in [20], [21]. Furthermore, we will restrict KBs to be *unfoldable* [22], which is defined as follows.

A fuzzy TBox $\mathcal{T}$ is *unfoldable* iff it verifies the following three constraints: (i) every axiom in $\mathcal{T}$ is either of the form $\langle A \sqsubseteq C, 1\rangle$ or $A \equiv C$, where A is an atomic concept [2]; (ii) there is no concept A such that it appears more than once on the left hand side of some axiom in $\mathcal{T}$; and (iii) no cyclic definitions are present in $\mathcal{T}$. We will say that A *directly uses* primitive concept B in $\mathcal{T}$, if there is some axiom $\tau \in \mathcal{T}$ such that A is on the left hand side of τ and B occurs in the right hand side of τ. Let *uses* be the transitive closure of the relation *directly uses* in $\mathcal{T}$. $\mathcal{T}$ is *cyclic* iff there is A such that A uses A in $\mathcal{T}$. Analogously, a fuzzy KB is said to be *unfoldable* when its TBox is unfoldable.

Unfoldable TBoxes can be eliminated through an *expansion process* [23].Essentially, each axiom $A \sqsubseteq C \in \mathcal{T}$ can be replaced with $A = C \sqcap A^*$, where A^* is a new concept name.

[1]For ease of presentation, we identify the interpretation of ls, rs, tri, trz and @ with the functions themselves.

[2]In particular this forbids concept $\top$ on the left hand side of axioms.

Concept		Semantics
$(\top)^{\mathcal{I}}(x)$	=	1
$(\bot)^{\mathcal{I}}(x)$	=	0
$(A)^{\mathcal{I}}(x)$	=	$A^{\mathcal{I}}(x)$
$(C \sqcap D)^{\mathcal{I}}(x)$	=	$C^{\mathcal{I}}(x) \otimes D^{\mathcal{I}}(x)$
$(C \sqcup D)^{\mathcal{I}}(x)$	=	$C^{\mathcal{I}}(x) \oplus D^{\mathcal{I}}(x)$
$(\neg C)^{\mathcal{I}}(x)$	=	$\ominus C^{\mathcal{I}}(x)$
$(@(C_1, \ldots, C_n))^{\mathcal{I}}(x)$	=	$@({C_1}^{\mathcal{I}}(x), \ldots, {C_n}^{\mathcal{I}}(x))$

Concept		Semantics

$(a{:}C)^{\mathcal{I}}$	=	$C^{\mathcal{I}}(a^{\mathcal{I}})$
$((a,b){:}R)^{\mathcal{I}}$	=	$R^{\mathcal{I}}(a^{\mathcal{I}}, b^{\mathcal{I}})$
$(C \sqsubseteq D)^{\mathcal{I}}$	=	$\inf_{x \in \Delta^{\mathcal{I}}} \{C^{\mathcal{I}}(x) \Rightarrow D^{\mathcal{I}}(x)\}$

Fig. 3. Semantics of fuzzy concepts and axioms.

Let $\mathcal{K}'$ the obtained knowledge base. $\mathcal{K}'$ can be *expanded* by substituting every concept name A occurring in $\mathcal{K}$, which is defined in $\mathcal{T}$, with its defining term in $\mathcal{T}$.

Note that reasoning with fuzzy GCIs requires so-called blocking conditions [1] and are known to work properly for Zadeh logic only [24]. See [22] for problems risen by GCIs within Lukasiewicz logic. These problems do not appear here due to our, by purpose, simplified assumptions.

The basic idea of the reasoning algorithm is as follows and is common to most fuzzy DLs algorithms (see, e.g. [21]). Consider $\mathcal{K} = \langle \mathcal{T}, \mathcal{A} \rangle$, where $\mathcal{T}$ is unfoldable. In order to solve the BED problem, we combine appropriate DL tableaux rules with methods developed in the context of *many-valued logics* (MVLs) [13]. In order to determine e.g., $bed(\mathcal{K}, a{:}C)$, we consider an expression of the form $\langle a{:}\neg C, 1 - x \rangle$ (informally, $\langle a{:}C \leq x \rangle$), where x is a $[0,1]$-valued variable. Then we construct a tableaux for $\mathcal{K} = \langle \mathcal{T}, \mathcal{A} \cup \{\langle a{:}\neg C, 1 - x \rangle\} \rangle$ in which the application of satisfiability preserving rules generates new fuzzy assertion axioms together with *inequations* over $[0,1]$-valued variables. These inequations have to hold in order to respect the semantics of the DL constructors. Hence, we *minimise* the original variable x such that all constraints are satisfied[3].

Similarly, for $C \sqsubseteq D$, we can compute $bed(\mathcal{K}, C \sqsubseteq D)$ as the minimal value of x such that $\mathcal{K} = \langle \mathcal{T}, \mathcal{A} \cup \{\langle a : C, x_1 \rangle\} \cup \{\langle a : D, x_2 \rangle\} \rangle$ is satisfiable under the constraints expressing that $x_1 \Rightarrow x_2 \leq x, x_1 \in [0,1]$ and $x_2 \in [0,1]$, where a is new abstract individual.

Finally, $bed(\mathcal{K}, (a,b){:}R)$ is equivalent to $bed(\mathcal{K} \cup \{\langle b : B, 1 \rangle\}, a{:}\exists R.B)$, where B is a new concept (which does not appear in $\mathcal{K}$).

Therefore, the BED problem can be reduced to minimal satisfiability problem of a KB. Finally, concerning the best satisfiability bound problem, $bsd(\mathcal{K}, C)$ is determined by the maximal value of x such that $\langle \mathcal{T}, \mathcal{A} \cup \{\langle a{:}C, x \rangle\} \rangle$ is satisfiable.

In general, depending on the semantics of the DL constructors and fuzzy domain predicates we may end up with a general, bounded *Mixed Integer Non Linear Programming* (MINLP) optimization problem. In this paper, however, due to our restrictions above and those we will impose to AOs, we will end up with a *Mixed Integer Linear Program* (MILP) optimization problem [25]. Interestingly, as for the MVL case, the tableaux we are generating contains *one* branch only and, thus, just *one* MILP problem has to be solved.

We recall that a general MILP problem consists in minimizing a linear function with respect to a set of constraints that are linear inequations in which rational and integer variables can occur. More precisely, let $x = \langle x_1, \ldots, x_k \rangle$ and $y = \langle y_1, \ldots, y_m \rangle$ be variables over $\mathbb{Q}$ and $\mathbb{Z}$ respectively, over the integers and let A, B be integer matrices and h an integer vector. The variables in y are called *control variables*. Let $f(x,y)$ be an $k+m$-ary linear function. Then the general MILP problem is to find $\bar{x} \in \mathbb{Q}^k, \bar{y} \in \mathbb{Z}^m$ such that $f(\bar{x}, \bar{y}) = \min\{f(x,y) \mid Ax + By \geq h\}$. Furthermore, we say that $M \subseteq [0,1]^k$ is MILP-representable iff there is a MILP (A, B, h) with k real and m $0-1$ variables such that $M = \{x : \exists y \in \{0,1\}^m$ such that $Ax + By \geq h\}$. In general, we require that a constructor f is MILP representable. In particular, the sets $g(f) = \{\langle x_1, \ldots, x_k, x \rangle \colon f(x_1, \ldots, x_k) \geq x\}$ and $\bar{g}(f) = \{\langle x_1, \ldots, x_k, x \rangle \colon f(x_1, \ldots, x_k) \leq x\}$ should be MILP-representable.

For instance, under Łukasiewicz t-norm, $x_1 \otimes x_2 \geq l$ can be written as $\{l \leq y, x_1 + x_2 - 1 \leq l, x_1 + x_2 - y \geq l, y \in \{0,1\}\}$. Therefore, $g(\otimes)$ is MILP representable.

To guarantee that our reasoning process ends up to solve a MILP problem, we require that every constructor is MILP representable. For instance, classical logic, Zadehs fuzzy logic, and Lukasiewicz connectives, are MILP-representable. It is not difficult to see that indeed the functions ls, rs, tri and trz are MILP representable as well (see, e.g. [20], [21]).

To guarantee that also a concept expression of the form $@(C_1, \ldots, C_n)$, involving an AO $@$, can be handled appropriately by our reasoning method, we have further to impose that $@$ is indeed MILP representable. For instance, it is easy to see that this is the case of the weighted sum, $@^{\text{ws}}_W$, while more difficult is the notably case of the OWAs, $@^{\text{owa}}_W$, for which we provide the encoding in the Appendix. Therefore, this covers also the case of quantifier based OWAs. Note that in this latter case, no particular restriction is due on the quantifier except of being monotone and computable in finite time. Furthermore, we may support also so-called OWA approximations such as those proposed in [26], [27], that are less demanding from a computational point of view.

Like most of the tableaux algorithms, our algorithm works on *completion-forests*. Let $\mathcal{K} = \langle \mathcal{T}, \mathcal{A} \rangle$ be a fuzzy KB. A completion-forest $\mathcal{F}$ for $\mathcal{K}$ is a collection of trees whose

[3]Informally, suppose the minimal value is $\bar{n}$. We will know then that for any interpretation $\mathcal{I}$ satisfying the knowledge base such that $(a{:}C)^{\mathcal{I}} < \bar{n}$, the starting set is unsatisfiable and, thus, $(a{:}C)^{\mathcal{I}} \geq \bar{n}$ has to hold. Which means that $bed(\mathcal{K}, a{:}C) = \bar{n}$

distinguished roots are arbitrarily connected by edges. Each node v is labelled with a set $\mathcal{L}(v)$ of expressions of the form $\langle C, l\rangle$, where $C \in sub(\mathcal{K})$ ($sub(\mathcal{K})$ is the set of named concepts appearing in $\mathcal{K}$), and l is either a rational, a variable x, or a negated variable, i.e., of the form $1 - x$, where x is a variable. The intuition is that v is an instance of C to degree equal or greater than the evaluation of l.

Each edge $\langle v, w\rangle$ is labelled with a set $\mathcal{L}(\langle v, w\rangle)$ of expressions of the form $\langle R, l\rangle$, where $R \in \mathcal{R}_\mathcal{K}$ ($\mathcal{R}_\mathcal{K}$ is the set of roles in $\mathcal{K}$). The intuition here is that $\langle v, w\rangle$ is an instance of R to degree greater or equal than the evaluation of l.

The forest has associated a set $\mathcal{C}_\mathcal{F}$ of constraints of the form $l \leq l'$, $l = l'$, $x_i \in [0, 1], y_i \in \{0, 1\}$, where l, l' are arithmetic expressions, on the variables occurring in the node labels and edge labels.

The algorithm initializes a forest $\mathcal{F}$ to contain *(i)* a root node v_0^i, for each individual a_i occurring in $\mathcal{A}$, labelled with $\mathcal{L}(v_0^i)$ such that $\mathcal{L}(v_0^i)$ contains $\langle C_i, r\rangle$ for each fuzzy assertion $\langle a_i{:}C_i, r\rangle \in \mathcal{A}$, and *(ii)* an edge $\langle v_0^i, v_0^j\rangle$, for each fuzzy assertion $\langle (a_i, a_j){:}R_i, r\rangle \in \mathcal{A}$, labelled with $\mathcal{L}(\langle v_0^i, v_0^j\rangle)$ such that $\mathcal{L}(\langle v_0^i, v_0^j\rangle)$ contains $\langle R_i, r\rangle$. $\mathcal{F}$ is then expanded by repeatedly applying the completion rules described below. The completion-forest is complete when none of the completion rules are applicable. Then, the MILP problem on the set of constraints $\mathcal{C}_\mathcal{F}$ is solved.

With x_α we denote the variable associated to the *assertion* α of the form $a{:}C$ or $(a, b){:}R$. x_α will take the truth value associated to α. With x_c we will denote the variable associated to the concrete individual c.

Let us discuss now how to deal with feature roles. Let $\mathcal{F}$ be a forest, p an abstract or concrete feature such that we have two edges $\langle v, w_1\rangle$ and $\langle v, w_1\rangle$ such that $\langle p, l_1\rangle$ and $\langle p, l_2\rangle$ occur in $\mathcal{L}(\langle v, w_1\rangle)$ and $\mathcal{L}(\langle v, w_2\rangle)$, respectively (informally, $\mathcal{F}$ contains $\langle (v, w_1){:}p, l_1\rangle$ and $\langle (v, w_2){:}p, l_2\rangle$). Then we call such a pair a *fork*. As p is a partial function, such a fork means that w_1 and w_2 have to be interpreted as the same individual. Such a fork can be deleted by adding both $\mathcal{L}(\langle v, w_2\rangle)$ to $\mathcal{L}(\langle v, w_1\rangle)$ and $\mathcal{L}(w_2)$ to $\mathcal{L}(w_1)$, and then deleting node w_2. At the beginning, we remove the forks from the initial forest. We assume that forks are eliminated as soon as they appear (as part of a rule application) with the proviso that newly generated nodes are replaced by older ones and not vice-versa.

Now we are ready to present the inference rules. Recall that $\mathbf{d} \in \{ls, rs, tri, trz\}$, while $@ \in \{@^{\text{avg}}, @_W^{\text{ws}}, @_W^{\text{owa}}\}$:

($\bot$). If $\langle \bot, l\rangle \in \mathcal{L}(v)$ then $\mathcal{C}_\mathcal{F} = \mathcal{C}_\mathcal{F} \cup \{l = 0\}$.

(R). If $\langle R, l\rangle \in \mathcal{L}(\langle v, w\rangle)$ then $\mathcal{C}_\mathcal{F} = \mathcal{C}_\mathcal{F} \cup \{x_{(v,w):R} \geq l\} \cup \{x_{(v,w):R} \in [0, 1]\}$. The case for concrete roles T is similar.

(f). If $\langle f, l\rangle \in \mathcal{L}(\langle v, w\rangle)$ then $\mathcal{C}_\mathcal{F} = \mathcal{C}_\mathcal{F} \cup \{x_{(v,w):f} \geq l\} \cup \{x_{(v,w):f} \in \{0, 1\}\}$. The case for concrete features t is similar.

(C). If $\langle C, l\rangle \in \mathcal{L}(v)$ then $\mathcal{C}_\mathcal{F} = \mathcal{C}_\mathcal{F} \cup \{x_{v:C} \geq l\} \cup \{x_{v:C} \in [0, 1]\}$.

($\sqcap$). If $\langle C \sqcap D, l\rangle \in \mathcal{L}(v)$ then *(i)* append $\langle C, x_{v:C}\rangle$, and $\langle D, x_{v:D}\rangle$ to $\mathcal{L}(v)$, and *(ii)* $\mathcal{C}_\mathcal{F} = \mathcal{C}_\mathcal{F} \cup \{x_{v:C} \otimes x_{v:D} \geq l\}$.

($\sqcup$). If $\langle C \sqcup D, l\rangle \in \mathcal{L}(v)$ then *(i)* append $\langle C, x_{v:C}\rangle$ and $\langle D, x_{v:D}\rangle$ to $\mathcal{L}(v)$, and *(ii)* $\mathcal{C}_\mathcal{F} = \mathcal{C}_\mathcal{F} \cup \{x_{v:C} \oplus x_{v:D} \geq l\}$.

($\neg$). If $\langle \neg C, l\rangle \in \mathcal{L}(v)$ then *(i)* append $\langle C, x_{v:C}\rangle$ to $\mathcal{L}(v)$, and *(ii)* $\mathcal{C}_\mathcal{F} = \mathcal{C}_\mathcal{F} \cup \{x_{v:\neg C} = 1 - x_{v:C}\}$.

($\forall$). If *(i)* $\langle \forall R.C, l_1\rangle \in \mathcal{L}(v)$, $\langle R, l_2\rangle \in \mathcal{L}(\langle v, w\rangle$, and *(ii)* the rule has not been already applied to this pair then *(i)* append $\langle C, x_{w:C}\rangle$ to $\mathcal{L}(w)$, and *(ii)* $\mathcal{C}_\mathcal{F} = \mathcal{C}_\mathcal{F} \cup \{x_{w:C} \geq l_1 \otimes l_2\}$.

($\exists$). If $\langle \exists R.C, l\rangle \in \mathcal{L}(v)$ then *(i)* create a new node w, and *(ii)* append $\langle R, x_{(v,w):R}\rangle$ to $\mathcal{L}(\langle v, w\rangle)$, and *(iii)* append $\langle C, x_{w:C}\rangle$ to $\mathcal{L}(w)$, and *(iv)* $\mathcal{C}_\mathcal{F} = \mathcal{C}_\mathcal{F} \cup \{x_{w:C} \otimes x_{(v,w):R} \geq l\}$.

($\forall_\mathbf{D}$). If $\langle \forall T.\mathbf{d}, l\rangle \in \mathcal{L}(v)$, the case is similar as in rule ($\forall$).

($\exists_\mathbf{D}$). If $\langle \exists T.\mathbf{d}, l\rangle \in \mathcal{L}(v)$, the case is similar as in rule ($\exists$).

($\mathbf{d}$). If $\langle d, l\rangle \in \mathcal{L}(v)$ then $\mathcal{C}_\mathcal{F} = \mathcal{C}_\mathcal{F} \cup \{\gamma(v{:}\mathbf{d}, l)\}$, where the set $\gamma(v{:}\mathbf{d}, l)$ is obtained from the MILP representation of $g(\mathbf{d})$ by replacing all occurrences of x with l and x_1 with x_v.

($\bar{\mathbf{d}}$). The case $\langle \neg\mathbf{d}, l\rangle \in \mathcal{L}(v)$ is similar as in rule ($\mathbf{d}$), where we use the MILP representation of $\bar{g}(\mathbf{d})$ in place of $g(\mathbf{d})$.

(@). If $\langle @(C_1, \ldots, C_n), l\rangle \in \mathcal{L}(v)$ then *(i)* append all $\langle C_i, x_{v:C_i}\rangle$ to $\mathcal{L}(v)$, and *(ii)* $\mathcal{C}_\mathcal{F} = \mathcal{C}_\mathcal{F} \cup \{\gamma(x_{v:C_1}, \ldots, x_{v:C_n}, l)\}$, where the set $\gamma(x_{v:C_1}, \ldots, x_{v:C_n}, l)$ is obtained from the MILP representation of $g(@)$ by replacing all occurrences of x with l and x_i with $x_{v:C_i}$.

Now, the following proposition can be shown.

Proposition 1 (Termination, Soundness, Completeness): For a given a KB $\mathcal{K}$ (i) the tableau algorithm terminates; (ii) if the expansion rules can be applied to $\mathcal{K}$ such that they yield a complete completion-forest $\mathcal{F}$ such that $\mathcal{C}_\mathcal{F}$ has a solution, then $\mathcal{K}$ has a model; and (iii) if $\mathcal{K}$ has a model, then the expansion rules can be applied in such a way that the tableaux algorithm yields a complete completion-forest for $\mathcal{K}$ such that $\mathcal{C}_\mathcal{F}$ has a solution. □

IV. Representation of some AOs in Fuzzy OWL 2

In this section, we will consider the representation of fuzzy ontologies using a fuzzy extension of OWL 2[4]. In particular, we will show how to represent weighted concepts, OWA operators, and quantifier-guided AOs.

The idea of this methodology for fuzzy ontology representation is to use an OWL 2 ontology and to extend their elements with annotations representing the features of the fuzzy ontology that OWL 2 cannot directly encode. In order to separate the annotations including fuzzy information from other annotations, we use a new annotation property called `fuzzyLabel`, and every annotation is identified by the tag `fuzzyOwl2`, with an attribute `fuzzyType` that specifies the type of element that is being annotated. For full details, we refer the reader to [7].

Now we are ready to show how to represent some cases of AOs, namely weighted concepts, OWA operators, and quantifier-guided AOs. For each of these concepts, we create a new concept and add an annotation property to it (describing the type of the constructor and the value of their parameters).

[4]http://www.straccia.info/software/FuzzyOWL/

Hence, the domain of the annotation is an OWL 2 concept declaration, and the value of the attribute `fuzzyType` is `concept`.

Then, we use a tag `Concept`, with an attribute `type`, describing the type of fuzzy concept that is represented, and other attributes that depend on the concept constructor. In the case of the concept constructors that we consider in this section, such attributes will be used to represent the weights, the concepts to be aggregated, and (possibly) the quantifier. Let us consider each case in detail.

A. Weighted sum concepts

The value of the attribute `type` is `weightedSum`. There are also several additional tags, each of them represented by a pair formed by a weight and a concept. Such pairs are usually called weighted concepts in the fuzzy DL literature and can be considered as fuzzy concepts themselves. For coherence, the syntax of a weighted concept use another tag `Concept`, with the `type` being `weighted`, and attributes `value` and `base` for the weight and the name of the base concept, respectively. Formally, the syntax for the annotation of weighted sum concepts is the following:

```
<fuzzyOwl2 fuzzyType="concept">
  <Concept type="weightedSum">
    (<WEIGHTED>)+
  </Concept>
</fuzzyOwl2>

<WEIGHTED> := <Concept type="weighted" value="<DOUBLE>"
              base="<STRING>" />
```

B. OWA aggregation concepts

Now, the value of the attribute `type` is `owa`. Due to the reordering step, it is not necessary to associate every weight to a particular concept, so we use two separate list of weights and concept names. The formal syntax is the following:

```
<fuzzyOwl2 fuzzyType="concept">
  <Concept type="owa">
    <Weights>
        ( <Weight><DOUBLE></Weight> )+
    </Weights>
    <Names>
        ( <Name><STRING></Name> )+
    </Names>
  </Concept>
</fuzzyOwl2>
```

Example 3: Assume that we want to represent the concept $@^{\text{owa}}_{W}(Cheap, CloseToVenue, Comfortable)$, where $W = (0.1, 0.3, 0.6)$. So, we create a new atomic concept A and annotate it as follows: (the example uses OWL/XML syntax [28]):

```
<AnnotationAssertion>
  <AnnotationProperty IRI='#fuzzyLabel'/>
  <IRI>#A</IRI>
  <Literal datatypeIRI='&rdf;PlainLiteral'>
    <fuzzyOwl2 fuzzyType="concept">
      <Concept type="owa">
        <Weights>
            <Weight>0.1</Weight>
            <Weight>0.3</Weight>
            <Weight>0.6</Weight>
        </Weights>
        <Names>
            <Name>Cheap</Name>
            <Name>CloseToVenue</Name>
            <Name>Comfortable</Name>
        </Names>
      </Concept>
    </fuzzyOwl2>
  </Literal>
</AnnotationAssertion>
```

C. Quantified-guided OWA aggregation concepts

This case is similar to the previous one, with the difference that we must also represent the quantifier. As possible quantifiers, we propose to use left-shoulder functions (Fig. 1 (b)) and linear functions (Fig. 1 (e))[5] restricted to the interval $[0, 1]$. These functions produce monotone quantifiers and have already being considered in Fuzzy OWL 2 [7].

So, the first step is to create a new datatype representing the quantifier, and add an annotation to it, specifying the `fuzzyType` as `datatype`, and including a tag `Datatype` with some attributes encoding the type of the function (`rightshoulder` or `linear`), and the parameters `a` and `b`. Formally, the syntax is the following[6]:

```
<fuzzyOwl2 fuzzyType="datatype">
  <DATATYPE>
</fuzzyOwl2>

<DATATYPE> :=
  <Datatype type="leftshoulder" a="<DOUBLE>" b="<DOUBLE>" /> |
  <Datatype type="linear" a="<DOUBLE>" b="<DOUBLE>" />
```

Now, the differences with the previous case is that the value of the attribute `type` is `qowa`, that there is an additional attribute `quantifier` relating the concept with the previously defined quantifier, and that the quantifiers do not need to be represented, as they are implicitly determined by the quantifier. Formally, the syntax is:

```
<fuzzyOwl2 fuzzyType="concept">
  <Concept type="qowa" quantifier="<STRING>" >
    <Names>
        ( <Name><STRING></Name> )+
    </Names>
  </Concept>
</fuzzyOwl2>
```

Example 4: Let $Q = linear(0.6, 0.4)$. We want to represent $@^{\text{owa}}_{W_Q}(Cheap, CloseToVenue, Comfortable)$. Note that $w_1 = Q(1/3) - Q(0) = 0.22$, $w_2 = Q(2/3) - Q(1/3) = 0.49 - 0.22 = 0.27$, and $w_3 = Q(1) - Q(2/3) = 1 - 0.49 = 0.51$. Now, we create a new datatype called Q and annotate it as follows:

```
<AnnotationAssertion>
   <AnnotationProperty IRI='#fuzzyLabel'/>
   <IRI>#Q</IRI>
   <Literal datatypeIRI='&rdf;PlainLiteral'>
   <fuzzyOwl2 fuzzyType="datatype">
     <Datatype type="linear" a="0.6" b="0.4" />
  </fuzzyOwl2>
  </Literal>
</AnnotationAssertion>
```

Then, we create a new atomic concept A and annotate it as:

```
<AnnotationAssertion>
  <AnnotationProperty IRI='#fuzzyLabel'/>
  <IRI>#A</IRI>
  <Literal datatypeIRI='&rdf;PlainLiteral'>
```

[5]Linear functions are determined by a parameter c that makes it possible to define $a = c/(c+1), b = 1/(c+1)$.

[6]Note that other functions (e.g. ls, tri, trz) can be used as fuzzy datatypes, but they are not covered here because they cannot be used as quantifiers.

```
    <fuzzyOwl2 fuzzyType="concept">
      <Concept type="qowa" quantifier="Q" >
        <Names>
            <Name>Cheap</Name>
            <Name>CloseToVenue</Name>
            <Name>Comfortable</Name>
        </Names>
      </Concept>
    </fuzzyOwl2>
  </Literal>
</AnnotationAssertion>
```

V. Conclusion

In this work we have shown how to include aggregation operators within fuzzy DLs. Our contribution consist of: (i) definition of syntax and semantics for fuzzy DLs supporting AOs; (ii) a reasoning algorithm for a wide class of AOs that are MILP representable, that includes average, weighted sum and notably OWA and quantifier-based OWA operators; and (iii) a mechanism to support these AOs in Fuzzy OWL 2, a fuzzy version of the standard ontology language OWL 2. Our approach is implemented in the plug-in Fuzzy OWL 2 and in the fuzzyDL reasoner [11].

Concerning future work, we note that the realm of AOs is quite large (see, e.g. [8]). It remains to see which of them and especially *how* they can be encoded within our reasoning algorithm framework based on (especially) MILP or, more generally, on MINLP optimisation tools.

Appendix

We succinctly show that OWA operators are MILP representable. Yager [17] has shown that the *maximisation* of $@^{\text{owa}}_W(x_1, \ldots, x_n)$ can indeed be encoded as a MILP problem. However, this encoding does not work in our setting as we are not maximising $@^{\text{owa}}_W(x_1, \ldots, x_n)$, but rather need to show that the set $g(@^{\text{owa}}_W) = \{\langle x_1, \ldots, x_k, x\rangle \colon @^{\text{owa}}_W(x_1, \ldots, x_k) \geq x\}$ is MILP representable. To this end, we need a different encoding. So, let $N = \{1, \ldots, n\}$. Similarly to [17], we introduce new $[0, 1]$-valued variables y_i ($i \in N$) and impose

$$y_1 \geq y_2 \geq \ldots \geq y_n \ . \tag{8}$$

The intuition is that y_i will take the value of the i-th largest of the x_j. Hence, by definition of OWA, y_i has weight w_i and therefore, we add also the constraint

$$\textstyle\sum_i w_i y_i \geq x \ . \tag{9}$$

The remaining of the encoding concerns now to establish which one among $x_1, \ldots, x_n$ are the y_i. Consider the following set of equations: for $i, j \in N$, $k = 2$, new binary variables z_{ij}

$$\begin{array}{lll} y_i \leq x_j + k z_{ij} & & x_j \leq y_i + k z_{ij} \\ \textstyle\sum_j z_{ij} = n - 1 & \textstyle\sum_i z_{ij} = n - 1 & z_{ij} \in \{0, 1\} \ . \end{array} \tag{10}$$

It can be verified that (i) if $z_{ij} = 0$ then $y_i = x_j$ is imposed; (ii) for any y_i, there is only one x_j imposed to be equal to y_i; and (iii) for any x_j, there is only one y_i imposed to be equal to x_j. That is, there is a bijection among the y_j and the x_i, which together with Eq. (8) guarantees that the equations Eq. (8) - (10) correctly encode $@^{\text{owa}}_W(x_1, \ldots, x_k) \geq x$.

***Abstract*—This paper concentrates on a fuzzy Description Logic with product t-norm and involutive negation. It does not answer the question posed in its title for this logic, but it gives strong indications that the answer might in fact be "no." On the one hand, it shows that an algorithm that was claimed to answer the question affirmatively for this logic is actually incorrect. On the other hand, it proves undecidability of a variant of this logic.**

***Index Terms*—Fuzzy Description Logics, Undecidability, Reasoning**

I. Introduction

Description logics (DLs) [1] are a well-investigated family of logic-based knowledge representation formalisms, which can be used to model a given application domain using terminological axioms and assertional axioms. On the terminological side, modern DL systems provide their users with so-called concept inclusion axioms. The availability of these axioms increases the complexity of reasoning, both from a complexity theoretic and a practical point of view. For example, for the standard DL $\mathcal{ALC}$, the complexity rises from PSpace to ExpTime if these axioms are added. In addition, the tableau-based reasoning procedure used by most DL systems run into a termination problem: one has to add so-called blocking conditions in order to ensure their termination [2].

Fuzzy variants of DLs were introduced in order to deal with applications where precise definitions are not possible [3]. Decidability of fuzzy DLs is often shown by adapting the tableau-based algorithms for the corresponding crisp DL to the fuzzy case. This was first done for the case of DLs without concept inclusion axioms [4], [5] or with only *crisp* concept inclusion axioms [6], [7], but then also extended to DLs with concept inclusion axioms [8], [9]. In particular, Bobillo and Straccia [10], [11] have developed such an algorithm for a DL with product t-norm and involutive negation. Whereas [11] focuses only on so-called acyclic TBoxes, the algorithm from [10] allows for general concept inclusion axioms. More precisely, this algorithm is supposed to check whether an ontology expressed in this DL has a so-called witnessed model. Actually, the proof of correctness of this algorithm implies that, whenever such an ontology has a witnessed model, then it has a finite model. However, it was recently shown in [12] that this is not the case in the presence of general concept inclusion axioms, i.e., there is an ontology written in this logic that has a witnessed model, but does not have a finite model. Of course, this does not automatically imply that the algorithm itself is wrong. In fact, if one applies the algorithm from [10] to the ontology used in [12] to demonstrate the failure of the finite model property, then one obtains the correct answer.

In this paper, we will first show that the algorithm is indeed incorrect by exhibiting an example ontology on which it gives an incorrect answer. This shows that the question of whether (witnessed) consistency of this logic is decidable or not is an open question. The second result shown in this paper gives an indication that the answer could in fact be "no." We prove undecidability for a slightly modified problem where (i) we allow not only $\geq$ but also $>$ in our fuzzy concept inclusion axioms, and (ii) consider a somewhat weaker notion of witnessed model.

II. Preliminaries

We introduce the logic *fuzzy $\mathcal{ALC}$ with product t-norm and involutive negation* and the tableau-based algorithm for this logic presented in [10], and then give an example that shows that this algorithm is not correct.

A. Fuzzy $\mathcal{ALC}$ with Product t-norm and involutive negation

The syntax of fuzzy $\mathcal{ALC}$ concepts is the same as for crisp $\mathcal{ALC}$. From two disjoint sets $\mathcal{N}_\mathcal{C}$ and $\mathcal{N}_\mathcal{R}$ of *concept-* and *role-names*, respectively, fuzzy $\mathcal{ALC}$ concepts are built using the syntax rule:

$$C ::= \top \mid \bot \mid A \mid C_1 \sqcap C_2 \mid C_1 \sqcup C_2 \mid \neg C \mid \exists r.C \mid \forall r.C,$$

where $A \in \mathcal{N}_\mathcal{C}$ and $r \in \mathcal{N}_\mathcal{R}$.

The syntax of the axioms in this logic is slightly different from the crisp case since they need to state a degree of truth with which they hold. A *fuzzy $\mathcal{ALC}$ ABox* is a finite set of *concept assertion axioms* of the form $\langle a : C \geq q\rangle$ and *role assertion axioms* $\langle (a,b) : r \geq q\rangle$, where C is a fuzzy $\mathcal{ALC}$ concept, $r \in \mathcal{N}_\mathcal{R}$, q is a rational number in $[0,1]$, and $a, b \in \mathcal{N}_\mathcal{I}$, with $\mathcal{N}_\mathcal{I}$ the set of *individual names*. A *fuzzy $\mathcal{ALC}$ TBox* is a finite set of *concept inclusion axioms* of the form $\langle C \sqsubseteq D \geq q\rangle$, where C, D are $\mathcal{ALC}$ concepts and q is a rational number in $[0,1]$. A *fuzzy ontology* $\mathcal{O} = (\mathcal{A}, \mathcal{T})$ consists of a fuzzy ABox $\mathcal{A}$ together with a fuzzy TBox $\mathcal{T}$.

The semantics of this logic extends the classical semantics of $\mathcal{ALC}$ by interpreting concepts and roles as fuzzy sets over an interpretation domain. Given a non-empty set Δ (the domain), a *fuzzy set* over Δ is a function $F : \Delta \to [0,1]$, with the intuition that an element $\delta \in \Delta$ belongs to F with *degree* $F(\delta)$. The semantics of the different concept constructors depends on the class of fuzzy operators chosen to interpret them. In this

978-1-4244-7316-8/11/$26.00 ©2011 IEEE

paper, we use the binary operators *product t-norm* $\otimes$, *product t-conorm* $\oplus$, and *residuum* $\rightarrow$, and the unary operator *involutive negation* $\ominus$ over the interval $[0,1]$. These operators are defined as follows, for every $\alpha, \beta \in [0,1]$:

$$\begin{aligned} \alpha \otimes \beta &:= \alpha \cdot \beta, \\ \alpha \oplus \beta &:= \alpha + \beta - \alpha \cdot \beta, \\ \alpha \rightarrow \beta &:= \begin{cases} 1 & \text{if } \alpha \leq \beta \\ \beta/\alpha & \text{otherwise,} \end{cases} \\ \ominus\alpha &:= 1 - \alpha. \end{aligned}$$

It is useful to notice that, for every $\alpha, \beta, q \in [0,1]$, we have $\alpha \rightarrow \beta \geq q$ iff $\beta \geq q \cdot \alpha$. In particular, this means that (i) $\alpha \rightarrow \beta \geq 1$ iff $\beta \geq \alpha$ and (ii) $1 \rightarrow \beta = \beta$. We will often make use of these properties in the rest of this paper.

The semantics of fuzzy $\mathcal{ALC}$ is based on the notion of an *interpretation*, which is a tuple $\mathcal{I} = (\Delta^{\mathcal{I}}, \cdot^{\mathcal{I}})$ where $\Delta^{\mathcal{I}}$ is a non-empty set, called the *domain*, and the function $\cdot^{\mathcal{I}}$ maps each individual name a to an element of $\Delta^{\mathcal{I}}$, each concept name A to a function $A^{\mathcal{I}} : \Delta^{\mathcal{I}} \rightarrow [0,1]$ and each role name r to a function $r^{\mathcal{I}} : \Delta^{\mathcal{I}} \times \Delta^{\mathcal{I}} \rightarrow [0,1]$. The interpretation function is extended to arbitrary fuzzy $\mathcal{ALC}$ concepts as follows. For every $\delta \in \Delta^{\mathcal{I}}$,

$$\begin{aligned} \top^{\mathcal{I}}(\delta) &= 1 \\ \bot^{\mathcal{I}}(\delta) &= 0 \\ (C_1 \sqcap C_2)^{\mathcal{I}}(\delta) &= C_1^{\mathcal{I}}(\delta) \cdot C_2^{\mathcal{I}}(\delta) \\ (C_1 \sqcup C_2)^{\mathcal{I}}(\delta) &= C_1^{\mathcal{I}}(\delta) + C_2^{\mathcal{I}}(\delta) - C_1^{\mathcal{I}}(\delta) \cdot C_2^{\mathcal{I}}(\delta) \\ (\neg C)^{\mathcal{I}}(\delta) &= 1 - C^{\mathcal{I}}(\delta) \\ (\exists r.C)^{\mathcal{I}}(\delta) &= \sup_{\gamma \in \Delta^{\mathcal{I}}} (r^{\mathcal{I}}(\delta,\gamma) \cdot C^{\mathcal{I}}(\gamma)) \\ (\forall r.C)^{\mathcal{I}}(\delta) &= \inf_{\gamma \in \Delta^{\mathcal{I}}} (r^{\mathcal{I}}(\delta,\gamma) \rightarrow C^{\mathcal{I}}(\gamma)). \end{aligned}$$

The interpretation $\mathcal{I} = (\Delta^{\mathcal{I}}, \cdot^{\mathcal{I}})$ satisfies the concept assertion $\langle a : C \geq q \rangle$ iff $C^{\mathcal{I}}(a^{\mathcal{I}}) \geq q$, it satisfies the role assertion $\langle (a,b) : r \geq q \rangle$ iff $r^{\mathcal{I}}(a^{\mathcal{I}}, b^{\mathcal{I}}) \geq q$, and it satisfies the concept inclusion $\langle C \sqsubseteq D \geq q \rangle$ iff $\inf_{\delta \in \Delta^{\mathcal{I}}} (C^{\mathcal{I}}(\delta) \rightarrow D^{\mathcal{I}}(\delta)) \geq q$. This interpretation is called a *model* of the ontology $\mathcal{O}$ if it satisfies all the axioms in $\mathcal{O}$.

An important notion in fuzzy DLs is that of witnessed models [13], [14]. A model is called *witnessed* if for every $\delta \in \Delta^{\mathcal{I}}$, role r and concepts C, D there exist $\gamma, \gamma' \in \Delta^{\mathcal{I}}$ such that

- $(\exists r.C)^{\mathcal{I}}(\delta) = r^{\mathcal{I}}(\delta,\gamma) \cdot C^{\mathcal{I}}(\gamma)$ and
- $(\forall r.C)^{\mathcal{I}}(\delta) = r^{\mathcal{I}}(\delta,\gamma') \rightarrow C^{\mathcal{I}}(\gamma')$.

Notice that, in the literature (e.g. [11], [12], [15]), witnessed models are usually required to satisfy additionally that, for every two concepts C, D, there is a γ such that

$$\inf_{\eta \in \Delta^{\mathcal{I}}} (C^{\mathcal{I}}(\eta) \rightarrow D^{\mathcal{I}}(\eta)) = C^{\mathcal{I}}(\gamma) \rightarrow D^{\mathcal{I}}(\gamma).$$

We call those witnessed models that satisfy this additional restriction *strongly witnessed* models.

The reason why we do not include this condition is that, in our opinion, it does not capture the spirit of fuzzy concept inclusions: the axiom $\langle C \sqsubseteq D \geq q \rangle$ is meant to constrain the interpretation of concepts and roles such that, for each individual $\delta \in \Delta$, we have $C^{\mathcal{I}}(\delta) \rightarrow D^{\mathcal{I}}(\delta) \geq q$. With this point of view, it is not really necessary that the infimum of the values for the residuum is indeed reached. In contrast, for the value restriction, this infimum is really the degree of this restriction, and thus it makes sense to require that this degree is witnessed by a role successor.

We say that an ontology $\mathcal{O}$ is *consistent* if it has a model, it is *witnessed consistent* if it has a witnessed model, and it is *strongly witnessed consistent* if it has a strongly witnessed model.

As it has been shown in [11], consistency does not imply witnessed consistency in fuzzy $\mathcal{ALC}$. However, it is standard in fuzzy DL to restrict reasoning to witnessed models only (see for instance [10], [11]).

Notation. *We will often use the expression $\langle C = q \rangle$ to abbreviate the two axioms $\langle \top \sqsubseteq C \geq q \rangle, \langle \top \sqsubseteq \neg C \geq 1 - q \rangle$, and the expression $\langle C \equiv D \rangle$ to abbreviate $\langle C \sqsubseteq D \geq 1 \rangle$, $\langle D \sqsubseteq C \geq 1 \rangle$. Likewise, $\langle a : C = q \rangle$ is an abbreviation for $\langle a : C \geq q \rangle, \langle a : \neg C \geq 1 - q \rangle$.*

Intuitively, the expressions $\langle C = q \rangle, \langle C \equiv D \rangle$, and $\langle a : C = q \rangle$ restrict every model $\mathcal{I}$ to be such that, for all $\delta \in \Delta^{\mathcal{I}}$, we have $C^{\mathcal{I}}(\delta) = q, C^{\mathcal{I}}(\delta) = D^{\mathcal{I}}(\delta)$, and $C^{\mathcal{I}}(a^{\mathcal{I}}) = q$, respectively.

B. The Original Algorithm of [10]

A tableau-based algorithm for deciding strongly witnessed consistency of a fuzzy $\mathcal{ALCF}(D)$ ontology was presented in [10].[1] However, as we will show, this algorithm is incorrect, even if restricted to fuzzy $\mathcal{ALC}$. We now briefly introduce the algorithm, leaving aside all the steps corresponding to expressivity beyond that of fuzzy $\mathcal{ALC}$. In the following, x (possibly with sub- or superindices) denotes a *continuous variable* taking values from $[0,1]$, q denotes a *constant* in $[0,1]$, l denotes a *literal*, that is, a continuous variable x, a *negated variable* $1 - x$ or a constant, and y denotes a *Boolean variable* taking values from $\{0,1\}$.

The algorithm constructs a completion forest; that is, a collection of trees whose roots may be arbitrarily interconnected by edges. Every node v in this forest is labeled by a set $\mathcal{L}(v)$ of labeled concepts of the form $\langle C, l \rangle$ and a set $\mathcal{C}(v)$ of inequalities. Intuitively, $\langle C, l \rangle \in \mathcal{L}(v)$ means that v belongs to C with degree at least l and the inequalities in $\mathcal{C}(v)$ constrain the valuations of the different variables used. Additionally, every edge (v_1, v_2) is labeled with a set $\mathcal{L}(v_1, v_2)$ of labeled role names $\langle r, l \rangle$ with the meaning that (v_1, v_2) are in an r-relation with degree at least l.

The algorithm initializes the completion forest to contain one *root node* v_i for each individual name a_i appearing in the ABox $\mathcal{A}$ with $\mathcal{L}(v_i) = \{\langle C, l \rangle \mid \langle a_i : C \geq l \rangle \in \mathcal{A}\}$ and $\mathcal{L}(v_i, v_j) = \{\langle r, l \rangle \mid \langle (a_i, a_j) : r \geq l \rangle \in \mathcal{A}\}$. The sets $\mathcal{C}(v_i)$ are all initialized as empty. This completion forest is extended

[1] Fuzzy $\mathcal{ALCF}(D)$ is fuzzy $\mathcal{ALC}$ extended with additonal constructors that are not relevant for this paper.

(A) if $\langle A, l\rangle \in \mathcal{L}(v)$ then add $x_{v:A} \geq l$ to $\mathcal{C}(v)$

$(\overline{A})$ if $\langle \neg A, l\rangle \in \mathcal{L}(v)$ then add $x_{v:A} \leq 1 - l$ to $\mathcal{C}(v)$

(r) if $\langle r, l\rangle \in \mathcal{L}(v, w)$ then add $x_{(v,w):r} \geq l$ to $\mathcal{C}(w)$

$(\top)$ if $\langle \top, l\rangle \in \mathcal{L}(v)$ or $\langle \neg\bot, l\rangle \in \mathcal{L}(v)$ then add $l = 1$ to $\mathcal{C}(v)$

$(\bot)$ if $\langle \bot, l\rangle \in \mathcal{L}(v)$ or $\langle \neg\top, l\rangle \in \mathcal{L}(v)$ then add $l = 0$ to $\mathcal{C}(v)$

$(\neg\neg)$ if $\langle \neg\neg C, l\rangle \in \mathcal{L}(v)$ then add $\langle C, l\rangle$ to $\mathcal{L}(v)$

$(\sqcap)$ if $\langle C \sqcap D, l\rangle \in \mathcal{L}(v)$ then add $\langle C, x_1\rangle, \langle D, x_2\rangle$ to $\mathcal{L}(v)$ and $x_1 \cdot x_2 \geq l$ to $\mathcal{C}(v)$

$(\overline{\sqcap})$ if $\langle \neg(C \sqcap D), l\rangle \in \mathcal{L}(v)$ then add $\langle \neg C \sqcup \neg D, l\rangle$ to $\mathcal{L}(v)$

$(\sqcup)$ if $\langle C \sqcup D, l\rangle \in \mathcal{L}(v)$ then add $\langle C, x_1\rangle, \langle D, x_2\rangle$ to $\mathcal{L}(v)$ and $x_1 + x_2 - x_1 \cdot x_2 \geq l$ to $\mathcal{C}(v)$

$(\overline{\sqcup})$ if $\langle \neg(C \sqcup D), l\rangle \in \mathcal{L}(v)$ then add $\langle \neg C \sqcap \neg D, l\rangle$ to $\mathcal{L}(v)$

$(\forall)$ if $\langle \forall r.C, l_1\rangle \in \mathcal{L}(v)$ and $\langle r, l_2\rangle \in \mathcal{L}(v, w)$ then add $\langle C, x\rangle$ to $\mathcal{L}(w)$ and $x \geq l_1 \cdot l_2$ to $\mathcal{C}(w)$

$(\overline{\exists})$ if $\langle \neg\exists r.C, l_1\rangle \in \mathcal{L}(v)$ and $\langle r, l_2\rangle \in \mathcal{L}(v, w)$ then add $\langle \neg C, 1 - x_1\rangle$ to $\mathcal{L}(w)$ and $x_{(v,w):r} \leq x_2, x_1 \cdot x_2 = 1 - l_1$ to $\mathcal{C}(w)$

$(\overline{\forall})$ if $\langle \neg\forall r.C, l\rangle \in \mathcal{L}(v)$ then create a new node w and add $\langle r, x_1\rangle$ to $\mathcal{L}(v, w)$, $\langle C, x_2\rangle$ to $\mathcal{L}(w)$ and $y \cdot x_1 + (1 - y) \cdot x_2 \geq y \cdot x_2 + (1 - y) \cdot x_1, l \leq y, y \cdot x_2 \leq x_1 - l \cdot x_1$ to $\mathcal{C}(w)$

$(\exists)$ if $\langle \exists r.C, l\rangle \in \mathcal{L}(v)$ then create a new node w and add $\langle r, x_1\rangle$ to $\mathcal{L}(v, w)$, $\langle C, x_2\rangle$ to $\mathcal{L}(w)$ and $x_1 \cdot x_2 \geq l$ to $\mathcal{C}(w)$

$(\sqsubseteq)$ if $\langle C \sqsubseteq D \geq q\rangle \in \mathcal{T}$ and v is a node in the forest, then add $\langle \neg C, 1 - x_1\rangle, \langle D, x_2\rangle$ to $\mathcal{L}(v)$ and $x_2 \geq x_1 \cdot q$ to $\mathcal{C}(v)$.

TABLE I
COMPLETION RULES FOR FUZZY $\mathcal{ALC}$ CONSISTENCY.
x, x_1, x_2, y ARE ALWAYS NEW VARIABLES

by application of the completion rules from Table I. As is standard with tableau-based algorithms, these rules are only applied as long as something new is added to the completion forest.

The main idea of these rules is that they decompose complex concepts into their subconcepts, while preserving the fuzzy semantics through the restrictions in $\mathcal{C}$. Assume for the moment that the algorithm has terminated (i.e., no more completion rules are applicable) and that the constraint system $\mathcal{C} := \bigcup_v \mathcal{C}(v)$ generated by the algorithm has a solution in $[0, 1]$. The claim is then that the completion forest obtained by the algorithm describes a model of the ontology, where the membership degree of a node v to a concept name A corresponds to the value of the variable $x_{v:A}$, and accordingly for roles. Conversely, from any model of the ontology it is possible to build a satisfying valuation of the variables in $\mathcal{C}$.

However, as it is also the case for crisp $\mathcal{ALC}$, this completion forest construction may not terminate, due to the fact that concept inclusions can express cyclic relationships between concepts, which may enforce an infinite generation of new individuals. In order to ensure termination, a blocking condition is used, which disallows the application of "generating" rules; i.e., the $(\exists)$ and $(\overline{\forall})$ rules cannot be applied in any node that is considered to be blocked.

Definition 1 (blocking [10]). *Two non-root nodes v, w are called* equivalent*, denoted as $\mathcal{L}(v) \approx \mathcal{L}(w)$, if $\mathcal{L}(v) = \{\langle C_1, l_1\rangle, \ldots, \langle C_k, l_k\rangle\}, \mathcal{L}(v) = \{\langle C_1, l'_1\rangle, \ldots, \langle C_k, l'_k\rangle\}$ and for every $1 \leq i \leq k$, l_i, l'_i are either both variables, or are both negated variables, or are both the same constant.*

A node v is directly blocked *iff it is not a root node and it has an ancestor w such that $\mathcal{L}(v) \approx \mathcal{L}(w)$; in this case we say that w is the* blocking *node of v. A node is* blocked *if it is directly blocked or its predecessor is blocked.*

With this blocking condition, it is not hard to show that the algorithm always terminates. It then answers that the input ontology $\mathcal{O}$ is strongly witnessed consistent iff the system of inequalities $\mathcal{C}$ generated by this terminating run on input $\mathcal{O}$ has a solution.

The idea behind the proof of correctness of this algorithm, as presented in [10], is that the variables appearing in blocking and blocked nodes can be evaluated to the same numerical value in a solution of $\mathcal{C}$. If correct, this proof would show that an ontology that has a strongly witnessed model always has a finite model. Indeed, the interpretation constructed from the completion forest generated by a terminating run of the algorithm is finite. Unfortunately, as we will see below, it need not be a model. The first blow to the claimed correctness of the algorithm came when it was shown in [12] that the logic does not have the finite model property. More precisely, in [12] the authors present a simple ontology that is strongly witnessed consistent, but does not have a finite model. Thus, the approach through which the algorithm tries to build a (finite) model is wrong. However, this does not automatically imply that the algorithm itself is wrong. In fact, if one applies the algorithm to the ontology used in [12], then one obtains the correct answer, namely that the ontology is strongly witnessed consistent. The authors conjecture in [12] that the algorithm is still correct.[2]

Note that the algorithm tries to construct a finite portion of a model. If the input ontology is indeed consistent, and thus has a (possibly infinite) model, then it is easy to see that this construction will always succeed (i.e., the constraint system generated by the algorithm is satisfiable). This means that the algorithm is complete.

Remark 2. *The algorithm from [10] is complete for strongly witnessed consistency; that is, it yields the right answer whenever the input ontology is strongly witnessed consistent.*

Unfortunately, as the following example shows, it is not sound since it fails to correctly identify inconsistency.

Example 3. *Consider the ontology with the following axioms:*

$ax_1 : \langle a : A \geq 0.1\rangle$
$ax_2 : \langle A \sqsubseteq (\forall r.A) \sqcap B \geq 1\rangle$
$ax_3 : \langle \top \sqsubseteq \neg B \geq 0.5\rangle$
$ax_4 : \langle \top \sqsubseteq \exists r.\top \geq 1\rangle$.

We will prove first that this ontology is inconsistent, and thus also not (strongly) witnessed consistent. We then show that the algorithm described above yields the wrong answer, i.e., it claims that the ontology is strongly witnessed consistent.

[2]Independently from us, a counterexample to the correctness of the algorithm in [10] has now also been found by the authors of [12]. This counterexample, which is presented in [16], is different from the one we give here. The paper [16], which is an improved version of [12], was available online only after we had submitted the present paper.

Suppose that there is a model (not necessarily witnessed) $\mathcal{I} = (\Delta^{\mathcal{I}}, \cdot^{\mathcal{I}})$ of this ontology, and let $v_0 \in \Delta^{\mathcal{I}}$ be any element of the domain. From axiom ax_4, we obtain that

$$1 = (\exists r.\top)^{\mathcal{I}}(v_0) = \sup_{\delta \in \Delta^{\mathcal{I}}} r^{\mathcal{I}}(v_0, \delta).$$

This means that there must exist $v_1 \in \Delta^{\mathcal{I}}$ such that $r^{\mathcal{I}}(v_0, v_1) > 0.99$.[3] From ax_3 it follows that $(\neg B)^{\mathcal{I}}(v_0) \geq 0.5$; i.e., $B^{\mathcal{I}}(v_0) \leq 0.5$; additionally, from ax_2 we know

$$A^{\mathcal{I}}(v_0) \leq (\forall r.A)^{\mathcal{I}}(v_0) \cdot B^{\mathcal{I}}(v_0) \leq (\forall r.A)^{\mathcal{I}}(v_0) \cdot 0.5,$$

or equivalently,

$$\begin{aligned} 2 \cdot A^{\mathcal{I}}(v_0) \leq (\forall r.A)^{\mathcal{I}}(v_0) &= \inf_{\delta \in \Delta^{\mathcal{I}}} r^{\mathcal{I}}(v_0, \delta) \to A^{\mathcal{I}}(\delta) \\ &\leq r^{\mathcal{I}}(v_0, v_1) \to A^{\mathcal{I}}(v_1) \\ &\leq 0.99 \to A^{\mathcal{I}}(v_1). \end{aligned} \quad (1)$$

Additionally, it holds that $0.99 \to A^{\mathcal{I}}(v_1) \leq 1$, and so $A^{\mathcal{I}}(v_0) \leq 0.5$. Recall that v_0 was an arbitrary element of the domain, and thus the previous holds also for v_1; in particular we have that $A^{\mathcal{I}}(v_1) \leq 0.5$ and $0.99 \to A^{\mathcal{I}}(v_1) = c \cdot A^{\mathcal{I}}(v_1)$, where $c = 100/99$. Since $2/c > 1$, it follows from the inequality (1) that

$$A^{\mathcal{I}}(v_0) < (2/c) \cdot A^{\mathcal{I}}(v_0) \leq A^{\mathcal{I}}(v_1) \leq 0.5.$$

Once again, since all the previous is true for any element of the domain, it follows that there must exist infinitely many elements $v_2, v_3, \ldots$ such that for every $n \geq 0$ it holds

$$(2/c)^n \cdot A^{\mathcal{I}}(v_0) \leq A^{\mathcal{I}}(v_n) \leq 0.5$$

But since $2/c > 1$, it then follows that $A^{\mathcal{I}}(v_0) = 0$. In particular, this is true for $v_0 = a^{\mathcal{I}} \in \Delta^{\mathcal{I}}$. But this is a contradiction to the assumption that $\mathcal{I}$ is a model of the axiom ax_1. Thus, the ontology is inconsistent.

Let us now analyse the execution of the algorithm on this input. The algorithm starts with a single root node v_0 with $\mathcal{L}(v_0) = \{\langle A, 0.1\rangle\}$ and $\mathcal{C}(v_0) = \emptyset$. Application of the rule $(\sqsubseteq)$ with axioms ax_2, ax_3 and ax_4 will add

$$\langle \neg A, 1 - x_1\rangle, \langle (\forall r.A) \sqcap B, x_2\rangle, \langle \neg\top, 1 - x_3\rangle, \langle \neg B, x_4\rangle, \langle \neg\top, 1 - x_5\rangle, \langle \exists r.\top, x_6\rangle$$

to $\mathcal{L}(v_0)$ and $x_1 \leq x_2, 0.5 \cdot x_3 \leq x_4, x_5 \leq x_6$ to $\mathcal{C}(v_0)$. The rule $(\sqcap)$ then adds $\langle \forall r.A, x_7\rangle, \langle B, x_8\rangle$ to $\mathcal{L}(v_0)$ and $x_2 = x_7 \cdot x_8$ to $\mathcal{C}(v_0)$. The rules $(A), (\overline{A})$, and $(\bot)$ then yield

$$0.1 \leq x_{v_0:A} \leq x_1,\ x_8 \leq x_{v_0:B} \leq 1 - x_4,\quad 1 - x_3 = 0,\ 1 - x_5 = 0.$$

Finally, an application of the rule $(\exists)$ produces a new node v_1 with labels $\mathcal{L}(v_1) = \{\langle \top, x_9\rangle\}$, $\mathcal{L}(v_0, v_1) = \{\langle r, x_{10}\rangle\}$, and $\mathcal{C}(v_1) = \{x_9 \cdot x_{10} = x_6\}$. The rule $(\forall)$ then adds $\langle A, x_{11}\rangle$ to $\mathcal{L}(v_1)$ and $x_{11} \geq x_7 \cdot x_{10}$ to $\mathcal{C}(v_1)$.

Notice that all the concepts and constraints added to the labels of v_0, except $\langle A, 0.1\rangle$, were caused by the axioms ax_2 to ax_4, and thus they will also be added to v_1. The result of the rule applications to this node is then

$$\begin{aligned} \mathcal{L}(v_1) = \{ &\langle A, x_{11}\rangle, \langle \neg A, 1 - x_1'\rangle, \langle (\forall r.A) \sqcap B, x_2'\rangle, \\ &\langle \neg\top, 1 - x_3'\rangle, \langle \neg B, x_4'\rangle, \\ &\langle \neg\top, 1 - x_5'\rangle, \langle \exists r.\top, x_6'\rangle, \langle \forall r.A, x_7'\rangle, \langle B, x_8'\rangle\}, \\ \mathcal{C}(v_1) = \{ &x_9 \cdot x_{10} = x_6, x_{11} \geq x_7 \cdot x_{10}, x_1' \leq x_2', \\ &0.5 \cdot x_3' \leq x_4', x_5' \leq x_6', x_2' = x_7' \cdot x_8', \\ &x_{11} \leq x_{v_1:A} \leq x_1', x_8' \leq x_{v_1:B} \leq 1 - x_4', \\ &1 - x_3' = 0, 1 - x_5' = 0\}. \end{aligned}$$

Once again we can apply the $(\exists)$ rule to obtain a new individual v_2. From the $(\forall)$ rule and again the application of $(\sqsubseteq)$ rule with axioms ax_2 to ax_4 we obtain

$$\begin{aligned} \mathcal{L}(v_2) = \{ &\langle A, x_{11}'\rangle, \langle \neg A, 1 - x_1''\rangle, \langle (\forall r.A) \sqcap B, x_2''\rangle, \\ &\langle \neg\top, 1 - x_3''\rangle, \langle \neg B, x_4''\rangle, \\ &\langle \neg\top, 1 - x_5''\rangle, \langle \exists r.\top, x_6''\rangle, \langle \forall r.A, x_7''\rangle, \langle B, x_8''\rangle\}, \\ \mathcal{C}(v_2) = \{ &x_9' \cdot x_{10}' = x_6', x_{11}' \geq x_7' \cdot x_{10}', x_1'' \leq x_2'', \\ &0.5 \cdot x_3'' \leq x_4'', x_5'' \leq x_6'', x_2'' = x_7'' \cdot x_8'', \\ &x_{11}' \leq x_{v_2:A}' \leq x_1'', x_8'' \leq x_{v_2:B} \leq 1 - x_4'', \\ &1 - x_3'' = 0, 1 - x_5'' = 0\}. \end{aligned}$$

At this point $\mathcal{L}(v_1) \approx \mathcal{L}(v_2)$, and hence node v_2 is blocked and the algorithm terminates.

It is easy to verify that the valuation that sets

$$\begin{aligned} 0.1 &= x_1 = x_2 = x_{v_0:A}, \\ 0.2 &= x_7 = x_{11} = x_1' = x_2' = x_{v_1:A}, \\ 0.4 &= x_7' = x_{11}' = x_1'' = x_2'' = x_{v_2:A}, \\ 0.5 &= x_4 = x_4' = x_4'' = x_8 = x_8' = x_8'' \\ &= x_{v_0:B} = x_{v_1:B} = x_{v_2:B}, \\ 0.8 &= x_7'' \end{aligned}$$

and all other variables to 1 satisfies all the constraints in $\mathcal{C}$. Thus the algorithm returns "strongly witnessed consistent" as an answer, which we have shown to be incorrect.

Notice that the arguments used to show inconsistency in this example do not depend on the exact value of the constant 0.1 in ax_1. In order to make the ontology inconsistent, any constant κ greater than 0 can be used. However, the algorithm multiplies this value with 2 three times before stopping (see the valuation of x_7'' above). To ensure that the algorithm finishes with a satisfiable system of constraints, the constant chosen has to be small enough to ensure that $8 \cdot \kappa \leq 1$.

We emphasize that the ontology from the previous example has no model at all, which means that the algorithm is incorrect even if we do not restrict to only strongly witnessed models. Thus, at this moment there is no known algorithm for deciding consistency, witnessed consistency, or strongly witnessed consistency of fuzzy $\mathcal{ALC}$ ontologies under the product t-norm and involutive negation. In fact, it is not even clear whether this is a decidable problem. In [13] it was shown that, in the absense of concept inclusion axioms,

[3] Notice that the choice of 0.99 is an arbitrary one; the same arguments can be used with any constant $\kappa > 0.5$.

consistency of fuzzy $\mathcal{ALC}$ with product t-norm and residual negation w.r.t. witnessed models is decidable; this result was extended to so-called quasi-witnessed models (but still without concept inclusion axioms) in [17]. However, there is so far no result regarding the use of involutive negation or concept inclusion axioms. In the following section, we show that for a small extension of this logic, witnessed consistency becomes undecidable.

III. An Undecidability Result

We now consider the logic fuzzy $\mathcal{ALC}^+$, which extends fuzzy $\mathcal{ALC}$ by *strict concept inclusions*.

Definition 4 (strict concept inclusion)**.** *A* strict concept inclusion axiom *is an expression of the form* $\langle C \sqsubseteq D > q \rangle$ *where* C, D *are fuzzy* $\mathcal{ALC}$ *concepts and* $q \in [0, 1)$*. An interpretation* $\mathcal{I}$ *satisfies this axiom if for every* $\delta \in \Delta^{\mathcal{I}}$ *it holds that*

$$C^{\mathcal{I}}(\delta) \to D^{\mathcal{I}}(\delta) > q.$$

For models that are not strongly witnessed, the semantics for strict axioms introduced above may differ from the one given by

$$\inf_{\delta \in \Delta^{\mathcal{I}}} (C^{\mathcal{I}}(\delta) \to D^{\mathcal{I}}(\delta)) > q$$

since the infimum may be q although there is no witness δ actually yielding the value q. In contrast, for the case of non-strict axioms, saying that the infimum is $\geq q$ is the same as saying that the values for all individuals are $\geq q$, i.e., $C^{\mathcal{I}}(\delta) \to D^{\mathcal{I}}(\delta) \geq q$ for all $\delta \in \Delta$. As argued before, we think that the essence of a concept inclusion axiom is to enforce the inequality for the value of all individuals, and not to say something about the infimum of these values. This explains why we do not use the infimum in our definition of the semantics for strict concept inclusions.

We will show that witnessed consistency of fuzzy $\mathcal{ALC}^+$ ontologies is undecidable, by a reduction from the Post correspondence problem, which is well-known to be undecidable [18].

Definition 5 (PCP)**.** *Let* $v_1, \ldots, v_m$ *and* $w_1, \ldots, w_m$ *be two finite lists of words over an alphabet* $\Sigma = \{1, \ldots, s\}, s > 1$*. The* Post correspondence problem *(PCP) asks whether there is a non-empty sequence* $i_1, i_2, \ldots, i_k$*,* $1 \leq i_j \leq m$ *such that* $v_{i_1} v_{i_2} \cdots v_{i_k} = w_{i_1} w_{i_2} \cdots w_{i_k}$*. If such a sequence exists, it is called a* solution *of the problem.*

We assume w.l.o.g. that $v_i \neq w_i$ for every $i, 1 \leq i \leq m$ since otherwise the problem has a trivial solution. Note that we assume the alphabet Σ to consist of the first s positive integers. We can thus view every word in Σ^* as a number in base $s+1$ representation in which 0 never occurs. Using this intuition, we will represent the empty word as the number 0.

Before describing the reduction in detail, we introduce a useful abbreviation.

Notation. *Let* C, D *be two concepts and* r *a role name. We use the expression* $\left\langle D \overset{r}{\rightsquigarrow} C \right\rangle$ *to abbreviate the two axioms* $\langle D \sqsubseteq \forall r.C \geq 1 \rangle, \langle \neg D \sqsubseteq \forall r.\neg C \geq 1 \rangle$.

To understand this abbreviation, consider an interpretation $\mathcal{I}$ satisfying $\left\langle D \overset{r}{\rightsquigarrow} C \right\rangle$ and let $\delta, \gamma \in \Delta^{\mathcal{I}}$ with $r^{\mathcal{I}}(\delta, \gamma) = 1$. From the first axiom it follows that

$$\begin{aligned} D^{\mathcal{I}}(\delta) \leq (\forall r.C)^{\mathcal{I}}(\delta) &= \inf_{\eta \in \Delta^{\mathcal{I}}} r^{\mathcal{I}}(\delta, \eta) \to C^{\mathcal{I}}(\eta) \\ &\leq r^{\mathcal{I}}(\delta, \gamma) \to C^{\mathcal{I}}(\gamma) = 1 \to C^{\mathcal{I}}(\gamma) \\ &= C^{\mathcal{I}}(\gamma). \end{aligned}$$

Analogously, from the second axiom we can deduce that

$$1 - D^{\mathcal{I}}(\delta) \leq 1 - C^{\mathcal{I}}(\gamma),$$

and hence $D^{\mathcal{I}}(\delta) = C^{\mathcal{I}}(\gamma)$. Thus, $\left\langle D \overset{r}{\rightsquigarrow} C \right\rangle$ expresses that the value of $D^{\mathcal{I}}(\delta)$ is propagated to the valuation of the concept C on all r successors with degree 1 of δ.

Let now C, D be two concepts and $\mathcal{T}$ the TBox

$$\begin{aligned} \text{ax}_1 &: \langle C \sqcup Y_1 \equiv X_1 \rangle \\ \text{ax}_2 &: \langle X_1 \equiv S \sqcap \neg Y_1 \rangle \\ \text{ax}_3 &: \langle \neg Y_1 \sqcap D \equiv Y_1 \rangle \end{aligned}$$

For every model $\mathcal{I}$ of $\mathcal{T}$ and $\delta \in \Delta^{\mathcal{I}}$ it holds that

$$C^{\mathcal{I}}(\delta)(1 - Y_1^{\mathcal{I}}(\delta)) + Y_1^{\mathcal{I}}(\delta) = X_1^{\mathcal{I}}(\delta), \tag{2}$$

$$X_1^{\mathcal{I}}(\delta) = S^{\mathcal{I}}(\delta)(1 - Y_1^{\mathcal{I}}(\delta)), \tag{3}$$

$$D^{\mathcal{I}}(\delta)(1 - Y_1^{\mathcal{I}}(\delta)) = Y_1^{\mathcal{I}}(\delta), \tag{4}$$
